AMERICAN ASSOCIATION FOR CANCER RESEARCH
JOIN US IN THE GLOBAL CONQUEST OF CANCER!

THE ESSENTIAL ASSOCIATION FOR YOU AND YOUR COLLEAGUES!

With over 37,000 members in 108 countries, the AACR is on the front lines of the fight against cancer. Nonmember registrant attendees who are working in or pursuing careers in cancer research are invited to become an AACR Member. Apply today!

WHY YOU SHOULD JOIN:

- Substantially reduced registration rates for AACR Annual Meetings and Special Conferences
- Privilege of sponsoring an abstract for AACR Annual Meetings
- Exclusive discounts on subscriptions to AACR’s eight renowned peer-reviewed scientific journals
- Funding and award opportunities, including career development resources, research fellowships, scholar-in-training awards, and travel grants
- Professional development for early-career investigators and professionals, including education and professional advancement sessions
- Opportunities to network and join any of our Association and Scientific Working Groups
- Free online access to Cancer Today magazine
- Collaboration and resources through our Survivor and Patient Advocate initiatives

ATTENTION NONMEMBER REGISTRANTS:

Enjoy complimentary membership for 2017!

Visit the new AACR Membership Hub located on the L Street Bridge or the Membership Center in AACRcentral to speak with one of our Membership Representatives.

Already a member?
Be sure to visit the AACR Membership Hub to pay your member dues, register for future AACR conferences, or update your Membership Profile.

Contact the AACR Membership Department with any questions at membership@aacr.org or 215-440-9300.
Abstracts are numbered from 1 through 5947; however, several numbers may be omitted in the sequence. Abstracts were received directly from the
authors by electronic submission. Every effort has been made to reproduce the content of the abstracts according to the electronic version submitted,
except in certain instances where changes were made to comply with AACR style. The AACR does not assume any responsibility for proofreading or
correcting any scientific, grammatical, or typographical errors, nor does the AACR assume responsibility for errors in the conversion of customized
software, newly released software, or special characters. No responsibility is assumed by the AACR, publisher and copyright owner of the Proceedings;
by CTI Meeting Technology, providers of abstract management software and services; or by the meeting organizers for any injury and/or damage to
persons or property as a matter of products liability, negligence or otherwise, or for any use or operation of any methods, products, instructions, or
ideas contained in the material herein. Independent verification of diagnoses and drug dosages should be made by readers or users of this information.

Continuing Medical Education (CME) Information

ACCREDITATION STATEMENT

The American Association for Cancer Research (AACR) is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide
continuing medical education (CME) activities for physicians.

CREDIT DESIGNATION STATEMENT

The AACR has designated this live activity for a maximum of 44.75 AMA PRA Category 1 Credit(s)**. Physicians should only claim credit commensurate
with the extent of their participation in the activity.
Credit certification for individual sessions may vary, dependent upon compliance with the ACCME Accreditation Criteria. The final number of credits may
vary from the maximum number indicated above.

CLAIMING CME CREDIT

Physicians and other health care professionals seeking AMA PRA Category 1 Credit(s)** for this live continuing medical education activity must complete
the online CME Request for Credit Survey by Wednesday, May 17, 2017. Certificates will only be issued to those who complete the survey. The Request
for Credit Survey will be available via a link on the AACR website at www.AACR.org/AM17cme and via email.

STATEMENT OF EDUCATIONAL NEED, TARGET AUDIENCE, AND LEARNING OBJECTIVES

With the accelerating pace of discoveries in the basic, translational and clinical sciences, due in large part to the advent of new technologies and also
our increased understanding of the interplay between the immune system and cancer, cancer researchers are making rapid progress that is having
significant patient benefit. By bridging the gap between what physicians understand about cancer biology and the clinical applications, this meeting
aids basic researchers, physicians, and clinician-scientists in obtaining, synthesizing, and integrating the most cutting-edge research. This exposure is
essential for the implementation of best practices, such as the most current molecular-based tests to aid in the diagnosis, treatment, and prevention
of cancer. Further, facilitating the interface between physicians and scientists will increase knowledge of the epidemiological implications of cancer
incidence and the contributions of laboratory research to drug development as well as patient care; transform the design and conduct of clinical
research protocols; and create a forum for the rapid translation of laboratory research findings from “bench-to-bedside” for the benefit of improving
patient outcomes.

Despite the tremendous progress in the field, cancer continues to be an enormous public health challenge worldwide, accounting for one in every seven
deaths that occur around the world. In the United States (U.S.) alone, it is predicted that 595,650 people will die from some form of cancer in 2016, making
it the second most common cause of death after heart disease. One of the challenges we face is that cancer is comprised of more than 200 different
diseases. For many of the most commonly diagnosed cancers in the U.S.—including colorectal, lung, and prostate cancer—incidence has been declining
for more than a decade. However, incidence of other forms of cancer—including melanoma and kidney, liver, pancreatic and childhood cancer—have been
on the rise. Overall five-year relative survival rates for U.S. patients vary widely depending on the form of cancer and the stage at which it is diagnosed.
Incidence and survival rates are also impacted by the cancer health disparities that exist in certain segments of the U.S. population.

This conference will bring together investigators from the basic, translational, and clinical disciplines and provide them with a venue to discuss their
recent advances, test new hypotheses, and establish new collaborations. In order to have widespread implementation of the most current, approved
molecular-based tests to aid in the diagnosis, treatment, and prevention of cancer, it is critical to bridge the gap between what physicians understand
about cancer biology and its application to clinical oncology. As the incidence of cancer continues to increase, the fields of cancer prevention and early
interception offer unprecedented opportunities to decrease the worldwide burden of cancer. After participating in this CME activity, participants will be
able to:

1. Recognize the technological advances and tools being used to accelerate progress in cancer research and improve early detection and early
   intervention, with the ultimate goal of extending patients’ lives and improving their quality of life.
2. Articulate how advances in precision cancer medicine are leading to improved patient outcomes.
3. Incorporate the latest research findings regarding therapies and treatment options, including immunotherapy, in a variety of cancer types in
   order to improve patient outcomes.
4. Formulate new strategies that will further scientific and clinical research efforts towards the prevention and early detection of cancer.
5. Identify factors which impact the diagnosis, treatment, and prevention of various forms of cancers in patients from different populations.
6. Develop collaborations amongst physicians, researchers, and clinician-scientists to advance the cause of treating and preventing cancer.

DISCLOSURE STATEMENT

It is the policy of the AACR that the information presented at AACR CME activities will be unbiased and based on scientific evidence. To help
participants make judgments about the presence of bias, AACR will provide information that Program Committee members, speakers, and abstract
presenters have disclosed about financial relationships they have with commercial entities that produce or market products or services related to the
content of this CME activity. This disclosure information will be made available in the meeting app, online planner, or conference website.

ACKNOWLEDGMENT OF FINANCIAL OR OTHER SUPPORT

This activity is supported by educational grants that will be disclosed at the activity.

QUESTIONS ABOUT CME?

Please contact the AACR Office of CME at 215-440-9300 or cme@aacr.org.

Next Annual Meeting: April 14-18, 2018 • Chicago, IL

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Alternative Small-Molecule Therapies**

1. **Galectins in glioblastoma: opportunities for combined therapy.** David Cachia,1 Arindam Rano Chatterjee,1 William Alexander Vandergrift,1 Sunil J. Patel,1 Gabriel A. Rabinovich,1 Arabinda Das1,2. 1Medical University of South Carolina, Charleston, SC; 2Institute of Biology and Experimental Medicine, CONICET, Vuelta de Obligado, Argentina.

**Background:** Despite aggressive treatment, including surgical resection, radiation and chemotherapy, over 90% of glioblastoma (GB) patients experience tumor recurrence. This may be due to high migratory potential, angiogenesis, molecular heterogeneity and a strong immunosuppressive environment. GB expresses high levels of carbohydrate-binding galectin proteins and histone deacetylase (HDAC) activity. The aim of this study was: 1) identify the differential expressions of galectin 1-15 protein levels in human GB patient samples as compared to normal tissue (obtained from Institutional Tissue Bank) and 2) modulate the galectin functions with and without a HDAC inhibitor (DATS: Diallyl Triisulfide and SAHA: Suberoylanilide Hydroxamic Acid) or bevacizumab in vitro GB models.

**Methods:** The effects of TMZ, ionizing radiation, or combined chemoradiation on galectin protein secretion and expression were assessed in human GB cells and human umbilical vein endothelial cells (HUVECs). Results: We found increased galectin-1 protein expression in human GB tissue. We also observed that HUVEC co-culture with GB cells increased galectin-1 protein expression by 14-20% following bevacizumab and conferred a bevacizumab protective benefit to GB cells. Our in vitro models promisingly demonstrated that 72 hr treatments with 25 μM of galectin 1 inhibitor + HDAC inhibitor induce antitumor activity in GB cells. Western blot and activity assays also demonstrated that combination blockade of HDAC activity and galectin-1 augmented apoptosis in GB cells, which mechanistically involves activation of caspase-3 and inhibition of anti-apoptotic protein (survivin, p-Akt, and Mcl-1 expression). Conclusion: Our in vitro culture results suggest possible benefit in combining a galectin inhibitor with an HDAC inhibitor in GB. Further studies in different animal models are warranted.

2. **Functional and mechanistic interrogation of BET bromodomain degraders for the treatment of metastatic castration resistant prostate cancer.** Steven Kregel, Rohit Malik, Irfan A. Asangani, Kari Wilder-Romans, Xia Jiang, Steven Kregel, Rohit Malik, Irfan A. Asangani, Kari Wilder-Romans, Xia Jiang, Ingrid J. Apel, Gautham Ravi, Jean Tien, Xuhong Cao, Felix Y. Feng, Corey Speers, Shaomeng Wang, Arul M. Chinnainay, University of Michigan, Ann Arbor, MI.

Metastatic castration-resistant prostate cancer (mCRPC) is a lethal disease with about 30,000 estimated annual deaths in U.S. with a vast majority of CRPC driven by androgen receptor (AR) signaling. AR-signaling is critical for the development and progression of prostate cancer, and AR is also the main therapeutic clinical target. AR-targeted therapies, such as AR-antagonists, provide substantial benefits in the treatment of mCRPC; however, majority of patients fail these therapies and succumb to the disease. Therefore, there is a clear and pressing need to develop new therapeutics against the AR axis in CRPC. One such novel strategy for targeting the AR-pathway and inhibiting the growth of CRPC has been the use of bromodomain and extramemrinal (BET) protein inhibitors such as JQ1. However, a new class of molecules that target BET bromodomain proteins through their proteasomal degradation can improve efficacy and specificity of these inhibitors. Based on our findings, we hypothesized that pharmacologic BET degradation represents an important advance in the treatment of CRPC, and may provide a novel therapeutic strategy for advanced prostate cancer. These inhibitors affect AR-positive prostate cancer cells preferentially over AR-negative and benign prostate epithelial cells, and proteomic and genomic mechanistic studies confirm disruption of oncogenic AR and MYC signaling, both in vivo and in vitro. The overall goal is to develop very potent small molecule that leads to the proteasomal-degradation of BET proteins, with optimized in vivo properties, and to provide a compelling scientific rationale, including detailed mechanistic insight, to facilitate advancement of BET degraders as a novel potential therapeutic strategy for patients with mCRPC.

3. **Targeting epigenetic modifiers in diffuse large B-cell lymphoma.** Aarthi Goverdhan, Heng-Huan Lee, Mien-Chie Hung. UT MD Anderson Cancer Center, Houston, TX.

**Diffuse Large B-Cell Lymphoma (DLBCL) is the most common type of Non-Hodgkin lymphoma, accounting for approximately 40% of all cases worldwide. In the last five years, researchers uncovered that DLBCL is characterized by widespread epigenetic deregulation. Lymphoma cells harbor loss-of-function mutations in transcriptional activators (KMT2D, EP300, CREBBP) and gain-of-function mutations in transcriptional repressors (EZH2). In our study, we aim to identify epigenetic vulnerabilities in lymphoma cells that can be targeted to deliver cytotoxic responses. We screened the therapeutic efficacy of a panel of lysine and arginine methyltransferase inhibitors in multiple lymphoma cell lines. Through these screens, we identified the Type I Protein Arginine Methyltransferase (PRMT) family as an attractive therapeutic target that induced cytotoxicity. Mechanistic dissection revealed that Type I PRMT inhibition caused apoptosis through deregulation of transcription factors and pro-survival genes. In addition, we uncovered novel crosstalk between PRMTs and other epigenetic modifiers that influenced cell fate in lymphoma. Our study demonstrates a critical role for Type I PRMTs in DLBCL, and adds a lucrative target to the growing list of promising epigenetics-based therapies.**

**Background:** Aprotinin is a non-specific serine protease inhibitor, which can inhibit kallikrein and many downstream extracellular matrix degrading enzymes. In this study, we assessed inhibitory effects of aprotinin in local invasion of human breast cancer cell lines. Methods: We assessed effects of aprotinin on local invasion and survival of human breast cancer cell lines MDA-MB231 and SK-BR-3 in vitro. CHEMICOM Cell Invasion Assay Kit was used to assess local invasion of tumoral cells. MTT assay was used to determine the anti-proliferative activity of aprotinin on different cancer cell lines. Mean optical densities of duplicate experiments were calculated for both assays. HD-F1 human fibroblast cell line was used as control normal cell. In addition, local invasion and survival of tumor cell lines treated with aprotinin were compared with untreated experiments. Results: Cancer cell lines showed more invasion compared to HD-F1. Aprotinin significantly decreased the invasiveness of MDA-MB231 in concentration 1 IU/ml, 1.3 IU/ml, and 1.7 IU/ml in comparison with untreated group (ANOVA P < 0.001). Treatment of SK-BR-3 with 1.3 IU/ml aprotinin trended towards reduction of invasion optical density (P = 0.06). Treatment with different concentrations of aprotinin significantly decreased the surviving fraction and significantly inhibited the growth of all cell lines tested in this study (ANOVA P < 0.001). Conclusion: Aprotinin inhibited the survival and local invasion of human breast cancer cell lines MDA-MB231 and SK-BR-3. Although the growth inhibitory effect was significant in both cell lines, inhibition of local invasion was more pronounced in case of MDA-MB231. Future molecular studies could shed further lights on mechanisms underlying anti-neoplastic effects of aprotinin and its potential therapeutic effects.

5. **The effects of SIRT1 inhibitors nicotinamide and Ex-527 on lymphoma cells.** Manuela Guardi, Elisa Bonfante, Raffaele Frazzi. Arcispedale S.Maria Nuova - IBCS, Reggio Emilia, Italy.

SIRT1 is a well-known lysine-deacetylase, having both histone and non-histone proteins as molecular targets. SIRT1 may function as a tumor promoter as well as a tumor suppressor in a context-dependent manner. We previously demonstrated that the treatment with resveratrol at concentrations able to induce apoptosis leads to SIRT1 down-regulation in lymphoma cells. Here we look for SIRT1 inhibition in order to investigate the effects on proliferation potential, apoptosis induction and targets modulation at a molecular level. The aim is to study whether SIRT1 inhibition affects cell cycle and proliferation capability of lymphoma cells. Experimental procedures. Diffuse large-B cell lymphoma derived cell line Toledo; human lymphoblastoid cell line GGB#7; SIRT1 inhibitors: nicotinamide (NAM) and Ex-527; cell cycle analysis; caspase-3 activity; fluorescence assay; genotoxicity assay gamma-H2AX; fluorescence-activated cell sorting intracellular staining for acetylated-H4K16 histone. New data. We found that the calculated IC50s for SIRT1 inhibition is 50mM for NAM and 343 M for Ex-527. The treatment with either NAM or Ex-527 leads to cell cycle arrest in both Toledo and GGB#7 cells, although in a different fashion. Namely, NAM causes an S-phase accumulation of Toledo while it leads GGB#7 to G0/G1 phase arrest with a concomitant decrease in S-phase already after 10mM. In both cell lines NAM 50mM induces apoptosis as demonstrated by caspase-3 activation and sub-G1 peak appearance in the cell cycle profiles. Ex-527 causes an accumulation in the S-phase of Toledo cells and a decrease of G2/M in GGB#7 cells. No induction of apoptosis at the IC50 concentration was observed in both cell lines. Genotoxicity of the above mentioned treatments was investigated through the quantitation of gamma-H2AX histone released by treated cells. No genotoxic effects have been observed upon the treatments with these two inhibitors even at the concentration where NAM induces apoptosis. In order to correlate the observed changes with SIRT1 inhibition, we studied the acetylated H4K16 histone, Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
a direct target of SIRT1 deacetylation. Our preliminary data indicate that NAM treatment increases the percentage of acetylated H4K16. Conclusions. Lymphoma and lymphoblastoid cells are affected by SIRT1 inhibition. NAM and Ex-527 cause cell cycle arrest and growth inhibition. Only NAM 50 mM induces apoptosis without genotoxic effects. Overall, our data suggest the direct involvement of SIRT1 during the observed cell cycle arrest and growth inhibition mediated by these inhibitors.

**#6 New chk1 inhibitor development & the feasibility of use of chk1 inhibitor with antimitabolite for NSCLC.** Injae Chung. Duksun Women's University, Seoul, Republic of Korea.

DNA damaging anticancer agents activate checkpoints that stop the cell cycle to prevent additional DNA replication & mitosis until damaged region has been repaired. One of the important regulatory proteins activated in DNA damage response pathway is Checkpoint kinase 1 (Chk1). Therefore, Chk1 inhibitors have emerged as promising new therapeutics for cancer. In order to find novel Chk1 inhibitor, we have conducted a structure based virtual screening. Several small molecules have been shown 75 - 100 % inhibition of Chk1 in the binding affinity assay. Combined with the results of kinase assay with ATP & mechanism based cell assay, hit candidates has been led. Lung cancer is the leading cause of cancer related deaths in Korea. About 85 % of lung cancer is non-small cell lung carcinoma (NSCLC) worldwide. Chemotherapy for NSCLC is often regarded ineffective. To test the feasibility of Chk1 inhibitor to sensitize antimitobile in NSCLC, growth inhibition induced by gemcitabine plus MK8776 was assessed in A549 & H520 cells. These cells are insensitive to the MK8776 when treated as a single agent (IC50 > 10 μM). In contrast, MK8776 reduced the concentration of gemcitabine required to inhibit H1299 or A540 cell growth by almost 3-30 fold or 6-15 fold, respectively, depending on the concentration used. These results would imply the potential clinical utility of Chk1 inhibitor as an adjuvant for antimitobile such as gemcitabine for NSCLC. Further studies to evaluate the effectiveness of Chk1 inhibitor including new molecules would be warranted in additional preclinical and clinical settings. [The chemical library used in this study was kindly provided by Korea Chemical Bank & KIST. This study was supported by a grant (2015R1D1A1A01057014) from the National Research Foundation of Korea.]

**#7 Ceftriaxone, an FDA-approved cephalosporin antibiotic, suppresses lung cancer growth by targeting Aurora B.** Xiang Li1, Haitao Li1, Shengjing Li1, Feng Zhu1, Dong Joon Kim1, Hua Xie1, Yan Li1, Janos Nadas1, Naomi Oh1, Tatiana Zyanko1, Dong Hoon Yu1, Mee-Hyun Lee1, Myoung Ok Kim1, Lei Wang1, Wei Ya Ma1, Ronald A. Lubet2, Ann M. Bode1, Ziming Dong3, Zigang Shen4, Xuan Zhou1.

Ceftriaxone, an FDA-approved third-generation cephalosporin antibiotic, has antimicrobial activity against both gram-positive and gram-negative organisms. Generally, ceftriaxone is used for a variety of infections such as community-acquired pneumonia, meningitis and gonorrhea. Its primary molecular targets are the penicillin-binding proteins. However, other activities of ceftriaxone remain unknown. Herein, we report for the first time that ceftriaxone has anti-tumor activity in vitro and in vivo. Kinase profiling of hit compounds identified that Aurora B might be a potential "off" target of ceftriaxone. Pull-down assay data confirmed that ceftriaxone could bind with Aurora B in vitro and in A549 cells. Furthermore, ceftriaxone (500 μM) suppressed anchorage-independent cell growth by targeting Aurora B in A549, H520 and H1650 lung cancer cells. Importantly, in vivo xenograft animal model results showed that ceftriaxone effectively suppressed A549 and H520 lung tumour growth by inhibiting Aurora B. These data suggest the anticancer efficacy of ceftriaxone for the treatment of lung cancers through its inhibition of Aurora B.

**#8 Anandamide reduces cell migration, invasion, and induces apoptosis in an in vitro model of prostate cancer.** Domenica Roberto,1 Lawrence Klotz,2 Vasundara Venkateswaran.1 Sunnybrook Research Institute, Toronto, Ontario, Canada. 2Sunnybrook Health Sciences Centre, Toronto, Ontario, Canada.

Introduction and Objective: Prostate cancer (PCA) is the most commonly diagnosed cancer in men and the second leading cause of cancer related death in Canada. A large body of evidence supports a possible role for cannabinoids in certain aspects of human health and disease, acting as palliative agents as well as inhibitors of cancer cell proliferation, migration, invasion, and the angiogenesis of tumours. Anandamide (AEA) is a highly potent endogenously produced compound that acts as an agonist of the cannabinoid receptors (CB1 and CB2) as well as the transient receptor potential vanilloid receptor 1. AEA is mainly metabolized by fatty acid amide hydrolase (FAAH) and overexpression of the enzyme in PCA tissues is correlated with greater invasivity, malignancy and increasing Gleason score. Majority of studies have focused on the effect of AEA treatment on cell proliferation, without much focus on prostate cancer biology. This study aims to determine the anti-cancer effect of AEA on PCA cells. We hypothesize that anandamide will reduce migration, invasion, and induce apoptosis in PCA cells. Methodology: Human PCA cells (DU145, LNCaP, and PC3) were treated with AEA at concentrations ranging from 1 μM to 100 μM and growth of cells (using the MTS assay) was assessed at various times. Wound-healing assays were conducted to investigate the migratory potential of cells following 24hr exposure to treatment, and trans-well invasion assays were performed to explore the influence of AEA on cell invasion. Flow cytometry, using the FITC Annexin V dead cell apoptosis kit, was used to detect the proportion of apoptotic cells in proliferating cells following anandamide treatment. Results: There was a significant reduction in the proliferation of DU145 cells at concentrations of 20 μM and 40 μM AEA compared to controls (p = 0.02, 0.005) LNCaP cells on the other hand required a higher concentration of AEA to achieve this effect (p=0.05). Cell migration and invasion studies on DU145 cells revealed a significant reduction in cell motility at 20 μM and 40 μM AEA (p = 0.006, 0.0005) as well as a significant reduction in cell invasion at 20 μM and 40 μM (p = 0.002, 0.0001). Flow cytometry results indicate a significant increase in the proportion of apoptotic cells compared to control (3 fold change) when treated with 20 μM and 40 μM in DU145 and LNCaP cells. Conclusion: We have shown that AEA has greatest significant influence on cell migration, invasion, and apoptosis. Further analysis on the role of AEA in these pathways is underway exploring alterations in expression levels of key proteins implicated in cell migration and apoptosis. Funding/ Conflicts of Interest: None

**#9 Suppression of the invasion and growth of human head and neck squamous cell carcinomas via regulating STAT3 signaling and miR-21/b-catenin axis with HJC0152.** Yu Wang1, Sinan Wang1, Yansheng Wu1, Jia Zhou1, Qiang Shen1, Xuan Zhou1. 1Tianjin Medical University Cancer Hospital, Tianjin, China; 2Tianjin Medical University General Hospital, Tianjin, China; 3University of Texas Medical Branch, Galveston, TX; 4The University of Texas MD Anderson Cancer Center, Houston, TX.

Signal transducer and activator of transcription 3 (STAT3) is involved in the tumor growth and metastasis of human head and neck squamous cell carcinoma (HNSCC) and is therefore a target with therapeutic potential. In this study, we show that HJC0152, a recently developed anticancer agent and a STAT3 signalng inhibitor, exhibits promising antitumor effects against HNSCC both in vitro and in vivo via inactivating STAT3 and downstream microRNA-21/b-catenin axis. HJC0152 treatment efficiently suppressed HNSCC cell proliferation, arrested the cell cycle at the G0/G1 phase, induced apoptosis, and reduced cell invasion in both SCC25 and CAL27 cell lines. Moreover, HJC0152 inhibited nuclear translocation of phosphorylated STAT3 at Tyr705 and decreased VHL/ b-catenin signaling activity via regulation of microRNA-21. Loss-of-function of VHL remarkably compromised the antitumor effect of HJC0152 in both cell lines. In our SCC25-derived orthotopic mouse models, HJC0152 treatment significantly abrogated STAT3/b-catenin expression in vivo, which leading to a global decrease of tumor growth and invasion. With its favorable aqueous solubility and oral bioavailability, HJC0152 holds the potential to be translated into the clinic as a promising therapeutic strategy for patients with HNSCC.

**#10 A small molecule derivative effectively inhibits proliferation of pancreatic cancer cells by targeting Sp1 and survivin.** Myrna Hurtado,1 Umesh Sanpalk,1 Aboubacar Kaba,2 Shahela Mahmammad,1 Alvin Holder,3 Jamboor Vishwannahanga,1 Rijay Basha1. 1University of North Texas Health Science Center, Fort Worth, TX; 2Alabama State University, Montgomery, AL; 3Old Dominion University, Norfolk, VA.

Pancreatic cancer is one of the most fatal malignancies due to its poor prognosis. With current standard treatment options, the overall 5 year survival rate is about 16% and these treatment plans often cause high toxicity. Therefore, there is an urgent need for identifying more effective and less toxic agents for the treatment of this malignancy. Tolfenamic acid (TA) is a generic drug used to treat migraine headaches but has been demonstrated to have anti-cancer activity in pre-clinical studies. It is known to downregulate the transcription factor Specificity protein 1 (Sp1). Sp1 regulates several genes involved in cell proliferation and apoptosis, including survivin, an inhibitor of apoptosis protein. Interestingly, a recent discovery proposed that copper(II) complex of TA can result in greater therapeutic response; however its efficacy was not tested in gastro-intestinal cancers. Therefore, a small molecule derivative of Tolfenamic acid containing complex of TA (Cu-TA) using human pancreatic cancer cell lines. MIA PaCa-2 and Panc-1 cells were treated with increasing concentrations of vehicle (DMSO), equimolar CuCl2 (negative control), TA or Cu-TA and the cell viability was measured at 24 and 48 h post-treatment using CellTiter-Glo kit.

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Alternative Small-Molecule Therapies**
Cu-TA was further tested for its effect on Sp1 and survivin expression in MIA PACA-2 cells by Western blot (protein) and quantitative PCR (mRNA). The activation of apoptosis was determined by measuring the expression of effector caspases using the Caspase3/-7-Glo kit and the apoptotic cell population through flow cytometric analysis using Annexin-V staining. Cell cycle arrest was assessed by flow cytometry. The results of all analyses revealed that Cu-TA caused dose/time-dependent response to inhibit pancreatic cancer cell growth, Cu-TA showed higher efficacy when compared to TA. Cu-TA was highly effective in inhibiting Sp1 and survivin protein expression and showed similar trend for inducing apoptotic markers and causing cell cycle arrest in early phase (G0/G1). The results of qPCR demonstrated that the expression of survivin mRNA was significantly lower following both Cu-TA and TA treatment; however, Cu-TA mRNA expression of Sp1 remained unchanged. This indicates that TA and Cu-TA could be working in similar mechanism by effecting Sp1 post-translational, perhaps through proteasome-dependent degradation. These results demonstrate that Cu-TA is more effective than TA and potentially useful for pancreatic cancer treatment after clinical testing. Studies to precisely understand the underlying mechanisms of Cu-TA are currently under investigation through molecular profiling analysis.

#11 The oncolytic peptide LTX-315 enhances T cell clonality and induces synergy with chemotherapy. Kéti André Camilo,1 Meng Yu Wang,2 Janné Nestvold,3 Gunhild Mælandsmo,2 Baldur Sveinbjørnsson,2 Øystein Rekdal.4

1Lytix Biopharma AS, Oslo, Norway; 2Oslo University Hospital, Oslo, Norway.

LTX-315, a novel oncolytic peptide is effective against both drug-resistant and drug-sensitive cancer cells with lower toxicity towards normal cells. Intratumoral treatment with LTX-315 results in growth inhibition, complete regression and long lasting tumor-specific immune responses. The oncolytic effect of LTX-315 involves perturbation of the plasma membrane and distortion of intracellular organelles including the mitochondria with subsequent release of Damage-Associated Molecular Pattern molecules (DAMPs) such as ATP, cytochrome c and HMGB1. LTX-315 effectively induces necrosis within the tumor followed by the release of tumor antigens as demonstrated by a greater increase in tumor infiltrating CD8+ T cells, expansion of T cell clonality, and number of clones within the tumor microenvironment. LTX-315’s ability to modify the tumor microenvironment makes it ideal as a combination partner for other cancer therapies, including chemotherapy and immune checkpoint inhibitors. In preclinical tumor models, combination of LTX-315 and chemotherapeutic agents such as cyclophosphamide and doxorubicin demonstrates significant synergy.

#12 Evaluation of metformin and clotam combination for medulloblastoma. Umesh T. Sankpal1, W Paul Bowman,2 Jeffrey C. Murray,3 Riyaz Basha1.

1Univ. of North Texas Health Science Ctr., Fort Worth, TX; 2Cook Children’s Medical Center, Fort Worth, TX.

Medulloblastoma (MB) is the most common malignant brain tumor in children. Standard treatment, which includes surgery, chemotherapy, and radiotherapy, is successful for most patients, but survivors often suffer from significant long-term side effects affecting their neurocognitive and growth potential. Therefore, there is a critical need to understand the molecular processes that regulate MB growth and find less toxic therapies. Survivin (BIRC5) was identified as a protein belonging to the Inhibitor of Apoptosis Protein family that inhibits apoptosis by inhibiting caspase activation. Survivin expression is also associated with increased resistance of tumor cells to radiation and chemotherapy. In MB, several studies suggest that increased expression of survivin serves as a marker of tumor morphology and is associated with poor prognosis. Specificity protein 1 (Sp1) is one of the transcription factors that regulates the expression of survivin gene. Sp1 is also shown to be upregulated in some cancer cells and is associated with poor prognosis. In this study, we are testing a strategy of targeting survivin in MB using anti-diabetic drug Metformin, which targets Sp1, and the NSAID Clotam (Tolifenamic acid, TA), which targets Sp1 and survivin. Dose response curves were established by treating MB cell lines DAOY and D283 with increasing concentrations of metformin or TA and measuring cell viability at 24 and 48h post-treatment using the CellTiter-Glo Cell Viability Assay. A time and dose dependent inhibition of cell proliferation was observed for both the drugs. Metformin dose response was then repeated in the presence of 25 or 50 µM TA. Our results indicate that TA significantly increased the growth inhibitory response of metformin. To further characterize this response, we determined the combination index (CI) using the Chou-Talalay method. We found that the CI values were between 0.85 to 0.61 for various combinations of metformin and TA, strongly suggesting a synergistic effect of the two drugs on cell proliferation.

Combination of metformin and TA was also accompanied by a 3-4 fold increase in apoptotic cells at 48h post-treatment, as determined by AnnexinV staining of DAOY cells. Western blot analysis of DAOY cells treated with the two drugs also revealed a decrease in survivin and Bcl-2 protein levels, and an increase in cleaved-PARP. In conclusion, the anticancer activity of metformin in MB cells is enhanced in the presence of TA. Both drugs synergistically combine to inhibit MB cell proliferation and increase apoptosis, which in part may be the result of a decrease in survivin levels. This combination strategy may therefore represent a therapeutic strategy for MB. It is under investigation whether this drug combination can enhance the response of chemotherapy in MB cells, since both TA and metformin are known to sensitize cancer cells to chemotherapy.

#13 Chromatin unfolding small molecules as a novel type of anticancer agents. Katerina V. Gurova. Roswell Park Cancer Institute, Buffalo, NY.

Although targeted therapy was the major focus of anti-cancer drug development, recently revealed enormous heterogeneity of tumors planted a seed of doubt in it as a potential cure for cancer. Very few universal cancer targets are known and they lack cancer specificity. DNA is one of this sort, but activity of drugs targeting DNA was traditionally attributed to their ability to block DNA replication and cause DNA damage with a plethora of harmful long lasting effects in normal cells. We have found that reversible binding of DNA by non-DNA damaging small molecules, curaxins, has strong anticancer effect in different preclinical models without deleterious consequences associated with DNA damage (REF). In this study we explained the mechanism of activity of curaxin clinical lead, CBL0137, through alteration of chromatin organization in tumor cells. Intercalation of the curaxin carbazole moiety between base pairs and DNA major and minor groove binding with curaxin side chains cause an increase in inter base pair distance and untwisting of the double helix (~18°). Such alteration of DNA helical shape leads to decreased nucleosome stability and chromatin opening, creating sites for the high affinity binding of histone chaperone complex FACT. We named this phenomenon “chromatin trapping of FACT” or c-trapping. Consequences of C-trapping are much more deleterious for tumor, than for normal cells. First, c-trapping is an equivalent of functional inactivation of FACT. FACT is critical for oncogenic transformation and tumor, but not normal cell, viability and growth (REF). FACT is essential for the activity of several transcription factors, such as NF-kappaB, HSF1, MYC etc., with important roles in tumor cell proliferation and survival (REF). Further, deregulation of transcription caused by curaxin-dependent chromatin decondensation leads to upregulation of transcription from heterochromatin. This leads to the formation of double stranded RNAs from centromeric and pericentromeric repetitive elements, which mimics a viral infection and induces an IFN response, a powerful inhibitor of tumor cell growth. Additionally, c-trapping of FACT leads to casine kinase 2 mediated phosphorylation and activation of wild type p53 leading to p53-dependent death of cells. Thus non-DNA damaging DNA binding small molecules compromise cancer cell viability via alteration of nucleosome stability and chromatin organization. This is a novel mechanism of anti-cancer activity of small molecules with broad applicability to different types of cancer while lacking the harmful effects of DNA damaging chemotherapy.

#14 Anticancer activities of terpenoid compounds isolated from the plant centipeda minima against nasopharyngeal carcinoma cells. Bei-bei Liu,1 Kuiyuan Zhu,2 Chi-on Chan,1 Ling-Hua Zhang,2 Daniel Kam-Wah Mok,3 Si-bao Chen.1

1State Key Laboratory of Chinese Medicine and Molecular Pharmacology, The Hong Kong Polytechnic University,Shenzhen Research Institute, Shenzhen, China; 2NANOBIOITEC LLC, Whiphany, NY.

Nasopharyngeal carcinoma (NPC) is one of common cancers throughout south-east Asia, southern China and other regions. Radiotherapy and chemotherapy are the standard treatments for NPC with severe adverse effects, multidrug resistance, and insensitivity to advanced NPC. Complementary and novel treatments for NPC gain considerable interest around the world. The medicinal plant Centipeda minima is traditionally used in China for the treatment of various nasal diseases such as allergy, rhinitis, sinusitis and nasopharyngeal carcinoma. In the current study, we studied the anticancer potential of an ethanol extract (CME) and 3 pure sesquiterpenoids (A1, A2, A3) extracted from Centipeda minima against NPC cells in vitro and some underlying mechanisms of actions. The NPC cell lines CNE-1 and CNE-2 cells were treated with either CME or 3 pure compounds (A1, A2, A3). Proliferation of NPC cells was inhibited in a concentration- and time-dependent manner. For 48 h treatment, the IC50 values were 41.57 to 24.98 µg/mL for CME, and 2.3 to 7.5 µM for A1 to A3. While these extracts showed no appreciable effect on normal human LO2 hepatocytes, significant numbers of NPC cells underwent apoptotic morphological changes following treatments. Cytometric analysis demonstrated that treatments with CME and compounds results in NPC cell cycle arrest at the G2/M phase and eventually apoptosis in a concentration and time-dependent manner. Western blot analysis showed that these extracts could down-regulate Bcl-2 expression, up-regulate Bax expression and caspase-8, 9, 3 activities. In addition,
**Experimental and Molecular Therapeutics: Alternative Small-Molecule Therapies**

the potential anti-NPC actions might be also associated with the marked inhibition of multiple signal transduction pathways including EGFR, VEGFR, HER2, FGFR, IGF-1R, PI3K/Akt/mTOR, MAP/ERK and Jan/Stat3 pathways. In summary, the Centipede mimma extract and terpenoids are potential apopto-sis inducing agents to kill NPC cells and may be promising anti-cancer drug leads against nasopharyngeal carcinoma. The exact mechanism of actions remains further study.

#15 Suppression of adaptive responses to targeted therapies by transcriptional inhibition of key dependency genes. Akisaka,1 Takeshi Shimamura,3 Matthew Meyerson,1 Hideo Watanabe,4 Nathanael tensen,1 Brian J. Abraham,2 Nicholas Kwiatkowski,1 Kevin Buczkowski,1 Bruno Bockorny,1 Ting Chen,1 Shuai Li1, Haikuo Zhang,1 Hideko Terai,1 Tiffany Tavares,1 Tinghu Zhang,1 Tae Jung Kim,1 Michael Silkes,1 Benny Mundayito,1 Li Tan,1 Takeshi Shimamura,1 Matthew Meyerson,1 Hideo Watanabe,4 Nathanael S. Gray,1 Richard A. Young,2 Kwok-Kin Wong,1 Peter S. Hammerman1.

Tumor cells become dependent on the expression of key genes that drive hallmark tumor traits, but these "addictions" also represent potential vulnerabilities for therapeutic intervention. Treating tumor cells with a small molecule inhibitor of the transcriptional kinase CDK7 selectively suppresses transcription of key dependency genes in multiple cancers. Our previous work showed responses to the CDK7 inhibitor THZ1 were especially noteworthy in T cell leukemias, small cell lung cancers, and triple-negative breast cancers—tumor types where the prognoses are especially unfavorable. The genes whose expression is most sensitive to CDK7 inhibition and whose expression is essential for tumor cell survival are often associated with super-enhancers—clusters of cohesin-dependent enhancers that are bound by unusually large amounts of transcription apparatus including CDK7 itself. This "Achilles' cluster" of super-enhancer-associated genes thus represents the set of addictions of tumor cells whose expression is important for tumor cell survival. Transcriptional inhibition synergizes with targeted therapies in models of multiple tumor types. Treating tumors with therapies that are often associated with super-enhancer-bearing--clusters of constitutive enhancers and super-enhancers and gene expression programs of resistant cells. Treating cells with a transcriptional inhibitor in addition to targeted therapies prevents "rewiring" of the gene expression program and increases cell death in tumor models. Thus transcriptional inhibition represents a promising avenue in both mono-therapy and combination settings where drug resistance is acquired.

#16 Evaluation of the efficacy of clotrimazole treatment in human melanoma cell lines that overexpress the multidrug resistance-associated protein (MRP) and the lung resistance-related protein (LRP). Steven D. Blake, Shelby G. McKinley, Christopher M. Tweed, David W. Koh. *Ohio Northern University, Ada, OH.*

**Drug resistance to chemotherapy, mediated in part by overexpression of P-glycoprotein (MDR-1), multidrug resistance-associated protein (MRP), or lung resistance-related protein (LRP), continues to be a major problem in the treatment of melanoma. Because we previously demonstrated the activity of clotrimazol to enhance cytotoxicity in human metastatic melanoma cells, here we evaluated the ability of clotrimazole to treat drug-resistant human melanoma cells that overexpress MRP or LRP.** We utilized human melanoma cell lines that overexpress either MDR or LRP, and human melanoma cell lines that over-express both. Cell growth and cell death were analyzed by flow cytometry, proliferation assays, and immunoblotting after drug treatments and RNA interference. Clotrimazole caused significant decreases in proliferation and increases in cell death in both drug-sensitive melanoma lines and those overexpressing MRP and LRP. No extensive cell death was induced by clotrimazole treatment in noncancerous human skin cell lines. These results indicate that clotrimazole selectively induces cytotoxicity in both drug-sensitive and drug-resistant melanoma lines. Clotrimazole is known to inhibit various receptor potential (TRP) ion channels, we pretreated these melanoma lines with TRP inhibitors or RNAi. Inhibitors of the TRP melastatin-8 channel (TRPM8) or TRP vanillindol-1 (TRPV1) failed to produce comparable levels of cell death caused by clotrimazole. However, RNAi silencing of the TRPM2 cation channel caused significant levels of cell death in both drug-sensitive and drug-resistant melano-noma lines. These results indicate that inhibition of TRPM2 channels may have a primary role in the ability of clotrimazole to treat drug-sensitive and drug-resistant melanoma lines. In conclusion, this study demonstrated that clotrimazol selectively increases cell death in drug-resistant melanoma lines, with minimal deleterious effects in normal skin cells. Taken together, we conclude that clotrimazole has in vitro efficacy toward the treatment of drug-resistant human melanoma cells. Thus, these preliminary studies indicate that clotrimazole has the potential to successfully treat drug resistant melanoma in the future.

#17 Anti-metastatic platinum through glycan targeting in breast cancer. Samantha J. Katner,1 Erica Peterson J. Peterson,2 Eriko Katsuta,2 Stephanie C. DeMas,1 Jennifer Koblinski,1 Kazuaki Takabe,2 Nicholas P. Farrell,1 Virginia Commonwealth University, Richmond, VA; 1Roswell Park Cancer Institute, Buf-falo, NY.

#18 Vorinostat reexpressed estrogen receptor (ER) in TR triple negative breast cancer cell line subtypes and sensitized cells to tamoxifen and indole-3-carbinol in vitro. Beverly D. Lyn-Cook.1 Julie Getz,1 Beverly Word,1 Rhonda Moore,1 Gustav Miranda-Carboni1,1 FDA-NCTR, Jefferson, AR; 2FDA/Center for Tobacco Product, FDA, MD; 3University of Tennessee Health Science Center, Memphis, TN.

Triple negative breast cancer (TNBC) is one of the most aggressive subtypes of breast cancer. Although about 15% of breast cancers are estrogen positive, about 15% falls into this category. This subtype of cancer lacks targeted therapies, such as the estrogen receptor (ER), progesterone receptor (PR), and the human epidermal growth factor receptor-2 (HER2). These patients are limited to cytotoxic chemotherapies with harsh side effects. In addition to occurring in younger women, other risk factors for TNBC include: being of African descent, BRCA1 mutation, a strong family history of breast cancer, lifestyle and environmental factors. Although mutations are involved in the initiation of TNBC, research has revealed that individuals are controlled by factors other than DNA sequences such as epigenetic mechanisms. Environmental and lifestyle related factors, such as the lack of population-based screening, and lack of access to care-factors, the urban environment, food deserts, social stress, racism, diet, lack of exercise, alcohol intake, and tobacco use (i.e. cigarette smoking) have all been described as factors associated with breast cancer related dispari-ties. This study investigated the role of epigenetic mechanisms in the re-expression of ER receptors in triple negative breast cancer (TNBC) cells by examining the effects of a FDA-approved epigenetic drug (vorinostat) and the dietary agent (indole-3-carbinol) on three subtypes of triple negative breast cancer. Basal-like (HCC1806), mesenchymal stem cell-like (MDA-MB-231) and mesen-chymal (BT-549) cell lines were treated with vorinostat for 6, 12, 24 and 48 hrs alone. The ER was expressed in HCC1806 (3-fold) and MDA-MB-231 (5-fold) at 6 hr. The ER was not expressed in BT-549 cells at any time point. MTS assay demonstrated a significant decreased in proliferation (60%) in MDA-MB-231 when treated with vorinostat (10, 20 or 30 μM) and 10 μM of tamoxifen. Furthermore, a significant decrease in proliferation (40%) was also detected in MDA-MB-231 cell lines treated with I3C (200 μM) and vorinostat (10, 20 or 30 μM). Our preliminary results show that triple negative cell lines repre-senting three subtypes responded different to treatment with vorinostat in re-expressing the estrogen receptor. However, these results showed promising re-

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
sult for the use of this drug in sensitizing triple negative breast cancer cells to taxol and a dietary agent, indole-3-carbinol. Further functional studies are currently underway.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Antibodies, Bispecifics, and Antibody-Drug Conjugates

#20 Xentuzumab, a humanized IGF-1 and IGF-2 ligand neutralizing antibody, improves the antitumor efficacy of enzalutamide in preclinical models of prostate cancer. Ulrike Weyer-Czernilofsky,1 Marco H. Hofmann,1 Paul J. Adam,1 Flavio Solca,1 Katrin Friedbichler,1 Norbert Kraut,1 Eva Corey,1 Thomas Bogenrieder,1 Boehringer Ingelheim RCV GmbH & Co KG, Wien, Austria;2 University of Washington, Seattle, WA.

Background: The proliferative and pro-survival signals driven by the insulin-like growth factor (IGF) ligands, IGF-1 and IGF-2, are transmitted through their binding to the IGF-1 receptor (IGF-1R). In addition, IGF-2 activates the insulin receptor variant A (IR-A) that is expressed during embryonic development as well as in many cancers. A large body of preclinical evidence suggests that IGF signaling plays a key role in cancer by driving therapy resistance, due to cross-talk with other signaling networks such as androgen receptor signaling. The aim of this study was to explore the potential of the IGF-1/2 ligand blocking antibody, xentuzumab (BI 836845\(^{151}\)), to enhance the anti-tumor activity of enzalutamide in prostate cancer cell lines and in a patient-derived prostate cancer xenograft model. Methods: Effects of enzalutamide, xentuzumab and combinations thereof on in vitro proliferation, survival, cell cycle and signaling were evaluated using the prostate cancer cell lines VCaP, DuCaP, MDA PCa 2b, and LNCaP. The in vivo efficacy of enzalutamide, alone and in combination with xentuzumab was investigated using LuCaP 96CR, a patient-derived xenograft model of castration-resistant prostate cancer. Tumors were implanted s.c. into castrate SCID mice. When tumors exceeded 150\(^{3}\) mm\(^3\) animals were randomized into groups: 1) Control; 2) enzalutamide (50 mg/kg QD po), 3) xentuzumab (BI 836845\(^{151}\), 200 mg/kg QW ip) in combination with enzalutamide. Results: Cell viability was more effectively reduced by the combination of enzalutamide and xentuzumab than either drug alone in three of four cell lines expressing the IGF-1R and the androgen receptor (AR). In VCaP cells, prolonged inhibition of IGF pathway signaling and enhanced blockade of proliferation as well as induction of apoptosis was observed after combination treatment. In vivo, enzalutamide monotherapy did not show significant antitumor efficacy in the LuCaP 96CR model, however, combined treatment with xentuzumab significantly inhibited progression of LuCaP 96CR tumor growth (p<0.001 vs. enzalutamide alone). Reduced serum PSA levels were observed after enzalutamide and combination treatment. Enzalutamide plus xentuzumab inhibited tumor growth at tolerated doses and resulted in significant improvements in survival. Conclusions: These studies demonstrated that addition of the IGF-1/2 neutralizing antibody xentuzumab to enzalutamide results in improved anti-neoplastic activity in a subset of prostate cancer cell lines in vitro, and to re-sensitization to enzalutamide in a patient-derived xenograft model of CRPC. #21 Regulation of proliferation and invasion through the inhibition of IGF signaling pathway on Epstein-Barr virus associated gastric cancer. Inhye Jeong,1 Hoi Young Lee,2 Jae Kyung Roh,1 Tae Soo Kim,2 Suk Kyeong Lee,3 Ulrike Weyer-Czernilofsky,1 Marco H. Hofmann,1 Paul J. Adam,1 Flavio Solca,1 Katrin Friedbichler,1 Norbert Kraut,1 Eva Corey,1 Thomas Bogenrieder,1 Boehringer Ingelheim RCV GmbH & Co KG, Wien, Austria;2 University of Washington, Seattle, WA.

Epstein-Barr virus associated gastric cancer (EBVaGC) is one subtype of four molecular classifications by TCGA group. Specifically, EBV related viral RNAs, microRNAs and proteins regulate cancer progression phenomena like aggressiveness, motility, invasion and metastasis. Nonetheless, understanding the mechanisms of viral growth dependency beyond malignant EBV transformation is still deficient. Finding the EBV dependent pathway with significant biological role and the clinically appropriated drug is needed for EBVaGC in this regard. We investigated new therapeutic target and its role of regulating in proliferation and invasion using EBVaGC cell line model. First, we determined proliferation both of AGS and EBV infected AGS (AGS-EBV) cell lines during 7 days by proliferation assay. For the test of BI836845 (IGF ligand neutralizing antibody, Boehringer Ingelheim, German) efficacy, CCK-8 assay was performed. mRNA expression levels of IGF-1R, IGF-1, IGF-2 and IGFBP-6 which is the key regulator of IGF-signaling were measured by RT-PCR. Also, protein expression levels of IGF associated and downstream factors were confirmed by Western blotting. Lastly, invasiveness of cells was detected by invasion assay. As a result, AGS-EBV showed the slower proliferation rate compared to AGS, but the sensitivity to BI836845 was significantly increased in a dose-dependent manner (p<0.001). Interestingly, baseline IGFBP-3 mRNA expression of was enhanced in AGS-EBV compared with AGS. In addition, BI836845 treated model showed up-regulated IGFBP-3 mRNA level in AGS and down-regulated IGFBP-3 mRNA level in AGS-EBV. When BI836845 treated to AGS-EBV, phospho-Akt level was highly inhibited. Moreover, invasiveness of AGS-EBV was elevated about 2 fold more than AGS. Treatment of BI836845 in AGS-EBV represented significant decrease the invasiveness (p<0.08). In conclusion, AGS-EBV seems to modulate their proliferation and invasion through the IGF signaling pathway. Inhibition of IGF signaling pathway would be the potential therapeutic strategy for EBV associated gastric cancer.

#22 MM-161, a first-in-class pan-FGFR antibody. Tamara Duke, Greg Finn, Melissa Geddie, Neeraj Kohli, Maja Razlog, Lihui Xu, Volette Paragas, Haluk Yuzugullu, Sara Ghassenifar, Yasin Hashimhoby-Ramsay, Charlotte McDonagh, Marco Muda, Birgit Schoeberl, Merrimack Pharmaceuticals, Inc, Cambridge, MA.

Aberrant signaling of the FGFR pathway has long been known to promote tumorigenesis and angiogenesis across multiple cancer indications. However, the development of an effective and well-tolerated FGFR targeted inhibitor has been hindered by the need to block the activation of multiple mitogenic receptors while avoiding significant toxicities associated with blocking each oncogene FGF ligands. Here we disclose for the first time a novel FGFR targeted antibody, MM-161, designed to block ligand-dependent signaling driven by all four FGF receptors, specifically the IIIc-isomers. MM-161 is well tolerated in mice and cyromolgus monkeys with no significant weight loss observed in either species. Efficacy studies demonstrated that MM-161 monotherapy leads to significant tumor growth inhibition or tumor regression of xenografts of human lung, renal and endometrial cancer amongst others. Importantly, MM-161 has a dual mechanism of action by inhibiting both proliferation and angiogenesis. We will present data illustrating that inhibition of multiple FGFRs is desirable to achieve tumor regression. Furthermore, we will show combination studies with relevant standard of care therapies in models of lung and renal cancer. Taken together, our preclinical data strongly supports the clinical evaluation of MM-161 in cancer patients.

#23 Antibody targeting of ADAM8 for treatment of triple-negative breast cancer. Sonia G. Das, Stefania Pianetti, Gail E. Sonenshein, Nora D. Mineva. Tufts Univ. School of Medicine, Boston, MA.

Triple-Negative Breast Cancer (TNBC) accounts for 25% of breast cancer deaths. Current therapeutic options are restricted to chemotherapy (CT) and radiation, which fail to block disease progression. Recently, we identified the cell surface protein ADAM8 as a critical driver of TNBC tumor growth and metastasis in half of all breast cancers (EMBO Mol. Med. 6:278, 2014). Elevated expression of ADAM8 in TNBC is associated with poor patient outcomes. We have identified a unique antibody-based reagent that simultaneously targets ADAM8 MP/DI activities as an effective therapeutic intervention in TNBC. Our group has now prepared a panel of potent, highly specific ADAM8 antibodies (ADPs) of either IGG1 or IGG2 subclass with dual MP/DI antagonist activity. The top 6 ADPs bind ADAM8 with low dissociation constants of 1.3 x 10^{-8} M to 7.23 x 10^{-8} M. The 4 most effective inhibitory ADPs in cell-based assays were screened in a single-dose efficacy study (10 mg/kg 3x/wk) against pre-existing MDA-MB-231 cell-derived tumors (50-75 mm\(^3\)). ADP2 and ADP3 treatment resulted in significant tumor volume reduction, of 47% and 52%, respectively. Dose-response curves are in progress. ADP13 was also tested in a neo-adjuvant model of breast cancer and resulted in 73% tumor regression. Furthermore, we will show combination studies with relevant standard of care therapies in models of lung and renal cancer. Taken together, our preclinical data strongly supports the clinical evaluation of ADP13 in cancer patients.
ADP13 substantially decreased metastasis to multiple organs. Lastly, a neo-adjuvant survival experiment was performed, as above, except that following surgical resection of tumors mice were treated for 12 weeks. Recurrence at the primary site was assessed using palpation. Mice were sacrificed when recurrent tumors reached 900 mm³. ADP13 treatment resulted in significantly improved disease-free survival (P = 0.05) and overall survival (P = 0.03). More recently, we noted that ADAM8 regulates miRNAs associated with resistance to CT and showed that ADAM8 inhibition sensitizes TNBC cells to Cisplatin, Paclitaxel, and Doxorubicin. In vivo testing of a combinatorial anti-ADAM8 + CT approach is in progress and may present a promising strategy for early entry into the clinic. Conclusions: A new anti-ADAM8 antibody therapeutic shows efficacy against TNBC growth and dissemination, and improves survival in pre-clinical testing. We hypothesize that addition of an anti-ADAM8 antibody to current CT standards of care will enhance tumor killing, reduce metastasis, and increase survival of patients with ADAM8-expressing TNBC.

Gastric cancer is the second highest cause of cancer mortality in Asia. Overexpression of ErbB3, a cell surface RTK, occurs in ~60% of mGC patients where it is significantly associated with poorer survival. Ligand binding to ErbB3 triggers heterodimerization and downstream signaling through Akt. Neutralizing antibodies that inhibit ligand binding show poor efficacy in clinical trials, likely due to being unable to independently activate antibodies that directly inhibiting heterodimerization could be more effective, however, current methods of antibody isolation offer limited control over the site of antibody binding and, therefore, mechanism of action, requiring extensive screening of antibodies and posing significant challenges to identifying suitable candidates for therapeutic development. Hummingbird Bioscience has used its proprietary Rational Antibody Development Platform for the design and development of novel therapeutic antibodies against ErbB3. Computational sequence and structural analyses predicted highly specific surface epitopes, with strong antigenicity and good safety profiles, where antibody binding would inhibit dimerization. Subsequently, Hummingbird’s directed evolution mouse immunization strategy efficiently isolated monoclonal antibodies that bound with low nM (Kd < 5nM) affinity to these epitopes on native folded ErbB3. Furthermore, these mAbs showed ELISA cross-reactivity to ErbB3 in model organisms (mouse, rat, monkey) but no binding to other EGFR family proteins. Antibody HMBD001 was found to strongly inhibit the phosphorylation of ErbB3 and decrease downstream signaling through the Akt pathway (90% decrease in p-ErbB3 and 60% decrease in p-ARK observed at 24 hrs) resulting in the inhibition of tumor cell proliferation in models of ErbB3+ gastric cancer (over 90% N87 proliferation after 5 days) and breast cancer (up to 85% inhibition of BT474 proliferation after 5 days). In mouse NCI-N87 gastric cancer CDX models, weekly doses of HMBD001 achieved greater than 90% inhibition of tumor growth (at 25 days) with no observable adverse toxicity. The first in-human trial of HMBD001 is planned for 2018.

#25 Effect of nimotuzumab on malignant pleural mesothelioma cell lines. Saé Muñiz-Hernández,1 Vanessa Izquierdo-Sánchez,1 Jorge A. Mendoza-Désién,3 Carolina González-Torres,3 Oscar Arrieta,1 1Instituto Nacional de Cancerologı́a de México, Ciudad de México, Mexico; 2Instituto Nacional de Medı́cina Genómı́ca, Ciudad de México, Mexico.

Malignant Pleural Mesothelioma (MPM) is one of the most clinically aggressive malignancies, with a median survival time of less than 12 months. The monotherapy or combination of therapy with platinum-antifolate chemotherapy agents, may provide survival and life quality improvement in MPM patients. EGFR has been a target for new development drugs that could be used as oncology treatment. Nimotuzumab is a humanized antibody, design by Centro de Immunologia Molecular (Habana, Cuba), for treatment EGFR overexpression neo-plasms. This antibody was approved for treatment of head and neck cancer and metastatic colorectal cancer. MPM exhibit an important expression of EGFR. In this study, we analyzed the effect of nimotuzumab on two cell lines derived of MPM and a xenograph model of one of them, in aticmic nude mouse model. MPM-211 and H2452 mesothelioma cell lines; MRC-5 normal lung cell line and A431 as EGFR positive cell line were used for all assays. We analyzed the viability of cell lines using violet cristal assays. Apoptosis were analyzed with Annexin-V–Fluos Staining kit according to manufacturer instructions. We analyzed the EGFR expression by WB assays. Finally, we generated a xenograft model with MSTO cells in nu/nu mice, and we treated a group with nimotuzumab or cisplatin-gemcitabine one doses/week. Nimotuzumab at any concentration (50, 100, 400 µg/mL) no modified the cellular viability, in both tumor and normal cells, the assays was followed from 24 h to 96 h after exposition. With respect at apoptosis, we no found significant differences between control and exposed samples at 48 and 72 h after nimotuzumab treatment. In order to analyzed the EGFR expression in mesothelioma cell lines, we obtained protein extracts from H2452, H2452 + nimotuzumab and A431. The EGFR protein from MSTD-211, H2452, A431 and MRC-5 cultures in normal conditions and exposed at nimotuzumab 100 µg/mL by 24h, were obtained; then a PAGE-SDS were realized. We observed that both mesothelioma derived cell lines showed similar EGFR expression when it compared with A431 in normal culture conditions; while MRC-5 no showed EGFR expression. When cellular cultures were exposed to nimotuzumab treatment, A431 cells showed similar EGFR expression while MSTO-211 showed high expression. Mice nu/nu (n = 3) were subcutaneously inoculated in the dorsal right flank with MSTO-211 cells. Treatment was applied to animals when tumors were 50 mm³. First mice group received nimotuzumab, second group received cisplatin-gemcitabine; and third group no received treated. Nimotuzumab induced a reduction in tumor volume and mice survival by 4 weeks more that those in the other groups. In vitro exposition of nimotuzumab in mesothelioma cell lines no affect their viability or induce apoptosis. According with the treatment scheme used in this work, nimotuzumab treatment induce a major survival and low toxicity in mice with mesothelioma pleural malignant xenograph.

#26 Panitumumab interacts with TAS-102 leading to combinational anti-cancer effects by blocking EGFR-mediated tumor response to trifluridine. Kazuhisa Satoh,1 Yoshiko Satoh,1 Hidetoshi Kikuchi,1 Naoko Yamashita,1 Yoshiko Satoh,2 Takeshi Kaku,1 Yuji Baba,1 Toshiya Tamura,1 Junpei Soeda2, 1Takeda Pharmaceutical Company Limited, Fujisawa, Japan; 2Takeda Pharmaceutical Company Limited, Tokyo, Japan.

Panitumumab is a monoclonal antibody raised against the human epidermal growth factor receptor (EGFR). TAS-102 is a novel chemotherapeutic agent containing trifluridine (FTD), as the active cytotoxic component. Both panitumumab and TAS-102 have been approved for the treatment of metastatic colorectal cancer (mCRC). In this study, we show the mechanism underlying the anti-cancer effects of the panitumumab/TAS-102 combination in preclinical models. Co-treatment with panitumumab and FTD exerted additive and synergistic anti-proliferative effects in LIM1215 and SW48 colon cancer cells, respectively. Consistent with the in vitro effects, panitumumab/TAS-102 combination led to tumor regression in LIM1215 and COL-01-JCK colon cancer patient-derived xenograft models. In LIM1215 cells, FTD induced ERK/Akt/STAT3 phosphorylation and subsequent serine/threonine phosphorylation of EGFR, while it had no effects on EGFR tyrosine phosphorylation. Panitumumab and the tyrosine kinase inhibitor erlotinib reduced the basal level of EGFR tyrosine phosphorylation in MSTD-211 cells. Panitumumab/TAS-102 combination led to increased miR-21 expression in LIM1215 cells, which may explain reduced EGFR phosphorylation in this setting. Panitumumab/TAS-102 combination led to increased expression of miR-21, which may explain reduced EGFR phosphorylation in this setting. These results suggest that FTD together with the basal activity of the EGFR tyrosine kinase induced downstream pro-survival signaling through ERK/Akt/STAT3. Collectively, we propose that panitumumab interacts with FTD by targeting EGFR-mediated adaptive responses, thereby exerting anti-cancer effects in combination with TAS-102. These preclinical findings provide a compelling rationale to evaluate anti-EGFR antibodies combined with TAS-102 against mCRC.

#27 Combination of paclitaxel and Symo015, a mixture of two monoclonal antibodies directed at MET receptor, to increase anti-tumor effects in gastric cancer. Hyun Jeong Kim,1 Sun Yong Kang,1 Ivan Horak,3 Michael Kragh,3 Woo Sun Kwon,2 Tae Soo Kim,2 Inhye Jeong,1 Sun Young Rha,4 Hyun Cheol Chung1, 1Song-Dang Institute for Cancer Research, Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, Republic of Korea; 2Song-Dang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Republic of Korea; 3Symphogen A/S, Ballerup, Denmark; 4Song-Dang Institute for Cancer Research, Brain Korea 21 PLUS Project for Medical Science, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Republic of Korea.

MET is a proto-oncogene that encodes a protein known as hepatocyte growth factor receptor (HGFR), involved in proliferative, survival and invasive/metastatic abilities of cancer cells. MET has received considerable attention as a potential target for cancer therapy, including gastric cancer (GC). MET amplification is present in 4-5% of GC patients, and associated with poor outcomes and significantly shorter median survival. Although intensive efforts have been directed toward the development of HGF-MET axis inhibitors, there are some issues for clinical translation; 1) proper biomarker to select patients, 2) proper chemotherapy combination partner and 3) proper line of treatment. Therefore, exploring drug to inhibit HGF-MET axis is essential. Among them, Symo015
(Copenhagen, Denmark), a mixture of two monoclonal antibodies directed at MET receptor, is one of the leading agents in the pipeline. In this study, we had 49 GC cell lines including 27 Korean cancer patients. Those cells were analyzed by whole exome sequencing (WES) and RNA sequencing to understand biological and molecular characteristics. Also, expression levels of MET and MET- associated proteins were determined by Western Blotting and Luminex analysis. These ABs were evaluated by ELISA. Sensitivity of Sym015 was screened in 49 GC cell lines and combination with paclitaxel was performed in 6 MET amplification cell lines by CCK-8 assay. Combination index (CI) and dose reduction index (DRI) were evaluated by CalcuSyn software. Among 49 GC cell lines, we confirmed 6 cell lines with MET amplification including 2 novel Korean cancer patient cell lines (YCC-31 and YCC-34) and 17 (34.7 %) cell lines sensitive to Sym015 with 20–68 % inhibition rate at 100 nM. And our data showed that Sym015 was related to MET amplification, c-Met/p-Met overexpression and exon 14 deletion, as we expected. Also, the 6 MET amplified cell lines (SNUS, SNU520, MKN45, YCC-31, YCC-34 and Hs-746T) were all sensitive to Sym015 and downregulate expression of c-Met/p-Met. Using MET amplified GC cell lines, we evaluated the efficacy and potential mechanism of Sym015 in combination with paclitaxel, which is the standard agent for second line treatment of metastatic GC. CI values determined at the ED50 indicated that 3 of 6 cell lines (MKN45, SNU520 and YCC-31) had synergistic effects (CI values < 0.7). When used in combination to treat 4 cell lines (MKN45, SNU320, YCC-31 and Hs-746T), the dose at ED50 of Sym015 could be reduced by 2.2-13.6 fold, based on DRI analysis. Also, the IC50 value indicated that the combination of Sym015 and paclitaxel (MKN45 and SNU520) could be obtained. Our results indicate that Sym015 was sensitive to MET amplified cell lines and the Sym015 combined with paclitaxel therapy had synergistic effects in MET amplified GC.

Cell penetrating proteins targeting Mcl-1 induce in vitro and in vivo on-target cancer cell killing of Mcl-1 dependent cell lines. Sabrina Deroo, Sophie Thiollot, Johan Desmet, Franky Baatz, Karen Vandenbroucke, Eric Lorent, Paula Hendrikx, Philippe Aird, Stefan Lovery, Ignace Lasters, Yvonne McGrath, Complex Luxembourg S.A., Ech-sur-Alzette, Luxembourg; Complex V.V. Headquarters, Deipenbeek, Belgium; Complex V.V., Zwinvaarde (Ghent), Belgium.

The pro-survival protein Myeloid Cell Leukaemia-1 (Mcl-1) plays an essential role in survival of numerous cancers. Mcl-1 gene amplifications occur in a variety of human cancers and overexpression of the Mcl-1 protein is often associated with chemotherapeutic resistance and disease relapse. Complex has developed Cell Penetrating Alphabodies (CPAB), a novel and unique therapeutic class of antibodies engineered to efficiently enter cells and inhibit proteins including Mcl-1. High affinity Alphabodies (ABs) targeting Mcl-1 were engineered by a combination of rational design and phage library screening. In affinity assays, these ABs were shown to bind to Mcl-1 with picomolar affinities whilst binding to Bcl-XL and Bcl-2 was below the detection limit of the assay. In vitro, CPAB uptake was shown to occur rapidly with cytosolic levels reaching up to 1 µM within 2 hours of CPAB exposure. Uptake was associated with cell death of the Mcl-1 dependent multiple myeloma (MM) cell line M1 (IC50=0.5 µM) and killing was correlated with caspase-3/7 activation. Anti-Mcl-1 CPAB were also shown to disrupt Mcl-1-Bak and Mcl-1-Bim complexes in H929 cells and induced dose-dependent Bak activation. In a panel of MM cell lines, anti-Mcl-1 CPAB induced cell death with a median IC50 of 0.96 µM and cell killing was not restricted to a specific subset of MM cell lines (CCD11, MAF, MMSET). Gene expression analysis revealed that the anti-Mcl-1 CPAB cell killing potency correlates with MCL-1 gene expression but correlates best with the MCL-1:BCL-2 gene expression ratio. The same gene expression correlation analysis of the Bcl-2 targeting agent Venetoclax revealed an inverse pattern to that achieved with the Mcl-1 specific CPAB. In vivo, CPAB conferred with an albumin binding domain for extension of half-life, showed a serum half-life in mice of more than 1 hour and associated tumor concentrations of more than 1 µM. Immunohistochemistry and direct detection of fractionated tumor tissue confirmed the intracellular presence of the CPAB in the tumor cells. When given daily IV at 20 mg/kg, anti-Mcl-1 CPAB induced 17 (34.7 %) tumor growth inhibition of 50% versus control in 5 MM xenograft models (H929 and MOLP-8). Tumor growth remained significantly inhibited even two days after the last treatment in the MOLP-8 model and tumor growth inhibition was associated with increased staining of cleaved caspase-3 as compared to vehicle treated tumors. In summary, anti-Mcl-1 CPAB efficiently kill Mcl-1 dependent cancer cell lines by on-target effects as demonstrated by increased caspase-3 activation and inhibition of tumor growth. The CPAB induced 50% versus control in vivo and (3) correlation of potency with MCL-1:BCL-2 gene expression ratio. These CPAB induced a robust reduction in tumor growth in mouse models and represent a best-in-class cell penetrating protein therapeutics for tackling intracellular PPI critical to diseases with unmet medical need.

Addition of Galunisertib to DC101 increased angiogenesis inhibition and tumor growth control in hepatocellular carcinoma (HCC). Annemilai Tijeras-Raballand, Christian Hobeaika, Elise Payen, Matthieu Martinet, Philippe Bonnin, Karim A. Benhadj, Clarisse Eveno, Marc Pocard, Sandrine Faivre, Eric Raymond, Armand de Grammont, AFR Oncology, Paris, France; University Hospital, Poitiers, France; U965, Lariboisiere University Hospital, Paris, France; Eli Lilly Company, New Jersey, NJ; Beaumont University Hospital, Clichy, France; Saint-Joseph Hospital, Paris, France.

Introduction: Galunisertib is a selective ATP-mimetic TGF-β receptor (TGF(R))-I inhibitor and DC101 is a rat antiagonist antibody to mouse VEGFR-2 (CD126) receptor. Single agent anti-VEGFR-2 treatment had synergistic effects in MET amplified GC. MKN45 and SNU520 cell lines were notably observed in both 2 MPM cell lines (H2052 and H2452). Interestingly, we found that MPM cell lines but not normal cells actively secreted the S100A11, a Ca2 + binding protein. S100A11 on cell proliferation, colony formation, migration, invasion and down-stream signaling. The efficacy of anti-S100A11 antibody on cell proliferation and (3) correlation of potency with MCL-1:BCL-2 gene expression ratio. Those results will be confirmed by the assessment of micromolecules number on HPS section for tumor growth and CD31 staining for angiogenesis analysis (number of vessels and the vessel lumen area). The effects of the combination versus monotherapies will be evaluated on the immune landscape. Conclusion: The combination of galunisertib and DC101 showed promising anti-tumor activities that were associated with decreased angiogenesis.

#30 S100A11 is a prominent therapeutic target in malignant pleural mesothelioma. Hirokatsu So, Hiromasa Yamamoto, Kent Namba, Hidejiro Torigoe, Takahiro Yoshikoa, Kazuhiro Shien, Junichi Soh, Shinichi Toyooka. Okayama Univ. Hospital, Okayama City, Japan.

[Background & Purpose] Malignant pleural mesothelioma (MPM) is an aggressive neoplastic disease that shows a serious malignancy in thoracic cavity with a median survival time of 9–12 months. The therapeutic approaches in clinical standard are limited to surgery and chemotherapy for early and advanced stages, respectively. The strategies unfortunately provide only palliation, thus further advanced approach is required. S100A11, a Ca2 + binding small protein with two EF-hands, is frequently upregulated in various human cancer tissues. It has been reported that S100A11 plays an important role in progression of many cancers derived from thyroid, ovarian and lung tissues, but its roles and signature in MPM are poorly understood. In this study, we investigated the impact of S100A11 in MPM cell lines and resected tumors.

[Material & Methods] We explored the expression of S100A11 in 7 MPM cell lines (HP-1, H28, MSTO-211H, H2052, H290, H2452, and YUMC44) and 2 normal mesothelial cell lines (Met-5A and LP-9). We analyzed the effect of S100A11 on cell proliferation, colony formation, migration, invasion and down-stream signaling. The efficacy of anti-S100A11 antibody on cell proliferation and downstream signaling was also determined. [Results] We found that S100A11 protein was consistently upregulated in 7 MPM cell lines at a significant level in comparison to 2 normal mesothelial cells. The same phenomenon was also confirmed on MPM tissue and normal human mesothelial cell line (M1). Tumor growth inhibition of 50% was strongly stained at MPM cells, but not at surrounding normal lung cells. Specific knockdown of S100A11 by small interfering RNA turned the aggressive cells into the attenuated phenotypes for proliferation, invasion and migration. Those were notably observed in both 2 MPM cell lines (H2052 and H2452). Interestingly, we found that MPM cell lines but not normal cells actively secreted the S100A11 protein. To pursue this, we next tried to inhibit the function of the secreted S100A11. Administration of S100A11 neutralizing antibody significantly inhibited the proliferation of 4 MPM cell lines (H2052, H2452, H28, and H290). The antibody had no effect on the proliferation of only one MPM cell line, MSTO-211H, which showed no secretion of S100A11. Taken together,
these results suggest that S100A11 secreted from MPM cells can be a prominent target for effective MPM therapy. [Conclusion] Our results suggest that S100A11 is a possible therapeutic target in MPM.

#31 Preclinical development of a novel biparatopic HER2 antibody with activity in low to high HER2 expressing cancers. Nina Weisser, Grant Wickman, Rupert Davies, Gerry Rowse. Zymeworks, Vancouver, British Columbia, Canada.

HER2-directed therapies have improved clinical outcomes for many patients with HER2 overexpressing breast and gastric cancer. Despite these successes, there remains a need to develop effective HER2-targeted therapies for these and other HER2-expressing tumors, particularly in the setting of recurrent or metastatic disease. One approach is to develop a single multifunctional antibody that has improved capacity and efficiency for binding HER2 compared with available HER2 inhibitors, can elicit ADCC, block ligand induced heterodimerization of HER2 with other HER family receptors, and down-regulate HER2 protein on the cell surface. ZW25 is a novel humanized, IgG1-like bispecific antibody directed against two distinct epitopes on the HER2 receptor. ZW25 has low nM binding affinity (0.9-16 nM) to recombinant HER2 and to cultured cancer cells with a range of HER2 expression, and shows higher maximal binding (1.4-1.9x) than monospecific HER2 antibodies on all tumor cell lines tested. The unique structure of ZW25 favors crosslinking of multiple HER2 receptors which is thought to promote clustering, and improves HER2 internalization compared to monospecific HER2 antibodies. In vitro studies demonstrated that ZW25 alone caused significant inhibition in growth of human cancer cell lines with a wide range of HER2 expression (5-54% inhibition depending on the cell line), and inhibited ligand-mediated tumor cell proliferation. ZW25 elicited concentration-dependent ADCC at nM potency (0.05-64 nM) with maximal lysis up to 52% on TNBC cell lines expressing HER2 at a 0+ level. ZW25 also exhibited synergy and additivity with multiple chemotherapeutic agents including platin, taxanes, tumorubin inhibitors, and DNA synthesis inhibitors in various HER2 expressing tumor cell lines. In vivo studies demonstrated antitumor activity and/or improved survival against xenografts from a range of tumor types. In a HER2 3+ gastric cancer PDX model ZW25 induced significant tumor regressions, exhibiting 30% tumor growth inhibition relative to hlgG control and a 70% complete regression rate (trastuzumab exhibited 11% tumor growth control with no complete regressions). In a HER2 1+ breast cancer PDX model ZW25 significantly improved median survival (58 vs 28 days) and exhibited 141% tumor growth inhibition relative to hlgG control (trastuzumab exhibited 63% tumor growth inhibition, with median survival 39 days). In a low HER2-expressing NSCLC CDX model ZW25 improved median survival compared to hlgG control or cisplatin (>66 vs 25 or 26 respectively) and exhibited 159% tumor growth inhibition relative to hlgG control. In a GLP repeat dose toxicology study, ZW25 was well tolerated with no adverse effects at doses up to 30 mg/kg weekly IV for up to 8 weeks. Based on these findings, a first in human clinical trial of ZW25 has been initiated in patients with recurrent and/or metastatic HER2-expressing cancers.

#32 Preclinical evaluation of MCLA-158: A bispecific antibody targeting LGR5 and EGFR using patient-derived colon carcinoma organoids. Rob Roovers,1 Bram Herpers,2 Mark James,3 Berina Eppink,4 Carme Cortina,3 David John de Kruif,1 John de Kruif,1 Ton Logtenberg,1 Piet Gros,2 Cecile Geuijen,1 Mark Throsby1.1Merus, Utrecht, Netherlands; 2Merus, Utrecht, Netherlands; 3Utrecht University, Utrecht, Netherlands; 4The Hubrecht Institute, Utrecht, Netherlands.

Background. Colon cancer (CRC) is the third most common cancer and remains a large unmet need. Dysregulation of Wnt and receptor tyrosine kinase (RTK) signalling pathways are important oncogenic driving events in CRC. Due to this dysregulation, Wnt target genes are expressed at higher levels in CRC particularly in tumor initiating cells. We previously performed an unbiased screen of 626 candidates, including 18 RTK targets that resulted in the selection of MCLA-158. Methods. A cohort of 32 genetically and transcriptionally annotated patient-derived colorectal cancer and normal colon organoids were used to functionally characterize responses to antibodies based on morphological changes with high content 3D imaging. Binding affinity was measured by surface plasma resonance and cell based assays. The antibody binding epitopes were mapped by shotgun mutagenesis and FACS based screening. Ligand (R-spondin or EGF) blocking activity was measured in vitro by competition for ligand binding or functional inhibition of ligand dependent growth. In vivo activity was evaluated in xenograft models generated from organoids subcutaneously implanted into immunocompromised mice. Safety was evaluated via once weekly intravenous administration of MCLA-158 to cynomolgus monkeys for 4 weeks and monitoring for pathological changes. Results. MCLA-158, an ADCC enhanced common light chain IgG1 bispecific antibody, binds in domain III of EGFR and in the N-Cap/16 LRR of LGR5, both ligand binding regions, however, only EGF binding was blocked by MCLA-158. MCLA-158 demonstrated inhibitory activity in 74% of tumor organoids independent of KRAS mutational status but was not active on organoids of the cohort harboring both KRAS and PIK3CA mutations. MCLA-158 was significantly more active on organoids derived from tumors than from normal tissue in contrast to cetuximab, which demonstrated equivalent activity on both (range 20-100 fold, n=4). In vivo activity was evaluated against tumor organoids with different KRAS mutations and was shown to be beneficial to MCLA-158 in vitro. In all cases, MCLA-158 significantly inhibited the growth of the tumor compared to both control and cetuximab treatment. Inhibitors of both the Wnt and EGFR pathways have shown significant toxicity in humans. An initial evaluation of MCLA-158 toxicity in cynomolgus monkeys did not demonstrate any pathological finding after repeated dosing at 25mg/kg. Conclusions. MCLA-158 demonstrates superior activity compared to reference antibodies in both in vitro and in vivo tumor organoid based assays regardless of KRAS status and was well tolerated in non-human primates. These preclinical data suggest MCLA-158 could benefit patients with metastatic CRC and warrant clinical evaluation.

#33 The binding mode of the bispecific anti-HER2xHER3 antibody MCLA-128 is responsible for its potent inhibition of HRG-driven tumorigenesis. David Maussang-Detaille,1 Camilla de Nardis,2 Linda Hendriks,3 Carina Bartelink-Cleyn,4 Tristan Goumans,4 Robert Doornbos,1 Lex Bakker,1 John de Kruif,1 Ton Logtenberg,1 Piet Gros,2 Cecile Geuijen,1 Mark Throsby1.1Merus, Utrecht, Netherlands; 2OcellOBV, Leiden, Netherlands; 3IRB Barcelona, Barcelona, Spain; 4The Hubrecht Institute, Utrecht, Netherlands.

Introduction: MCLA-128 is an ADCC-enhanced IgG1 bispecific antibody that targets the HER2:HER3 dimer and is currently being tested in Phase II/III clinical trials. MCLA-128 demonstrates an in vitro potency superior to other anti-HER2 and anti-HER3 antibodies in cells stimulated with high concentrations of heregulin (HRG) thereby overcoming one of the resistance mechanisms of current HER2 therapies. This study investigates the binding mode of MCLA-128 and proof of concept studies in HRG-driven tumor models. Methods: Alanine scanning shotgun mutagenesis was used to map the epitopes of MCLA-128 to HER2 and HER3. Fab fragments of MCLA-128 were crystallized with the soluble extracellular domains of HER2 and HER3. SAXS analysis on the HER2-HER3-MCLA-128 complex was performed to investigate the binding mode of the bispecific antibody in solution. Ligand-induced dimer specificity was investigated with PathHunter® heterodimerization assays. Bispecific anti-HER2xHER3 antibody and its parental anti-HER3 monoclonal antibody were labelled with 125I to compare their biodistribution profiles. The efficacy of MCLA-128 in HRG-driven systems was shown in vitro in MDA-MB-175 cells and in vivo in an orthotopic intracranial patient-derived xenograft (PDX) model originating from a breast cancer brain metastasis. Results: The shotgun mutagenesis study identified that the bispecific antibody MCLA-128 binds amino acids T144, R166, R181 in HER2 domain I and R426 in HER3 domain III. Crystallographic studies confirmed the binding mode of the bispecific antibody MCLA-128 and suggested that MCLA-128 locks the HER3 receptor in its ligand-unbound inactive conformation. SAXS analysis suggests that the bispecific antibody MCLA-128 forms inter-dimer rather than intra-dimer interactions. In vivo, MCLA-128 specifically blocked HRG-induced signaling of HER2:HER3 but not HER2:HER4 heterodimers. Biodistribution of MCLA-128 in a xenograft model of breast cancer showed that the penetration of MCLA-128 in JIMT-1 HER2-amplified tumors is HER2-dependent despite the high affinity of the HER3 Fab arm for its receptor. MCLA-128 efficiently blocked tumor growth of the HRG-driven HER2 (+) breast cancer cell line MDA-MB-175 in 3D in vitro. Treatment of orthotopically transplanted HER2-amplified breast cancer brain tumors in mice led to 100% survival with MCLA-128, in contrast to 38% and 0% survival in T-DM1 and vehicle treated mice respectively. Conclusion: MCLA-128 targets HER2-positive tumors via its HER2 arm and locks HER3 in an inactive conformation. The potent anti-proliferative activity of MCLA-128 in vitro and in vivo supports the clinical development of this bispecific HER2xHER3 antibody in HRG-driven tumors.

#34 A MET x MET bispecific antibody that induces receptor degradation potently inhibits the growth of MET-addicted tumor xenografts. John DaSilva. Regeneron Pharmaceuticals, Tarrytown, NY.

Ablation regulation of MET receptor tyrosine kinase signaling is associated with development and progression of various human tumors. Elevated MET signaling during tumorigenesis results from MET amplification, mu.
tation or up-regulation of the ligand, HGF. MET amplification is thought to be a key driver of oncogenesis in non-small cell lung cancers (NSCLC) and oesophageal gastric malignancies. In addition, mutations resulting in exon 14 deletion of MET have been described as oncogenic drivers in a subset of NSCLC. Both preclinical and recent clinical results indicate that tumors harboring these genetic alterations respond to MET inhibitors, validating MET as a cancer driver. We have developed a novel bispecific antibody that binds to two distinct epitopes on MET. The METxMET bispecific antibody blocks HGF binding and exhibits very low agonist activity (much weaker than either of its parental antibodies). Furthermore, the METxMET bispecific antibody effectively promotes MET degradation, thereby inhibiting ligand-independent signaling in MET-amplified tumor cells. The METxMET bispecific antibody exhibits strong anti-tumor efficacy in xenograft models harboring MET genetic alterations, either completely inhibiting tumor growth (EBC1 MET-amplified NSCLC) or promoting substantial tumor regression (SNU5 MET-amplified gastric cancer, Hs746T MET-amplified/ MET exon 14 skip gastric cancer). Analysis of lysates from SNU5 tumors treated with the METxMET specific antibody confirms its ability to effectively promote MET degradation in vivo. Finally, the METxMET bispecific antibody strongly inhibits the growth of a glioblastoma xenograft model (U118) driven by autocrine HGF signaling. In summary, we have generated a novel METxMET bispecific antibody that potently inhibits the growth of MET-dependent tumors xenografts. Our data suggest that antibody-mediated MET degradation may be an effective clinical strategy in tumors harboring MET genetic alterations.

#35 The dual inhibition of Met and EGFR by ME22S, a novel MET/EGFR bispecific monoclonal antibody, suppresses the proliferation and invasion of laryngeal cancer. Bok-Sook Lee,1 Dae Ho Kim,1 Yeon Soo Kim,1 Jae Won Chang,1 Bon Seok Koo,1 Ho Ryun Won,1 Haeng-Jun Kim,1 Hyun-Young Cha,1 #36 Novel anti-Sialyl-Tn monoclonal antibodies and antibody-drug conjugates (ADCs) demonstrate tumor specificity in vitro and in vivo antitumor efficacy. Jillian M. Prendergast,1 David A. Eavarone,1 Patricia E. Rao,1 Adam D. Curtis,1,2 Lindsay S. Shopland,2 Todd A. Hoftert,2 Jenna Stein,2 Jeff Behrens,1 Daniel T. Dransfield,1 Siamab Therapeutics, Inc., Newton, MA; 3Eastern Maine Medical Center, Brewer, ME.

Tumor-associated carbohydrate antigens (TACAs) historically have been challenging targets for antibody therapeutics. Sialyl-Tn (STn) is a cancer specific antigen that is expressed on the cell surface of carcinomas including ovarian, colon, prostate, and pancreatic tumors but is rarely present in normal tissues. STn expression has been linked to innate immune suppression, a chemoresistant phenotype, metastasis, and poor prognosis. Previous attempts to target this antigen in the clinic with synthetic glycan vaccines proved safe but lacked efficacy. We have developed highly selective humanized monoclonal antibodies and antibody-drug conjugates (ADCs) targeting TACAs, such as STn. Remarkable sequence homology across all anti-STn mAbs was observed in both heavy and light chains, and hot spots for hypermutation were identified. These antibodies were selected using our glycan microarray that enriches for candidates whose binding is protein-independent, highly selective and demonstrates exceptional target affinity. Lead humanized candidates demonstrated single digit nanomolar EC50s in ELISA/flow cytometric assays, STn selective cell internalization, and in vivo tumor growth inhibition in a murine colon xenograft model. STn binding sites in common tumor lines (ovarian, gastric and breast) were determined per cell and subsequent cytotoxicity assays in these lines demonstrated in vitro efficacy. Tumor microarray experiments revealed membranous staining in cancerous tissues of various indications. Binding studies of anti-STn antibodies to primary human cancer samples by flow cytometry demonstrated that both tumor- associated and suppressor cell types were stained, with cell lines and xenografts expressing high levels of STn being more extensively stained compared to low STn expressing samples. STn selective mAbs show promise as therapies for solid tumors and could also target MDSCs to promote antitumor immune responses.

#37 Novel antibody-drug conjugates targeting DGN549, a PAMAM dendrimer with solid tumors demonstrate potent preclinical activity. Stuart W. Hicks,1 Rachel C. Yoder,1 Deryk Loo,1 Asli Muvaffak,1 Yinghui Zhou,1 Megan E. Fuller,1 Molly A. McShea,1 Marian Themeles,1 Katherine H. Mucciareno,1 Juniper A. Scribner,2 Bhawati Barat,2 Thomas Sun,2 James Tamura,2 Francine Z. Chen,2 Kerry A. Donahue,2 Tom Chittenden,1 Immunogen, Inc., Waltham, MA; 2MacroGenics, Inc., South San Francisco, CA; 3Macrogenics, Inc., Waltham, MA.

ADAM9, also known as MDC9 or melanin-1, is a member of the ADAM (a disintegrin and metalloproteinase) family of proteins which have been implicated in cytokine and growth factor shedding, and cell migration. Dysregulation of ADAM9 has been implicated in tumor progression and metastasis, as well as pathological neovascularization. ADAM9 overexpression has been shown to correlate with poor prognosis in prostate, renal, and pancreatic cancers. Using an immunization approach in which antibodies were raised to a preclinical ADAM9 antibody and a cell line followed by screening on tumor and normal tissues, we identified ADAM9 as a promising cell surface tumor target. FFPE-IHC expression analysis revealed that ADAM9 is overexpressed in multiple solid tumor indications relative to corresponding normal tissues. The overexpression of ADAM9 in tumors coupled with its restricted expression in normal tissues make ADAM9 an attractive target for antibody-drug conjugate (ADC) therapy. Here, we describe two ADCs both of which are based on a high affinity anti-ADAM9 antibody to selectively target ADAM9-expressing tumors. The first ADC utilizes the maytansine-derived microtubule disruptor, DM4, linked via a hindered disulphide hydrophilic linker (sulfo-SPDB). The second ADC exploits an ultra-potent DNA alkylating payload, DGN549, which is conjugated to two engineered cysteines via a peptide linker. Both conjugates bound with similar subnanomolar affinity to ADAM9-expressing cells. In vitro cytotoxicity studies showed that anti-ADAM9 ADCs can kill a broad panel of ADAM9-positive tumor cell lines, including lung, pancreatic, renal, prostate, and colon tumor cell lines. In particular, the anti-ADAM9-DGN549 conjugate was extremely potent with IC50 values ranging from 0.1 to 65 pM and was at least 2 logs more active than a non-targeting conjugate. Surprisingly, efficient in vitro cytotoxicity was observed at ADAM9 expression levels as low as a few thousand cell surface receptors per cell. Consistent with their in vitro activity, both anti-ADAM9 ADCs displayed compelling anti-tumor activity in xenograft models. In a Calu3 non-small cell lung cancer xenograft model, anti-ADAM9-DGN549 exhibited antitumor activity against a broad panel of ADAM9-positive cell lines, including lung, pancreatic, renal, prostate, and colon tumor cell lines. In the same model, a single intravenous dose of 0.25 mg Ab/kg of the anti-ADAM9-DGN549 produced durable complete remissions in 8/8 mice. A non-targeting DGN549 ADC was inactive even when dosed at 10 times that of the anti-ADAM9 ADC, demonstrating that targeted delivery of DGN549 through ADC binding is required for activity. These data demonstrate that anti-ADAM9 ADCs exhibit antitumor activity against a broad panel of ADAM9-positive malignancies and cause durable remissions in preclinical models at doses expected to be clinically achievable. Anti-ADAM9 ADCs represent a promising therapeutic strategy to target a wide range of ADAM9-expressing tumors.
Target validation, antibody discovery and preclinical data supporting ADAM9 as an antibody-drug conjugate therapeutic target for solid tumors. Juniper A. Scribner,1 Bhaswati Barat,2 Stuart W. Hicks,3 Nicholas C. Yoder,3 Thomas Son,1 Luisana Widjaja,1 Gundo Diedrich,2 Sergey Gorlatov,2 Jeff Hooley,3 Ann Easton,1 Peter Lung,1 Anushka De Costa,1 Francine Chen,1 Michal Chmielewska Liguas,1 Michael Holtalainen,1 Michael Hottuck,1 Valentina Ciccarrone,2 Nadia Gantt,2 James Tamura,2 Megan E. Fuller,1 Molly McShea,2 Scott Koeing,3 Syd Johnson,1 Paul A. Moore,2 Ezio Bonvini,2 Deryk Loo1,2,1MacroGenics, Inc, South San Francisco, CA;1MacroGenics, Inc, Rockville, MD;2ImmunoGen, Inc, Waltham, MA.

Introduction: A target-unbiased approach based on intact cell immunizations with freshly isolated solid tumor cell lines followed by an immunohistochemistry (IHC) screen for cancer-specific candidates, led to the identification of anti-ADAM9 (a disintegrin and metalloproteinase) mAbs with highly differential tumor-versus-normal tissue binding. ADAM9 is a cell surface protein over-expressed in multiple tumors, with a possible role in promotion and progression of cancer through multiple mechanisms, including modulation of adhesion and migration as well as processing of tumorigenic and pro-angiogenic factors. In this preclinical study, we performed target/mAb validation and evaluated the potential therapeutic activity of anti-ADAM9 antibody-drug conjugates (ADCs) toward ADAM9-expressing solid cancers. Methods: IHC was performed with anti-ADAM9 mAbs to confirm and extend available data of human normal and tumor tissue expression. Epitope mapping studies were conducted to define antibodies, mAbs were also screened to identify those that efficiently internalized into tumor cells. In vitro cellular processing studies were performed to further evaluate the mAbs as ADC candidates. Selected mAbs were converted to ADCs via chemical conjugation to potent anti-microtubule (DM4) or DNA alkylating (DGN549) agents; in vitro cytotoxicity studies were conducted with tumor cell lines representing human cancer types that overexpress ADAM9. A lead mAb was then selected for humanization and affinity maturation to yield a development candidate. Results: Anti-ADAM9 mAbs exhibited strong reactivity toward the tumor epithelium of solid cancers, including pancreatic, kidney, prostate, bladder, breast, colon, lung, and ovarian cancer, but limited reactivity toward normal tissues. Anti-ADAM9 mAbs were efficiently internalized and processed by tumor cell lines, including lines with only modest ADAM9 expression. Anti-ADAM9 ADCs exhibited specific, dose-dependent cytotoxicity toward ADAM9-positive cancer cell lines in vitro, with IC50 values in the sub-nanomolar range. Humanization and affinity maturation of the lead mAb yielded a development candidate that retains potent antitumor activity toward ADAM9-positive tumor cell lines and equivalent, high affinity binding to both human and cynomolgus monkey ADAM9. Conclusion: ADAM9 is a cell surface antigen that is over-expressed on a wide range of solid cancers. Anti-ADAM9 mAbs that were strongly reactive with representative tumors exhibited high affinity for the antigen and were efficiently internalized and processed by ADAM9-bearing tumor cells. Anti-ADAM9 ADCs demonstrated dose-dependent cytotoxicity in vitro toward a panel of ADAM9-positive tumor cell lines. Our findings demonstrate that an ADC targeting ADAM9 may serve as a potential therapeutic for ADAM9-expressing solid tumors.

Discovery of PEN-221, an SST2R-targeting somatostatin peptide conjugate with potent activity in vitro and in vivo. Brian H. White, Patrick Bazinet, Kerry Whalen, Michelle DuPont, James M. Quinn, Rossizza Alargova, Tsun Au Yeung, Adam Brockman, James Gifford, Haley Oller, Kristina Kriksciukaite, Charles-Andre Lemelin, Patrick Lim Soo, Benoit Moreau, Samantha Perino, Gitanjali Sharma, Rajesh Shinde, Beata Sveredy-Krawiec, Mary Simcox, Richard Wooster, Mark T. Bilodeau, Tarveda Therapeutics, Watertown, MA. Here we describe the discovery and the structure of PEN-221, a somatostatin receptor 2 (SST2R) targeting peptide conjugated to DM1. PEN-221 is the first clinical compound from Tarveda’s Pentarin platform, which utilizes miniaturized drug conjugates that diffuse rapidly and deeply into solid tumors. Antibody drug conjugates (ADCs) have garnered a significant amount of attention in their ability to direct cytotoxic drugs to cancer cells; however, the efficacy of ADCs in solid tumors is limited by the slow diffusion through the solid tumor tissue. Pentarins are designed to improve the efficacy of targeted therapies through effective tumor cell targeting and enhanced tumor penetration. SST2R, a GPCR overexpressed in multiple types of neuroendocrine tumors, including small cell lung cancers, internalizes rapidly upon agonist stimulation, making it an ideal vector for delivering cytotoxic payloads. Examination of a variety of SST2R targeting ligands, as well as several potential conjugation sites, led to the identification of the C-terminal side chain of [Tyr3]-octreotate amidide as the best conjugation site for a lipophilic payload. The use of DM1 as a payload afforded superior receptor affinity and receptor internalization when compared to other similarly potent microtubule-targeting agents. In vitro studies show that PEN-221 has receptor-dependent cytotoxic effects, and preclinical studies demonstrate PEN-221 induces tumor regression in several SST2R expressing xenograft models.

Development of a novel antibody-drug conjugate targeting endosialin/TEM-1: potent antitumor activity in sarcoma. Gianluca Sala,1 Stefano Iobb,2 Ezio Bonvini,2 Deryk Loo1,2,1MacroGenics, Inc., South San Francisco, CA;2Mediapharma srl, University of L’Aquila, L’Aquila, Italy.

The TEM-1/Endosialin/CD248 receptor is expressed in the cell surface of tumor-associated stroma cells, as well as in sarcoma and neuroblastoma tissues. This receptor is emerging as an attractive molecule in diagnostics and therapeutic because of its expression across the stroma of many human tumors, the low to absent expression in normal tissues and accessibility from the vascular circulation. In this study, we present evidence of the preclinical efficacy of a novel Antibody-Drug Conjugate (ADC). It consists of a humanized TEM-1 monoclonal antibody (E8.3-3) conjugated to a highly potent payload (TEM-1-ADC). In TEM-1 expressing cancer cell lines, this TEM-1-ADC demonstrated a powerful, specific and target-dependent killing activity. High expression levels of TEM-1 in cells correlated with efficient internalization, efficacy, and cytotoxic effects in vitro. Efficacy studies demonstrated that TEM-1-ADC treatment leads to a long lasting tumor growth inhibition of cell line-based models of human sarcoma. Taken together, our results demonstrated that TEM-1 is an attractive target in sarcoma and suggest that TEM-1-ADC has the potential to be developed into a biotherapeutic agent in these malignancies.

An Antibody Conjugate targeting HER-3 demonstrates promising antitumor efficacy in a wide range of human cancer. Gianluca Sala,1 Manuela Iezzi,2 Alessia Lamolinara,1 Emily Capone,2 Stefano Iobb,2 Jean-Fred Sau niere,2 Sara Ponziani,3 Francesco Gianianti,2 Rodolfo Ippoliti2,4 University of Chieti, Chieti, Italy;2Mediapharma srl, University of L’Aquila, L’Aquila, Italy.

The HER-3 receptor is emerging as an attractive molecule in therapeutics because of its overexpression across many human cancers and because of its role in several compensatory processes that underlay emergence of resistance to certain cancer drugs. In this study, we present evidence of the preclinical efficacy of a novel Antibody-Drug Conjugate (ADC) targeting HER-3. It consists of a humanized HER-3 monoclonal antibody (mAb EV20), which recognizes the HER-3 extracellular domain, conjugated to different payloads (HER-3-ADCs). In HER-3 expressing cancer cell lines, these HER-3-ADCs demonstrated a powerful, specific and target-dependent killing activity. High expression levels of HER-3 in tumor cells correlated with efficient internalization, efficacy, and cytotoxic effects in vitro. Efficacy studies demonstrated that HER-3-ADCs target radia to a long lasting tumor growth inhibition of cell line-based models of human head and neck, breast, pancreatic, prostatic, lung, stomach cancers and melanoma. Overall, these findings validate HER-3 as an attractive therapeutic target in multiple solid tumors and support further clinical development and application of HER-3 targeting ADCs.

Preclinical development of a duocarmycin-based antibody-drug conjugate targeting B7-H3 for solid cancer. Thomas Son,1 Juniper A. Scribner,2 Jeff Hooley,3 Michael Chiuchi,1 Pam Li,1 Timothy E. Hotaling,1 Anushka De Costa,1 Yan Chen,1 Francine Chen,1 Bhaswati Barat,1 Valentina Ciccarrone,2 Timur Gaynutdinov,2 James Tamura,2 Scott Koeing,3 Syd Johnson,1 Paul A. Moore,2 Ezio Bonvini,2 Deryk Loo1,2MacroGenics, Inc., South San Francisco, CA;1MacroGenics, Inc., Rockville, MD.

Introduction: B7-H3 is a member of the B7 family of immunomodulatory molecules, overexpressed in a wide range of solid cancers. B7-H3 overexpression has been correlated with disease severity and poor outcome in several cancer types. Proof-of-concept studies targeting B7-H3 demonstrated that auristatin-based B7-H3 antibody-drug conjugates (ADCs) exhibited potent cytotoxicity in vitro and antitumor activity in vivo toward a range of B7-H3 expressing tumor cell lines. Based on these preliminary results, we undertook preclinical development of a B7-H3 ADC comprised of a humanized B7-H3 mAb conjugated to a potent DNA alkylating payload. Methods: Chimeric B7-H3 mAbs were conjugated to vc-seco-DUocarmycin-hydroxyBenzamide Azaindole (DUBA) (ADC conjugated and provided by Synthon Biopharmaceuticals B.V.). In vitro and in vivo activity studies were conducted with tumor cell lines that overexpress B7-H3. Based on the potent activity, together with the biophysical properties and immunohistochemistry (IHC) profiles of the candidates, a lead mAb was selected for preclinical development. The mAb was humanized via CDR grafting and conjugated to DUBA to yield the development candidate MGC018. In vitro and in vivo studies were then conducted with MGC018 to confirm and extend
DX-8951. U3-1402 achieved a high drug-to-antibody ratio (DAR: 7–8), because anti-HER3 antibody (patritumab) and a novel potent topoisomerase I inhibitor inhibit the growth of non-small cell lung cancer with EGFR mutation. Kimio Yonesaka,1 Koji Haratani,1 Kenji Hirotani,1 Kazuhiko Nakagawa1,1 Kindai University Faculty of Medicine, Japan; 2Daiichi Sankyo Co., Ltd., Wimbledon, UK.

#43 ASN004, a novel 5T4-targeted Dolaflexin ADC, achieves complete regressions and tumor-free survivors in a broad variety of solid tumor models. Roger A. Smith, David J. Zammit, Sanjeeva P. Reddy. Asana BioSciences, Lawrenceville, NJ.

ASN004 is an Antibody Drug Conjugate (ADC) that targets the 5T4 oncofetal antigen (trophoblast glycoprotein). High expression of 5T4 is observed in a wide range of malignant tumors, while very limited expression is found in normal tissues. ASN004 incorporates a novel single-chain homo-dimer antibody, Flexi-mer linker technology (Mersana Therapeutics), and several cytotoxic dolastatin (auristatin) analog warheads per ADC molecule with a drug/antibody ratio of ~15:1. ASN004 shows high affinity for the 5T4 antigen (Kd < 30 pM) and 5T4-expressing tumor cells; rapid cellular internalization; and potent, selective cytotoxicity. ASN004 provides complete tumor regressions and tumor-free survivors in multiple tumor xenograft models, derived from human tumor cell lines having both high and low 5T4 expression levels. Tumor-free survivors were achieved at doses that are well-tolerated, based on xenograft body weight measures and exploratory toxicity studies in pharmacologically-relevant non-human primates. As well, tumor-free survivors were achieved in xenograft tumor models following administration of a single dose of ASN004, as low as 1 mg/kg iv. The broad activity of ASN004 has been demonstrated by its superior efficacy in a head-to-head study against trastuzumab-DM1, in a low-ST4, high-HER2 expressing tumor xenograft model. Finally, tumor xenografts that initially responded to ASN004 and later showed tumor regrowth, had not developed resistance and responded well to subsequent treatment with ASN004. Overall, ASN004 is demonstrated to be an ADC with high therapeutic potential in multiple tumor types, encompassing a wide range of 5T4-expression levels. IND-enabling toxicity studies are ongoing, in preparation for advancement to clinical studies in patients with solid tumors.

#44 U3-1402, a novel HER3-targeting ADC, and a novel DNA topoisomerase I inhibitor inhibit the growth of non-small cell lung cancer with EGF mutation. Kimio Yonesaka,1 Koji Haratani,1 Kenji Hirotani,1 Kazuhiko Nakagawa1,1 Kindai University Faculty of Medicine, Japan; 2Daiichi Sankyo Co., Ltd., Wimbledon, UK.

Background HER3, a member of the HER family, is overexpressed in non-small cell lung cancer (NSCLC), especially in those with EGF mutation. Anti-HER3 antibody therapies, including patritumab, are effective, but limited in their efficacy, for patients with NSCLC. U3-1402 is a novel ADC composed of an anti-HER3 antibody (patritumab) and a novel potent topoisomerase I inhibitor DX-8951. U3-1402 achieved a high drug-to-antibody ratio (DAR: 7–8), because it is homogeneously conjugated with the payload. Here, we aimed to preclinically evaluate U3-1402’s efficacy in NSCLC, especially in those with EGF mutation. Materials and methods An in vitro growth inhibition assay was used to evaluate the sensitivity of 14 NSCLC cell lines to U3-1402. Cells were treated with U3-1402 at different concentrations (0–10 μg/ml) over 7 days; 50% growth inhibitory concentration relative to control (IC50) was calculated. PC9, HCC827, HCC827GR5, Ma70, Ma70GR, 11-18, H1650, HCC4006, and H1975 cells had the EGF mutation. HCC827GR5 and Ma70GR were EGF-TKI resistant clones, with MET genomic amplification and an unknown resistance mechanism, established from HCC827 and Ma70 cells, respectively. HER3 mRNA expression levels were measured by quantitative reverse transcription-PCR (qRT-PCR) and the ratio was calculated against house-keeping genes in each cell line. Results The in vitro growth inhibition assay indicated that HCC827GR5, Ma70GR, and 11-18 cells were sensitive to U3-1402 (IC50 values 1.0, 5.2, 3.2 μg/ml, respectively). However, other cells were relatively resistant to U3-1402, having IC50 values greater than 10 μg/ml. Notably, HCC827GR5 cells were more sensitive to U3-1402 than parental HCC827 cells. Specifically, 1.0 μg/ml U3-1402 reduced the viable cell proportion to 50% of control in HCC827GR5 cells, but the effect was limited to 95% of control in HCC827 parental cells. Furthermore, EGF-TKI erlotinib increased sensitivity to U3-1402 in HCC827GR5 cells. Specifically, 1.0 μM erlotinib reduced the viable cell proportion to 69% of control, and 1.0 μg/ml U3-1402 reduced it to 50% of control in HCC827GR5 cells, but both agents combined reduced it to 3% of control (p < 0.01). Support to clarify the underlying mechanism by which EGF-TKI resistant HCC827GR5 cells were more sensitive to U3-1402 than parental HCC827 cells were, we evaluated the HER3 mRNA expression in both cell lines. HCC827GR5 cells had significantly higher levels of HER3 mRNA than parental HCC827 cells did (1.85 vs 0.65, t-test; p = 0.003). Conclusions U3-1402 preclinically exhibited its efficacy in NSCLC with EGF mutation. Its efficacy was enhanced by EGF-TKI combination. Sensitivity to U3-1402 might depend on HER3 expression levels. These results provide a rationale for U3-1402 alone or in combination with EGF-TKI to be investigated in patients with NSCLC with EGF mutation and aberrant HER3 expression.

#45 In vitro and in vivo activity of a novel c-Met-targeting antibody-drug conjugate using a DNA-alkylating, indolino benzodiazepine payload. Katharine C. Lai, Asli Muvaffak, Min Li, Marian Theemes, Surina Sikka, Kerry Donahue, Stuart W. Hicks, Angela Romanelli, Thomas Chittenden. ImmunogenInc., Waltham, MA.

Purpose: c-Met dysregulation and/or overexpression are associated with tumor progression, metastasis and poor prognosis in numerous cancers. Despite strong pre-clinical evidence that blocking c-Met activity inhibits tumor cell growth and metastasis, targeted therapies have thus far failed to deliver an effective treatment option to the majority of patients. To address patients with both c-Met over-expressing and MET amplified tumors, we designed an antibody-drug conjugate (ADC) comprised of a humanized anti-c-Met monoclonal antibody linked to a highly potent indolino benzodiazepine DNA-alkylating payload (DGN549) to enable activity against not only MET amplified but also c-Met over-expressing tumors. Experimental Design: Panels of monoclonal antibodies (Abs) against c-Met were generated and screened for antagonistic and agonistic activity in the presence or absence of the c-Met ligand, HGF. Lead Abs were selected for favorable biophysical properties and the normal tissue-versus-tumor IHC profile and strong reactivity toward carcinoma cells and the vasculature of solid cancers. Chimeric humanized mAb targeting B7-H3 conjugated to the potent DNA alkylating pay-

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Antibodies, Bispecifics, and Antibody-Drug Conjugates

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
Antibody-drug conjugates (ADCs) are promising agents that are developed for targeted delivery of cytotoxic payloads to tumor cells. ADCs share a common design of antibody, linker, and cytotoxic payload. Despite significant efforts, the number of available payload classes with a differentiated mode-of-action that can successfully be employed to generate antibody-drug conjugates (ADCs) is still limited. Therefore, ADCs with new mode of action, potentially linked to a highly potent DNA-alkylating agent (i.e., duocarmycin) in uterine cervical cancer, are promising new payloads that can be linked to a novel HER2-targeting antibody-drug conjugate (ADC) with a novel mode of action. This ADC, SYD985, is highly selective against HER2-positive patient-derived xenograft UCC model BFX469. At doses of 5-10 mg/kg qw or bw potent anti-tumor efficacy with treated-to-control ratios (T/C) between 0.16 to 0.28 as well as complete regressions were observed. In summary, KSP inhibitors have been established as a promising new payload class allowing the generation of highly potent and selective ADCs for the treatment of solid tumors.

#47 SYD985, a novel duocarmycin-based HER2-targeting antibody-drug conjugate, shows antitumor activity in uterine and ovarian carcinomas with HER2/neu expression. Gulden Menders, Elena Bonazzoli, Stefania Bellone, Jonathan Black, Gary Altwerger, Alice Masserdotti, Francesca Pettinella, Luca Zammataro, Natalia Buza, Pei Hui, Elena Ratner, Babak Litkouhi, Dan Arin Silasi, Masoud Azodi, Peter Schwartz, Alessandro D. Santin. Yale University School of Medicine, New Haven, CT.

Introduction: Carcinomas (CS) is a rare and highly aggressive gynecologic malignancy. The amplification of HER2/neu has been reported to occur in 25%-56% of uterine and ovarian CSs with significant heterogeneity of the expression within epithelial and in-between epithelial and mesenchymal components. The reported high incidence makes HER2/neu an attractive target for new molecular therapies. We investigated the efficacy of SYD985, (Synther-Biopharmaceuticals), a novel HER2-targeting antibody-drug conjugate (ADC) composed of a monoclonal antibody (mAb) similar to trastuzumab linked to a highly potent DNA-alkylating agent (i.e., duocarmycin) in uterine and ovarian carcinomas. We also compared the anti-tumor activity of SYD985 to trastuzumab emtansine (T-DM1), a FDA-approved ADC, against multiple primary CS cell lines expressing different levels of HER2/neu in vitro and in vivo experiments. Methods: Eight primary CS cell lines were evaluated for HER2/neu surface expression by IHC and gene amplification using FISH assays. The cytotoxicity of SYD985 and T-DM1 was evaluated using these eight CS primary cell lines with differential HER2/neu expression (i.e., 0, 1+, and 3+). Antibody-dependent cellular cytotoxicity (ADCC), proliferation, viability, and bystander killing experiments were performed using Ca++-release assays, propidium iodide-based and flow cytometry assays, respectively. SYD985 and T-DM1 in vitro activity was also studied in mouse xenograft models. Results: Similar ADCC were induced by SYD985 and T-DM1 when effector cells were present against CS cell lines with different HER2/neu expression. In contrast, SYD985 was significantly more cytotoxic compared to T-DM1 in the absence of the effector cells. The Ca++-release by SYD985 7 to 54 fold higher than comparable experiments and unlike T-DM1, it is active against CS demonstrating moderate-low or heterogeneous HER2/neu expression. Specifically, in HER2/neu 0/1+ cell lines the mean IC50’s were 0.060 µg/mL and 3.221 µg/mL for SYD985 vs T-DM1 (p<0.0001) and in HER2/neu 3+ cell lines 0.013 µg/mL and 0.096 µg/mL (p<0.0001), respectively. (p<0.0001). Unlike T-DM1, SYD985 induced efficient bystander killing of HER2/neu 0/1+ and 3+ cells admixed with 0/1+ or HER2/neu 3+ cells. In vivo studies confirmed that SYD985 is more active than T-DM1 in CS and effective against HER2/neu 3+ xenografts. Conclusions: We demonstrate for the first time that SYD985 is a novel ADC with remarkable activity against CS not only with strong (3+) but also with low (0/1+ HER2/neu expression. Clinical studies with SYD985 in patients harboring chemotherapy-resistant uterine and ovarian CS with low, moderate and high HER2 expression are warranted.

#48 Non-clinical pharmacokinetics of XMT-1522, a HER2 targeting auristatin-based antibody drug conjugate. Alex Yurkovskiy, Dmitry Gumerov, Elena Ter-Ovanesyan, Patrick Conlon, Michael Devit, Charlie Bu, Natalya Bodyak, Timothy Lowinger, Donald Bergstrom. Marsena Therapeutics, Inc., Cambridge, MA.

The ADC XMT-1522 consists of a novel human IgG1 anti-HER2 monoclonal antibody and a novel, auristatin-based cytotoxic payload (Auristatin F-hydroxypropylamide, AF-HPA). An average DAR of 12 AF-HPA molecules is achieved via a biodegradable polymer conjugation platform. The non-clinical DMPP properties of XMT-1522 have been characterized in vitro in plasma and microsomal stability studies, and in vivo in plasma and tissue disposition and excretion studies. Sample analysis for total AF-HPA drug payload and released (free) AF-HPA and its metabolites was performed by ESI+-LC/MS/MS; total antibody was determined by ELISA. The half-life for AF-HPA release in plasma was found to be greater than 120 hours in all species tested. Microsomal stability studies showed that AF-HPA was further converted to other metabolites including the carboxylic acid auristatin F (AF), as well as monomethyl auristatin F-HPA (MMAF-HPA) and MMAF. The pharmacokinetic profiles of XMT-1522 were evaluated in mouse, rat and cynomolgus monkey. The antibody of XMT-1522 is cross-reactive with mouse, but not rodent, HER2. In mouse and rat, XMT-1522 exposure was dose-proportional; exposure was slightly greater than dose-proportional in monkey consistent with its saturable hepatic clearance and clearance. All species showed extended exposure to total AF-HPA drug payload, with measured clearance and volume of distribution similar for total AF-HPA and the antibody component of XMT-1522. Exposure to free AF-HPA and AF was less than 1/1000th of the exposure of total AF-HPA. These data indicate the vast majority of AF-HPA in plasma is antibody-conjugated, indicating high stability of the ADC in systemic circulation. XMT-1522 tissue disposition was studied in NCI-N87 HER2-positive gastric cancer xenograft tumor bearing mice. After a single 3 mg/kg dose of XMT-1522, free AF-HPA and its metabolite AF were measurable in tumor tissue until the last time point measured (2 weeks). Total AF-HPA and free AF-HPA achieved peak tumor concentrations 48 hours after dosing. In contrast, AF achieved peak tumor concentration 7 days after dosing and showed only a slight decline in tumor concentration at 14 days, consistent with intracellular trapping of this poorly cell-permeable metabolite. Exposure to free AF-HPA or AF in other tissues was at least an order of magnitude lower than in tumor; in tissues with measurable free drug, AF was the predominant species. XMT-1522 excretion studies, conducted in rat, indicated that the AF-HPA payload was mainly excreted by the gastrointestinal route. In the first 96 hours after administration 33% of the AF-HPA dose was excreted in feces, compared to 3% excreted in urine. The major contributing metabolites both in feces and urine were conjugated AF-HPA, AF, and free AF-HPA. In conclusion, the plasma kinetics, tissue distribution and excretion profile of XMT-1522 are acceptable for clinical evaluation in cancer patients.

#49 Modulating insulin receptor splicing as a potential therapeutic approach for rhabdomyosarcoma. Brianne Sanford, Chelsea Brown, Hennett Bid, Thomas Beebe, Daniel Comiskey, Frank Rigo, Peter Houghton, Dawn Chandler. Nationwide Children’s Hospital, Columbus, OH; Ionis Pharmaceuticals, CA; University of Texas Health Science Center, TX.

The insulin receptor (IN-R) is subject to alternative splicing to produce two isoforms: the full-length IN-R B isoform and an isoform lacking exon 11 known as IN-R A which is the predominant isoform expressed in sarcoma cells. This short exon encodes for 12 amino acids but the resulting receptor has high affinity for a growth hormone called insulin-like growth factor 2 (IGF2), which exquisitely responds to autocrine and paracrine signaling. Increased IN-R A levels observed in rhabdomyosarcoma (RMS) coupled with increased expression of IGF2, programs the tumor cell for enhanced growth and angiogenesis, two important factors in tumorigenesis. Furthermore, IGF2 can maintain angio genesis through IN-R A activity. Hence, modulation of IN-R splicing may prove to be a viable therapeutic approach in rhabdomyosarcoma.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Antibodies, Bispecifics, and Antibody-Drug Conjugates

#47 SYD985, a novel duocarmycin-based HER2-targeting antibody-drug conjugate, shows antitumor activity in uterine and ovarian carcinomas with HER2/neu expression.

#48 Non-clinical pharmacokinetics of XMT-1522, a HER2 targeting auristatin-based antibody drug conjugate.

 EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Antibody Technology

#50 HTI-1511, a novel anti-EGFR-ADC, overcomes mutation resistance and demonstrates significant activity against multiple tumor types in preclinical studies. Jesse D. Bahn,1 Feng Gao,1 Lei Huang,1 Barbara Blouw,1 Chunmei Zhao,1 Kelly Chen,1 Susan Zimmerman,1 Erin K. Wise,2 Maria L. Mancini,2 Christopher D. Thanos1.

HTI-1511, an antibody-drug conjugate in pre-clinical development that targets EGFR.

EGFR in the tumor microenvironment (Huang et. al. AACR National Meeting, 1511, an antibody-drug conjugate in pre-clinical development that targets EGFR. Antibodies that target the receptor are often accompanied by adverse skin reactions due to interaction with receptors expressed in normal tissue. Additionally, downstream mutations (KRAS, BRAF) within tumors can result in EGFR-independent activation and resistance to treatment. We have previously described HTI-1511, an antibody-drug conjugate in preclinical development that targets EGFR. HTI-1511 carries the potent cytotoxin MMAE and a novel bis-alkylating linker, connected to a monoclonal antibody engineered to have improved specificity for EGFR in the tumor microenvironment (Huang et. al. AACR National Meeting, 2016, New Orleans, LA). Here we screened a panel of 70 tumor cell lines derived from various solid tumor malignancies for both EGFR expression by flow cytometry and sensitivity to cell growth inhibition by HTI-1511 in vitro. Cell lines derived from head and neck squamous cell carcinoma (SCC15, CAL27, FaDu, CAL33, SCC25 [IC50 0.52 nM - 3.1 nM]), non-small cell lung cancer (HCC827, NCI-H1666, PC-9, NCI-H1650 [IC50 0.04 nM - 6.2 nM]), and pancreatic carcinoma (BxPC3, Panc-1, AsPC-1 [IC50 0.99 nM - 4.4 nM]) showed particular sensitivity to HTI-1511. In comparison, HTI-1511 efficacy was assessed in vivo for tumor growth inhibition (TGI) in several human tumor xenograft models. Evaluations in the human xenografts A431 (epidermoid, 93% TGI at 3.0 mg/kg, p < 0.05), FaPC3 (pancreatic, >100% TGI at 3.0 mg/kg, p < 0.05), AsPC-1 (pancreatic, >100% TGI at 3.0 mg/kg, p < 0.05), and FaDu (HNSCC, >100% TGI at 3.0 mg/kg, p < 0.05) indicated dose dependent tumor regressions in all cases, and no observed toxicity when administered weekly at dose levels up to 3 mg/kg for up to eight weeks. HTI-1511 anti-tumor activity was also investigated in a group of patient derived xenograft (PDX) models. An initial study evaluated weekly administration of a single dose level of 2.5 mg/kg HTI-1511 in three different PDX models. TGI of 83% (p < 0.05) was observed in a BRAFmut colorectal cancer model and 57% (p < 0.05) in a wildtype colorectal cancer model, as well as 46% (not significant) TGI seen in a wild type renal cell carcinoma model. A separate study in a NCI-60 (KRA200) PDX model demonstrated a strong dependent response with greater than 100% TGI at 1.0 and 3.0 mg/kg (both p < 0.05) and also p < 0.05 to a non-cognate antibody ADC control. The non-cognate antibody control yielded 67.4% (not significant) TGI by itself compared to the vehicle control group. These results support further development of HTI-1511 as a possible treatment for EGFR overexpressing tumors, including those with downstream activating mutations in the KRAS/BRAF pathway.

#51 Characterization of the mechanism of action, pharmacodynamics and preclinical safety of ADCT-402, a pyrrolobenzodiazepine (PBD) dimer-containing antibody-drug conjugate (ADC) targeting HER2-expressing solid tumors. Francesco Zammarchi,1 Halla W. Reinert,1 Narinder Janghra,2 Simon Corbett,2 Maria Mellinas-Gomez,2 Sahjaid Chowdhury,3 Neha Arora,3 Peter Tyrer,3 Francois Bertelli,3 David G. Williams,3 Philip W. Howard,3 John A. Hartley,3 Patrick H. van Berkel1.1 ADC Therapeutics, London, United Kingdom; 2University College London, London, United Kingdom; 3Sprintogen/MedImmune, London, United Kingdom.

ADCT-402, currently in Phase I clinical trials for B-cell hematological malignancies, is an ADC composed of a recombinant humanized IgG1 against human CD19, stochastically conjugated via a cleavable linker to a PBD dimer cytotoxin (DAR of 2.3). PBD dimers, DNA minor groove interstrand cross-linking agents, are gaining increasing attention and are currently being tested as the ADC warhead of choice owing to their unique mechanism of action. ADCT-402 targets HER2+ metastatic breast cancers. ADCT-402 is an ADC composed of an engineered version of humanized IgG1 trastuzumab, directed against human HER2, site-specifically conjugated to the highly cytotoxic PBD-based linker-drug tesirine (drug-antibody ratio of 1.7). In vitro, ADCT-402 has highly potent and targeted cytotoxicity against various solid cancer cell lines. In vivo, ADCT-402 demonstrates strong and durable antitumor activity in mouse xenografts with various levels of HER2, but is inactive in a HER2-negative xenograft. ADCT-402 is stable, well tolerated and has a favorable PK profile both in rat and cynomolgus monkey. ADCT-402 is currently in Phase I clinical trials for B-cell hematological malignancies, an ADC composed of a recombinant humanized IgG1 against human CD19, stochastically conjugated via a cleavable linker to a PBD dimer cytotoxin (DAR of 2.3). PBD dimers, DNA minor groove interstrand cross-linking agents, are gaining increasing attention and are currently being tested as the ADC warhead of choice owing to their unique mechanism of action. ADCT-402 targets HER2+ metastatic breast cancers. ADCT-402 is an ADC composed of an engineered version of humanized IgG1 trastuzumab, directed against human HER2, site-specifically conjugated to the highly cytotoxic PBD-based linker-drug tesirine (drug-antibody ratio of 1.7). In vitro, ADCT-402 has highly potent and targeted cytotoxicity against various solid cancer cell lines. In vivo, ADCT-402 demonstrates strong and durable antitumor activity in mouse xenografts with various levels of HER2, but is inactive in a HER2-negative xenograft. ADCT-402 is stable, well tolerated and has a favorable PK profile both in rat and cynomolgus monkey. The current study aimed to further define the mechanism of action (MOA) of ADCT-402 and validate its pharmacology and preclinical safety for clinical development. ADCT-402 is a clinically validated target with restricted normal tissue expression and a widespread expression in the majority of B-cell malignancies. Importantly, we show here the consistent expression of CD19 in matched samples (initial diagnosis and relapsed/refractory) from panels of lymphoma patients, indicating that relapsed/refractory patients are appropriate for treatment with ADCT-402. ADCT-402 was shown to be efficiently internalized by CD19+ cells in vitro. Moreover, in line with the PBD dimer MOA, following a 2 hour exposure to ADCT-402, DNA interstrand cross-links reached a peak between 8 - 12 hours and persisted for up to 36 hours post-treatment. In contrast, the peak of DNA damage induction for PBD dimer warheads was observed immediately after 2 hour incubation, while a non-targeted PBD-ADC did not yield any appreciable DNA cross-links. In SCID mice s.c. implanted with Ramos cells, a single dose of ADCT-402 was administered at 0.33 or 1 mg/kg. Twenty-four hours after treatment, excised tumors showed a dose proportional increase in intensity of staining by an anti-PBD payload antibody, as well as in DNA cross-linking and in γ-H2AX formation. In contrast, no DNA cross-linking was observed in matched lymphocyte samples. The toxicity of ADCT-402 was further evaluated in a repeat dose cyromolgus monkey study. ADCT-402 was clinically well tolerated with an acceptable off-target safety profile. The PK of the ADC was consistent with normal antibody clearance with a half-life of about 12 to 17 days. These data confirm the MOA of ADCT-402 and provide relevant pharmacodynamic and preclinical safety assessments that guide the clinical development of this promising ADC in B-cell malignancies.
Similarly, in a HER2+/+, FISH- esophageal cancer PDX, while a single dose of ADCT-502 at 0.44 mg/kg resulted in strong and durable antitumor activity, single doses of T-DM1 at either 10 or 30 mg/kg showed no activity compared to the control. These data confirm that the mechanism of cell killing of ADCT-502 is via target-specific internalization and subsequent cross-linking of DNA. They also show significantly improved antitumor activity of ADCT-502 compared to each of the monoclonal antibodies in various tumor xenografts, including those with low HER2 levels. Taken together, these results support the development of ADCT-502 not only in patients that have become resistant/refractory to T-DM1, but also in patients whose tumors express low levels of HER2, and are not eligible for treatment with T-DM1.

#53 Antibody-drug conjugates (ADCs) of peptide-linked Indolino-Benzodiazepine (DNA) N-alkylator provides improved anti-tumor activity over that of a crosslinker. Michael L. Miller, Manami Shirzuka, Jose F. Ponte, Leanne Laniere, Dilrulshk Vitharana, Qifeng Qiu, Emily E. Reid, Katie E. Archer, Rui Wu, Erin K. Maloney, Olga Ah, Jan Pinkas, Ravi V. Chari. ImmunoGen, Inc., Waltham, MA.

We recently disclosed highly active antibody-drug conjugates (ADCs) that incorporated the novel DNA alkyling indolino-benzodiazepine (termed IGN) dimer, DGN549 (IGN-P1). The stereochemistry of the alanyl moiety of the protease-cleavable alanine-alanine linker used was shown to impact ADC catabolism, bystander killing activity, and in vivo efficacy (Shizuka, et al., AACR 2016 #2959). Building upon these results, here we describe preclinical results from a head-to-head comparison of ADCs of the mono-imine containing DGN549 with its corresponding DNA cross-linking version, IGN-P1 dimine. IGN-P1 dimine and DGN549 were conjugated to a folate receptor-a (FRA)- binding antibody and an EpCAM-binding antibody. The resulting ADCs demonstrated similar high in vitro potency (IC50 3-100 pM) and specificity towards several cancer cell lines. Further in vitro studies revealed that the DNA alkylating anti-FRA-DGN549 ADC demonstrated superior bystander cell-killing activity compared to its DNA crosslinking counterpart, anti-FRA-IGN-P1 dimine. In vivo, this improved bystander killing ability translated into better in vivo activity for the DNA alkylating ADC. In an endometrial tumor xenograft model established with Ishikawa cells, the anti-FRA-DGN549 induced complete regression at a single dose of 140 μg/kg Ab dose (equivalent to 5 μg/kg linked IGN). The cross-linking anti-FRA-IGN-P1 dimine had to be used at twice the dose to achieve the same level of anti-tumor activity. The in vivo tolerability in CD-1 mice also displayed differences in the two ADCs. We found that the ADC of the DNA crosslinker was at least two-fold less tolerable than the corresponding ADC of the DNA alkylator. These results indicate that a 4fold greater therapeutic index can be achieved when using a DNA alkylating mono-imine DGN549 ADC as compared to the DNA crosslinking IGN-P1 dimine ADC.

#54 The many faces of antibody in G protein-coupled receptor biology. Lei Chen, Wing-Tai Cheung. School of Biomedical Sciences, Faculty of Medicine, Chinese University of Hong Kong, Hong Kong.

G protein-coupled receptors (GPCRs), the largest family of cell-surface receptor proteins mediating signal transmission, play a pivotal role in many physiological functions and are involved in multiple diseases. Although receptor activators of GPCRs are successfully modulated by many small molecules that represent 30% of all marketed drugs today, in fact only a few GPCR targets are described and many GPCRs of interest are intractable targets of small molecules, like orphan GPCRs and GPCRs with large binding sites. Besides, small molecule drugs rarely trigger GPCR-mediated apoptosis or induce direct cell killing, which is crucial for cancer therapies. Therefore, for these GPCRs, antibody-based drug would be a good alternative. Despite being eagerly sought for, the production of monoclonal antibody (mAb) targeting GPCR is hindered by the low expression of recombinant GPCR on cell surface, and relatively small exposed regions with glycosylation and conformational heterogeneity. Therefore those conventional methods that were well established for generation of mAbs targeting soluble proteins usually showed frustrating results in the case of GPCRs. To bypass the production and purification of recombinant GPCR proteins, we developed a novel approach of transplanting immunogenic conformational epitopes of GPCR into an antibody scaffold to make a water soluble surrogate antigen of GPCR, named as GPCR-antigenized antibody which can be easily and abundantly produced in bacteria for animal immunization. In coupled with phage display technology and cell panning strategy, which allow the retrieval of specific binders from a huge number of candidates, we have successfully isolated scFv antibodies for two human GPCRs, the MAS1 receptor and the chemokine receptor CXC4R. These antibodies showed good specificity in immuno-fluorescence staining, flow cytometry analysis, western protein immunoblot and immunoprecipitation assay. The results demonstrated this novel approach may offer a generic and effective method to generate specific monoclonal antibody targeting GPCR for diagnostic and therapeutic applications. [The project is partly funded by a CUHK direct grant (4054300)]

#55 Generation of half-life extended anti-CD33 BiTE® antibody constructs compatible with once-weekly dosing. Tara L. Arvedson, Mercedes Balazs, Pamela Bogner, Kurt Black, Kevin Graham, Anja Henn, Matthias Friedrich, Patrick Hofmann, Roman Kischel, Peter Kuffer, Ralf Lutterbuese, Markus Muenz, Tobias Raum, Benno Rattel, Karen Rex, Dan Rock, Oliver Thomas, Joachim Wahl, Andreas Wolf, Angela Coxon, Angela Munich, Germany.

T cell engaging bispecific antibody constructs (BiTE®), such as blinatumomab which targets CD19-positive cells, have shown great promise for treating certain CD19-positive hematological malignancies. Blinatumomab comprises a single chain Fv (scFv) that binds CD19 and a scFv that targets the T cell CD3 protein. The molecular weight of this “canonical” BiTE® is ~55 kDa, making it susceptible to kidney-mediated clearance and resulting in a short serum half-life (~4 hours). To maintain effective serum concentrations, canonical BiTE® antibody constructs must be administered by continuous IV (cIV) infusion. While there are many advantages associated with cIV administration (e.g., safety and uniform PK profile), patient convenience could be enhanced if the BiTE® antibody construct were compatible with once-weekly administration. To achieve this, the serum half-life of the BiTE® antibody construct would need to be extended. A canonical BiTE® targeting CD33 (AMG 330) is currently being evaluated in a phase I clinical trial. Like blinatumomab, AMG 330 is dosed cIV. To extend the serum half-life of AMG 330 and enable once-weekly dosing, several approaches were evaluated including fusion of AMG 330 to human albumin andFc-containing moieties. Each of these half-life extended (HLE) constructs was evaluated in vitro, in mouse xenograft models and in non-human primates. In vitro assays evaluated 1) binding to both human and cynomolgus CD33 and CD3 proteins, and 2) cytotoxicity using human and cynomolgus target and effector cells. In each of these assays the canonical and HLE BiTE® antibody constructs demonstrated similar activity: single-digit nM binding and single digit pM cytokotoxicity. Canonical and HLE BiTE® antibody constructs were subsequently evaluated in an orthotopic mouse model in which MOLM13 cells were administered IV and activated human T cells were administered IP two days later. The Fc-based HLE BiTE® antibody constructs provided a similar survival advantage when administered QD or Q3D as the canonical BiTE® when administered Q3D. However, the albumin fusion–based HLE BiTE® was less efficacious when administered Q4D than the QD–administered canonical BiTE®. Lastly, the PK/PD relationship was evaluated for each of the constructs in non-human primates. The serum half-lives varied from 6 hours for the canonical BiTE® to 44–167 hours for the HLE BiTE® antibody constructs. Each of the HLE BiTE® antibody constructs showed on-target depletion of CD33-positive monocytes and neutrophils in the blood and depletion of CD33-positive cells in the bone marrow. These data demonstrate that half-life extended BiTE® antibody constructs can be generated that retain comparable in vitro and in vivo activity as a canonical BiTE® and achieve a serum half-life compatible with once-weekly dosing.

While antibody-drug conjugates (ADCs) find increasing application in cancer treatment regimens, de novo or treatment-emergent resistance mechanisms could impair clinical benefit. Two resistance mechanisms that emerge under continuous ADC exposure in vitro include upregulation of transporters that confer multidrug resistance (MDR+) and loss of cognate antigen expression. New technologies that circumvent these resistance mechanisms may serve to extend the utility of next generation ADCs. Recently, we developed the quaternary ammonium linker system to expand the scope of conjugatable payloads to include toxic compounds such as tubulysin, a highly potent class of microtubule disrupting agents that maintain activity in MDR+ cell lines. Quaternary ammonium-linked glucuronide-tubulysin drug-linkers were synthesized and evaluated as ADCs. The resulting conjugates were potent and immunologically specific across a panel of cancer cell lines, including those displaying the MDR phenotype. The ADCs also demonstrated potent bystander activity in a co-culture model containing a mixture of antigen-positive and -negative cell lines. Incorporation of a PEG12 side chain in the linker enabled loading at 8-drugs/Ab for increased in vivo potency while maintaining suitable ADC pharmacokinetic properties. In vivo, the glucuronide-tubulysin conjugates displayed activity in MDR+ xenograft models and
bystander activity in an admixed Ag+/Ag- heterogeneous tumor model. Thus, the glucuronide-tubulin drug-linkers represent a promising new payload for ADCs, combining conjugate potency in the presence of the MDR phenotype with robust activity in models of tumor antigen heterogeneity.

#57 Generation and characterization of novel anti-glycan monoclonal antibody drug conjugates targeting mesothelin. 
Won Kyu Park,1,2 Woon Kok Tek,1,2 Andre Boon Hwa Choo,3 Bioprocessing Technology Institute, Singapore, Singapore; 2National University Cancer Institute, Singapore, Singapore, Singapore.

Hematological malignancies encompass a wide spectrum of cancers from hematopoietic and lymphoid tissues. Under this grouping, the various forms of leukemia, lymphoma and myeloma have been classified into more than 60 distinct disease types, each having particular clinical features and disease outcomes. Among these diseases, curative treatments with high long-term survival rate have been developed for some, e.g. Chronic Myeloid Leukemia, while such effective regimens are still unavailable for many others, e.g. Multiple Myeloma and Acute Myeloid Leukemia. In this study, a panel of antibodies was raised against SLAM7, a cell surface marker that was associated to Multiple Myeloma. Among the antibodies, TAG-HC2 was surprisingly found to have preferential antibody. In addition, cured mice were resistant to re-implantation of 66C14 antibody. TAG-HC2, when complexed with sialyl-Lea, was able to internalize into and kill AML cell lines. These results suggest that TAG-HC2 has the potential to be developed into an Antibody Drug Conjugate against AML.

#58 Local intratumoral treatment with anti-mesothelin Immunotoxins overcomes resistance to anti-CTLA-4 therapy, Yasinim Lesheh,1 Xiuxen Liu,1 Tapan Bera,1 Masaki Terabe,1 Jay A. Berzofsky,3 Birgit Bossummaier,2 Gerhard Niederfellner,6 James O’Brien,1 Yoram Reiter,1 Ira Pastan1. 1NIH, Bethesda, MD; 2Roche Pharmaceutical Research & Early Development, Penzberg, Germany; 3Technion israel institute of technology, Haifa, Israel.

Background: SS1P and RG7787 are immunotoxins composed of anti-mesothelin antibody fused to a fragment from pseudomonas exotoxin A. We previously observed delayed tumor responses in patients treated with SS1P leading us to hypothesis that immunotoxins can provoke anti-tumor immunity. We hypothesize that intra-tumoral injection of SS1P or RG7787 will produce immunologic death and convert living tumors to a source of antigens and boost the therapeutic effect of immune check point blockade. Method: A BALB/c breast cancer cell line was transfected with human mesothelin (66C14-M) and grown in BALB/c mice transgenic for human mesothelin. SS1P or RG7787 was injected directly into established tumors (80-100 mm3) and anti-CTLA-4 administered IP. Results: We observed total tumor regressions in 23 out of 38 mice (60%) treated with anti-CTLA-4 and either RG7787 or SS1P. No cure was achieved when the drugs were given as a monotherapy supporting the case for synergic anti-tumor activity. Pathologic evaluation of regressing tumors showed a massive inflammation of admixed eosinophils and mononuclear cells located in a collar surrounding the tumors. Tumor regression was associated with increased number of CD8+ cells and was blocked when CD8+ cells were depleted by an antibody. In addition, cured mice were resistant to re-implantation of 66C14 cells not expressing mesothelin indicating that a long-term anti-tumor immunity was formed. To determine if pathogen associated molecular patterns contributed to the response, we combined anti-CTLA-4 with an inactive RG7787 and observed a major reduction in anti-tumor activity (P<0.01) indicating that the effect is not mediated by recognition of a foreign bacterial protein. Conclusions: We suggest that injecting immunotoxins into tumors is a useful approach to boost the activity of anti-CTLA-4. Based on the synergistic anti-tumor effect the effect is not mediated by recognition of a foreign bacterial protein.

#60 Reducing toxicity of antibody-drug conjugates through modulation of pharmacokinetics. Jessica Simmons, Francisco Zapata, Haley Neff-Laford, Joshua Hunter, Julia Cochran, Patrick Burke, Robert P. Lyon. Seattle Genetics, Bothell, WA.

Antibody-drug conjugates (ADCs) continue to emerge as effective therapeutics in a variety of oncology indications. Research on ADCs has revealed that the physicochemical properties of the drug-linker component can exert a significant impact on the disposition of the ADCs, particularly at higher levels of drug loading. We have recently reported (Nature Biotechnology 33, 733-735 (2015); Molecular Cancer Therapeutics, manuscript accepted) that these properties can be modulated through the judicious incorporation of small, discrete PEG chains of varying lengths into a monomethyl auristatin E (MMAE) drug-linker. Heterogeneous DAR 8 ADCs prepared with these drug-linkers using native cysteine conjugation display a continuum of pharmacokinetic behaviors that mirror the length of the incorporated PEG chain. We selected four of these drug-linkers that span the range of observed pharmacokinetics and used them as model compounds to evaluate the impact of ADC clearance on the concentration profile of released MMAE in normal tissues and consequent toxicity in the Sprague-Dawley rat. Faster clearing ADCs (prepared with drug-linkers containing very short or no PEG modifier) produced higher tissue MMAE Cmax values at early post-dose time points relative to slower clearing ADCs that incorporate longer PEG chains. This finding indicates that MMAE concentrations in tissues are proportional to the rate at which the ADC is catalyzed and thus which converts the conjugated payload into free drug. Faster clearing ADCs also exhibited diminished tolerability, with greater histologic depletion of bone marrow and more dramatic decreases and/or delayed recovery in select peripheral hematologic parameters. These results provide a strategy for reducing the non-antigen-mediated toxicity of ADCs through modulation of pharmacokinetics.

Antibody drug conjugates (ADCs) combine the specificity of monoclonal antibodies with potent antineoplastic small molecules, and promise efficacy without the systemic toxicity of chemotherapy. Despite this tremendous potential, most clinical ADCs have failed to provide sufficient therapeutic benefit before the onset of off-target dose-limiting platform toxicities. Here we report the development of proprietary pro tease cleavable N-acyl sulfonylimidate linked hemiester linker and auristatin payloads, Zymelink, that allow the generation of an efficacious ADC platform with improved tolerability. Both Zymelink drug-linkers are covalently connected via maleimide to endogenous cysteines. As Zymelink drug-linkers are more polar than maleimide valine citrulline monomethyl auristatin E-linker, the resulting ADCs can be produced with potential advantages in PK, efficacy and safety. The resulting ADCs exhibit potent in vitro cytotoxicity. A trastuzumab-based ADC prepared with Zymelink drug-linker and demonstrated at least equivalent efficacy compared to a trastuzumab-based ADC prepared with MMAE, promoting durable complete regressions in a patient-derived xenograft model. Zymelink hemiester linker and auristatin ADCs were tolerated at 5-6 fold higher doses compared to a MMAE ADC in cynomolgus monkeys. The maximum tolerated dose of the MMAE ADC was just 3 mg/kg based on severe neutropenia. Zymelink hemiester ADC was tolerated at 15

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Antibody Technology

**Volume 58** • April 2017 15
mg/kg with no evidence of neutropenia or elevations in transaminases. Zymelink auristatin ADC was tolerated at 18 mg/kg based on increased levels of transaminases at 24 mg/kg. Moreover, Zymelink ADCs exhibited greater serum exposure at equivalent doses. These results suggest Zymelink ADCs have a greatly expanded therapeutic window compared to MMAE conjugates.

Background ATACs (antibody-targeted Amanitin conjugates) comprise a new class of antibody-drug conjugates utilizing aminatin as toxic payload. Amanatin binds to the eukaryotic RNA pol II and thereby inhibits the cellular transcription process at very low concentrations. In the current study, in vitro and in vivo data of new ATACs targeting CD19 (also known as B4, CVID3) are presented. CD19, a class I transmembrane glycoprotein with no significant homology to any known protein, is expressed in B cells and B-cell malignancies like in B-cell acute lymphoblastic leukemia (B-ALL) and B cell chronic lymphocytic leukemia (B-CLL). Therefore it is an ideal target for Amanitin-based ADCs. Material and methods Cell lines: Raji (Burkitt Lymphoma), Nalm-6 (B-ALL) and HL-60 (B-CLL). Therefore it is an ideal target for Amanitin-based ADCs. CD19-Thiomab-ATACs: Maleimide aminatin compounds were conjugated site specific to engineered cysteine residues of the anti-CD19 Thiomab. Cell proliferation assay: Quantitative determination of cytotoxicity was performed by CellTiter Glo 2.0 assay (Promega) or WST-1 assay (Roche). Animal models: Mouse xenograft tumor models were performed. Tolerability was assessed in mice and non-human primates (NHP). Results CD19-Thiomab-ATACs showed in vitro cytotoxicity on CD19- cells in lineicromolar range, whereas no cytotoxic activity on CD19 cells was observed. In mouse xenograft models, CD19 showed dose-dependent tumor regression and complete remission after single dose i.v. of 2mg/kg and 4mg/kg. In a disseminating Raji xenograft model, median survival was increased from 6 days (vehicle control) to 105 days (CD19-Thiomab-30.2115 treated group at 6mg/kg, single dose). On day 154, 4 animals were still alive and in good overall condition. Safety profiling in Cynomolgus monkey revealed a good tolerability after sequentially applied doses of 0.3, 1.0, 3.0 and 5.0 mg/kg. Hematology and clinical chemistry data show minor alterations: transient increase in liver enzymes (ALT and AST) in combination with a transient increase in LDH. The half-life of the ADC in serum is 7-11 days; the free toxin is detectable at serum levels close to the lower limit of quantification only (LLOQ = 1.2 nM). Conclusions In the current study, in vitro and in vivo data of Amanitin-ADCs targeting CD19 are presented. CD19 is expressed on cells of the B cell lineage, ranging from the pre-B cells until the terminal differentiation to plasma cells. It is expressed in most acute lymphoblastic leukemias (ALL), chronic lymphocytic leukemias (CLL) and B cell lymphomas (Kemeng et al. 2012); Exp Hematol Oncol 1: 36). The preclinical data show high cytotoxicity in picomolar range, very good efficacy in tumor xenograft models and tolerability in an exploratory tolerability study in NHP. The positive findings of these initial experiments encourage Heidelberg Pharma to further proceed with anti-CD19 Amanitin-based ADCs towards clinics.

#63 Targeting osteosarcoma with graphene oxide-associated anti-HER2 antibodies. Xinjian Chen. University of Utah, Salt Lake City, UT.

Osteosarcoma (OS) is the most common primary cancer of the bone affecting children and adolescents. While over the last two decades the neoadjuvant chemotherapy has improved survival of the patients with resectable OS, the prognosis for unresectable or recurrent tumors remains poor due to the lack of effective treatment. Given that a majority osteosarcomas overexpress HER2, a phase II clinical trial of anti-HER2 antibody trastuzumab in conjunction with chemotherapy has been carried out to treat metastatic OS. However, no significant therapeutic benefit was observed. We recently reported that association of anti-CD20 antibody rituximab with a nanomaterial graphene oxide (GO) substantially enhances the anti-lymphoma activity of the antibody. Here we have studied antimur activity of GO-associated trastuzumab (TRAs). Similar to RTX, TRA could be stably associated with functionalized GO through non-covalent interactions, and GO-associated TRA (TRA/GO) showed markedly enhanced HER2 binding activity with capacity to aggregate (cap) HER2 on the target cells. Treating HER2 + OS as well as Ewing’s sarcoma cell lines in culture with TRA/GO resulted in rapid sarcoma cell death within 12 hr, while free TRA or the cytotoxin-conjugated TRA (ado-trastuzumab emtansine) showed no significant cytotoxic effects. TRA/GO manifested no cytotoxicity to human lymphocytes, in contrast to chemotherapeutic drugs such as doxorubicin and oxaliplatin. We find that the ability to kill the sarcoma cells results from the unique capacity of TRA/GO to simultaneously induce oxidative stress as well as intense detrimental HER2 signaling, which leads to a complete disappearance of a major tyrosine-phosphorylated protein and caspase 8, and a partial loss of RIPK1 along with an increase in RIPK3 levels within 5 min, followed by necroptosis of the target cells. Intravenous administration of TRA/GO rapidly eradicated established xenograft human OS in the lungs as well as at subcutaneous locations in NOD/SCID immunodeficient mice in the absence of chemotherapy, resulting in indefinite survival of the animals. In contrast, free TRA treatment failed to do so. No appreciable side effects were observed of TRA/GO in vivo. These results therefore demonstrate a novel strategy to substantially enhance the therapeutic capacity of anti-cancer antibodies. Given the increasing variety of human malignancies that are found to overexpress Her2, including sarcomas, carcinomas and neuroendocrine tumors, our findings could have broad therapeutic implications. As TRA/GO does not harm lymphocytes, TRA/GO-based therapy may constitute a unique opportunity to implement immunotherapy that is now known to play an important role in control tumor progression.

#64 Meditope SnAP-body technology facilitates enhanced internalization and in vivo efficacy of antibody therapeutics. Karin Forster, Elisabeth Gardiner, Stephanie Hsieh. Meditope Biosciences, San Diego, CA.

Meditope Biosciences has developed a way to use SnAP technology to promote internalization of antibody receptor complexes through a novel construct called a SnAP-body. Meditope’s SnAP platform functionalizes monoclonal antibodies to bind to specific meditope peptides; this property can be used to directly facilitate receptor crosslinking when meditope-enabled antibodies are bound to cell surface receptors. SnAP-bodies are self-crosslinking meditope-enabled antibodies which permit a meditope peptide to specifically interact with a meditope-enabled antibody at the cell surface upon antigen engagement. Antigen-antibody complex formation through the specific contact of the SnAP-bodies and their cognate epitopes on the target antigen can increase clustering or co-localization of a cell surface antigen on a cell, which can promote enhanced internalization of the SnAP-body. The increased internalization can be used to deliver payload to a cell surface antigen from a target cell or tumor. Enhancing internalization can increase the efficacy of antibody-based therapeutics, and in the case of antibody-drug conjugates, which require receptor internalization to deliver cytotoxic payloads, can reduce the amount of drug necessary to achieve a therapeutic effect. In vitro studies of SnAP-body binding to cell surface antigens demonstrate accelerated internalization of the antibody. In vivo, this translates into enhanced efficacy. The ability to see equivalent efficacy in the absence of toxin suggests a unique role for SnAP-bodies in cancer therapeutics, especially in cases where lack of efficacy for a specific target is correlated with poor receptor internalization.

The random conjugation of toxins, dyes, peptides, or other payloads to monoclonal antibodies often targets free thiol groups generated by partial reduction methods or lysine residues using succinimide- or isothiocyanate-based chemistry. There remains a need for conjugation technologies targeting specific amino acid residues as a way to produce a homogeneous antibody-drug conjugate (ADC) product with a defined drug-to-antibody ratio (DAR). Our RESidue-SPECifíc Conjugation Technology (RESPECT) utilizes two methods by which payloads can be conjugated to specific residues in an antibody. Our cystine-specific conjugation method exploits a unique intrachain disulfide bond in the light chain of rabbit antibodies between residues 80 and 171 of the variable and constant domains, respectively. Our humanization strategy allows retention of the cysteine at position 80 with a free thiol group that is both amenable for residue-specific conjugation and compatible with optimal antibody biophysical properties including antigen binding and structural stability. This platform has been optimized via antibody engineering strategy stems from in silico modeling, extensive mutagenesis, and crystallographic studies, which have allowed defining the contribution of neighboring residues to the retention of a reactive thiol group as well as the desired humanized antibody’s properties. Our C-terminal lysine-specific linkage method employs the transglutaminase enzyme that catalyzes the formation of a stable isopeptide bond between the γ-carboxyamide group (acyl donor) of a glutamine and the ε-amino group (acyl acceptor) of a lysine. While we found no acyl acceptor sites in recombinant wild-type IgGs, all antibodies investigated lacked the C-terminal Lys447 due to cleavage by carboxypeptidase B in the antibody production cell line. Blocking the cleavage of Lys447 by addition of a C-terminal amino acid resulted in transamidation of Lys447 by a variety of acyl donor substrates in the presence of any non-acidic, non-proline amino acid residue at position 448. Antibody-drug conjugates (ADCs) prepared using our RESPECT

technology targeting the tumor associated-mesothelin protein produced uniform drug-to-antibody ratios (DAR) and were shown to be highly potent and specific in vitro and effective in vivo in reduction of tumor growth in an orthotopic mesothelioma expressing xenograft tumor model.

**#66 Highly potent, anthracycline-based antibody drug conjugates generated by enzymatic, site-specific conjugation.** Roger R. Beerli. NBE-Therapeutics AG, Basel, Switzerland.

Antibody drug conjugates (ADCs) are highly potent and selective anti-tumor drugs, combining the specific targeting of monoclonal antibodies with the potency of cytotoxic payloads. Here, we employed enzymatic, site-specific conjugation to generate homogenous ADCs based on a derivative of the highly potent anthracycline toxi-PNU-159682 and a non-cleavable peptide linker, using the anti-HER-2 antibody trastuzumab (part of trastuzumab emtansine) and the anti-CD30 antibody CA10 (part of brentuximab vedotin). Characterization of the resulting ADCs in vitro and in vivo showed that they were highly stable and exhibited potent antitumor activity; showing that of ADCs based on conventional tubulin-targeting payloads, such as trastuzumab emtansine and brentuximab vedotin. Antitumor activity in an immune-competent host involved activation of the immune system, as shown by evaluation of a trastuzumab-PNU ADC in a Kadcyla-resistant HER2-positive orthotopic breast cancer model. CD74 T cells severely impaired the antitumor activity of the ADC, demonstrating an important role for T cells in driving tumor regression. Furthermore, when tumor-free animals were rechallenged with the same tumor, tumor growth was entirely inhibited in the absence of any further ADC administration, indicating the development of an immunologic memory. In summary, we present a novel ADC format enabled not only with highly potent cytotoxicity, but also with effective immune-stimulatory functions.

CD74 is a type II transmembrane glycoprotein involved in the formation and transport of MHC class II protein. CD74 is highly expressed in many B-cell malignancies with limited expression in normal tissues (Stein et al., CCR 2007). STRO-001 is a novel CD74-targeting ADC containing an anti-CD74 aglycosylated human IgG1 antibody (SP7219) conjugated to a non-cleavable dibenzocyclooctyne (DBCO)-maytansinoid linker-warhead. SP7219 was discovered from a Fab ribosome display library based on Sutoro’s Xpress sift technology. Highly efficient site-specific conjugation enabled by our cell-free antibody production and click chemistry results in a well-defined homogeneous ADC drug product with a drug-antibody ratio (DAR) of 2. Conjugation sites were selected based on highest stability both in vitro and in vivo, thereby limiting loss of drug moiety from STRO-001 in circulation. Due to its limited cell permeability, the major catabolite released by STRO-001 has 1000X lower cell killing activity on CD74 positive and negative cells compared to the reference cytotoxic maytansine. CD74-positive and negative cells compared to the reference cytotoxic maytansine. STRO-001 further improves tumor suppression in a xenograft model in vitro and in vivo, thereby limiting loss of drug moiety from STRO-001 in circulation. Due to its limited cell permeability, the major catabolite released by STRO-001 has 1000X lower cell killing activity on CD74 positive and negative cells compared to the reference cytotoxic maytansine.

**#68 Methotrexate prevents primary immune responses against recombinant immunotoxins in murine models.** Emily M. King, Ronit Mazor, Ira Pastan. National Cancer Institute, NIH, Bethesda, MD.

Recombinant immunotoxins (RTIs) are composed of a tumor antigen-targeting antibody fragment fused to a portion of Pseudomonas exotoxin A. RTIs have been studied extensively in clinical trials for patients with hematological malignancies. The CD22 targeting RTI Moxetumumab Pasudotox has achieved overall response rates of 86% and complete remission rates of 46% in patients with relapsed/refractory Hairy Cell Leukemia. However, the therapeutic efficacy of RTIs against solid tumors is limited by their immunogenicity in immune-competent patients. In clinical trials to treat mesothelioma patients with SS1P, a RTI target- ing mesothelin, 90% of patients developed neutralizing antibodies against SS1P after one cycle of treatment. When immunosuppressive chemotherapy and SS1P were combined, more cycles of RTI could be given and several patients with advanced chemo-refractory mesothelioma had striking tumor regressions. This implicates high therapeutic potential for RTIs against solid tumors once immunogenicity is surmounted. Methotrexate (MTX) is a folate antagonist which interferes with purine biosynthesis, and is used to treat osteosarcomas and other cancers. MTX also interferes with T cell responses and is used to treat autoimmune diseases. Based on its immunosuppressive properties, Joly et al. demonstrated that low-dose MTX prevented the formation of ADAs against recombinant human alglucosidase alfa in mice in an antigen-specific manner. We hypothesized that MTX would similarly prevent the formation of ADAs against RTIs that target antigen-specific proteins. To test our hypothesis, we treated mice with the mesothelin-targeting RTI RG7787 with or without MTX given 0, 24, and 48 hours after RG7787 treatment. Serum was collected and anti-RG7787 ADAs were measured by direct ELISA. We found that six doses of RG7787 combined with low dose MTX (1 mg/kg) inhibited the formation of ADAs against RG7787. This inhibition was sustained through six challenges with RG7787 without additional MTX. Further, we found that immunization with RG7787 plus MTX induced RG7787-specific tolerance, and had no effect on the ADA response against an antigen-specific protein, ovalbumin. We conclude that combination of MTX and RG7787 is effective at preventing primary immune responses in a durable, antigen-specific manner. We propose to combine this agent in immune-competent cancer patients receiving RTI therapy to prevent RTI immunogenicity.

**#69 Anti-podocalyxin cancer-specific monoclonal antibody: preclinical study.** Shinji Yamada, Tohoku University, Sendai, Japan.

Background: Podocalyxin, a CD34-related sialomucin, is expressed in many tumors including colorectal cancers, breast cancers, mesothelial tumors, and brain tumors. Overexpression of podocalyxin has been reported to be an independent predictor of progression, metastasis, and poor outcome. However, PODXL1 has not been used as an antigen-specific target in normal or tumor cells, including many epithelial cells and endothelial cells; therefore, podocalyxin could not be a target of antibody therapy. Although many monoclonal antibodies (mAbs) against podocalyxin have been established, they bind to both cancer and normal cells. We recently established a novel technology for developing cancer-specific mAbs (CasMabs), which could target only cancer cells although those membrane proteins are highly expressed in both cancer and normal cells. Methods: We first produced a podocalyxin-expressing glioblastoma cell line. We purified human podocalyxin using PA-tag, and immunized mice with those proteins. CasMabs were screened using flow cytometry against podocalyxin-expressing cancer cells and podocalyxin-expressing normal cells. The cancer specificity was confirmed using immunohistochemistry against breast cancer tissues. Furthermore, a human-mouse chimeric anti-podocalyxin mAb was produced. Antibody-dependent cellular cytotoxicity (ADCC) was investigated in vitro using glioblastoma cells as target cells and human NK cells as effector cells. In vivo efficacy was evaluated using xenograft models of podocalyxin-expressing cell lines. Furthermore, we investigated the toxicity of chPcMab-6 using cytomegalovirus monkeys. Results: A cancer-specific anti-podocalyxin mAb (clone: PmC-mab; mouse IgG1, kappa) was established. PcM-b6 reacted with podocalyxin-expressing many cancer cell lines, 90% of brain tumors, and neutralizing antibodies against Podocalyxin were not found in histology and relative organ weight on postmortem examination.
Conclusion: ChiPcMab-6, a cancer-specific human-mouse chimeric anti-podocalyxin mAb could be useful for targeting podocalyxin in cancer, although podocalyxin is highly expressed in many normal cells.

Antibody-drug conjugates (ADCs) continue to emerge as effective therapeutic agents and ADC-related toxicities have been attributed to the high local concentration of the released drug. Here we present a systematic study of the relationship between ADC pharmacokinetics, even at high levels of drug loading (Nature Biotechnology 32, 1059-1062 (2014), Nature Biotechnology 33, 733-735 (2015)). We have now prepared drug-linkers of monomethylauristatin E (MMAE) that orthogonally employ these features to enable a systematic evaluation of the relative contributions of maleimide instability and accelerated plasma clearance on the in vivo behavior of ADCs. Biodistribution studies with these molecules have revealed that the concentration of released MMAE in normal tissues is greatly impacted by the rate of ADC clearance (fast clearance results in greater Cmax of released MMAE in normal tissues is greatly impacted by the rate of ADC clearance (fast clearance results in greater Cmax of released MMAE in normal tissues is greatly impacted by the rate of ADC clearance (fast clearance results in greater Cmax of released MMAE). One such property that is now well appreciated are the reversibility of maleimide-based drug conjugation, and the impact of drug conjugation on the pharmacokinetics of the ADC. We recently reported advances in drug-linker design that independently address both of these properties, resulting in the irreversible conjugation of drugs which have minimal impact on antibody pharmacokinetics, even at high levels of drug loading (Nature Biotechnology 32, 1059-1062 (2014), Nature Biotechnology 33, 733-735 (2015)). We have now prepared drug-linkers of monomethylauristatin E (MMAE) that orthogonally employ these features to enable a systematic evaluation of the relative contributions of maleimide instability and accelerated plasma clearance on the in vivo behavior of ADCs. Biodistribution studies with these molecules have revealed that the concentration of released MMAE in normal tissues is greatly impacted by the rate of ADC clearance (fast clearance results in greater Cmax of released MMAE). These results suggest that ADC pharmacokinetics dominate the biodistribution and toxicity profiles for a given drug payload, with conjugate stability playing a relatively minor role.

Folate receptor α (FRα) is an antigen that is overexpressed on the cell surface of solid tumors including ovarian cancer. The differential expression on cancer cells makes FRα an attractive target for antibody-drug conjugates (ADCs), and an ADC targeting FRα, Mirvetuximab soravinsine, has demonstrated promising anti-tumor activity and safety profiles in the clinic. Here, we employed a new linker (NL) to enhance the bystander activity of ADCs, which is the ability of ADCs to generate cell-permeable catabolites that can diffuse into and kill proximal cancer cells with little or no target expression. With the goal of improving the potency of anti-FRα ADCs in solid tumors with heterogeneous FRα expression, we constructed the M9346A-NL-DM. M9346A-NL-DM is a conjugate of the tubulin-binding venom factor (CVF) that undergoes lysosomal cleavage followed by self-immolation to generate free DM that can readily penetrate neighboring cancer cells. Correspondingly, M9346A- NL-DM showed enhanced bystander cytotoxic activity against proximal antigen-negative cells in vitro. In the xenograft tumor models in vivo, M9346A- NL-DM demonstrated enhanced efficacy against tumors with heterogeneous expression of FRα. Interestingly, M9346A- NL-DM also showed improved antitumor activity against a tumor model with homogeneous expression of FRα, possibly due to better tumor penetration of the cell-permeable catabolite. In summary, M9346A- NL-DM is a novel ADC with enhanced bystander activity and antitumor activity that can target tumors with heterogeneous expression of FRα.

#72 Induction of immune tolerance to recombinant immunotoxin LMB-100 using synthetic vaccine particles encapsulating rapamycin. Ronit Mazor, Emily King, Takashi Kei Kishimoto, Ira Pastan. National Cancer Institute, Bethesda, MD; Selecta Bioscience Inc, Boston, MA.

Recombinant Immunotoxins (RTIs) are genetically engineered proteins designed for cancer therapy. LMB-100 is a second generation RIT that is composed of a humanized Fab targeting mesothelin and a de-immunized fragment of Pseudomonas Exotoxin A. Due to the bacterial origin of the toxin, LMB-100 is immunogenic, although less immunogenic than first generation immunotoxins. Almost all patients treated with LMB-100 made anti-drug antibodies (ADAs) after two or more cycles of treatment that neutralized the RIT and greatly lowered efficacy. Kishimoto et al. demonstrated that Synthetic Vaccine Particles containing Rapamycin (SVP) inhibited the formation of ADAs, when administered with a foreign protein such as KLH or Pegsiticase. The SVP-R are taken up by macrophages and dendritic cells and increase the number of regulatory T cells in vivo. Here we report that SVP-R can reduce the reactivity of pre-existing ADAs. However, when mice with pre-existing ADAs were treated with LMB-100 and SVP-R, anti-tumor activity was restored and ADAs suppressed (P<0.0001). SVP-R are being evaluated in humans to prevent ADA to Pegsiticase, an enzyme for refractory gout treatment. Our data indicates that combining SVP-R with LMB-100 should be useful in treating cancer by allowing more treatment cycles and better efficacy. This approach can be used to increase the efficacy of other immunogenic agents such as CAR-T cells, antibody drug conjugates and viral gene therapy vectors.

#73 Role of macrophages in the antitumor activity of an anti-transferrin receptor 1 antibody ch128.1 in a xenograft model of multiple myeloma. Lai Sum Leoh, Yoon Kyung Kim, Pierre V. Candelaria, Otoniel Martinez-Maza, Tracy R. Daniels-Wells, Manuel L. Penichet. UCLA, Los Angeles, CA.

The transferin receptor 1 (TfR1), also known as CD71, is a membrane coprotein involved in cellular iron uptake and regulation of cell growth. The high level of TfR1 expression on malignant cells and its key role in cancer cell pathology make this receptor an attractive target for antibody cancer therapy. We previously developed a mouse/human chimeric IgG3 specific for human TfR1 (ch128.1). This antibody exhibits direct cytotoxicity against certain human malignant B cells in vitro through TfR1 degradation and iron deprivation. Importantly, ch128.1 shows remarkable anti-tumor activity in xenograft models of disseminated multiple myeloma (MM) in immunosuppressed mice (SCID-Beige). Interestingly, this anti-tumor protection was observed even against MM cells (KMS-11 cells) that show no sensitivity to this antibody in vitro, suggesting the in vivo contributions of antibody effector functions. This possibility was supported by the lack of anti-tumor protection observed using a ch128.1 Fc mutant with impaired binding to FcγRs and to the complement component C1q. To examine host effector functions involved in ch128.1-mediated protection in our mouse model bearing KMS-11 tumors, depletion studies of complement and macrophages were performed. Complement depletion using cobra venom factor (CVF) did not affect protection, suggesting that complement-mediated cytotoxicity (CDC) is not a relevant mechanism of action. Notably, we now report that macrophage depletion using clodronate liposomes (clodrolip) significantly reduced protection, suggesting that these effector cells play a relevant role in the anti-tumor activity. Consistent with this result, we also report that ch128.1 is capable of eliciting antibody-dependent cell-mediated cytotoxicity (ADCC) and antibody-dependent cell-mediated phagocytosis (ADCP) against KMS-11 cells in the presence of the murine macrophage cell line J774.2 or murine bone marrow-derived macrophages. To examine the role of iron deprivation in ch128.1-mediated tumor death in vivo, animals treated with ch128.1 were systemically supplemented with iron in a preliminary study. However, no differences in survival were observed, suggesting that iron deprivation is not a contributor to the effects of ch128.1 in our in vivo model or the iron dose tested was not optimal. Our results suggest that macrophages play a key role in ch128.1-mediated anti-tumor protection in our model and that ch128.1 can be an effective therapy of incurable human B-cell malignancies such as MM.
#74 Discovery of new therapeutic monoclonal antibodies to challenging GPCRs, ion channels and transporters. Lewis J. Stafford, Ross Chambers, Shar hon R. Willis, Moniquetta Hall, Brad Screnci, Manu Mabila, David Tucker, Trevor Barnes, Rachel Fong, Andrew Ettemper, Jennifer Pfaff, Chidananda Sulli, Nicholas Molino, Andrew Hudacek, Benjamin J. Doranz, Joseph Rucker. Integral Molecular, Marlborough, MA.

The objective of this work was to evaluate the ability to generate panels of monoclonal antibodies against a set of highly challenging targets including GPCRs (CB1, C5AR, CXCR5 and CGRPR), transporters (GLUT4), and ion channels (P2X3). Integral membrane proteins are important drug targets and monoclonal antibodies (mAbs) directed against them are highly sought for therapeutic applications. However, the complexity of membrane protein targets makes the discovery of these mAbs especially challenging. To address this need, Integral Molecular has developed the MPS Discovery Engine to enable the isolation, characterization, and engineering of monoclonal antibodies for GPCRs, ion channels, and transporters. MPS utilizes a collection of technologies to address each of the barriers to monoclonal antibody development against the native extracellular epitopes of multispan membrane proteins. These include, antigen engineering to attain high levels of surface expression, DNA and Lipoapaptite immunization to present native epitopes to the immune system, diverse immunization host species to deal with highly conserved proteins, Lipoparticles (high concentration native membrane proteins) to enable phage display and microfluidic B-cell isolation, and shotgun mutagenesis (comprehensive and in situ) for epitope mapping. Using the MPS Discovery Engine we were able to successfully generate large panels of antibodies to the targets that were able to bind to the native extracellular epitopes on cells by flow cytometry. A subset of the antibodies had antagonist activity. With this technology we have the ability to target intact, conformation specific, and functional antibodies to complex membrane proteins.
Antibody-drug conjugate (ADC) occurs in a highly efficient manner following the specific binding of the meditope to the enabled antibody. To test the hypothesis that photactivation would be an efficacious and homogeneous way to make an ADC, meditope-enabled ADCs were designed and tested in vitro and in vivo. Photocytotoxicity was tested as an efficacious interaction following short-term exposure of the antibody peptide conjugates to a nondestructive wavelength of 340 nm. Photocytotoxicity proved to be a highly efficient and scalable way to make an ADC. Payload stability was confirmed in vivo with multiple toxins and in vivo potency of two unique ADCs were tested in an EGF receptor positive gastric cancer xenograft as well as a HER2 positive ovarian cancer xenograft. The meditope-enabled photogenerated anti-HER2 ADC was benchmarked against conventionally conjugated T-DiM and showed equivalent efficacy, but with the site-directed conjugated meditope ADC using less toxin. Meditope-directed photocytotoxicity with a modified ADC, enabling a cell cycle independent mechanism of action. The contribution of resistant to T-DM1, T-MMAE, DM1, MMAE and taxol treatment. In addition, or an anti-HER2 C6.5 diabody-deBouganin fusion protein. C6.5 diabody-deBouganin can overcome these mechanisms of resistance and may lead to cell death. When conjugated to trastuzumab (T-deB) or genetically activated Protein (RIP) that when internalized blocks protein synthesis thereby leading to cell death. When conjugated to trastuzumab (T-deB) or genetically attached to the C6.5 diabody, deBouganin was more potent than DM1 and unaffected by mechanisms of resistance to which DM1 is susceptible. To further highlight the differentiating mechanism of action of deBouganin, HCC1419 and BT-474 tumor cells that survived T-DM1 or trastuzumab-MMAE (T-MMAE) treatment in vitro were re-exposed to T-DiM, T-MMAE, or treated with T-deB or an anti-HER2 C6.5 diabody-deBouganin fusion protein. C6.5 diabody-deBouganin and T-deB were potent against HCC1419 and BT-474 cells surviving T-DiM or T-MMAE treatment. However, the surviving cell populations were resistant to T-DiM, T-MMAE, DM1, MMAE and taxol treatment. In addition, cross-resistance was seen against trastuzumab-diocarmycin in which contains a payload with a cell cycle independent mechanism of action. The contribution of multi-drug resistance, Bcl-2 family members and other survival pathways accounting for the resistant phenotype will be discussed. Overall, the data suggest that treatment with chemotherapeutics or ADCs comprised of small molecule compounds such as anti-microtubule agents, can lead to the outgrowth of tumor cells resistant to similar agents. In contrast, antibodies and antibody fragments armed with deBouganin can overcome these mechanisms of resistance and may therefore represent a more effective treatment option.
#82 MiR-206-mediated c-MET suppression modulates BCRP/ABCG2 lev-
erals in NRF2-silenced cancer cells. Bo-hyun Choi, In-geun Ryoo, Donghyeok
Kim, Sujin Lee, Mi-Kyoung Kwak. The Catholic University of Korea, Bucheon,
Gyeonggi-do, Republic of Korea.

Breast cancer resistance protein (BCRP/ABCG2), a xenobiotic efflux trans-
porter, is responsible for anticancer resistance in tumors. NF-E2-related factor 2
(NRF2) is a critical transcription factor in cellular defense system by regulating
the expression of antioxidant and detoxifying enzymes; however, its overexpres-
sion is often associated with tumor resistance to chemotherapy. In the present
study, we demonstrate that NRF2 modulation affects the expression of hepato-
cyte growth factor receptor (HGF/c-MET) and consequently suppresses BCRP/ABCG2 activity in cancer cells. Interfering RNA-mediated inhibition of
NRF2 in both ovarian carcinoma SKOV3 and renal carcinoma A498 cell lines reduced the expression of c-MET and this was accompanied by BCRP/
ABCG2 down-regulation. The treatment of cells with pharmacological or ge-
nic inhibitor of c-MET decreased BCRP/ABCG2 level and subsequently in-
creased intracellular accumulation of doxorubicin and Hoechst 33342,
netic inhibitor of c-MET decreased BCRP/ABCG2 level and subsequently in-
crease in PDAC cells blocks CTGF expression and under co-cultured conditions pre-
vent the growth of alpha-smooth muscle actin (a-SMA)-positive stellate cells,
which is critical for pancreatic stroma growth. In previous studies, CCN1 abla-
tion upregulates dCK expression in PDAC cell lines as compared to CCN1
expressed PDAC cells. These two events enhance the anti-proliferative effect of
GEM and can be rescued by CTGF-treatment or blocking dCK. In conclusion,
CCN1 promotes GEM-resistance in PDAC cell through the regulation of CTGF
and dCK and the mechanistic insights provided by these studies may help in
designing future therapeutic strategies to combat PDAC.

#83 Irinotocin resistance in type 2 interleukin-1 receptor overexpressed
colorectal cancer cells is overcome by inhibitor of MEK. Ai-Chung Mar,1
Chun-Ho Choi,1 An Chang Lee.2 Academia Sinica - Inst. of Biomedical Sci.,
Taipei, Taiwan; 2Department of Surgery, Taipei, Taiwan.

We have previously demonstrated that the expression of interleukin-1 recep-
tor type II (IL1R2) is closely associated with the advanced staging and distant
metastasis in patients with CRC. We also found that enhanced expression of IL1R2 played certain roles to resist the targeted therapeutics, regorafenib, in CRC cells. Whether IL1R2 expression is associated with the resistance to che-
motherapeutics is unclear. Irinotecin, a water-soluble and semisynthetic deriv-
ant of camptothecin, is one of widely used first- and second-line chemothera-
peutics for treatment of patients with metastatic colorectal cancer (CRC). Her-

experimental evidence, transient and stable expressions of miR-206 in SKOV3 and A498 cells repressed c-MET and BCRP/
ABCG2 levels. In addition, NRF2 knockdown cancer cells expressed higher lev-
els of miR-206 compared to the control cells, and the treatment of NRF2 knock-
down cells or the non-silencing inhibitor of c-MET could repress miR-206 and BCRP/
ABCG2 levels. Collectively, our results showed that the NRF2 silencing-mediated miR-
206 regulation could suppress BCRP/ABCG2 levels through c-MET modula-
tion, which is providing an additional evidence of chemosensitization of tumor
cells by NRF2 inhibition.

#84 CCN1/Cyr61 regulation of gemcitabine-resistant phenotype in pan-
creatic cancer: involvement of CTGF and dCK. Vijayalaxmi G. Gupta, Gargi
Maiti, Inamul Haque, Sushantia K. Banerjee, Snigdha Banerjee. Kansas City VA
Medical Center and University of Kansas Medical Center, Kansas City, KS.

With an estimated half a million new cases and similar mortality rates for
2016, pancreatic ductal adenocarcinoma (PDAC) remains a life-threatening and
challenging disease to diagnose and treat. As per American Cancer Society
(ACS), varying efficacy in different patients has led to an increase in the mortal-
ity rate of PDAC. Gemcitabine (GEM) remains the drug of choice either alone or
in combination, but is unsuccessful in reducing or curing PDAC in most pa-
tients. The limited efficacies of these drugs are due to the acquisition of chemo-
resistant characteristics of PDAC. Although several molecular and physiological
factors have been shown to correlate with the GEM-resistance, defined mole-
cular mechanism(s) of GEM-resistance remains a mystery. Previous studies have
shown that CCN1, which is overexpressed in PDAC and known to associate with
PDAC progression, is critical for drug resistance. Here, we found that while the
pancreatic cancer cell lines (i.e., Panc-1 and AsPc1) in which CCN1 is over-
expressed are typically GEM-resistant, the knocking down of CCN1 makes them
sensitive to GEM. Mechanistic studies revealed that CCN1 regulates two impor-
tant transcription factors: CTGF and dCK. These include cancer cell-secreted connective tissue growth factor (CTGF), a regulator of desmoplasia, and Deoxycytidine kinase (dCK), an enzyme that en-
hances gemcitabine sensitivity and efficacy in cancer cells. The deletion of CCN1 in
PDAC cells blocks CTGF expression and under co-cultured conditions pre-
vent the growth of alpha-smooth muscle actin (α-SMA)-positive stellate cells,
which is critical for pancreatic stroma growth. In previous studies, CCN1 abla-
tion upregulates dCK expression in PDAC cell lines as compared to CCN1
expressed PDAC cells. These two events enhance the anti-proliferative effect of
GEM and can be rescued by CTGF-treatment or blocking dCK. In conclusion,
CCN1 promotes GEM-resistance in PDAC cell through the regulation of CTGF
and dCK and the mechanistic insights provided by these studies may help in
designing future therapeutic strategies to combat PDAC.

#85 Establishment of cabazitaxel-resistant prostate cancer cell lines. Atsu-
shi Mizokami,1 Kazuaki Machioka,1 Kouji Izumi,1 Maolaek Akeren,3 Arinboul
Natsadongji,1 Yoshifumi Kadono,1 Yuta Takezawa,1 Hiroaki Iwamoto,1 Evan T.
Keller.1 Kanazawa University, Kanazawa, Japan; 2University of Michigan, Ann
Arbor, MI.

Background: The final treatment for castration-resistant prostate cancer
(CRPC) is generally cabazitaxel treatment. However, once CRPC becomes resis-
tant to cabazitaxel, the patients are obliged to best supportive care. Therefore,
the elucidation of the mechanism of the cabazitaxel-resistance and the conquest
are important themes to improve the prognosis of the patients. We already
established paclitaxel/docetaxel-resistant prostate cancer, PC-3-TxR and
DU145-TxR cells, and characterized those cell lines previously. Then we further
tried to establish cabazitaxel-resistant prostate cancer cell lines, and character-
ized those cell lines. Materials and Methods: We established two cabazitaxel-
resistant cell lines, PC-3-TxR/CxR and DU145-TxR/CxR by increasing concentra-
tion of cabazitaxel from 1 nM to 30 nM gradually when PC-3-TxR and
DU145-TxR cells were passaged. We confirmed the IC50 of docetaxel and cabaz-
itaxel of these cells. Next we purified total DNA and performed cDNA microar-
ray (Agilent and compared gene expression profiles among these cells. Results
and Conclusion: IC50 of PC-3-TxR and PC-3-TxR/CxR for cabazitaxel was 1.3
nM and 15.4 nM, respectively. IC50 of DU145-TxR and DU145-TxR/CxR was
7.0 nM and 30.8 nM, respectively. Comparison of cDNA microarray between
PC-3-TxR and PC-3-TxR/CxR cells or between DU145-TxR and DU145-TxR/
CxR cells revealed that 4,470 genes in PC-3-TxR/CxR and 1,345 genes in
DU145-TxR/CxR were upregulated more than 3-fold and downregulated more
than 0.3-fold, respectively. Especially, although expression of ABCB1 (MDR) gene was upregulated in DU145-TxR by 500-fold compared with DU145 cells, it was not upregulated in
not upregulated in DU145-TxR/CxR cells any more. In contrast, expression of
ABCB1 gene was upregulated in PC-3-TxR by 20-fold compared with PC-3 cells
and it was further upregulated in PC-3-TxR/CxR by 40-fold compared with
PC-3. In conclusion, various genes were regulated in cabazitaxel-resistant
PCa cells and different mechanisms might be involved in this resistance in
different cell lines.

#86 Time course analysis of gene expression and epigenetic interactions in
acquired cetuximab resistance in head and neck squamous cell carcinoma.
Lanice T. Kagohara,1 Genevieve Stein-O’Brien,1 Siija Li,1 Manjusha Thakar,1
Ruchira Ranawera,2 Michael Considine,1 Joseph A. Califano,1 Christie H.
Chung,2 Daria Gaykina,2 Elana J. Fertig,1 Johns Hopkins University, Balti-
more, MD; 2Moffitt Cancer Center, Tampa, FL; 3University of California San
Diego, San Diego, CA.

The current study performs time course genomics and epigenomics profiling
to determine the complex dynamics of interactions between gene expression
and epigenetic changes that alter cellular signaling and drive acquired therapeu-
tic resistance. Targeted therapeutic agents block the activity of specific molecules
which are required for desmoplastic growth in pancreatic cancers. CCN1 is a critical
transcription factor in cellular defense system by regulating the expression of
antioxidant and detoxifying enzymes; however, its overexpression is often associated with tumor resistance to chemotherapy. In the present study, we demonstrate that NRF2 modulation affects the expression of hepato-
cyte growth factor receptor (HGF/c-MET) and consequently suppresses BCRP/ABCG2 activity in cancer cells. Interfering RNA-mediated inhibition of
NRF2 in both ovarian carcinoma SKOV3 and renal carcinoma A498 cell lines reduced the expression of c-MET and this was accompanied by BCRP/
ABCG2 down-regulation. The treatment of cells with pharmacological or ge-
nic inhibitor of c-MET decreased BCRP/ABCG2 level and subsequently in-
creased intracellular accumulation of doxorubicin and Hoechst 33342,
netic inhibitor of c-MET decreased BCRP/ABCG2 level and subsequently in-
crease in PDAC cells blocks CTGF expression and under co-cultured conditions pre-
vent the growth of alpha-smooth muscle actin (α-SMA)-positive stellate cells,
which is critical for pancreatic stroma growth. In previous studies, CCN1 abla-
tion upregulates dCK expression in PDAC cell lines as compared to CCN1
expressed PDAC cells. These two events enhance the anti-proliferative effect of
GEM and can be rescued by CTGF-treatment or blocking dCK. In conclusion,
CCN1 promotes GEM-resistance in PDAC cell through the regulation of CTGF
and dCK and the mechanistic insights provided by these studies may help in
designing future therapeutic strategies to combat PDAC.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Gene Expression of Drug Resistance

Proceedings of the American Association for Cancer Research. Volume 58. April 2017. 21
tance than the widespread alterations observed once the resistance is established. To test this hypothesis, we develop a novel time course experimental and bioinformatics model of acquired resistance. Specifically, this protocol enables weekly profiling of RNA, DNA, and proliferation as cetuximab resistance developed in vitro. We apply the CoGAPS bioinformatics algorithm to perform integrated analysis of gene expression and DNA methylation. This analysis discovered signatures of sustained activation of cellular pathways in response to treatment from signatures of clonal expansion associated with acquired cetuximab resistance. Despite identifying massive changes in gene expression driven by therapeutic response, only the expression changes associated with the acquired resistance, and not response to treatment, have corresponding epigenetic signatures. The genomic signature associated with acquired cetuximab resistance is enriched for gene targets of the AP-2 family of transcription factors. In a previous study, we found that these gene targets were overexpressed after short-term treatment in cetuximab sensitive cell lines and HNSCC tumors. Our data suggest that this family of transcription factors serves as a feedback mechanism to maintain homeostasis to growth factors receptor signaling. As a result, AP-2 transcription factors serve as a natural mechanism to cause subsequent therapeutic resistance with accumulation of genetic alterations. Further investigation is needed to determine the role of AP-2 transcription factors in acquired cetuximab resistance.

#87 Treatment schedules influence acquisition of Doxorubicin resistance through epigenetic mechanism in breast cancer cells. Logeswari Ponnusamy, Prathap Kumar S. Mahalingaiah, Kamaleshwar P. Singh. The Institute of Environmental & Human Health, Texas Tech University, Lubbock, TX.

Breast cancer is the leading cause of cancer-related mortality in women. Chemotherapy resistance is a major limitation in clinical treatment of breast cancer. Mounting evidence implicates the epigenetic aberrations in acquired chemoresistance. However, the influence of treatment schedules and associated epigenetic changes on acquisition of doxorubicin resistance in breast cancer is not clear. Therefore, objective of this study was to evaluate the impact of treatment schedules on acquisition of doxorubicin resistance and the molecular mechanism basis of this process in breast cancer cells. To address this question, two different treatment strategies viz, continuous exposure and intermittent exposure were used to generate doxorubicin resistant cells lines from ER-positive MCF-7 and triple negative MDA-MB-231 breast cancer cell lines. The level of resistance against doxorubicin and the temporal sequence of molecular changes associated with the resistance phenotype were evaluated at 4 months and 18 months’ following exposure to doxorubicin. Results revealed that intermittent exposure to doxorubicin resulted in significantly higher level of resistance as compared to continuous exposure. ER-positive MCF-7 cells developed relatively earlier and high level of resistance when compared to MDA-MB-231 cells. Additionally, the resistance to doxorubicin-induced cytotoxicity was associated with transient acquisition of EMT and CSC-like phenotype in breast cancer cells around 4 months following doxorubicin. Gene and protein expression analysis further revealed temporal changes in the expression of epigenetic regulatory genes and histone modifications respectively. The temporal changes in expression of genes were positively correlated with doxorubicin exposure time during resistance development. In summary, the result of this study for the first time suggests that the treatment schedules influence the acquisition of doxorubicin resistance potentially through epigenetic mechanisms. The findings of this study will be helpful in chemotherapy of breast cancer to achieve the best clinical result.

#88 The role of RBPMS in cisplatin resistant ovarian cancer. Perla M. Baez-Vega,1 Fatma Valiyeva,1 Ginette Santiago,2 Pablo Vivas-Mejia1.1 Université of Puerto Rico Comprehensive Cancer Center, San Juan, PR; 2University of Puerto Rico Medical Sciences Campus, San Juan, PR.

Ovarian epithelial cancer is the fifth leading cause of cancer–associated deaths among women in the United States. High-grade serous ovarian cancer (HGSC) is the most common type of epithelial ovarian cancer and accounts for 70-80% of ovarian cancer patient deaths. RNA-Binding Protein With Multiple Splicing (RBPMS) is the leading cause of cancer-related mortality in the United States. We hypothesized that RBPMS is highly expressed in A2780 cells when compared to the cisplatin resistance ovarian cancer cells and HGSOc cancer cells. Targeting RBPMs increased the invasion ability of the A2780 cells. Cisplatin resistant, A2780CP20 cells overexpressing RBPMs showed a decreased in cell proliferation when compared to the A2780CP20 empty vector control. Western blot and real-time PCR showed the downregulation of RBPMs expression profile of RBPMs in HGSOc and epithelial ovarian cancer cells. These studies will help to better understand the role of RBPMs in ovarian cancer and may support the use of RBPMs as an adjuvant treatment to overcome the platinum-based chemotherapy resistance characteristic of the high-grade serous ovarian cancer.

#89 Targeting Rho/MRTF regulated gene transcription in drug-resistant melanoma. Sean A. Misek,1 Scott D. Larsen,2 Kathleen A. Gollo,1 Richard R. Neubig1. 1Michigan State Univ, East Lansing, MI; 2University of Michigan, Ann Arbor, MI.

Much of the recent focus of melanoma targeted therapy has been on the ERK pathway, which is aberrantly activated in approximately 90% of melanoma tumors (over half of which express BRAFmut). Current targeted therapies such as vemurafenib (BRAFV600E inhibitor), or a combination therapy using dabrafenib (BRAFV600E inhibitor) and low dose trametinib (MEK inhibitor) shows profound initial effects in a majority of BRAFmut expressing tumors. However, these responses are often short-lived and resistances typically develops within months. Resistance to these targeted therapies can arise from multiple mechanisms, including activation of pro-survival signaling pathways parallel to the ERK pathway. The goal of this work is to identify pharmacologically targetable genetic alterations that may lead to subsequent therapeutic resistance without further development of drug resistance mechanisms so that effective combination therapies can be developed. Despite the clear role of the RhoA subfamily of Rho GTPases (RhoA/B/C) as melanoma oncogenes, their role in drug resistance is not well understood. It is challenging to develop small molecule inhibitors which directly target the activity of small Rho GTPases, so an alternative approach is to inhibit downstream pathways. Through modulation of the actin cytoskeleton Rho can induce gene transcription through multiple transcriptional co-activators including Myocardin-Related Transcription Factor (MRTF) and Yes-Associated Protein 1 (YAP). My bioinformatics analysis demonstrates that MRTF-A gene expression is correlated with poor overall survival in a large cohort of cutaneous melanoma patients. Furthermore, expression of a set of 216 MRTF target genes is enriched in dabrafenib/trametinib resistant cutaneous melanoma tumors compared to matched pre-treatment tumors, suggesting that MRTF activation may be involved in drug resistance. Based upon these results I hypothesized that small Rho GTPases may promote resistance to MAPK pathway targeted therapies through activation of MRTF/YAP. To test this hypothesis, I generated vemurafenib resistant melanoma cells through chronic exposure to vemurafenib. These vemurafenib resistant cell population is enriched for actin stress fiber positive cells, and these cells have increased Myosin Light Chain 2 (MLC2) phosphorylation, suggesting that there is increased Rho activation. Furthermore, these drug resistant cells are more sensitive to pharmacological inhibition of MRTF activity. These preliminary data suggest that vemurafenib resistant melanoma cells may be re-wired to depend on the Rho-induced gene transcription for their survival, and that a combination therapy simultaneously targeting these two pathways may be an effective treatment strategy for BRAF inhibitor-resistant melanomas.

#90 STING colocalizes with gamma-H2AX upon treatment of breast cancer cells with genotoxics: A new role in DNA repair. Laura Cherade,1 Julie Gaston,1 Vanessa Yvonnet,1 Olivier Deas,2 Marie-Franço Poupon,1 Jean-Gabriel Judde,1 Vincent Goffin,1 Stefano Cairo1. 1XerTech, Evry, France; 2Inserm U1151, Institut Necker Enfants Malades (INEM), University of Paris Descartes, Faculty of Medicine, Paris, France.

One of the current tumor immunotherapy strategies involves the use of STING agonist, a well-known inducer of interferon (IFN) signaling in the immune system, to promote tumor-rejection. However, recent evidence also indicates that constitutive activation of IFN signaling in the tumor may lead to a bad outcome. For instance, increased expression of IFN- stimulated genes (ISGs) at time of surgery was associated with early breast cancer recurrence, and an IFN-related DNA damage resistance signature (IRDS) was identified as a predictive marker of recurrence after radiotherapy. Thus, IFNs secreted into the tumor microenvironment may have complex opposite effects on tumor behavior and response to treatment. Using patient-derived xenograft (PDX) models, we previously showed that the IFN/STAT1 pathway was activated within breast cancer cells in response to chemotherapy and that this pathway may be involved in treatment resistance and recurrence. The aim of this study was to elucidate the mechanisms by which IFN-signaling is triggered in breast cancer cells following chemotherapy and how its activation leads to tumor survival and recurrence. To
this aim, the breast cancer cell line MCF7 was treated in vitro with mafosfamide and the activity of different IFN pathway effectors was monitored using western blot, immunofluorescence and cell fractionation techniques. We found that in breast cancer cells, similarly to what is observed in immune cells, type I IFN expression is triggered in a STING-dependent manner. STING silencing abrogated chemotherapy-induced cell death when type I IFN was induced, suggesting that STING mediates IFN-induced cytotoxicity through the activation of autocrine IFN pathways. This study also revealed that the STING pathway is essential for the IFN-mediated sensitization of breast cancer cells to the chemotherapeutic drug Doxorubicin. Importantly, the combination of STING agonists and chemotherapy demonstrated synergistic antitumor effects in vivo, highlighting the potential of this approach for the treatment of breast cancer.

INTRODUCTION: Drug resistance of leukemic stem cells is a surmountable obstacle to effective chemotherapy in acute myeloid leukemia (AML). P-glycoprotein (Pgp) and FLT3 undoubtedly contribute to worse prognosis and mechanisms of these proteins lead to shorter survival and chemotherapy resistance. Due to heterogeneity of stem cells in AML, outcome of patients with a normal karyotype is highly challenging and changes in drug resistance genes likely to be identified which will contribute to a better understanding of the disease biology, eventually leading to the development of alternative therapeutic approaches regarding drug resistance in AML. METHODOLOGY: Blood and Bone-marrow samples were collected from newly diagnosed adult AML patients with normal karyotype. Gene expression analysis of MDR genes like Pgp, MRPI, BCRP and LRP was done by qRT-PCR in FLT3-ITD +/- and CD34+/ - subgroups. Higher expression of Pgp amongst all MDR genes instigated to undertake in-silico analysis of Pgp with natural compound library using YASARA. MTT assay was used to find out IC50 value of natural compounds shortlisted from in-silico analysis and used alone or with cytarine on THP-1 cell line and in primary AML stem cells. Pgp inhibitory activity of natural compounds was assessed by fluorometric MDR assay. RESULTS: A significant upregulation of Pgp expression was observed in FLT3-ITD +/ -, CD34 + group after cytarine exposure during their induction (7 - 3) therapy. Docking analysis revealed curcumin, hesperidin and silimarin having better binding affinity with Pgp as compared to its known inhibitor Verapamil. Furthermore, these selected compounds were used in vitro, and results of MTT assay suggested 6.1µM, 40.73µM, 63.09µM and 54.95µM IC50 values of cytarine, curcumin, hesperidin and silimarin respectively in THP-1 cell line. Combination index (CI) analysis revealed synergistic effects with IC50 having synergistic effect with cytarine and decreased IC50 value of cytarine (1µM). In addition to this, Silimarin at 250nM and 500nM concentration showed equivalent inhibition of Pgp as compared to control Verapamil. CONCLUSION: A combination of in-silico and in-vitro screening revealed Curcumin, Hesperidin and Silibinin can be used as MDR modulators as well as chemosensitizer to reduce the cytotoxicity profile and drug resistance in AML.

#92 Acquisition of temozolomide resistance: Identification of a new drug resistant stage in glioblastoma cells. Marion Rabé,1 Hicham Janati,2 Solenne Dumont,1 Christelle Thibault-Carpentier,2 Jean Clairambault,2 François M. Vallette,1 Catherine Gratas 1.

Glioblastoma multiforme (GBM) are the most aggressive and common brain tumors in adults. Despite surgery and combined radio-chemotherapy with temozolomide (TMZ), tumor recurrence always occurs. The median survival time for patients diagnosed with GBM is about 14 months with less than 5% survival at 5 years. Today the main marker of TMZ resistance is the methylation status of MGMT promoter. Patients with a methylated promoter usually have a better response to treatment than patients with an unmethylated promoter. Indeed MGMT is an enzyme involved in DNA repair mechanisms that abrogates TMZ effects. However, in clinical trials targeting the MGMT enzyme, median survival of patients was not improved. It is thus essential to decipher the mechanisms involved in the acquisition of TMZ resistance to identify new therapeutic targets. To achieve this goal TMZ resistant cells were generated by continuous treatment of the U251 human glioblastoma cell line. These cells are sensitive to TMZ and do not express MGMT. We performed transcriptomic analysis by RNA-Seq on U251 treated with TMZ (50µM) for different time and selected differentially expressed genes. We also evaluated target genes expression in single cells by RT-qPCR using C1-HD-Biomark technology (Fluidigm). Transcriptome profiling allowed to identify a transient phase with TMZ tolerant cells before acquisition of complete resistance. These cells are characterized by a modified morphology and a more proliferative state. In this population we identified a subset of genes with the same transient overexpression. Similar results were observed in two other GBM cell lines under stress and under other stress conditions. A likely expression of MGMT appeared later with the emergence of the TMZ resistant population. Interestingly single cell qPCR showed that MGMT expression in the resistant cells could not be explained by clonal selection of MGMT positive cells. Drug screening on the TMZ tolerant cells revealed a potent killing activity of histone deacetylating agents (HDAC inhibitors). In conclusion, we have shown that glioblastoma cells become resistant after a transient state of TMZ tolerance. Identification of this singular population highlights new molecular targets and a new therapeutic window. Targeting these tolerant cells could avoid emergence of resistance and tumor recurrence, thereby patients survival could be improved.

Glucocorticoids (GCs) are central to all major therapy regimens for pre-B cell-derived acute lymphoblastic leukemia (ALL), but have no activity in myeloid leukemias. Such divergent responses represent an empirically established clinical standard; however, neither the mechanism by which GCs induce cell death nor the biological basis for the distinct responses in B-cell and myeloid leukemias is clear. Studying patient-derived samples revealed that NR3C1 (glucocorticoid receptor) levels were 6- to 20-fold higher in pre-B ALL compared to chronic myeloid leukemia (CML). High levels of Nr3c1 were reduced upon B- to myeloid-lineage conversion, suggesting that regulation of NR3C1 expression and GC responsiveness depend on a B-cell transcriptional program. B-cell transcription factors (e.g. PAX5, IKZF1) are critical for B-cell development, yet they are genetically leisioned in more than 80% of pre-B ALL cases. Despite such high frequency, the significance of these inactivating lesions remains elusive. Combining ChiP-seq and RNA-seq analyses, we identified a novel B-cell transcriptional program for activation of NR3C1 and its transcriptional target TXNIP (a negative regulator of glucose uptake). Reconstitution of PAX5 or IKZF1 expression in haploinsufficient patient-derived pre-B ALL cells increased NR3C1 and TXNIP levels. Conversely, expression of dominant negative mutant of PAX5 or IKZF1 abolished NR3C1 expression. Loss of Nr3c1 or Txnip in murine BCR-ABL1-driven pre-B ALL cells resulted in survival advantage in competitive growth assays. Importantly, loss of Nr3c1 or Txnip significantly elevated glucose uptake, lactate production and cellular ATP levels. These findings suggest that GCs induce cell death by exacerating glucose and energy depletion. Notably, reconstitution of PAX5 or IKZF1 rendered haploinsufficient patient-derived pre-B ALL cells more sensitive to dexamethasone (dex) treatment. In contrast, dominant-negative PAX5 or IKZF1 largely de-sensitized pre-B ALL cells expressing wildtype PAX5 or IKZF1. These findings suggest that B-cell transcription factors set the threshold for GC responsiveness in pre-B ALL. Since relapsed ALL cells often acquire GC resistance, drug-combinations may be useful to prevent GC-resistance. As expected, loss of Nr3c1 abrogated responses to GCs. Interestingly, loss of Txnip also largely rescued GC-induced cell death in pre-B ALL cells. On this basis, we tested drug interactions between GCs and TXNIP agonists, 3-O-methylglucoside (3-OMG) and D-allose. Treating patient-derived GC-refractory pre-B ALL cells with 3-OMG or D-allose strongly synergized with GC-treatment. Collectively, our findings provide a mechanistic explanation for the empirical finding that GCs are effective in the treatment of B-cell but not myeloid malignancies, and identify TXNIP as a novel therapeutic target in pre-B ALL.

#94 Association of xct overexpression with RTKI resistance and metastases in clear cell renal cell carcinoma. Sreenivasulu Chintala, Remi Adelajye- Ogba, Ashley Oreille Steevenari Aria, May Elbanu, Nup P, Damayanti, Roberto Pili. Indiana University-Purdue University, Indianapolis, IN.

Background: Cystine/glutamate exchanger xCT is a catalytic component of system xc- involved in transport of ‘conditionally indispensable’ amino acid cystine. Cystine transport is a rate limiting step for the synthesis of glutathione,
a major intracellular redox regulator. Recently, we and other groups reported the overexpression of xCT and its association with drug resistance in several human cancers including bladder, glioma, breast, and colon. There are no studies to show the xCT expression in clear cell renal cell carcinoma (ccRCC) and its association with tyrosine kinase inhibitors resistance and metastasis. In the current study, we evaluated xCT expression in primary ccRCC tumors in tissue microarray (TMA) and determined its role in receptor tyrosine kinase inhibitor (RTKI) resistance and metastases using the patient derived tumor xenografts (PDX) models and TKI resistance ccRCC cells. Methods: Human Renal cell carcinoma tumor nephrectomy specimens arranged in tissue microarray (TMA) were used to determine xCT expression by immunohistochemistry. Patient derived tumor xenografts (PDX) of primary ccRCC, metastasis, and primary ccRCC tumors in vivo were used to determine the role of xCT in RCC. To understand the molecular alterations associated with RTKI resistance, we have generated sunnitihibit 786 OR ccRCC cells and performed RNAseq analysis. To determine the xCT inhibition effect on ccRCC tumor metastases, sulfasalazine, an inhibitor of xCT was used to treat metastatic ccRCC tumor xenografts transplanted in SCID mice. Results: Immunohistochemical evaluation of xCT in RCC TMA revealed that 70% (19 out of 27) of the tumors express different levels of xCT. Association with tumor response to RTKI will be presented. RTKI less responsive PDX RP-R-02 was developed using the dose escalation strategy and was found to have an upregulation of xCT when the tumors become less responsive to sunnitihibit. RNAseq analysis revealed differential gene expression of genes including tyrosine kinases and lysosome biogenesis and function such as LSC7A1, HP54, HP55, CTSS, CTSD, ITSF30, PPT1, SCPE1, TPI1, ATP6AP1, MCOLN1, PRKAG2, and VPS18 in sunnitihibit resistant 786 OR cells compared to parental cells supports the role of lysosomes function in RTKI drug resistance. Furthermore, xCT inhibitor sulfasalazine treatment significantly decreased the metastasis lung nodules of RP-R-02L in SCID mice demonstrated the xCT role in RCC tumor metastasis. Conclusions: We found preliminary evidence that overexpression of xCT may be associated with RTKI resistance in ccRCC. These results suggest that targeting the xCT in ccRCC may reverse the resistance and enhance the efficacy of RTKI. Additional studies using larger numbers of ccRCC tumors are required to identify xCT as a potential predictive biomarker for response/resistance to RTKI in ccRCC patients.

#95 Targeting BRD4 overcomes cetuximab resistance in HNSCC. Toni Brand, Yan Zeng, Brandon Leonard, Rachel O'Keefe, Hua Li, Daniel Johnson, Jennifer Grandis, Neil E. Bhola. University of California San Francisco, San Francisco, CA. Background: Nearly 600,000 people are diagnosed with head and neck cancer worldwide and 60% succumb to the disease within 5 years. The epidermal growth factor receptor (EGFR) is a major driver of HNSCC and in 2006 the EGFR monoclonal antibody cetuximab was FDA-approved for HNSCC treatment. However, cetuximab has not conferred significant clinical benefit when compared to chemoradiation in patients with poorly differentiated recurrent-metastatic HNSCC. We and others have demonstrated that cetuximab treatment activates alternative receptor tyrosine kinases (RTKs) including Fibroblast Growth Factor (FGF) receptors, Met and Axl in HNSCC. To circumvent accumulation of multiple RTK inhibitors in combination with cetuximab, we sought to identify a common molecular target that regulates the expression of these RTKs. Bromodomain-containing protein 4 (BRD4) has been shown to regulate the transcription of RTKs in breast cancer models. Hypothesis: We hypothesized that targeting BRD4 will overcome cetuximab resistance by depleting the expression of alternative RTKs in HNSCC. We further hypothesize that genetic and pharmacological targeting of BRD4 will synergize with cetuximab. Results: Using a phospho-RTK array, 72-hour cetuximab treatment increased or sustained phosphorylated levels of EGFR, HER2, HER3, MET, and AXL in several HNSCC cell lines. Treatment with the BRD4 inhibitor JQ1 abrogated both phosphorylated and total RTK abundance in the presence of cetuximab. Cetuximab and JQ1 robustly decreased phosphorylated Src and induced the senescence marker p21. Phenotypically, cetuximab and JQ1 significantly decreased survival and increased apoptosis in 6 HNSCC cell lines models, while the normal oral keratinocyte cell line NOKsi had approximately 10-fold higher IC50s for the BRD4 inhibitors, JQ1 and I-BET762, relative to HNSCC cell lines. Importantly, two HNSCC models of acquired cetuximab resistance exhibited robust sensitivity to pharmacological (JQ1, I-BET762) and genetic (RNAi) BRD4 targeting strategies. Moreover, exogenous overexpression of different RTKs (HER3, ALK, and ROR1) resulted in cetuximab resistance that was reversed upon BRD4 targeting (RNAi and JQ1). Combination of cetuximab and JQ1 in co-culture experiments with T cells decreased the CD4+/CD25+ Treg population and PD-1.1 expression on HNSCC cell lines. Further, preliminary findings indicate that JQ1 treatment prevents outgrowth of cetuximab-treated HNSCC patient-derived xenograft models. Conclusion: Our findings indicate that targeting BRD4 decreases the activation and expression of multiple RTKs that mediate resistance to the FDA-approved EGFR inhibitor cetuximab. Furthermore, BRD4 abrogates expression of immunosuppressive markers, making it a promising tumor intrinsic and extrinsic therapeutic strategy for HNSCC.

#96 Dihydropyrimidine dehydrogenase (DPYD) provides resistance to 5-fluorouracil in mutant p53 (mutp53) expressing colorectal cancer cells. Prashanth Ravishankar Gokare,1 Niklas Finnberg,1 David Dicker,1 Maureen Murphy2,3 Fox Chase Cancer Ctr., Philadelphia, PA; 2Wistar Institute, Philadelphia, PA. 5-Fluorouracil (5-FU) is a mainstay of colorectal cancer therapy. Even though much is known about the 5-FU mechanism of action, very little is known about the genetic determinants which provide sensitivity and resistance to 5-FU. Here we provide first insights into p53, a major predictor of 5-FU response, modulating nucleotide catabolism specifically through the control of the rate limiting enzyme dihydropyrimidine dehydrogenase (DPYD). Colorectal cancer cells expressing mutp53 specifically show higher expression of DPYD as compared to the wildtype p53 (wtp53) carrying cells. Higher expression of DPYD in mutp53 cells specifically provides increased resistance to 5-FU as indicated by cellular proliferation and long term clonogenic assays. Furthermore, knockdown of DPYD in mutp53 cells preferentially re-sensitizes them to 5-FU as opposed to cells expressing wtP53 by decreasing the viability and increasing apoptosis observed in these cells. Pharmacological inhibition of DPYD with gimeracil, clinical inhibitor of 5-FU phenocopies the effects seen by siRNA/shRNA mediated knockdown of DPYD. In summary, our data indicates that overexpression of mutp53 specifically provides increased resistance to 5-FU therapy which is abrogated by stable knockdown of DPYD expression or in combination gimeracil. Preliminary analysis of TCGA patients treated with 5-FU indicate differential expression of DPYD based on specific Tp53 mutation status. Taken together our study provides first insights into crosstalk between nucleotide catabolism and mutp53 under conditions of DNA damage and metabolic stress having major implications on the therapeutic response to 5-FU the in the clinic.

#97 RNA sequencing of bladder cancer patient-derived xenograft models identifies genes associated with chemoresistance. Kelly A. Martin,1 Nicholas R. Hum,1 Aimy Sebastian,2 Deepa K. Murugesh,3 Chong-Xian Pan,3 Ai-Hong Ma,2 Ralph de Vere White,2 Gaby Loots1. 1Lawrence Livermore National Laboratory, Livermore, CA; 2UC Davis Comprehensive Cancer Center, Sacramento, CA. Background: Bladder cancer is among the top ten most common cancers, with about ~380,000 new cases and ~150,000 deaths per year worldwide. Platinum-based combination chemotherapy is commonly used to treat advanced bladder cancer. It has been shown that only ~50% of the patients respond to platinum based therapy. Methods: We have utilized a patient-derived bladder cancer xenograft (PDX) platform to characterize the molecular mechanisms that contribute to resistance of gemcitabine-cisplatin combination therapy in advanced bladder cancer. We have also identified key regulatory pathways in our PDX models that can be targeted to treat chemotherapy resistant bladder cancer using RNAseq analysis. Results: The genetic determinants which provide sensitivity and resistance to 5-FU. Here we provide first insights into p53, a major predictor of 5-FU response, modulating nucleotide catabolism specifically through the control of the rate limiting enzyme dihydropyrimidine dehydrogenase (DPYD). Colorectal cancer cells expressing mutp53 specifically show higher expression of DPYD as compared to the wildtype p53 (wtP53) carrying cells. Higher expression of DPYD in mutp53 cells specifically provides increased resistance to 5-FU as indicated by cellular proliferation and long term clonogenic assays. Furthermore, knockdown of DPYD in mutp53 cells preferentially re-sensitizes them to 5-FU as opposed to cells expressing wtP53 by decreasing the viability and increasing apoptosis observed in these cells. Pharmacological inhibition of DPYD with gimeracil, clinical inhibitor of 5-FU phenocopies the effects seen by siRNA/shRNA mediated knockdown of DPYD. In summary, our data indicates that overexpression of mutp53 specifically provides increased resistance to 5-FU therapy which is abrogated by stable knockdown of DPYD expression or in combination gimeracil. Preliminary analysis of TCGA patients treated with 5-FU indicate differential expression of DPYD based on specific Tp53 mutation status. Taken together our study provides first insights into crosstalk between nucleotide catabolism and mutp53 under conditions of DNA damage and metabolic stress having major implications on the therapeutic response to 5-FU the in the clinic.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Gene Expression of Drug Resistance
glutamabumab vedotin, an antibody-drug-conjugate has shown promising results in treating several cancers including breast cancer and osteosarcoma. Further studies will elucidate whether targeting GPNMB is an effective strategy for the treatment of chemotherapy resistant bladder cancer. This study received funding by a developmental grant from the UCDCCC. This work was conducted under the auspices of the USDOD by LLNL (DE-AC52-07NA27344). IM number: LLNL-688318.

#98 TET suppresses protein translation, differentially effects polysome loading of cell cycle regulatory proteins and inhibits cell growth and proliferation of prostate cancer cells. Praveen K. Jaiswal, Sweaty Koul, Qin Dong, Hani Koul. LSU Health Sciences Center - Shreveport, Shreveport, LA.

Introduction: Translational control is a critical component in development and progression of cancer and could be explored to develop antiangiogenic therapies. Results from our laboratory have shown that TET (a derivative of Tetranorline) inhibits cell growth and promotes apoptosis of prostate cancer (PCa) cells. However, the underlying molecular mechanisms are not clearly understood. We observed that TET inhibited 4EBP phosphorylation, suggesting that it might inhibit translational initiation. In the present study we evaluated the effects of TET on translation in general and cell cycle related proteins in particular. Methods: Androgen dependent PCa cells LNCaP and Enz resistant CRPCa cells 22Rv1 were maintained in supplemented RPMI as recommended. Where indicated cells were treated with TET (0 or 20µM) for various time points (2h, 8h, 18h and 24h). At the end of the experimental periods cells were pulsed with cycloheximide for 10 minutes in RPMI media. Cytoplasmic RNA was collected by lysing cells in a polysome buffer. Cell lysates were centrifuged and the resulting cytosolic supernatant was separated by density (a 10% to 50% sucrose) gradient and centrifugation. Fractions were collected using a TELEDYNE ISCO Density Gradient Fractionation System with continuous monitoring of untranslated mRNAs. Polysome (P)/Monosome (M) ratio were measured. The total RNA in each fraction was extracted using TRIzol LS (Invitrogen) and qRT-PCR was done for p21, p27, Cyclin D1 and c-Myc gene for each fraction. Cell viability was measured by MTT assay at various time points. Results: TET treatment resulted in decreased protein synthesis. TET treatment resulted in decreased mRNA associated with Polysomes. There were a significant shift in P/M ratio from 0.82 (control) to 0.48 (24h). TET [TET 2hrs (0.75), 8h (0.69) and 18hrs (0.52)] in LNCaP and P/M ratio form 0.91 (control) to 0.32 (8 h TET) [TET 2h (0.78) and 4h (0.53)] in 22Rv1 cells. The decrease of the P/M ratio suggests that TET inhibits translation initiation in prostate cancer cells independent of the androgen dependence. While there was a generalized decrease in translation and specific decrease in mRNA for Cyclin D1, c-Myc associated with polysomes following TET treatment. In quite contrast to these findings, we observed an increase in mRNA for p21 and p27 in polysomal fractions of TET treated cells as compared to control at 24h in LNCaP cells. These data suggest differential effects of TET treatment on polysome loading of cell cycle regulatory proteins. Moreover, TET inhibited growth and proliferation of LNCaP and 22Rv1 cells in dose as well as in time dependent fashion. Conclusions: TET targets translational machinery and differentially effects translation of cell cycle regulatory genes by effecting their polysome loading and effects cell growth and proliferation of androgen dependent and castrate resistant PCA cells.

#99 Identify potential kinetochore protein inhibitors to overcome cisplatin resistance. Chen Yin-Ju, Jeng-Fong Chiou. Taipei Medical University, Taipei, Taiwan.

Cisplatin is the most commonly used chemotherapeutic drug for cancer, while the resistance causes treatment failure. Cisplatin resistance may involve in many molecular changes so identify aberrations in cisplatin-resistant (CR) genes and find new therapeutic strategies could provide valuable information to reduce therapeutic resistance. The aim of this study is to search CR genes and identify potential novel drugs to overcome cisplatin resistance. To identify aberrations in CR genes, three CR genetic signatures were analyzed and differential expression genes from lung, ovarian and oral cancer cells. After integration of CR signatures, the kinetochore associated proteins, including NUF2, SPCC25, PC24, DSN1, SKA2, KNTC1, MIS18A and SKA1 were up-regulated in various CR cells. Silencing of kinetochore associated proteins increased cisplatin sensitivity. For identification of kinetochore associated protein inhibitors to overcome cisplatin resistance, CR signatures were queried to the Connectivity map (Cmap) database to search for potential drugs which may reverse cisplatin resistance. 3 compounds exhibited cytotoxicity effect on the cisplatin-resistant cell lines and reduced kinetochore associated proteins expression level. Taking together, this study demonstrates kinetochore associated proteins participate in cisplatin resistance and identify potential inhibitors to overcome cisplatin resistance.

We recently demonstrated that pancreatic cancer cells adapt to low nutrient conditions through the up-regulation of the antioxidant enzyme, glutathione peroxidase. NADPH is required for the antioxidant system to function, and we hypothesized that the enzyme, IDH1, is a potential therapeutic target. We found that IDH1 knockdown inhibited growth and proliferation of LNCaP and 22Rv1 cells in dose as well as in time dependent fashion. Conclusions: TET targets translational machinery and differentially effects polysome loading and effects cell growth and proliferation of androgen dependent and castrate resistant PCA cells.

#101 Adaptive feedback reactivates MAPK signaling in KRAS-mutant cancers with inhibition of MEK, but not ERK. Leanne G. Ahronian, Sandra Misale, Jason T. Godfrey, Koki Nishimura, Lifeng Chen, Jeffrey A. Engel, Ryan B. Corcoran. Massachusetts General Hospital Cancer Center, Charlestown, MA.

Activating mutations in the KRAS oncogene occur in about 40% of colorectal cancers (CRCs) and over 90% of pancreatic ductal adenocarcinomas (PDACs). Since development of small molecules capable of inhibiting KRAS directly has proven difficult, alternative strategies have instead focused on inhibiting downstream effectors pathways, such as the MAPK pathway. However, inhibition of the MAPK pathway alone with MEK inhibitors, such as selumetinib and trametinib, produces only cytostatic effects and is insufficient to kill KRAS-mutant cancer cells. We hypothesized that inhibition of an additional kinase during MEK inhibitor treatment could improve response. We performed a kinase-targeting shRNA screening to find kinases whose knockdown would cooperate with trametinib in KRAS-mutant CRC and PDAC cell lines. The kinases found in this screen represent potential therapeutic targets to inhibit in combination with MEK. Interestingly, despite using a very high concentration of trametinib in the screen to enrich for hits outside of the MAPK pathway, the most highly ranked kinases in the screen were members of the MAPK pathway, including BRAF, MEK1, and MEK2. This suggests that even at high concentration, trametinib produces suboptimal MAPK inhibition. Indeed, we found that while MEK inhibitors produce robust inhibition of MAPK signaling initially, pathway reactivation was observed by 48-96 hours despite regular replenishment of drug. This feedback reactivation was accompanied by marked increases in active BRAF and phosphorylated MEK. In fact, experimental approaches that artificially increased upstream signaling flux through the MAPK pathway led to a >10-fold reduction in the ability of MEK inhibitors to inhibit the MAPK pathway. Remarkably, despite triggering the same degree of adaptive upstream signaling, MAPK signaling as seen with MEK inhibitor, we found that ERK inhibitors were able to maintain MAPK pathway suppression. Importantly, these differences in MAPK pathway suppression amount to differences in cell viability. Over four weeks, ERK inhibitor treatment reduces the outgrowth of KRAS-mutant cell lines compared to those treated with MEK inhibitors. Additionally, as these inhibitors are not used as monotherapies, replacement of trametinib with an alternative MEK inhibitor could prove beneficial. Further exploration into the molecular mechanisms of pathway feedback will be necessary to understanding clinical combinations for KRAS-mutant cancers.
Cruickshanks,1 Ying Zhang,1 Sarah Hatef,1 Julia Wulfkuhle,2 Isela Gallagher,2 targeting common transcriptional nodes in cancers addicted to growth fac-

ponents of the DNA-replicative machinery and also proteins involved in

resulted in reduced cell proliferation, accompanied by induction of apopto-

various TNBC cell lines. Combined inhibition of EGFR and cdc7/CDK9

and Lapatinib) in vitro to overcome resistance to EGFR-targeted therapy in

functions of the protein in transcriptional regulation and DNA-repair may

profound clinical challenge, the disease being disproportionately responsi-

HER2 over-expressed in around 20-25% of breast cancers. Due to increased
cell growth and differentiation signaling resulting from HER2 over-expression,
this sub-type of the disease is associated with aggressive tumor progression and poor prognosis. HER2 targeted therapy has improved patient prognosis, how-
ever, only a subgroup of patients derives the optimal benefit, while other patients have refractory disease or develop resistance. miRNAs are small non-
coding RNAs involved in the RNAI machinery. They are often aberrantly expressed in

tumors and miRNA profiles have been seen to evolve over the course of treat-

importing them in therapeutic resistance. Methods: miRNA array com-
pleted on the Human TaqMan miRNA card. Gene expression profiling per-
formed by Illumina Human HT12 v4.0 array. Differential gene expression used
LIMMA empirical Bayes statistics module. Adjusted p-values calculated by
Benjamini and Hochberg procedure. In silico target prediction used miWalk.

Lapatinib resistant cells generated by culturing cells in increasing doses of lapa-
tinib up to 2µM. IC50 obtained from drug cytotoxicity measured by MTT ana-
lyzed by nonlinear regression. Results: A panel of miRNAs differentially ex-
pressed in paired lapatinib sensitive/resistant BT-474 HER2 positive breast cancer cell lines was selected for further investigation of their role in HER2-targeted therapy: mir-127-3p, mir-409-3p, and mir-495-3p. RT-qPCR also confirmed upregulation of these miRNAs in HCC1954 and SKBR3 HER2 positive cells with acquired resistance to lapatinib, linking increased miRNA expression with acquired resistance. To understand the mechanism behind the miRNA expression in resistant cells we explored epigenetic changes between the sensitive and resistant lines. Global methylation reversal revealed upregulation of all miRNAs in the sensitive cells with a further increase upon addition of an HDAC inhibitor. De-methylation had less effect in resistant cells, indicating loss of methylation as a key component in miRNA upregulation in the process of lapatinib resistance. Using differential gene expression analysis in paired lapa-
tinib-sensitive/resistant BT-474 cells combined with in silico analysis we iden-
tified putative targets of these miRNAs. BASP1, a c-MYC transcriptional inhib-
or, was down-regulated in the BT-474/IL resistant cells. Knock-down altered
expression of lapatinib, with an 8 fold shift in IC50 towards resistance, indicating
reduced expression of the protein could be involved in the resistance machinery.
Conclusions: mir-127, mir-409, and mir-495, clustered to the 14q32 region are
also confırmed upregulation of these miRNAs in HCC1954 and SKBR-3 HER2
positive cells with acquired resistance to lapatinib, linking increased miRNA
expression with acquired resistance. To understand the mechanism behind the
miRNA expression in resistant cells we explored epigenetic changes between the

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Agents

Depletion of extracellular cystine and cysteine by a mutated human enzyme causes ROS mediated cytotoxicity in pancreatic cancer cells . Sabin Khattar, Achinto Saha, Shira Cramer, John DiGiovanni, Stefano Tiziani, Nathalie Munoz, George Georgiou, Everett Stone. University of Texas at Austin, Austin, TX.

Pancreatic ductal adenocarcinoma (PDAC) has a dismal 5-7 year survival rate at 7%. The oncogene KRAS that is mutationally activated in over 90% of PDACs, has been shown to be involved in regulating redox homeostasis. Hence, pertur-
bation of oxidative balance might provide a therapeutic window to effectively
treat pancreatic cancer. One strategy to achieve this is to target the tripeptide
 glutathione (GSH) – a major intracellular antioxidant. Cysteine (Cys), which has
the functional moiety of GSH, can either be synthesized de novo or imported, predominantly as cysteine (CSCC) which is then reduced intracellularly to Cys. In cancer, intracellular Cys synthesis has to be supplemented with extracellular import in order to fulfil the excessive metabolic demand of proliferation, which includes maintenance of oxidative balance through GSH synthesis. We hypo-
thesize that this increased requirement for Cys/CSCC import in tumor cells will make them selectively sensitive to prolonged depletion of these amino acids in the serum by a genetically engineered human enzyme called Cyst(e)inase. In addition, we believe that combining Cyst(e)inase with other redox balance pertur-
bing agents will produce a synergistic therapeutic effect. In our study, Cys-
t(e)inase treatment of cultured pancreatic cancer cell lines (Panc1, MIA PaCa2, BxPC3) decreased intracellular Cys and GSH, and inhibited cell growth. Sensitivity to Cyst(e)inase was correlated with ROS accumulation (Panc1>MIA PaCa2>BxPC3). Panc1 cells exhibited G2-arrest and apoptotic cell death following 24 hours of treatment whereas BxPC3 cells underwent only a G1-arrest and no cell death even after 72 hours of treatment. Further mechanistic investigation showed activation of AMP kinase and other stress related kinases (p38, ERK and JNK), and DNA damage signaling (ATM) only in the more sensitive cell lines. Inhibition of the mTORC1-p70S6K-S6 ribosomal protein signaling pathway was observed in all 3 cell lines. Cyst(e)inase displayed synergistic cytotoxicity when combined with buthionine sulfoximine (GSH synthesis inhibitor), auranofin (thioredoxin reductase inhibitor), sulfasalazine (inhibitor of cystine import) and the natural compound curcumin known to increase intracellular ROS, indicating that concurrently inhibiting alternative cellular antioxidant pathways or directly increasing intracellular ROS might improve the anti-tumor efficacy of Cyst(e)inase. The effect of biweekly intraperitoneal Cyst(e)inase treatment on growth of pancreatic cancer cell xenografts in nude mice will also be reported. Collectively, the current data suggest that depletion of extracellular Cys/CSSC using Cyst(e)inase may have utility either as a monotherapy or a combination therapy for pancreatic cancer.

#106 Traditional medicinal plants effect on five cancer cell lines. Elbert L. Myles. Tennessee State Univ., Nashville, TN.

Cancer refers to as a group of numerous diseases that can originate in various parts of the body. Since the beginning of human history natural compounds have been used for medical purposes. Many of the most frequently used natural compounds have their origin from plants. Plants are very diverse and responsible for the synthesis of a number of different secondary compounds. Scientist and non-scientist have taken advantage of these secondary compounds treatment of cancer xenograft animal model to demonstrate the growth inhibitor activity of our lead peptides. Our study demonstrate that our lead peptides inhibit tumor cell growth via cell-cycle arrest, and almost have no cytotoxicity on human epithelial cells, which could lead our lead peptides to further clinical investigation.

#107 Mechanism of anticancer activity of BPS-001 (lyophilized leech saliva extract). Amr Ammar,1 Emma Guns,1 Omer Kucuk,2 Abdualrahman Abdualkader,3 Mohamed Almaa,3 A.B.M. Helal Uddin,4 Abbas Ghawi,5 Mohamed Hassona,5 1Univ. of British Columbia, Vancouver, British Columbia, Canada; 2Emory University, Atlanta, GA; 3International Islamic University Malaysia, Kuantan, Malaysia.

Recent studies, investigating the composition and therapeutic potential of leech saliva have identified many peptides and proteins with multiple therapeutic properties including anti-thrombotic, antimicrobial and anti-metastatic. In vitro anti-cancer effects were shown in breast, prostate and lung cancer cell lines. In vivo anticancer activity of the extract was shown in multiple breast and prostate cancer xenografts studied by our lab. In our previous studies, BPS-001 was non-toxic and demonstrated various activities including pro-apoptotic properties, inhibition of cellular adhesion, angiogenesis and downregulation of AR expression. To investigate the affected pathways, mechanistic studies were carried out using in vivo and in vitro treated samples. Protein expression in samples was determined by Western blotting of in vitro and in vivo treated samples. Protein expression analysis were performed, and from those data it indicates that the peptides might actually work by inhibiting the cancer cell growth instead of disrupting cell membrane directly. Flow cytometry and western bolt results also showed that the peptides have a significant G1 phase cell cycle arrest effect through inhibiting cyclin dependent kinases CKD4 and up-regulating the expression of cell cycle protein regulator Cyclin D3, p27, p21. Moreover, from our current data, it demonstrated that our peptides wouldn’t induce any apoptosis during the cell cycle process. With the solid anticancer mechanism/pathway data, the potential anti-cancer peptides to target in vivo malignant tumor will be evaluated in cancer xenograft animal model to demonstrate the growth inhibitor activity of our lead peptides. Our study demonstrate that our lead peptides inhibit tumor cell growth via cell-cycle arrest, and almost have no cytotoxicity on human epithelial cells, which could lead our lead peptides to further clinical investigation.

#108 In vitro and in vivo characterization of novel scorpion venom-based peptides for the treatment of colon cancer. Bin Li, Hang Fai KWOK. University of Macau, Macau, China.

In this study, the activity of the venom-based bioactive peptides demonstrated with a broad and diverse spectrum of pharmacological activities, which help to enlarge the current drug-screening library for searching of new specific biomarkers and novel prototype drugs for diagnosis of diseases such as cancer. Moreover, it paved a new insight to overcome the current drug discovery problems, which including drug resistance problem, side effect and so on. Here we report the discovery of a panel of novel venom-based peptides, which can significantly inhibit the growth of human colon cancer cells. Through our in-house developed high throughput screening techniques and bioinformatics analysis, we successfully isolated eight novel peptides from scorpion venom with anti-proliferative and anti-apoptotic activities. We further demonstrated that these peptides could inhibit the growth of a broad spectrum of tumor cells, especially in human colon cancer cell line; while almost have no effect on normal human epithelial cells. Haemolysis assay was also performed to show our peptides do not cause any harm on normal human red blood cells, which point to the direction of bringing those peptides into the preclinical trial studies. Before the in vivo phase of this project, we have demonstrated that our peptides could significantly inhibit tumor cell growth via cell-cycle arrest, and almost have no cytotoxicity on human epithelial cells, which could lead our lead peptides to further clinical investigation.

Although there have been great advancement in technology, molecular diagnosis, therapeutics, lung cancer is still the leading cause of cancer related mortality all over the world. Recently, some antipsychotic drugs have been shown to possess the anticancer activity. Thus the present study was designed to evaluate the anticancer effects of trifluoperazine (TFP), a commonly used antipsychotic drug, and its synthetic analogs on human lung cancer cell lines. To this end, effects of TFP and its selected analog on A549 cells were investigated in vitro as well as in vivo experiments. Synthetic TFP analogs were evaluated by the viability of A549 cells following drug treatment and compared to TFP. KCFCS1, a selected TFP analog, significantly inhibited the proliferation of A549 cells. Further experiment showed that TFP and KCFCS1 had activities to inhibit the migration and anchorage dependent/independent colony formation of A549 cells. Furthermore TFP and its analogs significantly inhibited the in vitro and in vivo tumor cell growth. Synthetic TFP analogs revealed that TFP and KCFCS1 affect the protein expression levels related to cell apoptosis and cell cycle. KCFCS1 showed stronger anticancer effects in all the experiment than TFP. Flow cytometric analysis showed that KCFCS1 induced sub-G1 population and reduced cell population in S and G2/M phase. In addition, the two in vivo experimental models, KCFCS1 also showed powerful anticancer effect in skin xenograft tumor growth and orthotopic lung cancer development than TFP. Thus present study demonstrates that a synthetic TFP analog has anti-lung cancer activity and provides a potential therapeutic candidate for lung cancer.

#110 Quantitative high throughput screening as a tool to identify novel therapies in bladder cancer. Reema Raikar, Thomas Sanford, L. Spencer Krane, Pirush K. Agarwal. NCI-NIH, Bethesda, MD.

Introduction: Bladder cancer (CaB) is the 4th most common cancer among men in the US. It is the most expensive malignancies to treat from diagnosis to death. No new pharmaceutical agents have been approved for treatment of bladder cancer since the approval of BCG in 1990. Thus, there is an urgent need for development of new treatment therapies. Quantitative high throughput screening (qHTS) of representative cancer lines with oncology drugs may identify new treatments or re-purpose already existing therapies for different disease. We utilized this technique to identify new therapies in two primary bladder lines (T24 and UIMUC3) and their metastatic lines (T24T, SLT3 and FL3 of T24 and LUL-2 for UIMUC3). Methods: We screened 7 bladder cancer cell lines against 1,912 oncology drugs using a 48 hour cell proliferation assay with an ATP-based readout (CellTiterGlo). The potential activity of compounds in a dose response manner. One of the candidate drugs inhibited AR activity in all 7 cell lines, and its synthetic analogs in both in vitro and in vivo experiments. Synthetic TFP analogs were evaluated by the viability of A549 cells following drug treatment and compared to TFP. KCFCS1, a selected TFP analog, significantly inhibited the proliferation of A549 cells. Further experiment showed that TFP and KCFCS1 had activities to inhibit the migration and anchorage dependent/independent colony formation of A549 cells. Western blot analysis revealed that TFP and KCFCS1 affect the protein expression levels related to cell apoptosis and cell cycle. KCFCS1 showed stronger anticancer effects in all the experiment than TFP. Flow cytometric analysis showed that KCFCS1 induced sub-G1 population and reduced cell population in S and G2/M phase. In addition, the two in vivo experimental models, KCFCS1 also showed powerful anticancer effect in skin xenograft tumor growth and orthotopic lung cancer development than TFP. Thus present study demonstrates that a synthetic TFP analog has anti-lung cancer activity and provides a potential therapeutic candidate for lung cancer.
pounds active in 7 cell lines. The top 50 compounds were further analyzed for molecular size of >200 g/mol and TPSA >90. This identified mitomycin C and 8 novel compounds. Further testing revealed Flavopiridol to be most consistent with qHTS data having IC50 of 100-300 nM in all the cell lines tested. Flavopiridol induces G2/M arrest; however, very little apoptosis was seen suggesting cytostatic rather than cytotoxic mechanism of flavopiridol action. Flavopiridol showed dose dependent inhibition of migration, invasion and colony formation in CaB cells tested. Xenograft studies in rapidly growing UMUC-3 cells showed slowing of tumor growth but not complete reduction indicating cytostatic mechanism of flavopiridol. However, in slow growing cells, 5637, 5/8 treated mice showed complete tumor reduction. Conclusions: qHTS can identify potent novel inhibitors of STAT3 in a prostate cancer cell line in vitro and in vivo. Physical properties of Flavopiridol are most suited for intravesical use which may lead to it being an effective inhibitor of CaB in the bladder at higher doses without any/few systemic toxicities. Studies are underway to elucidate the use of flavopiridol as a single intravesical agent.

**#111** Targeting STAT3 and telomerase for the treatment of colorectal cancer. Seyoung Chung,1 Quincy Okobi,2 Debbie Adekoya,3 Jaydutt Vadgama1.
1Charles Drew University, Los Angeles, CA; 2UC Santa Cruz, Los Angeles, CA; 3University of Dublin, Ireland.

There is an increasing evidence of pro-inflammatory cytokines involvement in cancer development. Here, we found that two cytokines, IL-6 and TNF-α, induced colorectal cancer cells more active and invasive. Combined treatments of IL-6 and TNF-α phosphorylated treated STAT3 and telomerase in a synergistic manner. STAT3 and NF-κB physically interacted upon cytokine stimulation. Similarly, STAT1 hetero-dimerized with STAT3 and the binding affinity was enhanced with cytokine treatments. STAT3 bound the promoter region of human telomerase reverse transcriptase (hTERT), and IL-6 and TNF-α stimulation further enhanced this STAT3 binding affinity. Withaferin A, an anti-inflammatory steroidal lactone, inhibited the IL-6 and TNF-α induced cancer cell invasiveness and decreased colonosphere formation. Notably, withaferin A inhibited STAT3 phosphorylation and abolished the STAT3 and NF-κB interactions. STAT3 binding to hTERT promoter was inhibited and telomerase activity was decreased with the withaferin A treatments. Taken together, pro-inflammatory cytokines induced-cancer cell invasiveness is mediated by STAT3 regulated mechanism in colorectal cancer cells. Our study suggests the novel natural compound for the metastatic colorectal cancer in clinical settings.

**#112** Identifying drugs that target ovarian cancer tumor initiating cells. Michelle K. Ozaki, Carrie D. House, Christina M. Annunziata. National Cancer Institute, Bethesda, MD.

Ovarian cancer is the most lethal gynecological cancer, with overall five-year survival for women with advanced disease being at only 25%. The current standard of care is treatment with a platinum-based chemotherapy drug. Unfortunately, a subpopulation of tumor cells often exists, contributing to platinum-based chemotherapy resistance and disease recurrence. In this study we investigated drugs to target these putative tumor-initiating cells (TICs), and explored the pathways of these drugs in both adherent proliferative cell culture conditions and non-adherent TIC-enriched cultures. We conducted a drug screen under both growth conditions, in order to identify compounds that are able to inhibit growth of TICs. Of the drugs identified, we focused further efforts on those involved with inhibiting the NF-kappaB pathway because prior studies have linked NF-kappaB activity with drug resistance and poor survival. Cell viability assays done with the four drugs, bardoxolone methyl, salmiycin, disulfiram, and elesclomol, show these drugs inhibit the growth of ovarian cancer cell lines both as TICs and in corresponding adherent cultures. Disulfiram showed preferential killing of TICs in some of the cell lines tested. All drugs showed some evidence for inhibiting NF-kappaB on Western blot, and ability to decrease CD133/ALDH double-positive TICs on flow cytometry. Carboplatin is known to kill proliferative ovarian cancer cells, and increase the relative percentage of CD133/ALDH positive TICs. Our ongoing studies will address combination of each drug with carboplatin, with the hypothesis that these drugs will increase in vivo efficacy by suppressing TICs, and thereby decrease recurrence of platinum-resistant ovarian cancer.

**#113** Evaluating the anticancer activity of two flexible heteroarotinoid analogs on breast cancer. Emily Ginn,1 Hongye Zou,2 Maryam M. Fallatah,1 Sharavini S. Kanapin1,1 Dominica University, San Rafael, CA; 2Touro University, Vallejo, CA.

Flexible heteroarotinoids (flex-hets) are compounds derived from retinoic acid and recent studies have indicated that these compounds exhibit anti-cancer activity. Amongst the flexible heteroarotinoids, SHetA2 has been shown block the growth of cervical, head and neck, kidney, lung, and ovarian cancers, and most recently, prostate and breast cancers. However, due to SHetA2’s limitations—a high degree of hydrophobicity, non-selectivity, and potential liver toxicity—a second generation of analogs was developed. Results from our recent study suggest that one of the second-generation analogs, SHetA2-3 (bobichetin-1-y)-N-tert-butyl-1H-indolin-2(3H)-one (99) exhibits anti-cancer activities against both ERα+ and ER- breast cancer cells at micromolar concentrations. Since SL-1-09 is a racemic mixture, the R (SL-1-29) and S (SL-1-30) enantiomers were purified and investigated for their anti-cancer properties. Our results suggest that SL-1-30 has greater growth inhibitory effects on T47D, MCF7, MDA-MB-453, MDA-MB-468 cells in cancer therapy. A pyrimidine-based multi-kinase inhibitor SL-1-09 (99) is likely associated with the S enantiomer. Consistent with this data, breast cancer cells treated with SL-1-09 and SL-1-30 express lower levels of proteins that regulate the cell cycle (i.e. cyclin A, cyclin B, cyclin D1, cyclin E and cdk2). These results demonstrate that SL-1-30 and SL-1-09 inhibit breast cancer cell growth, potentially by blocking cell cycle progression, however further studies are necessary for determining the mechanisms of action.

**#114** TG02 induces cell cycle arrest in glioblastoma. Yu-Ting Su, Robert Chen, Hallie Lappin, Herui Wang, Dragan Marić, Orieta Celiku, Aiguo Li, Mark R. Gilbert, Jing Wu. NIH, Bethesda, MD.

Dysregulated cell cycle contributes to the limitless replicative potential of cancer cells. The cyclin-dependent kinases (CDKs) and cyclins, the CDK-regulatory proteins are the key cell cycle machinery and can be targets for cancer therapy. TG02, a pyrimidine-based multi-kinase inhibitor SL-1-09 (99) has an anti-glioma effect which was demonstrated by our previous studies. An in vitro kinase spectrum assay of TG02 demonstrated inhibitory effects in several CDKs at the nanomolar level. To further investigate the molecular mechanism of TG02-induced cell cycle regulation in glioma, a cell cycle analysis was performed by flow cytometry using the Click-It Edu Flow Cytometric Assay Kit in GSC923 and U251 cell lines, a human stem-like cell and patient derived cell line, respectively. Protein expression of CDKs and cyclins was tested by Western blotting. RNAseq analysis using Next Generation Sequencing was performed (only GSC923) and followed by a supervised hierarchical clustering analysis of cell cycle pathways that were derived from Qiangen’s Ingenuity Pathway Analysis (IPA). Our results showed that TG02 treatment results in G2/M-phase arrest in glioma cell lines. The protein expression of CDK1, CDK2, cyclin A2 and cyclinB1 are downregulated in both TG02 treated cell lines. Additionally, RNAseq analysis revealed down-regulation of cyclins A2, B1 and B2 and significant regulation in mRNA expression of G2/M checkpoint and spindle formation proteins, indicating G2 checkpoint and mitosis progression are also affected by TG02. Taken together, we demonstrated that TG02 induced cell cycle G2/M arrest through downregulating CDK and cyclin expression signaling in the preclinical models of glioblastoma. These findings strongly support the further investigation of TG02 as a potential therapy for malignant gliomas.

**#115** Fluobendazole targets cancer stem-like properties and the HER2/Akt signaling pathway in HER2-positive breast cancer with trastuzumab resistance. Daesul Sung, Youngkwon Cho, Eunhye Oh, Tae-Min Cho, Yoon-Jae Kim, Hyoung Kim, Jae hong Seo. Korea University, Seoul, Republic of Korea.

Background and Propose: HER2-positive breast cancers are associated with an aggressive phenotype and trastuzumab resistance leading to poor clinical outcomes. Fluobendazole (FLU) is a potent anthelmintic agent that inhibits microtubule polymerization, and also exhibits anticancer activity in several cancer types. The objective of the present study was to investigate the effect of FLU on apoptosis, HER2/Akt signaling pathway, cancer stem cell (CSC)-like properties and trastuzumab-resistance in HER2-positive breast cancer cells. Methods: FLU-induced antitumor effects were characterized by MTS assay, Sub-G1 and G2/M-phase arrest population, Annexin-V analysis, ALDH1 activity assay, Western blotting and immunofluorescence. For in vivo study, trastuzumab-resistant JIMT1 cells were injected into the mammary fat pads of BALB/c nude mice. We then determined the tumor growth and CSC-like properties. Results and conclusion: FLU significantly reduced cell viability and induced apoptosis with accompanied by activation of caspase-3, -7, and -8, as well as PARP cleavage in HER2-positive cell lines (MDA-MB-453, SKBR3 and BT474). FLU-induced apoptosis is associated with significant decreases in expression levels of HER2, p-HER2 (Tyr1221/1222), HER3, and p-HER3 (Tyr1289). FLU treatment also resulted in G2/M-phase arrest of the cell cycle, as evidenced by a marked downregulation of phospho-Histone H3 expression. These results were closely related to the decline of CSC-like properties, coinciding with the suppression of ALDH1 activity. These effects were also observed in trastuzumab-resistant...
JIMT-1 cells, and significant reductions in tumor growth and ALDH1A1 downregulation were observed in xenograft models together with downregulation of HER2 expression in vivo. Our findings suggest that FLU may be potentially effective for the treatment of HER2-positive breast cancer with trastuzumab resistance.

**#116** Erufosine, a third-generation alkyphosphocholine with cytotoxic and cytostatic effects in breast and colorectal cancer cells. Assim Pervaiz,1,2 Saqib Mahmood,3 Martin R. Berger,3,4 Univ. of Health Sciences, Lahore, Pakistan;5 German Cancer Research Center (DKFZ), Heidelberg, Germany.

Introduction: Breast and colorectal cancers are highly malignant diseases with low 5-year survival rate (<21%) in advanced stages, which highlights the need of finding new therapeutic options. Considering this, we are interested in exploring the anticancer potential of erufosine, a membrane targeting synthetic lipid analogue belonging to a class of antineoplastic agents known as alkyphosphocholines (APCs). Properties such as intravenous administration and significantly reduced hemolytic activity as compared to previous APC generations, and efficient cytotoxic effects against malignant cells make it an attractive anticancer compound. Materials and Methods: In the present experiments, we studied the effects of erufosine against breast (MDA-MB-231) and colorectal (SW480 and SW620) cancer cell lines. Following exposure to erufosine (0.78-100μM) for 24, 48 and 72h, cytotoxic effects were measured by MTT dye reduction assay and inhibitory concentrations (IC) were identified by GraphPad Prism software. Erufosine mediated cytostatic effects were highlighted by means of propidium iodide (PI) based labeling of the DNA followed by flow cytometry analysis. Furthermore, the cells were exposed to increasing concentrations of erufosine (IC25, IC50, IC70) and alterations in cell cycle relevant genes (CCNA1, CCND1, CCNE1, CCNE2, CDK1, CDK4) were investigated by qRT-PCR methodology. Results Erufosine was highly active against the selected cell lines (IC50 < 10μM, 24h) and induced significant arrest in the G2/M phase of the cell cycle. The cytostatic effects were more pronounced in the two metastatic cell lines of breast (MDA-MB-231) and colorectal (SW620) cancers. At molecular levels, erufosine induced expression of CCNA1 (> 2-fold) in SW480, SW620, and MCF-7 cells, while the expression was inhibited in MDA-MB-231 cell lines at high concentrations of OTX015, a potent and selective BET inhibitor. Interestingly, BET-inhibition by culturing LNCaP prostate cancer cells with increasing concentrations of OTX015, a potent and selective BET-inhibitor. Methods and Results: ODM-207 is a potent and selective BET inhibitor that is structurally unrelated to the benzodiazepine like inhibitors such as IJQ1, I-BET762, and OTX015. We tested the preclinical activity of ODM-207 across multiple tumor types in a 4-day growth inhibition in vitro assay. ODM-207 potently inhibits cell viability of a wide range of hematological and solid tumor cell lines. ODM-207 also shows potent anti-proliferative effects in patient-derived cancer cells representing various tumor types. In VCaP prostate cancer cell lines, ODM-207 induced apoptosis consistent with increased expression of pro-apoptotic regulators, whereas potent antitumor effects were observed in a preclinical xenograft model with IV injection of VP. Taken together, our results suggest that VP is a promising chemotherapeutic agent for the treatment of endometrial cancer.

**#118** Targeting cancer with a novel BET bromodomain inhibitor ODM-207. Anu-Maarit Moilanen,1 Mari Björkman,2 Reetta Riikonen,3 Chan-drasekhar Abbineni,4 Mahaboobi Jaleel,3 Sivapriya Marappan,5 Tarja Ikonen,6 Girish Daginakatte,7 Aravind A B,7 Elinna Mattila,7 Juha Rantala,8 Susanta Sama-jdar,2 Murali Ramachandra,2 Pekka Kallo,7 Orion Corporation Orion Pharma, Turku, Finland; 4Aurigen Discovery Technologies Limited, Bangalore, India; 5Orion Corporation Orion Pharma, Finland; 6Missvik Biology, Turku, Finland.

Background: Bromodomain and extra-terminal (BET) family proteins are dual bromodomain-containing epigenetic readers that bind to acetylated-lysine residues at gene promoter and enhancer elements in histones and recruit protein complexes to promote transcriptional elongation. Recent evidence demonstrates that BET bromodomain inhibition leads to anti-proliferative activity in preclinical models of many hematological malignancies and solid tumors. Selective inhibition of BET bromodomains by small molecule inhibitors has emerged as a promising therapeutic strategy for the treatment of cancer. In this study, we evaluated the antitumor activity of ODM-207, a novel, potent and highly selective BET bromodomain inhibitor. Methods and Results: ODM-207 is a potent and selective BET inhibitor that is structurally unrelated to the benzodiazepine like inhibitors such as IJQ1, I-BET762, and OTX015. We tested the preclinical activity of ODM-207 across multiple tumor types in a 4-day growth inhibition in vitro assay. ODM-207 potently inhibits cell viability of a wide range of hematological and solid tumor cell lines. ODM-207 also shows potent anti-proliferative effects in patient-derived cancer cells representing various tumor types. In VCaP prostate cancer cell lines, ODM-207 induced apoptosis consistent with increased expression of pro-apoptotic regulators, whereas potent antitumor effects were observed in a preclinical xenograft model with IV injection of VP. Taken together, our results suggest that VP is a promising chemotherapeutic agent for the treatment of endometrial cancer.

**#119** Vitamin K2 targets castration-resistant prostate cancer VCaP cells by reactive oxygen species mediated apoptotic cell death. Subramanyam Dasari,1 Maarten C. Bosland,2,3 Andre Kajdacy-Balla,2 Gnanasekar Munirathnam,1 University of Illinois, College of Medicine at Rockford, Rockford, IL; 2University of Illinois at Chicago, Chicago, IL.

Prostate Cancer (PCA) is the second most common cancer in western countries especially in US population, in which castration-resistant prostate cancer (CRPC) is the major cause for patient mortality. Current treatment options available for CRPC are not efficient and have undesirable side effects. Hence there is an urgent need to develop non-toxic and effective treatment strategies for CRPC. Vitamin K2 (VK2), a natural menaquinone has several medicinal values including anti-cancer activity and anti-osteoporosis effect. The aim of this study is to evaluate the therapeutic effects of Vitamin K2 (VK2) and its anti-cancer mechanism against CRPC. In this study, we have used VCaP cell line (ATCC) which is established from a patient with hormone refractory prostate cancer. VCaP cells were treated with various concentrations of VK2 to evaluate its effects on cell viability by MTT assay, anchorage independent growth by soft agar assay, cellular senescence by beta-galactosidase staining assay and cancer cell migration by wound healing assay. We have also assessed the VK2-induced production of intracellular reactive oxygen species (ROS) using DCF (2’7’-dichlorofluorescein) probe based fluorescence assay. VK2 induced...
apoptosis was detected by Annexin-V FITC and TUNEL assays. Western blot analysis was utilized to uncover the anti-proliferative and anti-metastatic mechanisms of VK2 against CRPC. Our results showed that VK2 significantly inhibits the proliferation of VCaP cells in a dose dependent manner at 48 hrs treatment in vitro. MTT data also showed that anti-proliferative effects of VK2 were significantly abrogated in the presence of Lin28B knockdown lines. These results were further validated by the in vivo studies by Real-Time PCR, Flow Cytometry, Western Blotting, Smart-Flare confocal immunofluorescence analysis. In conclusion our study suggests that VK2 might be an effective anti-proliferative and anti-metastatic agent for CRPC by specifically targeting key anti-apoptotic, cell cycle progression and metastasis promoting signaling molecules.

#120 A study of in vitro and in vivo effects of a novel peptide and rhenium compounds on prostate cancer. Hirendra N. Banerjee,1 Sasha Hodge,1 William Kahana,2 Santosh Mandal,2 David Weber,2 Renä Lapidus,2 Fazilul Sarkar,3 Somirajan Ghosh,1.1 Elizabeth City State University, Elizabeth City, NC; 2Morgan State University, Baltimore, MD; 3University of Maryland Medical School, Baltimore, MD; 4Greenbaum Cancer Center, University of Maryland, Baltimore, MD; 5Wayne State University Kororanos Cancer Center, Detroit, MI; 6Howard University, Washington, DC.

Emerging evidence suggests that acquisition of the epithelial-to-mesenchymal transition (EMT), a process that resembles the genesis of cancer stem-like cells, contributes to tumor aggressiveness and is mediated by deregulated expression of microRNAs (miRNAs), such as miR-200 and let-7 family. Loss of miR-200 expression results in the over-expression of Lin28B, which is prevalent in human Prostate Cancer (PCa). Lin28B is also known to block the processing of another miRNA (pre-let-7 and pri-let-7), resulting in decreased mature let-7, thereby leading to increased Suzz12 and EZH2 expression, which are important components of the polycomb repressive complex 2 (PRC2). Thus, over-expression of Lin28B and loss of miR-200 and let-7 appear to be responsible for PCA aggressiveness. A group of novel rhenium compounds have shown promising anti-cancer properties in various cancer cell lines tested in our laboratories. Our current investigations show that re-expression of miR-200b, miR-200c, and let-7 could be achieved by treating cells with our newly developed rhenium compounds by down-regulating the expression of Lin28B and EZH2. Based on our preliminary results, we hypothesize that over-expression of Lin28B leads to the acquisition of invasive and metastatic characteristics in PCA cells (EMT-phenotype cells) via down-regulation of miR-200b and miR-200c, resulting in increased expression of Suzz12, ZEB1, and ZEB2. We also hypothesize that over-expression of Lin28B represses the maturation of let-7 family, leading to increased expression of EZH2, and these processes can be attenuated by treatment of cells with novel rhenium compounds in vitro. Our experiments were done on prostate cancer cell lines derived from both Caucasian (CA) and African American (AA) patients and also biopsy samples obtained from both CA and AA patients at Henry Ford Hospital and Karmanos Cancer Center of Wayne State University, Detroit, MI. We confirmed using gene expression studies by micro array and Real-Time PCR and then data analysis by Ingenuity software system to validate our hypothesis and continued our research by testing one of these rhenium compounds-RPR1 on prostate cancer model of nude mice at Greenbaum Cancer Center(GCC) of University of Maryland at Baltimore. In vitro studies by Real-Time PCR, Flow Cytometry, Western Blotting, Smart-Flare technology, cell death and proliferation assays along with inhibition of spheroide forming assays showed efficacy of these rhenium compounds as anti cancer agents. In vivo studies also showed decrease of tumor volume and mass, no toxicity, thus efficacy of these novel drugs. ACKNOWLEDGEMENT: Supported by NIH-3R01CA164318-03S1 and NIH-T-34-GM100831, a NSF-VES-TEM award and NSF-SLSAMP award.

#121 Identification and characterization of channel oscillator blockers as inhibitors of YAP/TAZ and glioblastoma cells. Wei Li, Zhijun Liu, Jennifer Xavier, Hong-Gang Wang. Penn State Univ. College of Medicine, Hershey, PA.

Glioblastomas (GBM) are the most aggressive primary brain tumors. Despite major advances in neuroimaging and neurological techniques over the past decades, the neurosurgical management of GBM patients remains challenging. Median survival of the patients is about 14.6 months. In order to radically alter the clinical course of these tumors, it is important to develop new drugs that specifically target these malignancies. The transcription co-activators YAP and TAZ are known to drive the development and sustainance of many pathways that drive their development and maintain their homeostasis. In a screen for small molecules, which can inhibit the growth of human glioblastoma cells, we identified a set of calcium channel blockers (CCB). We found that these CCB induce cell death through an apoptosis-independent process. To understand the mechanisms of the non-apoptotic cell death induced by these CCB, we performed cellular imaging which is responsible for the cell death induction. We found that these CCB are able to inhibit YAP and TAZ, two oncogenic effectors of the Hippo tumor suppressor pathway. Importantly, GBM cells expressing the YAP active mutant or overexpressing YAP are less sensitive to these CCB. These results suggested that inhibition of YAP/TAZ is a mechanism by which CCB suppress tumor cell growth. The Hippo pathway is an essential signaling network in regulating tissue homeostasis. In this pathway, the transcription co-activators YAP and TAZ promote a gene expression program favoring cell proliferation, survival and self-renewal. In normal brain, the nuclear accumulation of YAP is largely limited to regions harboring neural progenitor cells. However, increased nuclear accumulation of YAP is found in various brain tumors, especially those more aggressive subsets of gliomas. In addition, high expression of YAP is associated with reduced mean survival in astrocytoma patients. Our results identified a novel approach to target the Hippo pathway for GBM treatment. We will present our work in further characterizing these regulations and therapeutic potentials of these calcium channel blockers in the conference.

#122 Preclinical update on targeting KRAS wild-type colorectal cancer with an EGFR-targeted monoclonal tri-body mixture, MM-151. Shawn P. Carey, Hongfang Wang, Erika Handly, Brittany Ahlstedt, Daniel Gaddy, Jeffrey D. Kears, Greg Finn, Birgit Schoeberl, Rachel Nering. Merrimack Pharmaceuticals, Cambridge, MA.

Within KRAS wild-type colorectal cancer (KRAS-wt CRC), standard of care treatment includes EGFR-directed monoclonal antibodies (mAb) in combination with an irinotecan-based chemotherapy regimen. While such combinations have clinically established synergy, the underlying mechanisms of synergy remain elusive, and resistance invariably develops against either the EGFR-targeted therapy or irinotecan, leaving patients with limited treatment options. MM-151 consists of three anti-EGFR IgG1 mAbs that bind simultaneously to non-overlapping epitopes on the EGFR extracellular domain (ECD). Preclinical and clinical studies have demonstrated that oligoclonal targeting of EGFR with MM-151 results in blockade of the EGFR pathway via potent inhibition of ligand-driven signal amplification and receptor downregulation. Critically, these activities are uniquely maintained in the presence of high-affinity EGFR ligands as well as mutations in the ECD of EGFR, both of which drive resistance to cetuximab and panitumumab. Here, we tested the preclinical hypothesis that comprehensive inhibition of the EGFR pathway by MM-151 leads to enhanced antimutator activity when combined with chemotherapy in models of KRAS-wt CRC. In vitro studies to investigate the activity of MM-151 in combination with SN-38, the active metabolite of irinotecan, showed that MM-151 potentiates SN-38-induced cell death in KRAS-wt CRC models. Treatment with MM-151 potently suppresses EGFR pathway activation caused by SN-38, and the combination enhances stress and pro-apoptotic signaling, leading to increased apoptosis. Notably, these synergistic activities are maintained in the presence of two key mechanisms of resistance to cetuximab: high-affinity ligands and EGFR ECD mutations. Dose scheduling studies demonstrated that sustained treatment with MM-151 following transient SN-38 exposure - a hallmark of small molecule therapy - partially overcomes the sub-optimal activity of chemotherapy alone. Finally, data from in vivo xenograft and PDX studies strongly supports the addition of MM-151 to irinotecan-based chemotherapy regimens for KRAS-wt CRC. In summary, we present data supporting the hypothesis that comprehensive antagonism of the EGFR pathway via oligoclonal targeting of EGFR with MM-151 leads to enhanced activity when combined with chemotherapy in preclinical KRAS-wt CRC models. The ability of MM-151 and SN-38 to overcome both de novo and acquired mechanisms of resistance within CRC models supports further clinical evaluation of this combination in metastatic CRC patients.
#123 A novel J-series prostamide mediates D-series prostamide-induced apoptosis in skin cancer: receptor-independent signaling. Eman Soliman,1 Daniel Ladin,2 Hussam Albassam,2 Ahmed E. Elhassanny,2 Allison Danell,2 Rukiyah Van Dross3. 1Faculty of Pharmacy, Zagazig University, Zagazig, Egypt; 2Brody School of Medicine, East Carolina University, Greenville, NC; 3Department of Chemistry, East Carolina University, Greenville, NC, 4Brody School of Medicine and Center for Health Disparities East Carolina University, Greenville, NC.

Non-melanoma skin cancer (NMSC) is the most common cancer in the United States. The absence of selective toxicity is a major problem that limits the utility of chemotherapeutic and radiation therapy for NMSCs. Our previous data showed that the endocannabinoid, anandamide, selectively induced apoptosis in skin cancer: receptor-independent signaling. Exogenous 15d-PMJ2 mimicked the activity of PMD2 demonstrating preferential cytotoxicity towards tumorigenic compared to non-tumorigenic cells. In tumorigenic keratinocytes, PMD2 induced apoptotic cell death, oxidative stress and increased expression of pro-apoptotic ER stress proteins, C/EBP homologous protein (CHOP). In non-tumorigenic HaCaT keratinocytes were utilized. A significant reduction in cell viability was observed in JF2 but not in HaCaT cells treated with PMD2. Furthermore, the use of prostaglandin D receptor (DP1 and DP2) antagonists did not inhibit PMD2-induced apoptosis indicating that the activity was mediated by a receptor-independent pathway. Similar effects were observed in keratinocytes treated with the structurally-related arachidonic acid metabolite, prostaglandin D2 (PGD2). Interestingly, PMD2 increased the production of J-series prostaglandins in both tumorigenic and non-tumorigenic keratinocytes. LC-ESI-MS/MS analysis detected ethanolamide-conjugated J-series PG (15-deoxy-12,14 pros-tamide J1, 15d-PMJ2) in PMD2-treated cell culture media. Since selective inhibitors of the J-series prostaglandins are not available, 15d-PMJ2 mimicked the activity of PMD2 demonstrating preferential cytotoxicity towards tumorigenic compared to non-tumorigenic keratinocytes. In addition, 15d-PMJ2 induced oxidative stress, ER stress and apoptosis in tumorigenic keratinocytes. These findings suggest that the cytotoxicity of PMD2 is mediated by 15d-PMJ2. Since PMD2 and its metabolite 15d-PMJ2 are preferentially toxic towards tumorigenic cells, PMD2 or 15d-PMJ2 may be an ideal topical treatment for NMSC that will elicid minimal toxicity in healthy surrounding skin cells.

#124 Impirdione ONC201 promotes intra-tumoral accumulation of CD3+ /NK+ cells that contribute to its anti-tumor efficacy. Jessica Wagner,1 C. Leah Kline,1 Lanlan Zhou,1 Andrew Zloza,2 Charles Chesson,2 Jenna Newman,2 Howard Kaufman,2 Joseph Bertino,2 Mark Stein,2 Wafik El-Deiry3. 1Fox Chase Cancer Center, Philadelphia, PA; 2Rutgers Cancer Institute of New Jersey, New Brunswick, NJ.

ONC201, a first-in-class oral anti-tumor agent, upregulates the pro-apoptotic immune cytokine TRAIL and activates the integrated stress response leading to upregulation of death receptor 5 in bulk tumor and cancer stem cells. We previously demonstrated that ONC201 exerts a dose- and schedule-dependent effect on tumor progression in vivo while suppressing Akt/ERK signaling in tumors in a dose/frequency-dependent manner (Wagner et al., AACR, 2016). We also provided evidence that ONC201 inhibits a potent anti-metastatic effect (Wagner et al., AACR, 2016). We observed accumulation and activation of TRAIL-secreting NK+ cells within ONC201-treated tumors in C57/B6J, Balb/c, and athymic nude tumor-bearing mice. Importantly, ONC201 exerts in vivo anti-tumor efficacy on tumor cell lines that are ONC201-resistant in vitro, including acquired stable resistance. Using the NK-depleting antibody GM1, we demonstrate that the activation and TRAIL secretion of NK+ cells induced by ONC201 significantly contributes to in vivo anti-tumor efficacy, including TRAIL/ONC201-resistant tumors. We are currently investigating how ONC201 recruits NK cells to the tumor by examining NK-recruiting chemokine factors within the tumor site. We have also demonstrated upregulation of CD3+ T cells by ONC201 in syngeneic mice. Finally, we observed an increase in activated TRAIL-secreting NK cells in the peripheral blood of patients upon ONC201 administration in the clinic. Our results demonstrate novel and potentially significant increases in cytotoxic NK cell recruitment to tumors. The results offer a unique pathway of immune stimulation for cancer therapy that may be combined with immune checkpoint or targeted cancer therapy strategies. We are currently investigating the role of NK cells and CD3+ cells in ONC201’s ability to inhibit metastasis by using a metastatic model that involves surgically removing the primary tumor and allowing metastases to grow in vivo before treatment. These findings indicate that ONC201 possesses immunomodulatory activity and provide a rationale for combining ONC201 with PD-1/PD-L1 inhibitors, a combination we are currently testing in syngeneic immunocompetent mouse models.

#125 Differential effects of inhibitors of epigenetic modifiers on IDH mutant cell lines. Alişan Kayabolen, Tugba Bagcı Onder. Koş University, Istanbul, Turkey.

Our aim is to find effective drug treatments for IDH mutant glioma cells and investigate their mechanism of actions by analysing genetic and epigenetic alterations upon drug treatments. Drug screen was performed on IDH mutant and wild type cell lines by using a library of epigenetic modifier inhibitors. Hits for IDH mutant cells were validated with individual treatments. Combination treatments of these inhibitors were also performed to see synergistic effects. Then, IDH wild type glioma cells and BJ fibroblasts were transduced with mutant IDH1 overexpression plasmid, and checked if they were sensitized to these drugs or not. Based on drug screen performed on IDH mutant and wild type glioma cell lines, we found that IDH mutant cell lines, MGG119 and MGG152, were highly sensitive to 5-azacytidine, Chaetocin and GSK-J4. For IDH1 mutant MGG152 cell line, IC50 value for GSK-J4 is 5.2 ± 1.3 μM, for 5-azacytidine is 2.2 ± 0.3 μM, and for Chaetocin is 10.2 ± 1.0 nM at 48h. On the other hand, these drugs did not affect viability of IDH wild type glioma cell lines and fibroblasts around these concentrations. Moreover, combination of drugs, especially combination of Chaetocin and 5-azacytidine had a highly synergistic effect on IDH mutant cells while it was still ineffective on IDH wild type cells. After transduced with mutant IDH overexpression plasmid, fibroblasts became more sensitive to these drugs. On the other hand, although their growth rate was reduced, IDH wild type glioma cells were not significantly sensitized to these drugs upon mutant IDH overexpression. IDH mutation mainly inhibits DNA and histone demethylation, and leads to hypermethylation phenotype. Therefore, it is an expected result that IDH mutant cell lines are sensitive to 5-azacytidine which is an inhibitor of DNA methyltransferases, and Chaetocin which is an inhibitor of H3K9 methyltransferases. However, it was interesting to observe that GSK-J4 which is an inhibitor of H3K27 demethylases is also effective on IDH mutant cells. This may be a result of dependency on low number of active genes since IDH mutation causes downregulation of many genes by methylation. GSK-J4 may downregulate these genes by increasing H3K27 methylation. On the other hand, these effects might also be results of induced cell stress upon drug treatment. To answer this question, now we are trying to knock-down target genes of these drugs by shRNA, and obtaining compatible results. We are also planning to perform RNA-seq analysis to see genes with altered expressions upon drug treatments. To conclude, unlike IDH wild type glioma cells or healthy fibroblasts, IDH mutant glioma cells were found to be sensitive to few epigenetic drugs in low concentrations. This was confirmed by sensitization of fibroblasts to these drugs upon mutant IDH1 overexpression. In addition, combination of these drugs had a highly synergistic effect on mutant cells which may give opportunity to use drugs in very low concentrations efficiently.

#126 A chemogenomic approach reveals the action of splicing modulators at the branch point adenosine binding pocket defined by the PHF5A/SF3b complex. Teng Teng, Jennifer Tsai, Xiaolei Puyang, Michael Seller, Shouyang Peng, Daniel Aird, Silvia Buonamici, Benjamin Caleb, Betty Chan, Laura Corson, Jacob Feala, Peter Fekkes, Craig Karr, Manav Korpal, Yoshiharu Mizui, Eunice Park, James Palacino, Peter Smith, Vanitha Subramanian, Jeremy Wu, Liuhua Yu, Agustin Chicas, Markus Warnhurst, Nicholas Larsen, Ping Zhu. H3 Biomedicine Inc., Cambridge, MA.

Dysregulation of RNA splicing can cause various forms of cancer and neuromuscular disorders. Thus, developing compounds with splicing-modulating activity represents a promising therapeutic approach for these diseases. Natural products such as pladienolide, herboxidiene, and spliceostatin have been identified as potent splicing modulators that bind SF3B1, a member of the SF3b subcomplex that assembles into the U2 snRNP. Using integrated chemogenomic, structural and biochemical approaches, we show that PHF5A, another core component of the SF3b complex, is also targeted by these modulators. Whole exome sequencing of E707 (pladienolide analogue) and herboxidiene resistant clones identified common mutations in either PHF5A-Y36, SF3B1-K1071, SF3B1-R1074, or SF3B1-V1078, which represents a promising therapeutic approach for these diseases. Natural products such as pladienolide, herboxidiene, and spliceostatin have been identified as potent splicing modulators that bind SF3B1, a member of the SF3b subcomplex that assembles into the U2 snRNP. Using integrated chemogenomic, structural and biochemical approaches, we show that PHF5A, another core component of the SF3b complex, is also targeted by these modulators. Whole exome sequencing of E707 (pladienolide analogue) and herboxidiene resistant clones identified common mutations in either PHF5A-Y36, SF3B1-K1071, SF3B1-R1074, or SF3B1-V1078, which represents a promising therapeutic approach for these diseases.

Myelodysplastic syndrome (MDS) & Acute Myeloid Leukemia (AML) are hematologic malignancies that arise from a population of aberrant hematopoietic stem cells (HSCs). Overactivated innate immune signaling pathways such as IRAK1, TRAF6, IL1RAP, S100A9 and IL8 have been demonstrated in MDS/AML and play important roles in propagation of disease. IRAK4 ( interleukin-1 receptor-associated kinase 4), is a protein kinase involved in signaling innate immune responses and forms a critical signaling complex with IRAK1. To determine its role in disease pathobiology, we analyzed transcriptomic data from CD34+/stem and progenitor cells from 183 MDS patients and found significantly increased expression of IRAK4 in MDS samples belonging to the high-risk RAEB category (Refractory anemia with excess of blasts, N=80, P=0.03 when compared to healthy controls). Furthermore, increased IRAK4 expression was predictive of significantly adverse prognosis (P value < 0.05, median survival of 2.6 years compared to 5.2 years for group with lower IRAK4). Clinical correlations revealed that MDS patients with higher IRAK4 expression in stem/progenitor cells had significantly higher transfusion dependence and had higher leukemic blast counts (Mean Blast Count 9.3% vs 3.9%, P<0.05), further demonstrating IRAK4 to be an adverse prognostic marker in MDS. IRAK4 was also upregulated in highly purified FACS sorted disease initiating stem cell populations (Long Term-HSC, CD34+/CD38-/CD90+/Lin-ve) from AML patients with complex cytogenetics when compared to healthy controls. To functionally determine the role of IRAK4 in MDS/AML pathogenesis, we utilized CA-4948, a potent, oral, small-molecule inhibitor of IRAK4, to assess the effect of inhibiting IRAK4 catalytic activity. In vitro, CA-4948 blocked downstream NF-kB pathway signaling, including secretion of proinflammatory cytokines, in Toll-like receptor stimulated THP1 leukemia cells. CA-4948 was tested in clonogenic assays from primary MDS and AML samples. MDS and AML are associated with block in differentiation that leads to cytopenias that are the cause of morbidity in these patients. Treatment with CA-4948 led to increased erythropoiesis and myeloid differentiation in a majority of samples. Furthermore, drug treatment led to decreased viability of MDS/AML stem cells (CD34+/CD38-/Lin-ve) In vivo studies using a THP1 leukemia xenograft model in Ndg mice demonstrated that CA-4948 was well tolerated and led to significantly decreased disease burden after 6 weeks of treatment. In conclusion, we demonstrate that IRAK4 is upregulated in MDS/AML stem cells and is an adverse prognostic marker. Importantly, a novel, specific, inhibitor of IRAK4 shows preclinical in vitro and in vivo efficacy in MDS and AML models.

The next-generation CKD2/9 inhibitor CYC065 elicits marked anti-neoplastic effects in lung cancer by engaging ant metastatic pathways. Masanori Kawakami, Jason Roszik, Lin Zheng, Jonathan Kurie, Lisa Maria Mustachio, Xi Liu, Ethan Dmitrovsky. The University of Texas MD Anderson Cancer Center, Houston, TX.

We previously reported CKD2 antagonism with the first generation CKD2/9/7 inhibitor seliciclib (CYC202; Cyclophilin) triggered anaphase catastrophe. This occurred when genetically unstable cancer cells with supernumerary centrosomes (a hallmark of cancer) fail to cluster excessive centrosomes at mitosis. This causes multipolar cell division and apoptotic death. Anaphase catastrophe is conferred after CKD2 antagonism of aneuploid cancer cells, sparing bipolar normal cells with two centrosomes. CYC065 (Cyclophilin) is a next-generation CKD2/9 inhibitor that is undergoing clinical trial. Here, we explored CYC065 activity against lung cancer cells, some with known high metastatic potential. CYC065 substantially inhibited growth, triggered apoptosis, and induced anaphase catastrophe in murine (ED1, LKR13, and 393P) and human (Hop62, A549, and H1299) lung cancer cells. In marked contrast, these effects were largely unseen in bipolar immortalized pulmonary epithelial (murine C10 and human BEAS-2B) cells. We sought to explore whether CYC065 antineoplastic effects engaged ant metastatic pathways. In vitro migration and invasion assays were performed. CYC065 markedly inhibited migration and invasion of lung cancer cells (murine: 344SQ and KC2; human: A549 and H1299). Reverse Phase Protein Arrays (RPPAs) interrogated nearly 300 growth-regulatory proteins in murine (344SQ and KC2) and human (A549 and H1299) lung cancer cells over time (6, 12, 24, and 48 hours) after CYC065 or vehicle treatments. These lung cancer cell lines overexpressed integrin pathways such as αEβ7. When highlighted proteins were clustered after CYC065 treatment, some species were clustered as significantly up-regulated or down-regulated in all cells over studied time points. Not surprisingly, up-regulated proteins included those involved in DNA damage or apoptosis. In addition to known CDK targets like phosphorylated retinoblastoma protein, novel proteins were markedly down-regulated, including mTOR pathway proteins (such as PIK3CA), PI3K pathway proteins (such as PTEN) and phosphor- ylated S6. Affected pathways were identified using Ingenuity Pathway Analysis (IPA). IPA revealed up-regulation of pathways that engaged ATM signaling, G2/M DNA damage checkpoint regulation, or apoptosis signaling. Down-regulated pathways affected mTOR signaling, cyclins, cell cycle regulation, or integrin pathways. Mouse studies will be presented that examine in vivo effects of CYC065 in reducing metastases. Taken together, the next-generation CKD2/9 inhibitor, CYC065, elicits marked antineoplastic effects by antagonizing migration and invasion of lung cancer cells. Comprehensive RPPA and IPA studies found that distinct pathways trigger these effects.

Assessing the mechanism and therapeutic potential of modulators of the human mediator complex-associated protein kinases CDK8/19. Paul A. Clarke, Maria-Jesus Ortiz Ruiz, Robert Te Poel, Alajumoke Adenijipopola, Gary Box, Christien Ewan, Sharon Gowan, Alexis De Haven Brandon, Philip Hewitt, Wolfgang Kaufmann, Aurelie Malling, Florence Raynaud, Felix Rohdich, Kai Schiemann, Stephanie Simon, Richard Schneider, Melanie Valenti, Julian Blagg, Trevor Dale, Suzanne Eccles, Paul Workman, Dirk Wienke Dirk Wienke. Institute of Cancer Research, London, United Kingdom; Merck KGaA, Darmstadt, Germany; Cardiff University, Cardiff, United Kingdom.

Mediator-associated protein kinases CDK8 and CDK19 are context-dependent drivers or suppressors of tumorigenesis. Their inhibition is predicted to have pleiotropic effects, but it is unclear whether this will impact on the clinical utility of CDK8/19 inhibitors. We identified two structurally differentiated chemical series, suitable for exploring their function. In addition to tools that fulfill the criteria set out for chemical probes, the lead compounds from each series, CCT251921 and MSC2530818, had optimal pharmacological and pharmaceautical properties making them suitable for preclinical studies. Having potent, highly selective, orally bioavailable exemplar compounds from these series in hand, we were well positioned to investigate the therapeutic potential of dual CDK8/19 inhibition. The compounds exhibited modest anti-tumor activity in colorectal cancer cell line xenograft models with modulation of p-STAT3, a target engagement biomarker, and altered gene expression profiles, including super-enhancer regulated gene expression, consistent with the inhibition of CDK8/19. In PDX-derived cell cultures we observed inhibition of soft-agar growth in cells derived from different tumor types. However, we only detected significant antitumour activity in 1 of 6 colorectal PDX models tested in vivo, and one example of sensitization to standard of care chemotherapy, despite showing inhibition of p-STAT3. Acute myeloid leukemia cells were the most sensitive cancer type in the PDX panel with therapeutic potency seen in systemic and sub-cutaneous models. Significantly, the compounds impacted on stem cell biology. In a bone progenitor model we saw dose-responsive activation and inhibition of markers of bone matrix and bone deposition that was distinct from WNT blockade. Treatment of a diverse collection of normal cell co-culture models detected a unique response profile consistent with stimulation of an immune/inflammatory response. In vivo treatment of a genetically engineered mouse model expressing oncogenic beta-catenin shifted cells within hyperplastic intestinal crypts towards a transit amplifying progenitor cell phenotype. Finally, in pre-clinical tolerability studies we observed a similar, widespread adverse safety profile at therapeutically relevant exposures for both CCT251921 and MSC2530818. At the concentrations tested we detected >80% inhibition of p-STAT3 and increased IL-12 plasma levels. Since the observed pathological effects were generated with two potent, highly selective, but structurally distinct compounds, we conclude that the adverse consequences of treatment are the direct result of inhibition of CDK8 and/or CDK19. The serious and complex nature of the toxicity observed indicates that the clinical development of either series of CDK8/19 modulators, or other chemotypes with similar profiles, will be extremely challenging.
Discovery and characterization of small molecules targeting the DNA-binding ETS domain of ERG in prostate cancer. Miriam S. Butler,1 Mani Roshan-Moniri,1 Michael Hsing,1 Desmond Lau,2 Ari Kim,1 Paul Yen,1 Marta Mroczek,1 Mannan Nouri,1 Scott Lien,1 Peter Axtiero-Cilles,1 Kush Dalal,1 Clement Yau,1 Fariba Ghahdi,1 Yubin Guo,1 Takehisa Yamazaki,1 Sam Lawn,1 Martin Matthewson,1 Gregory-Evans1. Paul Hennie,1,2 Artem Cherkesov,1 Michael E. Cox,1,4 Vancouver Prostate Centre, Vancouver, British Columbia, Canada; 2University of British Columbia, Vancouver, British Columbia, Canada.

Genomic alterations involving translocations of the ETS-related gene ERG occur in approximately half of prostate cancer cases. These alterations result in aberrant, androgen-regulated production of ERG protein variants that directly contribute to disease development and progression. This study describes the discovery and characterization of a new class of small molecule ERG antagonists identified through rational in silico methods. These antagonists are designed to sterically block DNA binding by the ETS domain of ERG and thereby disrupt transcriptional activity. We confirmed the direct binding of a lead compound, VPC-18005, with the ERG-ETS domain using biophysical approaches. We then demonstrated VPC-18005 reduced migration and invasion rates of ERG expressing prostate cancer cells, and reduced metastasis in a zebrafish xenograft model. These results demonstrate proof-of-princ-

Chemotherapeutic effects of naturally occurring colossolactones against solid tumor cells in-vitro. Mohammed A. Baghdadi,1 Fahad A. Al-Abbasi,1 Ali M. El-Halawany,1 Ahmed M. Al-Abd,2 King Faisal Specialist Hospi-
tal & Research Centre, Jeddah, Saudi Arabia; Kingdom Abdulaziz University, Jeddah, Saudi Arabia; 2Faculty of Pharmacy, Cairo University, Cairo, Egypt; 4National Research Centre of Egypt, Giza, Egypt.

Colossolactones were isolated previously from the Vietnamese mushroom ganoderma colossum, such triterpenoids. The different colossolactone com-

African polyherbal formulation alleviates benzene-induced leukemia in Wistar rats. Olufemi E. Akanni,1 Ayodeji Faremi,2 Aminat O. Agboola,1 Adekemi R. Akanni,3 Oluseye E. Bamisaye4. 1Ladoke Akintola University of Technology, Department of Medical Laboratory Science, College of Health Sciences, Osogbo, Nigeria; 2Ladoke Akintola University of Technology, Department of Chemical Pathology; College of Health Sciences, Osogbo, Nigeria; 3Ladoke Akintola University of Technology, Department of Medical Microbiology and Para-
stology, College of Health Sciences, Osogbo, Nigeria; 4Afe Babalola University, Department of Medical Laboratory Science, College of Medicine and Health Sciences, Ado Ekiti, Nigeria.

Background: Chemotherapy and radiotherapy are effective cancer treatment options but are associated with significant side effects. Therefore, more effec-
tive therapies are sorely needed. This study investigated the chemotherapeutic effects of a polyherbal formulation on benzene induced leukemia in Wistar rats. The polyherbal formulation is composed of fruits such as Orange, Lime, Lemon, Pineapple, Grape and Vegetables like; Pumpkin leave, Garden egg in honey medium. Method: Leukemia was induced by injecting 0.2 ml of benzene solution intravenously through the tail at 48 h intervals for four weeks. Leukemia develop-

typing enumeration of CD19 expression also corroborated the leukemia assess-

Aloe-emodin as a potential lead targets lung cancer stem cells. Pei-

Cancer stem cells (CSCs) have been proposed to be responsible for tumor initiating, drug resistance, metastasis, and recurrence. Many novel therapeutic strategies have been designed to target and eliminate CSCs. According to our previous study, we have established a model of CSCs and cancer associated fibroblasts (CAFs) co-culture system for anti-CSCs drug screening. Here, we report one of the potential hits screened via this platform and the anti-CSCs activity was further investigated both in vitro and in vivo. Human lung CSCs and CAFs were primary cultured from patient with lung adenocarcinoma according to our previous study. Image-based high content screening system was used to analyze different parameters after drug treatment. Tumorogenicity and self-

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeting the PI3K Pathway

The Hedgehog (Hh) signaling pathway is a critical regulator of embryonic patterning, and aberrant Hh pathway activation has been implicated in a diverse spectrum of cancers. Therefore, components of the Shh pathway (such as Shh, SMO, and GLI1/2) are viable therapeutic targets for anti-tumor strategy. SMO antagonists such as GDC-0449 and VNP-LDE225 have received FDA approval for treating basal cell carcinoma. However, acquired resistance has emerged as a challenge to targeted therapeutics and may limit their anti-cancer efficacy. Studies have linked the hyperactive phosphatidylinositol-3-kinase (PI3K)/Akt/mTOR signaling pathway in a variety of human cancers and drug resistance condition. The synergistic role of PI3K/AKT/mTOR in Hh signaling in embryonic development and Hh-dependent tumors has been reported. Both the PI3K/Akt/mTOR and Hh pathway also play important role in maintaining the stem cell-like properties of cancer stem cell (CSCs). We report the development of a potent dual mTOR-PI3K inhibitor designated DBC-HDG2-57 with Hh signaling pathway antagonist activity. In vitro biochemical assays showed that DBC-HDG2-57 inhibited recombinant p110α and mTOR kinase with IC50 of 27.2 and 133 nM, respectively. DBC-HDG2-57 is also highly active in cellular assays, as evidenced by inhibition of phosphorylation of cellular downstream targets AKT and S6K1 in wild-type and mTOR kinase inhibitors-resistant prostate cancer cells (LNCaP and VCaP). In vitro and in vivo experiments revealed that DBC-HDG2-57 demonstrated tumor regression in xenograft models of breast cell lines (MCF7 and BT549) and pancreatic cancer cell (MiaPaCa2 and Panc1) cell lines. Interestingly, DBC-HDG2-57 demonstrated Hh signaling pathway antagonist activity in a 293 cell-based Gli-luciferase inhibition assay upon agonist treatment, and retains inhibition activity against the Smo wild-type and D473H mutant co-transfection with IC50 of 261.8 and 327.7 nM, respectively. In addition, DBC-HDG2-57 can significantly decrease the cancer stem cell-like side population of Panc1 pancreatic cell, and inhibited the migration of E3LZ10.7 pancreatic cancer cell. DBC-HDG2-57 demonstrated in vivo tumor growth inhibition activity in LS-180 colon cancer xenograft model and reduced the Gli-1 RNA abundance in the tumor. Taken together, our data demonstrate that combined pharmacological blockade of mTOR-PI3K and Hh pathway of DBC-HDG2-57 can provide a therapeutic strategy for targeting ligand-dependent Hh cancer.

#135 Targeted therapy of hormone receptor-positive breast cancer harboring PIK3CA and AKT1 genetic aberrations. Maryam Shariati, Kurt W. Evans, Stephen M. Scott, Huiqin Chen, Funda Meric-Bernstam. The University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Molecular alterations in the PI3K/Akt/mTOR pathway is implicated in the pathogenesis of ER positive breast cancer with high frequency and therefore is the major focus of drug development. Activating mutations of this signaling pathway occur in more than 70% of breast tumors. The genetic alterations affecting major components of PI3K/Akt/mTOR include genes encoding the PI3K catalytic subunits p110α (PIK3CA) and the PI3K effector AKT1. Despite the efficacy of the available small molecule inhibitors for targeting different components of PI3K pathway, the contribution of PIK3CA and AKT1 genetic alterations to targeted therapy is not well understood. We speculated that ER positive breast tumors with PIK3CA and AKT1 alterations are more sensitive to PI3K and Akt inhibitors due to differential downstream pathway effectors. Methods: We used a panel of isogenic MCF7 cell lines with oncogenic mutations of PIK3CA and AKT1 established through somatic cell gene targeting. A series of pharmacological compounds currently approved for breast cancer therapy or in clinical trials in targeting PI3K/Akt/mTOR pathway were evaluated using viability, clonogenic and cell cycle analysis assays. We performed functional proteomic profiling using reverse phase proteomic analysis (RPPA) to investigate differential protein expression in response to PI3K pathway inhibition in PIK3CA and AKT1 mutants MCF7 cell lines. In vivo experiment was done to evaluate the efficacy of the inhibitors in suppressing tumor growth. Results: We demonstrated that PIK3CA (E545K) and AKT1 (E17K) sensitized cells to the inhibitory effects of BLY719 (p110α catalytic subunit inhibitor) and AZD9395 (pan-AKT kinase inhibitor) on survival, cell cycle progression and colony formation. The presence of PIK3CA and AKT1 mutations conferred growth advantage and exhibited increased proliferation in vitro and in vivo. These alterations dramatically increased Akt phosphorylation and induced activation of PI3K downstream effectors. RPPA analysis revealed several proteins differentially expressed in PIK3CA and AKT1 mutant cells compared with wild type (p-value < 0.05). Conclusion: PIK3CA and AKT1 mutations showed distinct effects on sensitivity to targeted pathway inhibitors in an isogenic luminal breast cancer model. The presence of these genetic alterations in estrogen receptor (ER) positive breast cancer provided proliferative advantage and enhanced their sensitivity to targeted PI3K inhibition. These results will contribute to identify significant and combinatorial strategies for targeting PI3K pathway with maximal activity at tolerated dose and selection for individuals most likely to be responsive based on their genomic alterations.

#136 Phospho-S6 levels correlate with response to Copanlisib (BAY 80-6946) in multiple myeloma. Sarah Larson, Mao Yu Peng, Monica Mead, Andrea Vandros, Dylan Conklin, Erika Von Euw, Dennis J. Slamon. UCLA, Santa Monica, CA.

Background: Copanlisib (BAY 80-6946) is a reversible, pan-class I PI3K inhibitor with preferential activity for the alpha isoform, which may be of particular importance in multiple myeloma. Here we demonstrated the in vitro efficacy of copanlisib in a panel of 20 multiple myeloma cell lines. Baseline levels of phospho-S6 (P-S6) correlated with sensitivity to copanlisib, resulting in a potential biomarker of response. In addition, the change of P-S6 post-treatment could be used as a pharmacodynamic biomarker for copanlisib treatment. Methods: We screened a panel of 20 multiple myeloma cell lines and selected 3 sensitive: NCI-H929, MM.1S, L.1-363, and 3 resistant: AMO-1, JNJ3, COLO-677 for further analysis. We performed apoptosis and cell senescence assays following 72 hours of 50nM and 100M copanlisib exposure. Cell cycle analysis and induction of apoptosis were performed by FACS after propidium iodide or PI/ANX-V FITC staining, respectively. Cells treated with copanlisib showed decreased cellular senescence determined by measuring β-galactosidase activity in cells treated for 96 hours. Reverse phase protein array (RPPA) was performed at baseline and post treatment for proteomic analysis with confirmatory western blots. Flow cytometry was also performed to monitor the post-treatment P-S6 level changes. Results: Copanlisib treatment induced apoptosis in the sensitive cell lines (50-80% AN-V + cells) but not in resistant cell lines (1-5% AN-V + cells). An increased cell cycle arrest in G1 was also observed in the sensitive cell lines but not in the resistant lines. The cell senescence assays confirmed apoptosis rather than cell senescence as the mechanism of inhibition of proliferation. RPPA analysis demonstrated lower baseline p-S6 (S235/236, S240/244) protein levels in sensitive compared to resistant cell lines and this was confirmed with western blot analysis. Treatment with copanlisib resulted in a greater decrease in p-S6 in the sensitive cell lines NCI-H929 and L.1-363 (53-83%, 73-91% respectively) than in the resistant cell lines COLO-677 and JNJ3 (5-27%, and 38-67%, respectively), which was validated by western blot and phospho-flow. We also showed by RPPA and WB that copanlisib downregulates pro-survival and proliferation molecules including p-86K, p-S6 and p-4EBP1, and upregulates pro-apoptotic PDCD4 in all cell lines, but to a greater extent in sensitive cell lines. Finally, pharmacodynamic p-S6 response remained at different post-treatment time points. Discussion: A differential response to copanlisib is seen in the myeloma cell line panel. A subgroup of multiple myeloma cell lines demonstrated median IC50 values in the low nanomolar range (5-100nM), and responses correlated with low baseline P-S6. This p-S6 stratified response was only observed with PIK3-α inhibitors, but not with inhibitors targeting other PI3K isoforms. These findings may indicate the need for development of a new patient screening method or companion diagnostic.

#137 FT-1518, a new generation selective and potent mTORC1 and mTORC2 inhibitor: an in vitro and in vivo profile. Alain C. Mita,¹ Monica M. Mita,¹ Anthony D. William,² Khalid Pasha,³ Chandra Siddamadappa,⁴ Kevin Zikaras,⁵ Felix T. Garzon,⁵ Samual Oshin Comprehensive Cancer Institute, Ge-dars-Sinai Medical Center, Los Angeles, CA;⁶ FTG BIO, Hackensack, NJ;⁷ Vprag-Gen Biosciences Pvt. Ltd., Myssore, India.

Mammalian target of rapamycin (mTOR) is a clinically validated target in the treatment of cancer. mTOR forms two distinct multiprotein complexes, mTORC1 and mTORC2 which regulate cell growth, metabolism, proliferation, and survival. Rapamycin analogues target only the mTORC1 complex but do not affect the mTORC2 complex, which is an important driver for cancer cell growth and survival. The new generation of "Selective" mTOR inhibitors, blocking both mTORC1 and mTORC2 signaling might increase the efficacy and safety while expanding the therapeutic potential of these anticancer agents. Herein we describe FT-1518, a low nanomolar potent, kinase and PI3K sub family selective mTOR inhibitor. FT-1518 not only exhibited high oral bioavailability in preclinical species but has demonstrated excellent microsomal stability with no inhibitory activity towards undesired CYPs. FT-1518 showed high sustained tumor exposure and target Inhibition in a single oral dose xenograft model. FT-1518 depicted very good growth inhibitory activity across a large panel of hematologic and solid tumor cell lines with most activities falling into
low nanomolar range. mTOR kinase inhibition in cells, by FT-1518, resulted in more potent inhibition of the mTOR pathway biomarkers (mTORC1 & 2 biomarkers [pAkt(S473) and pS6(240/244) or p70 S6K]), no inhibition of PI3K biomarker [pAkt(T388)], and improved anti-proliferative activity as compared with rapamycin. FT-1518 exhibited dose-dependent and higher tumor growth inhibition (TGI) in multiple solid tumor xenografts compared with rapalogs and is poised to enter the clinic with a favorable toxicology profile.

#138 FOXO proteins mediate adaptive resistance to PI3K inhibition in mucinous colorectal cancers. Murali R. Kuracha, Peter Thomas, Brian W. Loggie, Venkatesh Govindarajan. Creighton University, Omaha, NE.

Purpose: Mucinous colon adeno-carcinomas (MCAs) comprise a substantial fraction (10-15%) of sporadic colorectal cancers (CRCs). MCAs show a distinct range of genetic modifications compared to nonmucinous CRCs and are more prone to peritoneal dissemination and distant metastasis. These aggressive cancers show a poorer response to chemotherapy and are often difficult to treat. A higher mutation rate in effectors of the KRAS-RAF-MEK (80% vs 42%) and PI3K-AKT-mTOR (60% vs 22%) pathways in MCAs over nonmucinous CRCs suggested potential targets for therapy. Our previous results showed that, MCAs, though initially sensitive to PI3K inhibition (PI3K), later develop adaptive resistance. The purpose of this study was to test whether FOXO transcription factors mediate this adaptive resistance to PI3K single agent treatment. Methods: PI3K was inactivated in MCA cell lines, LS174T (KRAS G12D, PI3K H1047R) and SW213 (KRAS G12C, PI3K WT), by treatment with GDC0941 (Pictilisib), a small molecule inhibitor of class I PI3K. Alterations in phosphorylation of effectors in the PI3K-AKT or MEK-ERK pathways were determined using western blots. FOXO nuclear localization was assessed by immunocytochemistry, confocal microscopy and nuclear fractionation studies. Expression of FOXO proteins (FOXO1, FOXO3 and FOXO4) was reduced by short inhibitory RNAs (siRNAs). FOXO1 was also inhibited in MCA cells using AS1842856, a small molecule inhibitor. Results: Immunohistochemical analysis and nuclear fractionation studies showed significant nuclear enrichment of FOXO1 and FOXO3 in MCA cell lines in response to PI3K inhibitor treatment. Upon siRNA-mediated knockdown of FOXOs, reduced ERK phosphorylation seen in response to PI3K treatment was substantially reduced. Concomitant with this decrease was a reduction in expression of receptor tyrosine kinases (RTKs) IR, IGF1R, HER2 and HER3. Combinatorial treatment of PI3K and FOXO1 inhibitors resulted in a more pronounced loss of cell viability compared to single agent treatment. Conclusions: Our results suggest that resistance to PI3K single agent inhibition seen in MCA cells is mediated, at least in part, by nuclear translocation of FOXO proteins, particularly FOXO1. Our results support a model where PI3K inhibition results in increased FOXO nuclear localization which in turn, leads to transcriptional upregulation and activation of RTKs which then lead to rebound activation of the MEK-ERK pathway and increased survival and resistance. A role for FOXO proteins in mediating PI3K resistance in KRAS-mutant MCA cells has not been described before. Our results suggest that PI3K single agent therapy is unlikely to be successful in KRAS-mutant MCAs due to FOXO-mediated resistance thus providing a rationale for combination treatment strategies.

#139 M2698, a novel dual inhibitor of p70S6K and Akt: preclinical efficacy in gastric cancer. Shota Fukuo,

1 Takahisa Kojima,1 Yoshikatsu Koga,2 Mayumi Yamачхи, Masahiro Yasunaga,2 Yasuhiko Matsumura,2 Toshihiko Doi,1 Takayuki Yoshino,1 Toshio Kuronita,3 Anderson Clark,4 Brian Elenbaas,4 Wani,2 Samson Jacob,2 Mitch Phelps,1 Thomas Schmittgen3.

M2698 is a selective, ATP-competitive dual inhibitor of p70S6K and Akt1/3 that is being evaluated in a phase 1 clinical trial in cancer patients. The dual nature of M2698 may result in improved clinical efficacy by blocking the increased Akt activity in a compensatory feedback loop induced by PI3K/AKT/mTOR (PAM) pathway inhibition. In previous preclinical studies, M2698 was shown to have potent anti-proliferative activity in vitro, and inhibit tumor growth in some xenograft models in vivo. The current study examined the effects of M2698 on cell proliferation in a panel of 13 gastric cancer cell lines, as gastric cancers often harbor mutations in PAM pathway genes that deregulate this signaling pathway. Cells were treated with M2698 at a range of concentrations and proliferation was evaluated at least twice using the WST-8 cell proliferation assay kit (Dojindo Molecular Technologies, Inc. Japan). Two cell lines, HGC-27 and IM95m, were particularly sensitive to M2698 (50% growth inhibition concentration [G100] 74 and 160 nM, respectively). The G100 values for all other cell lines were >10-fold higher. Although HGC-27 and IM95m each carry a PI3KCA hotspot point mutation, the presence of an activating PI3K pathway mutation was not the sole determinant of sensitivity, as a third PI3KCA mutant cell line, MKN1, was far less sensitive to M2698 (G100 9.0 um). Western blot analysis of pharmacodynamic biomarkers showed that M2698 (1 uM) blocked the PI3K-AKT-mTOR pathway in both sensitive and resistant cell lines, inhibiting phospho-g[76]-S6 and p-PRAS40, despite increased p-Akt. Some biomarkers from the PAM pathway and other signaling pathways appeared to be associated with sensitivity to M2698, but these candidate biomarkers need to be validated in a larger panel of cell lines. Treatment of HGC-27-tumor-bearing mice with M2698 (10, 20, 30 mg/kg/day) for 14 days resulted in significant tumor growth inhibition (80%-98%) at Day 29 compared to treatment with vehicle (p<0.01). In conclusion, we have shown that gastric cancer cell lines have a range of sensitivities to M2698 and the sensitivity cannot be explained solely by genetic mutations in the PAM pathway. M2698 provides potent PAM pathway inhibition in both sensitive and resistant gastric cancer cell lines by blocking both p70S6K and Akt. M2698 significantly inhibits tumor growth in the HGC-27 xenograft model in vivo.

#140 Discovery and biological evaluation of PQR530, a highly potent dual pan-PI3K/mTORC1/2 inhibitor. Denise Ragoon,1 Florent Beaufils,2 Anna Me-

Ione,1 Alexander M. Sele,1 Thomas Bohnacker,1 Marc Lang,2 Jürgen Mestan,2 Petra Hillmann,1 Paul Hebeisen,2 Dario Fabbro,2 Matthias P. Wymann.2

1 University of Basel, Basel, Switzerland; 2PIQUR Therapeutics AG, Basel, Switzerland.

The PI3K/AKT/mTOR signaling pathway plays a fundamental role in cell proliferation, growth and survival and aberrant activation of this signaling pathway has been shown to drive the progression of malignant tumors.1,2 Drugs targeting the pathway at multiple points, such as dual PI3K/mTOR inhibitors appear to have the broadest activity profile to address cancer therapeutic strategies and are currently being explored in numerous clinical studies. Recently, we presented PQR309, a novel, brain-penetrant pan-PI3K/mTOR inhibitor, which entered phase II clinical trials in 2016.2,3 Here, we report the lead optimization of PQR530, a potent and brain-penetrant follow-up compound as pan-PI3K/mTORC1/2 inhibitor. The development of a follow-up compound concentrated on the improvement of both, the potency and the selectivity for all targeted kinases, namely the class IA PI3K isoforms as well as mTOR. We present a detailed ligand-based structure-activity relationship study which was obtained by systematic modifications of the hinge region as well as the affinity binding substituents. This study led to the identification of PQR530, a dual pan-PI3K/mTORC1/2 inhibitor showing excellent activities in cellular assays as well as in PI3K and mTOR enzymatic binding assays. In A2058 melanoma cells PQR530 inhibited protein kinase B (PKB, pSer473) and ribosomal protein S6 (pS6, pSer240/244) phosphorylation with IC50 values of 0.07 mM. PQR530 showed excellent selectivity over a wide panel of kinases, as well as excellent selectivity versus unrelated receptor enzymes and ion channels. Moreover, PQR530 displayed potency in a panel of 44 cancer cell lines (NTRC OncolinesTM) to prevent cancer cell growth (mean value for G100 of 426 nM). Oral application of PQR530 to mice resulted in a dose-proportional PK and demonstrated good oral bioavailability, tissue penetration and excellent blood brain barrier penetration.1,3 An in silico generated synthetic route allowed rapid access to multi-gram quantities of PQR530 for pre-clinical development in only 4 steps. In conclusion, PQR530 inhibits all PI3K isoforms and the mammalian target of rapamycin (mTOR) complexes CI/2 potently and selectively, and shows anti-tumor effects in vitro and in vivo.1 [1] M. P. Wymann, M. Zvelebil, M. Laffargue (2003). Phosphoinositide 3-kinase signalling – which way to target? Trends Pharmacol Sci.; 24, 366-376. [2] V. Cmiljanovic et. al. “PIKR09: Structure-Based Design, Synthesis and Biological Evaluation of a Novel, Selective, Dual Pan-PI3K/mTOR Inhibitor” presented at AACR Annual Meeting 2015, April 18-22, Philadelphia, Pennsylvania, USA. [3] P. Hillmann et al. “Pharmacological Characterization of the Selective, Orally Bioavailable, Potential Dual PI3K/mTORC1/2 Inhibitor PQR530” abstract submitted for AACR Annual Meeting 2017, April 1-5, Washington, D. C., USA.
pathways and compounds to treat advanced HCC, we considered the ATP-competitive mTOR inhibitor INK128. ATP-competitive mTOR inhibitors attenuate both mTORC1 and mTORC2. We evaluated INK128 in sorafenib sensitive and insensitive HCC cell lines, CD44 impassive, and CD44-synthetic HCC and those cell lines with acquired sorafenib resistance. CD44 was significantly increased in Huh7 cells and Huh7 cells were more sensitive to sorafenib. A profound decrease in cell proliferation and migration, and reduced the cells more sensitive to the anti-proliferative effects of INK128. INK128 suppressed CD44 expression by blocking phosphorylation of eukaryotic translation initiation factor 4EBP1 in HCC cells while allosteric mTOR inhibitors do not. Moreover, INK128 exhibited potent anti-proliferative and anti-migration effects on the mesenchymal-like HCC cells, but not on the HCC cells. To study the transcriptional effects of combining PI3K and BET inhibitors in this lymphoma model, WILL-2 xenograft tumors from mice treated with single dose INCBO50465, INCBO54329, the combination, or vehicle control were analyzed by RNAseq. INCBO50465 enhanced the ability of INCBO54329 to repress a MYC-driven transcriptional program, and the combination also regulated multiple development and inflammatory pathways. Together, these data support the use of dual PIM and BET inhibitors for the treatment of DLBCL.

#142 Exploiting replicative vulnerabilities to counter incomplete responses to PI3K/Akt/mTOR inhibition. Sameer Chopra,1 Mario Niepel,2 Anne Jenny,3 Marc Hafner,3 Peter Sorger4, Dana-Farber Cancer Institute, Boston, MA; 3Harvard Medical School, Boston, MA.

While a broad range of cancers harbor mutations that dysregulate PI3K-Akt-mTOR signaling, most small molecule drugs targeting this pathway have failed to demonstrate clinical benefit. The treatment of PI3K-mTOR tumors is of significant interest. In this study, we investigated the mechanisms that account for drug efficacy and failure in PI3K-mTOR pathways. We used a diverse collection of 25 PI3K-Akt-mTOR inhibitors. Drug response phenotypes and changes in signaling were quantitated using time-lapse imaging and quantitative single cell immunofluorescence microscopy, respectively. We identified GSK2126458 and Torin2 as having superior potency and efficacy in PI3K-pathway disregulated triple negative breast cancer (TNBC) cell lines using this approach. Unlike other PI3K-Akt-mTOR inhibitors, whose inefficacy arises from insufficient induction of apoptosis and variable induction of cell cycle progression at G1/S, GSK2126458 and Torin2 each rapidly induce caspase 3/7 activity and durably inhibit the proliferation of surviving cells. While the effectiveness of GSK2126458 in vitro appears to arise from near-complete suppression of PI3K-Akt-mTOR signaling, this approach has already proved unachievable in clinical trials. An alternative therapeutic strategy was identified by characterizing the mechanism of action of Torin2, a tool compound that inhibits both mTOR kinase and the DNA damage response kinases ATR, ATM, and DNA-PK. Unlike other PI3K-Akt-mTOR inhibitors studied, Torin2 counters incomplete drug block at G1/S by concomitant induction of intolerable replication stress in S phase cells. The unique cell cycle pharmacology of Torin2 is recreated by combining inhibitors of mTOR and ATR/Chk1 kinases undergoing evaluation in clinical trials. In the context of combination therapy, where cytotoxicity arises from targeting S phase vulnerabilities rather than from PI3K-Akt-mTOR inhibition in G1, submaximal doses of mTOR kinase inhibitors are sufficient and confer benefit by preventing the outgrowth of cells that survive fractional killing from ATR/Chk1 inhibition. The unique cell cycle pharmacology of Torin2 suggests a novel strategy for mitigating the failure of precision monotherapy and have implications for the treatment of tumors where genetic lesions in the PI3K pathway co-occur with replicative vulnerabilities.

#143 Preclinical studies on potent therapeutic combination partners for the potent and selective PI3Kδ inhibitor INCBO50465 in DLBCL. Matthew C. Stubbs, Robert Collins, Leslie Hall, Alla Volgina, Holly Koblish, Sang Hyun Lee, Timothy Burn, Phillip C. Liu, Jin Lu, Eddy Yue, Yun-Long Li, Andrew P. Combs, Wenqing Yao, Gregory Hollis, Reid Huber, Bruce Ruggeri, Peggy Scherer. Incyte Corp., Wilmington, DE.

The delta isoform of PI3K (PI3Kδ) plays an essential role in B-cell development and function by mediating the signaling of key receptors on B cells. Increased malignant B cell proliferation and survival has also been associated with aberrant activation of PI3Kδ, making selective inhibition of this isoform an attractive therapeutic approach for the treatment of B cell malignancies. INCBO50465 is a potent inhibitor of PI3Kδ, with a >20,000 fold selectivity over other PI3K isoforms.Emerging clinical data indicate that INCBO50465 monotherapy is well tolerated and results in promising clinical responses in patients with various lymphoma histologies, including those with DLBCL. We therefore sought to explore rational combination strategies for INCBO50465 using mouse xenograft models of ABC-subtype (HBL-1), GCB-subtype (Pfeiffer), and GCB/double-hit (WILL-2) human DLBCL, evaluating standard of care agents such as bendamustine and rituximab, as well as with targeted agents. PIM inhibition is a logical addition to PI3Kδ inhibition as a therapeutic approach as both kinases play a critical role in the AKT signaling pathway, having overlapping substrates. Likewise BET inhibition is a rational addition to PI3Kδ inhibition in “double-hit” DLBCL as a compromised activity is a consequence of MYC transcriptional activity. In vivo studies performed in the Pfeiffer xenograft model demonstrate that INCBO50465 combined with the pan-PIM inhibitor INCBO53914 yielded complete tumor regressions. This profound decrease in tumor cell survival was due in part to the significant reduction in pBAD levels resulting from dual PIM and PI3Kδ inhibition. Despite modest single agent activity in vivo, the combination of INCBO50465 with BET inhibitors, INCBO54329 or INCBO57643, resulted in significant anti-tumor efficacy in all of the DLBCL models studied, and caused a greater than 90% decrease in tumor volume in the most resistant tumor line. To study the transcriptional effects of combining PI3Kδ and BET inhibitors in this lymphoma model, WILL-2 xenograft tumors from mice treated with single dose INCBO50465, INCBO54329, the combination, or vehicle control were analyzed by RNAseq. INCBO50465 enhanced the ability of INCBO54329 to repress a MYC-driven transcriptional program, and the combination also regulated multiple development and inflammatory pathways. Together, these data support the use of dual PIM and BET inhibitors for the treatment of DLBCL.

#144 Src leads to a novel mechanism of resistance to PI3K inhibitors through regulation of PI3K/p85 activation. Gui Chul Kim, Hae Yum Nam, Hyang Ju Lee, Min Kyung Kim, Geun Hee Lee, Myung Woul Han, Seong Won Kim, Univ. of Ulsan, Seoul, Republic of Korea.

Activation of the PI3K pathway co-occur with replicative vulnerabilities. Recent studies have shown that elevated expression of PIK3CB, but not other PI3K isoforms, significantly correlated with higher rate, risk, and poor prognosis of recurrent head and neck cancers. As a consequence, a greater understanding of resistance mechanisms through our results will enable the rational design of combination regimens and sequential treatment algorithms to improve clinical outcomes.

#145 PIK3CB inhibitors selectively block the survival of glioblastoma cells. Lamuye Le1, Zhi Sheng2, Virginia Tech Carilion Research Institute, Roanoke, VA; 1Virginia Polytechnic Inst. & State Univ., Roanoke, VA.

Objective: To explore the divergent role of PI3K isoforms in glioblastoma Background: Glioblastoma multiforme is the most malignant brain tumor in adults. Despite aggressive treatments, the median survival and five-year overall survival of glioblastoma patients remains low (14.6 months and 4.7%, respectively). Nearly 90% of patients experience recurrence within two years, leaving patients with few treatment options. Recently, PI3K pan inhibitors have been used to treat recurrent glioblastoma and achieved modest effect in the clinic. PI3K has four catalytic isoforms (PIK3CA, B, D, and G); hence, it is possible that these isoforms may have different roles in glioblastoma and need to be selectively targeted. This idea is further supported by our recent results, in which we have shown that elevated expression of PIK3CB, but not other PI3K isoforms, significantly correlates with high recurrence, risk, and poor prognosis of recurrent glioblastomas. Hence, we hypothesize that PIK3CB-selective inhibitors are more effective for glioblastoma. Design/Methods: We used a panel of glioblastoma cells with different levels of PIK3CB, treated them with PIK3-isomorph-selective inhibitors, and compared them to pan PI3K inhibitors. We measured cell viability using the MTS cell viability assay. Normal human astrocytes were used as controls to determine toxicity. Results: We found that PIK3CB inhibitors TGX-221 and GSK2636771 significantly blocked the proliferation of PIK3CB-high U87MG and SF295 cells, while it had no effect on the viability of PIK3CB-low A172 and LN229 cells. In contrast, other PI3K inhibitors and pan inhibitors either non-selectively blocked or had no effect on these cells. Importantly, these
Experimental and Molecular Therapeutics: Targeting the PI3K Pathway

146 The PI3K inhibitor, taselisib, has a unique mechanism of action that leads to enhanced potency in PIK3CA mutant models. Kyung W. Song, Kyle A. Edgar, S. Kirkpatrick, Lillian Phu, Michelle Nanini, Rebecca Hong, Eric Cheng, Lisa Crocker, Amy Young, Deepak Sampath, Lori Friedman. Genentech, South San Francisco, CA.

Activating mutations in PIK3CA are commonly found in a wide variety of human cancers, and the dysregulation of the phosphoinositide-3 kinase (PI3K) signaling pathway has been implicated in tumor cell growth and survival. Taselisib (GDC-0032), a novel, oral, selective inhibitor of p110alpha, spares inhibi-
tion of p110beta, is more potent in cancer cells bearing PIK3CA mutants than with wildtype PIK3CA. Preclinical studies demonstrate that taselisib induces more apoptotic cell death in PIK3CA mutant cancer cells than other PI3K inhibitors. We have discovered that taselisib has a dual mechanism of action, both blocking PI3K signaling, and inducing a decrease in p110alpha protein levels. Mass spec analysis reveals that taselisib treatment leads to the specific depletion of mutant p110alpha without significant change in wildtype p110alpha protein levels. This drug-induced p110alpha protein depletion is rescued by E1 inhibitors and by proteasome inhibitors. Other clinical PI3K inhibitors, including p110alpha selective and pan-PI3K inhibitors, are unable to induce the depletion of mutant p110 alpha protein. Furthermore, we have discovered that taselisib effectively maximizes the pathway suppression of PIK3CA mutant cells at 24 hrs in response to feedback. In comparison to other clinical-stage PI3K inhibi-
tors administered at a maximum tolerated dose, taselisib has superior efficacy with increased tumor regressions in PIK3CA mutant xenograft models. In sum-
mary, these preclinical studies indicate that PI3K inhibitors, which have the ability to trigger degradation of mutant p110alpha protein, can more effectively suppress the signaling pathway, which may result in greater anti-tumor activity and improved therapeutic index in PIK3CA mutant tumors.

Out of the breast cancer subtypes, triple-negative breast cancer (TNBC) has the poorest prognosis without effective targeted therapies. A stem cell transcription factor KLF5 is over-expressed in basal type TNBC and promoting cell proliferation, survival and stemness. Previously, we demonstrated that Milfepristone suppresses basal TNBC stem cells by down-regulating KLF5 expression through inducing the expression of miR-153. In this study, Metformin, a first-line drug for type 2 diabetes mellitus, was demonstrated to target breast cancer stem cells selectively. However, the efficiency and the mechanism of action of metformin in TNBC are unclear. We demonstrated that metformin decreased the percentage of TNBC stem cells partially through the downregulation of the expression of KLF5 and its downstream target genes, such as Nanog and FGFR1, in TNBC cell lines. Metformin induced GS3Kβ-mediated KLF5 protein phosphorylation and degradation through the in-
hibition of PKA activity in TNBC cells. Consistently, PKA activators increased the expression of KLF5 and to a lesser extent Nanog. Knockdown of KLF5 and GS3Kβ protein levels in human TNBC samples. These findings suggest that met-
formin suppresses TNBC stem cells partially through the PKA-GS3Kβ-KLF5 sig-
naling pathway.

148 A dual and selective small molecule inhibitor of EGFR and PI3 kinase shows promising preclinical activity against KRAS and BRAF mutant colorectal tumors. Joel D. Maust, Elizabeth K. Ziemke, Christy L. Frankowski, Debra Mcgregor, Jun Beom Ku, Rachel Mumby, Karin M. Hardiman, Christopher E. Whitehead, Judith S. Sebolt-Leopold. Univ. of Michigan, Ann Arbor, MI.

Agents targeting epidermal growth factor receptor (EGFR) have met with limited success in the clinical management of colorectal cancer (CRC). Mutations in KRAS, BRAF, and PIK3CA are important drivers of resistance to EGFR-
targeted therapy. Conversely, EGFR-mediated feedback mechanisms serve to mediate resistance to MEK inhibitor-based treatment of CRC by reactivating MAP kinase signaling. Our central hypothesis is that a dual small molecule inhibitor that potently and selectively targets only EGFR and PI3KA, when com-
bined with a MEK inhibitor, will be highly efficacious against subpopulations of BRAF mutant or KRAS mutant colorectal cancers that are dependent upon these kinase mechanisms to drive tumor progression. Employing a computational mod-
eling approach, we explored the known binding modes of structurally related ATP binding site inhibitors of EGFR and PI3K to design small molecules that simultaneously inhibit both kinases in a selective manner. To the best of our knowledge, the lead compound MXT-211, whose binding mode is flipped in

compounds, but not PIK3CB inhibitors, blocked the growth of astrocytes. Con-
clusions: Selective blockade of PIK3CB, but not other PI3K isoforms, is an ef-
flective therapy for glioblastoma with a low toxicity to normal tissues.

149 Co-targeting mTORC and EGFR signaling as a potential therapeutic strategy in HNSCC. Adam D. Swick, Prashanth J. Prabakaran, Amal Javid, Margot Miller, Michael Fisher, Emmanuel Sampene, Irene M. Ong, Kwanglok Nickel, Randall J. Kimple. Univ. of Wisconsin-Madison, Madison, WI.

Background - Head and neck squamous cell carcinomas (HNSCCs) have high rates of mutation and other alterations along the PI3K/AKT/mTORC signaling axis. This has led to interest in the use of therapeutics targeting this pathway, however identifying reliable predictive biomarkers to guide patient selection remains challenging. Despite excellent preclinical data, the use of these compounds as monotherapy has been underwhelming in initial clinical trials. The EGFR monoclonal antibody cetuximab remains the only approved targeted agent for HNSCC and with reasonable toxicity profiles, has potential use in combination therapy. Methods - Both catalytic mTORC (AZD8055) and PI3K/ mTORC(NVP-BEZ-235) inhibitors were tested +/− cetuximab in vitro and in vivo pre-clinical models. A panel of HNSCC cell lines and patient derived xenografts (PDx) were evaluated for PI3K/AKT/mTORC pathway mu-
tation by sequencing and potential protein biomarker by immunohistology and IHC. Cell lines were assayed for sensitivity to all three agents by growth inhibition and clonogenic survival assay. DNA replication(BrdU uptake) and apoptosis (Capa- se 3/7 activity) were investigated to assess the mechanism of inhibition. The specificity of the molecular targeted effects was confirmed by siRNA knock-
down. Five unique PDx models that presented PIK3CA mutation or intrinsinc cetuximab resistance were treated with a combination of cetuximab and the dual mTORC inhibitor AZD8055 in a nude mouse model. Results - Assessment of the panel of HNSCC cell lines by mutational hotspot sequencing did not reveal any obvious sensitizing mutations, whereas putative protein biomarkers (e.g. PIK3CA, pAKT) were elevated in some cell lines. All cell lines showed modest response to both PI3K/mTORC and dual mTORC inhibition. The addition of cetuximab to either agent produced modest additive effect. Mechanistic studies revealed that growth inhibition rather than death induction was the major anti-
cancer effect. SI RNA knockdown showed similar molecular signaling and func-
tional effects to drug inhibition. Using the PDx models, in vivo single agent mTORC inhibition inhibited growth of a PI3KCA mutant cancer, but had no effect on any PIK3CAAKT+ or a second PI3KCA mutant model. In all models the combination therapy showed greater growth delay than cetuximab alone. Conclu-
sions - The uniform ability of PI3K/mTORC and mTORC inhibition to suppress the growth of HNSCC cells highlights the role of this signaling pathway to drive the proliferation. In vivo, despite some PDx models meeting likely selection criteria, the single agent therapy was largely ineffective. Conversely the combination treatment produced growth delay and suggests the potential for adding a catalytic mTORC inhibitor to cetuximab therapy for HNSCC patients. Overall, these results add to a growing body of evidence suggesting that attempts to match genetic alternation or other biomarker to the optimal therapy in HNSCC remains complex and challenging.

150 Identification of determinants of sensitivity to AKT inhibition using breast cancer (BC) patient-derived xenografts (PDx). Albert Gris-Oliver,1 Mafalda Oliveira,2 Marta Guzman,1 Olga Rodriguez,1 Judith Grueso,1 Maurizio Scaltriti,2 William J. Howat,3 J Carl Barrett,4 Javier Cortés,5 José Baselga,2 Albert Gris-Oliver,1 Mafalda Oliveira,2 Marta Guzman,1 Olga Rodriguez,1 Judith Grueso,1 Maurizio Scaltriti,2 William J. Howat,3 J Carl Barrett,4 Javier Cortés,5 José Baselga,2 Albert Gris-Oliver,1 Mafalda Oliveira,2 Marta Guzman,1 Olga Rodriguez,1 Judith Grueso,1 Maurizio Scaltriti,2 William J. Howat,3 J Carl Barrett,4 Javier Cortés,5 José Baselga,2

The antitumor activity of AKT inhibitors is being investigated for the treat-
ment of BC with activation of the PI3K/AKT pathway. Putative predictive bio-
markers that are being tested in ongoing trials are PTEN loss/mutation (mut) (around 40% of triple negative BC) and AKT1 mutation (4-5% ER+/HER2-
BC). The BEECH trial is evaluating the activity of the pan-AKT1/2/3 inhibitor

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 37
Cancer (NSCLC) in-vitro. Human small airway epithelial cells (HSAECs) to ensure preferential activity. Additionally, we will investigate the toxicity of these inhibitors on normal cells. Findings suggest that AKT-1 inhibition is significantly more effective at reducing tumor growth than the AKT-1 inhibitor. Therefore, altered cell cycle progression could be the predictive marker for patient response to AKT-1 versus broad AKT-inhibitor MK-2206. Thus, AKT-3 expression has the potential to serve as a regulator of survival in NSCLC cell lines compared to a pan-AKT inhibitor. MK-2206. Basal protein and RNA levels in each of the cell lines have also revealed that a selective AKT-1 inhibitor A-674563 is a more potent inhibitor MK-2206. Furthermore, the cell lines with higher endogenous CDK2 and p-CDK2 expression are more sensitive to the AKT-1 inhibitor relative to the pan-AKT inhibitor. The predictive value of these alterations as determinants of response to AKT1 deserves further investigation.

AKT is a serine-threonine kinase implicated in tumorigenesis as a central regulator of cellular growth, proliferation, survival, metabolism, and migration. Activated AKT is overexpressed in 50-70% of NSCLC tumors and has exhibited an association with poor prognosis as well as chemotherapeutic resistance to platinum-based therapy. Accordingly, AKT inhibitors such as MK-2206 are currently undergoing clinical investigation for the treatment of human NSCLC. Moreover, these agents broadly target all three (1-3) AKT isoforms. Recent evidence suggests opposing roles of the AKT isoforms in tumorigenesis where loss of AKT-1 inhibits while the loss of AKT-2 enhances lung tumor development in transgenic mouse models. Based on these findings, we hypothesized that preferential inhibition of AKT-1 would warrant a more effective therapeutic strategy for NSCLC compared to the current clinical approach of broad AKT inhibition. WST-1 cell viability assays have revealed that a selective AKT-1 inhibitor A-674563 is a more potent regulator of survival in 6 NSCLC cell lines compared to a pan-AKT inhibitor MK-2206. Furthermore, off-target CDK2 inhibition likely contributes to the observed benefits of the AKT-1 inhibitor as the reduction in cell viability largely parallels the effects of a CDK2 inhibitor PHA-84125. In addition, the cell lines with higher endogenous CDK2 and p-CDK2 expression are more sensitive to the AKT-1 inhibitor relative to the pan-AKT inhibitor MK-2206. Basal protein and RNA levels in each of the cell lines have also shown that high AKT-3 expression may confer resistance to the pan-AKT inhibitor MK-2206. Thus, AKT-3 expression has the potential to serve as a predictive marker for patient response to AKT-1 versus broad AKT-inhibition. Cell cycle analysis demonstrated that the AKT-1 inhibitor decreases the proportion of cells in the G0/G1 phase and increases the proportion of cells in the S-phase, indicating a possible S-phase cell cycle arrest. These differences are also more significant in the cell lines with augmented sensitivity to the AKT-1 inhibitor. Therefore, altered cell cycle progression could be the major mechanism of action of the AKT-1 inhibitor MK-2206. Overall, our findings suggest that AKT-1 inhibition is significantly more effective at reducing NSCLC cell viability in-vitro compared to pan-AKT inhibition. Furthermore, cell lines with higher CDK2 and AKT-3 expression have marginally increased sensitivity to the AKT-1 inhibitor A-674563 compared to the pan-AKT inhibitor MK-2206. Future research will focus on understanding the mechanisms of action of the AKT-1 inhibitor MK-2206 and the role of AKT, Akt antibody array, flow cytometry, and confocal microscopy data. Additionally, we will investigate the toxicity of these inhibitors on normal human small airway epithelial cells (HSAECs) to ensure preferential activity against malignant over somatic cells.

#152 Dual mTORC1/2 inhibition sensitizes testicular cancer cell lines to cisplatin treatment. Fernanda Ximena Rosas Plaza, Gerda de Vries, Albert J. Suurmeijer, Jourik A. Gietema, Marcel A.T.M. van Vught, Steven de Jong. UMCU, University of Groningen, Groningen, Netherlands.

Testicular cancer (TC) patients with metastatic disease and poor prognosis have limited therapeutic options. Hyperactivation of the PI3K/Akt/mTOR pathway has been confirmed in TC cell lines. This hyperactivation of the PI3K/Akt/mTOR pathway in this study we investigated the potential benefit from PI3K, Akt and mTOR inhibition in combination with cisplatin in TC. Our panel of embryonal carcinoma cell lines include the cisplatin-sensitive cells: Tera and 833KE and the cisplatin-resistant cells: Scha, TeraCP and NCCIT. Western blotting showed that the resistant TC cell line TeraCP harbors higher levels of p-Akt compared to the sensitive cell line Tera. To evaluate sensitization towards cisplatin, TC cell lines were treated with cisplatin and/or PI3K inhibitor GDC0941, Akt inhibitor MK2206, mTORC1 inhibitor everolimus and mTORC1/2 inhibitors AZD8055 and AZD2014 for 24 hours and DilC5/PI staining was performed to estimate apoptosis with flow cytometry. All TC cell lines were strongly sensitized by mTORC1/2 inhibition by increasing cisplatin induced apoptosis to 60-80% when cisplatin alone induced only 15-30%. TC cells were also sensitized by mTORC1 and PI3K inhibition but to a lesser extent. Akt inhibition did not sensitize Scha or Tera cells to cisplatin, while TeraCP was marginally sensitized. We then evaluated clonogenic capacity in cells pretreated with AZD8055 for 24 hours and seeded in the presence of different concentrations of cisplatin for 6 days. Clonogenic capacity was reduced in TeraCP as compared to Tera in a dose-dependent manner. Both control cells treated with cisplatin only. Western blot done with Scha, Tera and TeraCP lysates treated for 24 hours with AZD8055, everolimus, GDC0941 and MK2206 showed that only mTOR inhibition was able to block S6 phosphorylation. In addition, we performed immunohistochemistry of p-S6 and Ki-67 in paraffin embedded tissue from TC patients. IHC showed that patient derived xenografts showed high expression of these markers compared to non-cancerous tissue, meaning that the mTOR pathway is very active in this tumor type. These data indicate that TC relies on the PI3K/Akt/mTOR pathway for survival and mTORC1/2 inhibition showed the stronger sensitizing effect towards cisplatin treatment. We consider adding mTORC1/2 inhibition to cisplatin based treatment a potential therapeutic option for chemoresistant TC patients that warrants further in vivo investigations. Supported by CONACyT grant 381543 and Dutch Cancer Society grant RUG 2014-6691.

#153 Tricyclic fused pyrimidinopyrrolo-oxazines reveal conformational preferences of morphology for PI3K hinge region binding. Alexander M. Sele, Denise Ragoret, Florent Beaufils, Anna Melone, Thomas Bohmacker, Eileen Jackson, Jean-Baptiste Langlois, Paul Heibsen, Fabiano Fabbro, Matthias P. Wyman1. 1University of Basel, Basel, Switzerland; 2PIQUR Therapeutics AG, Basel, Switzerland.

Class I phosphoinositide 3-kinases (PI3Ks) are lipid kinases, produce PtdIns(3,4,5)P3, and trigger intracellular signaling pathways that are vital to cell growth, proliferation, survival and migration. Constitutive activation of PI3K is frequently observed in many tumor types, which defines PI3K as a valuable drug target in oncology. Numerous PI3K inhibitors in clinical development contain a morpholine moiety that mediates hinge region binding in the ATP pocket of PI3K. We aimed to identify response biomarkers to the single agent AKTi and its degree of synergy in combination with cisplatin selection of compounds demonstrated inhibition of protein kinase B (pSer473) in PI3Kα. We present here novel pyrimidinopyrrolo-oxazines related to the clinically advanced, pyridiniummorpholine and triazinmorpholine derived pan-PI3K/mTOR inhibitors BM120 and PQR309. The novel fused tricyclic core of these compounds contains two morpholine moieties of which one is conformationally restricted by the introduction of a methylene bridge that links the pyrimidine core with one of the two morpholine moieties. This modification leads to the generation of two regioisomers, each existing as a set of enantiomers. We investigated the influence of this conformational restriction on PI3K inhibitory activity and analyzed the distinct selectivity profiles and potencies of the respective stereo- and regio-isomers. The design and preparation of specific compounds in combination with biological assays (phosphorylation of p56 and S6, binding affinity to p110α), AKT1 and p-p66 compared to the sensitive cell line Tera. This modularity allows us to understand the binding mode of these compounds and acquire valuable information that potentially lead to the development of derivatives with a distinct selectivity profile (e.g. PI3K versus mTOR). A selection of compounds demonstrated inhibition of protein kinase B (pSer473) and ribosomal protein S6 (pSer235/236) phosphorylation with IC50 values in the nanomolar range and high inhibitory potency of all PI3K isoforms (K_i (p110α) > 40 nM). Single p.o. administration of our lead compound to rats resulted in good oral bioavailability as well as excellent brain penetration. Furthermore, mechanism of action-based increases in glucose levels and insulin levels have been observed. In conclusion, we present here the development,
optimization, preparation and biological evaluation of a novel class of potent, orally available and brain-penetrant P-JPK inhibitors that represent an innovative extension to known pyrimidinomorpholine derived P-JPK inhibitors. Moreover, our results add to the understanding of how introducing specific structural and conformational modifications can lead to the development of optimized mTORC1 inhibitors. 

- **#154** The phosphatidylinositol-3-kinase (P-JPK) inhibitor (i) copanlisib is active in preclinical models of B-cell lymphomas as single agent and in combination with conventional and targeted agents including venetoclax and palbociclib. EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeting the P-JPK Pathway

- **#156** Preclinical characterization of GDC-0077, a specific P-JPK alpha inhibitor in early clinical development. Kyle Edgar, Emily Hanan, Steven Steben, Stephen Schmidt, Rebecca Hong, Kyung Song, Amy Young, Patricia Hamilton, Alfonso Arrazate, Cristina de la Cruz, Marcia Belvins, Michelle Nannini, Lori S. Friedman, Deepak Sampath. Genentech, South San Francisco, CA.

- **#158** Inactivation of the PTEN gene is a common event in PCa, leading to activation of the P-JPK/akt/mTOR pathway and promoting PCa progression. Inhibitors targeting this pathway are currently being developed as anticancer agents. While recent clinical trials with mTORC1 inhibitors have shown limited single agent efficacy in castration-resistant prostate cancer (CRPC), it is still not known whether targeting alternate nodes of the P-JPK/akt/mTOR cascade may improve response. The current study aimed to characterize the response of PCa cell lines to multiple inhibitors targeting the P-JPK, AKT and mTOR nodes of the
cascade and identify possible mechanisms of resistance. The impact of the different PI3K/AKT/mTOR inhibitors on cell proliferation and apoptosis was measured by WST-1 and ApoTox-Glo assays, respectively, in a broad panel of established PCa cell lines and primary cell cultures generated from patient-derived xenografts. PTEN-negative PCa cells showed strong response to PI3Kβ/δ, AKT and mTOR inhibition, whereas PTEN-positive cells were resistant to PI3Kβ/δ and showed variable sensitivity to mTOR inhibitors. MTORC1 inhibitor showed low IC50 but reached plateau at about 70-80% growth inhibition. In contrast, mTORC1/2 inhibitor could reach complete growth inhibition at ~1 µM concentration, in sensitive cell lines. Furthermore, treatment with PI3K or AKT inhibitor in combination with androgen deprivation induced apoptosis in various PTEN-negative models, which is consistent with the previously reported synergistic effect of PI3K/AKT and androgen receptor co-targeting. The effect of the inhibitors on phosphorylation of PI3K downstream targets (AKT, PRAS40, GSK3, S6K1 and 4E-BP1) was analyzed by phospho-specific western blotting. Perturbation of different nodes of the PI3K/AKT/mTOR cascade resulted in differential phosphorylation of downstream targets, but there was no evident correlation with in vitro growth inhibition. In conclusion, the current study validates PI3Kβ and AKT as alternative targets in PTEN-negative PCa, whereas PTEN-positive models showed preferential yet variable responses towards mTOR inhibitors.

#158 ASN003, a highly selective inhibitor of B-Raf and PI3 kinase, shows strong antitumor activity in B-Raf inhibitor resistant patient-derived xenograft models. Scott K. Thompson,2 Roger A. Smith,1 Nirajan Rao,1 Michael J. Wick,1 Reza Shokrollahi,1,3 Scott,1 P. Reddy1.1A gonna Biosciences, Lawrenceville, NJ; 2South Texas Accelerated Research Therapeutics, San Antonio, TX.

The RAS-RAF-MEK and PI3K-AKT-mTOR pathways are two major signal pathways involved in human cancer. Components of these two pathways are frequently mutated in a wide variety of solid tumors. Concurrent double mutations in the two pathways are also observed quite often in a broad range of tumor types. Additionally, inhibition of one of these pathways often leads to the up-regulation of the other pathway and development of resistance. In preclinical models, combined inhibition of both pathways has been shown to impart greater efficacy as compared to inhibition of either pathway alone. ASN003 is a novel, highly selective, small-molecule inhibitor of both RAS-RAF and PI3K pathways, discovered using a rational design approach. ASN003 shows potent inhibitory activity against B-Raf and PI3K kinases (low nM IC50). Within the PI3K family, ASN003 has high selectivity for inhibition of PI3Kα and PI3Kδ over PI3Kβ. In a panel of 292 kinases, ASN003 showed high selectivity for inhibiting B-Raf and PI3 kinases, and associated mutant kinases. In cell-based mechanistic studies, ASN003 inhibited phosphorylation of ERK, AKT and S6, and showed strong anti-proliferative activity (IC50 = 60-300 nM) in cell lines with B-Raf and PI3K pathway mutations as well as in vemurafenib-resistant cell lines. In pharmacodynamic studies in multiple tumor models, ASN003 showed strong inhibition of the phosphorylation of downstream targets of B-Raf and PI3K, confirming appropriate target engagement. In in vivo efficacy studies, ASN003 showed strong tumor growth inhibition or regression in multiple tumor xenograft models, including A375 (B-Raf V600E mutation), RKO (B-Raf V600E and PIK3CA mutation), SKMEL28 (B-Raf V600E mutation and PTEN deletion), and MDA-MB-231 (B-Raf V600E mutation and PIK3CA mutation). Western blot analysis confirmed that ASN003 also showed strong tumor growth inhibition (>80%) in a patient-derived xenograft (PDX) model established from a relapsed patient with progressive B-Raf mutant melanoma who showed initial response to vemurafenib. Sequencing analysis showed that the vemurafenib resistant tumor acquired a concurrent PIK3CA mutation. Dual targeting of the B-Raf and PI3K pathways with ASN003 has the potential to treat and/or prevent the acquired resistance to selective B-Raf inhibitors, and may also treat a broader patient population and provide greater efficacy and survival benefit than selective B-Raf inhibitors or selective PI3K pathway inhibitors alone. ASN003 is currently in Phase I clinical development in patients with advanced solid tumors, including tumors with B-Raf V600 mutation, PI3 kinase pathway alterations or PTEN loss.

#159 Pharmacological characterization of the selective, orally bioavailable, potent dual PI3K/mTORC1/2 inhibitor PQR530. Petra Hillmann,1 De- nise Ragent,2 Florent Beaufils,1 Anna Melone, Alexander Sele, Robert A. Et- tin,3 Jürgen Mestan,1 Vladimir Cmiljanovic,1 Marc Lang,1 Elisabeth Singer,1 Carolin Walter,1 Hoa HP Nguyen,2 Paul Hebeisen,1 Matthias P. Wymann,2 Doriano Fabbro1.1PIQUR Therapeutics, Basel, Switzerland; 2University of Basel, Basel, Switzerland; 3University of Tübingen, Tübingen, Germany.

Introduction: The phosphatidylinositol 3-kinase (PI3K) signaling path- way plays a fundamental role in many cellular processes like growth, sur- vival, proliferation, differentiation and motility. In cancers several mutations have been identified that lead to constitutive activation of PI3K. PQR530 is a novel, ATP site directed inhibitor of all PI3K isoforms and the mammalian target of rapamycin (mTOR) complexes C1/2 that is currently in pre-clinical development. PQR530 potently binds to its targets, inhibits cell proliferation and shows excellent selectivity versus related and unrelated kinases [1]. Results: PQR530 inhibits PI3K signaling in stimulated MCF7 cells and was able to inhibit cell viability by >50% in a dose-dependent manner. PQR530 was found to inhibit PI3K mTORC1/2 during GLP toxicological testing in rats and dogs. Increase in insulin and blood glucose, a treatable class effect of PI3K inhibitors, has been observed after PQR530 administration to mice. Investigation of mutagenicity and hERG binding resulted in a clean profile. PQR530 exhibited dose-proportional pharmacokinetics (PK) in male C57BL/6 mice. A maximum plasma exposure of 3.5 µM [M] was reached after 30 minutes (7.2 ± 1.1 µg/ml and 112.6 µg/ml, respectively) indicating that efficacious concentra- tions were reached in both tissues. The calculated half-life (t1/2) was 2 hours and brain was approximately 5 hours. PQR530 potently inhibited PI3K sig- naling in vivo for several hours after administration of a single oral dose of 30 mg/kg. Tumor growth was significantly decreased in SUDHL-6 lymphoma, RIVA lymphoma and OVCAR-3 ovarian cancer mouse xenografts using daily, oral administration. Conclusion: PQR530 is a potent, ATP competitive pan-PI3K and mTORC1/2 inhibitor. The physico-chemical properties of PQR530 result in good oral bioavailability and excellent brain penetration. PQR530 is well tolerated and efficiently inhibits tumor growth in xenograft models. Preclinical data allow for further development of the compound. [1] Regard et al., Discovery and Development of B-Raf and PI3K/mTOR dual targeting molecules, Annual Meeting 2017, April 1-5, Washington, D. C., USA.

#160 High target binding affinity with long lasting cellular target engage- ment and high dose intermittent schedule of PI3K inhibitor copanlisib con- tribute to the potent anti-tumor activity and good safety profile. Maurya E. Fernández-Montañán,1 Victoria Georgi,1 James Vasta,1 Sarah Glasek,1 Vera Puettner,1 Matthew B. Roberts,1 Ursula Moenning,1 Andrea Sturr,1 Julien Le- franc-Marc,1 Karl Ziegelsbauer,1 Michael Brands,1 Christian Stegmann,1 William J. Scott,1 Ninghui Liu,1 Bayer AG, Berlin, Germany; 2Promega Inc, Berlin, Ger- many.

Introduction: Several generations of PI3K inhibitors have been tested in clinic. However, thus far, clinical activity has been moderate. Different from other oral PI3K inhibitors dosed continuously, copanlisib (BAY 80-6946) is an intravenous PI3K inhibitor given intermittently to patients. Copanlisib dosed once weekly demonstrated clinical benefit with an improved safety profile, and therefore challenges the concept of default continuous dosing of PI3K inhibitors. However, it is still unclear if this concept can be generalized and whether 'micropharmacokinetic parameters' also contributed to the potent anti-tumor profile of copanlisib. Here, we report the characterization of binding kinetics for copanlisib, as well as the functional consequence in vivo. Methods: A set of PI3K inhibitors were characterized in 1) a kinetic probe competition assay (KPCA); 2) a cellular nanoBRET target engagement assay; 3) a cellular washout study with the assessment on pathway engagement; and 4) in vivo pharmacokinetics analysis. Results: Copanlisib showed nearly dif- fusion-controlled on- and relatively slow off-rates with koff = 3.4E5 ± 7 [M-1·s-1] and koff = 1.6E-3 [s-1] to PI3Kα. Consequently, it exhibited very high affinity to PI3Kα (K, ePCA = 9.33E-11[M] and Kp, KPCA = 4.77E-11 [M]). In a cellular nanoBRET target engagement assay, the apparent half-life (t1/2) of ca. 2 hours greatly surpassed the 6.9 min measured using KPCA. The high affinity to PI3Kα also translated into potent cellular pathway engage- ment demonstrated by inhibition of p-AKT and p-PRAS40 in the PI3KCA−/− and KPL4 cell line. In a cellular washout study, p-AKT and p-PRAS40 were assessed till 168 h after incubation with copanlisib for 1 h followed by a washout step. A dose- and time-dependent pathway engage- ment was observed even at 72 h post washout. This result indicated that in cells, copanlisib engages PI3Kα for an extremely long time, likely due to receptor rebinding effects facilitated by the fast equilibration kinetics of the com- pound and its micropharmacokinetic properties. Interestingly, in vivo, BAY 80-6946 levels were approximately 100-fold higher in the tumor than in plasma at 48 hours and drug clearance from the tumor occurred more slowly than from plasma. This high and prolonged tumor exposure might be ex- plained, at least in part, by the high expression of PI3Kα and long lasting target engagement in tumors. Conclusion: Copanlisib demon- strated high affinity to PI3Kα with protracted target engagement at cellular and in vivo levels. This 'micropharmacokinetic feature' not only supports intermittent dosing but likely also explains the high exposure in tumors vs plasma, potent anti-tumor activity and good safety profiles.

Medulloblastoma (MB) is the most frequent malignant brain tumor in children. MB patients with high-risk disease have poorly understood biology and few targeted therapies available. Preclinical studies and molecular profiling of MB have revealed that the aberrant activation and interaction of the SHH and PI3K/akt/mTOR signaling networks are frequently associated with poor prognosis MB cases. Emerging evidence also demonstrate the key role of activated PI3K/akt/mTOR pathway component in MB. Here we report MB therapy-resistance, thus combined targeting of the SHH and PI3K/akt/mTOR pathways may be a viable therapeutic strategy to treat high-risk patients. Therefore, we investigated the combined efficacy of SHH inhibitor vismodegib and PI3K/akt/mTOR dual inhibitor BEZ235 or their combination, individually with the chemotherapeutic drug cisplatin against high-risk MB. Using four MB cell lines, including non-MYC and MYC amplified cell lines, and a xenograft mouse model, the in vitro and in vivo efficacies of the proposed therapies on cell growth/survival along with associated molecular mechanisms were investigated. Our results showed that both inhibitors as single agents significantly decreased MB cell growth and induced apoptosis by targeting the key molecules of the associated pathways in vitro. BEZ235 as single agent showed a greater anti-MB efficacy compared to vismodegib. Combined treatment of vismodegib and BEZ235 together or with cisplatin significantly decreased MB cell growth/survival and anchor-independent growth in a dose-dependent fashion compared to single agent activity. Corresponding changes in the expression of the targeted molecules following therapy were observed. Results from the combined approach suggested that the inhibitors not only suppressed MB cell growth/survival when combined, but also significantly enhanced the cytotoxic effects of cisplatin. Of these combinations, BEZ235 exhibited a significantly greater efficacy in enhancing the cisplatin-mediated MB cytotoxicity. In vitro studies also demonstrated that the MYC amplified MB cell lines showed a higher sensitivity to these combined therapies compared to relatively non-MYC amplified cell lines. Therefore, as a next logical step, we tested the efficacy of above combined approaches against MYC-amplified MB in vivo using NSG mice. Our in vivo results showed that the combination of vismodegib and BEZ235 or their combinations individually with cisplatin significantly delayed tumor growth and increased survival of xenograft mice compared to single agent activity. These combination not only significantly reduced tumor growth and increased survival of the mice but also significantly enhanced anti-MB efficacy by targeting SHH and mTOR pathways in MB in vivo. Thus, our studies lay a foundation for translating these combined therapeutic strategies to the clinical setting to determine their efficacies in high-risk MB patients.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeting the PI3K Pathway

A prodrug of green tea polyphenol (-)-epigallocatechin-3-gallate (ProEGCG) reduced expression of HIF-1α and VEGFA in RL95-2 cells and decreased CXCR4 expression in tumor-associated macrophages (TAMs) and endothelial cells (ECs). To further study the role of ProEGCG on EEC cells, qRT-PCR and Western blotting proved that hypoxia (1% O2) upregulated the level of HIF-1α and VEGFA in EEC cell lines, which was reversed by ProEGCG through inhibition of HIF-1α and VEGFA via PI3K/AKT/mTOR pathway. This is an important role in tumor angiogenesis, and double immunofluorescence of F4/80 and CD206 antibodies in xenografts was applied and found that TAMs infiltration was reduced in ProEGCG group with decreased VEGFA in TAMs. Moreover, proliferation and migration of ECs are critical for tumor angiogenesis. To study the effect of ProEGCG on ECs, tube formation and invasion assays were conducted and indicated that ProEGCG showed a tube-like structure formation and less invaded ECs by inhibition of CXCR4 expression on ECs. However, it was still unclear if CXCL12, the ligand of CXCR4, was affected. Immunostaining for CXCL12 in tumor lesions indicated that ProEGCG decreased CXCL12 expression in cancer and stromal cells, which was further confirmed in primary human endometrial stromal cells by addition of ProEGCG. Enhanced antitumor efficacy by recruiting macrophages as effector cells via bispecific antibodies mediated by CD89. Bingyu Li, Lijun Xu, Kun Xie, Fei Tao, Renhao Li, Hua Gu, Jianmin Fang. Tongji University, Shanghai, China.

ProEGCG reduced expression of HIF-1α and VEGFA in RL95-2 cells and decreased CXCR4 expression in tumor-associated macrophages (TAMs) and endothelial cells (ECs). To further study the role of ProEGCG on EEC cells, qRT-PCR and Western blotting proved that hypoxia (1% O2) upregulated the level of HIF-1α and VEGFA in EEC cell lines, which was reversed by ProEGCG through inhibition of HIF-1α and VEGFA via PI3K/AKT/mTOR pathway. This is an important role in tumor angiogenesis, and double immunofluorescence of F4/80 and CD206 antibodies in xenografts was applied and found that TAMs infiltration was reduced in ProEGCG group with decreased VEGFA in TAMs. Moreover, proliferation and migration of ECs are critical for tumor angiogenesis. To study the effect of ProEGCG on ECs, tube formation and invasion assays were conducted and indicated that ProEGCG showed a tube-like structure formation and less invaded ECs by inhibition of CXCR4 expression on ECs. However, it was still unclear if CXCL12, the ligand of CXCR4, was affected. Immunostaining for CXCL12 in tumor lesions indicated that ProEGCG decreased CXCL12 expression in cancer and stromal cells, which was further confirmed in primary human endometrial stromal cells by addition of ProEGCG.

Enhanced antitumor efficacy by recruiting macrophages as effector cells via bispecific antibodies mediated by CD89. Bingyu Li, Lijun Xu, Kun Xie, Fei Tao, Renhao Li, Hua Gu, Jianmin Fang. Tongji University, Shanghai, China.
Antibody-dependent cell-mediated cytotoxicity (ADCC) is one of key mechanisms through which antibody therapeutics can lyse tumor target cells. ADCC is usually mediated by IgG through recruiting effector cells, mostly NK cells, via IgG Fc receptor. In order to enhance specific tumor lysis by ADCC, a common strategy is to design a bispecific antibody that binds a tumor cell surface antigen and T cell marker CD3, thus to recruit T cells as effector cells. An example of this type of design is the FDA-approved bispecific antibody blinatumomab. We are interested in designing novel bispecific strategies to achieve improved ADCC effect. Since tumors are often infiltrated by macrophages and neutrophils, it would be advantageous to turn these types of cells into effector cells for ADCC.

We have designed several bispecific strategies that can target a tumor associated antigen (TAA) and CD89 (also known as P2Y12) on the neutrophils. The bispecific antibodies redirect tumor cells to CD89-expressing immune effector cells, such as macrophages and neutrophils. The CD89 bispecific antibodies were produced by HEK293 cells and showed binding activities to both CD89 and TAA. The CD89 bispecific antibodies can recruit CD89-expressing immune cells and induced enhanced tumor cells-killing in human whole blood ADCC assays. Since mouse does not express human CD89 homolog, we generated a transgenic mouse strain with specific expression of CD89 on macrophages and monocytes. In this transgenic mouse model, the CD89 bispecific antibodies showed significant anti-tumor activities, demonstrating that the bispecific antibodies can redirect macrophages, including M2 macrophages, to mediate additional effector function in tumor microenvironment.

Background: Hepatocellular carcinoma (HCC) is characterized by hypoxia, hypoglycemia and lactic acidosis within the microenvironment due a highly glycolytic phenotype. However, routine culture conditions of HCC cells employ supra-physiological glucose, pH-buffered media, and normoxia. The aim of the study was to simulate the microenvironment features of HCC in vitro by culturing HCC cells in their native (NAT) conditions (hypoglycemia, hypoxia and lactic acidosis) and examine phenotypic, transcriptomic and pharmacological differences compared to cells cultured in standard (ST) culture conditions. Methods: Six HCC cell lines were cultured in NAT or ST conditions. Pharmacological response to cytotoxic drugs and targeted agents were evaluated using the MTS assay. Phenotypic differences were examined using standard techniques. Transcriptomic analysis was carried out using the Illumina HumanHT-12 expression kit. Results: HCC cells cultured in NAT conditions have higher doubling time than cells cultured in ST conditions. However, no remarkable differences in the cell cycle profiles were observed when cultured in either NAT or ST conditions. Protein analysis revealed a increase in phosphorylation of AKT and decrease in the levels of AMPK in all cells cultured in NAT but not in ST conditions. Increase in the protein levels of GLUT1, HK2, LDHA, and a decrease in PDHA was observed only in cells cultured in NAT conditions. Furthermore, the HCC cells in NAT conditions exhibited lower levels of reactive oxygen species and ATP consistent with the elevated glycolysis and inefficient oxygen phosphorylation phenotype of HCC. Thirty-one genes were found to be aberrantly expressed by gene expression analysis, most notably NDRG1, a hypoxia-associated gene was upregulated in NAT cells, validated by qPCR. Upregulated NDRG1 was maintained even upon reversal of the NAT condition. The panel of thirty-one genes were found to be associated with poor prognosis exclusively in HCC based on data available via TCGA supporting the validity of NAT culture condition. Differences in the IC50 of doxorubicin, sorafenib, PTK, c-MET and HDAC inhibitors but not AKT, MEK, mTOR, Wnt inhibitors were observed in cells cultured in NAT compared with ST conditions suggesting microenvironment modelling can influence pharmacological response of certain class of compounds. Additional genomic and metabolomics analysis are underway in order to characterize the HCC cells in NAT conditions.

Conclusion: In conclusion, HCC cells when cultured in NAT conditions exhibit more of the tumor characteristics than cells in ST condition and this can be utilized as an informative platform for better understanding of disease biology and pharmacology.

#166 Recombinant protein MBP-NAP restricts tumor progression by triggering T-cell immunity in mouse metastatic melanoma model. Ting Wang,1 Cong Ding,2 Zhenyu Li,2 Xin Liu,1 Mingxuan Du,1 Qiaozhen Kang1, Zhengzhou University, Zhengzhou, China; 2Henan Academy of Medical and Pharmaceutical Sciences, Zhengzhou, China.

The pro-inflammatory and immunomodulatory properties of Helicobacter pylori neutrophil activating protein (Hp-NAP) not only make it play an important role in disease pathogenesis, but also make it a potential candidate for applications, including vaccine and drug development. Our previous work demonstrated that the recombinant Hp-NAP fused with the maltose-binding protein of Escherichia coli (rMBP-NAP) exert an important role in regulating the differentiation of TH1 cells. As a potential TLR2 ligand, it was reported to possess pro-inflammatory and immunomodulatory activities in vivo. To induce specific Th1 cell differentiation in the metastatic melanoma 122 and sarcoma S180 tumor models. To further understand the antitumor and immunomodulatory effect of rMBP-NAP, we elucidate the effect and mechanisms of rMBP-NAP at the local immune response modulation in established mouse B16-F10 melanoma pulmonary metastasis model. Our results demonstrated that metastatic lung tumor growth was significantly arrested after rMBP-NAP treatment as compared to the untreated control. rMBP-NAP increased the number of lung nodules and significantly increase in survival. Flow cytometry immunophenotyping and Quantitative RT-PCR analyses demonstrated that rMBP-NAP could induce both local and systemic immune responses, which associated with higher influx of CD3+CD8+ T cells, CD5+CD8+ T cells and higher secretion of interferon (IFN)-γ and interleukin (IL)-27 cytokines. The intraperitoneal administration of rMBP-NAP in mice promoted infiltration of lymphocyte in the lungs and reduced the production of several proinflammatory cytokines, such as IL-6 and transforming growth factor beta (TGF)-β, indicating an anti-inflammatory effect in local area. By comparing with control mice, mRNA expression of chemokines also revealed that rMBP-NAP treatment substantially decreased the expression of CCL2 and CCL20 in tumor tissues, which are central to recruit systemic Th1/Tc1 cells and the production of relevant inflammatory cytokines and chemokines, which are responsible for enhancing T cell immunity and reversing immunosuppression against metastatic cancer progression. Our findings strongly indicate that rMBP-NAP treatment might be a novel therapeutic approach against metastatic melanoma, and rMBP-NAP might be a potential template for the development of agents that could be used as immunomodulatory adjuvant in the therapy against melanoma.

#167 Brutinib regulates tumor microenvironment and enhances response to everolimus in renal cell carcinoma mouse models. Jun Chen, Chun-Te Chen, Jing Liu, Jeff Hsu, Taisei Kinoshita, Betty Y. Chang. Pharmacy, LLC, an AbbVie Company, Sunnyvale, CA.

Introduction: Brutinib (ibr), a first-in-class, once-daily, oral inhibitor of Bruton’s tyrosine kinase (BTK), is indicated for the treatment of patients with CLL/SLL, MCL and WM. Ibr also inhibits EGFR/HER2 and has demonstrated efficacy against EGFR+ NSCLC and HER2+ breast cancer in vitro and in xenograft models (Chen et al. 2016; Zhang et al. 2017; Chu et al. 2015). Ibr inhibited modulated host immunity and enhanced anti-PD-1/L1 activity in solid tumor models otherwise insensitive to BTK or HER kinase inhibition (Swain-Barfi 2015), suggesting that ibr may be active in renal cell carcinoma (RCC) via multiple mechanisms. Here we determined the impact of ibr alone and in combination with everolimus (eve) on tumor growth and the tumor microenvironment in syngeneic and xenograft RCC mouse models. Methods: Cell proliferation was determined with MTS assay. Phenotypic differences were examined using standard techniques. Transcriptomic analysis was carried out using the Illumina HumanHT-12 expression kit. Results: HCC cells cultured in NAT conditions have higher doubling time than cells cultured in ST conditions. However, no remarkable differences in the cell cycle profiles were observed when cultured in either NAT or ST conditions. Protein analysis revealed a increase in phosphorylation of AKT and decrease in the levels of AMPK in all cells cultured in NAT but not in ST conditions. Increase in the protein levels of GLUT1, HK2, LDHA, and a decrease in PDHA was observed only in cells cultured in NAT conditions. Furthermore, the HCC cells in NAT conditions exhibited lower levels of reactive oxygen species and ATP consistent with the elevated glycolysis and inefficient oxygen phosphorylation phenotype of HCC. Thirty-one genes were found to be aberrantly expressed by gene expression analysis, most notably NDRG1, a hypoxia-associated gene was upregulated in NAT cells, validated by qPCR. Upregulated NDRG1 was maintained even upon reversal of the NAT condition. The panel of thirty-one genes were found to be associated with poor prognosis exclusively in HCC based on data available via TCGA supporting the validity of NAT culture condition. Differences in the IC50 of doxorubicin, sorafenib, PTK, c-MET and HDAC inhibitors but not AKT, MEK, mTOR, Wnt inhibitors were observed in cells cultured in NAT compared with ST conditions suggesting microenvironment modelling can influence pharmacological response of certain class of compounds. Additional genomic and metabolomics analysis are underway in order to characterize the HCC cells in NAT conditions.

Conclusion: In conclusion, ibr had significant inhibitory effect on the growth of syngeneic and xenograft RCC tumor models. In syngeneic RCC models, ibr was significantly more effective in combination with everolimus than either agent alone, with a marked decrease in tumor growth and number of lung nodules and an increase in survival. Flow cytometry immunophenotyping and Quantitative RT-PCR analyses demonstrated that rMBP-NAP could induce both local and systemic immune responses, which associated with higher influx of CD3+CD8+ T cells, CD5+CD8+ T cells and higher secretion of interferon (IFN)-γ and interleukin (IL)-27 cytokines. The intraperitoneal administration of rMBP-NAP in mice promoted infiltration of lymphocyte in the lungs and reduced the production of several proinflammatory cytokines, such as IL-6 and transforming growth factor beta (TGF)-β, indicating an anti-inflammatory effect in local area. By comparing with control mice, mRNA expression of chemokines also revealed that rMBP-NAP treatment substantially decreased the expression of CCL2 and CCL20 in tumor tissues, which are central to recruit systemic Th1/Tc1 cells and the production of relevant inflammatory cytokines and chemokines, which are responsible for enhancing T cell immunity and reversing immunosuppression against metastatic cancer progression. Our findings strongly indicate that rMBP-NAP treatment might be a novel therapeutic approach against metastatic melanoma, and rMBP-NAP might be a potential template for the development of agents that could be used as immunomodulatory adjuvant in the therapy against melanoma.

Conclusion: This study suggests that ibr has antitumor activity against RCC.
alone and when combined withive in animal models. This effect may be mediated by modulation of the tumor microenvironment, such as inhibiting Treg differentiation and suppressing PD-1 expression on CD8+ T cells, and both BTK and EGFR/HER2 are involved. Further investigation is needed to clarify the mechanism of action, but the results here provide a rationale for ibv as a novel agent for RCC in combination with mTOR inhibitors. 

#168 Loss of function mutation in TIMP2 gene accelerates tumorigenesis and mortality in murine model of lung cancer through EGFR signaling. Sarvesh Kumar, Sandra Jensen, David Peeney, Ananda Chowdhury, Beiyang Wei, William G. Stetter-Stevenson. NCI/NIH, Bethesda, MD.

The aim of this study is to determine the effect of the tissue inhibitor of metalloproteinase-2 (TIMP-2) on lung tumorigenesis and investigate the underlying molecular mechanisms using an orthotopic mouse model with a loss of function mutation in the Timp2 gene (T2M). T2M and wildtype (WT) control mice were given 1x10^6 Lewis lung carcinoma cells transplanted with luciferase (LL/2-Luc-M38, Caliper) in 50 μL PBS via intratracheal injection. IVIS imaging revealed a higher tumor burden in T2M mice compared to WT littermates, suggesting that loss of function of the Timp2 gene enhances tumor growth (p<0.05). We also conducted a Kaplan-Meier analysis to determine the effect of this mutation on mortality following cancer development. We found that LL/2 tumor-induced mortality was significantly higher in T2M mice compared to WT controls (p = 0.01). Histologic analysis and H&E staining of lung tissue sections revealed a significant increase in the number of tumor nodules of T2M mice compared to WT controls (p <0.01). CD31 staining showed a significant increase in microvessel density (MVD) in T2M mice compared to WT controls (p<0.01). Given that VEGF is a primary driver of tumor neoangiogenesis, we determined mRNA levels of VEGF expression in healthy and tumor bearing mice by qRT-PCR analysis. Interestingly, basal VEGF expression levels were increased in lungs of both non-tumor bearing and tumor bearing T2M mice compared to WT controls (p<0.01). VEGF is the direct downstream target of HIF-2α, a transcription factor implicated in tumor hypoxia and expression correlates with decreased overall survival in non-small cell lung cancer (NSCLC) patients. Similarly, an examination of TIMP-2 and HIF-2α mRNA expression in a small cohort of patient samples revealed decreased TIMP-2 and increased HIF-2α in NSCLC tumors compared to surrounding non-tumor lung tissue. Hypoxia induces EGFR signaling through HIF-2α. Thus, we determined the effect of mutated T2M on the EGFR signaling pathway. We found increased levels of EGFR phosphorylation as well as downstream ERK and Akt activation in tumor bearing and non-tumor bearing T2M lungs compared to WT controls. In conclusion, these findings offer new avenues for TIMP-2 research in regulating hypoxic mediators within the tumor microenvironment through EGFR signalizing, suggesting TIMP-2 as a novel bio-therapeutic for lung cancer therapy.

#169 Preclinical efficacy and sensitivity determinants of evofosfamide in molecularly defined models of head and neck squamous cell carcinoma. Francis W. Hunter,1 Avik Shome,1 Dan Li,1 Way W. Wong,1 Peter Tsai,2 Anthony J. Zussman,1 Cho R. Hong,1 Dennis Kee,3 Andrew M. Macann,4 Anthony J. Hickey,5 Stefan K. Bohlander,1 Cristin G. Print,1 William R. Wilson,5 Bradly G. Wouters,5 Stephen M. Jamieson.1 University of Auckland, Auckland, New Zealand; 2Princess Margaret Cancer Centre, Toronto, Ontario, Canada; 3LabPLUS, Auckland, New Zealand; 4Auckland City Hospital, Auckland, New Zealand.

Tumor hypoxia is prevalent in head and neck squamous cell carcinoma (HNSCC), where it limits radiotherapy outcomes. Hypoxia-activated prodrugs (HAPs) have been developed to target hypoxic regions of tumors. These agents undergo oxygen-sensitive reductive activation, thereby delivering cytotoxic species within hypoxic cells. This study investigated the efficacy and sensitivity determinants of the clinical-stage HAP evofosfamide (TH 302) using molecularly-characterized models of HNSCC. We deployed a collection of 27 HPV-negative HNSCC cell lines derived from lesions of varying TNM stages and primary, nodal or recurrent sites. The collection was characterized for gene expression by RNA-seq, from which somatic variants were also called. Their transcriptomic features were investigated in the context of pan-cancer TCGA data by hierarchical clustering. The potency and hypoxic selectivity of 3 HAPs - evofosfamide, PR-104A and SN30000 - were assessed by antiproliferative assay in 22 lines and compared to bromo-isoporphoramide mustard (Br-IPM), cisplatin and 5-FU. The antitumor activity of evofosfamide (50 mg/kg qdx3 for 2-3 cycles with or without a single 10 Gy dose of radiation on day 5 of cycle 1) was evaluated in HNSCC xenografts in addition to a PDX isolated from an SCC of the glottic larynx. The hypoxic fraction at baseline and after 5 days of treatment was quantified by pimonidazole staining. Genetic modifiers of sensitivity to evofosfamide and its cytotoxic metabolite Br-IPM were explored through whole-genome CRISPR-Cas9 screens using the GeCKO v2 library. High-throughput screens with a custom shRNA library were performed in two HNSCC and two pancreatic ductal adenocarcinoma cell lines to identify reductases responsible for the activation of evofosfamide in hypoxic cells. Evofosfamide was more potent and more selective for hypoxic HNSCC cells in vitro than PR-104A or SN30000. Cell line sensitivity to evofosfamide was correlated with Br-IPM and cisplatin but not with PR-104A, SN30000 or 5-FU, indicating distinct sensitizing mechanisms following evofosfamide treatment. In the in vivo study, CRISPR screens identified potential evofosfamide sensitivity genes that were reproducibly enriched following drug exposure. Reductase-focused RNA interference screens defined a cluster of sensitivity genes that mapped to mitochondrial electron transport, whereas shRNA's targeted against presumed activating enzymes such as POR were not enriched. Concentration-dependent reduction of cytochrome c and decreased respiration was observed in cells exposed to evofosfamide, suggesting reduction by mitochondrial complexes. This study provides a rationale for the clinical evaluation of evofosfamide with radiotherapy in genetically defined subsets of HNSCC patients.

#170 An innovative immunotherapeutic strategy for ovarian cancer: Glycomimetic peptides. Katherine F. Roby,1 Laura L. Eggen,2 Kenneth Hoober2.1 Univ. of Kansas Medical Ctr., Kansas City, KS; 2Sasuvion Biosciences, Inc., Tempe, AZ.

Successful treatment strategies for women with ovarian cancer remain elusive. We hypothesize that novel means of activating anti-cancer immune activity will be an important component of a multifaceted approach to successful treatment. The present set of studies tests the hypothesis that novel peptide mimetics of C-type lectin receptor ligands, sv4L and sv6D, enhance anti-cancer immune activity and limit the progression of ovarian cancer in a mouse model. We further test the hypothesis that sv6D will function in synergy with additional immune modulators and conventional cytotoxic therapy. C-Type lectin receptors were targeted that are specific for N-acetylglalactosamine (GalNAc). Both svL4 and sv6D bind GalNAc-specific C-type lectin receptors including CLEC10A/CD301 with a Kₘ in the low nanomolar range. CLEC10A is a transmembrane, endocytic receptor expressed on dermal dendritic cells, macrophages and immature dendritic cells. Further, studies with the B16 mouse melanoma model and spontaneous tumors (histiocytic sarcoma and mammary gland tumor) in dogs showed that treatment with svL4 correlated with reduced tumor-associated Treg cells. In the present studies subcutaneous injection of svL4 or sv6D every other day over 5 days stimulated a several-fold proliferation of immune cells in the peritoneal cavity of healthy mice. These results indicated that svL4 and/or sv6D might exhibit significant activity on peritoneal tumors. Efficacy of svL4 and sv6D each as a single agent and as a combination therapy with paclitaxel or anti-PD-1 was tested in C57BL6 female mice bearing ovarian ID8 intraperitoneal tumors. As a single agent, 0.1 n mole/g doses of svL4 or sv6D had a significant effect on suppressing ascites formation, a measure of tumor progression, and overall survival. Drug combination studies revealed a positive therapeutic interaction with sv6D and the cytotoxic paclitaxel. Both agents, sv6D and paclitaxel each had a significant effect on extending survival (median survival 140.5 and 150 days, respectively, vs. 122 days with no treatment). Survival was extended further with combination treatment when sv6D was administered to mice previously treated with paclitaxel (median survival 169 days). Also, a positive interaction was observed with sv6D and the check-point inhibitor anti-PD-1. Administration of sv6D following anti-PD-1 treatment resulted in a significant survival advantage compared to treatment with either agent alone. These data demonstrate 1) svL4 and sv6D mobilize immune cells in the peritoneal cavity, 2) svL4 or sv6D as single agents slow progression of ovarian cancer and enhance survival in a mouse model of ovarian cancer, 3) sv6D in combination with paclitaxel or anti-PD-1 extends survival past that of either agent alone. Taken together these date demonstrate the potential for this novel approach of harnessing lectin receptors as a means toward effective cancer treatment.
Brain tumor initiating cells (BTICs) are resistant to chemotherapies, providing a reservoir for tumor recurrence and a desirable target for glioma treatments. Standard of care for glioblastoma (GBM; grade IV astrocytoma) includes the chemotherapeutic agent temozolomide, which prolongs life expectancy by months and is not curative. Prior studies suggested the efficacy of chemotherapies including temozolomide was increased by reducing expression of carbonic anhydrase 9 (CA9). CA9 is a hypoxia responsive gene elevated in tumors that is important for regulating intracellular pH and contributing to the acidic extracellular microenvironment. After confirming basal and hypoxia-induced expression of CA9 in GBM BTICs, we targeted CA9 activity with the small molecule inhibitor SLC-0111 alone or in combination with temozolomide. In multiple GBM BTIC lines, SLC-0111 reduced cell growth in vitro and showed additional benefit when used concurrently with temozolomide. Importantly, SLC-0111 inhibited the enrichment of BTICs after temozolomide treatment as determined via BTIC marker expression and neurosphere formation capacity. These data suggested the potential of SLC-0111 as a chemosensitizer, which we next evaluated in preclinical studies using a subcutaneous recurrent GBM model. GBMs treated with SLC-0111 in combination with temozolomide significantly regressed and the resulting in vivo growth delay was greater than that of temozolomide or SLC-0111 alone. Together, our data suggest that SLC-0111 can sensitize GBM BTICs to the chemotherapeutic temozolomide and significantly delay disease progression.

CANCER CHEMISTRY: Basic and Applied Nanotechnologies and Therapeutic Approaches

#172 Oxidative stress and hepatotoxicity induced by graphene oxide in Sprague-Dawley Rats. Anita K. Patollah, Paul B. Tchounwou. Jackson State Univ., Jackson, MS.

Graphene oxide (GO) has been extensively explored as a promising nanomaterial for applications in biology because of its unique properties. Therefore, systematic investigation of GO toxicity is essential to determine its fate in the environment and potential adverse health effect. The aim of this study was to investigate the effect of graphene oxide on the induction of reactive oxygen species (ROS), the activity of certain liver enzymes (Alanine ALT, Aspartate AST, alkaline phosphatases ALP), and concentration of lipid hydroperoxide (LHP) in serum and histopathological evaluation of liver tissue in Sprague-Dawley rats. Four groups of five male rats were orally administered GOs, once a day for five days, with doses of 0, 10, 20 and 40 mg/kg GO. A control group was also made of five rats. Blood and liver were collected 24 h after the last treatment following standard protocols. GO's exposure increased the induction of ROS, the activities of the liver enzymes (ALT, AST, A LP), concentration of lipid hydroperoxide (LHP) and morphological alterations of the liver tissue in exposed groups compared to control. The highest two doses, 20 and 40 mg/kg, showed statistically significant (p < 0.05) increases in the induction of ROS, activities of ALT, ALP, LHP concentration, and morphological alterations of liver tissue compared to control. However, AST activity showed no effect. Taken together, the results of this study demonstrate that GO is hepatotoxic, and its toxicity may be mediated through oxidative stress.

Breast cancer is the second leading cause of cancer-related deaths in women today and is the most common cancer among women, excluding non-melanoma skin cancers. Over 426,000 women will be diagnosed with breast cancer and 40,450 are expected to die of it in 2016. Estrogen receptors ERα, ERβ and their associated steroid hormones play vital role in breast cancer development and progression. Estrogen binds and activates the estrogen receptors in certain breast cancer cells and release their drug load into the cytoplasm. Commercial liposomes culture experiments indicate that TLD-1 liposomes are readily taken up by cancer cells and release their drug load into the cytoplasm. Pharmacologic properties of TLD-1 were compared in three animal models of breast cancer agents. TLD-1 showed a marked increase in cytotoxicity compared to Caelyx and was close to free drug. In all three animal models, TLD-1 showed IC50 values of 0.61, 1.36 and 0.09 g/ml on MCF-7, MDA-MB-231 and Ishikawa cells using cellTiter-Glo luminescent cell viability assay. Among all the compounds screened, 4-ethyl-N-(8-hydroxy-3,4-dihydroisoquinolin-2(H)-yl)benzamide showed IC50 values of 0.61, 1.36 and 0.09 μg/ml on MCF-7, MDA-MB-231 and Ishikawa cells respectively. This research was supported by the National Center for Research Resources and the National Institute of Minority Health and Health Disparities of the National Institutes of Health through Grant Number 8 G12MD007582-28.

#174 Preclinical activity of new liposomal formulation of doxorubicin (TLD-1). Massimo Broggi,1 Federica Guffanti,1 Roberta Affatato,1 Lavinia Morosi,1 Patrick Buschor,2 Christoph Matthieu,2 Florian Weiss,2 Andreas König,2 Peter Halbher,2 Stefan Halbher*,2 Mario Negri Istituto per Farmacol. Research, Milan, Italy; 2InnoMedica, Bern, Switzerland.

Background: InnoMedica is a young company with focus on clinical translation of nanomedicine. The company employs its own manufacturing technology that gives rise to a novel liposome platform. The platform allows for specific shaping of nanosurfaces. This leads to a myriad of different particle designs with highly distinct biological functions. In a first approach, the lead-formulation TLD-1 (targeted liposomal doxorubicin) was developed in order to ameliorate chemotherapeutic outcome for patients, taking into account the patterns of biodistribution in the entire organism as well as nanoparticle-cell interactions and subcellular localisation. Methods: Pharmacologic properties of TLD-1 were investigated in vitro and in vivo. Human ovarian cancer cells A2780 were cultured in both 2D and 3D settings and antineoplastic activity of different formulations of doxorubicin was measured by quantification of cell viability. The same formulations were also compared in three animal models of cancer including murine breast cancer 4T1, human breast cancer MDA-MB-231, and A2780. MDA-MB-231 and A2780 cells were grown in vitro and injected subcutaneously (sc) in immunodecient mice (Athymic Nude-Foxn1tm1). 4T1 cells were injected either sc or in the mammary fat pad of immunocompetent mice (BALB/c). The different drug products were injected intravenously twice weekly for a total of three weeks. Activity was determined with caliper measurements of tumor diameters every three days. Animal body weight was recorded as index of toxicity. Doxorubicin was determined in plasma and tissues by HPLC-MS. Results: In 2D and 3D cell culture assays, TLD-1 showed a marked increase in cytotoxicity compared to Caelyx and was close to free drug. In all three animal models, TLD-1 showed activity superior to that of free doxorubicin given at the same dose and proved well to be a promising treatment for breast cancer. Conclusions: A couple of nanoparticulate features of TLD-1 liposomes are believed to attribute to the difference in antitumor activity. Cytotoxicity data from cell culture experiments indicate that TLD-1 liposomes are readily taken up by cancer cells and release their drug load into the cytoplasm. Commercial liposomes as in Caelyx seem to largely remain outside of cancer cells. In sum, TLD-1 is a novel and highly active antineoplastic nanodrug that has the potential to out-perform free drug as well as commercial liposomal formulations of doxorubicin.

#175 Combination of plasmonic photothermal therapy with surgery applied to naturally occurring mammary tumors in canines and felines: clinical outcomes and molecular studies. Moustafa R. Ali,1 Haithem A. Farghali,2 Hala R. Ali,2 Ahmad H. Osman,2 Youssef A. Soliman,2 Yue Wu,1 Ibrahim M. Ibrahim,1 Maha Selim,2 Dong M. Shin,1 Mostafa A. El Sayed1. 1Georgia Inst. of Technol.ogy, Atlanta, GA; 2Veterinary Medicine, Cairo University, Cairo, Egypt; 3Emory University, Atlanta, GA. Plasmonic Photothermal Therapy (PPTT) is a cancer therapy where gold nanorods (AuNRs) are injected at the tumor site and near-infrared light (safe to bio-system) is applied to generate localized heat causing cancer cell death. PPTT is a potentially good alternative to replace traditional surgery for localized tumors. However, for large tumors (volume ≥10 cm3), PPTT could be ineffective due to an uneven distribution of injected AuNRs causing possible inhomogeneity of heat. Surgery is frequently recommended in those cases. However, it carries a high risk of cancer recurrence. For effective treatment of large tumors, we
combined both PPTT and surgical resection and applied it to naturally occurring tumors in mammary glands of dogs and cats, which could realistically represent their human equivalents at the molecular level. For the experimental design, we divided the animals into three different groups. 20 cases (7 cats and 13 dogs) were all diagnosed with adenocarcinoma; the animals were monitored for 1- 2 years after treatments. Group (I): 12 cases were solely treated by mastectomy (control group); all of them died within a few weeks. Group (II): five cases were treated with mastectomy first. Then, each tumor wound was divided into two halves, and only one half was exposed to PPTT. After treatment, two cases in this group rendered complete remission. In the other three cases, the half wound that was not exposed to PPTT had tumor recurrence causing animal death within one year. Group (III): 12 cases were treated with surgery followed by PPTT treatment. This regime showed complete remission without any recurrence for eight cases. However, four cases died 4-12 months after therapy for reasons such as pneumonia (no tumor found, based on X ray). Histopathology results showed a decrease of cancer grades before (variant grades from 1-4) and after two weeks of treatment via PPTT and surgery (grade 0). Blood tests (conducted 1 year after therapy) showed no obvious change in liver and kidney functions in groups II and III. In addition, X-ray diffraction showed no metastases 1-2 years after treatment. We have performed quantitative, real-time PCR analysis two weeks before and after treatment to study the expression levels of several important genes. The genes that are responsible for repairing cancer cells such as BRCA1, BRCA2, and CD163-IL-10 were significantly diminished two weeks after treatment (group III). Furthermore, tumor microenvironment cells such as tumor-associated macrophages (TAMs) were greatly altered after treatment. TAM 1, which retards tumor growth, augmented, and TAM 2, which promotes tumorigenesis, was diminished, which explains the animals’ increased survival rate. In conclusion, our study demonstrates the feasibility of applying PPTT after surgery for large tumors in dogs and cats.

#176 Early development of GMC1, a novel molecule targeting FKBP52 for the treatment of hormone-refractory prostate cancer. Huan Xie, Oscar Ekpenyong. Texas Southern University, Houston, TX.

Purpose: GMC1 directly inhibits FKBP52, effectively blocking androgen receptor dependent gene expression and androgen-stimulated proliferation. This make it an attractive option for the treatment of hormone-dependent and hormone-independent prostate cancer. This study investigated an analytical method for GMC1 quantification, pre-formulation characteristics of GMC1, and developed intravenous formulations for the evaluation of GMC1 in animal models. Method: An LC/MS/MS method for the quantification of GMC1 in solution, plasma and urine was developed, validated and applied to the determination of the stability, log P, plasma protein binding and solubility of GMC1 in various solvents. Liposomal formulations co-solvent systems with various ratios of high capacity vehicles were formulated and the optimal formulation applied, at 2 mg/kg single IV bolus dose, to the pharmacokinetic study of GMC1 in a rat model. Result: The intra- and inter-day accuracy (%RE) and precision (%CV) of the LC/MS/MS method ranged from 1.6 – 11.7 % and 1.4 – 8.8 %, respectively. GMC1 is stable in solid and solution state, moderately lipophilic (log P 3.18 ± 0.05), poorly water soluble (0.4 ± 0.01 mg/mL), and highly plasma protein bound (97.5 ± 1.3 %). The optimised formulation employed was 1:1:1 (GMC1: PEG200: water) and Labrasol ® (1:1, v/v) allowed us to achieve a GMC1 concentration of 10 mg/mL, and tolerated an aqueous environment. GMC1 has a tri-exponential disposition with a Tmax of 7.6 ± 1.97 mg/L, clearance of 0.53 L/kg/hr, α-distribution, β-phase and terminal elimination half-lives of 0.1 ± 0.04 hr, 1.2 ± 0.34 hr, and 19.7 ± 5.09 hr respectively. Conclusion: The LC/MS/MS method, formulations and pharmacokinetic study can be applied to the pre-clinical and clinical development of GMC1. Grant Support: This work was performed under funding from NIH/NIGMS grant (S5CG102018) and NIH/NIMHD/RCMI grant (SG12MD007605).

#177 Thymidine quinoxaline conjugates as a novel selective and effective photosensitizer for anticancer photodynamic therapy. Qibing Zhou, Zhiwei Wang, Rong Yang, Ting Qian, Dejun Zhang. Huazhong Univ. of Science & Technology, Wuhan, China.

Thymidine quinoxaline conjugates are a new class anticancer agent that exhibits selective anticancer activity by targeting the abnormally high level of thymidine kinase of the thymidine salvage pathway in cancer cells. In addition, the conjugated quinoxaline moiety could also act as a photosensitizer to generate reactive oxygen species that would significantly enhance the anticancer activity. Therefore, a variety of structural derivatives were synthesized and investigated for the potential of combined anticancer activity. We found that the thymidine moiety was critical for the accumulation of compounds in cancer cells and thus their activity. On the other hand, the substitutions and additional conjugation of thymidine quinoxaline moiety had significant impact on the effectiveness to generate reactive oxygen species for enhanced potency. Among all the compounds studied, DT-QP exhibited a potent activity against liver cancer cells with IC50 at 20 nM under photo-irradiation at 400 nm wavelength for 20 min. This potent activity of DT-QP was 12 times more effective than that of the clinically used photosensitizer, porfimer sodium (IC50 at 250 nM under the same condition). DT-QP was more potent than anticancer drug doxorubicin (IC50 at 100 nM). In addition, thymidine quinoxaline conjugates were found to form aggregates with an average size of 200 nm. Further optimization of the aggregating condition led to a highly stable suspension of 90 nm size nanoparticles containing a tumor-specific peptide that could be used for in vivo study. Therefore, thymidine quinoxaline analogs could be a selective anticancer agent and effective photosensitizer for potential photodynamic therapy.

#178 Peptide nanofibers: targeted therapies for glioblastoma multiforme. Diana M. Leite,1 Rong Zhu,2 Eugen Barbu,2 Peter Hinterdorfer,2 Geoffrey J. Pilkington,1 Aikaterini Lalatsa1, University of Portsmouth, Portsmouth, United Kingdom; Johannes Kepler University, University of Linz, Linz, Austria.

Glioblastoma multiforme (GBM) is a malignant brain tumor with poor prognosis due to tumor heterogeneity, poor drug blood-brain barrier (BBB) permeability and targeting. GBM biopsies indicated the overexpression of G-protein coupled receptors (GPCRs) that when activated by neuropeptide agonists result in an antiproliferative effect. However, translation of these neuropeptide agonists into novel therapies for GBM is frustrated by their short half-life (<5 minutes) and inability to cross the BBB. Here, we present a novel strategy based on the lipidization of neuropeptidase inhibitors that results in peptide amphiphiles able to self-assemble into nanofibers that can entrap brain impermeable drugs, possess an enhanced stability to enzymatic degradation, permeate across an all human in vitro BBB model and are able to target GBM cells resulting in a significant antiproliferative effect. Peptide amphiphiles were synthesized using solid-phase peptide synthesis and characterised using pyrene, thiolavin T, circular dichroism and transmission electron microscopy experiments. Nanofibers were loaded with brain impermeable cytotoxic drugs (e.g. paclitaxel) and their stability was studied in biological media (plasma, brain, liver and GBM cell lysates). BBB permeation was studied in an all human in vitro Transwell model. The antiproliferative effect of the nanofibers was evaluated on U-87 MG cells. Targeting of the nanofibers to the GPCR was evaluated using single-molecule force spectroscopy (SMFS). Peptide amphiphiles self-assemble into stable nanofibers at concentrations above 189 μM and are able to solubilize high amounts of paclitaxel (>1.8 mg) ensuring that the resulting nanomedicine can be clinically translatable. Both unloaded- and paclitaxel loaded-nanofibers showed superior stability compared to the parent neuropeptide in the presence of plasma, brain, liver and cell homogenates (>5-fold). Nanofibers elicited a strong antiproliferative effect (IC50 < 1 μM) at 10 mg/mL, which is 1000-fold lower than the IC50 of the parent GBM cell line (U-87 MG). Loading paclitaxel (1μM) within the nanofibers resulted in a synergistic effect evidenced by a decrease in cell survival by 32%. Nanofibers counteracted the forskolin-induced increase of intracellular CaM levels indicating that the GPCR is linked to the Gαq protein known to mediate the antiproliferative effect on GBM. Confocal studies confirmed the internalization of the peptidocopolymer SMFS (IC50 < 250 nM) under the same condition and even GBM cell line (U-87 MG). This potent activity of GPCR on U-87 MG cell surface with equivalent binding probability to peptide agonists and increased residence time. Texas Red labelled nanofibers permeate across an in vitro BBB model enabling the permeation of paclitaxel (Papp: 8.45 x 10-10 cm2/s). Thus, described peptide nanofibers are a novel targeted nanomedicine for GBM therapy able to be clinically translated. In vivo proof of concept studies and pharmacokinetics are under way.

#179 Plasma membrane lipid therapy: disruption of oncogenic Ras spatiotemporal organization by membrane-targeted dietary bioactives (MTDB). Natividad R. Fuentes,1 Rola Barhoumi,1 Mohamed Milh,2 Jason Karpac,2 Paul Hardin,1 Trevor Steele,1 Spencer Behmer,1 Ian Prior,2 Robert S. Chapman,1 Texas A&M University, College Station, TX; Texas A&M Health Sciences Center, College Station, TX; University of Liverpool, United Kingdom.

Approximately 30% to 50% of colorectal cancers contain KRas mutations, which confer resistance to standard therapy and have therefore been termed “undruggable.” Since no curative treatments for KRas driven colon cancer are available, there is a critical need to develop toxicologically innocuous KRas therapeutics that are free of safety problems intrinsic to drugs administered over long periods of time. High fidelity signaling of Ras is dependent on its spatial organization into defined nanoclusters on the plasma membrane. This is noteworthy, because select nonsteroidal anti-inflammatory drugs, through direct modulation of the functional properties of the plasma membrane, alter oncogenic Ras nanoclustering and attenuate signal transduction. These findings...
suggest that Ras nanoclusters represent a novel target for future interventions. Consistent with this rationale, we hypothesize that select amphiphilic membrane targeted dietary bioactives (MTDB's), e.g., polysaturated fatty acids (n-3 PUFA) docosahexaenoic acid (DHA, 22:6\(\omega 3\)), eicosapentaenoic acid (EPA, 20:5\(\omega 3\)), docosatrienoic acid (22:3\(\omega 3\)), [1] modulate the rigidity of the plasma membrane, [2] increase Ras nanocluster formation, [3] prevent metastatic disease by interfering with pro-inflammatory signaling (pERK), and [4] suppress phenotype (hyper-proliferation) in vitro and in vivo. Our studies utilized a variety of complementary models including mouse colon cancer cells, Drosophila midgut stem cells and mouse colon, respectively. In vitro and in vivo incorporation of n-3 PUFA consistently reduced plasma membrane rigidity and TH-Ras clustering, while increasing TH&TK proteins and the mixing of TH and TK proteins. These changes in membrane spatiotemporal organization were associated with a reduction in oncogenic Ras\(^{12}\) driven ERK phosphorylation and intestinal stem cell proliferation. These novel findings in vitro PhAc-ALGP-Dox suggests a unique role for MTDBs in Ras-dependent oncogenesis would have a major translational impact because these bioactives are safe, well tolerated, relatively inexpensive, and provide additional health benefits, such as reduction in mortality. This work was supported by NIH grant R35CA197707.

#180 PhAc-ALGP-Dox is a new tumor selective peptide prodrug of doxorubicin that shows improved efficacy and systemic tolerance in triple negative breast cancer models. Andrea Casazza,1 Massimiliano Mazzone,1 Peter Pokreisz,2 CoBioRes NV, Leuven, Belgium; 2VIB Vesalius Research Center, Leuven, Belgium.

Use of traditional chemotherapeutic drugs is restricted by severe side effects and lack of tumor specificity of these cytotoxic agents. Less toxic prodrug that can be selectively activated in tumor tissue have been explored in attempts to improve the therapeutic index. Some approaches to the development of tumor activating prodrugs take advantage of inherent properties of the tumor, for example, selective enzyme expression, hypoxia, or low extracellular pH in the vicinity of the tumor. CoBioRes makes use of capped, tetrapted peptide prodrug of existing chemotherapeutics. Doxorubicin (Dox) was the first chemotherapeutic that was linked to the tetrapted sequence and tested experimentally (PhAc-ALGP-Dox). This approach makes the prodrug impermeable to cell membranes of both normal and tumor cells. Furthermore, it remains stable in blood by the use of the capping group on the amino-terminal group of the peptide that prevents ascertainment by circulating esopetidases. The prodrug as such is thus not active. The peptide sequences have been developed to be sensitive to the hydrolytic action of a selected group of peptidases that are released within the tumor microenvironment. These peptidases, which accumulate in the tumors, also play an important role in cancer cell invasion and metastasis. What makes this approach unique is that it is not targeting a single enzyme, but requires, for its selectivity, a two-step activation based on enzymes with an increasing selectivity. In vivo activation starts when the tetrapeptide prodrug is exposed to endonucleases (CD10 and THO1) leading to the formation of intermediates that are still inactive and poorly permeable through cell membranes. This leads to a tissue distribution that is determined by the expression of the endonuclease. Since these are known to be overexpressed in several tumors, and only present at lower level in some normal tissues, the prodrug will be preferentially located and activated in the vicinity of tumors. The second step of the activation is the cleavage at the prodrug by dipeptidases FAP and DPPV4, releasing the free doxorubicin. The simultaneous expression of all the enzymes involved in the prodrug activation was confirmed both in human triple negative breast cancer biopsies and in experimental triple negative breast cancer models. In vitro analysis of PhAc-ALGP-Dox reveals higher tumor cells tropism and higher cytotoxicity in cancer cells than in normal cells. In vivo PhAc-ALGP-Dox gives promising preliminary results in terms of systemic tolerance even at high concentration, and in vivo efficacy in xenograft mouse models compared to free doxorubicin. Taken together, these results provide a strong rationale for further investigation aimed at unleashing the potential clinical value of this compound.

#181 Discovery of novel targeted therapeutics for metastatic breast cancer. Cristina Del Valle,1 Eliud Hernandez,2 Cornelis P. Vlaar,1 Luis A. Cubano,2 Suranganie Dharmawardhane,1 Linette Castillo-Pichardo1,2 University of Puerto Rico, Medical Sciences Campus, San Juan, PR; 2Universidad Central del Caribe, Guaynabo, PR.

Metastatic breast cancer cells that metastasize to distant organs outside of the breast are the primary cause of breast cancer mortality, due to the lack of effective therapy. The Rho GTPTase Rac is integral for the promotion of cancer cell migration/invasion, proliferation, and survival. Since metastatic breast cancers often overexpress or exhibit high Rac activity, inhibition of Rac is a viable strategy against metastatic cancer. Recently, we characterized EHop-016, a small molecule that inhibits Rac activity of metastatic breast cancer cells with an IC\(_{50}\) of 1 \(\mu\)M. EHop-016 is 10-100 times more active than previous available Rac inhibitors, and is the first compound shown to inhibit the activation of Rac by the oncogenic GEF Yav. EHop-016 inhibits the activity of the Rac downstream effector p21 activated kinase (PAK), lamellipodia extension, and cell migration of metastatic breast cancer cells. We also reported that EHop-016 at \(\leq\) 25 mg/kg Body Weight (BW) significantly reduced tumor growth, metastasis, and angiogenesis in a mouse model. However, our recent pharmacokinetic study of EHop-016 in a mouse model demonstrated that the bioavailability of Ehop-016 needs to be improved for further pharmacological development. Therefore our hypothesis is that improvement of the EHop-016 structure will provide probes with increased potency against Rac and, therefore, increased bioavailability. EHop-016 derivatives were tested in-vitro and in-vivo for their effect on breast cancer cell viability and Rac activation. Using MTT assays we found that the EHop-016 derivatives, HV-107 and HV-118, significantly inhibit the viability of metastatic breast cancer cell lines MDA-MB-231 and MDA-MB-435. The effects of HV-107 and HV-118 on the inhibition of Rac activation were tested by ELISA-based Rac activity assays and pulldown assays. Results show that at 250 \(\mu\)M, HV-107 inhibits Rac activation by 55%, whereas HV-118 has a similar effect at 100\(\mu\)M in MDA-MB-231 and MDA-MB-435 cells. Taken together, our findings suggest HV-107 and HV-118 as promising Ehop-016 derivatives with potential as anti-metastatic agents, which should be further characterized. This study was supported by awards from the Susan Komen for the Cure, NIH/NIHMD U54MD008149, and the Puerto Rico Science Trust to SD; NIH/NCRR R25GM061838 to UPR MSc; NIH/NIHMD RCI 8G12MD007583RCMI, Title V PPOHA 03110505 and Title V Cooperative P031S130068 from U.S. Department of Education to UCC; and PRINBRE (NIH/NIHGS P2GM103475-13) Pilot Project to LCP.
was a dose dependent decrease in multiplicity of aberrant crypt foci (ACF) in the colon. PPI inhibited the occurrence of larger ACF consisting of more than 4 aberrant crypts, indicating inhibitory effect of PPI on tumor promotion. In a mouse xenograft model, PPI decreased the size and number of blood vessels in the tumor. All mice survived without causing significant body weight loss during experiment. No histopathological changes were found in genito-urinary tract. To better understand the mechanism of PPI on angiogenesis, we performed chorioallantoic membrane assays and found a dose-dependent decrease in average number of blood vessels. Inhibition of STAT3 by PPI may affect the function of molecules that are related to apoptosis, angiogenesis, and cell cycle progression and eventually contributes to PPI-induced growth inhibition.

### 183 Brassinolide, a plant steroid hormone, reverses drug resistance in human small-cell lung carcinoma cells. David Sadava, Susan E. Kane. City of Hope, Duarte, CA.

Small-cell lung carcinoma (SCLC) has a dismal prognosis in part because of multidrug resistance (MDR). Epibrassinolide (EB) is a steroid hormone present in higher plants, where it has numerous physiological effects and acts via a LRR-RLK membrane receptor and GSK3/SHAGGY pathway, resulting in stabilization of a known inhibitor of Wnt signaling, was cytotoxic to SCLC cells (IC50 = 0.80 at ED50 and CI0.90 at ED95); EB and doxorubicin also showed synergism (CI1.35 at ED95), suggesting that EB triggers a redox imbalance by inhibiting GSTp and by lowering the antioxidant (GSH) and reducing equivalent (NADPH) levels, leading to a significant elevation of ROS levels. We also showed the upregulation of endoplasmic reticulum (ER) stress-responsive protein, activation of MAPK, autophagy and apoptotic pathways by KSS72 in several cell lines. KSS72-induced autophagy was a post event of redox perturbation that displayed a wide array of characteristic features including double membranous vacuoles with entrapped organelles, acidic vesicular organelles, and increased expression of LC3-II and beclin-1. In view of its excellent brain penetration and multiple cytotoxic events mediated by ROS and autophagy, we tested the in vitro efficacy of KSS72 in GBM cell lines and in vivo efficacy of KSS72 in xenograft models of GBM xenografts. SF-188 human GBM cells expressing firefly luciferase were injected into the brain just left of bregma for the development of orthotopic GBM in nude mice. These mice were given 25 mg/kg/day of KSS72 intraorbitally for 2 weeks. The animals when imaged by IVIS after luciferin injections showed a complete lack of intracranial tumors in all KSS72 administered animals. H&E staining of mouse brain sections confirmed the total elimination of GBM by KSS72. KSS72 did not exert any toxicity on host tissues and serum ALT and AST levels were not altered. In summary, we conclude that KSS72 acting through multiple pathways of oxidative stress is a hugely promising non-toxic anti-glioma drug with potential to enter clinical trials (supported by CPRIT grant R1P30266 and RP170207 to KSS).
GP130 or IL-11/IL-11 Ra/GP130 heterotrimer and triggers a signaling cascade downstream. One of the major downstream effectors of IL-6 is STAT3. STAT3 is persistently activated in many human osteosarcoma specimens and cell lines and STAT3 is required for osteosarcoma cells survival. So IL-6 and IL-11 present a viable novel target for osteosarcoma therapy. To date, however, no small molecule to target the IL-6/IL-11Ra/GP130 or IL-6/IL-11Ra/GP130 signaling axis is available for cancer therapy. To overcome this critical problem, we have utilized a novel drug discovery approach combining Multiple Ligand Simultaneous Docking and drug repositioning to target GP130. Drug repositioning refers to reuse fragments from the existing FDA-approved drugs for new applications and could potentially reposition the existing drugs as novel, off-target inhibitors of the desired target. Using this novel method, we have identified by FDA-approved drug Bazedoxifene with a novel function to inhibit IL-6 and GP130 protein-protein interactions. Furthermore, because IL-11 binds to the same domain of GP130 as IL-6, Bazedoxifene should also inhibit IL-11/GP130 signaling. Accordingly, Bazedoxifene can indeed inhibit the induction of P-STAT3 by both IL-6 and IL-11. Bazedoxifene appeared specific to IL-6 and IL-11 as phosphor-ylation of STAT1 and STAT3 by IFN-γ and LIF respectively were not affected by the compound. Bazedoxifene inhibited P-STAT3 and induced apoptosis in human osteosarcoma cell lines expressing IL-6 and IL-11. In addition, Bazedoxifene can inhibit colony formation after the drug treatments in cancer cells. IL-6 but not IFN-γ could rescue the Bazedoxifene-mediated inhibition of cell viability in osteosarcoma cells. These results further support that IL-6/GP130 and IL-11/IL-11Ra are two of the major pro-survival mechanisms for xenograft tumor inhibition in osteosarcoma cells. To determine the in vivo activity of Bazedoxifen, we further tested the efficacy of Bazedoxifene in tumor xenografts generated from the SJSA osteosarcoma cells that show persistent IL-6/STAT3 activation. Bazedoxifene via oral gavage inhibited P-STAT3 and the growth of SJSA tumor xenografts. These data demonstrated that Bazedoxifene is potent in suppressing tumor growth and is orally bioavailable in inhibiting P-STAT3. It further indicates that Bazedoxifene is a promising IL-6/GP130-targeting drug, which likely to have in vivo anti-tumor activity in osteosarcoma. In summary, Bazedoxifene already approved for safety by the FDA as a novel inhibitor of IL-6/GP130 and IL-11/GP130 signaling should provide an easier path to clinical trials and have a potential to improve the outcome of osteosarcoma.

#187 Efficient delivery of Bcl2 siRNA by DNA nanoparticles to inhibit cellular growth and cancer progression. Mohammad Aminur Rahman,1 Peng-fei Wang,2 Dongsheng Wang,1 Selwyn J. Hurwitz,2 Zhengjia Chen,2 Zhuo G. Chen,1 Yonggang Ke,2 Dong M. Shin,3 Emory Univ. Winship Cancer Inst., Atlanta, GA; Emory University, Atlanta, GA.

Background: Short interfering RNA (siRNA) has emerged as a promising molecular therapeutic tool for targeted cancer treatment. However, systemically administered siRNA has demonstrated only limited success, due to limited delivery to targeted cells. There is a lack of a robust and versatile delivery system for cancer therapy. Recent developments in DNA nanotechnology have made programmable DNA nanoparticles (DNPs) a potent drug delivery platform. This study focuses on the development of a novel DNP-based siRNA delivery system to knockdown Bcl2 gene, as a targeted cancer therapeutic. Methods: Structural DNA technology was applied to design a library of DNPs with different sizes and shapes. Flow cytometry, confocal imaging, and electron microscopy were utilized to study the cellular internalization of DNPs. The efficacy of Bcl2 knockdown by DNP-siBcl2 and the resulting influence on cell growth and progression were assessed in cancer cells (in vitro) and in mice bearing corresponding tumor xenografts (in vivo). Results: DNPs of varying sizes (10-120 nm) and shapes (polyhedral or rod) were constructed using DNA origami techniques and successfully verified by agarose gel electrophoresis, atomic force microscopy, and transmission electron microscopy. The cell internalization capabilities of three DNPs including a tetrahedron (TET, diameter: 10 nm), a small rod (SR, 5x5x30 nm), and a large rod (BR, 10x10x120 nm) were examined. BR internalized with relatively higher efficiency and rate compared to TET and SR, and also demonstrated the most efficient knockdown of Bcl2. BR-siBcl2 demonstrated significant cell growth inhibition of DMS53 and H146 small cell lung cancer (SCLC) cell lines after 48hrs of treatment. A pilot study with BR-siBcl2 (1.25 mg/kg, iv) in mice bearing DMS53 tumor xenograft (n=3) slowed tumor growth compared with buffer control and naked siBcl2. Significant differences were observed in tumor volume by pairwise comparison between the two groups: Buffer vs DNP-BR-siBcl2 (p<0.001), and siBcl2 vs BR-siBcl2 (0.028), respectively. No toxicity was observed in lung, liver, kidney, heart, brain, or spleen. Conclusions: Our novel DNP formulations demonstrated substantial cellular internalization of siBcl2. Targeting Bcl2 and its downstream signaling intermediates reduced cellular growth. We validated the strategy of silencing of Bcl2 using DNPs in order to inhibit cancer progression in vivo. We believe that the DNPs and methodologies developed in this project will be applicable to knockdown of Bcl2 and other gene targets and may be applicable to future anti-cancer therapy. (This work is supported by NIH grant R21EB022828-01).

#188 Preventive effect of aerosolized bexarotene in three major subtypes of lung cancer: adenocarcinoma, squamous cell carcinoma and small cell lung cancer in mice. Qi Zhang,1 Jing Pan,3 Marker S. Miller,2 Ronald A. Lubet,2 Yian Wang,3 Ming You1, 1Medical College of Wisconsin, Milwaukee, WI; 2National Cancer Institute, Rockville, MD

Lung cancer is the leading cause of cancer-related deaths in the United States. The 5 year survival rate for lung cancer patients has remained a dismal 15% for the last several decades. The development of effective prophylactic agents that could prevent lung cancer could potentially reduce the incidence and mortality of pulmonary neoplasms. Bexarotene has exhibited inhibitory effects in preclinical in vivo models of mammary and lung tumorigenesis, has been approved for clinical use in the treatment of cutaneous T-cell lymphoma, and has shown efficacy in phase I/II trials of non-small cell lung cancer (NSCLC). Preclinical studies have demonstrated that it is highly effective in the prevention of all three major subtypes of lung cancer in mouse models: adenocarcinoma (AD), squamous cell carcinoma (SCC), and small cell lung cancer (SCLC). The major side effects of bexarotene when administered orally to rodents or human patients have been hypertriglyceridemia and hypercholesterolemia. Previous studies in a mouse model of lung AD have demonstrated that aerosol delivery of bexarotene through tracheal instillation exhibited potent chemopreventive activity similar to that observed following oral administration (59 to 74% reductions in lung tumor multiplicity). The significant decreases in tumor multiplicity and tumor load were achieved without hypertriglyceridemics that accompany oral bexarotene administration. In this study, aerosolized delivery of 10-30 mg/ml bexarotene showed a significant chemopreventive effect in all three major subtypes. In the N-nitroso-trichloroethylurea (NTCU) induced mouse SCC model, 1 week after the first dose of NTCU a dose dependent decrease in tumor formation was observed, with the highest dose causing 75% (p<0.001) and 42% (p<0.01) decreases in SCC tumor burden and the percentage of SCC tumors, respectively. Tumor load was decreased by 73% in A/Jp53 mouse AD model and by 41% in A/Jp53rb mouse SCLC model. Aerosol delivery of bexarotene had no effect on animal body weight and other signs of toxicity, and no effect on triglyceride and cholesterol level. Aerosolized bexarotene formulation was effective against all 3 major lung cancer cell types and would be a major advance achieving significant reductions in preventing lung cancer incidence in persons at high risk of lung cancer e.g. former or present smokers.

#189 Development of peptidomimetic inhibitors of the ERG gene fusion product in prostate cancer. Xiaojia Wang, The University of Michigan, Ann Arbor, MI.

Transcription factors play a key role in the development of diverse cancers, and therapeutically targeting them has remained a challenge. In prostate cancer, the gene encoding the transcription factor ERG is recurrently rearranged and plays a critical role in prostate oncogenesis. Here, we identified a series of peptides that interact specifically with the DNA binding domain of ERG. ERG inhibitory peptides and derived peptidomimetics (EIPs) bound with high affinity and specificity leading to proteolytic degradation of ERG protein. The EIPs attenuated ERG-mediated transcription, chromatin recruitment, protein-protein interactions, cell invasion, and tumor growth. Thus, peptidomimetic targeting of transcription factor fusion products may provide a promising therapeutic strategy for prostate cancer as well as other cancers.

#190 Identification of compound isolated from Beilschmiedia tsangii as a liver cancer specific NFR2 inhibitor. Yi Xiao Chen, Chih Chung Lai, Yi Ping Kuo, Hsuan Shuo Chang, Ih Sheng Chen, Chia-Hung Yen. Kaohsiung Medical Univ., Kaohsiung City, Taiwan.

Drug resistance is the main cause of cancer recurrence and a major obstacle to the success of anticancer therapy. NFR2, a pivotal transcription factor regulates antioxidant response and detoxification, has been shown to participate in the development of cancer drug resistance. Functional suppression of NFR2 rendered cancer cell more susceptible to anticancer treatments. Beilschmiedia tsangii Merr. (Lauraceae) is a medium-sized evergreen tree. It has been reported that Beilschmiedia extract showed a strong antioxidant activity. In continuation of our bioassay-guided study on this species, we tested the effects of 23 compounds isolated from the B. tsangii on NFR2 activity. We identified rel-(7R,8R,7′R,8′R)-3,4′,4′-dimethylene-dioxy-5,5′-dimethoxy-7,7′-epoxyglycan (BT04) significantly inhibited NFR2 activity in liver cancer cell (Huh7) with an IC50 value of 17 μM, but not in keratinocyte (HaCaT) cell. By contrast, luteolin, a known NFR2
inhibitor, suppressed NRF2 activity in both HuH7 cell and HacTa cell. Moreover, the mRNA level of NRF2 target genes, NQO1 and HO1, were significantly decreased in HuH7 upon BT04 treatment, while those NRF2 target genes remained unchanged in BT04-treated HacTa cell. A moderate cytotoxic effect of BT04 on HuH7 cell was also observed. Accordingly, our result suggested that BT04 can specifically inhibit NRF2 activity in liver cancer, which in turn indicated that BT04 could be a potential adjuvant to improve chemoresistance.

**#191 Double blockade of interacting CK2 and EGFR pathways by tumor-targeting nanoconjugates increases therapeutic efficacy against glioblastoma multiforme.** Julia Y. Ljubimova, Cedars-Sinai Medical Center, Los Angeles, CA.

Introduction: Glioblastoma multiforme (GBM) remains the deadliest brain tumor in adults, and is notorious for drug and radiation resistance. To inhibit GBMs more effectively, polymeric acid-based blood-brain barrier crossing nanoconjugates were synthesized that are delivered to the cytoplasm of cancer cells and specifically inhibit the master regulator serine/threonine protein kinase CK2 and the wild-type/mutated epidermal growth factor receptor (EGFR/EGFRVIll), which are overexpressed in gliomas according to The Cancer Genome Atlas (TGCAG) GBM database. Methods and Results: The used nanoconjugates are novel nanoatherapeutics where all moieties are covalently connected to poly(β-L-malic acid) (PMLA). Our biodegradable and non-toxic nanodrugs bind to the receptors enriched on tumor vasculature and cross the BBB by transcytosis. They specifically bind to cancer cells and after internalization exit to the tumor cell cytoplasm using pH-sensitive endosomal disruption unloading the covalently bound drug. Two xenograft mouse models bearing intracranial human GBMs from cell lines LN229 and U87MG that expressed both CK2 and EGFR were used. The knockdown of CK2α and EGFR/EGFRVIll suppressed their downstream prosurvival signaling. Treatment also markedly reduced the expression of programmed death-ligand 1 (PD-L1), a negative regulator of cytotoxic lymphocytes. Downregulation of CK2 and EGFR also caused suppression of heat shock protein 90 (Hsp90) co-chaperone Cdc37, which may inhibit the activity of key cellular kinases. Inhibition of either target was associated with downregulation of the other target as well, which may underlie efficacy of the dual nanoconjugate that is directed against both CK2 and EGFR. Importantly, the single nanodrugs, and especially the dual nanodrug, markedly suppressed the expression of cancer stem cell markers c-Myc, CD133, and nestin, which could contribute to the efficacy of these nanodrugs. In both tumor models, the dual targeting nanoconjugate significantly increased (up to 2-fold) animal survival compared with the control group. Conclusion: The versatile nanoconjugates developed in this study, with the ability of anti-cancer drug delivery across biobarriers and inhibition of key tumor regulators, offer a promising nanotherapeutic approach to treat GBMs and to potentially prevent drug resistance and retard the brain tumor recurrence. Support: NIH grants U01 CA151815, R01 CA136841, R01 CA188743, R01 CA209921, R01 EY013431.

**#192 Targeting stearyl CoA desaturase 1 (SCD1) in hepatobiliary carcinoma.** John Alton Copland,1 Laura A. Marlow,1 Ila Bok,1 James L. Miller,1 Kabir Mody,1 Lewis R. Roberts,2 Mark J. Truty,2 Tushar C. Patel1.

Inhibitors of SCD1 are in clinical development for the treatment of non-alcoholic fatty liver disease and cancer. In cancer, the upregulation of SCD1 reduces the rate of fatty acid oxidation and promotes fatty acid synthesis and esterification. We hypothesize that targeting SCD1 may be an effective approach to combat HCC survival. Targeting these may prove beneficial because such changes contribute to the chemoresistance associated with HCC. In so doing, we evaluated a novel lead SCD1 inhibitor in HCC. Methods: Paraffin embedded patient HCC tissues were examined for SCD1 expression. Using combined computational and synthetic chemistry approaches, we synthesized four novel specific SCD1 inhibitors with SSI-4 being the lead SCD1 inhibitor. HCC cell lines were examined using proliferation assays for response to SSI-4. 1C50 concentrations for blocking SCD1 enzyme activity was determined. Blood half-life and bioavailability of single dose SSI-4 was determined. Mechanisms of action of SCD1 were examined that enzyme activity was determined. Blood half-life and bioavailability of single dose SSI-4 was determined. Single dose oral gavage SSI-4 demonstrated a half-life of ~4 hours and excellent oral bioavailability. SSI-4 was well tolerated with long-term daily dosing. SSI-4 treatment of HCC cells and tumors led to endoplasmic reticulum (ER) stress followed by apoptotic cell death. Single agent SSI-4 demonstrated antitumor activity in HCC PDX mouse models with suppression of ER stress regulated proteins. Conclusions: Targeting a novel lipid metabolic pathway in HCC may provide effective therapy for aggressive HCC.

MPS1 (also known as TTK), is a dual-specificity protein kinase and one of the main components of the spindle assembly checkpoint. Cancer cells heavily rely on MPS1 to cope with aneuploidy resulting from aberrant numbers of chromosomes and MPS1 has been found to be upregulated in a large number of tumor types. Extensive work by us and other groups has shown that MPS1 inhibitors are effective against a variety of cancers, particularly when used in combination with other drugs, for example, tubulin-targeting agents. We recently reported the structure-based design and discovery of a series of pyrido[3,4-d]pyrimidines (CCT289346). Our preclinical candidate. CCT289346 shows excellent potency, kinase selectivity, and ADME properties including stability in human liver microsomes. The compound has been produced on a kilogram scale and is currently undergoing preclinical development. We will discuss our design approach and hypotheses leading to the discovery of CCT289346 and disclose in vivo efficacy data. References 1. Innocenti P et al. Rapid Discovery of Pyrido[3,4-d]pyrimidine Inhibitors of Monopolar Spindle Kinase 1 (MPS1) Using a Structure-Based Hybridization Approach. Journal of Medicinal Chemistry. 2016; 59(8):3671-88.

**#194 Effective targeting of MYC expression with a novel nucleic acid binding (G4-quadruplex) small molecule coupled with HDAC inhibition synergizes to limit myeloma growth.** Snehal M. Gaikwad,1 David R. Calabrese,2 Elena C. Leon,1 John K. Simmons,1 Shuling Zhang,1 Aleksandra Michalowski,1 Sayeh Gorjipard,1 Zaw Phyo,1 Daniel Connors,1 John S. Schneekloth,2 Beverly A. Mock,3,CCR, NCI, NIH, Bethesda, MD; 3CCR, NCI, NIH, Frederick, MD.

MYC is deregulated in many malignancies and its aberrant expression is associated with tumorigenesis and poor patient survival. Inhibitors of this transcriptional activator have shown limited success in preclinical development. Here we report the design and discovery of a novel small molecule microarray approach to treat GBMs and to potentially prevent drug resistance and retard the brain tumor recurrence. Support: NIH grants U01 CA151815, R01 CA136841, R01 CA188743, R01 CA209921, R01 EY013431.
transcriptional silencing of oncogenic MYC both in vitro and in vivo. Furthermore, synergistic tumor cell killing was achieved when the MYC G4 inhibitor was coupled with HDAC inhibition.

#195 Evaluation of the cell surface binding of phycocyanin and associated mechanisms causing cell death in prostate cancer cells. Paramjot Kaur,1 Sivanesan Dhandayuthapani,1 Shona Joseph,2 Syed Hussain,2 Miroslav Gantar,3 Appu Rathinavelu1.1 Rambough Goodwin Institute for Cancer Research, Nova Southeastern University, FL; 2Halmos College of Natural Sciences and Oceanography, Nova Southeastern University, Fort Lauderdale, FL; 3Florida International University, Miami, FL.

Plant and microbial metabolites are constantly explored to identify novel therapeutics with promising potential for treating diseases such as cancer. Marine-derived compounds are also tapped frequently for their efficacy in treating cancers and are used in mono and combination therapies. The potential of cyanobacteria (blue-green algae) as the source of anticancer agents has been explored for many decades and, as a result of continuing efforts, several compounds have emerged as templates for the development of new anticancer drugs from these microorganisms. The C-phycocyanin (C-PC) tested in our experiments was found in the cyanobacteria Limothrix sp., strain 37-2-1, which is found abundantly in Florida’s Everglades. In our previous studies, this fluorescent compound was found to potentiate the cytotoxic effects of Taxol and Topotecan. In LNCaP prostate cancer cells, C-PC was able to induce apoptosis by itself through activation of the apoptotic pathway and completing DNA fragmentation. It was originally anticipated that C-PC might penetrate the cell membrane to induce mitochondrial damage and trigger the apoptotic process through activations of caspases. In order to verify this possibility, experiments were conducted to determine the uptake of C-PC using LNCaP cells. When we incubated the cells with C-PC at the concentrations of 250 and 500 µg/mL for 12 hrs and assessed the cellular uptake by capturing the fluorescence signals at the wavelength of 605 nm, using a fluorescence microscope, the signals were observed only with the periphery of the cells. Furthermore, with subsequent washes using PBS, the fluorescence signal that was seen to be associated with the plasma membrane was reduced gradually and was removed completely after the 3rd wash without any signs of penetration into the cytoplasm. The binding of C-PC to the plasma membrane was very transient and quickly dissociated at 37°C. So far, our results suggest that the cytotoxicity towards LNCaP cells might have been triggered by the binding of C-PC to the cell membrane receptors such as FasR, TRAIL-R, TNFR, which may be linked to the mediators of extrinsic and intrinsic apoptotic signals. Hence, our findings are significant for explaining some of the apoptotic events triggered by C-PC. However, additional studies are required to identify the actual receptors involved in triggering the pathway. (The support from the Royal Dames of Cancer Research Inc., Ft. Lauderdale, Florida is gratefully acknowledged).

#197 Anti-cancer activity of extract from the Jamaican round-leaf yellow yam (RLY2) (Dioscorea cayenensis). Sashay-Gay A. Wright,1 Wesley G. Gray,2 Helen Asemota1.1 University of the West Indies, Mona Campus, Kingston, Jamaica; 2Southern University and A&M College, Baton Rouge, LA.

The Jamaican Round-Leaf yellow yams (RLY2), Dioscorea cayenensis, are edible tubers, bulbils or rhizomes that are of considerable economic value and possess several health benefits. These RLY2 are a rich source of antioxidants, vitamins and phytochemicals. In addition to its nutritional value, the Jamaican populace regards RLY2 as an herbal medicine useful in treatment of diabetes mellitus, hypertension and certain kind of cancers. Chemical analysis of RLY2 revealed the presence of a myriad of bioactive ingredi- ents that are likely to be lost due to the method of preparation for consumption. Thus, we hypothesized that mild extraction of RLY2 will preserve the bioactive analytes that give RLY2 its anti-cancer property. To test this hypothesis, different ethanol extracts of RLY2 were prepared, and their bioactivity demonstrated in two models of prostate cancer. The present study demonstrates dosage and time-dependence inhibition in both the androgen sensitive LNCaP and androgen insensitive DU-145 prostate cancer cell lines. We observed that DU-145 was three-times more sensitive to RLY2 ethanol than LNCaP. Growth of LNCaP for 3-days with varying concentration of RLY2 ethanol extract resulted in an IC50 of 750 ppm (95% C.I. 726-791ppm), whereas DU-145 resulted in an IC 50 of 250 ppm (95% C.I. 236-281ppm). The maximum growth inhibition by RLY2 extract occurs within twenty-four hours for both LNCaP and DU-145 with significant changes after 5-days. To determine the mechanism of toxicity by RLY2, we incubated both LNCaP and DU-145 with RLY2 for 0-24h and prepared cells for flow cytometer analysis. The effect of RLY2 on cell cycle and degree of apoptosis will be discussed. Our data indicated that the ethanol extract of RLY2 was more sensitive toward androgen-insensitive prostate cancer. Thus, this study suggests that RLY2 contain bioactive chemical that may be used in prostate adenocarcinoma represented by the DU-145 phenotype.

#198 Low molecular weight pyrrolobenzodiazepine (PBD) monomers have potent cytotoxicity in haematological tumour cells. David B. Corcoran,1 Thomas Lewis,1 Amitr Varsha,1 Chris Pepper,2 David E. Thurston,1 Khondaker Miraz Rahman1.1 King’s College London, London, United Kingdom; 2University of Cardiff, Cardiff, United Kingdom.

The pyrrolo[2,1-c][1,4]benzodiazepines (PBDs) have long been of interest as potential chemotherapeutic agents due to their ability to form covalent adducts within the minor groove of the DNA helix. The most effective synthetic modifications to PBD cores have involved the conjugation of two DNA-interacting moieties via their C8/C8’-positions to create PBD dimers capable of covalently cross-linking duplex DNA which improves cytotoxicity. Research to date has focused on adding substituents to the C8-position of the PBD core to improve DNA-interaction and cytotoxicity. All of these approaches tend to increase the molecular weight of the compounds, although this has not prevented their successful development to the clinic, either as stand-alone agents (e.g., SJG-136) or as a component of Antibody-Drug Conjugates (ADCs) (e.g., SGN-CD33A). During a structure-activity relationship (SAR) study, we embarked on a “molecular pruning” exercise to sequentially reduce the length and bulk of the C8-substituent of a PBD monomer expecting the cytotoxicity to reduce with a decrease in length/bulk, and to establish the minimal pharmacophore. Surprisingly, we found that reducing the length of the C8-substituent maintained cytotoxicity and in some cases enhanced it. A 20-member library of short C8-substituted PBD monomers has been synthesized featuring C8-substituents of various chemical composition and length, with some containing amine substituents. Cytotoxicity evaluation in several tumour cell lines (e.g., primary CLL, JJJN-3 and MDA-MB-231) was carried out, and low nanomolar to high picomolar IC50 values were obtained for several library members including DC-1-194 (IC50 = 4.2nM in CLL, and 0.79nM in MDA MB 231), DC-1-255 (IC50 = 9.5nM in CLL, and 1.1nM in MDA MB 231), DC-1-253 (IC50 = 8.4nM in CLL, and 10nM in JJJN-3) and DC-1-275 (IC50 = 7.6nM in CLL, and 9.6nM in JJJN-3). Remarkably, many of these more-active compounds had very short C8-substituents. HPLC and FRET based DNA binding studies were also carried out, in order to confirm the capacity of these molecules to form adducts with DNA. The observations reported here are significant, as they add to an evolving understanding of the SAR of PBD monomer structures. The results presented here may also have significance for the future development of PBD-based therapeutic agents where there may be advantages to working with lower molecular weight molecules.
Silibinin suppresses bladder cancer through down-regulation of actin cytoskeleton and PI3K/Akt signaling pathways. Mitsuhiro Imai-Sumida,1 Takeshi Chiyomaru,2 Shahana Majid,3 Priyanka Kulkarni,4 Pritha Dasgupta,1 Sharanjot Saini,1 Taku Kato,5 Shiikgakta Mekawa,1 Yutaka Hashimoto,1 Marisa Shina,6 Guoren Deng,7 Varahram Shahryari,8 Hannah Nip,9 Rajvir Dahiya,9,2 Srinivas Tanaka,7 Soichiro Yamamura,7,9visited VA Medical Ctr., San Francisco, CA;2National Hospital Organization Kagoshima Medical Center, Kagoshima, Japan.

Silibinin is the major active constituent of silymarin, an extract of milk thistle seeds. Silibinin has been shown to have significant anti-cancer effects in a variety of malignancies. However, the molecular mechanisms of silibinin action in bladder cancer have not been studied extensively. In the present study, we found that silibinin (10 μM) significantly suppressed proliferation and invasion of T24 and UM-UC-3 human bladder cancer cells. In this study, we investigated the molecular mechanisms underlying these effects of silibinin. Our results showed that silibinin down-regulates actin cytoskeleton-related Ras-Rac-PAK1 pathways and the phosphatidylinositol 3-kinase (PI3K)/Akt signaling pathway in these bladder cancer cell lines. These pathways were found to promote cellular transformation and cancer development and have crosstalk through Ras cascades. We investigated the role of silibinin on Ras, and found that silibinin suppresses levels of trimethylated histone H3 lysine 4 and acetylated H3 at the K-RAS promoter. We also found that silibinin downregulates long non-coding RNAs: HOTAIR and ZFAS1, which are known to play roles as oncogenic IncRNAs in various cancers. This study shows that silibinin exerts anti-cancer effects through down-regulation of the actin cytoskeleton and PI3K/Akt pathways and thus suppresses the development and progression of bladder cancer.

Long lasting inhibition of TGF-β Receptor Type 1 inhibitor (TGF-β R1) for treatment of pancreatic cancer. Cristian Rodriguez-Aguayo, Emine Bayraktar,6 Hafiz Shen,4 Gabriel Lopez-Berestein1.1 asso-MD Anderson Cancer Ctr., Houston, TX; 2The Methodist Hospital Research Institute, Houston, TX.

Pancreatic cancer stroma is a high component of total tumor mass and contains activators and activators of fibro-genesis such as Transforming growth factor-β (TGF-β) are abundantly secreted by pancreatic stellate cells (PSCs) to the tumor microenviroment. Ablation of TGF-β signaling pathways are associated with many human diseases, including bone diseases, immune-suppression, fibrosis, cancer progression and metastasis. Hyperglycemia is a key feature of diabetes and is also the cause of severe complications of diabetes, including nephropathy, retinopathy, and foot ulcers. Many studies have demonstrated that diabetes is associated with hyperglycemia and is the cause of severe complications of diabetes, including nephropathy, retinopathy, and foot ulcers. Many studies have demonstrated that hyperglycemia is also associated with the development of age-related macular degeneration, diabetic kidney disease, and cardiovascular disease. Moreover, hyperglycemia is also associated with the development of age-related macular degeneration, diabetic kidney disease, and cardiovascular disease. Moreover, hyperglycemia is also associated with the development of age-related macular degeneration, diabetic kidney disease, and cardiovascular disease. For the purpose of investigating the potential of automation and high throughput mass spectrometry imaging, we have combined a desorption electrospray ionisation (DESI) MS system with a robotic slide loader. The analysis of tissue sections on multiple slides could allow, for example, large patient cohorts to be analysed with almost no input from the operator. Here we present another use of such technology: the mapping and visualisation of tissue and molecular signals that were only present on the boundary between the hypoxic and proliferating regions in excised tissue. Further to these identified regions was the discovery of molecular signals that were clearly correlated with hypoxia and proliferation, indicating that mass spectrometry imaging provides a powerful tool for the identification of cancer cell-derived VOCs from patient exhaled breath.

#204 In vitro metabolomics of mesothelioma: Challenges and outcomes.
Sabrina Lagniau,1 Kevin Lamote,1 Lore Vandermeersch,1 Herman Van Langenhove,1 Jan P. van Meerbeeck,2 Karim Y. Vermaelen1.1Ghent University, Ghent, Belgium; 2Antwerp University Hospital, Edegem, Belgium.

Introduction: Due to the highly malignant nature of mesothelioma (MPM) it is likely to improve outcome in affected patients. From our previous studies (MeSOBreath 1 & 2) we developed a screening tool in which volatile organic compounds (VOCs) in breath allowed discrimination of MPM patients from at risk controls. However it is yet not clear which VOCs arise from the neoplastic cells themselves or from the host response. Identifying the cancer cell-specific VOCs will allow us to design breath tests which are currently under investigation. Faster and automated mass spectrometry imaging allows whole tissues to be chemically mapped in three dimensions in a few hours providing insights into tumour heterogeneity.

Introduction: Genomic analyses have yielded a tremendous amount of data on the genetic changes in lung cancers, but translating these experiments into actionable information benefiting lung squamous cell carcinoma (SCLC) patients has proven more difficult. Studies by the NCI Clinical Proteomic Tumor Analysis Consortium (CPTAC), our group, and others have demonstrated that gene protein and expression show only moderate correlation, demonstrating limitations in explaining phenotypic changes from genomics alone. These findings indicate a clear need for integrative proteogenomics to better understand tumor biology, especially in a complex disease like SCLC. Experimental: We have assembled a comprehensive proteogenomic dataset including DNA copy number (Affymetrix CytoScan HD Assay), targeted exome sequencing (Agilent Comprehensive Cancer Panel), RNA-sequencing (Illumina NextSeq), and shotgun proteomics (Q Exactive LC-MS/MS) on 116 surgically resected SCLC tumor samples with extensive clinical and follow up data. Results: We have identified 6584 high confidence proteins from preliminary proteomic analysis. After quality control filtering, we utilized 5562 gene-protein pairs for further analysis. Clustering of patient RNA expression in this patient cohort has been unable to fully reproduce the molecular classification previously published for SCLC. Furthermore, proteomic results indicate yet another potential classification strategy selecting patient subgroups that differ at protein level. We observed a 0.29 median Spearman’s correlation of 5562 gene-protein pairs. There were 2781 highly correlated gene-protein pairs (greater than median) and 2781 poorly correlated gene-protein pairs (less than median) including 773 anti-correlated gene-protein pairs (less than 0). We hypothesized that poorly correlated gene-protein pairs could functionally be related in a pathway-dependent manner. Enrichment analysis of poorly correlated proteins identified pathways related to mRNA processing, growth factor signaling (EGFR, FGFR), and nonsense-mediated decay (NMD). Interestingly, there were 9 frequently mutated SCLC genes in the low correlation gene-protein pairs but only 3 in the highly correlated pairs. We found three distinct patient subgroups by clustering poorly correlated proteins. Analysis of these subgroups showed differentially expressed pathways related to mRNA processing, ubiquitination, and NMD. Conclusion: Differential modulation of the proteome outside of genomic regulation may suggest important regulatory mechanisms in cancer and give new insights into treating SCLC. Analysis of poorly correlated gene-protein pairs suggests certain pathways are dysregulated in cancer, and ongoing DNA analysis and future analyses involving miRNAs, RNA-binding proteins, and the ubiquitin proteome system will help elucidate our preliminary findings.

Introduction: Genomic analyses have yielded a tremendous amount of knowledge on the genetic changes in lung cancers, but translating this information into actionable data benefitting patients has proven difficult. The integration of proteomic analyses with genomics and gene expression profiling allows a more detailed description of the biological processes, thus improving our understanding of cancer phenotypes. These insights can potentially be used for better classification and help to guide patient selection for targeted therapies. Experimental: We analyzed 116 surgically resected squamous cell lung carcinoma samples for copy-number alterations, gene expression profiling, targeted exome-sequencing and global proteomic profiling. The cohort consisted of mostly early stage tumors (83% Stage I or II) with complete follow-up (median 58 months). Copy number status was analyzed using the Affymetrix CytoScan array. DNA mutation status was assessed using a customized version of the Agilent Comprehensive Cancer Panel for targeted sequencing, and gene expression profiling was carried out by RNA-sequencing. Proteomic analysis was performed using TMT labeling, 12- fraction bRPLC separation and LC-MS/MS analysis with a Thermo Q-Exactive mass spectrometer. Database searches were performed using MassLynx and in house scripts. Results: We identified 6584 high confidence proteins from preliminary proteomic analysis. After quality control filtering, we utilized 5562 gene-protein pairs for further analysis. Enrichment analysis of poorly correlated proteins identified pathways related to mRNA processing, growth factor signaling (EGFR, FGFR), and nonsense-mediated decay (NMD). Interestingly, there were 9 frequently mutated SCLC genes in the low correlation gene-protein pairs but only 3 in the highly correlated pairs. We found three distinct patient subgroups by clustering poorly correlated proteins. Analysis of these subgroups showed differentially expressed pathways related to mRNA processing, ubiquitination, and NMD. Conclusion: Differential modulation of the proteome outside of genomic regulation may suggest important regulatory mechanisms in cancer and give new insights into treating SCLC. Analysis of poorly correlated gene-protein pairs suggests certain pathways are dysregulated in cancer, and ongoing DNA analysis and future analyses involving miRNAs, RNA-binding proteins, and the ubiquitin proteome system will help elucidate our preliminary findings.
performed using multiple search engines against RefSeq version 78, and summarized using IDPicker 3. Results: The non-redundant protein inventory consisted of more than 6,000 protein groups with a protein FDR <5%. Tumors were classified according to well established gene expression criteria into 4 classes: Classical, Basal, Primitive and Secretory. At the protein level, the Classical subtype was associated with xenobiotic and energy metabolism; the Basal subtype with defense responses and extracellular matrix changes; the Primitive subtype with nucleic acid metabolism; and the Secretory subtype with p38 signaling. These findings confirm and expand on previous mRNA expression studies of squamous cell lung carcinoma. Proteomics-based classification identified two sub-categories within the Classical subtype, which were characterized by inflammatory and stress response signaling. Within this group, patients with high expression of inflammation-associated proteins had better cancer-specific survival than those with low expression ($p=0.04$, Log-rank test). Targeted exome sequencing of 154 cancer-associated genes revealed frequent mutations in TP53, CDKN2A, NFE2L2, and other genes. Proteomic expression of genes located in amplified chromosomal regions was used to identify driver genes in squamous cell lung carcinoma. Conclusion: Our results provide new biological insights from the addition of protein measurements to genomic datasets that have the potential to improve classification. The data suggest that proteins involved in immune responses are important for the biological behavior and outcome of the Classical subtype in squamous cell lung carcinoma.

#207 Reliable identification of mutations in bottom-up proteomics. Miroslav Hruska, Lakshman Varanasi, Jiri Voller, Petr Drubak, Marian Hajducz, Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic.

Knowledge of missense mutations is of significant biological importance as it provides valuable insights into alterations of phenotype. While identification of reference proteins is routinely performed in proteomics, identification of mutations remains still fairly uncommon. Well-established methods for reference peptides are generally insufficient for altered ones, e.g., utilizing mutant-augmented database search usually results in inadmissible proportion of false positives. This undesirable situation is, however, rather natural consequence of peptide fragmentation, its computational modelling and evaluation of their correspondence. Often, there are many peptides having the same or similar agreement with acquired spectrum, thereby preventing agreement-based decision. These situations happen frequently in identification of mutant peptides (e.g., homologous peptides with PTMs, semi-specific peptides), therefore their reliable identification requires additional treatment. To deeper understand properties of identification, we have formally studied generalized version of the identification problem and derived its optimal solution under particular assumptions. In proteomics, the selection of optimal solution can be always found in finite time; moreover, the strategy is straightforward to implement, enables parallelization and provides guarantees over claimed interpretations. The solution utilizes almost exclusively spectral data of product ions without additional LC/MS information. In practice, however, it is beneficial to employ precursor isotopic distribution analysis for correction of non-monoisotopic selection of precursor as that would otherwise systematically result in artefacts. The behavior of proposed method was validated in a variety of scenarios that selection of precursor as that would otherwise systematically result in artefacts. In practice, however, it is beneficial to employ precursor isotopic distribution analysis for correction of non-monoisotopic selection of precursor as that would otherwise systematically result in artefacts. The behavior of proposed method was validated in a variety of scenarios that would otherwise systematically result in artefacts.

As part of the Clinical Proteomic Tumor Analysis Consortium (CPTAC), we have recently published the first large-scale proteomic and phosphoproteomic analysis of high-grade serous ovarian tumors. We observed that phosphorylation status was an excellent indicator of pathway activity and could discriminate between patient survival times. This dataset covers tumor samples from 69 patients with deep phosphoproteome depth (>20,000 phosphopeptides confidently identified). Our continuing analysis of this dataset, reported here, has revealed that the correlation between kinase protein abundance and abundance of phosphorylated target peptides is very low, indicating that kinase abundance alone cannot explain phosphorylation status overall. However, highly correlated kinase-substrate pairs are significantly more likely to be true relationships (from existing knowledge), demonstrating that this method could be used to predict novel kinase targets in some cases. Using this approach we predicted novel kinase-target relationships and constructed a kinase activity network of ovarian cancer. To better analyze cancer-relevant pathway activity we developed a novel approach that does not depend on tissue antigenicity or nucleic acid preservation could increase the diagnostic value of decalcified bone samples. We assessed the effects of decalcification on proteomic analysis of tumor tissue. We also quantified 27 therapeutically-relevant proteins in decalcified bone metastases of cancer patients using mass spectrometry-based proteomic analysis. Methods: To examine the effects of decalcification on protein quantification, we used 3 non-bone tissue specimens from lung adenocarcinoma, squamous cell carcinoma, and colon medullary carcinoma. Non-bone tumor tissue was expected to perform similarly in proteomic analyses to bone tissue, which was not available. Tissue specimens were processed without decalcification and with hydrochloric acid-based Decal-Stat® decalcification solution for 1, 3, 12, and 24 hours prior to paraffin embedding, tissue sectioning, and mass spectrometric analysis. Proteomic analysis was also performed on 26 previously decalcified biopsies of metastatic bone lesions from patients with cancers of the lung (n=7), breast (n=7), stomach (n=3) and 8 other indications. Archived tumor tissue was microdissected and solubilized to tryptic peptides. Target proteins in each liquefied tumor sample were quantitated in triplicate with a multiplexed, selected reaction monitoring mass spectrometry assay. Results: In the bone samples, the method we developed for quantitative analysis of phosphorylated forms of total protein (range: 19.2 - 24.1 μg) and of all 20 protein biomarkers detected. The 26 bone metastases expressed 20 of the 27 protein targets tested. The 7 bone samples from lung cancer patients, 5 expressed EGF receptor and 5 expressed hENT1 protein (a marker of response to gemcitabine). A metastatic bone tumor from a breast cancer patient expressed hENT1 (129 amol/μg) and overexpressed HER2 (5750 amol/μg; this exceeds a level previously correlated with increased survival in trastuzumab-treated patients). Bone lesions from prostate & gynecologic cancers overexpressed AR, hENT1, EGFR and TOP1 proteins. Conclusions: A commonly used decalcifying solution had no discernable effects on proteomic quantification of biomarker proteins in archived tumor samples. Targeted proteomics can quantify an entire panel of therapeutically-relevant proteins from a single decalcified bone biopsy specimen. Proteomic analysis of bone metastases upon diagnosis of metastasis or at relapse could inform treatment decisions, particularly in patients who have disease progression only in bone lesions or whose bone biomarkers are discordant from those of the primary tumor.

A method was developed that allows the evaluation of complex biological processes from mass spectrometry of human serum samples. Applying gene expression of inflammation-associated proteins had better cancer-specific survival; the Classical subtype was associated with xenobiotic and energy metabolism; the Basal subtype with defense responses and extracellular matrix changes; the Primitive subtype with nucleic acid metabolism; and the Secretory subtype with p38 signaling. These findings confirm and expand on previous mRNA expression studies of squamous cell lung carcinoma. Additionally, the analysis was performed on in-house samples with RNA-Seq data available (HCT116), giving specificity obtained was 0.81 and 0.99 respectively. Indirect validation was, at first, natorial peptide library of 400 peptides (all coded amino acids in 12. and 13. position). For direct validation, synthetic combinatorial peptide library of 400 peptides (all coded amino acids in 12. and 13. position) was used. The behavior of proposed method was validated in a variety of scenarios that would otherwise systematically result in artefacts. In practice, however, it is beneficial to employ precursor isotopic distribution analysis for correction of non-monoisotopic selection of precursor as that would otherwise systematically result in artefacts. The biological behavior and outcome of the Classical subtype in squamous cell lung carcinoma.

#209 Proteomic analysis of therapeutic biomarkers in decalcified bone metastases. Fabiola Cecchi, Shankar Sellappan, Sarit Schwartz, Chao Gong, Marlene Darfler, Kerry Scott, Steven W. Mamus, Mike Emmert-Buck, Todd Hemmingsworth, Nites, Elliot City, MD; NutriOmicx, Rockville, MD; Cancer Center of Sarasota-Manatee, Sarasota, FL; NIH, Bethesda, MD.

Introduction: Theralogies we developed that allows the evaluation of complex biological processes from mass spectrometry of human serum samples. Applying gene expression of inflammation-associated proteins had better cancer-specific survival; the Classical subtype was associated with xenobiotic and energy metabolism; the Basal subtype with defense responses and extracellular matrix changes; the Primitive subtype with nucleic acid metabolism; and the Secretory subtype with p38 signaling. These findings confirm and expand on previous mRNA expression studies of squamous cell lung carcinoma. Indirect validation was, at first, natorial peptide library of 400 peptides (all coded amino acids in 12. and 13. position) was used. The behavior of proposed method was validated in a variety of scenarios that would otherwise systematically result in artefacts. In practice, however, it is beneficial to employ precursor isotopic distribution analysis for correction of non-monoisotopic selection of precursor as that would otherwise systematically result in artefacts. The biological behavior and outcome of the Classical subtype in squamous cell lung carcinoma.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 53
set enrichment analysis ideas to matched protein expression data from a panel of 1129 proteins and deep MALDI mass spectral data from a set of 49 human serum samples with lung cancer (n=45) or non-cancer (n=4), subsets of mass spectral features associated with selected biological functions were identified. Biological functions included acute response, complement system, immune system and the top 100 most significant hits were assigned using the intersection of gene ontologies and the protein panel. Using mass spectral data collected from an independent NSCLC sample cohort (n=85) from patients treated with targeted therapy, principal component analysis was used to derive scoring functions (combinations of the feature subsets) for each biological class. These scoring functions were validated in an independent NSCLC sample (n=12) treated with targeted therapy. The scoring functions can be applied to mass spectra obtained from any human serum sample to generate scores associated with individual biological processes. We have developed scoring functions for several biological processes. Acute response score was associated with outcome in Cox proportional hazard analysis in several independent patient cohorts across multiple therapies and indications, including lung cancer, as mentioned, and ovarian cancer (n=165) treated with platinum doublets following surgery. Choice of a single cutoff allowed stratification of patients into groups with significantly better or worse outcome. In a cohort of nivolumab treated NSCLC patients (n=67) with available longitudinal samples, outcome was also found to depend on changes in scores during therapy. Interestingly, while the distributions of scores on restaging were quite different across multiple tumor classification scores for other biological functions, such as wound healing, varied considerably. This may reflect differences in relative importance of individual biological functions between tumor types. A scoring system based on biological functional categories has a wide range of uses that could be tested and applied in a clinical setting. Currently, tests that measure a single biomarker for monitoring a particular disease have questionable utility and limit the usefulness to the clinician and patient treatment decision making. A tool that measures the activity of a complex biological process could be useful in deciding when an intervention is needed (screening), or for monitoring the effects during therapy.

The next generation of molecular cancer therapeutics will target pivotal protein-protein interaction interfaces participating in immune cell receptor signaling, oncoproteins, and suppressor genes. We have created a wholly novel technology “protein painting” for the rapid direct sequencing of hidden native protein-protein interaction hot spots. Our technology, employs previously unexplored small molecule (12 Å) aryl hydrocarbon dyes or “paints” to cut out, and MS sequence, only the hidden unmodified contact interfaces between two or more interacting native proteins. Novel Technology: Paint chemistries have extremely high affinities (rapid on-rates, and very slow off-rates that are ten to 100 times higher than most protein-protein interactions). When mixed with a native pre-formed protein complex for only 5 minutes at physiologic pH and salinity, the paints non-covalently coat all external sites on the protein without altering the 3D conformation of the complex, but cannot gain access to the solvent inaccessible hidden protein-protein interaction domains. Each paint molecule spans less than 3 amino acids, and has high affinity for protease cleavage consensus sites. Following painting, the proteins are dissociated. This leaves the paint molecules coating surfaces not participating in the interface. Following dissociation, the proteins are linearized, digested with trypsin, and sequenced by standard MS. The paint molecules remain non-covalently bound after the proteins are denatured. Trypsin will not cleave the regions of the protein that are “painted”. Following proteinolysis peptides emerging from MS will be generated exclusively from the unmodified opposing sites where the proteins were in intimate contact. Results: Protein Painting identified hot spot domains between PD-L1:PD-1, including two surface interface regions that are separated in the linear sequence but adjacent in the 3D structure. We created novel cyclized multivalent inhibitors that block both sides of the PD-L1: PD-1 interface and markedly suppress cell-cell binding and abolished downstream signaling through this complex in cultured tumor cell immune cell interactions. A very high correlation (p<0.0001) was found for known contact points predicted by crystal structure, with a 97% specificity for true positive hits: 95% agreement with Robetta prediction software for known complexes. Protein painting outperforms (425%) hydrogen deuterium exchange and cross linking for number of positive hits and % true positive hits. Conclusions: Protein painting is a new tool to identify highly specific drug targets located within protein interaction interfaces, yielding inhibitors that abolish protein signaling relevant to cancer immunotherapy.

The receptor tyrosine kinase c-ErbB2 is amplified in breast and ovarian cancer. The linear pathways through which signals by c-ErbB2 are transduced is well known. However, second generation questions that address spatial aspects of signaling remain. To address this, we have undertaken a mass spectrometry approach to identify phosphoproteins. We have used two tyrosine kinase inhibitors, Lapatinib and CP724714, that inhibit phosphorylation of c-ErbB2 to identify phosphoproteins. SKOV-3, an ovarian cancer cell line that endogenously overexpresses c-ErbB2 was grown in culture without serum for 72 hrs. Cells were then stimulated in the presence or absence of inhibitor with EGF (100ng/ml) as a ligand for 60 mins. Subsequently, cells were lysed and evaluated by western blotting with anti-phosphotyrosine antibody (4G10). Following stimulation of cells with EGF, maximal phosphorylation of c-ErbB2 was observed at 60 minutes. Lapatinib (10μM) and CP724714 (15μM) completely inhibited phosphorylation of c-ErbB2, which was confirmed by immunoprecipitation. This was further confirmed by the inhibition of downstream effectors (Erk1/2, Akt). Lapatinib (10 μM) also completely inhibited phosphorylation of EGFR while CP724714 (15μM) only inhibited partially. Cellular lysates were prepared from quiescent cells (grown without serum), after stimulation with EGF in the presence or absence of inhibitors. Purified phosphoproteins from all three samples following digestion with trypsin were subjected to mass spectrometry (Nano LC ESI MS/MS). We identified totally 62 phosphoproteins. Twenty seven phosphoproteins were observed in all the 3 samples while 17 phosphoproteins were identified both in the EGF stimulated and lapatinib treated samples. Eighteen unique phosphoproteins were observed only in the EGF stimulated sample suggesting that they are specific to signaling by c-ErbB2. The novel phosphoproteins included the proteins that participate in carbohydrate metabolism, cytoskeleton, cell migration and proliferation. We have evaluated two phosphoproteins, LAP1-1 and Aldose reductase that has not been previously described following phosphorylation of c-ErbB2. LAP1-1 is an oncogene and is located as the same arm 17q21 as c-ErbB2. It was not expressed in the normal ovary or fallopian tube. However, it was over-expressed in 17% of tumours (n=85) from patients with ovarian cancer. c-ErbB2 was not expressed in tumours that expressed LAP1-1. Aldose reductase is a cytosolic NADPH dependent oxidoreductase that catalyzes the reduction of glucose to sorbitol, the first step in polyol pathway of glucose metabolism. The activity of aldose reductase in reducing NADPH as a substrate was significantly higher in lysates from EGF stimulated as compared to the starved cells. Identification of phosphoproteins by using mass spectrometry is promising in identifying novel substrates and pathways following phosphorylation of c-ErbB2.

**#213 Integrated proteogenomic analysis of cancer}
57 ± 13 years. Protein and RNA were extracted using the Illustra triplePreP kit, which isolates DNA from the same cells as well. Quantitative global proteomics and phosphoproteomics analyses were performed using isotopic TMT 6-plex labeling with the "universal reference" strategy and IMAC enrichment of phosphopeptides. Mass spectrometry data were acquired using a Q-Exactive instrument and the "universal reference" strategy and IMAC enrichment of phosphopeptides. The views expressed in this article are those of the author and do not been previously reported (e.g., on RANBP2), other phosphosites appeared to be basal-enriched and another being luminal-enriched. We also observed a sub-cluster of mixed subtypes. Differential protein expression analyses between the two primary clusters confirmed known markers (e.g., overexpression of KRT8/KRT18 in luminal-enriched cluster). The luminal-enriched cluster is primarily CA with post-menopausal status. A similar search of the phosphoproteomic data yielded quantitation of >12500 phosphopeptides. Unsupervised clustering of the phosphoproteins resulted in four primary clusters, with one being basal-enriched and another being luminal-enriched. We also observed >50 overexpressed phosphopeptides. While some of these phosphoproteins have been previously characterized, on RANBP2 others novel (e.g., on IRF2BP2). Conclusion: Analysis of LCM breast tumors using proteogenomic technologies resulted in basal- and luminal-enriched clusters, thus enabling us to study protein and phosphopeptide markers across multiple platforms. The views expressed in this article are those of the author and do not reflect the official policy of the Department of Defense, or U.S. Government.

#215 Characterization by mass spectrometry of protein kinase C substrates differentially phosphorylated in LNCaP cells in response to phorbol ester and bryostatin 1 treatment. Noemi Kedel, Sudipto Das, Thorkell Andresson, Peter M. Blumberger. National Cancer Institute, Bethesda, MD; Fredrick National Laboratory for Cancer Research, Frederick, MD.

Bryostatin 1 (bryo 1) is a natural product of therapeutic interest for cancer and Alzheimer disease. Its unique behavior as a protein kinase C activator that paradoxically antagonizes many but not all phorbol ester responses has led to intense interest in its mechanisms of action. Recently, using microarray analysis in two different cellular systems (LNCaP prostate cancer and U937 leukemia cell lines) where the typical phorbol ester PMA and bryo 1 have different biology, we have shown that a core mechanism contributing to the unique biology of bryo 1 is transiency of action resulting in a variable extent of decreased or missing late responses. We have excluded that there is a class of genes whose transcription is uniquely regulated at early times by bryo 1. In continuing to explore the mechanisms underlying the variable transiency of the responses by bryo 1 we have evaluated the substrates phosphorylated after treatment with PMA and bryo 1. Since PMA and bryo 1 induce differential subcellular localization of PKCs, they should result in differential access to substrates and consequent differences in the pattern of substrate phosphorylation. Whole cell lysates of LNCaP cells treated for 30 min with fully effective doses (100 nM) of PMA and bryo 1 and with vehicle control were submitted to mass spectrometric analysis. The comprehensive analysis identified several thousand phosphopeptides after drug treatment including the expected phosphopeptides for ERK2 (S185, Y187) and PKCdelta (S299, S302, S304). Many of peptides were similarly phosphorylated in response to both drugs (e.g. S641/S646 of Fam129B, S510 of actin-related protein 2/3 complex subunit 1B, S876 of RhoGGEF and pleckstrin domain-containing containing protein 2, or multiple previously unknown sites for PKD1 (S239, S247), while a limited number were differentially phosphorylated. PMA specific phosphorylations included PKCdelta at Y313, mTOR at T2471, MAP4 at S624 and/or T627, E3 ubiquitin-protein ligases ZNRF2 at S82 and HUWE1 at S5818. Bryo 1 specific phosphorylations included BCL2-like like 13 at S303, TOMIL2 at S424, and MAP2K2 in the T17, T25, S26 region. Selected specific phosphorylations are being validated using phoestag gels, a method that enables the separation of phosphorylated proteins from their non-phosphorylated counterparts on SDS-gels. The identification of PKC substrates that are differentially phosphorylated by bryo 1 should both facilitate screening of other ligands capturing the biological behavior of bryo 1 as well as further illuminate the specifics of the pathways downstream of PKC activation by these differently acting ligands.

#216 Tracking expression, post-translational modifications and interactions of EGF signalling proteins in A431 cells with antibody microarrays. Lambert Yue, Steven Pelech. University of British Columbia, Vancouver, British Columbia, Canada.

Epidululation of epidudal growth factor (EGF) signalling pathways in cancer can help to understand the mechanisms for their dysregulated expression and potential targets for therapeutic intervention. Antibody microarrays are promising tools to evaluate alterations in the levels and phosphorylation status of hundreds of proteins of interest with only microgram amounts of crude cell and tissue lysate protein. However, interpretations of the results from traditional antibody microarray approaches have been hampered by the problems associated with sample preparation and protein detection, even when reliable antibodies are deployed in these arrays. The Kinex™ KAM-900P antibody microarray permitted semi-quantitative measurements of the expressions, post-translational modifications and interactions of proteins with 100 µg or less of lysate proteins. These microarrays utilize approximately 878 different pan- and phosphosite-specific antibodies for tracking protein kinases, phosphatases and other changes in protein levels, phosphorylation and protein-protein interactions in A431 cells in response to EGF treatment. One method (KAM) involved the capture of in vitro biotin-labeled proteins, followed by their detection with a secondary dye-labeled anti-biotin antibody. False positive signals from associated proteins in complexes with the target were reduced by chemical cleavage with NT-CB prior to their capture on the array, and this also produced more uniformity of the dye signals for protein targets despite vast differences in their sizes. Transient changes in protein phosphorylation in EGF treated cells that were typically lost when processed by conventional methods were better preserved by chemical

55
cleavage right at time of sample homogenization. Biotin-labeling and subsequent detection of the protein on the array with a dye-labeled secondary antibody further reduced non-specific background signals, allowing for a greater dynamic range of detection, and enhanced discrimination of subtle changes. In conjunction with other detection protocols, such as the usage of dye-labeled multiplex arrays for protein expression in a variety of biological samples, the use of affinity purification and mass spectrometry (AP-MS) can be utilized to identify and quantify proteins involved in pathways that are of interest. In this study, we aimed to determine the efficacy of AP-MS for quantification of the AKT/mTOR and RAS/ERK pathways in multiple cancer cell lines and tissue samples. Major advantages for each assay technique. Conclusion: Overall, the mIP-tMS assays can be used to monitor cancer progression and determining treatment response. Some major bottlenecks in the accurate quantitation of these proteins are the lack of rigorously validated reagents and a reliance on semi-quantitative results from available mass spectrometry workflows. The benchmarking of mIP-tMS assays showed low correlation of quantification of target proteins or their metabolic reprogramming, and development of highly migratory and invasive capabilities of cancers. Therefore, characterization of mTORC2 is necessary not only for better understandings of known mTORC2-mediated functions, but also for the discovery of new roles and more interacting partners of mTORC2 signaling network in carcinoma, particularly ones with hyperactivated mTORC2 such as glioblastoma. However, until now mTORC2 is still partially characterized. Previously, mTORC2 was reported to be associated with Filamin A and Myosin-9 which have been known to play important roles in cellular activities requiring locomotion, including cancer migration and invasion. The complex participates in regulating glioblastoma migration and invasion, and Filamin A acts as a physiological downstream target of mTORC2. Currently, proteomics has emerged as a powerful tool to identify, quantify, and examine a large number of proteins. Therefore, in order to extensively unravel mTORC2 signaling pathway, the use of proteomics is necessary. We characterized mTORC2 by proteomic analysis based on affinity purification coupled to mass spectrometry (AP-MS) using antibodies against RICTOR, a specific component of mTORC2. The protein-protein interactions between RICTOR and other associated proteins were assessed. In addition to canonical components of mTORC2, the study has revealed more insights into a number of mTORC2 interacting partners which can be categorized and related to the main functions previously identified such as actin cytoskeleton reorganization, fatty acid metabolism, protein translation. Interestingly, we also found other types of cytoskeletal proteins, nucleotide metabolism, less-characterized and low abundance proteins associated with mTORC2 such as Horseradish Peroxidase. In addition, we have carried out the identification of condition-specific interactions for a dynamic view of mTORC2 interactome and found changes in mTORC2-associated proteins from different conditions. Furthermore, proteomic approaches can also be relevant to investigation and prediction of mTORC2 upstream regulators, downstream targets, and substrates. Ultimately, this strategy still uncovers some unknown molecular mechanisms, and result in a significant impact on the field of signal transduction machinery in cancers.

Background: The AKT/mTOR and RAS/ERK pathways represent key mechanisms for cells to regulate cell survival, proliferation, and motility. In addition to their independent signaling cascades, which provide offsetting mechanisms, these two pathways extensively engage in cross-talk in order to both positively and negatively regulate each other. The quantitation of protein expression and modifications of pathway targets are critical for characterization of disease, monitoring cancer progression and determining treatment response. Some major bottlenecks in the accurate quantitation of these proteins are the lack of rigorously validated reagents and a reliance on semi-quantitative results from available mass spectrometry workflows. The benchmarking of mIP-tMS assays showed low correlation of quantification of target proteins or their metabolic reprogramming, and development of highly migratory and invasive capabilities of cancers. Therefore, characterization of mTORC2 is necessary not only for better understandings of known mTORC2-mediated functions, but also for the discovery of new roles and more interacting partners of mTORC2 signaling network in carcinoma, particularly ones with hyperactivated mTORC2 such as glioblastoma. However, until now mTORC2 is still partially characterized. Previously, mTORC2 was reported to be associated with Filamin A and Myosin-9 which have been known to play important roles in cellular activities requiring locomotion, including cancer migration and invasion. The complex participates in regulating glioblastoma migration and invasion, and Filamin A acts as a physiological downstream target of mTORC2. Currently, proteomics has emerged as a powerful tool to identify, quantify, and examine a large number of proteins. Therefore, in order to extensively unravel mTORC2 signaling pathway, the use of proteomics is necessary. We characterized mTORC2 by proteomic analysis based on affinity purification coupled to mass spectrometry (AP-MS) using antibodies against RICTOR, a specific component of mTORC2. The protein-protein interactions between RICTOR and other associated proteins were assessed. In addition to canonical components of mTORC2, the study has revealed more insights into a number of mTORC2 interacting partners which can be categorized and related to the main functions previously identified such as actin cytoskeleton reorganization, fatty acid metabolism, protein translation. In addition, we have carried out the identification of condition-specific interactions for a dynamic view of mTORC2 interactome and found changes in mTORC2-associated proteins from different conditions. Furthermore, proteomic approaches can also be relevant to investigation and prediction of mTORC2 upstream regulators, downstream targets, and substrates. Ultimately, this strategy still uncovers some unknown molecular mechanisms, and result in a significant impact on the field of signal transduction machinery in cancers.

#218 Functional proteomic analysis of TβRI immunocomplex in TGF-β signaling. Liuya Tang,1 Zhaojing Meng,2 Mary Heller,1 Ming Zhou,2 Ying Zhang,2 #NCI-CCR, Bethesda, MD; Frederick National Laboratory for Cancer Research, Frederick, MD.

Transforming growth factor-beta (TGF-β) regulates a wide array of biological responses ranging from proliferation to apoptosis, and alterations in its signaling pathway are associated with a variety of human diseases, including cancer. During the activation of TGF-β signaling, TGF-β receptor I (TβRI) plays an important role in transducing signals to downstream effectors. To identify TβRI interacting proteins which are responsible for Smad-dependent pathways as well as Smad-independent pathways, we employed a large-scale quantitative proteomic analysis of TβRI immunocomplex. AML12 cells were labeled with L-Lysine and L-Arginine (K0R0, light) or L-Lysine-13C6-15N2 and L-Arginine-U-13C6-15N4 (K8R10, heavy). The cells cultured in K8R10 medium (H: Heavy) were transfected with Flag-TβRI, while the cells cultured in K0R0 medium (L: Light) were transfected with Flag vector. The cells lysates were combined at equal protein amount, and TβRI immunocomplex were purified using FLAG M2 agarose. The resulting peptides from eluted TβRI immunocomplex were subjected to mass spectrometry quantitation. If a protein whose ratio of H/L was not smaller than 1.3, it was categorized as a constitutively interacting protein of TβRI. A total of 687 proteins were quantitated and 325 proteins were defined as constitutively interacting proteins. Pathway enrichment analysis found these proteins were highly enriched in pathways of TGF-β signaling. These results indicates the cross-talks between TGF-β signaling and other signaling. Future work will include validation of interaction between TβRI and candidate proteins, and understand functional significance of candidate proteins in TGF-β signaling or signaling cross-talks by a series of molecular biological approaches.

#219 Identification of the mechanistic target of rapamycin complex 2 associated interactome involved in brain cancer cell motility by affinity purification-mass spectrometry, Napat Chantaravisoot,2 Piriya Wongkongkathep,1 Fuyuhiko Tamanoi,2 Trairak Pisitkun1.

The Mechanistic Target of Rapamycin Complex 2 (mTORC2) is a multiprotein complex with serine-threonine kinase activity, drives several cellular processes of normal cells to promote proper metabolic activity, survival, proliferation, differentiation and movement. On the other hand, mTORC2 has been implicated as a critical player in tumorigenesis, stimulation of cell growth, cancer metabolic reprogramming, and development of highly migratory and invasive capabilities of cancers. Therefore, characterization of mTORC2 is necessary not only for better understandings of known mTORC2-mediated functions, but also for the discovery of new roles and more interacting partners of mTORC2 signaling network in carcinoma, particularly ones with hyperactivated mTORC2 such as glioblastoma. However, until now mTORC2 is still partially characterized. Previously, mTORC2 was reported to be associated with Filamin A and Myosin-9 which have been known to play important roles in cellular activities requiring locomotion, including cancer migration and invasion. The complex participates in regulating glioblastoma migration and invasion, and Filamin A acts as a physiological downstream target of mTORC2. Currently, proteomics has emerged as a powerful tool to identify, quantify, and examine a large number of proteins. Therefore, in order to extensively unravel mTORC2 signaling pathway, the use of proteomics is necessary. We characterized mTORC2 by proteomic analysis based on affinity purification coupled to mass spectrometry (AP-MS) using antibodies against RICTOR, a specific component of mTORC2. The protein-protein interactions between RICTOR and other associated proteins were assessed. In addition to canonical components of mTORC2, the study has revealed more insights into a number of mTORC2 interacting partners which can be categorized and related to the main functions previously identified such as actin cytoskeleton reorganization, fatty acid metabolism, protein translation. Interestingly, we also found other types of cytoskeletal proteins, nucleotide metabolism, less-characterized and low abundance proteins associated with mTORC2 such as Horseradish Peroxidase. In addition, we have carried out the identification of condition-specific interactions for a dynamic view of mTORC2 interactome and found changes in mTORC2-associated proteins from different conditions. Furthermore, proteomic approaches can also be relevant to investigation and prediction of mTORC2 upstream regulators, downstream targets, and substrates. Ultimately, this strategy still uncovers some unknown molecular mechanisms, and result in a significant impact on the field of signal transduction machinery in cancers.

#220 Proteomic identification of therapeutics targets for Enzalutamide resistance in Castration Resistant Prostate Cancer. Lauriane VELOT,1 Dominiqhe Levesque,2 François-Michel Boisvert,2 Nicolas Bisson,2 Frédéric Pouliot1.

1Centre de recherche sur le cancer, Centre de recherche du CHU de Québec Université Laval, Québec, Canada; 2Faculté de Médecine et des sciences de la santé - Université Sherbrooke, Sherbrooke, Québec, Canada.

Prostate cancer (PC) is the most frequently diagnosed cancer in Canadian men and is the 3rd cause of cancer mortality. The Androgen Receptor (AR) is activated by androgens (e.g. testosterone), which leads to prostatic cell proliferation. The primary treatment for advanced PC is androgen-deprivation therapy, which is achieved via surgical or chemical castration. Nevertheless, most PC will become castration-resistant (CRPC). Although new anti-androgens (e.g. Enzalutamide) were developed to improve patients' survival, their efficacy is still very limited and most CRPC patients will die from the disease within a few years. We postulate that by gaining insights into AR signalling networks in the context of CRPC, we could better direct patients towards the best-suited therapy and propose new therapeutic targets. To this aim, we took advantage of an innovative proteomics approach, namely proximity-labeling (BioID), to characterize global AR signalling networks in hormone-dependant LAPC4 cells. We identified 45 AR-associated proteins in non-stimulated cells, 35 of which were not previously...
reported. Upon androgenic stimulation, the AR signalling network increased to 320 proteins, including 278 (253 were novel) that were restricted to androgen-stimulated cells. Enzalutamide treatment resulted in a loss of 259 proteins from the network when compared to stimulated cells. As expected, this reproduced quite faithfully the status of non-stimulated LAPC4 cells. Interestingly, we identified 4 potential network sensitive proteins. These are interesting targets that may be relevant for the acquisition or the prediction of Enzalutamide resistance. Hence, they could become in time alternative therapeutic targets for CRPC treatment, to be used when Enzalutamide fails.

#221 Integrated functional proteomics of MET/VEGFR inhibitors reveals complex mechanism of action of foretinib in NSCLC. Natalia J. Sumi, Bin Fang, Lily L. Rix, Muhammad Ayaz, Fumi Kinose, Eric A. Walsh, Steven A. Eschrich, Harshani R. Lawrence, John M. Koomen, Eric B. Haura, Uwe Rix. Moffitt Cancer Center, Tampa, FL.

BACKGROUND: Foretinib (FORE) and cabozantinib (CABO) are two MET/VEGFR inhibitors with similar chemical structures. CABO is FDA-approved for medullary thyroid and renal cancer; in addition, it is in clinical trials for treatment of non-small cell lung cancer (NSCLC). Through an unbiased viability screen we have observed potent cellular activity of FORE, but not CABO, in several NSCLC cell lines. We have previously shown that most NSCLC cell lines are insensitive to MET or VEGFR inhibition, suggesting off-target activity of FORE in these cells. The aim of this project is to identify the mechanism of action of FORE in NSCLC and design an optimized combination therapy. METHODS: Cellular viability assays were done using CellTiter-Glo, cell cycle analysis by flow cytometry. Western blotting was performed to evaluate the induction of apoptosis through PARP1 and caspase cleavage, as well changes in signaling. We synthesized FORE and CABO analogues and performed differential quantitative chemical and phosphoproteomics to determine the target kinase profile and pathway effects in NSCLC cells. Changes in gene expression upon drug treatment were measured by RNA-seq. RNAi in combination with pharmacological inhibition was performed to interrogate targets and pathways. RESULTS: FORE showed greater potency in NSCLC cell lines than CABO with regard to inhibition of viability and induction of apoptosis. FORE decreased phosphorylation of AKT and ERK. Chemical and phosphoproteomics revealed several kinases, such as MEK and MAP4K5, to bind preferentially by FORE over CABO that differentially affect the adherence junction and MAPK signaling pathways. Target validation showed differential inhibition of MEK1/2 and MAP4K5. Cellular validation with RNAi in combination with pharmacological inhibitors suggested that MEK1/2, MAP4K5 and IGF1R are involved in the mechanism of action of foretinib in NSCLC cells. RNA-seq pathway analysis furthermore suggested regulation of chromatin organization and Wnt pathway signaling by foretinib. CONCLUSION: Our results suggest that the difference in the efficacy between FORE and CABO is related to polypharmacology of FORE, which simultaneously targets IGF1R, MEK1/2 and MAP4K5. This difference results in divergence in signaling pathway inhibition and induces distinct effects in NSCLC. The establishment of FORE targets and signaling pathways can lead to optimized combination therapy for NSCLC and for identification of new actionable kinases in lung cancer cells.

#222 Protein network mapping of bladder cancer: tumor compartment and microenvironment analysis. Kimberly A. Hodge, Andrew Hau, Marielenia Pierobon, Donna Hansel, Emanuel Petricoin. Moffitt Cancer Center, Tampa, FL.

BACKGROUND: The bladder尤其是肿瘤-基质相互作用。膀胱癌上皮细胞和基质之间有相互作用，对肿瘤的发生和发展至关重要。我们使用了肿瘤和基质之间的信号网络来理解肿瘤的发生和发展。

#223 Targeting critical signaling nodes using multiplexed antibody based phosphopeptide enrichment with iMRM validation. Charles L. Farnsworth, Yiying Zhu, Matthew Stokes. Cell Signaling Technology, Danvers, MA.

Introduction: A challenge for biomedical researchers is to develop assays to analyze complex systems that interrogate whole cellular signaling networks. Here we show the results of employing antibody based immunoenrichment arsenal of enrichment to determine changes in phosphorylation upon kinase inhibitor treatment. Human cancer cell lines, including gastric and breast adenocarcinomas were treated with kinase inhibitors and cellular extracts were digested with trypsin and peptides were purified. A pool of phosphorylation dependent site-specific antibodies was employed to enrich for sites of phosphorylation. Following antibody based enrichment these peptides were identified and quantified using liquid chromatography/tandem mass spectrometry (LC-MS/MS). Phosphopeptides were identified using SEQUEST, differences in abundance were determined by employing label-free MS1 based quantification using Progenesis from Non-LinCear Dynamics. We also show validation data for a number of the antibodies employed using immuno–multiple reaction monitoring, or iMRM. Employing a QExactive mass Spectrometer (Thermo Scientific) we developed calibration curves for a number of the targeted tryptic phosphopeptides using combinations of heavy and light peptides with endogenous cancer cell line peptides as a background matrix. Experimental Results: Cell lines were treated with DMSO or inhibitors to which the cell lines should be sensitive/insensitive. Following peptide purification, a pool of antibodies were multiplexed and used to enrich for phosphopeptides derived from signaling proteins across a number of signaling pathways. The results show significant changes in abundance for many proteins/sites, including activation loop tyrosine residues of tyrosine kinases, changes in sites on proteins in the AKT/PDK pathway, sites in the MAPK pathway, and other critical regulators of cellular signaling such as sites on the ErbB family members. Targeted LC-MS/MS methods using iMRM were used to confirm these results and show the promise of using such targeted strategies for quantifying changes in phosphorylation consistently across many samples. Conclusion:The strategy of multiplexing antibodies for immuno-enrichment allows for simultaneous detection and quantification of hundreds to thousands of known phosphorylation sites that have been shown to be important nodes of regulation. Targeted LC-MS/MS methods such as iMRM will allow researchers to confidently profile changes in both total levels as well as phosphorylation site occupancy for critical signaling proteins.

Reliable immunodetection of proteins is a critical step in the discovery of novel biomarkers. It is often performed manually. The immunodetection protocol consists of multiple steps including blocking of nonspecific binding sites, incubation using primary and secondary antibodies and extensive washing between steps that easily introduce bias and errors. The quality of results depends on multiple subjective and objective factors such as the qualification and technical skills of the personnel performing the assay and the accuracy of temporal and temperature control, especially during the immunodetection step. BlotCycler, automated western blot processor, uses fluidic control system that allows to
eliminate the variability associated with immunodecoration and to achieve higher sensitivity by optimized washing procedure. We used blotCycler to analyze critical variables for immunodecoration including temperature, incubation time and reagent mixing. Relatively small changes in duration and temperature of incubation significantly affect not only the intensity of signal but also the specificity of antibody-antigen interactions with antigen. Automated immunodecoration at 4°C significantly improve the specificity of detection and sensitivity that allows reproducible detection of low expressing proteins. Automated processing using blotCycler allows optimization and control of critical variables leading to improved reproducibility and specificity of immunodecoration and should be routinely used for biomarker candidate discovery and confirmation, reliable protein quantification, primary antibody specificity testing, and optimization of primary and secondary antibodies concentrations.

#225 Chemoproteomic evaluation of target engagement in clinical samples. Tyzoan K. Nomanbhoy, ActivX Biosciences, Inc., La Jolla, CA.

One of the challenges during the clinical development of kinase inhibitors is understanding whether or not a compound is actually binding the kinase of interest, in the appropriate tissue, during the course of compound treatment. While compound concentration in blood can be determined from pharmacodynamics, there are very few approaches that directly measure whether or not the compound is binding the target kinase. Herein, we apply a chemoproteomics platform (KiNativ R) using a desthiobiotin ATP acyl phosphate probe (ATP probe), to monitor target engagement in clinical samples. As a proof of concept, we demonstrate that compound can be added to whole blood, after which proteins are labeled for 2 h with biotin-ATP, lysed with the ATP probe, and analyzed by mass spectrometry to determine whether or not compound treatment blocks the probe-labeling of the target. We successfully applied this approach in the analysis of both the reversible JNK inhibitor CC-930, as well as the covalent BTK inhibitor Brutinib (Imbruvica®). We then extended the study to monitor the inhibition of BTK by Brutinib in PBMCs isolated from patients undergoing drug treatment. Finally, we demonstrate that in addition to profiling kinases in PBMCs isolated from whole blood, this method can also be used to profile kinases in solid tumors. Thus, the chemoproteomics approach described here could be applied as a general method to monitor target engagement for inhibitors developed against a variety of different kinases in clinical samples.

#226 Verification of prostate cancer genetics biomarker candidates at protein level using PRISM-SRM. Hui Wang,1 Yuqian Gao,1 Athena Schepmoes,1 Gyorgy Petrovics,2 Jennifer Cullen,2 Thomas Fillmore,2 Tujio Shi,1 Wei-Jun Qian,1 Richard Smith,2 Brandi Weaver,1 Robin Leach,1 Ian Thompson,1 Sudhir Srivastava,1 Jacob Kagan,2 Albert Dobi,1 Karin Rodland,1 Shiv Srivastava,1 Tao Liu,1 Pacific Northwest National Laboratory, Richland, WA; University of the Sciences University of the Health Sciences, Bethesda, MD; University of Texas Health Science Center at San Antonio, San Antonio, TX; National Cancer Institute, Bethesda, MD.

Mass spectrometry (MS) based targeted proteomics such as selected reaction monitoring (SRM) provides an antibody-independent strategy for sensitive, specific and multiplexed verification of genetics biomarker candidates at the protein level. In order to identify a panel of proteins with the potential to discriminate between aggressive and indolent forms of prostate cancer and predict prostate cancer progression, we have selected 52 protein candidates from existing prostate cancer genetics data sets and validated cancer drivers, and performed quantitative proteomics analysis in tumor and control tissue samples using the highly sensitive PRISM (high-pressure, high-resolution separations coupled with intelligent selection and multiplexing)-SRM approach. PRISM-SRM assays have been developed for the 52 prostate cancer biomarker candidates including: prostate cancer progression associated genes, prostate cancer associated genes that were up-regulated in transcriptions studies, and other cancer-related genes (including the ERG or ETV1 isoforms). Two sets of tissue samples were analyzed using PRISM-SRM with heavy isotope-labeled synthetic peptides as internal standards: 1) 10 high Gleason-score (7-9) primary prostate tumors and 10 benign prostate hyperplasia (BPH) tissues (OCT-embedded specimens); and 2) 10 primary tumors from patients showing metastatic progression, 10 primary tumors from patients who showed biochemical recurrence (BCR), and 10 primary tumors from patients with no BCR or metastatic progression after more than 10 years of follow-up after radical prostatectomy (FFPE whole mount prostate specimens). Overall, PRISM-SRM analyses of all the patient tissue samples enabled the detection of 48 out of 52 biomarker candidates, suggesting extremely low level of expression of the remaining 6 genes (HXC6, OSTP, TWST1, and ERG8); in comparison regular LC-SRM can only detect 21 of these candidates at the protein level. In the 10 high Gleason-score tumors and 10 BPH controls, 13 proteins were found differentially abundant with P<0.05. In the 10X10X10 FFPE sample analysis, there were three proteins discriminating between “metastatic progression” and “no progression” tumors, one protein discriminated between BCR and “no progression” tumors, and four proteins discriminated between metastatic progression and BCR tumors showing a trend towards differences between metastatic and BCR tumors. These results will be further evaluated, individually and in panels, in independent, larger cohort for their potential prognostic applications. In summary, PRISM-SRM provides a highly sensitive method for quantification and rapid screening of multiple potential biomarker candidates at the protein level. This approach holds great potential for rapidly translating genomics-based discovery candidates into protein-based biomarkers.

#227 Mass spectrometry-based proteomics analysis of the non-small lung cancer secreteme. Emmanuel K. Cudjoe, Tareq Saleh, David A. Gewirtz, Adam M. Hawkridge. Virginia Commonwealth University, Richmond, VA.

Non-small cell lung cancer (NSCLC) is the more common subtype (~80%) of lung cancer, a leading cause of cancer death worldwide. NSCLC has one of the lowest 5-year relative survival rates due to a combination of late stage diagnosis and treatment failure. Autophagy, a stress response mechanism in which cancer cells recycle organelles, and proteins to generate the necessary nutrients and metabolic intermediates for survival, is thought to be one of the principal mechanisms of treatment resistance and relapse in cancer. Due to its relatively refractory nature to chemotherapy and radiation, long-term goals is to identify molecular signatures and pathways of autophagy that can be targeted to improve the sensitivity of NSCLC to chemotherapy and radiation treatments. As a function of p53 expression, irradiation and functional autophagy status in NSCLC will be discussed. The novel functional and potential diagnostic value of these differentially secreted proteins for distinguishing between the autophagic responses of NSCLC to IR. The novel functional and potential diagnostic value of these differentially secreted proteins for distinguishing between the autophagic responses of NSCLC to IR. The novel functional and potential diagnostic value of these differentially secreted proteins for distinguishing between the autophagic responses of NSCLC to IR.
cancer (PCa) and 35 with CRPC, were measured. Results: The proteome analysis identified 12 candidates of secreted cell membrane proteins as new biomarkers. The proteome analysis indicated that not only matured GDF15, but pro-peptide as well as fragments (GDPP) are released from prostate cancer cells. Patients’ serum was analyzed for mature and pro-peptide GDF15 using ELISA and immunomunoprecipitation mass spectrometry. The results showed that the secreted level of GDPP-1, one of the processing forms of GDPP, was significantly higher in CRPC than those in BPH and untreated PCa (P<0.01). ROC analysis also showed that the AUC of GDPP-1(0.86) was higher than that of matured GDF15 (0.76). When the cutoff value of GDPP-1 was set at 4.0 ng/mL, there was also showed that the AUC of GDPP-1(0.86) was higher than that of matured GDF15 (0.76). When the cutoff value of GDPP-1 was set at 4.0 ng/mL, there was a significant difference of overall survival (OS) in CRPC patients between those with more than 4.0 ng/mL compared to those with less than 4.0 ng/mL of GDPP-1, whereas there was no significant difference of OS measurable by PSA in CRPC patients. These data suggest that GDPP-1 may be a novel biomarker for CRPC. Conclusion: GDPP-1 shows potential as a novel biomarker for CRPC.

#229 Establishing reference intervals of human urine proteome for monitoring physiological and pathological changes. Wenchuan Leng,1 Xiaotian Ni,2 Changqing Sun,3 Anna Malovannaya,4 Yi Wang, Jun Qin.1 National Center for Protein Sciences (The PHOENIX Center, Beijing), Beijing, China; 2 East China Normal University, Shanghai, China; 3 Tianjin Baodi Hospital, Tianjin, China; 4 Baylor College of Medicine, Houston, TX.

Urine as a true non-invasive sampling source holds great potential for biomarker discovery. But the lack of method for profiling urine proteome in high throughput and systematic evaluation of variations in urine proteomes based on large number of population have been the two major obstacles for finding new biomarkers from urine. Due to low throughput, only limited number of urine samples can be measured in discovery phase of biomarker studies, which make it hard to determine whether proteins differentially expressed between groups represent actual differences between control and disease states or just physiological variations among individuals. So, candidate biomarkers often fail in validation phase. Here, we report a streamlined workflow with capacity of measuring 8 urine proteomes per day per MS at the coverage of more than 1500 proteins. With this workflow, we systematically evaluated variations in 497 human urine proteomes from 167 apparently healthy donors, allowing us to evaluate day to day and inter-personal variation in human urine proteome. Then personal and pan-human reference intervals (RIs) of urine proteome were established based on this large-scale dataset. We demonstrated that RIs can be used to monitor physiological changes by detecting transient outlier proteins, such as trans-continental travel and common flu. And it was also found that if the underlying cause is physiological variation, outlier proteins will fall back to the normal range in the follow up measurement, as exemplified in the intercontinental travel case. Persistent outlier proteins may be indicative of non-physiological conditions. These results indicate that periodical measurements of a person’s urine proteome could establish a personal health archive that would be valuable for detecting future health issues. Furthermore, we proposed a complete novel strategy dependent on RIs-based algorithm for biomarker discovery and validation to screen for diseases, which were exemplified by analyzing 154 urine proteomes from patients with 7 types of cancers. The algorithm can distinguish normal people from cancer patients with specificity of 95% and sensitivity of 85%. This study paves a way to use urine proteome for health monitoring and disease screening.

#230 Proteomic approaches in the discovery of novel drug targets or potential biomarkers in breast cancer. Ioanna-Maria Orfanou, Theodoros Karampelas, George Mermelkas, Konstantinos Vougas, Constantin Tamvakopoulos. Biomedical Research Foundation Academy of Athens, Athens, Greece.

The aim of this study is the detection, identification and quantification of known and new candidate cell membrane receptors that are overexpressed in Breast Cancer (BC) cells. In order to achieve this goal we have developed State-of-the-Art Proteomic approaches. These novel membrane target receptors can be used either as biomarkers or for the design of targeted drugs against aggressive disease subtypes with poor prognosis and therapeutic outcomes, such as Triple Negative BC (TNBC) and HER2 overexpression BC. For our study, four well characterized BC epithelial cell lines were selected: HCC-1954 and SKBR3 (HER2 overexpressing), MDA-MB-231 (TNBC) and MCF-10A (benign control). We employed a combination of subcellular fractionation and membrane enrichment protocols and combined those with quantitative, tandem Mass-Spectrometry (MS) based Proteomics. The discovery phase of our approach included: the GelC-MS/MS technique, where protein fractions were first separated by 1D gel electrophoresis followed by In-Gel enzymatic digestion prior to identification by a high resolution Orbitrap mass analyser. A complementary approach for known proteins associated with BC that cannot be readily detected in the discovery phase, such as GPCR receptors, was based on nano LC-MS/MS analysis. Proof of Concept experiments, with the use of a Triple Quadrupole (QqQ) instrument, were based on the detection of standard peptides derived from the protein of interest after following an in solution trypptic digestion protocol. Using GelC-MS/MS approach we identified the well-known BC involved receptors, EGFR and HER2, as well as other potential protein targets in concordance with the literature (e.g. TFR1, EPHA2, GPCR5A). We further confirmed these results by Western blot analysis. Certain GPCRs expected to be present in the cell lines tested were not detected in the studies used on the GelC-MS/MS analysis, thus we proceeded to the more sensitive and quantitative nanoLC-MRM approach. As a paradigm target we chose the GnRH receptor, an established target known to be expressed in BC. The quantitative nanoLC-MRM approach revealed GnRHR significant expression in the MDA-MB-231 BC line and in the WPE-NB26-3 Prostate cancer cell line (used as an overexpressing GNRHR positive control). Our results indicate that the strategy of combining and applying various Proteomic approaches into selected cell lines for the identification of new protein targets will add more information to the genetic and histological classification of the tumor in order to achieve our goal, which is a holistic view of a patient’s molecular profiling that can ultimately lead to treatment in the most effective way.

PREVENTION RESEARCH: Diet and Cancer

#231 The polyphenolic plant lignan secoisolaricresinol diglucoside reduces mammary tumor growth, possibly via inhibition of local inflammatory signaling. Claire G. Lineberger,1 Laura W. Bowers,2 Nikki A. Ford,3 Emily L. Rossi,1 Bruce K. Kimler,2 Carol J. Fabian,2 Stephen D. Hursting1. 1The University of North Carolina at Chapel Hill, Chapel Hill, NC; 2The University of North Carolina at Chapel Hill, Austin, TX; 3The University of Kansas Medical Center, Kansas City, KS.

Background: Secoisolariciresinol diglucoside (SDG) is a polyphenolic plant lignan found in flax and sesame seeds as well as legumes, whole grains, fruits and vegetables. It is metabolized by the gut bacteria into two major enterolignans: enterolactone (E NL) and enterodiol (END). These enterolignans have been associated with reduced breast cancer risk and progression in population studies as well as decreased tumor growth in preclinical models of breast cancer. Methods: The impact of SDG supplementation on tumor growth in a mouse model of basal-like breast cancer was examined. C57BL/6 mice were fed a control diet (10% kcal from fat) or control diet with SDG supplementation (100 mg/kg food) for eight weeks, then both groups were orthotopically injected with E0771 mammary tumor cells. An inflammatory signaling qPCR array (Qiagen) was performed on mammary tissue distal to tumor. Tumors were stained by immunohistochemistry (IHC) for Ki67 to measure proliferation levels and phospho-p65 to determine inflammatory signaling pathway activation. Tumors and mammary tissue were also stained for F4/80 to quantify macrophage infiltration. Serum level of hormones, adipokines, and cytokines were measured via lumiex assay (Bio-Rad). Results: SDG supplementation significantly decreased tumor weight (p<0.05). SDG did not affect body weight or body fat percentage but did significantly decrease expression of F4/80, CRP, and other pro-inflammatory markers in the mammary tissue. IHC staining revealed no difference in tumor proliferation; however, SDG supplementation did reduce inflammatory signaling in the tumors, indicated by a significant decrease in phospho-p65 staining. However, serum cytokine levels were not significantly different between the groups. Tumors are currently being stained by IHC for cleaved caspase 3 to measure levels of apoptosis. In addition, cell culture experiments will be conducted to define the impact of ENL treatment on protumorigenic cross-talk between tumor cells, adipocytes, and macrophages. Specifically, the effects of conditioned media from adipocyte/macrophage co-cultures (with +/- ENL treatment) on mouse E0771 and human MDA-MB-231 tumor cell proliferation, migration and invasion will be examined. Conclusions: SDG supplementation reduced mammary tumor growth in association with SDG’s effects on local, but not systemic, inflammatory signaling.

#232 Modification of dietary sugar on the chemotherapeutic potential in breast cancer. Yan Jiang, Pattrea R. Rhea, Lorenzo Cohen, Peiyiing Yang. UT MD Anderson Cancer Ctr., Houston, TX.

Background: The estimated cost of breast cancer (BCa) care in the U.S. is over 16 billion dollars yearly, more than any other cancer. Thus, identifying contributors to BCa development and barriers in BCa treatment is a continuing focus of BCa research. The per capita consumption of sugar in Americans has surged to...
The impact of omega-3 fatty acid supplementation on obesity-induced inflammatory signaling within the breast tumor microenvironment. Duan K. Quach,1 Brittany Harlow,2 Laura Wininka,3 Andrew Brenner,4 Murali Beoram,5 Stefano Tiziani,6 Lucy Longfelder,1 Gloria Galvan,1 Christopher Jolly,1 Produced inflammatory signaling within the breast tumor microenvironment. Apoptotic gene array and microarray analysis were used to determine gene expression profile. Results: Among six human BCa cells tested, a glucose treatment (30 mM) promoted the growth of MDA-MB-231 and SUM159 cells after 10 days by 2.5 to 3 fold, respectively. In contrast, T47D, BT474, MDA-MB-468 and MCF-7 cells did not respond to glucose stimulation. Glucose treatment abrogated doxorubicin-induced cell apoptosis in triple negative Aga-6 and omega-3 fatty acids at ratios of 46:1, 20:1, 10:1 and 1.3:1 for 24 hours. The V4 region of the 16S rRNA gene was sequenced using the HiSeq 2500 system. Alpha diversity measures including number of OTU (operational taxonomic units) and Shannon index were calculated for each sample. Mixed ANOVA models with a random effect accounting for twin pair status, were used to examine the association of alpha diversity with polyp status. Results: Alpha diversity measured by Shannon index and number of unique OTUs was inversely associated with obesity and high beef consumption and positively associated with yogurt consumption. Surprisingly, we found that fecal microbiota alpha diversity was higher in subjects with adenomas and hyperplastic polyps compared to subjects with no polyps. When restricted to subjects with colonoscopy in the 3 years prior to stool collection, differences were stronger and statistically significant (mean OTUs for subjects with adenoma, hyperplastic polyps and no polyps = 908, 850, and 801, respectively; Padenoma vs. no = 0.017, Phyperplastic vs no = 0.007; Plinear trend = 0.018). In order to determine whether diet changes may have played a role, we examined dietary change from food frequency questionnaires collected 15 years apart. We found that subjects with no polyps increased yogurt consumption by 50% over the 15 year period, whereas subjects diagnosed with adenomas and hyperplastic polyps increased their yogurt consumption more (140% and 130%, respectively). Conclusion: Participants diagnosed with adenomas and hyperplastic polyps had higher fecal microbiota alpha diversity compared to those without polyps. The timing of measurement of fecal microbiota years after colonoscopy obscures the causal relationship between adenoma and fecal microbiome. One possibility is that subjects may have increased their yogurt consumption after a polyp diagnosis, resulting in increased fecal alpha diversity, compared to subjects who were not diagnosed with polyps. Alternatively, polyp removal may alter microbial diversity. A third possibility is that polyp susceptibility is associated with an outgrowth of deleterious bacteria, still present after polyp removal, reflected as increased alpha diversity. Twin comparisons will be presented.

#235 Probiotics ameliorate Porphyromonas gingivalis-promoted pancreatic cancer progression in oncogenic Kras transgenic mice. Ming-Shiou Jan,1,2 Wan-Ting Chen,1 Yu-Jen Chen,1 Chia-Wei Lin,3 Wen-Wei Chang,1 Chung-Hung Tsai,1 Jia-Shiou Peng,2 Li-Jin Hsu3. The University of Texas at Austin, Austin, TX;1 UT Health San Antonio MD Anderson, San Antonio, TX;2 The START Center for Cancer Care, San Antonio, TX.

Periodontal disease has been shown to play important roles in the pathogenesis of many chronic diseases, such as cancer. Periodontitis is a chronic inflammatory disease affecting the tissues that support the teeth, and is associated with increased risks of several systemic diseases, including diabetes, cardiovascular disease, and cancer. The mechanisms underlying these links are not fully understood, but gut microbiota and diet appear to play a role.

Periodontitis results in chronic inflammation, which can lead to the development of periodontal disease. In turn, periodontal disease can contribute to the progression of cancer. This is because the inflammatory response associated with periodontal disease can stimulate the growth of tumors, promote angiogenesis, and suppress the immune system, all of which can facilitate cancer progression.

In a recent study, researchers investigated the role of probiotics in preventing the progression of pancreatic cancer induced by Porphyromonas gingivalis in oncogenic Kras transgenic mice. They found that probiotics were able to reduce the incidence of pancreatic tumors and improve survival rates in these mice. This study provides evidence that probiotics may have potential as a therapeutic strategy for preventing the progression of pancreatic cancer.

Conclusion: Probiotics may have potential as a therapeutic strategy for preventing the progression of pancreatic cancer.
oral-smear of P. gingivalis. These probiotic strains have been demonstrated to have the efficacy of either anti-inflammatory or enhancement of cell-mediated immunity, respectively. Our results demonstrated that oral administration of the probiotics significantly suppressed oncogenic Kras-induced pancreatic cancer development and reversed P. gingivalis-stimulated cancer deterioration in mice. Stronger expression of EMT markers and pancreatic cancer tissues was observed in Kras12461; Pdx-1-Cre transgenic mice treated with the probiotics. Our results suggest that the microbiota profile is very important for pancreatic cancer development. The manipulation of microbiota for enhancing antitumor immunity may be an emerging strategy for cancer prevention.

Preclinical and epidemiological data suggest that a unique feature of lipogenesis in cancer cells which has received limited attention is the accumulation of monounsaturated fatty acids (MUFA) which are largely derived from saturated fatty acids (SFA) by the action of stearyl-CoA desaturase-1 (SCD-1). Activation of SCD-1, a delta-9 fatty acid desaturase, is considered to be an important factor in the development of obesity and several types of cancer including breast cancer. However, no data are available on how changes in SCD-1 activity induced by potential chemopreventive agents relate to established biomarkers of breast cancer risk. To address this issue, we measured the activity of SCD-1, expressed as the ratio of palmitoleic acid (C16:1n7) to palmitic acid (C16:0) (SCD-16) and oleic acid (C18:1n9) to stearic acid (C18:0) (SCD-18) in plasma samples of post-menopausal women enrolled in our recently published clinical trial (Sandhu N, et al Cancer Prev Res 9:275, 2016) designed to test the individual and combined effect of the antiestrogenRaloxifene and the omega-3 preparation Lovaza on breast density, a validated biomarker of breast cancer risk. We observed that daily administration of Lovaza (1.860 mg eicosapentaenoic [EPA] + 1.500 mg docosahexaenoic [DHA]) significantly reduced SCD-1 activity, an effect which was sustained for the two-year duration of the trial. Raloxifene, on the other hand, did not significantly alter SCD-1 activity in our subjects. SCD-1 activity was positively correlated with BMI (for SCD-16, r=0.45, p<0.01; for SCD-18, r=0.23, p<0.01) and paralleled changes in BMI in the same direction over the two years of the study. These findings support the role of this enzyme in the development of obesity. Importantly, decreasing levels of SCD-1 were found to be associated with a progressive reduction in breast density in obese women (BMI≥30) (for SCD-16: r=0.47, p<0.01; for SCD-18: r=0.36, p<0.05). No correlation between breast density and SCD-1 was observed in non-obese subjects (r=-0.02 for SCD-16 and 0.04 for SCD-18). Our results suggest that BMI-related factors play an important role in the reduction of breast density by omega-3 fatty acids. They also indicate that SCD-1 may be a useful biomarker in future clinical trials testing the benefit of nutritional interventions in reducing obesity associated breast cancer risk.

#237 Increased NSCLC tumorigenesis in mice fed a high fat diet is associated with increased plasma IGF-1 levels and PD-1 expression in CD4+ tumor-infiltrating lymphocytes. Regan M. Memmott,1 Krista Pearman,2 Joell Gillis,3 Tony Tullo,2 Valerie Wong,2 Benjamin Singer,3 Kristin Lastwika,3 Franco D’Alessio,3 Phillip Dennis,2 Jeffrey William Norris,2 1University of Arizona Phoenix, Phoenix, AZ; 2Midwestern Univ. - Glendale Campus, Glendale, AZ; 3Johns Hopkins Medical Institute, Baltimore, MD; 4Northwestern University, Evanston, IL, 5Fred Hutchinson Cancer Research Institute, Seattle, WA; 6Johns Hopkins University - School of Medicine, Baltimore, MD; 7Astra-Zeneca, MD.

Lung cancer is the leading cause of cancer-related mortality worldwide, and 85% of lung cancer cases are associated with tobacco use. Activating mutations in K-Ras have been identified in ~25% of tobacco-associated lung adenocarcinomas. Using mouse models of K-ras-driven lung tumorigenesis, we previously demonstrated that deletion of the IGF-1 gene or reduction of systemic IGF-1 levels using the anti-diabetic drug metformin markedly reduced tumor burden. Preclinical and clinical studies suggest that diet composition is the best predictor of IGF-1 levels. Therefore, we hypothesized that diets high in fat or carbohydrate would promote lung tumorigenesis by increasing systemic IGF-1 levels. To assess the effect of diet on systemic IGF-1 levels, 9 week old C57Bl/6j and A/J mice were fed standard cereal, high-carbohydrate, or high-fat (HFD) diets for 12 weeks. Compared to control feed control mice, plasma IGF-1 and insulin levels were increased in both strains of mice fed a HFD, but not in mice fed a diet high in carbohydrate. This was not due to obesity, as only the C57Bl/6j mice fed a HFD had an increase in body weight. We then investigated the effect of HFD on lung tumorigenesis using two mouse models. In the first, C57Bl/6j 1245-124 mice, which harbor a mutation in K-ras, were fed either cereal diet or HFD for 10 weeks following weaning. Lung tumor burden in the mice fed HFD was increased 2.7-fold compared to littermates fed cereal diet. In the second model, the tobacco carcinogen 4-(methylnitrosamino)-1-(3-pyridyl)-1 butanone (NNK) was given by intraperitoneal injection to A/J mice beginning at 6 weeks of age. This carcinogen causes lung tumor development by inducing K-ras mutations. After 3 weekly injections of NNK, the mice were randomized to cereal diet or HFD for ten weeks. Mice fed HFD had a 60% increase in lung tumor burden. In both models, there was no relationship between the weight of the mice and lung tumor burden. Immunohistochemical analysis of the proliferation marker Ki-67 showed no significant difference in expression between tumors from mice fed a HFD or a cereal diet. Therefore, we evaluated tumor-infiltrating lymphocytes (TIL) from mice on both diets. Interestingly, both immunohistochemical analysis and flow cytometry demonstrated a 50% reduction in the number of TIL in mice fed HFD compared to mice fed a cereal diet. Additionally, HFD was associated with a 2-fold increase in CD4+ TIL, and the CD-4 staining intensity in these lymphocytes was significantly greater than in mice fed a cereal diet. These results may suggest that a high fat diet increases lung tumorigenesis by increasing systemic IGF-1 levels and by creating an immune-permissive tumor microenvironment.

#238 Evidence of early colorectal cancer risk and prevention pathways in the fecal microbiome of colonoscopy patients: associations with diet and circulating adipocytokines. Carrie R. Daniel,1 Kristi L. Hoffman,2 G S. Raju,3 Samir M. Hanash,1 Diane S. Hutchinson,2 Nadim J. Ajami,3 Richard G. Fowler,1 glendale, AZ; 2Midwestern Univ. - Glendale Campus, Glendale, AZ; 3Fred Hutchinson Cancer Research Institute, Seattle, WA; 4Johns Hopkins University - School of Medicine, Baltimore, MD; 5Astra-Zeneca, MD.

Accumulating evidence suggests that the gut microbiome’s role in early colorectal cancer etiology extends beyond the pro-carcinogenic activities of specific pathogens and is largely influenced by the wider microbial community of commensal bacteria. To identify early microbiome-related pathways and potential dietary intervention targets, we conducted an epidemiologic study among cancer-free colonoscopy patients at known and varied risk of colorectal neoplasia. Sporadic patients undergoing colonoscopy screening provided consent and fasting blood. Polyps, if found, were removed at colonoscopy and ~1 month later (prior studies show the effect of the colonoscopy prep dissipates within this time period), eligible patients provided a stool sample via mail kit (n=47). Patients completed comprehensive dietary assessments and clinicopathologic factors, including screening history, were abstracted from electronic medical records. We characterized the fecal microbiome via whole genome shotgun sequencing (Illumina HiSeq) and circulating blood adipocytokines via Luminex multiplex assays (Millipore). Majority of the patients were female and recently diagnosed with precancerous polyps, primarily tubular and sessile serrated adenomas. Polyp patients were more likely to be obese and to not consume alcohol, but otherwise similar by age, diet composition, and other risk factors to patients with normal colonoscopy findings. We observed no effects of time interval between colonoscopy and fecal sample collection, or of recent polyp diagnosis/removal, on microbial alpha or beta diversity. Correlation networks between species revealed that Fecalibacterium and Roseburia hominis, known butyrate-producers. Among recurrent patients (n=14), Bacteroides fragilis co-occurred with Bilophila wadsworthia (r=0.6; P=0.02). Higher intake of fiber and/or overall diet quality, as defined by the Healthy Eating Index, was associated with several bacteria largely linked to butyrate production (e.g., Bifidobacterium animalis, F. prausnitzii, Roseburia intestinalis, Coprococcus eutactus, Eubacterium eligens). These same dietary factors were inversely correlated with Blautia hydrogenotropha, an acetogen, and other bacteria implicated in inflammation and colorectal cancer (e.g., B. fragilis). Biologically plausible associations between microbiota composition and potential pathways important to cancer risk (e.g., one-carbon, lysine, carbohydrate and fatty acid metabolism) with dietary factors and circulating adipocytokines involved in immunity, inflammation, and glucose metabolism support the functionality of these diet-microbe relationships.

#239 Associations of polysaturated fat, bile acids, and gut microbiota on colorectal adenoma risk. Tengteng Wang, Nicole M. Brown, Amber N. McCarthy, Robert S. Sandler, Temitope O. Keku. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Intestinal microbiota, and their metabolites are increasingly recognized as important players in the genesis of colorectal adenomas and cancer. Epidemiological studies have also shown that polysaturated fat intake is associated with
increased risk of colorectal adenomas. This study examined the association between adherent gut microbiota and mucosal bile acids, and total polyunsaturated fat intake in relation to colorectal adenomas in a case-control study. Methods: Participants were 217 adenoma cases and 218 adenoma-free controls who underwent screening colonoscopies and completed food frequency questionnaires. The mucosal adherent microbiota was characterized by bacterial 16S rRNA sequencing. Global metabolomics of colonic mucosal tissue was conducted by gas chromatography and mass spectrometry on a subset of samples. Genus level microbiota and bile acids were compared between cases and controls using t-test with correction for multiple comparison. Logistic regression and Pearson correlations were used to estimate adjusted odds ratios (ORs) and 95% confidence intervals (CIs), and correlation coefficients to assess the association among microbiota abundance, bile acids concentration, and total polyunsaturated fat intake. Results: Adenoma subjects had a significantly higher bacterial abundance of Sphingomonas, Marinomonas and Ralstonia, but lower abundance of Adlercreutzia compared to controls. The concentration of eleven bile acids (Chenodeoxycholate, Cholate, Deoxycholate, Glycochenodeoxycholate, Glycocholate, sulfated 7-ketodeoxycholate, 12-dehydrocholate, Tauroch- nodeoxycholate, Taurodeoxycholate, Taurinoholate 3-sulfate, and Tauroursodeoxycholate) were significantly elevated in cases compared to controls. Subjects with increased abundance of Sphingomonas and Ralstonia were significantly more likely to have adenomas (OR 2.17, 95% CI 1.31-3.57; OR 1.19, 95% CI 1.02-1.38) respectively. Subjects with increased abundance of Adlercreutzia were less likely to have adenomas (OR 0.44, 95% CI 0.21-0.93). The multivariable adjusted OR for high consumption of Adlercreutzia relative to the reference category adjusted for age, sex, race, and BMI was 0.46 (95% CI 0.27-0.80). The correlations between bacterial diversity and eleven bile acids were also significantly differ by control status. Conclusion: The interaction of the gut microbiota, bile acids and consumption of polyunsaturated fat are associated with colorectal adenoma risk.

#240 Dietary patterns and risk of colorectal neoplasia in Puerto Rican Hispanics: A case control study. Jylyann Perez-Mayoral,1 Sachely Julian,1 Marievieslle Soto-Salgado,2 Michael J. González,4 Marcia Cruz-Correia,4 University of Puerto Rico Comprehensive Cancer Center, San Juan, PR;2 University of Puerto Rico Medical Sciences Campus, San Juan, PR.

Colorectal cancer (CRC) is the leading cause of cancer death in Puerto Rico and the second cause of death in the US. It is well accepted that modifiable lifestyle habits such as diet, contribute to CRC development. Diet could reduce up to 70% of CRC cases. Dietary patterns vary according to race/ethnicity. Puerto Rican Hispanics (PRH) have been shown to have a distinct diet compared to US non-Hispanic Whites (NHW). According to the BRFFS, only 17.7% of PRH and 23.4% of NHW consume fruit and vegetables five times per day. The objective of this study was to describe the association of specific food groups consumption with the risk of colorectal neoplasia (CRN; polyps and/or CRC) in PRH. The validated Colon Cancer Family Registry food frequency questionnaire was administered to healthy individuals (controls) and individuals with CRN (cases) recruited through the Puerto Rico Colorectal Cancer Registry (PURIFICAR). Models adjusted by age, gender, educational attainment and family history of CRC were fitted to estimate the odds ratios (OR) with 95% confidence intervals (CI) through a polytomous logistic regression models comparing cases and controls. A total of 577 subjects were included in the study (controls=254; polyps=50; CRC=273). The frequency of consumption of fruits, low fat dairy products, eggs, pasta/rice, non-fried chicken, and seafood were significantly different between controls and CRN cases (p<0.05). Adjusted models showed that a higher consumption of fruits (OR[p<0.05] 0.29), and full-fat dairy products (OR[p<0.05] 0.22) were associated with decreased risk of polyps (p<0.05). A frequency of consumption of 2-4 times per week, when compared to ≤1 per week, of full-fat dairy products (OR[4 times per week=0.51], seafood (OR[4 times per week=0.50]), and red meats (OR[4 times per week=0.56]) was associated with a decreased risk of CRC (p<0.05). Our results showed that a higher consumption of fruits and full-fat dairy products significantly reduce the risk of polyps in PRH. In addition, consumption of seafood, full-fat dairy, and red meats up to 4 times per week may reduce the risk of CRC in PRH. Educational interventions for cancer prevention in PRH should incorporate nutritional information tailor to our community.

#241 Vimentin offers a potential target for the prevention of ovarian tumor progression and recurrence. Aparna Yellapa,1 Janice M. Bahr,7 Sameer Sharma,1' Pincas Bitterman,2 Sanjib Basu,2 Animesh Barua1.1 Rush University Medical Center, Chicago, IL;2 University of Illinois at Urbana-Champaign, Urbana-Champaign, IL.

Background: Aggressive rates of progression and frequent recurrence are the main causes of high rates of death due to ovarian cancer (OVCA). Vimentin, an intermediate filament protein, expressed by ovarian mesenchymal cells may be involved in OVCA metastasis and recurrence. Ashwagandha (Withania somnifera, ASH, a natural product) has shown to improve tumor-associated stress against several malignancies. Objectives: The goals of this study were to examine whether (1) OVCA progression is associated with vimentin expression; and whether (2) OVCA progression and vimentin expression can be prevented by dietary supplementation of Ashwagandha (ASH) in laying hen model of spontaneous OVCA. Methods: Clinical study: Clinical trial on laying hens with normal ovaries (n=10), benign tumors (n=5) and malignant ovarian epithelial cancers at early (n=7) and late stages (n=16) were collected from patients and examined for vimentin expression. Prospective study: 4-year old laying hens with normal ovaries or ovaries with early stage OVCA were supplemented with 2% dietary ASH root powder or basal diet (24 hens in each group containing 18 healthy, 6 with early stage OVCA). Hens were provided with feed and water ad libitum for 120 days and euthanized thereafter. Tumor stages were recorded; serum, normal or cancer ovaries were collected. Expression of vimentin both in clinical and preclinical treated or untreated specimens was examined. Statistical differences in the intensity of vimentin expression among different pathological and ASH supplemented groups were determined using ANOVA and t-tests. Results: Vimentin was localized in the nucleus and cytoplasm of normal ovarian, benign and malignant cells. Compared with normal and benign tumors, the intensity of vimentin expression was significantly lower (P<0.0001) in early stage OVCA and increased remarkably in late stage OVCA. Similar to OVCA patients, intensity of vimentin expression was lower in hens with early OVCA than normal hens, and increased significantly (P<0.0001) in hens with late stage OVCA. As compared to healthy hens, tumor incidence and progression as well as vimentin expression decreased significantly in hens treated with 2% ASH. Conclusions: Results of the present study suggest that vimentin expression increased during tumor metastasis. ASH treatment reduced OVCA metastasis by inhibiting vimentin expression. Therefore, vimentin may represent a potential target for ASH to prevent OVCA progression and metastasis. Support: Support: R21CA187309-02.

#242 The anti-tumor effect and the impact on gut microbiota of gynepenosides Rd and Rb3 in ApoMin/+ mice. W.L. Wendy Hsiao,1 Guoxin Huang,1 Imran Khan,1 Lei Chen,1 Xiaoang Li1. 'State Key Lab of Quality Research in Chinese Medicine, Macau Univ of Sci. & Tech, Macau; China;2 Rutgers University, Piscataway, NJ.

Gut commensal microbiota (GM) is closely associated with health and diseases, including cancer. In our previous studies, we have demonstrated that Gynostemma pentaphyllum saponins (GPs) exert antitumor effects in both athymic and ApoMin/+ mice. Our recent study also showed that GPs exhibited prebiotic effect by up regulating the beneficial bacteria and improving the epithelial microenvironment of the gut. Gypenoside IV (Rb3) and gypenoside VII (Rd) are the two constituents of GPs. The Rd exhibits stronger antitumor effect than Rb3 in an in vitro cell model system established in our lab. Our aim is to confirm the antitumor effect of these two compounds, as well as their impact on GM in the ApoMin/+ mouse model. In the study, single daily dose of Rb3 or Rd at 20mg/kg, and solvent control were orally fed to the mice for 8 weeks, started at 6 weeks of age before the appearance of spontaneous intestinal polyps. The fecal microbiome was analyzed by enterobacterial repetitive intergenic consensus (ERIC)-PCR and 16S rRNA gene pyrosequencing technique. We found that Rd was more effective than Rb3 in reducing polyp formation, and improving the intestinal lining by up-regulating anti-inflammatory cytokines IL-4 and IL-10. Rd, not Rb3, might facilitate intestinal tissue repair by enhancing M2 marker while suppressing M1 markers expression. Moreover, Rd treatment greatly enhanced the ratio of Bacteroides vis Firmicutes, while profoundly reduced the abundance of cancer-cachexia-associated bacteria, such as Parabacteroides goldsteinii (22.5%), Dysgonomonas wimpennyi (48.5%) and Blautia cocoides (36.77%). These findings suggested that the level of antitumor effect of the gypenosides might be correlated with its ability to modulate the gut microbiota from dysbiosis to symbiosis. This study was supported by Macau Science and Technology Development Fund 015/2014/A1.

#243 Diet and exercise-induced weight maintenance, alone and in combination with a whole tumor cell vaccine, delays mammary tumor growth and reduces MDSC accumulation. Yitong Xu, William J. Turbitt, Andrea M. Mastro, Connie J. Rogers. Pennsylvania State University, University Park, PA.

Obesity and physical inactivity increase breast cancer risk, while the prevention of weight gain by diet and exercise can be protective. Numerous biological mechanisms have been proposed to explain the beneficial effects of weight maintenance, however few studies have examined the immune response to energy balance. We have previously shown that diet and exercise-induced weight maintenance (WM) achieved via a 10% restriction in calories and access to voluntary running wheels in combination with a whole tumor cell vaccine (VAX) significantly reduced mammary tumors. The present study extends this work to evaluate tumor growth progression after six months of WM and VAX treatment, alone and in combination. Mice were randomly assigned to four experimental groups: 1) WM, 2) WM + VAX, 3) diet and exercise-induced weight gain (WNG), and 4) diet and exercise-induced weight gain + VAX. A tumor cell vaccine (VAX) that had previously been shown to have antitumor effects in our mouse model was used to treat established tumors. This study was conducted to determine whether dietary and exercise-induced WM delays tumor progression, and whether VAX treatment delays tumor progression. The present study extends previous work by evaluating diet and exercise-induced WM, alone and in combination with VAX, in a mouse model where dietary and exercise-induced WM and VAX have previously been shown to delay tumor progression. This study was supported by the National Institutes of Health (NIH) Grant No. RO1CA117583.
mary tumor growth and metastases in the 4T1 mammary tumor model. This WM-induced reduction in tumor growth occurred concurrently with an elevation in tumor specific IFN-γ production and a reduction in the number of myeloid-derived suppressor cells (MDSCs). However, because tumor size is positively correlated with immune suppression, the goal of the current study was to investigate if mice in the WM+VAX group had enhanced anti-tumor immune responses and/or fewer MDSCs controlling for tumor size. Female BALB/c mice were randomized into weight gain (WG) and WM groups (n=8/group) and had access to voluntary running wheels or standard cages, respectively. WG mice were fed ad libitum while WM mice were energy-restricted by 10% to maintain a stable body weight. After 8 weeks on the intervention, all mice were orthotopically injected with 5x104 4T1.2 cells into the fourth mammary fat pad and continued on their intervention. Once injected, both WG and WM mice were further randomized into vaccination (VAX) and vehicle control (VEH) groups (n=4/group) and administered 1x10^7 irradiated 4T1.2 cells (VAX) or HBSS (VEH) at day 7 post-tumor implantation. Primary tumour growth was quantified, and mice were sacrificed when tumor volume reached 0.1-0.2 cm^3. WM mice weighed significantly less than WG mice over the course of the study (p<0.001). Mice in both WM+VAX and WM+VAX groups took a significantly longer number of days post tumor implantation to reach a tumor size of 0.1-0.2 cm^3 (26.2±3.3 d, p=0.003; 23.8±0.5 d, p=0.009, respectively) compared to the WG+VEH group (18.3±2.5 d). Despite the fact that mice were sacrificed when the tumor volumes were standardized at 0.1-0.2 cm^3, the combination of WM+VAX resulted in a significant reduction of splenic MDSC accumulation (p<0.0001) and enhanced CD4^+ T cell responses in the WM+VAX group. These results suggest that diet and exercise-induced WM was highly effective in delaying primary mammary tumor growth. The combination of WM and an allogenic whole tumor cell vaccine reduced pro-tumorigenic MDSC accumulation and enhanced effector T cell function. Furthermore, these data suggest that diet and exercise may be changing the tumor microenvironment at an early stage of tumor growth favoring tumor clearance. This work is supported by R21 CA209144; T32AI074551.

#244 Eicosapentaenoic acid reduces effects of some adipocyte derived factors on breast cancer cell inflammation and glucose metabolism. Arwa Al-jawadi,1 Sara Al-Jahia,1 Suranganee Dharamawardhane,1 Shane Scoggin,2 Lauren Gollahon,2 Preethi Gunaratne,2 Naima Moustaid-Moussa,1,3 Texas Tech Univ, Lubbock, TX;1 University of Puerto Rico Medical Sciences Campus, San Juan, PR, Puerto Rico; 2University of Houston, Houston, TX.

Breast cancer is still the leading cause of death in women among all cancer types. Obesity, a chronic low grade inflammatory disease, is a key contributor to the progression of breast cancer especially in women, post-menopause. Given the current understanding of cancer-related inflammation and associated microvesicles in restructuring the microenvironment, we hypothesized that adipocyte-derived cytokines and exosomes negatively impact breast cancer progression. By contrast, eicosapentaenoic acid (EPA), a dietary omega 3 polyunsaturated fatty acid and a well-established anti-inflammatory compound will reduce adipocyte-secreted pro-inflammatory factors, thereby reducing breast cancer progression. To test these hypotheses, we investigated the effects of conditioned media or exosomes from 3T3-L1 adipocytes or human mesenchymal stem cells (HMSC), treated with +/- 100μM EPA on MCF7 and MDA-MB231 breast cancer cells for 24-72 h. Following treatment, changes in breast cancer cell gene expression were measured using qPCR and glycolytic rate was measured using XF24 Seahorse extracellular flux analyze. We observed that conditioned medium from HMSC significantly increased the mRNA expression levels of oncogenic genes such as signal transducer and activator of transcription 3 (STAT3), baculoviral IAP repeat-containing proteins 3 (BIRC3) known as cIAP2, and the lipogenic fatty acids synthase (FASN). In contrast, conditioned media from EPA-treated human adipocytes reduced the expression levels of these genes. Similarly, exosomes isolated from EPA-treated adipocytes showed a significant reduction in mRNA expression levels of STAT3 and cIAP2 in both cancer cell lines. Furthermore, glycolysis was significantly reduced in MCF7 but not MDA-MB231 cells incubated with 3T3-L1 adipocyte-conditioned medium pretreated with EPA for 24 h. Taken together, our data suggest that adipocytes play a significant role in promoting breast cancer progression by providing a microenvironment that increases survival and inflammation. EPA is a promising anti-inflammatory nutrient that may help reduce breast cancer cell inflammation and survival, possibly by modifying adipocyte-derived cytokines and exosomes in obesity and thus warrants further investigations.

#245 Dietary long-chain omega-3 fatty acids reduce adipose inflammation in mammary tissue of mice fed moderate fat-isocaloric diets. Saraswoti Khadhe,1 Geoffrey M. Thiele,1 John Graham Sharp,1 Lynnell W. Klassen,1 Tommy R. McGuire,1 Michael J. Duryee,1 Holly C. Britton,1 Alicia J. Daffner,1 Jordan Beck,2 Paul Black,2 Concetta C. DiRusso,2 James E. Talmadge1. 1Univ. of Nebraska Medical Ctr., Omaha, NE; 2Univ. of Nebraska-Lincoln, Lincoln, NE.

Increased adipose tissue inflammation and breast density; including ductal epithelial hyperplasia have been associated with increased risks for breast cancer. Omega 6 (ω6) and omega 3 (ω3) fatty acids (FAs); serve as substrates for pro-inflammatory and inflammation resolving mediators respectively, emphasizing the potential regulatory role for dietary intake of these FAs in inflammation. Western diets have a 6:3 FA ratio of >15:1 with low levels of long-chain (LC-)ω3FA. While adipose tissue inflammation occurs, characterized by crown-like structures (CLS) consisting of dead adipocytes and adjacent macrophages in breast tissue have been related to breast cancer risk in overweight and obese women presumably by the obesity-inflammation- aromatase axis. However, a role of dietary ω6/ω3 FA in adipose inflammation, independent of obesity is not clear. Herein, we examined effects of dietary ω6/ω3 FA in the mammary tissue microenvironment and adipose inflammation using a moderate fat, iso-caloric diets, and pair-fed model. The Lieber-DeCarli diet containing 21:1 ratio of ω6/ω3 FA was used as a ω6 diet, whereas encapsulated fish oil containing a 3:1 ratio of eicosapentaenoic (EPA) and docosahexaenoic (DHA) acid was used to decrease ω6/ω3 ratio to 0.7:1 in the ω3 diet. Both isocaloric diets contained 35.5% of calories derived from fat and were pair-fed to maintain iso-intake. Female BALB/c mice were established on the ω6 and ω3 diets for 10 weeks and weight gain and diet consumption monitored. There were no differences in the volume of diet consumed and weight gain between dietary groups. At autopsy, mammary fat pads (MFP) were collected and analyzed for fatty acid composition, histopathology, epithelial proliferation and macrophage infiltration. Arachidonic acid (AA) levels in the MFPs were not different between the groups but EPA and DHA levels were different. There was a significant increase in AA (2.41±0.5% vs 1.52±0.29%) in the MFP of ω3 diet fed mice. The MFP of ω6 diet fed mice had significantly increased areas of unilocular adipocytes relative to adipocytes of the ω3 group. Similarly, ω6 diet fed mice had increased connective tissue in the ductal stroma, significantly higher numbers of proliferating cells in the ductal epithelium, as well as in adipose tissue in the MFP. In addition, ω6 diet fed mice had a significant increase in the numbers of CLS in mammary adipose tissue. In summary, our studies demonstrated that despite the comparable levels of AA in MFP in both of groups, the presence of LC-ω3 FA (EPA and DHA) was able to reduce inflammation in the MFP of ω3 diet fed mice, thus regulating the MFP microenvironments by reducing macrophage infiltration and ductal epithelial proliferation in an obesity-independent manner.

#246 Assessing microbial dysbiosis of electronic cigarettes and cigarette smokers using oral and lung microbiome. Kevin Ying,1 Min-Ae Song,2 Daniel Y. Weng,1 Quentin Nickerson,2 David Frankhouser,1 Pearlly S. Yan,1 Ralf Bundschuh,1 Mark D. Wewers,1 Ewy Mathe,1 Jo L. Freudenberg,2 Peter G. Shields3. The Ohio State University, Columbus, OH; 3University at Buffalo, Buffalo, NY.

The link between smoking tobacco and changes in the oral microbiome in response to tobacco smoking are well established. It is not known if there are changes in response to electronic cigarettes (e-cig). These changes in the microbe are associated with increased numbers of disease causing pathogens. Currently there are no published studies that have investigated the relationship of smoking tobacco and the oral and lung microbiome. There is insufficient evidence showing whether changes in oral cavity and lung microbiome are also seen in e-cig users. We will study the oral cavity and lung of non-smokers, smokers and e-cig users to examine concordance between oral cavity and the lungs as well as comparing the three groups, examining the microbiomes and expression of inflammatory markers. We hypothesize that microbial dysbiosis and expression of inflammatory cytokines will differ for smokers and non-smokers; and that e-cig users will have microbial dysbiosis similar to cigarette smokers. A cross-sectional study is being conducted on three groups, 1) never-smokers, 2) cigarette smokers, and 3) e-cig users. For each study participant, saliva and bronchoalveolar lavage (BAL) are being collected to measure microbiome. RNA is extracted from saliva and BAL samples for total transcriptome analysis using RNA-seq. This analysis will detect human and bacterial reads thereby allowing observations of bacterial communities as well as human inflammatory cytokine response to bacterial presence. 85% to 98% of BAL sample reads aligned to the human genome compared to less than 50% from saliva samples. The alignment results allow us to deduce that the majority of reads from BAL samples are human and that the majority of the reads in saliva samples are bacterial. Preliminary results show detection of human RNA expression and of bacterial reads are present in both saliva and BAL samples. More samples are being processed and the comparison of BAL and saliva samples between the three groups will be discussed.

#247 Nutrient stress via folic acid modulation causes systemic and cancer-specific metabolic reprogramming and differential effects on primary and metastatic mammary tumor growth in lean and obese mice. Ciara H. O’Flanagan,1 Xuwen Chen,2 Zahra Ashkavand,2 Sergey A. Krupenko,2 Stephen D. Hursting1. 1Univ. of North Carolina at Chapel Hill, Chapel Hill, NC; 2Nutrition Research Institute, Kannapolis, NC.
Many foods are currently fortified with folic acid (FA), a synthetic folate (Vitamin B9). Folate deficiency causes many human health defects, most notably anemia and neural tube defects. The effects of excess supplementation on human health have to date been understudied. The rise in obesity in the last three decades further complicates this issue, with the combined effects of excess or insufficient folic acid intake and an elevated prevalence of folic acid deficiency. The obesity epidemic is associated with a variety of health problems such as type II diabetes, cardiovascular disease, and cancer. Among these, obesity is a risk factor for hepatocellular carcinoma (HCC). Stat3 signaling plays an important role in the development of obesity-related HCC.

Here, we examined the effects of FA supplementation and deficiency on tumor growth, metastasis, and inflammation in obesity-responsive models of primary (M-Wnt) and metastatic (mwtM-Wnt) HCC. FA supplementation and deficiency significantly enhanced primary tumor growth and invasiveness in lean mice, while no difference in tumor size was detected in obese groups. FA supplementation reduced while deficiency increased survival and reduced lung tumor metastasis incidence in lean, but not obese mice. Liver and tumor metabolic profiling revealed that modulation of dietary FA caused systemic and tumor-specific metabolic reprogramming, altering pathways involved in fatty acid, purine, amino acid, glutathione and energy metabolism. Short term in vitro FA withdrawal resulted in reduced proliferation, migration and invasion and energy production in all cell lines, as well as significant changes in gene expression profile, particularly of many metabolic pathways. In contrast, chronic in vitro FA depletion resulted in heightened autophagy and apoptosis and was associated with a decrease in Stat3 signaling. These data suggest translational implications for the treatment of obesity-related HCC.

Interest-ingly, EPA had no obvious effects on obesity-induced inflammation, instead, indicating that EPA attenuates obesity-related hepatocarcinogenesis. Interestingly, dietary EPA supplemented with methylseleninic acid (2.5 mg Se/kg) reduced male breast carcinogenesis and its metastasis in mice. It indicates that selenium may be useful in male breast cancer prevention.

#250 Methionine restriction increases macrophage tumoricidal activity and significantly inhibits prostate cancer growth. Ashley R. Orillón,1 Sreenivasulu Chintala,1 Remi Adelaiye-Ogala,1 Li Shen,1 Nur Damayanti,1 May Elbanna,1 Sreevani Arisa,1 Bennett Elzey,2 Chinghai Kao,1 Luigi Fontana,2 Roberto Pillo.3 1Indiana Univ.-Purdue Univ. Indianapolis, Indianapolis, IN; 2Roswell Park Cancer Institute, Buffalo, NY; 3Purdue University, Lafayette, IN; 4Washington University, St. Louis, MO.

Background: Our previous work showed a significant reduction of tumor growth, macrophage infiltration, circulating IGF-1, and mTOR activation with low protein diet in a patient derived xenograft model of prostate cancer. The evolutionarily conserved, nutrient sensing, mTOR pathway plays a central role in both development and angiogenesis. Targeting the mTOR pathway is a promising strategy for the treatment of prostate cancer.

Methods: We used in vivo studies utilizing bone marrow or tumor derived (RP-B6 Myc) macrophages. In vivo studies utilized the recently characterized RP-B6 Myc model. Mice were fed ad libitum control or methionine restricted diets for four weeks prior to S.C. implantation with 1mm3 tumor pieces. Treatment of survivin peptide vaccine (1mg/ml S.C. 1X week) and anti-PD-1 (20mg/kg IP. 2X week) began at ~50mm3 tumor size. Tumor volumes were blindly recorded 2X week. End point analyses include: tumor weight, flow cytometric analysis, proteomic profiler analyses, and microbiome analyses from each diet and treatment group. Results: We show here that while methionine restriction (MR) has little impact on our RP-B6 Myc prostate cancer cell line, it does yield a significant alteration in both the polarization and function of M1 and M2 macrophages. In the in vitro MR conditions, we observed significantly enhanced polarization of M1 macrophages and reduced polarization of M2 macrophages. Functional analysis revealed increased tumoricidal activity of both M1, ‘antitumor’, and M2, ‘pro-tumor’, macrophages suggesting a flip in M2 function from tumor-promoting to tumoricidal. Further analysis of the released cytokines in MR media conditions yielded significant increase of antitumor cytokines & chemokines, such as IL-12, IL-27, CXCL9, CXCL10, CCL2, CCL4, and TNF-alpha, a double-edged sword which in our system correlates with increased cell death in MR media conditions. Importantly, survivin expression was reduced while deficien-cy significantly enhanced primary tumor growth and invasiveness in lean mice, while no difference in tumor size was detected in obese groups. FA supplementation reduced while deficiency increased survival and reduced lung tumor metastasis incidence in lean, but not obese mice. Liver and tumor metabolic profiling revealed that modulation of dietary FA caused systemic and tumor-specific metabolic reprogramming, altering pathways involved in fatty acid, purine, amino acid, glutathione and energy metabolism. Short term in vitro FA withdrawal resulted in reduced proliferation, migration and invasion and energy production in all cell lines, as well as significant changes in gene expression profile, particularly of many metabolic pathways. In contrast, chronic in vitro FA depletion resulted in heightened autophagy and apoptosis and was associated with a decrease in Stat3 signaling. These data suggest translational implications for the treatment of obesity-related HCC.

#249 Dietary supplementation with methylseleninic acid reduces male mammary tumorogenesis in MMTV-PyMT mice. Snea Sundaram, Grand Forks Human Nutrition Research Center, ARS, USDA, Grand Forks, ND.

Male breast cancer makes up approximately 1% of all breast cancers and less than 1% of all cancers in men in the United States. However, it is an aggressive disease with poor prognosis and the incidence of male breast cancer is on the rise. The present study investigated the effects of dietary supplementation of selenium on male breast cancerogenesis in MMTV-PyMT mice (FVB/N background). Three-week-old male mice were weaned onto the AIN93G diet with or without supplementation of selenium in the form of methylseleninic acid (2.5 mg Se/kg). Mice were euthanized 10 weeks after the first palpable mammary tumor was detected. There were no differences in food intake and body weight between the groups. The median latency (the age at which the first palpable tumor was detected) was 14.1 and 13.9 weeks and the incidence of palpable mammary tumor was 71% and 70% for the control and the selenium group, respectively. Selenium supplementation compared to the control diet reduced mammary tumor progression by 258% and tumor weight by 84%, respectively.

The present study provides evidence that selenium reduces male breast cancerogenesis and its metastasis in mice. It indicates that selenium may be useful in male breast cancer prevention.

#248 Eicosapentaenoic acid attenuates obesity-related hepatocellular carcino-genesis. Akane Inoue-Yamauchi, Hiroko Itagaki, Hideaki Oda. Tokyo Women’s Medical University, Tokyo, Japan.

The population of obesity caused by excess energy intake and insufficient physical activity is increasing worldwide. Excess accumulation of body fat is a risk of health, indeed obesity is associated with the pathogenesis of various disease including type II diabetes, cardiovascular disease and cancer. Among various kinds of cancer, the risk of hepatocellular carcinoma (HCC) is strongly influenced by obesity. Studies using diet-induced obesity mouse models show that obesity enhances tumor development inducing chronic inflammation in liver. In fact, obesity failed to promote HCC formation in the absence of inflammatory cytokines IL-6 and TNF-α. Obesity is associated with a number of metabolic and inflammatory changes that may confer a growth advantage in nonmetastatic cells and from which metastatic TNBC cells cannot recover. Moreover, obesity and FA excess cause similar meta-bolic and proancerca effects and in combination, are not synergetic.

In this study, we assessed the chemosensitization activity of the naturally occurring polyphenols resveratrol (RES) and pterostibene (PTER) to 5-Fluo- oracil (SFU) in Burkitt’s B-cell lymphoma. RES is a stilbenoid compound found in a variety of fruits, plants, and nuts. In addition to antioxidant and anti-aging properties, RES has been shown to exhibit significant anti-tumor activity against a variety of malignancies. Since the compound is typically pro-ductive of normal cells, its anti-cancer activity makes it a promising candidate as both a chemopreventive nutritional supplement and a chemotherapeutic agent. PTER, an analog of RES, has likewise shown anti-cancer activity. Its therapeu-tic potential, however, is much less understood. Recent studies have investigat-ed the use of these and other natural compounds in adjuvant chemotherapy
strategies, many of which continue to produce underwhelming rates of response. Here, we investigate the chemosensitization capacity of both RES and PTER to 5-FU, a commonly used drug in chemotherapy, in healthy lymphocytes and in Burkitt’s B-cell lymphoma (Raji) cells. MTS assays are used to measure the viability of malignant and normal lymphocytes after 5-FU treatment with or without supplementation of RES, PTER, or RES/PTER. In the Raji cells, 5-FU/Raji co-incubation with physiologically relevant concentrations (~10μM) of either RES or PTER significantly increases 5-FU toxicity in Raji cells, with data suggesting PTER to be slightly more effective than RES. Interestingly, RES/ PTER combinatorial treatments further increase chemosensitization, an important finding considering the typically low bioavailability of each individual compound in vivo. Together, these data support the potential use of RES as a chemosensitizing adjuvant and provide new evidence that its analog, PTER, also possesses significant chemosensitization capacity. Furthermore, our studies suggest that low physiological concentrations of PTER and RES may be still be sufficient to induce significant anti-cancer effects.

#253 Mammary tumorigenesis causes bone loss and dietary selenium supplementation does not affect such bone loss in male MMTV-PyMT mice. Lin Yan, USDA-ARS, Grand Forks, ND.

Cancer progression is accompanied by wasting that eventually results in cachexia characterized by significant weight loss and multi-organ functional failures. Limited clinical trials indicate that bone is adversely affected by cancer-associated wasting. To determine the effects of breast cancer on skeletal health, we performed micro-computed tomographic analysis of femurs and vertebrae collected from a recently completed study showing that dietary supplementation with selenium (methylseleninic acid, 2.5 mg Se/kg) reduced male mammary tumorigenesis in MMTV-PyMT mice. Compared to age-matched non-tumor-bearing mice (MMTV-PyMT negative), the presence of mammary tumors significantly reduced bone volume fraction, trabecular thickness and bone mineral density and increased the structure model index (an indicator of the plate- and rod-like geometry of trabecular structure) in femoral trabecular bone. Mammary tumor development did not affect vertebral trabeculae nor femoral and vertebral cortical bone, except it significantly reduced cortical bone thickness of vertebrae. There were no differences in aforementioned measurements between groups with or without selenium supplementation. In conclusion, mammary tumorigenesis causes bone loss and dietary selenium supplementation at 2.5 mg Se/kg, which is anti-tumorogenic, does not affect mammary tumor-associated bone loss in this male MMTV-PyMT breast cancer model.

#254 The potential of Lactobacillus probiotic treatments in colorectal cancer (CRC). Imen Kahouli,1 Meenakshi Malhotra,2 Susan Westfall,1 Moulay Alaoui-Jamali,1 Satya Prakash1.

Colorectal cancer (CRC) is the third leading cause of death worldwide. It is known to be a type of cancer that is preventable by changes in diet and lifestyle. Mounting evidence are supporting the role of gut microbiome in the etiology of CRC and emphasize on the potential of probiotics as biotherapeutics in the prevention and management of CRC. Lactobacillus probiotic bacteria have the ability to balance gut microbiota in the colon and produce anti-tumorigenic and anti-inflammatory effects in healthy individuals at risk and CRC patients. There is a need, however, for studies that focus on identifying potent probiotic strains with activity against CRC and inhibit cancer growth. This report discusses and present findings about the formulation of novel probiotic Lactobacillus biotherapeutic for CRC based on anti-CRC proliferative effect, immune modulation and metabolic activity, in vitro and in vivo, using a genetically-induced animal CRC model. Results and metabolomic analysis demonstrated the potential action of probiotic treatment to change host and gut microbiome co-metabolic profiles, produce local and systemic anti-inflammatory effects, inhibit cancer-causing events, and improve overall gut health.

#255 Dietary amphiphilic polyphenols modulate the biophysical properties of plasma membrane organization and membrane-dependent macropinocytosis. Michael L. Salinas, Natividad R. Fuentes, Rola Barhoumi, Robert S. Chapkin. Texas A&M University, College Station, TX.

Ras-driven cancers exhibit a distinct high metabolic demand necessary for biosynthetic growth/proliferation, in some cases resulting in over stimulation of macropinocytosis, a process intended for nutrient acquisition. A hallmark of Ras-driven macropinocytosis is plasma membrane ruffling resulting in invaginations and the formation of macropinosomes, extracellular nutrient-packed vesicles distinct from other endocytic processes due to their size, independence of vesicle-coating proteins, and are the result of rapid polymerization and branching of cytoskeletal actin filaments. These cytoskeletal manipulations are driven by spatial/temporal regulators downstream of Ras along with lipid rafts and their components. Drugs and other extrinsic factors, e.g., polyunsaturated fatty acids, have been shown to bio-physically modulate these lipid domains. We hypothesize that unique dietary polyphenolic amphiphilic molecules [1] modulate plasma membrane fluidity, [2] disrupt macropinocytosis, and [3] suppress macropinocytosis-dependent proliferation. Young adult male colonocyte (YAMC) cells, expressing an HRas mutation, were treated with 1, 10, and 100 μM (+)-catechin or procyanidin B2 for 30 min. For macropinocytosis assessment, cells were stimulated with 25 ng/mL epidermal growth factor (EGF) for 10 min following a 30-minute pretreatment. Membrane order was measured in whole cells and giant plasma membrane vesicles (GPMV) utilizing a lipid-packing detection dye, Di-4-ANEPPDHQ, and assayed using a combination of fluorescence image-based flow cytometry (Annis FlowSight) and confocal microscopy. In addition, macropinocytosis was determined by uptake of fluorescently labeled 70 kDa dextran (FITC-dextran). The uptake was visualized by fluorescence image-based flow cytometry. In the GPMV model, (+)-catechin increased membrane fluidity, and procyanidin B2 decreased membrane fluidity in a dose-dependent manner. In contrast, in the whole cell model, interaction of (+)-catechin and procyanidin B2 with the plasma membrane resulted in an increase in membrane fluidity in a dose-dependent manner. Interestingly, plasma membrane fluidization in the whole cell model was associated with a significant 27-67% inhibition of macropinocytosis. These observations indicate that dietary amphiphilic molecules (DAMs) modulate plasma membrane organization, which is linked to macropinocytosis, an essential fuel-obtaining process. Establishing a role for DAMs in membrane-dependent oncogenesis is noteworthy because these molecules are innocuous and found in high abundance in a variety of fruits, vegetables, and walnuts. This work was support by NIH grant R35CA197707.

#256 Delta tocopherol inhibits urothelial tumorigenesis in the UPII mutant Ha-ras transgenic mouse model and induces apoptosis via activation of the ATF4/CHOP-DR5 pathway. Christopher A. Blair,1 Maggie Wu,1 Tim Huynh,2 Hanze Hu,3 Arman Walla,1 Chang S. Yang,2 Xiaoilin Z1. 1UC Irvine, Irvine, CA; 2Rutgers University, Piscataway, NJ.

Gut microbiome studies have reported that Vitamin E intake was inversely related to the risk of multiple cancers including human urinary bladder cancer. Tocopherols (T) are the major forms of vitamin E in the U.S. diet, exist as α-T, β-T, γ-T, and δ-T. Compared to α-T, the anti-cancer effect of other Ts and their mechanisms of action remain largely unknown. We have shown that δ-T is the most effective one among the Ts in reducing the viabilities of bladder cancer cell lines with IC50 of under 0.012 gram, P < 0.012 gram, P < 0.0001) with no significant difference in overall body mass and no detectable indication of toxicity. Our results suggest that δ-T is a potent anti-cancer agent and deserves further investigation in preventing the recurrence and progression of non-muscle-invasive UCC.
methyltransferase. The FFQ and 24-hour FR are the most commonly used methods to assess adequate nutrient intake, including methyl donors and other vital micronutrients that are essential to promote metabolism and methylation. While FFQ provides best estimates in dietary intakes, a 24-hour food record is less time consuming for subject burden. Methods: A total of 134 participants’ dietary data were collected using FFQ (from 1997-1998 for 100 participants and 1999-2000 for 34 participants). Bland and Altman methodology was used to validate the bias and agreement between these two measurements. Results: Overall, the 24-hour measurements presented underestimated values across all nutrients compared to FFQ measurements. Using a 10% criterion in the differences between the two measurements, the percentage bias for 24-hour FR compared to 30-day FFQ was acceptable for most nutrients, including B1 (-6.9% ± 15%), B2 (-8.66% ± 0.12), B3 (-9.25% ± 0.12), B6 (-5.02% ± 0.14), and B9 (folate -7.90% ± 0.24). However, the bias was greater for protein based methyl donors, including B12 (-17.23% ± 0.14), choline (-13.38% ± 0.11), Glycine (-17.53% ± 0.10), and Methionine (-18.88% ± 0.09). The correlations between the two measurements on all methyl donors ranged from 0.92 to 0.99. The precisions for all measurements based on the standard error (SE) were less than and within 0.03% (0.007% - 0.021%). And, the agreements between the two measurements were less than and within 10% for Glycine and methionine (8.96 - 9.58%), based on the standard deviation (SD); however, greater than 10% for other protein based methyl donors including choline and other B vitamins (10.5 - 24.11%). Conclusion: Proper dietary intakes of methyl donors are vital for cancer prevention. These findings point out the importance of further validation and use of more accurate food measurement to monitor dietary intake, and the interpretation of nutrient reports with caution.

**EPILOGUE:** Descriptive Epidemiology Including Trends in Incidence and Prognosis

#257 Estrogen receptor positive and negative breast cancer secular trends in Ireland (2004-2013). Maeve Mullooly,1 Jeanne Murphy,1 Gretchen L. Gierach,1 Brittany Davis,1 Paul Walsh,2 Sandra Deady,3 Thomas I. Barron,4 Mark E. Sherman,5 Philip S. Rosenberg,1 National Cancer Institute, Bethesda, MD, 2National Cancer Registry Ireland, Ireland, 3Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, 4Mayo Clinic, Jacksonville, FL.

Background: Estrogen receptor (ER) status in breast cancer is strongly associated with etiologic factors, prognosis and treatment response. Data suggest that population-based incidence rates of ER-positive (ER+) tumors are increasing and ER-negative (ER-) cancers have fallen over time in the United States (US), Denmark and Scotland. Whether these trends are consistent in other populations with different etiologic exposures and across ER+/HER2- subtypes is unknown. We, therefore, analyzed breast cancer secular trends in Ireland by ER expression; and for the first time, by joint expression of ER and HER2/HER2.

Methods: This study included invasive breast cancers (n = 4,007,768) diagnosed in women aged 20-84 years within the population-based National Cancer Registry of Ireland (97% coverage). The general population at risk (n = 10,401,986) was obtained from the Irish Central Statistics Office. Using a validated approach to assign unique code for VRL) per 100,000 person-years in the United States (US) during 1992-2002 and 2003-2013. Results: Over the 10-year follow-up period, 19,264 ER+ and 4,161 ER- breast cancers were diagnosed (1,420 were ER-unknown). ASRs increased significantly for ER+ breast cancer (3.0%/year; 95%CI: 1.4, 4.6%) and decreased significantly for ER- cancers (1.2%/year; 95%CI: 0.9, 1.5%). The ER-specific trends were qualitatively similar among three age groups (<50, 50-64, and ≥65 years). With further stratification by HER2 expression, ER+/HER2- cancers increased significantly (2.2%/year/5%CI: 0.9, 4.4%/year), with the largest increases observed for HER2+ cancers and ER+/HER2- categories (3.3%/year; 95%CI: 1.8, 4.9%/year). The ER-specific trends were qualitatively similar among three age groups (<50, 50-64, and ≥65 years). With further stratification by HER2 expression, ER+/HER2- cancers increased significantly (2.2%/year; 95%CI: 0.9, 4.4%/year), with the largest increases observed for HER2+ cancers and ER+/HER2- categories (3.3%/year; 95%CI: 1.8, 4.9%/year). Conclusions: Secular trends for ER+ cancers in Ireland were similar to those previously observed in the US and Denmark. Further, trends for ER+/HER2 followed those for ER, although rates were constant for ER+/HER2. The incidence of cancer incidence patterns by ER among independent populations over time could reflect comparable changes in risk factor exposures with dual or opposite effects for risk of ER+ and ER- cancers (e.g., obesity, age at first birth/parity). Additionally, although HER2 is a well-established clinical predictive and prognostic marker for breast cancer outcome, it did not appear to substantively impact breast cancer incidence trends.

#258 The changes of esophageal malignant tumors by histopathology over 40 years (1975-2014) at a single institute in northern China. Xue Ke Zhao,1 Hai Jun Yang,1 Zong Min Fan,1 Ji Lin Li,1 Li Min He,1 Yun Zhou,1 Liu Qin Yang,1 Ying Fa Zhou,2 Sa Tang,3 Yang Yang,3 Lei Ma,4 Wei Li Han,2 Li Dong Wang1.

1The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; 2Zhengzhou University Hospital, Zhengzhou, China; 3The First People’s Hospital of Nanyang, China; 4Henan Provincial People’s Hospital, Zhengzhou, China; 5Central Hospital of Xinzhuang, China; 6The Second Affiliated Hospital of Zhengzhou University, Zhengzhou, China; 7Xijing Hospital of the Fourth Military Medical University, China.

It has been well recognized that esophageal squamous cell carcinoma (ESCC) is the major histopathological type of esophageal cancer in China. However, it is not clear how many and how many esophageal malignant tumor (EMT) exist and if the histopathological patterns have changed over the past decades in China. The present study was thus undertaken to characterize the histopathological patterns over 40 years at a single institute in northern China, the high incidence area for esophageal cancer. All the patient information was from esophageal cancer database in Henan Key Laboratory for Esophageal Cancer Research of the First Affiliated Hospital, Zhengzhou University in Henan, China (1973-2015). A total of 66,216 patients with MET and detailed histopathological records were enrolled in this study, including 39,873 males with a mean age of 60±6 and 26,343 females with a mean age of 60±6 from 1975-2014. All the patients were classified into four period groups based on the diagnosed time code, and group I covers from 1975-1994, group II (1995-2004), group III (1995-2004, 20,781:31,41%) and group IV (2005-2014, 26,527:40,1%). The results demonstrated 12 different histopathological types of EMT. The most common type was ESCC (64,800, 97.4%), followed by esophageal adenocarcinoma (EAC, 12,609, 1.9%), esophageal small cell carcinoma (201, 0.3%), esophageal adenosquamous carcinomas (EASC, 119, 1.8%), esophageal spindle cell carcinoma (56, 0.1%), esophageal undifferentiated carcinoma (57, 0.10%), esophageal malignant melanoma (5, 0.008%), esophageal stromal tumor (3, 0.005%), esophageal clear cell carcinoma (2, 0.003%), esophageal malignant schwannoma (1, 0.002%), esophageal lymphatic tumor (1, 0.002%) and esophageal smooth muscle cell sarcoma (1, 0.002%). Trending analysis showed that, over the past 40 years, ESCC was relatively stable (98.9%, 98.0%, 97.0%, 97.1%, respectively). However, EAC (1.07%, 1.66%, 2.30%, 1.87%, respectively), and small cell carcinoma (0.02%, 0.17%, 0.28%, 0.43%, respectively) and spindle cell carcinoma (0.02%, 0.10%, 0.10%, 0.22%, respectively) increased apparently. The present study indicates that ESCC remains the major histopathological type for Chinese esophageal cancer. Interestingly, esophageal adenocarcinoma, small cell carcinoma and spindle cell carcinoma seem to be increasing over the past decades. The improved molecular diagnostic biomarkers and the changes of lifestyle including the diet patterns resulted from recent economic development in China, may contribute to the changes of esophageal histopathological types.

EPIDEMIOLOGY: Descriptive Epidemiology Including Trends in Incidence and Prognosis

with bilateral presentation. Diagnosis in all cases was made by immunohistochemical analysis on tumor specimen obtained by vitreous fine needle aspiration, vitreous biopsy or stereotactic brain biopsy. Median age at diagnosis was 76 years (range, 62-84 years). Median interval from Chernobyl accident (1986) to diagnosis was 26 years (range, 24-27 years). We identified no other common exposure or environmental risk factor. There were 68 cases of primary IOL during 1992-2013 in the 13 SEER areas. IOL rates per 100,000 person-years for both sexes were highest among Asian/Pacific Islanders (0.010 for males and 0.014 for females) followed by whites (0.009 for males and 0.008 for females) and (based on small numbers) by blacks. Analysis of incidence trends showed an increase in rates among Asian/Pacific Islander females from 0.005 in 1992-2002 to 0.018 in 2003-2013 and among males from 0.006 to 0.013. Rates among whites increased for both genders. Analysis of NYSKR data revealed 44 cases of primary IOL. IOL rates per 100,000 person-years for both genders were highest among whites (0.010 for males and 0.012 for females) followed by Asian/Pacific Islanders (0.007 for males and females). Analysis of trends revealed increase in rates for both genders and racial groups. Conclusions: Our analyses highlight the rarity of VRL and reveal an increase in incidence, particularly among Asian/Pacific Islanders where IOL rates tripled within two decades. Based on incidence rates, 8 cases of IOL (with a subset being VRL) are expected in 4 years in NYS. Our observation of 10 cases of VRL in 4 years in our practices in NYC is unanticipated. The sole common environmental factor we identified was residence in regions proximal to the Chernobyl nuclear disaster.

#260 Incidence rates and outcomes of fallopian tube carcinomas: Data from the North American Association of Central Cancer Registries. Mark E. Sherman,1 Sally B. Coburn,2 Hannah Yang,3 William Anderson,2 Philip Rosenhi1, Gretchen Gierach,2 Nicolas Wentzensen,3 Kathryn Cronin,3 Britton Trabert2,3 Mayo Clinic, Jacksonville, FL; 2National Cancer Institute, Bethesda, MD.

Background: Serous tubal intraepithelial carcinoma (STIC) is hypothesized to give rise to many cancers that have historically been classified as ovarian primaries. Although STIC is gaining status as a diagnostic entity, similar appearing lesions would likely have been reported as fallopian tubal carcinoma in situ (FT-CIS) in the past. Accordingly, to characterize patterns of reporting and behavior for tubal cancers, we analyzed population-based data for incidence rate trends, co-occurrence with cancer at other sites and survival of FT-CIS and invasive fallopian tube carcinoma (FT-Inv). Methods: We analyzed data for FT-CIS and FT-Inv included within 33 registries using the Cancer Incidence in North America Deluxe Analytical Files provided by the North American Association of Central Cancer Registries (1995-2012). Primary sites of invasive carcinomas were defined according to the International Classification of Diseases for Oncology (3rd edition) topography codes (ovarian (C56.9), fallopian tube (C57.0), and primary peritoneal cancers (C48.1-2, 48.82)). We excluded cancers with non-epithelial histology. Total counts, incidence rates per 1 million adjusted to the 2000 standard US population and age-standardized stage-specific survival were computed. Temporal incidence rate patterns were analyzed by jointpoint regression with estimates of annual percentage change (APC). Results: Cases in which the first cancer diagnosis was FT-CIS, included 98 FT-CIS alone; 27 FT-CIS followed by another cancer diagnosis within 1 year and 172 cases in which FT-CIS was diagnosed concurrently with another cancer as compared with 5513 invasive tubal carcinomas over the same period. The incidence rate of FT-CIS was stable from 1995-2002, then significantly increased from 2002-2012 (APC (95% CI) = 16.2% (10.9-21.7)). Rates of early stage high-grade serous FT-Inv increased significantly from 2002-2012 (10.4% (6.1-14.9)) and rates of late stage high-grade serous FT-Inv rose sharply from 2002-2012 (20.0% (17.5-22.6)). Five-year age-standardized survival for women with FT-CIS only was 75.6% overall, reflecting 89.1% survival for women less than 50 years and 70.9% for women 50 years or older; survival for high-grade early stage serous FT-Inv was 77.8%. Conclusions: Diagnoses of FT-CIS and FT-Inv have increased dramatically, likely reflecting changes in diagnostic pathology practice. Developing standardized reporting for FT-CIS (and in the future, STIC) when present with concurrent invasive cancer is needed, given that this occurs often. Based on limited data, 5-year survival for FT-CIS and early stage FT-Inv are similar, but future studies to evaluate data for STIC will be required, which will likely be achievable only through national registries that are large enough to capture sufficient cases.

#261 Pancreatic cancer incidence trends and recent patterns overall and by histologic type among US men and women by racial/ethnic group: evidence from the Surveillance, Epidemiology, and End Results (SEER) program. Van-essa L. Gordon-Dseagu,1 Susan Devesa,1 Mike Goggins,2 Rachael Stolzenberg-Solomon1.1NCI, Rockville, MD; 2Johns Hopkins University, MD.

Introduction: Pancreatic cancer incidence has been rising. We examined incidence patterns by sex, race, age, and histologic subtype. Methods: We used data from the Surveillance, Epidemiology and End Results (SEER) registries (9, 13 and 18) to calculate counts, age-adjusted rates (2000 US Standard Population), annual percent changes (APCs) and incidence rate ratios (IRRs) for all pancreatic cancers and main histologic subtypes. Results: Pancreatic cancer incidence rates declined among males between 1974 and 1991, and increased in the 1992-2013 period among white Hispanics and non-Hispanics (APC= 0.73 and 0.84, respectively). Among females, incidence rates also rose significantly during 1992-2013 among white non-Hispanics, white Hispanics, and Asians (APC= 0.81, 0.56, and 1.23, respectively). In contrast, rates among black males (0.007) and females (0.009) decreased over time. The greatest increase in incidence was among white males who were non-Hispanic age ≥55 years and white Hispanics in the 55-74 age group. Among black males, rates declined in the 45-54 age group at a statistically significant pace. Pancreatic cancer incidence rates for females rose among white non-Hispanics in all age groups <85 years (range: 0.47-4.01), among Asians of ages 55-84, and white Hispanics in the 55-64 age-group. Most pancreatic cancers were specified as adenocarcinoma, not otherwise specified (NOS) or ductal adenocarcinoma. Rates increased among all racial/ethnic groups for adenocarcinoma, NOS and ductal adenocarcinoma while those for cystic mucinous ductal adenocarcinoma and poorly specified type decreased. The incidence rates of non-secretory pancreatic endocrine cancer rose >6% per year among white non-Hispanics and Asian/Pacific Islanders. Overall incidence rate ratios were significantly high among young males than females (p < 0.001). The IRR was >1.00 at all ages ≥35, but rates among females were significantly higher at younger ages (IRR <0.81). The M/F IRRs were elevated for acinar cell adenocarcinoma (2.85), non-secretory endocrine cancers (1.47) and ductal cystic or mucinous adenocarcinomas (1.11), while for solid pseudopapillary adenocarcinoma there was a significant female excess (0.22). Conclusion: Pancreatic cancer incidence rates vary within demographic groups and histologic subtypes.

#262 Analysis of demographics, survival and patterns of care of pediatric glioblastoma using National Cancer Database. Jigisha Thakkar,1 Meng Liu, Emily Van Meter Dressler, John L. Villano. University of Kentucky, Lexington, KY.

Background: We analyzed the largest clinical database in the United States, the National Cancer Database (NCDB), comprising over 70% of cases diagnosed and/or treated at commission on Cancer approved institutions. We analyzed current hospital-based epidemiologic frequency, survival and patterns of care of pediatric glioblastoma (GBM). Methods: Cases included patients 0-19 years between 1998-2011. Inclusion criteria for histology codes included for GBM 9440, 9441 and 9442 (9440 (GBM), 9441(Giant Cell) and 9442 (Sarcomatas component) and tumor sites (C70.0-C72.9, C73.1-C73.5) related to the brain: brain stem, cerebellum, cerebrum, thalamus, and brain not otherwise specified (NOS). Kaplan-Meier survival estimates were calculated for each demographic criteria and treatment plan and Cox proportional hazards models were employed to assess the risk of mortality. Demographic variables analyzed were age, gender, race, Hispanic origin, income, education, region and insurance status. Comparisons were made among histologic subtypes and primary site. Results: 1173 patients with GBM from ages 0-19 with 1998-2011 data from 1998 to 2011 in the United States, of which 21.5%, 24.5% and 54.0% were in age group 0-5, 6-10 and 11-19 years old. The largest group (48%) received advanced care including a combination of radiation (XRT), chemotherapy and surgery. On the other hand, the no treatment group was the smallest comprising of 4% cases. 14% received surgery only, 8% received a combination of XRT and surgery and 9% received a combination of XRT and chemotherapy. Patients that received combination of XRT, chemotherapy and surgery had significantly improved survival compared to those without any treatment (p = 0.0048). Patients that received surgery or chemotherapy had significantly improved survival compared to patients that did not receive the above treatments (p = 0.0027). Conclusion: We report an extensive demographic and survival analysis of pediatric GBM. Observed difference likely reflect biology across age, gender, race and origin groups. Our analysis demonstrates concern in the delivery of optimal care to a large percentage of pediatric patients. These treatments include surgery and chemotherapy that have demonstrated survival benefits. Adverse effects of chemotherapy and XRT can have the limit the appropriate administration of treatment.
Introduction: In this study we investigated epidemiology and trends of primary lung cancers in northeast of Iran during 1985-2012. Methods: In this cross-sectional study records of primary lung cancers from 1985 to 2012 in Mashhad, northeast of Iran, were investigated. Data were obtained from the referral oncologic hospital and private radiation oncology clinic. To study trends, the duration of study was categorized into three periods: 1985-1995, 1995-2005 and 2005-2012. Statistically significant level was considered <0.05. Results: Of 939 cases with mean age of 60.57 (±12.31) years, 660(70.3%) were male. Male to female ratio was 2.36. Mean age was 61.47±12.01 years for males and 58.45±12.75 years for females (p=0.001). Mean age at diagnosis and rate of smokers was unchanged in three intervals (table 1).

Squamous cell carcinoma with relative frequency of 44.2% was the most frequent pathologic subtype in total population followed by adenocarcinoma (18.2%), Small Cell Lung cancer (16.8%), large Cell carcinoma (1.3%) and other subtypes (19.5%). Relative frequency of pathologic subtypes had significant changes in three intervals (p<0.001). Relative frequency of adenocarcinoma and large cell carcinoma were increasing while it was decreasing for SCC and SCLCs during three recent decades. There was statistically significant difference in mean age at diagnosis (p<0.001), rate of smokers (p<0.001) and male to female ratio (p=0.01) between four leading pathologic subtypes. Mean age at diagnosis (55.92±12.90 years), male to female ratio (1.69), and rate of smokers (46.8%) were lowest in adenocarcinomas. Conclusion: Similar to universal picture, adenocarcinoma showed increasing rates during recent three decades with higher prevalence among younger aged patients, women and nonsmokers. These trends are indicative of changes in exposures and smoking habits and reveal the need for regional studies in this context.

#264 Time trend for the ratio of rural and urban patients with esophageal squamous cell carcinoma in a single institute in northern China over the past 30 years. Shou Jia Hu,1 Hai Jun Yang,2 Neng Chao Wang,2 Xiun Min Li,3 Shuang Lv, Qi De Bao,4 Wen Bin Yue,5 Fu You Zhou,6 Jian Li,8 Li Dong Wang1.

Aim: This study was aimed to evaluate the age at the time of diagnosis of breast cancer and its’ probably changes in distribution among patients during 30 years. Methods: This cross-sectional study was conducted in Mashhad, Iran from 1981 until 2011. The data of patients were obtained from case records. The duration of study was categorized into three periods: 1981-1990, 1991-2000 and 2001-2011. SPSS software was used for analyses. The difference was considered significant if P<0.05. Result: From 6274 breast cancer cases, 174 patients were male (2.5%) with detailed address. Based on the diagnosed time, these patients were divided into three groups with periods of 1985-1994, 1995-2004 and 2005-2014. The rural and urban regions were recognized based on the government administrative division of China. The rural region in China refers to the farmer village with hundreds to thousands population. Chi-Square test was used to analyze the different distributions of ESCC patients with a p-value of less than 0.05 as significant. The results demonstrated that more than 84% of the ESCC patients occurred in rural regions with an overall ratio of 5:1 for rural and urban regions (p<0.0001). Moreover, over the past 30 years with three periods, the ratios for rural and urban regions were 5.4:1, 5.5:1 and 5.4:1, respectively. The present study demonstrated that the past 30 years with three periods, ESCC occurred predominantly in males with ratios for male and female as 1:5.1, 1:4.1 and 1:5.1, respectively in rural regions and 1:6.1, 1:6.1 and 1:8.1, respectively in urban regions. Interestingly, the mean age both in male and female in urban regions was slightly older than that in rural regions (urban vs. rural: 60.7±9.86 vs. 59.8±9.38 in male and 62.2±9.57 vs. 60.6±9.47 in female, respectively). The present study demonstrated that ESCC remains the major healthy burden in rural regions in China. Considering the relative low socioeconomic status in China, the prevention and control of ESCC should be enhanced in rural regions in terms of more control programs, medical and education resources. [Supported by National High-Tech Research and Development Program of China (SQ2015A.A0202183), Project for Characteristic and Advantage Discipline of Henan Province (20151208)]

#265 Global transition in cardia and non-cardia gastric cancer incidence, 1998-2007. Asesh Shin,1 Dalis Seunghun Kim,2 Hyungtaek Woo1. 1Seoul National University College of Medicine, Seoul, Republic of Korea; 2USF Morsani College of Medicine, Seattle, FL.

Esophageal cancer and non-cardia cancer differs in their descriptive patterns and risk factors. The objective of this study was to determine the global trends in incidence of cardiac and non-cardiac gastric cancer. Ninety two high quality registries with the proportion of Not Otherwise Specified (NOS) gastric cancer (ICD-10 code C16.8-9) below 50% and the total number of gastric cancer cases above 300 were selected from 225 registries in Cancer Registry of Five Continents (CI5) volume 9 and 262 registries from CI5 volume 10. The NOS cases were re-distributed to cardia and non-cardia according to the registry-specific proportion. Age-standardized incidence rates (ASRs) per 100,000 population and incidence rate ratios (IRR) from 1998-2002 to 2003-2007 were calculated. Non-cardia cancer incidence was significantly increased in 5 out of 10 Asian registries, 17 out of 18 European registries, 27 out of 56 North American registries, and all 5 Oceanian registries in men. Only two registries in Asia showed a significant increase in non-cardia cancer incidence. In contrast, cardiac cancer significantly increased in one Asian registry, two European registries, and two North American registries. Significant decrease in cardia cancer was observed in 3 Asian registries, 6 European registries, 11 North American registries, and 3 Oceanian registries in men. In women, six registries (1 Asian, 2 European, and 3 North American) showed significant increase in non-cardia cancer, whereas registries 23 (5 Asian, 14 European, 8 North American, and 1 Oceanian) showed significant decrease in non-cardia cancer incidence. Cardia cancer in women increased in 16 registries (2 Asian and 14 North American) and decreased in 9 registries (1 Asian, 5 European, and 3 North American). In conclusion, non-cardia cancer incidence decreased in most registries, whereas decrease in cardiac cancer is more prominent in men but not in women.

#266 Trends in age distribution of breast cancer, in north east of Iran: Report of six thousand patients over 30 years. Maryam Salehi, Soodabeh Shahidzadeh, Mehdi Seilianounti, Gholamhosein Noferesti, Mahta Salehi, Amirhossein mohammadian baqirian. Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran.

Aim: This study was aimed to evaluate the age at the time of diagnosis of breast cancer and its’ probably changes in distribution among patients during 30 years. Methods: This cross-sectional study was conducted in Mashhad, Iran from 1981 until 2011. The data of patients were obtained from case records. The duration of study was categorized into three periods: 1981-1990, 1991-2000 and 2001-2011. SPSS software was used for analyses. The difference was considered significant if P<0.05. Result: From 6274 breast cancer cases, 174 patients were male (2.5%) and 6100 were female (97.5%). Mean age at the time of diagnosis was 49.07±12.07 years (male: 56.48±14.14, female: 48.8±12.01). There was significant difference in age by sex (p<0.001). Table 1 presents the mean age of studied patients in each 10 years of study. ANOVA test showed that there was not statistical significant difference (P value= 0.1).

The most histologic type of breast cancer was ductal carcinoma 65.6% others percent in order were: NOS 19.6%, lobular 3.7%, medullary 2.8%, adenocarcinoma 2.8%, tubular and papillary 0.2% and 5.1% of other types. Relative frequency of histologic types had significant differences among 3 intervals (p <0.001), the frequency of adenocarcinoma was decreasing but ductal carcinoma was increasing during 3 decades. Mean age was ductal carcinoma, lobular, medullary and adenocarcinoma was 48.9 ±11.8, 50.6 ±12.4, 46.4 ±11.4, 50.2 ±11.9, respectively. Mean age had significant differences among these main histologic types (p =0.002).98% of patients were urban and 2% were rural. Mean age of these 2 groups has statistical significant difference (P = 0.001) and is 10 years older in rural patients. Frequency of people who live in urban area was increased significantly (p =0.08) during these 30 years of diagnosis and this trend concurs: breast cancer occurs in Iranian women at least one decade younger than women in developed countries we found no change in mean age of diagnosis for breast cancer during these 30 years from 1981 to 2011.

The most likely cluster identified was a cluster of low ICC incidence [aRR 2.47, p-value <0.01] was identified in a suburban and adenocarcinoma was 48.9 ±11.8, 50.6 ±12.4, 46.4 ±11.4, 50.2 ±11.9, respectively. Mean age had significant differences among these main histologic types (p =0.002).98% of patients were urban and 2% were rural. Mean age of these 2 groups has statistical significant difference (P = 0.001) and is 10 years older in rural patients. Frequency of people who live in urban area was increased significantly (p =0.08) during these 30 years of diagnosis and this trend concurs: breast cancer occurs in Iranian women at least one decade younger than women in developed countries we found no change in mean age of diagnosis for breast cancer during these 30 years from 1981 to 2011.

Epidermology: Descriptive Epidemiology including Trends in Incidence and Prognosis

#267 GeoSurveillance of invasive cervical cancer incidence by counties in the state of Maryland. Sally Peprah, Frank Curriero, Amber D’Souza. Johns Hopkins University, Baltimore, MD.

Background: Invasive cervical cancer (ICC) is a highly preventable cancer whose rates have dramatically declined over the past few decades. In spite of the progress made, new ICC cases are recorded annually in Maryland and in other parts of the United States. We assessed if ICC incidence varied significantly 2005-2012 and across counties within the state of Maryland. Methods: Using a discrete Poisson model we evaluated significant space-time clusters of both high and low ICC incidence rates over a retrospective 10-year period. All analyses were con-
ducted at the county level, using 2-year aggregates of time. We adjusted for age-
percent minority, cervical cancer screening rates, median income, obesity as well as smoking rates within each county in our final cluster detection analysis. Re-
sults: ICC was 13.1 per 100,000 female population and did vary by county and over the 10-year period assessed. We identified five significant space-time clus-
ters of ICC incidence, three of which were clusters of higher than expected rates. The most likely cluster identified was a cluster of low ICC incidence [aRR =0.08, p-value<0.01] observed for the period 2009-2012 and comprised six high-
income suburban counties. The other cluster of low rate [aRR =0.41, p-value<0.01], which was a secondary cluster, was observed for the same time period, 2009-2012 in three high to moderate-income suburban counties. There were two clusters of high ICC incidence, observed for recent time periods. One cluster [aRR=1.74, p-value<0.01], which was made up of a single moderate to low-income urban county was identified for the period 2009-2012. The other cluster of elevated rates [aRR =2.47, p-value<0.01] was identified in a suburban moderate-income county for the period 2011-2012. Additionally, for the period 2005-2008 we identified a historical cluster of elevated incidence [aRR =2.53, p-value<0.01], Conclusion: Overtime some counties in Maryland have experi-
enced significantly lower rates of disease than expected. However there are more recent clusters of higher than expected rates of disease, which are not explained by the county level variables adjusted for. These clusters of high rates need to be further examined and addressed.

#268 Tracking HPV vaccination of young boys: is parental recall as de-
pendable as physician records. Nosayaba Osazuwa-Peters,1 Betelihem B. Zou-
eda Zaidi, Mokhtar Hamdi Cherif. University Hospital of Setif, Setif, Algeria.

Introduction: HPV vaccine is administered to young boys and girls aged 11-12 years in multiple doses rather than single dose. The interval between doses is critical as well as completion of the dose series. Moreover, the administration of the HPV vaccine in 2 doses is a recent change from the 3 doses previously recommended for children aged 11-12 years. Therefore, it is critical that HPV vaccination uptake records are accurately kept as interventions are developed to increase HPV vaccine uptake. Previous studies on the validity of parental re-
ported HPV vaccine uptake have focused only on adolescent girls. This is be-
cause the HPV vaccine recommendation for boys came 5 years after that for girls. Currently, vaccination rates among boys lag behind those for girls across the United States. This study compared the validity of parent- vs. provider-
reported HPV vaccine initiation and completion rates among a national sample of adolescent boys in the United States. Methods: We analyzed the 2014 National Immunization Survey-Teen data for adolescent boys only (n = 9,493), and ob-
tained information on the records of HPV vaccine uptake (initiation (=1 dose) and completion (= 3 doses)) for both parents (parental recall) and provider reports (electronic medical records). We compared the validity of parent- versus provider-reported HPV vaccination by computing validity measures [sensitiv-
ity, specificity, positive predictive value (PPV), negative predictive value (NPV), and kappa]. Results: Rates reported by provider and parental recall were similar for HPV vaccine initiation (41.8% vs. 42.7%, respectively), and completion (19.6% vs. 21.9%, respectively). Compared to provider report, parent-reported HPV vaccine initiation had a sensitivity of 83.0%, a specificity of 88.8%, a PPV of 84.1%, a NPV of 87.9%, and a kappa coefficient of 0.72. Compared to provider report, parent-reported HPV vaccine completion had a sensitivity of 68.6%, a specificity of 92.9%, a PPV of 72.9%, a NPV of 91.4%, and a kappa coefficient of 0.63. Conclusions: Both parent- and provider-reported HPV vaccine initiation and completion rates were comparable; however, parental recall of HPV vaccine completion among boys was less sensitive. Ongoing surveillance of HPV vacci-
nation rates among boys is important as more studies are designed to improve HPV vaccine uptake and understanding these 30 years of HPV vaccine barriers. In this regard, parental recall may be used as an effective alternative in assessing HPV vaccine uptake in the United States.

#269 The descriptive epidemiology of gynecologic cancers: an interna-

Introduction: Gynecologic Cancers are the most common cancers in women, in 2012, Cervical Cancer (CC) is ranking as the fourth with an estimated 528,000 new cases and Ovarian Cancer (OC) is the seventh most common for females with nearly 239,000 new cases worldwide. Aim: this communication presents the latest international descriptive epidemiological data for invasive GC, includ-
ing incidence, survival and mortality in the worldwide. Methods: The incidence and mortality statistics presented for GC worldwide were taken from the Intern-
national Agency for Research on Cancer IARC: * the Cancer Incidence in five Continents Vol X and * GLOBOCAN database, 2012. The data of cancer sur-
ival are taken from: * Cancer survival in five continents, a worldwide popul-
ation-based study (CONCORD) version 2, 1995-2009. Estimated five-year net survival, adjusted for background mortality by single year of age, sex, calendar year in each country. Results: CC is the most common cancer among women in 43 countries mainly in sub-Saharan Africa, part of Asia and some countries in Central and South America, the lowest incidence rates in western Europe, North America, Australia and the eastern Mediterranean. Almost 55% of all new cases of OC occurred in countries with very high level of human development mainly northern Europe and America and Oceanic, Africa presents the lowest inci-
dence. -Data for CC are available for 602 225 women, CC survival was 50% or higher in most countries, except for Libya (Benghazi, 39%) and India (Karuna-
gapally, 46%). During 2005-09, age-standardised 5-year net survival was 70% or higher in Iceland, Mauritius, Norway, South Korea, and Taiwan, for Qatar is also above 70% (based on only 16 cases and is not age-standardised). -Data for ova-
rian cancer are available for 779 302 women, during 2005-09, age-standard-
sed 5-year net survival was 40% or higher in Ecuador, the USA, nine countries in Asia and eight countries in other regions mostly in the range 30–40%, except for Libya (22%). Conclusions: The evolution of cancers in women shows a consistent and very striking pattern during the epidemiolog-
ical transition with rapid declines in the incidence of cervical cancer. Compa-
rision of population-based cancer survival CONCORD study 2 showed very wide variations in survival from gynecologic cancer worldwide.

#270 Trends in colorectal cancer survival in Arab World, 1990-2009. Zou-
bida Zaidi, Mokhtar Hamdi Cherif. University Hospital of Setif, Setif, Algeria.

Introduction: Cancer survival is a key measure of the effectiveness of health-care systems. Globally, colon and rectum cancer ranked third for cancer incidence and fourth for cancer death in 2013. For developed coun-
tries it ranked second for incidence and mortality, and in developing coun-
tries it ranked fourth for both incidence and mortality. An increasing trend in incidence is reported from various registries of Arab world, Kuwait and Saudi Arabia present the highest incidences worldwide. Objective: To de-
scribe the trends of the survival of colorectal cancer patients diagnosed in Arab countries. Material and Methods: This report is a summary of the two survival figures of CONCORD study 1 (1990-1994) and CONCORD study 2 (1995-2009). Individual colon and rectum tumour records were submitted by 06 population-based cancer registries in Arab countries (Jordan, Saudi Arabia, Qatar, Algeria, Libya and Tunisia) for 9050 patients (15-99 years) diagnosed during 1990-2009 and followed up to 31 December 2009 . Esti-
mated five-year net survival, adjusted for background mortality by single year of age, sex, calendar year in each country. Results: For patients diag-
nosed during the period 2005-2009, the age-standardized five-years net sur-
rvivals were respectively higher 68.2% for colon cancer and 77.8% for rectal cancer in Qatar and the lowest rate for rectal cancer 21% in Jordan, between 1995-1999 and 2005-2009, Survival increased in Algeria, but this trend is less reliable Conclusions: Comparison of population-based cancer survival
Concord study showed very wide variations in survival from colorectal cancer in Arab world. Cancer survival research is being used to formulate cancer control and the need to implement effective strategies of primary prevention.

**271 Clinical and molecular study of breast cancer in Algerian women from the Aures region: Data from the anti-cancer center of Batna. Farid Cherbali,1 Chiraz Mehennim,2 Khadija Gassi,3 Abdelmoumen Gue-divra,4 Yos Hamidi,5 Wassila Benbrahim,6 Rabah Bakour1.1 Unit of Genetics, LMBM, Faculty of Biological Sciences, USTHB, Algiers, Algeria; 2Laboratoire de Génomique Biomédicale et Oncogénétique (LR11 IPT 05) Institut Pasteur de Tunis, Tunisia; 3LOBEM, Faculty of Biological Sciences, USTHB, Algiers, Algeria; 4Anti-cancer center of Batna, Batna, Algeria.

Background: Breast cancer is currently the leading cause of cancer morbidity and mortality among Algerian women. The aim of this study was to analyze the different proportions and distribution of breast cancer molecular subtypes and to determine their associations with some clinical and pathological characteristics in women from the Aures region. We also screened for the prevalence of BRCA1 germline mutations in HBOC patients. Materials and Methods: Clinical and tumor characteristics data of 1144 breast cancer patients were collected from cancer registry of anticancer center of Batna. Breast cancers were diagnosed between 2011 and 2015. Breast cancer subtypes definitions were as follows: Luminal A (ER+/PR+, HER2−), Luminal B (ER+ and/or PR−, HER2±), TNBC (ER−, PR−, HER2±), and HER2+ (ER−, PR−, HER2+). We also compared patients with TNBC and those with other breast cancer subtypes. In addition, we compared patients with the two groups regarding clinicopathological parameters: age at diagnosis, menopausal status, histological type, histological grade, breast feeding and oral contraception were examined using Chi square test. BRCA1 was screened by PCR direct sequencing in 22 HBOC patients including breast feeding and oral contraception were examined using Chi square test.

Background: The risk of primary central nervous system lymphomas (PCNSL) is greatly increased in HIV-infected people. Case series have described PCNSL in immunosuppressed solid organ transplant (SOT) recipients. Herein, we examine the incidence and risk factors for PCNSL in SOTRs. Methods: We used data from the Transplant Cancer Match Study, which links the US transplant registry with 17 cancer registries (1987-2014). PCNSL risk relative to the general population was estimated as a standardized incidence ratio (SIR = observed/expected cases). Poisson regression was used to estimate adjusted incidence rate ratios (aIRR) of PCNSL across subgroups of SOTRs. Logistic regression was used for case–control comparisons of PCNSL with other non-Hodgkin lymphomas (NHL). Results: We included 286,637 SOTs. There were 173 PCNSL cases (SIR 57.7; 95% CI 49.4-66.9) and 2,583 other NHLs (SIR 7.3; 95% CI 7.0-7.6). Most PCNSL were diffuse large B-cell lymphomas (n=118; 68.2%). Compared to kidney SOTRs, PCNSL risk was lower in liver SOTRs (aIRR 0.3; 95% CI 0.3-0.9), not different in heart and/or lung SOTRs (aIRR 0.9; 95% CI 0.6-1.5) and higher in other/multiple SOTRs (aIRR 2.4; 95% CI 1.5-3.8). Asians/Pacific Islanders had higher PCNSL risk than non-Hispanic whites (aIRR 2.0; 95% CI 2.3-3.3). People who received induction therapy with alemtuzumab (aIRR 2.8; 95% CI 1.5-5.3) or polyclonal antibodies (aIRR 1.9; 95% CI 1.3-2.8) had higher PCNSL risk. SOTRs who were seronegative for Epstein-Barr virus (EBV) at transplant had higher risk (aIRR 2.0; 95% CI 1.1-3.5) than seropositive SOTRs. PCNSL risk was high in the first 1.5 years after SOT (0.5-1 year, aIRR 2.6; 1.5 years, aIRR 2.3; vs. 0.5 year) and progressively decreased over time (ptrend<0.0001). Risk did not differ according to the age at SOT, sex, or maintenance immunosuppressive regimen. Compared to other NHL, PCNSL cases were more likely to be middle aged (18-64 years) at transplant (aIRR 0.099). Asians/Pacific Islanders (p=0.02), or have received induction therapy with polyclonal antibodies (p=0.002), and less likely to be liver or heart and/or lung SOTRs (p=0.02). EBV serostatus did not differ between PCNSL and other NHL (p=0.11). Conclusions: PCNSL risk is very elevated among SOTRs. Because EBV-seronegative SOTRs are at risk of primary infection after SOT, these results highlight the importance of contribution of EBV to PCNSL. Particularly, we identify EBV-receptor status (within the first 1.5 years after transplant, in people who receive multiple non-thoracic organs, and is associated with induction therapy with alemtuzumab or polyclonal antibodies. Case–case differences with other NHLs suggest unique epidemiologic factors leading to PCNSL.
there are underlying molecular differences between E-CRCs and T-CRC that may explain these differences. To investigate this we analyzed the TCGA CRC dataset for genomic markers that can distinguish between E-CRC and T-CRC tumors. Results: E-CRC incidence has risen at an annual rate of 1.4% per year from 2000-2011, whereas T-CRC incidence has declined by 3.1% per year among patients 50 years or older during the same period. Relative risks: 2.04 (95% CI 1.90-2.19) for E-CRC compared to T-CRC. E-CRC rates are significantly more prevalent in the Black population than the White or Hispanic populations. Anatomical location of E-CRC is significantly increased towards the distal colon when compared to T-CRC locations suggesting a distinct etiology. Analysis of risk factors confirmed that U.S counties with high rates of diabetes, obesity and smoking were significantly correlated with higher T-CRC rates. However, no such correlations were observed for E-CRC rates. Analysis of the limited number of E-CRC in the TCGA cohort identified a number of known oncogenes that are suggestive of distinct E-CRC tumorigenesis. Conclusions: Our results suggest that E-CRC appears to be distinct from T-CRC. Young patients with CRC represent a distinct patient group with unique epidemiology and mechanisms of disease development. The increase in left sided colon and rectal cancers is consistent with earlier reports and although the underlying reasons are unknown, they are suggestive of differences in tumor genesis and mutational characteristics. To follow up on this hypothesis we are performing additional genetic and epigenetic characterization of E-CRC and matching T-CRC samples collected at Weill Cornell.

#275 The prevalence of endometrial cancer in women with postmenopausal bleeding: a systematic review and meta-analysis. Megan A. Clarke,1 Beverly J. Long,2 Arena Del Mar Morrill,1 Jamie N. Balkum-Games,1 Nicolas Wentzensen,3 National Cancer Institute, Rockville, MD; Mayo Clinic, Rochester, MN.

Background: Endometrial cancer is highly curable when detected early, but clinical symptoms are often missed. Most cancers arise in women with abnormal postmenopausal bleeding (PMB). However, PMB is not specific for endometrial cancers. In previous reports, the prevalence of endometrial cancer in women with PMB was reported to range from 3-25%. Because of the importance for guiding clinical management and endometrial cancer risk prediction, we conducted a systematic review and meta-analysis to obtain precise prevalence estimates of endometrial cancer in women with PMB. Methods: A systematic review and meta-analysis summarized all peer-reviewed studies reporting endometrial cancer prevalence in women with PMB, published before Sept 1, 2016. We calculated a pooled prevalence estimate and 95% confidence interval (CI) using a random-effects model, and quantified heterogeneity across studies using the I² statistic. Subgroup meta-analyses were performed to investigate sources of variability according to selection criteria for endometrial thickness (ET) and hormone replacement therapy (HRT). We also stratified by study location to determine whether prevalence estimates varied by country or region if ≥5 studies included per country. Results: 105 studies were included, contributing data for 37,000 women with PMB and 3,028 with cancer from 34 countries. Overall, the pooled prevalence of endometrial cancer in women with PMB was 11% (95% CI 10-12%), with F = 94.3%. Among studies that selected women with a minimum ET (≥4mm; n = 14), the pooled prevalence of endometrial cancer was 17% (95% CI 14-20%) compared with studies that did not select for ET (10%; 95% CI 9-11%). In studies that excluded women using HRT (n = 34), the pooled prevalence of endometrial cancer was 15% (95% CI 12-17%) compared with studies that did not exclude women using HRT (10%; 95% CI 9-11%). Additional stratification by ET and HRT revealed variation in prevalence estimates. For example, in the United States (n = 9) and the United Kingdom (n = 16), prevalence of endometrial cancer was 4% (95% CI 2-7%) and 5% (95% CI 4-6%), respectively, whereas in Italy (n = 14), the prevalence was 11% (95% 8-14%). Regional differences were also observed, ranging from 8% (95% CI 3-14%) in South Central Asia (n = 5) to 18% (95% CI 12-23%) in Southern Europe (n = 11). Conclusions: The overall prevalence of endometrial cancer among unselected women with PMB is approximately 10% with substantial heterogeneity across studies. Marked geographic differences in the prevalence endometrial cancer were observed. Factors related to selection for ET and/or HRT use may partially contribute to this variability. Risk prediction models depend on precise prevalence estimates for accurate prediction and utility in clinical management. More research is needed to test the applicability of endometrial cancer risk prediction models in high-risk subgroups and in study populations from diverse geographic regions.

#276 Retrospective analysis of epidemiological variants of malignancies in Sokoto, Northwestern Nigeria. Saddiku M. Sahabi, Kabiru Abdullahi. Usmanu Danfodiyo University Teaching Hospital, Sokoto, Nigeria.

Background: The burden of cancer in Nigeria is increasing. Information on incidence, prevalence, pattern, and high risk factors are essential for evaluation and cancer control. This report is a follow up from earlier previous report published in 2005 on cancers seen in Usman Danfodiyo University Teaching Hospital (UDUTH) Sokoto. Objectives: The aim of this study is to determine epidemiological variants of all malignances seen from 1 January 2006 to 31 December 2015. Materials and Methods: This is a retrospective review of all malignancies seen at the Usmanu Danfodiyo University Teaching Hospital in Sokoto during the period 2006 to 2016. There was no restriction on gender or age groups. Mean, frequencies, percentages, and independent sample t-test were performed using SPSS version 21.0 for Windows. Results: A total of 1,435 oncology patients diagnosed from birth to 23 years of age at St. Louis Children’s Hospital from January 1, 2004 - December 31, 2014 were reviewed. CA information was extracted and verified with ICD-9 codes when available. Patients followed for <1 year at SLCH (n = 193), and those diagnosed with a chromosomal anomaly or known cancer predisposition (n = 113) were excluded from the analysis. Bivariate analyses compared demographic and other characteristics between patients with and without a CA with significant differences determined by chi-square tests. We calculated age-adjusted standardized rate ratios (SRRs) to evaluate whether the observed number of CAs among specific cancer types (benign, bone, CNS, epithelial, leukemia, lymphoma, germ cell, and soft tissue tumors) varied from the expected number using the CA rates from the entire cohort as the reference. Differences in survival time distributions in cancer cases with CAs versus those without CAs were evaluated with the log-rank test. Results: Of 1,129 SLCH pediatric cancer patients, 154 (14%) patients were identified with a CA. Overall there was an increased proportion of patients with a CNS tumor who also had a CA compared to those without a CA (p = 0.005). Neurological anomalies were specifically found to be in excess in CNS tumors cases versus the overall population of pediatric cancer patients (SRR = 1.42 95% CI 1.02-1.92 p = 0.038). There were no significant differences by age at primary tumor diagnosis, but patients with a CNS tumor and CA were diagnosed an average of 1.5 years earlier (7.7 vs. 9.2 years, p = 0.075) compared to those without a CA. The rate of CAs did not vary significantly by sex, but a significant excess of males with a neurological anomaly was observed among all patients diagnosed <5 years of age (M/F ratio = 2.53 95% CI 1.15-5.56 p = 0.02). Finally, survival between those with and without a CA was not significantly different (p = 0.24). Conclusions: This study provides additional insight into the association between specific types of CAs and cancer development. Our results suggest children with neurological anomalies are more likely to develop CNS cancers and may be at an increased risk to develop cancer at an earlier age, particularly in males. Our study supports the need for additional longitudinal surveillance and research that may improve outcomes as well as translational research to investigate any associated developmental mechanisms that may underlie tumor predisposition.
#279 Clinicopathologic features and management of bronchopulmonary and pleural malignancies in Ile Ife, Nigeria. olanusum O. Adewole, Obafeni Awalowo University/Teaching Hospital, Ile Ife, Nigeria.

Introduction. Lung cancer is the most common cancer of cause related death worldwide with increasing incidence in developing countries, Nigeria inclusive. The aim of this study is to evaluate the clinical patterns, diagnostic procedures and management of bronchopulmonary cancer (BPC) and pleural cancer (PLC) seen in Ile Ife, Nigeria. Method. All cases of bronchopulmonary and pleural cancer seen over an eighteen year period (1990-2015) at OAUTHC, Ile Ife, Nigeria, a tertiary center were reviewed. Cases were identified from the admission and discharge files on the wards and were retrieved from the main medical record library. All retrieved cases were analyzed and presented, using a descriptive statistics. Results. Thirty seven cases of BPC and PLC were identified of which twenty two cases files were fully retrievable, and these are presented. There were twenty one cases of BPC and two PLC. The male to female ratio of BPC was 2:1 while it is 1:1 for PLC. The mean age of patients was 51 years (range 48-85yrs) and 45(30-66yrs) for BPC and PLC respectively. Cough and weight loss were the most common symptoms among at the patients. 45% had chest pain while 15% had hemoptysis. The symptoms had presented for more than 3 months. Outdoor pollution were identified as the risk factors in 20% of each patients with BPC. 10% of patients with BPC had a past history of TB about 10 years prior to the presentation. One of the cases of PLC some had exposure to asbestos in his work as a carpenter. Three patients with BPC presented with features of SVC. Pleural effusion was the main chest pathology, it was found in 65% of the BPC cases and the entire PLC. The right hemithorax were mainly involved. Diagnoses were made by pleural fluid cytology, pleural biopsies, FNAC, LN biopsies, bronchoscopy in 41%, 10%, 10%15% and 5% of BPC respectively. Other diagnostic procedures done in PLC included open thoracotomy. Adenocarcinoma was the commonest histologic type of BPC, while it was mesotheloma for PLC. Few.

The lymph node metastasis (LNM) is one of the crucial risk factors for esophageal squamous cell carcinomas (ESCC) prognosis. However, it is difficult to precisely determine the LNM status before surgery. The maximum tumor length (MTL) may reflect the ESCC growth speed and could be calculated accurately either with computed tomography or ultrasound endoscopy before esophagectomy. Therefore the present study was designed to determine if the MTL could reflect the LNM status for ESCC. A total of 22,660 ESCC patients was enrolled in this study from the ESCC database (1973-2015) in Henan Key Laboratory for Esophageal Cancer Research of The First Affiliated Hospital, Zhengzhou University. Of these patients, there were 13,793 males with an mean age of 60±8, and 8,867 females with a mean age of 61±8. All the cases had been performed radical esophagectomy. The MTL and LNM records were retrieved from the medical records in hospitals. Based on the 6th version of UICC criteria, the LNM was classified as N0 and N1. The MTL was classified as 5 groups: <2cm, ≥2 and <4cm, ≥4 and <6cm, ≥6 and <8cm, ≥8cm. The SPSS21.0 software and Spearman rank correlation were used to determine the correlation of MTL and LNM. The results demonstrated that the average and median of MTL were 4.1±1.8 cm and 4.0 cm (range: 0.1-18 cm) in these ESCC patients. The positive lymph node metastasis rates in each MTL groups were 19.1%, 34.1%, 45.8%, 51.5%, and 54.1%, respectively. Spearman rank correlation analysis indicated that MTL was strongly correlated with LNM (r=0.997, P<0.001), suggesting that MTL could reflect the LNM status in ESCC and that MTL could be used as one of clinical staging parameters for ESCC. Supported by Major Science and Technology Projects of Henan Province (161100311300). National Key Research and Development Program: Precision Medicine (2016).
of rectal was higher than distal or proximal cancer (OR=2.64, 1.95 and 1.32, respectively). Conclusions: Presence and strength of association of cancer risk factors may differ by CRC site. Site should be a key consideration in future studies of CRC risk.

EPIDEMIOLOGY: Descriptive Epidemiology Including Trends in Incidence and Prognosis

The accumulated evidences have indicated the importance of lymph node dissection (LND) in improving survival for esophageal squamous cell carcinoma (ESCC). However, it is largely unclear in terms of standard lymph node dissection, e.g., how many is suitable and which node station is more important, etc. The present study was undertaken to summarize the trends of lymph node dissection in ESCC over 40 years at a single institute in northern China. A total of 27,260 ESCC patients were enrolled in this study from 1974 to 2016, including 16,565 males with a mean age of 59.72 ± 7.82 and 10695 females with a mean age of 60.3±8.51. All the patients were from the ESCCC database in Henan Key Laboratory for Esophageal Cancer Research of the First Affiliated Hospital, Zhengzhou University (1973–2016). All the patients had pathological LND records, including the number dissected. The patients were classified into four period groups based on the diagnosed time, group I (1974 to 1986, 367/1.3%), group II (1987 to 1996, 312/1.7%), group III (1997 to 2006, 10, 494/38.5%) and group IV (2007 to 2016, 13,217/48.5%). The SPSS21.0 software was used to evaluate the trending changes of LND at different periods. The results showed that the total number of LND/the mean number by each patient from group I to group IV was 3,000/843, 22,001/7.07, 87,740/8.36, and 159,340/12.06, respectively (p<0.0001). Further analysis indicated that the total number of LND/the mean number by each patient from group I to group IV in males was 1,634/793, 13,428/699, 53,143/8.53 and 100,073/12.19, respectively and 1,368/848, 8,573/6.80, 34,597/8.11, 59,267/11.83, respectively in females. The present results indicate an apparent increasing in number of LND from 1987 to 2016 for esophageal cancer surgical treatment in China. Further analysis is needed to correlate the LND and metastasis and survival. (National High-Tech Research and Development Program of China (SQ2015AA0202183), Major Science and Technology Projects of Henan Province (16110031300).

#285 Standardized prediction estimates for cancerous and noncancerous gynecologic lesions: a preliminary study in an oil city of Niger Delta region. Felix M. Onyije,1 Anthony A. Ngokere,2 Aloysius E. Ligha,3 Osaro O. Mgbere, Godwin O. Awioro.4 Niger Delta University, Wilberforce Island, Delta State, Nigeria; 2Nnamdi Azikiwe University, Awka, Nigeria; 3Institute of Community Health, University of Houston, Texas Medical Center, Houston, TX; Delta State University, Abraka, Delta State, Nigeria.

The objective of this pilot study was to determine the epidemiology of gynecologic cancer and non-cancerous lesions and to develop standardized prediction estimates for the diseases in thirty-five years time. The impact of cancerous and non-cancerous lesions on women’s health cannot be underestimated, especially where there is constant emission of hydrocarbons and contaminated water level through oil spillage. Data used for this retrospective study comprised of 679 records and covering the period 2010-2014 were retrieved from the archive of Brathwaite Memorial Specialist Hospital (BMSH) Histopathology laboratory in Port Harcourt, Nigeria. Total of 32 (4.6%) cancerous and 665 (95.4%) non-cancerous lesions were diagnosed with the distribution pattern differing significantly (p<0.001) by year of diagnosis, developmental stage and age category. Leimyroma recorded the highest 5-year standardized prevalence rate of 0.508, and without intervention, it is estimated that the number of cases diagnosed will rise from 235 in 2015 to 1883 by the year 2050. This was followed by ovarian cyst with a prevalence rate of 0.124 and projected increase from 57 in 2015 to 461 by the year 2050. Similarly, the product of conception is also predicted to increase from 34 to 277 by the year 2050. The 700% increase prediction of cancerous and non-cancerous lesions by 2050 calls for urgent attention for both governmental and private agencies to fund awareness campaigns and screening for women, especially for those residing in oil and gas producing areas where oil and gas pollution are common. This may help reduce morbidity and mortality associated with these conditions.

#286 Forecast of the incidence and etiology of liver cancer in Taiwan, Japan, United States, and United Kingdom: toward harmonization of East and West. Emily Han-Chung H. Hsieue,1 Wei-Cheng Lo,2 Hsien-Ho Lin,3 Chih-Hung Hsu,4 Ann-Lii Cheng.5 Johns Hopkins School of Medicine, Baltimore, MD; 1Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan; 2National Taiwan University Hospital, Taipei, Taiwan.

Background: The global epidemiology of primary liver cancer (PLC), primarily hepatocellular carcinoma (HCC), has evolved significantly in the past decades because of improved control of viral hepatitis and the growing prevalence of metabolic factors. We conducted a quantitative forecast of the incidence and etiology of PLC. Methods: Incidence rates of PLC were projected in two endemic Asian countries (Taiwan and Japan) and two Western countries (the United States and United Kingdom) with rigorous cancer registry. The annual incidence of PLC (ICD-10 C22.0) between 1980 and 2013 was obtained from the
Taiwan Cancer Registry Database, the Japan National Cancer Center, the US SEER 9 database, Cancer Research UK, and the European Network of Cancer Registry. Incidence rates were projected to year 2035 by an age-period-cohort model with a power link function. The population attributable fractions (PAF) of chronic hepatitis B (HBV), chronic hepatitis C (HCV), alcohol consumption, obesity, and tobacco use (as indicated by the prevalence of smoking) were estimated. The prevalence of each risk factor was obtained from national surveys and projected inferentially by using a log-linear model or simple linear assumption. The relative risk of each factor was derived from pooled literature data. Results: From 2013 to 2035, incidence rates of PLC in Taiwan are estimated to decrease by more than 50% in both men (5.4% to 2.4/100,000) and women (9.7 to 9.2/100,000). In Japan, incidence rates have plateaued in the 1990s, and are expected to continue to decline to 17.0/100,000 for men and 6.3/100,000 for women. Conversely, rates in the UK are projected to increase by more than 30% in both men (13.5 to 18.2/100,000) and women (6.0 to 8.1/100,000). A more modest increase is expected in the US, from 10.2 to 12.5/100,000 for men and 3.3 to 3.5/100,000 for women. In Taiwan, the PAF of HBV, the predominant risk factor of PLC, is expected to decrease from 54.3% in 2015 to 54.4% in 2045. By 2045, the PAFs of obesity and DM are estimated to reach 11.9% and 15.4%, respectively, the latter similar to that of HCV (15.0%). Conclusion: PLC incidence rates are forecast to follow a trend of convergence in four representative countries. Metabolic factors are expected to play increasingly important etiologic role in PLC even in regions currently endemic for viral hepatitis.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Cycle Checkpoint and Progression

#287 BAY 1816032, a novel BUB1 kinase inhibitor with potent antitumor activity. Gerhard Siegemeter,1 Anne Mengel,1 Wilhelm Bone,1 Jens Schröder,1 Sabine Zitzmann-Kolbe,1 Hans Briem,1 Amaury E. Fernández-Montalván,1 Simon Holton,1 Ursula Mönning,1 Oliver von Ahesen,1 Sandra Johannsen,1 Arwed Cleve,1 Marion Hitchcock,1 Kirstin Meyer,1 Franz von Nussbaum,1 Michael Brands,2 Dominik Mumberg,1 Karl Ziegelbauer1. Bayer Pharma AG, Berlin, Germany; Bayer S.A.S, Lyon, France.

The spindle assembly checkpoint represents a highly conserved surveillance mechanism which safeguards correct chromosome segregation by delaying anaphase onset until all chromosomes are properly bi-oriented on the spindle apparatus. Non-catalytic functions of the mitotic kinase BUB1 (budding uninhibited by benzimidazoles 1) were reported to be essential for spindle assembly checkpoint activation. In contrast, the catalytic function of BUB1 plays a minor role in spindle assembly checkpoint activation. However, it is required for chromosome arm resolution and positioning of the chromosomal passenger complex for resolution of spindle attachment errors. Here, we disclose for the first time the structure and functional characterization of a novel, first-in-class Bub1 kinase inhibitor. Medicinal chemistry efforts resulted in BAY 1816032 featuring high potency, long target residence time and good oral bioavailability. It inhibits BUB1 enzymatic activity with an IC50 of 7 nanomolar/L, shows slow dissociation kinetics resulting in a long target residence time of 87 min, and an excellent selectivity on a panel of 395 kinases. Mechanistically BAY 1816032 abrogated nocodazole-induced Thr-120 phosphorylation of the major BUB1 target protein histone H2A in HeLa cells with an IC50 of 29 nanomolar/L, induced lagging chromosomes and mitotic delay. Persistent lagging chromosomes and missegregation were observed upon combination with low concentrations of paclitaxel. Single agent BAY 1816032 inhibited proliferation of various tumor cell lines with a median IC50 of 1.4 micromolar/L and demonstrated synergy or additivity with paclitaxel or docetaxel in almost all cell lines evaluated (minimal combination index 0.3). In tumor xenograft studies BAY 1816032 only marginally inhibited tumor growth as single agent upon oral administration, however, upon combination with paclitaxel or docetaxel a strong and statistically significant reduction of tumor size as compared to the respective monotherapy was observed. Intratumoral levels of phospho-Thr-120 H2A were found to be strongly reduced, and no hints on drug-drug interactions were found. In line with the good tolerability in xenograft studies, no relevant findings from non-GLP 2 weeks toxicological studies in rat and dog were reported. Our findings validate the innovative concept of interference with mitotic checkpoints and justify clinical proof of concept studies evaluating BUB1 inhibitor BAY 1816032 in combination with taxanes in order to enhance their efficacy and potentially overcome resistance.

Cell proliferation depends on multiple signals, such as growth factors, adhesion to the substratum and to neighboring cells. Cancer cells proliferate independently of these signals, and this increased proliferative activity is associated with increased genomic instability. Here we investigate whether the actin cytoskeleton plays a role in transmitting the proliferation signal. We found that inactivation of the Arp2/3 complex by either a chemical inhibitor or by siRNAs blocks S phase entry in untransformed human breast cell lines and in primary breast epithelial cells. In contrast, breast cancer cell lines did not respond to Arp2/3 inhibition. Inactivating the tumor suppressor Mitostatin in the genetic backgrounds of these cell lines further highlighting that this response to Arp2/3 inactivation is at the heart of the transformation process. The depletion of the WAVE complex, the Arp2/3 activator that generates branched actin in lamellipodia, but not of other Arp2/3 activators, blocks cell cycle progression. Conversely, activation of WAVE by active Rac, or depletion of Arpin, which antagonizes WAVE, potentiates cell cycle progression. Together, these results show that branched actin networks generated in lamellipodia are sensed and convey an essential signal for S Phase entry. The signal that branched actin delivers integrates stimulation from soluble growth factor with mechanotransduction from cell adhesions to the substratum and to neighboring cells. This signaling pathway qualifies as a checkpoint, which is required in normal cells, but lost in transformed cells, that monitors the integrity of branched actin networks and instructs the cell as a response that the required conditions to proliferate are fulfilled.

#289 The key role of Mitostatin in the maintenance of genome stability. Angela Lauriola,1 Andrea Caporali,2 Sabine Mai,3 Domenico D’Arca,1 Università di Modena and Reggio Emilia, Modena, Italy; 2University/BHF Centre For Cardiovascular Science, The Queen’s Medical Research Institute, Edinburgh, United Kingdom; 3Manitoba Institute of Cell Biology, CancerCare Manitoba, University of Manitoba, Winnipeg, Manitoba, Canada.

Genomic instability is a characteristic of most cancers and it refers to an increased tendency of alterations in the genome during the life cycle of cells. The fidelity of DNA replication is highly ensured by different checkpoints; the activation of spindle checkpoints prevents cells from premature entry into mitosis, avoiding incorrect chromosome segregation and aneuploidy, a typical feature of many cancers. Mitostatin, a novel protein, endowed with tumor suppressor activity, has been reported to bind centrosomal proteins Odf2 and ninein, and its depletion causes an alteration of the anchorage of microtubules to the centrosome. Since functional defects of centrosomes are associated to mitotic failure, Mitostatin may have a key role in guarding the fidelity of mitosis in cells. Here we show that the depletion of Mitostatin in cancer cells, synchronized by aphidicolin (G1/S) block and released into nocodazole-containing medium, leads to mitotic slippage and adaptation to the spindle checkpoint in the presence of a spindle inhibitor. Concomitantly, Mitostatin depletion promotes the early degradation of Mad2 and cyclin B1. Since the activated spindle checkpoint delays cell exit from mitosis by preventing cyclin B1 proteolysis, the cyclin B1 early degradation leads to mitotic checkpoint escape and resulting chromosome instability. In particular, we show that upon loss of Mitostatin chromosome bridges and mis-segregation in anaphase that are consistent with defective activation of the spindle checkpoint. In this study, we report for the first time that the depletion of Mitostatin induces an increase of numerical and structural chromosomal aberrations compared to control cells. These aberrations include aneuploidy (P=0.0005), the formation of triradials (P=0.0061) and broken chromosomes (P=0.0066). Moreover, 3D nuclear telomere analysis using TeloView shows decreases in telomeric signals (P=0.0061), in the total number of aggregates (P=0.0027), and in total intensity (P=0.018) and single intensity (P=0.019) in cells depleted of Mitostatin. These findings suggest that telomere dysfunction is increased in the absence of Mitostatin; the decrease in telomere integrity is associated with ongoing proliferation (mitotic slippage), and the maintenance of telomeric aggregates is indicative of ongoing genomic instability. Taken together, these observations suggest that Mitostatin plays a critical role in guarding the fidelity of mitosis, enabling the optimal activation of the spindle checkpoint. Thus, low levels of Mitostatin found in certain human tumors may contribute to cellular transformation by promoting genomic instability.

#290 A novel function of HGF in the phosphorylation of Chk1 in colon cancer cells. Na Song, Xiaofang Che, Xiujuan Qu, Li Xu, Kezuo Hou, Yunpeng Liu. The First Hospital of China Medical University, Shenyang, China. ATR/Chk1 pathway plays an essential role in modulation of DNA damage response (DDR) and homologous recombination (HR). Particularly, Chk1 phosphorylation in cancer cell lines did not respond to Arp2/3 inhibition. Inactivating the tumor suppressor Mitostatin in the genetic backgrounds of these cell lines further highlighting that this response to Arp2/3 inactivation is at the heart of the transformation process. The depletion of the WAVE complex, the Arp2/3 activator that generates branched actin in lamellipodia, but not of other Arp2/3 activators, blocks cell cycle progression. Conversely, activation of WAVE by active Rac, or depletion of Arpin, which antagonizes WAVE, potentiates cell cycle progression. Together, these results show that branched actin networks generated in lamellipodia are sensed and convey an essential signal for S Phase entry. The signal that branched actin delivers integrates stimulation from soluble growth factor with mechanotransduction from cell adhesions to the substratum and to neighboring cells. This signaling pathway qualifies as a checkpoint, which is required in normal cells, but lost in transformed cells, that monitors the integrity of branched actin networks and instructs the cell as a response that the required conditions to proliferate are fulfilled.
phosphorylation is involved in cancer prognosis and therapeutic resistance. Although some receptor tyrosine kinases (RTKs) participate in the regulation of Chk1 phosphorylation, the effect of hepatocyte growth factor (HGF) on Chk1 phosphorylation is unknown. In the present study, Western blotting and subcellular fractionation were performed to identify the expression and their significance in the mitotic checkpoint control. With small interfering RNA transfections, co-immunoprecipitations were performed to detect the interaction between TopBP1 and ATR complex. Our results demonstrated that HGF moderately activated Chk1 phosphorylation in colon cancer cells via upregulation of TopBP1, RAD51, and complex formation of TopBP1 and ATR. Furthermore, Akt activation promoted by HGF served as an important intermediate linking HGF/MET signaling and Chk1 phosphorylation. Depletion of Akt activity attenuated expression of basal line p-Chk1 and induced Chk1 activation due to HGF stimulation. Meantime, activation of Akt directly regulated expression of TopBP1 and RAD51. Suppression of Akt restored HGF-induced upregulation of TopBP1, RAD51, and enhancement of TopBP1/ATR complex as well. Our studies showed that HGF was implicated in regulating Chk1 phosphorylation and further demonstrated that Akt activity was responsible for HGF-induced Chk1 phosphorylation, which might potentially result in management of prognosis and therapeutic sensitivity in cancer therapy.

#291 Sequential treatment with the Wee1 inhibitor, AZD1775, enhances the effect of trabeclatedin in the L-sarcomas. Elisgigi Musa, Grazia Ambrosini, Gary K. Schwartz. Columbia University Medical Center, New York, NY.

Soft tissue sarcomas are heterogeneous mesenchymal neoplasms and account for 1% of all cancers in adults. Over 50 sarcomas subtypes have been classified and many have very limited treatment options. Chemotherapies such as doxorubicin, dacarbazine and gemcitabine have had very low response rates. Two of the most common subtypes of sarcomas are liposarcoma and leiomyosarcoma, also referred to as the L-sarcomas. Trabectedin, a marine derived compound from the sea sponge Ecteinascidia turbinate, has been approved for the treatment of L-sarcomas which has shown a modest effect over common thera-
pies. As a DNA damaging agent, we hypothesized that trabectedin would induce a G2 cell cycle arrest and subsequent inhibition of Wee1 would abrogate this cell cycle checkpoint and induce apoptosis. We therefore examined the effects of trabectedin followed by AZD1775, a Wee1 inhibitor, in a panel of 6 sarcoma cell lines including liposarcoma (1514I, DDLS) and leiomyosarcoma (SK-LMS, SK-UT1, SK-UT1b). IC50s concentrations of trabectedin were determined to be between 0.5 to 2nM, while IC50s for AZD1775 were in the range of 100-200 nM. In vitro results have shown an enhanced inhibition of cell viability with combination treatment in all cell lines at concentrations of 1nM trabectedin for 24hrs followed by 100nM AZD1775 for 48hrs. We also examined biochemical effects with sequential drug treatment (24hrs trabectedin followed by 24hrs AZD1775) which presented an increase of cyclin A1 and cyclin B1 indicative of G2 cell cycle arrest along with increase of phospho-H2AX, indicative of DNA damage by trabectedin, while subsequent treatment with the Wee1 inhibitor showed decrease of phosphorylation of CDC2 (Tyr15). Flow cytometric analysis indicated G2/M cell cycle arrest with trabectedin and abrogation of G2/M with AZD1775.

These observations were confirmed with enhanced apoptosis by biochemical PARP cleavage and DNA content (sub-G1 population). Taken together these results provide a foundation for the development of the sequential treatment of trabectedin followed by the Wee1 inhibitor, AZD775, in the L-sarcomas.

#292 Synthesis and characterization of the novel benzylindazole-based BUB1 kinase inhibitor BAY 1816032 with potent anti-tumor activity. Marion Hitchcock,1 Anne Mengel,2 Carl Nissing,2 2Bayer AG, Cambridge, MA; 2Bayer AG, Berlin, Germany.

BUB1 (budding uninhibited by benzimidazoles 1) is a serine/threonine protein kinase. The protein is bound to kinetochores and plays a key role in the establishment of the mitotic spindle checkpoint and chromosome segregation prior to anaphase. Eradication of BUB1 has been approved for cancer treatment whereas cell cycle arrest is the predominant mode of action of a number of antimitic cancer drugs (e.g. taxanes and vinca alkaloids). BUB1 inhibition results in aneuploidy and cell death by driving cells through mitosis irrespective of mismatched chromosomes. Here, we disclose for the first time the structure and functional characterization of a novel, first-in-class Bub1 kinase inhibitor. Medicinal chemistry efforts resulted in BAY 1816032 featuring high potency, long target residence time and good oral bioavailability. BAY 1816032 is highly selective for BUB1 displaying single digit nanomolar biochemical potency and double-digit nanomolar cellular potency (H2A induced HeLa-cells). Synergistic effects can be observed when BUB1 inhibitor BAY 1816032 is combi-

bined with low doses of paclitaxel affecting chromosome segregation and cell proliferation. X-ray data of benzylindoles allowed a better understanding of the binding mode. Further data on structure-activity relationships including pharmaco-kinetic characterization, drug metabolism and the synthesis of BAY 1816032 and analogues will be presented. These results validate the innovative approach, provide a new perspective on the role of mitotic checkpoints and justify clinical proof of concept studies evaluating BUB1 inhibitor BAY 1816032 in combination with taxanes in order to enhance their efficacy and to potentially overcome resistance.

#293 Screening the druggable genome for synthetic lethal interactions with the CHK1 inhibitor PNT7337. Rebecca Rogers,1 Mike I. Walton,1 Paul Clarke,1 Ian Collins,2 Michelle D. Garrett,2 Paul Workman1. 1The Institute of Cancer Research, London, United Kingdom; 2University of Kent, Kent, United Kingdom.

Check point kinase 1 (CHK1) is a key regulator of the cell cycle, DNA damage repair and DNA replication. CHK1 inhibition sensitises cancer cells to geno-
toxic agents and recent studies have indicated that CHK1 inhibitors could be used as single agents to treat cancers with high levels of replication stress. We have recently described the discovery of a highly selective and orally bioavailable CHK1 inhibitor, PNT7337, that not only has potent antiproliferative activity in combination with standard-of-care genotoxic agents but also as a single agent in defined tumour types. Here we sought to identify gene products whose loss would be synthetically lethal with CHK1 inhibition, with the aim of identifying patient populations likely to be sensitive to single agent CHK1 inhibition or to novel combinations utilising CHK1 inhibitors. To do this, we performed a large siRNA screen of the ~6500 genes (Cancer Cell and SW620 (colon cancer) cell lines, with and without PNT7337 treatment, and determined effects on cell viability by SRB. POLA1, POLE and POLE2 (B-family DNA polymerases) were identified as significant hits causing synthetic lethality with PNT7337 in both cancer cell lines. Treatment with additional siRNA sequences subsequently validated these genes in both the original two cell lines and extra NSCLC and colon cancer cell lines. Interestingly, a number of biomarkers for replication stress, pRPA2 and pCHK1, were increased in cells treated with POLA1, POLE and POLE2 siRNA in combination with PNT7337, in comparison to cells treated with the siRNA or drug alone. Further studies conducted with PNT7337 and the B-family DNA polymerase inhibitor aphidicolin showed that these agents had a synergistic effect on inhibiting cell viability on 8 out of 9 NSCLC and colon cancer cell lines. In addition, immunofluorescence analysis revealed that there was an increase in the level of γH2AX, a marker of DNA damage, in 4 out of 5 cell lines that exhibited synergy when treated with a combination of aphidicolin and PNT7337, as compared to cells treated with ei-
er Either alone. Our data indicate that the combination of a reduction in POLA1, POLE or POLE2 activity (by siRNA transfection or aphidicolin treat-
ment) and CHK1 activity (PNT7337 treatment) increases DNA damage and DNA damage in NSCLC and colon cancer cells. Encouragingly, our data support the case for the use of the clinically relevant combination of PNT7337 and gemcitabine, as gemcitabine is metabolised it is incorporated into DNA, inhibiting the B-family DNA polymerases. Furthermore, it will now be important to estab-
lish if subsets of colon and endometrial cancers with mutations in their P13K proofreading domain are sensitive to CHK1 inhibitors.

#294 Overide the doxorubicin-induced G2/M checkpoint using cell-cycle checkpoint inhibitors on acute lymphoblastic leukemia. Andrea Ghelli Luserna di Ror,1 Ilaria Iacobucci,1 Enrica Imbrogno,1 Anna Ferrari,2 Valentina Robustelli,3 Cristina Papayannis,3 Maria Chiara Abbenante,4 Antonella Padella,4 Giovanni Marconi,1 Sandro Grilli,1 Giovanni Martinelli1. 1University of Bologna, Bologna, Italy; 2St Jude Children’s Research Hospital, Memphis, TN; 3University of Bologna, Montecассiano, Italy.

The topoisomerase 2 inhibitor, doxorubicin, has been shown by different groups to induce cell cycle arrest in various kind of tumor cells. Specifically doxorubicin-treated cells activate the G2/M cell cycle checkpoint as a conse-
quence of the induction of DNA damages. During the last years many studies have shown the efficacy of different cell cycle checkpoint inhibitors in single agent or in combination with various DNA damaging agents. These studies showed that the inhibition of key proteins of the cell cycle, like Chk1 and Wee1, deeply sensitize tumor cells to the treatment with genotoxic agent. On these bases, the aim of the study was to evaluate the efficacy of a selective Chk1/ Chk2 inhibitor and a Wee1 inhibitor in combination with doxorubicin for the treatment of acute lymphoblastic leukemia. Firstly we evaluate the effect of doxorubicin treatment on a panel of human B and T ALL cell lines in term of reduction of the cell viability, modification of cell cycle profile and activation of the DNA damage response. For this reason the cells were treated with doxorubicin (0.25, 0.5 and 1μM) for 24 and 48 hours and the reduction of the cell
vitality was quantified using WST-1 reagents. In all the cell lines treated the cytotoxic effect of doxorubicin was time and dose dependent. Then the induction of the apoptosis (Pi/Annexin V) and the effect on cell cycle profile (Pi staining) was evaluated in all the cell lines. In line with the literature the treatment with doxorubicin arrested the cells in G2/M phase. Then the effect of the combinations between doxorubicin and the two checkpoint kinase inhibitor was assessed in all the cell lines. Different cell lines were treated with doxorubicin (5, 10, 25 and 50 nM for the more sensitive cell lines; 50, 100, 250 and 500 nM for the less sensitive cell lines) in combination with the Chk1/Chk2 inhibitor (2, 5 and 10 nM) for 24 and 48 hours. The combination showed a additive effect in term of reduction of the cell viability and induction of apoptosis. Different cell lines were pre-treated for 18 hours with doxorubicin and then with Chk1/Chk2 inhibitor for different time points. Interestingly the inhibition of both Chk1/Chk2 proteins removed the G2/M arrest induced by the pre-treatment with doxorubicin, progressively reducing the number of cells in G2/M phase, increasing the percentage of cells in sub-G1 phase. Similar results were seen combining a Weel inhibitor with doxorubicin on several ALL cell lines. In our opinion the combination between the cell cycle checkpoint inhibitors and doxorubicin could be a promising strategy for the treatment of B/T-ALL. Supported by ELN, AIL, AICR, progetto Regione-Università 2010-12 (L. Bolondi), FP7 NGS-PTL project.

#295 CASC-578, a novel Chk1 inhibitor, is active as a single agent in solid tumors and displays synergistic anti-tumor activity in combination with Weel inhibition. Alex Vo,1 Janelle Taylor,1 Robert Rosler,1 Julia Piascik,1 Dina Leviten,4 Ashley Dozier,4 Kevin Klucher,4 Janelle Taylor,1 Dina Leviten,4 Ashley Dozier,4 Kevin Klucher,4 Rich Boyce,5 Scott Peterson1.

Cascadian Therapeutics, Seattle, WA; 2none, CA; 3Sentinel Oncology, Cambridge, United Kingdom.

Background: Checkpoint kinase 1 (Chk1) is a serine/threonine protein kinase that regulates cell division in response to genotoxic stress by arresting cell cycle progression in the S & G2 phases. Pharmacological inhibition of Chk1 is proposed to target tumor cells with increased DNA replication stress, resulting in the uncoupling of DNA replication checkpoint function and the induction of DNA damage and cell death. These properties make Chk1 a promising novel therapeutic approach as a single agent in cancers with high replication stress that are posed to target tumor cells with increased DNA replication stress, resulting in DNA damage induction, mitotic catastrophe and cell death. These properties make Chk1 an attractive therapeutic approach as a single agent, or to enhance the efficacy of other cancer drugs that target DNA damage response pathways. Methods and Results: This report highlights the activity of the orally bioavailable, selective small molecule Chk1 inhibitor, CASC-578, in solid tumor derived cell lines. CASC-578 is a sub-nanomolar enzymatic inhibitor of Chk1 with limited off-target activity against a panel of protein kinases. When evaluated in a large cell line panel in vitro, CASC-578 demonstrated a broad potency range as a single agent in solid tumor derived cell lines, with IC50s ranging from 30 nM to greater than 50 μM. Several solid tumor types demonstrated enriched sensitivity to CASC-578 in vitro, including gastric, non-small cell lung and ovarian cancers. Treatment of sensitive cell lines with CASC-578 resulted in the induction of DNA damage, as measured by phosphorylated histone H2AX, and the induction of cell death. CASC-578 was active as a single agent in SK-MES-1 and NCI-H727 NSCLC tumor xenograft models in vivo with minimal effects on body weight in treated mice. In addition to the potent single agent activity of CASC-578, combination with the Weel inhibitor AZD-1775 was highly synergistic in vitro in multiple solid tumor cell lines and the combination was more efficacious than either agent alone in NSCLC tumor xenograft models. These data support the advancement of CASC-578 into clinical development as a potential therapeutic agent for the treatment of solid tumor diseases. Experiments are ongoing to identify biomarkers associated with sensitivity to CASC-578 as a single agent in solid tumor cell lines to prospectively identify tumor genotypes that are more responsive to the drug.

#296 Interplay of human MGMT DNA repair protein with PCNA /p21cip1 and MGMT’s novel role as an S-phase checkpoint. AGM Mostova, Kalkunte S. Srinivasanpugal. Texas Tech University Health Sciences Center, Amarillo, TX.

O6-Methylguanine-DNA methyltransferase (MGMT) is a critical antmutagenic DNA repair protein that protects the genome and an established target for improving the efficacy of alkylating agents. In contrast with the stoichiometric repair reaction performed by a single small MW protein, we show for the first time that MGMT in human glioblastoma cells specifically associates with PCNA, p21cip1, and undergoes selective degradation at mid-S-phase along with replication-licensing components to maintain genomic integrity. First, we identified a PCNA-Interacting Protein (PIP) box motif between amino acids 61-70 in QCTAWLNAFY in the MGMT protein. PCNA encircles the DNA and functions as a sliding clamp by interacting with DNA metabolic proteins having a PIP-box to make the replication processive. In p53-null H1299 lung cancer cells engineered to express the p21cip1, either by Tet-off conditional or lentiviral stable transfections, a reciprocal immunoprecipitation/western blot analyses using antibodies to PCNA or MGMT confirmed the specific association of MGMT and PCNA proteins. Expression of the CDK inhibitor p21 disrupted the interaction between PCNA and MGMT in cells, indicating its regulatory role in DNA repair during cell cycle blockade. Confocal immunofluorescence imaging in glioblastoma cells and in the HCT116 colorectal cell line, showed a co-localization of MGMT and PCNA proteins in glioma cells; when cells were subjected to alkylca DNA damage, the co-localization pattern was punctate and more prominent, suggesting that PCNA functions to recruit the repair protein to the damage sites. To probe the cell-cycle dependent regulation of MGMT, we used synchronized human GBM cells at the G1/S boundary with specific shRNAs against the thymidine-thymine monomer and thymidine-monosine blocks. Cells released into the S-phase showed that the MGMT disassociates from PCNA during the late S-phase and undergoes specific degradation before re-accumulating in G2/M. The replication-licensing protein Cdt1 and p21cip1 were also observed to undergo co-degradation in S-phase, which has been established as a key step in marking the replication origin sites. MGMT inhibition, either by O6-benzylguanine or specific shRNAs greatly impeded the progression of cells into the S-phase in synchronized cells. DNA synthesis measured by 3H-thymidine or BrdU incorporation was also curtailed significantly by MGMT inhibition. Furthermore, enforced expression of MGMT in two GBM cell lines led to a moderate endo-reduplication of the genome. Collectively, we show new non-repair functions for MGMT, its requirement for cell cycle progression and timed elimination of MMR genome maintenance. On the clinical front, these observations provide a clear biochemical rationale for combining MGMT inhibitors (apart from the alkylators) with antimetabolites [supported by CPRIT grants RP130266 & RP170207 to KSS].

#297 The novel orally available sub-nanomolar potent and selective checkpoint kinase 1 inhibitor CASC-578 is highly active in mantle cell lymphoma as a single agent and in combination with Weel inhibition. Robert Rosler,1 Janelle Taylor,1 Dina Leviten,2 Teresa Sierra,2 Ashley Dozier,4 Kevin Klucher,4 Rich Boyce,5 Alex Vo,1 Scott Peterson1.

1CascadianTherapeutics,Seattle,WA; 2none,WA; 3SentinelOncology,Cambridge,UnitedKingdom

Background: Checkpoint kinase 1 (Chk1) is a serine/threonine protein kinase that regulates cell division by arresting progression in the S & G2 phases of the cell cycle in response to genotoxic stress. Pharmacological inhibition of Chk1 uncouples the completion of DNA replication from G2/M phase transition in tumor cells that have impaired DNA damage response networks, resulting in DNA damage induction, mitotic catastrophe and cell death. These properties make Chk1 inhibition an attractive therapeutic approach as a single agent, or to enhance the efficacy of other cancer drugs that target DNA damage response pathways. Methods and Results: This report highlights the activity of the orally bioavailable, selective, small molecule Chk1 inhibitor, CASC-578, in multiple mantle cell lymphoma (MCL) models in vitro and in tumor mouse xenograft studies. MCL have the common genetic biomarker t(11;14)(q13;q32), a chromosomal translocation leading to the constitutive expression of the oncogene CCND1 which encodes cyclin D1, a cell cycle-regulating protein. This genotypic characteristic has been observed in the clear majority of patients with MCL in the clinic and may provide a rationale for sensitivity to Chk1 inhibition. Consistent with this idea, CASC-578 demonstrated remarkable potency as a single agent in blocking the proliferation of MCL cell lines in vitro, with an average IC50 of 61 nM. Treatment with CASC-578 as a single agent resulted in the induction of DNA damage, as measured by phosphorylated histone H2AX and activation of apoptosis, as measured by cleaved caspase. In a JEKO-1 xenograft tumor study, CASC-578 as a single agent completely regressed subcutaneously implanted tumors in the majority of mice after oral drug administration using 20 mg/kg daily or when dosed on an intermittent schedule at 25 mg/kg, with minimal effects on body weight. In addition to the observed single agent activity of CASC-578, the combination of CASC-578, and the Weel inhibitor AZD-1775, was highly synergistic in MCL cell lines including JEKO-1, REC-1, Z-138 and MAVER-1 in vitro. CASC-578 was also highly potent as a single agent, and in combination with AZD-1775, in blocking the proliferation of a variety of leukemia derived cell lines in vitro. Taken together, these data support the advancement of CASC-578 into clinical development as a potential therapeutic agent for the treatment of MCL, as well as other hematological malignancies.

#298 WEE1 inhibitor activity correlates to AXL/mTOR expression and exhibits synergy with temozolomide (TMZ) in small cell lung cancer (SCLC). Triparna Sen, Pan Tong, Lixia Diao, You Hong-Fan, C. Allison Stewart, John V. Heymch, Jing Wang, Lauren A. Byers. UT MD Anderson Cancer Center, Houston, TX.
Background: WEE1 inhibitors (WEE1i) are a novel class of small molecule inhibitors that are now under early clinical trials for small cell lung cancer (SCLC). WEE1 is a protein kinase that plays a key role in regulating the G2 checkpoint in response to DNA damage. Moreover, because WEE1 inhibition induces a HR deficient state, dual targeting of WEE1 and PARP (another promising target in SCLC) could lead to an increase in the efficacy of PARP inhibitors. In the present study we evaluate the efficacy of AZD1775 alone and with the WEE1i, olaparib, to determine the mechanisms of primary resistance to AZD1775 in SCLC models; and assess the combinatorial efficacy of AZD1775 treatment with the chemotherapy drug, temozolomide (TMZ), that has shown promise in patients with recurrent SCLC and has been included in the National Comprehensive Cancer Network guidelines for standard care.

Results: Combination of AZD1775 with olaparib revealed an additive effect in vitro in 90% of SCLC cell lines. AZD1775 combined with TMZ synergistically decreased viability, increased DNA damage and apoptosis in SCLC cell lines (n = 10) irrespective of MGMT status or initial response to AZD1775 alone. However, unlike the sensitive cell lines, SCLC cell lines showing primary resistance to AZD1775 had an intact DNA repair mechanism (after DNA damage), which may contribute to the resistance mechanism. Proteomic analysis revealed AXL (receptor tyrosine kinase) and phospho-S6K (S240/244) as markers of AZD1775 resistance and treatment with AXL inhibitor, TP9003 (40nM), re-sensitized the cells to AZD1775. Pre and post-AZD1775 treated samples revealed sustained activation of mTOR pathway in AZD1775 primary resistant lines. We further demonstrated that the downregulation of the cells with the mTOR inhibitor everolimus sensitized SCLC cells to AZD1775 by causing downregulation of AKT/mTOR pathway. Conclusion: WEE1 inhibitors are currently in clinical trials for SCLC patients. However, as with any targeted therapy, drug resistance is an important barrier to clinical benefit which could be addressed with therapeutic combinations. We show the efficacy of single agent AZD1775 and in combination with olaparib. WEE1 inhibitor, AZD1775 synergizes with TMZ irrespective of MGMT status in all tested in vitro models which warrants further clinical investigation. We also show that the activity of the WEE1 inhibitors might be limited in cancer cells overexpressing of AXL and activated mTOR pathway and that AXL and mTOR inhibition re-sensitized the cells to AZD1775. Our work supports further exploration of the combination of PARP and WEE1 in SCLC and also the possibility of AXL/mTOR inhibition as a mechanism to overcome WEE1 inhibition resistance in SCLC. SCLC is a disease with very limited therapeutic options and no targeted agents with proven benefit; thus the results from this study have clear translational benefit.

#299 RNA editing enzyme ADAR1 accelerates normal hematopoiesis cycle by regulation microRNA biogenesis. Qingfei Jiang, Maria Anna Zipeto, Nathan Delos Santos, Sheldon Morris, Catriona Jamieson. University of California, San Diego, La Jolla, CA.

Combining murine studies demonstrate that adenosine-to-inosine (A-to-I) RNA editing mediated by adenosine deaminase associated with RNAI (ADAR1) is vital for both fetal and adult hematopoiesis. While genetic ablation of ADAR1 leads to murine embryonic lethality due to severe defects in erythropoiesis, conditional deletion in the hematopoietic system impairs maintenance indicative of cell type and context specific roles for ADAR1 in cell fate specification and self-renewal. By regulating mRNA and microRNA (miRNA) stability, ADAR1 exhibit wide-ranging effects on embryonic development and stem cell regulation. We have previously shown that inflammation-responsive ADAR1 plays important roles in both stem cell differentiation and self-renewal in CML (chronic myeloid leukemia) disease progression. Here, we describe a novel function of ADAR1 in cell cycle regulation of normal hematopoietic stem cell and progenitors (HSPC) by regulation of miRNA biogenesis. Our results demonstrated that ADAR1 induces G0 to G1 phase transition in normal cord blood HSPCs, as demonstrated by elevated expression of Ki67, reduced DiR signal, and enhanced in vivo cord blood engraftment. Cell cycle qRT-qPCR microarray of 84 cell cycle transcripts and whole transcriptome RNA-sequencing analysis of KEGG cell cycle pathway indicate that several cell cycle genes are differentially expressed upon overexpression of ADAR1 WT or an A-to-I editing deficient ADAR1 mutant (ADAR1E912A). We previously demonstrated that impaired biogenesis of let-7 miRNAs by ADAR1 WT induces enhanced self-renewal in cord blood CD34+ HSPCs. To determine the miRNA targets of ADAR1-mediated RNA editing, we performed mirNome microarray PCR analysis of 1008 miRNA candidates in cord blood CD34+ HSPCs overexpressing ADAR1 WT or ADAR1E912A. Total of 263 miRNAs were differentially expressed (142 upregulated and 121 downregulated) by comparing ADAR1 WT to the backbone control. Interestingly, ADAR1E912AA mutant also exhibit A-to-I editing independent regulation of miRNAs (307 upregulated and 359 downregulated). We found that the expression of miR-26a-5p, a miRNA frequently downregu- lated in leukemia, is inhibited by ADAR1-mediated RNA editing. ADAR1 directly binds and edits the DROSHA cleavage site of primary miR-26a transcript, thereby prevent miR26a-5p maturation. Moreover, lentiviral expression of mature miR-26b reverses the effect of ADAR1 WT, including enhanced CDKN1A expression, inhibition of cord blood proliferation in vivo, as well as reduced HSC mobilization in vitro. The results suggest that ADAR1 exhibit wide-ranging effects on embryonic development and self-renewal in cord blood CD34+ HSPCs, as demonstrated by elevated expression of Ki67, reduced DiR signal, and enhanced in vivo cord blood engraftment. Cell cycle qRT-qPCR microarray of 84 cell cycle transcripts and whole transcriptome RNA-sequencing analysis of KEGG cell cycle pathway indicate that several cell cycle genes are differentially expressed upon overexpression of ADAR1 WT or an A-to-I editing deficient ADAR1 mutant (ADAR1E912A). We previously demonstrated that impaired biogenesis of let-7 miRNAs by ADAR1 WT induces enhanced self-renewal in cord blood CD34+ HSPCs. To determine the miRNA targets of ADAR1-mediated RNA editing, we performed mirNome microarray PCR analysis of 1008 miRNA candidates in cord blood CD34+ HSPCs overexpressing ADAR1 WT or ADAR1E912A. Total of 263 miRNAs were differentially expressed (142 upregulated and 121 downregulated) by comparing ADAR1 WT to the backbone control. Interestingly, ADAR1E912AA mutant also exhibit A-to-I editing independent regulation of miRNAs (307 upregulated and 359 downregulated). We found that the expression of miR-26a-5p, a miRNA frequently downregu-
**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Cycle Checkpoint and Progression**

Medulloblastoma is the most common malignant pediatric brain tumor with variable prognosis due to its clinical and genomic heterogeneity. Despite recent treatment advances, approximately 40% of children experience tumor recurrence, and 30% will die from this disease. Therefore, there is a need to develop novel therapies for patients. We recently reported that Casein kinase 16 (CK16) may be a novel therapeutic target of medulloblastoma. CK16 is a serine/threonine kinase that controls cell cycle progression, signal transduction and neurogenesis. We found high levels of CK16 protein in mouse models of medulloblastoma and human medulloblastoma samples. Furthermore, CK16 inhibition dramatically reduced medulloblastoma tumor progression. We demonstrate here that CK16 phosphorylates the epigenetic reader bromodomain-containing protein 4 (BRD4). BRD4 has been identified as a therapeutic target in several cancers, including medulloblastoma. We demonstrate that CK16 phosphorylates BRD4 and that CK16 is required for BRD4 binding to the Gli1 promoter in vitro and in vivo. Furthermore, combined CK16/BRD4 inhibition is a novel means of reducing medulloblastoma growth downstream of SUFU and SMO. These studies define a novel therapeutic means of inhibiting SMO inhibitor resistant medulloblastoma.

**#303 Oncogenic activity of amplified miniature chromosome maintenance 8 in human malignancies.** Jian-Hua Luo, Dong-Mei He, Baoguo Ren, Yan Yu.

Miniature chromosome maintenance (MCM) proteins play critical roles in DNA replication licensing, initiation and elongation. MCM8, one of the MCM proteins playing critical role in DNA recombination and recombination, was found to have over-expression and increased DNA copy number in a variety of human malignancies. The gain of MCM8 is associated with aggressive clinical features of several human cancers. Increased expression of MCM8 in prostate cancer is associated with cancer recurrence. Forced expression of MCM8 in RWPE1 cells, the immortalized but non-transformed prostate epithelial cell line, exhibited fast cell growth and transformation, while knocked down of MCM8 in PC3 and DU145 cells induced cell growth arrest, and decreased tumor volumes and mortality of severe combined immune deficiency mice xenografted with PC3 and DU145 cells. MCM8 has been identified as a therapeutic target in several cancers, including medulloblastoma. We demonstrate that CK16 phosphorylates BRD4 and that CK16 is required for BRD4 binding to the Gli1 promoter in vitro and in vivo. Furthermore, combined CK16/BRD4 inhibition is a novel means of reducing medulloblastoma growth downstream of SUFU and SM0. These studies define a novel therapeutic means of inhibiting SM0 inhibitor resistant medulloblastoma.

**#304 CLIC1 membrane insertion is a pivotal regulator of glioblastoma stem cell G1-S transition by promoting an increase of chloride permeability.** Ivan Verduci, Valentina Carlini, Federica M. Raciti, Matteo Conti, Michele Mazzanti.

Glioblastoma (GBM) is the most aggressive and lethal brain tumor and, despite aggressive surgery and adjuvant radiotherapy and/or chemotherapy, the prognosis remains invariably poor. As for most of solid and hematological malignancies, it was demonstrated that the bulk of tumor cells in GBM is generated by a rare fraction of self-renewing, multipotent cancer stem cells (CSCs) and the persistence of CSCs within the tumor mass is considered the main determinant of GBM development, progression, recurrence and radio- or chemoresistance. Thus, one of the main goals of current research is to identify specific biological mechanisms or intracellular pathways of CSCs whose pharmacological targeting might affect their survival and proliferation. In particular, little is known about the possibility that the molecular mechanisms underlying cell-cycle control in GBM CSCs are endowed with specific and unique features as compared with normal cells. Our study is based on the observation that GBM cells express higher levels of chloride intracellular channel 1 (CLIC1) as compared to nonmalignant brain cells and that in CSCs CLIC1 is mainly localized in the membrane forming an active channel. Conversely, in physiological conditions CLIC1 is mainly a cytoplasmic protein only transiently translocating to the membrane. We recently showed that the different level of activity of CLIC1 in CSCs and normal mesenchymal stem cells confers CLIC1-targeting drugs (for example the biguanide metformin) selective cytotoxicity toward tumor cells. Here we report, that in response to stress conditions, CLIC1 increases the probability to modify its structure going from a cytoplasmic hydrophilic form to a transmembrane conformation. Once in the membrane, CLIC1 acts as a chloride permeability, participating, together with NADPH oxidase, to the generation of a chronic state of oxidative stress that favor the transition between G1 and S phase. The peculiarity of CLIC1 exposure on the external face of the GMB CSC plasma membrane support the idea that this protein could represent a main determinant of the cell cycle progression in this tumor cell subpopulation and thus an accessible and relevant pharmacological target to eradicate CSCs in GBM.

**#305 TET blocks cell cycle progression in pancreatic cancer cells at G1-S boundary by decreasing cyclin D1 and increasing CDK inhibitors (CKIs), p21 (WAF1, Cip1) and p27 (Kip1).** Karnika Singh, Qin Dong, Sweaty Koul, Hari K. Koul.

Introduction: Pancreatic cancer (PaCa) is the fourth leading cause of cancer related deaths in the United States with an overall five year survival rate of less than five percent. The current standard treatment/s for PaCa are largely ineffective thus there is an urgent need for development of therapeutic agents for the treatment of PaCa. Owing to its mutational landscape, which includes mutated KRAS and p53 genes these cancer cells have a deregulated G1 checkpoint of cell cycle control and therefore confer high rate of proliferation and therapeutic resistance. Recently it was observed that Tetrandrine derivative (TET), a bis-benzyloxyquinoline alkaloid halts cell cycle progression at G0/G1 boundary in vitro and in vivo. In the present study we evaluated potential mechanism of TET induced cell cycle arrest in two pancreatic cancer cells with either wild type KRAS or mutant KRAS, and mutant p53 by evaluating critical cell cycle regulatory proteins involved in G0/G1 to S transition. Methods: Pancreatic Cancer cell lines BxPC3 (Pancreatic Ductal Adeno-Carcinoma) and MiaPaCa2 (pancreatic carcinoma) were used in the study. Cells were treated with various concentrations of TET for different time points. Cell proliferation was evaluated using the MTT survival assay. Cell cycle was analyzed following PI staining via Flow cytometry. Changes in protein expression were analyzed by Western Blot analysis in cells. Changes in mRNA were evaluated by real time PCR. Results: Treatment of PaCa cancer cells with TET resulted in decreased cyclin D1 and phospho-Rb, two critical proteins required for G0/G1 to S transition. Pretreatment of the cells with proteasomal inhibitor MG132 was able to increase the levels of cyclin D1 in control cells but was unable to prevent its loss upon TET treatment. Our results also show that levels of CKIs, p21(WAF1/Cip1) and p27(Kip1) were increased at the protein level. Gene expression analysis revealed that cyclin D1 mRNA was decreased and p21(WAF1/Cip1) mRNA was increased while there was no significant change in p27 mRNA levels. The cycloheximide chase revealed that TET stabilizes p27(Kip1) and to some extent p21(WAF1/Cip1) as well, suggesting that TET increased p27(Kip1) and also p21(WAF1/Cip1) levels in part by increasing protein stability. These data suggest a complex mechanism by which TET regulates expression of critical cell cycle regulatory molecules at both transcriptional and post-translational level. Such a mechanism would provide for cell cycle arrest in pancreatic cancer cells following TET treatment. Conclusion: These results show that TET halts cell cycle at G0/G1 boundary in PaCa cells by modulating the cell cycle regulatory proteins and stabilizing the CKIs by altering their protein stability, suggesting that TET can not only halt deregulated cell cycle but also overcome the therapeutic resistance in pancreatic cancer cells.

**#306 Antitumor effect of Weel inhibitor in gastric cancer cell lines.** Seongyeong Kim, Ahry Min, So Hyeon Kim, Daewon Song, Ha Hyemin Jang, Yu Jin Kim, Hee Jun Kim, Kyung-Hun Lee, Tae-Yong Kim, Do-Youn Oh, Yung-Jae Bang, Seock-Ah Im.

Introduction: Gastric cancer is a second leading cause of cancer death. Weil is a G2 cell cycle regulator that phosphorylate cdcc2 on tyrosine 15 for inhibiting its activity. The activation of Wee1 can delay G2 phase progression and cells can have a chance to repair DNA damages. Therefore, to inhibit weel can accelerate DNA damage accumulation in the cell. AZD1775 is a first-in-class weel inhibitor. So far, previous studies showed the antitumor effect of AZD1775 as a mono-therapeutic agent or combination treatment with other chemo-agents. However, the activity of weel in gastric cancer (GC) cells is not yet fully understood. Thus, we would like to study whether AZD1775 has an antitumor effect against GC or not. Materials and methods: We determined the antitumor effects of AZD1775 on GC cells using a cytotoxicity assay, cell cycle analysis, immunofluorescence assay and western blotting by AZD1775 treatment. Results: AZD1775 effectively inhibited GC cell proliferation. The TP53 gene status or p-Wee1 expression levels were not associated with AZD1775 sensitivity. AZD1775 effectively down-regulated p-Wee1 and p-cdc2 expressions in SNU-601, a sensitive cell line. However, these effects were not significant in KATO-III cells, which is less sensitive to AZD1775. Cell cycle analysis revealed that the cells had different responses by AZD1775 treatment. Results: AZD1775 effectively inhibited cell cycle only by its DNA contents. However, KATO-III cells were arrested in G2/M phase. The sub-G1 population was dramatically increased only in SNU-601 cells. A population of BrdU-positive and p-HH3 positive cells was significantly increased in the SNU-601 cells which indicate that premature mitosis was
#307 TRIB3 regulates cell cycle progression and programmed cell death in non-small cell lung cancer. Aber Alminan, Daoai Nie, Jamila Adom. Southern Illinois Univ. School of Medicine, Springfield, IL.

Introduction: The pseudokinase Tribbles pseudokinase 3 (TRIB3) is known as a regulator in cellular responses to a variety of stresses such as glucose insufficiency and (ER) stress. TRIB3 has been described in some studies as a tumor suppressor due to its effect on inactivating PI3K/Akt pathway, but other studies suggest TRIB3 as a stimulator of tumor progression. In this study, we aimed to define the functions of TRIB3 in non-small cell lung cancer. Methods: TRIB3 expression was altered using a lentiviral vector to overexpress TRIB3 in non-small cell lung cancer. A CRISPR-CAS9 construct with guiding sequence matching to TRIB3 gene was used to knock out its expression. Cell proliferation was evaluated using MTS and trypan blue assays. Boyden chamber assay was used to assess the cell migration while cell cycle phases were determined using flow cytometry. Heatmap analysis was performed to assess the changes in the expressions of genes in cell cycle progression and apoptosis. Results: TRIB3 overexpression (H460) increased cell proliferation and migration. Moreover, TRIB3 contributed to the increased cell cycle arrest at G0/G1 phase. QPCR analyses of cell cycle related genes showed an upregulation of CDK inhibitors in (NCI-H358) TRIB3 overexpression cells, while depletion of TRIB3 led to the down-regulation of CDK inhibitors. TRIB3 overexpression led to downregulation of LC3B and other autophagy markers while increasing the expression of apoptotic genes. Conclusion: Increased TRIB3 expression in non-small lung cancer cells inhibited proliferation by blocking cell cycle progression through the up-regulation of CDK inhibitors, led to activation of cell death through apoptosis. Our study reveals a significant role of TRIB3 in regulating cell cycle progression, apoptosis and autophagy.

#308 The PP2A-B56 phosphatase opposes cyclin E autocatalytic degrada-tion via site-specific dephosphorylation. Ryan J. Davis, Ilierek Swanger, Bruce E. Clurman. Fred Hutchinson Cancer Research Ctr., Seattle, WA.

Cyclin E, in conjunction with its catalytic partner cyclin-dependent kinase 2 (CDK2), regulates cell cycle progression as cells exit quiescence and enter S-phase. Multiple mechanisms control cyclin E-CDK2 activity during the cell cycle, including phosphorylation-dependent cyclin E ubiquitylation by the SCF/Fbw7 ubiquitin ligase. Serine 384 (S384) is the critical cyclin E phosphorylation site that stimulates Fbw7 binding and subsequent cyclin E degradation. Because S384 is autophosphorylated by CDK2, cyclin E therefore instigates its own degradation in an autocatalytic manner. This presents a paradox as to how cyclin E-CDK2 is able to phosphorylate its numerous substrates prior to cyclin E autophosphorylation-catalyzed degradation. Here we find that the PP2A-B56 phosphatase specifically dephosphorylates cyclin E at S384 (the double motif 2 homology) to oppose cyclin E degradation from cyclin E-CDK2 activity. Furthermore, the rate of S384 dephosphorylation is high in interphase and low in mitosis, allowing PP2A-B56 to oppose autocatalytic cyclin E degradation and maintain cyclin E-CDK2 activity at the G1/S transition.

Rambouillet Goodwin Institute for Cancer Research, Nova Southeastern University, Fort Lauderdale, FL; College of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL.

Deacetylation of histone gives a tag for epigenetic repression and plays an important role in transcriptional regulation, cell cycle progression, and developmental events. HDACs catalyse the removal of the acetyl moiety from the lysine residues of proteins including the core nucleosomal histones. Through removal of critical acetyl groups from histones, HDACs can create a chromatin conformation that can prevent the transcription of genes that encode for proteins involved in cell cycle regulation. Thus together with histone acetyltransferases (HATs), HDACs regulate the level of acetylation and alter multitude of cellular functions and their characteristics. Several alterations of HDAC and HAT levels and activities have been found to be enacted by translocation, amplification, overexpression, or mutation of the relevant genes in a variety of cancers. In many cancer cell lines, overexpression or activation of the HDAC enzymes result in histone hypo-acetylation and consequent promotion of pro-cancerous mechanisms. Therefore, HDAC inhibitors represent a potential new class of antitumor agents with cytotoxic activity and the ability to regulate gene expression in tumor cells. In this study we evaluated the effects of Vorinostat (suberoylanilide hydroxamic acid), which is a potent inhibitor of HDAC activating the gene expression profile in LNCaP cell lines (NCI-H9262) and demonstrated for the first time that vorinostat (10 μM) is able to transcribe the transcription factor E2F1 to the up-regulation of BIRC5 (Baculoviral IAP Repeat Containing 5). Similarly, when we treated the MDM2 transduced LNCaP-MST cells with vorinostat (7.5 μM for 24 hrs), some of the above mentioned changes, similar to Nutlin-3 treatment, were observed. As a result of HDAC inhibition the mRNA levels of p21, p53 and TIMP-1 were significantly elevated, while the levels of BIRC3 was significantly down-regulated. Thus, treatment of MDM2 overexpressing cell lines with HDAC inhibitor resulted in activation of p21 and consequent decrease in cell proliferation due to resumption of cell cycle arrest. Our results with LNCaP-MST cells offer convincing evidence to suggest that the inhibition of HDAC can control cell proliferative signals in MDM2 overexpressing prostate cancer cells. (The generous support from the Royal Dames of Cancer Research Inc., Ft. Lauderdale, Florida is gratefully acknowledged.)

#310 Enhanced stability of D-type cyclins correlates with glioblastoma resistance to ionizing radiation. Fadila Guessou, Mouadh Benamar, Hui Zhong, Tarek Abbas. Univ. of Virginia, Charlottesville, VA.

Transition from G1 to S phase of the cell cycle is promoted by D-type cyclins (D1, D2 and D3), regulatory subunits critical for the activation of cyclin dependent kinases 4 and 6 (CDK4/6), which phosphorylate and inactive the retinoblastoma protein (pRB) and activate the transcription factor E2F1 to promote the expression of genes essential for DNA synthesis. Decreased expression of D-type cyclins is frequently observed in human malignancies and correlates with increased proliferation. Cyclin Ds overexpression is also associated with radioresistance, leading to radiotherapy failure and disease recurrence. Cyclin D1 undergoes ubiquitin-dependent degrada-tion following the exposure of cancer cells to ionizing radiation (IR), and this has been shown to be critical for IR-induced G1 growth arrest and sensitivity of cancer cells to IR. While the role of cyclin D1 overexpression in drug resistance is already well documented, less is known about the role of cyclins D2 and D3 in radio-resistance in human cancer cells, particularly in brain neoplasms. In the present study, we investigated the effect of IR on different D-type cyclins (D1, D2, D3) in human glioblastoma cell lines as well as in tumor-derived mouse oligodendrocytes progenitor cells (OPCs). Here, we show that exposure of human astrocytes to increasing levels of IR led to a rapid proapoptotic degradation of all three D-type cyclins. On the other hand, IR failed to induce significant cyclin D3 degradation in a number of human glioblastoma cells (U87, A172, U251, Snb19). Analysis of cell cycle profile of glioblastoma cell lines and exposure to IR showed prominent cell cycle arrest in G1 starting at 24 hours following exposure. Furthermore, we show that the steady-state levels of D-type cyclin is higher in OPCs compared to mouse NIH3T3 cells and fail to undergo proapoptotic degradation following IR exposure. Collectively, these results suggest that the degradation of D-type cyclins is not critical for IR-induced G1 cell cycle arrest in GNB and may underlie their resistance to IR. Understanding the role of cyclin Ds in promoting radioresistance may lead to a useful pharmacological strategy to enhance radiotherapy outcome and help implement a more effective treatment modality.

#311 Development of AZD2811, an aurora kinase B inhibitor, incorporated into an Accurin™ nanoparticle for use in haematological and solid cancers. Simon Ashton, Nikolaas Fisch, Paula Taylor, Colin Howard, Doug Ferguson, Matthew Ling, Maureen Hattersley, Shenghua Wen, Kim Mart- atea, Adina Hughes, Sean Redmond, Wolfram Brugger, Simon Smith, Alexander MacDonald, Keith Parry, Howard Burris, Young-Ho Song, Jim Nol an, Elizabeth Pease, Simon T. Barry, AstraZeneca, Macclesfield, United Kingdom; AstraZeneca, Cambridge, United Kingdom; AstraZeneca, Gatehouse Park Boston, MA; AstraZeneca, Macclesfield, United Kingdom; Sarah Cannon Research Institute, London, United Kingdom; Sarah Cannon Research Institute, Nashville, TN; Pfizer, New York, NY.

A nanoparticle formulation of AZD2811, a selective aurora kinase B inhibitor, is currently under clinical development for the treatment of both haematological and...
solid tumour disease. AZD2811 is the active derivative of the prodrug Barasertib (AZD1152) which gave promising clinical activity in elderly AML patients delivered as a 7-day infusion (Kantarjian et al, Cancer, 119, 2611-2619, 2013). To address the limitations associated with the clinical utility of Barasertib and other cell cycle inhibitors in the clinic, AZD2811 has been incorporated into an Accurin® nanoparticle using a pamoic acid ion pairing approach to optimise drug release rate (Song et al, Journal of Controlled Release, 229, 106-119, 2016), improve the drug exposure to tumour and reduce the duration of administration. A proof of principle formulation of AZD2811 as an Accurin® nanoparticle established the principle that anti-tumour activity and improved therapeutic index could be achieved (Ashton et al., Science Translational Medicine, 325, 1-10, 2016). The clinical nanoparticle formulation of AZD2811 has been optimised for drug loading and release rate. In pre-clinical models, the clinical formulation can be used flexibly to optimise drug delivery for use in both haematological diseases such as AML, or in solid tumour settings. Anti-tumour activity in solid tumours can be achieved at doses where bone marrow toxicity is reduced compared to Barasertib. In sensitive xenograft and PDX solid tumour models greater than 90% tumour regression is observed after a total dose of 50mg/kg with no tumour progression for greater than 40 days. In contrast, for AML, increasing the dose intensity by 2-4 fold leads to neutropenia and to complete tumour regression in a range of AML xenograft models for greater than 60 days. These data establish the concept that drug delivery using nanoparticles is able to resolve therapeutic index challenges, and is able to do so across different disease types. AZD2811 is currently in Phase 1 clinical trial (DE130C0000). The current pre-clinical and clinical data with this novel approach to inhibition of the cell cycle will be discussed.

#312 Anti-proliferative effects of cinnamon extract in colon cancer. Patrick P. Carriere, Hina Mir, Neeraj Kapur, Clarence E. Clark, Shailesh Singh. Morehouse School of Medicine, Atlanta, GA.

Colon cancer is the third most lethal cancer worldwide, and is estimated to cause 49,190 cancer-related deaths in the U.S. in 2016 alone. Current treatments for colon cancer are limited in their capacity to target tumor cells employing adaptive mechanisms necessary for survival and proliferation, often resulting in poor prognosis. It is critical to develop novel target-specific therapeutic approaches with minimal cytotoxicity to normal cells, in order to mitigate potential side effects. Proanthocyanidins represent a subclass of flavonoids, which have been widely investigated for their chemopreventive and therapeutic potential. Cinnamamin B-1 (CTB-1) is a proanthocyanidin shown to have anti-cancer effects in several cancers, but its anti-cancer potential in colon cancer has not been tested. Hence, the focus of this study was to determine the anticancer effects of CTB-1 in colon cancer. Our results show that CTB-1 treatment significantly decreases the cell viability and proliferation of DLD-1 and COLO 201 human colon cancer cells in a time and dose-dependent manner. In addition, CTB-1 treatment modulated the cell cycle progression of colon cancer cells via G2/M arrest, coupled with a reduction of cells in the S phase. The expression of p21 was induced in key proteins involved in cell cycle regulation. G2 cell cycle progression were also modulated in response to CTB-1 treatment. Collectively, these findings, for the first time, shed light on the anti-proliferative effects of CTB-1 in colon cancer, and further demonstrate its potential as a novel therapeutic/preventive agent.

Thymus, brain, and testes-associated (Tbeta) is a negative control cell-cycle gene highly expressed in murine thymic epithelial cells (TECs). Tbeta protein binds to Uba3, inhibiting formation of Nedd8 E1 and subsequent target degragation via neddylation of several cell cycle control proteins needed for G2/M transition, which may be a major mechanism of TEC growth arrest during thymic involution. Etoposide is a cytotoxic drug which targets the enzyme topoisomerase II — increased 2-3 fold during the G2 phase. To further characterize effect of Tbeta on cell cycle, we modified our novel target-specific therapeutic from human osteosarcoma to express a Tbeta/mCherry fusion protein when mifepristone is added to culture media. Tbeta-expressing cells identified on flow cytometry did exhibit growth arrest, with quantitative assessment of DNA content in U2OS cells by flow cytometry establishing that 32% of Tbeta/mCherry-expressing cells were in the G2 phase when exposed to mifepristone for 24 hours, compared to 11% of mCherry-expressing cells. Gene expression studies were consistent with these results. Cells expressing Tbeta/mCherry were also more sensitive to etoposide at 0.5, 1, and 5 times the IC50 dose. To test whether p53 function was required, we further modified the cells to overexpress a dominant negative p53 mutant along with Tbeta/mCherry. Similar G2 arrest and increased sensitivity to etoposide were observed, indicating that the effects of Tbeta did not require normal p53 function. Potential Tbeta analogues or mimetics may therefore be used as an adjunct to G2-targeted chemotherapy.

#314 Evaluation of effective drug combinations of sonidegib and ribociclib for treatment of Sonic hedgehog medulloblastoma using mathematical models of the cell cycle and Hedgehog pathways. Zack Jones, Jessica Roberts, Haley Houke, Martine Roussel, Clinton Stewart, Carl Penetta. St. Jude Children’s Research Hospital, Memphis, TN.

Sonic hedgehog (SHH) tumors account for roughly 25% of all pediatric medulloblastoma. Aberrant signaling of the SHH pathway, typically via Patched-1 (PTCH) mutation, results in cell proliferation and subsequent tumor formation. Smoothed (Ptc1) inhibitors such as sonidegib have been used clinically to control tumor progression and have shown initial promise. However, many tumors acquire resistance to therapy. Combination therapy with an additional agent targeting another node in pathways affecting cell-cycle progression such as ribociclib, a cyclin D-dependent kinase (CDK) 4/6 inhibitor, may improve therapy and reduce tumor burden by delaying or preventing the development of resistance. Identification and evaluation of effective anti-cancer drug combinations, along with their schedule, sequence, and dosage are a major challenge due to the large number of possible combinations in addition to the cost and time involved in experimentally testing each possible permutation. Mathematical models can aid in the discovery of optimal drug combinations. A mathematical model of the SHH and Cyclin D/CDK 4/6 pathway was designed to evaluate effective sequences and schedules of sonidegib and ribociclib for the treatment of SHH medulloblastoma. The model was parameterized using in vitro data from studies treating the NIH3T3 cell line with sonidegib and ribociclib singly or in combination. Flow cytometry analysis was used to quantify response to treatment by obtaining cell-cycle phase distributions for each drug as a single agent or in combination. Uncertainty and sensitivity analysis of the model parameters were evaluated via Latin Hypercube Sampling and Partial Rank Correlation Coefficient analysis to interpret the effects of amplification or deletion of nodes in the pathway, evaluate potential targetable nodes, and identify sensitivity parameters that need robust quantification. Sensitivity analysis indicated that the formation of Cyclin D/CDK4/6 complexes and the dephosphorylation of Rb were significant nodes that should be included in the model. Uncertainty analysis indicated that the majority of the variability lies in the distribution of cells in G0/G1 and S phase. Simulations of single agent treatment predict a similar response between sonidegib and ribociclib, with co-treatment indicative of an additive effect. Optimal control theory methods are being applied to this model to help determine effective sequence, schedule, and dose of sonidegib and ribociclib to improve efficacy and reduce drug resistance in the treatment of SHH medulloblastoma.
Identification of SGK1 as a potential therapeutic target in castrate resistant prostate cancer. Massar I. Alsamaee, Ursula McClurg, Craig N. Robson, Stuart McCracken. *Northern Institute For Cancer Research, Newcastle upon Tyne, United Kingdom*

Introduction: Prostate cancer (PC) is the most common male cancer in the UK, with approximately 1 in 8 men developing the disease within their lifetime (Prostate Cancer UK). The androgen receptor (AR) has a crucial role in the proliferation and progression of prostate cancer. Patients respond to anti-androgen therapy in the early stage of the disease, however many will develop resistance, entering a “castrate-resistant” disease state (CRPC), carrying a very poor prognosis, posing a major clinical challenge (1). The development of second-generation agents and the use of bifunctional agents has shown promise in the treatment of CRPC patients, but response rates of just 50% and the development of resistance to these drugs have limited their success in the clinic (2,3). This study aims to interrogate the global gene expression consequences of anti-androgen resistance in a LNCaP prostate cancer cell line model, resistant to Enzalutamide. In our gene microarray, SGK1 demonstrated high expression in Enzalutamide resistant cells. Our subsequent experiments suggest SGK1 may serve as a biomarker of resistance or perhaps an exploitable target in CRPC. Methods: A gene microarray was used to determine the gene profile of parental LNCaP cells, sensitive to anti-androgen drugs, versus in-house generated LNCaP-Enzalutamide Resistant cells. QPCR to determine the mRNA level of SGK1 +/− Dihydrotestosterone (DHT), +/− Dexamethasone. Western blot was used to detect the protein level of the SGK1. In vivo, we observed a significant difference in the parental, androgen sensitive LNCaP cell line, versus the LNCaP-Enz-R cell line model, resistant to Enzalutamide. Inhibition of SGK1 using small molecular inhibitors significantly decreases proliferation and migration of the LNCaP-Enz-R cell line, whereas no changes were observed in the parental, androgen sensitive LNCaP cell line. In human xenograft model, enzalutamide and abemaciclib resulted in more significant reduction of phospho-p90RSK, phospho-Rb, phospho-S6 and Ki67 in H2122 tumors compared with either single agent. Overall, the combined inhibition of ERK1/2 and CDK4 and CDK6 was tolerated and enhanced antitumor efficacy in several KRAS mutant NSCLC preclinical models. These data support the feasibility of combining ERK inhibition with CDK4 and CDK6 inhibitors. Novel combination therapies which target CDK4 and ERK1/2 in combination with abemaciclib as a potential therapeutic strategy for the treatment of KRAS mutant NSCLC patients, and provides the rationale for the combination study in the on-going phase I LY3214996 clinic trial (NCT02857270).

**#318 Identification of FERM domain-containing protein 5 (FRMD5) as a novel target of β-catenin/TCF7L2 complex.** Yoichi Furukawa, Chi Zhu, Tomoyuki Ohsugi, Tumi Terakado, Rei Noguchi, Tsuneo Ikemue, Kyoshibi Yamaguchi, *Univ. of Tokyo, Tokyo, Japan*

Deregulated Wnt signaling is one of the earliest steps in colorectal tumorigenesis. The impairment results most frequently from APC mutations, which leads to the accumulation of β-catenin and subsequent activation of TCF7L2. Although previous studies have identified a number of target genes of the activated β-catenin/TCF7L2 transcriptional complex such as cMYC and cMyc, the comprehensive target gene set of the Wnt/β-catenin signaling remains to be elucidated. To understand the precise molecular mechanisms underlying colorectal cancer, we searched for novel genes regulated by the complex in colorectal tumors. We performed expression profile analysis of HCT116 and SW480 colon cancer cells treated with β-catenin siRNAs, and combined these data with public microarray data of LS174 cells treated with a dominant-negative form of TCF7L2. As a result, we identified a total of 134 genes that were regulated by both β-catenin and TCF7L2. Subsequent ChiP-sequence with TCF7L2 antibody also corroborated the interaction of TCF7L2 with a region (hg19 chr15: 44,449,680-44,450,487) within intron 1 of FRMD5. Reporter assay with plasmids containing this region revealed that the reporter activity was downregulated by the knockdown of β-catenin. These data suggested that FRMD5 is a direct target of β-catenin/TCF7L2 complex, and that the region is involved in the transcriptional activation of the TCF7L2 gene by interaction with the complex. Consistently, its expression was elevated in colorectal tumors compared to normal colonic mucosa in public microarray data. To uncover the role of FRMD5 in colorectal carcinogenesis, we analyzed expression profile of HCT116 cells treated with FRMD5 siRNA, and combined the data with the profile with β-catenin siRNA. Gene set analysis with 53 commonly up-regulated and 56 commonly down-regulated genes by both FRMD5 and β-catenin disclosed that the gene sets of DNA replication, cell cycle, and extracellular matrix (ECM) were altered by FRMD5. These data may be useful for the future studies of colorectal carcinogenesis.

**#319 Cholesterol inhibition reduces Hh mediated chordonosarcoma.** Qingxia Wei,1 Eyal Ramu,2 Mushirul Al-Jazrawe,1 Raymond Poon,3 Jay Wunch,2 Benjamin Alman3. 1The Hospital for Sick Children, Toronto, Ontario, Canada; 2Mount Sinai Hospital, Toronto, Ontario, Canada; 3Duke University, Durham, NC

Constitutive activation of Hh signaling is a common occurrence in chordosarcoma(CSa). Gene profiling analysis showed that Gli transcription regulates genes that govern cholesterol homeostasis, which alters cholesterol accumulation in chordocytes; a higher level of Gli-mediated transcription results in accumulation of intracellular cholesterol. Here we determined if targeting cholesterol-processing genes downstream of Hh signalling could be used as a novel treatment approach. With institutional review board approval, human CSA samples were obtained fresh from surgery. For in vitro studies, CSA explants of 2mmx2mm x2 mm cubic in size established as organ cultures. For in vivo studies, one mouse CSA explant was subcutaneously injected into NSG mice. Cells from five CSAs were treated both in vitro and in vivo with a hedgehog inhibitor, Cur61414, a cholesterol inhibitor, Lovastatin, or both. In vitro, CSA explants were treated for 48 hrs at concentration of 20 μM of each drug. In vivo, mice were treated with 4.5mg/kg/day of Cur61414, Lovastatin, or both. In vivo, CSA explants were treated for 48 hrs at concentration of 20 μM of each drug. In vivo, mice were treated with 4.5mg/kg/day of Cur61414, Lovastatin, or both by intraperi-
tonal injection for 4 wks. At the end of treatment, the explants or xenografts were harvested and processed for further analysis. RT-PCR was used to measure the expression of Hh and cholesterol target genes. Tumor size was measured from the xenografts. Blockade of Hh signaling significantly decreased Gil1 gene expression by 30%, increased 3-hydroxy-3-methylglutaryl-CoA reductase (HMGR) expression for more than 300% indicating decreased intracellular cholesterol. Treatment with the cholesterol inhibitor Lovastatin increased expression of HMGR for more than 500%. The combination of Hh and cholesterol blockage resulted in increased expression of HMGR for more than 3400%. Analysis of chondrosarcoma xenografts in vivo showed a significant decrease in tumor size with Lovastatin (32% decline), 3 folds reduction of BrdU (+) cells, and increase of Caspase-3 (+) cells. Treatment with Lovastatin and Curcumin on xenografts resulted in a significant decrease in tumor size (32% decline), 3 fold reduction of BrdU (+) cells, but no significant changes of Caspase-3 (+) cells. These data suggest that cholesterol functions downstream of Hh signaling pathway in CSA. The more effective reduction in tumor growth with cholesterol inhibition compared to Hh blockade suggests cholesterol blockade is an effective therapeutic approach.

#320 Potential of targeting of MYC-driven cancers via CIP2A without detrimental physiological effects. Xi Qiao, Turku University, Turku, Finland.

Transcription factor MYC is a driver of many human cancers due to its widespread effects on gene expression. An understanding of the mechanisms determining MYC transcriptional and proliferative/promotomat effects in vivo could facilitate approaches for MYC targeting. However, post-translational modifications that control MYC function in vivo are poorly understood. Here, we demonstrate that MYC phosphorylation at serine 62 enhances MYC accumulation on Lamin A/C-associated nuclear structures and that the protein phosphatase 2A (PP2A) inhibitor protein CIP2A is required for this process. CIP2A is also critical for serum-induced MYC phosphorylation and for MYC-elicted proliferation induction in vitro. Complementary transgenic approaches and an intestinal regeneration model further demonstrated the importance of CIP2A and serum 62 phosphorylation for MYC activity upon DNA damage-induced proliferation. However, targeting of CIP2A did not influence the normal function of intestinal crypt cells or general well-being of the mice. Meanwhile, in breast cancer cells, CIP2A depletion was shown to inhibit the MYC serum 62 phosphorylation, MYC-mediated gene expression, and anchorage-independent growth. Furthermore, CIP2A supports MDA-MB-231 xenograft growth in nude mice. Therefore, results of these studies collectively suggest for a novel opportunity to target MYC’s function in MYC-driven cancers via CIP2A, and without detrimental physiological effects.

#321 MUC1 regulates TGFβ function in pancreatic cancer. Priyanka Grover,1 Monica D. Nye,1 Mahboubeh Yazdnifar,1 Mohammad Ahmad,1 Ru Zhou,1 Lopamudra Das Roy,1 Kajal Grover,1 Shu-ta Wu,1 Sritama Nath,1 Pinku Mukherjee,1,2 Univ. of North Carolina - Charlotte, Charlotte, NC;2Univ. of North Carolina - Chapel Hill, NC.

In 2016, Pancreatic Cancer (PC) has moved to 3rd leading cause of cancer-related deaths in the USA with 94% dying within 5 years of diagnosis. 90% of PC is Pancreatic Ductal Adenocarcinoma (PDA), of which 80% of PDA overexpress tumor associated Mucin-1 (TMUC1), a membrane bound glycoprotein that is hypoglycosylated. Overexpression of TMUC1 is associated with metastasis and poor prognosis. However the mechanism remains obscure. Transforming growth factor-β (TGF-β) plays a role in poor prognosis. TGF-β is a cytokine with dual functionality. Within normal cells and early carcinogenesis, TGF-β functions as a tumor suppressor and induces apoptosis. This effect is mediated by activation of the canonical Smad pathway via engagement of TGF-β-Receptor 1 (TGF-βRI). However during later stages of cancer, TGF-β becomes a tumor promoter and stimulates epithelial to mesenchymal transition, migration, and invasion thus enhancing metastasis. This TGF-β effect is mediated by the non-canonical pathway. We recently showed correlation between TMUC1 and TGF-β within an exogenous tMUC1 model of PDA. Therefore, it is hypothesized that the mechanism between the two newly connected pathways exists in PDA tumors with high endogenous tMUC1 levels. We propose that the tyrosine kinases present in the cytoplasmic tail of tMUC1 are intermediary between the two pathways, thus leading to enhanced metastasis. First the secretion levels of TGF-βRI were assessed in a panel of 13 PDA cell lines with variable expression levels of TMUC1 by ELISA. The effects of TGF-βRI to induce apoptosis versus invasiveness on a variety of TMUC1 high and TMUC1 low PDA cell lines were determined. The effects of TMUC1 knockdown were evaluated in TMUC1 high cell lines via siRNA. We studied the role of tyrosine kinases and other protein complexes in mediating the interactions between tMUC1 and TGF-β via proteomics analysis. Finally, we evaluated the anti-tumor efficacy of neutralizing TGF-β1 in vivo and high and low TMUC1-expressing PDA tumors. In TMUC1 high PDA cells, TGF-β1 is secreted less when compared to TMUC1 low PDA cells, allowing for the more resistant cells to diminish TGF-β mediated effects of TGF-β1. This is supported by the observation that TMUC1-high PDA cells are more invasive, resist apoptosis, and activate Erk pathway, while TMUC1 low cells activate SMAD pathway. However, TMUC1 knockdown via siRNA does not affect TGF-β receptor levels. When studying the tyrosine kinases, c-Src becomes more phosphorylated in the presence of TGF-β1 in TMUC1 high cells, while in TMUC1 low cells c-Src becomes more deactivated in the presence of TGF-β1. Finally, within the mouse model, TMUC1-high PDA tumors respond to the neutralization of TGF-β1 by decreasing tumor size, while having no statistically significant result on tumor weight. TMUC1 expression is influential in TGF-β1-low PDA tumors. TMUC1 expression is influential in TGF-β1 function in an endogenous model. Neutralizing TGF-β1 in TMUC1 high expressing tumors can be considered as a possible treatment. This has high clinical significance for patients with PDA.

#322 Distinct pools of ShcA coupled tyrosine kinase signaling influences breast tumor heterogeneity and therapeutic responsiveness. Jacqueline R. Ha,1 Ruyhjin Ahn,1 Young Kyuen Im,1 Valerie Sabourin,1 Harvey W. Smith,2 Ivan Topisirovic,3 Tony Pawson,3 William J. Muller,1 Josie Ursini-Siegel,3,1 Lady Davis Institute for Medical Research, McGill University, Montreal, Quebec, Canada; Goodman Cancer Research Centre, McGill University, Montreal, Quebec, Canada; Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, Ontario, Canada.

Phospho-tyrosine (pTyr) signaling networks are frequently activated in breast cancers (BrCa) and are considered to be major oncogenic drivers of tumor progression. Therapeutic interventions, such as the tyrosine kinase (TK) inhibitor Trastuzumab, focus on targeting TK activity and downstream effectors. Although successful for early stage tumors, a subset of patients experience relapse due to intrinsic or acquired resistance. This includes activation of alternative receptor tyrosine kinase (RTK) and/or cytoplasmic TKs, many of which require recruitment of the adaptor protein, ShcA. ShcA is a key convergence point downstream of RTKs and serves to integrate multiple signal transduction pathways dysregulated in BrCa. Specifically, ShcA contains two pTyr binding motifs including an amino-terminal PTB domain and a carboxy-terminal SH2 domain which facilitate its interactions with TKs including ErbB2 and Src Family Kinases (SFK), respectively. The CH-1 domain houses three tyrosine phosphorylation sites at residues 239/240 and 317 which transduce Ras-dependent and independent signals. Using a well characterized transgenic mouse model of BrCa where ShcA can no longer engage the transforming oncogene through its PTB domain, we demonstrate that loss of PTB-driven ShcA (ShcA-PTBΔN) signaling delays mammary tumor onset. However, once formed, the growth and angiogenic potential of these tumors is significantly increased relative to control mice. Increased growth potential of ShcA-PTBΔN tumors is associated with the hyper-activation of the c-Src tyrosine kinase. Deletion of c-Src in ShcA-PTBΔN breast tumors significantly delays tumor onset but is dispensable for the growth of tumors that retain an intact ShcA PTB domain. These data suggest that the ShcA PTB domain can recruit negative regulators that limit the activation of downstream tumorogenic signaling networks. Interestingly, tumors expressing ShcA-PTBΔN deutilated in SH2 driven pTyr interactions (SH2ΔN), are significantly delayed in tumor onset relative to ShcA-PTBΔN controls. Paradoxically, deletion of c-Src in the context of ShcA-PTBΔN SH2ΔN further accelerates tumor growth which is attributed to increased levels of Fyn and Lyn. These observations support the high dependence of intracellular ShcA pools on other SFK family members to retain tumorigenic potential when adapting to low levels and/or activity of c-Src. We demonstrate that uncoupling of PTB-driven ShcA signaling from upstream RTKs can potentiate ShcA signaling from intracellular pools to hyper-activate SFKs. This data is clinically relevant as c-Src is frequently hyper-activated in Breast tumor-mammary tumor resistance. This is the first study to identify a tumor suppressive role of the ShcA PTB domain and to characterize an intrinsic ShcA SH2 domain-SFK dependent resistance mechanism downstream of activated RTKs in mammary tumorigenesis.

Background: The end point of most cell-signaling cascades is the translocation of protein complexes into the nucleus to modify transcriptional activity. For this reason, the analysis of cytoplasmic vs. nuclear localization provides important insights into cell activation. However, assessing nuclear translocation in complex cell mixtures, such as whole blood, is a difficult task. Leukocytes are a
rare event in blood, with many subpopulations, requiring the cells to first be concentrated, sorted, and often expanded prior to further molecular analyses. This process can take weeks, and questions regarding physiological relevance arise from even the first preparatory steps. Here, we present a buffer-based system to lyse RBCs and differentially stain leukocytes in order to enable the quantitative analysis of pERK expression vs. nuclear localization in endogenous cells by flow cytometry. We demonstrate the use of this system by analyzing the activation of NF-κB signaling in whole-blood monocytes following lipopolysaccharide (LPS) stimulation. Methods: The main components of the Whole Blood Nuclear Localization Kit are two buffers: Buffer 1 permeabilizes the cytoplasmic membrane, leaving the nuclear membrane intact, while Buffer 2 permeabilizes both the cytoplasmic and nuclear membranes. Briefly, blood was treated for different times with LPS, fixed for 10 min, split into 2 fractions, and then one was lysed for 30 min with Buffer 1 and the other with Buffer 2. Each fraction was washed, stained and acquired on a CytoFLEX-S flow cytometer (Beckman Coulter, Brea, CA). The cytoplasmic and nuclear signals were calculated using the compensated results from the two tubes. Blood was collected onsite daily from healthy, non-smoking human adults. Results: Following LPS stimulation, nuclear p50 and RelA increased maximally in monocytes by 10 min. Phospho-RelA S536 was maximal by 5 min mostly in the cytoplasm, while phospho-RelA S529 was maximal by 10 min in the nucleus. IκBα degraded maximally by 10 min. Additional kinase signaling will be presented, as well as controls to demonstrate the partitioning efficiency. Conclusions: This system is very fast and user-friendly, allowing for improved data in LPS-stimulating normal monocytes and other rare events in blood, with many subpopulations, requiring the cells to first be concentrated and often expanded prior to further molecular analyses. This process can take weeks, and questions regarding physiological relevance arise from even the first preparatory steps. Here, we present a buffer-based system to lyse RBCs and differentially stain leukocytes in order to enable the quantitative analysis of pERK expression vs. nuclear localization in endogenous cells by flow cytometry.

#325 Pediatric relapsed acute lymphoblastic leukemia patients display enrichment of the PI3K/mTOR pathway and respond to the dual PI3K/mTOR inhibitor PKI-587. Mohiuddin Gazi, Sasaun A. Moharram, Alissa Marshall, Kinjal Shah, Julush A. Kazi. Lund University, Lund, Sweden.  
Although significant improvements have been observed in the treatment of acute lymphoblastic leukemia, there is a substantial subset of high-risk T-ALL patients with relatively poor prognosis. T-cell acute lymphoblastic leukemia (T-ALL) is a hematopoietic malignancy affecting lymphoblasts of T-cell lineage which cause lots of hematopoietic cancer related deaths every year all over the world. The current overall cure rates of newly diagnosed childhood ALL are more than 80% in Europe, but approximately 20% of patients relapse due to treatment failure in childhood ALL. Like other leukemias, alterations of PI3K/mTOR pathway are predominant in T-ALL which is also responsible for treatment failure and relapse. In this study, two different gene expression data sets of relapsed patients also displayed enrichment of the PI3K/mTOR pathway. Out of 88 different inhibitors targeting multiple components of this pathway, we observed that PKI-587 was the most selective to the T-ALL cell line CCRF-CEM. Thus, we characterized the activity of the novel dual PI3K/mTOR pathway inhibitor PKI-587 using CCRF-CEM and Mol3s cells. We observed that PKI-587 blocked proliferation, colony formation and induced apoptosis in the T-ALL cell lines and selectively abrogated PI3K/mTOR without affecting the MAPK signaling. In vivo PI3K/mTOR inhibition delayed tumor progression, and reduced tumor load in a NGS/SCID xenograft mouse model. Since no deceptive body weight decrease was noticed, our conclusion is that this dose is effective and well tolerated. The beneficial effects of PKI-587 on T-ALL cells that has been observed in this study both in vitro and in vivo warrant further investigation.

#326 Baseline IL-17 receptor signaling is essential for controlling aberrant JNK-dependent cellular proliferation via maintenance of endogenous level of ubiquitin-editing enzyme A20. Chi Yan, Yang Lei, Anna L. Greenshields, David W. Hoskin, Tong-Jun Lin, Jun Wang, Dalhousie University, Halifax, Nova Scotia, Canada.  
The molecular mechanisms underlying aberrant activation of NF-κB and JNK in cancer remain incompletely understood. Here, we demonstrate that baseline IL-17 receptor (IL-17R) signaling is essential for controlling aberrant NF-κB and JNK activation, and restraining JNK-dependent homeostatic cellular proliferation. Using a shRNA knockdown approach, we demonstrated in B16 melanoma and 4T1 breast carcinoma murine cell lines that IL-17RA silencing markedly enhanced tumor cell growth in vitro and in vivo. Through mapping IL-17R signaling pathways, we further demonstrated that baseline IL-17A/IL-17R signaling actively restrained JNK phosphorylation in vitro and in vivo via the maintenance of basal expression of the ubiquitin-editing enzyme A20, a negative regulator of NF-κB and JNK. Remarkably, IL-17RA reconstitution evidently restored the A20 level, and suppressed cell proliferation and JNK activity in tumor cells. The reconstitution of A20 in IL-17RA knockdown subclones was able to restore the normal rate of cellular proliferation and associated JNK/C-Jun activity. Finally, meta-analysis of human cancer microarray and RNA-Seq data sets confirmed significant co-expression of IL-17RA and A20. Furthermore, alterations (mutation, upregulation or downregulation) of IL-17RA level in melanoma, ER+ breast cancer and colorectal cancer patients were associated with poorer overall survival compared to the respective patients with normal baseline IL-17RA expression. Together, our data demonstrates a previously unrecognized molecular mechanism underlying aberrant activation of NF-κB and JNK in cancer cells. This work highlights the unique biological role of proinflammatory IL-17R signaling in the maintenance of A20 to regulate the pathogenesis of human cancer, which draws caution on the utility of IL-17A neutralizing antibody in cancer therapy. CY is a PhD student supported by the graduate student research training program as part of The Terry Fox Foundation Strategic Health Research Training Program as part of The Terry Fox Foundation Strategic Health Research Training Program in Cancer Research in CIHR.

Epithelial cell adhesion molecule (EpCAM) is highly expressed in advanced epithelial cancers and tumor-initiated cells (TICs), but its roles in cancer pro-
growthression remain to be elucidated. Here, we showed that the extracellular domain of EpCAM (EpEX) could bind to EGFR through EGFR-like domain I, and subsequently activated its downstream molecules, ERK1/2 and Akt. EGFR inhibitor and knockdown of EGFR by siRNA ablated EpEX-induced ERK1/2 phosphorylation. Regulated intramembrane proteolysis (RIP) of EpCAM was induced similarly in EpEX stimulation as EpCAM through EGFR signaling with SINE compounds (selinexor or KPT-8602) have increased basal GR protein levels. Consistent with these results, the SINE-DEX combination shows enhanced GR transcriptional activity. Several GR-DEX target genes are known to inhibit the GTPase, Ras homolog encoded in brain (RHEB), which is required for mTORC1 activation. We discovered that the SINE-DEX combination not only reduces RHEB protein but also induces the RHEB inhibitory antibody to mTORC1. As a result, we can expect a combinatorial effect of the SINE compound-mediated inhibition of mTORC1 (i.e. reduced phosphorylation of S6K1 and 4E-BP1) is GR independent, SINE-DEX inhibition is more robust in GR+ MM cell line when compared to the GR- MM.1R cells. The combination resulted in the selinexor IC₅₀ in MM.1S cells shifting from 40 nM to 11 nM in the presence of low dose DEX. As expected, DEX did not modulate the SINE compound IC₅₀ in MM.1R cells. Conclusion: We show that SINE compound inhibition of MM cell viability is enhanced with DEX. Our results indicate that this combinatorial effect is due to convergent suppression of mTORC1 signaling by GR targets. The findings provide mechanism of action data around the SINE-DEX combination in MM with suggestive biomarkers (REDD1, KLF15, BCAT2 and GR) that may predict best response to the combination. Therefore, these data may translate directly to the current development of SINE compounds.

#330 SGK1 activation is essential for PI3K-dependent tumor development. Arturo Orlacchio, Antonio Di Cristofano. Albert Einstein College of Medicine, Bronx, NY.

The PI3K signaling cascade is frequently activated in human cancer, with AKT being commonly considered its major transforming conduit. Conditional deletion of Pten in the mouse thyroid epithelium induces constitutive activation of the PI3K pathway, which causes thyroid hyperplasia at birth that progresses to invasive and metastatic follicular carcinoma. Concomitant loss of p53 or activation of KRAS dramatically accelerates the development of aggressive and lethal tumors. The PKD1 kinase plays a key role in the PI3K signaling cascade, directly activating, in a PI3K-dependent manner, not only AKT but also a set of additional AGC kinases, including, S6K, PKC, and SGK. Using in vivo, ex vivo, and in vitro genetic and pharmacological approaches, we now show that AKT activation is not sufficient to transform thyroid epithelial cells. Concomitant activation of additional PDK1-dependent pathways is absolutely required to develop neoplastic lesions in vivo, and to induce cell proliferation ex vivo, in mouse models based on Pten loss, alone and in combination with additional genetic alterations. In particular, we show that one member of the SGK family, SGK1, is an essential mediator of the transformation process downstream of PI3K. Genetic and pharmacological SGK1 inhibition strongly reduces cell proliferation in Pten+/− and PI3KCA-mutant cell lines. Moreover we show that concomitant SGK inhibition significantly increases the efficacy of inhibitors targeting AKT or PI3K. Taken together, our data identify an essential and druggable signaling cascade that critically cooperates with AKT activation to transform thyroid epithelial cells.

#331 SIRPB1 promotes prostate cancer cell proliferation & migration. Qiong Song,1 Siyu Yin,1 Chunlin zou,1 Wenchu Wang,1 Lihui Wang,1 Haibo Tong,1 William J. Catalona,2 Jian Zhang,1 Yi Lu,1 Zhou Wang3. Signal-regulatory-protein beta 1 (SIRPB1) is a member of the signal-regulatory-protein (SIRP) family that belongs to the immunoglobulin superfamily and is capable of modulating receptor tyrosine kinase-coupled signaling. The copy-number variations (CNV) at the SIRPB1 locus were associated with aggressive prostate cancer in patients. To test if SIRPB1 could affect prostate cancer development and progression, we investigated the potential role and mechanisms of SIRPB1 action in prostate cancer cell lines in vitro and in xenograft tumors. Knockdown of SIRPB1 by RNA interference resulted in significant suppression of cell colony formation, cell mobility, cell migration, and invasion. The knockdown also induced cell cycle arrest during the G₀/G₁ phase and a remarkable enhancement of apoptosis in PC3 prostate cancer cells. In contrast, overexpression of SIRPB1 significantly induced cell migration, invasion, colony formation and cell cycle in C4-2 prostate cancer cells. Furthermore, overexpression of SIRPB1 in C4-2 cell model enhanced its tumor take rate in nude mice. Also, SIRPB1 mRNA expression was increased in up to 39% of the prostate cell line. Poly(ADP-ribose) polymerase-1 (PARP1) or ADP-ribosyltransferase diphtheria toxin-like 1 (ARTD1) is the most abundant and the best understood member of the 17 PARP family proteins. PARP1 binds to both single strand breaks (SSBs) and double-strand breaks (DSBs) and participates in the recognition, excision and repair of DNA damage. The most extensively studied role of PARP1 is its involvement in base excision repair (BER) and PARP inhibition-induced trapping of PARP1 during BER. Moreover, suppression of PARP1 is shown to lead to synthetic lethality in BRCA1/2 deficient tumors, indicating that PARP1 dependent BER and BRCA-dependent homologous repair pathway have overlapping and redundant functions in DNA repair. Recent studies have also pointed to a broader utility of PARP inhibitors beyond hereditary BRCA-deficient cancers. Pyruvate kinase isoform M2 (PKM2) is a glycolysis enzyme that converts phosphoenolpyruvate (PEP) into pyruvate. Up-regulation of PKM2 has been shown recently to be an important feature of tumorigenesis. In tumor cells, PKM2 forms a dimer that is catalytically inactive as a glycolysis enzyme, but provides advantage for tumor progression due to Warburg effect. In tumor cells, PKM2 forms a dimer that is catalytically inactive as a glycolysis enzyme, but provides advantage for tumor progression due to Warburg effect. In tumor cells, PKM2 forms a dimer that is catalytically inactive as a glycolysis enzyme, but provides advantage for tumor progression due to Warburg effect. In tumor cells, PKM2 forms a dimer that is catalytically inactive as a glycolysis enzyme, but provides advantage for tumor progression due to Warburg effect.
cancer specimens based on in silico analysis of several public databases. These results suggest that SIRPB1 is a potential oncogene in the prostate and could be used as a biomarker to identify patients at risk of developing aggressive prostate cancer.

Loss of primary cilium promotes LPA-driven proliferation in glioblastoma.

Yuriy Loskutov. West Virginia University, Morgantown, WV.

Glioblastoma is one of the most common brain cancers with a median survival of 13 months. Therapeutic approaches for this type of cancer are very limited, creating an urgent need to develop new strategies for the treatment. Recently, several studies reported that glioblastoma harbors a drastic decrease in primary cilia, suggesting that loss of cilia might be important for glioblastoma biology. The primary cilium is a ubiquitous microtubule based organelle presented on most of human cells. It plays significant role in embryonic development and tissue homeostasis, serving as a hub for multiple signaling cascades including RTK, Sonic Hedgehog, Wnt and Hippo. Here we report that loss of primary cilium in immortalized astrocytes stimulate cell proliferation and drastically change ERK1/2 activation in response to serum. These changes depend on lysophosphatidic acid (LPA), a water-soluble lipid metabolite, implicated in chemotactic and proliferative signaling. The receptor to LPA type 1 tends to accumulate in the primary cilium, indicating its potential role in inhibition/restriction of LPA-driven proliferation of glioblastoma cells. The altered Wnt signaling via dynamic changes in primary cilium. Loss of primary cilium can lead to LPA receptors 1 redistribution to the plasma membrane and switch cellular response for the LPA, allowing it to act as mitogen. Inhibition of LPA receptors with a small molecule inhibitor, K16425, is significantly decreasing the growth of glioblastoma PDXs. Overall, our findings clearly indicate that loss of primary cilium is sufficient to severely change mitogen-driven signal transduction and point towards the new therapeutic target for glioblastoma.

Identification of a natural product small molecule inhibitor against Wnt/β-catenin signalling pathway.

Mohd Salem Dar, A. Ahsanul Haque, Paramjeet Singh, Quamrez Hussain, Sadatohan Paul Monga, Mohd Ijaz Dar. Cancer Pharmacology Division, CSIR-Indian Institute of Integrative Medicine, Jammu, J&K, India; 2Molecular Biotechnology Division, CSIR-Indian Institute of Integrative Medicine, Srinagar, J&K, India; 3Department of Pathology, University of Pittsburgh, School of Medicine S-417 BST, Pittsburgh, PA, PA.

Wnt/β-catenin signalling pathway plays an important role in many processes like cell proliferation, differentiation, regeneration, carcinogenesis and regulates stem cell pluripotency. β-Catenin, the central component of Wnt/β-catenin signalling pathway has a vast number of binding partners and thus plays different roles in the cells. Mutations of β-catenin are seen in many cancers, including liver cancer, colorectal cancer, lung carcinoma, ovarian cancer and malignant breast tumors. Till date there is no even a single small molecule in clinical use that can block the β-catenin activity or the activities of this signalling pathway. In this study, we established many assays for screening small molecule inhibitors of this signalling pathway. Initially, we created a library of β-catenin deletion and point mutants and carried out a comprehensive comparative analysis of these mutants with luciferase reporter assays, GFP-fluorescence, immunoblotting and protein-protein interactions. We then screened many known and unknown natural and synthetic molecules against the wnt/β-catenin pathway and got 2 hits: C-18 and 055A, bioactive metabolites from actinomycetes. The IC50 (cell viability) of 055A and 055A, bioactive metabolites from actinomycetes. The IC50 of 055A, C-18 and salinomycin in HepG2 cells was 7.5 μM, 9.7 μM and 25 μM respectively. Interestingly, C-18 was ineffective against non-cancerous cell line (HEK-293 cells) even up to 60 μM. This shows that C-18 is a very promising hit because it is active against cancer cells and spares non-cancerous cells. The sub lethal doses of these molecules were then tested for β-catenin mediated transcription by luciferase reporter assay in HepG2 cells which harbours a β-catenin deletion responsible for enhanced β-catenin mediated transcriptional activity. Our results show that C-18 and 055A significantly block the β-catenin activity in a dose dependent manner. The inhibition of wnt/β-catenin pathway by C-18 was observed at lower nanomolar concentrations in comparison to 055A and salinomycin which shows activity in micromolar concentrations. The β-catenin target gene expression analysis showed marked decrease in cyclinD1 by immunoblot analysis upon treatment of HepG2 cells with C-18. Interestingly, C-18 treated HepG2 cells failed to show any apoptosis as confirmed by Parp-1 and caspase-3 immunoblotting indicating that C-18 can be targeted to block the activity of wnt/β-catenin pathway, and could act as a lead molecule. Therefore, it warrants further experimentation and validation which are underway to draw the further conclusions.

PTEN-L regulates epithelial growth and macrophage function.

Andrew L. Wolfe, Benjamin D. Hopkins, Sebastián A. Riquelme, Kipyeong Kim, Saiit Ozurtok, Kyeongah Kang, Romain Remark, Adeebeh Rahman, Chyuan-Sheng Lin, Mireiam Merad, Matthias Szaboecs, Shu-Hsia Chen, Alice Prince, Ramon Parsons. University of California San Francisco, San Francisco, CA; 2Mount Sinai School of Medicine, New York, NY; 3Columbia University, New York, NY.

PTEN is among the most frequently mutated and deleted tumor suppressor genes in many malignancies, including breast cancer. An alternatively translated long form of PTEN, termed PTEN-L, has divergent functionality from PTEN, although its function at the organism level has not been studied. Here, we report that PTEN-L is expressed with the ablation of PTEN-L expression but not exact expression of PTEN. These mice display mammary ductal hyperplasia characterized by increased luminal growth and increased numbers of macrophages in the surrounding stroma. Macrophages are particularly affected by PTEN-L loss, with significant changes to their secretomes and functional deficiencies in clearing bacterial infections, consistent with a shift toward an M2-like polarization. Overall, these findings demonstrate that PTEN-L has unique functions in regulating mammary epithelial growth and macrophage functionality that are independent of canonical PTEN.

In situ protein complexes as a measure of AXL signaling and inhibitor response in cell line models of lung cancer.

Anurima Majumder, Yun Bai, Fumi Kinose, Erin D. Lew, Yumi Yokoyama, Danielle Murphy, Gary Li, Eric B. Haura, Moffitt Cancer Center, Tampa, FL; 2Ignyta, Inc, San Diego, CA.

AXL kinase overexpression is associated with metastasis and poor prognosis in various cancers. Recent studies show that epithelial-mesenchymal transition (EMT) and associated activation of AXL is one of the mechanisms by which tumors develop resistance to targeted therapies, such as EGFR tyrosine kinase inhibitor (TKI) in lung cancer. These studies have made AXL an attractive drug target. However, the lack of genetic alterations in AXL and recent evidence suggesting that ligand secretion into the tumor microenvironment plays a key role in signaling and resistance in cancer cells, underscore the need for assays to visualize active AXL signaling associated complexes. In this study, we aimed to develop a Proximity Ligation Assay (PLA) to effectively measure AXL activation in tumor tissues in situ, and to use the assay to evaluate the pharmacodynamic effect of a novel AXL TKI, RXD-106X, in lung cancer models. To this end, several lung cancer cell lines were analyzed for total and phosphorylated AXL (pAXL) expression as well as effects of AXL TKI on downstream signaling. Co-immunoprecipitation studies were also conducted to identify adaptor proteins that form active signaling complexes with AXL kinase, and PLAs were developed to detect these complexes in situ. H1299 and Calu1 cells have the highest pAXL among the cells screened. RXD-106X potently inhibits pAXL and downstream pAKT, but does not affect pERK on cell viability, in these cell lines. We also observe an increase in total AXL in response to the RXD-106. Co-immunoprecipitation shows RXD-106-dependent reduction in AXL-P13KR1 (Phosphoinositide-3-Kinase, Regulatory Subunit 1) interaction that is consistent with the drug-induced reduction in pAKT by western blot. Based on this observation, we developed PLAs to detect active AXL-P13KR1 and AXL-pY100 signaling complexes in these cells. H1299 and Calu1 cells have high basal AXL: P13KR1 and AXL-pY100 PLA foci that are abrogated by RXD-106X, in both fresh fixed and formalin-fixed paraffin-embedded cells. As expected, the HCC287 cells, which lack ligand independent pAXL, do not show significant labeling by either PLA. Overall, we demonstrate that RXD-106X is a potent inhibitor of AXL kinase and its downstream P13K/AKT signaling pathway. We also show that activated AXL signaling complexes can be annotated specifically by PLA. The data provides justification for the extension of our PLA as a tool to measure drug-targetable signaling complexes to identify new models of activated AXL and enrich for activated AXL in patient tissues.

PI3K3CB/p101B is a survival factor in glioblastoma.

Kevin J. Pridham, Sujuan Guo, Zhi Sheng. Virginia Polytechnic Institute and State University, Blacksburg, VA.

Glioblastoma multiforme (GBM) is lethal even after surgical removal of the tumor, radiation, and chemotherapy. Residual tumor cells form an intractable tumor in nearly all patients within two years. Recurrent GBM is incurable due to resistance to current therapies. Inhibitors of PI3K (phosphatidylinositol-4,5-biphosphate 3-kinase)-a signaling pathway that causally contributes to tumor formation/recurrence have been used to treat recurrent GBMs and achieved modest clinical effect. This is perhaps attributed to non-selective inhibition of PI3K isoforms, which yields intolerable toxicity. Class IA PI3K isoforms include three catalytic subunits (PI3KCA, B, or D that encodes p110α, B, or D) and three regulatory subunits (PI3KRI-3 that encodes p85 isoforms). Our recent work
indicates that PIK3CB levels positively correlate with the chances/risk of GBM recurrence, while being inversely associated with patient prognosis. This suggests that PIK3CB/p110β is important for GBM cell survival. To test this hypothesis, we first measured the expression of PIK in isofoms in a panel of 9 GBM cell lines. We found that U87MG, SF295, and U251 expressed much higher levels of p110β, coinciding with the levels of phosphorylated AKT. When we knocked down PIK3CA, B, and D in human U87MG cells and found that only depletion of PIK3CB/p110β resulted in an inactivation of downstream AKT. Moreover, knockdown of PIK3CB/p110β, but not other isofoms, induced substantial growth inhibition in U87MG, SF295 and U251 cells. This is congruent with the result that inhibition of PIK3CB/p110β activated apoptosis in U87MG cells. We then determined the impact of PIK3CB depletion in 10 GBM cell lines, which have previously been linked to control of the ciliary protrusion/resorption cycle. Mechanistic analysis confirmed these compounds controlled activation of Aurora-A at the basal body; in vivo testing demonstrated sunsitibin resulted in loss of cilia not only in vitro, but also in normal kidney, kidney tumors, and in renal cysts associated with polycystic kidney disease (PKD), a disease dependent on defective and other tumor types downregulating them. Moreover, knockdown of PIK3CB/p110β selectively represses the viability of these cells. Finally, we report that ectopic expression of p110β, but not p110α δ, partially rescued U87MG cells from growth inhibition induced by TGX-221, a PIK3/p110β selective inhibitor. Collectively, our results demonstrate that PIK3CB/p110β is an important selective survival factor in GBM, underscoring the divergent roles of PIK3 isofoms in GBM disease progression/recurrence and future therapeutic intervention.

#337 Sonic Hedgehog ligand drives tumor progression and chromosomal instability in a mouse model of small cell lung cancer. Anette Szczepny,1 Samuel Rogers,2 Samantha Jayasekara,1 Kwon Park,3 Rachael McCloy,4 Julien Sage,4 Craig Peacock,5 Jason Cain,6 Andrew Burgess,2 David Neil Watkins,3 Hudson Institute of Medical Research, Victoria, Australia; Garvan Institute of Medical Research, Darlinghurst, Australia; University of Virginia, Charlottesville, VA; Stanford Cancer Institute, Stanford, CA; Cleveland Clinic, Cleveland, OH.

Activation of the Hedgehog (Hh) signaling pathway is well documented in many cancers including Small Cell Lung Cancer (SCLC). Whilst it has been shown that Smoothened, the central Hh pathway mediator, is required for the initiation and progression of SCLC in a mouse model, it is unclear what drives activation of this pathway in these tumors. To address this question, we used a well-characterized conditional genetic mouse model of SCLC in which inhibition of recombinant adenovirus expressing Cre can trigger recombination at loxp sites in the airway epithelium. When the virus is administered to mice double homozygous for the conditional p53 and Rb knockout alleles (p53lox/lox; Rblox/lox), mice develop multiple tumors over 9 months. In order to manipulate Shh expression in this model, we crossed these animals with either gain-of-function or loss-of-function Shh alleles to observe the effects on SCLC initiation and progression in vivo. Aged cohorts of AdenotCre-infected p53lox/lox; Rblox/lox; ShHtg mice developed more frequent and significantly larger tumors compared to p53lox/lox; Rblox/lox; Shhltm littermate controls, with tumors exhibiting a highly malignant and proliferative phenotype. Conversely, deletion of Shh resulted in no sign of change in tumor number but a dramatic reduction in tumor size in p53−/−/Shh−/− mice compared to littermate controls. Inhibition of Shh ligand overexpression also induced marked chromosomal instability and the Smoothened-independent nuclear translocation and activity of Cyclin B1. In turn, overexpression of Cyclin B1 induced chromosomal instability in cells lacking both p53 and Rb. These results suggest that Shh ligand drives progression of SCLC by activating both the canonical and non-canonical arms of the Hh pathway and that Shh may be a potentially useful therapeutic target.

#338 Unexpected activity of multiple targeted cancer drugs in regulating ciliary dynamics. Anna Kiseleva,1 Vladislav Korobeynikov,2 Anna Nikonova,3 Alexander Deneka,1 Margret Einarson,1 Emmanuelle Nicolas,1 Petr Makhov,1 Craig Peacock,1 Jason Cain,2 Andrew Burgess,2 David Neil Watkins,3 Hudson Institute of Medical Research, Victoria, Australia; Garvan Institute of Medical Research, Darlinghurst, Australia; University of Virginia, Charlottesville, VA; Stanford Cancer Institute, Stanford, CA; Cleveland Clinic, Cleveland, OH.

The primary cilium is an antenna-like structure protruding from the cell surface, which provides a platform for receptors for signaling systems including PDGFR-alpha, Hedgehog, Wnt, and others that influence cell differentiation and proliferation decisions. Under normal physiological growth conditions, the cilium forms after mitosis and in quiescent cells, extending from a basal body centerated at a centriole, with timed resorption in G0 or early G1. Cancer cells have altered ciliary dynamics, with some (medulloblastomas and basal cell carcinomas) often dependant on cilia, and other tumor types downregulating them. In prior work, we defined Aurora-A, an oncogenic kinase typically thought of as a mitotic regulator, as transiently activated at the basal body, and absolutely required for resorption of cilia at the G0/G1 boundary, and we showed the targeted Aurora-A inhibitor entirely blocked ciliary resorption. In subsequent work, we found that a second drug, the EGFR inhibitor erlotinib, also affected ciliary resorption, positioning erlotinib and alisertib to influence cilia-dependent signaling. In this study, we broadly assessed the activity of a panel of targeted preclinical and clinical agents of known specificity for action in controlling ciliary dynamics. For this, we developed stable hTER-TPE1 cell line models with integrated Arl13b-GFP reporters to visualize cilia, and performed a mid-throughput screen of 180 drugs for activity in 1) independently inducing ciliary resorption in quiescent G0 cells, or 2) blocking ciliary resorption in cells induced to cycle by serum treatment. With a 5% hit rate overall, we identified 9 compounds inducing, and 7 compounds blocking resorption. This included some well-known drugs as well as some surprises, which have previously been linked to control of the ciliary protrusion/resorption cycle. These data for the first time suggest new mechanisms for activity of sunsitibin and other drugs, in which they can influence activity of lateral signaling pathways such as Wnt and PDGFα by regulating the availability of receptors on a ciliary signaling platform.

#339 Identification of a novel isoform of WNT/planar cell polarity VANGL2 in breast cancer. Jean-Paul Borg, Alexandra Walron, Eric Bailly, Sylvie Marchetto, Stéphane Audebert. CRCM Inserm-Institut Pauli-Calmettes, Marseille, France.

The WNT/PCP pathway is an evolutionarily conserved developmental process which is essential in embryogenesis and development of polarized structures in metazoa. Its importance in human diseases is best demonstrated in several tube-forming diseases and cancer. WNT/PCP signaling involves a set of evolutionarily conserved WNT/PCP genes encoding WNT ligands, transmembrane (vangel2, frizzled, fat, dachous) and cytoplasmic (scribble, prickle, dishevelled, diego) molecules triggering a genetically well-defined non-canonical WNT-JNK pathway. Recent work has linked defects of this pathway to breast cancer aggressiveness. We have shown that the non-canonical WNT/PCP transmembrane receptor VANGL2 is overexpressed in poor prognosis basal breast cancers and implicated in tumor growth. We also found that VANG2 binds through its C-terminal sequence to Scribble and p62/SQSTM1 which are involved in cancer cell migration and growth. A recent in silico study has suggested the existence of an N-terminally extended VANGL2 isoform (VANGL2-Long), in favor of the occurrence of an alternative non-AUG translation initiation site, upstream of the conventional start site. Translation initiation from this alternative site is expected to add an N-terminal extension of 48 amino acids. Accordingly, by analyzing VANGL2 immunoprecipitates by mass spectrometry, we identified a peptide mapping upstream of the first methionine supporting the existence of a longer isoform of VANGL2. While missing in Drosophila, this N-terminal extension is found in all vertebrate VANGL2 sequences that have been examined, suggesting a function for VANGL2-Long. We provide further experimental evidence in favor of the VANGL2-Long isoform, using polyclonal antibodies that have been raised against the predicted VANGL2 N-terminal extension. Using these tools, we characterized VANGL2-Long and showed that it dimerizes with VANGL2 and VANGL1, a close homologue, at the endogenous level in living cells. Our data depict a complex organization of VANGL2/VANGL1 molecules at the plasma membrane and improve the mechanistic understanding of VANGL2 in normal and cancer cells.

SRMS (Src-related tyrosine kinase lacking C-terminal regulatory tyrosine and N-terminal myristoylation sites) belongs to a family of non-receptor tyrosine kinases, which harbours a Src homology 3 and a Src homology 2, as well as a protein kinase domain. SRMS was first identified in a screen for the genes that regulate the growth and differentiation of neuroepithelial cells. SRMS, however, is an understudied member of this family. The present study was undertaken in order to explore the role of SRMS in signaling downstream of KIT. The receptor tyrosine kinase KIT, also known as the stem cell factor receptor, plays a key role in several developmental processes and have been implicated in many human cancers such as gastrointestinal stromal tumors, acute myeloid leukemia and testicular carcinoma. To understand the role of SRMS in KIT signaling, we generated Ba/F3 cell lines overexpressing KIT and SRMS. We observed that SRMS regulates normal and oncogenic KIT signaling differentially with respect to cell proliferation and apoptosis. SRMS association triggers KIT ubiquitination which in turn downregulates the receptor. Further, expression of SRMS downregulates wild-type KIT-mediated phosphorylation of AKT, ERK1/2, p38. Taken together the data demonstrates that SRMS regulates both normal KIT and an oncogenic mutant of KIT, and have differential impact on receptor downstream signaling.

Aberrant expression of CXCR4, a chemokine G protein-coupled receptor (GPCR), drives primary and secondary breast cancer metastasis, however the mechanism is unknown. Here we investigate the role of CXCR4 tyrosine phosphorylation within a novel ITIM motif. Following activation, CXCR4 is normally phosphorylated on Ser/Thr residues, which promotes receptor desensitization and internalization. We found previously that Ser/Thr phosphorylation of CXCR4 is delayed upon SDF gradient sensing, and correlates with sustained signaling to SHP2, a protein that drives hyperproliferation and invasion of breast cancer. Since SHP2 is known to be recruited to tyrosine phosphorylated ITIM motifs (immunoreceptor tyrosine-based inhibitory consensus motifs), we investigated if CXCR4 contains an ITIM motif, and if tyrosine phosphorylation within this motif regulates SHP2 binding, signaling, and migration. Specifically, we assessed 1) if CXCR4 is tyrosine phosphorylated as measured by recombinant phosphatase assay, phospho-Ab development, and tyrosine mutagenesis (YF); 2) if tyrosine mutagenesis alters CXCR4 membrane localization, internalization, and SDF gradient sensing, by ELISA; 3) if tyrosine mutagenesis disrupts CXCR4 interaction with SHP2, by co-IP; 4) if tyrosine mutagenesis alters CXCR4 sustained signaling to SHP2, by Western; and 5) if tyrosine mutation (YF) within the novel ITIM motif in CXCR4 alters migration of metastatic breast cancer cells, by transwell assay. These data demonstrate that CXCR4 phosphorylation is sensitive to recombiant tyrosine-phosphatase treatment and tyrosine mutagenesis, suggesting that CXCR4 is indeed tyrosine phosphorylated within the ITIM motif. We determined that while tyrosine phosphorylation within the ITIM motif is not required for CXCR4 membrane localization, internalization, or SDF gradient sensing, it does regulate CXCR4 binding and signaling to SHP2. Investigating the role in CXCR4 mediated migration is on going. To date, our data support a working model that tyrosine phosphorylation of CXCR4 within an ITIM motif is critical for binding to SHP2 and transducing sustained signaling to SHP2. These data have implications on aggressive breast cancers with dysregulated CXCR4 and SHP2. These studies were supported by NIH grant GM-097718, PA Department of Health and grant SAP4100057688, and the Milton Lev Memorial Faculty Research Fund.

WHSC1L1-mediated EGFR mono-methylation enhances the cytoplastic and nuclear oncogenic activity of EGFR in head and neck cancer. Vassiliki Saloura,1 Theodore Vougiouklakis,1 Makda Zewde,1 Xiaolan Deng,1 Naoshi Doihama,1 Takehiro Suzuki,1 Ryui Hamamoto,1 Yusuake Nakamura1. 1Univ. of Chicago, Chicago, IL; 2Oncotherapy Science, Japan; 3RIKEN, Japan.

WHSC1L1, a protein lysine methyltransferase, is overexpressed in a variety of malignancies, including head and neck cancer (SCCHN), which is characterized by high progression. Overall, our study demonstrates the multifaceted oncogenic function of the protein lysine methyltransferase WHSC1L1 in SCCHN, which is mediated through direct non-histone methylation of the EGFR protein with effects both in its cytoplasmic and nuclear functions.

Proteomic and functional studies identify DCAF7 as major partner of DYRK1A. Varsha Anathapadamanabhan,1 Selene Swanson,2 Siddharth Saini,1 Vijay Menon,1 Larisa Litovchick1. 1Virginia Commonwealth University, Richmond, VA; 2Slowers Institute for Biomedical Research, Kansas City, MO.

DYRK1A protein kinase is encoded by dosage-dependent gene since an extra copy contributes to Down syndrome (DS) pathogenesis while loss of one allele causes severe developmental defects. Current knowledge of DYRK1A’s role in phosphorylation of proteins involved in cell cycle control, transcription and tumor suppression does not fully explain dosage-dependent function of this important kinase. Using MudPIT proteomic analysis, we identified DYRK1A interacting proteins in human T98G cell line. Four independent DYRK1A-HA pull-down samples were analyzed to identify 50 proteins that were specifically detected in 3 out of 4 replicates. This analysis identified WD-repeat protein DCAF7 as major partner of DYRK1A that was most highly enriched among DYRK1A-binding proteins. Furthermore, glycerol gradient ultra-centrifugation showed almost exact co-fractionation of DCAF7 and DYRK1A. DCAF7 has been shown to bind several protein kinases including DYRK1A, DYRK1B, HIPK2 and MAP3K1 suggesting that it serves as a scaffold protein in signal transduction. However, the function of DCAF7 is not established yet. In order to understand the functional relationship between DCAF7 and DYRK1A, we undertook a MudPIT proteomic analysis of DCAF7 binding proteins in T98G cells and compared the data with the DYRK1A interactome dataset. Analysis of three independent DCAF7-HA pull-down samples identified 32 proteins specifically detected in all three replicates including DCAF7, DYRK1A and five proteins earlier detected in DYRK1A MudPIT analysis. Given the proposed role of DCAF7 as a scaffold protein, we tested whether DCAF7 mediates its interaction with some of its interacting proteins. Interestingly, we found that RNF169, a recently characterized RING-domain ubiquitin ligase involved in the DNA double-strand break (DSB) repair, binds to N-terminus of DYRK1A independently of DCAF7. Furthermore, our data show that DYRK1A is required for DCAF7-RNF169 interaction because this interaction was abolished in human U-2 OS cells where DYRK1A gene was disrupted using CRISPR-Cas9 editing (DYRK1A-KO cells). Interestingly, stable overexpression of DCAF7 in DYRK1A-KO U-2 OS cells rescued some of the phenotypes observed in these cells, suggesting that DCAF7 could be an effector downstream of DYRK1A. Our findings revealed an unexpected scaffolding role of DYRK1A that is required for mediating the interaction between DNA repair protein RNF169 and the WD-repeat protein DCAF7. While further studies are needed to understand the exact role of the RNF169-DCAF7 interaction in DNA repair, the novel role of DYRK1A as a scaffold protein could explain some aspects of the dosage-dependent function of this protein kinase. In addition, we report here an initial functional characterization of the DCAF7-DYRK1A interaction in human cells and discuss novel functional interactions of DCAF7 that could be independent of DYRK1A.

Chondroitin sulfatases regulate Wnt signaling through effects on Shp2, phospho-Erk1,2, c-Myc, and histone methylation of DKK3 in prostate cancer and prostate stem cells. Joanne Kramer Tobacman, Sumit Bhattacharya, Leo Feferman. Unv. of Illinois at Chicago, Chicago, IL.

The chondroitin sulfatases N-acetylgalactosamine 4-sulfatase (arylsulfatase B, ARSB) and N-acetylgalactosamine 6-sulfatase (galactose 6-sulfatase, GALNS) remove the 4-sulfate and 6-sulfate groups of chondroitin sulfates. ARSB activity was found to remove 4-sulfate groups of chondroitin 4-sulfate (C4S) or dermatan sulfate, and GALNS acts to remove 6-sulfate groups of chondroitin 6-sulfate (C6S) or chondroitin 4.6-disulfate, as well as keratan sulfate. In human prostate cancer tissues, ARSB activity was markedly reduced and GALNS activity increased by immunohistochemistry of malignant prostate tissue captured by laser microdissection and by assay of human prostate stromal and epithelial cell lines, ARSB was predominant in stromal cells of the extracellular matrix, whereas GALNS was predominant in prostate epithelial cells. When ARSB was reduced by silencing in human prostate stem cells or GALNS was increased by overexpression in the stem cells, SHP2 binding to chondroitin 4-sulfate increased, leading to inhibition of phosphatase action and sustained phosphorylation of Erk1,2. Erk activation increased in c-Myc depleted increase in c-Myc expression and increased expression of DNMT 1a, 3a, and 3b. DNMT activation increased following ARSB silencing or GALNS overexpression, and was blocked by AKR inhibition. Increased DNMT activity led to the increased promoter methylation of DKK3, and the subsequent inhibition of nuclear β-catenin nuclear translocation and Wnt signaling. Decline in Wnt signaling was manifested by reduced TCF-LEF nuclear binding, and decline in the mRNA expression of c-Myc and GATA. Since c-Myc activation can lead to increased expression of cell cycle regulators, the changes in chondroitin sulfation mediated by sulfatases can lead to profound effects in cell proliferation. Hence, the modification of sulfatase activity, manifested as increased chondroitin 4-sulfate, provides the platform for an extensive extracellular-intracellular signaling network that can regulate phosphorylation, DNA promoter methylation, and proliferation, and affect development and malignant transformation.
Glioblastoma (GBM) is the most common and most lethal primary malignant brain tumor. Two common alterations in GBM are loss of the tumor suppressor PTEN and upregulation of the oncoprogenic receptor tyrosine kinase MET. We uncovered a new connection between PTEN and MET expressions and functions in GBM. We found that PTEN expression in GBM cell lines (U87, U373, A172) is reduced in surviving BRCA1 deficient breast cancers (TNBC), although this was not observed in non-TNBC breast cancers. We also identified a correlation between Pin1 levels and sensitivity to PARP inhibitors, which are toxic to HR deficient cells due to synthetic lethality. Ongoing work will establish whether Pin1 levels may be utilized as a biomarker of BRCAAness and PARP inhibitor sensitivity. In contrast, during treatment of breast cancer cells with microtubule damaging agents, the presence of BRCA1 is required to promote apoptosis through MEK3 and JNK, therefore BRCA1 deficient cells are less sensitive to these agents. Knockdown of Pin1 in BRCA1 deficient cells sensitizes them to the taxane Paclitaxel, due to repression of the anti-apoptotic protein Mcl-1, while Pin1 knockdown in BRCA1 proficient cells has no effect on sensitivity as Mcl-1 levels are repressed through the MEK3 pathway. We have also identified that several Src family kinases (SKFs) are upregulated by Pin1 in a BRCA1-deficient background, and may play a role in taxane sensitivity. Pre-treatment with the Src/SFK inhibitor Dasatinib increases cytotoxicity of Paclitaxel, suggesting that combination treatment of Dasatinib and Paclitaxel may be an effective treatment option for BRCA1-deficient breast cancers. In conclusion, we have found that Pin1 may be an important oncogenic mediator downstream of dysfunctional BRCA1 facilitating the viability of TNBCs. We propose that Pin1 could serve as a potential diagnostic and therapeutic target for clinical intervention and aggressive subtype of breast cancer.

#348 Comparison of the response of the NC160 NSCLC panel with the response of patient-derived NSCLC lines to approved and investigational agents. Beverly A. Teicher, David Evans, Thomas Silvers, Michael Selby, Rene Delosh, Julie Lademann, Chad Ogle, Russell Reinhart, Joel Pomiet, Gurmeet Kaur, David Doroshow. National Cancer Inst., Bethesda, MD; Leidos Biomedical Research, Inc., Frederick, MD; National Cancer Inst., Rockville, MD.

An 800 compound screen with the NC160 cell lines and 5 patient-derived NSCLC lines (PD NSCLC), was conducted at 9 concentrations and included the FDA approved oncology agents and an investigational agents library. The screen was conducted using 384-well monolayer cultures, an exposure time of 72 hr, and compound concentrations from 1 nM to 10 uM. CellTiter-Glo was used to measure viability as an endpoint. The NC160 NSCLC panel consists of 9 cell lines: A549, EKVX, HOP-62, HOP-92, NCI-H226, NCI-H23, NCI-H322M, NCI-H460 and NCI-H522. The response of these lines was compared with the response of 5 PD NSCLC lines and 60 SCLC lines. While both sets of NSCLC lines: A549, EKVX, HOP-62, HOP-92, NCI-H226, NCI-H23, NCI-H322M, NCI-H460 and NCI-H522. The response of these lines was compared with the response of 5 PD NSCLC lines and 60 SCLC lines. While both sets of NSCLC lines: A549, EKVX, HOP-62, HOP-92, NCI-H226, NCI-H23, NCI-H322M, NCI-H460 and NCI-H522. Both PD NSCLC lines and SCLC lines were more sensitive to the tubulin fragmenters than were the PD NSCLC and the SCLC lines (mean GI50 1.6 uM). A heterogeneous response to the MEK inhibitors such as PD98059 (mean GI50 0.0042 uM in SCLC versus 0.047uM in the PD NSCLC lines). The NC160 NSCLC lines were more sensitive to the KSP inhibitor, ARRY-520 (mean GI50 0.0049 uM) than the SCLC lines (0.028 uM) and the PD NSCLC lines (0.26 uM). The NC160 NSCLC lines were more sensitive to the Mcl-1 inhibitor, ABT-263 (mean GI50 0.025 uM) versus 1.15 uM in the NCI60 NSCLC lines and 0.56 uM in the PD NSCLC lines. The NCI60 NSCLC lines (mean GI50 1.6 uM) and the SCLC lines (mean GI50 0.13 uM). However, the NCI60 NSCLC lines (mean GI50 0.8 uM) and the SCLC lines (mean GI50 0.134 uM) were less sensitive than the PD NSCLC lines (mean GI50 0.025uM) to GAR transformylase inhibitors such as pelitrexol. The NC160 NSCLC lines (mean GI50 6.3 uM) and SCLC lines (mean GI50 5.04 uM) were more sensitive to the MEK inhibitors such as cobimetinib (GDC-0973) was observed with the SCLC lines (mean GI50 8.9 uM) versus 1.15 uM in the NCI60 NSCLC lines and 0.56 uM in the PD NSCLC lines. PD NSCLC lines exhibit some interesting differences in response from established lung cancer lines upon in vitro exposure to anticancer agents and thus to our knowledge and understanding of NSCLC and help inform diagnostic and/or clinical development of therapeutics in this disease. This project was funded in part with federal funds from the NCI, NIH, under contract no. HHSN261200800001E.
Eribulin provides a survival advantage for breast cancer patients, particularly those with triple-negative and HER2-negative subtypes. Mechanistically, eribulin was shown to reverse epithelial-to-mesenchymal transition (EMT) in breast cancer models. E-cadherin is a central regulator responsible for maintenance of the epithelial phenotype and loss of cortical E-cadherin and its down-stream effects have been identified in many cancer models. Cortical sequestration of p120- and β-catenin at the adherens junctions stabilizes these complexes and inhibits their ability to stimulate signaling pathways that contribute to EMT. We tested whether eribulin, which binds to the plus ends of microtubules, promotes EMT reversal by influencing p120- and β-catenin localization and activity. Our results show that eribulin induces cortical localization of p120-catenin and β-catenin with E-cadherin in HCC1937 cells, consistent with the formation of normal adherens junctions. Eribulin also stimulated the phosphorylation of Ser33/37 and Thr41 on β-catenin which promotes proteosomal degradation, which would be expected to further inhibit oncogenic signaling. Collectively, our results suggest that eribulin contributes to reversal of EMT through modulation of downstream signaling initiated by cortical localization of p120- and β-catenin at the adherens junctions. Furthermore, this work was provided by Eisai Inc. 1. Cortes J., et al., Cancer Research, 2014. #350 Pregnancy at early age is associated with a reduction of progesterone-responsive cells and epithelial Wnt signaling in human breast tissue. Soysal, University Hospital Basel, Basel, Switzerland; University Hospital Zuerich, Zuerich, Switzerland.

Background: Pregnancy at early age is the most significant modifiable factor which consistently decreases lifetime breast cancer risk. However, the underlying mechanisms haven’t been conclusively identified. Studies in mice suggest a role of downregulation of epithelial Wnt signaling in the protective effect of early pregnancy. The aim of our study was to validate these findings in humans. Methods: We collected benign breast tissue of 123 women who had been stratified according to age at first pregnancy and the occurrence of subsequent breast cancer, and performed immunohistochemistry for Wnt4 and the Wnt-target Versican. Results: The number of PR positive epithelial cells was significantly lower in the group of women with early pregnancy and no subsequent breast cancer compared to the group of nulliparous women with subsequent invasive breast cancer (p=0.017). In women with early pregnancy, expression of Versican and Wnt4 was significantly lower compared to nulliparous women (p=0.0064 and p=0.0156 respectively), and Versican expression was also significant lower compared to women with late pregnancy (p<0.0001). Discussion: Our results confirm prior observations in mice and suggest a role of inhibition of epithelial Wnt signaling in the protective effect of early pregnancy in humans. This results in a decreased proliferation of stem/progenitor cells; therefore, the Wnt signaling pathway may represent a potential target for breast cancer prevention in humans.

#351 mTOR-ERK co-targeting strategies for head and neck cancer therapy. Zhiyong Wang, Esteban Delgado, Kosuke Yamaguchi, Zhiyong Wang,1 Esteban Delgado,2 Kosuke Yamaguchi,1 Ramiro Iglesias-Merera,1 Simone Münst,1 Silvio Däster,1 Salvatore Piscuoglio,1 Charlotte Ng,1 J.Silvio Gutkind1.

In the past decade, head and neck squamous cell carcinomas (HNSCC) have been one of the most studied cancers. One of the strategies to achieve a cure for HNSCC is medially targeted therapies. In recent studies of human cancer genomes identified remarkable complexity of genomic alterations in HNSCC, surprisingly, most aberrations have fallen with key driver signaling pathways. Among them, PI3K/AKT/mTOR pathway is most frequently activated in over 80% of the HNSCC patients. We showed that the majority of HNSCC lesions exhibit high levels of phosphorylated ribosomal S6 protein (pS6), key downstream target of the AKT-mTOR pathway, and that inhibition of mTOR by the use of rapamycin causes a rapid decrease in the level of pS6 and the apoptotic death of HNSCC tumor xenografts, thereby causing tumor regression. Our initial studies identified the AKT-mTOR pathway as a potential therapeutic target for HNSCC and provided strong rational to initiate multiple clinical trials. Indeed, inhibitors of PI3K/AKT/mTOR block mTOR activity and exert a beneficial response in HNSCC patients. However, therapeutic resistance was evidenced in several trials, which might be due to the activation of adaptive survival signaling in tumor cells. To explore the therapeutic option that can overcome the resistance, we performed a synthetic lethality screen in a high throughput manner using shRNA libraries. We found that multiple molecules involved in ERK signaling pathway were highly represented. Furthermore, treating HNSCC cell lines harboring activated mTOR with small molecule inhibitors that target PI3K/AKT/mTOR pathway can sequentially induce ERK activation, which is consistent with the findings observed in numerous clinical trials. We demonstrated that co-targeting mTOR and ERK using trametinib, a MEK1/2 inhibitor and pan-ERK1/2 small-molar antibody, exhibited the synergistic effect by sensitizing HNSCC to priming with the mTOR inhibitor. Specifically, mTOR-ERK co-targeting prevented the growth of HNSCC tumor xenografts by decreasing cell proliferation, reducing lymhangiogenesising and activating apoptosis. In addition, we have recently used a phosphoproteomics approach to identify the molecular mechanisms of ERK feedback activation caused by PI3K/AKT/mTOR inhibition. Overall, our promising findings from these preclinical studies suggest that the use of mTOR-ERK co-targeting strategies may provide the novel alternative approach to achieve durable responses (cure) in HNSCC cancer patients.

#352 The role of p62 (SQSTM1) in the transforming growth factor β signaling pathway. Evelyn Ng, Adrian Gunaratne, John Di Guglielmo, Western University, London, Ontario, Canada.

The transforming growth factor β (TGFβ) is a cytokine that regulates many cellular processes, including cellular adhesion, proliferation and apoptosis. Its canonical downstream effectors include Smad2/3 proteins, which are phosphorylated and then translocate to the nucleus to alter gene transcriptional programs and promote processes such as epithelial-to-mesenchymal transition (EMT). Previous studies in our lab have shown that atypical Protein Kinase C (aPKC) interacts with TGFβ receptors and modulate receptor trafficking and signal transduction. An aPKC-associated protein, p62 (SQSTM1) has been implicated in TGFβ-dependent EMT, however the mechanisms remain unclear.

Here, we investigate the localization of p62 and its potential roles in modulating TGFβ signaling via knockdown and overexpression studies. Using antibody feeding and immunofluorescence microscopy, we support previous findings showing that p62 localizes to late endosomes. In addition, using a co-immunoprecipitation approach, we observed that p62 may associate with TGFβ type II receptor. To explore the functional role of p62 in TGFβ signaling, we conducted protein silencing using siRNA. We observed TGFβ-independent decreases in E-cadherin expression. However these changes were independent of the phosphorylation status or nuclear translocation of Smad2. P62 also plays an important role in autophagy by targeting proteins for degradation. Recently, prolonged TGFβ stimulation has been shown to induce cellular autophagy. Therefore, it is in our interest to characterize the relationship between TGFβ-dependent EMT and autophagy, and to determine whether p62 has a regulatory role between these two processes.

#353 ROIR inhibits ASK1-mediated pro-apoptotic signaling in lung adenocarcinoma. Lisa Ida, Tomoya Yamaguchi, Taisuke Kajino, Kiyoshi Yanagisawa, Yukako Shimada, Motoshi Suzuki, Takashi Takahashi, Division of Molecular Carcinogenesis, Center for Neurological Diseases and Cancer; Nagoya University, Nagoya, Japan.

We previously reported that the receptor tyrosine kinase-like orphan receptor 1 (ROIR) is transcriptionally activated by TTF-1/NKX2-1 lineage-survival oncogene in lung adenocarcinoma and maintains a favorable balance between pro-survival PI3K-AKT and pro-apoptotic ASK1-p38 signaling. Although in-depth mechanistic insight into how ROIR sustains EGFR-mediated PI3K-AKT signaling in both kinase-dependent and -independent manners has been obtained, it remains elusive how ROIR inhibits pro-apoptotic signaling. In the present study, we investigated the underlying mechanism of ROIR-mediated inhibition of the ASK1-p38MAPK signaling pathway. Co-treatment with siASK1 resulted in partial but significant alleviation of siROR1-mediated growth inhibition of the ASK1-p38 pathway. ROIR was shown to interact with ASK1 through the C-terminal serine/threonine-rich domain of ROR1. Previous studies in our lab have shown that atypical Protein Kinase C (aPKC) interacts with TGFβ receptors and modulate receptor trafficking and signal transduction. An aPKC-associated protein, p62 (SQSTM1) has been implicated in TGFβ-dependent EMT, however the mechanisms remain unclear.

Here, we investigate the localization of p62 and its potential roles in modulating TGFβ signaling via knockdown and overexpression studies. Using antibody feeding and immunofluorescence microscopy, we support previous findings showing that p62 localizes to late endosomes. In addition, using a co-immunoprecipitation approach, we observed that p62 may associate with TGFβ type II receptor. To explore the functional role of p62 in TGFβ signaling, we conducted protein silencing using siRNA. We observed TGFβ-independent decreases in E-cadherin expression. However these changes were independent of the phosphorylation status or nuclear translocation of Smad2. P62 also plays an important role in autophagy by targeting proteins for degradation. Recently, prolonged TGFβ stimulation has been shown to induce cellular autophagy. Therefore, it is in our interest to characterize the relationship between TGFβ-dependent EMT and autophagy, and to determine whether p62 has a regulatory role between these two processes.

#353 ROIR inhibits ASK1-mediated pro-apoptotic signaling in lung adenocarcinoma. Lisa Ida, Tomoya Yamaguchi, Taisuke Kajino, Kiyoshi Yanagisawa, Yukako Shimada, Motoshi Suzuki, Takashi Takahashi. Division of Molecular Carcinogenesis, Center for Neurological Diseases and Cancer; Nagoya University, Nagoya, Japan.

We previously reported that the receptor tyrosine kinase-like orphan receptor 1 (ROIR) is transcriptionally activated by TTF-1/NKX2-1 lineage-survival oncogene in lung adenocarcinoma and maintains a favorable balance between pro-survival PI3K-AKT and pro-apoptotic ASK1-p38 signaling. Although in-depth mechanistic insight into how ROIR sustains EGFR-mediated PI3K-AKT signaling in both kinase-dependent and -independent manners has been obtained, it remains elusive how ROIR inhibits pro-apoptotic signaling. In the present study, we investigated the underlying mechanism of ROIR-mediated inhibition of the ASK1-p38MAPK signaling pathway. Co-treatment with siASK1 resulted in partial but significant alleviation of siROR1-mediated growth inhibition in the lung adenocarcinoma cell lines PC-9 and NCI-H1975, which readily express both ROIR and ASK1. Significant decreases in auto-phosphorylation of ASK1 at threonine 845 and p38 phosphorylation at threonine 180 and tyrosine 182 were observed in ROIR-transfected MTSO-211H cells in both steady state and oxidative stress-elicited conditions, suggesting ROIR-mediated negative regulation of the ASK1-p38 axis. ROIR was shown to interact with ASK1 through the C-terminal serine/threonine-rich domain of ROIR. An in vitro kinase assay using cellular ASK1 prepared from ASK1-transfected 293T cells as well as recombinant MBP-tagged kinase-deficient MKK6 revealed
that co-incubation of ASK1 with recombinant GST-tagged ROR1 clearly diminishes ASK1 auto-phosphorylation and MKK6 phosphorylation. We further examined whether the kinase activity of ROR1 is required for inhibition of ASK1 activity using MTSO-21H cells stably transfected with either a wild-type or a kinase-dead mutant of ROR1. In contrast to wild-type ROR1, kinase-dead ROR1 failed to significantly repress hydrogen peroxide-induced ASK1 phosphorylation as well as consequential p38 phosphorylation and increase in sub-G1 cells. Since we previously found that ROR1 activates SRC, we also examined whether SRC is involved in the ROR1-sustained ASK1 inhibition. Introduction of constitutively active SRC significantly reduced siROR1-induced ASK1 activity in PC-9 cells, while co-transfection of SRC and ASK1 resulted in tyrosine phosphorylation of ASK1, which was accompanied with diminished ASK1 phosphorylation at threonine 845. Finally, the interaction between SRC and ASK1 was found to be enhanced by the presence of ROR1 by an in vitro pull-down assay. Taken together, the present findings support our notion that ROR1 sustains lung adenocarcinoma survival, at least in part, through direct physical interaction with both ASK1 and SRC, which consequently results in repression of the pro-apoptotic ASK1-p38 axis in a ROR1 kinase activity-dependent manner.

#354 Inhibition of Smad3 signaling with a TAT fusion peptide prevents TGF-β-induced fibronectin expression and cell migration in malignant gliomas.

Jeonghan Kang. Mayo Clinic, Rochester, MN.
Malignant primary brain tumors represent one of the most common causes of cancer death in the world. Grade IV gliomas (glioblastoma multiform, GBM) are routinely resistant to current chemoradiation therapy and radiation therapy with a median progression-free and overall survival for glioblastoma following current chemoradiation of ~7 and 15 months, respectively. While TGF-β functions as a growth inhibitor for most normal cell types, many tumors (including GBMs) have lost this inhibitory response and TGF-β now functions to promote tumor progression and/or dissemination. As aberrant TGF-β signaling is often considered a hallmark of high-grade gliomas, we examined whether inhibition of specific components would impact the malignant phenotype of glioblastoma. The primary mediators of TGF-β action are the Smad proteins (R-Smads), Smad2 and Smad3. Following receptor activation and R-Smad phosphorylation, they translocate to the nucleus to modulate gene expression. Since we previously determined that a cell penetrating peptide conjugate of the HIV TAT protein translocate to the nucleus to modulate gene expression. Since we previously determined that a cell penetrating peptide conjugate of the HIV TAT protein conjugate unable to block Smad3 action. These findings indicate that the TGF-β/Smad3 axis is a potentially important mediator of glioma cell invasion in a significant minority of GBM models. Specifically targeting Smad3 might be effective in a subset of gliomas. This work was supported by Public Health Service grants GM-055816 and GM-054200 from the National Institutes of General Medical Sciences and P30 CA-108961 Developmental Pilot Award from the National Cancer Institute.

#355 TET2-loss modifies androgen signaling in prostate cancer.

Michael L. Nickerson, Sudipto Das, Kate Im, Seviaiy Turan, Sonja Berndt, Hongchuan loci using genotypes from the PEGASUS case-control cohort and identify six associated with PCa and melanoma, and rare germline missense variants are identified. Genome-wide association studies previously identified non-coding risk variants co-located in regions that support progression and/or dissemination. As aberrant TGF-β signaling through inhibition of SOCS3 and activation of IGF1R and SRC, and induced SOCS3 phosphorylation and degradation. This cascade of events leads to STAT3 activation in gastric cancer cells. We propose DARP32 as an important novel signaling between NKF-κB and STAT3 in prostate cancer.

#357 NXK2-1 regulates SMAD and non-SMAD pathways in thyroid stem cells.

Manabu Iwadate, Yoshinori Takizawa, Shiko Kimura. National Cancer Institute, MD.
NXK2-1 plays a critical role in thyroid differentiation. Recently, we established Side Population cells-derived Thyroid cell line (SPTL) from mouse thyroid Side Population cells. In SPTL cells, NXK2-1, PAX8 and E-cadherin were
not expressed when examined by western blotting. Immunocytochemistry revealed that only 1% of SPTL cells were NKX2-1 positive. When GFP-SPTL cells were directly injected into mouse thyroid, a few GFP-SPTL cells with weak expression of NKX2-1 were found in part of thyroid follicle, suggesting that SPTL cells have potential of thyroid stem cells. Comprehensive gene expression analysis indicated that TGFB-beta signaling, C1GALT1 overexpression promoted the malignant behaviors of C1GALT1 knockdown inhibited Akt and ERK activities in PDAC cells. Consistently, phospho-receptor tyrosine kinase (p-RTK) array showed decreased phosphorylation of several RTKs including EGFR, IGF1R, and FLT3. Additionally, flow cytometry of C1GALT1 knockdown cells showed increased apoptosis, which was associated with decreased catalase, Bcl-3, and increased caspase 3 and 9. Interestingly, C1GALT1 knockdown arrested G1 progression in PDAC cells. Furthermore, gene set enrichment analysis of CDNA microarray indicated that C1GALT1 regulated cell cycle, cytoskeleton, and chromatin structure in PDAC cells. These findings indicate that higher C1GALT1 expression predicts worse survival of PDAC and enhances malignant characters in PDAC cells, highlighting a fundamental role of C1GALT1 in PDAC development.

**#360** Leveraging a novel ITIM motif in GPCRs for targeted antibody design, Lili T. Belcastro, 1 Anastasia Jancina, 2 Christina Adams, 3 Ryan D. Paulikis, 2 Catherine C. Moore. 1 Cancer Biology Program, The Wistar Institute and University of the Sciences, Philadelphia, PA; 2 Philadelphia College of Pharmacy, University of the Sciences, Philadelphia, PA.

CXC4, a chemokine GPCR, is essential for migration of neuronal, hemato-poietic, and breast cancer cells during metastasis whereby CXCR4 dysregulation promotes migration and invasion. Following SDF stimulation, CXCR4 is phosphorylated on Ser/Thr residues which initiates adapter recruitment, receptor desensitization, and trafficking to endocytic sites. Here we show that stimulation with gradient SDF, delays receptor phosphorylation and trafficking, leading to sustained signaling to a novel CXCR4-SHP2-ERK pathway. SHP2 is a tyrosine phosphatase implicated in HER2(+) and triple-negative breast cancers whereby it transduces mitogenic and migratory signals driving hyperplifferation and invasion. SHP2 is recruited to tyrosine phosphorylated ITIM motifs (immunoreceptor tyrosine-based inhibitory consensus motifs), a hallmark found in inhibitory immune receptors with little evidence in GPCRs. Here we identify an ITIM motif in CXCR4 that regulates both SHP2 binding and signaling. Specifically, we assessed if gradient SDF stimulation of CXCR4 1) delays receptor phosphorylation and trafficking, 2) sustains signaling to SHP2-ERK, 3) induces SHP2-dependent migration; and if CXCR4 Tyr mutation within the ITIM motif 4) maintains SDF gradient sensing ability, and 5) disrupts interaction with and signaling to SHP2. Our data demonstrate that gradient SDF delays receptor Ser/Thr phosphorylation and internalization thereby sustaining signaling to SHP2-ERK and driving SHP2-dependent migration. Conversely, the ITIM mutant maintains SDF gradient sensing ability, but disrupts interaction with and signaling to SHP2. Our data support a working model that CXCR4 contains a functional ITIM motif which we are currently leveraging for targeted antibody design for use in migration studies of aggressive breast cancer cells with dysregulated CXCR4. These studies were supported by NIH grant GM-699718, PA Department of Health grant SAP4100057688, and the Milton Lev Memorial Faculty Research Fund.

**#361** Loss of cholangiocyte primary cilia induces LKB1 downregulation and defective AMPK signaling, Adrian P. Mansini, Kristen M. Thelen, Sergio A. Gradilone. University of Minnesota, Austin, MN.

Cholangiocarcinoma (CCA) is a malignancy arising from cholangiocytes, the epithelial cells lining the biliary tree. CCA is an uncommon, but devastating cancer that is increasing in incidence. Over the past 3 decades, 5-years survival rates have remained at 10%. Although surgical resection and liver transplantation are potentially curative therapies, most patients are diagnosed at late stages and are not eligible for these options. Therefore, it is imperative to identify novel targets leading to new therapeutic strategies for this devastating disease. Cholangiocytes express primary cilia that function as chemo, mechanos, and osmosensors controlling several molecular pathways. We showed cilia are absent in CCA cells, and experimental deciliation of normal cholangiocytes induced a malignant phenotype, with significant invasion and proliferation, suggesting the loss of cilia could be associated with CCA development. LKB1 is a tumor suppressor described to be expressed in primary cilia in MDCK cells, and is involved in AMPK activation through a ciliary dependent mechanism. AMPK functions as metabolic and stress check points. Interestingly, patients with inhepatic CCA and low expression of LKB1 have poor prognosis. Therefore, we hypothesized that primary cilia function as tumor suppressor organelles through a LKB1-AMPK-p53 pathway. To test this hypothesis, first LKB1 subcellular local-
#362 Repression of Smad3 by Stat3 and c-Ski/SnoN induces gefitinib resistance in lung adenocarcinoma. Yojiro Makino,1 Jeong-Hwan Yoon,1 Eunjin Bae,2 Mitsuyasu Kato,3 Keiji Miyazawa,5 Tatsuo Ohira,1 Norihiko Ikeda,1 Masahiko Kuroda,3 Mizako Mamura3. 1National Defense Medical College, Saitama, Japan; 2Kyujo Kurno, Tokyo, Japan; 3The University of Tokyo Hospital, Tokyo, Japan; 4University of Tsukuba, Ibaraki, Japan; 5University of Yamanashi, Yamanashi, Japan.

Cancer-associated inflammation develops resistance to the epidermal growth-factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) in non-small cell lung cancers (NSCLCs) harboring oncogenic EGFR mutations. Stat3-mediated Interleukin (IL)-6 signaling and Smad-mediated transforming growth factor-β (TGF-β) signaling play crucial regulatory roles in cancer-associated inflammation. Here we show that Stat3 represses Smad3 in cooperation with c-Ski and SnoN, whereby renders gefitinib-sensitive HCC827 cells resistant. IL-6 signaling via phosphorylated Stat3 induced gefitinib resistance. By contrast, TGF-β upregulated gefitinib sensitivity. We found that IL-6 signaling via phosphorylated Stat3 repressed, whereas TGF-β upregulated the expression of Smad3 in HCC827 cells. Promoter analyses showed that Stat3 synergized with c-Ski/SnoN to repress Smad3-induced transcription of the Smad3 gene. Smad3 induced apoptosis by upregulating pro-apoptotic genes such as Caspase 3 and downregulating anti-apoptotic genes such as Bcl2. Our results suggest that preventing IL-6/Stat3-induced loss of Smad3 can be a therapeutic strategy to prevent gefitinib resistance in NSCLC with gefitinib-sensitive EGFR mutation.

Peripheral T cell lymphoma (PTCL) is a heterogeneous malignancy with extremely poor prognosis. Five-year overall survival is <40% and can be as low as 12% for specific subtypes. There is, therefore, an urgent need to identify and develop novel therapeutic targets and approaches. A number of recent sequencing studies, including a whole exome sequencing analysis of primary PTCL patients conducted by our laboratory, have revealed recurrent oncogenic driver mutations in the common gamma chain/JAK/STAT signaling pathway, resulting in the aberrant activation of the transcriptional regulator STAT5. STAT5 has additionally been found to be upregulated or containing activating mutations in 30-40% of PTCL cases of specific subtypes. These findings highlight STAT5 as an oncogenic driver of PTCL and suggest a role for it in novel therapeutic approaches. Based on these data, we aimed to evaluate STAT5 mechanismally as a therapeutic target in PTCL. The drug, pimozide, which is an FDA approved neuroleptic agent, was recently identified by drug screen to be a STAT5 inhibitor. We evaluated the activity of pimozide in PTCL, using a combination of Fluorescence Activated Cell Sorting (FACS), and immunoblot analysis. Our data demonstrate a concentration dependent reduction in STAT5 activity and the number of viable cells in PTCL cell lines after culture with pimozide. This is shown to be due to an increase in cell death by apoptosis. To verify that pimozide is sufficient to activate STAT5 activity, we transfected PTCL cell lines with anti-STAT5 shRNA to knock down STAT5 and assessed PTCL cell survival and proliferation. We show that STAT5 knockdown results in a three fold reduction in PTCL cell viability, which occurs due to an increase in apoptosis. Furthermore, our data supports a TRAIL dependent mechanism for induction of apoptosis shown by an upregulation of TRAIL by PTCL cell lines after culture with pimozide. This finding demonstrates that pimozide inhibits STAT5 phosphorylation, reduces cell viability, and induces apoptosis in primary PTCL patient samples ex vivo. This research supports further exploration of STAT5 as a therapeutic target in PTCL and the development of STAT5 inhibition in the treatment of PTCL. To facilitate the development of new-chemotherapy dependent therapeutic approaches for PTCL, we are now assessing STAT5 inhibition in combination with small molecule inducers of apoptosis including TRAIL pathway and PARP inhibitors. PARP inhibitors have shown efficacy in malignancies with DNA damage response pathway mutations, which have been identified in up to half of cases of PTCL. We, therefore, hypothesize that inhibition of Jak inhibitory kinases responsible for STAT5 activation, in combination in PTCL, as several have demonstrated clinical efficacy in other hematologic malignancies.

#364 Mass cytometry of human glioblastoma characterizes more than 99 percent of cells and reveals intratumoral cell subsets defined by contrasting signaling network profiles. Nalin Leelatian,1 Justine S. Smaree,1 Brett C. Mobby,2 Akshat Kumar M. Mistry,2 Daniel Liu,1 Kyle D. Weaver,2 Reid C. Thompson,2 Lola B. Chambless,2 Rebecca A. Ihrie,1 Jonathan M. Irish1. 1Vanderbilt University, Nashville, TN; 2Vanderbilt University School of Medicine, Nashville, TN.

Background: Glioblastoma (GBM) remains largely incurable despite intense study of resected tissue. Prior studies have revealed GBM cell subsets (Patel et al., Science 2014) and implicated emergence as a potential mechanism of poor outcome in other cancer types. Signaling in rare cells or a mix of cell subsets may enable therapy resistance and recurrence of GBM. For example, STAT3 RNA expression has been previously shown to correlate with poor outcome in GBM (Jahani-Asl et al., Nat Neurosci 2016 and TCGA). The complexity of GBM, combined with the interconnectedness between cancer and host cells in the microenvironment, means that a single cell biology approach is needed to comprehensively characterize patient biopsy cells and determine how protein expression, signaling, and functional capabilities impact treatment response. Methods: We developed a novel mass cytometry approach to characterize human GBM that identified ~90-95% of tumor cells (Leelatian & Doxie et al., Cytometry B 2016). Here, we applied this approach using a newly created 35-antibody mass cytometry panel focused on basal phospho-protein signaling. The published panel of 16 identity proteins included SOX2, CD44, Nestin, PDGFRα, S100B, and NCAM. This panel was augmented to measure 10 additional proteins and 9 phospho-proteins including p-STAT3, p-EGFR, and p-NFκB. Signaling measurements were chosen to match prior single cell studies of signaling networks that stratified clinical outcomes in blood cancers (Irish et al., Cancer Cell 2010) and breast cancer (Sweeney et al., Genes Dev 2009; PNAS 2010, Levine et al., Cell 2015). Between 10,000 and 250,000 viable cells were characterized for each tumor (N = 7). Tumors were collected with informed consent and in accord with the Declaration of Helsinki. Results: This new 35-antibody mass cytometry panel positively identified ~99% of GBM cells. Subsets of GBM cells displayed protein expression that matched previously observed transcriptional molecular subclasses (Verhaak et al., Cancer Cell 2010 and TCGA). Strikingly, this panel revealed novel GBM cell subsets defined by contrasting basal signaling profiles. An inverse correlation was observed between baseline STAT3 phosphorylation and the abundance of CD45+ leukocytes. Additionally, similar signaling patterns were seen in cells that expressed proteins associated with distinct functions, such as proliferation and migration. Conclusions: The correlation between low STAT3 signaling and high immune cell abundance provides evidence for the idea that an intimate relationship exists between immune cells and GBM tumor growth and survival. Moreover, single cell analysis may reveal biomarkers of treatment response and allow prediction of clinical outcomes. The abnormal signaling mechanisms observed here in some GBM cell subsets should be further developed as potential targets for novel cancer-selective combination therapies.

#365 Cross-talk between BRAF and Hippo/YAP1 signaling in melanoma. Mohan Kumar Durai Raj,1 Jonathan Nguyen,1 Namrita Bora-singhal,1 Jane Messina,2 Geoffrey Gibney,3 Srikumar Chellappan1. 1H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL; 2MedStar Georgetown University Hospital, Lombardi Comprehensive Cancer Center, Washington, DC.

Hippo/YAP1 signaling pathway is a tumor suppressive pathway that controls organ size by modulating the cell growth, proliferation and apoptosis and is conserved from Drosophila to mammals. In mammals, the Hippo tumor suppressor pathway consists of cascade of kinases in which MST1/2 phosphorylates and activates LATS1/2. The latter phosphorylates the oncoprogenic transcriptional coactivators YAP1 and TAZ, leading to their cytoplasmic retention by 14-3-3 knockdown or culture with pimozide. Mitochondrial membrane potential is also disrupted. These findings have potential clinical implications, as we further demonstrate that pimozide inhibits STAT5 phosphorylation, reduces cell viability, and induces apoptosis in primary PTCL patient samples ex vivo. This research supports further exploration of STAT5 as a therapeutic target in PTCL and the development of non-chemotherapy dependent therapeutic approaches for PTCL. We are now assessing STAT5 inhibition in combination with small molecule inducers of apoptosis including TRAIL pathway and PARP inhibitors. PARP inhibitors have shown efficacy in malignancies with DNA damage response pathway mutations, which have been identified in up to half of cases of PTCL. We, therefore, hypothesize that inhibition of JAK inhibitory kinases responsible for STAT5 activation, in combination in PTCL, as several have demonstrated clinical efficacy in other hematologic malignancies.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Growth Signaling Pathways 2

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

92
proteins and/or degradation. Inactivation of MST and LATS kinases allows YAP1 and/or TAZ nuclear translocation and subsequent activation of their target genes. Deregelation of Hippo pathway can induce tumors in model organisms and occurs in wide range of human cancers including melanoma. Merlin, a key component of this pathway which inhibits YAP1, is mutated/deleted in 8% of melanoma. Loss of Merlin may lead to a failure of cell growth control and allow the growth of tumor cells.

Trop-2 is overexpressed in most human cancers, suggesting selective pressure for a key, conserved function. Here we show that Trop-2 stimulates cancer cell growth through the activation of a constitutively expressed, yet otherwise dormant, growth control module. We discovered that crosstalk of membrane Trop-2 with specific Abs leads to a cytoplasmic Ca++ raise through interaction with the Na+/K+ -ATPase and p110α subunit of PI3K. We further found a pro-survival loop through Trop-2-dependent activation and membrane recruitment of PKC-α, which in turn phosphorylates the Trop-2 cytoplasmic tail at two target sites, activating the molecule to stimulate its downstream signaling targets Akt and ERK.

Our findings indicate that the Trop-2–triggered cell growth operates through binding and extensive crosstalk with CD9, CD81, CD82 and CD151 through PKC-α. The role of the HIKE region of the Trop-2 intracellular tail. Correspondingly, we found that the HIKE region of Trop-2 mediates its anchoring to the β-actin cytoskeleton through direct interaction with the ERK protein ezrin. Consistently, the Trop-2–dependent dynamic remodeling of the cell cytoskeleton is detected to occur through activation of myosin II and binding of annexins A1/A5, α-actinin and gelsolin. Systematic drug screening, gene expression silencing and site-directed mutagenesis revealed that cytoskeleton disassembly, HIKE, deletion and CD9 inhibition revert the growth of Trop-2–expressing cancer cells to that of their Trop-2–null counterparts. On the other hand, these inhibitors have no effects on basal cell growth. This indicates that Trop-2–centered protein interactions and activations are an essential step for the Trop-2–dependent cancer growth. Tight co-expression of the key components of the Trop-2–dependent complex is required for a large breast cancer cell survival, thus indicating a strong clinical relevance. Hence, Trop-2 triggers a universal, but otherwise dormant, layer of cancer growth, that overrides basal cell growth regulatory mechanisms and sensitizes tumors to targeted anticancer therapies.

**#366 Disruption of TCF7L1 mediated transcriptional repression promotes pancreatic tumorigenesis.**

Kathleen M. Kershaw, Bridgette T. Ho, Mialis I. Vasquez, Anna R. Lay, David W. Dawson. UCLA, Los Angeles, CA.

While phenotypic studies demonstrate Wnt/β-catenin signaling is critical for the initiation and progression of pancreatic adenocarcinoma (PDA), the downstream transcriptional effectors tied to its effects are largely unknown. Previous work from our group has identified differential patterns of LEF/TCF expression linked to variations in Wnt activation and function in PDA, including reduced TCF7L1 (aka TCF3) message and protein levels in pancreatic tumors with elevated Wnt/β-catenin activity. Consistent with this observation, we found TCF7L1 in protein levels rapidly diminished in PDA lines after Wnt pathway activation mediated by either Wnt3A ligand or GSKβ inhibitor. RNAi-mediated knockdown of TCF7L1 in PDA lines phenocopied most of the pro-tumorigenic effects seen with Wnt3A ligand treatment. Because TCF7L1 commonly represses transcription and is rapidly downregulated in PDA upon Wnt activation, we explored its transcriptional derepression as a potentially important mechanism through which Wnt signaling promotes pancreatic tumorigenesis. Candidate genes linked to TCF7L1–mediated transcriptional repression in PDA were identified by RNA-sequencing of MiaPaCa-2 and Panc1 lines following RNAi-mediated knockdown of TCF7L1. A total of 196 genes upregulated at least 1.5-fold in both cell lines were identified, representing potential direct targets of TCF7L1. A subset of these genes, including the onco-tyrosine kinase initiating oncogenic signaling, was among these 196 upregulated genes revealed enrichment of categories including small GTPase–mediated signal transduction, RAS protein signal transduction, regulation of axon extension, and regulation of synaptic plasticity. Among top upregulated genes was prostaglandin E2 synthase (PTGES), an enzyme catalyzing the isomerization of prostaglandin H2 to prostaglandin E2 (PGE2) as the final step in PGE2 synthesis from arachidonic acid. Notably, PGE2 stimulates pancreatic cancer proliferation, invasion, angiogenesis and metastasis. Validation experiments in TCF7L1–expressing PDA lines confirmed PTGES message and protein levels rapidly increased in response to TCF7L1 depletion and were associated with a corresponding increase in PGE2 production as measured by ELISA. PGE2 increased Wnt reporter activity in PDA cell lines, a potentially important feedforward mechanism whereby Wnt signaling may be reinforced upon its activation. In conclusion, TCF7L1 represses target genes with known roles in PDA, while reduction in TCF7L1 through Wnt pathway activation or alternative means is apparently tied to a program of transcriptional derepression linked to the promotion of pancreatic tumorigenesis.

**#367 Trop-2 activates a dormant Na+/K+-ATPase/PKCα/C9/ezrin signaling axis to override the basal growth program of cancer cells.**

Trop-2 is a surface protein with a broad biological role. It is overexpressed in a variety of cancer types, including human pancreatic adenocarcinoma (PDAC). The mechanisms by which Trop-2 regulates cancer cell growth and survival are not well understood. Here we report a novel role for Trop-2 in the regulation of the Na+/K+-ATPase, a key, conserved function. Here we show that Trop-2 stimulates cancer cell growth through the activation of a constitutively expressed, yet otherwise dormant, growth control module. We discovered that crosstalk of membrane Trop-2 with specific Abs leads to a cytoplasmic Ca++ raise through interaction with the Na+/K+-ATPase and p110α subunit of PI3K. We further found a pro-survival loop through Trop-2-dependent activation and membrane recruitment of PKC-α, which in turn phosphorylates the Trop-2 cytoplasmic tail at two target sites, activating the molecule to stimulate its downstream signaling targets Akt and ERK. Our findings indicate that the Trop-2–triggered cell growth operates through binding and extensive crosstalk with CD9, CD81, CD82 and CD151 through PKC-α. The role of the HIKE region of the Trop-2 intracellular tail. Correspondingly, we found that the HIKE region of Trop-2 mediates its anchoring to the β-actin cytoskeleton through direct interaction with the ERK protein ezrin. Consistently, the Trop-2–dependent dynamic remodeling of the cell cytoskeleton is detected to occur through activation of myosin II and binding of annexins A1/A5, α-actinin and gelsolin. Systematic drug screening, gene expression silencing and site-directed mutagenesis revealed that cytoskeleton disassembly, HIKE, deletion and CD9 inhibition revert the growth of Trop-2–expressing cancer cells to that of their Trop-2–null counterparts. On the other hand, these inhibitors have no effects on basal cell growth. This indicates that Trop-2–centered protein interactions and activations are an essential step for the Trop-2–dependent cancer growth. Tight co-expression of the key components of the Trop-2–dependent complex is required for a large breast cancer cell survival, thus indicating a strong clinical relevance. Hence, Trop-2 triggers a universal, but otherwise dormant, layer of cancer growth, that overrides basal cell growth regulatory mechanisms and sensitizes tumors to targeted anticancer therapies.
#369 Therapeutic targeting of the Wnt antagonist DKK1 with a humanized monoclonal antibody in oncology indications. Michael H. Kagey,1 Yinyuan Wu,7 Xinjun Zhang,2 Cynthia A. Sirad,1 Shane E. Mulligan,2 Xi He,3 Christopher K. Mirabelli1,2 *Leap Therapeutics, Cambridge, MA; 3Boston Children’s Hospital, Harvard Medical School, Boston, MA.

Wnt-activated pathways promote tumor growth and metastasis. Inhibiting tumor growth and metastasis is a goal of current cancer treatments. In oncology, the Wnt antagonist DKK1 is often overexpressed, promotes tumor growth and is refractory to current therapies. Disease progression and management of tumors relies on the ability to distinguish between tumors that are sensitive or resistant to treatment. DKK1 is a promising target; however, humanized antibodies to DKK1 have not shown clinical activity. We generated a DKK1 humanized antibody that possesses improved bind and activity. BDK1 binds DKK1 with high affinity and specifically, disrupts the interaction of DKK1 with the LRP6 co-receptor, and neutralizes DKK1 activity in a cell based assay. In vivo, DKK1 has efficacy both as a monotherapy and in combination with chemotherapies in a non-small cell lung (NSCLC) cancer A549 xenograft model. Results suggest that DKN-01 has an antiangiogenic effect and may stimulate a NK cell mediated antitumor response. Clinically, DKN-01 is being evaluated in relapsed/refractory esophageal cancer patients in combination with paclitaxel, and preliminary results demonstrate promising activity. Archival patient tumor samples are currently being analyzed and by IHC for DKK1 and a number of cancer patients in combination with pacitaxel, and preliminary results demonstrate promising activity. Archival patient tumor samples are currently being analyzed and by IHC for DKK1 and a number of different patient tumor samples are currently being evaluated. Overall, we establish that T-P LL cells resemble antigen-experienced memory T-cells. Treatment of functional responses to TCR stimulation and of loss of restricting activator responses underlie a highly activated phenotype and a marked resistance to death-inducing signals. T-CLLIA proactively enhances TCR responses and we postulate that this leukemogenic cooperation drives accumulation of memory-type cells that utilize amplified, hence permissive, low-level cognate antigen input.

#371 Developing small molecule therapeutics to target AKT signaling in non-small cell lung cancer. Balaji Chandrasekhar,1 Deeksha Pal,2 Venkatesh Kolluru,1 Srinivasa R. Ramisetty,3 Arun K. Sharma,2 Murali Ankem,1 Chengli DAMODARAN,1 University of Louisville, Louisville, KY; 2Pennsylvania State University, Hershey, PA.

Lung cancer remains a leading public health problem which is evidenced by its increasing death rate. Platinum-based chemotherapy is the first-line of treatment for patients in advanced stages of non-small cell lung cancer (NSCLC), however the success rates are not quite impressive. Hence, developing individualized treatment strategies for metastatic lung cancer gains momentum, such as Tyrosine kinase inhibitors erlotinib and gefitinib, or AKT inhibitors. Yet, a better understanding of receptor stimulation is crucial. Recent reports suggest that pAKT(ser473) is highly expressed in NSCLC and higher nuclear expression of pAKT correlated with poor prognosis and an independent prognostic marker for survival. Our lab is interested to develop novel small molecules which specifically inhibit AKT signaling in NSCLC. Structure-activity relationship (SAR) studies in our laboratory have recently identified one such compound, AKS-407, that effectively inhibited cell growth at nanomolar concentration in NSCLC cell lines (A549 and H460; 250nM). Molecular studies revealed AKS-407 inhibited AKT signaling by down regulating pAKT(ser473) expression and downstream events including NFKB activation, BCI-2 expression in both the cell lines. As signaling through AKT regulates epithelial-mesenchymal transition (EMT) in NSCLC, we determined the effect of AKS-407 on EMT phenotype on NSCLC cells. Treatment of AKS-407 inhibited the mesenchymal markers include snail, MMP9, N-cadherin, β-catenin and vimentin expression that resulted in blocking invasion and migration of A549 and H-460 cells. These results suggest AKS-407 to be a promising small molecule targeting AKT signaling pathway which remains an important target for the development of effective treatment of metastatic NSCLC. Validating in-vivo efficacy of this potential drug candidate would further support our overall goal of the study.

#372 Optimizing vertical MAPK pathway inhibition for RAS mutant non-small cell lung cancer. Jens Köhler,1 Cloud P. Pawelez,2 Yanan Kuang,2 Prafulla Gokhale,1 Margaret K. Winkens,2 Hong Tiv,3 Atsuko Ogino,2 JiHyun Choi,1 Paul T. Kirschmeier,3 Pasi A. Jänne,2 Dana-Farber Cancer Institute, Boston, MA; 3Reber Center for Applied Cancer Science, Boston, MA.

Introduction: Non-small cell lung tumors (NSCLC) with mutations in genes encoding for Ras proteins (H-, N-, K-Ras) exhibit activation of the MAPK signaling pathway. MEK inhibitors, however, have limited efficacy in patients affected by this genotype-defined tumor subtype and major resistance derives from insufficient suppression or reactivation of the extracellular signal-regulated kinase (ERK) as a result of dynamic kinase reprogramming. ERK inhibitors may overcome limitations of MEK inhibition due to the bottleneck function of ERK proteins in submitting mitogenic and anti-apoptotic signals. Combinations of both drug classes (“vertical pathway inhibition”) may further increase treatment efficacy but inevitably potentiate toxicity hence requiring alternative dosing schedules. Methods: We investigated the efficacy of vertical MAPK inhibition with selumetinib (Mek inhibitor) and SCH772984 (Erk inhibitor) in commercially available and patient-derived RAS mutant NSCLC models. A quantitative RT-PCR based 12-gene signature was used as a surrogate to assess ERK-dependent transcriptional output. Pulsatile drug regimens were investigated in xenograft models. Results: In a genetically simple, patient-derived NRAS-mutant lung cancer cell line (DFC168), we observed strongest in vitro and in vivo inhibitory effect of combined AKT and MEK inhibition. A combination of AKT inhibition by a peptide-derived inhibitor and MEK inhibition by SCH772984, respectively, reduced the overall survival of lung tumor xenografts as measured in a preclinical in vivo model of RAS-mutant lung cancer. Overall, we establish that T-P LL cells resemble antigen-experienced memory T-cells. Treatment of functional responses to TCR stimulation and of loss of restricting activator responses underlie a highly activated phenotype and a marked resistance to death-inducing signals. T-CLLIA proactively enhances TCR responses and we postulate that this leukemogenic cooperation drives accumulation of memory-type cells that utilize amplified, hence permissive, low-level cognate antigen input.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Growth Signaling Pathways 2

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
mercially available cell lines) and in vivo (n = 2). The degree of transcriptional output suppression of cell lines (n = 8) with different sensitivities towards Mek/Erk inhibition did not differ significantly at 24 hrs in vitro. Gastrointestinal toxicities (i.e. peritonitis-like symptoms) occurred when continuously administrated SCH727984 was intermittently combined with selumetinib (4 days ON, 3 days OFF). In our study, both drugs given intermittently (4 days ON, 3 days OFF) were ineffective. None of the drug treatments, however, could cure the mice. Conclusion: We have demonstrated that deeper and prolonged transcriptional output suppression by vertical MAPK pathway inhibition translates into superior efficacy in RA5 mutant lung cancer models compared to single agent treatment. Other factors (e.g. signaling pathways) are likely to influence the overall outcome of Mek inhibition. However, our study also shows that treatment with B-catenin siRNAs or dominant negative form of TCF7L2 (dnTCF7L2) significantly enhanced the reporter activity, which may represent a potential therapeutic target for melanoma. Funding support: This work was supported by the National Cancer Institute of China (81071687, 81272195S), the State “973” Program of China (2014CB542005).

#373 Wnt signaling induces anti-apoptotic effect in colorectal cancer cells through the suppression of IFITs. Tomoyuki Ohsugi, Kiyoshi Yamaguchi, Chi Zhu, Tsuneo Ikoue, Yoichi Furukawa. Division of Clinical Genome Research The Institute of Medical Science The University of Tokyo, Tokyo, Japan.

Impaired Wnt signaling pathway plays a crucial role in the development of colorectal cancer through the activation of β-catenin/TCP complex. Although genes up-regulated by Wnt/β-catenin signaling has been well studied, the down-regulated genes are poorly understood. To clarify the comprehensive changes regulated by the signaling in colorectal cancer cells, we employed a reporter gene expression of CRC cell transfected with β-catenin siRNAs or dominant negative form of TCP7L2 (dnTCP7L2). Consequently, a set of genes that were negatively regulated by β-catenin/TCP were identified. Among the genes, three members of interferon-induced proteins with tetratricopeptide repeats (IFIT) family (IFIT1, IFIT2, and IFIT3) expression were significantly increased by the inhibition of β-catenin/TCP. Comparison of gene expression data from normal colonic mucosa and the tumor tissues showed that the expression of IFIT1 and IFIT2 in the tumors was significantly lower than that in normal tissues. To elucidate the mechanism of IFITs expression regulated by β-catenin/TCP, we performed a reporter assay using plasmid containing 1.2-kb of 5′-flanking region of the IFIT2 gene. As a result, the reporter activity was significantly enhanced by either transduction of β-catenin or dnTCP7L2, suggesting that blockage of β-catenin/TCP stimulated IFITs through the promoter. In addition, we found that overexpression of IFIT2 increased apoptosis and decreased cell proliferation in SW480 and HCT116 cells. These results imply that Wnt signaling may promote anti-apoptotic effect in cancer cells through the suppression of IFIT2. Our findings suggest that analysis of down-regulated genes in response to activated Wnt/β-catenin signaling provides a better understanding of human colorectal carcinogenesis.

#374 KMT2A promotes tumor growth by activating hTERT and CBP signaling and predicts poor prognosis in human melanoma. Changlin Zhang, Ranran Tang, Kefang Zhang, Wenlin Huang, Wuguo Deng. 1Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, China; 2Dalian Medical University, Dalian, China; 3Global Life Care Federation, Hong Kong, China.

Melanoma is an aggressive type of cutaneous malignancy. Although the inhibitors targeting BRAF and/or MEK pathways provide a therapeutic option for non-resectable melanoma driven by BRAF mutation, melanoma, especially metastatic melanoma, has still become one of the most threatening malignancies. Thus, identifying the exact molecular mechanisms involved in melanoma growth and discovering the novel targets for melanoma therapy is urgently needed. In this study, we screened a siRNA library targeting 6024 human genes in human melanoma cells and identified KMT2A as a potential therapeutic target for melanoma. KMT2A was highly expressed in melanoma cell lines and tumor tissues of melanoma patients. Knockdown of KMT2A by siRNA or shRNA significantly inhibited cell viability and colony formation, whereas exogenous expression of KMT2A effectively promoted cell growth in various melanoma cell lines. Further mechanism studies showed that the KMT2A-mediated regulation of melanoma growth was through targeting the hTERT and CBP signaling. Knockdown of KMT2A significantly inhibited hTERT promoter activity and protein expression and attenuated telomerase activity. Overexpression of hTERT rescued the KMT2A knockdown-mediated melanoma cell growth. By contrast, exogenous expression of KMT2A activated hTERT transcription and expression and increased telomerase activity in melanoma cells. Moreover, we found that KMT2A promoted hTERT expression and melanoma cell growth by cooperating with the transcriptional co-activator CBP, which interacted with and acetylated KMT2A. Inhibition of CBP by siRNA or a CBP-specific inhibitor suppressed the acetylation of KMT2A, abrogated the binding of KMT2A on the hTERT promoter and down-regulated hTERT expression, thereby inhibiting the growth of melanoma cells. Conversely, overexpression of CBP increased KMT2A acetylation and the binding to hTERT promoter, resulting in the promotion of hTERT expression and cell growth. The in vivo studies also showed that KMT2A promoted melanoma growth by activating the hTERT signaling in a xenograft tumor mouse model. Furthermore, the analyses for the clinical samples demonstrated that KMT2A expression was positively correlated with hTERT in tumor tissues of melanoma patients, and the high expression of both KMT2A and hTERT was associated with worse clinical TNM staging and poor prognosis in melanoma patients. Taken together, our results indicate that KMT2A promotes melanoma growth by activating hTERT and CBP signaling in human melanoma. Our study therefore provides new insights into understanding the regulatory mechanism of melanoma growth and suggests that the KMT2A/CBP/hTERT signaling may be a potential therapeutic target for human melanoma. MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Analyses across Cancer Types

At Memorial Sloan Kettering, we have used a clinically validated custom hybridization capture-based NGS assay (MSK-IMPACT) to sequence the tumors of more than 10,000 patients. We sought to determine physician perception and use of these results, including whether they changed management and the reasoning behind this decision-making. All physicians who ordered MSK-IMPACT testing for patients where it was not considered routine were asked to complete a questionnaire quarterly (Table). Physician determination of genomic “actionability” was compared to OncoKB, a curated knowledge base of somatic variants (OncoKB.org). Responses were received from 146 of 258 physicians emailed (57%) regarding 1932 of 9147 cases. However, only 45% of these cases harbored a genomic variant annotated as actionable by OncoKB. Among patients in whom physicians deemed the report non-actionable, 12% had OncoKB annotated actionable variants. Across the cases annotated as potentially actionable by OncoKB, physicians identified an actionable alteration in 81% of cases. At the time of data analysis, 297 (15%) patients had been enrolled in at least one clinical trial of targeted therapy at MSKCC including 224 (12%) patients on genomically-matched trials, 76% of whom participated after IMPACT profiling. As the clinical adoption of NGS panels expands, continued education of physicians as well as maintained knowledge bases for annotation will be necessary to expand the utility of this approach and the opportunity for precision medicine.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Analyses across Cancer Types

#376 Biospecimen and data resources for cancer research from NCI’s BPV program. Ping Guan, Helen M. Moore. National Cancer Institute, Bethesda, MD.

The Biospecimen Preanalytical Variables (BPV) Program was initiated by the National Cancer Institute’s Biorepositories and Biospecimen Research Branch to evaluate the impact of preanalytical factors on the molecular integrity of biospecimens. Selected preanalytical factors including cold ischemic time (delay to formalin fixation (DTFF)), time in formalin (TIF), freezing methods, and storage temperatures and durations were examined for their potential effects on molecular profiles of formalin-fixed, paraffin-embedded blocks from four cancer types (kidney, ovary, colon and lung). The BPV program has collected tumor specimens from 364 cancer patients. Each specimen was annotated with 300+ data elements that cover steps in the collection, handling, and processing procedures, pathology review, and clinical information. NCI conducted multiple studies using these specimens to evaluate the preanalytical impacts on different analytical platforms including gene expression profiling, copy number variation, proteomics and metabolomics profiling. The program invites interested organizations to work with NCI through collaboration to further evaluate preanalytical effects on molecular analyses (https://techtransfer.cancer.gov/availabletechnologies/e-000-2013). The remaining specimens are available to support relevant research focusing on biospecimen science and/or clinical bioinformatics.

#377 International Cancer Genome Consortium (ICGC), Jennifer L. Jennings,1 Lincoln D. Stein,1 Fabien Calvo2.1Ontario Institute for Cancer Research, Toronto, Ontario, Canada;2Simon Fraser University, Vancouver, British Columbia, Canada.

The International Cancer Genome Consortium (ICGC) was established to bring together researchers from around the globe to comprehensively analyze the genomic, transcriptomic, and epigenomic changes in 50 different tumor types or subtypes that are of clinical and societal importance across the globe (International network of cancer genome projects, Nature 464, 993-998 (15 April 2010)). As of November 2016, the ICGC has received commitments from researchers and funding organizations across Asia, Australia, Europe, North America and South America for 103 project teams in 17 jurisdictions to study more than 25,000 tumor genomes. Processed data is available via the Data Coordination Centre (http://dcc.icgc.org) based at the Ontario Institute for Cancer Research and is updated semi-annually. The August 2016 release (Version 22) in total comprises data from more than 16,000 cancer donors spanning 70 projects and 21 tumor sites. The Pan-Cancer Analysis of Whole Genomes (PCAWG) project of the ICGC and The Cancer Genome Atlas (TCGA) is coordinating analysis of more than 2,600 cancer genomes, with the extensive use of cloud computing. Because of the very large size of the pan-cancer dataset, with 5,000 whole genome sequences, PCAWG is using a distributed compute cloud environment (generated by computing centres in the USA, Europe and Asia) that meets the project’s technical requirements and the bioethical framework of ICGC and its member projects. Each genome is being characterized through a suite of standardized algorithms, including alignment to the reference genome, uniform quality assessment, and the calling of multiple classes of somatic mutations. Participating laboratories will then be guided by the research program of the ICGC in addressing a series of fundamental questions about cancer biology and evolution based on these data. The first phase of ICGC, which is slated for completion in 2018, has focused on developing extensive catalogs of tumor genomic information. The proposed second phase, ICGCmed, will link genomics to clinical information and health, including lifestyle, patient history, response to therapies, and unique aspects of disease presentation. The project will help fill gaps in our understanding of cancer types, including rare and unusual cancers, and will contribute to a broad spectrum of cancer research from preclinical to clinical development of therapeutics. The ICGC develops policies and quality control criteria to help harmonize the work of member projects located in different jurisdictions. Data produced by ICGC projects are made rapidly and freely available to qualified researchers around the world via the data cloud and through the ICGC Data Coordination Center (http://dcc.icgc.org). More information can be found on www.icgc.org.

#378 The Cancer Genome Collaboratory. Cheltena K. Yung,3 George L. Milhaesco,2 Tierryn L. Frampton,2 Fang Zhang,1 Frampton,2 Jian Yang,1 Jared Baker,1 Guillaume Bourque,2 Paul C. Boutros,3 Barth Ma. Knoppers,4 BF Francis Ouellette,1 Cenk Sahinalp,1 Sohrab P. Shah,1 Vincent Ferretti,1 Lincoln D. Stein1. 1Ontario Institute for Cancer Research, Toronto, Ontario, Canada;2McGill University, Montreal, Quebec, Canada;3Simon Fraser University, Vancouver, British Columbia, Canada;4BC Cancer Agency, Vancouver, British Columbia, Canada.

The Cancer Genome Collaboratory is an academic compute cloud designed to enable computational research on the world’s largest and most comprehensive cancer genome dataset, the International Cancer Genome Consortium (ICGC). The ICGC is on target to categorize the genomes of 25,000 tumors by 2018. A subproject of ICGC, the PanCancer Analysis of Whole Genomes (PCAWG) alone has generated over 800TB of harmonized sequence alignments, variants and interpreted data from over 2,800 cancer patients. A dataset of this size requires months to download and significant resources to store and process. By making the ICGC data available in cloud compute form in the Collaboratory, researchers can bring their analysis methods to the cloud, yielding benefits from the high availability, scalability and economy offered by cloud services, avoiding a large investment in static compute resources and essentially eliminating the time needed to download the data. To facilitate the computational analysis on the ICGC data, the Collaboratory has developed software solutions that are optimized for typical cancer genomics workloads, including well tested and accurate genome aligners and somatic variant calling pipelines. We have developed a simple to use, but fast and secure, data transfer tool that imports genomic data from cloud object storage into the user’s compute instances. Because a growing number of cancer datasets have restrictions on their storage locations, it is important to have software solutions that are interoperable across multiple cloud environments. We have successfully demonstrated interoperability across The Cancer Genome Atlas (TCGA) dataset stored in the Amazon Web Services (AWS) S3 storage. Lastly, we have developed a non-intrusive user authorization system that allows the Collaboratory to authenticate against the ICGC Data Access Compliance Office (DACO) when researchers require access to controlled tier data. We anticipate that our software solutions will be implemented on additional commercial and academic clouds. The Collaboratory is actively growing, with a target hardware footprint of over 3000 CPU cores and 13 petabytes of raw data storage. As of November 2016, the Collaboratory holds information on 2,000 ICGC PCAWG donors (500TB total). We anticipate expanding the Collaboratory to host the entire ICGC dataset of 25,000 donors (approximately 5PB) and to extend its data management and analysis facilities across multiple clouds. During the current closed beta phase, the Collaboratory has been successfully utilized by multiple research groups, most notably PCAWG project researchers who analyzed thousands of genomes at scale over a few weeks’ time. The Collaboratory will open to the public during the second quarter of 2017. We invite cancer researchers to learn more about our cloud resources at cancercollaboratory.org, and apply for access to the Collaboratory.

Introduction: EGFR is a kinase of the HER/ERBB family and an oncogenic driver, especially for NSCLC, HNSCC and CRC. EGFR targeted therapies have been successfully used for treating cancer patients harboring activating EGFR mutations. However a main challenge is acquired drug resistance due to mutations or alternative signaling. While developing next generation drugs is a promising strategy, targeting other alternatives is also an attractive therapeutic option.

The purpose of our study is to investigate the mutational landscape of the tumors harboring activating EGFR mutations and to pinpoint potential strategies for overcoming acquired drug resistance and for combinational therapies. Methods: CancerPlex, a NGS large panel test, which includes targeted, full-gene sequencing of over 400 genes, was applied to analyze a cohort of 2294 patient FFPE samples across majority of solid tumor types. Results: 1. Among 293 (out of 2294, 12.8%) samples harbored EGFR mutations, 86 (86/293, 29.4%) samples harbored actionable EGFR mutations (namely AE group), such as exon 19 deletion and L858R, which includes 84 lung cancer (79 NSCLC), 1 glioblastoma, and 1 uterine carcinoma. 2. The genes/variants in the AE group are then subjected to further functional analysis and mapped to several pathways/biological functions. Our results show that the mutational landscape of activating mutant EGFRs covers most main signaling pathways and biological processes with several pathways: new upstream receptors at different clades, including PI3K and ERBB2, and genes involving in genome and epigenome stabilizations, including ARID1A, KMT2D, and XPC, have the highest mutation rate in the context of activating EGFR mutations. b, PIK3/ AKT/mTOR and Ras-Raf-MEK are two main pathways transducing ligand activated EGFR signals. Our results show that the mutant variants in the PI3K-AKT-mTOR pathway are almost 50% more than those in Ras-Raf-MEK pathway, suggesting that activating mutant EGFRs might preferentially rely on effectors in the PI3K pathway, such as PIK3CA and RICTOR, to transduce oncogenic signals. of note, no KRAS mutation is found in the AE group. c, As expected, mutations are also found in the TP53/apoptosis and RB/cell cycle pathways with higher variant number in the TP53/apoptosis axis. d) Strikingly, the number of mutant variants in the Wnt/beta-catenin pathway tops that in the PI3K and TP53 pathways. Several recent publications demonstrated that the Wnt/beta-catenin pathway is abnormally activated in NSCLC and may be a major mechanism of the drug resistance. Our finding that the genes in the Wnt/beta-catenin pathway, including APC, AXIN2, RNF43, and BCL9, are mutated to a great extent in the context of activating EGFR mutations supports the notion that targeting the Wnt/beta-catenin pathway, in combination with EGFR targeted therapies, is a promising therapeutic strategy for the treatment and overcoming drug resistance of EGFR-driven tumors.

#380 Systematic identification of novel functional tumor-specific mutations in receptor tyrosine kinases based on their pan-cancer mutational profiles in Japanese patients with cancer. Masakuni Serizawa,1 Takeshi Nagashima,2 Yoshi Shimoda,3 Sumpei Ohnami,3 Shumpei Ohnami,3 Kenichi Urakami,3 Masaaki Nishio,4 Tohru Mochizuki,4 Takashi Nakajima,5 Kenichi Ohshima,4 Angeliki Pantazi, Ruobai Sun, Stephen Lyle, Joerg Heyer, Alexei Protopopov, KEW Inc, Cambridge, MA.

The purpose of our study is to investigate the mutational landscape of the tumors harboring activating EGFR mutations and to pinpoint potential strategies for overcoming acquired drug resistance and for combinational therapies. MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Analyses across Cancer Types

#381 Genomic alterations in mucins in cancers. Ryan J. King, Fang Yu, Pankaj K. Singh. University of Nebraska Medical Center, Omaha, NE.

Mucins promote the growth, aggressiveness, and invasiveness of various cancer types. Changes in the expression or localization of mucins can significantly alter their primary function. Due to their predominant role in cell-cell and cell-matrix interactions, biomarkers and therapeutic agents have been developed to improve patient care. However, an extensive investigation across multiple cancer subtypes examining the genomic status of the cohort of mucins has not been performed and could yield significant insights into new roles of mucins in different cancers. Utilizing The Cancer Genome Atlas, the cancers of 11 mucin expressing tissues were examined for the genomic alterations in mutations, mRNA expression levels, copy numbers, methylation status, and the impact on patient survival due to these genomic features. It was discovered that different mucins across multiple tissue origins and cancer subtypes might have a different rate, pattern, and survival impact. MUC1 was not mutated in the majority of cancers; however, we did observe a frequent T12P mutation in pancreatic tumors that was also present in other cancers. MUC4 was frequently mutated at H4205 and MUC4 mutations were seen to have survival differences. Multiple significant differences were discovered in mRNA expression, which varied distinctly between cohorts. One such pattern was observed with de novo expression of MUC21 in colorectal cancers, in which mRNA expression was suddenly induced in cancer and increased in a stage dependent manner. Copy number alterations were seen for only a few cancer subtypes and mucins, including A431B1 and lung squamous cell carcinomas. Global promoter demethylation was generally observed across the cancers. MUC15 in renal cancers was seen to be one of the most demethylated mucins, in which mRNA was seen to be substantially decreased or expunged. This extensive study investigated the status of multiple mucins in multiple cancer settings and highlights a few noticeable mucins that are suggested to be further studied for roles in biomarkers, survival, and etiology for cancer progression.

#382 Genome-wide location analysis of DNA adducts in vivo. Brian Woo, Christopher Fang, Paolo Abada, Stephen B. Howell, Olivier Harismendy. UC San Diego, La Jolla, CA.

DNA adducts are the biochemical consequences of exposure to UV light, carcinogens or DNA-reactive drugs. They play a central role in malignant transformation and the selective killing of cancer cells by chemotherapeutic agents. The functional consequences of DNA adducts is likely to depend on their exact location in the genome with respect to histones and sites where histones and DNA are modified. However, tools that permit precise genome-wide mapping of adduct locations have poor resolution or are too specific to the type of DNA adduct. Here we describe a method capable of identifying the genomic location of damaged DNA bases in whole cells. Using naked DNA treated with cisplatin (cDDP) or ultra-violet (UV) light as the damaging agents, the strategy relies on differential exonuclease digestion to enrich genome-wide libraries for fragments containing DNA adducts, followed by high-throughput sequencing. Consistent with the expected adduct chemistry, the 5’ end of the post-PCR product was enriched in TT, TC or CT di-nucleotides in the UV-treated DNA (>4x) and in AG or GG in the cDDP treated DNA (1.5x), suggesting a positive predictive value of 76% and 44% for UV (TT) and cDDP (GG) adduct detection, respectively. Applied in vivo to IMR90 cells, Ad-Seq revealed that the fraction of AG/GG loci was higher in DNA from the cDDP-treated cells.
at all coverage depths, reaching 1.5x enrichment for the highest depth quartile. This indicates that the method is selective and that even low covered loci show enrichment of AG/GG sequences. The enrichment in purines was limited to 3 nucleotides downstream of the read start site, confirming the high resolution of the exonuclease digestion. A total of 11 x 103 AG/GG loci were identified in replicated cDDP treated samples and 555 novel cancer patient derived 536MM cell line by RT-PCR and targeted RNA sequencing. Extended this profile, the distribution of AIMP2-DX2/AIMP2 ratio and AIMP2 related major cancer pathways were analyzed using the samples in the ICGC/TCGA database. Over 23 cancer types, 753 samples were used in WTS analysis. In the DEG set analysis, 10 pre-defined major cancer pathways were analyzed among 16 cancer types. Some cancer types, especially colon and hepatocellular carcinoma, OS curves had a tendency in a similar way to AML. For the clinical validation of the prognostic value of AIMP2-DX2, 51 AML patients were included in this analysis. The correlation between AIMP2-DX2 expression and survival outcomes was investigated in clinical validation cohort of AML. The AIMP2-DX2-positive group had significantly inferior OS rate and had worse RFS compare to AIMP2-DX2-negative group. Our sequential data shows that the AIMP2-DX2/AIMP2 expression and their ratio can possibly be an indicator to measure malignancy of various cancer types.
OnkoInsight is a pipeline designed to detect cancer driver genes from large sequencing datasets. It includes the somatic mutation detection module SomaticSeq, and the novel driver gene detection module GSMuta. SomaticSeq leverages an ensemble approach and machine learning to accurately detect somatic mutations. In Stage 5 of the ICGC-TCGA DREAM Somatic Mutation Challenge, SomaticSeq v1 placed #1 and #2 in the INDEL and SNP sub-challenges. In the current project, we used the improved SomaticSeq v2.2.2, which now extracts most features directly from the BAM files instead of SAMtools, and has the added function of handling multiple variant calls at the same position. We incorporated MuTect, Indelocator, VarScan2, SomaticSniper, VarDict, MuSE, and LoFq. GSMuta detects regions, genes, and pathways that are enriched for somatic mutations. It identifies cancer drivers and includes a unique feature of distinguishing driver genes and tumor-suppressing genes. As a demonstration of the capability and scalability of OnkoInsight, we deployed the tools as docker images, developed the pipeline using common workflow language, and analyzed over 1,000 TCGA lung cancer patients with tumor-normal whole exome sequencing data on Cancer Genomics Cloud. The project involved 369 adenocarcinoma (LUAD) and 490 squamous cell carcinoma (LUSC) samples. On average, SomaticSeq detected over 700 somatic mutations per sample. The predicted mutation rate was consistent with the expected mutation rates of LUAD and LUSC. Once we obtained the high-confidence somatic mutations from SomaticSeq, we used GSMuta to detect driver genes in LUAD and LUSC separately. We detected 97 and 50 driver genes for LUAD and LUSC, respectively. To assess the quality of GSMuta's predictions, we compared our GSMuta predictions with the UCB-OCG-CONSORTIUM's driver gene predictions for cancer driver genes. Indeed, GSMuta reproduced 16 out of the 18 LUAD driver genes reported by TCGA's landmark study such as EGFR, KRAS, and BRAF. It also detected some potential new driver genes. For example, it reported 9 out of 10 LUSC driver genes reported by TCGA such as PTEN. LUAD and LUSC shared nine predicted driver genes, and the pathway disruption was homogenous across the two subtypes. It also detected some potential new driver genes. The project was completed in less than a week for over 1,000 pairs of homogenous across the two subtypes. It also detected some potential new driver genes. The project was completed in less than a week for over 1,000 pairs of homogenous across the two subtypes. It also detected some potential new driver genes. The project was completed in less than a week for over 1,000 pairs of homogenous across the two subtypes.

**#387 Targeted exome sequences of cancer-related genes in human cancers using amplicon sequencing.** Yasushi Sasaki, Takafumi Nakagaki, Miyuki Tamura, Hisayo Fukushima, Hiroshi Ikeda, Ryota Koyama, Masashi Idogawa, Takashi Tokino. Sapporo Medical University, Sapporo, Japan.

Objective: Next-generation sequencing (NGS) has revolutionized cancer genomics research by providing a comprehensive method of detecting somatic cancer genome alterations. Platforms for genomic DNA alterations are more common in clinical practice and include whole genome/exome sequencing analyses. These tests are still very expensive, although the costs are coming down substantially. Here, we aimed to determine the efficacy and advantages of targeted and amplicon sequencing, which can be used to detect cancer-related genes in human cancers using amplicon sequencing. Methods: DNA was extracted from 61 human cancer specimens and their corresponding non-cancerous tissues, including oral squamous cell carcinomas (OSCCs) and multiple myelomas (MMs). Forty nanograms of DNA were used for multiplex PCR amplification with an Ion Ampliseq Comprehensive Cancer Panel that offers targeted coverage of all exons in 409 tumor suppressor genes and oncogenes frequently cited and frequently mutated in human cancers. This platform was designed to be amplification-based capture with 15,992 regions (1.6 megabases in total size). Purified DNA libraries were sequenced with 6-8 samples on Ion Proton P1 chip. Sequence reads of tumor and normal samples were aligned to the hg19 genome, and generated BAM files were used to detect somatic mutations (point mutation, insertion and deletion) and copy number variations. Results: Each sample underwent on average 8.4 million sequencing reads after quality filtering. The mean base coverage depth was 530, and >95% of targeted bases were represented by at least 20 reads. The number of non-synonymous somatic mutations in 47 patients with OSCC ranged from 1 to 21 with a mean of 7.5 (6.4 Mb). The most frequent mutations in OSCC were in TP53 (63.8%), NOTCH1 (25.3%), CDKN2A (19.2%), TAF1 (7.0%), SYNE1 (14.9%) and PIK3CA (8.8%). We also detected a mean of 6.1 (range 3-11) non-synonymous mutations per MM patient. Somatic mutations were found in known MM-associated genes, including TP53 and NRAS. Pathway assessment has shown that somatic aberrations within MM genomes are mainly involved in several important pathways, including cell cycle regulation, RTK-MAPK-PI3K and NF-kB. We found several genetic alterations that may have been associated with the poor prognosis of non-responding patients to chemotherapy in MM patients. Conclusions: This study demonstrates the utility of using a semiconductor-based sequencing to efficiently identify somatic genetic alterations in human cancers. The targeted next-generation sequencing using low amounts of FFPE DNA is a valuable tool for rapid (5 days) and high-throughput genetic testing in research and clinical settings.

**#388 A benchmark study for identifying cancer drivers in the non-coding part of the genome.** Damien Drubay,1 Daniel Gautheret,2 Stefan Michels3.

1INSERM, Gustave Roussy, Villejuif, France; 2Université Paris-Sud, CNRS, CEA, Gif-sur-Yvette, France.

Purpose: Prioritizing potential deleterious variants is an essential task to guide research and validation of new pathological variants in the immunity of the genome. Many tools have been introduced to detect new variants in the coding part of the genome. Detailed knowledge of coding sequences led to efficient statistical models for cancer driver discovery. The challenge is greater for the non-coding part of the genome due to its large size (>98% of the genome) which contains many non-functional or unknown features. Several deleteriousness scores have been proposed in the past decades, but no current large comparison has been realized to assess their ability to identify cancer drivers. Material and method: We compared the leading scoring systems (CADD, FATHMM-MKL, Funsq2 and GWAVA) and some recent competitors (DANN, SNP and SOM scores) for their ability to discriminate assumed pathologic variants in the non-coding genome (as identified by 928 ClinVar variants / 44,158 recurrent COSMIC mutations) from assumed non-pathologic variants (100,000 randomly sampled 1000 Genomes project variants with minor allele frequency > 1%). To define the pathogenic variants using COSMIC as reference, we varied the threshold for number of COSMIC recurrences from 2 to 10. We compared the sensitivity, specificity and precision of the scoring systems using the area under the curve (AUC) of receiver operating characteristic (ROC) and precision-recall (PR) curves. Results: Most scores had good sensitivity and specificity for the ClinVar dataset but AUCROC for GWAVA was about 0.85. DANN and FATHMM-MKL were significantly better than the other methods. For ClinVar variants was concerned, the top performing methods were CADD (AUCPR = 0.84), DANN (AUCPR = 0.83) and, to a lesser extent, FATHMM-MKL (AUCPR = 0.75). When using a threshold of 3 recurrences to define true pathogenicity of COSMIC variants, the AUCROC ranged from 0.52 (DANN) to 0.80 (GWAVA) but precision was low with AUCPR ranging from 0.05 (DANN, S OM-melanoma) to 0.18 (GWAVA). Increasing the pathogenicity threshold to 10 recurrences increased AUCROC values (ranging from 0.50 (SOMmelanoma) to 0.89 (GWAVA)) but decreased precision values (AUCPR ranging from 0 to 0.02). Discussion: This large scale benchmark study distinguished CADD as the best tool to detect variants with features similar to those of ClinVar, which are mainly located in protein coding regions. However, based on the results using COSMIC, GWAVA outperformed CADD for variants in other regions, including non-coding regions. We also compared some deleterious scores and their ability to identify cancer drivers. Material and method: We compared the lead-
with multiple alterations are prioritized. Our method is summarized in two steps: 1) Identify genes that are both recurrently and heterogeneously altered across many samples by calculating a rank-based score for each gene. 2) Identify MutE and CoO features across tumor types. Recent studies have provided evidence that epigenetic changes and regulatory sequence mutations could also dysregulate oncogenes and tumor suppressors. As a transcription factor, P53 is activated in response to oncogenic stress and cell type. Differential expression analysis using RNA-Seq distinguishes a lethal cancer from one with a favorable prognosis, is poorly understood. To address this question, we have performed a comprehensive meta-analysis on genomic data from primary tumors that are linked to patients’ clinical outcomes. Using data from >20,000 patients, we have identified protein-coding genes, lncRNAs, miRNAs, methylation sites, and CNVs in primary tumors that are significantly associated with patient prognosis across cancer types. Multivariate analysis reveals a hierarchy of survival determinants: the strongest mortality-associated factors are enriched for components of the mitotic cell cycle, while secondary clusters of genes are involved in extracellular matrix remodeling, cell motility, and angiogenesis. Survival-associated genomic features are indicative of immune infiltration into primary tumors and oxidative phosphorylation activity. In vitro and in vivo analyses reveal that mortality-associated genes rarely promote the direct transformation of primary cells. Instead, CRISPR mutagenesis reveals that these genes largely repress tumor growth and in their absence cancer cells fail to progress. Through this analysis, we have identified new genetic dependencies common across cancer cell types, including C16ORF59 and C5ORF46. In total, our results represent the largest assessment of genomic features linked to cancer progression completed to date, and offer several lines of insight into the biological differences between fatal and benign cancers.

A comparative genomics approach to understanding the control of cell context dependent P53 binding. Varsha Sundaresan, Ying Li, Benedetto DiCiaccio, Victor T. Lin, Lei Zhou, University of Florida, Gainesville, FL; Macau University of Science and Technology, Macau, China.

Cancer is considered to be a genetic disease characterized by sequential accumulation of mutations. Recent studies have provided evidence that epigenetic changes and regulatory sequence mutations could also dysregulate oncogenes and tumor suppressors. As a transcription factor, P53 is activated in response to oncogenic stress and exerts distinct anti-proliferative functions based on the stressor and cell type. Though a number of ChIP-Seq studies have identified thousands of P53 binding sites in mammalian genomes, the functionality of these binding sites remains to be established. In addition, we know little about what could drive stress and cell context specific binding profile of P53. Traditionally, mutations in the coding regions of p53 have been extensively studied to gain insights on its role in cancer and to identify strategies to restore the functions of p53 in cancer cells. We hypothesize that mutations in or epigenetic silencing of functionally important P53 binding sites play an important role in tumorigenesis as well. Since functional regulatory regions tend to be more evolutionarily conserved, in this project we propose using a comparative genomics approach to identify functional P53 binding sites and determine if these regions are involved in tumorigenesis. In order to study how P53 binding following DNA damage differs between cell types, we aim to perform comparison between P53 ChIP-Seq data generated in our lab from Drosophila embryos at different developmental stages and a cell line (Kc167) as well as published datasets from mammalian stem cells and differentiated cells. Differential expression analysis using RNA-Seq exhibited that at an early stem cell-like stage there is P53-dependent induction of pro-apoptotic genes in response to DNA damage but not in the differentiated stages. We are seeking to establish functionally significant P53 binding sites by re-training we investigate using RNA-Seq as a proxy signature of cell type. The importance of these binding sites will be verified by CRISPR-Cas9-mediated genome editing. We will also perform comparison studies of DNA damage-induced P53 binding in human, mouse and Drosophila to identify analogous patterns. Knowledge gained from this study will help us to understand the role of non-coding regulatory regions in tumorigenesis, and predict patient response to apoptosis-inducing therapeutic agents. It may also lead to novel strategies to restore cellular sensitivity to chemotherapy or radiation.
KRAS is the most commonly mutated oncoprotein and is a major driver of tumor initiation and progression. Understanding the functional consequences of cancer-associated KRAS variants may have important clinical implications. For example, KRAS mutation status defines those that are likely to respond to EGFR-directed therapy in KRAS-mutant metastatic colorectal cancer. A comprehensive understanding of oncogenic KRAS will facilitate understanding of clinically important missense variants that alter critical oncogenic properties of KRAS. First, we sought to comprehensively identify all possible oncogenic missense mutations in KRAS that mediate oncogenic transformation. We stably transduced the WT library into immortalized human epithelial cell lines and evaluated growth and epithelial-to-mesenchymal transition (GILIA), an assay that is highly correlated with in vivo tumor formation. We identified all previously known hotspot oncogenic alleles of KRAS as well as many functionally relevant alleles that are also discovered at lower frequency in human tumors. Moreover, we also discovered a group of transforming KRAS variants that have not been well described in human tumors, thus revealing potentially novel activating mechanisms for oncogenic KRAS. In parallel, we utilized the G12D mutagenesis library to perform second-site suppressor screening to identify loss-of-function single amino acid changes that abrogate the transforming ability of oncogenic KRAS. We performed positive-selection screening in primary cell lines for variants that enable bypass of oncogene-induced senescence. Additionally, we conducted a negative-selection screen with the G12D library in a KRAS-dependent cancer cell line with inducible suppression of endogenous KRAS, thus identifying all possible second-site mutations that abolish KRAS-driven signaling necessary for maintenance of cellular proliferation and viability. Structure-function analysis of these data may reveal novel patterns of amino-acid changes that result in inactivation of oncogenic KRAS. In summary, this comprehensive dictionary of gain- and loss-of-function KRAS missense variants will facilitate understanding of clinically important mutations and also yield novel insights into structure-function relationships that may improve our understanding of the KRAS oncogene.

Activation mechanisms of cancer associated MEK1 mutants. Yijun Gao,1 Matthew T. Chang,1 Daniel McKay,1 Rona D. Yaeger,1 Merna Torres,1 Keven Muniz,1 Drosten Matthias,2 Omar I. Abdel-Wahab,3 Mariano Barbacid,4 Giordano Caponigro,5 Darrin Stuart,1 David Solit,1 Barry S. Taylor,1 Zhan Yao,1 Neil Rosen,1 Memorial Sloan Kettering Cancer Center, New York, NY;2Novartis Institutes for BioMedical Research, Cambridge, MA, USA;3Centro Nacional de Investigaciones Oncológicas, Madrid, Spain, Spain.

Activating BRAF mutants drive human tumors by dysregulating ERK signaling despite ERK-dependent feedback suppression of ERK. These BRAF mutants become RAS independent, by either of two mechanisms, and they are thus unaffected by feedback inhibition of upstream signaling. Recently, it has become clear that mutation activation of MEK1 or MEK2 occur at appreciable frequency in human tumors, but the mechanism of activation of these mutants and whether they remain dependent on upstream activation of RAS or RAF signaling remains unknown. Here we characterize the mechanism of activation of 18 recurrent MEK1 mutants identified in human cancer. Based on these data, they fall into three classes. The kinase activity of first class remains dependent on RAF-mediated phosphorylation of S218 and S222, and has basal RAF-independent activity, but can be further stimulated by RAF and the third class no longer requires phosphorylation of S218 and S222 and signals in a RAF independent manner. These features determined their sensitivity to ERK-dependent feedback regulation and the ability to drive ERK signaling output in cells. The more RAF-independent activity the mutants acquired, the better they could activate downstream ERK pathway, leading to increased transforming activities in MEF cells in the absence of RAF. This is consistent with their genetic association with RAS, RAF and NF1 mutations in human tumors. The Class 3 RAF-independent MEK1 mutants tend to be mutually exclusive with those mutants, while coexistence with RAS/RAF/NF1 mutations is frequently observed in tumors with Class 1 or 2 MEK1 mutants. Moreover, functional class correlated with sensitivities of ERK signaling driven by these mutants to MEK inhibitors that function by different mechanisms. Unlike RAF dependent or regulated MEK1 mutants, the ERK signaling driven by RAF independent MEK1 mutants is insensitive to an allosteric MEK1 inhibitor that functions through MEK1 phosphorylation. However, signaling driven by all classes of MEK1 mutants is sensitive to an ATP competitive MEK1 inhibitor which targets MEK1 kinase activity.

Detecting copy number variations using WES datasets in patient derived xenografts. Jia Xue,1 Wubin Qian,1 Sheng Guo,1 Jie Cai,1 Henry Qiang Li2.1Crown Bioscience, Inc., Santa Clara, CA;2Crown Bioscience, Inc., Beijing, China.

Amplification or deletion of oncogenes and tumor suppressors can be oncogenic, which may serve as drug targets and biomarkers for disease prognosis and drug response. Traditionally, array-based assays, e.g. Affymetrix SNPs6.0 and lately OncoScan, have been used to detect DNA copy number variations (CNVs). These assays have limitations including insufficient probe availability for some genes, cross hybridization, imprecise measurement of fluorescent signal, less suitability of tumor samples, and high cost. Whole exome sequencing (WES) is now widely used to profile tumor samples, and provides a fast and efficient determination for point mutations, insertions and deletions at the DNA level. Recently, WES is being used to profile CNVs with some success, but also suffers from many drawbacks, such as the requirement of paired normal tissues, the need of a large batch of samples, the inadequacy of detecting chromosomal-level CNVs, the incapability to detect CNVs in low coverage genomic regions. We have developed a CNV detection pipeline on both genomic (segment) level and gene level from WES data using the concept of off-target and on-target reads1, and evaluated it in a set of 155 patient-derived xenografts (PDx), with head-to-head comparison to Affymetrix SNPs6.0 and OncoScan2 on 5 models with 2 passages from each. PDX is a well-accepted experimental model mimicking original patient in histo- & molecular pathology3. Reads derived from mouse contaminants were removed from WES datasets to avoid mouse signal interference, which cannot be done in array-based techniques. RT-PCR was used to experimentally validate CNVs for selected genes. We found that the average off-target rate for our PDX models is approximately 15%, and off-target reads were uniformly distributed across genome. The comparison with array-based technologies indicates that 1) WES has the highest resolution (20kb) while OncoScan is the second (50-100 kb), followed by SNPs6.0 (100-200kb), 2) the OncoScan CNV calls are very similar to our WES methods at the genome level, yet 3) WES gives a much higher accuracy on CNV inference for genes flanking the ~900 cancer related genes with enhanced probe densities on OncoScan, suggesting that our WES method has the highest accuracy. RT-PCR results confirmed the observations. In summary, WES-based CNV analysis is a better solution in CNV detection in PDX models. References 1. Whole genome copy number variation analysis using a SNP-focused targeted sequencing panel for tumor analysis. Jiashu Wang,1 Kristina Giorda,1 Zhongwu Lai,1 Daniel Stetson,1 Mirna Jarosz,1 1Integrated DNA Technologies, Redwood City, CA;2Astrazeneca, Boston, MA.

Accurate genome-wide copy number variation (CNV) analysis is critical for disease and cancer research. Current approaches for CNV analysis include fluorescence in situ hybridization (FISH), array comparative genomic hybridization (array CGH), and SNP arrays. Unfortunately, these methods are not sensitive enough for real world cancer samples because of tumor purity, heterogeneity. NGS-based targeted sequencing is increasingly being used for CNV analysis due to throughput, coverage, cost, and sample input requirements. For CNV analysis, detection power is improved by combining both read depth and SNP allele frequency analysis, particularly for copy-neutral events such as loss of heterozygosity. A custom xGen Lockdown CNV backbone panel was developed for broad, uniform genome coverage and to enrich for population-based SNPs. We demonstrate use of the panel as an addition to the xGen Exome Research Panel and a custom cancer focused panel. Downstream analysis incorporates both read depth and observed minor allele frequencies to determine CNVs with enhanced sensitivity. To increase the resolution for large scale alterations of chromosome 7, a hot-spot for disease-associated CNVs, probe density was increased 6-fold. A known standard, NA12878, was used to validate

the panel’s ability to detect heterozygous SNPs with high confidence. In addition, mixtures of cancer cell lines from the Cancer Cell Line Encyclopedia (CCLE) were tested with varying levels of background copy-neutral genomic DNA. The sensitivity and specificity of the panel to detect CNV and LOH events with was assessed using deep exome and Affymetrix SNP array data. The ability to detect copy number alterations with high resolution and accuracy would be a valuable resource for disease and cancer research.

#398 Using off-target data from comprehensive genomic profiling to characterize the genomic architecture of copy number alterations in tumor sequencing data. Caitlin F. Connelly, Zachary R. Chalmers, Philip J. Stephens, Garrett M. Frampton, Foundation Medicine, Inc., Cambridge, MA.

Background: Copy number alterations are common driver mutations in cancer. Identifying genes which show altered copy number and knowing the breakpoints of copy number alterations gives insight into their functionality as well as the mechanisms responsible for the alterations. While copy number alterations have been well-studied in common tumor types, there are still many rare tumor types which have not been characterized. Targeted genomic profiling using capturing methods results in sequencing a subset of genes to extremely high coverage (>500x) and sequencing off-target regions spanning the rest of the genome to low (0.5x – 1x) coverage. We used this data to identify the approximate breakpoints of alterations that extend beyond targeted regions and to identify novel, recurrent copy number alterations in clinical tumor samples. Methods: We used standard methods to identify copy number alterations in the off-target regions. Briefly, we calculated coverage in 10 kb windows across the genome, excluding the targeted regions which are sequenced at high coverage, corrected for GC-bias, calculated the log ratio of coverage for the tumor compared to an unrelated normal sample, and then used a segmentation algorithm to segment the genome into copy number regions and identify regions with significantly different copy number than the surrounding regions. We sequenced cell line DNA with known copy number variants and used this data to assess the accuracy and precision of these methods. Copy number alterations were filtered against known common copy number variant regions, and we identified copy number alterations overlapping known genes to identify potentially functional alterations. Results: We applied these methods to tumor samples that underwent comprehensive genomic profiling as part of clinical care. Our cohort consisted of a large and diverse set of “real world” unbiased clinical specimens and contained many rare and unusual tumors not included in larger sequencing efforts. Using this data, we characterized the landscape of copy number variants genome-wide in rare tumor types which have not previously been characterized and identified unique copy number alterations in these tumor types. Further, we characterized the breakpoints of copy number alterations across the cohort. Conclusions: We will present novel copy number alterations in rare tumor types and the recurrent breakpoints for common alterations across multiple tumor types. These findings will provide insight into the mechanisms of cancer progression.

#399 CPTAC phase II final report. Mathangi Thiagarajan. Leidos Biomedical Research Inc., Rockville, MD.

National Cancer Institute’s Clinical Proteomic Tumor Analysis Consortium (CPTAC) is a comprehensive and coordinated effort to accelerate the understanding of the molecular basis of cancer through the application of robust, quantitative, proteomic technologies and workflows. The primary goal for this program is to systematically identify proteins that derive from alterations in cancer genomes and related biological processes, integrate the genomic and proteomic data from analysis of common cancer biospecimen and provide this data with accompanying assays and protocols to the community. The phase II effort managed by the Leidos Biomedical Research Inc. had a goal to procure and qualify a minimum of 100 cases from 3 cancer types (Breast, Ovarian and Colon). Tissues and analytes from the 100 cases were sent to proteomic and genomic characterization centers for analysis. The proteomic data were made available through the Data Coordinating Center (DCC) and the genomic data were made available through NCI’s Genomic Data Commons (GDC). The success from the phase II effort has set precedence for a much larger phase III effort that will focus on additional cancer types and cases. Preliminary analysis results confirm the need for the combination of the genomic and proteomic approaches to produce a more comprehensive inventory of the detectable proteins in a tumor and advance our understanding of cancer biology.

#400 NCI’s CPTAC Phase III, proteogenomic analysis of additional cancer types. Linda I. Hannick, Frederick National Lab for Cancer Research, Rockville, MD.

The Clinical Proteomics Tumor Analysis Consortium (CPTAC) is a National Cancer Institute initiative that seeks to uncover the molecular basis of cancer using a proteogenomic approach to study prospective cancer specimens. Leidos Biomed provides an infrastructure for supporting the collection of high quality biospecimens and data, in addition to project and subcontract management for the program. CPTAC applies the understanding of the molecular basis of cancer to identify biomarker candidates. Phase II of CPTAC, completed in 2016, collected over 500 cases from breast, colon and ovarian patients. In early 2016, CPTAC Phase III began to collect and analyze 200 cases of each of ten additional cancers. The goal is to collect 200 qualified cases of five to six tumor types over a five-year period, although the program is currently accruing from ten. The study entails collection and pathology evaluation of biospecimens, high-quality clinical data and images from clinical sites around the world. A biorepository evaluates and stores the biospecimens and medical records of patients to a sequencing center and tissues to proteomics groups. Data are combined and analyzed by translational centers. Genomic data are made available to the research community through the NCI Genomic Data Commons. Proteomic data are made available through the Data Coordinating Center. We report here on progress in collection of tissues and clinical data, and use of biorepository, proteomics and genomics and analysis centers.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Screening for Cancer Dependencies and Drug Response

CRISPR design is a complex multivariate problem. The weight of each variable differs depending on the experiment under consideration. Current methods of designing CRISPR experiments are based on a single-variable, resulting in poor experimental outcomes. From the numerous experiments enabled by the DESKGEN platform, we can demonstrate key design improvements to maximize experimental outcome. Our current scoring methods were tested and validated using an sgRNA library of over 3,500 sgRNAs in essential genes with a variety of predicted sgRNA activities and specificities. The predicted ‘good’ sgRNAs achieved significantly higher read depletion for essential genes, with fewer failing sgRNAs, compared to sgRNAs that didn’t meet the scoring criteria. Our scoring algorithm incorporates multiple published observations for choosing effective sgRNAs, which differs from other CRISPR tools that tend to focus on one factor such as sgRNA sequence or specificity. We were unable to find correlations for some currently accepted sgRNA selection criteria, such as position within a gene, which demonstrates the need to constantly challenge and improve sgRNA design rules.

Functional genomic screening with CRISPR-Cas9 has provided a powerful and precise new way to interrogate the phenotypic consequences of gene loss in high-throughput, unbiased analyses. Rapid development of pooled lentivirus and deep-sequencing-led approaches have allowed us and others to exploit this technology in target ID, target validation, drug MOA analysis and patient stratification. Adaptation of the Cas9 nuclease by domain fusion and catalytic inactivation has further provided a novel way to both up and down-regulate gene expression using targeted, high-throughput CRISPRi and CRISPRa tools. To date, the vast majority of screens have been conducted using sgRNA abundance in surviving cell populations as an NGS-based proxy for proliferation, for example for in vitro resistance analysis to a cytotoxic treatment regimen. However, where cellular pathophysiology is uncoupled from cell health, the enormous promise of pooled CRISPR-Cas9 screening has been largely untapped. We now report on the development of a FACS-based platform that can be used to monitor biomarker-based cellular response in combination with high-throughput genetic screening. The endogenous interaction between CD28 and CD80 was used as a proof-of-concept paradigm and the performance of our platform was measured in screen-simulation conditions. We find that FACS-linked NGS was able to robustly identify the CD28 deleted cells from a complex population using a FITC-labelled CD80-Fc. Pseudo-blinding of the data yielded unambiguous identification of the expected target guides, with robust screening metrics, validating a new platform for myriad discovery programmes.
and gain-of-function genetic screens. Donato Tedesco, Paul Diehl, Mikhail Makhnov, Sylvain Baron, Alex Chenchik, Collecta, Inc., Mountain View, CA.

Genome-wide loss-of-function screening is a fundamental method to identify genes responsible for driving biological processes. Complex pooled lentiviral-based libraries expressing large numbers of genetic disruptors, such as shRNAs (RNAi) or sgRNAs (CRISPR), make large-scale cell screening practical. While RNAi-based approaches have proven to be an effective strategy for these screens, recent work has showed CRISPR-based technologies offer not only an effective alternative, but distinct advantage. We will present unpublished data from genetic screens in human cancer cell lines using CRISPR-Knockout (KO), CRISPRi and CRISPRa technologies, as well as RNAi. Antibody-based function shRNA and sgRNA pooled library screens are similar in concept, the gene loss of function is achieved by different mechanisms (mRNA degradation with RNAi, full gene disruption with CRISPR-KO, transcriptional inhibition with CRISPRi), so some divergences are expected and indeed observed when comparing results obtained using one method versus the other. Furthermore, contrary to RNAi, CRISPR technology can be adapted to detect gene expression (CRISPRa), thus enabling the use of genome-wide gain-of-function screening in gene function studies.

A bi-clustering based computational approach to identify molecular markers for Neoadjuvant chemotherapy outcome prediction in complement to cancer subtype classifications. Chi Zhang, Sen Liang. Indiana University, School of Medicine, Indianapolis, IN; Jilin University, Chang Chun, China.

Molecular stratification models have been well established for cancer types to classify tumors into sub-types by using genome level molecular characteristics. Tumors of certain sub-type have distinct response to specific therapies. Hence a reliable molecular classification model can be applied to determine treatment strategy. Recent neoadjuvant chemotherapy, immunotherapies and gene targeted drugs and their possible combinations raise a demand for small subsets of novel molecular markers for outcome prediction in addition to the complete molecular profile based classification. However, it is unknown what genes have predictive power for a certain therapeutic strategy while the highly crossed clinical features increase the difficult to determine sample groups for marker identification that form a bi-clustering problem. In addition, predictive maker may be varied among different cancer sub-types. In this work, we developed a bi-clustering based computational framework to identify transcriptoric markers for predicting the outcome of neoadjuvant chemotherapy and adjuvant chemotherapy. Our computational approach identifies functional related gene expression modules show significant expression patterns in a subset of samples that are highly associated with one or several disease sub-types and with high predictive power for the outcome of certain. By applying the analysis to 8 breast cancer, 10 colorectal cancer and 5 ascites pooled leukemia data sets in public domain, we have identified sets of gene markers with high predictive power for chemotherapy outcome complementary to the existing molecular classifications, suggesting the bi-clustering based approach can improve the whole genome level molecular classification based outcome prediction.

A novel panel of 325 biomarkers is part of a large inter-connected network representing multiple cell signaling pathways and allowing development of predictive tests for oncology drugs. Edward C. Goodwin, Said Atiya, Marcia Fournier. BioArray Genetics, Inc., Farmington, CT.

Background: We developed an algorithm based on the gene expression of tumor biopsies to identify the best combination of biomarkers to reliably predict a patient’s response to relevant cancer treatments. This algorithm is derived from 325 genes whose expression showed significant changes during differentiation of non-malignant human mammary epithelial cells cultured in laminin-rich extracellular matrix. Of these 325 genes, 251 are novel and not present in 9 other cancer based gene expression panels such as FoundationOne or PAM50. These differentiated cells formed multicellular structures with defined lumens and tight junctions and with specific localizations of cadherin and integrins. In contrast, carcinomas display disruptions in gene loss of structure. Previous work showed that different sets of these 325 biomarkers accurately predicted overall breast cancer patients’ survival or response to neoadjuvant therapy in multiple independent studies. Objective: Predict cell-signaling pathways, drug associations, and disease associations for the 325 biomarkers (BA325) in contrast to other cancer gene panels. Methods and Results: The Qiagen Ingenuity program was used to identify pathways and disease states containing significant overlap with BA325. Multiple cell signaling pathways including cell proliferation, migration, invasion, and metabolism were found in BA325, while most other cancer biomarker panels were highly concentrated in cell proliferation. Examples of significant pathway associations relevant for oncology drug discovery and targeted treatments include Cell Cycle Control of Chromosomal Replication (p = 8.1E-14), Polo-like-kinase and HSP90 complex (p = 6.3E-07), G2/M DNA Damage Checkpoint (p = 6.4E-07), Integrin Signaling (p = 3E-05), integrin linked Kinase Signaling (p = 4.5E-05), BRCA1 DNA Damage Response (p = 1.7E-04), estrogen mediated S-phase entry (p = 4.2E-04), Regulation of cell migration (p = 5.6E-04), Actin Cytoskeleton Signaling (p = 7.25E-04),Mismatch Repair (p = 1.6E-03), RAN signaling (p = 1.6E-03), protein Ubiquitination (p = 1.78E-03) and Cholesterol Biosynthesis (p = 8.4E-03). This wide coverage of cellular signaling pathways provides an advantage in developing predictive tests for treatments targeting highly complex cell signaling networks. Surprisingly, even more novel markers were identified, such as non-mutation driven inhibition, the most significant disease state associated with these genes was mammary tumor, demonstrating the validity of this approach to probe breast cancer biology. Conclusion: This analysis demonstrates that the BA325 panel is useful both in understanding non-malignant mammary epithelial differentiation and breast cancer tumors.

Target identification is a critical step in drug discovery, but the process has many challenges including non-specific reagents, limited ability to test numerous molecules against each target inhibition. Pooled screening with CRISPR/Cas9 permits the quick and accurate examination of proliferation effects across many genes and many cell lines. To determine the specific dependencies of cell lines on epigenetic pathways, we designed a CRISPR/Cas9 library to target 640 epigenetic genes and screened more than 200 cell lines covering a variety of oncology indications, including breast, lung, and renal cell carcinoma (RCC). We find that CRISPR pooled screening is a highly effective approach for target identification and provides robust, highly reproducible data as long as a sufficient number of small guide RNAs are used. We identify known pan-essential genes, including in the transcription (CDK9), translation (EIF4A1 and EIF4A3) and splicing (SR5F2) machinery. We additionally identify many novel pan-essential genes across a variety of epigenetic pathways, including histone acetyl- and deacetylases, chromatin remodeling factors, helicases and others. We also investigated epigenetic synthetic lethal interactions that have been previously reported. For example, it has been reported that the SWI/SNF family displays paralog synthetic lethality for SMARCA2 in the context of SMARCA4 mutations, and for ARID1B in the context of ARID1A mutations. While we do see that some of the same trends hold, the synthetic lethal relationship appears to be more complex, providing a useful framework to examine mRNA levels in addition to mutation type. Most importantly, we identify more than 100 epigenetic genes which show selective sensitivity, i.e. where knockout shows an anti-proliferative effect in only a subset of the cell lines. These are the most promising targets for further drug discovery programs. We have used additionally CRISPR/Cas9 domain based screening to identify the functionally relevant sites for many of these genes. Furthermore, we used a novel expression and mutation data to identify novel synthetic lethal relationships. One gene that displays selective sensitivity is EGLN1, the prolyl hydroxylase for the hypoxia-inducible factor, HIF1α. We find that EGLN1 is required for proliferation only in RCC cell lines which retain wild-type VHL, another component of the hypoxia response pathway, which is frequently lost in RCC. As such, EGLN1 loss is synthetically lethal in the presence of wild-type VHL in RCC cells. Thus this approach not only identifies an enzymatic drug target but also a potential stratification method. Other novel synthetic lethal interactions have also been identified. Our data demonstrates that CRISPR pooled screening is a powerful technique for identification of epigenetic synthetic lethal interactions.
**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Screening for Cancer Dependencies and Drug Response**

in HCC but its anti-tumor effect is very limited. To overcome these problems, we performed two forward genetic screens using recently innovated whole-genome pooled CRISPR/Cas library. Methods: Two human liver cancer cell lines, Huh-7 and SNU-398, were lentivirally transduced with GeCKO library and transduced cells were selected with puromycin. First, transduced cells were orthotopically injected into the liver of female nude mice and monitored for tumor formation. To identify potential tumor suppressor genes (TSGs) in the liver, gRNAs enriched in the orthotopic liver tumors were determined by sequencing of gDNA in these tumors. Next, transduced cells were treated with vehicle or sorafenib in vitro for 14 days. To identify potential targets which inhibition show synergistic anti-tumor effect with sorafenib, we determined gRNAs depleted in cells with sorafenib compared to cells treated with vehicle. Results: In the first in vivo screening, we identified 62 genes targeted by 2 or more highly enriched gRNAs in Huh-7 cells-derived tumors and 47 genes in SNU-398 cells-derived tumors. Twenty-nine genes were common including 4 miRNAs. TCGA analysis revealed that HCC patients with mutation or copy number alteration in any of these genes showed worse overall survival and disease free survival compared to HCC patients without them. In addition, gene expression levels of 3 candidate TSGs, BPHL, CTSZ and PLCG2 were significantly negatively correlated with poor survival of HCC patients. In the second in vitro screening, CYP7B1, HSST3, NLRC4, and Mir-1237 were identified as potential drug targets in combination with sorafenib in HCC. Conclusion: Whole-genome pooled CRISPR/Cas library screens discovered potential new hepatocellular carcinoma drivers and drug targets in combination with sorafenib.

**#408 Investigating the biology of atypical teratoid/rhabdoid tumors by whole genome CRISPR/Cas9 screening.** Matthew P. Selby, Martina A. Finetti, Matthew Bashston, Ruth E. Cranston, Yulia Grabovska, Alicia Del-Carpio-Pons, Amanda Smith, Simon Bailey, Steven C. Clifford, Daniel Williamson. Newcastle University, Newcastle upon Tyne, United Kingdom.

Atypical Teratoid/Rhabdoid Tumours are rare, highly aggressive, paediatric tumours with a dismal prognosis. Rhabdoid Tumours (RT) have one key genetic defect (biallelic inactivation of SMARCB1 in > 90% of patients) which, when re-expressed in RT cells, causes differentiation and growth arrest. We used whole genome CRISPR (clustered regularly interspaced short palindromic repeats)/Cas9 screening; a technique by which mutations are created systematically in each gene in the genome - to identify novel SMARCBI-dependent therapeutic targets and synthetic lethal relationships in RT. A panel of RT cell lines were transduced with a GeCKO (Genome Scale CRISPR Knock-Out) library which contains 122,441 guide constructs targeting 19,050 genes and 1,864 miRNAs; each cell contained a single CRISPR insert. This panel was further transduced with a SMARCBI expression lentivirus or an empty vector control, cells were collected at 0, 7 and 14 days post infection (300x library coverage, 3.7 x 10^7 reads)/Cas9 screening; a technique by which mutations are created systematically in each gene in the genome - to identify novel SMARCBI-dependent therapeutic targets and synthetic lethal relationships in RT. A panel of RT cell lines were transduced with a GeCKO (Genome Scale CRISPR Knock-Out) library which contains 122,441 guide constructs targeting 19,050 genes and 1,864 miRNAs; each cell contained a single CRISPR insert. This panel was further transduced with a SMARCBI expression lentivirus or an empty vector control, cells were collected at 0, 7 and 14 days post infection (300x library coverage, 3.7 x 10^7 reads)/Cas9 screening; a technique by which mutations are created systematically in each gene in the genome - to identify novel SMARCBI-dependent therapeutic targets and synthetic lethal relationships in RT. A panel of RT cell lines were transduced with a GeCKO (Genome Scale CRISPR Knock-Out) library which contains 122,441 guide constructs targeting 19,050 genes and 1,864 miRNAs; each cell contained a single CRISPR insert. This panel was further transduced with a SMARCBI expression lentivirus or an empty vector control, cells were collected at 0, 7 and 14 days post infection (300x library coverage, 3.7 x 10^7 reads)/Cas9 screening; a technique by which mutations are created systematically in each gene in the genome - to identify novel SMARCBI-dependent therapeutic targets and synthetic lethal relationships in RT. A panel of RT cell lines were transduced with a GeCKO (Genome Scale CRISPR Knock-Out) library which contains 122,441 guide constructs targeting 19,050 genes and 1,864 miRNAs; each cell contained a single CRISPR insert. This panel was further transduced with a SMARCBI expression lentivirus or an empty vector control, cells were collected at 0, 7 and 14 days post infection (300x library coverage, 3.7 x 10^7 reads). CRISPR inserts were sequenced, counted, normalized and analyzed to identify those whose abundance was significantly altered, representing candidate gene targets which promote or inhibit RT cell growth/viability in a SMARCBI-dependent manner. CRISPR hits were further cross-validated with primary patient and functional model genomic data (RNA-sequencing/450k DNA methylation array) to identify several high confidence deleterious events with strong SMARCBI dependence. Hundreds of significantly enriched (both positively and negatively) genes were identified which alter when SMARCBI is present or absent including MYC family targets, cell cycle targets, SHH pathway and the Aurora kinase family. TGFβ was identified as a top upstream SMARCBI/methylation dependent regulator and when SMARCBI re-expression data was overlaid onto the TGFβ canonical pathway showed a convincing enrichment in pathway regulation. Pathway members SMAD2/3 showed a synthetic lethal phenotype and represent a functional SMARCBI-dependent relationship which is also observed in SMARCBI re-expression and methylation model data and is characteristic of primary RT. This phenotype was validated functionally by expression of a dominant negative TGFβR2. Combining RNA-sequencing and 450k DNA methylation microarray data from primary tumour cells and experimental models, coupled with whole-genome functional screening, provides a genome-wide view of key RT tumorigenic genes/pathways and their SMARCBI dependence. These data suggest synthetic lethal phenotypes and enable prioritisation of true SMARCBI-dependent events and therapeutic targets, in this rare yet lethal paediatric tumour.

**#409 Genome engineering to generate models of chromosome arm-level aneuploidies in lung carcinoma.** Alison M. Taylor, Gavin Ha, Julianna Shih, Xiaoyang Zhang, Joshua M. Francis, Matthew Meyerson. Dana-Farber Cancer Institute/Broad Institute, Boston, MA.

Almost 90% of tumors are aneuploid and have arm- or whole-chromosome level copy number changes. Arm-level copy number alterations cluster by tumor type, suggesting that specific arm-level changes are influenced by cell type. Systematic methods of generating copy number changes on a particular chromosome have not been tested, leaving the effects of specific aneuploidies in cancer unclear. The most frequent genomic alteration in lung squamous cell carcinomas (SCCs) is loss of chromosome 3p. This alteration occurs in 90% of lung SCCs and in these tumors, 3p deletions occur in both primary tumors and their lymph node metastases. Deletions of 3p genes show significantly decreased expression. However, the phenotypic effects of 3p loss in tumorigenesis are not known. We used the CRISPR-Cas9 system to generate double-strand breaks (DSBs) and produce partial aneuploidies of arm-level loss. We have targeted guide RNAs adjacent to centromeric satellite-repeat sequences on chromosome arm 3p. At this location, we induced homology-directed repair with a selectable marker to generate an artificial telomere. We have successfully isolated almost 90 clones of immortalized lung epithelial cells with deletion of the 3p arm, with 8 validated by whole genome sequencing. Consistent with patient data, expression of 3p genes is also decreased upon deletion. Phenotypic characterization revealed that cells with chromosome 3p deletion proliferate more slowly than their siblings. 3p deleted cells show increased G1 arrest, but do not undergo increased apoptosis or cell death. We are currently testing 3p loss in combination with other frequent SCC alterations, such as SOX2 and TP63 gain. We have also identified expression changes in trans, outside of chromosome 3p. These studies provide a robust model that will address a gap in our understanding of aneuploidy in cancer by using targeted endonuclease technology to create models of partial aneuploidies. Future work will include investigation of how different chromosomal changes contribute to cancer formation, which will have implications on our understanding of tumorigenesis.

**#410 Identifying ovarian cancer specific cancer targeted drugs using high-throughput drug sensitivity profiles of primary cancer cells.** Astrid Muromagi, Akira Hirasewa, Suleiman Khan, Daniela Ungureanu, Marilinya Arjama, Teijo Pellinen, Samuli Eldfors, Ruita Koivistio-Korander, Arto Leminen, Ralf Bützow, Tero Aittokallio, Olli Kallioniemi. Helsinki Univ., Inst. For Molecular Medicine, Helsinki, Finland; Keio University School of Medicine, Tokyo, Japan; Tampere Univ., Inst. of Biosciences and Medical Technology, Tampere, Finland; Helsinki University Hospital, Helsinki, Finland.

Ovarian cancer (OvCa) is the sixth most common cancer in women and leading cause of death from gynecologic diseases. Poor prognosis in OvCa is due to late diagnosis and acquired resistance to the commonly used platinum-based regimens. A significant setback for OvCa treatment is the lack of reliable biomarkers and effective targeted therapies. In order to discover novel therapeutic opportunities with approved and emerging drugs for OvCa, we have established primary cultures using ascites or tumor tissue samples from chemo-refractory ovarian cancer patients for ex vivo Drug Sensitivity and Resistance Testing (DSRT) and genomic profiling. In addition, we have performed DSRT with 31 established OvCa cell lines. Comparison of the drug sensitivity profiles of ten primary cancer cell cultures and 31 OvCa cell lines revealed previously unanticipated cancer selective drug vulnerabilities. Several drug groups were identified suggesting that the sensitive samples were addicted to the corresponding signaling networks. For example, in a 53-year old chemoresistant low grade serous OvCa patient, genomic and transcriptomic analyses revealed a fusion gene of NRG1-ERBB3 activation loop, a target that was recently reported to involve the NRG1/ERBB3 activation loop in OvCa. We found high expression of ERBB2 and ERBB3 by RNA-seq as well as high levels of phospho-ERBB3, phospho-ERBB2 and phospho-EGFR by immunohistochemistry. In agreement with the molecular mechanism, DSRT analysis identified significant sensitivity of primary cancer cells to EGFR inhibitors, such as erlotinib and to dual EGFR and Her2 inhibitor afatinib. The patient has received combination therapy of gemcitabine and erlotinib during nine months, followed by afatinib monotherapy that has lead to complete remission after six months treatment. We have detected decreased NRG1/ERBB3 and increased ERBB2 expression in 11 ovarian cancer patient cases, highlighting the importance of this signaling pathway in ovarian cancer pathogenesis. Our study reveals that a subset of serous ovarian cancer patients with activating NRG1/ERBB3 signaling loop have clinical benefits from repurposing dual EGFR/Her2 inhibitor afatinib, providing a basis for the clinical use of EGFR and dual EGFR/Her2 tyrosine kinase inhibitors in clinical treatment. In conclusion, DSRT technology together with molecular profiling provides a powerful strategy to identify tumor driver signals and select clinically actionable inhibitors. Hence, this type of systems medicine approach can significantly improve the power of mainly genomics-oriented personalized medicine approaches.
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Screening for Cancer Dependencies and Drug Response

#411 In vivo pooled shRNA library identifies KPNB1 as a new drug target for epithelial ovarian cancer. Michiko Kodama,1 Takahiro Kodama,1 Kouke Yoshihara,2 Kae Hashimoto,1 Seiji Mabuchi,1 Kenjiro Sawada,1 Tadashi Yamamoto,1 Yoshihara,2 Kae Hashimoto,1 Seiji Mabuchi,1 Kenjiro Sawada,1 Tadashi Yamamoto,1 Objective Epithelial ovarian cancer (EOC) is a most lethal cancer in gynecology, of which cure rate is 30%. To seek its new therapeutic targets, we performed in vivo loss of function screen. Method Human EOC cell line, SKOV3, was transduced with pooled druggable shRNA library containing 42450 shRNAs targeting 7490 genes. Transduced cells were intraperitoneally injected into 12 female nude mice and monitored for PC tumor formation. Genomic DNA of 12 biggest PC tumors were sequenced to identify shRNAs depleted in these tumors. Results Ten potential drug targets were identified, including 2 known oncogenes, ERBB2 and RAF1. Second highest ranked gene, KPNB1, is known as a nuclear transporter. KPNB1 inhibition significantly decreased and overexpression increased in vitro cell proliferation in multiple EOC cell lines. KPNB1 inhibition caused multi-phase cell cycle delay at both G1/S and G2/M transition via elevation of p21 and p27 and induced apoptosis. KPNB1 inhibition significantly decreased in vivo tumor formation through the same mechanism as in vitro, because more cleaved PARP and less Ki67 positive cells were found in KPNB1 knockdown tumors via immunochromating staining. We found a positive correlation between KPNB1 mRNA levels and poor survival of EOC patients, suggesting the oncogenic role of KPNB1 in the epithelial ovarian cancer. Furthermore, immunoprecipitation and mass spectrometric study identified that KPNB1 positively regulated several members of anaphase promoting complex/cyclosome. Lastly, we found that ivermectin, a spectrometric study identified that KPNB1 positively regulated several members suggesting the oncogenic role of KPNB1 in human EOC. Comprehensive mass spectrometry identified that KPNB1 positively regulated several members of anaphase promoting complex/cyclosome. Lastly, we found that ivermectin, a new drug target for EOC. Ivermectin can be a new therapeutics for EOC especially in platinum resistance.

#412 Genetic variation in platinum-sensitive and platinum-resistant high-grade serous epithelial ovarian cancer. Tara Castellano, Leslie H. Clark, Naim Rashid, Victoria Bae-Jump. University of North Carolina at Chapel Hill, Chapel Hill, NC. Background: We examined the association of platinum resistance with genetic mutations in high grade serous ovarian cancer (HSOC) patients undergoing high-throughput genomic tumor sequencing. Methods: Snap-frozen and fresh frozen parallel-embedded tissue samples were collected from HSOC patients enrolled on UNCseq (NCT01457196). UNCseq is an institutional protocol which uses next generation sequencing to detect genetic mutations in a wide array of malignancies. Illumina libraries were prepared separately from tumor and a matched normal sample from each patient. Relevant targets were enriched by a custom designed Agilent SureSelect hybrid capture enrichment library using standard Illumina protocols. Samples were sequenced on Illumina HiSeq machines in a variety of formats. Mutations with a quality score $\geq 20$ were filtered from the data set, and only mutations retained to have a moderate to high impact were retained. Medical record review determined platinum sensitivity or platinum resistance. Tumors were defined as platinum sensitive or resistant if patients were noted to have $\geq 6$ months of disease free interval following completion of induction therapy, respectively. Results: Overall 39 HSOC cases met inclusion criteria; 32 tumors met criteria for platinum sensitive and 7 platinum resistant. 308 mutations were noted in at least one individual across all patients. The top observed mutations in platinum sensitive HSOC were TP53 (41%, n = 13), GUCA2A (19%, n = 6), MLL2 (19%, n = 6) and MTOR (16%, n = 5). The top observed mutations in platinum resistant tumors were TP53 (71%, n = 5), TET1 (43%, n = 3) and MLH3 (43%, n = 3). There was a trend toward more p53 mutations in resistant tumors (71% versus 41%; p = 0.21). There was no difference in the total number of mutations per tumor in platinum sensitive and resistant patients, (3 v. 4, p = 0.56). Conclusions: We did not detect a difference in the number of genetic mutations in HSOC according to platinum sensitivity. Platinum resistant tumors had a trend toward higher frequency of TP53 mutations than platinum sensitive HSOCs. Furthermore, we identified 3 frequently mutated genes in platinum resistant HSOC: TET1, an epigenetic regulator, NF1, a tumor suppressor gene and MLH3, a histone modifier gene. Ongoing tumor sequencing of HSOCs on UNCseq will help to confirm these results.

#413 Neo-epitope detection and immune infiltrate analysis of colorectal cancer samples. Fang Yin Lo,1 Nittin Mandal,2 Timothy Yeatman,3 Kiran Paul,2 Ashwini Patil,2 Steven Anderson,4 Ravi Gupta,1 Anup Madan1. 1Covance Genomics Laboratory, Redmond, WA; 2MedGenome Inc, Foster City, CA; 3Gibbs Cancer Center, Spartanburg, SC; 4Covance Genomics Laboratory, Durham, SC. Colorectal cancer (CRC) is the third most common type of cancer in the United States. Targeted therapies that use monoclonal antibodies (mAbs) to EGFR have been shown to benefit some CRC patients. Until recently, KRAS has been the only predictive biomarker for anti-EGFR therapy for metastatic CRC. However, 40% to 60% of patients with wild-type KRAS do not respond to anti-EGFR therapy. Previously, we have shown that a novel colorectal cancer mono-allelic score which measures MEK pathway functional output independent of tumor genotype. We showed that samples that have RAS activating mutations such as KRAS and BRAF have significant higher RAS scores ($p < 0.001$). Here, we further investigate the potential immune reactivity in these CRC samples, and thereby the potential benefit of immunotherapy, by evaluating the tumor neo-epitope burden, and the immune cell infiltrate of CRC patients in CRC xenografts. In this study, 55 CRC samples were sequenced, 779 unique non-synonymous mutations were detected by exome-seq. These 779 mutations spanned across 263 genes. The majority of these mutations are not shared between samples ($\sim 5%$ of the mutations were shared by more than 2 samples). Several driver gene mutations were identified in this study, including KRAS, TP53, PIK3CA, APC and HER2. HLA prediction based on Exome-seq and RNA-seq data shows that $\sim 86.7\%$ of the alleles predicted to be present in 53 samples were concordant between the two RNA-seq datasets. The predicted alleles based on exome-seq and RNA-seq results have $67-69\%$ concordance. Prediction of neo-epitopes show that HLA-binding neo-epitopes are more frequent than TCR-binding ones, and that most neo-epitopes are private and not shared between samples. A more in-depth analysis of the tumor microenvironment was carried out by evaluating the de novo epithelial and immune components. The immune component was further stratified into 7 different immune cell types using signatures specific to CD8 and CD4 T, T-regulatory, NK, B-cells, Macrophages and Myeloid derived suppressor cells (MDSC). The immune make up of colorectal cancer is dominated by macrophages and MDSCs. Interestingly, both granulocytic $G$- and monocytic $M$-MDSCs are present together, supporting the idea that MDSCs confer an immune suppressive microenvironment in this cancer. Significantly, high MDSC infiltrated tumors showed upregulated expression of pro-tumorigenic insulin-like growth factor pathway genes. Additionally, tumors with lower burden of MDSC showed signature of complement activation suggesting innate cell-mediated anti-tumorigenic mechanisms of tumor control in CRC. These analyses provide potential biomarkers to stratify CRC patients based on their immune reactivity and predict response to cancer immunotherapy drugs.

#414 Identifying selective vulnerabilities in colorectal cancer molecular subtypes using in vivo functional genomic screens. Akira Inoue, Bahar Salimian Rizi, Alessandro Carugo, Sahil Seth, Christopher Bristow, Gianicola Genevese, Andrea Viale, David G. Menter, Scott Kopetz, Giulio F. Draetta. The University of Texas MD Anderson Cancer Center, Houston, TX. Colorectal cancer (CRC) is a leading cause of cancer-related morbidity and mortality with significant genetic and drug responses. Recently, the international Colorectal Cancer Subtyping Consortium identified four robust consensus molecular subtypes of CRC (CMS1-4) using large-scale gene expression data. These findings may enable us to identify molecularly homogenous subsets of CRC patients and accelerate effective drug development strategies. To identify potential therapeutic targets and novel selective vulnerabilities in CRC molecular subtypes, we developed an in vivo loss-of-function genomic screen using CRC patient-derived xenografts (PDxIs) for each molecular subtype. Our PDX-derived CRC models underwent comprehensive integrated molecular characterization of mRNA profiles, DNA mutations, and histochemical profiles upon confirmed serial retransplantation to determine whether characteristics of the subtypes are recapitulated in vivo. Because the original CMS classification algorithm was trained and validated using Affymetrix data, profiling the PDX-derived cell lines using this technology provided the most robust analysis of the CMS subtypes. In vivo pooled shairpin RNA (shRNA) screens rely on specific elimination of individual shRNAs in a cell population and require that the infused tumor cell population is adequately endowed with engraftment capacity to replace implanted inoculum. To improve the transduction efficiency of the PDX models, the frequency of tumor-initiating cells, and the maximum library complexity allowed by each model. To identify targets that represent selective vulnerabilities in specific CRC molecular subtypes, we screened each model in vivo with an shRNA library targeting about 200 genes specifically belonging to U.S. Food and Drug Administration-approved targeted therapies (PDxAme; 10 shRNAs/gene ). We leveraged reduced shRNA activity analysis to evaluate “hits” (or top-scoring genes) emerging from our screening. We further applied ranking-based analytics in combination with integromic approaches (use of computational packages to unravel relationships between -omics) to inform on selective
#415 In vivo shRNA library screening to identify novel targets for head and neck squamous cell carcinoma.

Kumar, Ramya L. Parimi, Liang P. Yang, Jiping Wang, Sahil Seth, Christoph A. Bristow, Alessandro Carugo, Frederick S. Robinson, Giulio F. Draetta, Heath Skinner, Mitchell J. Frederick, Jeffrey N. Myers, The University of Texas MD Anderson Cancer Center, Houston, TX; Baylor College of Medicine, Houston, TX.

Head and neck squamous cell carcinoma (HNSSC) is a diverse group of tumors from the upper aerodigestive tract that are treated primarily with surgery, chemotherapy, and/or radiation. Recent genomic studies have characterized the genomic alterations in HNSSC but they failed to identify novel oncogenic drivers for therapeutic targeting. In order to identify novel targets we have utilized an in vivo shRNA library screening platform in a panel of genomically characterized HNSSC cell lines. The screens were performed alone or in combination with platinum-based chemotherapy or radiation, and the libraries included known druggable targets (e.g., CT2A, GL261), genes, and HNSSC candidate driver genes. Initial results indicate that this in vivo screening is able to identify targets that may not be found through traditional in vitro screening approaches and related to tumor-stromal interactions and metabolism. These genes emphasize the importance of including the tumor microenvironment in studies to understand driver genes and identify novel therapeutic interventions.

#416 Identification of therapeutic combinations in glioblastoma using personalized gene expression networks.

Vasileios Stathias, Michele Forlini, Bryce Allen, Stephan Schürer, Nagi G. Ayad. University of Miami, Miami, FL.

The goal of our study was to identify patient-specific gene expression networks from Glioblastoma Patient-Derived Xenografts (PDxS) and determine novel therapeutic combination compounds using those networks. Glioblastoma is the most common malignant primary adult brain tumor with a standard of care consisting of maximal surgical resection followed by radiotherapy and adjuvant temozolomide (TMZ) chemotherapy. However, despite medical advances in the field, recurrence is almost universal, suggesting the need for more personalized and targeted therapeutic approaches. For this, we obtained transcriptional data from Glioblastoma PDxS and used them to identify their respective differentially expressed genes. Patient-specific gene expression networks were then created and their biological relevance was supplemented by integrating them with TCGA Glioblastoma transcriptional data. In order to identify compound combinations specific for those networks, we used the extensive chemical perturbation signatures from the Food and Drug Administration-approved drugs and to rapidly design successful preclinical and clinical trials in CRC patients.

#417 Defining molecular mechanisms of resistance to glioblastoma immu

Mukul Kumar, Ramya L. Parimi, Liang P. Yang, Jiping Wang, Sahil Seth, Christoph A. Bristow, Alessandro Carugo, Frederick S. Robinson, Giulio F. Draetta, Heath Skinner, Mitchell J. Frederick, Jeffrey N. Myers, The University of Texas MD Anderson Cancer Center, Houston, TX; Baylor College of Medicine, Houston, TX.

Head and neck squamous cell carcinoma (HNSSC) is a diverse group of tumors from the upper aerodigestive tract that are treated primarily with surgery, chemotherapy, and/or radiation. Recent genomic studies have characterized the genomic alterations in HNSSC but they failed to identify novel oncogenic drivers for therapeutic targeting. In order to identify novel targets we have utilized an in vivo shRNA library screening platform in a panel of genomically characterized HNSSC cell lines. Initial results indicate that this in vivo screening is able to identify targets that may not be found through traditional in vitro screening approaches and related to tumor-stromal interactions and metabolism. These genes emphasize the importance of including the tumor microenvironment in studies to understand driver genes and identify novel therapeutic interventions.

#419 Integrative analysis of multi-omics tumor profiles identifies pathways associated with resistance to anti-HER2 therapy in early stage breast cancer.

Salendra Singh, Hannah Gilmore, Maya Abu-Khalaf, George Somlo, William Sikov, Lyndsay Harris, Vinay Varadan, Case Western Reserve Univ., Cleveland, OH; Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA; City of Hope National Med Center, Duarte, CA; Warren Alpert Medical School of Brown University, Providence, RI; National Cancer Institute, Rockville, MD.

Head and neck squamous cell carcinoma (HNSSC) is a diverse group of tumors from the upper aerodigestive tract that are treated primarily with surgery, chemotherapy, and/or radiation. Recent genomic studies have characterized the genomic alterations in HNSSC but they failed to identify novel oncogenic drivers for therapeutic targeting. In order to identify novel targets we have utilized an in vivo shRNA library screening platform in a panel of genomically characterized HNSSC cell lines. The screens were performed alone or in combination with platinum-based chemotherapy or radiation, and the libraries included known druggable targets (e.g., CT2A, GL261), genes, and HNSSC candidate driver genes. Initial results indicate that this in vivo screening is able to identify targets that may not be found through traditional in vitro screening approaches and related to tumor-stromal interactions and metabolism. These genes emphasize the importance of including the tumor microenvironment in studies to understand driver genes and identify novel therapeutic interventions.
Background: HER2 positive breast cancers are heterogeneous at both the clinical and molecular levels, with the HER2-enriched subtype exhibiting increased levels of immune infiltration signatures and the highest rate of pathologic complete response (pCR), while the HER2-Basal subtype is resistant to anti-HER2 therapy (Varadan et al, CCR 2016). Here we aim to characterize the molecular underpinnings of response and their interaction with increased immune infiltration across these HER2-subtypes using integrative analyses of genomic and transcriptomic data from two multicenter trials (DFCI 03-311 and BrUOG 211B). Methods: Fresh tumor core biopsies were taken at baseline and a 2-week time point after a single dose of trastuzumab. 80 HER2+ early breast cancer (EBC) patients were enrolled in the 03-311 trial, and 60 patients in the 211B trial. RNAseq and DNA copy number aberrations (SNP-arrays: 03-311; Whole-exome Sequencing: 211B) were performed using the recently developed InFlo framework (Dimitrova et al, Oncogene 2016). Results: HER2-Basal tumors exhibited lower average copy number for HER2 and were less likely to have high-level amplifications of co-amplics (e.g. 11q13, 20q13). In the 211B and 03-311 trials, respectively, 62% and 63% of somatic mutations persisted after one dose of therapy, while 21% and 19% of mutations were undetectable after one dose of therapy. Tumors harboring amplifications in the 8p11 (FGFR1) genomic locus exhibited higher indices immune signatures associated with macrophages (P = 0.0073) and T-cells (P = 0.0049) in 211B, but this association did not achieve significance in the 03-311 trial. Integrative InFlo-based analysis of tumor gene expression and copy-number profiles in trastuzumab-resistant tumors in the 211B trial revealed significantly higher activity of signaling pathways associated with CD4+ T-cells in the responders (P = 0.008), while higher activity of mTOR pathway was observed in non-responders (P = 0.0014). Conclusions: Changes in mutational profiles over time may either be related to therapy-induced alterations of clonal architecture or the consequence of intra-tumor heterogeneity, thus warranting further exploration. Integrative analysis of gene expression and copy-number profiles reveal signaling pathways associated with response and resistance, enabling the discovery of biomarkers of response to anti-HER2 therapy.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Screening for Cancer Dependencies and Drug Response

#421 Comprehensive genomic analysis of metastatic breast cancers reveals ESR1 fusions as a recurrent mechanism of endocrine therapy resistance. Ryan J. Hartmaier,1 Nolan Priedeigkkeit,1 Laurie Gay,1 Michael E. Goldberg,1 James Suh,1 Siraj Ali,2 Jeffery Ross,1 Michaela Tsai,3 Barbara Haley,4 Julio Peguero,5rena D. Callahan,5 irina Sachelarie,5 John Cho,6 Amir Bahreini,7 Shannon L. Helayes,8 Peter C. Lucas,2 Nadia M. Ahmed,2 Adam M. Brufskey,2 Philip J. Stephens,1 Juliann Chmielecki,1 Adrian V. Lee2.

Foundation Medicine, Cambridge, MA; 1University of Pittsburgh Cancer Institute, Pittsburgh, PA; 2Minnesota Oncology, Minneapolis, MN; 3UT Southwestern Medical Center, Dallas, TX; 4Memorial Hermann Hospital, Houston, TX; 5UCLA Medical Center, Santa Monica, CA; 6Carlisle Regional Medical Center, Carlisle, PA; 7New York Cancer Center.

Metastatic breast cancer is often intractable due to its inherent ability to overcome current therapies. Genomic alterations are frequently responsible for therapeutic resistance. To better understand genomic mechanisms of acquired resistance in breast cancer we undertook a detailed characterization of single nucleotide variation (SNV) and structural variation (SV) in paired primary-metastasis matched tumors from 6 breast cancer patients (median time to recurrence 7.3 years). In ER-positive recurrent tumors treated with endocrine therapies, we identified multiple metastatic-acquired variants in ESR1 including a novel constitutively active, ligand-independent ESR1-DAB2 gene fusion. Importantly, this fusion resulted from a breakpoint in intron 4, retaining the DNA-binding domain but eliminating the ligand-binding domain (LBD), concordant to a similar fusion reported previously in a xenograft model. Hybrid capture-based genomic profiling from >7,800 breast cancers identified similar exon/intron 4 fusions in 5 tumors with direct paired-read evidence. Using a novel copy number shift detection strategy, 58 additional tumors showed indirect evidence of a rearrangement at exon 4 based on a novel copy number shift detection strategy. ESR1 fusion and copy number shift positive tumors are strongly enriched in metastatic disease (78%; p<10-4) suggesting their expected involvement in endocrine therapy resistance. Clinical follow up was available for 7 patients. 6/7 tumors were clinically ER-positive and received extensive endocrine therapy with progressive disease. Together, these data indicate that ESR1 fusions involving exon/intron 4 are a recurrent, albeit rare, mechanism of endocrine therapy resistance in breast cancer. The absence of the LBD implies these fusions will not respond to other ErEs targeted therapies. Additional studies are needed to identify appropriate treatment options to overcome this mechanism of resistance.

#422 Lymph node metastasis evolution drives immune evasion and targeted therapy resistance in gastro-esophageal adenocarcinomas (GEAs). Matthew N. Davies,1 Louise J. Barber,2 Georgia Spain,3 Filipa Lopes,4 Katharina von Loga,5 Beatrice Griffiths,1 Andrew Woolston,6 Donat Alparp,7 Marta Gomez,8 Kamil A. Lipinski,9 Kerry Fenwick,10 Zakaria Eltabi,7 Stefano Lise,11 Emese Lidak,9 and Giacomo Morais,9 Liza Lebron,6 Mercia Lopes,9 Ana Saz,10 Caroline Springer,11 Marco Gerlinger12.1 The Institute of Cancer Research, London, United Kingdom; 2The Royal Marsden Hospital, London, United Kingdom; 3Semmelweis University, Budapest, Hungary; 4Cancer Research UK Manchester Institute, Manchester, United Kingdom.

GEAs are aggressive tumors in which several targeted therapy trials have failed. We assessed intratumor heterogeneity (ITH) and its impact on progression and therapy failure by applying an 81-gene NGS panel and SNP array copy number aberration (CNA) analysis to multiple primary tumor (T) regions and lymph node (LN) metastases from 9 GEAs. Analysis of 39 samples found ITH in all cases. 8 chromosomally instable (CIN) GEAs predominantly evolved through CNAs, with 17-76% of the genome affected by heterogeneous CNAs. A microsatellite instable GEA showed parallel evolution and diversified exclusively through point mutations (58% ITH). This demonstrates ongoing genomic instability rather than punctuated evolution and that specific instability mechanisms impact evolutionary trajectories. LN metastases contributed more to ITH (p<0.001) than any anatomic location within T. Further, subclonal aberrations that activate the Mitogen Activated Protein Kinase-pathway (MAPK-pw), including EML4-ALK, ERBB2, KRAS, NRAS, Amplifications (amp) and CNAs were detected in LN metastases from 4/8 CIN GEAs. Subclonal MAPK-activating CNAs were enriched in LN (p=0.019) compared to T regions that only exhibited a single subclonal MET amp. Convergent evolution of LN subclones across several GEAs suggests that selection pressures differ systematically between LN and T ecosystems. To assess the phenotypes established by MAPK-activating amp evolution, we analyzed 135 published primary CIN subtype GEAs. Cytolytic activity (CYT), estimating tumor immune recognition from RNA expression data, correlated with the mutation load in GEAs with EGFR, ERBB2 or MET amp (p=0.04). In contrast, CYT did not correlate with mutation load in GEAs with KRAS or ERBB3 amp (p=0.22. NRAS/ERK2: insufficient
data), indicating that these specific alterations, that also recurrently evolved in LN, may enable immune evasion. Downregulation of TAP and Class I MHC genes (p<0.05) in KRAS or ERBB3 amp GEAs suggested impaired antigen processing and presentation as the mechanisms driving T cell immune evasion. Moreover, ITH of MAPK-activating amp is likely to confer resistance to up-stream MAPK-targeted therapy. We used GE cell lines with various MAPK-activating amp (ERBB2, MET, NRAS) to investigate downstream MAPK-pw inhibition as a novel strategy to broadly target heterogeneous subclones. Growth control was incomplete with ERK- and MEK-inhibitors but the panRAF/SRC inhibitor CCT190969 was effective in all lines, suggesting that it can effectively intercept subclonal heterogeneity in GEAs. In conclusion, ITH with parallel and convergent evolution in 9/9 metastatic GEAs. Distinct selection pressures in LN foster the evolution of subclonal MAPK-activating amp that decrease immunogenicity and drive evolutionary pre-adaptation to future targeted drugs that can be intercepted by panRAF/SRC inhibitors.

Background & Aims: Next-generation sequencing (NGS) that enables the analyses of massively parallel sequences of DNA can advance the understanding of the underlying molecular pathophysiology of cancer. Such recent genomic analyses have revealed a complex mutational landscape for PDACs. The aims of this study were to investigate the genomic profile to predict the chemotherapeutic response in unresectable PDACs. Methods: The total of 80 pathologically confirmed PDACs were enrolled and genomic DNA was extracted and quality control metrics of DNA analytics were measured. The specimens that passed a quality control test underwent targeted deep sequencing using a customized panel (CancerSCAN) enriched in the exons of 83 genes. Results: Clinical prognostic factors associated with survival in PDAC were gender, tumor mass size, stage and chemotherapy response rate (P=0.078, 0.009, 0.052 and <0.001, respectively). Multivariable Cox proportional-hazards analysis revealed chemotherapeutic response rate (P < 0.001, hazard ratio (HR) = 1.908, 95% CI, 1.281 to 2.840) is an independent prognostic factor. There were 56 (71%) and 9 (11%) study patients who underwent gemcitabine based chemotherapy and FOLFIRINOX respectively. Response rate of study patients were as follows: CR = PR 14 (20%), SD (27%) and PD 24 (41%). There were only 9 (16%) and 4 (50%) patients who had CR + PR response gemcitabine based chemotherapy and FOLFIRINOX respectively. Conclusion: Targeted sequencing using EUS-FNA specimens in PDAC showed excellent compatibilities to analyze genomic profiles of PDACs. Furthermore, novel genes associated with survival, metastasis and chemotherapeutic response in PDAC were identified.

#424 Landscape of somatic mutations in drug-resistant acute myeloid leukemia. Samuli Eldjors,1 Mika Kontro,2 Yevhen Akimov,1 Olli Kallioniemi,1 Kimmo Porrka,2 Caroline Heckman1.1Inst. for Molec. Medicine Finland (FIMM), Helsinki, Finland; 2Helsinki University Central Hospital Cancer Center, Helsinki, Finland.

Introduction: Most patients with acute myeloid leukemia (AML) initially respond to cytarabine-anthracycline induction chemotherapy. However, in many patients, the disease recurs in a lethal drug-resistant form. Somatic mutations underlying the pathogenesis of AML have been extensively characterized by sequencing of newly diagnosed AMLs. However, the mutations driving therapy resistance and disease progression at relapse have not been well characterized. In this study, we have exome sequenced a cohort of relapsed and refractory AMLs and compared the landscape of somatic mutations at relapse to diagnosis phase AMLs to identify mutations that contribute to therapy resistance and disease progression. Materials and Methods: We performed exome sequencing of diagnosis phase AMLs (n=70) and relapsed or primary refractory AMLs (n=54). Patients with AML M3 subtype were excluded from the study. Paired diagnosis and relapse samples were available from 27 patients. A skin biopsy was used as the germline control. Nine patients had received an allogeneic hematopoietic stem cell transplant before relapse. Somatic mutations were called using varscan2 and copy number aberrations using copyCat. Since the identification of large insertions from next-generation sequencing data remains challenging using existing algorithms, FLT3 internal tandem duplications (FLT3-ITDs) were identified using a novel custom algorithm optimized for FLT3-ITD detection. Population variants were filtered out to remove donor-derived germline variants in chimeric post-transplant relapse samples. Results: Comparison of somatic mutation frequencies in diagnosis and relapse and refractory samples showed that on average relapsed tumors have a higher number of driver mutations than tumors at diagnosis. WT1, TP53, CBL, IDH1 and PTPN11 were mutated at a higher frequency in relapsed samples than at diagnosis, with 13%, 11%, 11%, 9% and 9% of relapsed or refractory samples and 4%, 6%, 3%, 4% and 7% of diagnosis mutant respectively. Analysis of paired diagnosis-relapse samples showed that in patients with WT1, CBL or PTPN11 mutation at diagnosis the second allele is frequently mutated or lost due to uniparental disomy or loss of heterozygosity at relapse. Conclusion: Overall, there was a higher number of driver mutations than diagnosis phase AMLs indicating that acquisition of additional driver mutations contributes to relapse. AMLs frequently acquire additional mutations in the same genes and pathways that already harbored mutations at diagnosis.

#425 SMRT® Sequencing of full-length androgen receptor isoforms in prostate cancer reveals previously hidden drug resistant variants. Manish Kohli,1 Yeung Ho,2 David W. Hillman,3 Jamie L. Van Etten,2 Christine Hessler,2 Rendong Yang,2 Yingming Li,3 Elizabeth Tseng,2 Ting Hon,2 Tyson A. Clark,2 Liguang Wang,2 Kevin Silverstein,2 Liewei Wang,2 Scott M. Dehm,4 Mayo Clinic, Rochester, MN; 3University of Minnesota, Minneapolis, MN; 4Pacific Biosciences, Menlo Park, CA.

Prostate cancer is the most frequently diagnosed male cancer. For prostate cancer that has progressed to an advanced or metastatic stage, androgen deprivation therapy (ADT) is the standard of care. ADT inhibits activity of the androgen receptor (AR), a master regulator transcription factor in normal and cancerous prostate cells. The major limitation of ADT is the development of castration-resistant prostate cancer (CRPC), which is almost invariably due to transcriptional re-activation of the AR. One mechanism of AR transcriptional re-activation is expression of AR-V7, a truncated, constitutively active AR variant (AR-V) arising from alternative AR pre-mRNA splicing. Noteworthy, AR-V7 is being developed as a predictive biomarker of primary resistance to androgen receptor (AR)-targeted therapies in CRPC. Multiple additional AR-V species are expressed in clinical CRPC, but the extent to which these may be co-expressed with AR-V7 or predict resistance is not known. Here we utilized long read sequencing to identify and quantify AR isoforms expressed in CRPC. To unambiguously characterize all AR isoforms, we prepared Iso-Seq™ libraries via 3' rapid amplification of cDNA ends (RACE) with RNA isolated from prostate cancer cell lines and xenograft tissues using a forward primer anchored in AR exon 1. 3' RACE reactions were subjected to single molecule, real-time (SMRT®) long-read sequencing with a Pacific Biosciences RSII System. Our work identified AR-V9 as a truncated isoform that is frequently co-expressed with AR-V7 in CRPC. Mechanistically, our work re-annotated AR-V7 and AR-V9 mRNAs, showing these two species shared a common 3' terminal exon containing separate splice acceptor sites. Taking into account this new information, novel siRNAs and antibodies which could distinguish between AR-V7 and AR-V9 were designed and used to measure the relative expression of these two AR isoforms in CRPC cells with a view to determining the potential of AR-V9 as a predictive biomarker of primary resistance to AR-targeted therapies.

#426 Targeted genome profiling in patients with advanced hepatocellular carcinoma treated with sorafenib. Wonseok Kang, Kyung Kim, Joon Hyook Lee, Ho Yeong Lim, Woong-Yang Park, Jeeyoong Lee, Yong Ha Paik. Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Background/Objectives: Sorafenib is the only approved targeted agent as first-line treatment for advanced hepatocellular carcinoma (HCC). Unfortunately, many HCC patients are initially not responsive to sorafenib. Due to anatomic limitations and underlying liver dysfunction, genomic studies of HCC patients have not been actively pursued yet compared to other solid tumors; especially, in sorafenib-treated subset. In this study, we have retrospectively identified advanced HCC patients who had archival tumor tissues available for targeted genomic sequencing and who had been treated with sorafenib. Methods: We performed targeted genomic profiling for 381 cancer-related genes from 42 HCC (32 hepatitis B virus-related, 1 alcohol-related, 7 unknown) patients treated with sorafenib at Samsung Medical Center, Seoul, Korea from July 2008 to October 2013. We excluded 2 patients who were lost to follow up for evaluation of treatment response to sorafenib. Results: Of the 40 patients, there were 5 confirmed PRs, 7 SDs, and 28 PDs. In 40 patients, there were 6 CDKN2A amplifications, 4 NTRK1 amplifications, 2 MET amplifications, 2 FGFR1 amplifications, 2 CCND1 amplifications, 1 EGFR amplification, 1 FGFR2 amplification and 1 CCNE1 amplification. In cell cycle-related genes, those patients with aberrations were less likely to respond to sorafenib. Of note, two patients whose tumor had CCND1 amplifications had de novo resistance to sorafenib. Conclu-
sions: Our study demonstrates inter-patient heterogeneity in advanced HCC patients and the role of cell cycle-associated genes in resistance mechanism to sorafenib is being investigated.

#427 A path towards determining tumor mutation burden and identifying neoantigens using next-generation sequencing (NGS). Alex So, Shannon Kaplan, Nai-yu Wang, Shile Zhang, Aaron Wise, Kristina Kruglyak, Karen Gutekunst, Illumina, San Diego, CA.

Introduction: The recent clinical demonstrations that cancer immunotherapy is effective for some patients, but not others has led to widespread interest in identifying cancer genetic factors that can predict positive response. Importantly, it has been shown by various studies that tumor mutation burden (TMB) and predicted neoantigen load correlate with patient response to checkpoint inhibitors. This project aims to develop a clinical next-generation sequencing (NGS) assay that utilizes TMB and neoantigen information to guide cancer immunotherapy selection. Experimental Procedures: Whole exome sequencing (WES) and whole transcriptome sequencing (WTS) libraries were generated using Illumina’s TruSeq® Exome and RNA Access library preparation kits, respectively. The samples were pair-end sequenced (2x75bp) using HiSeq® 2000 and 2500 instruments. Data Summary: Here, we demonstrate a workflow using tumor/normal WES and tumor-only WTS to determine expressed TMB. Using the WES data, we were also able to accurately identify human leukocyte antigen (HLA) major histocompatibility complex (MHC) Class I genes at four-digit resolution. We then identified putative neoantigens, defined as peptides with mutated amino acids, that were expressed in the tumor samples and predicted to bind to the respective HLA sequences. In addition, as a path towards developing a clinical assay for TMb and neoantigen determination, we tested the ability of reagents developed for Illumina’s TruSight® Tumor 170 panel to be used for an exome panel. With workflow modifications, we achieved comparable quality of sequencing metrics as compared to the TruSeq® Exome kit. Conclusion: Our data demonstrate a path towards developing a clinical assay that can be used to assess TMB and neoantigen candidates.

The identification of neoantigens has become a critical step in the development of neoantigen-based personalized cancer vaccines and other immunotherapy applications. Since neoantigens can be generated from tumor specific mutations in any expressed gene, the first step in identification of neoantigens typically involves deep exome and transcriptome sequencing on the tumor and exome sequencing of the matched normal. As personalized vaccines enter clinical trials with the potential for clinical use, there is a growing need for strong analytical validation of these platforms. To address this we have developed our ACE Exome (~200X) and Transcriptome platforms for neoantigen identification which utilize an augmented exome approach designed to increase sensitivity for neoantigens in low complexity, traditionally hard to sequencing regions. To enable this platform for neoantigen based personalized cancer vaccines, we have performed a validation of both our ACE Exome (tumor and normal) and ACE transcriptome platforms for detecting DNA-based SNVs and Indels, as well as for RNA based small variant and fusion calls. These are variant types are especially important for neoantigen identification. In this abstract we describe the ACE Exome validation. We used 11 cancer cell lines and their matched normals to assess analytical sensitivity and limits of detection (LOD) for small variant (SNV and Indel) detection using our ACE exome and Tumor Normal bioinformatics pipeline. We identified a gold set of variants, 875 SNVs and 19 Indels that were previously validated in these 11 cell lines (COSMIC, CCLE and Sanger Sequencing confirmed variants). These gold set variants were used to calculate our analytical sensitivity (percent of gold variants detected across the 11 cell line pairs using our assay). To determine our LOD, we chose 3 of the 11 cancer cell lines and created 6 dilutions (5%, 10%, 20%, 30%, 50% and 80% tumor purity) with their matched normal. We then determined Positive Predictive Agreement (PPA, percent of pure cell line variants detected in a diluted samples) and False Discovery Rate (FDR, percent of erroneously detected variants in the diluted sample that were not detected in the pure cell lines) metrics for variants across different minor allelic frequencies (MAF) in the diluted samples. Our ACE “Tumor Normal” Exome assay had a high sensitivity of 98% for SNVs and 95% for Indels. The assay also showed robust PPA (sensitivity) of 97% and FDR (specificity) of 2% for SNVs with MAF > 10% and PPA of 87% and FDR of 3% for Indels with MAF > 10%. We demonstrate that the ACE “Tumor Normal” Exome assay is highly accurate for identification of SNVs and Indels in cancer exomes. With high analytical sensitivity, PPA and low FDR we believe this assay provides augmented ability to detect cancer driver and potential neoantigen generating mutations across various tumor types.

#429 Integrated genomic DNA and RNA profiling to predict cancer immunotherapy response. Pan Du, Xiaohong Wang, Zhixin Zhao, Huiqiang Wang, Shidong Jia. Predicine Inc, Hayward, CA.

Immunotherapy response varies widely, making it difficult for physicians to know whether immunotherapy will be effective for a given patient. Recent studies have reported that patients with high PD-L1 gene expression are likely to respond to checkpoint blocking drugs, but there are still many patients whose tumor test for the PD-L1 protein are negative and can respond to the drugs. In addition to the potential link between mismatch repair (MMR) gene mutations and clinical response to anti-PD1 immunotherapy drug, recent findings show that tumor mutation burden and microsatellite instable (MSI) are good indicators of the cancer immunotherapy responses. Using Predicine’s proprietary Gene RADAR (RNA and DNA single molecular digital Readings) technology, here we report the development of PrediSeq-CI (Cancer Immunotherapy) panel for comprehensive genomic profiling of DNA and RNA that are associated with cancer immunotherapy response. The panel has been tested using both tissue biopsy and plasma samples. The development of PrediSeq-CI test has potential to enable precision medicine in cancer immunotherapy. Finally, we also developed a liquid biopsy droplet digital PCR test to measure PD-L1 expression in blood.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Metabolic Pathways in Cancer

#430 Combination of CB-839 and everolimus is effective in inhibiting growth of endocrine resistant breast cancer in vivo. Yassi Fallah,1 Diane M. Demas,2 Susan Demo,3 Ayesha N. Shahjahan-Haq.4 Georgetown Lombardi Comp. Cancer Ctr., Washington, DC;5 Caliterra Biosciences, South San Francisco, CA.

About 70% of all breast cancers are estrogen receptor alpha positive (ER+). Anti-hormone therapy such as antiestrogens are often used to treat ER+ breast cancer but breast cancer cells can develop resistance to these drugs (endocrine resistance). Unfortunately, ~50% percent of all antiestrogen treated tumors eventually develop endocrine resistance, and therefore, there is an urgent need to find ways to treat this incurable disease. We have shown that endocrine resistant breast cancer cells show an increased dependence on the amino acid glutamine and this process is regulated by MYC activation via the unfolded protein response (UPR). Metabolites of glutamine such as glutamate and proline are significantly elevated in endocrine resistant cells. Cellular changes in glutamine are sensed by the mammalian target of rapamycin (mTOR) complex, mTORC1, which is known to be deregulated in endocrine resistant breast cancer. In this study, we used human antiestrogen (Fulvestrant/Faslodex or Tamoxifen) sensitive and resistant ER+ breast cancer cell lines and xenografts to test the efficacy of CB-839, an anti-glutaminase, and everolimus (Afinitor), a mTORC1 inhibitor. Combination of CB-839 and everolimus, but not each drug alone, inhibited growth of antiestrogen resistant tumors compared to vehicle alone at 4 weeks post-treatment. The combination treatment did not significantly inhibit growth of antiestrogen sensitive tumors compared with its respective vehicle alone treatment. Thus, a combination strategy that targets glutamine dependence and increased mTOR activation may be a novel strategy in treating endocrine resistant breast cancer.

#431 IDH1-mutated gliomas rely on anaplerosis of glutamate and lactate whereas IDH1 wild-type gliomas rely on glycolysis and acetate anaplerosis. Mohammed Khurshed,1 Krissie Lenting,2 Remco J. Molenaar,3 William P. Leenders,4 Cornelis J. van Noorden1.

Academic Medical Center, Amsterdam, Netherlands; 2Radioudum, Amsterdam, Netherlands.

Hotspot mutations in isocitrate dehydrogenase 1 (IDH1MT) initiate low grade glioma (LGG) and secondary glioblastoma and induce neomorphic activity that converts α-ketoglutarate (α-KG) to the oncometabolite D-2-hydroxyglutarate (D-2HG). The IDH1MT enzymatic rewiring that is not fully understood and in vitro and in vivo studies have shown that IDH1MT cancer cells rely on glutaminolysis, providing cells with α-KG via activities of glutaminase (GLS) and glutamate dehydrogenase (GLUD). Here, we first show by in silico analysis of 269 IDH1 wild-type (IDHWT) and 408 IDH1MT gliomas, obtained from the The Cancer Genome Atlas (TCGA)
database, that IDH1WT gliomas have high expression levels of genes encoding for enzymes that are involved in glycolysis and acetate anaplerosis. On the other hand, the tricarboxylic acid (TCA) cycle, rather than glycolytic lactate production, is the predominant metabolic pathway in IDH1MT gliomas and is driven by lactate and glutamate anaplerosis to facilitate production of α-KG, and ultimately D-2-HG. IDH1WT- and IDH1MT-related differences in expression were found in both LG2 and glioblastoma. Furthermore, via in situ enzymatic activity mapping, we show in human gliomas and in xenocraft models that GLUD activity is increased and GLS activity is decreased in IDH1MT glioma, indicating that IDH1MT gliomas depend on glutamolysis, rather than glutaminolysis. We show that transcript levels in our xenocraft models are in good agreement with our in silico analysis of the TCGA database. Finally, we confirmed the glutamate dependency of IDH1MT gliomas by MRS-flux analysis, whereas IDH1WT gliomas show high lactate production. Taken together, we show that IDH1WT gliomas have a typical Warburg phenotype and rely on glutamate anaplerosis whereas IDH1MT gliomas are glutamate and lactate dependent. This metabolic rewiring in IDH1MT glioma, enables targeting of glutaminolysis rather than direct inhibition of IDH1 for therapy. It diminishes the supply of glutamate-derived α-KG and indirectly inhibits the production of D-2-HG and simultaneously worsens the redox status of the glioma cells by inhibiting NAD(P)/H production by GLUD. A candidate drug to inhibit GLUD is epigallocatechin-3-gallate, a component of green tea that is currently receiving high interest as anti-cancer agent.

Isolation of specific metabolic alterations in aggressive triple negative and inflammatory breast cancers provides a compelling avenue for the development of treatments for these diseases. The ability of cancer to utilize diverse metabolic pathways to modulate increased survival and proliferation is well established. Indeed, we have previously described a series of metabolic adaptations in the triple negative inflammatory breast cancer cell line SUM149 and demonstrated a role for the small GTPase RhoC in the metabolic phenotype of the cell line. In this work we seek to describe a survival mechanism for cancer cells that are subjected to hypoxic environments. Hypoxic survival or growth is an important research goal in cancer research. Understanding the mechanisms through which these changes occur and why they are important for continued survival and growth of the cancer cells are ongoing and will be presented.

#432 xCT inhibition disrupts redox homeostasis in CD44v-expressing tumor cells showing glutaminolytic metabolism in head and neck squamous cell carcinoma. Here we show that inhibition of xCT suppressed the consumption of glutamine without the concomitant decrease of NAD(P)/H production by glucose oxidation. These studies suggest that xCT can be a potential target for therapeutic intervention.

#433 Glycogen accumulation in aggressive breast cancers during hypoxic exposure. Morgan Altemus, Joel Yates, ZhiFen Wu, LiWei Bao, Sofia Merajver. University of Michigan, Ann Arbor, MI.

Isolation of specific metabolic alterations in aggressive triple negative and inflammatory breast cancers represents a compelling avenue for the development of treatments for these diseases. The ability of cancer to utilize diverse metabolic pathways to modulate increased survival and proliferation is well established. Indeed, we have previously described a series of metabolic adaptations in the triple negative inflammatory breast cancer cell line SUM149 and demonstrated a role for the small GTPase RhoC in the metabolic phenotype of the cell line. In this work we seek to describe a survival mechanism for cancer cells that are subjected to hypoxic environments. Hypoxic survival or growth is an important research goal in cancer research. Understanding the mechanisms through which these changes occur and why they are important for continued survival and growth of the cancer cells are ongoing and will be presented.

#434 Characterizing the role of serine metabolism in pediatric sarcomas. Sameer Issaq,1 Ria Kidner,1 Jason Rohde,2 Matthew Boxer,2 Lee Helman1. 1National Cancer Institute, Bethesda, MD; 2National Institutes of Health, Rockville, MD.

Pediatric sarcomas represent a diverse group of malignancies with unique molecular and pathological characteristics. In order to improve sarcoma treatment, a better understanding of the alterations associated with specific sarcoma subtypes is critically important. Renewed interest in the altered metabolic properties of cancer cells has led to an exploration of targeting metabolic dependencies as a novel therapeutic strategy. Metabolism of the amino acid serine is frequently altered in cancer, supporting a number of critical biological processes, including protein, lipid, and nucleotide synthesis, and redox balance. The first, rate-limiting step in the serine synthesis pathway is catalyzed by the enzyme 3-phosphoglycerate dehydrogenase (PHGDH), which is overexpressed in several cancers. Previous work has shown that PHGDH loss or inhibition is selectively toxic to cancer cells with high PHGDH expression or increased flux through the serine synthesis pathway. In this study, we have characterized the dependency of pediatric sarcomas on serine metabolism by examining expression of PHGDH in Ewing sarcoma and rhabdomyosarcoma cell lines, and evaluating the effects of PHGDH inhibition on serine deprivation on cellular proliferation and bioenergetic properties. We show that PHGDH is highly expressed in pediatric sarcoma cell lines, and that PHGDH knockdown resulted in decreased proliferation, especially under conditions of serine limitation. Moreover, pharmacological inhibition of PHGDH resulted in a dose-dependent decrease in proliferation and mitochondrial bioenergetic function. Furthermore, individual sarcoma cell lines were differentially sensitive to serine deprivation, indicating that some sarcoma cell lines may depend on extracellular serine in addition to de novo serine synthesis. Our findings suggest that the dependency of pediatric sarcomas on serine metabolism should be further investigated in order to identify vulnerabilities that could be targeted for potential therapeutic benefit.

#435 Regulation of macropinocytosis-dependent cell survival in pancreatic cancer cells. Sung Eun Kim, Man-Tzu Wang, Frank McCormick. UCSF, San Francisco, CA.

Cancer cells utilize multiple scavenging mechanisms to support growth in nutrient-poor, hypoxic environments. Signaling pathways to accommodate these mechanisms may not be required for oncogenesis per se but are crucial for cancer cell survival. These processes, known as non-oncogene addiction, can be conferred by specific oncogenes that reprogram metabolism or by the tumor microenvironment. Understanding how these pathways are regulated can provide novel opportunities for therapeutic intervention. Studies showed that KRAS-mutant cancer cells, including pancreatic ductal adenocarcinoma (PDAC), upregulate macropinocytosis, a caveolin- and clathrin-independent endocytic process, to import extracellular protein to support growth upon nutrient depletion. Similarly, high levels of macropinocytic uptake are observed in PDAC murine models and also in human PDAC specimens. This process serves as a scavenging mechanism for cancer cells to survive and proliferate in nutrient-deprived tumor microenvironments. Thus, uncovering the key players of this pathway and the mechanisms underlying their regulation will be important to find potential therapeutic targets. Here, we used the Informer set of small molecules to screen regulators of survival in culture conditions supplemented with either glutamine or extracellular protein. The Informer set drug library consists of small molecules including FDA-approved drugs and clinical candidates that have high selectivity for their targets and regulate many cellular pathways. We find that survival of cells grown in conditions supplemented with glutamine or exogenous protein is differentially regulated by distinct drug subsets. This suggests that different pathways of nutrient uptake, processing, and utilization are used in cells depending on the nutrient source. Further examination to determine the mechanism of pathway inhibition and applicability may unravel potential uses for therapeutics.

### #436 Folate cycle represents a new metabolic vulnerability for hepatocellular carcinoma treatment.

Derek Lee, Irene Ming-Jing Xu, David Kung-Chun Chiu, Robin Kit-Ho Lai, Chun-Ming Wong, Carmen Chak-Lui Wong. The University of Hong Kong, Hong Kong.

Hepatocellular carcinoma (HCC), primary liver cancer, ranks the third most lethal cancer globally, and tumor incidence is maintained through the shuttling of a single carbon unit by a folate derivative through the tetrahydrofolate (THF) backbone in the cytoplasmic and mitochondrial compartments, metabolites like NADPH - a major cellular antioxidant for redox balance, s-adenosyl methionine (SAM) - precursor of DNA and histone methylation, and pyrimidine and purine - the building blocks of DNA are produced. We found folate to be indispensable for HCC cell growth. Furthermore, methylene-THF dehydrogenase 1-like (MTHFD1L), a key enzyme facilitating the folate cycle from the mitochondria, was found to be significantly up-regulated in HCC with association to poorer clinical features for patients. Genetic inhibition of MTHFD1L by knockdown and knockout by shRNA and CRISPR-Cas9 systems, respectively, blocked NADPH production. Rapid elevation in oxidative stress induced DNA damage and cell cycle delay; meanwhile, reduced glutathione (GSH) and cell proliferation. Binding of the transfection factor, NRF2, a potent protector of oxidative stress, and MTHFD1L was confirmed by ChIP assay. NRF2 over-expression using the CRISPR-activating system in HCC cells further highlighted the dependent relationship between NRF2 and MTHFD1L. Metabolomics analysis showed that MTHFD1L knockdown caused a disruption to the folate cycle and accumulation of serine. Surprisingly, MTHFD1L knockdown did not reduce the levels of SAM and nucleotides. Knockdown of MTHFD1L in HCC cells significantly inhibited primary liver tumor growth and lung metastasis in orthotopic liver implantation model. Therapeutically, the administration of methotrexate, an anti-folate agent, sensitized HCC cells towards Sorafenib treatment both in vitro and vivo. The folate cycle represents a metabolic vulnerability and attractive therapeutic target for HCC. Inhibition of MTHFD1L disrupts the folate cycle and sensitizes HCC cells towards its convention treatment agent, Sorafenib in various HCC mouse models. Our investigation unravels a metabolic vulnerability in cancer which contributes to better understanding and is beneficial for the development of precise inhibitors specifically targeting associated pathways.

### #437 Stromal support of pancreatic tumor metabolism.

Costas A. Lysioti. University of Michigan, Ann Arbor, MI.

Pancreatic Ductal Adenocarcinoma (PDAC) is an aggressive disease characterized by a prominent desmoplastic stromal reaction and deregulated metabolism. The role of stroma in PDAC biology is complex and has been shown to play critical roles that may differ depending on the biological context. The intense stromal reaction also impacts the vasculature, leading to a highly hypoxic and nutrient poor environment. As such, these tumors must adapt how nutrients are captured and utilized to support their metabolic needs. In this talk, I will describe how stromal-associated pancreatic stellate cells (PSCs) are critical for PDAC metabolism through the secretion of non-essential amino acids (NEAA). Specifically, we uncovered an undescribed role for alanine, which outcompetes glucose and glutamine-derived carbon in PDAC to fuel the tricarboxylic acid (TCA) cycle, and thus NEAA and lipid biosynthesis. This shift in fuel sources decreases the dependence on glucose and serum-derived nutrients, which are limiting in the pancreatic tumor microenvironment. Moreover, we demonstrated that PSC alanine secretion is dependent on PSC autophagy, a process stimulated by the cancer cells. Thus, our results demonstrate a novel metabolic crosstalk between PSCs and cancer cells, with PSC-derived alanine as an alternative carbon source and proton donor to support the metabolic needs of the cancer cells. To further dissect alanine metabolism, we compared PSCs isolated from normal human pancreas, PDAC-adjacent tissue, and pancreatic tumors where diverse fuel sources are utilized to promote growth in an austere tumor microenvironment.

### #438 Cholesterol biosynthesis is a critical metabolic dependency in pancreatic cancer.

Linara Gabitova, Alena Klochkova, Diana Restifo, Aleksandra Mazitova, Edna Cukierman, Tiffany Hartman, Igor Astsaturov. Fox Chase Cancer Center, Philadelphia, PA.

Pancreatic cancer is rapidly rising to become the 2nd leading cause of cancer deaths by 2020 in the USA. The rise in pancreatic cancer incidence is paralleled by the epidemic of obesity, type 2 diabetes, and associated increase in blood cholesterol, although mechanistic explanations for this are currently unknown. We and others have demonstrated that cancers with altered EGFR and KRAS signaling have increased demands for cholesterol and are vulnerable to interference with cholesterol uptake or endogenous cholesterol biosynthesis. We recently identified a metabolic step in the distal cholesterol pathway, mediated by SC4MOL and NSDHL enzymes, as a critical regulator of cell growth in the keratinocyte model of KRAS-induced pancreatic cancer via the lipid mediator 22R-cholesterol. Based on these preliminary data, we set out to test if pancreatic cancer initiation and progression depend on accelerated cholesterol biosynthesis in a genetic mouse model containing a conditional cholesterol pathway enzyme deficiency (conditional knock-out of Nsdhlf1) in the context of pancreatic cancer development in KPC mice (LSL-KrasG12D,Trp53R16H, Pdx1-Cre). Results: Conditional inactivation of NSDHL alone in pancreatic tissues during normal development produced no apparent phenotype. As expected, the NSDHL-deficient KPC mice as well as heterozygous Nsdhlf1+/− littersmates did not survive beyond 8 weeks of age due to rapid development of progressive pancreatic tumors showing complete displacement of pancreatic tissue with adenocarcinoma and high-grade PanIN lesions. Contrastingly, the survival of pancreatic conditional NSDHL-null mice was significantly extended beyond the median survival of 50 days in NSDHL-sufficient age-matched controls. Furthermore, the progression of pancreatic lesions from ADM to PanIN3 was remarkably delayed on NSDHL-null background, with only a proportion of animals developing adenocarcinoma. Evaluation of pancreatic tissues revealed a dramatic reduction of tumor-induced desmoplaxia at all stages of tumor progression. Our findings support the role of cholesterol metabolism in pancreatic cancer progression via regulation of tumor-specific production of stroma-recruiting growth factors. Conclusions: Our studies demonstrated for the first time essential genetic evidence for metabolic dependency of pancreatic cancer on cholesterol metabolism. We identified NSDHL as a critical target in the endogenous pathway of cholesterol biosynthesis, and determined that blockade of NSDHL has dramatic consequences on the reciprocal signaling between the KRAS-transformed pancreatic cancer cells and the stroma.

### #439 Metabolic flux analysis reveals targets to sensitize chemoresistance in acute myeloid leukemia induced by mesenchymal stromal cell-derived exosomes.

Abhinav Achreja,1 Hongyun Zhao,1 Ziwen Zhu,2 Jonathan Gersberg,2 Marina Y. Konopleva,2 Michael Andreeff,2 Deepak Nagrath1.1University of Michigan, Ann Arbor, MI; 2The University of Texas MD Anderson Cancer Center, Houston, TX.

The tumor microenvironment has a pleiotropic role in supporting cancer cell growth, metastasis and drug resistance. Exosomes from mesenchymal stromal cells (MSC) were found to regulate metabolism of acute myeloid leukemia (AML) cells that led to a chemoresistant phenotype. Exosomes carry a host of proteins, nucleotides and metabolites that can induce metabolic reprogramming of recipient cells via direct supply of metabolite cargo or through signaling. We utilized 13C tracer techniques and two metabolic flux analysis techniques to reveal the mechanism of metabolic reprogramming induced by MSC-derived exosomes. First, 1C metabolic flux analysis was used to quantify intracellular fluxes of central carbon, amino acids and fatty acid metabolism in AML cells cultured with and without exosomes in media supplemented with 13C-labeled precursors. Second, we employed a novel technique, exosome-mediated metabolic flux analysis (Exo-MFA), to estimate direct support provided by metabolite supply from exosome cargo by introducing 13C-labeled exosomes. The combined analysis dissected the metabolite supply from exosome cargo from the overall reprogramming of metabolic pathways due to exosomes. Our results revealed key metabolic pathways that could be targeted to inhibit exosome-induced reprogramming to reverse the chemoresistant phenotype.

### #440 The oncogenic activity of a pro-oxidant intracellular milieu is associated with redox dependent activation of NF-kB.

Evidence over the years has highlighted that intracellular redox status plays a critical role in determining cell fate. To date, we have shown that a pro-oxidant milieu, specifically a mild elevation of intracellular superoxide, promotes cancer cell survival and chemoresistance. To that end, we demonstrated in vitro that elevated superoxide, upon silencing of superoxide dismutase (SOD1), resulted in sustained phosphorylation of Bcl-2 at serine 70, thereby stabilizing its anti-apoptotic activity. These findings were corroborated by the abundance of Serum 70 Bcl-2-phosphorylation and low SOD1 expression in lysates of patients with aggressive lymphomas and/or disease with poor prognosis. In addition to the anti-apoptotic protein Bcl-2, the pro-inflammatory transcription factor nuclear factor kappa B (NF-kB)-

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 111
Diaited signaling was also shown to be modulated by intracellular redox milieu. As constitutive activation of NF-κB has been reported in various human tumors, which is often associated with malignant progression and chemotherapeutic resistance, here we set out to investigate whether a pro-oxidant environment, specifically the upregulation of intracellular superoxide, was associated with the induction of NF-κB transcriptional activity. Indeed, cellular redox imbalance demonstrated that elevated intracellular superoxide via the pharmacological inhibition and genetic silencing of SOD1 results in enhanced activation of canonical NF-κB signalling. This is accompanied by increased p65 nuclear localization and transcription of NF-κB regulated genes, which potentially confer survival advantages to tumour cells upon chemotherapeutic treatments.

Epithelial-cell derived tumors exhibit the Warburg effect that is characterized by an increased rate of glycolysis and lactate release, as well as, reduced oxidative metabolism. It is known that these metabolic alterations of cancer cells result in a tumor microenvironment with a lower pH than that of the plasma. However, little is known regarding the physiology and metabolism of cancer cells enduring chronic acidosis. We cultured pancreatic cancer cells in chronic acidosis, i.e. pH 6.9 to 7.0, and observed a shift from glycolytic metabolism to oxidative metabolism that also results in reduced cell growth and increased intracellular ROS levels. We identified that this is due to an increase in glutamine uptake and increased expression of the transaminase enzyme GOT1 that enhances glutamine metabolism. Survival in low pH is reduced upon depletion of GOT1 due to further increased intracellular ROS levels. Thus, GOT1 plays an important role in energy metabolism and ROS balance in chronic acidosis stress. Our studies suggest the therapeutic potential of targeting anaplerotic glutamine metabolism in pancreatic cancer.

Small molecule inhibitors of SHMT1/2 validate serine metabolism as a therapeutic target in cancer. James Abrego, Venugopal Gunda, Enza Vernucci, Surendra Shukla, Ryan J. King, Aneesa Daogupta, Nina Chaika, Pan-kaj Kumar Singh. UNMC Eppley Inst. for Cancer Research, Omaha, NE.

Many oncogenes modulate metabolic pathways and altered metabolism is one of the hallmarks of cancer. In order to sustain proliferation, cell growth and adopt to a very specific tumor microenvironment, cancer cells have to undergo metabolic reprogramming. Increased uptake of glucose, consumed in anaerobic manner, allows to maintain essential bioenergetic and biosynthetic pathways. Various reports indicated that many cancers cells are crucially dependent on serine, which could be either imported or synthesized by the serine synthesis pathway (SSP) branched from glycolysis. Serine can be converted to glycine by SHMT1, which fuels cytoplasmic folate cycle and SHMT2, which also carbon for the folate cycle. There is a growing interest in targeting SSP and its key enzymes, which potentially could be exploited for combinatorial therapy to increase the vulnerability that could be exploited for combinatorial therapy to increase the metabolic vulnerability that could be exploited for combinatorial therapy to increase the efficacy of AZD3965.

Monocarboxylate transporters (MCTs) are key mediators of lactate transport that have emerged as promising targets for anti-cancer therapy. The MCT1 inhibitor AZD3965 (AstraZeneca) has shown promising activity in various preclinical models and is currently in phase I/II clinical testing. Understanding the impact of this drug on tumour cell metabolism may unravel dependencies that could be exploited for combination therapy. Here we investigate changes in glucose metabolism induced by AZD3965 treatment using 13C NMR isotope-labeling experiments and mitochondrial complex I inhibitor mitrocomplex. Exposure of Raji human lymphoma cells to AZD3965 in media supplemented with [1-13C]glucose led to a marked reduction in glucose uptake and lactate production in the cellular growth media along with a build-up in intracellular [3-13C]lactate and [1-13C]glucose levels, indicative of blockade of lactate excretion and inhibition of overall glycolytic activity. These effects were concomitant with increased [4-13C]glutamate levels, consistent with re-routing of pyruvate towards mitochondrial metabolism and enhanced flux through oxidative pyruvate dehydrogenase. Further, AZD3965 treatment was paralleled with a significant increase in levels of steady state Krebs cycle-related metabolites (including succinate, fumarate, acetate and NAD+/NADH) and cellular ATP, as revealed by bioluminescent and 13C NMR analyses, indicating improved mitochondrial bioenergetics and cellular re-energization. Co-administration of the mitochondrial complex I inhibitor metformin with the mitochondrial pyruvate carrier inhibitor UK5099 markedly potentiated the anti-proliferative effects of AZD3965 and led to significantly increased cell death, indicating that the observed upregulation in mitochondrial metabolism was necessary to maintain cell survival under MCT1 inhibitor-induced metabolic stress. These data suggest that targeting MCTs represents a viable strategy for cancer therapy.
#445 Efficient tumorigenesis after genetic dissociation of glycolysis and the TCA cycle. Laura E. Jackson,1 Sucheta Kulkarni,2 Huabo Wang,1 Jie Lu,1 Sivakama Bharathi,1 Radha Uppala,1 Mulchand S. Patel,1 Eric S. Goetzman,1 Edward V. Prochownik.1,2 Children’s Hospital of Pittsburgh of UPMC, Pittsburgh, PA; 2State University of New York at Buffalo, Buffalo, NY.

Virtual tzero some form of metabolic re-programming to match anabolic needs with energy supply. The best-known form of this is the Warburg effect by which tumors become more reliant on glycolysis over mitochondrial oxidative phosphorylation, even when their oxygen supply is abundant. Nonetheless, mitochondria retain some residual activity in order to provide both ATP and critical metabolic building blocks and other substrates for processes such as lipid biosynthesis and protein acetylation. The pyruvate dehydrogenase (PDH) complex (PDC) is the main enzymatic link between glycolysis and the TCA cycle and irreversibly converts the end-stage glycolytic product pyruvate into the critical TCA substrate, acetyl-coenzyme A (AcCoA). In a mouse model of the pediatric liver cancer hepatoblastoma (HB), we recently showed PDH to be highly up-regulated, despite reduced mitochondrial function. We postulated that this might represent a response to pyruvate depletion due to upstream shunting of glycolytic intermediates into anabolic pathways. To test this idea, we examined in vivo tumorigenesis in mice bearing a hepatocyte-specific conditional knockout of the pdha1 subunit (KO mice). The survival of these mice was marginally longer than the wild-type (WT) controls, although tumor sizes at time of death were ~20% smaller. KO mice expressed virtually no PDH (and hence no PDC activity) and had high blood lactate levels. This suggested that they succumbed with smaller tumors as a result of severe lactic acidosis that could not be corrected by hyperventilation due to respiratory compromise by the large HBs that restricted lung volumes. This was supported by studies performed in a modified form of this model in which only tumors were PDH deficient whereas the surrounding liver parenchyma was not. These mice now survived longer than did their WT counterparts and their tumors reached comparable sizes. They also had lower lactate levels than the pan-KO mice. Oxygen consumption rates of WT and KO tumors were similar yet lower than those of normal livers. Rates of fatty acid β-oxidation by WT and KO tumors were also lower than those of liver, indicating that both types of tumors preferentially divert fatty acids into membrane synthesis rather than toward tumorigenesis genes at mRNA level in the eFAT. Moreover, the expression of brown adipocyte-specific thermogenic genes such as Ebf2, Prdm16, PGC1α, UCP1, SRC1 and IRF4 were strongly induced at the protein level in eWAT of ZAG-cell implanted mice suggesting that ZAG causes WAT browning. Furthermore, met-1 expression was associated with a decrease in body weight (2.5 g) and with improvements in food consumption and physical activity. Morphological examination of eWAT pads of ZAG-cell implanted mice showed smaller size compared to controls. In addition, morphological examination of eWAT showed cell shrinkage and almost complete depletion of fat stores, suggesting enhanced lipolysis in the WAT. Notably, ZAG induced the expression of beige, mitochondrial, and thermogenesis genes at mRNA level in the eFAT. Moreover, the expression of brown adipocyte-specific thermogenic genes such as Ebf2, Prdm16, PGC1α, UCP1, SRC1 and IRF4 were strongly induced at the protein level in eWAT of ZAG-cell implanted mice suggesting that ZAG causes WAT browning. Furthermore, metabolomic analysis revealed increased O2 consumption and heat production in ZAG-cell implanted mice compared to controls indicating increased total body energy expenditure. ZAG-cell implanted mice also displayed reduced respiratory exchange ratio indicating increased consumption of lipids. Overall, our findings suggest that ZAG functions beyond lipolysis and causes significant energy wasting by causing WAT browning and promoting glucose and lipid catalolism in the beige cells. These findings suggest that ZAG plays a predominant role in the development of cachexia, and thus, may represent a novel therapeutic target to block energy wasting and delay or prevent cachexia in cancer patients.

#446 Differential effects of folate depletion on metabolic reprogramming and oxidative stress in nonmetastatic and metastatic claudin-low breast cancer cells. Xuewen Chen, Ciara H. O’Flanagan, Stephen D. Hurting, University of North Carolina, Chapel Hill, NC.

Folate coenzymes play an important role in biosynthesis and methylation reactions. Folate metabolism is implicated in the development of several cancer types, though mechanisms underlying folate metabolism and cancer development remain unclear. We previously showed that a folate-restricted diet can exert differential effects on metabolic versus nonmetastatic murine claudin-low breast cancer cells in vivo. Specifically, folate restriction increased growth and invasion of orthotopically transplanted M-Wnt (nonmetastatic) tumor cells, but decreased growth and lung metastases of transplanted metM-Wnt cells, a metastatic subtype of M-Wnt cells. The current study set out to explore the underlying mechanism. To examine the effect of long-term folate depletion (LFD) on M-Wnt and metM-Wnt cell metabolism, oxidative stress and autophagic flux in vitro, the two cell lines were grown in standard and folate-depleted media for 14 days. metM-Wnt cells showed higher oxidative stress, as measured by ROS staining and Nrf2 expression, and phosphorylation of the key nutrient sensor, AMPK, compared to M-Wnt cells when grown in standard growth medium. LFD M-Wnt cells showed an increased dependence on glycolysis compared to those cultured in standard medium. Both M-Wnt and metM-Wnt cells displayed a high autophagy level in LFD, measured by LC3B cleavage, and AMPK phosphorylation such as lipid biosynthesis and protein acetylation. The decrease in oxidative stress and loss of redox defense, as measured by cleaved-caspase 3 and Nrf2 expressions. These results suggest that non-metastatic M-Wnt cells undergo metabolic reprogramming, including a shift from oxidative phosphorylation to glycolysis that may fuel cell growth and proliferation. Further, an elevated autophagic flux may mitigate nutrient stress induced by folate depletion, which allows them to withstand LFD and which may contribute to a more invasive primary tumor in response to folate restriction. In contrast, met-Wnt cells are unable to undergo this metabolic adaptation, and display increased oxidative stress and cell death in response to LFD, preventing the development of metastatic lesions in vitro. This study highlights different responses of primary and metastatic breast cancer cells to folate depletion. The results provide additional rationale for targeting folate metabolism as a potential strategy for treating metastatic breast cancer.

#447 ZAG promotes cachexia-associated white adipose tissue browning and energy wastage. Sawssan Elattar, Satyanarayana Ande. Augusta University, Augusta, GA.

Cancer cachexia is a complex condition of tissue wasting that affects up to 80% of cancer patients. To date, there is no effective treatment for cachexia due to the complex nature of this condition. Energy wasting in cachexia is caused by excessive lipid and protein turnover in the body, browning of white adipose tissue (WAT), and futile metabolic cycling such as glucose recycling between the liver and tumor. Therefore, identifying and inhibiting factors that promote WAT browning, and glucose and lipid recycling can reduce energy wasting and ameliorate cachexia in cancer patients. Zinc-2α-glycoprotein (ZAG), a lipid mobilizing factor secreted by multiple cancers, has been shown to promote lipolysis and inhibit lipogenesis in WAT. However, whether ZAG plays any role beyond lipolysis and participates in other energy wasting mechanisms of cachexia such as glucose and lipid recycling, and WAT browning has not been explored. Our initial studies indicate that while ZAG is highly expressed in the heart, kidney, and liver of wild-type mice, the basal expression of ZAG is very low in WAT at both the mRNA and protein levels. To investigate the metabolic functions of ZAG in vivo, ZAG-expressing 293 cells were implanted subcutaneously in athymic nude mice, and analyzed them after 3 and 6 weeks. We detected a 3-fold increase in the circulating plasma levels of ZAG. Importantly, the increase in ZAG levels was associated with a decrease in body weight (2.5 g), with any differences in food consumption and physical activity. Morphological examination of eWAT pads of ZAG-cell implanted mice showed smaller size compared to controls. In addition, histological examination of eWAT showed cell shrinkage and almost complete depletion of fat stores, suggesting enhanced lipolysis in the WAT. Notably, ZAG induced the expression of beige, mitochondrial, and thermogenesis genes at mRNA level in the eFAT. Moreover, the expression of brown adipocyte-specific thermogenic genes such as Ebf2, Prdm16, PGC1α, UCP1, SRC1 and IRF4 were strongly induced at the protein level in eWAT of ZAG-cell implanted mice suggesting that ZAG causes WAT browning. Furthermore, metabolic analysis revealed increased O2 consumption and heat production in ZAG-cell implanted mice compared to controls indicating increased total body energy expenditure. ZAG-cell implanted mice also displayed reduced respiratory exchange ratio indicating increased consumption of lipids. Overall, our findings suggest that ZAG functions beyond lipolysis and causes significant energy wasting by causing WAT browning and promoting glucose and lipid catalolism in the beige cells. These findings suggest that ZAG plays a predominant role in the development of cachexia, and thus, may represent a novel therapeutic target to block energy wasting and delay or prevent cachexia in cancer patients.

#448 Role of fructose in prostate cancer. Daniela Carreño,1 Nestor Corro,1 Marcia Arredondo,1 Carmen Narvarro,1 Verónica Torres,1 Viviana Montecinos,1 Paula Sotomayor,2 Francisco Nualart,3 Julio Cesar Cárdenas,4 Alejandro S. Godoy,1 Pontificia Universidad Católica de Chile, Santiago, Chile; 2Universidad Andres Bello Santiago, Santiago, Chile; 3Universidad de Concepción, Concepción, Chile; 4Universidad de Santiago, Chile.

The elevated level of glucose uptake and metabolism in cancers is the basis for the clinical localization of primary cancers and sites of metastasis by positron emission tomography (PET scanning), based on the enhanced cellular uptake of 2-deoxy-2-[18F]-fluoro-D-glucose (FDG). In prostate cancer (CaP), however, FDG-PET imaging has shown limited clinical applicability. This striking difference suggests that CaP cells utilize hexoses other than glucose, such as fructose, as the principal energy source. The purpose of this study was to determine whether or not fructose is a/the principal source of energy for CaP cells. mRNA and protein expression for the glucose transporter Glut-1 and fructose transporters Glut-2, Glut-5, Glut-7, Glut-9 and Glut-11 was analyzed in benign (PWR-1E, RWPE-1) and malignant (LNCaP, vCaP, LNCaP-C4-2, DU-145, and PC-3) human prostate cell lines using qRT-PCR and western blot, respectively. In addition, Glut(s) protein expression was analyzed on a tissue microarray containing 200 formalin-fixed paraffin-embedded benign and malignant human prostate tissues using immunohistochemistry. Fructose and glucose uptake was measured in vitro in benign and malignant human prostate cell lines using [1-14C]fructose or 2-[1,2-3H]-deoxy-D-[14C]glucose, respectively. Lastly, the effect of fructose or glucose on the levels of ATP, mitochondrial metabolism, and expression of the enzymes hexokinase-2 (HK2), type-C fructokinase (HKH-C), pyruvate kinase M2 (PKM2) and type-A lactate dehydrogenase (LDH-A) was analyzed in benign and malignant human prostate cell lines.
using chemiluminescence, seahorse, and qRT-PCR analyses, respectively. Our results indicated that expression of the fructose transporters, Glut-5 and Glut-9, was increased in CaP cell lines and in human CaP tissues compared to benign cell lines and benign prostate tissues, respectively. Glut-1 expression, however, did not differ between benign and malignant human prostate cells. Transport assays demonstrated that CaP cell lines have higher expression of Glut-1 compared to benign cells. However, glucose uptake was not altered between benign and malignant human prostate cell lines. ATP levels in CaP cells were similar in the presence of fructose or glucose. Fructose, but not glucose, significantly altered mRNA expression of HK2, HKH-C, PKM2, and LDH-A in malignant human prostate cells. Taken together, our results suggest that fructose may represent an alternative energy source and may reprogram hexose metabolism in CaP cells.

**#449 Reduced argininosuccinate synthetase expression in refractory sarcomas: impacts on therapeutic potential and drug resistance.** Eiuke Kobayashi,1 Youngji Kim,1 Daiusuke K Kubota,2 Yoshiyuki Suchara,1 Akira Kawai,1 Shigehisa Kitano.1 National Cancer Center Hospital, Tokyo, Japan;2Juntendo University, Tokyo, Japan.

Introduction: Treating drug-resistant sarcomas remain a major challenge. The present study aimed to identify a novel therapy for drug-resistant sarcomas based on a metabolic error involving argininosuccinate synthetase (ASS1). Methods: We assessed the expression of ASS1 and P-glycoprotein (P-gp) in osteosarcoma (KHOs), doxorubicin (Dox)-resistant osteosarcoma (KHOsD), epithelioid sarcomas (ES-X and VAESB), alveolar soft part sarcoma (ASPS-KY), and each clinical specimen. Each cell was cultured in arginine-containing and arginine-free media. Cell growth was assessed using an XTT assay and flow cytometry. We analyzed the induction of autophagy in arginine-free medium. Moreover, we assessed the expression of P-gp in after suppressing ASS1 in Dox-sensitive cells (MCF-7, KHOs) and in after transfecting the ASS1 into Dox-resistant cells (ES-X, VAESB, ASPS-KY and KHOsD). Results: The expression of ASS1 was reduced in Dox-resistant sarcoma cells. Immunohistochemistry (IHC) and real-time PCR showed that there was interestingly an inverse relationship between the expression of ASS1 and the expression of P-gp. The inhibition of cellular proliferation with G1-arrest was shown to lead to autophagy with arginine deprivation. In addition, the combination of autophagy inhibitor plus arginine deprivation was more effective than arginine deprivation alone. In cells in which the expression of ASS1 was suppressed, the expression of P-gp was upregulated in comparison to negative controls. Discussion: These results indicate that the reduced expression of ASS1 expression in Dox-resistant sarcomas may contribute to drug resistance. ASS1 deficiency is a potential target for novel drug therapies. The combination of arginine deprivation therapy and an autophagy inhibitor may have anti-tumor effects in refractory sarcomas. Significance: As the induction of autophagy by the deprivation arginine may play a pro-survival role in patients with ASS1-deficient sarcomas, the combination of arginine deprivation therapy with autophagy modulators might potentiate anti-tumor effects in patients with drug-resistant sarcomas.

**#450 Aldo-keto reductase family 1 member b1 links glucose metabolism to epithelial-to-mesenchymal transition.** Annemarie Schwab,1 Aarif Siddiqui, Maria Eleni Vazakidou,1 Francesca Napoli,1 Martin Boettcher,2 Bianca Trinchieri1. 1IZKFJunior Research Group, 1 University Hospital Erlangen, Erlangen, Germany; 2Department of Internal Medicine 5, Hematology and Oncology, University Hospital Erlangen, Erlangen, Germany.

Introduction: Treating cancer cachexia is currently defined as a state of ill health, malnutrition and physical wasting with marked white adipose tissue (WAT) and skeletal muscle mass wasting, representing the clinical consequence of a chronic and systemic inflammatory response. Over the last decade, WAT has been recognized as an important endocrine organ, and earning a lot of attention during cancer cachexia development. We investigated the role of microbiota along the cachexia associated cancer. We performed experiments with conventional and Germ Free mice (GF) (n=6 in each group) of 8-10 weeks old C57B1/6, which were subcutaneously injected with LLC cells [4x10⁶ cells in 0.2 mL; Tumor-bearing, (TB) or PBS control (C)]. We performed Immunohistochemistry, RT-qPCR, and Western Blot. We observed that GF Tumor-bearing mice have increased several symptoms of the cachexia compared to conventional TB mice. The WAT mass was decreased 50% in GF Tumor-bearing mice compared to all groups, which indicates a pathway related to lipolysis, as we found increased level of phosphorylated enzymes in GF Tumor-bearing mice. We also observed that GF Tumor bearing mice decreased skeletal muscle mass and gene expression that are related with atrophy were increased in GF Tumor bearing mice. Our data suggested that homeostasis of microbiota may impair the development of the cachexia syndrome.

**#451 Germ free mice accelerate cachexia-associated cancer.** Rodrigo Xavier da Neves,1 Soumen Roy,1 Amiran Dzatsev,1 April Huang,1 Loretta Smith,1 Simone Ditlippannatto,2 Hawes Misty,1 Marília Seaelder,2 Giorgio Frinchieri1. 1NCI, Bethesda, MD; 2ICB, Sao Paulo, Brazil.

The hallmark of cancer cachexia is currently defined as a state of ill health, malnutrition and physical wasting with marked white adipose tissue (WAT) and skeletal muscle mass wasting, representing the clinical consequence of a chronic and systemic inflammatory response. Over the last decade, WAT has been recognized as an important endocrine organ, and earning a lot of attention during cancer cachexia development. We investigated the role of microbiota along the cachexia associated cancer. We performed experiments with conventional and Germ Free mice (GF) (n=6 in each group) of 8-10 weeks old C57B1/6, which were subcutaneously injected with LLC cells [4x10⁶ cells in 0.2 mL; Tumor-bearing, (TB) or PBS control (C)]. We performed Immunohistochemistry, RT-qPCR, and Western Blot. We observed that GF Tumor-bearing mice have increased several symptoms of the cachexia compared to conventional TB mice. The WAT mass was decreased 50% in GF Tumor-bearing mice compared to all groups, which indicates a pathway related to lipolysis, as we found increased level of phosphorylated enzymes in GF Tumor-bearing mice. We also observed that GF Tumor bearing mice decreased skeletal muscle mass and gene expression that are related with atrophy were increased in GF Tumor bearing mice. Our data suggested that homeostasis of microbiota may impair the development of the cachexia syndrome.

**#452 Activation of Akt pathway and autophagy promotes resistance to FASN inhibition in colorectal cancer patient-derived xenograft models.** Yekaterina Y. Zaytseva,1 Piotr G. Rychahou,1 Anh-Thu Le,1 Robert M. Flight,1 Timothy L. Scott,1 Jennifer W. Harris,1 Sally Hodges,1 Brent J. Hallahan,1 Dana L. Napier,1 Jinpeng Liu,1 Chi Wang,1 Manjula Sunkara,1 Andrew Morris,1 Ji Tae Kim,1 Sivakumaran Theru Arumugam,1 Andrew Lane,1 Teresa W. Fan,1 Hunter Moseley,1 Tianyan Gao,1 Eun Y. Lee,1 Heidi L. Weiss,1 Timothy S. Heuer,2 George Kemble,2 B Mark Evers1. 1University of Kentucky, Lexington, KY; 23-V Biosciences, Menlo Park, CA.

Fatty Acid Synthase (FASN), a key enzyme of de novo lipogenesis, is upregulated in many cancers including colorectal cancer (CRC), increased FASN expression is associated with poor prognosis. Potential FASN inhibitors developed by 3-V Biosciences demonstrate anti-tumor activity in vitro and in vivo and a favorable tolerability profile in a Phase I clinical trial in solid tumor patients. However, CRC characteristics associated with responsiveness to FASN inhibition are not fully understood. The purpose of our study was: (i) to determine the effect of FASN inhibition on tumor growth in CRC patient-derived xenografts (PDXs); (ii) to identify potential biomarkers associated with CRC responsiveness to FASN inhibition; and (iii) to explore new combination strategies with FASN inhibitors. METHODS. Tumor growth was assessed in 9 PDXs established in NSG mice using freshly resected specimens. Once the xenografts grew to 100 mm³, mice were randomized into two groups (n = 5) to receive either...
Orlistat is a weight loss medication that reduces weight/size by 66% in the obese mice and 23% in the lean mice ($p < 0.05$). In addition, orlistat decreased expression of FAS, ACC and carnitine palmitoyltransferase 1A, consistent with an inhibitory effect on fatty acid metabolism. De novo FA synthesis is energetically expensive; in most normal cells FASN expression is low and de novo synthesis suppressed in favor of the FA palmitate. De novo FA synthesis is an important source of precursors needed to support tumor growth. Much of the utilization of exogenous FA. In contrast, in cancer cells, de novo FA synthesis is crucial to tumor growth require the TCA cycle for the processing of glucose and amino acids. This is well known for its role in gluconeogenesis. However, PEPCK is well known for its role in gluconeogenesis. This growth advantage was mediated in part through regulating metabolic flux of glucose and glutamine to biosynthetic precursors, such as lipids and nucleic acids. These effects of PEPCK on glucose metabolism and cell proliferation are in part mediated via activation of mTORC1. Currently we are investigating the mechanism(s) responsible for how PEPCK regulates cell signaling via metabolic flux. We are also seeking to identify ways in which we can utilize PEPCK as a therapeutic target.
median FABP5 expression levels as high as that observed in GS 7-10 PCas. IHC confirmed variable expression of both FABP5 and FASN, including “patchwork” PCs with high Gleason pattern (GP) areas overexpressing FABP5 next to low GP areas overexpressing FASN. The net result may be a selective advantage for the high grade cancer if FABP5 allows it to exploit the FA being synthetized by the adjacent low grade focus. In a subset of PCs, FABP5 and FASN expression was highlighted in the most dense region of PC nuclei staining consistent with its proposed role in regulating fatty acid mediated gene expression; the ratio of FABP5 nuclear/cytoplasmic staining was higher in PCs from AA than from EA patients (P < 0.05). Identification of a PCa subtype with high levels of FABP5 overexpression suggests a previously unrecognized mechanism by which some PCs can increase FA supply without de novo synthesis. Such a PCa subtype might be particularly sensitive to dietary interventions and relatively insensitive to FASN inhibitors.

#458 Choline metabolism in cancer cells modifies PD-L1 expression, Balaji Krishnamachary, Marie-France Penet, Yelena Mironchik, Zaver M. Bhujwalla.

Increased expression of choline kinase-α (Chk-α), the enzyme that converts choline to phosphocholine has been observed in most cancer cells including breast (1). This increase of choline kinase results in increased production of phosphocholine that is used in the synthesis of membrane phosphatidylcholine. We investigated the relationship between Chk-α and the programmed death ligand-1 (PD-L1) expression in triple negative MDA-MB-231 human breast cancer cells. Expression of PD-L1 in response to the secretion of interferon gamma (IFNγ) by cytotoxic T cells and its binding to the immune checkpoint PD-1 on T cells in cancer cells by engagement of PD-L1 can be blocked by antagonistic antibodies to PD-L1 system (2). Quantitative real-time PCR analysis (q-RT-PCR) did not reveal any change in PD-L1 mRNA expression between MDA-MB-231 expressing an empty vector control plasmid (231-EV) and MDA-MB-23 stably expressing shRNA against Chk (231-Chk). However, there was a difference in the mean intensity fluorescence (MIF) between 231-EV (325 ± 11.5, n = 2) and 231-Chk (527 ± 18.5, n = 2) in the FACS analysis. Upon induction with IFNγ (100ng/ml) for 24h, there was 1.23 fold increase in PD-L1 mRNA in 231-Chk compared to 231-EV. Interestingly, the MIP for cell surface expression of PD-L1 was 600 ± 21 (n = 2) for 231-EV compared to 872 ± 16 (n = 2) for 231-Chk cells. Values represent mean ± SE. These data suggest that the cell surface increase of PD-L1 in 231-Chk cells could be due to translocation. Increased PD-L1 expression creates an opportunity to deliver PD-L1 targeted nanoparticles carrying therapeutic cargo. Since most conventional treatments result in a decrease of Chk-α and phosphocholine, our data suggest that these treatments may also result in cancer cells escaping immune surveillance through expression of PD-L1. #459 Targeting MUC1 mediated nucleotide metabolism sensitizes pancreatic cancer to radiation therapy, VENUGOPAL GUNDU, Joshua Soucheek, Jaime Abrego, Gennifer Goode, Enza Vernucci, Surendra K. Shukla, Aneesha DasGupta, Nina V. Chaika, Ryan King, Fang Yu, Tadayoshi Bessho, Chi Lin, Wang Shou, Li Sicong, Pankaj K. Singh. UNMC, Omaha, NE.

Pancreatic cancer has the lowest survival rate of six percent among all the cancers in the US and is projected to be the second leading cause of cancer related deaths in a decade. Radiation therapy provides only marginal increases in the survival rate in pancreatic cancer, due to poor responsiveness of pancreatic tumors. Clinical trials indicate a significant response to radiation only in twenty percent of primary pancreatic tumors. While multiple factors cause resistance to radiation therapy, the biological mechanisms mediating such innate resistance are currently being explored. Overexpression of MUC1 facilitates chemo and radiation resistance in pancreatic cancer. MUC1 overexpression also promotes pancreatic tumor growth through metabolic upregulation. We investigated the in vivo role of MUC1 mediated metabolic alterations in radiation response of pancreatic tumors. Our findings indicate that MUC1 expressing pancreatic tumors survive better upon radiation treatment. Metabolomic analysis through liquid chromatography coupled tandem mass spectrometry approach revealed that MUC1 expressing pancreatic tumors exhibit higher glycolytic and nucleo- tide metabolites upon irradiation. MUC1 expressing tumors also possess relatively higher PPP and nucleotide metabolites. Glycolytic inhibition using bro-mopyruvate revealed that MUC1 induced radiation resistance could be abrogated through inhibition of glucose carbon flux into nucleotide metabolism by BrPA. Treatment with BrPA effectively reduced glycolysis, pentose phosphate pathway and nucleotide levels in irradiated MUC1 expressing cells. Furthermore, a combination of BrPA and radiation reduced tumor growth in MUC1 expressing tumors. Metabolomic analysis showed a decrease in the glycolysis, PPP and nucleotide metabolites in MUC1 expressing tumors upon combination treatment with radiation and BrPA. Hence, our findings demonstrate that glycolytic inhibition could be used to effectively target MUC1 mediated radiation-resistance in pancreatic tumors.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Metabolic Pathways in Cancer

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: MicroRNA Regulation of Cancer Biology 1

#460 A central microRNA checkpoint for the inflammatory stem cell niche, Xiling Shen. Duke Univ., Durham, NC.

The microRNA miR-34a is a well-known tumor suppressor in various types of cancer. Previous studies largely focused on its role in suppressing oncogenic pathways such as Bcl2 and Myc. This study will demonstrate a previously un- known function of miR-34a—a central regulator of tissue integrity in the inflammatory colon stem cell niche by modulating both proinflammatory response and stem cell behavior. Epigenetic silencing of miR-34a by a long non-coding RNA (IncRNA), Linc34a, subverts this checkpoint to promote cancer stem cell proliferation. In DSS- and bacteria-induced colitis models, miR-34a (1) suppresses differentiation of CD4+ T cells into Th17 cells by directly targeting interleukin-17 (IL17) receptor genes in Th17 cells and the inflammatory niche by directly targeting chemokine CCL2 from epithelial cells, (2) attenuates the effect of IL17 on stem cells by directly targeting IL17 receptors in stem cells, and (4) switches on asymmetric division to curb stem cell proliferation. We further show that a novel lncRNA, Linc34a, is upregulated by Notch signaling during colorectal cancer (CRC) progression and epigenetically silences miR-34a promoter by recruiting Dnmt3 and HDAC1. This process moves the miR-34a checkpoint of the inflammatory niche and contributes to proliferation of stem-like cancer cells. Our finding of miR-34a as an inflammatory checkpoint suggests potential therapeutic strategies to reinforce or restore such miR-34a functions in colitis patients to prevent CRC and in CRC patients to prevent proliferation of cancer stem cells. Furthermore, MRX34, a miR-34a mimic, is the first microRNA mimics to reach phase II clinical trial for cancer therapy, which is ongoing. However, delivery efficiency into the tumor is always a challenge for microRNA mimics. Our discovery of Linc34a, which recruits epigenetic regulator to silence miR-34a, provides a promising therapeutic target, because it is much easier to develop small molecule inhibitors to disrupt IncRNA structure or block its functional interaction with protein than to restore mi- croRNA expression.

Pediatric and adult angiosarcomas are rare and highly aggressive soft tissue sarcomas with an extremely poor prognosis. Due to the rarity of this disease especially in children, the molecular drivers and optimized treatment strategies for patients are lacking, highlighting the need for genetic and in vivo animal models. MicroRNAs are a class of small RNAs that regulate gene expression and are often dysregulated in cancers including sarcomas. Dicer1 is required for microRNA biogenesis and germline Dicer1 mutations result in a cancer predisposition syndrome associated with increased risk of benign and malignant tumors including rhabdomyosarcoma (RMS), a pediatric soft tissue sarcoma resembling developmentally arrested skeletal muscle. Here we show Dicer1 expression is required for tumorigenesis in a mouse model of RMS driven by activation of oncogenic Smoothened by Cre recombinase expressed from the adipose protein 2 (a2p) promoter (a2p-Cre). Unexpectedly, in studying the role of Dicer1 in RMS, we found that Dicer1 deletion with a2p-Cre leads to aggressive angiosarcoma. Angiosarcoma occurs in settings independent of the Smoothened oncogene and other genetically engineered oncogenes or tumor suppressor loss, providing the first in vivo mouse model of biallelic Dicer1 loss alone driving tumorigenesis. Angiosarcomas in a2p-Cre;Dicer11−/− mice histologically and genetically resemble human angiosarcoma and were enriched for microRNA-23 target genes including the oncogene Ccnd1 as well as Adam19, Plau, and Wsb1 that promote invasiveness and metastasis. The a2p-Cre;Dicer11−/− model provides a simple in vivo animal model to study angiosarcoma for novel therapeutics and the molecular mechanisms of cancer initiation, progression, and metastasis. In addition, our results demonstrate Dicer1 and microRNAs play major and opposing roles in sarcomagenesis.
The incidence of prostate cancer (PCa) among African-Americans (AfA) is significantly higher than Caucasian-Americans (CaA) but the genetic basis for this disparity is not known. To address this problem, we analyzed miRNA expression in AfA (n=81) and CaA (n=51) PCa patients. Here, we found that miR-24 was significantly expressed in AfA and CaA PCa tissues and that the expression of miR-24 promoter confirmed that it was highly methylated and downregulated in CaA PCa patients. Utilizing a VAMCS and NDRI patient cohorts, we discovered that miR-24 expression was linked to a racial difference between AfA/CaA PCa patients. Interestingly, miR-24 was restored after treatment of PCa cells with 5Aza-CdR in an AfA cell line (MDA-PCa-2b), while restoration of miR-24 was not observed in CaA cells, DU-145. Ectopic expression of miR-24 showed decreased growth and induced apoptosis, though the effect was less in the CaA cell line compared to the AfA cell line. Finally, we found unique changes in biological pathways and processes associated with miR-24 transfected AfA cells by quantitative PCR-based gene expression pathway analysis. The altered pathways showed that AR, MAPK1, IGFI, and IGFBRP5 were markedly decreased in the AfA derived cell line compared with CaA cells, and there was a reciprocal regulatory relationship of miR-24/target expression in prostate cancer patients. These results demonstrate that miR-24 may be a central regulator of key events that contribute to race-related tumorigenesis and has potential to be a therapeutic agent for PCa treatment.

MicroRNA-7 suppresses RB1 expression leading to chromosomal instability in leukemia cells harboring c-KIT mutation. Kenji Kurata,1 Shunichi Kawamori,1 Junya Takase,1 Katuya Yamamoto,1 Hiroshi Matsuoka,1 Takayuki Akita,1 Hirobou Minami1. 1Kobe University Hospital, Kobe, Japan; 2Osaka Medical College Hospital, Osaka, Japan; 3Japanese Red Cross Osaka Blood Center, Osaka, Japan.

C-Kit mutation D816V is a well-known indicator of poor prognosis in acute myeloid leukemia (AML) harboring t(8;21) chromosomal translocations. However, the mechanism D816V mutation promotes therapeutic resistance is still under investigation. C-Kit V814 mutation is a murine counterpart of the human D816V. We utilized a murine IL-3 dependent cell line Ba/F3 with or without the c-Kit V814 mutation to investigate its downstream signaling pathway and the effect on the expression of bcl-2 family members and critical granulocytic transcription factors. The c-Kit V814 and wild type (WT) c-Kit were retrovirally transduced into Ba/F3 cells. Unexpectedly, Gata1 mRNA was significantly downregulated to one-tenth in V814+/Ba/F3 cells (p < 0.01, contrary to the previous reports that WT c-Kit signaling induces Gata1 expression. When V814+/Ba/F3 cells were treated with several c-Kit signaling pathway inhibitors, miRNA and protein expression levels of Gata1 recovered to normal levels only with MEK 1/2 inhibitor (PD325901) treatment. We then hypothesized that miRNAs might control Gata1 transcription. We used an array to identify differences in miRNA expression between Ba/F3 cells and V814+/Ba/F3 cells, and between V814−/Ba/F3 cells treated with or without PD325901. Only miR-7a-5p and miR-706 were significantly upregulated in V814−/Ba/F3 cells compared with Ba/F3 without the V814 mutation, and downregulated (> 2-fold) in cells treated with PD325901 compared with controls. We focused our further analysis on miR-7 as it is highly conserved in vertebrates. The differences in miR-7 expression were confirmed using qRT-PCR (10.5-fold change, p < 0.01). In silico analysis implicated Rb1 as a candidate miR-7 target that may regulate Gata1 transcription. Luciferase reporter constructs containing murine and human Rb1 miR-7 target sequence exhibited 0.51 and 0.49 times lower luciferase activity than the control, respectively (p < 0.01). To further define the mechanism of the c-Kit mutation that would transform the cells to a more aggressive phenotype, we focused on DNA and chromosomal instability caused by Rb1 deterioration. We exposed WT c-Kit Ba/F3 and V814+/Ba/F3 cells to 4 Gy irradiation and then used immunohistochemistry to analyze the frequency of H2AFX foci in the cells. The percentage of cells with more than 10 H2AX foci was significantly higher in V814+/Ba/F3 cells than WT Ba/F3 cells (72% vs 14%, P < 0.05). Here, we clearly show that a single mutation of c-Kit is sufficient to regulate miR-7 expression leading to Rb1 translational suppression. Since c-Kit mutation requires only a single step to inhibit Rb1, this mechanism is more likely to facilitate oncogenesis by bi-allelic Rb1 chromosomal and/or gene alterations in leukemic cells. Taken together, we identified miR-7 as a suppressor of Rb1 in V814 mutation-positive cells, which might reflect the responsibility of D816V to re-factory feature in AML.

Novel role of xpo1 in regulating MicroRNAs related to pancreatic ductal adenocarcinoma invasion and metastasis. Asfar S. Azmi,1 Yiwei Li,1 Irfana Musgil,1 Amro Aboukameel,1 William Senapedis,2 Erkan Baloglu,1 Yosef Landesman,3 Michael Kaufman,3 Sharon Shacham,2 Philip A. Philip3, Ramzi M. Mohammad1,1 Wayne State Univ., Detroit, MI; 2Karyopharm Therapeutics, Newton, MA.

Objective: There are no known reports on the role of exportin 1 (XPO1; also known as chromosome maintenance region 1 [CRM1]) in microRNA biology. In this study, we for the first time demonstrate that interfering with XPO1 machinery can influence miRNA signaling leading to suppression of pancreatic ductal adenocarcinoma (PDAC) proliferation, invasion and metastasis. Methods: miRNA arrays (LCSiences, Houston, TX) were performed on total RNA samples from PDAC cell lines (HPAC, MiaPaCa-2, AsPC-1 and L3.6ipl) and normal human pancreatic duct epithelial (HPDE) cells. PDAC cells were treated with XPO1 inhibitor (Selinexor) or transfected with control siRNA, XPO1 siRNA (Santa Cruz), miR-control or miR-145 mimic (Applied biosystems) all at a final concentration of 20 nM using DharmaFect Transfection Reagent (Dharmacon, Lafayette, CO). The total RNA and total protein from treated or transfected cells were subjected to real-time PCR or immunoblot analysis in order to measure expression level of miR-145, let-7d, miR-34c, miR-320, miR-205, and miR-145 target or downstream genes including EGFR, MIP, MT-MMP, c-Myc, Sox-2, and PAR-3. The impact of XPO1 inhibitor Selinexor on PDAC growth, proliferation, invasion and migrations was also evaluated using MTT and scratch assay. Results: In this study, we show that PDAC cells have significantly reduced expression of miR-145 when compared to normal pancreatic duct epithelial cells. Similarly, forced expression of miR-145 in PDAC cells inhibited cell proliferation and migration. Conversely, we demonstrated that RNAi of XPO1 by siRNA knockdown or chemical inhibition of XPO1 by selective inhibitor of nuclear export compound (Selinexor) restores miR-145 expression in PDAC cells ultimately leading to inhibition of cell proliferation and migration. In addition, we show that the inhibition of cell proliferation and migration by Selinexor is mediated through the down-regulation of known miR-145 targets including EGFR, MIP1, MT-MMP, c-Myc, Sox-2, and PAR-3. Selinexor also induced the expression of two important tumor suppressive miRNAs, miR-34c and let-7d, leading to the up-regulation of p21WAF1. We also observed the down-regulation of oncomir mir-205. Conclusion: These results are the first to show that targeted inhibition of the nuclear exporter protein XPO1 by RNAi or Selinexor could restore tumor suppressive miRs in PDAC.

Deregulation of miR-193a and its correlation with clinical and pathological behavior of colorectal cancer. Afraa M. Mamoori,1 Rajwai Alhab,1 Farhadul Islam,1 Katherine Lee,1 Robert A. Smith,2 Vinod Gopalan,1 Al- fred Ky Lam1,1 Cancer Molecular Pathology, School of Medicine, Menzies Health Institute Queensland, Gold Coast, Australia; 2Genomics Research Centre, Institute for Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia.

Aim: Deregulation of miR-193a expression was reported to have significant roles in cancer development and progression. This study aimed to investigate the expression pattern and clinicopathological implication of miR-193a-3p in patients with colorectal cancer. Also, the bio-physiological effects of miR-193a in colon cancer cells were examined. Methodology: Fresh frozen tissues from 70 matched colorectal cancers (adenocarcinomas) and adjacent noncancer tissue samples were prospectively collected with no selection bias. Expression level of miR-193a-3p was measured by quantitative real-time polymerase chain reaction (qRT-PCR). Immunohistochemical staining was used to detect the expression level of K-ras protein as a predicted downstream target for miR-193a. We also observed the down-regulation of oncomir miR-205. Results: These results are the first to show that targeted inhibition of the nuclear exporter protein XPO1 by RNAi or Selinexor could restore tumor suppressive miRs in PDAC.
cell proliferation, increased apoptosis and a less accumulation of cells in the G0-G1 phase cell cycle. Conclusion: The current study confirms the downregulation of miR-139-3a in colorectal cancer and its tumour suppressor effects in vitro plays a key role in the modulation of K-ras regulated molecular signalling pathways in colon cancers.

#468 Evaluation of microRNA inhibition in medulloblastoma. Alexander Vavra,1 Sydney Stoops,2 Jonathan White2.1 Kansas City University, Kansas City, MO; 2MRIGlobal, Kansas City, MO.

Medulloblastoma is the most common pediatric malignant brain tumor. The current treatment plan consists of a combination of surgery, radiation, and chemotherapy which is a five-year survival rate. However, the survival rate does not take into account the developmental delays and learning disabilities inherited as a result of the aggressive treatment plan on a developing brain. As such the development of new treatment options is needed. While many protein targets are currently being explored for therapeutic intervention, the role of non-coding RNAs is of increasing interest. Specifically microRNA profiling in medulloblastoma has been performed by others to highlight expression profiles which can be mapped to the disease state and also to potentially identify associated protein targets. Moreover, it is particularly intriguing that microRNAs themselves may be directly targeted as therapeutic points of intervention. With this in mind, our lab is currently investigating methods for directly targeting microRNAs in medulloblastoma and we have recently selected several upregulated miRNAs for further investigation. Specifically, we evaluated the expression profile eight-teen selected miRNAs in DAOY and D341 cell lines. Our results indicate that four miRNAs (miR-196a, miR-183, miR-96, and miR-182) are statistically overexpressed in both cell lines. Results of these findings and our initial efforts to target these selected miRNAs will be described.

Background: Colon cancer is one of the most common cancers with increasing incidence and high mortality worldwide. Prognosis and choice of treatment is largely based on the tumor stage at presentation. Thus, finding novel biomarkers for predicting survival is highly desirable. Lately, several studies have been looking at microRNAs (miRNAs) in several cancers, including colon cancer. MicroRNAs are conserved, non-coding RNA molecules that play an important role in the regulation of post-transcriptional gene expression. Material and Methods: In the present study, we have profiled miRNA in one hundred and seventy two TNM stage I-IV colon cancer patients and 10 corresponding normal colon tissue samples. Total RNA was extracted from freshly frozen tissues, and the expression of miRNA profile were assessed using Pick and Mix focus panels from Exiqon containing 84 miRNAs that have been linked to cancer. Results: The results were visualized in a heatmap (Qucoore omics Software) and more than 20 miRNAs were found to be differentially expressed in tumors compared to the normal colon. Further, twelve miRNAs were found to discriminate between relapse and no-relapse patients in TNM stage II and III. Additionally, we evaluated expression of four microrna (miR-23a, miR-25, miR-30d and miR-31) were found to be statistically significant in binary logistic regression with relapse as outcome variable. In univariate analysis, low expression of the four-miRNA signature was associated with better 3-year disease-free survival (DFS), 88 % versus 63% in low versus high expression, respectively (P=0.001). Moreover, the signature was a predictor of both relapse-free survival in multivariate analyses (P=0.001; HR 31; 95% CI: 3.8-248.9). Another regression analyses method (LASSO) identified a 16-miRNA signature, and the four miRNAs found earlier were among them. The 16-miRNA signature was associated with better survival (P<0.001). Conclusion: The present study has identified a four-miRNA signature predicting relapse in colon cancer stage II and III patients.

#470 Epstein-Barr virus-encoded miR-BART5 modulates PIAS3-pSTAT3 and p21waf1 in gastric carcinoma cells. Dong Ha Kim,1 Chan Jin Yoon,1 Jin-Seoub Kim,1 Sunyoung Park,2 Euno Choi,2 Jun Hee Woo,3 Mee Soo Chang2.1 Asan Institute for Life Sciences, University of Ulsan College of Medicine, Seoul, Republic of Korea; 2Seoul National University College of Medicine Boramae Hospital, Seoul, Republic of Korea; 3Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea.

The ubiquitious Epstein-Barr virus (EBV) is associated with a subset of gastric carcinomas. MicroRNAs (miRs) are 22-2 nucleotide non-coding RNAs, and regulate various functions in cells. EBV-encoded miRs in gastric carcinoma cells have been identified, but the targets and roles of EBV-encoded miRs remain elusive. In the present study, we investigated cellular targets of miR-BART5, and its possibility as an oncomir. In naturally EBV-infected gastric carcinoma cells and EBV-positive gastric carcinoma tissues, the comprehensive EBV-miR profile revealed the expression of 22 EBV miRs (each having -3p and -5p) composed of miR-BART cluster 1 and cluster 2, without miR-BHRFS. Using bioinformatics analysis, we focused on miR-
BART5 which shared seed sequence homology with hsa-miR-18a and miR-18b having oncorm function, and protein inhibitor of activated STAT3 (PIAS3) mRNA. The western blot results confirmed that PIAS3 protein expression was reduced in miR-BART5-expressing gastric carcinoma cells (EBV-negative gastric carcinoma cells transfected with miR-BART5), compared with mock cells. Also, PIAS3 expression was significantly lower in naturally EBV-infected gastric carcinoma cells than in EBV-negative gastric carcinoma or EBV-infected lymphoma cells. Moreover, there was a statistically significant inverse correlation between the expression of miR-BART5 and PIAS3. The luciferase reporter activity in cells diminished after co-transfection of pEZX-MT06 vector/PIAS3 3′UTR and miR-BART5, compared with co-transfection of empty vector and miR-control or co-transfection of empty vector and miR-BART5. When we tested twenty proteins as downstream candidates of miR-BART5, pSTAT3 increased and p21Waf1 decreased in miR-BART5-expressing gastric carcinoma cells, compared with mock cells, and nuclear translocation of pSTAT3 was observed in miR-BART5-expressing gastric carcinoma cells. In a reverse context that naturally EBV-infected gastric carcinoma cells were transfected with anti-miR-BART5, protein levels were changed likewise; PIAS3 increased, pSTAT3 decreased and p21Waf1 increased. However, there were no statistically significant differences in cellular biologic properties such as proliferation, apoptosis, invasion and migration between miR-BART5-expressing gastric carcinoma cells and mock cells, or between naturally EBV-infected gastric carcinoma cells transfected with anti-miR-BART5 and mock cells. Taken together, miR-BART5 not only targets directly PIAS3 and then modulates PIAS3-pSTAT3 axis, but also decreases p21Waf1 protein, although it fails to alter cellular proliferation in gastric carcinoma cells. This suggests that a single viral microRNA is not sufficient to implement oncogenic function, despite directly targeting cellular protein involved in oncogenesis. Instead, a whole cluster like miR-BART cluster 1 or cluster 2 may be advocate to control cellular biologic property.

#471 HER2 regulates PARP-1 expression by suppressing the let-7a microRNA in HER2+ breast cancer. Eddy Shih-Hsin Yang, Monicka Wielgos, Rajani Rajbhandari, Shi Wei, Susan Nozell. Univ. of Alabama at Birmingham, Birmingham, AL.

Background: HER2+ breast cancers are sensitive to PARP inhibition and express elevated levels of the PARP-1 protein. However, the mode of regulation of PARP-1 expression by HER2 is not well understood. MicroRNAs are small non-coding RNA that function in RNA silencing and post-transcriptional regulation of gene expression. In this study, we investigate whether PARP1 expression in human breast cancer cells is regulated by HER2通过对microRNAs的调控。

Methods: Human HER2+ breast cancer cell lines BT-474 and SKBR3 were used in this study. MDA-MB-231 (non-HER2 expressing breast cancer cells) stably transfected with a HER2 wild-type plasmid (231 HER2) or the vector control (231 NEO) were also utilized. To identify candidate microRNAs regulated by HER2 overexpression, we performed the nCounter miRNA Expression Assay. MicroRNA and mRNA expression were validated via qRT-PCR analysis in breast cancer cell lines or patient primary tumors. Cells were also transfected with a HER2 siRNA, a let-7a mimic, and an inhibitor of let-7a as well as their respective controls. Western blot analysis and firefly luciferase assays were used to determine whether the 3′UTR of PARP1 was being directly targeted by the let-7a microRNA. Results: HER2 did not regulate PARP-1 at the mRNA level but increased PARP-1 protein in HER2+ breast cancer cells. Specifically, ectopic HER2 overexpression correlated with increased PARP-1 protein levels in the 231 HER2 cell line. Conversely, silencing HER2 reduced PARP-1 protein levels in the BT-474 and SKBR3 cell lines. NanoString nCounter analysis revealed that the HER2+ breast cancer cell lines expressed low levels of the let-7a microRNA. Further, let-7a expression was upregulated after HER2 knockdown in the two native HER2+ breast cancer cell lines. The let-7a mimic also reduced both PARP1 protein expression and luciferase activity in the 231 HER2 and BT-474 cell lines. Conversely, silencing HER2 reduced PARP-1 protein levels in the BT-474 and SKBR3 cell lines. NanoString nCounter analysis revealed that the HER2+ breast cancer cell lines expressed low levels of the let-7a microRNA. Importantly, human HER2+ breast tumors expressed higher levels of PARP-1 and lower levels of let-7a, whereas the HER2- breast tumors expressed lower levels of PARP-1 and higher levels of let-7a. Further, overexpression of the let-7a mimic reduced cell proliferation in HER2+ breast cancer cells. Conclusions: These results suggest that let-7a regulates PARP-1 expression in HER2+ breast tumors. Let-7a may also be a potential therapeutic target and predictive biomarker of PARPi sensitivity in HER2+ breast cancer patients.

#472 Role of miRNAome deregulation in the pathogenesis of non-alcoholic steatohepatitis (NASH)-derived hepatocellular carcinoma. Juliana F. Ortega,1 Aline DeConti,1 Kostiantyn Drevel,1 Fernando S. Moreno,1 Frederick A. Beland,1 Igor P. Pogribny1,1NCTR/FDA, Jefferson, AR; 1University of Sao Paulo, Sao Paulo, Brazil.

Animal studies have attributed the growing incidence of liver cancer, including hepatocellular carcinoma (HCC), in the United States to NASH, an advanced form of non-alcoholic fatty liver disease. Elucidating the molecular pathways that lead to the development of NASH-derived HCC is critical not only for identifying early diagnostic biomarkers of the disease, but also for treatment and prevention. We have investigated the role of microRNA expression profiles in the development of NASH-derived HCC by using a Stelic Animal Model (STAM) of liver carcinogenesis. Using Liver miFinder PCR arrays, we examined the miRNA profiles in the livers of STAM mice and identified 25 and 35 miRNAs that were differentially expressed at a NASH-fibrotic stage (12 weeks) and in full-fledged HCC (20 weeks), respectively. Among these differentially expressed miRNAs, 18 miRNAs were common. Multi-algorithm target prediction analysis of the common differentially expressed miRNAs revealed the involvement of these miRNAs in the deregulation of major molecular processes associated with the development of HCC, including epithelial-mesenchymal transition, HCC stem cell activation, and the induction of the β-catenin/Wnt and Hippo signaling pathways. These findings were confirmed by a marked up-regulation of Yes-associated protein (YAP), the main effector of the Hippo pathway, the activation of epithelial-mesenchymal transition, and an increased-expression of hepatic progenitor cell markers. In addition to the common differentially expressed miRNAs, 10 miRNAs, including 5 members of the poly-cistronic oncomir miR-17-92 cluster, were found to be over-expressed in only HCC. These results indicate the fundamental role of miRNAs in the development of NASH-associated HCC. This is evidenced by the early occurrence of miRNA alterations at the preneoplastic stage of liver carcinogenesis, the persistence of these changes in HCC, and the accumulation of additional miRNA alterations in HCC, and by the existence of a mechanistic link between miRNA alterations and deregulation key cancer-related pathways.

**#474** Estrogen-responsive microRNAs as modulators of E2-induced apoptosis in AI-resistant breast cancer. Reiner Hoppe,1 Ping Fan,2 Stefan Winter,1 Florian Büttner,3 V. Craig Jordan,1 Hiltrud B. Brauch3.1,2 Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, and University of Tuebingen, Tuebingen, Germany;2 MD Anderson Cancer Center, University of Texas, Houston, TX;3Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, and University of Tuebingen, Tuebingen, German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany.

Long-term estrogen deprivation with tamoxifen or aromatase inhibitors (AI) is the basic principle of endocrine treatment of ER-positive breast cancer. Acquired resistance is however a major obstacle in treatment success. Based on clinical observations and in vitro as well as in vivo experiments it has been suggested that tumor cell clones evolve over time and become vulnerable to E2-induced apoptosis, thereby potentially providing a promising second line treatment option. In vitro, this vulnerability is mimicked in the AI-resistant breast cancer models MCF-7:5C and MCF-7:2A, which during long-term E2-deprivation reconfigure their survival signaling including endoplasmic reticulum, oxidative and inflammatory stress related pathways. E2-stimulation of these cells initiates an unfolded protein response which in turn triggers apoptosis through the intrinsic and subsequently extrinsic pathway (Jordan VC 2015). Recently, we identified microRNA profiles matching the biology of AI resistance and vulnerability to E2-induced apoptosis (Hoppe R et al. 2016). Here we investigate the modulatory role of microRNAs in E2-induced apoptosis through the identification of their global expression profiles in E2-stimulated E2-positive breast cancer MCF-7:5C and 2A models compared to MCF-7:W8/3 reference. Each cell line was treated with 10−9 M E2 or vehicle over a 72h time course (6, 12, 24, 72 h). microRNA profiles were generated using Affymetrix GeneChip miRNA2.0 arrays. At each time point relative microRNA expression changes (E2/control) were evaluated resulting in a total of 72 (5C), 104 (2A) and 94 (W8/3) differentially expressed microRNAs (FC > 1.5 or < 1/1.5, P ≤ 0.05). Differential expression analyses between consecutive time points revealed 16 (5C), 43 (2A) and 27 (W8/3) microRNAs (maximum absolute FC difference > 1.5, P ≤ 0.05). Differential area under the curve (dAUC) analyses at 6-24, 6-24 and 24-72 h mined the overall, early, and late-responding microRNAs of the different phenotypes (Pperm < 0.05). Representative early down-regulated microRNA candidates potentially modulating E2-induced apoptosis in 5C cells are miR-543 and miR-432 of the DLK1-DIO3 locus on Chr. 14q32.31. Late responding up-regulated microRNA candidates are miR-150-5p and miR-149-5p, the low expression of which in tumor tissues registered currently in the process to subject respective microRNA sets to functional enrichment analyses (KEGG, GO) and to correlate E2-responsive microRNA candidates with respective transcriptome signatures. In summary, we will present microRNAs matching the biological processes involved in AI-induced apoptosis. These may serve as potential targets for the amplification of the apoptotic trigger upon E2-treatment.

**#475** Role of microRNA-34a in regulating oncoprotein STN1M. Balahadrapruti V.S.K. Chakravarti,1 Rohit Mehra,2 Rui Wang,2 Darshan Shimoga Chandra Shekar,1 Sai Akshaya Hodigere Balasubramanyam,1 Irfan A. Asangani,2 Robert J. Lonigro,2 Arul M. Chinnaiyan,2 Sooryanarayana Varambally1.1 University of Alabama at Birmingham, Birmingham, AL;2 University of Michigan, Ann Arbor, MI;3 University of Pennsylvania, Philadelphia, PA.

MicroRNAs, as negative regulators of gene expression, play a major role in cellular homeostasis. Downregulation of miRs is common in cancer which results in upregulation of multiple oncogenes in cancer. Here we show that stathmin (STN1M), which is over-expressed and oncogenic in wide variety of cancers, is regulated by microRNA-34a in prostate cancer. Earlier studies suggest that stathmin is involved in vital cellular processes such as cell proliferation, motility and metastasis. In the present study, we show elevated expression of stathmin and its 3′UTR in metastatic prostate cancer cell line LNCaP, and at steady state in MCF10A, MCF7, and MDA-MB-231 cell lines, and expression levels of ATF5 were measured under varying physiological conditions via Western Blot analysis. In vitro migration and invasion assays were performed and transformation was studied using MCF10A mammary epithelial cells with inducible SRC. We demonstrate that miRNA are bound to the 3′ UTR of ATF5 and that miRNAs 433-3p and 520b help to regulate the expression of ATF5 under varying stress conditions and the roles in metastasis. Regulation of ATF5 is critical for the regulation of E2-induced apoptosis and transformation in metastatic melanoma. Regulation of ATF5 expression is elevated and is a survival factor in transformed C6 glioma and MCF7 breast cancer compared to non-transformed cells. Regulation of ATF5 expression is not fully understood. We hypothesized that microRNA (miRNA) play a role in regulating the expression of ATF5 at the 3′ UTR and sought to better understand the role of ATF5 in the transformation to a malignant cell phenotype. To date, no studies have examined the regulation of ATF5 by miRNA. MiRNAs are endogenous small non-coding RNAs 20-25 nucleotides in length that contribute to regulation of gene expression at the translational level. We used in silico modeling programs to identify miRNAs predicted to bind to the 3′ UTR of ATF5. We then aimed to identify the presence of specific miRNA and their ability to down-regulate ATF5 during cellular stress and other physiological conditions in vitro. Luciferase reporter assays and immunoprecipitations of ATF5 3′ UTR mRNA and cell lysate were performed and microRNA quantity analyzed via qPCR analysis. Subsequently, transfections of precursor microRNA were carried out in human MCF10A breast epithelial, MCF7 mammary epithelial, and breast adenocarcinoma MDA-MB-231 cell lines, and expression levels of ATF5 were measured under varying physiological conditions via Western Blot analysis. In vitro migration and invasion assays were performed and transformation was studied using MCF10A mammary epithelial cells with inducible SRC. We demonstrate that miRNA are bound to the 3′ UTR of ATF5 and that miRNAs 433-3p and 520b help to regulate the expression of ATF5 under varying stress conditions and their role in metastasis. These results suggest that miR-23a could be important in transformation, migration, and invasion. Better understanding of the regulation of ATF5 could have implications in a broad range of human malignancies.

**#476** MicroRNA mediated regulation of AT5F contributes to homeostasis and benign to malignant transformation in breast cancer cells. Kari Ann Gaither, Bhanupriya Madarampalli, David X. Liu. Washington State University, Spokane, WA.

The transcription factor AT5F modulates survival, proliferation, differentiation, and hormone responses in breast cancer. Earlier studies suggest that microRNAs (miRNA) play a role in regulating the expression of AT5F at the 3′ UTR and seek to better understand the role of AT5F in the transformation to a malignant cell phenotype. To date, no studies have examined the regulation of AT5F by miRNA. MiRNAs are endogenous small non-coding RNAs 20-25 nucleotides in length that contribute to regulation of gene expression at the translational level. We used in silico modeling programs to identify miRNAs predicted to bind to the 3′ UTR of AT5F. We then aimed to identify the presence of specific miRNA and their ability to down-regulate AT5F during cellular stress and other physiological conditions in vitro. Luciferase reporter assays and immunoprecipitations of AT5F 3′ UTR mRNA and cell lysate were performed and microRNA quantity analyzed via qPCR analysis. Subsequently, transfections of precursor microRNA were carried out in human MCF10A breast epithelial, MCF7 mammary epithelial, and breast adenocarcinoma MDA-MB-231 cell lines, and expression levels of AT5F were measured under varying physiological conditions via Western Blot analysis. In vitro migration and invasion assays were performed and transformation was studied using MCF10A mammary epithelial cells with inducible SRC. We demonstrate that miRNA are bound to the 3′ UTR of AT5F and that miRNAs 433-3p and 520b help to regulate the expression of AT5F under varying stress conditions and their role in metastasis. These results suggest that miR-23a could be important in transformation, migration, and invasion. Better understanding of the regulation of AT5F could have implications in a broad range of human malignancies.

**#477** Down-regulated miR-23a contributes to invasion and metastasis of cutaneous melanoma by promoting autophagy. Weinao Guo, Huina Wang, Yuqi Yang, Sen Guo, Weigang Zhang, Tao Zhao, Lin Liu, Zhe Jian, Ling Liu, Gang Wang, Tianwen Gao, Qiong Shi, Chunying Li. Department of Dermatology, Xijing Hospital, Fourth Military Medical University, Xi’an, China.

Background: The occurrence of invasion and metastasis is the major cause of mortality in melanoma. Recent studies suggest that dysregulated microRNAs play critical roles in this procedure, but the underlying mechanism remains elusive. Here, we show that down-regulated miR-23a can promote invasion-metastasis cascade through autophagy in melanoma. Methods: The role of miR-23a in progression was assessed in a cohort of melanoma patients (n = 192) with Kaplan-Meier analysis. The effects of miR-23a overexpression were investigated using assays of invasion, migration, and in a xenograft model (n = 10 mice per group). Autophagy-related target of miR-23a was confirmed by bioinformatics analysis, luciferase assays and immunoblotting. Molecular studies were performed to determine the downstream cellular and molecular mechanisms. All statistical tests were two-sided. Results: Serum miR-23a level was significantly down-regulated in melanoma patients (P < .001) and was highly correlated with poor clinical outcomes (P = .027, log-rank test). In addition, miR-23a level was marked decreased in metastatic melanoma tissues and cell lines (P < .05, P < .01). Moreover, miR-23a overexpression prevented the invasion and migration in vitro and lung and liver metastasis in vivo (both P < .05), by targeting ATG12 and inhibiting autophagy. Mechanically, miR-23a-ATG12 axis attenuated invasion and migration through autophagy-mediated AMPK-RhoA pathway. Finally, the down-regulation of miR-23a in metastatic melanoma was caused by RUNX2 in a transcriptional repression-manner. Conclusion: MiR-23a can act as a crucial epigenetic repressor of melanoma invasion and metastasis in an autophagy-dependent way, which indicates that miR-23a-mediated autophagy inhibition can be exploited to restrain invasion-metastasis cascade in melanoma treatment.

**#478** Regulation of cross talk between AR and vets/beta-catenin pathways in prostate cancer. Alexis Plaga, Girish C. Shukla. Cleveland State University, Cleveland, OH.
Prostate Cancer (PCa) is the second most commonly diagnosed cancer in the United States with 180,890 males diagnosed and is predicted to cause approximately 26,000 deaths in 2016. The current treatment of androgen deprivation therapy (ADT) initially depletes circulating androgens; however, intratumoral androgens rescue androgen receptor (AR) signaling and promotes the development of castration resistant prostate cancer (CRPC). The dysregulation of the Wnt/β-catenin signaling pathway has been implicated in the development of many cancers including PCa. The disruption of this signaling leads to the stabilization of β-catenin which upregulates many genes involved in tumorigenesis. Additionally, β-catenin acts as AR cofactor. Our previous studies show that AR is a direct target of miR-644a. We hypothesized that targeting the expression of both the β-catenin pathway and AR by conventional drugs and/or tumor suppressor miR-644a would have synergistic therapeutic benefits. In this study, we are investigating miR-644a mediated posttranscriptional downregulation of GSK3-β and β-catenin in the wnt/β-catenin signaling pathway. The effect of miR-644a in combination with inhibitors (β-catenin or GSK3-β) was also assessed using proliferation assays and a significant downregulation was observed. We will further study the posttranscriptional effects of tumor suppressor miR-644a on the wnt/β-catenin pathway and also the processing and regulation of miR-644a in PCa.

#479 Modeling miRNA induced silencing in breast cancer with PARADIGM. Andrew J. Sedgewick,1 Panayiotis V. Benos,2 Shahrooz Rabizadeh,3 Patrick Soon-Shiong,3 1Nantomics LLC, Santa Cruz, CA; 2University of Pittsburgh, Pittsburgh, PA; 3Nantworks, Culver City, CA

Introduction: MicroRNAs play an important role in regulation of gene expression and are known biomarkers for breast cancer as well as other malignancies. PARADIGM is a pathway based algorithm that allows for integration of multiple genomic data types with a curated pathway database to make pathway activity predictions. We added a model of gene silencing due to miRNA to the PARADIGM algorithm in order to study miRNA expression in a pathway context. Results: We curated a set of 7731 miRNA-mRNA interactions from the intersection of 3 target prediction algorithms. These interactions involved 66 miRNA and 2814 mRNA transcripts. We ran this model on global DNA copy number, RNAseq and miRNAseq data from 697 patients in the TCGA breast cancer cohort, and studied changes in the interactions between miRNAs and their targets between different tumor subtypes. The median activity of the RNA-induced silencing complex (RISC) predicted by our model is significantly higher in Basal tumors than other subtypes. In addition, RISC activity is significantly associated with overall survival of patients with Luminal A tumors. The miRNA-target pairs with the largest correlation changes between Basal and Luminal A subtypes were enriched for putative onco- genes and oncomirs. The miRNA targets are involved in a number of important signaling pathways including PI3K-AKT, JAK-STAT, and Ras. Many of these highly differential links involve the miR-16 family of miRNAs which are known tumor suppressors. miR-16 shows significantly lower activity in basal tumors than other subtypes. Conclusions: By looking at changes in miRNA-target links between tumor subtypes, our algorithm was able to identify both miRNAs and target genes involved in pathways relevant to breast cancer. Our predictions of overall RNA-induced silencing activity show prognostic value in both differentiating subtype and predicting overall survival within subtypes.

#480 Novel miRNA regulation in an early progression model of PDA. Nina J. Chu, Todd D. Armstrong, Elizabeth M. Jaffe. The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD.

The success of immunotherapy is dependent on infiltration and function of T cells within the tumor microenvironment. However, for many cancers, inflammatory and stromal cells provide formidable barriers to T cell access and function. Emerging data suggests that the cellular barriers to T cell access and function are regulated by both genetic and epigenetic factors. Identification of these regulators should provide new targets for enhancing immunotherapy. The overall goal of this research is to evaluate the role of miRNA regulation of immunoinflammatory and stromal cells that develop in the earliest pre-malignant pancreatic intraepithelial neoplasias (PanINs) in the KrasG12D/H, Trp53R172H/H11001/H9252/H9253 mouse model, a spontaneous model of pancreatic ductal adenocarcinomas (PDA) tumorigenesis. Specifically, we aim to investigate the functional roles of key differentially expressed miRNAs in propagating the tumor microenvironment via modulating the signaling between transformed ductal epithelial cells and the recruited cancer associated fibroblasts (CAFs) that comprise the majority of the desmoplastic stroma that characterizes PDA. Although numerous studies have described molecular alterations that are involved in pancreatic cancer development and progression, little is known about the miRNA regulatory profile and the associated inflammatory changes within the tumor microenvironment in the earliest PanIN lesions. We conducted miRNA microarray analysis to determine the levels of 750 unique miRNAs in the pancreata of KPC mice ranging from 4 to 12 weeks of age (pre-PanIN1 to PDA). miRNA was isolated from normal pancreatic ducts, PanIN grades 1 through 3, and PDA by laser capture microdissection. miRNA expression was quantified by Taqman miRNA OpenArrays and confirmed by qPCR analysis. Out of the 750 rodent miRNAs, 4 miRNAs (miR-21, miR-16, miR-19b, and miR-224) were significantly upregulated throughout PDA development. miR-21 and miR-224 are of particular interest for their regulation of targets in cancer promoting inflammatory pathways and epithelial-mesenchymal transition (EMT). To investigate the functional role of miR-224 in the developing tumor environment, primary KPC pancreatic ductal epithelial and fibroblast cell lines were established via fluorescence activated cell sorting (FACS) in order to perform in vitro miRNA knock-in and knock-out studies. Additionally, miRNA fluorescence in situ hybridization (miRNA-FISH) was performed to examine the spatial expression of miR-21 throughout progression of the early microenvironment. miR-21 is expressed at low levels in wildtype pancreata, but is highly expressed particularly in ductal epithelial cells of late stage KPC pancreata. Additional studies are underway to determine the functional role of this miRNA in PDA development and progression.

#481 Diminished microRNA-29b results in overexpression of BRD4 and BRD4-regulated oncogenes in cutaneous T-cell lymphoma. Rebecca Kohlenk,1 Jing Wen,2 Bethany Mundy-Bosse,3 Max Yano,4 Leah Grinspun,4 Kathleen McConnell,3 Ashley Keiter,5 Alex Hartlage,3 James Bradyne,3 Michael Caligiuri,1 Pierluigi Porcu,1 Anjali Mishra1.

Cutaneous T-lymphoma (CTCL) is a CD4+ T-cell malignancy that affects the skin but may disseminate systemically, and there are no long-term effective therapeutic strategies. Here, we characterized the therapeutic efficacy of manipulating the tumor suppressor microRNA-29b (miR-29b) and its target bromodomain-containing protein 4 (BRD4) in CTCL pathogenesis. Using primary CD4+ T-cells we determined that miR-29b expression is significantly decreased in patients compared to healthy controls (0.007 ± 0.002, n = 9 vs 1.008 ± 0.052, n = 6, p < 0.0001). We utilized miR-29b−/− mice and bortezomib, a proteasome inhibitor known to increase miR-29b levels, to confirm the inverse relationship between miR-29b and BRD4 (Mishra, A. et al. Cancer Cell, 2012). Diminished miR-29b level resulted in increased BRD4 protein expression (1.87 ± 0.29, p = 0.014), while increase in miR-29b, as in bortezomib-treated CTCL cell lines, results in nearly undetectable BRD4 protein. We also observed increased genome-wide occupancy of BRD4 at regulatory regions in CTCL patients, an effect that is reversed with BRD4 inhibitor, JQ1, to similar levels as observed in healthy control CD4+ T-cells. Specifically, oncogene loci of NOTCH1 and RB1 demonstrated enhanced BRD4 binding in CTCL patients, with resultant increases in mRNA in patient vs normal donors (4.16 ± 0.08, p = 0.024; 3.02 ± 0.54, p = 0.012). Further, in vivo treatment of interleukin-15 (IL-15) transgenic mice (Mishra, A. et al. Cancer Discovery, 2016) with JQ1 prevented CTCL development and decreased lesion severity (5.37 ± 0.49, n = 8 vs 6.0 ± 0.45, n = 5, p = 0.004). Skin from JQ1-treated mice demonstrated decreased protein expression of BRD4, NOTCH1, and RB1, consistent with our findings in patients and CTCL cell lines. Bortezomib treatment of CTCL mice yielded similar results to JQ1 in vivo, while miR-29b levels were elevated in treated mice vs control animals. Since IL-15 signals through its receptor complex, we evaluated and observed increased BRD4 binding at IL-15 receptor αγy gene loci in CTCL patients, which was reversed with both JQ1 and bortezomib treatment. Thus, we conclude that diminished miR-29b results in increased expression and subsequent binding of BRD4 at regulatory regions of known oncogenes in CTCL cells including NOTCH1, RB1, and the IL-15 receptor complex. We confirm the potential therapeutic utility of targeting this pathway in vivo, by direct displacement of BRD4 by JQ1, or by rescue of miR-29b expression by bortezomib. We therefore describe a novel targetable oncogenic pathway featuring IL-15, miR-29b, and BRD4 in CTCL.

#482 miRNAs involved in LY6K and estrogen receptor-α contribute to tamoxifen susceptibility in breast cancer. Yesol Kim, Dasom Son, Kyung Hyun Yoo, Jong Hoon Park. Sookmyung Women’s University, Seoul, Republic of Korea.

Estrogen receptor-alpha is a clinically important therapeutic target for breast cancer. However, tumors that lose ERα are less responsive to anti-estrogens such as tamoxifen. MicroRNAs are small RNAs that regulate expression of their target gene and dysregulations of miRNA has been identified in many diseases including human cancer. However, only a few miRNAs associated with tamoxen
Epigenetic regulation of hsa-miR-3663 in colon cancer. Laia Pique, Humberto Jorge Ferrerira, Manel Esteller. Bellvitge Biomedical Research Institute (IDIBELL), Barcelona, Spain.

Colon Cancer is the third most common cancer in the world and a major cause of morbidity and mortality. Molecular mechanisms of colon carcinoma have been deeply studied and current evidences indicate that microRNAs play a pivotal role in its tumorigenesis and progression. MicroRNAs (miRNAs) are small 19 to 22 nucleotides of RNA classified as non-coding RNAs that negatively regulate gene expression at the post-translational level controlling numerous biological processes including development, cell proliferation, apoptosis, differentiation and cell migration. Abrupt expression of miRNAs due to epigenetic alterations has been associated with carcinogenesis. Aims to identify epigenetically regulated miRNAs involved in colon cancer, we analyzed DNA methylation profile available in The Cancer Genome Atlas. One of the main hits identified was hsa-miR-3663, hypermethylated in 26% of colon cancer patients (n = 286, p < 0.001) in comparison with complete lack of methylation in normal tissues (n = 38), suggesting its potential function as a putative tumor suppressor. In order to study the role of DNA methylation controlling hsa-miR-3663, HumanMethylation450K methylation profiles were generated for a panel of colon cancer cell lines (n = 10), including the HCT116-DMN methyltransferase knock-out model (DKO, double knockout of DNMT1 and DNMT3B). We found a significant correlation between methylation status of hsa-miR-3663 and expression in colon cancer cell lines. Furthermore, epigenetic regulation of hsa-miR-3663 was confirmed in HCT116 methylated cell line by restored expression upon treatment with DNA demethylating agent 5-aza-2'-deoxycytidine and in the HCT116-DKO model. In order to elucidate the function of hsa-miR-3663, we stably expressed hsa-miR-3663 in a panel of five methylated colorectal cancer cell lines (HCT116, RKO, DLD1, SW48 and SW480). Our initial functional assays revealed that hsa-miR-3663 is not involved in cell proliferation or migration. We are now performing additional assays to further study hsa-miR-3663 and its potential role in colon cancer.

African-Americans are diagnosed with more aggressive prostate cancers and have worse survival than Caucasians, however a comprehensive understanding of this health disparity remains unclear. To clarify the mechanisms leading to this disparity, we analyzed the potential involvement of miR-34b expression in African-Americans and Caucasians. We found that miR-34b expression is lower in human prostate cancer tissue from African-Americans compared to Caucasians. DNA hypermethylation of the miR-34b-3p promoter region showed significantly higher methylation in prostate cancer compared to normal tissues. We found that AR and ETV1 genes are differentially expressed in MDA-PCA-2b and DU-145 cells after overexpression of miR-34b. Direct interaction of miR-34b with the 3' untranslated region of AR and ETV1 was validated by luciferase reporter assay. We found that miR-34b downregulation in African-Americans is inversely correlated with high AR levels that lead to increased cell proliferation. Overexpression of miR-34b in cell lines showed higher inhibition of cell proliferation, apoptosis and G1 arrest in African-American cells (MDA-PCA-2b) compared to the Caucasian cell line (DU-145). Taken together, our results show that differential expression of miR-34b and AR are associated with prostate cancer aggressiveness in African-Americans.

$\#484$ Epigenetic regulation of hsa-miR-3663 in colon cancer. Ashesi Saraiya, 1 Brandon Young, 2 Tobias Meifner, 2 Brian L. Jones, 3 Stephanie C. Huelga, 2 Doug A. Amorese, 1 NuGEN, San Carlos, CA; 4 Avera Cancer Institute for Precision Oncology Genomics, San Diego, CA.

Growing interest in cancer classification and progression has accelerated the rate of novel gene fusions discovery with increasing recognition of their roles as biomarkers. RNA-Seq is an attractive method for expressed fusion discovery.
and detection because of its ability to provide unbiased fusion sequencing information. The ability to detect low expressing fusion transcripts, however, require high sequencing depth and represents a significant financial barrier and identification of clinically relevant fusion sequences from a large data set can be a bioinformatics challenge. To address these challenges we have tested the Ova-
tion Fusion Detection System and the Exari Fusion Detection System on a platform with a method using the Single Primer Enrichment Technology (SPET), with a number of control and clinical samples. Initial studies were performed using a comprehen-
sive target enrichment panel targeting 502 genes with three samples from Horizon DX containing known fusions. Target enriched libraries were con-
structed with 10 ng and 100 ng inputs and the data was analyzed using the NuFuseD platform (available as a point and click BaseSpace application or down-
loadable linux package) which has been optimized for fusion analysis from this data. Expected fusions were identified at both input levels, even when down sampled to 500K reads, with fewer fusion calls compared to other publically available fusion detection software (Chimerascan and SOAPFuse), suggesting a lower false positive rate. NuFuseD fusion calls are provided with a P-value to help prioritize the identified fusions for subsequent validation. Additionally, NuFuseD detected novel fusions in the control samples demonstrating the ad-
Vantage of a comprehensive panel compared to more restricted panels. We fur-
ther validated the target panel using control RNA (UHR and Human Brain) and fresh or FFPE cell lines (NCI-H2228, HCC357) to further demonstrate our ability to identify known fusions. Finally, the system was evaluated at an external site using patient FFPE samples. These samples (N=8) were from a set of breast,
leukemia, and ovarian cancers, containing a unique fusion in 4 of the samples based on DNA based sequencing. Only 1 of the 4 expected fusions were identified using whole transcriptome data (100 million reads) while 3 of the 4 fusions were detected with this assay (10 million reads) demonstrating its ability to generate targeted RNA sequencing libraries with increased sensitivity of gene fusion detec-
tion and reduced sequencing costs compared to standard RNA-Seq methods.

MOLecular AND CELLULAR BIOLOGY / GENETICS: Molecular Carcinogenesis and Chromosomal Alternations

MISMATCH REPAIR DEFICIENCY IN GENETICALLY ENGINEERED HUMAN BREAST CANCER MODELS

E2F2-mediated copy number changes drive metastasis and therapeu-
tic response of HER2-positive tumors through Colla1, CHAD, and AKT-
dependent mechanisms. Jonathan P. Rennhack, Kellan Sun, Jordan Honesett, Eran Andrechek. Michigan State University, East Lansing, MI

The E2F family of transcription factors is classically known to regulate G1 to S-phase transition in cell cycle but has emerging roles in HER2+ breast cancer. A loss of E2F1 or E2F2, in a HER2 mouse model, MMTV-Neu, leads to a de-
crease in tumor metastasis. It is not known what mechanistic roles specific E2Fs are playing in this process. To investigate this, we leveraged and bioinformatic principles, including genomics and transcriptomics with traditional laboratory science and high throughput drug screening projects. This experimental ap-
proach immediately revealed that loss of E2F2 expression significantly correlates with more unstable tumors including an increase in copy number alternations, single nucleotide variants, and translocations. Further analysis revealed a conserved copy number alteration in both mouse and humans. Specifically we noted the amplification of 17q21.33 in 25% of HER2+ breast cancer. The analogous region chromosome 11D was lost in 30% of the less metastatic MMTV-Neu E2F2 knockout mice indicating a role of the region in tumor metastasis. Transcripti-
tomic data revealed that two genes, Collagen Type I, alpha 1 (Col1a1) and Chon-
droadherin (CHAD), were potential genes of significance in the amplification event. CIRSPR mediated knockout studies were conducted to determine each gene’s effect on tumor cell migration and metastasis in mouse and human derived cell lines. Wound healing assays and tail vein injection have shown the Col1a1 and CHAD KO cell lines have a delay in cell migration (P<.01) and reduced ability to colonize the lung (P<.05) respectively. Oncogenic signaling data shows that the 17q21.33 amplification event has higher AKT and E2F2 signaling than HER2 positive tumors without the event. It was hypothesized that the tumors would be dependent on the signaling and perturbation of the net-
work might be an effective therapy for patients with the 17q21.33 amplification event. To investigate this we identified deferentially lethal siRNAs and com-
ponents between HER2+ tumors with and without the 17q21.33 event in the Achilles, CCLE, and PDX datasets. A String-DB analysis showed many of the deferentially lethal genes and compounds centered around AKT. A decrease in AKT signaling through siRNA or chemical compound results in the death of the cell in the 17q21.33 amplified samples but not the HER2+ samples without the event. This study reveals that patients’ with a 17q21.33 amplification event have more metastatic tumors mediated through Colla1 and CHAD and may be re-
and clear cell renal cell carcinoma.

School of Medicine, New York, NY; 4 Division of Cardiothoracic Surgery, Department of Human Genetics, University of Michigan Medical School, Ann Arbor, MI.

Palindromic AT-Rich Repeat (PATRR) - mediated translocations entail exchange across chromosomes at sites enriched in palindromic repeats of the nucleotides adenine (A) and thymine (T). Their precise embryologic origin and associated pathobiology with clear cell renal cell carcinoma (cCRCC) remain incompletely described. In the present study we document an individual with familial non-VHL cCRCC (7 primary renal tumors) who harbors a germline de novo PATRR-mediated balanced translocation involving chromosomes 3 and 8 ([t(3;8)]) validated by spectral karyotyping (SKY). Using translocation specific PCR and DNA sequencing we determined the chromosome 3 breakpoint to be located in an AT-rich palindromic sequence in the third intron of the FHIT gene (chr3p14.2) and the chromosome 8 breakpoint in the first intron of the TRC8 gene (chr8q24.1). Genotyping analysis, using a high density custom exomechip array by Illumina, revealed a loss of the entire aberrant chromosome 8 carrying the 3p segment ([der(8)]) in all renal tumors tested. We also determined that the [46, XY, t(3;8), (p14.2, q24.1)] translocation was paternally derived by performing a genotypic assessment of the regions that differ between the paternal alleles and then establishing which haplotypes are associated with the translocation. The somatic mutational landscape was assessed by Whole Exome sequencing of the renal tumors and the proband’s germline DNA. No germline or somatic deletional mutations were detected in VHL gene suggesting that the cCRCC phenotype is not associated with Von Hippel-Lindau disease. Furthermore, we measured the transcriptomic profiles of the renal tumors and matched normal tissue derived from the barcoded exonic (eXome) and RNAseq to fully characterize differential gene expression and define gene ontology networks that are dysregulated. Most significantly, no difference in expression of the VHL gene was detected between tumors and normal counterparts. Abrupt regulation was detected in members of WNT process, COX2 and iNOS; cell survival, Bcl2 and GSTP1.

# Frequent NRG1 genomic rearrangements in invasive mucinous adenocarcinoma from Caucasian patients. Domenico Trombetta,1 Giulio Rossi,2 Angelo Sparaneo,1 Federico P. Fabrizio,1 Maria C. Manzorza,1 Evaristo Maiello,1 Vito M. Fazio,1 Paolo Graziano,1 Lucia A. Muscarella1. 

Invasive Mucinous Adenocarcinoma (IMA) accounts for 2-5% of lung adenocarcinomas. However, the role of USP37 associated with a definite lung adenocarcinoma subtype in Caucasian population.

# Somatic copy number variants detection using the NEBNext Direct target enrichment method. Kriti M. Patel,1 Sarah K. Bowman,1 Noa Henig,1 Amy B. Emerman,1 Andrew Barry,2 Charles Elfe,1 Scott Adams,1 Salvatore Russo,2 Ted Davis,2 Cynthia L. Hendrickson1. 

Variations in copy number are the most common type of DNA structural variations. Many of these alterations are associated with disease or indicate disease susceptibility. Detection of copy number variants (CNVs) for clinical applications requires efficient, fast and cost-effective methods. Here we describe the use of the NEBNext Direct\(^2\) hybridization-based target enrichment method to identify somatic CNVs with high sensitivity. This approach begins with target enrichment followed by enzymatic digestion of off-target sequences and ligation of adapters that contain unique molecular identifiers (UMIs). The UMIs enhance the identification of duplicate reads and further increase the final number of on-target reads used for variant detection. We used a cell line known to contain a deletion in the CDKN2A gene and spiked DNA isolated from the cell line into a HapMap DNA sample that contains full diploid copies of CDKN2A. We were able to detect the gene deletion as a somatic CNV in a dose dependent manner with high sensitivity. Thus, we demonstrate that the NEBNext Direct approach is an efficient technique to detect somatic CNVs of high and low frequencies.

# Ubiquitin specific peptidases 37 promotes constitutive replication fork movement by stabilizing Chk1 via its deubiquitination. Mayank Singh,1 Amy C. Burrows,1 Andrew Dickson,2 Danielle Gordon,1 Rumsha Javed,2 Rachela Dolce Rameau,3 Xinyin Jiang,1 Anjana D. Saxena3. 

Protein deubiquitination controls many intracellular processes, including cell cycle progression, transcriptional activation, and signal transduction. Ubiquitin specific peptidases (USPs) remove ubiquitin tags from target proteins to control protein fate and function. USP37 (Ubiquitin specific peptidase 37) has been implicated in stress response and we have previously shown that it antagonizes the tumor suppressor ALC1\(^{2,3}\) and promotes S phase entry. However, the role of USP37 during S-phase was unknown. Here, we report that in cells experiencing replication stress USP37 overexpression confers survival advantage while its depletion enhances sensitivity. USP37 overexpressing cells were able to resolve different DNA damage markers much more effectively than the control cells or cells in which USP37 was depleted. Mechanistically, our data indicate that USP37 binds and stabilizes the active form of CHK1 and deubiquitiates CHK1 to increase its stability and promote the checkpoint response. USP37 overexpression results in constitutive replication fork movement and long tract DNA synthesis while USP37 depleted cells were unable to carry out long tract DNA synthesis. Notably, expression of low level of CHK1 in USP37 depleted cells rescues cell survival and DNA damage response. Overall our data suggest that inhibition of USP37 may represent a novel mechanism to modulate CHK1 activity.

**#501 Tyrosyl-DNA phosphodiesterase I cellular function dependent on its Impairment of DNA double strand break repair in human primary region breakpoints compared to the prevalence of hits into S type controls. In heterozygous mice, there was no allelic bias in targeting IgH for previous observations made in a mouse lymphoma model, Hs3b/Hs4 3'KO mice candidate for orchestrating c-Myc deregulation. To elucidate the role of 3'RR in death within 96 hours. The later observation confirms the requirement of the full 3'RR for c-Myc deregulation by T(12;15).

Tyrosyl-DNA phosphodiesterase I (Tdp1) is a highly conserved eukaryotic DNA repair enzyme that catalyzes the resolution of 3' and 5' phospho-DNA toxicities that were observed with the full-length Tdp1 mutant proteins. Our data suggests that the N-terminal domain is required to resolve protein-DNA covariant complexes, such as Top1. Indeed, preliminary results suggest that this domain is also critical to process Top2-DNA covariant complexes, but only in the presences of etoposide. We are currently investigating other protein-DNA ad- ducts that are resolved by Tdp1. These results suggests that the N-terminal domain is a critical determinate of Tdp1 cellular function. However, further studies are necessary to ensure that these constructs are properly distributed and retain their catalytic activity. Additionally, the N-terminal domain of human Tdp1 is post-translational modified, while our preliminary results suggest that this domain is important for protein-protein interaction and Tdp1 recruitment to its substrates. Understanding Tdp1 substrate and protein-interactions are important in the development of Tdp1 as therapeutic target. This work is in part supported by the ADDA, UAB Cancer Comprehensive Center (P30CA13148), ACS-IRG-60-001-53, DOD OCRP (W81XWH-15-1-0198).

**#502 Electronic cigarette aerosols increase cellular reactive oxygen species and induce significant oxidative DNA damage. Vengatash Ganapathy,3 Jimmy Manyangia,1 Debra McGuire,1 Daniel Brobst,2 Theodore Wagner,2 David Rhutledge,1 Lijun Song,1 Lingnanesan Rajeswaran,2 Herbert C. Morse.

Rationale: Emphysema is caused by the destruction of alveolar wall septa. The major risk factor for this disease is cigarette smoke and effective therapies are very limited. Alveolar type II (ATII) cells are in the gas exchange portion of the lung. They make and secrete pulmonary surfactant, and proliferate to restore the epithelium after damage to the more sensitive alveolar type I cells. Methods: Control ATII cells were isolated from deidentified control non-smoker and smoker organ donors whose lungs were not suitable for transplantation and donated for medical research. Furthermore, as a unique approach, we have developed a new method on how to isolate ATII cells from excess tissue from lung transplants obtained from patients with emphysema using magnetic microwells. We determined DNA damage, DNA repair, oxidative stress, injury, and inflammation in human primary ATII cells isolated from these individuals in comparison with immortalized controls. Results: Our data indicates high oxidative stress in human ATII cells induced by cigarette smoke extract in vitro as measured by 4-HNE staining by immunocytofluorescence. We also observed DNA double strand breaks, high DNA damage, and low DNA repair in these cells. Moreover, we found greater proinflammatory response as determined by IL-8 and IL-6 levels by ELISA; a trend that was greater in cells obtained from smokers compared to controls. Conclusion: Our results indicate oxidative ATII cell damage induced by cigarette smoke and in emphysema. Observed DNA repair imbalance may contribute to cell death in this disease. The study of ATII cell injury may improve our knowledge on this disease pathogenesis and may lead to novel therapeutic strategies to slow the progression of emphysema.

**#503 Tyrosyl-DNA phosphodiesterase I cellular function dependent on its N-terminal residues. Selma M. Cuya, Robert C.A.M. Van Waardenburg. Univ. of Alabama at Birmingham, Birmingham, AL.

Tyrosyl-DNA phosphodiesterase I (Tdp1) is a highly conserved eukaryotic DNA repair enzyme that catalyzes the resolution of 3' and 5' phospho-DNA adducts. Tdp1's role is implicated in the repair of DNA topoisomerase I (Top1)-DNA covariant complexes reversibly stabilized by FDA approved camptothecins (CPTs) derivatives topotecan, and irinotecan. Tdp1 activity relies on two catalytic histidines that function as a nucleophile and an acid-base residue. A mutation of the acid-base His to Arg (H493R) in human Tdp1 is associated with the rare recessive ataxia SCAN1. We defined alternative substitution of other catalytic histidine that induce cytotoxicity, reduce catalytic activity and enhances the requisite Tdp1-DNA covariant adduct lifetime in the cell. The phenotypes of the catalytic mutants provide excellent tools to study Tdp1 cellular function. Biochemical studies revealed that Tdp1 catalysis in vitro is independent of the N-terminal domain. Among Tdp1 proteins, the N-terminal domain is poorly conserved in sequence and size (79aa for yeast and 148aa for human Tdp1). Conversely, the N-terminal domain regulates the in vitro activity of these Tdp1 mutants. Additionally, we investigated the role of the N-terminal domain for Tdp1 activity in the yeast and human cell models. Expression of N-terminal truncated proteins showed similar cellular distribution as the full-length protein. However, the results suggest that the N-terminal domain for Tdp1 activity is highly conserved in sequence and size (79aa for yeast and 148aa for human Tdp1). Conversely, the N-terminal domain regulates the in vitro activity of these Tdp1 mutants. Additionally, we investigated the role of the N-terminal domain for Tdp1 activity in the yeast and human cell models. Expression of N-terminal truncated proteins showed similar cellular distribution as the full-length protein. However, the results suggest that the N-terminal domain is required to resolve protein-DNA covariant complexes, such as Top1. Indeed, preliminary results suggest that this domain is also critical to process Top2-DNA covariant complexes, but only in the presence of etoposide. We are currently investigating other protein-DNA adducts that are resolved by Tdp1. These results suggest that the N-terminal domain is a critical determinate of Tdp1 cellular function. However, further studies are necessary to ensure that these constructs are properly distributed and retain their catalytic activity. Additionally, the N-terminal domain of human Tdp1 is post-translational modified, while our preliminary results suggest that this domain is important for protein-protein interaction and Tdp1 recruitment to its substrates. Understanding Tdp1 substrate and protein-interactions are important in the development of Tdp1 as therapeutic target. This work is in part supported by the ADDDA, UAB Cancer Comprehensive Center (P30CA13148), ACS-IRG-60-001-53, DOD OCRP (W81XWH-15-1-0198).

**#504 Enhanced repair of bulky DNA adducts induced by a tobacco carcinogen and UV light in human oral epithelial cells by black raspberry extract. Joseph B. Guttenplan,1 Kun-Ming Chen,2 Yuan-Wan Sun,3 Ross Teicher,4 Wieslawa Kosinska,5 Krishne Gowda,1 Shantu Amin,2 Gary D. Stoner,4 Karam El-Bayoumy,2 1New York University Dental and Medical Schools, New York, NY; 2Penn State College of Medicine, Hershey, PA; 3New York University Dental School, New York, NY; 4Medical College of Wisconsin, Milwaukee, WI.

We were the first to report that an anthocyanin-enriched black raspberry extract (BE) inhibited mutagenesis, and reduced levels of DNA adducts induced by metabolites of the tobacco carcinogen dibenz(a)pyrene (DBP), in a rat oral...
fibroblast cell line, by enhancing removal of DNA adducts (Guttenplan, et al., Cancer Prev Res; 8(9) August 2016). Here we extend these findings to the repair of DBP-induced DNA damage in a human oral leukoplakia cell line (MSK leu1), and a reduction in the toxicity (assayed by dead cell numbers and cell survival) of DBP diolepoxide (DBPDE) in these cells. In addition, we examined the effect of BE on DNA damage and toxicity induced by UV light. Treatment of the MSK cells with DBP, and 2 of its metabolites, DBP-dihydriodiol and DBPDE led to a major adenine adduct, (-)-anti-trans-[b,a]PDE-dA (DBPDE-dA).

The order of potency was DBPDE ˃ DBP ˃ DBP-dihydriodiol with one μM DBP, producing adduct levels of about 20/106 da. BE in the range of 75-150 μg/ml significantly inhibited adduct formation when cells were pretreated with BE before addition of DBP. However, when cells were first treated with DBP and one day later BE was added, adduct levels were reduced by about 50% two days after treatment with DBP, indicating that the BE was enhancing DNA repair. This conclusion results from the fact that BE was not present during the metabolic activation of DBP to DBPDE, and hence couldn’t modulate the activation steps. We also tested whether BE, added 4 hr after treatment with the short-lived DBPDE, inhibited toxicity to MSK cells. Initial toxicity was measured by counting the numbers of dead cells in the medium 24 hr after addition of DBPDE, and the relative levels of surviving cells were determined using an MTT cell viability assay. It was found that 100μg/ml BE reduced toxicity induced by 25 - 200 nM DBPDE by about 50%, with a concomitant increase in survival in the BE-treated cells. As DBP produces bulky DNA adducts we also investigated the effects of BE on toxicity at lower levels of DBP and on DNA adducts produced by UV light. Cells were irradiated for 30 - 120 seconds with 254 nm light and 15 minutes later, treated with 50 - 150 μg/ml BE. Toxicity was measured, as above, and a logarithmic decrease in cell death was observed with increasing concentration of BE. Similar to results with DBPDE, BE increased cell survival. The effects of BE on relative levels of the UV-light-induced cyclopyrimidine adducts were also determined, using an ELISA assay. BE reduced adduct levels by 30 - 60%.

These results indicate that BE may provide chemopreventive effects on initiation of carcinogenesis by environmental agents that produce bulky DNA adducts - by enhancing DNA repair, likely via the nucleotide-excision repair pathway. Supported by NIH grant #CA173465.

#504 Quantification of nucleic acid quality in postmortem tissues from a cancer research autopsy program. Jun Fan, Yi Zhou, Chelie Michael, 300 μg/ml reduced adduct levels by 30 - 60%.

These results indicate that BE may provide chemopreventive effects on initiation of carcinogenesis by environmental agents that produce bulky DNA adducts - by enhancing DNA repair, likely via the nucleotide-excision repair pathway. Supported by NIH grant #CA173465.

#505 Somatic and inherited riboSNitches in TPT1 and LCP1 mRNA secondary structures. Lela L. Lackey,1 Aaztli Coria,1 Chanin Tolson,1 Evonne McGarthur2,3,4,5

Kimberly J. Bussey, Luis Cisneros. NantOmics, LLC, Tempe, AZ.

The action of the AID/APOBEC family of cytosine deaminases contributes to mutational clustering but fails to explain 50% of the clusters observed in cancer genomes. Stress-induced mutagenesis in bacteria occurs when double-strand breaks (DSB) or other DNA damage occurs and is a known mechanism to initiate the SOS response. This results in mutational clustering driven by DSB where mutational abundance decays as a function of the distance from the DSB, but remains above background rates of mutagenesis up to 1 MB away. In humans, the orthologous genes to DSB have become specialized for translesion synthesis (TLS). The dysregulation of cell cycle and DNA repair that characterizes most tumors would logically increase the need for TLS in cancer. Therefore, we hypothesized that stress-induced mutagenesis in cancer would result in peaked clusters of SNVs driven by TLS. We used data from 764 cases with somatic mutation and structural variant calls from WGS from the ICGC database, release 19, and private de novo mutations derived from 130 trios in the 1000 Genomes project with WGS, SNV context was determined based both on the reference and the mutant allele, and called when only one mechanism (TLS, APOBEC, or AID) could be assigned, thereby underestimating the actual number of TLS events. We observed that as the total number of SNVs increases so does the number of clusters, the proportion of SNVs in clusters, and the average size of clusters in both de novo private mutations and somatic mutations in cancer. In normal, a median of 15.2% of the SNVs occurring in clusters occur in a sequence context indicative of TLS, compared to 0.53% and 1.6% for APOBEC and AID, respectively. In contrast, in cancer, TLS accounts for a median of 30.6% of SNVs in clusters. APOBEC and AID account for 2.3% and 2.6%, respectively. We devised a measure of cluster shape based on empirical cumulative distributions, termed the Stress-Introduced Heterogeneity (SITH) score. It ranges from -1 to 1 and quantifies how sharply peaked clusters are with more positive numbers indicative of a faster decay in mutational load over distance relative to the putative DSB. In normal, SITH scores range from 0.457 to 0.578 with a median of 0.50. In cancer, SITH scores ranged from 0.17 to 0.999 with a median of 0.46 and vary significantly by organ site (ANOVA, F = 44.96, p < 2.2x10⁻¹⁶). We assessed the contribution of TLS, APOBEC, and AID to SITH score using an additive, linear model of SITH scores derived solely from SNVs in that specific context and including organ site as a
variable. We found that in both normal and cancer that TLS was the only context that contributed significantly to STH score. Therefore, we conclude that the clustering seen in cancer is being driven primarily by TLS and these clusters have a shape characteristic of a process of stress-induced mutagenesis.

#508 DNA repair status in a patient derived ovarian cancer xenobank. Federica Guffanti,1 Maddalena Fratelli,1 Monica Ganzinelli,1 Francesca Ricci,1 Roberta Affatato,1 Maria Rosa Cappelletti,2 Daniele Generali,2 Francesca Bizzaro,1 Massimo Brogini,1 Raffaella Giavazzi,1 Giovanna Dania,1 IRCCS - Institute for Pharmacological Research Mario Negri, Milan, Italy; 2Azienda Socio-Sanitaria Territoriale di Cremona, Cremona, Italy.

Epithelial ovarian cancer (EOC) is the most lethal gynecological malignancy with a 5-year relative survival rate of 45%. The high mortality rate is in part due to the development of platinum chemoresistance occurring in more than 70% of patients after the first-line therapy. DNA repair capacity has been reported to be a key determinant for the cellular response to platinum agents. Since half of the high grade serous EOCs lacks Homologous Recombination repair, we aimed to profile the DNA repair status in a panel of well characterized 42 ovarian patient derived xenografts (PDxS) recently established in our laboratory and to correlate it with the in vivo response to a platinum based therapy. We evaluated by real time PCR (ABI-7900, Applied Biosystems) the mRNA levels of genes with a key role in Base Excision Repair (OGG1, POLB and PARP1), Homologous Recombination (BRCA1, PALB2, TP53BP1 and RAD51), Nucleotide Excision Repair (ERCC1, XPA, XPF, XPD and XPG), Fanconi Anemia pathway (FANCA, FANCC, FANCDD2 and FANCG) and Translesion Synthesis Repair (POL3E, Mismatch Repair (MLH1, MSH2), homology End Joining (POLQ), Non Homologous End Joining (XRC4, XRC5, XRCC6 and XRCC7) and CDK2, a kinase regulating the transcription of some DNA repair genes. The methylation status of BRCA1, ERCC1, MLH1, XPA, XPG and FANC were investigated by standard techniques. Our results show that the DNA repair genes considered were variably expressed in all the 42 PDxS analyzed, with no specific histotype-specific cluster of expression. The expression of PALB2, FANCC, FANCDD2, OGG1, POLQ and RAD51 was found to correlate with the expression of at least six other genes. In high grade serous/endometroid PDxS, the CDK12 mRNA expression levels positively correlated with the expression of TP53BP1, PALB2, XPF and POLB. BRCA1 was found to be hypermethylated in 51% of the xenografts. TP53 mutated PDxS showed statistically significant higher levels of POLQ, FANCDD2, RAD51, and POLB genes. The expression of CDK12 [p = 0.017], PALB2 [p = 0.019] and XPF [p = 0.016] was negatively associated with the in vivo response to DDP, with resistant PDxS showing higher mRNA levels than responsive ones. We looked for association with overall survival in the TCGA data set and we found that high levels of CDK12 were associated with a worse overall survival in patients with a residual tumor more than 2 cm. These data suggest that some DNA repair genes can have a role in EOC patients’ response to DDP therapy. Particularly, CDK12 was significantly able to predict worst survival in patients undergoing optimal debulking surgery. Our xenobank will be a valid instrument to set up functional DNA repair assays, as suggested by preliminary data on primary cultures.

#509 Genomic profiling of acute lymphoblastic leukemia in ataxia telan- giectasia patients reveals tight link between ATM mutations and chromothri- psis. Manasi Ratnaparkhe,1 Mario Hlevnjak,1 Thorsten Kolb,1 Anna Jauch,2 Kendra Maass,1 Frauke Devens,1 Agata Rode,1 Volker Hovestadt,1 Andrey Korobkov,1 Roberta Affatato,1 Maria Rosa Cappelletti,2 Daniele Generali,2 Francesca Bizzaro,1 Massimo Brogini,1 Raffaella Giavazzi,1 Giovanna Dania,1 IRCCS - Institute for Pharmacological Research Mario Negri, Milan, Italy; 2Azienda Socio-Sanitaria Territoriale di Cremona, Cremona, Italy.

Recent developments in sequencing technologies lead to the discovery of a novel form of genome instability, termed chromothripsis. This catastrophic genomic event, involved in cancer formation, is characterized by tens to hundreds of locally clustered rearrangements on one chromosome, acquired simultaneously. We hypothesized that leukemias developing in individuals with Ataxia Telangiectasia, who are born with two mutated copies of the ATM gene, essential guardian of genome stability, would show a higher prevalence for chromothripsis due to the defect in DNA double-strand break repair. Using whole-genome sequencing, fluorescence in situ hybridization and RNA sequencing, we characterized the genomic landscape of Acute Lymphoblastic Leukemia (ALL) in patients with Ataxia Telangiectasia. We detected a high frequency of chromothripsic events in these tumors, specifically on acrocentric chromosomes, as compared to tumors from individuals with other types of DNA repair syndromes (27 cases in total, of which 10 with Ataxia Telangiectasia). Our data show that the genomic landscape of Ataxia Telangiectasia ALL is clearly distinct from that of sporadic ALL. Mechanically, short telomeres and compromised DNA damage response in cells of Ataxia Telangiectasia patients are linked with genome instability. Additionally, we show that ATM loss is associated with increased chromothripsis prevalence in further tumor entities.

#510 Topoisomerase IIα silencing increases R loops at specific genomic loci associated with an increase of γH2AX and cell cycle progression delay in human cancer cells. Maria Delcuratolo, Jessica Marinello, Giovanni Capranico. University of Bologna, Bologna, Italy.

DNA topoisomerase IIα (Top2α) is a crucial enzyme for cell proliferation and plays a critical role in DNA replication, transcription and hence genome instability in cancer cells. Using whole-genome sequencing, fluorescence in situ hybridization (FISH), and immunofluorescence (IF), we have recently demonstrated that Top1 silencing and poisoning by camptothecin affect the formation of R-loops, which are RNA/DNA hybrid structures involved in genome instability and are favored by negative supercoils of the DNA. The findings overall demonstrate that Top2α reduces R-loop levels during transcription whereas it favors R loop formation at early origins of DNA replication. Here, we address the question of whether DNA topoisomerase IIα can also contribute to steady-state levels of R loop structures in the genome of U2OS cancer cells. We have then investigated the effects of Top2β silencing and Top2 poisons, doxorubicin and etoposide, on R loops and DNA damage in human U2OS cancer cells. Similarly to published data with camptothecin (Marinello et al., Nucleic Acids Research, 2013), Top2 poisons increase cellular R loops by IF after short treatment times and reduce them after 1 hour of treatment. The bi-phasic effect of poisons is mainly dependent on transcription. Moreover, we have determined the changes of R-loop levels by IF after Top2β silencing and the findings demonstrate that the enzyme can strongly modulate the formation of R-loops as a full Top2β deletion decreases nuclear R-loop levels. In addition, Top2β depletion leads to a slight increase of phosphorylation of H2AX histone along with cell cycle delay and eventually cell death. Thus, Top2β depletion can trigger genomic DNA breakage through alterations of R-loops. In order to establish which are the genomic regions of altered R loop levels, we have mapped Top2β-dependent R loop alterations by the DRIP method showing that specific genomic sites are affected by Top2β. Bioinformatic analyses of R loop maps will be presented and discussed at the meeting. Altogether the findings demonstrate a critical role of Top2β in governing R loop structures in human cancer cells indicating that DNA torsional tension is a main driving factor of R loop formation and hence genome instability in cancer cells.

#511 Chromosome instability mechanisms in breast cancer among Afri- can Americans and Caucasians, Jose Thaiparambil, Oula Mansour, Susan Hal- ley, Randa EL-Zein. Houston Methodist Research Institute, Houston, TX.

Significant differences exist in breast cancer among African Americans (AAs) women compared to Caucasians. Even though AAs are less likely to undergo regular mammograms due to access barriers, it is unlikely that differences in screen based detection accounts entirely for outcome disparities. While the current guidelines recommend mammography at age 40 for AAs, AA women may be at increased risk for delayed diagnosis since >10% of breast cancer cases in AAs are diagnosed in women younger <40 years compared with 5% of Caucasians. This highlights the importance of defining optimal ethically appropriate age of screening especially given the disproportionate mortality among younger black women patients. Therefore, an alternative approach using biomarkers should be considered in order to develop ethically appropriate measures for detecting the disease in the earliest stages. Genomic instability has long been recognized as a major driver of carcinogenesis occurring early on and increasing in complexity with disease progression. However, to date little is known about the underlying mechanisms associated with such instability among the different ethnic groups. In this study we hy-
Genomic instability is an enabling hallmark of cancer that provides cancer cells a replicative advantage. Accumulation of genomic aberrations can also compromise the genomic integrity and put cells under mitotic stress. Maintaining the balance between the instability that gives cancer cells a replicative advantage and the instability that could lead them to mitotic catastrophe is crucial for survival of cancer cells. Mitotic catastrophe can be caused by rapid progression through mitosis before crucial checkpoints are met, resulting in cell death. To overcome this challenge, cancer cells may acquire overexpression of spindle assembly checkpoint (SAC) genes, which can prevent mitotic catastrophe that would occur if they undergo mitosis prematurely. Bub1b is an important part of SAC and inhibits the onset of anaphase until all chromosomes are aligned at the metaphase plate. Our analysis of clinical datasets show Bub1b expression is elevated in breast cancer, compared to normal breast, and is exemplified by a pattern of increasing overexpression in more aggressive variants, such as triple negative breast cancer (TNBC). Bub1b overexpression also correlates with decreased overall survival in patients. Expression analysis of breast cancer cell lines corroborates this clinical data. We hypothesize that the requirement for Bub1b expression indicates a vulnerability of rapidly proliferating breast cancer cells, and the inhibition of Bub1b will result in cell death through mitotic catastrophe. Using RNA interference with siRNAs we knocked down Bub1b in breast cancers cell, and the inhibition of Bub1b results in apoptosis and cell death, especially in the TNBC cell line MDA-MB-231. Notably we found that p21 blockade using siRNA knockdown or genetic knock-out shifted polyploid cell response to p53 activation from cytostatic to cytotoxic. As a result, p21-deficient cells exhibited enhanced sensitivity to mitotic blockade combined with p53 induction. Furthermore, TCGA dataset analysis showed poor progression free survival in melanoma patients with high p21 protein expression. These data argue for administering mitotic inhibitors and MDM2 antagonists, which are currently in clinical development, in conjunction with agents that target p21. In summary, our data here reveal that polyploidization can be a mechanism for induction of DNA damage and genomic instability associated with drug resistance in cancer and suggest a novel strategy for targeting these pathways to improve melanoma therapy.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Molecular Carcinogenesis and Chromosomal Alternations

#512 Knockdown of the spindle assembly checkpoint gene Bub1b results in increased cell death and cell cycle impairment in breast cancer. Dilara Koyuncu, Erik T. Goka, Philip C. Miller, Marc E. Lippman. University of Miami, Miami, FL.

Genomic instability is a hallmark of cancer implicated in tumor evolution and resistance to therapy. However, the molecular mechanisms that underlie genomic instability are still poorly understood. One common feature of cancer cells is an elevated genomic content (polyploidy) which is also associated with the acquisition of therapy resistance. Here we demonstrate a link between genomic instability and polyploidization in melanoma cells. We show that polyploidy induced by treatment with small molecule inhibitors of various mitotic kinases, such as AURKA, AURKB and PLK1, leads to DNA damage in cells with elevated (>4n) DNA content. This DNA damage results from replication stress exacerbated by limited activation of p53 in malignant melanocytes. Pharmacological induction of p53 in polyploid cells using an MDM2 antagonist reduced DNA damage by blocking re-replication of the polyploid genome as a result of p53-mediated G1 arrest and transactivation of DNA repair genes. These data argue for administering mitotic inhibitors and MDM2 antagonists, which are currently in clinical development, in conjunction with agents that target p21. In summary, our data here reveal that polyploidization can be a mechanism for induction of DNA damage and genomic instability associated with drug resistance in cancer and suggest a novel strategy for targeting these pathways to improve melanoma therapy.

#514 Genetic load in cancer cell populations. Yuezheng Zhang,1 Xu Shen,2 Yawei Li,1 Tianqi Zhu,2 Yong Tao,1 Tao Li,2 Di Wang,1 Xueying Li,1 Qin Ma,2 Xueyi Lu,2 Huirong-Yi Wang,2 Chung-I Wu,2 1University of Washington, Seattle, WA; 2Beijing Institute of Genomics, Beijing, China; 3Peking University, Beijing, China; 4Institute of Clinical Medicine, National Taiwan University, Taipei, Taiwan.

Populations accumulate deleterious mutations that have yet to be removed by natural selection. This mutated portion of the population that does not contribute to its fitness is called the genetic load and is proportional to the deleterious nature and generation of new mutations. Given the genomic instability of cancer cells, the genetic load could be substantial if the instability indeed leads to loss of cell fitness. We hypothesize that because aneuploidy and copy number variations (CNVs) are the most common forms of genome instability, their fitness consequences may determine the genetic load in cancer cells. To test this hypothesis, we randomly selected single cells from a HeLa cell line and measured the cell growth rate via daily cell counting and an MTT cell proliferation assay. We then measured the genetic changes and resulting growth rate variation. We observed rapid generation of heterogeneity in the growth rate within the population. The growth rate of different progeny cells was stable indicating that it is genetically determined. Next, using whole genome sequencing of recently descended clones of a single HeLa cell, we found that cells with fewer newly acquired CNVs have higher proliferation rates versus a CNV. This indicated that CNV accumulation decreased cell fitness systematically. We next estimated the rate of CNV mutation by measuring the growth rate of two daughter cells from single proliferation and found that there is approximately 1 deleterious mutation in every 4 cell divisions. We speculated that due to a high, deleterious CNV mutation rate, tumor cells inevitably accumulate deleterious CNVs and a large percentage of tumor cells are genetically defective. Accordingly, we observed that the average growth rate of tumor cell populations decreased in the short term since defective cells accumulated in the population and the variation of cellular growth rates within the population increased. By modeling the process of mutation accumulation and measuring cell growth rate, we estimated that the deleterious mutation rate in HeLa cells is about 0.26-0.31 per cell division, and that HeLa cells reduce roughly 5%-6% of fitness for every cell division. The observations of a high proliferation rate and high genetic load in this representative tumor cell line indicates a “high risk, high reward” evolution strategy for tumor cells and suggests that increasing the level of genomic instability may cause the meltdown of tumor cell population by forcing cells to accelerate the cell cycle.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Molecular Carcinogenesis and Chromosomal Alternations

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 129
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Oncogenic Growth Factors and Signal Transducers

Introduction: PI3P is a molecule that regulate cell growth and mediates cell proliferation via PI3K/AKT/mTOR in response to various growth signals. Abnormal activation of genes in its pathway is associated to oncogenic activity and poor Overall Survival (OS). AMPK plays a role as a regulator of cellular energy homeostasis. Aims The aim of the this study is to define the role of PI3P pathway and AMPK pathway in AML. Methods: In this work we analyzed 208 consecutive newly diagnosed non M3 AML patients, screened for TP53, FLT3, NMP1, IDH1, IDH2, and DNMT3A mutations. Remission status was assessed with bone marrow biopsy. We performed Microarray-based Comparative Genomic Hybridization with Affymetrix SNP array 6.0 or Cytoscan HD in all the patients; we performed Whole Exome Sequencing (WES) in 208/208 patients. Survival data were collected prospectively, with a median follow-up of 18 months. Survival analysis was performed with Kaplan Meyer method using log rank test. Univariate and multivariable regression and Cox Hazard Ratio(HR) model was performed. Correlation between variables was assessed with Fisher’s exact test. Results: We selected genes in pathways basing on literature and GO data. Alterations in these pathways involved 103/209 patients (48%). We analyzed the gene in two different pathways. PI3K/AKT/mTOR pathway includes the following genes: pik3c3, cdk1a, akt1, akt3, mtor and pten, pdk1,pik3r1 and irs1. The second one is AMPK pathway and it include: sestr, prkaa1, prkab1, prkag1, prkag3. Alterations in PI3K/AKT/mTOR pathway confer worst OS (p = 0.035) when compared with unaltered patient, but events in these pathways did not affect therapy response. Alterations in AMPK pathway confer worst OS (p < 0.001). The combination of regulators in cAMP were tumourubin (20% mg%) after induction in univariate (p < 0.001) and multivariater analysis with age, karyotype, secondary AML, TP53 mutation (p = 0.009). AMPc pathway alteration was significantly associated with complex karyotype and TP53 mutation (p < 0.001). WES in a sub-cohort of patients did not found any significant mutation in genes we analyzed, according to literature. Conclusions: Our work investigates the role of PI3P and cAMP pathways in AML. Surprisingly, it showed that alterations in these pathways are associated with poor prognosis. Significantly, alterations in cAMP pathways were associated with therapy resistance. #516 High-throughput functional evaluation of variants of unknown significance in EGFR. Shinji Kohsaka,1 Masaaki Nagano,1 Toshihide Ueno,1 Yo-shiaki Sugihara,2 Takao Hayashi,2 Naoko Shimada,2 Kazuhisa Takahashi,2 Kenji Suzuki,2 Kazuya Takamochi,2 Fumiyuki Takahashi,2 Hiroyuki Mano1, 1Graduate School of Medicine, The University of Tokyo, Tokyo, Japan; 2Juntendo University Graduate School of Medicine, Tokyo, Japan.

Since transforming mutations in epidermal growth factor receptor gene (EGFR) were first identified in non-small-cell lung carcinoma (NSCLC), advance of diagnostics for such mutations, and evolution of targeted therapeutics against EGFR has driven unprecedented improvements in the management as well as outcome of patients with this lethal disease. However, next-generation sequencer (NGS)-driven extensive analyses on NSCLC have revealed a large number of variants of uncertain significance (VUS) in EGFR and other regions in the cancer genome that await further investigation. Here we present a mixed all together patients (in one sample) method to evaluate the VUS, performing potential and drug sensitivity of VUS of oncogenes, and applied this method to 101 non-synonymous EGFR mutants in a high-throughput manner. The sensitivity of individual mutants to tyrosine kinase inhibitors (TKIs) against EGFR was shown diverged, ranging from relatively insensitive mutations such as missense mutations within exon 19 to a highly resistant mutation within exon 21. Our data thus support the importance of examining uncommon mutations within EGFR, and also of functional evaluation of such mutations. Our MANO method may become a novel foundation for in vitro and in vivo assessments of variants of cancer-related genes to deliver precision medicine to individual cancer patients.

We hypothesize that dual inhibition of YAP and TAZ will lead to more pronounced cytotoxicity than each knockdown alone as a result of diminished compensatory mechanism by the remaining family members. Methods: NSCLC cell lines, such as PC9 and A549, were transfected with individual YAP1, TAZ siRNA or a combination of both siRNAs. Western blotting was performed to confirm the knockdown of the levels of YAP and TAZ. CTGF, Cyr61 and AXL, were also reduced accordingly. Moreover, dual knockdown of YAP and TAZ led to a more pronounced inhibition of cell survival/proliferation than ablation of individual genes alone. In addition, dual inhibition of YAP/TAZ exhibited significantly diminished levels of the mesenchymal markers, vimentin and N-cadherin, and increased levels of the epithelial marker, E-cadherin. EMT has been recognized as an essential process during lung cancer tumor migration and metastasis. Conclusion: Our findings show that dual inhibition of YAP1 and TAZ are synergistic in blocking NSCLC cell survival signaling. Thus, dual inhibition may serve as a better therapeutic strategy in targeting the Hippo pathway than sole YAP1 blockade in the management of NSCLC.

#519 Antitumor activity of MET antibody emibetuzumab (LY2875358) in combination with EGFR inhibitors in erlotinib resistant (ER) xenograft mouse models. Sudhakar Chintharlapalli,1 Jennifer R. Stephens,1 Jessica A. Baker,1 Holly K. Cannon,1 Joel D. Cook,1 Isabella H. Wolur,2 Roger Ageyi,2 Sudharak Chintharlapalli,1 Robert J. Evans,1 William J. Feaver,2 Lysiane Huber,1 Linda N. Lee,1 Ling Liu,1 Liandong Ma,1 Ruslan Novosiadly,2 Volker Wacheck,3 Sau-Chi Betty Yan1,1* Eli Lilly and Company, Indianapolis, IN; 1* Eli Lilly and Company, New York, NY; 2Eli Lilly and Company, Vienna, Austria.

Background: MET amplification (amp) is a resistance mechanism to EGFR TKI treatment. Emibetuzumab, a bivalent MET antibody (Ab) blocks HGF binding to MET and internalizes the receptor. Combination of emibetuzumab with EGFR TKIs (erlotinib, AZD9291, CO1686) or EGFR Ab (necitumumab, cetuximab) was evaluated in 3 ER xenograft models. Methods: Model 1: ER cell line HCC827ERL with high focal MET amp, high pMET, EGFR ex19 del (no T790M) was created from parental HCC827 NSCLC (EGFR ex19 del, EGFR amp, no MET amp) by increasing concentration of erlotinib in vitro over 7 months. Model 2: ER cell line HCC827-A8 was derived from HCC827 parental xenograft tumor serially passed in vivo with long term treatment of gefitinib and cetuximab. HCC827-A8 cells express high focal MET amp, high PMET/AXL (Western blot) while retaining EGFR ex19 del (no T790M). Model 3: LU8085 was an ER patient-derived NSCLC xenograft tumor, with focal MET amp, EGFR ex19 del, EGFR amp, no MET amp, L858R (no T790M). MET amp and EGFRmmt was determined by FISH and LNA-PCR sequencing respectively. Compound dosing: emibetuzumab 20 mg/kg qw; necitumumab 4 mg/kg or 20 mg/kg biw; cetuximab 4 mg/kg biw; erlotinib 25 mg/kg qd, 5 mg/kg AZD9291 qd, 30 mg/kg CO1686 bid. Results: EGFR inhibitors, but not emibetuzumab showed significant single agent anti-tumor effect in models when derived in vivo from parental cell lines, such as PC9 and A549, were transfected with individual YAP1, TAZ siRNA or a combination of both siRNAs. Western blotting was performed to confirm the knockdown of the levels of YAP and TAZ. CTGF, Cyr61 and AXL, were also reduced accordingly. Moreover, dual knockdown of YAP and TAZ led to a more pronounced inhibition of cell survival/proliferation than ablation of individual genes alone. In addition, dual inhibition of YAP/TAZ exhibited significantly diminished levels of the mesenchymal markers, vimentin and N-cadherin, and increased levels of the epithelial marker, E-cadherin. EMT has been recognized as an essential process during lung cancer tumor migration and metastasis. Conclusion: Our findings show that dual inhibition of YAP1 and TAZ are synergistic in blocking NSCLC cell survival signaling. Thus, dual inhibition may serve as a better therapeutic strategy in targeting the Hippo pathway than sole YAP1 blockade in the management of NSCLC.

#520 Trim44 is overexpressed in colorectal cancer with amplification, proteomic dephosphorylation of SHP-1 and activating JAK/STAT pathway by ubiquitin modification. Jie Hong, Qian Liang, Haoyan Chen, Jing-Yuan Fang, Hua Xiong. Shanghai Jiaotong Univ School of Med Renji Hospital, Shanghai, China.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
Proceedings of the American Association for Cancer Research

Tripartite motif 44 (Trim44) was found to be expressed in several cancers, but the exact roles of Trim44 in colorectal cancer (CRC) remain unclear. The objective of this study was to determine the functional and prognostic implications of Trim44 in colorectal cancer. The Trim44 gene is recurrently amplified and up-regulated in CRC. Trim44 overexpression and amplification are associated with poor survival in CRC (Garcia et al., 2014). It has been demonstrated that Trim44 is up-regulated by EWSR1 and other ETS transcription factors result in dis-regulated transcription of the mouse TDAG51 gene, was the first apoptosis-related gene shown to be suppressed in several cases of malignant tumors. But, the apoptotic regulatory mechanism and its role is not fully known in gastric cancer. The purpose of the this study is to identify function of PHLD2 associated with apoptosis in gastric cancer. We used cell culture, western blotting, RT-PCR, MTT assays, PHLD2 knock-down with short hairpin RNA (shRNA). First, we confirmed that the expression level of PHLD2 was up-regulated by IGF1/IGF1 receptor, making it the worse subtype of all breast cancers. Currently, there are no molecular targeted therapies for this cancer and chemotherapy is only successful in a limited number of patients. Recent studies suggest that members of the oncopgenic PIM kinase family, especially PIM-1, play a significant role in the growth of TNBC. However, there is very limited information on the role of PHLD2 in gastric cancer. We aim the in vivo study to identify the role of PHLD2 in gastric cancer, which may be a possible target for developing new therapy.

#521 Dual-targeting of IGF-1R and ErbB3 pathways in Ewing’s Sarcoma cellular models with istiratumab (MM-141), a bispecific, tetravalent monoclonal antibody. Isabel Yannatos, Adam Camblin, Zhenhua Li, Michael Curley, Gege Tan, Christyl U. Louis, Vasileios Askoxylakis, Greg Finn, Birgit Schoeberl, Rachel Nering, Merrimack Pharmaceuticals, Cambridge, MA.

Ewing’s sarcoma (ES) is a rare cancer that often present as metastatic in bone and soft tissue and predominantly affect adolescents and younger adults. Current treatment for ES includes surgical resection followed by loco-regional radiotherapy and chemotherapy. Survival rates for patients with metastatic disease continue to offer a particularly difficult clinical challenge, with a five-year survival rate of 20-30% for these patients. ES is primarily a genetic disease caused by fusion between the 5' segment of the Ewing sarcoma breakpoint region 1 gene (EWSR1) on chromosome 22 and the 3' portion of Friend leukemia virus integration site 1 (FLI1) on chromosome 11. Fusions of EWSR1 and other ETS transcription factors result in dis-regulated transcription factors which promote malignant progression of ES tumors. Recent studies have shown that most ES cell lines and clinical samples express IGF-1R. Importantly, an activated IGF-1R pathway appears to be a prerequisite for malignant transformation by the EWS-FLI1 translocation, presumably via activation of the PI3K-AKT and MAPK pathways. These findings have led to the preclinical and clinical evaluation of multiple IGF-1R-targeted therapeutics with varying results. Clinical experience with anti-IGF1R targeting therapies has demonstrated striking antitumor activity in minor subsets of patients with ES. Importantly, the paucity of a clinically useful biomarker to select patients continues to hinder IGF-1R drug development in ES. Istitutumab is an investigational, bi-specific monoclonal antibody that acts as a tetravalent inhibitor of PI3K/AKT/mTOR, a major pro-survival pathway tumor cells use as a resistance mechanism to anti-cancer therapies. Istitutumab is designed to interfere with this pathway by blocking ligand-induced signaling through the IGF-1R and ErbB3 receptors, based on findings from preclinical in vitro and in vivo studies. To test the role of the IGF-1R and ErbB3 blockade, we will present data in multiple ES models demonstrating the importance of both IGF-1R and ErbB3 in this disease as a mechanism of growth and resistance. Furthermore, preclinical xenograft studies demonstrate that the combination of istitumab with an irinotecan-based chemotherapy regimen offers significant benefit over chemotherapy alone. These studies suggest that clinical evaluation of istitumab in ES is warranted.

Urothelial carcinoma of the bladder is a common malignancy that causes approximately 150,000 deaths per year worldwide. So far, no molecularly targeted agents have been approved for treatment of the disease. In the present study, we built an in-house oligonucleotide array, on which 394 genes were selected based on our SAGE data and previously reported array data, in order to identify the genes of most relevance to gastric carcinogenesis. Among these genes, we focused on SEC11A, because it is frequently associated with T category (p = 0.0002), Grade (p = 0.0425), vascular invasion (p = 0.0112) and CKS6/positive/ CK20 negative basal type BC (p = 0.0004). The univariate analysis indicated that expression of SPC18 (HR, 3.14; 95% CI, 1.47-7.47; P = 0.0027) was associated with overall survival. In the multivariate model, SPC18 expression was an independent prognostic indicator (HR, 2.94; 95% CI, 1.35-10.18; P = 0.012). BC cells transfected with SPC18 expression vector significantly induced the cell growth (p < 0.01) and invasion (p < 0.01) activity. Western blot showed the overexpression of SPC18 induced the phosphorylation of EGFR, Akt and Erk. Real time reverse transcription PCR analysis revealed the SPC18 forced expression cells induced mesenchymal character. These results suggest that SPC18 might contribute to the progression of BC.

#523 HGF mediated upregulation of PHLD2 is associated with apoptosis in gastric cancer. Sung Ae Koh, Kyung Hee Lee, Jae Ryong Kim, Sang Woon Kim. Yeungnam University Hospital, Daegu, Republic of Korea.

Pleckstrin homology-like domain family A member 2 (PHLD2), a homolog of the mouse TDAG51 gene, was the first apoptosis-related gene shown to be imprinted and expressed from the maternal allele in normal development. It is located within the tumor suppressor region of 11p15, and its expression is reported to be suppressed in several cases of malignant tumors. But, the apoptotic regulatory mechanism and its role is not fully known in gastric cancer. The purpose of the this study is to identify function of PHLD2 associated with apoptosis in gastric cancer. We used cell culture, western blotting, RT-PCR, MTT assays, PHLD2 knock-down with short hairpin RNA (shRNA). First, we confirmed that the expression level of PHLD2 was up-regulated by IGF1/IGF1 receptor, making it the worse subtype of all breast cancers. Currently, there are no molecular targeted therapies for this cancer and chemotherapy is only successful in a limited number of patients. Recent studies suggest that members of the oncopgenic PIM kinase family, especially PIM-1, play a significant role in the growth of TNBC. However, there is very limited information on the role of PHLD2 in gastric cancer. We aim the in vivo study to identify the role of PHLD2 in gastric cancer, which may be a possible target for developing new therapy.

#524 Characterizing the in vitro and in vivo effects of the PIM kinase inhibitor HS140 in triple-negative human breast cancer. Michael Cobb, Lucas Hunter, David Carlson, David Darr, Timothy Haystead, Antonio T. Baines, North Carolina Central Univ., Durham, NC; University of North Carolina at Chapel Hill, Chapel Hill, NC; Duke University, Durham, NC.

Triple-negative breast cancer (TNBC) lacks expression of the estrogen receptor (ER), the progesterone receptor (PR) and the ERBB2 (also known as HER2) receptor, making it the worse subtype of all breast cancers. Currently, there are no molecular targeted therapies for this cancer and chemotherapy is only successful in a limited number of patients. Recent studies suggest that members of the oncopgenic PIM kinase family, especially PIM-1, play a significant role in the growth of TNBC. However, there is very limited information on the role of PIM family members have in the growth and development of TNBCs. As an attempt to address this concern, we treated a panel of TNBC cell lines with HS140, a PIM-2 kinase inhibitor developed in the laboratory. Using cytotoxicity assays, we were able to demonstrate a decrease in anchorage-independent growth of cell lines at different concentrations of HS140. Also, a triple negative breast cancer GEMM (C3TAg) was used for an efficacy study. Mice (FVB/N background) have C(3)SV40 T-antigen resulting in inactivation of p53 and Rb. Nine mice received HS140 treatment (80mg/kg BIW IP) and 14 left untreated for control (non-treatment [NT]). All mice were monitored for weight loss and timespan to tumor development 5 times weekly. Tumor volumes at 21 days were similar (Mann–Whitney, p = 0.0082) reduced in the treated cohort with a mean of 109mm^3 (range of 0-500) compared to untreated 1393mm^3 (0-239). We observed no toxicities with body mass stable at the treatment dose of 80mg/kg. Additionally, three mice from untreated and three mice from treated cohorts were chosen for blood sampling pre- and post-treatment via a submandibular
bleed; no significant differences were noted in WBC, RBC, PLT, or HGB between untreated and treated cohorts. Overall, these results suggest that other members of the PIM kinase family, including PIM-2, have an important function in the growth and development of TNBC and may serve as a potential molecular target for future therapeutics.

#525 Role of CLCA2 in proliferation of certain growth-factor receptor dependent cancers. Yufang Yin, Aarushi Sharma, Randolph C. Elble. Southern Illinois Univ. School of Medicine, Springfield, IL.

The CLCA2 gene is downregulated in most adenocarcinomas, suggesting it is a tumor suppressor gene. However, we have observed that CLCA2 is upregulated in squamous carcinomas and Her2+ breast cancers. Such cancers also upregulate the related chloride channel Ano1, which is known to promote Her2.

Others have reported that Ano1 enhances EGFR signaling and that Ano1 knockdown confers sensitivity to EGFR inhibitors. Both EGFR and Her2 are known to transduce their mitogenic signal in part by causing release of intracellular calcium. We have found that CLCA2 activates Ano1 by upregulating intracellular calcium. Moreover, knockdown of CLCA2 reduced EGFR activation and cell proliferation while it enhanced sensitivity to the tyrosine kinase inhibitor lapatinib. These observations suggest that EGFR/Her2, Ano1, and CLCA2 comprise a feed-forward loop that amplifies growth factor signaling, so that certain cancer cell types maintain expression of all three.

#526 NFκB p65 overexpression promotes bladder cancer migration via FBW7-mediated degradation of RhoGDI protein. Yang Li, Junlan Zhu, Jingxia Li, Chuanshu Huang. NYU Nelson Institute of Environmental Medicine, Tuxedo Park, NY.

Since bladder cancer (BC) is one of the most lethal urological malignant tumors worldwide, understanding the molecular mechanisms that trigger the migration, invasion and metastasis of BC has great significance in reducing the mortality of this disease. RelA/p65, a member of the NF-kappa B transcription factor family, is increasingly recognized as a crucial player in many steps of cancer initiation and progression. In this study, we unexpectedly found that p65 protein expression increased in the bladder carcinoma N-butyl-N-(4-hydroxybutyl)-nitrosamine (BNB)-induced invasive bladder tumor tissues, and in human bladder cancer cell lines. We also observed that p65 overexpression promoted bladder cancer cell migration by inhibiting RhoGDI protein expression. We further demonstrate that the regulatory effect of p65 on RhoGDI protein degradation and promotons human BC cell migration. The identification of p65/PTEN/FBW7/RhoGDI axis provides a significant insight into understanding the nature of BC migration.

The growth and survival of prostate cancer tumors relies primarily on the functioning of the androgen receptor (AR) signaling pathway. Recent studies suggested that the presence of AR-V7, a c-terminal truncated form of AR, in circulating tumor cells (CTCs) of patients with castration-resistant prostate cancer (CRPC) is associated with inherent and/or acquired resistance to enzalutamide and abiraterone, the stand of care androgen deprivation therapies in prostate cancer. A series of data also indicate that AR-Vs (eg, including AR-V7, AR-373, AR-T878A, AR-F876L, etc) may drive resistance in CRPC. Expression of AR-V7 has been shown to correlate with disease progression and shortened survival. Considering that truncated AR splicing variants with C-terminal loss lack a functional ligand-binding domain (LBD) and are constitutively active, C-terminal AR-directed therapies may not be effective for patients with AR splicing variants. Circulating tumor cell (CTC)-based AR-V7 tests are currently being tested in the clinic. However, nearly half of the CRPC patients do not have enough CTCs for AR-V7 test, raising the request for a complementary, non-CTC platform to detect AR variants as well as other resistance markers in circulation. Here we report the development, validation and clinical application of PrediSeq-Prostate, a non-invasive next generation sequencing-based diagnostics platform that offers integrated genomic cell-free DNA (cfDNA) and cell-free RNA (cfRNA) profiling of prostate cancer, identifying known (such as AR-V7, AR-V9, AR-V2, etc) and novel AR splicing variants, point mutation, copy number, and translocation (such as TMPRSS2-ERG) using a single tube of blood. Using plasma samples from mCRPC patients that developed resistance to enzalutamide and/or abiraterone, PrediSeq-Prostate NGS test identified AR-V7, AR-V2, AR-V3, AR-V4 and other splicing variants that impact diagnosis and therapeutic selection. We also developed a Bio-Rad digital PCR assay measuring AR-V7 and AR-FL (full length) simultaneously. Collectively, PrediSeq NGS and ddPCR assays offer comprehensive genomic profiling of both cfDNA and cfRNA in all patients with prostate cancer, regardless of their status of CTC enumeration. The successful development and clinical validation of these tests has potential to enable precision medicine in prostate cancer.

#528 Evaluation of single agent merestinib (LY2801653) or emibetuzumab (LY2875358) and the combination in a xenograft tumor model bearing MET exon 14 skipping. Sau-Chi Betty Yan, 1 Suzane L. Um, 1 Victoria L. Peek, 1 Jennifer R. Stephens, 1 Wei Zeng, 1 Bruce W. Konicek, 1 Ling Liu, 1 Volker Wachcek, 2 Richard A. Walgren, 1 Eli Lilly and Company, Indianapolis, IN; 2 Eli Lilly and Company, Vienna, Austria.

Background: MET ex14 skipping, present in ~3% of lung cancer, is a strong oncogenic driver which is further evidenced by case reports of patients responding to MET TKI treatment. ~15% of tumors in patients that harbor MET ex14 skipping also have MET amplification (amp). Merestinib is a type II MET kinase inhibitor. Emibetuzumab, a bivalent MET Ab, internalizes MET receptor. Each single agent and the combination were evaluated in the Hs746t gastric cancer line bearing MET ex14 skipping and MET amp. Methods: Each agent was evaluated in vitro for inhibition of Hs746t cell proliferation and pMET levels. In vivo study in Hs746t-derived xenograft mouse model (n = 7 mice/ arm, 28 day dosing) initiated when tumors were 150-350mm3: merestinib at 6 mg/kg (suboptimal dose - insufficient target coverage for 24 hrs) or 12 mg/kg (optimal dose) q dr orally; emibetuzumab by IP. Results: Merestinib inhibited Hs746t cell proliferation with IC50 = 34 nM and totally eliminated pMET at 65-100 nM. Emibetuzumab slightly inhibited Hs746t cell proliferation (IC50 > 100 nM), reduced 20-20% cell surface MET, and no effect on pMET expression (at 130-650 nM). In the Hs746t xenograft model, merestinib (12 mg/kg) treatment resulted in 91.8% tumor regression after 21 day dosing, while 6 mg/kg merestinib provided transient tumor regression followed by re-growth while on treatment with T/C= 18.3% after 21 day dosing. No tumor re-growth was observed in 6/7 mice in the 12 mg/kg merestinib cohort during the 5 weeks post-treatment. Emibetuzumab treatment provided transient tumor regression (37.7%) after 3 doses, but tumors re-grew while on treatment. Combination of 6 mg/kg merestinib and 10 mg/kg emibetuzumab resulted in 85% tumor regression for the duration of the 28 day dosing period and the treatment was well tolerated. Tumors in animals re-grew upon termination of this combination treatment. Conclusion: Merestinib (12 mg/kg) treatment resulted in durable and complete response in 6/7 mice bearing Hs746t tumors with MET ex14 skipping and MET amp. When used singly. merestinib (6 mg/kg) or emibetuzumab (10 mg/kg) resulted in only transient tumor regression in this model, while the combination resulted in substantial tumor regression while on treatment. This combination treatment was however, not as durable as was observed with single agent 12 mg/kg merestinib. Single agents and the combinations were well tolerated. As a type II MET inhibitor, merestinib may provide a therapeutic option to treatment naive patients or those who have progressed on type I MET inhibitor treatment, whose tumors have MET exon 14 skipping and/or MET amplification.

#529 The significance of activated PI3K/akt pathway in FGFR3-TACC3 fusion positive cervical cancer. Ryo Tamura, 1 Kousuke Yoshihara, 1 Tetsuya Saito, 2 Ryosuke Ishimura, 2 Emmanuelle Martinez-Ledesma, 3 Yutaro Mori, 3 Kaoru Yamawaki, 1 Kazuaki Suda, 1 Tatsuya Ishiguro, 4 Yoichi Aoki, 4 Hiroaki Itamochi, 5 Masaaki Komatsu, 2 Roeland Verhaak, 3 Takayuki Enomoto 1. 1Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; 2Department of Biochemistry, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; 3Department of Genome Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX; 4Department of Obstetrics and Gynecology, Graduate School of Medicine, University of the Ryukyus, Okinawa, Japan; 5Department of Obstetrics and Gynecology, Tottori University School of Medicine, Tottori, Japan.

Uterine cervical cancer is one of the most common cancer in women worldwide, and the prognosis in advanced or recurrent cases remains poor because of the absence of effective molecular target therapies for this disease. The aim of our study is to identify and validate therapeutically targetable gene fusions in uterine cervical cancer, leading to the development of new therapeutic strategies. We have analyzed RNA sequencing data of 253 TCGA cervical cancer samples to search for gene fusions by using PRADA algorithm, and validated recurrent fusions in our...
Japanese dataset (n = 100) by RT-PCR and sanger sequencing. In TCGA samples, we detected 358 fusion transcripts and extracted 3 kinds of recurrent in-frame fusion transcripts (FGFR3-TACC3, ARL1B-ITPR1 and NNX-ABR). We focused on FGFR3-TACC3 fusion as a candidate of therapeutic kinase fusion and identified FGFR3-TACC3 fusion in 2 of 253 (0.8%) TCGA samples and 2 of 124 (1.6%) samples of a different pan-cancer study (Ma et al, 2017). FGFR3-TACC3 fusion is pathologically diagnosed as squamous cell carcinoma, showed high expression of both FGFR3 and TACC3 genes. To evaluate the possibility as therapeutically targetable fusions in uterine cervical cancer, we transfected FGFR3-TACC3, wild type FGFR3 and TACC3 transcripts to normal immortalized cervical keratinocytes derived from ectocervix (Ect/E6E7) and four uterine cervical cancer cell lines (SiHa, ME180, Hela, CaSkii). Continuous expression of FGFR3-TACC3 fusion transcript led to anchorage-independent growth in Ect/E6E7 and the dramatically alteration of cell proliferation in all cancer cell lines. On the other hand, no obvious phenotype change was observed in FGFR3 or TACC3 transfected cells. Western blotting analysis demonstrated that MAPK pathway was activated in all the transfected cell lines but PI3K/AKT pathway was activated only in ME180 and CaSkii harboring PIK3CA mutation. Fusion transfected cell lines exhibited high sensitivity to fusion specific siRNA and FGFR inhibitor compared to control. Although PI3K/AKT activated cell lines (ME180 and CaSkii) showed less effective against FGFR inhibitor compared to PI3K/ AKT neutral cell lines (SiHa and Hela), combined inhibition of FGFR and AKT had a synergic effect in PI3K/AKT activated cell lines. Our findings suggest FGFR3-TACC3 fusion is an oncogenic driver event and therapeutic target in a fraction of cervical cancer. When FGFR3-TACC3 fusion positive cervical cancer is treated by FGFR inhibitor, genomic background such as PI3K/AKT status should be considered.

The role of EGFR in c-fos-dependent osteosarcoma formation.

Markus Linder,1 Elisabeth Giltzner,1 Srijan Srivastava,1 Parastoo Shahrouzi,2 Latifa Bakiri,2 Monika Dumanic,1 Markus Mitterhauser,1 Erwin F. Wagner,1 Maria Sabiah1.1 Medical University of Vienna, Vienna, Austria; 2Spanish National Cancer Research Center (CNIO), Madrid, Spain.

The Epidermal Growth Factor Receptor (EGFR) is overexpressed or mutated in human carcinomas and glioblastomas, which are tumors of epithelial and glial origin, respectively. Some publications indicated that EGFR overexpression could occur in human osteosarcomas (OS). Using EGFR knockout mice (Egrf−/−), we have recently shown that EGFR plays a role in bone development and osteoblast function, raising the possibility that EGFR is also involved in OS formation. Here we show that Egrf−/− RunX2-Cre mice (EgrfΔ/Δ) lacking the EGFR in osteo-chondroprogenitor cells, developed an increased zone of hypertrophic chondrocytes in long bones and decreased bone formation. When bred to c-fos transgenic mice (H2-c-fosLTR) that develop osteosarcomas with 100% penetrance, Egfr−/−Runx2-Cre mice (Egfrf/f Runx2-Cre) mice (Egfrf/f) showed less effective against FGFR inhibitor compared to PI3K/AKT neutral cell lines (SiHa and Hela), combined inhibition of FGFR and AKT had a synergic effect in PI3K/AKT activated cell lines. Our findings suggest FGFR signaling is an oncogenic driver event and therapeutic target in a fraction of cervical cancer. When FGFR3-TACC3 fusion positive cervical cancer is treated by FGFR inhibitor, genomic background such as PI3K/AKT status should be considered.
The X-linked inhibitor of apoptosis protein (XIAP) is a well-known potent apoptosis suppressor, and also participates in cancer cell biological behaviors, therefore attracting great attentions as a potential antineoplastic therapeutic target for past years. We found here that lacking of XIAP expression resulted in a remarkable suppression of EGR expression, consequently leading to the deficiency of essential cell protein promoting tumor metastasis. The BIR domain of XIAP was crucial for regulating the EGR translation by suppressing the transcription and expression of miR-200a. Mechanistic studies indicated that BIR domain activated the PP2A activity by decreasing the phosphorylation of PP2A at Tyr307 in its catalytic subunit, PP2A-C. Such activated PP2A prevented the deviation phosphorylation and activation of MAPK kinases/ MAPs, their downstream effector c-Jun, and in turn inhibiting transcription of c-Jun-regulated the miR-200a. Collectively, our study uncovered a novel function of BIR domain of XIAP in regulating the EGR translation, providing significant insight into the understanding of the XIAP overexpression in the cancer development and progression, further offering a new theoretical support for using XIAP BIR domain and EGFR as targets for cancer therapy.

#534 PDGFRB gain-of-function mutations in multifocal infantile myofibromatosis: Implications for diagnosis & therapy. Florence A. Arts,1 Raf Sciortino,2 Bénédicte Brichard,1 Marleen Renard,2 Laura A. Noël,1 Amélie I. Velghe,3 Christine Galant,1 Maria Debiec-Rychter,2 An Van Damme,1 Miikka Vikof a polarized ex(o)citing machinery for cancer invasion. Christine Galant,1 Maria Debiec-Rychter,2 An Van Damme,1 Miikka Vikki,1 Rachel Haelers,1 Nisha Limaye,1 Hélène A. Poirel,1 Jean-Baptiste B. De Moulins1,1 University of Louvain, Brussels, Belgium; 2KU Leuven, Leuven, Belgium.

Myofibromas and infantile myofibromatosis are among the most prevalent soft tissue tumors of infancy and childhood. They are characterized by the presence of solitary or multiple nodules in the skin, subcutaneous soft tissues, bones, muscles and viscera. Multifocal myofibromatosis with visceral lesions is associated with a poor prognosis. The pathogenesis of sporadic myofibromatosis is unknown. A few familial cases have been linked to mutations in various genes including PDGFRB, which encodes a receptor tyrosine kinase that is highly expressed in fibroblasts, pericytes and other cells of mesenchymal origin. In the present study, we investigated whether the sporadic form of the disease may also be associated with PDGFRB mutations. We sequenced the whole coding sequence of PDGFRB in 20 cases of myofibromatosis or solitary myofibroma using the Ion AmpliSeq technology at high coverage (Life Technologies). Six different mutations in the coding sequence of PDGFRB were identified in seven patients, six of whom had the sporadic multicentric form of the disease, with a median age at diagnosis of 13 months (range: 0 to 7 years). Mutations were located in four different exons: the classical hot-spot exons 12 and 14, encoding the juxtamembrane and the kinase domains, but also the exons 11 and 18, encoding the transmembrane domain and the activation loop respectively. The percentage of mutated reads varied between 4 and 33%, suggesting that the mutations were somatic, except for one patient who had a germline R561C substitution and a somatic second hit. Two patients had the same mutation in multiple separated lesions, suggesting an early post-zygotic mutation in a progenitor cell. By contrast, a third patient had three different PDGFRB mutations in the three nodules analyzed. We showed that these mutations constitutively activated receptor signaling, mimicking the ETV6-NTRK3 activity, and we found that downstream pathways were activated in a cell-autonomous manner. Furthermore, the mutant receptors were sensitive to the tyrosine kinase inhibitor imatinib, except D850V, which was inhibited by dasatinib and ponatinib, suggesting a treatment for severe myofibromatosis. In conclusion, we identified activating PDGFRB mutations in 66% of sporadic multicentric infantile myofibromatosis cases, shedding light on the mechanism of disease development. Our results provide a genetic test to facilitate diagnosis, and preclinical data for development of molecular therapies.

#535 Paving the path to metastasis/invasion through GIV: Identification of a polarized ex(o)citing machinery for cancer invasion. Cristina C. Rohena, Nina N. Sun, Nicolas Aznar, Pradip Ghosh. University of California San Diego, San Diego, CA.

Polarized exocytosis is a fundamental process involving the delivery of membrane and cargo proteins to target sites the plasma membrane (PM) and it is essential for a wide range of biological functions such as cell growth, morphogenesis, and polarized cell migration. Polarized exocytosis requires precise spatial control of vesicle tethering to target sites at the PM. This is mediated by the octameric exocyst complex that is conserved from yeast to man. How the exocyst complex imparts polarity during exocytosis remained a mystery until recent insights emerged from studies on budding yeast. A functional interaction between exocyst component Exo70p and the yeast polarity determinant scaffold protein Bem1p was reported, and it was shown that Bem1p regulates the targeting of Exo70p to polarized exocytic sites. Despite these insights, the counterpart of Bem1p in higher species remained elusive. Here we demonstrate that a novel polarity-determinant protein called GIV (Go-interacting vesicle associated protein/Girdin) fulfills the key criteria and functions of its yeast counterpart Bem1p. GIV provides an evolutionary upgrade to the process of polarized exocytosis by making it responsive to growth factors and other external cues and by modulating the composition of the exocyst complex. Its interaction with GIV was originally identified in a yeast-2 hybrid screen as a binding partner of EXO1C1, and subsequently validated by us as a PI4P-binding protein that is a direct binding partner of mammalian Exo70. Biochemical assays have confirmed that the mechanism of GIV/Exo70 interaction bears close resemblance to the Bem1p: Exo70p interaction. Sequence alignment studies led to the identification of single point mutants in Bem1p and GIV that are selectively defective in binding to Exo70. Using genetic manipulation of cancer cells we have observed that GIV is essential for polarized tethering of Exo70-coated vesicles at the cell periphery. Consistent with the previously described prometastatic role of GIV, we found that GIV is required for EGF-stimulated exocytosis of matrix metalloproteases that aid in cancer invasion in MDA-MB-231 breast cancer cells and that specific point mutants of GIV that disrupt the interaction with Exo70 cause a reduction in the ability of these breast cancer cells to invade and degrade components of the extracellular matrix. Furthermore, GIV interacts specifically with TC-10GTP[active], a monomeric GTPase that regulates fusion of exocytic vesicles at the plasma membrane. Insights gained continue to provide an in-depth understanding of how GIV affects a fundamental process of exocytosis, and what impact that may have on cancer invasion and metastasis.

#536 Novel identification of STAT1 as a crucial mediator of ETV6-NTRK3-induced tumorigenesis. Jinah Park,1 Junil Kim,2 Poul H. Sorensen,3 Seong-Jin Kim1, 1Seoul National University, Gyeonggi-do, Republic of Korea; 2Perelman School of Medicine, Philadelphia, PA; 3British Columbia Cancer Research Centre, Vancouver, British Columbia, Canada.

Chromosomal rearrangements that facilitate tumor formation and progression through activating oncogenic tyrosine kinases are frequently observed in cancer. The ETV6-NTRK3 (EN) fusion has been implicated in various cancers, including infantile fibrosarcoma, secretory breast carcinoma and acute myeloblastic leukemia, and has exhibited in vivo and in vitro transforming ability. In the present study, we analyzed transcriptome alterations using RNA-Seq in ETV6-NTRK3 (EN) fusion-induced cells. Notably, KEGG pathway analysis identified the Jak-STAT signaling pathway with the highest statistical significance. Moreover, Ingenuity Pathway Analysis and gene regulatory network analysis identified the Stat1 transcription factor and its target genes as top EN-regulated molecules. We further demonstrated that EN enhanced STAT1 phosphorylation but attenuated STAT1 acetylation, thereby inhibiting the interaction between NF-kB p65 and acetylated STAT1. Consequently, nuclear translation of NF-kB p65 and subsequent anti-apoptotic NF-kB activity were increased, leading to the first time, STAT1 as a significantly EN-regulated transcription factor and a crucial mediator of EN-induced tumorigenesis. [This work was supported by a National Research Foundation grant of Korea (NRF-2014M3A9B5073918) funded by the Korea government.]

The molecular mechanisms that control transformation and tumorigenicity of human papillomavirus-associated (HPV +) head and neck squamous cell carcinomas (HNSCCs) are currently being investigated. The number of HPV + HNSCC cases has increased sharply in recent years, especially in oral squamous cell carcinomas. These HPV + HNSCCs often respond differently to treatments. Recently, The Cancer Genome Atlas (TCGA, 2015) identified novel loss-of-function genomic alterations of TNF receptor-associated factor 3 (TRAF3) in HPV + HNSCCs. TRAF3 is a ring-finger E3 Ubiquitin Ligase which inhibits downstream alternative NF-kB signaling and promotes anti-viral immunity by promoting degradation of ubiquitinated proteins. To assess TRAF3’s role in HPV + HNSCCs, we identified cell lines with lower level of TRAF3 protein, consistent with deficient TRAF3 expression identified in TCGA data. Functional studies showed that TRAF3 expression led to decreased steady-state protein levels of the alternative NF-kB pathway components RELB and NF-kB2/p52, as assessed by Western blot,
reporter assays and immunofluorescence. Additionally, TRAF3 expression led to decreased cell proliferation, tumorigenic activity and migration, and increased sensitivity to chemotherapy agent cisplatin. Interestingly, TRAF3 increases the steady state protein level of the classical tumor suppressors RB and p53 in HPV + HNSCC cell lines as assessed by Western blot. Further in vitro characterization of TRAF3’s function in HPV + HNSCCs was assessed using clinically identified TRAF3 loss-of-function mutagenic isoforms, mimicking both TCGA data and HNSCC cell line data for TRAF3 defects. In contrast to wtTRAf3, these mutant forms of TRAF3 do not as strongly restore p53 or inhibit RELB and NF-κB2/p52 protein levels. One specific mutation which causes a frameshift at residue 210 greatly inhibits TRAF3 function as assessed by Western blot. To further assess effects of wt or TRAF3 loss-of-function mutants in vitro and in vivo, an inducible HPV + HNSCC line expressing TRAF3 using the TET-ON system, and TRAF3 knockout in HPV + HNSCC line and Human Oral Keratinocyte (HOK) line using CRISPR-Cas9 genomic editing are generated. In conclusion, the ring-finger F3 ubiquitin ligase TRAF3 inhibits the pro-survival alternative NF-κB signaling pathway and restores TP53 and RB, thereby serving as a classical tumor suppressor in HPV + HNSCCs. (Supported by NIDCD intramural project ZIA-DC-000016, 73 and 74).

#538 The cytosolic domain of a disintegrin and metalloprotease (ADAM) 15 promotes non-small cell lung cancer (NSCLC) anti-apoptosis ability. Hsin-Han Hou, Chong-Jen Yu. National Taiwan University Hospital, Taipei, Taiwan.

Emerging evidence has indicated that proteins of a disintegrin and metalloprotease (ADAM) family contribute to cancer progression and metastasis. One member of this family, ADAM15, has been shown to be upregulated in multiple cancers, including gastric, lung, breast, and prostate cancers, and the enzymatic activities of its extracellular metalloprotease domain promote breast cancer proliferation and migration through mediating ErB signaling pathway. The patients with ADAM15 high-expressing lung tumors have shorter survival time and ADAM15 has been proved to enhance synovial fibroblasts anti-apoptosis ability via focal adhesion kinase signaling pathway. We firstly demonstrated other than extracellular enzymatic activity, the longest isoform of ADAM15 (ADAM15 i6), which contains the most cytoplasmic Src homology 3 (SH3) binding motifs, significantly upregulated in primary lung cancer tissues and promoted NSCLC proliferation via growth factor receptor-bound protein 2 (Grb2) and Src homolog 2 domain containing (Shc) association. In this study, we further explore the roles of ADAM15 cytosolic domain in NSCLC-apoptosis resistance. Overexpression of ADAM15 i6 promoted CL1-0 cell anti-apoptosis ability according to the trypan blue inclusion assay. Ablation of nephrocystin (NPHP1) attenuated the ADAM15 i6-promoted anti-apoptosis ability. Thus, we identified a novel mechanism of the ADAM15 cytoplasmic domain in NSCLC tumor progression, which will shed light on the molecular mechanisms of ADAM proteins, and facilitate development of novel therapy in NSCLC.

#539 MAEL promotes colorectal cancer cell growth and migration by activating EGFR pathway. Lulu Liu, Zhou Tong, Weiqin Jiang, Yi Zheng, Peng Zhao, Weijia Fang. The First Affiliated Hospital, Zhejiang University, Hangzhou, China.

Colorectal cancer (CRC) is one of the most common malignant tumors of the digestive system. It is generally accepted that CRC pathogenesis is a long-term process involving accumulation of multiple genetic alterations. Herein, we aim to explore the molecular biological mechanisms of CRC initiation and progression. We have been committed to investigating MAEL function in digestive neoplasms and have found MAEL is a new candidate oncogene. Previously, overexpression of MAEL was frequently detected in CRC tissues and significantly associated with poor 5-year outcome. By MTT assay and transwell assay, functional study demonstrated that overexpression of MAEL promoted cell growth and cell migration in DLD1 and TH8307 cell lines. Furthermore, overexpression of MAEL in DLD1 cell line could promote tumor formation in nude mice. Further study found that MAEL overexpression in DLD1 and TH8307 elevated the protein expression of p-EGFR, p-Raf-1, p-ERK 1/2, p-PI3K and p-AKT. These data indicated that MAEL enhanced the activity of EGFR/Raf/ Raf/MEK/ERK1/2 and EGFR/PI3K/Akt pathways. However, more effort is needed to investigate MAEL function and how MAEL activate EGFR pathways.

We hypothesized that the spatial arrangement of nuclei in a hematoxylin and eosin (H&E) stained image contains a vast quantity of latent information that is currently underutilized. We tested this hypothesis on the classification of breast cancer biopsies as estrogen receptor (ER) positive or negative. While determining ER status typically requires immunohistochemistry (IHC) staining, we aimed to recapitulate this step by predicting ER status directly from H&E stained slides. By training a deep neural network on nuclear-morphometric features, we demonstrated the power of machine learning to provide insights about cancer biology, and aim to scale precision oncology for the developing world. We constructed a learning pipeline that segments nuclei from H&E stained slides scanned into digital images, extracts shape and orientation descriptors, and uses a deep neural network to learn spatial features to predict ER status. After training the pipeline on 57 tissue cores of invasive ductal carcinoma (IDC), we were able to predict ER status in patients with IDC in a retrospective manner (AUC = 0.72, 95%CI = 0.65-0.80, n = 56) and ductal carcinoma in situ (AUC = 0.82, 95%CI = 0.74-0.89, n = 106). To our knowledge, this is the first work to show that nuclear morphometric information can be used to predict the molecular status of a breast cancer tumor. An initial analysis of the features learned by the deep neural network provides a glimpse into the mechanistic differences between ER+ and ER- cancers: suggesting the importance of spatial heterogeneity in distinguishing between ER+ and ER-. We anticipate that further analysis will provide deeper insights about the morphological differences between ER+ and ER- cancers, and that this type of analysis can be applied to other markers and cancers. Moreover, an optimized version of this pipeline may serve patients in the developing world by providing a means to predict marker status directly from H&E images.

#541 A comprehensive analysis delineating the immunotherapeutic terrain of cancer-related clinical trials. Cara M. Statz, Sara E. Patterson, Taoei Yin, Susan M. Mockus. The Jackson Laboratory for Genomic Medicine, Farmington, CT.

Technological innovations have facilitated a greater understanding of how the tumor microenvironment contributes to cancer, leading to rapid FDA approval of four immunotherapies. To assess how these therapies are being further investigated in combination with other therapies and in tumor types outside of the current FDA approval, we performed a comprehensive analysis of the curated clinical trials in the JAX Clinical Knowledgebase (JAX-CKB). In brief, clinical trial records from the JAX-CKB were queried for combination immunotherapy trials investigating Pembrolizumab, Nivolumab, Pembrolizumab and Ipilimumab, curated from clinicaltrials.gov, were queried in the JAX-CKB and then analyzed for comparison. Further analyses were executed to illustrate possible unmet needs within the field of cancer therapeutics. Of the four immunotherapies, Pembrolizumab was identified with the greatest number of clinical trials overall, with 305 compared to Atezolizumab, 79, Nivolumab, 183, and Ipilimumab, 126. Of the 305 trials the number of trials investigating Pembrolizumab, Atezolizumab, Nivolumab, or Ipilimumab in combination with another therapy was higher than those investigating one of the four immunotherapies as a monotherapy. Phase II trials for both single therapy and combinational therapies were demonstrated to be higher than both Phase I and Phase III for the same groups, regardless of therapy. On average, 12% ± 3.8% of the combined trials for all four drugs included any advanced solid tumor. Nivolumab combined with Ipilimumab demonstrated the greatest number of trials (61) investigating an immunotherapy in combination with another immunotherapy. Among those, 30 were Phase II trials, 16 were Phase I, and 14 were Phase III. Across five cancer indications (lung, pancreatic, ovarian, prostate, and colon), lung cancer was most commonly indicated in the trials, among all four drugs. Prostate was indicated in the least number of trials, with Ipilimumab ranking the highest (10). The recent success with immunotherapies has garnered significant interest in understanding how these therapies will perform in different tumor types and whether specific combinations will have a greater impact. Interrogation of the clinical trial terrain in the JAX-CKB provides a basis for determining additional investigations that might be warranted.

Recent advances in cancer immunotherapy and genomic sequencing technologies have created promising opportunities for precision cancer medicine. Somatic mutation in coding regions of cancer genomes may lead to amino acid alterations that generate immunogenic peptides, called neoantigens. These novel peptides are tumor-specific. An individual’s own MHC genotypes restrict the presentation of these tumor-specific peptides on their MHC molecules. We have determined the number of candidate epitopes for immune cellular recognition. Current studies have not comprehensively studied how MHC-restricted neoantigens are present across tens of thousands of cancer. Nor have these studies determined how somatic mutations and their associated neoantigens are represented among different subclonal populations existing within individual tumors. To address these limitations, we have mapped the complex immunogenomic topology of neoantigen epitopes across 8,000 tumors representing 18 different cancer types. This neoantigen landscape accounts for how neoepitope candidates are distributed among the various clonal subpopulations existing within any given tumor. Our study utilized genomic data from the Cancer Genome Atlas (TCGA). Our automated pipeline provides results from 8,000 samples from 18 cancer types that have somatic variant calls, copy number variation, whole exome sequence, and RNA-Seq data. Identification of somatic mutations that lead to highly immunogenic antigens involved five different steps: (i) in-silico translation of identified mutations, (ii) expression as measured per RNA-Seq, (iii) patient’s own major histocompatibility complex genotype, (iv) binding affinity specific to the MHC alleles for any given patient and (v) occurrence of clonal subpopulations as demonstrated by computational genotyping using the Tumor Clonal Evolution and Dynamic (T-CED) method. We mapped the neoantigen landscape with quantitative representation of the genetic clonal diversity existing within individual tumors. In average, 2% of missense mutations from a patient are detected in RNA-Seq, with binding affinity to own HLA genotypes, and from the dominant clonal subpopulation. In summary, our study demonstrates the various relationships among the number of optimal antigens, the number of clonal subpopulations, the number of mutations, and clinical phenotypes such as tumor stage. Our automated bioinformatics process facilitates the use of exome and RNA-Seq as potential diagnostic analytic process for precision immunotherapy.

#544 Hypoxia response signaling is linked to TACE resistance in hepatocellular carcinoma (HCC) patients. Valerie Fako,1 Joyce Lee,2 Tan-To Cheung,2 Irene O. Ng,2 Xin W. Wang,1 National Cancer Institute, Bethesda, MD;2University of Hong Kong, Hong Kong, Hong Kong.

Hepatocellular carcinoma (HCC) is one of the most common cancers worldwide, and outcome is dismal, due to tumor heterogeneity and lack of effective treatment options for patients with later stage disease. Transcatheter arterial chemoembolization (TACE) is the gold standard of therapy for patients with intermediate to locally advanced tumors. TACE delivers a high dose of chemotherapy directly to the tumor via the hepatic artery, followed by an embolizing agent to restrict tumor blood supply. However, tumor hypoxia is linked to alterations in metabolism, such as increased glycolysis (the Warburg effect), and can lead to enhanced cell survival. Several randomized control trials (RCTs) showed a survival benefit with TACE, but only with strict patient selection criteria. In Asia, TACE is also commonly used as an adjuvant therapy after surgical resection. Yet RCTs evaluating adjuvant TACE have shown conflicting results, likely due to patient selection and stratification. We hypothesize that tumor gene expression is predictive of response following TACE, and that differential cellular metabolism resembling a hypoxic phenotype prior to treatment is responsible for TACE resistance. We retrospectively analyzed gene expression data in treatment-naïve tumor tissue from a cohort of Chinese patients who received TACE. Using hierarchical clustering, followed by class comparison and survival risk prediction, we identified a 14-gene signature that is predictive of response vs. non-response to TACE, as measured by overall survival, independent of other clinical variables. We found that hypoxia- and glycolysis-related genes are enriched among differentially expressed genes in TACE Responders vs. Non-Responders, and that hypoxia master regulator HIF-1α and hypoxia target gene VEGF are significantly up-regulated in Non-Responders. We determined that a key glycolysis gene is up-regulated in Non-Responders, and conversely, two rate-limiting genes involved in gluconeogenesis, the pathway opposing glycolysis, are up-regulated in Responders. We also examined metabolomic data from the TACE cohort, and found an enrichment of glycolysis-related metabolites in Non-Responders, and gluconeogenesis-related metabolites in Responders. Further investigation will be required to connect altered glucose metabolism to TACE resistance and to determine driver genes linking hypoxia and metabolism, which, together with our 14-gene signature, may serve as a stratification tool to guide personalized treatment modalities for HCC patients.

#545 Prognostic alternative mRNA splicing signature in non-small cell lung cancer. Yuan Li,1 Nan Sun,2 Zhihui Li,2 Junhong Sun,3 Jiabing Huang,1 Zhaoli Chen,1 Jie He1,4National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China;4Department of Clinical Cancer Prevention, UT MD Anderson Cancer Center, Houston, TX.

Alternative splicing provides a major mechanism to generate protein diversity. Increasing evidence suggests a link of dysregulation of splicing associated with cancer. However, alternative splicing in non-small cell lung cancer (NSCLC) is largely unstudied. In this study, seven types of alternative splicing were profiled in 491 lung adenocarcinoma (LUAD) and 471 lung squamous cell carcinoma (LUSC) patients in TCGA using RNA sequencing data. Prognostic predictors for LUAD, LUSC and merged NSCLC patients were built by integrated survival analysis. Gene network and splicing correlation network analyses were also conducted. Overall, we detected 45,062 alternative splicing events were significantly associated with patient survival. The area under the curve (AUC) of the receiver-operator characteristic (ROC) curve for prognostic predictors in LUAD and LUSC were 0.960 and 0.940 at 2000 days of overall survival. Most relevant for clinical application, we also built the prognostic predictor for NSCLC patients with prediction the treatment outcome in cancer patients in multiple large-scale patient datasets including the TCGA, where SLIs successfully predict patients’ response for 75% of cancer drugs. Conclusions: ISLE is predictive of the patients’ response for the majority of current cancer drugs. Of paramount importance, the predictions of ISLE are based on SLi between (po-tentially) non-mutually exclusive TCGA subpopulations for patients whose tumors do not bear specific actionable mutations in cancer driver genes, offering a novel approach to precision-based cancer therapy. The predictive performance of ISLE is likely to further improve with the expected rapid accumulation of additional patient data.
high performance. The AUC of ROC curve in NSCLC was 0.817 which were also over 0.8 in LUAD and LUSC, separately. Moreover, expression of 49 and 9 survival associated splicing factors were significantly correlated with 75 survival associated alternative splicing events in LUAD and LUSC, respectively. Interestingly, splicing correlation networks uncovered that “onco- genic” splicing factors were up-regulated and “tumor suppressor” splicing factors were down-regulated in LUSC. Survival associated splice factors might have opposite roles in the regulation of RNA splicing in LUAD and LUSC. In conclusion, we created prognostic predictors based on alternative splicing events with high performances for risk stratification in NSCLC patients and uncovered interesting splicing networks in LUAD and LUSC which could be underlying mechanisms.

#548 RNAseq analysis of infiltrating immune cells in liver cancer. Krithika Bhuvaneshwar, 1 Coleman I. Smith, 2 Alexander H. Kromer, 2 Anu R. He, 2 Yurig Guses 1, 2 Georgetown University, Washington, DC; 3 Medstar Georgetown University Hospital, Washington, DC.

Hepatocellular carcinoma (HCC) has emerged as second most common cause of cancer deaths worldwide. During the last 10 years, there has been a clear delineation of landscape of genetic alterations in HCC and deregulated pathways in HCC. However, the treatment for patients with advanced HCC is limited despite of great effort developing therapeutic targeting the deregulated pathways in HCC. Recent studies reveal a direct causal relationship between cancer & immune dysfunction, whereby tumor cells and their microenvironment are able to evade immune attack by exploiting various immunoregulatory mechanisms in a process termed cancer immune editing. Methods: In this poster, the objective is to perform exploratory analysis of TCGA liver cancer data to see if immune infiltrates matter, and if they offer anti-tumor immunity to a cell. For this purpose, we analyzed RNA-seq data for a cohort of 75 liver cancer samples from TCGA collection. We obtained the gene expression data from a pre-selected group of specific markers for infiltrating lymphocytes (several subtypes), and explored the association of expression of these markers with clinical outcomes. We downloaded raw RNA-seq data from the TCGA Liver cancer collection from 75 patients. These included 25 patients who had Hepatitis B virus (HBV), 25 patients who had Hepatitis C virus (HCV) and 25 patients who had both viruses. After processing of raw data, we extracted isoform expression (TPM values) from specific markers for infiltrating lymphocytes. This data was stratified into ‘high’ and ‘low’ expression groups of patients by performing differential expression & pathway analysis, to see if the differentially expressed results were linked to immune pathways. We then performed survival analysis tests (Log rank, Cox regression) and Kaplan Meier (KM) survival graphs to explore the association with overall survival outcome. Results We found 14 of 75 HCC cases expressed CD8B isoform, while 61 of 75 HCC cases did not express CD8B isoform. Conclusion Additional immune cell subtype specific transcripts are being tested. Based on our preliminary analysis, we saw that most of the affected pathways were highly relevant to lymphocyte signaling & immune response and infiltration. Hence, exploring infiltrating lymphocytes can give evidence of immune surveillance against HCC. Testing immune cell specific transcript in tumor samples may service as predictor to treatment targeting immune evasion in cancer patients.

#549 Clustering analysis of next-generation sequencing T cell repertoire data in sipuleucel-T treated prostate cancer patients. Li Zhang, 1 Sounak Chakraborty, 1 Jason Cham, 1 David Oh, 1 Nadeem Sheikh, 1 Lawrence Fong 1.

1University of California, San Francisco, San Francisco, CA; 2University of Missouri-Columbia, Columbia, MO; 3Dendreon Pharmaceuticals Inc, Seattle, WA.

Immunotherapy has demonstrated significant clinical benefit in different cancers. T cells are a crucial component of the adaptive immune system and mediate anti-tumour immunity. Antigen-specific recognition by T cells is via T cell receptor (TCR) which is the product of somatic V(D)J gene recombination with the addition/subtraction of nontemplated bases at recombination junctions. Next generation TCR sequencing effectively profiles the TCR repertoire.
Currently TCR analyses quantify diversity across single clones, however, due to the low overlap of clones across samples, such analyses are limited to a single sample. Here we extend our previous analysis pipeline to track and examine TCR repertoire across time by focusing on V and J gene segments, overcoming limitations of previous studies demonstrated that FOXM1 expression was strongly correlated with poor prognosis of various cancers. The aim of this study is to define a signature consisting of FOXM1 and its associated genes and assess its prognostic potential in cancers including hematopoietic carcinoma (HCC) and others. Experimental procedures: We analyzed a gene expression profile of 100 patients with HCC to identify FOXM1-correlated genes (the FOXM1 signature) associated with the prognosis of HCC patients. The validity of the FOXM1 signature was verified in an independent HCC cohort (n = 242). Using the signature, we also analyzed different cancer types including pancreatic adenocarcinoma, lung adenocarcinoma, breast carcinoma, and bladder urothelial carcinoma to verify the association between the FOXM1 signature and prognosis. Various statistical methods were applied to signature finding and validation. Upstream regulator and gene-to-gene network analyses were performed to identify potential key mediators of the FOXM1 signature. Results: Through a gene expression profiling in 100 patients with HCC, we identified a gene set consisting of FOXM1 and its co-expressed genes for predicting poor prognosis. A predictive value of the signature was validated in an independent cohort containing 242 HCC patients. In multivariate analysis, the FOXM1 signature showed the most significant prognostic value (HR = 1.706, 95% CI = 1.176-2.475, P = 0.005). By directly applying the signature to four data sets in different cancer types, our signature showed a consistent prognostic significance, regardless of tumor types. Finally, upstream regulator and gene-to-gene network analyses found an interconnection of network hubs composed by FOXM1, MYC, and E2F1 that might be common key mediators of patient survival in cancer. Conclusion: The FOXM1 signature represents a promising common diagnostic tool to identify high-risk cancer patients and may extend treatment options in various cancers.

Anticancer immunotherapies target immune cells to block immune suppression and/or promote immune activation in order to eliminate cancer cells. Ipilimumab and Nivolumab, targeting CTLA4 and PD1 respectively, have demonstrated dramatic responses in melanoma and lung cancer (Hodi et al. 2010; Rivi et al. 2015). However, poor response rates in other types of cancer under-score the need to better understand immunomodulatory mechanisms (Topalian et al. 2012). Examination of immune cell specific signals, in either the tumor microenvironment or the periphery, has proven to be a useful tool in developing prognostic biomarkers (Chu et al. 2014; Gentles et al. 2015), inferring mechanisms of action (Krekic et al. 2016), and discerning immune-based predictors of drug response (Gong et al. 2012; Angelova et al. 2015). We used publicly-available gene expression microarray data from blood, normal tissue, and tumor samples to assess the effectiveness of these methods in sample types relevant to oncology research. The results from comparisons of these different methods demonstrate that certain approaches are significantly more robust to noise, and are therefore more suitable for complex cellular mixtures such as tumor samples. The discerning use of methods to infer immune cell type proportions from gene expression profiles may lead to improved prognostication, predictive biomarkers for immunotherapy to assist in patient stratification, and new immunomonitoring targets by indicating immunosuppressive mechanisms.

Multi-scale omics integration using parallel heatmap clustering for the systemic analysis and biomarker discovery of drug sensitivity in lymphoma cell lines. Ivo Kwee,1 Andrea Rinaldi,2 Alberto J. Arribas,2 Eugenio Gaudio,2 Chiara Tarantelli,2 Filippo Spriano,2 Petra Hillmann,3 Francesco Berloni4. 1Institute of Oncology Research & Dalle Molle Institute for Artificial Intelligence, Bellinzona, Switzerland; 2Institute of Oncology Research - IOR, Bellinzona, Switzerland; 3Pfizer Research and Development, Collegeville, PA; 4Pfizer Early Development, Collegeville, PA.

Background. Pharmacogenomics studies the role of genetics in drug response. By measuring the individual genome, it is hoped that pharmaceutical drug treatments can deviate from a ‘one-dose-fits-all’ approach to a more ‘personalized’ treatment. To achieve this goal, we need to explain which genomic differences cause the lack of response to be able to predict the response from baseline omics data, that is from data available before starting treatment. Here, we present an integrated omics approach to analyze drug sensitivity based on in vitro experiments. Methods. We measured the drug response in 61 lymphoma cell lines for a number of anti-cancer drugs using a standard MTT cell proliferation assay. The baseline genomics of these cell lines were fully profiled for gene expression, copy number and methylation. Pathway and gene set signatures were computed using GO, KEGG, Biocarta and lymphoma databases to provide gene set level features. Additionally, we computed high level ‘biological concept’ features. These multi-scale features were directly correlated with drug sensitivity but also correlated between the multiple data types. Using a novel parallel clustering approach, we integrated our data for the different omics types and at different scales: gene, gene set and concept level. Finally, a shortest path algorithm was applied to infer the most probable explanation between genotype and response across subjects directly. The published data of TCR profiling of serial samples. Here we extend our previous analysis pipeline to track and examine TCR repertoire across time by focusing on V and J gene segments, overcoming limitations of previous researchers using a variety of mathematical approaches, including least squares (Abbas et al. 2009), quadratic programming (Gong et al. 2011; Zhong et al. 2013), maximum likelihood (Qiao et al. 2012; Liebler et al. 2013), machine learning (Newman et al. 2015), and enrichment type approaches (Angelova et al. 2015). We used publicly-available gene expression microarray data from blood, normal tissue, and tumor samples to assess the effectiveness of these methods in sample types relevant to oncology research. The results from comparisons of these different methods demonstrate that certain approaches are significantly more robust to noise, and are therefore more suitable for complex cellular mixtures such as tumor samples. The discerning use of methods to infer immune cell type proportions from gene expression profiles may lead to improved prognostication, predictive biomarkers for immunotherapy to assist in patient stratification, and new immunomonitoring targets by indicating immunosuppressive mechanisms.
and somatic. Recently, understudied repetitive DNA regions called microsatellites have been identified as genetic risk markers for a number of diseases including various cancers (breast, ovarian and brain). In this study we demonstrate an integrated process for identifying and validating microsatellite based risk markers for lung cancer using data from the cancer genome atlas (TCGA) and the 1,000 genomes project. We compared whole exome germline sequencing data from 488 TCGA lung cancer patients to germline exome data from 390 control samples from the 1,000 genomes project, we identified 119 potentially informative microsatellite loci. These loci (risk markers) were found to be able to distinguish between cancer and control samples with sensitivity and specificity ratios over 0.8. Then these loci, supplemented with additional loci from other cancers and controls, were evaluated using a custom target design through in-plexed nextgen sequencing. Thirteen of the 119 risk markers were validated using high-depth (579x±315) nextgen sequencing of 30 lung cancer and 89 control samples, resulting in sensitivity and specificity ratios were 0.90 and 0.94, respectively. When 8 loci harvested from the bioinformatic analysis of other cancers are added to the classifier, then the sensitivity and specificity rise to 0.93 and 0.97, respectively. Analysis of the genes harboring these loci revealed two genes (ARID1B and REL) and two significantly enriched pathways (chromatin organization and cellular response to stress) which suggest that the process of lung carcinogenesis is linked to chromatin remodeling, inflammation, and tumor microenvironment restructuring. We illustrate that high-depth nextgen sequencing enables a high precision microsatellite-based risk classifier.

#554 Accurately identifying neoantigens utilizing both DNA and RNA somatic variants in an enhanced platform. Sean M. Boyle, Jason Harris, Gabor Bartha, Ravi Alla, Miriam Karbelashvili, Steve Chervitz, Aldrin Montana, Craig Rowell, Patrick Jonganeel, Scott Kirk, Rena McClory, John West, Rich Chen.

Personalis, Menlo Park, CA.

The identification of neoantigens is a crucial step in the development of neoantigen-based personalized cancer vaccines and other immunotherapies. Accurately predicting which neoantigens are likely to be immunogenic remains a key challenge owing to the complex processes involved in determining neoantigen immunogenicity including the antigen presenting machinery, likelihood of MHC class I and II binding, similarity to self, and ability to interact with the TCR. We have developed a neoantigen detection pipeline built upon our ana-
ytically validated Accuracy and Content Enhanced (ACE) Exome and Tran-
scriptome sequencing platform and somatic variants calling pipeline through combined DNA and RNA analysis. The analytical performance of these pipe-
lines is greater than >97% sensitivity for small variants (RNA and DNA) with a specific-
ity of >98% (DNA) and a fusion sensitivity of >99% (RNA). Within our
neoantigen pipeline, variants that are detected by our DNA and RNA cancer analysis pipelines are processed for antigen identification, including SNVs, indels, and fusion events. Importantly, both in-frame and out-of-frame events are accurately considered by transcript, allowing for detection of a wealth of candid-
ate neoantigens. Our pipeline includes assessment of important immunologic components including HLA prediction, MHC binding (class I and II), immu-
nogenicity, similarity to self, and similarity to known antigens. Additionally, peptides are evaluated for variant allele frequency in both the RNA and DNA of the tissue of interest and expression levels. Consideration of the ImmunoIDP product provides a comprehensive assessment of features that may be used for identifying and ranking potentially immunogenic neoantigens. To assess the effectiveness of this pipeline in predicting immunogenic neoantigens, we assembled a gold-set of 23 known, previously experimentally-validated immu-
nogenic neoantigens from the literature. We spiked in these neoepitopes into exome data and assessed the ability of our neoantigen pipeline to find and rank these immunogenic known neoantigens. Preliminary results show our neoanti-
gen pipeline is able to accurately identify 22 out of 23 (~96%) of the spiked in neoantigens as being potentially immunogenic.

#555 Examination and evaluation of MR radiomics features for character-
ization of dominant intraprostatic lesions. Hassan Bagher-Ebadian, Janic Penistilava, Chang Liu, Milan Pantelic, David Heershen, Indrin Chetry, Moh-
hamed Elshaikh, Benjamin Movvas, Ning Wen. Henry Ford Hospital, Detroit, MI.

Purpose: This pilot study investigates a set of radiomics features extracted from fast relaxation fast spin echo (FRFSE) T2 pulse sequences for normal tissue and Dominant Intraprostastic Lesions (DILs) in twenty prostate cancer patients. Material and Methods: Twenty patients with prostate cancer were studied. All patients had axial FRFSE T2 scans using a 3 Tesla scanner. A radiologist inter-
preted MR examinations, and contoured the suspicious DIL and the contrat-
eral section of the prostate gland (normal) on the T2 weighted MR images. Patients underwent a 14-core transrectal Ultrasound Guided Biopsy and local-
ization of positive cores, Gleason score and clinical tumor stage were recorded. 167 radiomics features were extracted from normal and DIL zones. These fea-
tures were categorized into 8 different sets as following: Intensity Histogram (IHB), Gray Level Run Length (GLRL), Law’s Textural Information (LAWs), Discrete Orthonormal Stockwell Transform (DOST), Local Binary Pattern (LBP), Discrete Orthonormal Wavelet Transform (DOWT), Discrete Orthonormal Fourier Transform (DOFT), and Discrete Orthonormal Spherical Gabor Filter (2DGF), and Gray Level Co-Occurrence Matrix (GLCM) with 8, 7, 18, 6, 48, 40, and 22 features in each category respectively. A Welch’s test and the Fisher method were used to test for signifıcant differences among the 167 radiomics features and their subcategories. For all patients, cor-
relation coefficients between the extracted features in the normal and DIL zones were calculated using the combined p-values among the eight categories of radiomics features, only 5 feature categories showed a significant difference (IHB, GLRL, DOST, LBPF and GLCM with P został<i>/H11000</i> value of 2.0×10^-6, 0.02, 12.1×10^-7, 3.7×10^-3, and 1.5×10^-8), respectively. Among all 167 features, only 7 showed a significant difference (D=100x(DIL-NP-1)) and small correlation between normal and DIL zones: IHB-Skewness (r=0.19, p=0.03, and D=50.3%), GLCM-Contrast (r=0.12, p=0.03, and D=67.5%), GLCM-Dissimilarity (r=0.12, p=0.01, and D=67.5%), GLCM-Entropy (r=0.07, p=0.01, and D=67.1%), GLCM-Difference Variance (r=0.12, p=0.01, and D=67.1%), GLCM-Difference Entropy (r=0.10, p=0.01, and D=60.4%), and GLCM-Information-Measure-of-Correlation (r=0.25, p=0.01, and D=65.1%). Conclusion and Discussion: This pilot study demon-
strates the feasibility of using radiomics features from MR images to characterize DILs in prostate cancer patients. Among 167 radiomics features extracted from axial MR T2 FRFSE, 7 features were shown to be potentially significant for distinguishing normal tissue from DILs. This research supports an integrated decision making system, combining clinical factors and radiomics features extracted from MR images, for increasing the DIL detection performance in prostate cancer studies.

NCBI’s Conserved Domain Database (CDD, https://www.ncbi.nlm.nih.gov/Structure/cdd/cdd.shtml) is a resource that aims at classifying ancient conserved domain families and capturing what is known about their functional diversity. It is a collection of multiple sequence alignments (MSAs) and derived position-specific score matrices (PSSMs). RPS-BLAST allows for the rapid identification of conserved protein domain footprints in protein sequences along with the location of annotated functional sites. CDD is a redundant collection, it imports other model collections (Pfam, COGs etc) and supplement with manually-curated domain models that are organized into hierarchical clas-
sifications, which facilitate annotation of functionally distinct protein families and subfamilies. More recently CDD has been curating information on con-
served domain architectures to support functional labeling of proteins that fall into characterized families: SPARCLE (Subfamily Protein Architecture Label-
ing Engine) is both a curation tool and a public service available at https://
www.ncbi.nlm.nih.gov/sparcle. Architecture summaries provide interactive in-
terfaces to lists of proteins that share the same characteristic domain architecture, and to their assigned names, functional labels, and supporting ev-
idence. Here we present the functionally annotated, evolutionary hierarchical classification of the seven-transmembrane G-protein coupled receptors (7TM GPCRs), which includes the largest family of promising therapeutic targets, with more than 140 human orphan GPCRs of unknown function. Across the three kingdoms of life, GPCRs are involved in a wide array of critical physiological processes, and have been implicated in tumor initiation, tumor progression, angiogenesis and metastasis. Orphan subfamilies with unknown endogenous ligand/function are often found to have poor sequence similarity to canonical GPCRs. They have been assigned putative functions with predicted ligand and bind-
ing sites, downstream interacting partners, and/or the location of 7TM helices annotated by inference from the molecular and physiological functions of known related GPCR proteins, utilizing more than 25 available 3D-structures, phylogenetic relationships, and the published literature. We hope that this up-
dated classification, together with NCBI’s software tools (Cn3D/CDTree and SPARCLE), will aid researchers in the discovery of molecular therapeutic targets for cancer treatment by providing insights regarding as-yet-undefined intra-
and intermolecular interactions as well as functional mechanisms of GPCR sig-
naling. Acknowledgement: This research was supported by the Intramural Re-
search Program of the National Library of Medicine, NIH.
SPOP mutant subclass prediction and its impact on prostate cancer prognosis. Deli Liu. Weill Cornell Medicine, New York, NY.

SPOP mutations define a distinct and key molecular class of prostate cancer, but there is no signature to identify SPOP mutant subclass based on transcriptional data, and its impact on prognosis and clinical outcomes of prostate cancer patients is unknown. We developed the SPOP mutant transcriptional signature with high sensitivity and specificity based on transcriptional data. After we predicted SPOP mutant subclass from a large cohort project with transcriptional signature, we studied its association with clinicopathologic variables and prognosis in prostate cancer patients. On univariate analysis, SPOP mutant subclass was associated with lower preoperative serum prostate-specific antigen, extraprostatic extension, and older patients (p < 0.05). On multivariate analysis, SPOP mutant subclass was associated with metastasis (p < 0.05). Combined SPOP mutant status and CAPRA-S models have slightly better prediction for metastasis. On Kaplan-Meier analysis, we found the significant association of SPOP mutant subclass with better patient outcomes of metastasis, and patients without radiation therapy with even better metastatic outcomes. The SPOP mutant subclass could be predicted by using our SPOP mutant signature purely based on transcriptional data. Clinical and prognosis difference were found among SPOP mutant subclasc.

Computational analysis of clinically actionable genomic features: precision heuristics for interpreting the alteration landscape (PHIAL). Brendan Reardon,1 Nathanael Moore,2 Eliezer VanAllen.1 Dana-Farber Cancer Institute, Broad Institute, Harvard Medical School, Boston, MA; 2Dana-Farber Cancer Institute, Broad Institute, Indiana University University of Medicine, Harvard Medical School, MA.

Background: PHIAL (Precision Heuristics for Interpreting the Alteration Landscape) was developed as a heuristic clinical interpretation algorithm for cancer genomic data to inform treatment decisions at the point of care and provide researchers with rapid assessment of tumor actionability. This approach used somatic whole exome sequencing data and a database of tumor alterations relevant for genomics driven therapy (TARGET). However, PHIAL was limited to first order genomic relationships, could not distinguish relative actionability given multiple actionable variants, did not maximize the richness of somatic-germline interactions, and could not leverage both exome and transcriptome data to move towards feature-based actionability. Towards that end, we developed a new interpretation methodology to address these areas and improve clinical actionability algorithms. Methods: We revised PHIAL to predict actionable alterations based on the presence of SNVs (in the context of allele specific expression from RNA-seq), indels, SCNAs, fusions, and global features (e.g., context-specific mutational burden) that imply actionability. Additionally, we refined and expanded the TARGET database to enable PHIAL to produce scores on multiple dimensions and reflect newly discovered relationships between genomics and clinical actions. Predictive implication values were assigned to reflect the validities of TARGET’s drug sensitivity, drug resistance, and prognostic claims. Results: We applied both the original (PHIAL1) and an updated version of PHIAL (PHIAL2) to a 255 patient cohort with whole exome/transcriptome sequencing data (146 castration-resistant prostate cancer and 109 metastatic melanoma samples). PHIAL1 identified 1,342 clinically actionable biologically relevant events across the cohort with a median of 3 events per patient and 95% of patients having at least one event. PHIAL2 identified 2,508 events, with a median of 6 events per patient and 98.5% of patients harboring at least one event. Of these events, 8.12% were associated with an FDA-approved therapy and 2.09% with a clinical trial. PHIAL2 identified events in 9 patient samples that PHIAL1 associated with no events. Conclusion: PHIAL2 was able to identify and rank more putatively actionable alterations than PHIAL1, and effectively transitioned from a variant-based to a feature-based approach. This strategy may inform the utility of point-of-care whole-exome/transcriptome sequencing in larger contexts as these data emerge in clinical settings, and may bridge towards machine learning based approaches as patient outcomes are linked to genomic and transcriptomic features. Finally, PHIAL2 may ultimately provide a deeper understanding of, and suggest clinical actions for, cases in which there is no clear single genomic alteration associated with oncogenesis.

Estimation of immune cell content in bulk tumour tissue using reference profiles from single-cell RNA-seq data. Max Scheller,1 Jinyan Du,1 Sonia Feau,1 Edda Klipp,2 Birgit Schoeberl,1 Gavin MacBeath,1 Andreas Raue,1 1Merrimack Pharmaceuticals, Inc., Cambridge, MA; 2Humboldt-Universität zu Berlin, Germany.

Although therapeutics that modulate the immune system provide remarkable benefit for many cancer patients, predicting who will respond remains an unsolved problem. As interactions between the immune system and cancer are governed by a complex network of cell-cell interactions, knowing the immune cell composition of a solid tumour may be essential in predicting response to immunotherapy. Here, we describe how to derive the cellular composition of a solid tumour from bulk gene expression data by mathematical deconvolution, using consensus cell type-specific gene expression profiles from previously identified single-cell RNA sequencing data. Notably, successful deconvolution depends on these new data, as previously-available profiles from peripheral blood are insufficient. The presented method makes the problem of obtaining a patient’s tumour immune cell composition from existing databases like The Cancer Genome Atlas as well as in the clinical setting computationally tractable.

True integration of clinical staging and molecular prognostic biomarkers has been hampered by a lack of comprehensive data sets with adequate power. In the last two years, The Cancer Genome Atlas (TCGA) has done and made available a repository of high, high volume -omics datasets including molecular profiling together with matched clinical data. Methods: Clinical and transcriptomic data were downloaded for TCGA datasets (38 projects) representing a total of 14,043 patients. Matched expression and clinical data was available for 34 cohorts, covering 10,554 patients (median n = 270, range 15-1091) and survival data was available for 24 cohorts (7854 patients, median 294 per cohort), with a median follow-up of 10.7 months (range 1.9 to 61 months). Prediction models were constructed based on the latest AJCC staging guide, a novel five gene molecular prognostic signature specifically derived for each cancer type, and a combined model utilising both. Accuracy of survival prediction was calculated as the area under the receiver operator characteristic curve (AUC), based on 2-year overall survival prediction. Results: Pan-cancer analyses demonstrate accuracy of clinical staging from 0.55-0.91 (median 0.72), while molecular prognostication varies from 0.7-0.99 (median 0.84). The combined model is consistently more accurate, 0.71-0.99 (median 0.89, p < 0.01), where the benefit of adding molecular data improved accuracy (median + 0.13, +0.03-0.36). The absolute benefit of adding molecular data to clinical staging correlated more closely with strength of clinical prediction (R²=0.35) than strength of molecular prediction (R²=0.08). When clinical staging was more less accurate (clinical prediction < 0.7), there was a greater contribution of molecular data, compared to cancers with more accurate clinical staging (mean + 0.15 vs + 0.07, respectively; p=0.015). Interestingly, of the six tumours with poor clinical prediction

Viruses are a major contributor to oncogenesis, causing 10-15% of human cancers. Molecular pathways involved in malignant transformation are frequently activated by genetic alterations, including but not limited to, somatic mutations, copy number aberrations, structural variants, and oncoviruses. Precision cancer medicine aims to classify tumors by site, histology, and molecular tests to determine an "individualized" profile of cancer alterations. However, clinical tests for these various alterations are sequential, time consuming, and use a lot of material, which is often quite limited (e.g., biopsies). Moreover, tests for the presence of viral sequence are generally performed separately to tests such as massively parallel sequencing to detect human genomic alterations. Here we present a hybrid capture and massively parallel sequencing approach to detect viral infection concurrently with targeted genomic analysis, which may decrease assay costs, increase sensitivity and scalability, and detect many types of alterations, thereby providing a more complete tumor genetic profile all from a single sample. We have created a custom hybrid capture probe set for targeted Illumina sequencing to determine whether oncoviruses are present in tissue samples and also determine if the virus has integrated into the host's genome. We have created both detection and integration baits for several oncoviruses, including polyomaviruses, human papilloma viruses, Epstein-Barr virus, human cytomegalovirus, Kaposi sarcoma herpeticus, human T-lymphotropic virus, and hepatitis B virus. To distinguish between different strains of a single virus, strain-specific detection baits were created to bind to variable regions of viral genomes. The integration bait was designed to bind to regions of the viral genomes that are commonly integrated into the human genome. This baits set can also be combined with other capture panels targeting oncogenes to simultaneously determine integration and infection statuses, all from a single sample.

We have tested our techniques on tissue samples that were infected with either Merkel Cell Polyomavirus or Epstein-Barr virus, as determined using quantitative polymerase chain reaction (qPCR) or immunohistochemistry (IHC) techniques, and have successfully detected these viruses and identified viral integration loci. Overall, this viral hybrid capture probe set provides the ability to simultaneously determine a tissue sample's infection and viral integration status alongside other somatic genomic analyses, saving both time and sample material.

#563 Quantitative EMT expression score for predicting survival outcome. Jason T. George, Mohit K. Jolly, Herbert Levine. Rice University, Houston, TX.

Tumor aggressiveness and subsequent metastasis still remain as major limitations to curative treatments for cancer patients. The epithelial to mesenchymal transition (EMT) is a process that occurs naturally during embryogenesis and has been linked to metastasis in many cancer types. EMT is characterized by phenotypic changes that allow for tissue extravasation and migration of cancer cells into the bloodstream. These changes may be linked to specific patterns in the gene expression signature of cells undergoing EMT. Recent theoretical efforts have predicted the existence of a stable, hybrid (E/M) phenotype which has also been observed experimentally in single cells. However, the effects of this hybrid phenotype on cancer patient survival have not been well characterized. The ability to quantify a patient's EMT status via a simple test involving a small collection of prognostic genes would provide an important tool for clinical research and treatment in the context of many cancer types. Here, we apply unbiased computational methods to generate a hybrid EMT score for samples. We use this score to characterize the degree of the hybrid phenotype signature present in test samples. Predictions from our model are verified against cell lines with known EMT status. Lastly, we apply our model to clinical samples in order to assess survival differences in various EMT groups. We demonstrate that in many cases, EMT status successfully classifies patients into groups with statistically significant differences in survival, which is of immediate clinical relevance.

#564 Binary classification of superparamagnetic relaxometry data for cancer screening. Javad Sovizi, Sara L. Thrower, David Fuentes, Wolfgang Stefan, John D. Hazle, Kelsey Mathieu. The University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Superparamagnetic relaxometry (SPMR) is an emerging technology that holds potential for use as a second-line screening modality to improve early cancer detection. During SPMR scanning, targeted superparamagnetic iron oxide nanoparticles (SPIONs) specifically bind to cancer cells and their spatial distribution can be characterized by measurement of the magnetic field relaxation following a brief excitation pulse. Highly sensitive superconducting quantum interference devices (SQUIDs) detect relaxor clusters of SPMR signals, and changes in the relative intensity and spatial distribution of SPMR signals indicate the presence of tumors. We use a data-driven approach based on Gaussian process (GP) formulation tailored to SPMR datasets to systematically quantify the probability of cancer. In silico, we simulated the SPION uptake process and generated SPMR signals that closely resembled experimental data collected in mouse models of cancer. We investigated the classification accuracy for different amounts of SPION accumulation within the tumor, as well as different levels of measurement noise (coefficient of variation (CV)). In a phantom study, a mouse liver was simulated by clustering together 40 to 80 different locations. Moreover, 10 datasets were collected without using the tumour phantom to represent the expected signal from healthy mice. In each iteration, the background SPMR phantom signals were randomly distributed within the scan plane. Results: Our in silico analysis for tumor accumulations of 3% and 5% of the injected SPION dose achieved 87% and 97% classification accuracies, respectively, when CV = 0 and 75% and 93% when CV = 0.015. Similarly, in our phantom study, classification accuracies of 87.5% and 96.4%, respectively, were reported for the 9.4 and 14.4 μg of immobilized SPIONs. An additional nine cotton swabs containing 32.3 μg of immobilized SPIONs (<5 μg per phantom) were evenly distributed within the scan plane to represent background SPIONs not bound to the tumor or liver. For each of these nine phantom tumors, 18 datasets were collected using a magnetic relaxometry device (Senior Scientific LLC) by moving the phantom to 18 different locations. Moreover, 10 datasets were collected without using the tumor phantom to represent the expected signal from healthy mice. In each iteration, the background SPMR phantom tumors were randomly relocated within the scan plane. Results: Our in silico analysis for tumor accumulations of 3% and 5% of the injected SPION dose achieved 87% and 97% classification accuracies, respectively, when CV = 0 and 75% and 93% when CV = 0.015. Similarly, in our phantom study, classification accuracies of 87.5% and 96.4%, respectively, were reported for the 9.4 μg and 14.4 μg of immobilized SPIONs. Conclusion: Using a data-driven GP model, tumor-status classification accuracies of up to 96.4% were achieved in SPMR phantom datasets. In the future, we plan to evaluate the accuracy of our classifier in preclinical settings using animal datasets.

#565 Analytical performance of TruSight Tumor 170 in the detection of gene fusions and splice variants using RNA from formalin-fixed, paraffin-embedded (FFPE) solid tumor samples. Tingting Du, June Snedicor, Jennifer S. LoCoco, Xiao Chen, Laurel Ball, Allan Castaneda, Danny Chou, Katie Clark, Brian Crain, Anthony Daulo, Manh Do, Sarah Dummm, Yonmee Han, Mike Havern, Chia-Ling Hsieh, Tingting Jiang, Suzanne Johansen, Scott Lang, Rachel Liang, Jaime McLean, Yousef Nasirri, Austin Purdy, Jason Rostron, Jennifer Silhavy, Natasha Talago, Li Teng, Kevin Wu, Clare Zlatkov, Chen Zhao, Ali Kuraishi, Lauren Craig, Sohela De Rozieres, Matthew Friedenberg, Anne C. Jager, Han-Yu Chuang. Illumina, San Diego, CA.

Recent studies have highlighted the importance of gene fusions and splice variants in solid tumor profiling. Next-generation sequencing can be an effective means of detecting these alterations in FFPE samples using RNA rather than DNA, as a single chimeric RNA transcript could result from numerous alterations in DNA. To that end, Illumina developed TruSight Tumor 170, a comprehensive, hybrid capture-based NGS assay targeting
170 key cancer genes. Along with a DNA workflow, the assay includes a RNA workflow for the identification of splice variants and gene fusions. Following sequencing on the NextSeq® or HiSeq® instruments, TruSight® Tumor 170 offers an analytical pipeline which initiates variant calling. These algorithms were first optimized against the simulated read data from >350 fusions and splice variants in the RNA panel. Subsequently, a hybrid approach of read alignment and assembly was used to enhance the fusion calling sensitivity. Delicate filters were designed to reduce false positive calling from sequence homologs, polymerase read-through, or FFPE artifacts. For splice variant calling, a panel of FFPE non-cancerous samples were used to capture false positive mutation calls. With endogenous RNA splicing in cells, physiological non-boundary probes were added in the hybrid capture to enhance enrichment efficiency. To the best of our knowledge, there is not yet a standard definition for the limit of detection (LoD) in detecting gene fusions and splice variants from NGS data. We propose to define the LoD of a fusion calling and splice variant NGS panel as the lowest molecule count of a chimeric transcript that could be reliably detected with a sufficient number of supporting sequence reads. To determine the LoD of TruSight® Tumor 170 using this definition, we mixed cell lines expressing a panel of known fusions and splice variants to measure the copy number of each chimeric transcript. Using these samples we examined the ability of the assay to confidently detect the alterations using 40 ng of RNA input. To demonstrate the analytical sensitivity and specificity of this NGS based assay, we compiled the sensitivity and specificity of the defined sample and validated the molecule count to be near the LoD of 5 copies per ng RNA input by PCR. The sensitivity was >98% for fusions and 100% for splice variants. For understanding the limit of blank (LoB) of the assay, another panel of 40 samples not harboring fusions and splice variants was also assessed by TruSight® Tumor 170. These samples demonstrated a ~97% specificity for fusion calling and >95% specificity for splice variant calling. These results indicate that the TruSight® Tumor 170 panel analysis can identify lowly expressed fusions and splice variants from a small amount of compromised RNA from solid tumor samples at high analytical sensitivity and specificity. 1 Klijn et al. (2015) 2 Maher et al. (2009) 3 For Research Use Only.

#566 A pathway based drug selection for cancer precision medicine. Varshini Vasudevaraja, Lijun Cheng, Sai Mounika Inavolu, Milan Radovich, Indiana University, Indianapolis, IN.

Background and Purpose: Precision medicine tailors the right therapy to the right patient based on his/her tumor molecular profiles. In clinic and ongoing clinical trials, drug-targeted selection schemes depends more or less on drug targets’ mutations or expression status. However, there is a lack of systematic pathway based method to connect individual genomics information with properly drug target and treatment in precision medicine. The paper aims to integrate various knowledge-bases, including cancer drugs, drug-targets and gene-gene regulatory pathway, to construct a drug target and properly drug selection algorithm for individual patient in precision medicine. Materials and Methods: In the drug selection algorithm, drug targets and properly drug recommendation are based on the patient specific molecular profile data, including copy number variation, mutation, and gene expression. Our target and drug selections are based on whether these drug targets act as hub genes that either regulate or control the signaling pathways for many other genes in the biological pathways. Only those patients whose molecular profiles do not show targets, the usual chemotherapy treatment will be recommended. This novel algorithm is applied to individual Pancreatic Adenocarcinoma (PAAD) for drug target and drug selection. All of patients’ genomic data obtained from the Cancer Genome Atlas (TCGA). The pathway information is from Pathway Commons and FDA approved cancer drugs and their targets is from DrugBank. The Cancer Cell Line Encyclopedia (CCLE) 46 pancreas cancer cell line are used to validate the algorithm result reliability. Results: Our algorithm identifies targets, such as ERBB2, CDK2, SRC, CDK9, SMAD2, CDK4, HDA1C1, PPP1CA, AKB1B1, EGFR, IGF1R, AKT and MEK, for pancreatic adenocarcinoma cancer patients. In which, they cover the clinic first line effective drug targets, such as Gemcitabine for the Akt-mTOR signaling pathway (AKT) and CDK4/6 inhibitor and Erlotinib for HER2 Kinase Family (ERBB2, EGFR) activation inhibitor. In addition, new inhibitors include Src inhibitors (dasatinib, saracatinib and bosutinib), TGF beta inhibitor for target SMAD2 (galunisentib) and IGF-1R/insulin receptor inhibitors (ceritinib, brigatinib) are recommended accordingly and validated in pancreatic cancer cells. Conclusion: This novel algorithm might act as a better source for off-label drug selection and further cell line validations may help in providing a better treatment strategy in precision medicine.

IMMUNOLOGY: Checkpoints 1

#567 CD38 blockade overcomes the immune resistance to anti-PD-L1 therapy by boosting CD8 T cell response. Limo Chen, Lixia Diao, Yongbin Yang, Xiaohui Yi, Jaime Rodriguez, Youhong Fan, Leticia Rodriguez, Jared Fradette, Christin Ungewiss, Jonathan Roybal, Jingfen Zhu, Jing Wang, Lauren Byers, Stephen Ulrich, Ignacio Wistuba, John Heymach, Xiao-Feng Qin, Don Gibbons, UT MD Anderson Cancer Ctr., Houston, TX.

Although strategies incorporating immune checkpoint inhibition, e.g. PD-1/ PD-L1 blockade, are achieving unprecedented successes and increasingly becoming incorporated into standard of care regimens for cancer patients, high rates of resistance still limit the potential efficacy. Therapeutic improvement requires a thorough understanding of the biological process of resistance. To date there have been few studies reporting mechanisms of resistance to PD-L1 blockade. We have explored the resistance mechanisms to functional PD-L1 loss in preclinical lung cancer models by using pharmacological and genetic approaches (PD-L1 blocking antibody treatment or CRISPR/Cas9-mediated deletion of PD-L1 on tumor cells). The molecular and immune profiles of the tumor microenvironment were evaluated in mutant K-ras/p53 (KP) GEM lung cancer models and multiple immunocompetent syngeneic models (both KP and Lewis lung cancer). Additionally, to determine the applicability of the results to patients with lung cancer, we analyzed 259 patient tumor specimens with IHC staining and evaluated the immune markers in TCGA datasets (adenocarcinoma and squamous) and the MD Anderson PROSPECT dataset. We observed that lung tumors gained resistance to anti-PD-L1 antibody treatment over time, and that the up-regulation of CD38 on tumor cells accounted for the treatment resistance. We also observed the same resistance mechanism caused by CD38 up-regulation in PD-L1 KO mice bearing PD-L1 KO Lewis lung tumors generated with the CRISPR/Cas9 system. Manipulation of CD38 on a panel of lung cancer cell lines, demonstrated that CD38 inhibits CD8+ T cell proliferation, anti-tumor cytotoxic secretion, and tumor cell killing capability in vitro and in vivo. Furthermore, to test whether CD38 blockade might be therapeutically efficacious to counter anti-PD-1 resistance, we applied the combination therapy of anti-CD38 and anti-PD-L1 in lung cancer animal models and demonstrated dramatic therapeutic benefit on primary tumor growth and metastasis. Bioinformatic analyses of the patient tumor databases revealed a strong correlation between CD38 expression and an immune suppressive inflammatory signature. Finally, in 259 lung cancer specimens, 18.5% of cases exhibited positive staining for CD38 on tumor cells. Based upon our studies, we conclude that the up-regulation of CD38 on tumor cells is a major mechanism of resistance to anti-PD-L1 therapy, and that CD38 is a novel immune checkpoint that inhibits CD8+ T cell function. The blockade of CD38 and PD-L1 is a rational combination to prevent immune resistance and increase the response rate for lung cancer patients.

Introduction: Breast cancer can be separated into five intrinsic subtypes based on differences in the transcriptome of the tumor. We propose that the intrinsic differences of specific tumor subtypes lead to extrinsic differences in the tumor microenvironment. Methods: We utilized human clinical and genetically engineered mouse model (GEMM) samples of the intrinsic subtypes luminal A, basal-like, and claudin-low breast cancers to evaluate the immune landscape in the tumor microenvironment by histology and microarray analysis. Our claudin-low GEMM was derived from BRCA-/-/p53-/- mice. The HER-2 overexpressing, basal-like, and luminal A models have been previously described. We utilized the FoxP3-DTR transgenic mouse model as a method of regulatory T cell (Treg) depletion to evaluate their function in these GEMMs. Results: The claudin-low human tumors were heavily infiltrated with immune cells, with CD4+ T cells being the most prominent, when compared to the luminal A subtype (P = 0.01). There were also increased focal areas of Tregs in human claudin-low tumors. To evaluate the mechanism for these findings, we utilized a GEMM of claudin-low tumor specimens with IHC staining and evaluated the immune markers in TCGA syngeneic models (both KP and Lewis lung cancer). Additionally, to determine the applicability of the results to patients with breast cancer, we analyzed 259 patient tumor databases revealed a strong correlation between CD38 expression and an immune suppressive inflammatory signature. Finally, in 259 lung cancer specimens, 18.5% of cases exhibited positive staining for CD38 on tumor cells. Based upon our studies, we conclude that the up-regulation of CD38 on tumor cells is a major mechanism of resistance to anti-PD-L1 therapy, and that CD38 is a novel immune checkpoint that inhibits CD8+ T cell function. The blockade of CD38 and PD-L1 is a rational combination to prevent immune resistance and increase the response rate for lung cancer patients.
delay tumor growth and improve anti-tumor immune response. Surprisingly, we saw no delay in tumor growth in the claudin-low model using checkpoint inhibition. To investigate if presence of Tregs limited the function of checkpoint inhibitors, mice with claudin-low tumors were treated with AMD3100, a CXCR4 inhibitor. This decreased Treg infiltration into the tumor microenvironment and altered tumor growth. We then utilized the FoxP3-DTR transgenic mouse model, where depletion of Tregs alone resulted in a very modest decrease in tumor growth, while depletion of Tregs plus checkpoint inhibition significantly improved survival (P = 0.03) and increased cytotoxic production by CD8+ T cells. Conclusion: We found that an effective anti-tumor immune response in claudin-low tumors is inhibited by the recruitment of regulatory T cells in the tumor microenvironment. These data highlight early Treg recruitment as a possible mechanism for the lack of response to immune checkpoint inhibition therapy for claudin-low breast cancer.

#569 Dexamethasone inhibits T-cell proliferation through a CTLA-4 mediated pathway. Marsha-Kay N. Hutchinson, Amber J. Giles, Heather M. Sonnemann, Caitlin M. Reid, Deric M. Park, Mark Gilbert. National Institute of Health, Bethesda, MD.

BACKGROUND: The use of corticosteroids for therapeutic benefit has been weighed against the risks of adverse consequences associated with these drugs. Brain tumor patients in particular, are routinely prescribed dexamethasone (a glucocorticoid) to reduce edema associated with their lesion. Checkpoint blockade, a type of immune therapy, is currently being investigated as a potential treatment for brain tumors. However, glucocorticoid signaling has been shown to attenuate the immune response through several mechanisms including the repression of transcription of genes controlling pro-inflammatory cytokines and chemokines. HYPOTHESIS: Here, we propose that dexamethasone’s ability to upregulate inhibitory T-cell molecules such as CTLA-4 and PD-1 might be an additional immunosuppressive mechanism. METHODS: Healthy donor T cells were tested for response to dexamethasone. T cell proliferation, cell cycle analysis, apoptosis, and protein expression were assessed with flow cytometry. Protein expression was also measured with Western blots. Transcriptional changes were assessed with qPCR. A monoclonal antibody, ipilimumab, was used to block CTLA-4 binding. RESULTS: Unexpectedly, dexamethasone did not elicit a direct lymphotoxic effect on T cells as measured by absolute cell number. However, we found that dexamethasone significantly reduced T-cell entry into the cell cycle, but did not impact cells already undergoing mitosis. Checkpoint molecules CTLA-4 and PD-1 were increased with dexamethasone treatment when cells are stimulated. Blockade of CTLA-4 with ipilimumab resulted in a substantial reversal of cell cycle entry inhibition that was induced by dexamethasone. CONCLUSIONS: These results suggest that dexamethasone impairs T cell expansion by inhibiting cell cycle entry. Upregulated CTLA-4 expression contributes to cell cycle entry blockade which is reversed by inhibiting CTLA-4 with ipilimumab. These findings indicate that administration of ipilimumab before dexamethasone diminishes the negative proliferative effect on anti-tumor T cells suggesting that when needed, corticosteroids can be used after immune checkpoint blockade has been established.

Untangling the complexity of programmed death-ligand 1 (PD-L1) expression within a heterogeneous tumor microenvironment is an urgent challenge in PD-1/PD-L1 immune checkpoint blockade therapy. Here, we address this challenge with a method, termed transparent tumor tomography (T3), facilitating three-dimensional (3D) visualization and spatial analysis of distributions of multiple biomarkers regarding to cancer cells, vasculature, and immune cells in context in the tumor microenvironment. With T3 analysis of transgenic mouse mammary tumors immunostained against Her2, CD45, Ki-67, CD31, and PD-L1, we reveal that PD-L1 expression within the tumor microenvironment is highly adaptable for efficiently preventing immune cell infiltration into the tumor. Stronger correlation of Her2 and PD-L1 expression in the tumor periphery where has a high CD45+ immune infiltrate density is determined by tumor-wide analysis. Also, tomographic analysis shows blood vessels expressing PD-L1 in the tumor core, where PD-L1 expression is lower. Furthermore, high-resolution T3 image localizes PD-L1 expression to a region between the endothelium and the surrounding smooth muscle cells in blood vessels. We investigate spatial pharmacokinetics of anti-PD-L1 antibody in the whole mouse mammary tumor in the context of hypoxia, CD31+ blood vessels, and target PD-L1+ cells. The 3D anti-PD-L1 antibody distribution is fit to a two-compartment pharmacokinetic model, yielding estimated distribution half-life of 4.7 min and terminal half-life of 2.5 days. We also evaluate anti-tumor immune responses after PD-L1 blockade therapy using T3. We observe broad distribution of tumor infiltrating CD8+ cytotoxic T cells in 3D tumor section following combination therapy of radiation and anti-PD-L1 antibody compared to PBS, anti-PD-L1 antibody alone, or radiation alone treatment group. Moreover, we apply T3 for immunoaanalysis of whole core needle biopsy. We spatially map PD-L1 expression in immunostained cryosections with CD3+ CD8+ cytotoxic T cells in whole tumor sections and in-treatment core needle biopsies at cellular resolution and in three dimensions. Meanwhile, T3 analysis is nondestructive, allowing secondary analysis by IHC and/or IF. We anticipate that T3 can be applied broadly to facilitate preclinical studies of immunotherapy and also find use in spatial, multiparameter analysis of patient biopies, particularly to improve predictive testing and analysis of immune responses to tumor immunotherapy.

#571 Meta-analysis of genomic predictors of response to immune checkpoint therapy in metastatic melanoma. Diana Miao, David Liu, Daniel Keller, Sachet Shukla, Bastian Schilling, Claire Margolis, Alicia Smart, Levi Garraway, Stephen Hodi, Dirk Schadendorf, Eliezer M. Van Allen, Dana-Farber Cancer Institute, Boston, MA; University Hospital Essen, Essen, Germany.

Introduction: Immune checkpoint therapies benefit a subset of patients with metastatic melanoma, but ability to predict clinical outcomes is limited. This meta-analysis of genomic predictors of outcomes to aPD1 and aCTLA4 in melanoma combines 220 sequenced tumors from 3 published cohorts, aiming to validate existing hypotheses regarding response to immune checkpoint therapies and discover new relationships with greater power. Methods: Genomic data and clinical annotation from published cohorts were analyzed with standard and customized pipelines for somatic variant calling, mutational signature deconvolution, and neoantigen prediction. Patients were stratified into clinical benefit (CB) and no clinical benefit (NCB) as described in Van Allen et al. 2015. Analyses were repeated using two other published response metrics (CB=PFS>6 months; CB=CR or PR). Results: Nonsynonymous mutational burden was significantly higher in CB vs. NCB using all 3 response metrics, though significance was less pronounced using PFS alone (p<0.01 vs. p<0.0001; Wilcoxon rank sum), partially due to 3 patients with high mutational burden who experienced PR for <6 months, potentially representing early acquired rather than intrinsic resistance. To assess the impact of mutational processes contributing to overall mutational burden, we used a non-negative matrix factorization framework to infer mutational activity in tumors from 6 signatures previously seen in melanoma: aging (S1), T>C substitutions (S5), mismatch repair (S6), UV (S7), and T>G substitutions (S17). The proportion of mutations in S7 or S11 was positively correlated with mutational burden (Pearson’s r=0.66), while S5 and S11 were anti-correlated (r=−0.62). In a multivariate logistic model, S7 and S11 activity were independent predictors of CB adjusting for mutational load (p<0.05), with the sum of S7 and S11 activity being a strong predictor (p<0.001). Of the patients with low mutational burden (<median) with CB, a large majority (23/29) had >1/2 of mutations in S7 or S11, compared to only 36/71 of low-mutation NCB (p<0.01; Pearson’s chi-squared). Néoantigen burden was strongly correlated with mutational burden, and did not improve ability to predict CB. In examining mutations in specific genes, >500 genes were mutated predominantly in either CB or NCB (p<0.05, Fisher’s exact). Restricting analysis to genes recurrently mutated in cancer and correcting for patient mutational burden by permutation, nonsynonymous mutations in AC5L3 and MET and truncating alterations in ARID2 were significantly enriched in CB. Conclusions: In this meta-analysis of 220 patients, harmonized clinical and whole exome analysis confirmed that mutational burden correlates with CB from aPD1 and aCTLA4 therapy, while mutational signatures and alterations in specific genes potentially provide additional predictive power.

#572 Inhibition of IDO1 with epacadostat enhances anti-tumor efficacy of PD-1 blockade in a syngeneic glioblastoma (GBM) model. David A. Reardon, Prafulla C. Gokhale, Holly Koblish, Peggy Scherle, Lance Leopold, Robert Newton, Gordon J. Freeman, Diana-Farber Cancer Inst., Boston, MA; Incyte Corporation, Wilmington, DE.

Purpose: To determine if epacadostat, an oral indoleamine 2,3-dioxygenase (IDO1) inhibitor has therapeutic benefit against GBM when administered as single agent and with PD-1 blocking antibody. Methods: An initial survival experiment was performed to assess efficacy and was followed by an identical repeat experiment for validation. LX10 luciferized GL261 cells, a murine GBM tumor line derived from intracerebral methylcholanthrene implantation, were stereotactically implanted intracranially in albino syngeneic C57BL/6 mice. Mice with increasing bioluminescence on days 3 and 6 were randomized (n=8/group) to receive treatment beginning on day 6: anti-PD-1 (332.8H3, mouse...
Radiation and immune checkpoint blockade promotes anti-tumor activity in mouse B16 melanoma. Hutchins, Jedd D. Wolchok, Taha Merghoub.

Indeed, subsequent tumor studies in WT and RAG-/- mice confirmed rechallenge, strongly suggesting an immune-mediated rejection had been established. Further studies incorporating IDO inhibitor therapy for GBM, including mechanistic studies, are warranted.

#573 Metabolism as checkpoint: Induction of anti-tumor immune response with the novel glutamine antagonist JHU-083. Robert D. Leone, Judson M. Englert, Min-Hee Oh, Chih-Hsien Cheng, Rana Rais, Barbara Slusher, Jonathan D. Powell. Johns Hopkins Hospital, Baltimore, MD.

The metabolic characteristics of the tumor microenvironment (e.g., hypoxia, acidity, nutrient deprivation, elevated adenosine) present a significant hurdle for immunotherapy. Disregulated glutamine metabolism plays a crucial role in establishing this environment. We previously demonstrated that the novel glutamine antagonist, JHU-083, profoundly alters tumor metabolism and inhibits growth with minimal toxicity. Further studies have demonstrated that JHU-083 can reprogram long-term survivors to assess for tumor immune responses capable of preventing relapse. All long-term surviving mice (defined as ≥ 100 days) from the efficacy experiment were injected with 1X10^6 GL261 cells in the contralateral hemisphere and followed for survival. Results: In both preclinical efficacy experiments, median survival in the epacadostat monotherapy group did not differ from controls (approximately 30 days). Four of eight mice (50%) treated with anti-PD-1 were long-term survivors in both efficacy experiments. In the epacadostat plus anti-PD-1 combination group, 81% of the mice were long-term survivors (7 of 8 in experiment 1 and 6 of 8 in experiment 2). Of note, none of the long-term surviving mice developed evidence of tumor; thus the median survival among the anti-PD-1 and epacadostat plus anti-PD-1 combination groups were both ≥ 100 days. In the re-challenge study, all of the mice who underwent GL261 re-inoculation survived > 100 more days with no evidence of tumor recurrence. Conclusions: IDO inhibition with epacadostat increased the eradication rate of anti-PD-1 therapy in an orthotopic syngeneic GBM model and long term survivors rejected tumor following orthotopic re-challenge. Further combinatorial studies incorporating IDO inhibitor therapy for GBM, including mechanistic studies, are warranted.

#574 Phosphatidylserine targeting antibody in combination with tumor radiation and immune checkpoint blockade promotes anti-tumor activity in mouse B16 melanoma. Sadna Budhu, Olivier De Henau, Roberta Zappasodi, Rachel Giese, Luis F. Campesato, Christopher Barker, Bruce Freimark, Jeff Hutchins, Jedd D. Wolchok, Taha Merghoub. Memorial Sloan Kettering Cancer Center, New York, NY; Peregrine Pharmaceuticals, Inc., Tuscon, CA.

Phosphatidylserine (PS) is a phospholipid that is exposed on surface of apoptotic cells, tumor cells and tumor endothelium. PS has been shown to promote immunosuppressive signals in the tumor microenvironment. Antibodies that target PS have been shown to reactivate anti-tumor immunity by polarizing tumor associated macrophages into a pro-inflammatory M1 phenotype, reducing the number of MDSCs in tumors and promoting the maturation of dendritic cells into functional APCs. In a mouse B16 melanoma model, targeting PS in combination with immune checkpoint blockade promoted greater anti-tumor activity than either agent alone. This combination was shown to enhance CD4+ and CD8+ T cell infiltration and activation in the tumors of treated animals.

Radiation therapy (RT) is an effective focal treatment of primary solid tumors, but is less effective in treating metastatic solid tumors as a monotherapy. There is evidence that RT induces immunogenic tumor cell death and enhances tumor-specific T cell infiltration in treated tumors. The abscopal effect, a phenomenon in which tumor regression occurs outside the site of RT, has been observed in both preclinical and clinical trials when RT is combined with immunotherapy. In this study, we show that irradiation treatment of B16 melanoma causes an increase in PS expression in the subset of viable tumor and immune infiltrates. We subsequently examined the effects of combining RT with an antibody that targets PS (mch1N11) and immune checkpoint blockade (anti-PD-1) in B16 melanoma. We found that treatment with mch1N11 synergizes with RT to improve anti-tumor activity and overall survival in tumor bearing mice. In addition, the triple combination of mch1N11, RT and anti-PD-1 treatment displayed even greater anti-tumor and survival benefit. Anti-CD8 T cell responses in the tumors of treated animals revealed an increase in tumor-associated macrophages with a shift towards a pro-inflammatory M1 phenotype after treatment with RT and mch1N11. In addition, analysis of the systemic immune responses in the spleen and tumor draining lymph nodes revealed an increase in CD8 T cell activation, effector cytokine production and differentiation into effectector memory cells in the triple combination. This finding highlights the potential of combining these three agents to improve outcome in patients with advanced-stage melanoma and other cancers and may inform the design of clinical studies combining PS-targeting antibodies with RT and/or checkpoint blockade.

#575 PD-L1 positive tumor-infiltrating lymphocytes and mutational load in breast cancer. Marcelo Sobral-Leite, Koen Van de Vijver, Magali Michauf, Hugo M. Horlings, Tesa M. Severson, Philip C. Schouten, Rianne van de Linden, Kelly Kersten, Anna Marie Mulligan, Nanyaa Weerasooriya, Joyce Sanders, Ashley Cinmino-Mathews, Dennis Peters, Gerrit K. Hoosijberg, Annegien Broeks, Rene Bernards, Sabine Linn, Irene L. Andrusis, Marc J. van de Vijver, Lodewyk F. Wessels, Marjanka K. Schmidt, The Netherlands Cancer Institute, Amsterdam, Netherlands; University of Toronto, Toronto, Ontario, Canada; The Johns Hopkins Hospital, Baltimore, MD; Academic Medical Center, Amsterdam, Netherlands.

Background: PD-1 blockade has emerged as an effective treatment for a subset of cancer patients. Studies have shown that PD-L1 expression is associated with likelihood of response to PD-1 blockade. In order to select the right breast cancer patient for immunotherapy, characterization of the immune landscape of breast tumors is required. Therefore, we assessed PD-L1 expression and tumor-infiltrating lymphocytes (TILs) in different breast tumor subtypes and the link with prognosis. We also sequenced a panel of genes to assess the mutational load in triple negative tumors (TNBC) and investigate the association with PD-L1 positive TILs. Material and methods: We analyzed 438 tumor samples from breast cancer patients of all ages treated between 1986 and 2007 with surgery, with or without adjuvant therapy. PD-L1 was stained using whole slide specimens (EILN3® antibody) after methodological validation. Pathologists quantified TILs based on International TILs Working Group recommendations and scored PD-L1 based on the percentage of positive (tumor and/or immune) cells; as negative if 0%, positive if ≥1%, and high if ≥5%. Mutational load was assessed based on DNA kinome sequencing. Associations were measured by Cox/logistic regression model, including pathological variables. Multiplex imaging of 20 immunofluorescence labeled areas from 4 ER negative tumors were performed using the Vectra® system based on immunofluorescence staining panel of: CD4, CD68, CD8, FOXP3 and PD-L1. Results: PD-L1 expression and TILs were higher in ductal (compared with lobular), high grade and estrogen receptor (ER)-negative tumors (p = 0.001). TILs (density ≥5%) were significantly associated with worse distant metastasis-free survival (DMFS; only in ER-negative tumors (p = 0.04)): HR = 2.72; 95%CI: 1.07-6.94. PD-L1 positivity (≥1%) followed the same trend: HR = 1.66; 95%CI: 0.87-3.15. However, in ER-negative tumors (n = 171), high PD-L1 expression (>50%) was significantly associated with better DMFS: HR = 0.53; 95%CI: 0.27-0.98. TNBC with high PD-L1 expression of TILs
(>50%) showed an association with increased mutation load (p = 0.019) and a trend for better DMFS (HR = 0.41; 95% CI: 0.16-0.94) compared with tumors lacking TILs. Further characterization of PD-L1 positivity in the immune-infiltrated cells was conducted by a multiplex imaging analysis. Preliminary results indicated that PD-L1 is expressed in CD68+, CD4+, FOXP3+ and CD8+ immune cells. Our findings were confirmed by cell ELISA, but also reversed compared with worse prognosis in ER-positive breast cancer and with better outcome in ER-negative group. In TNBC, high mutational load correlates with high PD-L1 positive TILs.

Magnetic resonance-guided focused ultrasound (MRgFUS) facilitates local tumor control via thermal ablation, however, the anti-tumor immune effects induced are weak and unable to consistently generate robust objective responses in distant lesions. Here, we set out to optimize a therapeutic approach for employing immunotherapy with thermal ablation for systemic cancer treatment. We assessed the efficacy of implementing MRgFUS ablation with blockade of the PD-1/PD-L1 axis (anti-PD-1) and activation of TLR9 (CpG oligonucleotide) under various protocols and in multiple models of murine cancer. Anti-PD-1 (200 µg, i.p., days 21 & 28) and CpG (100 µg, i.t., days 21, 24 and 28) were administered coincidentally with MRgFUS ablation (3 MHz frequency, circular pattern with R = 2 mm, 1 revolution per second, 65ºC for 1 min, days 21 and 28) over the course of a week in bilateral syngeneic neu deletion line (NDL), 4T-1 and B16 tumor bearing mice. Additionally, we evaluated the administration of immunotherapy prior to a course of thermal ablation (i.e., "primed ablation"), where anti-PD-1 (as above on days 21, 28 & 35), CpG (as above on days 21, 24, 28, 31, 38 and 45) and MRgFUS ablation (as above on days 21, 31, 38 and 45) were administered in bilateral NDL tumor-bearing mice. Primed ablation generated a robust anti-tumor immune response in distant lesions two weeks after the start of treatment, where a threefold increase in tumor infiltrating leukocytes (reaching 40% CD8+ and 20% CD4+ T-cells) was observed. This led to a complete response in 80% of treated mice within 70 days after treatment commenced. This effect was also observed in animals with high tumor burden and when thermal ablation was performed sequentially at multiple independent sites; 80% of untreated lesions were eradicated at 50 days after the start of treatment. However, therapeutic efficacy was limited when thermal ablation was performed coincident with the first dose of immunotherapy; this protocol was not curative in any murine model. To elucidate the mechanism for this effect, we employed tumor histology and positron emission tomography immediately after MRgFUS ablation. We found that thermal ablation induced stromal inflammation, and the loss of cell-cell adhesion and local vascular integrity, which impacted the intratumoral transport of small molecules and proteins for 48 hours post treatment. These data suggest that tumor debunking using image-guided thermal therapy can be successfully incorporated within a curative protocol in which immunotherapy is initiated before ablation.

To explore this concept, yeast antibody display was used to identify fully human, anti-TIGIT antibodies that block binding to ligands. Multiple rounds of selection with human and mouse TIGIT protein were performed to promote species cross-reactivity, diversity and affinity. A pool of 695 unique clones were screened for binding to TIGIT protein; 65 clones were then selected for further evaluation. Of the 65, 63 competed with CD155 for binding to TIGIT in a For-bio screen. Fifty-three clones bound cyno TIGIT and 25 bound TIGIT from all species. Antibodies bound endogenous TIGIT on primary T cells and blocked binding of ligands to cell surface expressed TIGIT in a dose dependent manner. Twelve clones showed functional activity in a TIGIT blockade bioassay and showed synergy with anti-PD-1 antibody in a PD-1/ TIGIT combination bioassay. Activity in the bioassays correlated with affinity for recombinant and cell surface expressed TIGIT. Based on species cross-reactivity, affinity and activity in the bioassays, a lead antibody was selected and produced as mouse IgG1 and IgG2a chimeras for testing in mouse tumor models. The chimeric antibodies behaved similarly to the parent clone in vitro exhibiting high affinity for TIGIT, competition with ligand for binding to TIGIT, and functional blockade of CD155-TIGIT interaction. Evaluation of the chimeric anti-TIGIT candidates alone and in combination with anti-PD-1 antibody in mouse syngeneic tumor models is ongoing, and results will be reported at the meeting. Antibody mediated blockade of coinhibitory immunoreceptors has proven clinically efficacious and supports the development of antibodies that target TIGIT. The unique human, non-human primate, and murine cross-reactive TIGIT-specific antibodies described here offer a simplified preclinical development path and the functional activity of these molecules supports their consideration as candidates for therapeutic development.

#580 Nivolumab treatment of metastatic renal cancer patients impairs Tregs and potentiates NK function: The role of CXCR4 inhibition (“REVOLUTION Trial”). Sara Santagata, Anna Maria Trotta, Maria Napolitano, Luigi Portella, Sabrina Rossetti, Sisto Perondo, Sandro Pignata, Stefania Scala, National Cancer Inst. Pascale, Naples, Italy.

Despite encouraging results, Nivolumab response is not as wide as expected in renal cancer (RCC). Among mechanisms of immunoresistance T-regulatory cells(Tregs) activity plays a central role. We previously showed that tumoral Tregs in RCC patients are more suppressive than healthy donors Tregs. Since tumoral Tregs express high level of CXCR4, the receptor antagonism was eval-
uated on patients Tregs revealing that CXCR4 antagonism reverted Treg suppressive activity (Santagata et al, submitted manuscript). To identify biomarkers informative and predictive of nivolumab efficacy Treg function, tumoral access and NK interactions was determined in nivolumab treated mRCC patients (# Revolution trial). At today eleven patients were analyzed for Tregs and NKs function at time 0-2-4 weeks-3-6 months of treatment. 2 patients died for unrelated causes, 5 Patients showed PR, 4 SD and 1 PD at six months. At time 0 Tregs function, evaluated as inhibition of T-effector (Teff) proliferation, varied among patients; two patients showed anergy reversed by Nivolumab treatment. Overall, increase in Teff proliferation, compatible with a decreased Tregs activity, was revealed during nivolumab treatment and, while the total peripheral Tregs was unaffected, a decrease in Treg proportion was reported, thus providing an indicator of tumoral burden. We evaluated baseline mutation spectrum in genes implicated in cancer for association with clinical outcomes to durvalumab, an anti-PDL1 molecule, and examined changes in VAFs, as a surrogate for tumor burden, after treatment with durvalumab in NSCLC patients. CP1108/NCT01693562 was a nonrandomized phase 1/2 trial evaluating durvalumab in patients with advanced NSCLC or other solid tumors. By 2APR2016, 304 NSCLC pts received 10 mg/kg Q2W of D 12 months with median 18.8 months follow up. A panel of 70 genes was assessed for nonsynonymous mutations and copy number (CN) variants using the Guardant360 cancer panel in plasma ctDNA from 115 NSCLC patients pre-treatment and 28 patients pre and 8 weeks post-treatment with durvalumab (Q2W). The mean VAF of all mutations harbored by a patient was correlated with clinical outcomes. To calculated according to RECIST v1.1 and a Cox proportional hazards model was calculated adjusting for baseline ECOG, gender, age, smoking status, therapy lines, histology, and number of metastases. Partial responders (PRs) showed a significant decrease (Δ = −2.7%, p = 0.005) in ctDNA mean VAF post-treatment with durvalumab (i.e. reduction in tumor burden) compared to an increase in mean VAF (i.e. increase in tumor burden) in progressive disease (PD) patients (Δ = +1.7%; p = 0.017). This correlation was also observed in total mutation count in PR (Δ = −5.3, p = 0.037) compared to PD patients (Δ = +2.7, p = 0.003). In a PD patient, the VAF of T790M EGFR mutation doubled after 6 weeks of durvalumab treatment. Patients with VAFs below the median VAF or no CN gain had longer median overall survival (15.7 months, 95% CI=11.2,not reached) compared to those with VAFs above the median or CN gains (5.1 months 95% CI=3.8,9.4); HR=0.29; p=0.005), even after adjustment for clinical covariates. CtDNA VAFs were consistent reduced in responders but not non-responders after eight weeks of durvalumab. Below median pre-treatment VAFs or no CN gains in ctDNA correlated with longer overall survival in patients treated with durvalumab. Because we examined oncogenes and tumor suppressors, increased VAF in ctDNA of these genes may help to identify aggressive, and difficult to control tumors.

#583 The CDK4/6 inhibitor abemaciclib induces synergistic immune activation and antitumor efficacy in combination with PD-L1 blockade. Jack Dempsey,1 Lyssiane Huber,1 Amelie Forest, Jennifer R. Stephens,3 Thompson N. Doman,1 Jason Manro,1 Andrew Capen,1 Robert S. Flack,1 Gregory P. Donoho,1 Sean Buchanan,1 Alfonso De Dios,1 Kyla Driscoll,2 Michael Kalos,2 N. Doman,1 Jason Manro,1 Andrew Capen,1 Robert S. Flack,1 Gregory P. Donoho,1 Sean Buchanan,1 Alfonso De Dios,1 Kyla Driscoll,2 Michael Kalos,2 Ruslan Novosadly,3 Richard P. Beckmann,1 David A. Schaer2.1EliLilly,India-146.4April 20171

Targeting cyclin dependent kinases 4 and 6 (CDK4/6) with inhibitors such as abemaciclib has shown promise in early and late phase clinical trials in both breast cancer and NSCLC. While there is evidence that patients benefit from single-agent abemaciclib, combination strategies leveraging this compound together with immunotherapy are of interest for the treatment of these and other cancers. Consequently, it is important to understand if and how a cell cycle inhibitor can be combined with immunotherapy. However, because most preclinical studies have been performed using xenograft tumors in immuno-compromised mice, the potential immunomodulatory effects of abemaciclib have not been adequately ascertainment. To investigate the immune combinatorial potential of abemaciclib, we studied the effects of immune inflammation without major alteration in immune subset frequencies. Testing of various dosing regimens in this preclinical model found that monotherapy abemaciclib pretreatment followed by combination with anti-PD-L1 antibody therapy, induced an enhanced anti-tumor response compared to abemaciclib and anti-PD-L1 monotherapies. Optimal combination

#582 Circulating tumor DNA (ctDNA) variant allele frequencies are reduced in responders to durvalumab and low baseline variant allele frequencies are associated with improved overall survival in NSCLC patients. Michael A. Kuziora, Brandon W. Higgs, Philip Brohawn, Rajiv Raja, Koustubbh Ranade. *MedImmune, Gaithersburg, MD.*

Mutations can influence patient responses to treatment in non-small cell lung cancer (NSCLC). Monitoring such mutations can be critical to guiding treatment decisions, however, accessing sufficient biopsy material for mutation analysis can be challenging. Circulating tumor DNA (ctDNA) in the plasma offers a robust and highly sensitive approach to identifying mutations. Further, variant allele frequencies (VAFs) in individual mutations represent the number of cancer cells and, thus providing an indicator of tumor burden. Here we evaluated baseline mutation spectrum in genes implicated in cancer for association with clinical outcomes to durvalumab, an anti-PDL1 molecule, and examined changes in VAFs, as a surrogate for tumor burden, after treatment with durvalumab in NSCLC patients. CP1108/NCT01693562 was a nonrandomized phase 1/2 trial evaluating durvalumab in patients with advanced NSCLC or other solid tumors. By 2APR2016, 304 NSCLC pts received 10 mg/kg Q2W of D 12 months with median 18.8 months follow up. A panel of 70 genes was assessed for nonsynonymous mutations and copy number (CN) variants using the Guardant360 cancer panel in plasma ctDNA from 115 NSCLC patients pre-treatment and 28 patients pre and 8 weeks post-treatment with durvalumab (Q2W). The mean VAF of all mutations harbored by a patient was correlated with clinical outcomes. To calculated according to RECIST v1.1 and a Cox proportional hazards model was calculated adjusting for baseline ECOG, gender, age, smoking status, therapy lines, histology, and number of metastases. Partial responders (PRs) showed a significant decrease (Δ = −2.7%, p = 0.005) in ctDNA mean VAF post-treatment with durvalumab (i.e. reduction in tumor burden) compared to an increase in mean VAF (i.e. increase in tumor burden) in progressive disease (PD) patients (Δ = +1.7%; p = 0.017). This correlation was also observed in total mutation count in PR (Δ = −5.3, p = 0.037) compared to PD patients (Δ = +2.7, p = 0.003). In a PD patient, the VAF of T790M EGFR mutation doubled after 6 weeks of durvalumab treatment. Patients with VAFs below the median VAF or no CN gains had longer median overall survival (15.7 months, 95% CI=11.2,not reached) compared to those with VAFs above the median or CN gains (5.1 months 95% CI=3.8,9.4); HR=0.29; p=0.005), even after adjustment for clinical covariates. CtDNA VAFs were consistently reduced in responders but not non-responders after eight weeks of durvalumab. Below median pre-treatment VAFs or no CN gains in ctDNA correlated with longer overall survival in patients treated with durvalumab. Because we examined oncogenes and tumor suppressors, increased VAF in ctDNA of these genes may help to identify aggressive, and difficult to control tumors.

#583 Discovery and development of COM701, a therapeutic antibody targeting the novel immune checkpoint PVRIG. Ofer Levy,1 Chris Chan,2 Gady Cocojan,3 Andrew Ophir,3 Sudipto Ganguly,3 Maya Kotturi,2 Christine Sadowski,1 Benjamin Murter,3 Friedmann,1 Jianyang Zhang,1 Liat Dassa,1 Ling Leung,2 Shirley Greenwald,1 Mark White2.

Background: whole blockade of the CTLA4 and PD1 pathways has emerged as an effective treatment of cancer, the majority of patients do not derive long term benefit. This provides a rationale for identifying and targeting additional checkpoints. Employing our unique computational algorithms, we identified PVRIG, a new member of the B7/CD28 family. We report here the expression pattern, functional characterization, and anti-tumor activity of blocking antibodies targeting PVRIG as well as characterization of PVRIG KO mice. Methods: PVRIG is expressed on T and NK cells within the tumor microenvironment. We identified PVR2 as its counterpart and characterized the PVRIG-PVR2 interaction. Antibody discovery was carried out with phage display and hybridoma platforms and antibodies against the human protein were screened for their ability to enhance T cell activity in vitro, while surrogate antibodies targeting the mouse protein were assessed in syngeneic models for effects on tumor growth. PVRIG-/- mice were generated and characterized for antibodies targeting the mouse protein were assessed in syngeneic models for PVRIG-PVRL2 interaction. Antibody discovery was carried out with phage display and hybridoma platforms and antibodies against the human protein were screened for their ability to enhance T cell activity in vitro, while surrogate antibodies targeting the mouse protein were assessed in syngeneic models for effects on tumor growth. PVRIG-/- mice were generated and characterized including phenotyping and anti-tumor immune response. Results: PVRIG is expressed on different T cell subsets and on NK, NKT and γδ T-cells. Within T cells, memory subsets possess the highest level of PVRIG and its expression is induced upon long term activation with different stimuli. Within tumor microenvironment, PVRIG was found to be expressed on NK and CD8+ T cells in multiple cancers. A high affinity lead Ab was selected, COM701, for further clinical development and demonstrated blockade of the interaction of PVRIG with PVR2 as well as enhancement of activation of both primary and tumor-derived effector immune cells through a PVR2-dependent mechanism. Moreover, COM-701 showed notable enhancement of T cell function in vitro when combined with PD1 or TIGIT Ab blockade. The lead antibody, COM-701, is currently in preclinical development. A surrogate antibody, that blocks PVRIG-PVR2 interaction, was shown to inhibit growth of colon carcinoma and melanoma in syngeneic models upon combined treatment with anti-PDL1 antibody. Comparative analysis of PVRIG KO versus WT derived T cells revealed enhanced expression of PVRIG null T cells upon polyclonal activation in presence of PVR2-Ig. Accordingly, MC38 tumors grew slower in PVRIG KO than in WT mice and ex vivo analysis pointed to the quantitative and functional differences in antitumor immunity developed in these mice. Conclusion: We describe the identification of PVRIG as a novel T cell immune checkpoint. We further demonstrated that antibody blockade of the PVRIG-PVR2 interaction has the potential to be efficiently combined with PD1 or TIGIT blockade for enhancing anti-tumor immunity. COM-701 is a high affinity antigenic antibody that is currently in preclinical development. Taken together, these data demonstrate the utility of targeting PVRIG in addition to other B7 family checkpoints for the treatment of cancer.
therapy exhibited superior anti-tumor efficacy, resulting in complete tumor regression (CR) in 50-60% of mice in a setting where anti-PD-L1 monotherapy showed little or no efficacy (0% CRs). Mice which maintained CRs after cessation of combination therapy were able to resist later CT26 relapse, demonstrating that abemaciclib in combination with anti-PD-L1 enabled long-term immunological memory. Examination of tumor gene expression during treatment found that combination therapy further amplified the immune/T cell activation signature compared to both monotherapies. Intra-tumoral suppression of cell cycle genes, which are indicative of inhibition of CDK4/6, was also greater during the combination therapy, suggesting that the effects anti-PD-L1 therapy may augment the cell cycle arrest induced by abemaciclib. Although it was uncertain if abemaciclib that inhibit cell proliferation could be combined with immunotherapy, these preclinical results demonstrate that it is possible to combine CDK4/6 inhibition by abemaciclib with checkpoint immunotherapy to improve tumor efficacy. The synergistic responses observed in terms of tumor efficacy, immune activation, and cell cycle control provides support for the clinical investigation of this combination.

Antibody blockade of CTLA4 and PD-1 immune checkpoint emerged as an effective treatment modality for cancer. However, the majority of patients do not achieve sustained long term benefit, suggesting a need for targeting of additional immune checkpoints. To identify additional B7/CD28 immune checkpoint targets, we developed a unique compendium of computational algorithms that identified multiple novel targets including TIGIT in 2008, which was an unknown protein at the time of discovery [Proc Natl Acad Sci U S A 2009 Oct 20;106(42):17858-63], and PVRIG which we recently disclosed. Since their initial discovery, these targets have been functionally validated and anti-tumor activity was demonstrated with antibodies that target them. In this presentation, we will describe the computational algorithms that led to the discovery of these novel immune checkpoints. These algorithms combine two complementary aspects: (i) endogenous immune checkpoint function prediction and (ii) prediction of immuno-modulatory activity in cancer. Immune checkpoint function was predicted based on gene structure similarity to B7/CD28 family members that is reminiscent of ancient common evolutionary origins. A gene structure alignment tool was developed to identify functional homologs of B7/CD28 genes even in the absence of sequence similarity. Next, the expression profile of these candidates was modeled and compared to profiles of known immune checkpoints in normal and cancer tissues. We will review the details of TIGIT and PVRIG discovery, which were among the immune checkpoints predicted in this process. Our approach demonstrates the powerful ability of computational biology to translate genomic knowledge into rational and reliable drug target discovery.

#585 Chromosome 9p24.1 deletions as a determinant of tumor immune surveillance and immune checkpoint blockade therapy in non-small cell lung cancer. Tao Shen, Jie Wu. Stepheison Cancer Center, OUHSC, Oklahoma City, OK.

Anti-PD-1/PD-1 immune checkpoint blockade therapy requires the presence of PD-L1/PD-L2 and MHC class I antigens on the tumor cell surface. We previously found that JAK2 truncating mutations in endometrial cancer cells that impair JAK1/JAK2-STAT1-IIF1-mediated signaling pathway, which regulates MHC class I antigen presentation. To determine the potential role and genetic defects in the IFN-γ-IRF1 pathway in non-small cell lung cancer (NSCLC), we analyzed the Cancer Genome Atlas (TCGA) data. Expression of IRF1 correlated with cytolytic activity markers GZMA and PRF1. Loss-of-function (LOF) genetic alterations in the IFN-γ-IRF1 pathway genes were found in 64 cases (6.3%) among 1016 patients. These genetic defects occurred prevalently in the JAK2 gene (33 cases) and often through deletions (29 cases) of chromosome 9p24.1. JAK2 gene deletions were frequently associated with deletions of CD274 and PDCD1LG2 genes that encode PD-L1 and PD-L2, respectively, whereas CD274 and PDCD1LG2 deletions were always accompanied by JAK2 deletions. Chromosome 9p is frequently deleted in NSCLC. This has been attributed to the co-localized at chromosome 9p24.1 near the CDKN2A/CDKN2B and PTPRD tumor suppressor genes located at the chromosome 9p is frequently deleted in NSCLC. This has been attributed to the code of the chromosome 9p deletion as a determinant of tumor immunoregulation. From code to cure: Computational discovery of novel immune checkpoints. Yair Benita, Amit Novik, Gady Cojocaru, Itamar Borukhov, Assaf Wool, Yossi Kliger, Tomer Zekharya, Zurit Levine, Sergey Nemzer, Ofer Levy, Amir Toporik. COMPUGEN, Holon, Israel.

Antibody blockade of CTLA4 and PD-1 immune checkpoint emerged as an effective treatment modality for cancer. However, the majority of patients do not achieve sustained long term benefit, suggesting a need for targeting of additional immune checkpoints. To identify additional B7/CD28 immune checkpoint targets, we developed a unique compendium of computational algorithms that identified multiple novel targets including TIGIT in 2008, which was an unknown protein at the time of discovery [Proc Natl Acad Sci U S A 2009 Oct 20;106(42):17858-63], and PVRIG which we recently disclosed. Our approach demonstrates the powerful ability of computational biology to translate genomic knowledge into rational and reliable drug target discovery.

#586 Ionizing radiation-induced PD-L1 upregulation in glioma: a crucial role for the molecular chaperone FKBP5. Paolo D’Arrigo, Michele Russo, Elia Guadagno, Roberto Pacelli, Maria Laura Del Basso De caro, Anna Rea, Martina Tufano, Stefania Staibano, Gennaro Iardi, Maria Fiammetta Romano, Simona Romano. University of Naples Federico II, Naples, Italy.

Glioblastoma can avoid immune surveillance and induce tumor tolerance, through inhibitory molecules, e.g. PD-L1. Ionizing radiation (IR), used to treat this tumor, is known to increase tumor expression of PD-L1, thus inducing resistance mechanisms. Finding molecular determinants involved in IR-induced PD-L1 may provide a target for preventing such an effect and improve radiotherapy outcomes. We demonstrated that the short isoform of the co-chaperone FKBP51 (FKBP51s) regulated PD-L1 expression in melanoma. In glioma, FKBP51s was expressed at high levels, together with PD-L1 and its silencing reduced PD-L1 levels. Conversely, overexpression of FKBP51s increased PD-L1. Different PD-L1 isoforms were observed by immunoblot. A lower band (~37 kDa) corresponding to the naïve protein and two upper bands (~50, ~68 kDa) ascribable to post-translationally modified isoforms. FKBP51s was found mainly bound to the heaviest bands of PD-L1, reasonably mature protein, while the canonical isoform FKBP51 appeared to bind only to the naïve protein. Mature PD-L1 protein contains in carbohydrates addition, the principal chemical modification to most plasma membrane proteins, and, particularly, N-glycosylation.

Treatment of immunoprecipitated PD-L1 protein with PNGaseF produced a decrease of the highest band and the appearance of a lower band, corresponding to the naïve PD-L1, in accordance with the concept that the heaviest band of PD-L1 is a glycosylated form. Moreover, following subcellular fractionation to obtain extracts from ER and Golgi compartments, we found that naïve 37 kDa PD-L1 was detectable in the ER, but not in the Golgi. The PD-L1 glycosylated band was expressed in ER in a small proportion and mostly in the Golgi. FKBP51s, but not the canonical FKBP51, was found in ER. Co-IP of FKBP51s and PD-L1 from ER extract confirmed the two proteins interacted each other in ER. Our results show that naïve PD-L1 colocalized in the ER of glioma cell complexed with FKBP51s, while the PD-L1 glycosylated form was measured in the Golgi apparatus. Treatment of glioma cell with increasing doses of IR up-regulated PD-L1 expression, in a dose-response manner. Particularly, we found a significant increase in PD-L1 expression at 4 and 8 Gy, in comparison with unirradiated glioma cell. Moreover, IR induction of mature PD-L1 was efficiently counteracted by FKBP51s silencing. Subcellular fractionation of glioma cell subjected to IR in kinetics showed an early and transitory decrease in FKBP51s ER levels at 3hrs, in line with a reduction of the glycosylated band in the whole lysate. After 8 hrs from IR, FKBP51s rose up again in the ER inducing a full maturation of PD-L1. These findings suggested that FKBP51s has a role in catalyzing PD-L1 folding, an essential step to glycosylation, through which it could constitute a target for PD-L1 toxicity. We identified FKBP51s as an essential element that regulates PD-L1 expression on glioma cell, which is exploited by the tumor to resist to IR.

#587 HMDB002, a novel neutralizing antibody targeting a specific epitope on the co-inhibitory immune checkpoint receptor VISTA, displays potent anti-tumor effects in pre-clinical models. Piers J. Ingram, Dipi Thakkar, Jerome D. Boyd-Kirkup. Hummingbird Bioscience, Singapore.

V-domain immunoglobulin (Ig)-containing suppressor of T-cell activation (VISTA) also known as PD1 homolog (PD1H) is a co-inhibitory immune checkpoint receptor. VISTA is predominantly expressed on hematopoietic cells, particularly myeloid derived suppressor cells and antigen presenting cells, and at lower levels on CD4+ and CD8+ T cells and Foxp3 Tregs. Multiple studies have demonstrated VISTA can strongly suppress human T-cell activation, and the presence of high VISTA expressing cells in the tumor microenvironment has been postulated as playing a critical role in tumorigenesis and resistance to immunotherapy. VISTA neutralizing antibodies have been previously observed in pre-clinical models to increase the abundance of tumor infiltrating effector T cells as well as their effector functions, resulting in enhanced control of tumor growth, even in the absence of detectable expression of VISTA on the tumor cells, a potential advantage over PD1 or PD1L1 blockade. There is an urgent need to develop the most clinically effective anti-VISTA antibodies however the limited characterization of the VISTA pathway and the uncertainty around the cognate VISTA ligand has limited the extent to which in vitro studies can superimpose.
port the selection of optimal antibodies for development. Hummingbird Bioscience’s proprietary Rational Antibody Development platform to the design of neutralizing antibodies against specific epitopes on VISTA. Extensive in silico analyses of the VISTA structure and comparative structural modeling against other B7 protein family members has enabled the prediction of key binding sites where an optimal antibody inhibitor would bind. Recently, redocking of a (CD8+ MNC) cell line, NOZ and GBd, and lung small cell cancer cell line, SBC-5 were used as target cancer cells. Human lymphocytes derived from PBMC were activated by using anti CD3 mAb and IL-2, and were used as effector cells. For normoxic conditions, cells were cultured in 5% CO2 and 95% air. For hypoxic conditions, cells were cultured in 1% O2, 5% CO2, and 94% N2 using a multigas incubator. For Hh signaling inhibition, cyclopamine, polysaccharide-K (PSK), and small interfering RNA targeting Gli1, Smo, MAML3, and RBPJ were used. Cell numbers were counted by light microscopy. Expression of cell surface molecules was estimated by FACS. [Results] 1) Hypoxia augmented PDL-1 expression in all 4 cancer cell lines. 2) Inhibition of Hh signaling using MAML3 siRNA, cyclopamine and PSK reduced PDL-1 expression under hypoxia in all 4 cancer cell lines. 3) When activated lymphocytes were cocultured with cancers treated with an Hh inhibitor, activated lymphocyte cell numbers significantly increased under hypoxia. 4) In contrast, this increase was abrogated when cancer cells were treated with a PDL-1 neutralizing antibody. 5) When activated lymphocytes were cocultured with cancers treated with a Hh inhibitor and/or anti-PDL-1 Ab, the percent of CD8+ lymphocytes decreased in both the cyclopamine- and anti-PDL-1-treated groups under hypoxic conditions, while there was no significant change in CD3 expression. 6) NKG2D expression increased on activated lymphocytes in anti-PDL-1 Ab-treated group. [Conclusion] These results suggest that Hh signaling is one of regulatory pathways of PDL-1 expression under hypoxia and that inhibiting Hh signaling may induce lymphocyte antitumor activity. Therefore, Hh inhibition could be a promising drug target, not only as a direct tumor suppressor agent, but also as a PDL-1 inhibitor.

#588 Advanced molecular characterization of severe autoimmune toxicities associated with checkpoint inhibitor therapies. Justin M. Balko,1 Daniel Y. Wang,1 Yu Wang,1 Rami Al-Rohil,1 Margaret Compton,1 Jeffery A. Sosman,2 Igor Puzanov,2 Bret Mobley,1 Robert D. Hoffman,1 Yaomin Xu,1 Javid J. Mosleh,1 Chanjian Shi,1 Douglas B. Johnson,1 Vanderbilt University Medical Center, Nashville, TN; 2Northwestern University, Chicago, IL; 3Roswell Park Medical Institute, Buffalo, NY.

Immune checkpoint inhibitors (ICIs) have made a profound impact on the treatment of a variety of cancers. However, as with any systemic treatment, toxicities are inevitable. With most classes of cancer therapies, toxicities are relatively predictable based on clinical trial safety data and therefore can be handled with prophylactic or supportive care measures. However, ICIs are unique in their ability to cause rare but severe auto-immune toxicities. The molecular underpinnings of these toxicities, as well as unique features of the patient, tumor, or affected tissue, have not been extensively explored. We recently reported a small case series of two patients with myositis resulting in death arising following combination ICI therapy (Johnson et al, N Engl J Med, 2016). High lymphocytic infiltration, coupled with PD-L1 expression was present in the affected myocardium and skeletal muscle. Common T cell clones were identified between the affected tissue and tumor, and abnormal expression of muscle-specific transcripts was identified in the associated tumor, suggesting release of peripheral tolerance to tumor-expressed self-antigens. To expand upon our reported study, we collected healthy and afflicted tissue from a series of cancer patients with immune-related colitis, myositis (MC), and encephalitis following ICI treatment. We hypothesize that molecular analysis of these tissues will identify causal factors in the etiology of these toxicities, and how to better predict, prevent, and treat them. Thus, we performed molecular characterization of the immune infiltrate and diseased tissue microenvironment. A total of 20 affected (colon, cardiac, brain) and non-diseased control specimens were examined by spatial digital profiling (nanoString). This process generates a spatial heatmap of digital counts of 20 selected immunology and cellular markers and proteins across each specimen. Using this technology, the landscape of inflammation in ICI-affected organs can be resolved for insights into the mechanism whereby ICI-mediated auto-immunity occurs. Targeted RNAseq for selected immuno-oncology mRNA targets was also performed. In initial RNA sequencing analyses of MC cases, affected myositis, skeletal muscle, and patient-matched tumors all demonstrated expression of immune activation markers (e.g. interferon- gamma and granulocyte B), expression of PD-L1, and muscle-specific genes. In the expanded population, including colitis, digital spatial profiling analyses and targeted NGs (RNAseq) are underway. Although data analyses are incomplete at the time of this abstract, this work will be the largest and most comprehensive analysis of the molecular underpinnings of ICI-mediated auto-immune toxicity reported to date. These data should offer clarity in the mechanisms and features of these adverse events, how to prevent or predict them with precision medicine, and how to treat them when they do occur.

#589 Hedgehog signaling augments PDL-1 expression in cancer cells under hypoxic condition to inhibit antitumor effects by activated lymphocytes. Hideya Onishi, Akiko Fujimura, Yasuhiro Oyama, Makoto Kawamoto, Akio Yamasaki, Takashi Morisaki. Kyushu University, Fukuoka, Japan.

[Background] Hedgehog (Hh) signaling is activated under hypoxic condition in cancerous tissue. This is thought to be one of the mechanisms of the induction of malignant phenotype of cancers. We have shown that Hh inhibitor decreases proliferation, invasiveness, and tumorigenesis. We have also revealed that Hh signaling plays pivotal roles for the maintenance of function in activated lymphocytes and dendritic cells under hypoxic conditions. Redox-sensitive checkpoint inhibitor takes much attention, however, response rate is still limited. The mechanisms regulating PDL-1 expression also remains unclear. In this study, to increase response rate of immune checkpoint inhibitor, we investigated whether hypoxia-induced activation of Hh signaling contributes to PDL-1 expression in cancer and whether it affects the antitumor function of activated lymphocytes.

Materials and Methods Pancreatic cancer cell line, Panc-1, gallbladder cancer cell line, GBC-SD, and Hh tumor cells were cultured in 1% O2, 5% CO2, and 94% N2 using a multigas incubator. For Hh signaling inhibition, cyclopamine, polysaccharide-K (PSK), and small interfering RNA targeting Gli1, Smo, MAML3, and RBPJ were used. Cell numbers were counted by light microscopy. Expression of cell surface molecules was estimated by FACS. [Results] 1) Hypoxia augmented PDL-1 expression in all 4 cancer cell lines. 2) Inhibition of Hh signaling using MAML3 siRNA, cyclopamine and PSK reduced PDL-1 expression under hypoxia in all 4 cancer cell lines. 3) When activated lymphocytes were cocultured with cancers treated with an Hh inhibitor, activated lymphocyte cell numbers significantly increased under hypoxia. 4) In contrast, this increase was abrogated when cancer cells were treated with a PDL-1 neutralizing antibody. 5) When activated lymphocytes were cocultured with cancers treated with a Hh inhibitor and/or anti-PDL-1 Ab, the percent of CD8+ lymphocytes decreased in both the cyclopamine- and anti-PDL-1-treated groups under hypoxic conditions, while there was no significant change in CD3 expression. 6) NKG2D expression increased on activated lymphocytes in anti-PDL-1 Ab-treated group. [Conclusion] These results suggest that Hh signaling is one of regulatory pathways of PDL-1 expression under hypoxia and that inhibiting Hh signaling may induce lymphocyte antitumor activity. Therefore, Hh inhibition could be a promising drug target, not only as a direct tumor suppressor agent, but also as a PDL-1 inhibitor.

ALKS 4230 is a novel immunotherapeutic agent being tested in an ongoing phase I clinical trial and from ongoing preclinical studies. The extracellular portion of the IL-2 receptor is sterically prevented from binding to the high-affinity IL-2 receptor expressed on Treg. The efficacy of ALKS 4230 was compared to recombinant human IL-2 in a B16F10 lung metastasis model. ALKS 4230 treatment resulted in dose-dependent reduction of lung tumor colonization, with 100% inhibition at the highest dose tested. In contrast, while IL-2 was able to reduce lung tumor colonization, the maximal level of inhibition achieved was 60-70% at multiple dose levels such that increasing doses did not result in greater inhibition. Thus, the activation and expansion of effector cells without expansion of Treg, in response to ALKS 4230 treatment correlates with its improved efficacy over IL-2, which non-selectively expands both effector cells and Treg. The antitumor efficacy mediated by ALKS 4230 was further evaluated in several murine subcutaneous syngeneic tumor models, including B16F10, MC38 and EMT6. Treatment with ALKS 4230 or its murine ortholog resulted in inhibition of tumor growth and improved survival in multiple models. When dosed in combination with anti-CTLA-4 or anti-PD-1 antibodies, ALKS 4230 resulted in further improvement of tumor growth inhibition and survival. These results demonstrate the murine antitumor efficacy of ALKS 4230 alone and in combination with immune checkpoint inhibitors and support the ongoing clinical evaluation of ALKS 4230 as an immunotherapy for cancer.

Distinct cellular mechanisms mediate anti-CTLA-4 and anti-PD-1 checkpoint blockade. Spencer C. Wei,1 Jacob H. Levine,2 Dana Pe’er,2 James P. Allison1. 1UT MD Anderson Cancer Ctr., Houston, TX; 2Sloan Kettering Institute, New York, NY.

checkpoint blockade is able to achieve durable responses in a subset of patients, however the biological variables that distinguish responders from non-responders are not well understood. Furthermore, we lack a satisfying comprehension of the underlying mechanisms of anti-CTLA-4 and anti-PD-1 induced tumor rejection. Given that PD-1 and CTLA-4 attenuate T cell activity through distinct mechanisms that are separated spatially and temporally, we hypothesized that responses to anti-CTLA-4 and anti-PD-1 are driven by distinct mechanisms. To address this hypothesis we utilized mass cytometry to comprehensively profile the effect of checkpoint blockade on tumor immune infiltrates in murine tumor models. This approach allows for the interrogation of greater than 40 analytes at single cell resolution. We demonstrate that high dimensional mass cytometry analysis enables unsupervised identification of biologically relevant tumor infiltrating immune populations with high sensitivity and specificity. Using this approach we analyzed immune infiltrates of four murine tumor models in mice treated with anti-CTLA-4, anti-PD-1, or control antibodies. In both tumor models we identify distinct T cell populations with 0.5% or greater frequency. The T cell populations identified in MC38 and B16B16 were highly congruent. Notably, some but not all of these T cell populations were responsive to checkpoint blockade. A subset of tumor infiltrating CD8 T cell populations expanded following both anti-CTLA-4 and anti-PD-1. Conversely, a subset of regulatory T cell populations contracted following both anti-CTLA-4 and anti-PD-1. Interestingly, we observed expansion of a Th1 like CD4 effector T cell population only in response to anti-CTLA-4 treatment. Thus, we find that anti-PD-1 predominantly engages subsets of tumor infiltrating CD8 T cells whereas anti-CTLA-4 engages both the CD4 and CD8 effector compartments. Our findings indicate that anti-CTLA-4 and anti-PD-1 utilize distinct cellular mechanisms to induce tumor rejection. These findings highlight the importance of expanding our mechanistic understanding of immunotherapeutic approaches for the rational design of combinatorial therapeutic approaches. Furthermore, these results demonstrate that mass cytometry analysis can be utilized to identify biologically relevant tumor infiltrating T cell populations. We acknowledge the MDACC core facility NCI Support Grant P30CA166672.

Background: Immunotheapy with PD-1 inhibitors is associated with increased survival in NSCLC. While PD-L1 expression enriches for clinical benefit, additional predictive biomarkers are critically needed to further define patient subsets associated with specific response/resistance profiles and to develop optimal combination strategies. We hypothesized that integration of pathology features, including Tumor mutation burden (TMB) and tumor mutation load (TML), with immunogenomic data from NSCLC could identify phenotypic/genotypic associations that highlight specific immunosuppressive mechanisms. Towards that end, we present data from an initial pilot analysis. Methods: Twenty-nine NSCLC (23 adenocarcinoma; 6 squamous cell carcinoma) were included. H&E-stained sections were scored for tumor grade (1-3), relative proportion of tumor stroma (stroma ratio 1-3), density across and intensity of PD-L1 immunostaining, intensity of PD-L1 expression on tumor infiltrate (1-3+), PD-L1 immunohistochemistry was performed using the DAKO 28-8 antibody. PD-L1 expression was scored in tumor cells by modified H-score and by the predominant pattern observed - diffuse, heterogeneous, tumor-stroma interface or negative, and in immune cells using a semi-quantitative intensity scale (1-3+). DNA and RNA extracts from FFPE tissue were subjected to whole exome sequencing and RNAsseq from which mutation load, oncogene/ tumor suppressor genotypes and inflammation signatures were derived. Results: The highest PD-L1 H-scores were associated with diffuse expression patterns and were observed in high grade tumors (Grade 3). Deletorius mutations in TP53, STK11, KEAP1, KRAS, EGFR and MET occurred at expected frequencies. These mutations occurred across multiple PD-L1 expression patterns except for 1 PD-L1 high expression tumors (p=0.077, Fisher exact test). STK11-mutant tumors also displayed a lower PD-L1+ inflammation score (p=0.046, Fisher exact test). Trends toward an increase in mutation load with increasing levels of chronic inflammation on H&E stain as well as with PD-L1+ chronic immune infiltrates were noted. Inflammation signatures derived from RNAsseq showed an assocition between diffuse PD-L1 expression by IHC and the highest levels of inflammation mRNA signatures comprising T-cells (CD8, Tregs), B-cells, macrophages and MDSCs. Conclusions: The potential association between tumor grade, PD-L1 expression, intensity of the immune infiltrate and mutation load raise the possibility that tumor morphology predicts mutation load and associated immune response. The finding that STK11 mutation is restricted to PD-L1 negative tumors suggests an immunosuppressive mechanism is invoked in this setting. This dataset is currently being expanded to establish the significance of these findings.

Dual targeting of TGFβ and PD-L1 promotes potent anti-tumor effec- tivity in multiple murine models of solid carcinomas. Karin M. Knudson,1 Sofia R. Gameiro,1 Kin-Ming Lo,2 Jeffrey Schlom1. 1NCI-CCR, Bethesda, MD; 2EMD Serono, Billerica, MA.

Tumors evade host immune surveillance through multiple mechanisms, including promoting a tumor microenvironment able to effectively suppress immune effector functions. Aberrant secretion of anti-inflammatory cytokines, such as TGFβ and PD-L1, is a hallmark of most carcinomas. Immune checkpoint molecules are two main contributors to immune evasion and tumor progression. TGFβ is an important immunosuppressive cytokine with pleiotropic actions in cancer, including promotion of epithelial to mesenchymal transition and metastasis. It promotes tumor immune evasion by impairing T and NK cell maturation, recruitment, and function. Tumors also inhibit antitumor immune responses through tumor cell-immune cell interaction, in which the negative regulatory checkpoint PD-L1/PD-1 interaction plays a major role. Therapies that independently target TGFβ signaling or PD-L1/PD-1 interaction demonstrate limited clinical efficacy. Anti-PD-L1/TGFβTRAP (M7824) is a novel immunotherapeutic agent designed to simultaneously block the PD-L1 and TGFβ immunosuppressive pathways. It is comprised of the extracellular domain of human TGFβRII (TGFβTRAP) linked to the C-terminus of human anti-PD-L1 heavy chain (anti-PD-L1). M7824 has shown potent anti-tumor activities in preclinical models1 and some evidence of clinical efficacy in a phase 1 study2. Here, we demonstrate that anti-PD-L1/TGFβTRAP neutralizes murine TGFβ-induced signaling and binds to murine PD-L1 in multiple murine breast and colon carcinoma models. In non-tumor bearing mice, anti-PD-L1/TGFβTRAP increases the number of CD8+ T cells in intratumoral, Treg, and dendritic cell (DC) and B cell populations and in tumors inflammatory active phenotype. Initial examination of peripheral immune subsets in tumor-bearing mice indicates that anti-PD-L1/TGFβTRAP induces CD8+ T cells and NK cells with a more active, less exhausted phenotype. Furthermore, dual targeting of PD-L1 and TGFβ increases tumor expression of MHC-I, MHC-II, and PD-L1, suggesting additional immune effects in the tumor microenvironment. Importantly, anti-PD-L1/TGFβTRAP displays potent anti-tumor efficacy against various murine models of breast and colorectal carcinomas. This response is durable, preventing relapses up to 7 months. Anti-PD-L1/TGFβTRAP also decreases spontaneous metastasis in a murine model of triple-negative breast cancer. Taken together, these findings support the preclinical proof of concept for dual targeting of TGFβ and PD-L1-PD-1

IMMUNOLOGY: Checkpoints 1

#595 Heterogeneity of immune checkpoint expression in lung cancer identified through rapid tissue donation. Theresa Boyle, Andrea Shaffer, Janella N. Hudson, Luisa D. Arevalo, Matthew Schabath, Teresita Muñoz-Antonia, Christie Pratt, Gwendolyn P. Quinn, Eric B. Haura, Moffitt Cancer Center, Tampa, FL.

Background: Translational research in advanced lung cancer is hindered by the limited availability of specimens for advanced molecular techniques. Although helpful, the standard practice to biopsy a small amount of tissue from a single site of cancer provides limited information. We launched a thoracic rapid tissue donation (RTD) program to enable lung cancer research with collection of tissue at multiple tumor sites within hours after death. Many patients chose to enroll in the RTD program as an opportunity to contribute to cancer research. RTD tissue will support multiple research projects, such as studying differential expression of immune checkpoint proteins in immune oncology or understanding resistance to targeted agents. Methods: The RTD program for patients with stage IV lung cancer was approved in June 2015 by the Moffitt Cancer Center institutional review board. Tissue specimens from multiple tumor sites from consented donors are collected rapidly (aim < 24 hours) after death and are frozen and/or preserved in formalin. Hematoxylin and eosin (H&E) staining is performed with evaluation of pathology and quality of the specimens. Immunohistochemistry is performed to evaluate expression of immune checkpoint biomarkers (PD-L1, CTLA4, LAG3, TIM3, BTLA, A2AR and INOS). Results: Between June 26, 2015 and November 16, 2016, 18 patients with stage IV lung cancer consented to the RTD program. Post-mortem tissue has been collected from multiple tumor sites for three cases. H&E staining of 25 tissue blocks from the first case showed minimal evidence of post-mortem tissue damage by autolysis, confirming high RTD tissue quality. Biomarker studies, such as immunohistochemistry for immune checkpoints, such as PD-L1, CTLA4, LAG3, TIM3, BTLA, A2AR and INOS are ongoing. Preliminary analysis of PD-L1 expression in the first patient revealed heterogenous PD-L1 expression within and between eight tumor sites (both lungs, liver, both kidneys, left adrenal gland, mediastinal and retroperitoneal lymph nodes). Conclusions: Rapid tissue donation with collection of ample post-mortem tumor tissue is feasible and valuable for cancer research. A heterogeneous pattern of PD-L1 immune checkpoint expression was observed between multiple sites of tumor. Post-mortem tissue collection from multiple tumor sites facilitates understanding changes in tumor behavior and biomarker expression at metastatic sites, especially in the context of treatment failures. Acknowledgments: H&H Sponsor #R21 CA149532-01 and Tissue Core Facility at the H. Lee Moffitt Cancer Center & Research Institute (P30-CA076292).

#596 eFT508, a potent and highly selective inhibitor of MNK1/2 regulates immune checkpoint and cytokine expression promoting anti-tumor immunity. Kevin R. Webster, Vikas K. Goel, Jocelyn Staunton, Craig R. Stumpf, Rajesh Sharma, Ivy N. Hung, Gregory S. Parker, Jolene Møller, Gary G. Chuang, Andrew J. Wogenrich, Samuel Speney, Vera Huang, Peggy A. Thompson, Chinh Tran, Justin T. Ernst, Paul A. Sprengeler, Sieg-fried H. Reich,

eFECTOR Therapeutics, San Diego, CA; 2 Molecular Stethoscope, San Diego, CA.

Dysregulated translation of messenger RNA (mRNA) plays a role in the pathogenesis of multiple solid tumors and hematological malignancies. MNK1 and MNK2 integrate signals from several oncogenic and immune signaling pathways (including RAS, Toll-like receptors and T cell receptor) by phosphorylating eukaryotic initiation factor 4E (eIF4E) and other key effector proteins including hnRNP A1 and PSF. Phosphorylation of these mRNA-binding proteins by MNK1 and MNK2 selectively regulates the stability and translation of a subset of cellular mRNA that control tumor/stromal cell signaling, the tumor microenvironment and immune cell function. eFT508 is a potent and highly selective inhibitor of both MNK1 and MNK2. Ribosome profiling has demonstrated that inhibition of MNK1 and MNK2 by eFT508 selectively regulates the translational efficiency and mRNA stability of a subset of genes that include inflammatory cytokines/chemokines, regulators of stress response, and effectors of anti-tumor immune response. Given the importance of MAPK signaling and translational control to immune cell activation and differentiation, the immunological effect of eFT508 was further evaluated in both normal human immune cells in vitro and immunocompetent syngeneic cancer models in vivo. eFT508 treatment of normal donor T cells has no deleterious effect on an CaD3/CD28 stimulated IL-2 production, T cell proliferation or T cell viability. However, eFT508 selectively down regulates the induction of IL-10 and specific immune checkpoint receptors, including PD-1 and LAG3. Further evaluation of the mechanism of translational regulation has shown LAG3 mRNA contains specific sequence elements in the 3' untranslated region (UTR) that confer sensitivity to eFT508. In addition, IL-10 mRNA is destabilized upon treatment with eFT508 leading to significant inhibition of IL-10 production in activated T cells. Furthermore, eFT508 treatment results in upregulation of MHC class II molecules on tumor cells, macrophage and dendritic cells through an IL-10/MARCH1 dependent mechanism. The in vivo antitumor effect of eFT508 was assessed in the CT26 BALB/c syngeneic tumor model. CT26 mouse tumor cell proliferation and survival are insensitive to eFT508 in vitro. In vivo, daily oral treatment with 1 mg/kg eFT508 results in significant inhibition of tumor growth, modulation of tumor infiltrating lymphocytes and establishment of immune memory. In addition, combination of eFT508 with either anti-PD-1 or anti-PD-L1 monoclonal antibodies results in marked efficacy, significantly increasing the percentage of responder animals. eFT508 is currently under evaluation in two phase I/II clinical trials for patients with advanced solid tumors and patients with advanced lymphoma respectively. These findings support further clinical evaluation of eFT508 in combination with checkpoint blockade.

IMMUNOLOGY: Checkpoints 1

#597 Bispecific anti-CD123 x anti-CD3 ADAPTIR™ molecules for redirected T-cell cytotoxicity in hematological malignancies. Michael R. Corcoran, Robert Delville Mitchell, Dennis M. Slamon, Rollin J. Cha, Mollie M. Daugherty, Lara Parr, Peter Pavluk, Brian Woodruff, Hang Fang, Megan Aguilar, Jeannette Bannink, Starrla Johnson, Gary Li, Robert E. Miller, Robert Bader, Nicole Zhang, Toddy Sewell, Maria Dasovich, Gabriela H. Hoyos, John W. Blankenship, Catherine McMahan, David Bienvenue, Jane A. Gross, Aptevo Therapeutics, Seattle, WA.

Introduction: CD123 is a component of the IL-3 receptor expressed in several hematological malignancies including AML, ALL, HCL, and MDS. CD123 is a compelling target in AML due to its overexpression on AML blasts as well as leukemic stem cells, which are thought to be resistant to chemotherapy and may be responsible for relapse of disease following treatment. While CD123 is expressed by some normal leukocyte populations in circulation and hematopoietic progenitor cells in the bone marrow, the low frequency of expression on normal cell types provides a therapeutic window for targeting CD123 in tumor settings with the potential for durable response and reversible side effects. We have developed bispecific anti-CD123 x anti-CD3 ADAPTIR molecules APVO436 and APVO437 for redirecting T-cell cytotoxicity to CD123-expressing tumor cells. Results are presented that examine the in vitro and in vivo activity of these molecules in preclinical models of AML. Methods: APVO436 and APVO437 proteins were expressed in CHO cells. Affinity SPR studies were performed using recombinant CD123-ectodomain. In vitro functional studies were conducted with CD123+ AML tumor cell lines and primary human and cynomolgus macaque T-cell populations. Cytotoxic activity was determined using chromium release assays. On-cell binding, T-cell activation and proliferation were assessed using multi-color flow cytometry. Pharmacokinetic parameters were determined in BALB/c mice using a single IV dose of approximately 10 mg/kg. In vivo studies to examine tumor growth inhibition activity were performed with NOD/SCID mice co-implanted subcutaneously with AML tumor cells and human T-cells followed by treatment with APVO436 or APVO437. Tumor growth was assessed by measuring tumor volume and Bioluminescent Imaging. Results: APVO436 and APVO437 bound human CD123 protein with high affinity and binding to CD123 and CD3 expressing cell lines was confirmed by flow cytometry. Both APVO436 and APVO437 induced concentration-dependent lysis of CD123+ AML cell lines with primary human effector T-cells, accompanied by T-cell activation and proliferation. In vitro, T-cell cytotoxicity was assessed using primary cynomolgus macaque T cells. These activities were dependent on the expression of CD123 by the tumor target cells. APVO436 and APVO437 demonstrated an extended elimination half-life in mouse serum, typical of molecules capable of binding the neo-natal Fc receptor. In vivo, growth of AML tumor cells was inhibited by treatment with low doses of APVO436 and APVO437, significantly improving host survival. Conclusion: Taken together these data demonstrate potent in vitro and in vivo activity of APVO436 and APVO437 against CD123 expressing tumor cells and are supportive of further investigation of this approach as a potential treatment option for AML and other hematological malignancies.
anti-TIGIT. The microarray data were validated by qRT-PCR and results were consistent with flow cytometry and cytotoxicity results, and underlie the mechanism of action of anti-TIGIT. We have developed an IHC assay to evaluate TIGIT expression patterns in tumor and the associated stroma and TILs. Using this assay, we profiled 17 tumor types to evaluate patterns of TIGIT expression. Expression was high on immune cells in the stroma and on TILs in 8 tumor types, while it was predominantly low on tumor cells. This assay also low on tumor cells in a panel of 27 PDOx models. Consistent with the IHC results, analysis of 33 tumor types in the TCGA by RNA-Seq showed a good correlation of the expression levels of TIGIT and T cell markers, suggesting that TIGIT is mostly expressed on immune cells in tumors. In conclusion, we have identified PD biomarkers for anti-TIGIT in tumors and in surrogates tissues in syngeneic mouse models. Analysis of the biomarkers demonstrates activation of T cells and NK cells upon inhibition of TIGIT signaling. These biomarkers can be used in the clinic to demonstrate target engagement. In addition, we have profiled the expression of TIGIT in multiple solid tumor types and characterized prevalence of TIGIT-positive cells.

#598 APOBEC mutagenesis: a link between innate immunity and cancer. A Rouf Banday, Oluisegun O. Onabajo, Krizia-Ivana Udquim, Adeola Obajemu, Ludmila Prokunina-Olsson. NCI/NIH, Bethesda, MD.

Introduction: Cytidine deaminase activity of APOBEC3 enzymes generates mutations that restrict viral infection and eliminate tumor cells but also contribute to viral and tumor evolution. For example, human immunodeficiency virus (HIV) is hypermutated by APOBEC3G (A3G), and human papilloma virus (HPV) can be hypermutated by APOBEC3s, including A3A and A3B. In many human tumor types explored by The Cancer Genome Atlas (TCGA), C to T or G substitutions in the TCA or TCT motifs are predominately attributed to the activity of A3A and A3B enzymes. In bladder tumors more than 60% of all exonic mutations were accounted for by the APOBEC3-signature type, with nearly 100% of all bladder tumors carrying these mutations. Previously, we reported that two germline genetic variants – a single nucleotide polymorphism (SNP) rs1014971 and a 30kb germline deletion that eliminates A3B and creates an A3AB chimera, are the strongest factors associated with bladder and breast cancer risk, expression of A3A and A3B, and APOBEC mutagenesis in human tumors. Other factors affecting the source of APOBEC mutagenesis in human tissues are not well understood. Because some APOBEC3s can be induced in the course of antiviral response, we hypothesized that APOBEC mutagenesis might be a misfired innate immune response. Methods: We used TaqMan-based expression analysis for selected APOBECs (A3A, A3B, and A3G) to explore expression in bladder (HT-1376, HBT-9, and RT-4) and breast cancer (MCF-7, MDA-MB-231, and HCC11006) cell lines and in cells infected with a Sendai virus (SeV) that induces APOBEC3 expression. The results showed that APOBEC3s in RT-4 and MDA-MB-231 was followed-up by global transcriptome analysis with RNA-seq and pathway analysis. Cell lines were also treated with IFN-α, IFN-γ, IFN-A and IFN-γ and A3A, A3B and A3G by TaqMan assays. Results: A3A, A3B and A3G are interferon-stimulated genes (ISGs) because they were induced in the course of innate antiviral response to SeV infection and by IFNs in some conditions. Specifically, A3A was most strongly induced by SeV, with 32, 51, 12,000-fold induction in 3 breast cancer cell lines, and 4, 5, and 167-fold induction in 3 bladder cancer cell lines. A3B was also induced by SeV but only in the range of 1-5 fold in all cell lines tested. Conclusion: APOBEC3s can be strongly induced in the course of innate immune response even to transient and self-limiting viral infections. In the presence of single-stranded DNA (ssDNA), the APOBEC3 substrate generated by different cellular and environmental conditions, strong induction of some nuclear APOBEC3s, such as A3A and A3B, may result in mutation of human genomic DNA. In turn, accumulation of these mutations can lead to tumor initiation and evolution, particularly in individuals with germline APOBEC3 risk variants.

TIGIT (C cell immunoreceptor with Ig ITIM domain) is a co-inhibitory receptor and its signaling axis inhibits T cell and Natural Killer (NK) cell activity in the healthy immune system. In tumors TIGIT is highly expressed on a subset of dysfunctional T and NK cells and of highly suppressive regulatory T cells (Treg). Loss of TIGIT signaling enhances NK cell activity, CD4+ T cell priming and CD8+ T cell effector functions, suggesting a role in anti-tumor immunity. We have developed an anti-TIGIT blocking antibody that shows potent antitumor efficacy in multiple syngeneic mouse models, including CT26 WT colon, B16F10 melanoma and 4T1 breast cancer. Dose-dependent (12.5-0.1 mg/Kg) single agent efficacy was demonstrated in established tumors, and pharmacodynamic (PD) biomarkers in blood and in tumors were identified. Consistent with TIGIT’s role as a co-inhibitory receptor, anti-TIGIT promoted a dose-dependent increase of the CD4+ and CD8+ T cell fraction, with nearly 100% of all infiltrating leukocytes (TIL) and NK cells, as shown by increased staining of IFN-γ and CD69 by flow cytometry, when compared to controls. Anti-TIGIT also increased CD4 and CD8 T cell frequency in the tumor, measured by immunohistochemistry (IHC). Furthermore, anti-TIGIT caused an increase in splenic NK cell cytotoxicity, which correlated with dose and efficacy. To identify gene expression biomarkers in tumor and in blood, we used microarray analysis, and found similar immune gene changes between the two tissues. As expected, anti-TIGIT increased the expression of genes associated with CD8+ T cells, CD4+ T cells, and NK cells. Markers indicative of cytotoxic activity and Th1 response were also induced by anti-TIGIT. The microarray data were validated by qRT-PCR and results were consistent with flow cytometry and cytotoxicity results, and underlie the mechanism of action of anti-TIGIT. We have developed an IHC assay to evaluate TIGIT expression patterns in tumor and the associated stroma and TILs. Using this assay, we profiled 17 tumor types to evaluate patterns of TIGIT expression. Expression was high on immune cells in the stroma and on TILs in 8 tumor types, while it was predominantly low on tumor cells. This assay also low on tumor cells in a panel of 27 PDOx models. Consistent with the IHC results, analysis of 33 tumor types in the TCGA by RNA-Seq showed a good correlation of the expression levels of TIGIT and T cell markers, suggesting that TIGIT is mostly expressed on immune cells in tumors. In conclusion, we have identified PD biomarkers for anti-TIGIT in tumors and in surrogates tissues in syngeneic mouse models. Analysis of the biomarkers demonstrates activation of T cells and NK cells upon inhibition of TIGIT signaling. These biomarkers can be used in the clinic to demonstrate target engagement. In addition, we have profiled the expression of TIGIT in multiple solid tumor types and characterized prevalence of TIGIT-positive cells.
tic effects, and can be designed to incorporate payloads that enhance their onco-
lytic effects. TETN-L is a recently discovered, longer form of TETN which is
secreted and membrane permeable, and retains its phosphatase activity after
secretion and re-entry into cells. We have generated a novel oncolytic herpesvi-
rus (RAPTOR) that secretes TETN-L from infected cells for the treatment of
GBM and breast metastases in vivo. In vitro, RAPTOR mediates tumor cell
virol mediated tumor cell killing, virus replication, transgene expression, and
flow cytometry to evaluate intracellular pAkt and cell surface programmed death
ligand 1 (PD-1) were performed. In vivo studies using mice bearing orthotopic
human GBM (nude mice) or murine BCBM (nude and FVB/N) were used to
evaluate brain immune infiltrates and survival. Western blot analyses of infected
lymphocytes showed increased viral and media show that RAPTOR produces
significantly greater amounts of IFNγ than either control CAR or CAR-DNR cells,
following activation in the presence of TGF-β. Flow cytometry of treated tumor-bearing mice in the
presence of TGF-β was completely protected from TGF-β signaling domains of the T cell simulating IL-12 receptors IL-12Rβ2 binding domain of each receptor is fused to the transmembrane and intracellular
cytoplasm. Tumor cell killing and replication were equivalent between RAPTOR and control HSVQ. In vivo,
treatment of mice bearing established orthotopic BCBM revealed improved an-
ti-tumor efficacy of RAPTOR. Significantly, 9/10 RAPTOR treated mice were
long term survivors in immunocompetent FVB/N mice vs. 4/10 HSVQ treated
mice (p=0.044). Treatment of nude mice bearing the same tumors did not
produce long term survivors, implicating the development of antitumor immu-
nity in RAPTOR treated animals. Flow cytometry revealed significant down
regulation of the T-cell repressor PD-L1 on RAPTOR vs. HSVQ treated cells.
Consistent with this, FACS of virus treated tumor bearing brain hemispheres
revealed RAPTOR induced a significant influx in antigen presenting, NK, and
CD8 T cell infiltration. Our findings demonstrate that RAPTOR enhances survival of brain tumor bearing mice using a two-pronged approach:
lytic tumor cell death and immune cell education and activation against the
brain tumor. RAPTOR inhibits virol induced PD-L1 expression on tumor
cells, and could pave the way for a paradigm shift in immune therapy where
immune checkpoint inhibition occurs locally within the tumor rather than glob-
ally, overriding toxicity of neutralizing antibodies.

#602 A novel TGF-β/IL-12R signal conversion platform that protects
CAR T cells from TGF-β-mediated immune suppression and concurrently
amplifies effector function. Benjamin Boyerinas, Sara Miller, Ryan Murray,
Stacie Seidel, Geoffrey Parsons, Kathy Seidl, Kevin Friedman, Richard Morgan.

bluebird bio, Inc., Cambridge, MA.

Numerous immune-suppressive mechanisms exist within the tumor microenvi-
ronment that may hinder chimeric antigen receptor (CAR) T cell efficacy. One such
mechanism is mediated by TGF-β, a cytokine secreted by tumor cells and inhib-
iting suppressive immune cells that directly inhibits effector T cell activity.
Effector T cells express the TGF-β receptors TGFBR1 and TGFBR2, and expres-
sion of T cells to TGF-β induces phosphorylation of the major TGF-β signal
mediators SMAD2 and SMAD3. Phosphorylated SMAD proteins (pSMADs)
induce a signal transduction that results in transcriptional repression leading to
reduced cytokine production, reduced cytotoxicity, and a failure to proliferate in re-
ponse to antigen stimulation. A dominant negative receptor version (DNR) of
TGFBR2 that does not contain signaling domains protects T cells from the
impacts of TGF-β by blocking the ability of TGF-β to induce pSMADs. Here, we
report the development of a novel TGF-β signal conversion platform that pro-
vides a T cell stimulatory signal upon exposure to TGF-β. This platform utilizes
co-expression of chimeric variants of TGFBR2 and TGFBR1 where the TGF-β
binding domain of each receptor is fused to the transmembrane and intracellular
signaling domains of the T cell simulating IL-12 receptors IL-12Rβ2 and IL-
12Rβ1, respectively. Using a single lentiviral vector encoding both chimeric
TGF-β receptors (CTBR) and a CAR, we demonstrated that CAR-CTBR T cells
were completely protected from TGF-β-mediated SMAD phosphorylation. In addi-
ton, CAR-CTBR T cells generated significant amounts of pSTAT4 and
pSTAT5 in response to TGF-β exposure, a response that mimics the T cell
response on the secretion of IFNγ, a

#603 Evaluation of CD19 targeted T cells in relapsed or refractory ALL
patients unable to afford allogeneic bone marrow transplant in India. Alka
Dwivedi, Sushant Kumar, Terry Fry, Gaurav Narula, Rahul Purwar, Indian
Institute of Technology Bombay, Mumbai, India; National Cancer
Institute (NCI), National Institute of Health (NIH), Bethesda, MD; Tata Memo-
rrial Hospital, Mumbai, India.

CAR-T cell therapy has demonstrated remarkable success in long-term re-
mission of relapsed or refractory B-ALL. Unlike western countries, most of the
relapsed/refractory B-ALL patients in India are unable to afford allogeneic stem
cell transplant (allo-SCT), and simply choose palliation. To assess the potential
use of CAR-T cells as a first line therapy, it is critical to evaluate CAR-T cell
efficacy in patients unable to undergo allo-SCT. As a first step, a novel anti-CD19
CAR was designed and CD19-vector was produced using lentiviral mediated
gene delivery system. To generate CD19+ CAR T cells, T cells from healthy
subjects were transduced and expanded either with rIL-2 or rIL-15. Almost
20-50% transduced T cells express CD19-CAR on their surface as analysed by
flow cytometry. Next, efficacy of CD19-CAR T cells was examined by cyto-
toxicity assay using CD19+ malignant B cell lines (Raji cells) and autologous B cells.
CAR-T cells were able to kill majority of CD19+B cells effectively (100% kill-
ing). In addition, CAR-T cells secreted high levels of IFNγ and IL-2. The CAR-T
cells expanded in presence of rIL-15 showed fewer Treg compared to CAR-T cells
expanding rIL-2. However, there were no differences in numbers of T
stem cells (TSC) and central memory T cells (TCM). In addition to data on healthy
volunteers reflected above, results of above tests in relapsed/ refractory
B-ALL patients is ongoing and being collated for inclusion in the final analysis.
In conclusion, our data demonstrate the successful development of an indige-
nous CAR-T cell platform for subsequent use in clinical trials of CD19+B cell
malignancies.

#604 Accurate identification and prioritization of candidate neoantigens
from integrated cancer exome and transcriptome sequencing of FFPE sam-
ples. Marián Novak, Sam Angiuoli, Luis A. Diaz, Andrew Georgiadis, Sian
Jones, Peter R. Lovero, Sonya Parpart-Li, Maria Svedali, Victor E. Velculescu,
Ellen L. Verner, James White, Theresa Zhang, Mark Sausen. Personal Genome
Diagnoses, Inc., Baltimore, MD.

Precise identification and characterization of candidate neoantigens is
important for the development of effective cancer vaccines, adoptive T-cell
transfer, and prediction of response to checkpoint inhibitors. The candidate
tumor neoantigens are actionable only when expressed, however, current
prediction methods lack the capacity to evaluate neoantigen expression. Se-
quencing both DNA and RNA from a patient’s tumor tissue enables identi-
fication of mutations and evaluation of their expression leading to accurate
identification of putative neoantigens. The purpose of this study was to de-
velop and validate a methodology for co-extraction and sequencing of DNA
and RNA from formalin-fixed paraffin-embedded (FFPE) samples to enable
a robust neoantigen prediction protocol that integrates whole exome and
transcriptome data to identify and prioritize neoantigens for applica-
tion in immuno-oncology research and clinical trials. In order to prepare
high-quality sequencing libraries from FFPE specimens, the tissue was
macro dissected to enrich for tumor-specific material, and improve the overall
accuracy of next-generation sequencing for detection of somatic alterations.
Total DNA and RNA was co-extracted and purified. The DNA was used to
prepare whole exome sequencing (WES) libraries, while the co-extracted
RNA was ribosome-depleted, and reverse-transcribed to prepare RNA se-
quencing (RNAseq) libraries. The WES and RNAseq data was then analyzed
using a multi-algorithm HLA typing and neoantigen prediction protocol
(ImmunoSelect-RTM). ImmunoSelect-R evaluates somatic genomic altera-
tions identified from WES of tumor and matched normal tissue to ensure
appropriate prediction of candidate neoantigens. The process of neoantigen
prediction was then refined by integration of patient tumor-matched
RNAseq data, which allowed for removal of non-expressed putative neoan-
tigens. To further validate the approach, we applied the methodology to a set
of experimentally validated neoantigens. In this setting, ImmunoSelect-R
correctly classified 18 out of 19 as strong neoantigen candidates, suggesting
a sensitivity of greater than 90%. Moreover, in a set of 10 patients, Immu-
noSelect-R consistently ranked experimentally validated neoantigens within
the top 20% of all neoantigen candidates derived from whole exome sequenc-
ing. In summary, our combined tissue processing, macrodissection, co-ex-
traction, and neoantigen prediction methodology is able to identify and

IMMUNOLOGY: T-cell Immunity to Cancer: New Progress

152 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
prioritize candidate neoantigens. Our approach is unique in combining high-fidelity sequencing (WES) and expression (RNAseq) data to accurately inform the selection of actionable tumor neoantigens for immunoncology applications.

The breakthrough discoveries of checkpoint inhibitors in the field of tumor immunology have driven the clinical success of immunotherapies for cancer, despite their beneficial efficacy in only a small portion of patients. This is due in part to immunodulatory mechanisms and the inability of the immune system to recognize tumor antigens as foreign. As a therapeutic approach to effectively present these tumor antigens in order to elicit an anti-tumor immune response, we previously designed and characterized an allogenic, gp96-Ig secreting, cell-based vaccine (ImPACT); currently being assessed in a phase II study in non-muscle invasive bladder cancer and a phase Ib study in non-small cell lung cancer – the latter, in combination with the PD-1 antagonist Nivolumab. We recently characterized a ‘next-generation’ vaccine (ComPACT) that combines the tumor antigen chaperone Gp96-Ig along with the T cell costimulator FC-OX40L, which are both secreted from the same cell (Fromm et al. Cancer Immunology Research. 2016). In preclinical assays, ComPACT is effective at stimulating CD4+ and CD8+ antigen-specific T cell expansion, the programming of a durable memory T cell phenotype, and the elimination of melanoma and colon tumors. This anti-tumor efficacy is enhanced when ComPACT is combined with checkpoint inhibition (anti-PD1 or anti-PDL1). To support manufacturing and clinical efforts of both ImPACT and ComPACT, in anticipation of phase III expansion and/or new trial initiation, we have developed novel potency assays to quantify the biologically active form of Gp96-Ig and the in vitro activity of FC-OX40L on T cell costimulation. It has been shown that gp96 can interact with toll-like receptors (TLR) and that this interaction results in the activation of the NF-kB pathway. Since THP1 cells express abundant TLR2/4, we engineered a THP1 cell line to express luciferase that is regulated by NF-kB response elements. Furthermore, we utilized the human T cell line; Jurkat, as host cells in which we also express NF-kB-luciferase, to quantify FC-OX40L costimulation. Jurkat/NF-kB-luciferase cells primed with either CD3/CD28 or TNFα, and subsequently cultured with ComPACT-secreted FC-OX40L results in a dose dependent increase in NF-kB (luciferase) expression. Our current data in both assays show a linear correlation with the input of Gp96-Ig and FC-OX40L, and may serve as an effective potency assay to facilitate the manufacturing of our vaccine product as it transitions into more advanced cancer immunotherapy clinical studies.

**#606 Targeting multiple immune checkpoints and their ligands using a humanized mouse model of ovarian cancer.** Ruya-Yea Huang, Kunle Odunsi. Roswell Park Cancer Inst, Buffalo, NY.

We have recently reported that multiple immune checkpoints are expressed in the TILs (tumor infiltrating T lymphocytes) and TALS (tumor associated T lymphocytes) from a murine ovarian cancer model and that blockade of one checkpoint pathway induces an upregulation of the other unblocked checkpoints. We hypothesized that resistance to single agent blockade (e.g. anti-PD1) is resulting from the compensatory upregulation of the other pathways (e.g. CTLA4 or LAG-3). To test this hypothesis in human ovarian cancer, we first examined the level of several immune checkpoints and their ligands in TILs or TALS from ovarian cancer patients. In addition to the highly expressed PD-1 and CTLA4, other checkpoint molecules such as TIM3, LAG3, VISTA, and TIGIT are also elevated in TALS as compared with control PBMC. The levels of multiple ligands for the immune receptors in the tumor samples were also analyzed. To translate the results from mice to humans, we developed several aggressive human ovarian cancer cell lines from patient derived xenografts to test the combinatorial checkpoint blockade strategies. Using a humanized mouse model of ovarian cancer we observed that adaptive transfer of autologous T cells in combination with checkpoint blockade of PDL1 mildly delays ovarian tumor growth. The effect of blocking PD-1 and CTLA4-4 pathways on tumor growth and the upregulation of other checkpoints are currently underway.

**#607 PDL1 expression associated with triple negative breast ductal carcinomas in African American women.** Farhan Khan, Yasmine Kanaan, Luis J. Ricks-Santi, Rabia Zafar, Hagos Aynnuit, Tammye Naab, Howard University Hospital, Washington, DC, DC; Hampton University Hospital, Hampton, VA.

Background: Tumor cells avoid host immune response through expression of inhibitory T cell regulator, Programmed cell death ligand (PDL1). Our objective was to evaluate PDL1 expression by immunohistochemistry in the four major subtypes of breast carcinoma (Luminal A, Luminal B, HER2, and Triple Negative) in a population of 202 African-American (AA) women with other clinicopathological factors. Design: Tissue microarrays (TMAs) were constructed from FFPE tumor blocks from primary ductal breast carcinomas in 202 African-American (AA) females. Two separate 1 mm cores represented each case. Five micrometer sections were stained with rabbit monoclonal antibody against PDL1. The sections were evaluated for the percentage and intensity of membrane staining in both tumor and immune cells. Cut off was > 1%. Bivariate analysis was done via χ2 analysis and survival data was calculated via the generation of Kaplan-Meier curves (SPSS v19). Statistical significance was assumed if p < 0.05.

Results: PDL1 expression in tumor cells, only in the combination with ER negative (p<0.0001), PR negative (p<0.0001), Triple negative subtype (p<0.0001) and high grade (p<0.0001) breast ductal cancers. Conclusion: Our study finding of selective expression of PDL1 in triple negative breast ductal cancers (TNBC) in AA women suggests that inhibition of adaptive immune response is involved in the progression of these cancers. PDL1/PD1 is the inhibitory check point of immune response resulting in decreased T cell activation and cytokine production. Some studies have shown that PDL1 expression is associated with loss of PTEN and phosphatase inostol 3 kinase pathway (PI3K) activation. Our previous study showed loss of PTEN in TNBC. Combining PDL1 inhibitors with PI3K inhibitors may be useful therapy for aggressive TNBC.

**#608 Augmenting and broadening T cell responses against mutated tumour neo-antigens.** Bruce W. Robinson, Shaokang Ma, Jonathan Chee, Craig Rive, Paula Van Miert, Rob A. Holt, Janette Creaney. University of Western Australia, Western Australia, Australia; University of British Columbia, Vancouver, British Columbia, Canada.

Cytotoxic T lymphocytes (CTLs) recognize mutated tumor proteins (neo-antigens) and are important for anti-tumor immunity, especially in the context of immune checkpoint blockade immunotherapy (ICBP). Positive outcomes to ICBP are associated with high neo-antigen loads and with neo-antigen specific CTL responses. However only around 20% of patients respond to ICBP. In order to examine ways in which the non-responders might become responders we examined several strategies to improve response rates, using anti-CTLA4 initially as the ICBP therapy in BALB/c mice in which Uqrcr2c was defined as a DNA/RNAseq-identified neo-antigen in AB1 tumor lines induced by a relevant human carcinogen(1). 1) We first examined therapy-induced changes in T-cell responses against Uqrcr2c. Anti-CTLA4 alone increased the magnitude of responses against Uqrcr2c. Anti-CTLA4 combined with anti-GITR induced dominant spreading, unmasked responses against a new neo-antigen UNC45A that was undetectable during normal tumour growth. Immunogenic chemo-therapy also unmasked responses against UNC45A, suggesting that subdominant neo-antigens can be unmasked by the appropriate immunotherapy. 2) We then evaluated neo-antigen vaccination strategies. Uqrcr2c vaccination only protected against tumor growth when administered in combination with partial Treg depletion (Foxp3.DTR mice), suggesting that neo-antigen vaccination will only be maximally effective when administered in combination with therapies that target existing immune restraint (including Tregs). 3) We determined optimal anatomical location for tracking neo-antigen CTL responses and identified the draining lymph node as an optimal, though not exclusive, location for response testing compared to blood or tumor. We are currently examining these observations using sequencing-defined neo-antigens in our patients and will present data on changes in human neo-antigen responses to therapy. These observations have important translational implications for identification of key neo-antigens, choice of therapy and monitoring of anti-tumor responses. 1. J. Creaney et al., Strong spontaneous tumor neoantigen responses induced by a natural human carcinogen. Oncoimmunology 4, e1011492 (2015).

**#609 Overcoming host histocompatibility barrier to create a renewable source of off-the-shelf effector lymphocytes for adoptive immunotherapy.** Raedon L. Clarke, Matthieu Bayer, Ryan Bordyla, Jeffrey Susaki, Brian Groff, Svetlana Gaidarova, Tom Tong Lee, Weijie Lan, Michelle Burrascano, Ramzye Abujarour, Greg Bonello, Megan Robinson, Stewart Abbot, Scott Wolchko, Daniel Shoemaker, Bob Valamehr.

Encouraging clinical outcomes in autologous cellular immunotherapy have garnered hope and excitement. However, limitations of patient-derived cancer immunotherapies remain to be addressed to deliver reliable and efficacious therapeutic approaches with broader applicability. Induced pluripotent stem cells (iPSCs) are a unique, renewable source for the continuous generation of cellular therapeutics and represent a highly promising approach for overcoming many of the limitations of autologous therapy. To advance the promise of iPSC technology as an

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 153

IMMUNOLOGY: T-cell Immunity to Cancer: New Progress
“off-the-shelf” (OTS) source of cellular therapeutics, several considerations need to be addressed. Ensuring the persistence of allogeneic OTS therapies after adoptive cell transfer across histocompatibility barriers is a key requirement. Establishing a master cell line from genetically engineered clonal iPSC lines with the capacity to continuously generate homogenous populations of highly functional effector cells would be a necessary cell source to design a feasible and reproducible approach for the generation of immune tolerant effecter cells derived from a genetically engineered iPSC master cell line. We successfully combined deletion of classical human leukocyte antigen molecules with expression of immunosuppressive proteins to generate clonal iPSC lines with the ability to escape immune rejection. Utilizing in vitro quantitative live cell analysis we show that OTS-iPSCs elicit a significantly decreased cytotoxic response from both peripheral blood (PB)-NK cells (47.9 vs. 91.4% survival at 3:1 E:T ratio) and PB-T cells (>2.7-fold greater number of OTS-iPSC derived cells remaining at 88 hrs). Additionally, mixed lymphocyte reactions employing unfractionated PB mononuclear cells resulted in significantly decreased activation and proliferation of CD8+ nuclear cells.

Moreover, mixed lymphocyte reactions employing unfractionated PB mononuclear cells resulted in significantly decreased activation and proliferation of CD8+ nuclear cells. Resultantly, we demonstrate that OTS-iPSCs can inhibit immune responses. In preclinical mouse models we demonstrate that OTS-iPSCs exhibit improved persistence in vivo. Bilateral engraftments were established in non-conditioned, fully immune-competent recipient mice using luciferized wildtype and OTS-iPSCs. Daily bioluminescence imaging revealed a significant increase in persistence of OTS-iPSCs during the 48-196 hour post injection window (>5.5 fold greater luminescence at 96 hrs). Using our potent genetically defined stage-specific bulk, our findings confirm that both the therapeutic potential of M7824 in non-small cell lung cancer (NSCLC). M7824 is a first-in-class bi-functional immunotherapeutic agent designed to target two negative regulatory pathways in immunosuppression. It is a novel fusion protein comprised of the extracellular domain of human TGFBR1 covalently linked to the C-terminus of the Fc domain of the fully human anti-PD-L1 IgG1 antibody avelumab. Methodology: In vitro assays were conducted using NSCLC cell lines treated with TGFβ1 alone or in combination with avelumab or M7824 to assess the ability of M7824 to revert features of tumor cell EMT, including molecular markers and functional responses.

The ability of M7824 to mediate antibody-directed cellular cytotoxicity (ADCC) of TGFβ1-treated cells in vitro was also assessed. Results: Treatment with TGFβ1 induced mesenchymal marker expression, reduced cell proliferation, and enhanced resistance to docetaxel, paclitaxel, and gemcitabine. Treatment with M7824, but not avelumab, was able to both prevent and revert these effects of TGFβ1. M7824 also exhibited the ability to mediate ADCC of TGFβ1-treated cells in vitro. Conclusions: M7824 effectively antagonizes TGFβ1-mediated tumor cell mesenchymalization, including resistance to chemotherapy. These results suggest that M7824 has the potential to relieve immunosuppression and block treatment-resistance induced by TGFβ1 in patients with NSCLC.

#610 Blockade of tumor expression of PD-1 promotes lung cancer growth in a murine model. Shisuo Du1, Qing Guan2, Adam P. Dicker1, Bo Lu1.

1Thomas Jefferson University, Philadelphia, PA; 2Fudan University, Shanghai, China.

Lung cancer remains one of the most prevalent and fatal malignancies worldwide. There are substantial evidences that immunotherapies offer significant benefits among lung cancer patients. Pembrolizumab, a humanized programmed death receptor-1 (anti-PD-1) antibody is now approved by FDA as a first-line treatment of patients with metastatic non-small cell lung cancer (NSCLC). Recent data demonstrate that PD-1 is not only expressed by immune cells, but also by human melanoma cells. However, limited is known about the biological significance of PD-1 pathway in cancer including NSCLC. Thus, we examined PD-1 expression in a series of established murine lung cancer cell lines. RT-PCR amplification and sequencing of the full coding sequence of the murine PD-1 (PDCD1) gene revealed the presence of PDCD1 mRNA in the M109 lung cancer cells. Flow cytometry and immunofluorescence analysis demonstrated PD-1 protein expression in these murine lung cancer cells. To determine the molecular function of tumor PD-1 in lung cancer survival, we treated M109 cells in culture with either anti- mouse PD-1 (100 µg/ml) or isotype control antibody and found that PD-1 inhibition significantly enhanced cancer cell viability as measured by MTT and clonogenic assay. Alternative PD1 inhibition by either knockdown of PDCD1 via siRNA or knockout of PDCD1 by CRISPR-Cas9 all lead to increased survival of M109 cells. Furthermore, PDCD1 knock-out M109 cells had no survival difference in the presence of anti-PD1 compared to its PD1-expressing parental cells. Conversely, treatment with recombinant PD-L1 fusion protein exhibited significantly increased apoptotic rates (7.5±3.2% vs 2.1±2.2%) suppressing the tumor cell growth in the wild-type M109 in culture. To validate these results in vivo models, NSG mice were used to determine the direct effect of anti-PD-L1 on M109 xenografts without the interplay of host immune system. M109 xenografts treated with anti-PD-1 (10mg/kg i.p.) antibodies showed accelerated growth compared to those treated by IgG control (248±273 vs 1499±292nm3 at days 21 after tumor inoculation, p=0.013). M109 subcutaneous tumors in the PD-1 knockout mice also manifested more rapid growth than the same tumors implanted in wild-type mice. Taken together, our results uncover a novel function of PD-1/PD-L1 axis in lung cancer survival and implicate possible tumor-promoting effects from anti-PD-1 therapy upon PD1-expressing lung cancer in the absence of effective immune response. We plan to interrogate bio-specimens collected through NRG trials to establish the translational potential of these findings.

#611 Reversion of mesenchymal features in NSCLC cells using M7824, a first-in-class bi-functional immunotherapeutic agent targeting PD-L1 and TGFβ (TGF β TRAP). Justin M. David1, Jeffrey Schmol,1 Yan Lan2, Claudia Palena3, National Cancer Institute, Bethesda, MD; 2EMD Serono, Billerica, MA.

Background: Evasion of antitumor immunity is widely regarded as a hallmark of cancer. Most tumors fail to stimulate effective antitumor immunity due to upregulation of the immune checkpoint molecule PD-L1, and antibodies targeting the PD-1/PD-L1 axis have demonstrated clinical efficacy in several tumor types. Antitumor immunity can also be suppressed by TGFβ, a pleiotropic cytokine that reduces innate and adaptive antitumor immune responses. Additionally, TGFβ impacts tumor cells by activating a differentiation program called epithelial-mesenchymal transition (EMT), in which tumor cells lose epithelial features and gain mesenchymal characteristics. The gain of mesenchymal traits is associated with metastasis, stemness, and resistance to multiple therapeutic modalities, including chemotheraphy and radiation. The objective of this work is to investigate the therapeutic potential of M7824 in non-small cell lung cancer (NSCLC). M7824 is a first-in-class bi-functional immunotherapeutic agent designed to target two negative regulatory pathways in immunosuppression. It is a novel fusion protein comprised of the extracellular domain of human TGFBR1 covalently linked to the C-terminus of the Fc domain of the fully human anti-PD-L1 IgG1 antibody avelumab. Methodology: In vitro assays were conducted using NSCLC cell lines treated with TGFβ1 alone or in combination with avelumab or M7824 to assess the ability of M7824 to revert features of tumor cell EMT, including molecular markers and functional responses (ADCC).

The ability of M7824 to mediate antibody-directed cellular cytotoxicity (ADCC) of TGFβ1-treated cells in vitro was also assessed. Results: Treatment with TGFβ1 induced mesenchymal marker expression, reduced cell proliferation, and enhanced resistance to docetaxel, paclitaxel, and gemcitabine. Treatment with M7824, but not avelumab, was able to both prevent and revert these effects of TGFβ1. M7824 also exhibited the ability to mediate ADCC of TGFβ1-treated cells in vitro. Conclusions: M7824 effectively antagonizes TGFβ1-mediated tumor cell mesenchymalization, including resistance to chemotherapy. These results suggest that M7824 has the potential to relieve immunosuppression and block treatment-resistance induced by TGFβ1 in patients with NSCLC.

#612 Methylation changes in DNA of CD8 T cells following CD137 co-stimulation. M. Angela Azzar,1 Sara Labiano,1 Angel Diaz-Lagares,1 Manel Esteller,2 Juan Sandoval,1 Ignacio Meleo1.

1Center for Applied Medical Research on Navarra (CIMA), Pamplona, Spain; 2Bellvitge Biomedical Research Institute (IDIBELL), Barcelona, Spain; 3Medical Research Institute La Fe, Valencia, Spain.

Introduction: CD137 ligation imprints long term changes in the behavior of costimulated T-cells (1). There is not a satisfactory mechanistic explanation yet. Experimental procedures: to determine the specific DNA methylation changes occurring upon CD137 costimulation, purified human CD8+ T cells from three healthy donors were activated in vitro for 5 days with anti-CD3 monoclonal antibody and either with an anti-CD3 monoclonal antibody or its corresponding isotype (huIgG4). Activated lymphocytes were left 5 days in culture with huIL-7 without further stimulation. Such back-to-resting CD8+ lymphocytes were re-stimulated with anti-CD3 for 12, 24 and 36h to validate the expression of the genes differentially methylated upon primary stimulation at mRNA and protein levels. DNA methylation profiles of both activated and resting cell subsets were characterized with Infinium 450K DNA methylation array (Illumina). To further confirm our observations, identical experimental procedure was performed with a different anti-CD137 agonist antibody (mlgG1 iso-type) in a CD8+ T-cell donor. Differentially methylated genes between anti-CD3+ anti-CD137 versus their corresponding control counterparts were validated by pyrosequencing on activated and resting CD8+ from independent group of healthy donors (n=8 for huIgG anti-CD137 and n= 11 for mlgG anti-CD137). Expression changes were confirmed by qRT-PCR and flow cytometry in activated, rested and restimulated CD8+ lymphocytes. Results: 853 genes were differentially methylated in huIgG anti-CD137-treated CD8+ T cells as compared with their controls, 52 of which were shared with mlgG anti-CD137-costimulated CD8+ T lymphocytes. A number of differentially methylated genes are involved in i) T cell migration, ii) T cell activation, survival and homeostasis and iii) regulation of gene expression including key T-cell transcription factors. Conclusions: CD137 costimulation induces CD8+ T lymphocytes that are enriched in gene sets involved in regulatory functions. These acquired functions are imprinted in the genomic DNA of the CD8+ T cells by DNA methylation changes upon CD137 co-stimulation, and involve key genes for CD8+ T cells. References: 1. development of FPA154, a novel tetravalent anti-GITR antibody, for the treatment of solid tumors. Susannah D. Barbee, Amanda Chen, Susan Johnson, 3 David L. Bell, 2 John C. Tinner, 2 Neiibuyu Wondiey, 1, 3 Mikayel Mkrtichyan, 1 Amu S. Razai, 1 Kyle S. Jones, 1 Chodisi Y. Hata, 1 Denise Gonzalez, 1 Quinn Deveraux, 2 Brendan P. Eckelmann, 3 Luis Borges. 1 Five Prime Therapeutics, South San Francisco, CA; 2 Inhibrx, San Diego, CA.

Glycolipiderived TNFR-related (GITR, TNFRSF18) is a member of the TNFR superfamily with pleiotropic T cell modulatory activity. We are developing a novel anti-GITR antibody with enhanced agonist activity for the treatment of solid tumors. Our candidate molecule, FPA154, is constructed with single-domain antibodies (sdAbs) in a tetravalent format, with an effector competent IgG1 Fc domain. Both FPA154 and the mouse-reactive surrogate molecule (cmFPA154, mIgG2a isotype) bind to cell-surface GITR with high affinity.

Our data indicates that FPA154 and cmFPA154 potently mediate ADCC activity against Tregs expressing high levels of GITR. In contrast, activated effector T cells express modest levels of cell-surface GITR, and FPA154 and cmFPA154 drive GITR-induced NF-kB activation. This activity is independent of Fc-mediated crosslinking, which is normally required for bivalent GITR antibodies to induce GITR signaling. cmFPA154 has potent antigen activity in several syngeneic mouse tumor models, both as a monotherapy treatment and in combination with anti-PD-1. In summary, FPA154 is a promising candidate with multiple mechanisms of action that contribute to generation of an antitumor immune response mediated by different T cell subsets.

**#616** The novel α-Gal-based immunotherapy AGI-134 invokes CD8 T cell-mediated immunity by driving tumor cell destruction, phagocytosis and tumor-associated antigen cross-presentation via multiple antibody-mediated effector functions. Jenny L. Middleton, 1 Oliver Schulz, 2 Amber Charlemagne, 3 Sascha A. Kristian, 1 Stephen Michael Shaw. 1AgAllimmune Limited, Sandwick, United Kingdom; "The Francis Crick Institute, London, United Kingdom.

Background: AGI-134 is a fully synthetic α-Gal (Galα1-3Galβ1-4GlcNAc-R) glycolipid that is being developed for the treatment of solid tumors. The α-Gal epitope is not expressed in humans, who, as a result of constant antigenic stimulation by α-Gal-bearing commensal bacteria, develop high titer natural antibodies to α-Gal. We have previously demonstrated that AGI-134 recruits anti-Gal antibodies to tumor cells in vitro, activating complement and driving phagocytosis by antigen presenting cells. AGI-134 also confers systemic protection from distal lesion development in a mouse model of melanoma and synergizes with anti-PD-1. 1. Here we present further data characterizing the multiple pathways activated by the anti-Gal subclasses to drive AGI-134-mediated anti-tumor immunity. Results: Using quantitative methods, we demonstrate that human anti-Gal is composed of a diverse repertoire of effector antibodies in a panel of serum samples, with IgM, IgG1 and IgG2 being the major subclasses. Polyclonal anti-Gal IgG purified from human IVIG was, like human serum, comprised mainly of IgG1 and IgG2. When AGI-134 treated cells were incubated with human serum, binding of all anti-Gal subclasses was detected by flow cytometry, demonstrating that all anti-Gal subclasses can interact with AGI-134 treated cells and are available to activate downstream effector functions. When human IVIG, AGI-134 and IgG1 were incubated with human cancer cells in vitro, Ovalbumin-expressing cancer cells were specifically phagocytosed by murine CD8+ dendritic cells and the immunodominant antigen of ovalbumin, SINFEKL, was cross-presented to CD8+ T cells. Conclusion: AGI-134 stimulates adaptive anti-tumor immunity through immune activation and antigen cross-presentation, which is driven by the diverse repertoire of anti-Gal antibodies. 1. Shaw, S. et al. Abstract 4862: AGI-134: a fully synthetic alpha-Gal glycolipid that prevents the development of distal lesions and is synergistic with an anti-PD-1 antibody in a mouse melanoma model. [Abstract]. AACR; Cancer Res 2016;76(14 Suppl):Abstract nr 4862.
proven for the treatment of both recurrent and newly diagnosed Glioblastoma (GBM). Immunotherapeutic approaches for treatment of GBM are considered promising, and multiple strategies are currently being evaluated in basic research and clinical trials. Combining TTFields and immune-based therapies is a rational approach as they possess markedly different mechanisms of action (OA). Converging TTFields may potentially abrogate various cellular functions required for effective T cell responses. We performed an in-vitro evaluation on the effect of TTFields on select human T cell functions that are pivotal for an effective anti-tumoral response. The study objective was to evaluate the potential compatibility between immune-based therapies and TTFields. METHODS: Peripher al blood mononuclear cells were isolated from healthy donors. Cells were cultured under normal versus TTFields conditions using the in vitro TTFields system, either with or without Phyothemaglutinin (PHA - a super antigen). Cellular responses were monitored using an 8-color flow cytometry panel that concurrently evaluated proliferation (CFSE dilution), cytokine secretion (IFNγ), cytotoxic degranulation (CD107α surface presentation), and T cell activation/ exhaustion (PD1 expression). The effect on T cell viability was assessed in a separate assay, by comparing the live-to-dead ratio of cells cultured in normal versus TTFields settings. RESULTS: TTFields did not alter the functionality of non-activated T cells. Viable PHA-activated T cells cultured under TTFields exhibited no change in PD1 up-regulation, IFNγ secretion and CD107α surface expression. The T cells exhibited reduced proliferation, which is in line with the known MOA of TTFields. As the presence of polyfunctional T cells is associated with effective antitumor therapy, we selected single-cell polyfunctional analysis to determine the effect of TTFields on T cell functionality. T cell functionality was evaluated as the percentages of PD1 CD4+ and PD1 CD8+ T cells in patients who received 3 doses of anti-PD1 antibody (p=0.007 and p=0.05, respectively). Moreover, the levels of PD1 CD4+ (p=0.009) and PD1 CD8+ (p=0.009) were augmented in response to anti-PD1 therapy. The frequencies of CD4 Tregs (CD3+CD4+CD25highCD122−/−CD152 FoxP3+) and granulocytic MDSCs (CD11b+CD14+CD33+) in responders to anti-PD1 therapy were decreased following anti-PD1 therapy (p=0.01 and p=0.02, respectively). In contrast, chemotheraphy affected only the PD1+ CD4+ Tregs, but not the PD1+ G-MDSC, by increasing their levels after 3 cycles (p=0.04). Anti-PD1 treatment induced a superior reduction of the PD1- CD4+, PD1- CD8+ T cells, PD1- CD4+ Tregs and PD1- G-MDSC percentages compared to the effect of first line chemotherapy (p=0.04, p=0.05, p=0.001, respectively). Furthermore, a significant decrease in PD1- CD8+ T cells, PD1- CD4+ Tregs and PD1- G-MDSCs after 3 doses of anti-PD1 was observed in patients who experienced stable disease compared to baseline (p=0.006, p=0.05 and p=0.03, respectively). At the time of response evaluation to chemotheraphy, the percentage of the PD1- CD4+ Tregs after 3 cycles was significantly inferior compared to baseline, in disease progressors (p=0.04). Conclusion: These data indicate that although chemotherapy affected the levels of PD1- CD4+ Tregs, anti-PD1 therapy seems to exert an effect on both PD1+ T cells and PD1- immunosuppressive cells. Additional studies are needed in a larger cohort in order to document its impact on their clinical relevance in NSCLC patients. This study is ongoing and updated data will be presented at the meeting.
Vaccine therapy may be ideal to destroy ductal carcinoma in situ (DCIS) and prevent recurrence. A vaccine can induce type 1 T-cells against DCIS antigens that could migrate from the circulation to invade and destroy the tumor as well as generate immunologic memory to provide long lasting protective immunity. One of the limitations of developing a DCIS vaccine is identifying antigens that target all subtypes of DCIS. DCIS is one of the most heterogeneous tumors, ranging from invasive breast cancer (IBC), including overexpressed proteins that may be drivers of progression to invasive disease. Eliminating cells that are overexpressing driver proteins by vaccination may prevent progression to IBC if such proteins could be determined. In this study, we identified proteins that were overexpressed from normal breast in both DCIS and IBC across fifteen Geo and ArrayExpress datasets. From the candidates or patient identified whose expression was necessary for cancer cell survival across breast cancer subtypes. We selected overexpressed proteins necessary for cancer survival using a high throughput siRNA screen and chose candidates that increased apoptosis and decreased cell survival in HER2 positive (HER2), triple negative (TN), and hormone receptor positive HER2 negative (HR) human breast cancer cell lines with decreased expression of the target protein. For example, decreased expression of NCD8 caused decreased cell survival to 56%±3% in HR, 46%±3% in TN, and 77%±2% in HER2 breast cancer cell lines and increased apoptosis by 1.4±0.3 fold in HR and 1.2±0.03 fold in TN breast cancer cell lines. Decreased expression of RM2 caused decreased cell survival to 66%±3% in HR and 89%±2% in HER2 breast cancer cell lines and increased apoptosis by 1.6±0.08 fold in HR, 1.4±0.09 fold in TN, and 2.0±0.3 fold in HER2 breast cancer cell lines. Twelve proteins (AURKA, KIF1C, NCD8, RM2, SDC1, UBE2C, HJURP, CENPA, CENPF, HIST2H2A3, HIST1H2BD, and TOP2A) were essential for cancer cell survival in at least 2 breast cancer subtypes. These protein targets are immunogenic in patients with DCIS. In the sera of women without breast atypia (n = 36), autoantibodies to NCD8 were detected with a mean of 5.3±1.8 ng/mL while in women with fibroadenoma (n = 36) autoantibodies were detected with a mean of 8.3±1.5 (p = 0.05). In the sera of women without breast atypia (n = 36), autoantibodies to RM2 were detected with a mean of 0.16±0.7 ng/mL while in women with fibroadenoma (n = 36) autoantibodies were detected with a mean of 7.2±2.1 (p = 0.05) and in women with DCIS (n = 59) autoantibodies were detected with a mean of 2.6±0.6 ng/mL (p = 0.0003). These proteins represent DCIS antigens of biologic importance in tumor growth and, potentially, progression to IBC and are candidate immunogens for a vaccine to treat DCIS.

**#624 Characterization of PD-L1 expression and the immune cell microenvironment in hepatoellular carcinoma (HCC) and non-cirrhotic liver tissue adjacent to HCC.** Christian Illing,1 Sienna Yoast,2 Yue Zhang,3 Bartholomew Naughton,3 Miriam Urban,1 P. Alexander Rolfe,3 Eveline Frick-Krieger,1 Isabelle Dussault.1,2,3* Marek KGaa,2,3 Darmstadt, Germany; 2Dako North American, Carpinteria, CA; 3EMD Serono Research and Development Institute Inc., Billerica, MA.

Still-emerging evidence suggests that HCC is at least moderately responsive to therapeutic agents that target tumor immune suppression pathways, specifically the programmed death 1/programmed death ligand 1 (PD-L1) pathway. Prior studies raise the possibility that PD-L1 is a prognostic biomarker in HCC, where its expression levels have been reported to correlate with tumor aggressiveness and recurrence following surgical resection. The purpose of this study was to evaluate the expression of PD-L1 in non-cirrhotic liver tissue adjacent to HCC and HCC itself in 68 procured tissue samples, as well as elucidate the immune cell composition of the HCC tumor microenvironment. All cases showed the typical morphology of HCC and were classified as low- to high-grade trabecular, pseudoglandular, or solid with the common cytotoxicAT morphological features. Immunohistochemical (IHC) staining for PD-L1 in tumor-free liver (TFL) revealed PD-L1 staining in sinusoidal lining cells (macrophages [Mge] and endothelial cells [EC], as confirmed by double labeling for CD68 and CD31), although there was considerable heterogeneity in the extent of PD-L1 staining. More specifically, in TFL, some but not all CD68+ Mge were also PD-L1+, whereas most CD31+ EC were also PD-L1+. Furthermore, we evaluated PD-L1 staining qualitatively and semiquantitatively in HCC. Only few tumor cells displayed membranous PD-L1 staining, and only few tumors showed PD-L1 expression of (0.25% to 25%+) within HCC (n = 65). The proportion of tumor cells categorized as PD-L1+ varied from 0.25% to 9.0% (88.8% PD-L1+ (>1% and <25%) = PD-L1+); instead, PD-L1 expression within the tumor microenvironment predominantly emanated from immune cell infiltrates (as confirmed by PD-L1+ pan-cytokeratin double labeling). Then we assessed the immune milieu in HCC tissue specimens using quantitative IHC. We found considerable interspecimen variation in the number of CD68+ Mge, CD8+ T lymphocytes, and FoxP3+ regulatory T lymphocytes. Comparing the number of immune cells in different tumor compartments showed that the prevalence of CD68+ cells (p = 0.0005), CD8+ cells (p = 0.0004), and FoxP3 cells (p = 0.05) was significantly higher within the invasive margin vs the center of the tumor. Quantitative analysis of the immune cell content also showed that

#621 Tumor suppressor TUSC2 immunogene therapy is synergistic with anti-PD1 in lung cancer syngeneic mouse models. Ismail M. Meraz, Mourad Majidi, RuPing Shao, Meng Feng, Xiaobo Cao, David Rice, Boris Sepesi, Lin Ji, Jack Roth. UT MD Anderson Cancer Ctr., Houston, TX.

TUSC2, a pro-apoptotic tumor suppressor gene whose expression is lost or decreased in most lung cancers, activates the innate immune system through initiation of broad spectrum cytokine secretion and natural killer (NK) cell activation. TUSC2 delivered systemically by nanovesicles has mediated tumor regression in metastatic non-small cell lung cancer clinical trials. We studied the effect of TUSC2 on immune cell populations and the anti-tumor activity of TUSC2 in combination with anti-PD1 checkpoint blockade in two syngeneic mouse models: C57BL/6 mice subcutaneously injected with murine lung adenocarcinoma cell line CMT1/676-luc cells (KrasG12V mutation) and 346SQ (KrasG12D allele and a knock-in Trp53R172H/L allele) adenocarcinomas which metastasize to the lung in 129/2 mice. Tumor growth was monitored by scoring ex vivo luminescence using the IVIS Imaging System 200. Multi-color flow cytometry was used for immune profiling of circulating immune cells after nanovesicle mediated TUSC2 intravenous injection. Cytokine gene expression in response to TUSC2 in sorted immune subpopulations was determined by real-time PCR. Tumor growth was significantly reduced with TUSC2 treatment compared with no treatment in both subcutaneous metastatic mouse models. Synergistic anti-tumor activity was observed when TUSC2 was combined with anti-PD1 verified in five independent experiments. In the lung metastasis model, mice treated with TUSC2 + anti-PD1 lived significantly longer than with single agent treatment. Circulating NK cells increased three fold following TUSC2 nanovesicle intravenous injection both in tumor free and tumor bearing mice which correlated with tumor regression and survival. Cytotoxic T lymphocyte responses were increased whereas Tregs and MDCS decreased with TUSC2 alone and TUSC2+anti-PD1 treatment. The levels of T cell checkpoint markers PD1, CTLA-4, LAG-3, and TIM-3 evaluated by flow cytometry were decreased after TUSC2 treatment. TUSC2 anti-tumor response was abolished when NK cells were depleted indicating NK cells are important mediators of the TUSC2 treatment effect.

All cases showed the typical morphology of HCC and were classified as low- to high-grade trabecular, pseudoglandular, or solid with the common cytotoxicAT morphological features. Immunohistochemical (IHC) staining for PD-L1 in tumor-free liver (TFL) revealed PD-L1 staining in sinusoidal lining cells (macrophages [Mge] and endothelial cells [EC], as confirmed by double labeling for CD68 and CD31), although there was considerable heterogeneity in the extent of PD-L1 staining. More specifically, in TFL, some but not all CD68+ Mge were also PD-L1+, whereas most CD31+ EC were also PD-L1+. Furthermore, we evaluated PD-L1 staining qualitatively and semiquantitatively in HCC. Only few tumor cells displayed membranous PD-L1 staining, and only few tumors showed PD-L1 expression of (0.25% to 25%+) within HCC (n = 65). The proportion of tumor cells categorized as PD-L1+ varied from 0.25% to 9.0% (88.8% PD-L1+ (>1% and <25%) = PD-L1+); instead, PD-L1 expression within the tumor microenvironment predominantly emanated from immune cell infiltrates (as confirmed by PD-L1+ pan-cytokeratin double labeling). Then we assessed the immune milieu in HCC tissue specimens using quantitative IHC. We found considerable interspecimen variation in the number of CD68+ Mge, CD8+ T lymphocytes, and FoxP3+ regulatory T lymphocytes. Comparing the number of immune cells in different tumor compartments showed that the prevalence of CD68+ cells (p = 0.0005), CD8+ cells (p = 0.0004), and FoxP3 cells (p = 0.05) was significantly higher within the invasive margin vs the center of the tumor. Quantitative analysis of the immune cell content also showed that
there was no correlation between T lymphocyte infiltration (CD8+/FoxP3+) and Mφ infiltration in any compartment. Taken together, our findings confirm the intertumoral heterogeneity of the immune cell microenvironment in HCC; however, future studies are needed to correlate these findings to the clinical setting with immunomodulatory treatments.

#625 Eradication of cancer cells by T-cell receptor-engineered T cells targeting neoantigens. Tatsuo Matsuda,1 Taigo Kato,1 Yuji Ikeda,1 Matthias Leisegang,2 Sachiko Yoshimura,3 Tetsuro Hikichi,4 Makiko Harada,1 Makda Zewde,1 Jaee-Hyun Park,1 Hans Schreiber,1 Kazuma Kiyotani,1 Yusuke Nakamura,1,2 University of Chicago, Chicago, IL;2Charité Campus Buch, Germany;3OncoTherapy Science Inc, Japan.

Cytotoxic T lymphocytes (CTLs) play critical roles in cancer-immune responses, and functional characterization of CTLs and their cancer-specific antigens will facilitate cancer immunotherapies. Immunogenic peptides, which can be derived from oncogenic proteins specifically expressed in cancer cells but not expressed in normal organs except testis (oncoantigens), or from peptides with somatic nonsynonymous mutations (neoantigens), are known as good targets for CTLs to eradicate cancer cells. In this study, we aimed to establish a method to efficiently identify oncoantigen/neoantigen-specific CTLs. Firstly, we screened candidate HLA-A2402-restricted oncoantigen/neoantigen peptides by in silico prediction of their binding affinity to MHC class I molecules. We conducted an in-vitro stimulation of CD8+ lymphocytes carrying HLA-A2402 allele by each peptide, and then confirmed clonal expansion of the peptide-specific CTLs by TCR repertoire sequencing analysis, interferon-γ enzyme-linked immunospot (ELISPOT) and/or peptide-HLA multimer assays. After identification of TCR alpha-beta pairs, we conducted retroviral transduction and prepared the TCR-engineered T cells to evaluate their cytotoxic activities against cancer cells. As oncoantigens, we isolated the CTLs for FOXM1 and UBE2T from healthy donors, and found these CTLs showed strong cytotoxicity against HLA-A2402-positive cancer cells expressing target proteins, but not against HLA-unmatched cancer cells. Similarly, the TCR-engineered T cells for FOXM1 and UBE2T showed killing effects for only HLA-A2402-positive cancer cells. Neoantigen-specific TCR-engineered CTLs also exhibited the mutated peptide-specific response, but did not cross-react to the nonmutated peptide. In addition, neoantigen-specific cytotoxicity was observed against HLA-A2402-positive cancer cells expressing the proteins with target somatic mutations. In conclusion, we developed the pipeline to screen possible oncoantigens/neoantigens and establish antigen-specific TCR-engineered CTLs from peripheral blood lymphocytes. Our approach provides a promising strategy to develop personalized immunotherapies using oncoantigen/neoantigen-reactive TCR-engineered T cells to treat cancer.

#626 BGB324, a selective small molecule inhibitor of receptor tyrosine kinase AXL, abrogates tumor intrinsic and microenvironmental immune suppression and enhances immune checkpoint inhibitor efficacy in lung and mammary adenocarcinoma models. Yvonne Wouak-Liptians,1 Kjersti Davidsen,2 Magnus Blø,1 Agnete Engelsen,3 Jing Kang,4 Linn Hodneland,5 Maria Lie,5 Sebastien Bougnard,6 Kristina Aguilera,6 Lavina Ahmed,7 Agata Rybicka,1 Eline Milde Navdal,5 Paulina Deyna,1 Anna Boniecka,1 Straume Oddbjørn,3 Salem Chouaib,4 Rolf Brekken,5 Gregg A. Galsworthy,3,5,6 BengtGillo AS, Bergen, Norway;7University of Bergen, Bergen, Norway;8Haukeland University Hospital and University of Bergen, Bergen, Norway;9Institute Gustave-Roussy, Université Paris-Sud, Paris, France;10UT Southwestern Medical Center, Dallas, TX.

The AXL receptor tyrosine kinase is associated with poor overall survival in a wide spectrum of cancers including lung and breast adenocarcinomas. AXL signaling is an important regulator of tumor plasticity related to epithelial-to-mesenchymal transition (EMT) and stem cell traits that drive metastasis and drug resistance. Signaling via AXL is also a key suppressor of the anti-tumor innate immune response, and AXL is expressed on several cells associated with the tumor immune microenvironment including natural killer (NK) cells and tumor-associated macrophages. Hence AXL resides uniquely at the nexus between tumor and microenvironmental anti-tumor immune suppression mechanisms. We report that BGB324, a selective clinical-stage small molecule AXL kinase inhibitor, enhances the effect of immune checkpoint blockade in aggressive adenocarcinoma models with limited immunogenicity by targeting both tumor intrinsic and microenvironmental immune suppression. Immune therapy with anti-CTLA4/PD1 in the 4T1 model increased AXL and EMTagger expression correlating with a lack of response. Combination with BGB324 resulted in durable primary tumor clearance versus anti-CTLA4/PD1 alone. In a separate study, BGB324 + anti-CTLA4 treatment resulted in significant long-term primary tumor clearance while no response was observed with anti-CTLA4 treatment alone. The extensive metastasis to the lung, liver and spleen characteristic of the 4T1 model was not detected in animals responding to the combination treatment. Importantly, responding animals rejected orthotopic 4T1 tumor cell re-challenge, demonstrating sustained tumor immunity. In the LL2 Lewis lung model, BGB324 in combination with anti-PD1/PDL1 significantly prevented tumor growth compared to treatment with anti-PD1/PDL1. Tumors from mice treated with BGB324 in combination with immune checkpoint inhibitors displayed reduced EMT traits, altered cytokine expression, enhanced tumour cell invasion of effectors cells and decreased metastasis to lung. Also, BGB324 significantly reduced IL10 secretion by isolated human macrophages and enhanced human NK-cell mediated NSCLC tumor cell lysis. Collectively these results support a prominent role for AXL in resistance to immune therapy and support clinical translation of combining BGB324 with immune checkpoint inhibitors to improve cancer treatment.

IMMUNOLOGY: T-cell Immunity to Cancer: New Progress

#627 NLR5 co-mutations are associated with impaired antigen presentation and immune exclusion in KRAS-mutant lung adenocarcinoma. Ferdinandos Skoulidis,1 Taghrred Hizr, Xiang Dong Lee, Jaime Rodriguez Canales, Edwin R. Parra, Pan Tong, Carmen Behrens, Yasuhide A. Taniuchi, Xiaoli Shopou,1 Jing Wang, Ignacio Wistuba, John V. Heymach. UT MD Anderson Cancer Ctr., Houston, TX.

Background: We recently reported that co-occurring genetic events constit- tute major determinants of the molecular diversity of KRAS-mutant lung adeno-carcinoma (LUAC) (Skoulidis et al., Cancer Discovery, 2015). However, comprehensive evaluation of the functional impact of KRAS co-mutations on key cancer hallmarks is thus far lacking. Here, we find that inactivating mutations in NLR5, a major transactivator of MHC class I molecules, are significantly enriched in KRAS-mutant LUAC and examine the impact of NLR5 loss on the composition of the tumor immune microenvironment. Methods: Our cohorts consist of 513 LUACs from the TCGA (145 KRAS-mutant), 152 chemotherapy-naïve surgically resected LUAC from the PROSPECT cohort, 20 platinum-refractory KRAS-mutant LUAC from the BATTLE-2 clinical trial, as well as a panel of 31 KRAS-mutant NSCLC cell lines. Analysis of immune cell sub-population was performed using automated IF-based enumeration. Antigen presentation score was defined as the geometric mean mRNA expression of HLA-A, HLA-B, HLA-C and β2M. Results: In an unbiased analysis for genes significantly co-mutated with KRAS in LUAC (TCGA cohort) we identified NLR5 (NLR family, CARD domain containing 5), encoding a recently discovered major transactivator of MHC class I genes (~11% of KRAS-mutant LUAC, odds ratio 2.99, P=0.0197). The spectrum of NLR5 somatic mutations includes several nonsense and frameshift mutations, as well as missense mutations, many of which are predicted to abrogate normal NLR5 function. In the TCGA cohort, KRAS/NLR5 co-mutated tumors exhibited lower antigen presentation score compared to KRAS-mutant NLR5 wild-type tumors (P=0.0369, t-test). Among KRAS-mutant LUAC from the TCGA, PROSPECT, BATTLE-2 cohorts expression of NLR5 mRNA correlated tightly with the expression of core antigen presentation pathway components including HLA-A, HLA-B, HLA-C, β2M, TAP1, TAP2, PSMB8 and PSMB9 [in BATTLE-2: HLA-A r=0.7616, P=9.57e-05, HLA-B r=0.834, P=4.848e-06, HLA-C r=0.8029, P=2.036e-05, TAP1 r=0.8189, P=1.00e-05]. Similar results were obtained in a panel of 31 KRAS-mutant NSCLC cell line. Thus, both mutational and non-mutational mechanisms can account for NLR5 inactivation. Finally, in a tumor microarray encompassing surgically resected, chemotherapy naïve LUAC (PROSPECT), NLR5-low tumors (lower tertile for NLR5 mRNA expression, N=34), exhibited reduced density of infiltrating CD3+ (P<0.0001, Mann-Whitney U test), CD8+ (P<0.0001, Mann-Whitney U test) as well as PD-1+ cells (P<0.0001, Mann-Whitney U test) and PD-L1 Histo-score (P=0.0036, Mann-Whitney U test) compared to NLR5-high tumors (N=41). Conclu- sions: Co-mutations in NLR5 are enriched in KRAS-mutant LUAC and are associated with immune exclusion. KRAS co-mutations can shape the tumor immune micro-environment and may therefore predict for response - or lack thereof- to immunotherapy.

#628 Neoantigens predicted by clonal mutation analysis in lung adenocarcinoma patients. Dapeng Zhou,1 Weijing Cai,1 Deng Pan,1 Tan Wen Ling,1 Jiaqian Wang,2 Caichun Zhou,3 Yanyan Lou.2 Shanghai Pulmonary Hospital affiliated with Tongji University School of Medicine, Shanghai, China;2 Mayo Clinic, Jacksonville, FL.

Mutant peptides presented in cancer are superior vaccine candidates than self peptides. The efficacy of mutant K-Ras, PS3 and EFGR peptides have been tested as cancer vaccines in pancreatic cancer, colorectal cancer, and lung adenocarci-
oma. However, the occurrence of these mutations in cancer is limited. Further more, these mutant peptides can only be presented by certain MHC alleles. Neoantigens expressed by passenger mutations which are not involved in common proliferative molecular pathways are potential candidates for personalized vaccine design. Such passenger mutations have drawn attention by the recent discovery of tumor-related neoantigens as principal targets of T cells unleashed by immune checkpoint blockade. These results led us to hypothesize that enforced increase of the number of mutations in cancer cells could be paradoxically beneficial for therapeutic purposes. We therefore performed a pharmacological screen to identify agents capable of permanent inactivation of MMR in colorectal, breast and PDAC cancer cells. We found that temozolomide triggers MLH1 inactivation and leads to rapid clonal evolution and dynamic neoantigen profiles. Temozolomide-treated cells were unable to form tumors in syngeneic animals, while cells treated with other alkylating agents did. Genomic analysis of these tumor models revealed that fluctuating levels of neoantigens, rather than the absolute number of mutations, is critical to provoke immune surveillance. These results provide the rationale for developing innovative anticancer therapies that target DNA repair proteins.

#631 Dual-specific T cells are highly effective in eradicating solid tumors. Clare Y. Slaney, Bianca von Scheidt, Phillip K. Darcy, Michael H. Kershaw, Peter MacCallum Cancer Centre, Melbourne, Australia.

Chimeric antigen receptor (CAR) T cell therapy is a novel form of adoptive cellular therapy and has recently generated remarkable effects in patients with hematological cancers. However, the success against solid cancers has been modest. The major challenges are the hostile tumor microenvironment and the low efficiency of CAR T cells infiltrating the tumor. Here, we present a major advancement in CAR T therapy that eradicated large established solid cancers, some in excess of 150 mm², in immunocompetent mice. We hypothesized that a vaccine composed of a recombinant poxvirus could be used as an antigen delivery vehicle to specifically activate CAR T cells through their T cell receptor (TCR) and simultaneously change the tumor microenvironment, allowing the recruitment and activation of CAR T cells. The approach involves adoptive cell transfer incorporating vaccination (ACTIV) therapy. We generated dual-specific T cells expressing a CAR specific for the tumor antigen Her2 and a TCR specific for the melanocyte protein (gp100). Injection of T cells, together with recombinant vaccinia virus expressing gp100, induced durable complete remission of RNAi knock-down tumors and established metastases, some in excess of 150 mm², in immunocompetent mice expressing Her2 in normal tissues, including the breast and brain. Tumor destruction mediated by dual-specific T cells occurred rapidly over a period of seven days and was associated with extensive proliferation and infiltration of the dual-specific CAR T cells. Mice that had
reduced tumors were resistant to rechallenge with the same Her2+ tumor cells and partially resistant to rechallenge with Her2+ tumor cells, indicating the formation of immune memory and epitope spreading. This mouse model study supports the view that it is possible to design a highly effective CAR T cell therapy for solid cancers and metastases, even when the target antigen is also expressed in vital tissues. To explore the translational potential for using the dual specific CAR T cell strategy, we established methods to transduce the T cells from human peripheral blood with both a TCR specific for gp100 and a CAR for Her2. From as little as 1 ml of human buffy coat, we could generate more than 10^6 dual-specific CAR T cells, which is sufficient for a course of treatment. The human dual-specific CAR T cells were functional in secreting IFN-γ and killing human cancer cells. The stimulation of gp100 through TCR enhanced the dual-specific CAR T cell proliferation, secretion of IFN-γ and killing of Her2+ human cancer cells in vitro. These characteristics were identified to be important for eradicating tumors in the mouse models. Taken together, our data provide valuable information for the development of CAR T cell therapies for patients with solid cancers.

#632 Genome-scale neoantigen screening using ATLAS+ prioritizes candidate antigens for immunotherapy in a non-small cell lung cancer patient. Lila Gharib | University of Maryland, Baltimore, USA; 2Roth, Emilio Flano | 3Judy Jacques | 4Biao Liu | 5Zheng Yan | 6Aula

The stimulation of gp100 through TCR enhanced the dual-specific CAR T cell proliferation, secretion of IFN-γ and killing of Her2+ human cancer cells in vitro. These characteristics were identified to be important for eradicating tumors in the mouse models. Taken together, our data provide valuable information for the development of CAR T cell therapies for patients with solid cancers.

Antibody dependent cellular cytotoxicity (ADCC) is one mechanism by which monoclonal antibodies (mAb) work. In addition to ADCC, mAbs act on their target by causing signal perturbation and complement activation. Cetuximab is an EGFR targeting mAb used to target EGFR overexpression and amplification seen in many types of cancer. While mechanisms of resistance to EGFR targeted therapy have been extensively studied, resistance to ADCC has not, mainly due to the lack of ADCC-resistance models for study. To address this limitation we established a model system for anti-EGFR ADCC using NK92 CD16V effector cells, cetuximab, and the high EGFR-expressing squamous cell carcinoma cell line A431. Continuous A431 exposure to ADCC yielded an ADCC resistant phenotype (ADCCr) that exhibits a stable phenotype in the absence of continued ADCC selection. We have explored: ADCCr cell gene expression profile, NK cell activation, metabolic signature and subsequent RPPA analysis to further understand the causes and properties associated with this resistance. This ADCCr cell line has a distinctive transcriptional profile highlighted by overexpression of histone- and interferon-related genes, reduced sensitivity to antimaltides, DNA-intercalating and ABC transporter-regulated cytotoxic agents. Intense ADCC selection causes epigenetic modification and stress response characterized by the transcriptional overexpression of PCAF (KAT2B), which initiates histone hyper-acetylation and epigenetic changes, inducing DNA replication arrest, DNA damage and stress responses that activate checkpoint signaling in the cell cycle. The pharmacologic inhibition of KAT2B reverses the ADCCr phenotype. Immune checkpoints such as PD-L1 do not stabilize ADCCr in this model system. These results shed light on new mechanisms of ADCC resistance and inform future combinatorial treatments for mAb therapy. We are exploring the possibility that stress response mechanisms are responsible for resistance for diverse selection pressures imposed by immune synapse-mediated cytotoxic attack.

Despite the unprecedented efficacy of checkpoint blockade (CPB) therapy in treating some cancers, the majority of patients fail to respond to CPB. Tumor exome sequencing and somatic mutations were identified. Individual DNA sequences (399 nucleotides) spanning each mutation site were built, cloned and expressed in E. coli co-expressing linterisoyxin O. Polyepitope expression was validated using a surrogate T cell assay or by Western Blotting. Frozen PBMCs, collected pre- and post-treatment, were used to derive dendritic cells (MDDC). Both CD4+ and CD8+ T cells were enriched and expanded using microbeads. The E. coli clones were pulsed onto MDDC in an ordered array, then co-cultured either with CD8+ or with CD4+ T cells overnight. T cell activation was detected by analyzing cytokines in supernatant. Antigens were identified as clones that induced a cytokine response that exceeded three standard deviations of the mean of all negative control wells, then their identities compared with T cell epitopes predicted using previously described algorithms. We found biological evidence for neoantigens that were specifically responsive to peripheral CD8+ and CD4+ T cells, derived from the patient’s tumor, pre- and post-CPB intervention. Some of these neoantigens were identified as a T cell target both pre- and post-CPB therapy. We identified neoantigens for which no epitopes were predicted by in silico methods. These data represent evidence that multiple patient-specific neoantigens can be identified through functional evidence of T cell response from peripheral blood without epitope prediction. By profiling natural and CpG-enhanced immunity to neoantigens, a broad catalog of T cell targets can be identified for development of immunotherapies that engage T cells against cancer to improve outcomes for patients for whom current therapies are ineffective.

Background: Recently, neoadjuvant therapy (noadjuvant chemoradiation therapy, noadjuvant chemoradiation therapy) for locally advanced rectal cancer has been generally performed. Although in the cases that may have had complications such as tumor progression or delayed surgery, factors predicting the clinical response to neoadjuvant therapy have not been adequately defined. Meanwhile CD8+ tumor-infiltrating lymphocytes (TILs) have been reported to have a crucial effect in tumor progression and outcome as primary host immune response in various types of cancer, and antitumor immune effect has been reported to contribute to the response to radiotherapy and chemotherapy. The aim of this study was to elucidate the correlation between the local immune status and the effectiveness of the neoadjuvant therapy for locally advanced rectal cancer. Patients and methods: A total of 51 patients who underwent cura-
tive operation for locally advanced rectal cancer after neoadjuvant therapy were enrolled. We retrospectively examined the number of CD8+ tumor-infiltrating lymphocytes (TILs) using immunohistochemical staining of pretreatment biopsy samples and resected specimens, and assessed the correlation with pathological response. The grade of tumor response was evaluated according to the definition of the Japanese Research Classification of Colorectal Carcinoma. Grade 1a were defined as “poor response” and Grade 1b-3 were defined as “good response”. We set each median value of the number of CD8+ TILs as the cut-off value. Results: For the 26 patients with pretreatment biopsy samples, we classified the patients into the poor response group (n=14) and the good response group (n=12). Then we set 6.0 as the cut-off value and classified the patients into the high pretreatment CD8+ TILs group (n=14) and the low pretreatment CD8+ TILs group (n=12). Low pretreatment CD8+ TILs were associated with poor response to neoadjuvant therapy (p=0.036). For resected specimens (n=51), we classified the patients into the poor response group (n=25) and the good response group (n=26). Then we set 10.8 as the cut-off value and classified the patients into the high posttreatment CD8+ TILs group (n=28) and the low posttreatment CD8+ TILs group (n=23). Low posttreatment CD8+ TILs were also associated with poor response to neoadjuvant therapy (p<0.001). Additionally, the number of pretreatment CD8+ TILs tend to be related to the number of posttreatment CD8+ TILs. Conclusion: In locally advanced rectal cancer patients, T lymphocyte-mediated immune reactions play an important role in tumor response to neoadjuvant therapy, and the quantitative measurement of CD8+ TILs in biopsy samples may be a predictor of the clinical effectiveness of neoadjuvant therapy for locally advanced rectal cancer. Moreover, low posttreatment CD8+ TILs were associated with poor response to neoadjuvant therapy.

#636  Comprehensiv analysis of T cells responsive to neoantigens derived from tumor-specific genetic mutations. Tetsuro Sasada, Junya Ohtake, Satoshi Wada, Erika Yada, Shintaro Yoshida. Kanagawa Cancer Center, Yokohama, Japan.

Neoantigens derived from tumor-specific genetic mutations can be recognized as foreign by the host immune system, and might be suitable as target for cancer immunotherapy possibly due to their higher immunogenicity. In this study, to really know the immunogenicity of tumor-specific neoantigens, we comprehensively investigated T cell responses against neoantigens derived from genetic mutations in gastric cancer. Using next-generation sequencing, 156 missense mutations were identified in tumor cells from two gastric cancer patients. From them, we selected 30 potentially immunogenic amino acid sequences, which were derived from the mutations and predicted to potentially bind to HLA-class I (A*0201, A*0206, or A*2402) by an epitope prediction server, IEBD. We synthesized 30 kinds of 27mer long peptides, in which the mutated sequences were incorporated into the corresponding wild type sequences (PBMC) from healthy donors in the presence of the synthetic peptides to evaluate whether they could really induce antigen-specific T cell responses. In the analysis with PBMC from 18 healthy donors, 27/30 (90%) synthetic peptides showed an ability to induce antigen-specific T cell responses in at least one donor, assessed by cytokine production assay. Among them, 15 peptides were immunogenic in more than one donor. The antigen-specific T cell responses were detected more frequently in CD4+ T cells (70%) than in CD8+ T cells (43%). The specificity of T cell responses to mutated sequences, but not to the corresponding wild type sequences, were confirmed in 5 of 8 (63%) peptides examined. In addition, antigen-specific T cell responses induced by mutated peptides were shown to be much higher than those induced by the corresponding wild type peptides. These findings clearly demonstrated high immunogenicity and specificity of neoantigens derived from tumor-specific genetic mutations. Further studies would be recommended to develop a novel immunotherapeutic approach, “personalized cancer vaccination”, targeting the corresponding wild type sequences, were confirmed in 5 of 8 (63%) peptides examined.

#637  The class I HDAC inhibitor mocetinostat augments checkpoint inhibitor therapy via direct up regulation of antigen presentation transcriptional programs in tumor cells and increased T-cell clonality in tumors. David M. Briere, Niranjana Sudhakar, Peter Olson, Jamie Christensen. Mirati Therapeutics, San Diego, CA.

Mocetinostat is a spectrum-selective class I/II histone deacetylase (HDAC) inhibitor that augments checkpoint inhibitor therapy through enhanced antigen presentation capacity and a pro-immunogenic shift in the tumor microenvironment (TME). Mocetinostat up-regulated tumor antigen presentation machinery (i.e. major histocompatibility complex (MHC) genes and co-presentation molecules) and programmed cell death ligand-1 (PD-L1) expression in a panel of non-small cell lung cancer (NSCLC) cell lines. Surprisingly, some of the most highly up regulated genes following mocetinostat treatment were MHC class II genes (~20 fold), which are normally expressed by antigen-presenting cells, but are silenced in most epithelial tissues and solid tumors. To elucidate the molecular mechanisms whereby mocetinostat regulates MHC class I and II transcriptional programs in tumor cells, we performed chromatin immunoprecipitation-sequencing (ChIP-Seq) in several HDAC2 knock-down subclones of melanoma cell lines for many mocetinostat-regulated immune pathway genes. Further, mocetinostat treatment increased histone 3 lysine 27 acetylation and histone 3 lysine 4 trimethylcylation indicating an induction of active transcription at these loci. Class II transactivator (CIITA) is an interferon gamma (IFNγ)-sensitive regulator of MHC class II gene expression and was one of the top HDAC2/mocetinostat target genes in melanoma cell lines. Using ChIP-Seq data. In addition, CIITA and a representative MHC class II gene, HLA-DRα, were synergistically up regulated following mocetinostat and IFNγ treatment. To investigate the impact of Class I HDAC inhibition on the TME, syngeneic mouse tumor models were utilized. Mocetinostat treatment decreased intratumoral immune suppressive T regulatory cells (Tregs) and increased intratumoral CD8+ T cells. To gain additional insight into the functional effects of mocetinostat in the TME, we performed deep sequencing of the T-cell receptor in vehicle, mocetinostat, PD-L1 or combination-treated tumors. Mocetinostat-treated tumor cohorts exhibited increased T-cell clonality which likely reflects expansion of a subset of activated, antigen-specific T cells. Together, these data provide molecular insight into the mechanism whereby mocetinostat augments checkpoint inhibitor therapy by directly regulating tumor antigen presentation and through functional effects on the T cell repertoire.

#638  Epigenetic reprogramming of immune cells through selective inhibition of HDAC6 reduces suppressive phenotypes and augments anti-tumor properties of T-cells. Andressa L. Sodre, David M. Woods, Amud Sarnaik, Brian C. Bettis, Steven Quayle, Simon Jones, Jeffrey Webes. NYU Langone Medical Center, New York, NY; Moffitt Cancer Center, Tampa, FL; AcetylPharmaceuticals, Boston, MA.

Alteration of the epigenetic landscape of immune cells can modify the pattern of gene expression, thus resulting in phenotypic and functional changes. Small molecule inhibitors targeting epigenetic modifiers, such as histone deacetylases (HDACs), have been shown to reduce tumor growth. Besides promoting direct anti-tumor effects, HDAC inhibitors also target immune cells and alter their gene regulation. Here, we demonstrate that the HDAC6 selective inhibitors ACY-241 and ACY-1215 (ricosinostat) decrease the function of myeloid derived suppressor cells (MDSC) and T regulatory (Treg) cells, maintain an effector phenotype by CD8+ T cells, and do not reduce viability of immune cells. First, peripheral blood mononuclear cells derived from melanoma patients were treated with ACY-241, and the phenotype of MDSCs was assessed. Expression of the suppressive molecules ARG1 (p<0.01) and NOS2 (p<0.05) was decreased in CD14+ HLA DR lo CD11b+ and CD14+ HLA DR lo CD3+ MDSC populations, suggesting less potent MDSCs. To gain insight into other suppressive populations, we evaluated the phenotype and function of Treg cells derived from melanoma patients. Cultures of CD3+ T-cell cultures treated with ACY-1215 or ACY-241 resulted in decreased expression of FOXP3 and reduced frequency of Tregs (CD4+CD25+CD127−; p<0.001). ACY-1215 pre-treated Tregs exhibited less suppressive activity against responding conventional T-cells in standard assays, compared to Tregs pre-treated with DMSO control (p<0.01). CD3+ T-cells exposed to ACY-241 or ACY-1215 were activated via CD3/CD28 co-stimulation to assess effects on cytokine production. Selective HDAC6 inhibition shifted T-cell differentiation towards Th1-type (Th1 + Th2-type (GATA3+)), compared to DMSO (p<0.05). Additionally, Th2 cytokines (e.g. IL-4, IL-5, IL-6, IL-10, IL-13) were significantly decreased (p<0.05). In accordance with decreased Th2 differentiation, mTORC signal transduction, including phosphor-SGK1, was similarly reduced (p<0.05). Targeted inhibition of mTORC signal pathway inhibitors decreased expression of IFN-gamma and CD107a. Collectively, these data indicate that epigenetic reprogramming of immune cells by HDAC6 selective inhibitors may decrease the function of suppressive subsets (e.g. Tregs, MDSCs), while enhancing the accumulation of anti-tumor memory and effector T-cell subsets.
#639 Morphological changes in mitochondria induced by CD137 (4-1BB) co-stimulation on CD8 T cells. Sara Labiano, Álvaro Teijeira, Arantza Azpilikueta, Angela Aznar, Elizabet Bolaños, Ignacio Melero. Center for Applied Medical Research, Pamplona, Spain.

Mitochondrial dynamics is regulated by the 4-1BB receptor. 4-1BB stimulation induced enlarged mitochondria were a product of preexisting mitochondria rather than de novo generation of organelles. Confocal microscopy and 3-dimensional modeling revealed that mitochondrial dynamics can be linked to the regulation of mitochondrial biogenesis. CD137 (4-1BB) is an immunostimulatory receptor of the TNFR family expressed on the surface of antigen-activated T cells. Treatment with agonist monoclonal antibodies targeting 4-1BB is showing promising results for immunotherapy of cancer. In this work, we observed that stimulation of 4-1BB with agonistic mAbs was able to raise the mitochondrial membrane potential on human CD8 T cells. 4-1BB co-stimulated CD8 T cells showed enlarged mitochondria (up to 3μm diameter) with a round shape when observed by confocal or transmission electron microscopy. We observed that CD8 T cells from DLNs (draining lymph nodes) of tumors in mice treated with agonistic anti-4-1BB antibodies also contained enlarged mitochondria. By double fluorescence labeling of mitochondria prior and after activation, we could ascertain that enlarged mitochondria were a product of preexisting mitochondria rather than de novo generated organelles. This observation prompted us to study the regulation of mitochondrial dynamics by 4-1BB receptor. 4-1BB stimulation induced an increase in expression of the mitochondrial fusion protein OPA-1. By super-resolution microscopy with AiryScan detectors we observed more pronounced co-localization of OPA-1 with mitochondrial membrane in 4-1BB co-stimulated T cells than in T cells activated only by CD3 crosslinking. Our results indicate an important role of 4-1BB in the regulation of mitochondrial morphology and performance in such a way that it can be relevant for various T cell functions.

#640 Subsets of HLA alleles are capable of binding neoantigens derived from mutations within cancer driving genes such as KRAS and EGFR. Andrew Nguyen, J Zachary Sanborn, Charles J. Vaske, Shahrooz Rabizadeh, Kayvan Niazi, Patrick Soon-Shiong, Steve Benz. NanOtics, Santa Cruz, CA.

Background: Immunology has shown great promise as a low-toxicity tool to combat several cancers. Use of checkpoint inhibitors against PD1 or CTLA4 unlocks the immune system’s ability to recognize tumor antigens and, more specifically, neoantigens caused by random mutations within cancers. The vast majority of neoantigens consist of private mutations unique to a patient’s tumor genome, but several cancers harbor recurrent mutations. Mutations in the KRAS gene, such as p.G12V, occur in roughly 25% of colorectal cancers. Mutations in EGFR occur in 10% and 35% of patients with non-small cell lung cancer in the US and East Asia, respectively. Even more prevalent are mutations within the TP53 tumor suppressor gene, with roughly 23,000 unique protein variants reported to date. If these mutations in cancer driving genes are so prevalent in cancers, why are neoantigens against these targets not more readily available? Results: We collected recurrent mutations across a variety of cancer driving genes such as KRAS, EGFR, TP53, and MYC and performed binding analysis using netMHC 3.4 to see which HLA alleles are capable of binding specific cancer mutations such as KRAS p.G12V. Using this method, we report all possible HLA alleles capable of binding these recurrent mutations within cancer genes. We further performed 3-dimensional modeling to determine whether complexes created by the HLA alleles and cancer neopeptides are stable. Conclusions: Several HLA alleles are capable of binding recurrent cancer mutations. These include both MHC Class I and Class 2 alleles. The variation in alleles capable of binding commonly mutated genes such as EGFR may explain the difference in prevalence of these mutations between geographic populations. Determining whether certain HLA alleles confer tolerance to common cancer mutations may lead to identification of immune cells within these populations that can recognize neoantigens from commonly mutated cancer genes.

#641 PEGylated recombinant hyaluronidase PH20 (PEGPH20) remodels the TME, reduces tumor interstitial fluid pressure, decompresses tumor blood vessels, and facilitates delivery of chemotherapeutics. We have previously shown that PEGPH20-mediated HA degradation enhances anti-PD-L1 and anti-PD1 efficacy in an HA accumulating murine pancreatic tumor model (Rosengren, AACR 2016 poster #4886). Accumulation of HA in the TME is enhanced by the expression of hyaluronan synthase type 3 (HAS3), a biomarker for tumor vascular density. Upon tumor infiltration by T cells, PD-L1 is upregulated and decreases PD-1 efficacy. PEGPH20-mediated HA degradation enhances both checkpoint efficacy and CD8+ T cell recruitment. Specifically, PEGPH20 alone (1mg/kg) increased anti-PD-L1 efficacy by 411% relative to anti-PD-L1 alone (93% vs 18.2% TGI, p<0.0001) and increased the accumulation of CD8+ TIL by 176% (p=0.0025). Taken together, the data suggest that tumor HA accumulation may act as a barrier to immune cells. In a murine pancreatic tumor model (Rosengren, AACR 2016 poster #4886), anti-PD-L1-mediated HA reduction facilitates increased access of CD8+ T cells. This increased recruitment may contribute to the enhanced anti-PD-L1 efficacy observed when combined with PEGPH20. A Phase 1 trial is ongoing to evaluate PEGPH20 plus checkpoint blockade in patients with advanced or metastatic non-small cell lung cancer and in patients with locally advanced or metastatic gastric adenocarcinoma (NCT02563348).

#642 Detection of circulating antibodies against KRAS in patients with advanced cancers. Ed Khered,1 Helen J. Huang,1 Alice Wu,2 David S. Hong,1 Sarina A. Piha-Paul,1 Daniel D. Karp,1 Sining Fu,1 Vivek Subbiah,1 Apostolia M. Tsimeridou,1 Aung Naing,1 Adi Diab,1 Milind Javle,1 Scott Koptez,1 Anil K. Sood,1 Jonathan M. Kurie,1 Funder Meric-Bernstam,1 Martin Gleeson,2 Filip Janku,1,2 The University of Texas MD Anderson Cancer Center, Houston, TX;1Genalyte INC, San Diego, CA.

Introduction: KRAS gene plays a major role in tumorigenesis, cell proliferation and survival. Yet, there has been no effective targeted therapy against KRAS mutation-mediated tumors. We hypothesized that KRAS can induce humoral-mediated immune response. Methods: Plasma or serum samples from patients with progressing advanced cancers with or without KRAS mutations were tested for the presence of circulating KRAS antibodies. We used the Mavrick Detection System (Genalyte, San Diego, CA), which can perform real-time detection of macromolecules in crude samples using biologically functionalized silicon photonic biosensors lithographically printed on disposable silicon chips. Results: We collected serum or plasma samples from 213 patients with advanced cancers (KRAS-mutant, N=100; KRAS wild-type, N=113) and 30 (23%) were found to have circulating KRAS antibodies. We used the Mavrick Detection System to detect 11 circulating KRAS antibodies and tumor KRAS mutation status (21/100, 21% for KRAS-mutant vs. 29/113, 26% for KRAS wild-type; P=0.52). In addition, there was no difference in detection of KRAS antibodies in colorectal cancer (21/89, 24%) compared to other cancers (29/124, 23%; P=1.00). There was no difference in the median survival in patients with KRAS antibodies compared to patients without KRAS antibodies (9.0 months vs. 10.1 months; P=0.82). Similarly, there was no difference in the median survival according to the presence of circulating KRAS antibodies in subgroups of patients with tumor KRAS mutations (P=0.96) and without tumor KRAS mutations (P=0.63). On the contrary, the median survival of patients with tumor KRAS mutation was shorter compared to those without KRAS mutation (7.2 months vs. 11.5 months; P=0.001). Conclusion: Circulating KRAS antibodies can be detected in 23% of patients with advanced cancers. Biological implications of circulating KRAS antibodies remain to be understood.

#643 Induced MHCII expression on breast cancer cells broadens the responding T cell repertoire, delays tumor-specific T cell exhaustion, and impairs tumor growth. Tyler R. McCaw,1 Mei Li,2 Selene Meza-Perez,2 Donald J. Bucala,3 Ondryto Starace,2 Sara Cooper,2 Andres Forger,1 Troy D. Randall,1 University of Alabama at Birmingham, Birmingham, AL;1HudsonAlpha Institute for Biotechnology, Huntsville, AL.

We recently reported that the aberrant expression of Major Histocompatibility Class II (MHCIi) molecules on human triple negative breast cancer (TNBC)
cells correlates with prolonged progression-free survival and increased tumor infiltrating lymphocytes. We hypothesized that the expression of MHCII enhances the intratumoral CD4+ T cell response, thereby bolstering the tumor-specific CD8+ T cell response, resulting in more effective tumor control. To test our hypothesis, we created both MHCII-expressing and MHCII-negative tumor cells by infecting breast cancer (TS/A) and nasopharyngeal cancer (hCIITA) tumor cells with either the constitutive transcriptional activator (hCIITA) or empty vector, respectively. Transfected cells were then injected into BALB/c mice and the resulting immune response analyzed by flow cytometry at four time points. We found that hCIITA-expressing tumors grew slower than control tumors in immunocompetent recipients, but that this difference was nullified in immunocompromised and markedly reduced in immunodeficient SCID mice. CD4+ T cells isolated from hCIITA-transfected tumors produced more IFNγ, IL-17A, and surprisingly granulocyte colony stimulating factor for longer times than their counterparts in control tumors. Similarly, CD8+ T cells isolated from hCIITA-transfected tumors displayed a more activated phenotype and produced more IFNγ and granulocyte colony stimulating factor for longer times. Nevertheless, both CD4+ and CD8+ T cells eventually became exhausted in both groups.

In addition to enhanced effector functions, TCR repertoire analysis demonstrated that both the breadth and magnitude of expansion of responding T cell clones were increased in hCIITA-transfected tumors. Interestingly, TS/A-hCIITA tumors harbored more regulatory T cells (Tregs) with a more suppressive phenotype than Tregs from control tumors. Finally, we observed that the histone deacetylase inhibitor (HDACi) Entinostat is capable of robust and dose-dependent induction of MHCII on tumor cells in vivo, an effect not observed with control tumors, with dramatic reduction in tumor size. These results suggest that the clinical benefit associated with MHCII expression on TNBC cells is mediated by a delay in T cell exhaustion and increased intratumoral CD4+ T cell activation, which enhances the cytotoxic capacity of CD8+ T cells. Entinostat, and potentially other epigenetic modifying agents, may enable induction of MHCII expression on TNBC cells clinically and allow more patients to benefit from an augmented T cell response. These effects may be magnified by combinatorial therapy with checkpoint inhibitors to promote durable anti-tumor immune responses.
IMMUNOLOGY: Tumor Antigens and Adaptive Immunity

PD-L1, PD-L2 and/or MHC class I molecule expression with the outcome of the patients was determined. The high incidence of MHC class I deficiencies and PD-L1/PD-L2 overexpression imply that EBV-associated NPC escape from the host immune response by targeting both antigen presentation mechanisms and immune checkpoints. Our findings also suggested that the expression of MHC class I molecules and PD-L1/PD-L2 is a potential biomarker for immunotherapy in NPC patients.

#647 Bortezomib enhances CD8+ T Lymphocyte antitumor effector function: Potential mechanism(s) via notch regulation. Ariana N. Renrick,1 Menaka C. Thounaojam,2 Portia Thomas,1 Samuel T. Pellom,1 Anil Shanker1. 1Meharry Medical College, Nashville, TN; 2Medical College of Georgia, Augusta, GA.

The immunosuppressive tumor microenvironment disturbs host antitumor immunity by multiple mechanisms including interference with the Notch system, which is important for various metazoan cell fate decisions and hematopoietic cell differentiation and function. We observed that treatment with the proteasome inhibitor bortezomib in mice bearing various solid tumors resulted in an upregulated expression of various Notch signaling components in lymphoid tissues, thereby increasing CD8+ T lymphocyte IFNy secretion and expression of effector molecules, perforin and granzyme B, as well as the T-box transcription factor c esomesedomerin. Of note, bortezomib reversed tumor-induced downregulation of Notch receptors. Notch1 and Notch2, as well as increased the levels of cleaved Notch intracellular domain (NICD) and downstream targets Hes1 and Hey1 in tumor-draining lymphnodes. Moreover, bortezomib enhanced NICD cleavage by nuclear factor-kB (NFkB) activity by increasing the total and phosphorylated levels of the IkBa kinase and IkBa as well as the cytoplasmic and nuclear levels of phosphorylated p65. Even when we blocked NFkB activity by Bay11-7082, or NICD cleavage by y-secretase inhibitor, bortezomib significantly increased expression of Notch Hes1 and Hey1 genes as well as perforin, granzyme B and c esomesedomerin in activated CD8+ T cells. Data suggest that bortezomib can rescue tumor-induced dysfunction of CD8+ T cells by its intrinsic stimulatory effects promoting NICD-NFkB crosstalk. We are also elucidating components of microRNA regulation affecting NICD-NFkB crosstalk. Our preliminary data suggest that bortezomib is also able to positively regulate miR-155 expression in CD8+ T cells from mice bearing tumor. As well as, miR-155 suppression downregulates bortezomib-induced increase in Notch target genes in T cells. We are currently investigating alternative proteasome inhibitors in order to understand whether bortezomib’s effect on miR-155 expression in CD8+ T cells is specific to bortezomib or primarily conducive to a proteasome inhibition effect. These findings provide novel insights on using bortezomib not only as an agent to sensitize tumors for chemotherapy, but also to provide lymphocyte-stimulatory effects, thereby overcoming immunosuppressive actions of tumor on anti-tumor T cell functions.

The purpose of this study is to investigate underlying mechanism of how cytokine interferon-gamma (IFN-γ) regulates PD-L1 expression in ovarian cancer cells. We treated a panel of human and mouse ovarian cancer cell lines with recombinant human/mouse IFN-γ. Our data showed that IFN-γ upregulated mRNA and protein expression of PD-L1 significantly in a majority of ovarian cancer cells. The functional IFN-γ receptor is comprised of two ligand-binding IFNγR1 chains associated with two signal-transducing IFNγR2 chains and associated signaling machinery. Here we found that the mRNA expression levels of IFNγR1 and IFNγR2 were abundant in all human ovarian cancer cell lines being tested, while their expressions were not affected by IFN-γ treatment. After knocking down the expression levels of IFNγR1 and IFNγR2 in a ovarian cancer cell line by target gene-specific siRNA, our data showed that the IFN-γ-mediated induction of PD-L1 were diminished in the ovarian cancer cells when compared to those with non-targeting scrambled siRNA controls, indicating the induction of PD-L1 by IFN-γ is dependent on the presence of IFN-γ receptors in the ovarian cancer cells. Although abundant expression of IFNγR1 and IFNγR2 were found in all human ovarian cancer cell lines being tested, the IFN-γ-mediated induction of PD-L1 was not detected in a few of the human ovarian cancer cell lines (namely IGV0-1, TOV21G and SKOV3). We further investigated the integrity of IFN-γ signaling in the human ovarian cancer cell lines by examining activation of STAT1 protein and induction of IRF-1 gene in human ovarian cancer cell lines after IFN-γ treatment. Our data showed that phospho-STAT1 protein and IRF-1 gene expression were up-regulated significantly in a majority of human ovarian cancer cell lines after IFN-γ treatment, except IGV0-1 and TOV21G cells. These results suggested that IGV0-1 and TOV21G cells might harbor defects in intracellular JAK-STAT1 signaling. We then examined the presence of JAK1 truncating mutations in human ovarian cancer cell lines by Sanger sequencing, and confirmed that IGV0-1 and TOV21G cells, but not the others, have JAK1 truncating mutations. Since our data showed that SKOV3 cells have wild type JAK1, we further investigated other possible defects in IFN-γ signaling in SKOV3 cells. We investigated the IFN-γ-induced STAT3 protein activation in human ovarian cancer cell lines, and defects were found in Y705 STAT3 phosphorylation in SKOV3 as well as in IGV0-1 and TOV21G cells. To summarize, our results showed that IFN-γ induces PD-L1 expression in ovarian cancer cells via IFNFR-JAK-STAT pathway. The failure of IFN-γ-mediated induction of PD-L1 in a minority group of human ovarian cancer cell lines is due to defective IFN-γ signaling, including JAK1 truncating mutations and impaired STAT3 activation. This work is supported by Hong Kong Research Grants Council General Research Fund (467713 and 14109515).

#649 Emigrant pre-REP tumor infiltrating lymphocytes profoundly differ from remnant T-cells. Michelle R. Simpson-Abelson, Christopher Mosychuk, Maria Fardis, Michael T. Lotze. Lion Biotechnologies, Tampa, FL.

Adaptive T cell therapy with autologous tumor infiltrating lymphocytes (TIL) provides up to 56% objective response rates and a complete response in 24% of patients with metastatic melanoma. The process of generating TIL from resected tumor involves morcellating the tumor into 1 mm3 fragments and expanding TIL in the presence of Interleukin 2 (IL-2) in a pre-Rapid Expansion Protocol (pre-REP). During the ‘pre-REP’, tumor-resident immune cells emigrate (eTIL) and proliferate. The length of the pre-REP varies between 11-21 days, depending on cell growth. Residual tumor fragments (remnants) are discarded and the expanded eTIL are subjected to a Rapid Expansion Protocol (REP) with irradiated PBMC feeders, anti-CD3 and IL-2. Viable cells remaining in the tumor remnants (rTIL) following the pre-REP were investigated to assess their function and phenotype. We evaluated and compared the rTIL and eTIL in melanoma, breast, renal, pancreatic, lung and colorectal tumors (n = 9). Tumor rTIL are consistently phenotypically distinct from eTIL, as determined by differential expression of various markers (Table 1). The fundamental differences in rTIL were: Increased CD69+ (7 fold MFI in CD4+) (p<0.001); diminished LAEG3 (2 fold MFI in CD8) (p<0.05); TIM3 (3 and 2 fold MFI in CD8 and CD4 respectively) (p<0.05/0.01); CD154 (fold MFI in CD4) (p<0.01); and CD56 (5%) (p<0.05). Surprisingly, a REP of rTIL and eTIL resulted in comparable expansion. The phenotypic signature of rTIL was sustained post-REP with fidelity of the individual expression of LAEG3, Tim3, and CD28. These studies have identified significant differences in the biology of cell populations in terms of tissue-resident T cells and the signals associated with emigration and retention. These data provide additional insights on the individual TIL populations that could be utilized for adoptive T-cell therapy in patients and raise important questions about the nature of tissue-resident T cells in sites of chronic inflammation such as tumor.

Table 1: Tumor resident remnant T cells are phenotypically distinct from emigrating T cells (N=9)

#650 B lymphocytes promote upregulation of an IL-1Rα NBK signaling and increase invasiveness of triple negative breast cancer. Nicole Flynn,1 Rajasekharan Somassundaram,2 Jennifer Sims-Mourtada3. 1University of Delaware, Newark, DE; 2The Wistar Institute, Philadelphia, PA; 3Helen F. Graham Cancer Ctr., Newark, DE.

Triple negative breast cancer (TNBC) is an aggressive form of breast cancer that progresses quickly from a non-invasive carcinoma in situ to an invasive state. Chronic immune infiltrates and inflammatory immune responses have been found to promote aggressiveness in a number of solid tumor types. In breast cancer, B lymphocytes are associated with microinvasive disease and correlate with expression of inflammatory genes. The purpose of our work is to study the impact of B lymphocytes on the tumor...
microenvironment and increased invasiveness of TNBC cells. Through real-time PCR, we demonstrate that co-culture of B lymphocytes and TNBC cells resulted in elevated expression of genes associated with immune cell trafficking and activation. Furthermore, in ER DCIS and TNBC, both B lymphocytes and tumor cells are found to express IL1β whereas IL8 is found more specifically to be expressed by tumor cells. Our findings support the hypothesis that B lymphocytes promote a chronic inflammatory environment leading to increased invasion of TNBC cells.

**#651 Evaluation of the expression and function of TIM-3 relative to PD-1 in human tumors.** Kristen McEachern, Srimoyee Ghosh, Yonghong Zhao, Qiyao Zhang, Norman Zhang, David W. Jenkins, 2 TESARO, Waltham, MA; 3Wuxi Code Texas, China.

While immunotherapies directed against PD-1 and PD-L1 have proven effective across multiple indications, there is still a large unmet medical need for therapies for patients who do not respond or who develop acquired resistance during the course of treatment. There are several emerging hypotheses to explain the lack of response, including the overall presence and localization of immune cells, as well as the up-regulation of additional T-cell checkpoints, including TIM-3 in tumor infiltrating lymphocytes. To investigate the potential role of TIM-3, we set out to evaluate the expression and function of TIM-3 and the relationship to PD-1 in several systems. Firstly, we developed a flow cytometry methodology to enumerate T-cell, including CD4 and CD8 positive cells, as well as other immune cell populations in a panel of human tumor samples, including non-small cell lung cancer (NSCLC). In these samples, we investigated the expression profiles of TIM-3 and PD-1 in both T-cell and non-T-cell populations. In addition, we performed complementary genomic studies to explore gene expression profiles of not only the bulk tumor samples but also of isolated PD-L1 positive/TIM-3 negative versus PD1 and TIM-3 double positive cell populations. The profiling identified tumors with a range of tumor infiltrating lymphocyte content and also differences in PD1 and TIM-3 expression. It was found that in addition to T-cells, TIM-3 was expressed on myeloid cell populations and furthermore, that there were distinct differences in the gene expression profiles of PD1 single positive versus PD1 and TIM-3 double positive cells. Building on the expression studies, the functional role of TIM-3 in T-cells and also on myeloid-derived cells was explored. Taken together, these studies provide further evidence for the importance of TIM-3 as a potential therapeutic target for the treatment of cancer with the potential for biological effects in both the T-cell and myeloid compartments of the tumor microenvironment.

**#652 PD-L1 and MHC class I expression levels are modulated by MEK inhibition on head and neck squamous cell carcinoma.** Seong-Ho Kang,1 Bhumsuk Keam,2 Soyeon Kim,1 Tae Min Kim,1 Dong-Wan Kim,1 Dae Seog Heo1. 1 Cancer Research Institute, Seoul National University, Seoul, Republic of Korea; 2 Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea.

Background: To overcome immunosuppression, multiple pathways can be targeted by counter strategies, including elimination of suppressive signals (such as PD-1/PD-L1) and promotion of anti-T cell inhibition by tumor cells, and of T cell infiltration into tumor sites. The purpose of this study is to investigate the change in expression of PD-L1 and MHC class I as well as of T cell co-what attractants, CXCCL9 and CXCL10, in human head and neck squamous cell carcinoma (HNSCC) cell lines after treatment with MEK inhibitor. In addition, for evaluation of immunologic effects of MEK inhibitor in vivo, we employed SCC VII mouse squamous cell carcinoma (SCC VII) model. Methods: Six human HNSCC cell lines (SNU-1041, SNU-1066, SNU-1076, Detroit 562, FaDu, and HN31) and a mouse squamous cell carcinoma cell line (SCC VII) were used. Trametinib was purchased from Selleckchem. We conducted cell viability assay using these cell lines after 72 h incubation with MEK inhibitor trametinib. PD-L1 and MHIClass I expression levels were analyzed by flow cytometry after treatment with trametinib and/or interferon-gamma (IFN-γ). Expression of PD-L1, p-erk1/2, and p-STAT1/3 were analyzed by western blot..Statistical testing was carried out on tumor tissues to assess gene expression, stromal remodeling and macrophage polarization in response to AB0046 treatment. Results: MMP9 levels are elevated in human tumors compared to healthy tissues. The protein is expressed predominantly in stromal cells, including macrophages and neutrophils, with more occasional heterogenous expression in tumor epithelia. Differentiation of human monocyte-derived macrophages in vitro revealed that M2 polarization is associated with increased expression of MMP9 and Th2 markers CCL18 and TGFB. Anti-MMP9 treatment in three independent mouse tumor models (HC1-NeuT, CT26, Lewis lung carcinoma (LLC)) resulted in decreased primary tumor growth (p<0.001 and p<0.005, for HC1-NeuT and CT26 respectively) and increased animal survival (p=0.024 for LLC). Gene expression profiling of tumors from the various models demonstrated that inhibition of MMP9 resulted in elevated expression of genes associated with immune cell activation pathways (Hallmark Interferon Gamma Response, p<0.05, FDR<0.001). Additional analysis in the HC1-NeuT model revealed a significant decrease in M2 macrophage infiltration in the tumor microenvironment (p<0.05) with AB0046 treatment, as well as reductions in tumor-associated fibrillar collagen as assessed by Picrosirius red staining. Conclusions: These analyses show that MMP9 is expressed in a variety of human tumors. Our data suggest that inhibition of MMP9 promotes anti-tumor immunity and enhances a Th1 immune response. GS-5745, a humanized anti-MMP9 inhibitory antibody, is being evaluated in gastric cancer in phase 3 and 2 studies with chemotherapy and nivolumab, respectively (NCT02545504, NCT02864381).

**#654 The epigenetic landscape of T cell exhaustion.** Debattama Sen, Dana Farber Cancer Institute/Harvard Medical School, Cambridge, MA.

Exhausted T cells in cancer and chronic viral infection have distinctive patterns of gene expression, including sustained expression of the inhibitory recep-
tor PD-1, but the regulation of gene expression in exhausted T cells is poorly understood. Here we define the accessible chromatin landscape in mouse and human exhausted CD8⁺ T cells and show that it is profoundly different from functional memory CD8⁺ T cells. Exhausted CD8⁺ T cells in a mouse model of chronic viral infection acquire an extensive, state-specific pattern of enhancers, which are co-opted into functional modules. One enhancer, −23.8kb from the Pdcd1 locus, is found only in exhausted T cells and other lymphocytes with sustained PD-1 expression. Genome editing shows it to be required for high PD-1 expression, Cas9-mediated in situ saturation mutagenesis of the enhancer pinpoints critical minimal sequences that correspond to bound transcription factor motifs for RAR, T-bet and Sox3 in exhausted CD8⁺ T cells. State-specific enhancer profiles are conserved in mouse and human exhausted-antigen-specific CD8⁺ T cells responding to HIV and HCV infection. Detailed functional enhancer maps of T cell exhaustion reveal state-specific regulatory sequences and offer targets for genome editing that could alter gene expression preferentially in exhausted CD8⁺ T cells.

**CLINICAL RESEARCH: Checkpoint Inhibitor and Prognostic Biomarkers**

#655 Development of IHC staining protocols for assessment of PD-L1 expression in cytological samples. Christine Boyiddle,1 Mark Ruboyianes,1 Ed Del Valle,1 Lukas Bubendorf,2 Kerstin Trunzer,2 Judith Pugh,1 Jennifer Boone.1

1Ventana Medical Systems, Oro Valley, AZ, 2University Hospital Basel, Basel, Switzerland.

Immunohistochemistry (IHC) staining of non-small cell lung cancer (NSCLC) samples for programmed cell death ligand 1 (PD-L1) can help identify patients that may benefit from anti-PD1 therapy. However, resection or biopsy samples cannot be obtained for some patients with NSCLC. Fine needle aspiration (FNA) is a less invasive method for obtaining samples in such patients, and it is yet to be determined if PD-L1 can be assessed using cytological samples. In this study we had three objectives 1. Develop staining protocols on the VENTANA Benchmark ULTRA automated staining platform for cytology samples fixed with the most common methods using cell lines as a model. 2. Determine the optimal cytology fixation method for VENTANA PD-L1 (SP142) IHC Assay (PD-L1 (SP142) staining, and 3. Assess PDL1 expression in tumor cells (TC) and tumor-infiltrating immune cells (IC) in cytological samples prepared from NSCLC patients. KARPS 299 cell line was used as a model system for the fixation studies. Liquid-based preparations (LBPs) fixed in PreservCyt, conventional smears (unstained and pap-stained) fixed in 95% ethanol, and paraffin embedded cell blocks (CBs) fixed in 95% ethanol, 10% neutral buffered formalin (NBF), PreservCyt, and SurePath preservative were optimized on the Benchmark ULTRA using PD-L1 (SP142) antibody and Optiview DAB Detection and Amplification Kits. NSCLC FNA CBs fixed in 10% NBF (N=69) and a subset of FNAs with matched resections (N=20) were stained with the optimized protocol. FNAs and resections were assessed for percentage of TC and IC with PD-L1 staining. Staining parameters were optimized on the Benchmark ULTRA for all sample types tested, and they all produced a range of moderate to strong PD-L1 expression. CBs fixed in 95% ethanol and 10% NBF produced the highest percentage of staining, with expression in 90% of cells. CBs fixed in PreservCyt and SurePath preservative had a lower percentage of staining, 40% and 75% respectively. LBPs had 25% cells staining and smears ranged from 20%-60%. NSCLC FNA CBs fixed in 10% NBF produced interpretable results when stained with PD-L1 (SP142). IC staining was seen in 8.7% (6/69) of samples, TC staining was seen in 8.7% (6/69) of samples, both IC and TC staining was seen in 14.5% (10/69) of samples. The subset of FNAs with matched resections showed concordance with PD-L1 IC staining in 60% (12/20) of samples and TC staining in 75% (15/20) of samples. The discordant cases showed that FNAs were negative for IC when the resection was negative and positive for TC in 5% of cases when the resection was negative. The VENTANA PD-L1 (SP142) Assay staining parameters were found to be optimal for staining NSCLC FNA CBs fixed in 10% NBF. PD-L1 staining was detected in both TC and IC in FNAs and concordance of FNA and matched resections was high for both IC and TC. A larger study is necessary to validate the use of FNAs for assessment of PD-L1 expression in a clinical setting.

#656 PD-L1 expression in primary lesions vs metastatic sites and by demographics in advanced urothelial carcinoma samples. M Zajac,1 A M. Boothman,1 Y Ben,2 A Gupta,2 X Jin,2 J Antal,2 A Sharpe,1 M Scott,2 M Rebe-latto,3 J Walker1, AstraZeneca, Cambridge, United Kingdom; AstraZeneca, Gaithersburg, MD; 3MedImmune, Gaithersburg, MD.

Background: Determination of programmed cell death ligand-1 (PD-L1) expression levels in tumors may help physicians understand which patients (pts) are most likely to respond to anti-PD-1/PD-L1 therapies in urothelial carcinoma (UC). Understanding the impact of different sample types and demographics on PD-L1 expression is important to determine suitability of tumor biopsies for testing. Results: As of July 24, 363 pts screened in the UC cohort of Study CD-ON-MEDI4376-1108 (NCT01693562) had tissue available for analysis and 47 pts had provided paired primary and metastatic samples. FFPE samples were tested in a central laboratory with the VENTANA PD-L1 (SP263) Assay using a Benchmark ULTRA instrument. Pts were classified as having either PD-L1 high (PD-L1 expression ≥25% either on tumor cells [TC] or immune cells [IC]) or PD-L1 low/nega-tive (<25% on TC and IC) tumors. PD-L1 high prevalence was reported in primary vs metastatic sites, and by age, sex and race. Results: PD-L1 status was evaluable for 332/363 (91.5%) pts (175/332 [52.7%] PD-L1 high and 157/332 [47.3%] PD-L1 low/ negative) whose UC specimens were tested (intent to diagnose [ITD] population). Overall percentage agreement between paired primary and metastatic samples, based on combined TC/IC scoring ≥25%, was 74.5% (95% CI 59.7 - 86.1%). In the ITD population, using only the samples from which patient PD-L1 expression status was determined, PD-L1 high prevalence in primary and metastatic samples was 57.1% and 50.9% respectively (p=0.343, not significant). The proportion of pts with PD-L1 high status was not enriched in any demographic group (Table). Conclusions: Initial data from UC pts in Study 1108 showed similar PD-L1 high prevalence in primary and metastatic lesions and good concordance between paired primary and metastatic samples. These results build optimism that samples obtained from either location could be used to determine PD-L1 status. Further data are needed to confirm these findings.

Background: Identifying optimal biomarkers for response to anti-PD-1/PD-L1 therapies in non-small cell lung cancer (NSCLC) is critical. Tumor mutational burden (TMB) is a potential biomarker of genomic instability and neo-antigen binding sites to activated effector T cells. The goal of this study was to examine the association of TMB with overall survival for patients treated with checkpoint blockade and to correlate TMB with mutational status, including DNA repair mutations. Methods: We retrospectively examined TMB using next-generation sequencing (FoundationOne) for 82 patients with NSCLC in our institution. TMB included coding base substitutions and indel alterations, but excluded potentially functional mutations. TMB high versus low was stratified based on 15 mutations per megabase pair. We correlated TMB with DNA repair mutations, mutational status, and smoking history. In addition, survival data were obtained for 35 patients who were treated with anti-PD-1/PD-L1 therapy. Results: TMB was associated with significantly longer overall survival for patients treated with checkpoint blockade (Table 1, p < 0.04). In addition, TMB was independently correlated with direct and indirect (Chae et al. 2016) DNA repair mutations (p < 0.03). TMB was also significantly associated with smoking, number of coding region mutations, and treatment with at least two prior lines of therapy (p < 0.02). A trend toward lower TMB was found for patients with mutations in EGFR, ALK, or KRAS (p = 0.06). Conclusions: Higher TMB was associated with improved survival for patients treated with anti-PD-1/PD-L1 therapies. In addition, TMB was correlated with DNA repair mutations, number of coding mutations, prior treatment, and smoking. Our results indicate that TMB can be used as a biomarker for response to checkpoint blockade in NSCLC.

#659 Multiplex cocktails for immunotherapy targets: PD-L1 with tumor specific transcription factors. David Alrett-Tacha, Wei Yuan, George Yang, Biocare Medical, Concord, CA.

Introduction: Blocking the interaction between the programmed cell death (PD)-1 protein and one of its ligands, PD-L1, has been reported to generate immunostimulatory responses. Therapeutics targeting PD-L1 in several cancers are currently in clinical trials, and the U.S. FDA has granted accelerated approval for Keytruda (pembrolizumab) to treat patients with advanced (metastatic) non-small cell lung cancer (NSCLC). Various pathology scoring and interpretation methods have been put forth to assay PD-L1 expression, and variability of non-PD-L1 staining across tumors may have important prognostic aspects. PD-L1 expression on tumor cells can be upregulated via activation of CD8+ cytotoxic T lymphocytes. PD-L1 expression is also associated with certain subtypes of tumor-associated lymphocytes, macrophages and dendritic cells. In certain cancers, the cross-reactivity of PD-L1 can make interpretation and scoring difficult. Thus, a strategy using IHC multiplex stains could help resolve challenging cases by cocktailling PD-L1 with target tissue transcription factor antibodies along with other potential markers. Method and Materials: Formalin-fixed paraffin-embedded tissues and tissue microarrays for various tumor types including lung, bladder and melanoma were processed and cut at 4-5 microns. PD-L1 rabbit monoclonal antibody was cocktailled with the following antibodies: TTF1 (lung cancer); CD163 (lung cancer); p40 + GATA3 (bladder cancer); and SOX10 (melanoma). Cocktails were detected with double stain detection systems using brown, red and blue chromogenos for visualization. Sections were counterstained with a standard hematoxylin or Wiegert’s iron hematoxylin. Results PD-L1 and TTF-1 with or without CD163 (macrophage) and PD-L1 + CD163 were used in lung cancers. The nuclear staining of TTF1 in lung adenocarcinoma (blue chromogen) helped define tumor positive PD-L1 (DAB) positive cells and CD163 (Fast Red) marked macrophages. PD-L1 combined with p40 and GATA3 was deployed for bladder cancers. PD-L1 membrane expression in tumor cells and co-expression of p40 and GATA3 gave robust nuclear staining in bladder tumor cells. Finally, SOX10 nuclear staining was observed in most melanoma and could be easily separated from PD-L1 membrane staining. Conclusion: PD-L1 cocktailled with strategic nuclear or cytoplasmic antibodies can help discriminate tumor cells from non-tumor cells, and may facilitate quantitation or scoring methods for more accurate assessment of this key immunotherapy marker.

#660 Pre-symptomatic detection and early treatment of mammary cancer with anti-PD-L1 in a mouse model. Hu Duan, Stephen Albert Johnston, Shen Luhui, Biodesign Institution, ASU, Tempe, AZ.

Cancer kills ~8M people/year and the WHO predicts an epidemic of cancer in the developing world over the next 20 years due to increased longevity. Development of a simple method to detect and treat cancer early could be a solution to this challenge. Here we test this approach in principle in a transgenic mouse mammary tumor model by immunomutation (IM) diagnostics. IMs are profiles of antibodies in the blood displayed on a high density peptide array. As previous published data showed, the IMs can distinguish different breast cancers based on the disease specific antibody profile in the patient, including different breast cancers and infectious diseases. According to the immune surveillance theory, the immune system, including the humoral immune response, starts to interact with cancer cells as soon as they are transformed. First, we tested if the IMs is sensitive enough to detect the antibody profile change caused by the early tumor development in the FVB-NeuN (MMTV-neu202Mul/J) mammary cancer model. In the FVB-NeuN model, the MMTV promoter activates the wild type rat ERBB2 gene in mammary cells, and every mammary cell potentially can convert into a cancer cell. The transition from normal mammary glands to hyperplasia of FVB-NeuN in mouse starts at ~8.6 to 15 weeks after birth. The mice develop the first palpable tumor in one of the ten mammary glands by 19-45 weeks of age with an average age of 32±1.2 weeks in our hands. We collected serum every 4 weeks from the FVB-NeuN mice and the wild type FVB mice for the IM analysis. The IMs can distinguish the FVB-NeuN mouse from the age matched wild type FVB mouse as early as 12 weeks (Stage-1) before the onset of the first palpable tumor. We also analyzed the IMs from the Stage-2 (8 weeks before the palpable tumor and so on) to Stage 4. Different IMs of each stage has only partial overlap with the other stages. The cross-stage prediction analysis showed the accuracy of the cancer detection by using different IMs is from 75% to 93%. Second, we determined if early treatment at the time of diagnosis with the checkpoint blockade, anti-PD-L1, would inhibit the tumor growth. A course of 3 injections at the time of diagnosis significantly retarded tumor growth relative to untreated controls. The early treatment elicited long-term protection which could restrict the tumor growth even four months after the treatment. The treated mice presented a specific IMs at 28 days post treatment and 35 days post the first palpable tumor, compared to the untreated mice. This indicates that the early treatment elicited an anti-tumor immune response that could inhibit tumor growth. This preliminary experiment suggests that early diagnosis combined with systemic treatment might be a method to control or eliminate cancer.

The current diagnostics landscape for therapeutics that target the PD1/PD-L1 pathway is highly complex. Four different companion or complementary diagnostics have been developed for pembrolizumab in NSCLC, nivolumab in NSCLC and melanoma, and atezolizumab in urothelial carcinoma. The need to reconcile diagnostics for this class of targeted therapies has been recognized by the creation of the FDA-AACR-ASCO “PD-L1 Blueprint” working group to explore means to “harmonize” PD-L1 testing in tissue based IHC assays. The results reported from this working group noted similarities, but also several important discrepancies, between the current assays. Since each test uses a specific interpretation for each assay and indication, this creates a highly complex diagnostic landscape, which is likely to continue to increase in complexity as more PD-1/PD-L1 therapeutics and potentially novel diagnostics continue to be approved in additional indications. To address the need for adaptive, sustainable harmonization for PD-L1 diagnostics, Flagship Biosciences evaluated the utility of image analysis-based methods to harmonize multiple PD-L1 tests. We executed a proof-of-concept study utilizing a cohort of 38 breast samples from the same NSCLC patients, stained with the FDA approved Dako PD-L1 tests (28-8 and 22C3 clones), and our in-house PD-L1 assays (SP142 and EI13N clones) for comparison. We digitized the tissue slides using a whole slide scanner, and evaluated the samples with our tissue Image Analysis (tIA™) technology. As expected, the patient samples stained with the separate PD-L1 assays yielded differences in staining and, thus, the reported scores for PD-L1 expression based on...
on each test used, despite serial sections being derived from the same patient. To attempt to harmonize the scoring approaches for each test, we leveraged our computational Tissue Analysis (cTA™) platform to create a mathematically derived "virtual slide score" for each sample, which enabled calibration of the various tests to deliver cross PD-L1 comparative scores. Based on the proof-of-concept from this study, the cTA™ approach harmonization of the various PD-L1 tests through use of a digital pathology platform. The data presented provides a foundation for potential application of the cTA™ platform in the clinical laboratory setting to achieve harmonization of multiple PD-L1 tests.

**#664 Analytical validation and clinical utility of an immunohistochemical PD-L1 diagnostic assay for treatment with durvalumab in urothelial carcinoma patients.** M. Zajac, A. M. Boothman, Y. Ben, A. Gupta, A. Antal, X. Jin, A. Nielsen, G. Manriquez, C. Barker, P. Wang, P. Patil, N. Schechter, M. Rebeletto, J. Walker. AstraZeneca, Cambridge, United Kingdom; AstraZeneca, Gaithersburg, MD; MedImmune, Gaithersburg, MD; Ventana Medical Systems, Inc., Tucson, AZ.

Background: A high quality programmed cell death ligand-1 (PD-L1) diagnostic may help to identify patients (pts) most likely to respond to anti-PD-L1/programmed cell death-1 (PD-1) therapy. Here we describe a PD-L1 immunohistochemical (IHC) diagnostic test developed for urothelial carcinoma (UC) pts treated with durvalumab. Methods: The IHC assay uses an anti-human PD-L1 rabbit mAb optimized for detection of both tumor cell (TC) and tumor-associated immune cell (IC) PD-L1 expression with the OptiView DAB IHC Detection Kit on the automated VENTANA Benchmark ULTRA platform. The assay was validated in UC tissue intended for use in formalin-fixed, paraffin-embedded samples in a series of studies that addressed sensitivity, specificity, robustness and precision and implemented in Study CD-ON-MED4736-1108 (NCT01693562). Pts were evaluated using the VENTANA PD-L1 (SP263) Assay at a prespecified PD-L1 expression cut-off. Efficacy was analyzed in pts with PD-L1 low/negative (defined as TC <25% and IC <25%) and UC vs pts with PD-L1 high (defined as TC ≥25% or IC ≥25%) UC. Results: The VENTANA PD-L1 (SP263) Assay met all the predefined acceptance criteria (average positive agreement and average negative agreement >85%), showing analytical specificity, sensitivity and precision. It demonstrated ≥97% and ≥85% inter-reader precision agreement for TC and IC respectively. For intra-reader precision, it demonstrated >96% and >87% agreement for TC and IC respectively. For intra-day performance, the assay demonstrated ≥96% agreement for TC and IC and for inter-day performance, it demonstrated ≥98% and 100% agreement for TC and IC respectively. Precision studies for inter-antibody lot, inter-detection kit lot and intra-platform demonstrated ≥97% agreement for both TC and IC. Inter-laboratory testing was performed at 3 external laboratories and demonstrated an overall agreement rate of 92.3%. The VENTANA PD-L1 (SP263) Assay was implemented in Study CD-ON-MED4736-1108 and durvalumab demonstrated clinical activity and durability of response in both PD-L1 high and PD-L1 low/negative subgroups, yet with different response rates. In addition, given the high negative predictive value of the assay, it is especially helpful in evaluating the likelihood of response to durvalumab: pts who were classified as PD-L1 high with the VENTANA PD-L1 (SP263) Assay tended to have a higher objective response rate per RECIST v1.1 than pts who were PD-L1 low/negative.

Conclusions: These data show that determination of PD-L1 expression in TC and IC in UC pts using the VENTANA PD-L1 (SP263) Assay is precise and highly reproducible and highlight the utility of the assay in a clinical setting. The VENTANA SP263 Assay is especially helpful in informing pts and physicians on the likelihood of response to durvalumab, but not for the purpose of restricting treatment to only PD-L1 high pts.

**#665 Molecular and clinical analyses of patients with gynecologic malignancies treated with PD-1 directed immunotherapy.** Young Kwang Chae, Sabina Murshudova, William H. Bae, Jonathan F. Anker, Mario J. Pineda, Wilberto Nieves-Neira, Daniela E. Matei, John R. Lurain, Shohreh Shahabi, Francis J. Giles. Northwestern University, Chicago, IL; Yonsei University College of Medicine, Seoul, Republic of Korea.

Long term responses are seldom seen in treatments of advanced or recurrent gynecologic cancers. In contrast, immunotherapeutic strategies targeting immune checkpoints such as programmed cell death-1 (PD-1) are currently in active development in platinum resistant gynecologic malignancies with promising durable responses observed in subset of patients. We analyzed all 14 pts with gynecologic malignancies that were treated with PD-1 directed immunotherapy, nivolumab or pembrolizumab at the developmental therapeutics program (DTP) clinic in Northwestern University during 2015 till 2016. Seven patients had ovarian/fallopian/peritoneal cancer; six, endometrial cancer; 1, squamous cell carcinoma (SCC) of cervix that are refractory to standard-of-care.
chemotherapies. Comprehensive genomic profiling including microsatellite instability (MSI) status and tumor mutational burden (TMB) analyses was performed using next generation sequencing (NGS) (FoundationOne). Among 7 patients with ovarian/fallopian/peritoneal cancer (median age, 62 years), objective response rate (ORR) was 20%. One patient had partial response (PR), another one had stable disease (SD), and 4 patients had progressive disease (PD). Two patients were unable to be evaluated. In a patient with PR, CA 125 level normalized from 426.2 to 10.8 U/mL. Her tumor had very low TMB (1/Mbp). In all patients, TMB level varied from very low to low (1-5 mut/Mbp) with MSI status being stable. Progression free survival (PFS) ranged from 14 to 196 days; overall survival (OS) varied from 60 to 199 days. Among 6 patients with endometrial cancer (median age, 68 years), ORR was 20%. One patient had PR while four experienced PD. One patient whose disease could not be assessed due to early death from an event unrelated to treatment had a remarkable chemical response with a decrease in CA125 level from 5,889 to 182.1 U/mL after one single dose. Her tumor had MSI-stable status and intermediate TMB (6 mut/Mbp). In a patient with PR, CA125 level decreased from 1,216 to 226.5 U/mL. Her tumor had MSI-high status with unknown TMB. Of note, one of four patients with PD had MSI-high status and intermediate level of TMB. Other patients had tumor with MSI-stable status and low level of TMB (3-4 mut/MB). PFS ranged from 23 to 258 days; OS varied from 73 to 265 days. One patient with HPV positive SCC of cervix (34 year old) experienced PD. Her tumor had MSI-stable status with unknown TMB. PFS was 88 days; OS, 132 days. In summary, patients with ovarian and endometrial cancer treated with PD-1 directed immunotherapy demonstrated ORR of 20%. One additional patient with endometrial cancer had an exceptional chemical response. None of the tumors had high TMB (≥6/Mbp). No clear associations between genomic traits including TMB and MSI status and responses were found. Further larger prospective studies are warranted to explore potential biomarkers for response with immunotherapy in gynecologic malignancies.

CD37 tetraspanin as a novel biomarker for PD-1 blockade in diffuse large B-cell lymphoma. Zijun Y. Xu-Monette, Ken H. Young, UT MD Anderson Cancer Ctr., Houston, TX.

PD-1 immune checkpoint blockade reconstituting antitumor immunity has changed the cancer treatment paradigm. PD-1 blockade has been successful in many types of solid tumors and Hodgkin lymphoma, but not yet for diffuse large B-cell lymphoma (DLBCL), the most common aggressive B-cell lymphoma. We found several biomarkers including loss of CD37 tetraspanin expression in DLBCL correlated with increased PD-1 expression suggesting potential sensitivity of these DLBCL subsets to PD-1 blockade. CD37 (TSPAN26) is a member of the tetraspanin superfamily, widely expressed on normal and malignant mature B-cells and downregulated in plasma cells. It has been documented that CD37 plays important roles in T-cell-B-cell interactions, B-cell humoral response triggered by B-cell receptor cross-linking, and a balance between immune responses and tolerance. Interestingly, in a large cohort of DLBCL patients, we found that loss of CD37 expression in DLBCL predicts strikingly decreased overall and progression-free survival rates, and that PDCD1 gene expression was upregulated in CD37-negative activated B-cell-like (ABC) DLBCL by gene expression profiling, whereas the costimulatory molecule ICOSLG was upregulated in GCB-like cell-like (GCB) DLBCL. Using quantitative real-time multiplex technology, we further measured PD-1 and PD-1 ligand expression at the protein level on lymphoma cells and immune cells in the tumor microenvironment, and found that PD-1 protein levels were increased on both cytotoxic and helper T-cells infiltrating in CD37-negative DLBCL either of ABC or GCB subtype. These novel discoveries suggest that CD37 is important for sustained an-titumor adaptive immunity, that immune dysregulation plays an important role for poor clinical outcomes in DLBCL, and that CD37-negative DLBCL may be sensitive to PD-1 blockade. In summary, loss of CD37 tetraspanin was found to correlate with PD-1 overexpression in DLBCL clinical samples, and CD37 may serve as a novel biomarker for anti-PD-1 immunotherapy clinical trials in DLBCL.

Immunoprofiling circulating blood as a means to early detection of solid tumors. Amit Kumar, 1 Dimitry Gabrilovich, 2 Frank J. Rauscher, 2 George Dominguez, 2 Cyrus Shoelvar, 1 John Roop, 1 Anthony Campisi, 1 Alexander Polo 2. 1Itus Corporation, Los Angeles, CA; 2Wistar Institute, Philadelphia, PA.

Our goal was to evaluate whether profiling Myeloid Derived Suppressor Cells (MDSCs) in circulation correlated with the existence and stage of multiple biopsy-verified solid tumor types and to evaluate whether such analyses could enable early detection. The tumor micro-environment (TME) is replete with numerous immune cells, and the type and concentration of such cells can provide prognostic information. The link between high concentrations of MDSCs and poor prognosis is most likely due to the immuno-suppressive effects of such cells. Some fraction of these cells spill into the blood stream. We utilized flow cytometry to phenotypically quantify subsets of MDSCs and other leukocytes in the circulation of biopsy-verified cancer patients, as well as in age and sex matched healthy donors. Our results indicate a marked increase in MDSC levels in the circulation of tumor patients relative to healthy donors. We have analyzed patients presenting over a dozen solid tumor types (lung, breast, ovarian, colon, melanoma, liver, thyroid, pancreatic, uterine, osteosarcoma, appendiceal, jeio-myosarcoma, liposarcoma, and vulvar) and found notable differences in the immune-profiles of circulating blood in these patients. It appears that the immune response, as measured by our flow cytometry technique, is general for most tumor types. We will present correlations and inter-relations between different cell types and evidence of tumors. While our studies to date have been performed in an unblinded manner, we will present performance data (specificity and sensitivity) for our approach.

Evaluation of α-1-acid glycoprotein as a predictive biomarker for severe neutropenia induced by docetaxel in esophageal carcino ma patients. Yusuke Sasaki, 1 Ken Kato, 1 Hidekazu Hirano, 1 Hirokazu Shoji, 1 Yoshihata Honma, 1 Satoru Iwasa, 1 Atsuo Takashima, 1 Tetsuya Hanaguchi, 2 Kengo Nagashima, 3 Narikazu Boku 2. National Cancer Center Hospital, Hakodate Central General Hospital, Tokyo, Japan; 3National Cancer Center Hospital, Tokyo, Japan; 4Chiba University Graduate School of Medicine, Chiba, Japan.

Background: Serum α-1-acid glycoprotein (AAG) level is an independent predictor of response and a prognostic factor of survival in patients with non-small cell lung cancer treated with docetaxel chemotherapy. However, whether AAG is associated with the outcomes of esophageal cancer patients treated with docetaxel remains unclear. Methods: Between August 2009 and April 2014, pre-treatment serum samples were obtained from patients with clinical stage II/III esophageal cancer. Individuals were subsequently treated with neoadjuvant DCF or CF followed by surgery. DCF consisted of docetaxel and cisplatin on day 1, and continuous infusion of 5-fluorouracil on days 1-5, with this regimen repeated every three weeks for up to three cycles. CF consisted of cisplatin and 5-fluorouracil. Patients were divided into groups based on the median value of baseline AAG levels. Response to chemotherapy, survival, and the most severe grade of neutropenia were compared between the high and low AAG groups at each regimen. Results: A total of 129 patients were enrolled (44 received neo DCF and 85 neo CF). The median serum AAG level was 95 g/L (range 57-225 g/L) and 95 g/L (range 46-197 g/L) in the patients with neo DCF and CF, respectively. For all patients, overall survival (OS) was significantly shorter in the high AAG group (AAG ≥ 95 g/L) than the low AAG group (AAG < 95 g/L) (HR 2.18, p=0.03). Both in the neo DCF and neo CF patients, there was a similar trend in OS between individuals with high and low AAG levels. Multivariate analysis demonstrated that AAG levels (OR of AAG ≥ 95 g/L in both neo DCF and neo CF) was an independent prognostic factor. However, the relationship between response to chemotherapy and AAG level were similar both in DCF and CF patients. In addition, grade 4 neutropenia was observed in 50% of patients with low AAG level and 23% with high AAG (p = 0.06) in DCF patients. A correlation analysis revealed a statistically significant correlation between serum AAG level and nadir absolute neutrophil count (r = 0.53) and performance status in patients with high AAG. However, in CF patients, there was no difference in the frequency of severe neutropenia between individuals with high and low AAG level, and there was no correlation between AAG and nadir neutrophil count. Conclusions: Serum AAG level may be a prognostic marker for survival in stage II/III esophageal cancer patients treated with neoadjuvant chemotherapy. In addition, low serum AAG level is a potential predictive biomarker of docetaxel-induced severe neutropenia.

Quantification of estrogen (ER) and progesterin receptor (PR) as well as HER2/neu proteins and gene expression improves discrimination of clinical behavior by triple positive breast carcinomas. Zohair R. Hameed, Michael W. Daniels, D. Alan Kerr, James L. Wittliff. University of Louisville, Louisville, KY.

IHC analyses of ER, PR and HER2 proteins are used as clinical biomarkers for breast cancer management. However, IHC provides semi-quantitative results sometimes complicated by variation in methods and interpretation. Our goal was to ascertain clinical use of these three analytes to predict breast cancer recurrence when analyses for gene expression and protein products were quantified. Procedures: We examined ER and PR protein in 1059 de-identified carci-noma biopsies previously quantified by radio-ligand binding and/or enzyme immunoassay (EIA) using FDA approved reagents and HER2 oncoprotein determined by EIA to assess relationships between biomarker profiles and disease-free (DFS) and overall survival (OS) for 123 patients. Our comprehensive, IRB-approved Database also contained de-identified Microarray results obtained.
Gallbladder carcinomas involve multiple cascades of oncogenes like EGFR and Kras. Activation of Kras downstream pathways predict the sensitivity to anti EGFR treatment. For 2012, the first time it was established that GBC and cholangiocarcinomas have their unique somatic genomic landscape and thus be studied independently. This study evaluates whether EGFR is a prognostic factor in GBC and identifies the frequency of codon 12 and codon 13 Kras mutations, along with its association with subject survival. Seventy two GBC curative resections from North India were immunostained with anti EGFR monoclonal antibody and assessed for codon 12 and 13 KRAS mutation by real time PCR. Strong EGFR expression was observed in 25.4 percent cases. About 28/72; G12C, 17/72; G12R, 10/72; G12D and 18/72; G13D cases harboured point mutations in Kras gene, which was significantly higher as compared to control tissues. Multivariate analysis revealed that EGFR expression (p = 0.01; HR = 3.14; 95percent CI = 1.28-7.71) and codon-13 mutation (p = 0.001; HR = 38.34; 95percent CI = 4.90-300.01) had a significant impact on survival and were independent prognostic factors in GBC. Our study suggests that EGFR expression and codon 13 mutations are independent prognostic factors in the selected GBC cohort and showed a high frequency of Kras codon 12 mutations as well.

#670 Integrative genomic analysis of alterations driving anti-androgen treatment resistance in vitro. Dong Shen,1 Brendan Hodkinson,2 Deborah Ricci,1 Karin Verstraeten,2 Michael Schaffer,1 Michael Gormley,1 Shibu Thomas1,1 Janssen Research & Development, Spring house, PA; 2Janssen R&D BE, Beerse, Belgium.

Prostate cancer is one of the most frequently diagnosed cancers in the world. It is the second most common type of cancer and the fifth leading cause of cancer death in American men. Enzalutamide (MDV) and apalutamide (ARN-509) are recently the acquired F876L mutation of the androgen receptor (AR) was treated with prednisone in metastatic castration-resistant prostate cancer. Al- acetate (ABI) is an androgen biosynthesis inhibitor which is used in combina- It is the second most common type of cancer and the fifth leading cause of cancer death in American men. Enzalutamide (MDV) and apalutamide (ARN-509) are prostate cancer cells resistant to enzalut- amide and apalutamide. To systematically identify and understand the mecha- canisms of resistance, we evaluated 22RV1 and LNCaP prostate cancer cells which were resistant to the treatment of enzalutamide (MDV), apalutamide (ARN-509), and abiraterone acetate (ABI). We isolated the DNA and RNA from both resistant cells and their parent cell line. We did RNAseq for gene expression analysis, whole exome sequencing to identify the DNA alterations, and array CGH for copy number change analysis. We confirmed the acquired F876L mutation of the AR identified in LNCaP cells resistant to apalutamide. We identified the novel G644R and R630Q mutations of AR, R213* mutation of TP53, N372H mutation of BRCA1, and E626I mutation of ATM in LNCaP cells which were resistant to the treatment of enzalutamide and apalutamide. For copy number alterations, we identified acquired copy number gain on chromosome 3, 8, and 18 on 22RV1 resistant cells, and acquired copy number loss on LNCaP resistant cells. Besides acquired DNA alterations, we identified 16 up-regulated and 24 down-regulated genes which are common in both 22RV1 and LNCaP cells resistant to enzalutamide and apalutamide. Through pathway enrichment analysis, we identified the Wnt/B-catenin, cAMP signaling, and TREM1 signaling pathways were up-regulated in 22RV1 and LNCaP cells resistant to enzalut- amide and apalutamide. Detection of acquired genetic alterations in cells resis- tant to anti-androgen treatment provides us with important insights into the mechanisms of their resistance. Further testing of clinical samples collected at disease progression after treatment with these agents is required to validate these findings.

#671 Prognostic importance of EGFR expression and Kras gene mutations in gallbladder carcinoma. Anjali Singh,1 Abul Kalam Najmi,1 Pramod Mishra,2 Majid Talikoti,1 Jamia Hamdard, New Delhi, India; 2MAMC, Delhi University, New Delhi, India.

#672 Baseline serum albumin as a prognostic factor in patients with stage I and II colon adenocarcinoma. Luis F. Onate-Ocana, Instituto Nacional de Cancerología, Mexico City, Mexico.

Background: Patients with stage I or II colon carcinoma (CC) have a significa- nt risk of recurrence after adequately performed curative resection. Adjuvant chemotherapy has not improved recurrence or survival in such patients. In this study, a prognostic model in patients with stage I or II CC is presented. Methods: Consecutive cases with CC treated at a cancer center in Mexico City from January 2008 to December 2014, with diagnosis of adenocarcinoma by colonoscopy and biopsy were included in this cohort. Patients were treated according to standard guidelines. Follow-up continued until June 2016; the Kaplan-Meier method and the Cox model were used to analyze the association of prognostic factors and overall survival (OS). Results: 1,259 cases of CC were treated; only 496 patients have stage I and II CC and were included in the database: 234 women (47.2%) and 266 males (52.8%) and their mean age was 59.9 years (SD 14.9); 96, 339, 31 and 30 cases were TNM stages I, IIa, IIb, and IIIc, respectively. Multivariate analysis of prognostic factors is depicted below. Predicted survival functions using this model, defined 4 risk groups that showed better prognostic value than simple TNM stages I-IIc. Conclusion: A new, simple, cheap and widely available prognostic factor in patients with CC: Albumin and other clinical factors add significant prognostic information to TNM classification. Feasibly, it can be used to develop multivariate prognostic models with clinical impact defining the use of adjuvant chemotherapy. The use of histopathological and immunohistochemical markers could improve the prognostic information of this model.

#673 Exploration of tissue morphologies in breast cancer samples using unsupervised machine learning. Riku Turkki,1 Dmitrii Bychkov,1 Nina Linder,2 Jorma Isola,3 Heikki Joensuu,4 Johan Lundin,5 1Institute for Molecular Medicine Finland, Helsinki, Finland; 2Translational Cancer Biology Research Program, Helsinki, Finland.

We applied a machine learning approach for exploration of tissue morpholog- y in hematoxylin and eosin (H&E) stained breast cancer tissue microarray.
(TMA) samples. We then investigated whether the morphological categories produced were associated with clinically relevant molecular biomarkers and 10-year overall survival. The data set comprised digitized (0.22 μm/pixel) and H&E stained TMA spots from tumor samples of 490 women who were diagnosed with primary breast cancer within a Finnish breast cancer database (Fin-Proc) collected in 1973 and 1992. In order to quantitatively describe the morphologies of the TMA spots, we divided the tissue images into rectangular sub-images (224x224 pixels), and extracted features with a pre-trained convolutional neural network. We then clustered the sub-images (n = 147,266) with a non-linear data embedding algorithm that creates a two-dimensional mapping of the tissue morphologies. Lastly, we defined a quantitative profile for each tumor, describing the morphologies within the tissue spot image by dividing the two-dimensional map of morphologies into 128 separate clusters with k-nearest neighbor clustering. Visual inspection of the two-dimensional embedding of tissue spot images verified that the morphologies clustered coherently, i.e. similar looking sub-images formed distinct clusters in the map. Interestingly, some morphological patterns were strongly associated with tumor estrogen receptor content, progestosterone receptor content, human epidermal growth factor receptor 2 status, and the proliferation marker Ki-67 status (p <0.0001 for each comparison). In exploratory analyses we identified one morphological category that was associated with a favorable 10-year overall survival with a risk ratio of 0.68 (CI95% 0.53-0.89, p = 0.002, power = 0.87). Our work demonstrates that unsupervised machine learning can be applied to explore and better understand the role of morphological patterns in breast cancer. Method: We quantitatively assess the morphology of cancer tissue may complement molecular biomarkers and potentially reveal novel prognostic and predictive factors.

**#674 HPV16 was the preponderant type of HPV infection in cutaneous squamous cell carcinoma.**

Gang Shi,1 Anne C. Fischer,2 Jonathan M. Zelnik,3 Patti E. Gravitt,4 Max Fischer,4 Inbal B. Sander,1 Jonathan D. Cuda,1 Janis M. Taube,1 Mohammed Lilo,1 W P Andrew Lee,1 Anthony P. Tufaro1.

1Johns Hopkins University School of Medicine, Baltimore, MD; 2Florida Atlantic University, Boca Raton, FL; 3Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 4University of Maryland School of Medicine, Baltimore, MD.

Purpose: Human papillomavirus (HPV) has been well established as a causative factor in mucosal oropharyngeal cancer and anogenital surface malignancies. However, its etiological role in cutaneous squamous cell carcinoma (cSCC) is still debated. The aim of this study is to identify the presence of HPV types in cSCC and identify their associations with cSCC. Methods: 77 cSCC blocks from 54 patients underwent DNA isolation and a broad spectrum of HPV PCR tests to detect the presence of HPV genotypes by the use of a universal primer pair GP5+/GP6+. The resultant PCR products were cloned to T Vectors and subsequently underwent DNA sequencing and Nucleotide BLAST search to identify the HPV types in cSCC. To ensure the accuracy of the HPV PCR test, 16 blocks from 10 head and neck SCC (oropharyngeal) patients were also included in the HPV presence and type analyses. Cutaneous SCC patients' demographics, pathology and clinical parameters were compared and analyzed statistically in conjunction with the HPV test results. Results: HPV DNA was found in 37 of 77 (48.1%) blocks representing 32 of 54 (59.3%) cSCC patients. HPV16 was the predominant type of infecting HPV in cSCC and accounted for 35 of 37 (91.5%) HPV positive and 31 of 37 (84.2%) HPV positive patients and blocks. Other HPV genotypes found included HPV18, 57, 10, 2, accounting for 4 of 32 (12.5%), 2 of 32 (6.25%), 2 of 32 (6.25%), 2 of 32 (6.25%) of the HPV positive patients and 4 of 37 (10.81%), 2 of 37 (5.41%), 2 of 37 (5.41%) of the HPV positive blocks, respectively. HPV infection was significantly associated with the cSCC tumor size in this cohort of patients. Tumors with a size of ≤20mm were more frequently associated with HPV. Moreover, the average tumor size of the HPV positive group was also significantly smaller than that of the HPV negative group. Conclusions: HPV infection is very commonly found in cSCC patients and HPV16 is the major type of HPV involved in cSCC oncogenesis, accounting for >80% of HPV infections. HPV16 is a contributory factor in such appears to be contributing to a smaller size of cSCC, which may improve the prognostic classification of patients to provide a new insight into tumorigenesis.

**#675 The interaction between hedgehog and EMT pathway in non-small cell lung cancer and its prognostic implication.**

Ho Jung An,1 Jae-Tae Jung,1 Young Il Soa,2 Chang Suk Kang1.1 St. Vincent’s Hospital, The Catholic University of Korea, Suwon, Republic of Korea; 2Yeouido St. Mary’s Hospital, The Catholic University of Korea, Seoul, Republic of Korea.

Introduction: The Hedgehog (Hh) signaling plays essential role in transcription regulation and embryonic development. In many cancers including lung cancer, it is related to carcinogenesis and poor prognosis. This signaling also mediates epithelial to mesenchymal transition (EMT) by paracrine mechanism in various diseases. We aim to study the interaction between Hedgehog and EMT pathway and its clinical implication in non-small cell lung cancer (NSCLC). Method: Total 271 cases of NSCLC who received surgical resection in Yeouido St. Mary’s Hospital between 1997 and 2011 were included. For immunohistochemical analysis of Hh and EMT related proteins, 4um sections were cut and Hh and EMT pathway related proteins were immunostained (Shh, Patched (Ptc), Smoothened (Smoo), Glialoma-associated oncogene (Gli-1) and Suppressor of fused (Sufu), and EMT associated molecules including E-cadherin and vimentin were analyzed. Staining intensity (IS) was estimated as follows (0 no staining), + (1 weak), + (2 distinct), 3 (strong). Intensity score (IS) ≥1 was defined as positive. Medical record was retrospectively reviewed. The study was approved by the institutional review board the hospital. Results: The median age was 63 (18-84) years, and 65.3% were male. Squamous cell carcinoma was diagnosed in 113 (41.7%), adenocarcinoma in 153 (56.5%), and mixed type in 153 (56.5%). Stage 1 and 2 were 46.9% and 30.6%, respectively, and 8 cases had distant metastasis. The Hh proteins showed positive correlation each other. For EMT, the expressions of Hh protein was significantly correlated with tumoral and stromal positivity of vimentin, and inversely with positivity of E-cadherin (P = 0.002 and P = 0.028, respectively). In survival analysis, expressions of Shh and Gli1 were independent predictor of disease free survival and cancer-specific survival (P = 0.007 and P = 0.025, respectively). Conclusion: Expression of Hh protein is associated with epithelial-mesenchymal transition and associated with poor prognosis in NSCLC.

**#676 Nuclear expression of insulin receptor (InsR) adds prognostic information in primary breast cancer patients with high BMI.**

Sofie Björn,1 Anja H. Rosendahl,1 Maria Simonsson,2 Andrea Markkula, Karin Jirström, Signe Borgquist,1 Carsten Rose,1 Christian Ingvar,1 Helena Jernström,1 Lund University, Lund, Sweden.

Aim and Introduction: The aim of this study was to elucidate the prognostic importance of nuclear expression of the insulin receptor (nucInsR) in primary breast cancer. The nucInsR is important for the metabolism, for the insulin-like growth factor (IGF) signaling network and is implicated in breast cancer. Insulin and InsR are interlinked with obesity and body mass index (BMI), which are also associated with breast cancer. The nucInsR is present both in the membrane and cytoplasm and can additionally translocate to the nucleus. The role of nucInsR is not well understood and the prognostic importance is unclear. Methods: The tumor-specific expression of nucInsR was evaluated by immunohistochemistry on invasive breast cancer tissue microarrays from 984 primary breast cancer patients included in a population-based cohort in Sweden. Patients were followed for up to 11 years, the median follow-up for patients still at risk was five years. nucInsR in relation to prognosis was analyzed using Cox regression, adjusted for age, invasive tumor size, axillary lymph node involvement, histological grade, estrogen receptor (ER) status, BMI, tumor storage time, and treatment. Results: Status of nucInsR was available for 900 patients (91.5%). nucInsRstatus was present in 214 patients (23.8%) and was associated with lower age (P = 0.004), and lower waist-to-hip ratio (P = 0.006), but not with BMI, ER or PR status. During follow-up, 107 patients had a first breast cancer event. The risk of first breast cancer event was significantly lower in patients with nucInsR<sup>+</sup> status compared to nucInsR<sup>-</sup> patients (HR = 0.58, 95% CI 0.35-0.96) and not significantly different in patients with BMI >30 kg/m<sup>2</sup>. Conclusions: These results indicate that nucInsR status may add prognostic information in primary breast cancer depending on BMI.

**#677 Progralin/PGP88 tumor tissue expression further stratifies survival outcomes of patients classified by their Nottingham Prognostic Index.**

Ginette Serrero,1 Douglas Hawkins,2 Olga Ioffe,3 Pablo Bejarano,4 Binbin Yue1.1 AEG Pharmaceuticals, Inc., Columbia, MD; 2University of Minnesota, Minneapolis, MN; 3University of Maryland Greenbaum Comprehensive Cancer Center, Baltimore, MD; 4Cleveland Clinic Florida, Weston, FL.

Background: The Nottingham Prognostic Index (NPI) combines nodal status, tumor size and histological grade and is used to provide predictive value information on survival for patients with primary breast cancer. Attempts to improve the performance of NPI have been carried out by inclusion of other factors, such as biomarker expression as well as addition of other structural features such as vascular invasion. In the present study, we investigated whether expression of the survival factor PGP88 (progralin), known to be overexpressed in breast cancer, would improve NPI’s predictive value. GPP88/Progralin is an 88 kDa autocrine growth and survival factor that is overexpressed in estrogen receptor

Proceedings of the American Association for Cancer Research. Volume 58 • April 2017
positive (ER+), invasive ductal carcinoma (IDC) in association with resistance to anti-estrogens and aromatase inhibitor while the cells remain ER+. Previous training and validation pathological studies totaling 600 cases of ER+ IDC had demonstrated that GP88/Progranulin tissue expression was an independent prognostic marker of recurrence and mortality for early stage ER+ IDC. Methods: We processed 11 normal and 8 tumorous lung resection specimen. For all the kinomes extracted, we developed a corrective approach. We applied resection specimen. For all the kinomes extracted, we developed a corrective approach. The new biomarkers are essential for improving the survival and prognosis of hepatocellular carcinoma (HCC) patients. Alpha-fetoprotein (AFP) is the most widely used biomarker. But the low sensitivity and specificity limits its clinical application. Recent study validated the diagnostic capability of osteopontin (OPN) and dickkopf-1 (DKK1) and assessed the combination of AFP, DKK1, and OPN as a panel for the diagnosis of HCC. Based on these previous studies, we hypothesized that combination of OPN and DKK1 can be used as a marker for prognosis of patient to HCC after hepatectomy. From January 2006 to December 2008, patients undergoing hepatectomy for hepatocellular carcinoma were screened for samples that had been stored in the Bank of tumor. To target the selected patient, it was confirmed that the remaining tissue specimen is stored after diagnosis. Serum of the patients was used to investigate the OPN and DKK1 by ELISA. In the paraffin block were prepared unstained slide and OPN and DKK1 level checked by IHC. It examined the correlation between prognosis and biomarkers through statistical analysis. AFP, OPN (serum level) and DKK1 (serum level) were an independent prognostic factor for overall survival (OS) in HCC after hepatectomy (n = 60, P = 0.0204, 0.0167 and 0.0455 respectively). New biomarkers combinations based on the AFP existing biomarker were showing a falling curve of the overall survival (OS) and disease-free survival (DFS) in Kaplan Meier curve. In conclusion, combination of OPN, DKK1 and AFP as a biomarker could support the correct diagnosis for HCC after hepatectomy.

### #680 Prognostic impact of OPN and DKK1 in patient of hepatocellular carcinoma after hepatectomy, Yun Sung Seo, Hye Rim Byeon, In Hae Park, Seung Duk Lee. National Cancer Center, Goyang-si, Gyeonggi-do, Republic of Korea.

The new biomarkers are essential for improving the survival and prognosis of hepatocellular carcinoma (HCC) patients. Alpha-fetoprotein (AFP) is the most widely used biomarker. But the low sensitivity and specificity limits its clinical application. Recent study validated the diagnostic capability of osteopontin (OPN) and dickkopf-1 (DKK1) and assessed the combination of AFP, DKK1, and OPN as a panel for the diagnosis of HCC. Based on these previous studies, we hypothesized that combination of OPN and DKK1 can be used as a marker for prognosis of patient to HCC after hepatectomy. From January 2006 to December 2008, patients undergoing hepatectomy for hepatocellular carcinoma were screened for samples that had been stored in the Bank of tumor. To target the selected patient, it was confirmed that the remaining tissue specimen is stored after diagnosis. Serum of the patients was used to investigate the OPN and DKK1 by ELISA. In the paraffin block were prepared unstained slide and OPN and DKK1 level checked by IHC. It examined the correlation between prognosis and biomarkers through statistical analysis. AFP, OPN (serum level) and DKK1 (serum level) were an independent prognostic factor for overall survival (OS) in HCC after hepatectomy (n = 60, P = 0.0204, 0.0167 and 0.0455 respectively). New biomarkers combinations based on the AFP existing biomarker were showing a falling curve of the overall survival (OS) and disease-free survival (DFS) in Kaplan Meier curve. In conclusion, combination of OPN, DKK1 and AFP as a biomarker could support the correct diagnosis for HCC after hepatectomy.

### #681 Methylylomics profiling reveals epigenetically silenced HSYST2 sensitize ILS signaling and confers poor prognosis of ovarian cancer, Rui-Lan Huang,2 Hisang-Ju Chan,2 Lin-Yu Chen,2 Yaw-Wen Hsu,2 Tai-Kuang Chao,2 Po-Hsuan Su,2 Yu-Chun Weng,1 Chio-Chung Yuan,1 Hung-Cheng Lai1.1 Taipei Medical University-Shuang Ho Hospital, New Taipei, Taiwan;2 Taiwan International Graduate Program Molecular and Cell Biology, Ph.D. Program, Academia Sinica, New Taipei, Taiwan;3 Graduate Institute of Life Sciences, National Defense Medical Center, Taipei, Taiwan;4 Tri-Services General Hospital, National Defense Medical Center, Taipei, Taiwan.

The attempts of target therapy in ovarian cancer therapy mostly fail. There is need of biomarkers for better patient stratification in clinical trials. Epigenetics is a driving force for cancer development and may serve as a molecular marker of the disease. The present study was to analyze the clinical relevance of methylation phenotypes and figure out the mechanism in ovarian cancer. We integrated the analysis using public dataset of epigenomics and transcriptomics, and our hospital-based methylylomics database and tissue arrays of patients diagnosed with epithelial ovarian cancers (EOC). Bioinformatics results were verified and validated in cell lines and clinical samples. From 25 genes, we identified even genes, ADRA1A, CD248, HSYST2, NFEH, IGSF21, POU4F2, and TWIST1, of which hypermethylation was significantly correlated to the poor overall survival (OS). The association of NFEH and HSYST2 hypermethylation and poor 5-year OS was validated in our independent dataset and TCGA database. The NFEH/HSYST2 hypermethylated signature was an independent risk factor for 5-year OS (adjusted Hazard ratio = 2.93, 95% confidence interval 1.25 to 6.85, P = 0.013). In vitro experiment re-expressing HSYST2 repressed migration and invasion, and suppressed IL-6 signaling pathways. The combination of hypermethylation of HSYST2 and high expression of IL-6 confers the worse outcome. Our data suggested that methylation of NFEH/HSYST2 constituted a poor prognostic signature of ovarian cancer. The siluation status of proteoglycan modified by HSYST2 implicates an intrinsic sensitivity of ovarian cancer cells to IL-6, which shed a new light on the application of HS3ST2 as a biomarker for personalized medicine of targeting IL-6.

### #682 Novel Mesenchyme Homeobox2-target transcription axes are involved in cancer-drug resistance, overall survival and therapy prognosis in lung cancer patients: a functional epigenome wide study, Federico Avila Moreno,1 Leodl Armas Lopez,2 Patricia Piña-Sánchez,2 Oscar Arrieta,2 Enrique Gúzman de Alba,3 April Marcela Herrera-Solórito,1 Blanca Ortiz-Quintero,1 Patricia Santillán-Doherty,2 David C Christiani,1 Joaquin Zúñiga,1 Universidad Nacional Autónoma de México (UNAM), Mexico City, Mexico;2 Instituto Mexicano del Seguro Social (IMSS), Mexico City, Mexico;3 Instituto Nacional de Cancerología (INCAN), Mexico City, Mexico;4 Instituto Nacional de Enfermedades Respiratorias (INER) Ismael Cosío Villegas., Mexico City, Mexico;5 Harvard School of Public Health, Boston, MA.

In recent years, the development of targeted therapy for cancer has been a major focus of research and clinical practice. One of the major challenges in cancer treatment is the development of drug resistance, which can lead to treatment failure and poor patient outcomes. In this study, we aimed to explore the role of a novel transcription axis, consisting of the transcription factor Mesenchyme Homeobox2 (Mhx2) and its target transcription factor, in the development of drug resistance in lung cancer. We used a functional epigenome-wide approach to identify changes in DNA methylation, histone modifications, and non-coding RNA expression that were associated with drug resistance in lung cancer cell lines. Our results showed that changes in the expression of Mhx2 and its target genes were strongly associated with drug resistance, providing a potential mechanism for the development of drug resistance in lung cancer. These findings suggest that targeting the Mhx2-Moreno and Intoc molecule, which could serve as a potential therapeutic target to overcome drug resistance in lung cancer.
CLINICAL RESEARCH: Checkpoint Inhibitor and Prognostic Biomarkers

#683 Quantification of rare PD-L1 expressing leukocytes and CTCs in peripheral blood of cancer patients. Adam Jendrisak, Jiyoun Byun, Mahipal Suraneni, David Lu, Rachel Krupa, Sarah Orr, Ryon Graf, Yipeng Wang, Mark Landers, Ryan Dittamore. Epic Sciences, San Diego, CA.

Background: Expression of PD-L1 on tumor tissue is associated with improved response to PD-L1 checkpoint inhibitors. Additionally, expression of PD-L1 on infiltrating T cells is associated with immune exhaustion. Currently, PD-L1 analysis is performed on surgically removed or biopsied samples, usually taken long before clinical decision points. Animals are monitored for survival and tumor growth. The immune biomarkers in CTCs as well as leucocytes will allow real time assessment of liquid biopsy based platform that is capable of simultaneously measuring immune biomarkers in CTCs as well as leukocytes will allow real time assessment of response to immune checkpoints inhibitors.

Lung cancer remains the most progressive malignant disease strongly resistant to oncological therapies including platinum-derived cancer drugs and Epidermal Growth Factor Receptor (EGFR)-Tyrosine Kinases Inhibitors (TKIs). Homeobox-related gene (HOX) transcription factors as Mesenchyme HOX-2 (MEOX2) have previously been associated with cancer-drug resistance, progression and metastasis in lung cancer patients. However, transcriptional mechanisms epigenetically modulated have not totally been elucidated in lung cancer therapy resistance. Here an epigenomic strategy was conducted to identify a novel MEOX2 gene sequence-promoter targets profile, associated or involved in therapy resistance mechanisms in human lung cancer. For that chromatin from human non-small cell lung carcinomas (NSCLC), MEOX2 versus RNA Pol II immunoprecipitation and hybridization assays using genomic tiling-arrays and bioinformatics analyses were performed, which set of quantitative and functional assays with clinical-outcome validation predictions analyses, were assessed. Stringent bioinformatics results identified a common profile of 13 gene promoter sequences, which included in others Sonic Hedgehog-GLI-1, ALDH1A2, MMP24, RUFY3 and ZEB1 (FDR<0.1) in NSCLC patients with different clinical outcome data. GLI-1 promoter sequences upstream -2,192 to -109 quantitatively validated, were occupied by MEOX2 and RNA Pol II in both NSCLC cell lines and NSCLC patients, as well as significantly enriched with the histone activation marks H3K27Ac and H3K4me3, in addition, confirmed by the ENCODE database bioinformatics analyses. Furthermore, a set of genetic silencing functional assays validated a novel transcriptional MEOX2-GLI1 axis in a cisplatinum dose-dependent manner, involved in cellular migration, invasion, and proliferation capacity. Finally, MEOX2-GLI1 axis expression was clinically validated and analyzed using Kaplan-Maier survival analyses on an independent cohort of 90 NSCLC patients, identifying a significant MEOX2-dependent GI1-1 overexpression statistically associated with clinical poorer overall survival prognosis and treatment response into cisplatinum-based first-line therapy and/or second-line EGFR-TKIs target therapy protocols. In conclusion, a chromatin-immunoprecipitation and epigenome-wide analysis based on the MEOX2-transcriptional observation study, identified novel MEOX2-transcriptional gene promoter axes involved in embryonic development, oxidoreductase activity, matrix metalloprotease, cellular polarity, epithelial-mesenchyme phenotype, cancer cell migration and invasion pathways. Promoting cisplatinum-based resistance mechanisms and EGFR-TKIs based therapy response prognosis in human lung cancer.

#684 Integrative proteomics and transcriptomics to define the cell surface landscape of neuroblastoma. Amber K. Weiner,1 Simone Sidoli,1 Tina Glisovic-Aplenc,2 John M. Maris,2 Benjamin A. Garcia,1 Sharon J. Diskin2. 1Univ. of Pennsylvania School of Medicine, Philadelphia, PA; 2Children's Hospital of Philadelphia, Philadelphia, PA.

BACKGROUND. Neuroblastoma (NB) is an embryonal tumor of the sympathetic nervous system that accounts for 12% of childhood cancer deaths. Despite intense multimodal therapy, survival probability for high-risk NB patients remains below 50% and relapsed NB is essentially incurable. To date, the cell surface landscape of NB at diagnosis and relapse is currently unknown. An unbiased survey of these proteins and their isoforms will greatly facilitate the identification of candidate immunotherapeutic targets for preclinical validation. METHODS. To identify proteins on the cell surface of NB, we performed plasma membrane protein extraction utilizing an optimized sucrose density gradient methodology followed by nano-liquid chromatography coupled to mass spectrometry (nLC-MS/MS) in NB cell lines. Proteomic data is integrated with RNA-sequencing data to assess the correlation between these data types, determine differential expression between NB (n=2242) and normal tissues (n=7889), and investigate NB-specific isoforms. In parallel, we have developed a software tool to aid in proteomic data analysis and interpretation. RE-

CLINICAL RESEARCH: Childhood Cancer Clinical Translational Research

#684 Integrative proteomics and transcriptomics to define the cell surface landscape of neuroblastoma. Amber K. Weiner,1 Simone Sidoli,1 Tina Glisovic-Aplenc,2 John M. Maris,2 Benjamin A. Garcia,1 Sharon J. Diskin2. 1Univ. of Pennsylvania School of Medicine, Philadelphia, PA; 2Children's Hospital of Philadelphia, Philadelphia, PA.

BACKGROUND. Neuroblastoma (NB) is an embryonal tumor of the sympathetic nervous system that accounts for 12% of childhood cancer deaths. Despite intense multimodal therapy, survival probability for high-risk NB patients remains below 50% and relapsed NB is essentially incurable. To date, the cell surface landscape of NB at diagnosis and relapse is currently unknown. An unbiased survey of these proteins and their isoforms will greatly facilitate the identification of candidate immunotherapeutic targets for preclinical validation. METHODS. To identify proteins on the cell surface of NB, we performed plasma membrane protein extraction utilizing an optimized sucrose density gradient methodology followed by nano-liquid chromatography coupled to mass spectrometry (nLC-MS/MS) in NB cell lines. Proteomic data is integrated with RNA-sequencing data to assess the correlation between these data types, determine differential expression between NB (n=2242) and normal tissues (n=7889), and investigate NB-specific isoforms. In parallel, we have developed a software tool to aid in proteomic data analysis and interpretation. RE-
SULTS. To date, we have applied our proteomic approach to nine NB cell lines stratified by MYCN amplification. This methodology has yielded on average 66% (range: 60-68%) membrane protein enrichment with high reproducibility between biological replicates (80%; range: 78-84%). This has allowed us to confirm known cell surface proteins that are currently being developed as immunotherapeutic targets in neuroblastoma (e.g., GPC2 in NB-M1). We are also using this approach to investigate the mass spectrometry based proteomics data, where we identified 4826 membrane proteins, with RNA-sequencing data to evaluate proteins expressed uniquely in neuroblastoma and those that correlate with MYCN amplification. We are further determining how RNA and protein levels correlate on the cell surface and will utilize these data to detect NB-specific isoforms. In parallel, we have initiated a clinical trial at Baycrest Hospital in Toronto, an efficacious tool for applying to clinical trials whose cellular responses match clinically relevant differences between patient subsets, such as MYCN status, survival hazard ratio, or histopathological assessment. To evaluate the method, we used onTARGET prediction to identify compounds and gene targets relevant for clinical outcomes in the NIH-TARGET (n=249) and R2-AMC (n=98) neuroblastoma cohorts. The algorithm confirmed existing targets and made interesting predictions. Of the top-ranking compounds associated with a survival outcome, agents targeting the mTOR/P38 axis are highly prevalent. The algorithm correctly predicts targeting of the MYC pathway, and predicts possible modulators of MYC signaling, such as TRRAP, AU-RKA and BMP2. In addition to nominating agents with a favorable outcome, the algorithm can also flag compounds that might worsen prognosis, further facilitating prioritization of targets for evaluation. In summary, onTARGET may guide target selection for neuroblastoma studies and can be adapted for other cancers as well. The many targets that were identified immediately suggest an opportunity for continued evaluation in cells and in vivo models. This work has been initiated in collaboration with researchers at Lund University.

One of the main bottlenecks of anticancer drug development is the assessment of the in vivo relevance of emerging therapies. Previously, drugs that suppress the in vivo progression of neuroblastoma have been hard to identify. To address this problem, we propose a new computational technique, onTARGET, that enables researchers to select, with good accuracy, compounds that are likely to show meaningful activity in cell lines derived from neuroblastomas and patient tumors and potentially other cancers.

The in vivo activity of compounds that are selected by onTARGET can be validated through a panel of in vivo models, including human xenografts, both 11q-deleted and MYCN-driven transgenic nude mice, and both induced and primary patient-derived xenografts (PDXs) and patient tumors are ongoing to define the cell surface landscape in both diagnostic and relapsed NB.

### #686 GPC2 is an oncogenic and immunotherapeutic target in high-risk neuroblastoma

**Katherine S. Tajsic,1,2 Dustin M. English,1,2 Marcin K. Chojnowski,1,2 Robert C. Luo,1,2 Jessica A. Hightower,1,2 Michael L. Dyer,1,2 Maria F. Gotuzzo,1,2 Jennifer A. Monahan,1,2 Bryant B. Backer,1,2 Casey J. Kugler,1,2 Andrew J. Court,1,2 Michael E. Rock,1,2 Genie A. Sutcliffe,3 and Jeffrey I. Benkovic,1,2**

High-risk neuroblastoma (HR-NB) is the most common extracranial solid tumor in children and is characterized by aggressive behavior, limited response to conventional therapies, and high mortality rates. One of the main bottlenecks in the drug development process is the assessment of the in vivo relevance of emerging therapies. Previously, drugs that suppress the in vivo progression of Neuroblastoma have been hard to identify. To address this problem, we propose a new computational technique, onTARGET, that enables researchers to select, with good accuracy, compounds that are likely to show meaningful activity in cell lines derived from neuroblastomas and patient tumors and potentially other cancers. The algorithm correctly predicts targeting of the MYC pathway, and predicts possible modulators of MYC signaling, such as TRRAP, AU-RKA and BMP2. In addition to nominating agents with a favorable outcome, the algorithm can also flag compounds that might worsen prognosis, further facilitating prioritization of targets for evaluation. In summary, onTARGET may guide target selection for neuroblastoma studies and can be adapted for other cancers as well. The many targets that were identified immediately suggest an opportunity for continued evaluation in cells and in vivo models. This work has been initiated in collaboration with researchers at Lund University.

### #687 Targeting tumor-promoting neuroblastoma microenvironment: inhibition of tumor development and progression by targeting mPGES-1 expression by cancer associated fibroblasts

**Anna Kock,1 Per-Johan Jakobsson,1 Per Kogner1,2,3,4,5,6, and Christian Lindahl7**

The tumor microenvironment is a network of cells, cell-cell and cell-matrix interactions that provide cues for tumor proliferation, survival, and invasion. In neuroblastoma, the tumor microenvironment plays an essential role in disease progression and treatment resistance. Early targeting of mPGES-1 may inhibit CAF infiltration and tumor growth. In this study, we investigated the role of mPGES-1 in the tumor microenvironment of human neuroblastomas and developed a computational strategy that enables researchers to select, with good accuracy, compounds that are likely to show meaningful activity in cell lines derived from neuroblastomas and patient tumors and potentially other cancers.

One of the main bottlenecks of anticancer drug development is the assessment of the in vivo relevance of emerging therapies. Previously, drugs that suppress the in vivo progression of neuroblastoma have been hard to identify. To address this problem, we propose a new computational technique, onTARGET, that enables researchers to select, with good accuracy, compounds that are likely to show meaningful activity in cell lines derived from neuroblastomas and patient tumors and potentially other cancers. The algorithm correctly predicts targeting of the MYC pathway, and predicts possible modulators of MYC signaling, such as TRRAP, AU-RKA and BMP2. In addition to nominating agents with a favorable outcome, the algorithm can also flag compounds that might worsen prognosis, further facilitating prioritization of targets for evaluation. In summary, onTARGET may guide target selection for neuroblastoma studies and can be adapted for other cancers as well. The many targets that were identified immediately suggest an opportunity for continued evaluation in cells and in vivo models. This work has been initiated in collaboration with researchers at Lund University.

### #686 onTARGET: a new computational strategy to predict in vivo relevant targets against neuroblastoma

**Elin Almstedt, Ingrid Lönstedt, Cecilia Krona, Sven Nelander. Uppsala University, Uppsala, Sweden.**

One of the main bottlenecks of anticancer drug development is the assessment of the in vivo relevance of emerging therapies. Previously, drugs that suppress the in vivo progression of neuroblastoma have been hard to identify. To address this problem, we propose a new computational technique, onTARGET, that enables researchers to select, with good accuracy, compounds that are likely to show meaningful activity in cell lines derived from neuroblastomas and patient tumors and potentially other cancers. The algorithm correctly predicts targeting of the MYC pathway, and predicts possible modulators of MYC signaling, such as TRRAP, AU-RKA and BMP2. In addition to nominating agents with a favorable outcome, the algorithm can also flag compounds that might worsen prognosis, further facilitating prioritization of targets for evaluation. In summary, onTARGET may guide target selection for neuroblastoma studies and can be adapted for other cancers as well. The many targets that were identified immediately suggest an opportunity for continued evaluation in cells and in vivo models. BACKGROUND: The alpha particle emitting radiotherapeutic [211At]-MABG theoretically has superior radiobiological properties for anti-tumor efficacy compared to the currently used agent ([131I]MIBG). Specifically, [211At]-MIBG does not target microscopic deposits due to the long path length of the beta particles, while alpha particles have both a short path length and higher linear energy transfer that can create clustered DNA double strand breaks. Here we sought to define the anti-tumor activity of [211At]-MABG in preclinical models of human neuroblastoma (NB). METHODS: [211At]-MABG was synthesized using a bismuth target via the 209Bi(2n,2n)211At reaction and used for solid-phase radiosynthesis of [211At]-MABG (Ultraspace, Progenics, NY). We determined NET (SLG6A2) mRNA and protein expression in 35 NB cell lines and created isogenic pairs by overexpression of NET in 5 NB cell models. We performed uptake, cytotoxicity, and biodistribution studies using these models with [131I]MIBG and [211At]-MABG and extrapolated human dosimetry. Additionally, dose escalation studies with [211At]-MABG (n=10 at each dose, range 10-100 uCi) were performed to determine toxicity in SCID mice. Therapeutic in vivo trials were conducted with NET transfected xenografts and patient derived xenograft (PDX) models injected intravenously with escalating doses of [211At]-MABG and [131I]MIBG or vehicle (n=10 at each dose, range 10-100 uCi) and will be reported.

Introduction: The 5 year mortality rate for stage 4 metastatic neuroblastoma (NBL) is ~50%; however, the stage 4S subset of NBL is typically classified as low-risk with tumors exhibiting spontaneous regression. To date, the underlying genetic mechanisms influencing this distinct phenotype remain unknown. Method: To identify genetic determinants specific to the 4S phenotype, we performed genome-wide association study (GWAS) analyses. Blood DNA samples from 6,195 NBL patients and 11,384 non-NBL controls were genotyped using Illumina SNP arrays. European ancestry subjects were selected for inclusion in a discovery [stage 4S (n=148), stage 4 (n=996), non-NBL controls (n=9,923)] or replication cohort [stage 4S (n=76), stage 4 (n=608), non-NBL controls (n=1,461)]. Following imputation using 1KG Phase 3, we conducted case:case comparisons including 4S vs. 4 and stage 4S vs. 1, followed by comparisons of NBL cases in each group to matched non-NBL controls. Variants uniquely associated with 4S NBL were defined as those meeting the following criteria: (1) stage 4S vs. 4 meta P<5.0 x 10^-6 and P<0.005 in the discovery cohort (2) 4S vs. non-NBL control P<0.05 and (3) either not significant (P>0.05) or odds ratio in the opposite direction in 4 vs. non-NBL controls. Results: 4S-specific variants that met our criteria spanned multiple regions with several harboring genes important to neuronal function including 9q34 (SARDH/DBH; rs2502746), 1p32.2 (KCNAH; rs12112252), 1p34 (KCNS4; chr 1:41317634), 7q34 (CNOT3; rs79403134) and 2q24.1 (KCNJ3; rs78829625). At the 9q34 locus, rs2502746 showed further evidence as an expression quantitative trait locus (eQTL) for Dopamine Beta-Hydroxylase Antisense RNA1 (DHAS-AS1 P=1.9 x 10^-6 sun-exposed skin) and Sarcosine Dehydrogenase SARDH expression (P=2.5 x 10^-6 whole blood). Other 4S-specific loci observed include 3q27.3 (rs113207181), 8p23.1 (rs12548388), and 15q12 (rs62189512). Notably, none of the previously identified NBL susceptibility loci were found to be associated with 4S NBL in the 4S vs. non-NBL control comparison, suggesting a unique genetic basis for this enigmatic subset. Discussion: Although a unifying mechanism underlying 4S NBL has yet to be identified, our results suggest a potential role for ion-channel and neuronal function genes. Ongoing efforts include investigating the role these genes and associated pathways play in NBL, including an integrative genomic, epigenomic and transcriptome analysis of stage 4 and 4S NBL.

**#689** Immune checkpoint targeting to improve immunotherapy in neuroblastoma. Myrna L. Ortiz-Ruiz, H. Lee Moffitt Cancer Ctr. & Res. Inst., Tampa, FL.

Neuroblastoma (NB) is the most common extracranial solid tumor in children. Current treatments account for only the at most 40% of survival rate in high-risk NB patients. Hence, there is a need to develop new strategies that disrupt immunosuppressive signals in the tumor microenvironment in order to achieve robust anti-tumor immune responses. Co-inhibitory signals through receptors such as PD-1 can lead to the inactivation of T cells. On the other hand, co-stimulatory signals through receptors such as 41BB can enhance T cell activity against tumors. These receptors can serve as tools to develop strategies to optimize and enhance T cell anti-tumor functions. In this study, we used 9464D NB tumor mouse model to evaluate antibody treatment as a possible immunostrategy. We further examine the infiltration and function of T cells after targeting checkpoints in 9464D NB tumor bearing mice. Blockade of various receptors in mice bearing 9464D tumor showed that anti-41BB delayed tumor growth without MYCN amplification. MYCN is a regulator of ornithine decarboxylase (ODC), the rate-limiting enzyme of polyamine biosynthesis. Inhibition of this pathway in MYCN-amplified NB tumors has been shown to be a target for treatment. Alpha-difluoromethylornithine (DFMO) inhibits ODC and is currently being used in a Phase II clinical trial for NB. BET inhibitors JQ1 and OTX-115 have been shown to be effective against MYCN-amplified cancers; it is hypothesized that they downregulate MYCN as well as cancer stem cell (CSC) signaling. We propose that inhibiting MYCN with a BET inhibitor, coupled with inhibition of ODC with DFMO, will result in enhanced inhibition of NB growth and tumor-initiating properties. Methods: Single and combination drug treatments were conducted on BE(2)-C, SMS-KCN, CHLA90, and one patient-derived cell line. CellTiter-Glo Luminescent Cell Viability Assay was used to determine cell viability in 96-well plates. IC50 values were calculated with a four-parameter variable-slope dose response curve using GraphPad Prism v.5 software. Drug combination studies were conducted in MYCN amplified tumors BE(2)-C and SMS-KCN using ray designs to evaluate for synergism. Incucyte ZOOM Live-Cell Imaging system was used for kinetic monitoring of cytotoxicity and apoptosis in NB cells. Western blots measured protein levels of apoptosis markers (cleaved caspase 3 and cleaved PARP) and CSC markers (Nanog, Sox2, NF-kB, CXCXR4, Lin28B, and MYCN). Neurosphere assays were used to evaluate tumor initiation via sphere formation. Results: Cell viability of MYCN amplified NB showed an IC50 range of necheckpoint targeting. Also we want to test adoptive transfer of T cells in tumor bearing mice after BMT. Further we want to measure the infiltration of other immune cells, such as myeloid cells and Tregs, in the tumor environment and possible target immune suppressive populations to see the effects in tumor growth.
After T cell receptor (TCR) identification, retrovirally TCR transduced CD8+ generated by priming with A*02:01 overexpressed and required for proliferation in ES. We isolated HLA-A*02:01eral and in Ewing sarcoma (ES) in particular. ES is a highly malignant bone releasing IGFs from IGFBPs. The insulin/IGF-axis is involved in cancer in gen-

A*02:01- healthy donors directed against PAPPA, generated by priming with A*02:01 TCR peptide restricted T cells from A*02:01+ healthy donors directed against PAPPA, generated by priming with A*02:01 TCR peptide-loaded dendritic cells. After T cell receptor (TCR) identification, retrovirally TCR transduced CD8+ T cells were assessed for their in vitro specificity and in vivo efficacy in human ES bearing Rag2-/- mice. Engraftment in mice and tumor infiltration of TCR transgenic T cells in the mice was evaluated. The TCR transgenic T cell clone PAPPA-2G6 demonstrated specific reactive towards HLA-A*02:01+ PAPPA+ ES cell lines. We furthermore detected circulating TCR transgenic T cells in the blood in Rag2-/- mice and in vivo engraftment of the in bone marrow. Tumor growth in mice with xenografted ES was significantly reduced after treatment with PAPPA-2G6 TCR transgenic T cells compared to control treatment, and tumors from treated mice revealed tumor infiltrating PAPPA-2G6 TCR transgenic T cells. In summary, we demonstrate that PAPPA is a promising target for TCR based immunotherapy of ES. We demonstrate that TCR transgenic T cells recognize this target, home to the tumor, and causes tumor regres-

Pappalysin-1 is a suitable target for T cell receptor transgenic T cells to kill Ewing sarcoma in vivo and in vitro. Uwe Thiel,1 Andreas Kirschner, Melanie Thie1, Thomas GP Grünewald,2 Rebeca Alba Rubio,2 Günther Rich-

ter,3 Thomas Kirchner, Dirk Busch,2 Poul Sorensen,4 Stefan Burdach1. #692 Pappalysin-1 is a suitable target for T cell receptor transgenic T cells to kill Ewing sarcoma in vivo and in vitro.

#694 BK-216: a novel, first-in-class, small molecule inhibitor of EWS-FLI1 in early
development, for the treatment of Ewing Sarcoma. Sarvana P. Selvanathan,1 Eric Moseley,1 Garrett T. Graham,1 Katti Jessen,2 Brian Lan-

nutt,2 Aykut Uren,1 Jeffrey A. Toretsky3,3*Georgeotown University, Lombardi Comp. Cancer Center, Washington, DC; 3Oncertal Therapeutics, Inc., San Di-

go, CA.

One of the most significant challenges in creating more potent, less toxic treatments for patients to identify new cancer therapeutic targets that distin-

TK-216 displays anti-tumor activity in a number of ES xenograft

models and characterization of YK-4-279, an enantiomer-specific inhibitor of EWS-FLI1, which has been demonstrated to induce apoptosis, inhibit EWS-FLI1 trans-

scription, block RNA helicase A co-immunoprecipitation with EWS-FLI1, and result in alternative splicing to mimic EWS-FLI1 knockout. Continuous eff-

orts in structure-guided medicinal chemistry has yielded TK-216, an analog of YK-4-279 inhibitor of EWS-FLI1, which is 3-4 fold more potent with excellent drug-like properties. TK-216 potently inhibits the proliferation of ES cells. In-

duces apoptosis in a dose-dependent manner as measured by caspase-3 activity in multiple ES cell lines with different translocation variants. The effects of TK-

216 on alternative splicing (AS) were further validated using genes including ARID1A, CLK1, CASP3, PPP1R3B and RUNX2. The splicing pattern was similar between TK-216 and YK-4-279. In addition to the in vitro activity of TK-216, we show that TK-216 displays anti-tumor activity in a number of ES xenograft models. In summary, TK-216, a novel, first-in-class therapeutic which directly inhibits EWS-FLI1, offers a promising approach for the treatment of Ewing Sarcoma and is currently in Phase 1 clinical trials in patients with relapsed or refractory Ewing Sarcoma (clinicaltrials.gov - NCT02657005).

#695 Targeted nanoparticle therapy for poor prognosis Ewing’s sarcoma. Hyung-Gyo Kang,1 Jon Nagy,2 Julia Samulak,3 Timothy Triche1. USChil-

dren’s Hospital Los Angeles, Los Angeles, CA; 2Nano Valient Pharmaceuticals, Bozeman, MT.

Targeted nanoparticles have shown the potential to deliver anticancer drugs to cancer cells selectively and thus to overcome unexpected cytotoxicity and limited efficacy of chemotheraphy caused by non-selective delivery to normal cells. The optimal formulation of targeted nanoparticles for actual translational applications has not been established. By refining early formula-

tions and after extensive testing, we have created an optimized targeted delivery system, HPLNs (Hybrid Polymerized Liposomal Nanoparticles) and demon-

strated that this new, targeted nanoparticle technology overcomes many of these deficiencies. This technology has tremendous potential for treating virtually any type of cancer. The goal of our present study was to determine the efficacy and toxicity of this novel targeted nanoparticle in the treatment of Ewing’s Sarcoma, a rare and highly lethal cancer of children and young adults. The efficacy of this targeted delivery system was compared to 1) administration of the free drug and 2) the drug in untargeted nanoparticle form. Our studies have shown that HPLN-DDX targeted with human antiCD99 antibodies can successfully inhibit the growth of Ewing’s Sarcoma in murine models without any detectable off-
target toxicity. The deliverable for our study was to demonstrate that the effectiveness of doxorubicin in the treatment of recurrent Ewing's sarcoma could be dramatically improved when encapsulated in human antiCD99 antibody targeted HPLNs. At the same time, toxic side effects normally seen with free drug was not detectable. Success with human anti-CD99 antibodies targeted HPLNs containing doxorubicin was then compared to the control and experimental groups utilizing the student t-test. P-values <0.05 were considered statistically significant. Additional statistical analyses were conducted as per the Pediatric Preclinical Testing Program analysis plan. Results: Lenvatinib was generally well tolerated in vivo, without noted toxicity in any of the treated animals. Lenvatinib treatment led to delayed tumor progression in 4/5 models tested. Relative tumor volumes in the treatment group compared to the control group at week 3 in xenografts OS1, OS2, OS17, OS31, and OS33 were 0.77 (p = 0.013), 0.88 (p = 0.147), 0.49 (p < 0.001), 0.66 (p < 0.001), and 0.40 (p < 0.001), respectively. Despite delayed progression observed in the OS xenografts treated with lenvatinib, all groups experienced progressive disease by the end of the study period. Conclusions: Single agent lenvatinib demonstrates consistent anti-tumor activity in osteosarcoma patient derived mouse xenograft models. Preclinical studies, as well as clinical trials, have demonstrated the efficacy of tyrosine kinase inhibition in combination with mTOR in a variety of malignancies. The current study, along with prior data, suggests that targeting receptor tyrosine kinases, in addition to mTOR, may lead to more effective inhibition of osteosarcoma cell growth. Ongoing studies are assessing the efficacy of lenvatinib, administered in combination with mTOR inhibitor, everolimus, in osteosarcoma patient derived mouse xenografts.

#698 Functional outcome and socio-psychological problems for bone & soft tissue sarcoma patients in childhood & AYA generation. Kanya Honoki,1 Toshiaki Shinomiya,2 Hiromasa Fuji,1 Takashi Ishihara,2 Shinji Tsukamoto,1 Shingo Kishi,1 Yumiko Kondo,1 Akira Kido,1 Toshifumi Tsuchijichi,1 Midori Shima,1 Yasuhiito Tanaka1. 1Nara Medical Univ., Nara, Japan; 2Kandai Univ., Higashiosaka, Japan.

[Objective] To elucidate the problems between functional and sociological outcomes in patients of bone and soft tissue sarcomas in childhood and adolescent/young adult (AYA) generation. [Method] Clinical (prognostic and functional) and socio-psychological outcomes were retrospectively analyzed in 50 patients with bone and soft tissue sarcomas under 29 years old treated in our institute from 1998 to 2014. [Results] Twenty-two patients under 15 and 28 of AYA generation (15 to 29 years old) (28 male and 22 female) were subjected, including 35 cases of bone and 15 cases of soft tissue sarcomas, and 39 of extremity cases. Most common diagnosis was osteosarcoma of 27 cases. Limb-sparing surgery was performed in 30 cases, including 14 of prosthetic and 8 of biological reconstruction for bone tumors. Overall Survival rates were 79% for 2 year and 61% for 5 year follow-up periods. 70% of the patients experienced limited activities; 50% in high school and college students experienced drop-out or delay, suspension and repeating the same class; 56% faced to their job lost or limitation of job search; 20% experienced changes of relationship with families and partners (Table). Most taken palliative care intervention was the counseling for fear, pain, nausea and sleeplessness in patients and caregivers, besides pain management and psychological care. Correlation coefficient failed to show a significant correlation between functional score and sociological disability score both in all limb sparing cases (R² = 0.2664) and in osteosarcoma cases ((R² = 0.1757). [Conclusion] The sociological problems for patients in this particular group could be focused on school life, job search and relationship with families and partners. QOL is a multidimensional measure with various domains, such as physical, psychological, social well-being, spiritual health as well as functional ability, therefore, multi-disciplinary care for socio-psychological and psychological disadvantage must be taken for this group of patients at earliest convenience.

### #700 Characterization of the mode of action of Fenretinide treatment in alveolar rhabdomyosarcoma cells.

Eva Brack, Marco Wachtel, Beat W. Schaefer. University Children’s Hospital Zurich, Zurich, Switzerland.

Alveolar rhabdomyosarcoma (ARMS) is a highly malignant childhood malignancy characterized by a specific chromosomal translocation encoding the oncogenic transcription factor PAX3-FOXO1. As ARMS cells are addicted to the tumor-specific fusion protein, it may serve as an ideal therapeutic target. Previously, we have identified from a large drug library screen the compound Fenretinide (4-hydroxy-p-hydroxyanilide), which is already in clinical use, to inhibit both PAX3-FOXO1 expression as well as ARMS cell viability. The aim of this study was therefore to characterize the mode of action of Fenretinide in more detail. First, we were able to show that Fenretinide induced the generation of reactive oxygen species (ROS) in mitochondria. A more detailed characterization revealed that the Fenretinide-induced ROS derives from an interaction of Fenretinide around complex II of the mitochondrial respiratory chain, leading to the production of superoxides. ROS scavenging as well as complexing of iron ions completely abolished cell death. To identify the mode of cell death involved, we then used a range of pharmacological inhibitors of specific cell death pathways including Z-vad (pan-caspase inhibitor), Necrostatin-1 (necroptosis pathway inhibitor RIP-1 kinase inhibitor), 3-Methyladenine (3-MA) (autophagy pathway inhibitor (phosphatidylinositol 3-kinase inhibitor)) and Ferrostatin (ferroptosis pathway inhibitor) during Fenretinide treatment.

Surprisingly, none of these inhibitors alone was able to prevent cell death and even different combinations were not sufficient to completely inhibit cell death. CRISPR/Cas9 mediated depletion of key players in the apoptotic and necrotic pathway (Bak, Bax and RIPK1) confirmed the pharmacological data. We therefore conclude that the other, less characterized cell death pathways or a combination of several pathways including apoptosis and necroptosis might be crucial. Interestingly, electron microscopic examination of cells pointed towards an excessive accumulation of vacuoles to be characteristic. Taken together, our data show that Fenretinide shows high potential for the treatment of ARMS, inducing several forms of cell death mediated through the production of ROS. These properties open the search for additional compounds acting in a combinatorial manner.

---

### #701 Pazopanib synergizes with clofarim tosylate in the treatment of malignant rhabdoid tumors.

Celine Chaunvin¹, Aurianne Lescure¹, Wilfrid Richer¹, Arnaud Tautié-Espariat², Amaury Leruste³, Zhi-Yan Han⁴, Didier Surdez⁵, Stefano Cairo⁶, Eléna Del Nery⁷, Olivier Delattre⁸, Franck Bourdeaut⁹.

¹Curie Institute, Paris, France; ²Sainte-Anne Hospital, Paris, France; ³XenTech, Epernay, France.

Background: Rhabdoid tumors (RTs) are rare, highly aggressive pediatric malignancies which occur in kidney, soft-parts and brain of young children. They are characterized by a complete inactivation of the SMARCB1 tumor suppressor gene encoding a core subunit of the chromatin remodeling SWI/SNF complex. Prognosis for children with RTs is poor as, in many instances, these tumors are resistant to conventional chemotherapy. Hence, new therapies should be designed and biologically-driven strategies targeting the SMARCBI deficiency or its biological consequences have to emerge. Methods: For this purpose, we realized a high-throughput screening by using the Prestwick Chemical Library of 1200 FDA-approved drugs on two rhabdoid tumor cell lines and one SMARCB1 reexpressing cell line. Cell count was assessed by automatic cell counting using DAPI. Results: Among 10 drugs that showed cytotoxic activity specifically in SMARCBI-deficient cell lines, we identified vatalanib, a broad receptor tyrosine kinase (RTK) inhibitor. This prompted us to analyse the response to a wider number of 9 RTK inhibitors on 7 SMARCBI-deficient cell lines compared to 6 SMARCBI-expressing cell lines. “This supervised” screening confirmed the activity of vatalanib but showed that pazopanib had an even greater cytotoxic effect on SMARCBI deficient tumor cells. We also identified a potassium channel inhibitor (clofarim tosylate), that showed among the strongest cytotoxic activity as a single agent, and also synergistically reduced viability and induced apoptosis, when combined with vatalanib and pazopanib. With in vivo experiments on two patient-derived xenograft (PDX) models of rhabdoid tumor, we notably showed that pazopanib is effective in reducing tumor growth and that combination with clofarim tosylate enhanced the anti-tumor activity of pazopanib in the two PDX models. Interestingly, we also highlighted that pazopanib combined to conventional chemotherapies is even more efficient than chemotherapy alone. Finally, to identify candidate kinases that confer pazopanib sensitivity to rhabdoid tumor cell lines, we performed a phosphoarray experiment and found PDGFRα, PDGFRβ and FGFR2 as pazopanib targets, RTK that were among the most highly expressed in our in vitro profiling dataset. Conclusion: To conclude, our findings demonstrate that targeting PDGF and FGF axis is an effective means of therapy against rhabdoid tumors. We therefore propose that pazopanib should be tested in children with rhabdoid tumors in which there is a dire need for an effective therapy.
of 35 days for control against 21 days for CPd/nATF5, P=0.0013. CP-d/n-ATF5 also reduced SK-N-BE(2)C metastatic burden in the liver (P<0.05) and bone marrow (P<0.01). In the rhabdoid PDX model, there was a significant inhibition of tumors treated with CP-d/n-ATF5 as compared to Penetratin treatment, with a mean tumor volume of control 1283 ± 266.6 mm³ (n=15) vs CPd/n-ATF5 234.2 ± 43.7 mm³ (n=11), at day 10 within which tumors showed a median post-treatment time of 13 days to reach threshold volume. None of the CP-d/n-ATF5 treated tumors reached the threshold after 28 days of treatment with some tumors demonstrating regression, indicating a profound anti-tumor effect of the peptide. Conclusion: For our study shows that a novel ATP5-targeting peptide CP-d/n-ATF5 has broad and profound cytotoxic and apoptotic effects in several pediatric tumors in vitro and in vivo. Our study also indicates that CP-d/n-ATF5 has the potential to act as an anti-metastatic agent.

#703 Combinatory treatment for pediatric low grade glioma with the dual mTORC1/2 inhibitor TAK228 and MEK inhibitor Trametinib
Antje Arnold,1 Fausto Rodriguez,2 Charles George Eberhart,3 Eric Hutton Raabe3, Johns Hopkins University School of Medicine; Division of Neuropathology and Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD; Johns Hopkins University School of Medicine; Division of Neuropathology and Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD.

Pediatric low grade glioma (PLGG) is one of the most common childhood tumors. If the tumor is located in a region of the brain that is not accessible for surgical resection or if the tumor recurs after surgery, additional therapies are needed. Recent studies highlighted the important role of mTORC1/2 and MEK-activation in PLGG. The dual mTORC1/2-inhibitor, TAK228, and MEK-inhibitor, Trametinib, have been developed as promising candidates for targeted therapy PLGG. We hypothesized that TAK-288 and Trametinib would show synergistic effects both in vitro and in vivo in PLGG models. We treated the PLGG derived cell lines Res186 and Res259 with TAK-228, Trametinib, and vehicle. Cell growth was investigated using MTT-assay over different days and compared to the treatment with the vehicle. DNA replication was measured through bromodeoxyuridine (Brdu) incorporation assay and apoptosis was evaluated through cleaved caspase 3 (CC-3) staining. Cells were analyzed and counted with ImageJ. Activation of MAPK pathway was detected via Western Blot by phosphorylated pERK compared to total pERK. Cells were analyzed and counted with ImageJ. Activation of MAPK pathway was detected via Western Blot by phosphorylated pERK compared to total pERK. We observed a significant increase in Res186 cells after drug treatment. MAPK pathway was activated in a dose-dependent manner. Res186 have a significant reduction in cell growth after 4 days treatment (TAK-288: 20nM, **p<0.01; Trametinib: 20nM, **p<0.01). Res259 showed a significant reduction at the same time point, but with a higher drug dose (TAK-288: 50nM, *p<0.05; Trametinib: 50nM, **p<0.01). IC50 values for TAK-288 was 15nM for Res186 and 20nM for Res259 cells on day 4. IC50 values for Trametinib was 50nM for Res186 and 100nM for Res259. Staining for CC-3 showed a significant increase for apoptosis in Res259 cells after treatment with TAK-288 or Trametinib (**p<0.01). No positive CC-3 staining was detected in Res186 cells after drug treatment. MAPK pathway was activated in a dose-dependent manner as determined by phosphorylated pERK Western Blot after TAK-288 and inactivated after Trametinib treatment. No change in total ERK compensation was found. This suggests that the compensatory mechanism is independent of mTORC signaling by upregulating MAP kinase signaling. Our preliminary results show that the PLGG-derived cell lines are sensitive to TAK-228 and Trametinib treatment. All cell lines showed decreased proliferation at various doses of either inhibitor. The increased MAP kinase activity we identified after TAK-288 treatment suggests a compensatory mechanism that may render these cells especially sensitive to treatment with both TOC1/2 and MEK inhibitors. We will now investigate both drugs in vivo. Evidence of activity in murine models will be necessary to provide a pre-clinical rationale for combination therapy of these agents in aggressive PLGG.

#704 Therapeutic potential of Delta24-2ACT, a novel immunostimulatory oncolytic adenovirus, for the treatment of pediatric solid tumors: Initial study in pHHG, DIPG and osteosarcoma
Marcia García-Mouré,1 Naïara Martínez-Vélez,1 Enric Xipell,1 Marisol González-Huarriz,1 Ana Patiño,1 Oren J. Becher,2 Cande Gómez-Manzano,3 Juan Fueyo,3 Marta M. Alonso1.

#1University of Navarra, Pamplona, Spain;2Duke University School of Medicine, Durham, NC;3The University of Texas MD Anderson Cancer Center, Houston, TX.

Pediatric High Grade Glioma (pHHG), including Diffuse Intrinsic Pontine Glioma (DIPG), and osteosarcoma are amongst the most common and lethal pediatric solid tumors. Despite improvements in surgery, radiotherapy and chemotherapy, the outcome for children affected with these malignancies remains dismal since the current treatments are ineffective and ineffective in killing severe side effects. Thus, it is critical to implement novel and radically different therapeutic approaches to improve the survival and quality of life of these children. Delta24 is a modified adenovirus with a tumor dependent replication, and its antitumor effect has been tested in preclinical and clinical models of both high grade glioma and osteosarcoma. The adenovirus demonstrates a preferential tropism to tumor cells. Furthermore, this virus has the potential to induce antitumor immunity, by the virus and the immune system. Here we describe the generation of a new oncolytic adenovirus Delta24-2ACT, based on the Delta24 platform, encoding an immunostimulatory protein. For this project we used relevant immunocompetent pediatric solid models. The toxicity of the virus was assessed by dose-escalation experiments. Delta24-2ACT was well tolerated and did not lead to important adverse effects. The antitumor effect of Delta24-2ACT was evaluated in immunocompetent mice bearing orthotopic supratentorial glioma, DIPG or local osteosarcoma that spontaneously metastasize to lungs, obtaining significant tumor shrinkage or complete elimination in some of them. Delta24-2ACT also promoted an increased T-cell infiltration within the tumor and an enhanced antitumor immune response. Of importance, treatment with Delta24-2ACT led to a significant increase in median survival in all the tumor models tested and resulted in long-term survivors free of disease. Furthermore, in our osteosarcoma model local treatment of primary tumors with Delta24-2ACT reduced spontaneous lung metastases, which are usually the leading cause of death in most of the patients affected by osteosarcoma. Currently, we are performing re-challenge experiments to evaluate a possible memory effect mediated by the virus and mechanistic studies to elucidate the mechanism of action. Altogether, these results demonstrate the potential therapeutic benefit of Delta24-2ACT adenovirus in the treatment of pediatric solid tumors such as pHHG, DIPG and osteosarcoma, representing an important milestone in the fight against cancer.

#705 Elucidating pediatric brain tumor pathophysiology by assessing signal transduction pathway activation

A major problem in pediatric neuro-oncology is lack of insight into underlying tumor biology, making treatment with targeted therapy challenging for this group of patients. To enable targeted therapy choice, understanding of underlying signal transduction pathway activity is required, as well as availability of appropriate diagnostic tests to predict therapy response. We have developed a novel method to identify activity of the ER, AR, HH, Wnt, TGFbeta, NFKB, and PI3K signal transduction pathways in an individual tumor. Our method is based on measurement of signal transduction pathway activity using a knowledge-based Bayesian network computational model which infers the probability of activity of the respective transcription factor (Verhaegh et al, Cancer Res. 2014). Public patient sample datasets from the GEO database were used to investigate pathway activation in pediatric brain tumors. Currently, we are performing re-challenge experiments to evaluate a possible memory effect mediated by the virus and mechanistic studies to elucidate the mechanism of action. Altogether, these results demonstrate the potential therapeutic benefit of Delta24-2ACT adenovirus in the treatment of pediatric solid tumors such as pHHG, DIPG and osteosarcoma, representing an important milestone in the fight against cancer.

#706 Combination ionizing radiation and oncolytic Seneca Valley virus injection enhances tumor cell killing of pediatric gliomas. Yuchen Du, Baylor College of Medicine, Houston, TX.

Background and Purpose: Radiation therapy is the traditional and only therapy that offers benefits to patients with diffuse intrinsic pontine gliomas (DIPG) due to the aggressive pediatric central nervous system tumors without known curative therapies. However, unfortunately, efficacy of radiation therapy is transient. Seneca Valley virus-001 (SVV-001) is a novel non-pathogenic oncolytic picornavirus that can be systemically administered and pass through brain blood barrier (BBB). Phase 1 clinical trial of SVV has proven its efficacy in adults patients with cancers with neuroendocrine features and pediatric patients with non-central nervous system tumors.

We sought to examine if combining ionizing radiation with an oncolytic virus SVV-001 would lead to synergistic enhanced tumor cell killing and significantly improve therapeutic efficacy in vivo in DIPG patient tumor-derived intra-brain stem orthotopic xenograft mouse models (PDOX). Methods: By infecting PDOX derived tumor cells with green fluorescent protein (GFP)-coupled SVV (SVV-GFP) or SVV-001, in vitro virus infection and anti-tumor activity of SVV were examined by cell viability assay, Western Blotting for apoptosis and autophagy-related protein and immunohistochemistry (IHC) staining or Flow cytometry for cell mitochondria content. In vivo therapeutic efficacy was evaluated by systemic administration of SVV into PDOX derived DIPG xenografts alone or in combination with irradiation. Results: We first had established a novel panel of nine PDOX derived orthotopic xenograft mouse models of DIPG. Our data confirmed that SVV can infect and efficiently kill DIPG tumor cells in vitro by inducing apoptosis and autophagy, leading to improved animal survival in a subset of DIPG xenograft models. We found that the lack of mitochondria in the xenograft tumor cells in vivo impaired the intracellular replication of SVV-001 and subsequently compromised its oncolytic cell killing of tumor cells in vivo. Radiation induced elevated mitochondria biogenesis in tumor cells therefore boosted SVV oncolysis of tumor cells. Moreover, combining fractionated radiation with single i.v. injection of SVV led to significant improvement of animal survival in a subset of DIPG models. Conclusion: SVV-001 killed DIPG xenograft cells in vitro. Radiation activated mitochondria content of tumor cells in vivo which restored intracellular SVV-001 oncolysis. Combining radiation with single systemic administration of SVV synergistically enhanced animal survival in a subset of DIPG xenograft models.

#707 Personalization of dexamethasone in acute lymphoblastic leukemia. Rosanna K. Jackson,1 Ali Alhammer,2 Zach Dixon,2 Gareth J. Veal,1 Julie AE Irving1. 1Newcastle University, Newcastle, United Kingdom; 2Bristol University, Bristol, United Kingdom.

Synthetic glucocorticoids, such as dexamethasone (Dex), are pivotal in the treatment of acute lymphoblastic leukemia (ALL) but remain with significant variability, both in terms of toxicity and efficacy. We aimed to investigate three key variables to better understand how Dex personalization may be achieved: pharmacokinetics (PK), intracellular Dex accumulation, and cellular response, following Dex binding to the glucocorticoid receptor (GR) in ALL cells. For Dex PK studies, blood samples were collected post oral administration on one of the first three days of induction chemotherapy in 99 patients on the UKALL 2011 trial receiving either 0.8mg/m2 for 28 days (standard arm) or 10mg/m2 for 14 days (short arm). Plasma Dex levels were analysed using a validated LC/MS method, and a non-compartmental pharmacokinetic analysis. To assess intracellular Dex levels, cell lines, primagraft (n=9) and primary patient samples (n=6) were studied. The plasma Dex LC/MS method was optimized to quantify Dex in ALL cell lysates. Dex accumulation was also assessed using flow cytometric analysis of Dex conjugated to FITC. Cellular Dex sensitivity was assessed using Alamar Blue assays. There was a wide Dex PK variability, with $AUC_{0-12}$ and $C_{max}$ significantly higher on the short compared to the standard arm; 564 (202-1606) versus 408 (142-1009), median (range), $p=0.003$ and 0.0006, respectively. However there was substantial overlap between the two arms, with the standard arm exhibiting higher exposure on average than those on short therapy. These data suggest that while PK and cellular response are hugely variable, variations in drug accumulation do not appear to play a key role in Dex response in ALL cells. Importantly, 62% of patient cell samples had Dex GI50 values greater than plasma concentrations observed in any patient, on both arms on the UKALL 2011 trial. A combined approach incorporating PK assessments and cellular response in ALL cells should be further investigated, to allow a comprehensive understanding of Dex pharmacology with a view to optimizing its clinical utility.

#708 Prohibition is a prognostic marker of treatment failure and therapeutic target to block chemotherapy resistance in Wilms tumor. Michael Vincent Ortiz1, Melissa Burns2, Amy Eisenberg,3 Saima Ahmed,4 Lyvia Gaewsky,5 Gary Bradwin,6 Paolo Cifani,7 Anton Henssen,8 Ian Macarthur,9 Michael LaQuaglia,10 Anthony Letal11, Arlene Narango,12 Samantha Gadd,13 Yuh-Yun Chi,14 Jeffrey Dome,15 Elizabeth Perlman,16 Elizabeth Mullen,17 Hanno Steen,18 Alex Kendis19. 1Memorial Sloan Kettering Cancer Center, NY; 2Boston Children’s Hospital, MA; 3University of California, Berkeley, CA; 4Dana Farber Cancer Institute, MA; 5University of Florida, FL; 6Lurie Children’s Hospital of Chicago, IL; 7Children’s National Medical Center, DC.

Wilms tumor (WT) is the most common kidney tumor of children. Over the last three decades, clinical trials employing multi-modality therapies have resulted in overall survival of greater than 90% for patients with low-risk disease. In spite of these advances, treatment of patients with advanced, anaplastic, and relapsed Wilms tumors remains challenging, with substantial rates of treatment failure and death. To improve risk stratification and identify novel therapeutic targets, we used high-accuracy mass spectrometry urinary proteomics to identify urine tumors markers associated with relapsed WT and non-WT renal tumors. We measured urine proteins at diagnosis of 54 patients with relapsed WT, clear cell sarcoma, rhabdoid tumor, and age-matched controls, leading to the quantitation of 6,519 urine proteins. In particular, we identified specific urine WT markers, including those that were enriched in patients with relapsed WT, such as mitochondrial regulators prohibitin and DAD1, β-catenin antagonist DACT2, and DNA repair factor SUN1. Using a specific enzyme-linked immunosorbent assay (ELISA) developed to measure urine prohibitin in an independent cohort of 139 WT and control samples, we found that urine prohibitin concentrations over 1000 ng/mL were significantly associated with the risk of disease relapse, with an odds ratio of relapse of 1.53 and receiver operating characteristic area under the curve of 0.77 (95% confidence interval of 0.64-0.99). Immunohistochemical tumor analysis revealed that prohibitin was highly expressed in primary Wilms tumor specimens. Importantly, using loss- and gain-of-function genetic experiments, we found that prohibitin was required for the growth and survival of Wilms tumor cells, and its overexpression conferred concomitant resistance to vincristine, doxorubicin and actinomycin D. Consistent with prohibitin’s functions in mitochondria, we are using BH3 profiling to elucidate specific intrinsic apoptotic dependencies in distinct sub-sets of refractory Wilms tumors, as a prelude to rational combination blockade of chemotherapy resistance, such as blockade of BCL2 dependence using venetoclax. In all, the use of urine prohibitin measurements may improve initial therapy stratification, and enable monitoring of response to therapy and early detection of relapse. In addition, targeting of chemotherapy resistance induced by prohibitin overexpression may offer improved therapies for patients with relapsed or refractory Wilms tumors.

#709 Incidence and mortality of diethylstilbestrol-related clear-cell adenocarcinoma of the vagina and cervix: 40 years of long-term follow-up. Dezheng Huo, Diane Anderson, Arthur L. Herbst. Univ. of Chicago, Chicago, IL.

Objective: Women exposed to diethylstilbestrol (DES) in utero are at increased risk for the development of vaginal and cervical clear cell adenocarcinoma (CCA), and possibly of breast cancer, diabetes, and cardiovascular diseases as well. A peak in the age-incidence curve in DES-related CCA has been documented at ages 19 to 24. It is unknown if a second peak will occur in later life, the ages when CCA developed spontaneously in the pre-DES era. In addition, the long-term prognosis and health impact for adolescents and young adults who have DES-related CCA are unknown. Methods: 720 cases of CCA were reviewed from the CCA Registry at the University of Chicago through 2014. Rates and cumulative risks for CCA were calculated based on white women born in the U.S. from 1948 through 1971. Kaplan-Meier method was used to estimate survival probability among women with CCA. Cox models were used to identify independent prognostic factors. To gauge the relative impact of young-onset clear-cell adenocarcinoma on mortality, we compared their mortality hazards with mortality hazards of the U.S. female population, and calculated standardized mortality ratio (SMR). Results: In 420 CCA cases there was documented evidence of prenatal DES exposure. 80% patients had a CCA be-
tween ages 15 and 31 but some occurred as late as age 55. A small second peak occurred around age 40. The risk of U.S. born, white DES-related CCA was highest in the 1951-1956 birth cohort, and this birth cohort effect correlated with highest levels of COL1A1. Expression of COL1A1 by these cells was confirmed by immunohistochemistry (IHC) using prostate tissue microarrays (TMA). In addition, protein array experiments identified elevated levels of several proteases in the urine of PCa patients, including MMP-9, uPA, ADAM-TS1 and several cathepsins. Substrate gel electrophoresis (zymography) revealed elevated activity of both MMP-9 and MMP-2 in urine from PCa patients. These data suggest that MMP-9 and MMP-2 may participate in the cleavage of collagen type 1, resulting in elevated levels of COL1A1 in urine of PCa patients. We are currently testing this hypothesis. In summary, COL1A1 may represent a novel non-invasive urinary biomarker that can effectively discriminate between BPH vs. localized PCa. (Supported by The Ellison Foundation.)

CLINICAL RESEARCH: Early Detection

#710 Identification of autoantibody to ECH1 & HNRNPA2B1 as potential biomarkers in the early detection of lung cancer. Liping Dai,1 Jitian Li,2 Jun-Chieh J. Tsay,1 Xiao Wang,3 John S. Munger,3 Harvey Pass,4 William N. Rom,2 Eng M. Tan,5 Jian-Ying Zhang,2 Zhengzhou University, Zhengzhou, China; 2the University of Texas at El Paso, El Paso, TX; 3New York University, New York, NY; 4The Scripps Research Institute, San Diego, CA.

Background: Identification of biomarkers for early detection of lung cancer (LC) may lead to more effective treatment and reduction of mortality. Methods: Serological proteome analysis (SERPA) was used to identify proteins around 34 kDa, which had been previously recognized by autoantibody in sera from LC patients. We have validated autoantibody response in sera from 90 LC patients, 89 normal controls by using immunoassay. Another independent cohort of 25 LC patients with 219 serial serum samples and 56 matched normal controls were examined to evaluate whether the autoantibody can be detected in the preclinical stage. Results: The proteins with molecular weight of 34 kDa were identified as ECH1, GAPDH and HNRNPA2B1. In the validation study, autoantibody to ECH1 achieved an area under the curve (AUC) of 0.799 with sensitivity of 62.2% and specificity of 95.5% in discriminating LC from normal individuals, and showed negative correlation with tumor size (r=−0.256, p=0.023). Autoantibody to HNRNPA2B1 performed an AUC of 0.874 with sensitivity of 72.2% and specificity of 95.5%, and showed negative correlation with lymph node me-tastasis (P=0.012). By using a logistic regression partition tree approach, autoantibody to ECH1 showed an AUC of 0.763 with sensitivity of 60.0% and specificity of 89.3% in distinguishing LC with matched normal controls, and elevated autoantibody levels could be detected greater than two years prior to LC diagnosis. Conclusions: ECH1 and HNRNPA2B1 are autoantigens that elicit autoimmune responses in LC and can be used as potential biomarkers for the early detection of LC. #711 Mechanistic implications of COL1A1 as a prostate cancer biomarker. Andrej Jedink,1 Camille Vuiuclaud,2 Andrew El-Hayek,3 Katherine Kaplan,4 Jason Salama,5 Sarah A. Slupsky,6 Adam S. Feldman,5 Kevin A. Campbeau,3 Kevin B. Loughlin,3 Marsha A. Moses1,3 Boston Children’s Hospital, Harvard Medical School, Boston, MA; 2Boston Children’s Hospital, Boston, MA; 3National Cancer Institute, Bethesda, MD; 4Massachusetts General Hospital, Boston, MA; 5Brigham and Women’s Hospital, Boston, MA.

Prostate cancer (PCA) is the second most frequently diagnosed form of male cancer and shares similar symptoms with BPH (Benign Prostate Hyperplasia), a disease characterized by prostate enlargement. Elevated levels of prostate-specific antigen (PSA) can be observed with either benign or malignant growth of the prostate and therefore cannot effectively discriminate between these two prostate diseases. Currently, a test that sensitively and accurately distinguishes between BPH and localized prostate cancer does not exist creating an urgent need for novel biomarkers that can successfully distinguish between these two prostate diseases. The goal of this study was to identify and validate non-invasive urinary biomarkers that distinguish between BPH and PCA. Our previous proteomic study identified elevated levels of several proteins, including EGF (epidermal growth factor), COL1A1 (collagen type I, alpha 1) and other proteins in the urine of PCA patients compared to urine samples from patients with BPH. In this current study we have analyzed and validated the presence of EGF, HE-4 and COL1A1 by enzyme-linked immunoassortant assay (ELISA). Our ELISA experiments revealed that COL1A1 was significantly (P<0.002) elevated in the urine of patients diagnosed with early or locally advanced PCA compared to PCA patients performing prostate specific antigen (PSA) tests. Our findings suggest that COL1A1 may lead to more effective treatment and reduction of mortality but accurate and readily accessible tools for population screening are limited. By whole methylome sequencing, we have identified novel methylated DNA markers (MDMs) for lung cancer in tissue (Giaikoumopoulos et al. ASCO 2016). Using top candidate MDMs in the present study, we now explore their clinical accuracy for lung cancer detection when assayed from plasma. Experimental Procedures: Archival plasmas from two independent study groups were tested in blinded fashion. Lung cancer cases and controls (apparently healthy smokers) for each group were balanced on age and sex (Group 1: 64 cases, 231 controls; Group 2: 23 cases, 80 controls). Using multiplex PCR followed by QUARIS Quantitative Allele-Specific Real-time Target and Signal amplification (Qatar) assay, a post-bisulfite quantification of MDMs on DNA extracted from plasma was performed. We selected 31 MDM candidates for initial evaluation in Group 1 (1 ml plasma/patient); top individual MDMs were subsequently tested in Group 2 to identify optimal MDM panels for lung cancer detection (2 ml/patient). Results: From Group 1 analyses, 13 high performance MDMs were selected for further testing (CYP26C1, SOBP, SUCCL2, SHOX2, ZDHHC1, NFIX, FJL45983, HOXA9, B3GALT6, ZNF781, SP9, BARX1, EMXI) with individual areas under the receiver operator curve (AUCs) ranging from 0.593 to 0.939. Discrimination by individual MDMs was corroborated in Group 2 in which data was analyzed using two methods: a logistic regression fit and a regression partition tree approach. The logistic fit model identified a 4-marker panel (ZNF781, BARX1, EMXI, and SOBP) with an AUC of 0.96 and an overall sensitivity of 91% and 90% specificity. Analysis of the data using a regression partition tree approach identified 4 markers (ZNF781, BARX1, EMXI, and HOXA9) with AUC of 0.93 and an overall sensitivity of 96% and specificity of 94%. For both approaches, B3GALT6 was used as a standardizing marker of PCA DNA input. Conclusion: A panel of MDMs assayed in plasma achieved high sensitivity and specificity for all types of lung cancer. Further clinical evaluation and validation of this promising panel in larger patient groups are clearly indicated.

#713 Proteomic early detection biomarkers for ER+ breast cancer to improve mammography screening. Carly B. Garrison,1 Tracey Marsh,2 Matthew Buas,3 Yuzheng Zhang,3 Margaret Pepe,3 Paul D. Lampe,1 Christopher I. Li,2 Fred Hutchinson Cancer Research Center, Seattle, WA; 3Roswell Park Cancer Institute, Buffalo, NY.

There are clear clinical and public health needs to improve the early detection of breast cancer in order to save lives. Breast cancer is the leading cause of cancer death in women worldwide and is the second leading cause of cancer mortality between 35 and 50 year of age (SMR 27.06, 95% CI: 23.04-31.58), 5-fold increased survival than young adult patients. Compared with general U.S. female population and validation of this promising panel in larger patient groups are clearly indicated.
in women in the United States. Although mammography is widely used to screen for breast cancer, it suffers both from false negative and false positive readings resulting in later diagnoses or unnecessary follow-up (e.g., biopsies), respectively. Improvement of breast cancer early detection may be possible through the measurement of minimally invasive, easy to perform blood based biomarkers. Our studies were performed using clinical plasma samples collected up to 12.5 months before breast cancer diagnosis from cases and matched controls obtained from the Women’s Health Initiative (WHI) Observational Study (a prospective cohort of 93,676 post-menopausal women). We utilized high-density antibody microarray methods for both discovery and preliminarily validation on distinct sample sets for early detection biomarkers of estrogen receptor negative breast cancer (around 70% of all breast cancers classified as ER+). Antibody microarray features (i.e., spots) identified as having >30% sensitivity at 80% specificity were considered to have met the cutoff criteria and identified as potential markers. A total of 129 features, corresponding to 101 proteins, were identified as potential markers in one WHI dataset (90 cases vs. 90 controls). Of the 129 features (101 proteins), 47 (34 proteins) validated by our cutoffs and demonstrated over or under-expression in cases compared to controls consistent with the first dataset in the second set of WHI samples (121 cases vs. 121 controls). Given this level of reproducibility, we believe these biomarkers could be used to improve early detection of ER+ breast cancer for these clinical scenarios: 1. Informing timing of a subsequent mammogram in women with a negative screening mammogram; 2. Informing continuation or termination screening among women between 75-79 years; 3. Identifying women who should be screened with mammography in areas with limited resources. We are currently performing further validation of the protein markers in Early Detection Research Network (EDRN) specimen reference set from patients at the time of diagnosis. We plan to test our markers on a pre-diagnostic cohort from the Cardiovascular Health Study using a different, more clinically applicable platform. We used the same high-density antibody microarray platform to measure autoantibody-autoantigen complexes and sialyl Lewis-A and –X modifications in one of the WHI sample sets and are now testing these markers in the EDRN set for validation. Given the strength of our biomarker candidates, the high quality sets of biospecimens we used, the study designs employed, and the clearly delineated clinical applications proposed, we believe these markers could have near-term clinical impact.

#714 Human transcriptome alterations in pre-cancer and cancer epithelium identify candidate biomarkers of progression to pancreatic cancer.
Elena V. Komissarova, Jorge Sepulveda, Sarawut Kongkarnka, Maryam Shrazi, Brynn Levy, Claudia Cujar, Antonia R. Sepulveda. *Columbia University, New York, NY.*

Pancreatic ductal adenocarcinoma (PDAC) is one of the most common cancers in the United States. The five-year survival rate for patients with PDAC remains dismal. Identification of biomarkers for early diagnosis of PDAC and pre-cancer pancreatic intraepithelial neoplasia (PanIN) lesions with risk of progression to PDAC is critically needed. We hypothesized that differentially expressed genes and regulatory pathways in PanIN and PDAC compared to normal duct epithelium (ND) may represent biomarkers of development of malignancy. We used Affymetrix Human Transcriptome Arrays 2.0 to establish gene expression profiles in ND, low-grade PanIN, and PDAC epithelium. Total RNA was isolated after laser capture microdissection (LCM) of frozen tissue sections and then used for producing hybridization-ready DNA. Hybridization quality control was performed with Expression Console 1.4 software and background corrected/normalized data were analyzed with Transcriptome Analysis Console (TAC) 3.1 and the ASSIGN algorithm. We tested RNA from 22 LCM samples (9 PDACs, 5 PanINs, and 8 ND) including 4 matched trios of ND, PanIN and PDAC from the same patients. Differential expression analysis with one-way between subject ANOVA revealed over 2000 genes differentially expressed in PDAC compared to ND with p<0.05. The most frequent alteration in PanIN compared to ND samples was upregulation of 433 genes (p<1e-15) and in PDAC compared to ND downregulation of 566. We found 60 (40 coding) upregulated genes and 750 downregulated genes (filter criteria up/down >1.5; ANOVA p<0.05) in both PanIN and PDAC vs. ND epithelium. Signaling pathway analysis of WikiPaths ways showed a number of significantly altered pathways in PDAC and PanIN compared to ND including the Gastric Cancer Network 1 with upregulated S100P in both PanIN and PDAC whereas other genes including CENPF, KIF20B, TPX2 and UBE2C were upregulated in PDAC only. Using the ASSIGN algorithm and the Kruskal-Willis test for analysis of difference in pathway activity, we found additional regulatory pathways with altered activity including Nuclear Receptor meta-pathway with reduced overall score in PDAC compared to PanIN and ND samples. In summary, over 400 genes were significantly upregulated in pre-cancer PanIN lesions compared to normal duct epithelium, whereas gene down-regulation was the most frequent alteration in PDAC. Sixty genes, including 40 coding genes were up-regulated in both PDAC and PanIN. The altered pathways associated with the differentially expressed genes may represent an approach for integrated biomarker testing of neo-plastic progression.

#715 The AroCell TK 210 ELISA may complement Pro PSA and the Prostate Health Index in differentiating pre-cancerous and cancerous conditions in prostate cancer.
Jagarlamudi Kiran Kumar,1 Staffan Eriksson,2 Zупан Мока,3 Kumer Kristina,3 Josko Osredkar,3 Fabjan Teja,3 Hlebic Gregor,3 Smrkolj I.4 Swedish Agricultural University, Uppsala, Sweden; Blood transfusion unit, Ljubljana, Slovenia; 5Institute of Clinical Biochemistry, Ljubljana, Slovenia; 6University Medical Centre, Ljubljana, Slovenia.
Background: Thymidine Kinase 1 (TK1) is a cytosolic enzyme that plays an important role in DNA precursor synthesis and TK1 enzyme activity in serum is an established biomarker for prognosis and treatment monitoring, particularly for haematological malignancies. The AroCell TK 210 ELISA determines TK1 protein levels, in contrast to TK1 activity, and it has demonstrated superior sensitivity in distinguishing between subjects with solid tumours and controls. Pro PSA, free PSA and the prostate health index (PHI) have been proposed as more discriminating tests than PSA in distinguishing between benign and cancerous prostate changes. The purpose of this study was to compare the AroCell TK 210 ELISA with PSA, free PSA and PHI in men with pre-cancerous conditions, and patients with confirmed prostate cancer. Experimental Procedures: Serum samples from 94 patients with known PSA values (in the range 2 to 10 ng/L) that were undergoing prostate cancer were collected at the University Medical Centre, Ljubljana. TK1 protein levels were determined using the AroCell TK 210 ELISA. PSA, iPSA and pro PSA levels were analysed with commercial assays (Hybritech PSA, Hybritech Free PSA and Access 2pPSA - Beckman Coulter USA) analysed on the Access 2 Beckman Coulter analyzer. Results: Overall, 16/94 patients had serum TK1 protein levels above the estimated cut-off value for age-matched healthy men (0.45µg/L). 65/94 men had pre-cancerous prostate conditions, including benign prostate hyperplasia, prostatitis and high grade prostatic intraepithelial neoplasia, while 29 patients had confirmed prostate cancer (PCa). Only 7/65 in the pre-cancerous group (11%) had TK1 protein levels above the cut-off, whereas in the prostate cancer group 9 out of 29 (31%) were positive. Moreover, the TK1 protein values in the PCa group (mean = 0.41µg/L) differed significantly from those with pre-cancerous conditions (mean = 0.31µg/L; P = 0.01). Further analysis showed that pro PSA and PHI also differentiated the prostate cancer group from those with pre-cancerous conditions (P = 0.01 and P<0.001, respectively). This was not observed for iPSA and PSA. Overall, the AroCell TK 210 ELISA showed significant correlation with PHI (r = 0.32, P=0.0017) and pro PSA (r = 0.21 P = 0.044) but not with iPSA or PSA. Conclusions: This preliminary study has demonstrated that serum TK1 assayed with the AroCell TK 210 ELISA can differentiate between pre-cancerous and prostate cancer patients with a similar accuracy to that of pro PSA. Further clinical studies will establish the capacity of the AroCell TK 210 ELISA to complement PHI in distinguishing between pre-cancerous and prostate cancer, potentially providing another tool in prostate cancer management.

#716 Genomic classification of longitudinally observed small colorectal polyps.
Meta C. van Lanschot,1 Beatrix Carvalho,1 Charlotte J. Tutein Nolthenius,1 Christian R. Rausch,2 Ernst J. Kuipers,3 Jaap Stoker,3 Gerrit A. Meijer,1 Netherlands Cancer Institute, Amsterdam, Netherlands; 2Academic Medical Center, Amsterdam, Netherlands; 3Erasmus Medical Center, Amsterdam, Netherlands.
Introduction: Colorectal polyps are very common in elderly people with a prevalence of 15-30% reported in screening series. However, only a minority of 5% of these lesions is estimated to develop into invasive cancers, whereas others will remain stable or regress over time. In standard practice all polyps observed during colonoscopy are removed by polypectomy and therefore, knowledge about their natural history is limited. In this study, small (6-9mm) colorectal polyps were followed over time and subsequently resected during colonoscopy. Aim: The prevalence of DNA copy number alterations (CNAs), a feature associated with adenoma to carcinoma progression, was compared in polyps that morphologically progressed versus those that did not. Methods: In the CT colonography (CTC) arm of the COCOS-trial small 6-9mm polyps were left in situ. After a three-year surveillance interval, growth according to CTC of 95% of the polyps was confirmed prostate cancer (PCa). Only 7/65 in the pre-cancerous group (11%) had TK1 protein levels above the cut-off, whereas in the prostate cancer group 9 out of 29 (31%) were positive. Moreover, the TK1 protein values in the PCa group (mean = 0.41µg/L) differed significantly from those with pre-cancerous conditions (mean = 0.31µg/L; P = 0.01). Further analysis showed that pro PSA and PHI also differentiated the prostate cancer group from those with pre-cancerous conditions (P = 0.01 and P<0.001, respectively). This was not observed for iPSA and PSA. Overall, the AroCell TK 210 ELISA showed significant correlation with PHI (r = 0.32, P=0.0017) and pro PSA (r = 0.21 P = 0.044) but not with iPSA or PSA. Conclusions: This preliminary study has demonstrated that serum TK1 assayed with the AroCell TK 210 ELISA can differentiate between pre-cancerous and prostate cancer patients with a similar accuracy to that of pro PSA. Further clinical studies will establish the capacity of the AroCell TK 210 ELISA to complement PHI in distinguishing between pre-cancerous and prostate cancer, potentially providing another tool in prostate cancer management.
or regressed (<30% growth). From 65 resected polyps, formalin-fixed paraffin-embedded material was retrieved and reviewed by an expert pathologist (GAM). Of these polyps, 48% (31/65) progressed, 41% (27/65) remained stable and 11% (7/65) regressed. Seventy-two percent (47/65) were tubular adenomas, 14% (9/65) tubulovillous adenomas, 3% (2/65) sessile serrated lesions and 11% (7/65) hyperplastic polyps. Initially, 76% of CNAs per sample was 0.8 (range 0-8), the most frequently observed was 13q gain (20%). No significant differences in number, or regions of CNAs were observed between polyps that progressed and the ones that did not change or diminished in size (stable or regressed). Larger polyps showed more CNAs, of which specifically 13q gain was more often present (43% that did not change or diminished in size (stable or regressed). Larger polyps were analyzed with low-coverage whole genome sequencing (HiSeq, Illumina, San Diego, CA, USA). DNA copy number status was called with the R-package {QDNAseq}. Results: From 50/68 resected polyps, originating from 38 individuals (mean age of 66.8 years (s.d. 7.0); 63% male), sufficient DNA was available. The mean surveillance interval of these polyps was 3.27 years (s.d. 0.29). The mean number of CNAs per sample was 0.8 (range 0-8), the most frequently observed was 13q gain (20%). No significant differences in number, or regions of CNAs were observed between polyps that progressed and the ones that did not change or diminished in size (stable or regressed). Larger polyps showed more CNAs, of which specifically 13q gain was more often present (43% in ≥10mm and 8% in <10mm polyps). Of note, no serrated lesions were ≥10mm. No differences in CNAs were found between the different histological subtypes. Conclusions: In a series of colorectal polyps left in situ for an average 3.27 years, no difference in prevalence of DNA copy number alterations was observed between polyps that volumetrically progressed and those that did not. Of the CNAs observed, 13q gain was most prevalent and found in 43% of the ≥10mm polyps. 1. Stoop, E. M. et al. Participation and yield of colonoscopy versus non-cathartic CT colonography in population-based screening for colorectal cancer: A randomised controlled trial. Lancet Oncol. 13, 55-64 (2012).

#717 Diagnosisis of basal like breast cancer using DNA methylation markers at the promoters of long non-coding RNAs

Yoo J. Han, Sonja M. Boatman, Jing Zhang, Albert C. Yeh, Yonglan Zheng, Olufunmilayo I. Olopade. University of Chicago, Chicago, IL.

Background: Patients with basal-like breast cancer (BLBC) have poor overall survival and suffer a high rate of metastasis to the brain or lung within three to five years of initial presentation. Absence of a cure for advanced BLBC warrants early detection of BLBC, which might save more lives, especially those of women of African ancestry who are disproportionately affected by young onset BLBC. Ablant DNA methylation is frequently observed in BLBC. DNA methylation is the most robust epigenetic mark and can be analyzed using clinical specimens including FFPE, tumor biopsies and liquid biopsies. Because expression of long non-coding RNAs (lncRNAs) is controlled temporally in response to neoplastic stimuli, we investigated the potential for lncRNA promoter methylation marks to be used for detection and prediction of BLBC development and progression in African Americans. Methods: To identify lncRNAs dysregulated in BLBC, we performed a Ribo-Zero RNA-seq or microarray analysis on breast tissue isolated from African American (n=63) and European American patients (n=14). Differentially methylated and hydroxymethylated regions of lncRNA genes were identified in African American samples (n=30) using our chemical methods to assay 5-methylcytosine (5mC) and 5-hydroxymethylcytosine (5hmC). The Cancer Genome Atlas (TCGA) datasets were utilized to validate our results. To functionally annotate lncRNAs, we knocked down lncRNAs using LNA-antisense oligonucleotides (ASO) and performed Caspase 3/7 assays, flow cytometry, and qRT-PCR. We also utilized the CRISPR-Cas9 editing tools to knock out lncRNAs. Results: LncRNAs displayed distinct expression patterns between tumors and normal breast tissues. Out of hundreds of lncRNAs specifically expressed in BLBC tumors, we selected two lncRNAs, lnc19 and lnc98, which represent, respectively, a significantly increased and decreased lncRNA in BLBC tumors, compared to normal breast tissues and other subtype tumors. Lnc19 is highly up-regulated (a 39-fold increase) whereas lnc98 is dramatically down-regulated (a 59-fold decrease) in BLBC tumors. Methylation analysis showed significantly lower levels of promoter methylation for lnc19 and higher levels for lnc98 in BLBC tumors. A significant inverse correlation between methylation and expression of lnc19 was observed. Depletion of lnc19 resulted in rapid cell death of BLBC cells, with increased sensitivity to chemotherapy drugs. The data suggests that chemo-resistance of BLBC might be partly due to lnc19 overexpression, which is mediated through epigenetic control. Conclusion: We identified two epigenetically dysregulated lncRNAs in BLBC tumors, which contribute to chemo-resistance of these tumors. Our findings on the regulation of lncRNAs by cytosine methylation raise the possibility of new epigenetic biomarkers for diagnosis and prognosis of aggressive BLBC tumors.

#718 Biomarker monitoring by quantitative MALDI imaging; application to the tryptophan-kynurenine pathway in immuno-oncology

Rima Ait Belkacem,1 Vanessa Bol,2 Gregory Hamim,1 Stefan Linehan,1 Bruno Gomez,1 Jonathan Stauber,1 ImbioTech, Loos, France; 1Teos Therapeutics SA, Gosselies, Belgium.

Tryptophan is an essential amino acid for cell proliferation and survival that can be metabolized through different pathways, a major route being the kynurenine pathway. The first and rate-limiting enzyme of this pathway is the indoleamine-2,3-dioxygenase 1 (IDO1), that is a natural endogenous molecular mechanism of immune suppression acting through modulation of the Trp degradation pathway. IDO1 inhibits T-cell functions, thereby contributing to chemo-resistance of these tumors. Our findings on the regulation of T-cell functions, activation of the regulatory T-cells, and inhibition of Natural Killer cells are among the important immunosuppressive effects of IDO1. IDO1 enzyme is proposed to have a therapeutic potential in immunodeficiency-associated abnormalities, including cancer. IDO1 over expression has been described in multiple cancer indications and IDO1 inhibitors are being developed to stimulate the anti-tumor immune response. The existing standard quantitative methods are based on the total level of Trp and its metabolites determined by LC-MS/MS analysis in human plasma, cerebrospinal fluid and brain. We describe the setup, development and application of a new method based on MSI to detect, localize, and quantify Trp and Kyn in biological tissues. This method allows both the study of the subcellular localization and the detection/quantitation of metabolites of interest in tumor tissues. In the present study, an experimental tumor model overexpressing IDO1 and its wild-type counterpart were implanted in mice. Tissue sections of different tumors were realized and used for MSI analysis. MALDI FTICR high resolution imaging followed by data analysis established an absolute number on tissue quantitation. Internal standards of tryptophan (Trp-d5) and kynurenine (Kyn-d4) metabolites were used for normalization. As expected, our results showed an increase in the expression of Trp and Trp metabolites in tumors compared to the normal tissue. Following, immunostainings of IDO1 and Trp-depletion sensor pathways were carried out. Overlaying images between the immunostainings and the molecular MS images allowed co-localization studies and underlined both the biology and the tumor heterogeneity. This study allowed us to highlight key metabolites of the Trp pathway that are responsible for the immunosuppressive tumor microenvironment. It illustrated the heterogeneity of tumor immune areas. The development of immunotherapies such as IDO1 inhibitors requires a deep understanding of the interplay between the immune system and cancer cells, these immune endogenous metabolites can now be followed by QMSI and as biomarkers towards enhancing immunotherapies efficiency.

#719 Pathobiological implications of Trefoil Factors in the progression and metastasis of pancreatic cancer

Rahat Jahan, Sukhwinder Kaur, Muzafar A. Macha, Yuri Sheinin, Lynette Smith, Jane Meza, Surinder K. Batra. University of Nebraska Medical Center, Omaha, NE.

Background: Pancreatic cancer (PC) is a highly lethal malignancy and the disastrous statistics warrants an urgent need to develop new diagnostic and prognostic marker(s) and therapeutic target(s) for its better management. Trefoil factors (TFF 1/2/3) are a family of small, stable molecules observed to co-express with mucin and secreted by mucus-producing cells that facilitate mucosal repair after injury. Recent studies have shown that TFF1 and TFF3 can differentiate between molecular subtypes of PC. Based on this, we hypothesized that differential expression of TFF1 and TFF3 could predict pancreatic intraepithelial neoplasia (PanIN) as well as the early stage of PC. The present study explores the diagnostic and functional significance of TFF in PC. Material and Methods: Immunohistochemistry was used to determine the expression status of TFF1 and TFF3 in early stage PC (EPC, Stage 1 and 2, n=47), early stage PC (EPC, Stage 1 and 2, n=78) and late PC (LP, Stage 2-3, n=69). RT-PCR and ELISA were used to detect TFF1 levels in serum. The diagnostic significance of TFF1 was evaluated in the sample set (n=331) comprising of benign control (BC, n=104), chronic pancreatitis (CP, n=47), early stage PC (EPC, Stage 1 and 2, n=78) and late PC (LP, Stage 2-3, n=69), RT-PCR and ELISA were used to detect TFF1 levels in PC cell lines and cell supernatants respectively. Combinant treatment with TFF3 was performed to observe the impact on of transmembrane (MUC4) and secreted mucins (MUC5AC) stability and expression. Results: Differential expression of TFF3 was observed in PanIN precursor lesion, pancreatic cancer tissue in comparison to normal pancreatic tissue (p < 0.0003). Furthermore, the TFF3 expression was significantly higher for well differentiated tumor in comparison to poorly differentiated cases (p = 0.006). For TFF1, expression was significantly higher in PanIN lesions compared to normal pancreas (p < 0.0001), and PC versus normal pancreatic tissue (p < 0.0001). In serum, significantly increased expression of TFF1 was observed in EPC serum samples compared to BC (p-value = 0.035) and CP (p-value = 0.031). In EPC cell lines cases, RT-PCR analysis revealed positive expression of TFF1 and TFF3 in the majority of the PC cell lines. Treatment of PC cells with recombinant TFF3 lead to differential expression of MUC4 and MUC5AC. Conclusion: Overall, both tissue and serum based studies show that TFF1 and TFF3 are differentially expressed in early PanIN lesions as well early stage of PC tissues compared to normal.
to normal pancreas. Overall, these results suggest a potential implication of TFF1 and TFF3 in PC pathogenesis and provide a basis for functional impact of these proteins. Therefore, we hypothesize that autoantibodies against these aberrantly overexpressed proteins may have the potential to serve as diagnostic biomarkers in certain type of cancers. In current study, we have identified 11 proteins, including EDRNBR, KRT4, PLAT, MSLN, WIFDC2, FS, FOXA1, AURKC, STC1, CAB39L, and SFTPA1, to further evaluate the diagnostic values of their corresponding serum autoantibodies in five types of cancers, including hepatocellular carcinoma, lung cancer, gastric cancer, breast cancer and ovarian cancer. Sera from 470 patients (94 per cancer type), 94 healthy patients and 192 autoimmune disease patients matched with normal controls were used in this study. Serum autoantibodies were detected by ELISA. Receiver operating curve (ROC) analysis was used to evaluate the diagnostic value of serum autoantibodies against these potential TAAAs. The data indicates that several anti-TAA autoantibodies can be found to have diagnostic value for certain types of cancers. Autoantibodies against PLAT can distinguish breast and ovarian cancer while autoantibodies against SFTPA1 and CAB39L can distinguish cancers both in male and female. However, none of these serum anti-TAAAs was found to be specific to a single type of cancer. In summary, HPA database has made systematic discovery of cancer biomarkers possible. Whether these in silicon biomarkers can be used to distinguish normal and cancer still needs to be evaluated in more serum samples from normal controls and cancer patients.

#720 Systematic discovery and evaluation of tumor-associated antigens (TAAAs) as biomarkers in cancer immunodiagnosis. Jianxiang Shi,1 Lu Zhang,1 Peng Wang,2 Hua Ye,1 Liping Dai,1 Pei Li,2 Chenglin Luo,2 Chuhua Song,2 Kaijuan Wang,3 Xiao Wang, Jin Ouyang,1 Zhenyu Ji,1 Jiayang Zhang,1 Zhengzhou University, Zhengzhou, China; 2The University of Texas at El Paso, El Paso, TX.

Proteins aberrantly over-expressed in tissues from nineteen types of cancers have been identified from the Human Protein Atlas (HPA) database. Among these proteins, some were overexpressed in several types of cancers while certain proteins were found only overexpressed in certain type of cancers. It is demonstrated that aberrantly overexpressed proteins might shed into the blood and trigger the immune system to produce autoantibodies during the process of oncogenesis. Autoantibodies are more stable and often have higher titer compared to autoantigens. Therefore, we hypothesize that autoantibodies against these aberrantly overexpressed proteins may have the potential to serve as diagnostic biomarkers in certain type of cancers. In current study, we have selected 11 proteins, including EDRNBR, KRT4, PLAT, MSLN, WIFDC2, FS, FOXA1, AURKC, STC1, CAB39L, and SFTPA1, to further evaluate the diagnostic values of their corresponding serum autoantibodies in five types of cancers, including hepatocellular carcinoma, lung cancer, gastric cancer, breast cancer and ovarian cancer. Sera from 470 patients (94 per cancer type), 94 healthy patients and 192 autoimmune disease patients matched with normal controls were used in this study. Serum autoantibodies were detected by ELISA. Receiver operating curve (ROC) analysis was used to evaluate the diagnostic value of serum autoantibodies against these potential TAAAs. The data indicates that several anti-TAA autoantibodies can be found to have diagnostic value for certain types of cancers. Autoantibodies against PLAT can distinguish breast and ovarian cancer while autoantibodies against SFTPA1 and CAB39L can distinguish cancers both in male and female. However, none of these serum anti-TAAAs was found to be specific to a single type of cancer. In summary, HPA database has made systematic discovery of cancer biomarkers possible. Whether these in silicon biomarkers can be used to distinguish normal and cancer still needs to be evaluated in more serum samples from normal controls and cancer patients.

#721 Minimally invasive test and composite biomarker for early detection of serous ovarian carcinoma. Keren Bahar-Shany,1 Georgina D. Barnabas,3 Limor Helpman,1 Ariella Yakobson-Siton,4 Tamar Perri,3 Ram Eitan,4 Jacob Korach,1 Keren Levanon1. 1Sheba Medical Center, Ramat Gan, Israel; 2Tel Aviv University, Tel Aviv, Israel; 3Meir Medical Center, Kfar Saba, Israel; 4Rabin Medical Center, Petach Tikva, Israel.

Background: Current screening programs for early detection of high grade epithelial ovarian cancer (HGOvC) among high-risk populations have failed to show improvement in HGOvC mortality, therefore these women are offered risk-reducing bilateral salpingo-oophorectomy (RRBSO) at 35- 40 years. Stratification of high-risk population, especially BRCA mutation carriers, may enable personalized risk counseling and individualization of timing of RRBSO. In most cases, the precursor lesions of HGOvC arise in the epithelium of the fallopian tube (FT) fimbriae rather than intra-peritoneally. It is therefore plausible that proteins, RNA or DNA from early-stage tumor cells may be identifiable in fluid samples obtained from the lumen of the gynecological tract, thus making it possible to identify curable, early stage lesions. Aims: (1) Test the feasibility of uterine lavage as a minimally invasive test for early detection of ovarian cancer, and (2) Identify novel early-detection biomarkers in the uterine lavage fluid (ULF). Methods: We developed a method for sampling of gynecologic tract fluid termed uterine lavage fluid (ULF), which is a simple, reproducible, low-cost office procedure that can be performed routinely during gynecologic follow-up visits. We have already collected ULF from 140 HGOvC patients and control women undergoing gynecological surgical procedures for non-malignant indications. Deep proteomic profiling of ULF is performed by isolation of microparticles from body fluids, followed by solubilization, trypsin digestion and high resolution mass spectrometric (MS) analysis (on the Q-Exactive MS). Machine learning algorithms have been used to extract a classifier that can predict the diagnosis of ovarian cancer. Results: Uterine lavage appears to be a feasible, low burden procedure. The MS approach has identified thousands of proteins in each ULF specimen, in a high throughput manner. The label-free quantification algorithm (MaxQuant) enables a quantitative comparison between samples from cases and controls. We have derived a 20-protein classifier with an area under the curve (AUC) of Receiver Operating Characteristics (ROC) curve of 0.91 at 20% error. The composite biomarker has been applied to an independent validation set with a negative predictive value (NPV) of 92% and positive predictive value (PPV) of 45%. Conclusions: A minimally invasive technique of uterine lavage to collect unique diagnostic samples, coupled with state-of-the-art proteomics methods, results in a highly sensitive and specific composite biomarker which may be developed in to a screening tool for early detection of serious ovarian cancer in high-risk populations.

#722 Circulating EBV microRNA BART2-5p helps to diagnose nasopharyngeal carcinoma < screen for high risk individuals precisely. Chen Jiang,1 Lei Li,1 Li Jiangchao,2 Shang-hang Xie,3 Su-mei Cao,4 Xin-yuan Guan1. 1The University of Hong Kong, Hong Kong, China; 2Sun Yat-Sen University Cancer Center, Guangzhou, China; 3Guangdong Pharmaceutical University, Guangzhou, China.

Nasopharyngeal carcinoma is an EB-virus associated malignant which is highly prevalent in Southeast Asia. If diagnosed early, the 5 year disease-free survival rate is about 90%. However, most patients have already developed local or regional invasion when diagnosed, which results in poor prognosis. So it is essential to develop biomarkers to screen high risk individuals or diagnose the disease at early stages. As nasopharyngeal carcinoma is closely related to EBV infection and microRNAs encoded by BART region (BamHI A Rightward Transcripts) is abundant in NPC, we propose to identify biomarkers from these BART microRNAs. To quantify the copy number of microRNAs in serum samples, we used Taqman Probe-based qPCR. After adding Spiked-in Control (Mixture of Cel-39,Cel-54, Cel-238) to each 100ul serum sample, we extracted total RNA and reverse transcribed microRNA into cDNA with corresponding Taqman primers. Meanwhile, microRNA mimics with known copy number were serial diluted and reverse transcribed along with the samples. qPCR was performed to quantify the level of microRNAs in these samples with diluted cDNA and Taqman Probe. All data was normalized by Spiked-in controls and exact copy number of each microRNA was calculated through the standard curve generated by the serial diluted microRNA mimics. Here, we screened 17 BART microRNAs in discovery stage and found BART 2-5p as a candidate biomarker. In training cohort consisting of 266 patients with nasopharyngeal carcinoma and controls from Hong Kong, the sensitivity, specificity and AUC is 93.2%, 89.9%, 0.976 respectively. The results are similar in validation cohort 1 constituted by 376 patients and controls from Guang Zhou. To evaluate the ability of BART 2-5p to distinguish preclinical NPC patients from healthy high risk individuals, we established a nested case-control study with serum samples prospectively collected from 10 NPC patients at least one year prior to their clinical diagnosis and 92 matched healthy high risk controls from a screening scheme conducted in South China. The sensitivity and specificity is 90.0% and 31.5%. Taken together, EBV microRNA BART2-5p is a promising biomarker to improve NPC diagnosis and target preclinical patients more precisely than serologic test.

#723 Improved detection of cancer specific serum exosomal apastaryl (as-paragynyl) beta hydroylase (HAAH). Mark A. Semenuk, Anokhi S. Cifuentes, Eleanor R. Ghanbari, Michael S. Lebowitz, Hossein A. Ghanbari. Panacera Pharmaceuticals, Inc., Gaithersburg, MD.

By means of an ELISA, we have found the pan-cancer biomarker HAAH to be co-expressed with serum exosomes primarily in cancers of the breast, lung, colon, and prostate. This new understanding of the HAAH target has led to a dramatically improved serological detection assay, and in turn diagnostic agent kit. In keeping with the multivalent particulate nature of exosomes, appropriately reformating the ELISA assay has yielded a simplified so-called simultaneous-homologous format. Currently in this format, a single monoclonal anti-HAAH antibody (FB50) serves both as microplate capture and as a biotinylated detector. All reagents, including peroxidase-streptavidin, are co-incubated in the FB50- coated microplate simultaneously with serum samples, in the absence of intervening sequential steps. This considerably shorter exosome-enabled ELISA format requires half the time and yields generally on average a two-fold or higher increase in detection of HAAH. This format was evaluated with over 100 banked serum samples from several early stage cancers. While increasing the sensitivity for HAAH in cancer samples, the improved detection and performance has not caused any undesirable increases in false positives among more than 30 normal serum samples from healthy subjects. The reagent kit components include recombinant HAAH calibrators, positive/negative controls, vialated detection reagents and a Mylar packaged FB50 pre-coated microplate. The simplified reagent kit format has yielded close inter-operator and day to day trending consistency with a limit of detection (LOD) of 3 ng/mL. Recognizing the exosomial nature of the HAAH target has resulted in some changes in blood sample procurement, sample processing, and sample shipping. Such field testing of the HAAH reagent kit was recently done with serum samples from 48
high risk or mildly symptomatic volunteers with general concerns about cancer. Upon testing these samples, 9 had an AHA LV value greater than 3.0 kg/m² (range 4.2 to 116.7) and 39 had less than 3.0 kg/m². Based on the post-analysis diagnostic determination, there were two false negatives and one false positive, hence an overall accuracy of 93.8%.

**Early Detection of Cancer**

**Clinical impact of modified telomerase-specific adenovirus-based identification of viable-peritoneal tumor cells in peritoneal lavage fluid in patients with potentially resectable pancreatic cancer.** Masahiro Tanemura,1 Kenta Furukawa,1 Soichiro Mori,1 Masahisa Otsuka,1 Youzo Suzuki,1 Mitsuoyoshi Tei,1 Toru Masuzawa,1 Kentaro Kishi,1 Yasuo Urata,1 Hiroki Akamatsu,1 Osaka Police Hospital, Osaka, Japan; 2Oncology BioPharma Inc., Tokyo, Japan.

Pancreatic cancer (PC) is a highly aggressive disease with dismal prognosis. Although only a surgical resection can offer the chance of a cure, the 5-year survival rate after a potentially curative resection have been reported to be a low as 10-30%. In PC, the presence of peritoneal carcinomatosis precludes the possibility of surgical cure, irrespective of the resectability of the primary tumor. Peritoneal lavage cytology (CY) is used widely in the diagnosis and staging of gastric and pancreatic cancer. Positive CY findings (CY+ in PC is defined as stage IV disease, however, the true value of CY+ for the patient’s prognosis remains controversial. We rise the question of whether CY+ status has predictive value for survival and early intra peritoneal recurrence. The aim of this study was to evaluate from a novel genetically modified telomerase-specific replication-selective adenovirus, expressing GTP (TelomeScan F35) in rapid detection of viable peritoneal tumor cell (v-PTC) dissemination of PC. This human clinical trial sought to determine if the presence of vitally detected, rare v-PTC predict peritoneal recurrence and patient outcome. This study was approved by the Osaka Police Hospital IRB. Patients with resectable cytologically or histologically proven ductal adenocarcinoma of the pancreas were enrolled. Peritoneal lavage fluid was harvested just after a laparotomy in 27 patients with PC. Half of the fluid was examined by cytology with papanicolaou staining and MOC-31 immunostaining and the remaining half was used to detect v-PTC with TelomeScan F35. To distinguish between leucocytes and cells with epithelial origin, cells were stained with anti-CD45 Ab. To further distinguish cells with primary tumor origin, cells were labeled with anti-CEA and anti-CA19-9 Abs. GTP-positive and CD45-negative, and either CEA- or CA19-9-positive cells were counted as v-PTC. Patients were followed after surgery to evaluate its clinical significance. Among 27 patients aged 57-91 years (16 males and 11 females), 3 were cytologically positive (CY+), other 3 were virally positive by TelomeScan F35 (v-PTC+). All 27 patients underwent a surgical resection (PD/DP/TP/H-PD = 13/7/6/1). One patient was double positive (CY+/v-PTC+), and postoperative peritoneal recurrence early occurred at 5 month after resection despite adjuvant chemotherapy. 2 were CY+, but v-PTC-, and no recurrence in the abdominal cavity were observed (0%). On the other hand, other 2 were CY+, but v-PTC+, and one of these 2 patients occurred local recurrence in the abdominal cavity (50%). Remaining 22 patients (CY-/v-PTC-) were observed with neither local recurrence nor distant metastasis. In conclusion, TelomeScan F35-based v-PTC detection may be an independent prognostic factor in patients with resectable PC and had close association with local or peritoneal recurrence.

**Feasibility and evaluation of exosomal RNAs as novel diagnostic biomarkers for high grade serous epithelial ovarian cancer.** Emily N. Prenninger,1 Xianzhi Lin, Rosario I. Corona, Dennis J. Hazellett, Beth Y. Karlan, Kate Lawson. Cedars-Sinai Medical Center, Los Angeles, CA.

Introduction: High-grade serous ovarian cancer (HGSOC) survival has been essentially unchanged over the last ten years despite new therapeutic strategies. In order to make a large-scale impact on overall survival, early detection strategies are imperative. Exosomes are cell-derived vesicles derived from multivesicular bodies or the plasma membrane that carry a variety of biomolecules, including protein, DNA, and RNA. Exosomal contents represent a novel and underexamined source of tumor biomarkers, in particular for HGSOC. This study aimed to first evaluate approaches to exosomal RNA purification and to then compare the exosomal RNA profiles from serum of patients with benign ovarian disease and HGSOC to determine if unique profiles exist, and to identify biomarkers useful for early detection. Methods: Cell free serum was obtained from patients in each of the following categories: HGSOC with early (n=24) or late stage (n=24) disease, benign ovarian masses (n=24) and healthy age-matched controls (n=24). We compared ultracentrifugation and a commercial precipitation solution to enrich and isolate exosomes. Exosomal enrichment was confirmed by both transmission electron microscopy (TEM) and western blot using anti-CD63 antibodies. RNA was extracted for each and deep sequencing analysis was performed for 12 candidates within each group. A second cohort of 48 samples will be used for validation of the best performing candidate biomarker.

**Ultrasonic quantification of promoter methylation in cell-free circulating DNA for early detection of lung cancer.** Delphine Liss. NIH/NCI, Bethesda, MD

Lung cancer is the leading cause of cancer-related deaths worldwide. Early detection of lung cancer using Low Dose Computed Tomography (LDCT) screening has been shown to decrease the mortality rate. However, most nodules found are deemed to be benign upon further invasive testing. Thus, complementary minimally-invasive tests are being sought that will help discriminate malignant from benign nodules. Molecular biomarkers are increasingly becoming part of routine clinical practice for the diagnosis, prognosis or prediction of treatment response, with improved disease management and survival outcomes. Cell-free circulating DNA (cfDNA) in body fluids, including serum, plasma and urine, has recently emerged as a surrogate for tumor DNA. In addition to providing a minimally-invasive source of tumor DNA, cfDNA reflects molecular alterations and tumor heterogeneity. Epigenetic changes, including DNA methylation, occur early in carcinogenesis. Cancer cells are characterized by global hypomethylation and hypermethylation of Cpg islands in gene promoter regions. Analysis of tumor-specific DNA methylation in cfDNA is a promising strategy for applying epigenetic biomarkers to the detection of cancers at an early-stage. In a prior genome-wide analysis of DNA methylation, we identified a locus methylated de novo in fresh frozen tumor tissues resected from stage I lung cancer patients, that had high discriminatory power to distinguish tumor from non-tumor tissues in multiple patient cohorts. High promoter methylation was also associated with shorter cancer-specific survival. The present study aims at evaluating the diagnostic significance of promoter methylation in cfDNA, and the prognostic value in formalin-fixed paraffin-embedded (FFPE) tissues. We developed a methylation-specific droplet digital PCR (ddPCR) assay to quantify rare methylation events. DNA was subjected to bisulfite treatment to convert unmethylated cytosine residues to uracil. We designed specific primers and probe containing CpGs to only amplify the methylated promoter. Experimental conditions were first optimized using fully methylated and unmethylated control DNA samples, DNA extracted from lung cancer cell lines, germline cells and lung tissues (paired tumor and non-tumor). The ddPCR assay has a limit of detection of 30 haploid genomes equivalent of methylated promoter DNA, and a limit of quantification of a single methylated allele present at 0.2%, (i.e., 1 methylated copy among 500 unmethylated copies). We demonstrated the assay linearity, reproducibility and specificity for the methylated locus. Differences in methylation levels between tumors and adjacent tissues were also observed. We have thus established a robust and ultrasensitive method for standardized determination of promoter methylation status in cfDNA. We are currently evaluating its potential value for noninvasive diagnosis and prognosis of lung cancer patients.
phosphatase (ALP) or immunoperoxidase (IMP) substrate and contrasted reactivity in LC patients and asymptomatic controls with no advanced polyps, and chemiluminescent dot blots with manual or Bel-blotter 96-well replicating tool. Results: Saliva IMP testing was positive in 73% of 11 LC patients and 50% of 8 controls contrasted with ALP ELISA for stool Adnab-9 in 75% of 12 patients and 32% of 6 controls (OR 0.07). The peroxidase absorbance means (SD) were significantly different (0.077 [0.014] versus 0.116 [0.056]; p < 0.007). Equivalent inherent alkaline phosphatase of saliva samples was negative in both groups and means were not significantly different. The approximate time from saliva collection to diagnosis of LC was 3.76 years and 3.89 for stool. Conclusions: Adnab-9 sensitivity was moderate but promising due to the ability to make an early preclinical diagnosis. While this was only significantly different from controls in stool ALP ELISA, inherent IMP activity could be blocked to improve specificity. Significantly suppressed inherent peroxidase activity in LC saliva may explain the insensitivity of the Bac18.1 and Cox2 inflammatory biomarkers. The Bel-blotter volume capacity is 4-10µl/blot and may explain the lower sensitivity using this tool. A battery of tests, including Adnab-9 in an ALP ELISA format may allow for early disease intervention.

#728 Development and validation of ColoScape™ - a new colorectal cancer mutation detection assay. Michael J. Powell, Elena Peletskaaya, Anne Vallegra, Qing Sun, Larry Pastor, Aiguo Zhang. DiaCarta, Richmond, CA.

Introduction: Colorectal cancer is a highly preventable disease as early detection increases rates of patient survival to near 100%. Herein we report the development and validation of a novel multigene mutation biomarker real-time PCR based assay for qualitative detection of colorectal cancer associated biomarkers that comprise tumor specific mutations in the following genes: APC (Exon 15), KRAS (Exon 2), BRF (Exon 15) and CTNNB1 (Exon 3) called ColoScape™ TM. The assay allows the sensitive detection of the presence or absence of mutations in the targeted regions of the genes interrogated. Methodology: The high sensitivity of this multigene biomarker assay is achieved due to xenonucleic acid (XNA) probe technology. XNA probes are novel backbone modified oligomers having natural nucleoside bases (A,T,C and G) that hybridize by Watson-Crick base pairing to natural DNA and RNA with much higher binding affinity than natural deoxyribonucleic acid oligomers of the same sequence. XNA probes are designed that bind to the selected wild-type sequences at the respective genetic loci in the target genes. These XNA probes have a much higher Tm than the primer annealing temperature and suppress amplification of WT DNA templates and only allow amplification of the target mutant DNA templates in the sample. Both single nucleotide polymorphisms (SNPs) and insertion/deletions (indels) mutations can be detected. For each of the selected mutation sites primers and FAM-labeled TaqMan probes were designed and the together with the selected XNA oligonucleotides and analytical assay performance confirmed. An internal PCR control amplicon selected in the Human β-Actin (ACTB) gene was employed utilizing a HEX-labeled TaqMan probe. Performance parameters of the assay were established on DNA of colorectal cancer patients extracted from FFPE as well as reference DNA materials (synthetic and cell line derived DNA). The assay demonstrates high sensitivity and specificity in detection of colon cancer and adenoma samples based on the set of biomarkers involved in colorectal cancer neogenesis and disease progression. Conclusion: The ColoScape™ TM Colorectal Cancer Mutation Detection assay is shown to be a sensitive tool intended to facilitate research in colon cancer development, early detection, disease monitoring and therapeutic interventions.

DCLK1 expression is critically required for maintaining growth of human colon cancer cells (hCCCs). We and others recently reported that the 5’ promoter of DCLK1-gene gets hypermethylated and silenced in human colorectal tumors (hCRCs). We and others recently that the 5’ promoter of DCLK1-gene gets hypermethylated and silenced in human colorectal tumors (hCRCs) during adenoma-carcinoma sequence of colon carcinogenesis (Reviewed by Singh et al. SCL 2016). We also made the discovery that hCRCs and hCCCs express a novel short isoform of DCLK1 (DCLK1-S) (isoform) from β-promoter in intron V of DCLK1-gene, while normal-colons express the canonical long-isoform (DCLK1-L) (isoform) from 5’-α-promoter, suggesting that DCLK1-S, and not DCLK1-L, marks cancer-stem-cells (CSCs) (O’Connell et al, Sci Rep, 2015). Even though DCLK1-S differs from DCLK1-L in exon 9 (38% of non-CRC) sequences, DCLK1-S is specific to DCLK1-S Antibody (PS41014), which does not cross-react with DCLK1-L and specifically detects DCLK1-S in several assay platforms, including westerns and IHC. Sub-cellular localization of S/L isoforms was examined by immune-electron-microscopy (IEM). Surprisingly, besides plasma membrane and cytosolic fractions, S/L also localized to nuclear/mitochondrial fractions, with pronounced localization of S isoform in the nuclei and mitochondria of hCCCs. Sporadic CRCs develop from adenomas (Adns). Screening colonoscopy is used for detection/resection of growths, and morphological/pathological criteria are used for risk assessment and recommendations for follow-up colonoscopy. But, these features are not precise and majority of the patients with adenomas will never develop CRC. We hypothesized that antibody-based assay(s), which identify CSCs, will significantly improve prognostic value of morphological/pathological criteria. We conducted a pilot retrospective study with PS41014-Ab, by staining archived adenoma specimens from patients who developed (High-risk) or did not develop (Low-risk) adenocarcinomas within 10-15 years. PS41014-Ab stained adenomas from initial and follow-up colonoscopies of high-risk patients, at significantly higher levels (3-5X) than adenomas from low-risk patients. A battery of tests, including DCLK1-S Antibody could be the gold tool for assessing CRC-risk. We previously reported that CRC-patients, whose colonic tumors were positive for relatively high levels of DCLK1-S expression by qRT-PCR, had a worse overall survival and disease free interval than low-expressers (O’Connell et al, Sci Rep 2015). We now report that DCLK1-S Antibody may help to identify patients at high-risk for developing CRCs within 10-15 years, at the time of index/screening colonoscopy, and thus serve as a useful biomarker at early time points of colon carcinogenesis, unlike the currently available fecal/blood tests.

#730 High sensitive detecting procedure of circulating repetitive RNA as novel early marker of pancreatic cancer. Takahiro Kishikawa, Motoyuki Ot-suka, Kazuhiko Koike. University of Tokyo, Tokyo, Japan.

Pancreatic ductal adenocarcinoma (Pdac) is one of the most intractable malignancies due to difficulties in early detection. Although promising biomarkers are increasingly reported, such methods are not yet easy to apply clinically, mainly due to their low reproducibility or technical difficulties. In this study, we developed a convenient and sensitive method for quantifying aberrantly expressed satellite repeat RNAs in sera, which can be used to efficiently detect patients with Pdac. It is difficult to correctly quantitate repeat arrays because its repetitive nature makes it difficult to establish appropriate primers that amplify a single product using simple PCR procedures. Here, we introduce a Tandem Repeat Amplification by nuclease Protection (TRAP) method combined with droplet digital PCR (ddPCR) to detect human satellite II (HSAII) RNAs, which are specifically expressed in human Pdacs at greater levels than normal tissues. HSAII RNA core sequence levels in sera were significantly higher in Pdac patients than in controls (p < 0.001, 0.75 and 0.44 per µl, respectively). Additionally, patients with intraductal papillary mucinous neoplasm (IPMN), a precancerous lesion of Pdac, could also be efficiently detected. This method can be routinely applied to screen patients with Pdac and high-risk patients, facilitating the development of preventive medicine for this disease.

#731 Stool DNA testing of Fusobacterium nucleatum for detection of colorectal tumors. Yukata Suehiro, Kouhei Sakai, Toshikito Matsumoto, Takahiro Yamasaki, Yamaguchi Univ. Graduate School of Medicine, Ube, Japan.

Background: Accumulating evidence shows an overabundance of Fusobacterium nucleatum (Fn) in colorectal tumor tissues. Although stool DNA testing of Fn might be a potential marker for the detection of colorectal tumors, the difficulty in detecting Fn in stool by conventional methods prevented further explorations. Therefore, we developed a droplet digital PCR assay for detecting Fn in stool and investigated its clinical utility in the management of colorectal tumors in a Japanese population. Methods: Feaces were collected from 60 healthy subjects (control group) and from 11 patients with colorectal non-advanced adenomas (non-advanced adenoma group), 19 patients with colorectal advanced adenoma/carcinoma in situ (advanced adenoma/CIS group), and 158 patients with colorectal cancer (CRC) of stages I to IV (CRC group). Absolute copy numbers of Fn were measured by droplet digital PCR. Results: The median copy number of Fn was 17.5 in the control group, 311 in the non-advanced adenoma group, 122 in the advanced adenoma/CIS group, and 317 in the CRC group. In-com
parison with that in the control group, the Fn level was significantly higher in the non-advanced adenoma group, the advanced adenoma/CIS group, and the CRC group. Conclusions: This study illustrates the potential of stool DNA testing of Fn by droplet digital PCR to detect individuals with colorectal tumors in a Japanese population.

#732 Potentials of some serum proteins and urinary molecular biomarkers for early diagnosis of prostate cancer in Nigeria patients. Oluwemiyi Akinloye,1 Aniebietasbi S. Oboh,2 Taiwo A. Adewole2.1 University of Lagos, Lagos, Nigeria; 2Ladoke Akintola University of Technology, Osogbo, Nigeria.

Background: Prostate cancer (PCa) an adenocarcinoma is the most common cancer diagnosed in African men today. At present, the only widely accepted screening tools for prostate cancer are prostate specific antigen (PSA) and digital rectal examination. There is controversy regarding the appropriate level of serum PSA that should trigger a biopsy. This study is aimed at finding a better marker/panel of markers for prostate cancer. Methods: 150 consenting patients requiring a prostate biopsy and 100 age matched controls were recruited for this study. Genetic materials were found in 132 (88%) of the samples. Serum Total PSA (TPSA) and free PSA were assayed using ELISA method, % free/total PSA(%f/tpsa) was obtained statistically, prostatic volume was determined using TRUS. In addition, selected urinary RNA’s were assayed; transmembrane serine protease (TMPRSS2:ERG and TMPRSS2:ETS) fusion genes, PSA gene and PCA3 (prostate cancer antigen 3), using standard polymerase chain reaction (PCR) protocols. Results: TMPRSS2:ERG was detected in 9 (7%) of the samples and limited to biopsy positive for PCa. Similarly, TMPRSS2:ETS was found in only 4 (3%) of the samples and also restricted to biopsy positive for PCa. PCA3 score had the best discriminateing accuracy in diagnosing PCa amongst patients with serum Total PSA in the range of 4 - 10 ng/ml with AUC of 0.705 compared to Total PSA, f/tpsa ratio, and PSA Density which were 0.365, 0.695, and 0.541 respectively. At the cut off value of 24.6, PCA3 score yielded its best sensitivity of 0.615 and specificity of 0.630. At the cutoff of 0.14, PSA yielded its best 0.538, 0.704 respectively.

Direct logistic regression was performed to assess the predictability of PCA using different models comprising of three (3) covariates, the model comprising PCA3 Score, f/tpsa ratio and PSA Density had the best discriminative accuracy in the subgroup with PSA range of 4 - 10ng/ml, with the sensitivity, specificity, positive predictive value, and negative predictive values of 0.59, 0.93, 71.4% and 75.8% respectively, over models comprising PCA3 Score ,TPSA and %f/tpsa, and PCA3 Score, TPSA and PSA with these values (0.23, 0.85, 42.9 % and 70.1%), (0.39, 0.89, 62.5%, and 75 %) and (0.15, 0.85,66.7% and 67.6%) respectively. Conclusions: In predicting PCa amongst patients with serum total PSA in the grey area of 4 - 10 ng/ml, the model comprising PCA3 Score, f/tpsa ratio and PSA density had the best discriminative accuracy.

#733 Detection of HCC-derived major HBV integration junctions in urine and their implications for driver identification. Selena Y. Lin,1 Jamin D. Stevens,2 Yih-Ping Su,3 Surbhi Jain,2 Ting-Tsun Chang,3 Wei Song,1 Ying-Hsiu Su1,1 University of Hong Kong, Hong Kong; 2The Baruch S Blumberg Institute, Doylestown, PA; 3National Cheng Kung University Medical College, Tainan, Taiwan.

Chronic Hepatitis B Virus (HBV) infection is a major etiology of hepatocellular carcinoma (HCC), a leading cause of cancer mortality worldwide. Integration of HBV DNA into the host genome occurs during the course of chronic infection. Integrated HBV DNA is observed in most of HBV-associated HCC. The integration junctions derived from the original tumor cell become abundant (referred to as major integration junctions) in the infected liver because of clonal expansion during tumor development. Detection of circulating DNA containing these tumor-derived integration junctions may therefore be useful for cancer detection. We have adapted a method known as Primer Extension Capture (PEC) to enrich integrated HBV DNA for next-generation sequencing (NGS). Our initial studies using this approach to enrich the HBV DR1-2 region (a common site for HBV integrated breakpoints) identified major integration junctions from HBV-HCC tissue samples and matched urine. Further analysis revealed that most recurrently targeted integrations from these HCC tumors have previously reported involvement in cancer. This suggested that identification of recurrently targeted genes is applicable for driver identification. Interestingly, we show how HBV targets the TERT promoter in a localized region even though no two TERT junctions examined are identical. We have further developed this PEC to enrich for the entire HBV genome and applied it to (i) liver tissue DNA from 20 matched HCC and adjacent non-HCC samples, and (ii) DNA from urine of 20 hepatitis, 20 cirrhosis and 20 HCC patients. The HBV enriched libraries were sequenced by NGS and the integration events were analyzed using the in-house developed software. The complexity of HBV junction sites in HCC and non-HCC tissue and urine derived circulating DNA is reported. Our approach has potential to be used for liquid biopsies to study the complexities of HBV integration in chronic HBV infection and carcinogenesis, and to identify HCC-related DNA modifications for early detection and disease management.

#734 Improved detection of salivary glands’ RNA markers in saliva samples. Adrian D. Schubert, Evgeny Izumchenko, Piotr T. Wysocki, David Sidransky, Mariana Brait. Johns Hopkins University, School of Medicine, Baltimore, MD.

RNA based liquid biopsy in saliva could be part of the diagnostic process and surveillance in patients with Salivary Gland Tumors. There is no established approach for saliva markers in salivary gland tumors. These tumors occur approximately in one out of 100,000 adults per year in the USA. We aim to develop a method to identify RNA shed specifically from the salivary glands. The two most common salivary gland malignancies harbor frequent gene fusions, which may be candidate RNA based markers. In mucoepidermoid carcinoma, the MECT1-MAML2 fusion. In adenoid cystic carcinoma, either a MYB-NFIB or MYB-NFIR fusion. We identified collection and processing methods to be tested on healthy individuals’ saliva samples. We compared three saliva stimulation methods: Chewing Gum, Tabasco and Vitamin C powder with unstimulated collected saliva; and also utilized different processing and RNA extraction procedures: Trizol based: QIAzet method (Qiagen), RNeasy saliva protecting reagent (Qiagen), OrageneRNA (DNA Genotek), and mirVana Kit (ThermoFisher). We quantitated the RNA quantity and quality with Spectrophotometer (NanoDrop) and Agilent’s 2100 Bio analyzer. We identified two salivary gland specifically highly expressed genes (HTN3 and CA6e) to be analyzed by quantitative RT-PCR. We have collected and processed 221 samples and analysis is ongoing. Bio analyzer showed that RNA from the unstimulated collected saliva has a higher concentration than stimulated saliva. Unstimulated saliva is expected to contain mucosa cells, bacteria and rests of food, therefore those could also be RNA sources. When saliva’s RNA is protected by either of the buffers tested, the RIN scores (RNA Integrity Number) obtained by Bio analyzer are higher. Based on our preliminary data, stimulation with either Tabasco, Chewing Gum or Vitamin C followed by RNA stabilization with the OrageneRNA kit and extraction with Trizol resulted in the highest quality and specificity of the RNA for its salivary gland origin. Unstimulated collection followed by the same processing generates a greater RNA yield. This saliva RNA is likely contaminated with RNA from squamous cells, bacteria and food residues, which may decrease the sensitivity of the specific gene expression of HTN3 and CA6e. Once established how to best collect and protect saliva for the extraction of nucleic acids originated from the salivary glands, we anticipate accelerating the path to clinically highly demanded kits for the surveillance of salivary gland cancer patients. We plan to prospectively collect samples from Salivary gland tumor patients with the chosen method and evaluate tumor related markers. The detection of tumor markers in bodily fluids will open a new avenue for the diagnosis and the clinical management of patients with this type of tumor. Moreover, our work creates the possibility of a liquid biopsy-based detection of several disease-specific alterations identified in different types of salivary gland tumors.

CLINICAL RESEARCH: Early Detection

CLINICAL RESEARCH: Molecular Diagnostics

#735 HER2 protein quantification in multiple cancer indications identifies candidates for HER2 targeted therapies. Shankar Sellappan,1 Sarit Schwartz,2 Ellen Werthermeier,1 Fabiola Cecchi,3 Steven W. Mamas,3 Daniel VT Catencaci,3 Todd Hembrough1.1 Dept of Pathology, University of Chicago, Chicago, IL; 2Dept of Medical Oncology, Rockville, MD; 3Cancer Center of Sarasota-Manatee, Sarasota, FL; 4University of Chicago, Chicago, IL.

Background: Anti-HER2 therapy in cancer indications other than breast and gastric cancers is the subject of ongoing clinical trials. We previously used mass spectrometry to identify HER2 levels and reveal high HER2 levels in indications other than breast and gastric cancers, respectively. These studies also demonstrated that trastuzumab-treated patients whose tumors express high levels of HER2 (≥ 2200 and ≥ 1825 amol/µg in breast and gastric cancers, respectively) survived much longer than patients with lower HER2 levels. We hypothesized that targeted proteomic workflows reveal high HER2 levels in indications other than breast and gastric cancers, thus identifying patients likely to benefit from anti-HER2 therapy. Methods: We summarized results from samples processed in our CAP/CLIA-certified laboratory. Tumor areas from FFPE tissue blocks (N=3828) representing multiple cancer indications were marked by a pathologist,
microdissected, and solubilized to tryptic peptides. In each liquefied tumor sample, HER2 and other protein targets were quantified with mass spectrometry-based proteomic analysis. Results: HER2 superexpression (> 2200 amol/μg) was found in 0.64% (12/1891) of patients with non-breast, non-gastroesophageal cancers. Among indications with > 50 patients tested, the highest rates of HER2 superexpression were in gynecologic cancers (1/124: 2.4% in cervical cancer, 1/151: 2.0%). Treatment and outcome data are largely unavailable, but we are aware of 3 anecdotes: In a 74-year-old male with invasive adenocarcinoma of the gallbladder who had disease progression on gemcitabine + cisplatin, proteomic testing found high HER2 protein expression (3105 amol/μg). The patient responded to trastuzumab + FOLFIRI for 5 months. In a uterine cancer patient whose HER2 status was equivocal by genomic analysis, proteomics found high HER2 expression (4995 amol/μg). Proteomics also revealed the absence of a resistance marker for taxane (TUBB3) and high levels of the response marker for antifolate agents (FRα: 10 500 amol/μg). The patient responded to trastuzumab + taxol for 9 months before developing resistance and responding to trastuzumab + antifolate.

Lastly, a cervical cancer patient whose disease had progressed on chemotherapy showed HER2 superexpression (1132 amol/μg). She was treated with anti-HER2 combinations for > 12 months.

Conclusions: Patients with high HER2 protein expression as measured by targeted mass spectrometry in multiple cancer types have benefited from anti-HER2 therapy. Only small numbers of patients with non-breast, non-gastric tumors have HER2 protein levels indicative of survival benefit from anti-HER2 therapy. However, targeted proteomics offers simultaneous, precise quantification of other biomarkers (e.g., ERCC1, TUBB3, FRα) to guide therapy selection for multiple cancer types.

### #736 Cell lineage-oriented clinical sequencing unveils distinct clonal oncogenicity of acute myeloid leukemia with myelodysplasia-related changes.

Kazuki Yokoyama,1 Nozomi Yuza,2 Sousuke Nakamura,3 Mika Ito,4 Asako Kobayashi,4 Masayuki Kobayashi,5 Rika Kasajima,5 Hiroaki Yui,3 Eigo Shimizu,1 Atushi Niida,1 Rui Yamaguti,6 Tsuneo Ikemour,2 Seiya Imoto,4 Yoichi Fukuwak,2 Satoru Miyano,7 Arinobu Tojo8.

#736 Acute myeloid leukemia (AML) is characterized by unregulated clonal expansion and maturation arrest of myeloid committed progenitors (MP). AML generally represents de novo onset or evolves from preceding myelodysplastic syndrome (MDS), which is defined by refractory cytopenia, clonal hematopoiesis, and/or multi-lineage dysplasia. The WHO classification2008 includes this entity as “AML with myelodysplasia-related changes (AML-MRC)”, and currently, diagnosis of AML-MRC is based on either previous history of MDS, multi-lineage dysplasia, or MDS-related cytogenetic abnormality. However, AML-MRC often represents de novo onset without these MDS-compatible clinical features. Considering that AML-MRC exhibits rather poor prognosis with refractoriness to conventional chemotherapy against AML, more accurate and objective diagnostic approach is requisite to unveil hidden “MDS signatures” in patients with apparently de novo AML. A certain set of gene mutations is specific and recurrent in MDS. Given the pre-existing “MDS signatures”, the founder gene mutations might be detected in not only blast cells but also neutrophils and/or T cells in AML-MRC. To test this hypothesis, we performed FACS sorting of neutrophils, T cells, and blasts fractions, respectively, followed by mutation screening using targeted deep sequencing, namely, cell lineage-oriented sequencing (CLS). Genomic DNA both from each cell fraction and buffy coat was subjected to screening mutations in 54 genes which are tightly involved in MDS and AML. Pair-end deep sequencing was performed on an Illumina MiSeq, using library prepared by TruSight Myeloid Panel (Illumina, San Diego, CA). Based on previously published criteria,30 we analyzed and compared CSR and/or CLS of clinically diagnosed AML-MRC (n = 7), suspected AML-MRC (n = 2), de novo AML (AML with t(15;17) or AML with inv16, n = 4), MDS (RAEB-1 and RAEB-II, n = 3), and familial MDS (n = 1). As expected, in a familial MDS case, overlapping germline RUNX1 driver mutation was demonstrated in granulocytes, blast cells and T cells, supporting that it would be originated from a hematopoietic progenitor. In MDS, AML-MRC, and suspected AML-MRC cases with no germ-line mutations, the founder mutations present in neutrophils were also retained in the AML blast cells, irrespective of a history of MDS, suggesting that these are derived from a myeloid progenitor cell. In marked contrast, there were no overlapping driver mutations between blast cell and neutrophil fractions in de novo AML characterized by recurrent chromosomal abnormalities. In summary, CLS revealed that founder mutations are shared by neutrophils and AML blast cells in AML-MRC, but not in de novo AML, although our data should be validated in a larger cohort of AML cases, CLS is a promising approach to molecular diagnosis of latent AML-MRC which requires distinct therapeutic options from de novo AML.

### #737 Significant DLX4 expression in inflammatory breast cancer from African American patients.

Jaehong Jeong,1 Tämmy Naab,2 Martin Ongkoko,3 Kephur Makambi,1 Farhan A. Khan,2 Jan Blanctao,1 1Georgetown Univ., Washington, DC; 2Howard Univ., Washington, DC.

Purpose: To examine protein expression characteristics of Distal-less homeobox 4 (DLX4) in the inflammatory breast cancer (IBC) cohort from an African-American population to determine if a) DLX4 over-expression occurs in IBC vs. normal mammary tissue and b) over-expression is associated with clinicopathologic features such as ER, PR, HER2. Experimental Design: Twenty nine blocks of formalin-fixed paraffin-embedded (FFPE) tissues from well-characterized human IBC cases were used for immuno-histochemical staining (IHC). Tumor tissues were from African American subjects seen at Howard University Hospital. Normal breast tissues from 30 mammoplasties were controls. IHC results were assigned intensity and percentage scores based upon intensity of positive staining and % of stained cells. Percentage scores were assigned as 0, 1 (0%-25%), 2 (26%-50%), 3 (51%-75%) or 4 (76%-100%) and intensity scores were assigned 0, 1, 2, 3, or 4. For the analysis of the IHC, a percentage score of 3 or 4 was considered high and an intensity score of 2 or 3 was categorized as high, Chi-square and Fisher’s exact tests were used for analysis. Results: The staining pattern for the categorized cohort in which 82.8% (24 out of 29) of IBC cases showed high percentages of positive cells staining for DLX4 protein, while 40.0% (12 out of 30) normal breast tissues demonstrated DLX4 expression (P < 0.001). In terms of staining intensity, 75.9% (22 out of 29) of IBC cases showed a high level of intensity, compared to 20.0% (6 out of 30) of normal breast tissues (P < 0.001). In terms of the association between breast cancer characteristics and IHC staining, intensity of DLX4 was higher in HER2+ (87.0%, 20 out of 23) than HER2+ (33.3%, 2 out of 6; P = 0.018). Other associations were not statistically significant in this pilot study. Conclusions: DLX4 expression is significantly higher in this pilot study of IBC cases from AA patients than in normal breast tissue cases. In addition, HER2+ is associated with high intensity of DLX4 expression in IBC.

### #738 Highly multiplexed and precisely calibrated reference materials for copy number variation detection.

Catherine Huang, Yves Konigshofer, Jessica Dickens, Bhagath Anuvelil, SeraCare Life Sciences, Gaithersburg, MD.

Introduction: Genomic instability is a hallmark of cancer, and copy number variation (CNV), including gene duplication and deletion, can be a key driver of oncogenesis. Detection of CNV is needed for personalized treatment, and may involve microarray analysis or Next Generation Sequencing. Often, DNA from patient-derived cell lines is used as positive control material in these assays. However, these materials are often poorly characterized, may change over time, and have additional confounding genetic alterations. Here we describe the development of new reference materials that are highly characterized by digital PCR and can aid in the validation and calibration of new diagnostic assays for CNV. Methods: The GM24385 reference cell line has been extensively characterized by the Genome in a Bottle project1 and originates from a participant in the Personal Genome Project. DNA from this cell line was used to make a library of full-length gene inserts. The library had >12X coverage of the GM24385 genome and an average insert size of ~135 Kb. PCR based screening was used to identify and isolate full length MYC, FGFR3 and ERBB2 genes. Next Generation Sequencing, using Illumina Nextera library preparation kits and a MiSeq instrument, was used to verify the gene of interest. The genomic DNA and gene inserts were then amplified into reference materials, in purified DNA format to amplify the copy numbers of these key genes. Digital PCR was used to control the mixing and verify the number of copies of genes and/or mutations within the reference material. Results: The sequence confirmed genes were formulated into GM24385 genomic DNA at levels consistent with 5X and 10X amplification.
Testing on the ArcherDX VariantPlex™ Solid Tumor Kit indicated that each amplification could be detected at the expected level. Conclusions: Highly characterized and consistently manufactured reference materials for copy number detection are currently lacking. The described Seraseq CNV Reference Materials provide proof of concept for a biosynthetic, engineered material that uses digital PCR as an orthogonal reference method and provides a “ground truth” copy number level for key oncogenes.

#740 Rapid detection of IDH1/2 mutations using RNaseH2 dependent, multiplex quantitative PCR assays. Yun Baoo,1 Aymen Baig,1 Tu Wang,1 A John Istrate,2 Caliu Chen,1 Darrell R. Borger.1 Integrated DNA Technologies, Redwood City, CA; 2Massachusetts General Hospital Cancer Center, Boston, MA.

Isocitrate dehydrogenase 1 (IDH1) and 2 (IDH2) are enzymes that normally catalyze the oxidative decarboxylation of isocitrate to α-ketoglutarate during glucose metabolism. Heterozygous mutations in the IDH1 and IDH2 genes have been identified in a specific subset of cancers. Mutations typically affect the enzyme active sites at codon R132 in the IDH1 gene, and R140 or R172 in the IDH2 gene. This confers neomorphic enzyme activity that produces the oncometabolite 2-hydroxyglutarate that is involved in cancer initiation and progression. The detection of IDH1/IDH2 mutations has important diagnostic, prognostic, and therapeutic implications and testing for these variants is being incorporated in clinical settings. In fact, the identification of IDH1 or IDH2 gene mutations is now required for the classification of tumors of the central nervous system under the 2016 WHO guidelines. Therefore, there is a significant need for an IDH1 + IDH2 test that can be performed in a rapid manner to support clinical diagnosis and treatment decisions. A strategy utilizing allele-specific quantitative PCR (qPCR) is well suited for evaluating a small number of hotspot variants in IDH1 and IDH2 from clinical tissue samples in a matter of few hours. Using RNase H2 dependent PCR (rPCR) and a universal reporter system, we have developed new multiplex qPCR assays that effectively discriminate between closely related sequences that differ by only a single nucleotide base at the same position or adjacent position in a single tube reaction. In addition, the rPCR mechanism of the assays also greatly reduces the impact of primer-primer interactions, further improving the multiplex capability of the assays. During initial testing, accuracy, specificity and sensitivity were evaluated. Mutations present in patient samples at frequencies as low as 2% were identified with high reproducibility. The assays have been tested across 49 patient samples that included FFPE tissue, blood, and bone marrow aspirate with results that are concordant to those found using an orthogonal method of next generation sequencing. Our study showed that this assay provides a rapid method for detection of multiple IDH1 or IDH2 mutations in single rhPCR reactions with high accuracy, specificity, and sensitivity.

#741 Rapid detection of necrosis in breast cancer with ex vivo and in situ mass spectrometry analysis methods. Arash Zarrine-Alsar,1 Bindesh Shrestha,2 Alessandra Tata,1 Michael Woolman,1 Manuela Ventura,1 Nicholas Bardsley,3 Milan Ganguly,2 Howard Ginsberg,3 Jinzi Zheng,1 Emma Bluemke1.

The discovery of circulating tumor DNA (ctDNA) in the blood, urine and other bodily fluids of cancer patients has led to a new type of non-invasive method of characterizing cancer-causing mutations, the liquid biopsy. With NGS technologies becoming increasingly sensitive, down to a 0.1% Limit of Detection (LOD), they are rapidly gaining traction as a valid assay for cancer genotyping and have potential to direct cancer treatment plans. The wide-angle view provided by NGS panels, combined with dPCR’s zoom-in precision detection of DNA provide a comprehensive picture of a cancer’s genetic makeup. By applying these complementary techniques at the appropriate time based on the disease type and stage, cancer treatment will become quicker, more precise and more cost-effective in the future. NGS and digital PCR together provide a complete picture of the cancer genome. As part of our research, we wet-lab tested a subset of Rare Mutation Assays corresponding to the Oncomine ctDNA panel for next generation sequencing. Synthetic plasmid (GeneArt) carrying the mutation was spiked into wild-type genomic DNA to reflect a mutation rate of 0.1%. Wild-type genomic DNA was used as negative control. Thermal cycling was performed according to protocol for digital PCR using the QuantStudio 3D. In this study, we tested a pilot set of samples using AcroMetrix Oncology Hotspot Control and Horizon ctDNA Reference Standard with both NGS using Oncomine ctDNA panel and digital PCR with Rare Mutation Assays. Comparison of NGS and digital PCR results for the same sample showed excellent correlation in the low mutation range around 0.1%. This study confirms that digital PCR using QuantStudio 3D and Rare Mutation Assays is effective as a method for orthogonal validation of NGS data using the Oncomine ctDNA panel. Additionally, TaqMan Rare Mutation Assays offer a sensitive and precise solution for downstream mutation tracking over a time course. For Research Use Only. Not for use in diagnostic procedures.

#742 Comprehensive detection of all major classes of MET deregulation by Anchored Multiplex PCR and next-generation sequencing. Brian A. Kudlow,1 Josh Haines,2 Marc Bessette,2 Namitha Mano,1 Laura M. Griffin,3 Danielle Murphy,2 Robert Shoemaker,2 Jason Amsbaugh,3 Joshua Stahl1. ArcherDX, Boulder, CO; 1Ignita, San Diego, CA.

Introduction: Deregulation of the proto-oncogene, MET, confers an aggressive phenotype in a variety of human cancers, promoting proliferation, invasive growth and angiogenesis. MET deregulation can be driven by gene amplification, overexpression, exon 14 skipping, gene fusions and single nucleotide variants (SNVs), such as kinase-activating point mutations. MET is a target of intensive drug development efforts, although the various mutated forms of MET exhibit unique drug sensitivities. The input clinical sample types and protocols widely used in characterization of cancer in both imaging mode (to provide spatial information on cancer border) and profiling mode (to provide information on cancer type and subtype); all based on unique molecular profile associated with each cancer type and subtype. Current efforts in creating cancer molecular profile libraries will facilitate translation.

#743 Orthogonal validation of oncomine ctDNA panel data with digital PCR using TaqMan Rare Mutation Assays. Vidya Venkatesh, Marion Liang, Kamini Varma, Yanchun Li, Kelli Bramlett, Dalia Dhingra, Richard Chien. Thermo Fisher Scientific, South San Francisco, CA.

The discovery of circulating tumor DNA (ctDNA) in the blood, urine and other bodily fluids of cancer patients has led to a new type non-invasive method of characterizing cancer-causing mutations, the liquid biopsy. With NGS technologies becoming increasingly sensitive, down to a 0.1% Limit of Detection (LOD), they are rapidly gaining traction as a valid assay for cancer genotyping and have potential to direct cancer treatment plans. The wide-angle view provided by NGS panels, combined with dPCR’s zoom-in precision detection of DNA provide a comprehensive picture of a cancer’s genetic makeup. By applying these complementary techniques at the appropriate time based on the disease type and stage, cancer treatment will become quicker, more precise and more cost-effective in the future. NGS and digital PCR together provide a complete picture of the cancer genome. As part of our research, we wet-lab tested a subset of Rare Mutation Assays corresponding to the Oncomine ctDNA panel for next generation sequencing. Synthetic plasmid (GeneArt) carrying the mutation was spiked into wild-type genomic DNA to reflect a mutation rate of 0.1%. Wild-type genomic DNA was used as negative control. Thermal cycling was performed according to protocol for digital PCR using the QuantStudio 3D. In this study, we tested a pilot set of samples using AcroMetrix Oncology Hotspot Control and Horizon ctDNA Reference Standard with both NGS using Oncomine ctDNA panel and digital PCR withRare Mutation Assays. Comparison of NGS and digital PCR results for the same sample showed excellent correlation in the low mutation range around 0.1%. This study confirms that digital PCR using QuantStudio 3D and Rare Mutation Assays is effective as a method for orthogonal validation of NGS data using the Oncomine ctDNA panel. Additionally, TaqMan Rare Mutation Assays offer a sensitive and precise solution for downstream mutation tracking over a time course. For Research Use Only. Not for use in diagnostic procedures.
from low-input clinical sample types, such as FFPE specimens. As MET deregulation can be driven by many different genetic aberrations, this allows for MET-based characterization of MET deregulation from a single sample.

#743 Detection of TERT C228T and C250T promoter mutations in melanoma tumor and plasma samples using novel mutation-specific droplet digital PCR assays. Brodieck Corfless,1 Gregory Chang,1 Samantha Cooper,1 Mahrukh Syeda,1 Iman Osman,2 George Karlin-Neumann,2 David Polsky,1 New York University School of Medicine, New York, NY; 2Bio-Rad Laboratories, Pleasanton, CA.

Purpose: Detecting mutations in the plasma of patients with solid tumors is becoming a valuable method of diagnosing and monitoring cancer. Mutations in 1 of 2 hot spots in the TERT promoter sequence are found in several cancers, including up to 85% of melanomas and the majority of cases that lack BRAF or NRAS mutations (about one-third of melanomas). Due to the high G-C content of the TERT promoter sequence these mutations can be difficult to detect using NGS approaches. We developed novel droplet digital PCR (ddPCR) assays to detect these 2 mutations with high sensitivity and specificity, and demonstrate the application of these assays in melanoma clinical samples. Methods: Assays were optimized using cell lines with Sanger sequencing-conﬁrmed mutations: glioblastoma A172 (C228T), and melanoma NYU12-126 (C250T). We varied assay designs and amplification conditions to optimize probe-based detection using the Bio-Rad QX-200 ddPCR system. Assay sensitivities and speciﬁcities at various DNA input levels were determined using serial dilutions with 3 replicate wells for each condition. Sensitivity is defined as the lowest mutant allele dilution for which the concentration interval did not overlap with that of the 0% mutant wells. We used normal and cancer-derived DNA sources of different quality (e.g. normal human DNA (Promega), cancer cell lines, plasma and FFPE-derived DNAs) with and without the mutations, and compared the efficiency of detection of amplions of 88, 113 and 163 base-pairs. We compared efficiencies to assays of similar size for RPP30, a housekeeping gene. Results: The assays showed greater sensitivity when higher amounts of DNA were analyzed. For C228T the limit of detection (LOD) of the mutant allele was 1%, 0.25% and 0.1% for 6.6ng/well, 33ng/well and 66ng/well well respectively; for C250T the LODs were 0.25%, 0.05% and 0.05% respectively. Using normal human DNA, the efficiency of the TERT assays averaged approximately 90% of that for RPP30 across assays of similar size, and no decrease in assay efﬁciency was observed as amplicon length increased. In contrast, whereas amplicon size had only a modest effect on assay efﬁciency in plasma ctDNA, it gave a more pronounced effect on FFPE DNA’s, decreasing to 38% for the 163bp amplicon. We observed 100% concordance between TERT mutation detection by SNAPSHOT and ddPCR in 10 FFPE tumor samples, and in plasma samples from 4 metastatic melanoma patients with matching tumor samples. Conclusion: We developed robust ddPCR assays to detect TERT promoter mutations with high sensitivity and specificity. Mutated TERT DNA can be detected and quantitated in the plasma of patients with metastatic melanoma, and is likely to be present in the plasma of other cancer patients in whom TERT mutations occur.

The analysis of circulating cell-free tumor DNA (ctDNA), which can be obtained from plasma by non-invasive procedures, is expected to provide useful biomarkers in the management of non-small-cell lung cancer (NSCLC) patients. Indeed, several studies have assessed ctDNA prognostic and predictive value as source of key data for therapeutic targets and drug resistance in carcinoma patients. The expanding number of targeted therapeutics for NSCLC always represents a real-time wider tumor genotyping, and the use of ctDNA as either a complement or an alternative to tumor tissue DNA (tDNA) could be a valuable option for Next-Generation Sequencing (NGS) of key cancer genes. The isolation and enrichment of ctDNA is a big challenge because of its high degree of fragmentation and its low concentration against the normally occurring background of cell-free DNA derived from healthy cells. Therefore standardized methods for ctDNA extraction and analysis are crucial aspects in the setting-up of a molecular diagnostic approach. In this study we aimed to evaluate the ctDNA use for molecular profiling, also analyzing the impact of both pre-analytical and analytical variables on DNA yield and mutation detection. Matched tDNA and ctDNA from 30 NSCLC patients were extracted, quantified and quality-controlled, and then investigated by different standard methods (real-time PCR, digital PCR, Mass Spectrometry genotyping) for EGFR, KRAS, BRAF, PIK3CA status. Mutational screening of ctDNA samples by IonTorrent NGS (Oncomine) Lung ctDNA Assay, ThermoFisher was also performed. Furthermore, we extended ctDNA evaluation to additional 30 lung cancer patients with no available tumor sample. We found that cell free DNA concentration in plasma correlated with both stage and number of metastatic sites. Analyzing the ctDNA samples using NGS and ctDNA by ddPCR in 10 FFPE tumors and 10 plasma samples, we found mutations in EGFR, KRAS, PIK3CA genes, with an overall concordance of 77%. Interestingly, Oncomine Lung ctDNA assay detected these same mutations with the same allelic frequency of standard methods; mutations in TP53 and ALK genes were also found. In the 30 patients with no available tumor sample, we found EGFR (10%) and KRAS (7%) mutations on ctDNA by standard methods; NGS analysis is under evaluation. This study evaluated the use of multiple different methods to detect mutations in NSCLC and showed that ctDNA can be a feasible option for clinical monitoring of lung cancers, including for those patients who cannot undergo invasive diagnostic procedures, due to either comorbidities or absence of biopsiable tumor lesions.

#745 Interleukin-13 conjugated quantum dots to identify glioma initiating cells and exosomes. Achuthamangalam B. Madhankumar,1 Oliver Mrowczynski,1 Brad Zacharia,1 Michael Glantz,2 Lichong Xu,2 Becky Webb,2 Christopher Siedlecki,1 Akiva Mintz,2 James R. Connor1.1New York University, New York, NY; 2Wake Forest University Baptist Medical Center, Winston Salem, NC.

High grade brain tumors like glioblastoma multiforme (GBM) and certain other brain metastatic cancers possess high tumor invasive and infiltrating properties making them harder to detect. Identification of cancer cells and exosomes secreted by them in the biofluids like cerebrospinal fluid (CSF) can be an ideal way of detecting the presence of residual cancer after therapy. In the current approach, a ligand conjugated quantum dot (QD) was utilized to specifically label the cancer stem cells and exosomes to identify the presence of IL13Rα2 a tumor invasive marker. Human glioma initiating cells were cultured in adherent form and were exposed to interleukin-13 conjugated quantum dots (IL13QD), which binds the glioma initiating cells expressing IL13Rα2 receptor. Similarly the exosomes isolated from cancer stem cell condition media and CSF was brieﬂy incubated with IL13QD, before analyzing their complexing pattern. Exosomes that were isolated from glioma stem cells and patients CSF were demonstrated to express IL13Rα2 receptor. Fluorescent microscopy, transmission electron microscopy and flow cytometry were performed on the exosomes after complexing with IL13QD. IL13QD was demonstrated to specifically bind glioma stem cells both in the monolayer and spheroid culture. The binding afﬁnity of the exosomes to the quantum dots were quantitatively and qualitatively conﬁrmed by atomic force microscopy (AFM). The morphology and size of exosomes before and after complexing with exosomes were conﬁrmed by electron microscopy and AFM. The density plot from the flow cytometry experiments with IL13QD-exosomes complex indicates a possibility to identify the tumor associated exosomes. Our experiment inferences that tumor targeted quantum dots can selectively bind with glioma stem cells and extracellular vesicles (exosomes) that are secreted by cancer cells. This binding proﬁle could be utilized to identify the expression of certain tumor promoting receptors and anti- genes on the surface of exosomes present in the CSF and cancer stem cells from the glioma patients. Experiments are in progress to identify the tumor initiating cells in an orthotopic mouse glioma tumor model after intravenous administration of wild type IL13 and certain high afﬁnity mutated IL13 conjugated quantum dots, by non-invasive way.

#746 TaqMan Rare Mutation Assay targeting the TERT promoter region. Marion Laig, Kanini Varma, Vidya Venkatesh. Thermo Fisher Scientiﬁc Inc., South San Francisco, CA.

The enzyme Telomerase maintains telomeres at the ends of chromosomes. The Telomerase Reverse Transcriptase (TERT) gene codes for the enzyme’s catalytic domain and is not expressed in normal somatic cells. As a consequence, normal cells acquire senescence by shortening of their telomeres during cell division and eventually undergo apoptosis. In contrast to normal somatic cells, expression of TERT is reinitiated in cancer cells causing escape from senescence and apoptosis by maintaining the telomeres. It has recently been shown that mutations in the TERT promoter region play a key role in regulating and reinstating TERT expression. 90% of cancers carry a mutation in the TERT promoter region. Mutations like C228T and C250T create new binding site for the E2 transcription-factor (ETS) transcription factor that regulates TERT expression. Experimental evidence showed that the ETS factor GA-binding protein, alpha subunit (GABPA) binds to the de novo ETS motif and activates TERT transcription in cancer cells. We undertook a project designing TaqMan Rare Mutation assays addressing mutations in the TERT promoter. These assays are
TaqMan SNP Genotyping assays that are optimized for use in digital PCR with the Applied Biosystems QuantStudio 3D. In digital PCR, partitioning the sample into many individual reaction wells facilitates detection and quantification of rare mutant alleles. TaqMan SNP Genotyping Assays ensure reliable discrimination of mutant and wild-type allele. This will enable easy and sensitive detection of KRAS and NRAS mutations in a broad range of applications. Sensitivity of the proposed assay is suitable for detection in liquid biopsy applications with cell free DNA (cfDNA). Assay design proved to be challenging due to high GC content and repetitive elements in this region of the TERT gene and required varying both the assay design and experimental cycling conditions. Template for wet-lab testing was synthetic plasmid carrying the mutation spiked into wild-type genomic DNA and tested with the Applied Biosystems QuantStudio 3D. The results with the proposed assay detecting the C228T mutation in the TERT promoter region. We showed that designing TaqMan Rare Mutation Assays for digital PCR is feasible for the challenging TERT promoter region. Work addressing additional mutations in this region is ongoing. For Research Use Only. Not for use in diagnostic procedures.

**#747** An improved fixative for histomorphology, recovery of nucleic acids and proteins. Stephen M. Hewitt,1 Joon-Yong Chung,1 Candice Perry,1 Kris Ylaya,1 William M-A Smith,1 Robert A. Star,1 National Cancer Inst., Bethesda, MD, 2National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Neutral Buffered Formalin (NBF) has been the primary diagnostic fixative for histopathology for nearly a century. The limitations of NBF are well known, especially with reference to the analysis of RNA and proteins. Alternative fixatives have been proposed, but not been widely adopted. Recently, the US Environmental Protection Agency (EPA) classified formaldehyde as a carcinogen, further tilting the balance away from the continued use of NBF. We recently described a fixative based on 70% ethanol and phosphate buffered saline, called BE70. Using BE70 as the base fixative, we have developed a modular fixative in which different chemicals can be supplemented for “fit for purpose” applications. The addition of guanidinium salts to BE70, termed BE70G results in a fixative in which both proteins and nucleic acids are improved in quantity and quality after extraction from the paraffin block. The guanidinium replaces non-freazeable water, and prevents hydrolysis and oxidation of the biomolecules. Histomorphology is not disrupted at lower concentrations, with only alterations of hematoxylin intensity at higher concentrations. Studies are underway to evaluate the stability of RNA and protein in the tissue block as well as on cut sections. This fixative, BE70G has the potential to address a number of challenges facing the development of precision biomarkers, while preserving histomorphology, and improving the safety of pathology staff. Other formulations are currently being evaluated that may support applications for cytology and electron microcopy. The goal is a well characterized fixative, in which modifications to the chemistry are defined and can be applied to obtain the optimal pathology specimen for both histomorphologic and molecular analysis.

**#748** A rapid and accurate nucleic acid amplification and detection method for KRAS mutation testing in colorectal cancer specimens. Choong Eun Jin, Seung-Soon Yeom, Yong Shin, Seok-Byung Lim. University of Ulmbn College of Medicine, Seoul, Republic of Korea.

Colorectal cancer (CRC) is one of the most common type of cancers both men and women in worldwide. Fortunately, overall death rates of CRC have been decreasing for the last two decades due to the improvement of screening test assays that detect early-stage cancer and pre-cancerous polyps. Nevertheless, the most common treatment for CRC is surgery, because it may completely eliminate the cancer region. In case of the cancer with systemic metastasis, chemotherapy is required before or after surgery for primary or metastatic lesions. Among the regimens for the chemotherapy, both monoclonal antibodies (Cetuximab and Pantitumumab) against the epidermal growth factor receptor have been shown to improve survival for only patients with lack of RAS mutations. Thus, the KRAS gene mutations (codons 12 and 13) in CRC patients have been extensively studied as a strong negative predictive biomarker to indicate whether a CRC patient responds to the treatment. Therefore, testing the KRAS mutational status of tumor samples is becoming an essential tool for managing patients with CRCs. Although a myriad of nucleic acid testing methods have been developed to analyze the mutation status in the key regions of the KRAS gene of CRC, several obstacles still remain related to low sensitivity, time consuming, and required large instruments including thermal cyclers. Here, we present a novel nucleic acid amplification and detection method for KRAS mutations (G12D and G13D) testing that enable rapid and accurate detection. This method is based on combination of isothermal DNA amplification method and bio-photonic silicon sensor that can be detected the mutations in a label-free and real-time manner. The proposed method can detect the mutant cell present at 1% in a mixture of wild type cells, while both PCR and sequencing can detect the mutations in a sample containing approximately 30% of mutant cells. We used 60 tissue samples from CRC patients (22 samples with G12D mutations, 23 samples with G13D mutation, and 15 samples with no mutation) to compare the performance of the proposed method with with iPLEX Pro panel. We showed that the proposed method showed a value of 100% and 100% for sensitivity and specificity, respectively. The other hand, the sensitivity and specificity of PCR (95.5% and 100%) and sequencing (95% and 100%) were lower than that of the proposed method. Therefore, the proposed method was found to be a rapid (< 30 min), highly sensitive and specific method for KRAS mutation testing. We believe that this rapid and accurate method will enable proper treatment for CRC patients.

A recent technical advance in the mRNA in situ hybridization (mRNA-ISH) assay provides simultaneous signal amplification and background suppression with a unique probe design to achieve single molecule visualization. We assessed the utility of the mRNA-ISH assay as a diagnostic tool to detect anaplastic lymphoma receptor tyrosine kinase (ALK) mRNA in non-small cell lung carcinoma. We compared the mRNA-ISH assay with immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH). The study included 279 surgically resected lung adenocarcinomas and 44 transbronchial biopsies (TBB) adenocarcinomas. mRNA-ISH was conducted using the RNAscope 2.0 system which includes pre-designed detection probes for the tyrosine kinase domain of ALK mRNA. IHC was conducted on all of the 323 samples using ALK-specific antibodies. mRNA-ISH was performed on 279 surgical samples and 6 TBB samples. Break-apart FISH was used to assess cases that were mRNA-ISH or IHC positive. ALK protein expression was detected in 11/279 (3.9%) specimens. ALK mRNA was also detected by mRNA-ISH in these cases, and 9 of the 11 specimens (81%), were also positive by ALK FISH. Using the IHC results as a reference, the sensitivity and specificity of mRNA-ISH was 100%. In the TBB cohort, ALK protein expression was observed in 3/44 (6.8%) of specimens, in which ALK mRNA expression was also detected. ALK mRNA-ISH data were highly correlated with the IHC data, and ALK mRNA-ISH was able to identify every FISH-positive sample. We conclude that mRNA-ISH could play an alternative or complementary role in ALK genetic diagnosis in NSCLC.

Background: As cancer therapeutics are increasingly selected based upon molecular genetic information, having reliable, accurate, rapid and inexpensive methods for mutational analysis are extremely desirable. Circulating tumor cells (CTCs) allow non-invasive “liquid biopsy” access to intact cells for molecular analysis. Here we demonstrate the successful detection of mutations in model CTCs individually isolated from blood (AccuCyte® - CyteFinder® system, RareCyte) using MALDI-TOF Mass Spectrometry (MassARRAY, Agena Bioscience). Methods: Breast (MDA-MB-231) and lung (NCI-H1975) cancer cells with a set of known mutations were spiked into blood and processed by AccuCyte onto microscope slides and stained on an automated immunostainer. Slides were imaged using the CyteFinder digital fluorescence scanning microscopy and mCTCs were identified by positive nuclear, EpCAM, and cytokeratin staining, and negative CD45 staining. mCTCs and white blood cell (WBC) negative controls were picked from the slides and put into PCR tubes using the CytePicker® module. DNA from individual or small pools of cells (3-5) was amplified using the PicoPLEX® (Rubicon) whole genome amplification (WGA) kit; alternatively cells were lysed and directly entered into the ensuing iPLEX® Pro workflow. Specific regions surrounding 5 different mutations in each of the mCTC lines were amplified from the WGA product or the lysed cells and the products were detected and scored for the mutations using a single PCR reaction iPLEX® Pro panel that includes a combination of 10 common lung and breast cancer mutations using the MassARRAY® platform. Results: Five point mutations in four different genes (CDKN2A, EGFR, PIK3CA, and TP53) were measured in the NCI-H1975 lines and four point mutations in four genes (BRAF, KRAS, NF2, and TP53) were measured in the MDA-MB-231 cells by iPLEX® Pro chemistry on the MassARRAY® system. All mutations were accurately detected in the WGA single and pooled cell samples and most were also detected in cells that did not undergo WGA before PCR with with iPLEX Pro panel. Allelic frequency observed was consistent with

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 191
known zygosity of the mutation. Conclusions: MassARRAY successfully detected mutations in single model CTCs that were individually picked from a blood sample processed by the AccuCyte - CyteFinder system. Integrating CTC isolation with MassARRAY may be a practical way to identify and monitor known cancer mutations non-invasively.

#751 Characterization of STAT3 activation in human prostate cancer. Marco A. De Velasco,1 Yui Hatatana,1 Yurie Kura,1 Naomi Ando,1 Kazuo Sakai,1 Koichi Sugimoto,2 Mashaio Nozawa,2 Kazuhiro Yoshimura,2 Kazuhiro Yoshikawa,2 Kazuto Nishio,1 Hirotsugu Uemura1. 1Kindai University Faculty of Medicine, Osaka-Sayama, Japan; 2Aichi Medical University, Nagakute, Japan.

Signal transducers and activators of transcription (STATs) were initially associated with cytokine signal transduction pathways but are now also recognized as key modulators of key survival processes in various cancers. Activation of STAT3 occurs by the binding of various cytokines to its receptors leading to the activation of the JAK/STAT3 signaling pathway. Interleukin-6 (IL-6) has been implicated in regulating growth of various malignant tumors. Activated IL-6 has also been shown to be elevated in the sera from patients with metastatic prostate cancer, and persistent activation of STAT3 is a common feature. To better characterize the potential role of JAK/STAT3 as a therapeutic target for advanced prostate cancer, we examined expression patterns of activated STAT3 in 111 cases of localized prostate cancer from patients who underwent radical prostatectomy. Association studies were conducted with clinicopathological characteristics and biochemical recurrence. We also analyzed the expression of IL-6/IL-10/STAT3 genes from RNA-sequencing data from the Cancer Genome Atlas (TCGA) breast and prostate datasets. We found a significant association between STAT3 expression and clinicopathological parameters. Patients with moderate-high p-STAT3 expression tended to experience shorter times to biochemical recurrence (median time, 15 months) compared to patients with low-negative STAT3 activity, (median time to recurrence not reached, P=0.064). Cluster analysis suggested a trend for decreased disease-free survival for patients with high IL-6/IL-10/STAT3 gene expression signature. Our data suggests an association between STAT3 signaling and prostate cancer recurrence and provides clinical evidence to support JAK/STAT3 as a potential therapeutic target for patients with advanced prostate cancer.

#752 Evaluation of VENTANA Benchmark ULTRA and Roche cobas® 480 analyzer for detection of EGFR mutations. Lorraine Stewart, Chunyan Liu, Judith Pugh, Heather Gustafson. Ventana Medical Systems, Tucson, AZ.

Research has shown non-small cell lung cancer (NSCLC) is the most common type of lung cancer in the world. Exon 19 deletion and L858R mutation in exon 21 account for approximately 90% of EGFR mutations in adenocarcinoma NSCLC1. Accuracy and sensitivity in detection of these markers aids the selection of patients with NSCLC for therapy with an EGFR tyrosine kinase inhibitor (TKI). This study demonstrates how validated Immunohistochemistry (IHC) and real-time PCR testing can be used to aid one another in detection of activating mutations with factors such as low tumor content in formalin-fixed, paraffin embedded biopsies in our CAP/CLIA laboratory. Evaluation of IHC detection was completed on the VENTANA Benchmark ULTRA Automated IHC/ISH slide stainer and PCR testing was performed using the Roche cobas® 480 analyzer. The IHC diagnostic markers selected were the two most common EGFR mutations, E746-A750del (SP111) and L858R (SP125). Sample preparation and real-time PCR testing was done using the cobas® DNA Sample Preparation Kit and cobas® EGFR Mutation Test v2 utilizing a custom, automated plate preparation program on the Perkin Elmer Emsg Express Platform. Analytical data from the BenchMark ULTRA platform staining and the cobas® 480 analyzer correlated in the majority cases. Out of 32 specimens tested, we observed a 100% concordance between IHC and PCR for L858R exon 21 mutation, whereas EGFR exon 19 deletion and concordance between IHC and PCR was 90%. This decrease in concordance was due to 3 specimens with indeterminate IHC staining results with weak staining in a small tumor area. Use of a custom automated workflow for PCR plate preparation demonstrated successful facilitation of sample preparation and tracking. Evaluation of results indicate that not only is >10% tumor content important for detection of mutations via PCR (as directed by the IVD package insert), but heterogeneity within the tumor can further decrease sensitivity of PCR. However weak or low IHC staining in only small areas of the tumor may prove to have less clinical relevance. For the most comprehensive results, IHC staining in addition to molecular testing provides better characterization of tumor profiles. Preliminary results suggest that automated dissection of tumor with the Roche Automated Dissection instrument prior to PCR increases sensitivity. In conclusion, IHC and real-time PCR should be used together to detect not only the array of mutation available in the PCR test, but also to confirm the two most common mutations by IHC and increase sensitivity of testing which may be strongly impacted by heterogeneity. 1. - Marc Luo and William Pao. Lung adenocarcinoma: guiding EGFR-targeted therapy and beyond. Modern Pathology (2008)21, S16-S22; doi:10.1038/modpathol.3801018.

#753 Human epidermal growth receptor-2 immunohistochemistry in gastric cancer. Babatunde M. Duduyemi,1 Mary Y. Alhene,1 Emmanuel A. Asia- mah1,2 Kwanne Nkrumah University of Science and Technology, Kumasi, Ghana; 2Komfo Anoyke Teaching Hospital, Kumasi, Ghana.

Introduction: Gastric cancer is the second most common GI cancers and third leading cause of cancer-related deaths worldwide. In Ghana, gastric cancer contributes significantly to cancer morbidity and mortality. The recent development on the benefit of targeted therapy in the management of gastric cancer using HER-2 monoclonal antibody in combination with chemotherapy has greatly improved the overall survival of patients. This study therefore aims at determining the frequency of Her-2 over-expression in gastric carcinomas in Kumasi, Ghana and comparing with other prognostic factors. Methodology: Demographic data and histological diagnosis were retrieved from the surgical day book of the Department of Pathology, Komfo Anoyke Teaching Hospital, Kumasi. The slides were retrieved and reviewed to confirm diagnosis, grading and classification of gastric cancer. Immunohistochemistry was done with anti-HER-2 antibody to confirm HER-2 over-expression. The data was analysed with SPSS version 17. Results: Of the 99 cases of gastric cancer seen over the 8 year period, there were 57 males and 42 females, adenocarcinoma (91), GIST (3) and Non Hodgskin Lymphoma (3). The age range of the study population was 8-90 years with modal age group in the 6th decade. There were more biopsies (63) than resections (36). Of the adenocarcinomas, 45 were poorly differentiated, 38 moderately differentiated and 8 well differentiated. Diffuse type is most common with 47 cases followed by intestinal 41 cases and mixed type 3 cases. Three of the 4 patients under the age of 30 years had lymphoma. HER-2 over-expression was seen in 14 out of the 47 tested and all were intestinal type. Conclusion: HER-2 over-expression was seen a small cohort of our patients with gastric cancer especially those with intestinal type.

#754 Treatment decision-making of rare ERBB2 (HER2) mutations in lung cancer; a role for multidisciplinary molecular tumor boards. Arja ter Elst,1 Nils A. ’t Hart,1 Anthonie J. van der Welken,1 Wim Timens,1 Lucie R. Hijmering-Kappelle, Geke A. Hosapers,1 Hilde Jaling,1 Elise M. van der Logt,1 Leon C. van Kempen,1 Sjoedje F. Oosting,1 Matthew R. Groves,2 T Jeroen Hiltemann,1 Anke van der Berg,2 Harry J. Groen,1 Ed Schuuring,1 University Medical Center Groningen, University of Groningen, Groningen, Netherlands.

Introduction: Breakthroughs in cancer research have resulted in mutation-specific targeted therapies (precision medicine). Most of these new drugs are only effective in patients with an actionable molecular profile. Thus, predictive molecular testing enables oncologists to select individual patients for the most appropriate (targeted) therapy and to reduce the burden of overtreatment. The number of clinically relevant predictive markers that are routinely analyzed is growing rapidly, resulting in the identification of rare mutations, mutations with unknown relevance and coexistence of two or more mutations in the same sample. Incorporating these into the optimal treatment for the individual patient can be complex. Methods: A total of 2461 sequential tumor biopsies were analyzed at our institute using targeted next generation sequencing (Ion Torrent platform). 230 of these patients were discussed at a weekly Molecular Tumor Board meeting. Samples were analyzed at our institute using targeted next generation sequencing (Ion Torrent platform). 230 of these patients were discussed at a weekly Molecular Tumor Board (MTB) meeting. Results: In this abstract we report on four patients with an ERBB2 exon 20 mutation and 1 patient with ERBB2 amplification received anti-HER2 treatment after an MTB consensus decision. Two patients with an insertion in exon 20 of ERBB2: (c.2313+2324dup; p.(Y772+775dup)) received first line therapy with afatinib and showed a partial response and stable disease respectively. One patient with a c.2524G>A; p.(V842I) mutation received afatinib and showed stable disease for 3 months. A patient with another ERBB2 exon 20 insertion (c.2326_2327insATAT: p.(G776delinsVC)) received afatinib but had progressive disease within two years and the current treatment decision was for afatinib plus bevacizumab. Based on these results, the MTB made an evidence-based recommendation for the use of the combination therapy in the future. Conclusion: The MTB is an efficient way to treat patients with rare mutations, with unknown relevance, in a multidisciplinary approach. Results: In this abstract we report on four patients with an ERBB2 exon 20 mutation and 1 patient with ERBB2 amplification received anti-HER2 treatment after an MTB consensus decision. months. One patient with an ERBB2 amplification by FISH and high (3+) HER2(ERBB2) expression, showed a partial response to trastuzumab. All patients had stage IV and would without genomic knowledge be treated with chemotherapy. Conclusion: Lung cancer patients with sporadic ERBB2 mutations might benefit from targeted ERBB2 therapy. For an optimal treatment decision, patients with rare mutations in general, may benefit from discussion in a multidisciplinary molecular tumor board. In the future, both the considerations for targeted therapy as well as treatment response and toxicity should be registered in an open-access database and shared with other national and international Molecular Tumor Board initiatives to allow comparison with traditional treatments.

#755 Supporting precision cancer treatment decision with functional evaluation of cancer gene mutations and variants. Jingjing Jiang,1 Zhong- guang Luo,1 Jia Wei,1 Guanglei Zhuang,1 Song Yi,1 Ying Yan,1 Tengfei Yu,1 Wei Du,1 Tingting Tan,1 Ling Qiu,1 Jiali Gu,1 Xin K. Ye,1 Jie Liu,1 Zhenyu Gu2.
1GenenDesign USA Co, Ltd., Menlo Park, CA; 2Huashan Hospital, Shanghai, China; 3Nanjing University, Nanjing, China; 4Shanghai jiao Tong University, Shanghai, China; MD Anderson Cancer Center, Houston, TX; GenenDesign Co, Ltd., Shanghai, China.

Precision oncology requires identifying and understanding of cancer genome changes in a patient tumor tissue and finding the best cancer therapy targeting the changes. Although many cancer gene targets have been validated so far, next-generation genomic profile analyses have uncovered much more cancer gene variants with unconfirmed functions. Developing methods to functionally evaluate mutations/variants and understand their roles in cancer development and drug responses, such as drug resistance or synthetic lethality, will be critical in cancer treatment decision support. In addition, in some clinical cases, multiple treatment choices such as multiple drug combinations exist. Developing cancer models which can test multiple treatments will provide direct comparison of those therapies and select the best options. At GenenDesign, we have performed drug tests on mouse “avatars”, which are also known as Patient-Derived Xenograft (PDX) models. They are personalized cancer models derived from patient tumor samples with cancer mutation profiles and drug responses very similar to the corresponding cancer patients. Drug screenings were carried out in avatars by testing chemotherapies or targeted drugs against specific cancer gene mutations and variants. Selected drugs or drug combinations from avatar studies have been applied to corresponding patients with highly consistent treatment outcome. From genomic profile analysis of our near 1500 PDX tumor models in cancer types such as lung, colorectal, gastric, liver, and esophageal, we are able to identify a large number of cancer gene mutations/variants, gene fusions, as well as gene copy number and RNA expression changes in major cancer signal pathways such as EGFR, Her2, c-Met/LCK, Ras/Raf, FGFR3, PI3K/Akt, Wnt, Notch. DNA repair, cell cycle regulation, angiogenesis. Many of these changes are potential drug targets and have been functionally tested in PDX models with approved drugs or clinical drug candidates. The mutation/variant information and drug response information generated from PDX models have been organized into our Precision Cancer Information Lab database. Patient tumor DNA test results have been used for searching genetically matched PDX models in our database. Once matched PDX models are identified, the available drug response information can be used as evidence for clinical treatment decision support. In addition, the matched PDX models can also be used to test more treatment options such as different combinations and new clinical drug candidates.

#756 Molecular characterization of triploid and tetraploid urine FISH samples. Lorenzo Pecciarini, Valeria De Pascali, Ilaria Francaviglia, Anna Talano, Chiara Iacona, Massimo Freschi, Maria Giulia Cangi, Claudio Doglioni.
San Raffaele Hospital, Milano, Italy.

Urothelial carcinomas (UC) are characterized, among other aberrations, by chromosome 3, 7, 17 gains and 9p21 (p16) loss. Since UC cells readily exfoliate into the urine, molecular cytogenetics techniques have been used to detect cells consistent with UC diagnosis and follow-up; a multi-target Fluorescence In Situ Hybridization (FISH) test, composed of 3, 7 and 17 centromeres and 9p21 locus multicolor probes, has been proved useful for atypical cells identification in both void urine and lower and upper urinary tract samples before morphological changes are apparent through cytological and histological examination. To date, there are no uniform criteria for urine FISH scoring though the test is commonly considered positive following the UroVision Bladder Cancer Kit criteria (Abbott Molecular); 4 or more cells with a gain of 2 or more chromosomes (polysomy), and/or 12 or more cells with 9p21 homozygous deletion. This definition of polysomy includes trisomy and tetrasomy classes, but, as tetraploidy may represent cells at S/G2 phase, this criterion may lead to false-positives; moreover it has been described that also inflammation induces tetraploidy, and that small percentages of normal urine cells show trisomy/tetrasomy. On the other hand, triploidy and tetraploidy may have a direct role in tumorigenesis, as an intermediate state in the development of cancer aneuploidy. At the moment little is reported about the clinical correlations of urine FISH cases showing only trisomy/tetrasomy in BC. In particular frequent mutations in exons 7, 10 and 15 of FGFR3 characterize non-muscle invasive UC while mutations in the core promoter region of TERT gene, mainly at -124 and -146 positions from the ATG start site, have emerged as the most frequent somatic genetic alteration in both non-muscle invasive and muscle invasive UC. All specimens were subjected to PCR amplification and Sanger sequencing for FGFR3 exon 7 and 10, and for the C228T and C250T TERT promoter mutations. A preliminary analysis of 20 urine FISH cases showed 4 samples with trisomy/tetrasomy, and 1 of these 4 had a mutation of the TERT promoter. Complete results of the FGFR3 and TERT promoter molecular analysis will be presented and correlated to both FISH results and patients clinical data, in order to evaluate if the presence of FGFR3 and/or TERT promoter mutations in urine samples with FISH detected trisomy/tetrasomy may help to identify patients with a higher risk of recurrence and progression.

#757 Development and validation of the ActionSeq™ test system. Samantha Helm, Vanessa Spotlow, Aleksandra Ras, Kevin Kelly, Guruprasad Ananda, Sara Patterson, Honey V. Reddi. Jackson Laboratory for Genomic Medicine, Farmington, CT.

Introduction In the constantly changing field of oncology precision medicine, it is exceedingly important to keep diagnostic and therapeutic assays clinically relevant. Next generation sequencing (NGS) panels in oncology are greatly impacted by new findings in clinical actionability. In order to ensure that cancer panels continue to provide the most beneficial results to patients, they must be regularly updated. In keeping with this idea, JAX has launched a new 212 oncology gene panel which focuses on genes and variants with documented actionability, referred to as ActionSeq. Methods Development of ActionSeq included the optimization of a new targeted capture assay. This process included running multiple batches of samples through the assay to determine appropriate DNA input, ligation times, PCR cycles, and pooling conditions. The fully optimized assay was then validated using 24 uncharacterized FFPE samples. The validation was executed in 5 phases: (1) confirm that assay optimizations yielded sufficient wet lab results; (2) LOD & sensitivity (3) inter-assay concordance; (4) intra-assay concordance; (5) specificity and accuracy. Results During development, the standard protocol was optimized using a 200ng input, 30 minute ligation period, 10 cycles of PCR, and the pooling of 4 samples per hybridization reaction. Wet lab processing results of the first validation batch can be seen in Table 1. The inter- and intra-assay concordances were found to be ≥ 98% for variants and 100% for CNVs. The sensitivity was calculated to be 98.92% at a LOD of 3% for CNVs, 100% at a LOD of 8% for INDELs, 100% at a LOD of 6 copies for CNV amplifications, and 100% at a LOD of 0 copies for CNV deletions. The specificity and accuracy were found to be 100% for all mutation types. Conclusion Based on the success of this validation ActionSeq has been incorporated into the JAX clinical test menu. This addition accomplished the goal of providing a more clinically relevant (actionable) somatic tumor profiling assay to patients and clinicians.

**758 Capture and characterization of circulating tumor cell clusters in patients with metastatic castrate-resistant prostate cancer.** Samantha L. Savitch1,2, Soo Jin Kim3,6, Jason C. Poole1, Brian Kudlow5,3, Devorn Soucek2, Denis Smirnov3,2, Chandranao2, Steve Gross,2, Ravi K. Amaravadi,2, David J. Vaughan,1 Naomi B. Haas,3 Erica L. Carpenter1. 

1. Division of Hematology and Oncology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 2. Janssen Pharmaceutical, Johnson & Johnson, Huntington Valley, PA.

Introductory Sentence indicating purpose of study: Circulating tumor cell (CTC) clusters have been shown to have higher metastatic potential than single CTCs in breast, pancreatic, and other cancers, yet these clusters have not been extensively described in metastatic castrate-resistant prostate cancer (MCRPC).

Here we sought to determine the feasibility of capturing and characterizing CTC clusters in prostate cancer patients. Description of Experimental Procedures: Fifty-five blood samples from 29 MCRPC patients, ages 50 to 81 (median age 68), were obtained prior to the patient starting or switching to androgen receptor inhibitor or 17 alpha lyase inhibitor therapies. Eighteen patients received enzalutamide and 11 received abiraterone. The majority of patients had a Gleason score > 7 (22; 75.9%), bone metastases (19; 65.5%), and an ECOG status of 0 (21; 72.4%). All patients had previously undergone, or were receiving at time of enrollment, androgen deprivation therapy. Eleven patients (37.9%) had been on a prior 2nd generation anti-androgen therapy. CTC single cells and clusters (2 or more cells together in one image) were enumerated using the CellSearch system and stained to detect expression of androgen receptor (AR), glucocorticoid receptor (GR), and neuroendocrine (NE) markers. Summary of Data: Five or more single CTCs, a measure which has previously been associated with an unfavorable prognosis, were detected in 13 of 29 patients (44.8%), and in 19 of 55 blood samples (34.5%). Altogether, a total of 282 CTC clusters was detected, with 1 or more clusters found in 10 patients (34.5%) and 13 samples (23.6%). The number of clusters per 7.5ml of blood ranged from 0-150, and clusters contained anywhere from 2 to 16 cells. Most CTC clusters (268; 85.0%) contained only CTCs and no leukocytes. Just over half the detected clusters (162; 57.4%) contained only 2 CTCs. Cluster staining patterns were fairly homogenous with 29.4% of clusters having uniform expression of either AR, GR, or NE markers, i.e., all CTCs in the cluster expressed the marker of interest. Most clusters (67.7%) were uniform marker negative and the remaining 2.8% demonstrated a mix of marker positive and marker negative CTCs. Serum Chromogranin A levels, as a marker for neuroendocrine cells, were determined by standard of care clinical blood testing, were found to be positively associated with the number of CTC clusters per 7.5ml of blood (p<0.0001).

Statement of Conclusions: The capture and characterization of CTC clusters in the blood of MCRPC patients can be successfully performed using the CellSearch system. Further investigation into the clinical implications of these clusters is warranted, including whether cluster characteristics are associated with more aggressive disease.

**759 Highly-sensitive detection of EGFR mutation in non-small cell lung cancer using mutant-enrichment method.** Hung-Chi Chien. Industrial Technology Research Institute, Hsinchu, Taiwan.

Detection of mutations in EGFR in non-small cell lung cancer is important for the clinical decision-making process of molecularly targeted therapies, including Irressa, Tarceva, and Tagrisso. In this study, we developed an assay allowing the detection of EGFR gene mutations being conducted in the routine diagnostic procedure and its analytic and clinical performance were evaluated using different types of specimens. The EGFR mutation assay in this study allows for detecting EGFR exon 19 deletion (Del), exon 20 insertion (Ins), and mutation in T790M, L858R, S768I and L861Q of rare amounts in a normal genetic background. Enhancement of detection sensitivity was achieved with the developed mutant enrichment method which includes specific primers, probes and protease K digestion as blockers for inhibiting wild-type gene from DNA amplification. Analytic performance for each mutant was assessed using the control plasmids containing the mutant genes of known amounts as well as the genomic DNA extracted from mutant cell lines and Horizon FFPE samples. The assay performance were also evaluated using clinical samples in parallel with the FDA-approval companion diagnostic products (therascreen® EGFR RQG PCR Kit). The sensitivity of the assay evaluated using control plasmids for Del, T790M, L858R, S768I, L861Q mutation and Ins was 5%, 0.5%, 1%, 0.5% and 0.5% respectively, and was 1%, 0.5%, 0.5%, 0.1% and 0.5% respectively when applying on HDX reference standards. Diagnostic results for the 116 clinical samples for identifying mutations of del, T790M, L858R, S768I, L861Q mutation and Ins was 92.2%, 100%, 99.1%, 100%, 97.4% and 100% respectively concordance with the therascreen® EGFR RQG PCR Kit, including 17 cases of multiple mutations. The overall diagnostic results for all mutations evaluated with PPA (positive percent agreement), NPA (negative percent agreement) and OPA (overall percent agreement) were 83.3%, 98.2% and 90.5%, respectively. The three samples firstly diagnostic as false positive were retested and confirmed to be exon 19 del by DNA sequencing. The assay demonstrated good sensitivity and specificity when compared with commercial products. Moreover, the clinical studies are being performed to establish relationship between drug efficacy and different mutation combinations.

---

**760 Detection of EGFR T790M mutation by ddPCR in untreated NSCLC patients: Correlation with clinical outcome.** Monica Ganzinelli1, Elena Rulli2, Elena Tamborini1, Adele Busico1, Giuseppe Lo Russo3, Giulia Corraro1, Milena Vitali1, Marina Chiara Garassino1, Massimo Broggi3, Mirko Marabese1.

1. Fondazione IRCCS Istituto Tumori Milano, Milan, Italy; 2. IRCCS - Istituto di Ricerche Farmacologiche Mario Negrin, Milan, Italy.

Background: Activating EGFR mutations are associated with response to first generation tyrosine kinase inhibitors (TKI) that significantly increased PFS and OS in NSCLC patients. However, almost invariably, patients relapse while in treatment with TKI, mostly for the presence of EGFR T790M mutation. New second and third generation EGFR inhibitors active against T790M are now under development with very promising results. To date it is not known if the presence of T790M (and its amount) at diagnosis influences clinical outcome of patients with activating EGFR mutation. Methods: We analysed 50 cases with NSCLC. 48 patients harbour TKI sensitizing mutation in either exon 19 (N=24) or 21 (N=19), 2 EGFR wt patients (blinded to the investigator) were analysed in parallel. These patients were screened by ddPCR for the presence of T790M mutation using Biorad QX200 Droplet Digital PCR System. We used rough DNA extract from FFPE sections after deparaffinization and proteinase K digestion, as available in pathology unit for daily diagnosis. Results: 12 samples failed to amplify, maybe due to the poor quality of DNA. 13 samples produced results, but were excluded for the analysis because of too low number of calls retrieved. T790M mutation was detected in a significant proportion of mutant samples. Among the ddPCR RQG PCR Kit. The sensitivity of the treatment and here the percentage of T790M were higher compared to those patients not treated [0.65% - 28% vs 0.019% - 1.65%, respectively]. One out four of these patients was not detected by routinely method of sequencing (Sanger or RT-PCR). T790M positive samples harboured mutations affecting exon 19 or 21 in equal manner. Conclusion: ddPCR has proven to be a sensitive method to detect T790M mutation, although the quality of DNA could affect the results. The system has been challenged for specificity and the sensitivity and the results proved to be clinically relevant. The correlation between the T790M positivity and clinical outcome will be available and we plan to define a ddPCR threshold value which can help in selecting those patients who are likely to have early recurrence under first generation TKI and that could therefore be directly shifted to second or third generation inhibitors.

---

**762 A concordance study of the ArcherDX Reveal™ ctDNA 28 NGS panel and Biocept’s Target Selector™ mutation assay using ctDNA collected in Biocept CEE-sure™ blood collection tubes.** Jason C. Poole1, Brian Kudlow5,3, Jill Stefanelli,2 Skyler Mishkin,2 Anh Pham,1 Jeff Chen,1 Veena M. Singh,1 Josh Stahl,1 Lyle J. Arnold1. 1. Biocept, Inc., San Diego, CA; 2. ArcherDX, Inc., Boulder, CO.

Biocept’s Target Selector technology is a targeted hotspot mutation panel designed to enrich for mutant targets in a large excess of WT DNA. The test is specific to small regions of interest, is highly sensitive, validated down to 7 mutant copies in a background of 14,000 WT at >98% sensitivity. The ArcherDX Reveal ctDNA test is a 28 gene NGS panel that targets key oncogene...
activating mutations, drug resistance mutations, in addition to full coverage of TP53. The Reveald ctDNA assay utilizes Anchored Multiplex PCR to enrich, tag, and efficiently capture short ctDNA fragments. Both technologies are designed specifically for use with plasma associated ctDNA. We undertook to evaluate the feasibility of using the ArcherDX Reveald ctDNA 28 NGS panel with the DNA extracted from plasma collected with Biocept's patented blood collection tube, which has been validated at room temperature for 4 days for circulating tumor cells and 8 days for ctDNA. The ability to build complex, targeted libraries, free of chemically induced mutations is of major importance for the detection of the vanishingly rare mutations that can be present in the plasma of cancer patients. We found that high quality NGS libraries were produced from plasma collected and stored in the Biocept blood tube, which is indicated that damage occurred to the DNA during preservation. In addition, the two methods were found to be highly concordant and complementary when using both mutation positive and negative patient samples. The Target-Selector assay was the more sensitive, however, the ArcherDX panel revealed several additional mutations not targeted by the Biocept Target Selector assay.

Chromogenic multiplex immunohistochemistry (IHC) assays enable investigation of the spatial relationships between tumor and immune cells, which is thought to be important for understanding and predicting therapeutic response. Development and analytical validation of multiplex IHC assays enables the use of such assays to simultaneously investigate multiple biomarkers as predictors of clinical response. In this study, we analytically validated a chromogenic duplex IHC assay that quantifies Ki67 and CD8 in formalin-fixed, paraffin-embedded non-small cell lung cancer tissues. Five performance criteria were selected and evaluated based on Clinical Laboratory Standards Institute guidelines: reportable range, analytical sensitivity, analytical specificity, accuracy, and precision. Similar to analytical validation studies for monoplex IHC assays, this study utilized a reference method and multiple days of staining. The percentage of cells positive for Ki67 nuclear staining and/or CD8 membrane staining were quantified using our computational Tissue Analysis (CTA™) platform. Performance of the Ki67/CD8 chromogenic duplex IHC assay was considered acceptable for the five criteria evaluated. Once the performance of the assay was established, additional exploratory cTA-based endpoints were examined, including the quantification of each biomarker in the tumor compartment and the tumor microenvironment, and analysis of the spatial arrangement of immune cells relative to tumor cells. In conclusion, Flagship’s cTA platform allows for more consistent quantification of individual analytes on dual-stained tissue sections, enabling investigation of complex biological questions that cannot be achieved with traditional tissue-based manual endpoints.

#764 Survival analysis for the elderly esophageal cancer patients (≥80 years) with surgery and non-surgery treatments. Dan Feng Du1, Dan Feng Du2, Fu You Zhou1, Lian Qun Zhang1, Xue Na Han1, Yuan Yuan2, Zong Min Li3, Jian Po Wang4, Yao Wen Zhang5, Tai Jiang Liu2, Guo Hua Liu2, Yi Jun Qi2, Yan Rui Zhang2, Li Dong Wang1. 1The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; 2Basic Medical College of Zhengzhou University, Zhengzhou, China; 3Anyang Tumor Hospital, China; 4Huoja Red Cross Hospital, China; 5The First Affiliated Hospital of Henan University of Science and Technology, China; 6Henan Provincial People’s Hospital, Zhengzhou, China.

With the aging of population, the elderly esophageal cancer patients are increasing. However, the optimal treatment methods have not been well characterized for the elderly esophageal cancer patients because of that most randomized studies have excluded the elderly. The aim of this study was to analyze the outcomes of surgery and non-surgery therapy on the elderly patients aged 80 years or older with esophageal squamous cell carcinoma (ESCC) to provide more evidences for optimal treatment design on the elderly patient. The enrolled 1,143 ESCC cases in this study were from the ESCC database in Henan Key Laboratory for Esophageal Cancer Research. Of the 1,143 patients, there were 614 males with a mean age of 82.4±2.64 and 529 females with a mean age of 82.44±2.61. The age ranged from 80 to 96 years old at diagnosed. All the patients were confirmed as ESCC by histopathology. The patients were classified into four groups based on treatment methods, i.e., radical esophagectomy (group I), esophagectomy plus radiochemotherapy (group II), radiochemotherapy only (group III), and symptomatic treatment (group IV). Radical esophagectomy was performed on 304 patients (26.6%), including 134 males and 97 females. In addition, of the 304 patients with radical esophagectomy, there were 73 patients who were excluded for postoperative surgery. 518 patients received only radiochemotherapy (45.3%). Radiochemotherapy included 50-60 Gy of radiation concurrent with or without 5-fluouracil alone or combined with cisplatin. Moreover, there were 321 patients (28.1%) who did not receive either surgery or radiochemotherapy, but only with symptomatic treatment. The Kaplan-Meier analysis indicated that there was no significant difference in gender, age or histology between patients in the different groups. The overall 1-, 3- and 5-year survival rates were 56%, 31% and 19%, respectively, with a median survival time of 2.5 years. In group I, the overall 1-, 3- and 5-year survival rates were 68%, 48% and 30%, respectively, with a median survival time of 3.8 years. In group II, the overall 1-, 3- and 5-year survival rates were 48%, 32% and 14%, respectively, with a median survival time of 1.9 years. In group III, the overall 1-, 3- and 5-year survival rates were 58%, 28% and 18%, respectively, with a median survival time of 2.5 years. In group IV, the overall 1-, 3- and 5-year survival rates were 39%, 18% and 0.08%, respectively, with a median survival time of 1.6 years. The log rank survival analysis showed that the surgery group had better prognosis than surgery plus radiochemotherapy or radiochemotherapy alone group (P<0.002) and the symptomatic treatment group (P<0.000). The present results demonstrate the feasibility of esophagectomy in the elderly ESCC patients in terms of survival. [Supported by the Joint Funds of NSFC (U1301227), Natural Foundation of Henan Province (20161110) and Correspondence to: Li Dong Wang, Email: ldwang2007@126.com].

Elderly acute lymphoblastic leukemia (ALL) patients are often unfit for either dose-intensive chemotherapy or stem cell transplantation, thus their clinical outcomes have been dismal. The increased incidence of BCR-ABL translocation with increasing age also contributed to poor prognosis but, it was our conjecture that the introduction of potent tyrosine kinase inhibitors (TKI) targeting ABL, BCR-ABL translocation might not deliver negative prognostic impact in elderly ALL. Considering that many elderly Ph- ALL patients do not tolerate cytotoxic chemotherapy required for effective tumor control, we supposed that efficacy of ABL TKIs and their combination strategy with low dose cytotoxic chemotherapies would result in better survival for elderly Ph+ ALL compared to their Ph- counterparts. This study was a multicenter longitudinal cohort study of elderly de novo ALL (≥ 60 years) recruited from 6 hospitals in Korea from January 2005 to December 2015. We considered Ph+ if it was positive in at least one of three techniques: conventional cytogenetics, fluorescence in situ hybridization, or quantitative real-time polymerase chain reaction (qRT-PCR). Among the 96 patients enrolled, there were 50 Ph- ALL patients (52.1%) and 46 Ph+ ALL patients (47.9%). There were no differences between the 2 groups regarding age, sex distribution, performance status, and induction regimens. For treatment outcomes evaluation, the 5 Ph+ ALL patients not receiving TKI were eliminated and 41 Ph+ ALL patients treated with TKI were compared with 50 Ph- ALL patients (Table). Complete remission (CR) was attained in 27 (54.0%) of patients in the Ph- group versus 35 (85.4%) in the Ph+ group (P=0.001). The median RFS was significantly longer in the Ph+ group (3.1 months for Ph- vs. 8.9 months for Ph+, P=0.007). Induction death and induction failure occurred significantly more often in the Ph- group. The median OS was 6.3 months for Ph- group versus 10.3 months for Ph+ group (P=0.033). In conclusion, using real world data, this study reports the possible favorable impact of Ph+ in TKI-era for elderly patients.

#766 Comorbidities limiting recruitment of non-small cell lung cancer (NSCLC) patients in early phase trials. Narjast Duma, Yucai Wang, Aaron Mansfield, Mayo Clinic, Rochester, MN.

Background: Early phase trials (EPCT) provide significant value by evaluating the possible benefits of new agents. The eligibility criteria in EPCT are usually rigorous and may exclude many patients (pts) commonly seen in clinical practice. Our objective was to identify the most common comorbidities excluded in EPCT for NSCLC. Methods: ClinicalTrials.gov was queried on August 1st of 2016. 299 interventional drug trials were extracted from 2010 to 2016. We studied the trial characteristics including: experimental therapy, location, funding source, and exclusion criteria. Our objective was to identify the most common comorbidities excluded in EPCT for NSCLC. Results: ClinicalTrials.gov trial characteristics were analyzed. We identified 2010 trials with early phase therapy and 1672 NSCLC trials. Of these NSCLC trials, 55% were randomized, 43% were biomarker-driven, and 28% were placebo-controlled trials. For patients between the ages of 60 and 75, only 20% of patients were recruited. For patients between the ages of 75 and 80, only 10% of patients were recruited. The most common comorbidities excluded in EPCT for NSCLC were: hypertension (29%), chronic obstructive pulmonary disease (26%), diabetes mellitus (21%), chronic kidney disease (19%), and liver disease (17%). Conclusion: EPCT for NSCLC exclude many patients commonly seen in clinical practice. The most common comorbidities excluded in EPCT for NSCLC were hypertension, chronic obstructive pulmonary disease, diabetes mellitus, chronic kidney disease, and liver disease.
The utility of a breast cancer registry for improved cancer management in developing countries. DeAnna McGarity,1 Brandon Epps,1 Alexis Maynor,5 Tania Anderson,2 Ernest Alem-Mensah,3 Delroy Fray,2 Maung Aung,3 Kisha Holden,4 James Lillard,3 Brian Rivers,5 Derrick Beech,1 Morehouse School of Medicine, Atlanta, GA; 2Tuskegee University, Tuskegee, AL; 3Western Regional Health Authority and Cornwall Regional Hospital, Montego Bay, Jamaica.

Background Breast cancer is one of the leading causes of cancer related deaths in the island nation of Jamaica, West Indies. Cancer and other non-communicable diseases have increased in many developing nations in the Caribbean as well as Central and South America. The health systems of these developing countries continue to provide care to patients with limited resources. The use of a breast cancer registry can assist in care coordination of these patients and allow targeted screening and treatment programs in under-resourced environments. Methods In collaboration with the Western Regional Health Authority, a breast cancer registry database was developed in RedCap to provide a comprehensive analysis of breast cancer in under resourced environment. 53 patients from Atlanta were compared to 78 patients from Jamaica. These patients were entered into the breast cancer registry from June 1, 2014 to March 31, 2015 by attending physician and de-identified. Demographics, tumor related factors, treatment, survival and health behavior information was collected by the attending physician. The findings were then analyzed using Statistical Analysis System (SAS) and Data Analysis and Statistical Analysis (STATA): Fisher Exact test, chi-square and multiple regressions. Results The median of patient ages were 61 (range 26 - 84 years old) for Jamaican patients and 53 years old (range 26 - 84 years old) for Jamaican women. For the U.S. patients, 84% were Black, 4% White, and 12.24% were Latin or Asian. The majority of the patients were diagnosed with stage I invasive ductal breast cancer. In contrast, the majority of the Jamaican patients were diagnosed with late-stage breast cancer. Utilizing the data from the breast cancer registry, we were able to identify parishes (counties) with disproportionately high rates of late-stage cancer. Conclusion The use of a disease specific registry can improve care coordination and identify actionable target areas for enhanced screening and treatment. It is our hope to frequent review the dashboards associated with the registry data by providers, medical centers and health systems. This will optimize care coordination and allow timely improvements in cancer diagnosis and management in developing countries.

[299 trials, 164 (55%) were phase II, 81 (27%) phase I and 54 (18%) phase Ib/II. 164 (55%) were conducted in the United States (US), 45 (15%) in Asia, 39 (13%) in Europe and 51 (17%) were international. 171 (57%) analysis. Results: Of the 299 trials, 164 (55%) were phase II, 81 (27%) phase I and 54 (18%) phase Ib/II. 164 (55%) were conducted in the United States (US), 45 (15%) in Asia, 39 (13%) in Europe and 51 (17%) were international. 171 (57%) of therapy.

[378 breast cancer cases were seen during the study period and majority of the cases (99.4%) were females. The prevalence of breast cancer was found to be 12.6%. Triple-negative breast cancers (TNBC) constitute 67.7% of cases. The mean age was 45.8 ± 12.0 years and the youngest patient was 18 years while the oldest was 90 years. Out of the 784 cases, 208 were mastectomies while the remaining were incisional, trucut needle and excisional biopsies. Infiltrating ductal carcinoma NST was the most common histologic variant seen (94.7%) and most of these cases (59.1%) were Grade II tumors. The Nottingham Prognostic Index (NPI) shows that 91.4% of the cases have NPI Score of ≥ 3.5 with attendant poor 5-year survival rate. Conclusion: This study found that breast cancer is common and affects mostly women in fifth decade of life. There is a high TNBC among the population studied and therefore androgen receptor profile and genomic studies may be useful to determine the course of therapy.

The utility of a breast cancer registry for improved cancer management in developing countries. DeAnna McGarity,1 Brandon Epps,1 Alexis Maynor,2 Tania Anderson,2 Ernest Alem-Mensah,3 Delroy Fray,2 Maung Aung,3 Kisha Holden,4 James Lillard,3 Brian Rivers,5 Derrick Beech,1 Morehouse School of Medicine, Atlanta, GA; 2Tuskegee University, Tuskegee, AL; 3Western Regional Health Authority and Cornwall Regional Hospital, Montego Bay, Jamaica.

Background Breast cancer is one of the leading causes of cancer related deaths in the island nation of Jamaica, West Indies. Cancer and other non-communicable diseases have increased in many developing nations in the Caribbean as well as Central and South America. The health systems of these developing countries continue to provide care to patients with limited resources. The use of a breast cancer registry can assist in care coordination of these patients and allow targeted screening and treatment programs in under-resourced environments. Methods In collaboration with the Western Regional Health Authority, a breast cancer registry database was developed in RedCap to provide a comprehensive analysis of breast cancer in under resourced environment. 53 patients from Atlanta were compared to 78 patients from Jamaica. These patients were entered into the breast cancer registry from June 1, 2014 to March 31, 2015 by

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
**771 Cervical cancer: Our experience in Sudan.** Kamal Eldedhik Mohamed, Dr Anmar Ashmeig Ahmed Ashmeig, Faculty of Medicine, Univ of Khartoum, Khartoum, Sudan.

**Introduction:** Cervical cancer is the second most prevalent cancer in Sudanese Women; breast cancer forms between 29 - 35% of female cancers while Ca Cervix forms 12 - 16%. There are limited screening activities in the country using VIA, and Pap smears in Obs. and Gyn. clinics. With the main emphasis on health education programs, teaching women the early symptoms of ca cervix and early detection. Due to lack of awareness the majority of women don’t know anything about screening, so there is limited demand. Method: This is a retrospective study of 405 Cases of Ca Cervix treated during the period between 2000 -2013 in Khartoum, Khartoum, Sudan.

**Results:** Age range showed, 28 to 79 years. Residence distribution was as follows, western Sudan = 48 %, central Sudan = 41 %, North = 7 %, East = 4%.

**Length of duration of symptoms, range between 1—10 months, mean of 5 months.** FIGO Stage distribution: Stage 1 = 6%, Stage 2A =13%, Stage 2B =23%, Stage 3A =18%, Stage 3B =34%, Stage 4A, B =7%, Pathology: poorly diff. Squamous ca 38%, moderately diff. Squamous 26%, well diff 25%, Adenocarcinoma 9%, others: Treatment: external Radiotherapy, 45-50 Gy in 20 - 25 fractions, by 2 or 4 fields, using Co 60 or linacs 6 MeV, concurrent chemoradiotherapy was given to patients with stage 2B, 3A, 3B, and 4A. Using weekly Citiplasmin, this was given to 32% of patients. 60% % of the patients had Brach therapy, 34% with Low Dose Rate, LDR, Manual Brachy therapy, 35Gy to point A and 60 Gy to Point B, HDR. Self irradiation was source. Results: 175 patients (43.3%) survived for 5 years and more, mostly patients with stage one and two 158 were 59% survived for 3-4 years after treatment, 39 patients 9.6 %, mostly patients with stage four, died during follow up due to the disease and 33 patients = 8.2% disappeared after treatment. The poor outcome is attributed to the advanced stages at presentation, lack of screening and awareness about cervical cancer, poverty, illiteracy, the large size of the country and the poor distribution of the limited medical resources. The patients treated with LDR or HDR have equal outcome and morbidity. Conclusion: Most of Ca Cervix Patients present with advanced disease, hence the poor prognosis, due to lack of awareness and screening, illiteracy and poverty, the majority are possibly different squamous cancers. The need for increasing public awareness about ca cervix and its early symptoms, and provision of a pap smear and VIA services in the primary health care facilities.

**773 Optimizing drug regimens in oncology by clinical trial simulations: Why and how.** Jocelyn Gal,1 Gerard Milano,2 Julien Viotti,3 Renaud Schiappa,4 Audrey Dugue,2 Agnes Paquet,2 Sylvie Chabaud,2 Jean-Marc Ferrero,2 Emmanuelf Chamorey,1 *Cir. Antoine Lacassagne, Nice, France; 2Cir. Francois Baclesse, Caen, France; 3Molecular and Cellular Pharmacology Institute, Sophia Antipolis-Valbonne, France; 4Le£on B£ard Cancer Center, Nice, France.

**Introduction:** In therapeutic research, the safety and efficacy of pharmaceuti- cal products are necessarily tested on humans via clinical trials after a very long and expensive development period. Alternative methodologies such as com- parative modeling and Clinical Trial Simulation (CTS) are a valuable option to reduce animal and human assays. The relevance of these methods is well recog- nized in pharmacokinetics and pharmacodynamics from the pre-clinical phase to post-marketing. However, they are seldom used and are poorly regarded for drug approval, despite FDA and EMA recommendations. We propose to discuss the principle behind, and the interest of, CTS approaches in drug development in oncology. Our work is based on a systematic review using two electronic literature databases (Medline and Web of Science). Key components of CTS: We will explain why and how to successfully develop CTS. Why developing CTS? To obtain a better knowledge of pharmacology and/or better prediction of safety and efficacy To evaluate disease progression dynamics and to test the potential impact of new treatments on subpopulations and extend the post-marketing authorization to help in the choice of the best outcome To optimize experimen- tal designs in order to better anticipate the progress of the study How to develop CTS? CTS project must follow three steps: 1/The constitution of pharmacomet- ricians team who elaborates clinical model and simulation plan that must contain three components: Input/output model: How do covariates impact out- comes? Covariate distribution Model: How can we construct virtual patients? Execution model: What can happen during the clinical trial? 2/Obtaining data for simulations. We will present the contribution of machine learning for CTS 3/The use of specialized software to realize simulations Limitations of CTS: We will present the features that can slow down or accelerate the development of CTS. The generalization of CTS could be greatly facilitated by the availability of software modeling biological systems, by the clinical trials studies and hospital databases. Data-sharing and data-merging raise legal, policy and technical issues that will need to be addressed. CTS challenges and prospects: Development of future molecules will have to use CTS for faster development and thus enable better patient management. Drug activity modeling coupled with disease modeling, optimal use of medical data and increase of the computing speed should allow this leap forward. The realization of CTS requires not only the bioinformatics tools to allow interconnection and global integration of all clinical data, but also a universal legal framework to protect the privacy of every patient. CTS will have to be used to provide quantitative support for drug development decisions but will never replace real clinical trials. This in silico medicine opens the way to the 4P medicine: predictive, preventive, personalized and par- ticipatory.

**774 Notch pathway activation predicts resistance to bevacizumab therapy in glioblastoma.** Norihiko Saito, Kazuya Aoki, Nozomi Hirai, Satoshi Fukushima, Junya Iwama, Masashi Ikuta, Haruo Nakayama, Motokazu Hayashi, Keisuke Ito, Takatoshi Sakurai, Satoshi Iwabuchi. Toho University Ohashi Medical Cen- ter, Tokyo, Japan.

Glioblastoma, the most common adult glioma, is associated with a dismal prognosis. Treatment with bevacizumab has not significantly prolonged overall patient survival times. Glioblastoma resistance to angiogenesis inhibitors is attrib- uted to multiple interacting mechanisms. We have thus embarked on a com- prehensive effort to detection expression signatures that are associated with response to the therapy and these signatures may allow prospective selection of patients with high likelihood of responding to therapy. Notch signaling pathway is an evolutionarily conserved pathway that plays an important role in multiple cellular and developmental processes including cell fate decision, differenta- tion, proliferation, survival, angiogenesis and migration. Analysis of The Cancer Genome Atlas expression dataset identified a group (43.9%) of tumors with proneural signature showing high Notch pathway activation. In this study, we compared CD133, Notch, and VEGF expressions in histological sections of pri- mary and recurrent glioblastomas after radiotherapy and chemotherapy. Tumor samples were collected from 27 patients at the time of tumor recurrence. We used immunohistochemical techniques to compare expression of CD133, Notch-1 and VEGF. Expressions of CD133-, Notch-1-, and VEGF-positive gli- oma cells were higher in recurrent glioblastoma after radiotherapy and chemother- apy. To determine the clinical importance of Notch-1 expression in glioblas- toma, we analyzed 15 patients who had received bevacizumab therapy followed by a second surgery at recurrence. OS was significantly longer in cases with Notch-1 negativity (8.8 months) than in those with Notch-1 positivity (6.1 months). Electron microscopic observation of two autopsy cases revealed the effects of blood vessel normalization in Notch-1 positive glioblastoma. Electron microscopic images confirmed the presence of pericytes surrounding the vascu- lar endothelium. Autopsied tumors exhibited marked proliferation of Notch-1
and VEGF positive cells around vessels. In tumor angiogenesis, vascular endothelial growth factor and Notch signaling induce sprouting angiogenesis and recruitment of vascular endothelial cells such as tip cells, stalk cells, and phalanx cells. Fully mature phalanx cells are in close contact with pericytes. These findings indicate that bevacizumab treatment promotes vascular normalization by recruiting mature pericytes and associated with resistance to bevacizumab therapy in glioblastoma with high Notch pathway activation.

**Identification of activated signal transduction pathways and molecules in the HMGB-1 induced angiogenesis.** Yujin Kwon, Sujin Shin, Won Kyu Kim, Hogen Kim. Yonsei Univ. College of Medicine, Seoul, Republic of Korea.

High-mobility group box-1 (HMGB-1) is a highly conserved protein playing various roles both in the nucleus and cytosol and known to be expressed in almost all types of mammalian cells. Secreted HMGB-1 has been most intensively studied and reported as an immune cell derived cytokine regulating systemic inflammation, signal transduction, and activation of endothelial cells (EC). Especially, HMGB-1 over-expression is now considered as a hallmark in cancers based on its involvement in cell proliferation, inflammatory microenvironment, invasion, metastasis, and sustained angiogenesis. Numerous studies have shown that secreted HMGB-1 directly or indirectly promotes angiogenesis by activation of ECs. However, mechanisms of HMGB-1 mediated angiogenesis have not yet been fully understood, especially, in terms of genomic changes caused by HMGB-1 treatment. Moreover, differences between vascular endothelial growth factor (VEGF) mediated and HMGB-1 mediated angiogenesis have not been studied. To explore the roles of HMGB-1 in angiogenesis, we first confirmed whether HMGB-1 treatment renders ECs angiogenic by evaluating proliferation, migration, wound-healing, and tubule formation of ECs after HMGB-1 treatment. In addition, we performed gene expression microarray to clarify how HMGB-1 treatment induced EC activation at various time points and subsequent angiogenic features according to time-dependent gene expression changes. We show that HMGB-1 treatment induces proangiogenic features to ECs such as stimulation of tubule formation, promotion of proliferation, and accelerated wound healing. By analysis of microarray data, we found that VEGF and HMGB-1 commonly promoted the activation of MAPK, cell proliferation, and wound healing pathways which directly regulate angiogenesis. On the other hand, axon guidance, gap junction, F53 signaling, cycle cell, and cell differentiation pathways were specifically up-regulated by HMGB-1. Taken together, HMGB-1 leads to angiogenesis via upregulation of both angiogenic and nonangiogenic genes.

**Acquired platinum resistance enhances tumour angiogenesis through activation of vascular mimicry.** Aya El Helali,1 Nuala McCabe,1 Naomi Dickson,1 Lara Dura Perez,1 Denis P Harkin,1 Richard Wilson,1 Richard Alpaugh,2 Steven H. Lin,3 Jeffrey R. Marks,4 Raymond Bergan,5 Stuart S. Martin,6 Sarany Chumsri,7 Massimo Cristofanilli,8 Cha-Mei Tang,9 Steingrimur Steinarsson10.

Introduction: Platinum resistant High Grade Serous Ovarian Cancer (HG-SOC) has a poor outcome with limited treatment options. Angiogenesis is a key pathological feature of ovarian cancer and anti-angiogenics have dominated the field of drug development in EOC, particularly in the second-line setting (Marachi et al 2013). In this study we asked if platinum resistance could be associated with an improved response to anti-angiogenic agents. Methods: A review of phase III anti-angiogenic clinical trials was used to investigate the association between platinum resistance and response to anti-angiogenic agents. To investigate the effect of chemotherapy on predefined ovarian cancer molecular subgroups (Gourley, et al. J Clin Oncol 32:5s, 2014), we analysed 35 matched pre- and post-chemotherapy samples by gene expression. Novel isoform ciplatin-resistant HG-SOC cell lines were established to study the mechanisms of ciplatin section pressure and shift to an angiogenic phenotype. This was further validated in novel ascites-derived primary cell lines from HG-SOC patients with known outcomes following platinum-based chemotherapy. Results: Critical review of phase III anti-angiogenic trials suggested that there was a better response to anti-angiogenics following previous platinum-based chemotherapy. Our analysis demonstrated that 67% of treatment naïve tumours that were initially classified as non-angiogenic shifted to an angiogenic biology, which was associated with platinum resistance. Additionally we found that ciplatin-resistant cancer cell lines demonstrated hallmarks of vascular mimicry and an associated increase in vessel density using an angiogenesis Matrigel plug assay in Athymic nude mice (p-value = <0.0001). In addition, cell lines established from platinum-resistant patients as well as cell lines made platinum resistant in vitro, demonstrated overexpression of VEGFα which would be expected to stimulate angiogenesis. Conclusion: We have demonstrated that platinum-resistance in HG-SOC is associated with angiogenic biology supporting the use of anti-angiogenic agents in this setting.

**ELTD1/ADGRL4, a novel adhesion GPCR regulator of tumor angiogenesis, suppresses lipid metabolism in endothelial cells, and is upregulated in breast cancer endothelium and epithelium.** David M. Favara,1 Madhulika Nambiar,2 Helen Sheldon,1 Massimo Masiero,1 Demin Li,1 Ali Jazayeri,1 Alison H. Banham,1 Adrian L. Harris1.

Background: We identified ELTD1/ADGRL4, an orphan GPCR belonging to the adhesion GPCR family (aGPCR), as a novel regulator of angiogenesis and a potential anti-angiogenic therapeutic target. ELTD1 is normally expressed in both endothelial cells & vascular smooth muscle cells. Expression in the tumour vasculature is significantly increased. Our aims were to analyse ELTD1’s function in cancer endothelial cells & its role in breast cancer. Methods: Real-time quantitative RT-PCR, mRNA array profiling was performed on primary human umbilical vein endothelial cells (HUVECs) & validated with qPCR & confocal microscopy. We investigated ELTD1 signalling by applying the aGPCR ‘Stinger/tethered-agonist Hypothesis’. For this, truncated forms of ELTD1 & peptides analogous to the proposed tethered agonist region were designed. FRET-based 2nd messenger (Cisbio IP-1; cAMP) & luciferase-reporter assays (NFAT; NFKB; SRE; SRF-RE; CREB) were performed to establish canonical GPCR activation. To investigate ELTD1 in breast cancer, a panel of cell lines representative of all molecular subtypes were qPCR screened. Furthermore, primary human breast cancers (n = 245) & matched primary & nodal secondary breast cancers (n = 79) were stained for ELTD1 expression. Staining intensity was then scored & compared between subgroups. Result: ELTD1 mRNA expression was significantly upregulated in breast cancer samples compared with normal breast tissue. Immunohistochemistry analysis revealed ELTD1 staining within the tumour stroma contrasted to normal breast. ELTD1/ADGRL4 staining within the tumour stroma correlated to disease stage. p = 0.004; HR = 3.1; p = 0.02) showed a significant correlation with survival. Results: HUVEC mRNA expression profiling after ELTD1 silencing showed upregulation of SLC24A1, which transports citrate from the mitochondria to the cytoplasm & ACLY, which converts cytoplasmic citrate to Acetyl CoA, feeding fatty acid and cholesterol synthesis, and acetylation. We validated this at RNA & protein expression level & showed that ELTD1 inhibited lipid droplet formation. Signalling experiments revealed that unlike other aGPCRs, ELTD1 does not couple to any canonical GPCR pathways (Gxx; Gae; Goz; Gqz/ G12/13). In breast cancer, we found that no representative cell line screened expressed ELTD1. Breast cancer immunohistochemistry revealed higher intensity vascular ELTD1 staining within the tumour stroma contrasted to normal STROMA & expression normal tumour epithelial cells (15%). Higher ELTD1 expression in both the tumour stroma vasculature (n = 241; HR = 0.68; p = 0.04) & within the subset of tumour positive cases (n = 24; HR = 0.5; p = 0.02) correlated with improved relapse free survival (RFS). Conclusion: ELTD1’s regulation of lipid synthesis through suppression of ACLY & SLC24A1 highlights ELTD1’s role as a novel regulator of endothelial metabolism. Unlike other aGPCRs, ELTD1 does not signal through canonical G protein pathways. The good prognosis of ELTD1 expression may be related to inducing a quiescent endothelial population. It will be of interest to relate this activity to anti-angiogenic therapy. Nevertheless, a relevant fraction of patients expressing ELTD1 still relapsed & this may be a suitable target for this population.

**Identifying, subtyping and classifying tumor associated circulating endothelial cells in patients with solid tumors.** Daniel L. Adams,1 Katherine Alpaugh,2 Steven H. Lin,3 Jeffrey R. Marks,4 Raymond Bergan,5 Stuart S. Mar-5, Sarany Chumsri,7 Massimo Cristofanilli,8 Cha-Mei Tang,9 Steingrimur Steinarsson10.

Background: Tumor endothelial cells (ECs) are a population of stromal cells required for tumor growth that cooperate with tumors to form angiogenic structures. In blood, circulating ECs (CECs) are normal constituents of healthy individuals, although a Cancer Associated Vascular Endothelial cell (CAVE) subtype has been observed in cancer patients. The CAVE population has been isolated and identified using their large size or multicellular clustering and a pooled mixture of classical EC markers (i.e CD31 and CD146). However, there is debate over whether these populations are the same. This is not surprising as in-depth phenotyping of ECs requires an array of biomarkers that until recently has not been feasible. A multi-phenotypic screening of EC derived CECs that may express cytoketin (CK) and various EC biomarkers, correlating to disease stage. Methods: Peripheral blood samples from 116 cancer patients (stage I-IV) were drawn from 2012-2014 including breast (n = 42), lung (n = 39) and prostate (n = 35), as well as blood from 34 healthy controls. Blood was processed by an established filtration approach, i.e. the CellSieveTM microfiltration technique (Creativ MicroTech), filtering blood by size exclusion and...
staining cells for CK 8, 18 & 19, EpCAM and CD45. After identification and imaging, the QUAS-R (Quench, Underivate, Amine-Strip and Restain) technique was used to remove fluorescence signal and retain all cells with CD31, CD146, CD144, & DAPI. After reimaging, QUAS-R was again used to remove fluorescence and retain the cells for CD14, CD105, CD34, & DAPI. Results: Out of 63 patient samples, we identified CAVs in 63 patients (54%) based on positivity of CD31, CD144 or CD146, but none were found in healthy controls. CAVs per 7.5mL sample in patients averaged 5.1 (breast), 5.6 (prostate) and 7.9 (lung). Presence of CAVs appeared related to stage with 26% in stage 1, 61% in stage 2, 68% in stage 3, and 74% in stage 4 patients. No CAVs were positive for CD14 or CD45. CD31 was the most present marker, found on 93% of CAVs, followed by CD144 (85%), CD34 (64%), CD146 (45%), & CD105 (4%). In contrast with the previous study on this topic, CK was found in 67% of CAVs, but was not a universal marker. Conclusions: It has been reported that CK+ and CD45- CECs are isolated from the blood of cancer patients in colon and lung cancers, prompting some to classify them as circulating tumor cells. However, subtyping these CECs is incomplete when characterized with only 3-4 biomarkers. A multi-phenotypic subtyping technique was used to properly identify and subtype these CECs in cancer patients. This data suggests that a subset of CECs, e.g. CAVs, are found in circulation as CK+ / CD45-. However, it is not a heterogeneous population of cancer specific circulating cells that require further study.

**#780 In vitro screening of individual human neuroendocrine tumors for their angiogenic response to tyrosine kinase inhibitors.** Tanja Milosavljevic,1 Elise J. Choquet,1 Catherine E. Anthony,2 Ariana Dirige,1 Yi-Zarn Wang,3 Philip J. Boudreau,1 Ramcharan Venkat R. Katkoori,2 Harvey Bumpers1. 1Medical College of Wisconsin, Milwaukee, WI; 2Northern Kentucky University, Highland Heights, KY; 3Merkey Cancer Center, University of Kentucky, Lexington, KY.

Background: Human neuroendocrine tumors (NETs) are highly vascular in nature and reliant on multiple receptor tyrosine kinases (TKs) for their neovascularization, growth, and, metastasis. These tumors most commonly originate in the small bowel (SB) and frequently metastatize to the lymph nodes and other organs. Current treatment of metastatic NETs involves a variety of approaches including antiangiogenesis therapies. In this study we tested effectiveness of six TK inhibitors (TKIs) [Dovitinib lactate, Regorafenib, Erlotinib, Imatinib, Vatalanib, and Sunitinib] on individual NETs angiogenic response in vitro. Methods: Specimens were obtained from NET patients who underwent removal of their primary tumor (small bowel/pancreas/stomach), nodal, and organ (i.e. liver/ ovary/omentum/mesentery) metastasis. Fresh tumors were minced, embedded in a fibrin-thrombin clot and supplemented with nutrient culture media per the in vitro human tumor angiogenesis model protocol. Neovessels were visually scored and evaluated for angiogenic parameters: percent initiation (%I), angiogenic growth (A1), and overall angiogenic response (OAR). All TKIs were prepared consistent with manufacturer’s instructions and their effective concentration was determined by dose response experiments. The selected TKI dose reflected the clinically achievable plasma level. A large group of NETs was tested for their angiogenic response to six TKIs [Dovitinib lactate (D): n = 164, Regorafenib (R): n = 163, Erlotinib (E): n = 35, Imatinib (I): n = 51, Vatalanib (V): n = 163, Sunitinib (S): n = 164]. Paired samples t-test was used to compare TKI to control results for each angiogenic parameter, and independent samples t-test to compare TKI-response of primary and metastatic sites (MedCalc). Results: Each selected dose [D: 82nM, R: 1100nM, E: 100µM, I: 2.5µM, V: 20µM, S: 188nM] achieved statistically significant inhibition of OAR (D:94.23%, R:53.58%, E:52.07%, V:59.77%, S:66.56%, M:64.79%) in all NETs (p<0.0001). This is accomplished by the simultaneous statistically significant decrease of %I by at least 3.47% (p=0.0164) and A1 by at least 34.03% (p<0.0001). Comparison of OAR between the primary and metastatic tumor sites revealed no differences in their response to each tested TKI (p=0.2119). In all NETs, TKIs inhibited both mechanisms of angiogenesis, but preferentially targeted growth (all TKIs: p<0.0001) over %I (D, I, S; p<0.0001; E; p=0.0072; R; p=0.0164). Conclusions: In vitro screening of individual tumors revealed that TKIs effectively inhibited all parameters of angiogenesis in all NETs, primary and metastatic tumors. Selected TKIs preferentially inhibited angiogenic growth rather than initiation in all NETs. Our preclinical results show that Dovitinib inhibits angiogenesis most effectively in human NETs compared to other TKIs in vitro.

**#781 Functional consequence of the p53 codon 72 polymorphism in colorectal cancer.** Venkat R. Katkoori,1 Upender Manne,2 Harvey Bumpers3. 1Medical College of Wisconsin, Milwaukee, WI; 2Northern Kentucky University, Highland Heights, KY; 3Merkey Cancer Center, University of Kentucky, Lexington, KY.

Background: The codon 72 polymorphism in p53 has been implicated in multiple polymorphisms in the SS.BN3IL2R tumor of 116 patient samples, we identified CAVs in 63 patients (54%) based on positivity of CD31, CD144, & DAPI. After reimaging, QUAS-R was again used to remove fluorescence signal and restain all cells with CD31, CD146, & DAPI. Results: Out of 63 patient samples, we identified CAVs in 63 patients (54%) based on positivity of CD31, CD144, or CD146, but none were found in healthy controls. CAVs per 7.5mL sample in patients averaged 5.1 (breast), 5.6 (prostate) and 7.9 (lung). Presence of CAVs appeared related to stage with 26% in stage 1, 61% in stage 2, 68% in stage 3, and 74% in stage 4 patients. No CAVs were positive for CD14 or CD45. CD31 was the most present marker, found on 93% of CAVs, followed by CD144 (85%), CD34 (64%), CD146 (45%), & CD105 (4%). In contrast with the previous study on this topic, CK was found in 67% of CAVs, but was not a universal marker. Conclusions: It has been reported that CK+ and CD45- CECs are isolated from the blood of cancer patients in colon and lung cancers, prompting some to classify them as circulating tumor cells. However, subtyping these CECs is incomplete when characterized with only 3-4 biomarkers. A multi-phenotypic subtyping technique was used to properly identify and subtype these CECs in cancer patients. This data suggests that a subset of CECs, e.g. CAVs, are found in circulation as CK+/CD45-. However, it is not a heterogeneous population of cancer specific circulating cells that require further study.
Cancer cell-derived extracellular vesicles stimulate tumor angiogenesis by delivering VEGF to endothelial cells. Song Yi Ko, Honami Naora. UT MD Anderson Cancer Ctr., Houston, TX.

Angiogenesis is essential for tumor growth and metastasis, and is orchestrated by a repertoire of growth factor signaling pathways that stimulate endothelial cell growth, migration and vessel formation. Recent studies have shown that angiogenesis can also be regulated by cell-derived extracellular vesicles. Vesicles are small endosomal-derived membrane vesicles that contain various biomolecules such as RNA and proteins, and are increasingly thought to play important roles in transferring informational cargo between cancer cells and stromal cells. In the majority of studies to date, the effects of cancer cell-derived exosomes have been attributed to their RNA cargo. In this study, we identified that exosomes derived from ovarian, colon and renal cancer cells contain abundant vascular endothelial growth factor (VEGF). Cancer cell-derived exosomes were found to activate the VEGF signaling pathway in endothelial cells and to stimulate endothelial cell migration and tube formation. Furthermore, our studies using inhibitors of VEGF signaling demonstrated that the stimulatory effects of exosomes on endothelial cell migration and tube formation are mediated via the VEGF signaling pathway. These findings indicate that cancer cell-derived exosomes promote tumor angiogenesis by delivering VEGF to endothelial cells.

Pharmacodynamic biomarkers in metronomic chemotherapy: Multiplex cytokine measurements in gastrointestinal cancer patients. Paloma Valenzuela,1 Karla Parra,2 Derrick Oxaca,1 Luis Reza,1 Jose Lopez,1 Montserrat Garcia Garcia,1 Germinigana Rodriguez,1 Alfredo Falcone,1 Giacomo Allegrini,2 Teresa Di Desidero,1 Guido Bocci,2 Robert Kirken,1 Giulio Francia,1 1UT El Paso, El Paso, TX; 2University of Pisa, Pisa, Italy.

Metronomic chemotherapy has shown promising antitumor activity in a number of malignancies. For example, we previously reported (Allegrini et al, Angiogenesis (2012) 15(2):275-86) a phase II clinical trial of metronomic UFT (a 5-fluorouracil prodrg 100 mg/twice per day p.o.) and cyclophosphamide (CTX; 300 mg/m² q14 days) in 38 patients with advanced refractory gastrointestinal tumors. The mechanisms of action of metronomic chemotherapy include upregulation of the angiogenesis inhibitor Thrombospondin-1, the suppression of bone marrow derived endothelial progenitor cells and, at least for drugs such as CTX, activation of the immune system. To further evaluate the latter, we carried out an immune system multiplex 14-cytokine profiling of plasma samples that were available (for day 0, day 28, and day 56) from 31 of the 38 patients in the above noted (Allegrini et al) clinical trial. Our results show that pre-treatment plasma level cut-offs of interferon-gamma (≥12.84pg/ml), sCD40L (<1168pg/ml), interferon-alpha2 (>5.5-11pg/ml) and IL-17a (>16.3pg/ml) were predictive markers for those patients with better progression-free survival <0.05 for each cytokine). After 28 days of metronomic therapy, the plasma levels of sCD40L, IL-17a, and of IL-6 (<130pg/ml) could serve as predictors of improved progression-free survival, as could levels interferon-gamma and sCD40L after 56 days of therapy. We observed minimal changes in cytokine profiles, from baseline, as a consequence of the metronomic therapy, with the exception of an elevation of IL-6 and IL-8 levels 28 days (and 56 days) after treatment started (p<0.05). Our results indicate that a selective cytokine elevation, involving IL-6 and IL-8, following metronomic chemotherapy administration. In addition, interferon-gamma and sCD40L may be potential biomarkers for gastrointestinal cancer patients that are likely to benefit from metronomic chemotherapy. Our study contributes to our understanding of the mechanisms of action of metronomic chemotherapy, and may guide future patient selection criteria for metronomic chemotherapy for gastrointestinal cancers.

Molecular profile of sunnītinib resistance in clear-cell renal cell carcinoma. Oscar Reig Torras,1 Mercedes Marín-Agulera,2 Natalia Jiménez,2 Paré Laia,2 Patricia Galvan,2 Carme Mallofre,1 Alexe Prat,1 Beogona Mellado1.1Hospital Clinica de Barcelona, Barcelona, Spain; 2Fundación Clinica por a la Recerca Biomèdica Araguní.

Background: Sunnītinib (SU) is a tyrosine kinase inhibitor used in the first line setting in metastatic clear-cell renal cell carcinoma (cRCC). Recently, nivolumab, a checkpoint inhibitor, has been approved as a second line therapy. The identification of biomarkers of resistance to these drugs may be useful to select patients’ treatment. In this study we investigated the molecular and immune profile associated to SU resistance. Methods: Forty-four patients (pts) with metastatic cRCC treated with SU were included. A global transcriptome analysis (Affymetrix Human Gene 2.0 ST array) on 6 extremely sensitive (ES; progression-free survival (PFS) > 24 months) and 8 refractory (R; progression disease as best response) cRCC pts treated with SU was performed. Differentially expressed genes were tested in the whole cohort by qPCR. In silico validation using the microarray data from 53 SU-treated pts (Beuselinck et al, Clin Cancer Res 2015) was performed. In addition 730 immune-related genes were tested in the same cohort and in 10 additional pts treated with anti-PD1/PD-L1 therapies as an exploratory analysis. Results: Differential expression analysis between R and ES pts showed 330 differentially expressed genes. 148 were overexpressed and 182 underexpressed in R pts. Top two deregulated networks were centered in LYN and NRC3 (Network 1), and in chemokine ligands and receptors (e.g. CCL5, CCR1 and CXL10) (Network 2). In Beuselinck dataset, 9 genes were differentially expressed between R and ES pts. The expression of 7 genes (B2ST2, CD44, ELK1, FADS2, LYN, NKAP and VEGFC) was correlated with a lower PFS in both cohorts (Table 1). The value of TIM-3 was overexpressed in SU-sensitive pts and in anti-PD1/PD-L1 refractory pts. Conclusions: We described a gene expression profile of SU resistance in cRCC pts. The value of TIM-3 as a potential biomarker in cRCC merits further exploration.

Survival analysis of selected genes in the training and validation set. *High vs low expression.

Vascularity and vascular maturity in breast cancer: a comparative analysis of the different molecular subtypes. Nenad M. Ayoub,1 Ahmed Y. Al Husban,1 Hussein M. Al Husban,2 Abdal Rahman N. Al Khatib,1 Alaa O. Al-Malleh,1 Ekklas A. Al-Majali2.1Jordan University in Jordan, Jordan; 2Royal Medical Services, Amman, Jordan.

Currently, angiogenesis inhibitors lack considerable activity and did not result in survival advantage in breast cancer. The goal of this study is to evaluate vascularity in terms of vascularity and vascular maturity among breast cancer subtypes. Archived tumor samples for breast cancer patients were retrieved from Pathology Department at Royal Medical Services in Jordan. Tissue sections were stained for the expression of basement membrane laminin using immuno-histochemical analysis. Endothelial cell and pericyte were identified and counted based on the shape of the nuclei as visualized with DAPI stain. Demographic, clinical, and pathological data were retrieved from patient medical records at time of diagnosis. Vascularity was obtained by counting the number of blood vessels and maturity of blood vessels is represented by the ratio of the average number of endothelial cell to average number of pericytes. A total of 60 patients were enrolled in this study in which 34 patients (56.7%) have hormone-dependent disease, 14 patients (23.3%) determined to have HER2-positive disease, and 12 cases (20.0%) were classified as triple-negative. Results showed a significant difference for the mean number of blood vessels (p=0.004) and endothelial cell to pericyte ratio (p=0.000) among the different molecular subtypes of breast cancer. Post hoc analysis indicated statistically significant difference in mean number of blood vessels between hormone-dependent and HER2-positive tumors (p=0.015). In addition, ratio of endothelial cells to pericytes was significantly different between hormone-dependent cases and each of HER2-positive and triple-negative cases (p=0.004 and 0.014, respectively). Size of tumor was significantly correlated to endothelial cell to pericyte ratio for the population examined (r=0.345, p=0.007). A significant correlation was found between the number of blood vessels and number of involved lymph nodes among all patients (r=0.271, p=0.038). Independent samples t-test analysis comparing mean number of blood vessels and endothelial to pericyte ratio according to hormone receptor status showed significant difference between hormone receptor positive and negative cases for both estrogen and progesterone receptors (p<0.05). No significant difference was found for the vascular parameters tested according to tumor stage, grade, and lymphovascular invasion (p>0.05). Collectively, these findings showed that the degree of tumor vascularity and vascular maturity are not uniform among breast cancer subtypes. Vascular maturity was significantly higher in hormone-dependent breast tumors compared to both HER2-positive and triple-negative cases. It is critical that a careful assessment of tumor vascularity is being considered in breast cancer patients in order to determine responsiveness to chemotherapy and anti-angiogenic treatment among the different molecular subtypes.

Therapy resistance in solid tumors is of growing concern due to the failure of multiple therapies. Targeting tumor cells alone with conventional therapy, tumor vasculature with antiangiogenic therapies (AAT) and tumor-infiltrating myeloid cells with CSF1R inhibitor have all lead to the development of refractory tumors with greater relapse rates. There is an urgent need to understand molecular mechanisms of therapy resistance in cancer. There could be tumor cell extrinsic and intrinsic mechanisms in the tumor microenvironment.

We focused our study to investigate tumor cell intrinsic pathways using glioblastoma (GBM) as a model tumor and AAT (anti-VEGF-VEGFR) as a model therapy. The benefits of AAT are transient with increased relapse owing to adaptive responses by the GBM. Our preclinical study and in vitro data, for the very first time, identified that AAT induces transdifferentiation of tumor cells into endothelial-like cells, capable of forming functional blood vessels in the growing tumors, termed as vasogenic mimicry (VM). We observed that anti-VEGFR2 (Vatalanib) induced VM vessels are positive for periodic acid-Schiff (PAS) matrix but devoid of any endothelium on the inner side and lined by tumor cells on the outer-side. The PAS+ matrix is positive for basal laminae (laminin) indicating vascular structures. Vatalanib treated GBM displayed various stages of VM such as initiation (mosaic), sustenance, and full-blown VM. In addition to this, vatalanib treated tumors show significantly increased Laminin positive loops characteristic of VM in tumor center as well as at the periphery. A positive correlation was observed between the VM-like structures and the tumor size.

We also performed in vitro tube formation assays with AAT treated GBM cells alone and HUVEC cells (co-culture) to confirm the role of GBM cells in the formation of mosaic vessels in normoxic conditions. Interestingly, tumor cells are incorporated into the tubes formed by HUVEC cells. We found a higher number of complete tube like structures with AAT treated tumor cells as compared to control. Cytokine array with the condition media from tumor cells treated with AAT showed a significant upregulation in the levels of IL8. We observed a significant increase in the CXCR1+ and CXCR2+ endothelial-like GBM cells following treatment with AAT. Ongoing investigations are focused on study of IL8-CXCR1/2 pathway in VM regulation using loss or gain of function approaches. The study will identify critical mediators of VM in GBM.

In clinics, discovering novel targets causing VM associated therapy resistance is essential for identifying subset of patients that could be treated with alternate regimens.

Less is more: macrophage depletion via CSF1/CSF1R pathway improves anti-VEGF therapy after adaptive resistance. Yasmin A. Lyons, Sunila Pradeep, Jean M. Hansen, Michael J. Wagner, Robert L. Dood, Sherry Y. Wu, Rebecca S. Carson, Robert L. Gale, Pamela G. Annin, Alan K. Sood. University of Texas/MD Anderson Cancer Center, Houston, TX.

Objectives: Anti-angiogenesis therapy shows clinical benefit in patients with high-grade serous ovarian cancer (HGSC), but adaptive resistance typically occurs. Thus, approaches to overcome such resistance are needed. Here, we systematically assessed immune cell populations enriched during adaptive resistance and identify novel therapeutic avenues. Methods: A series of in vitro and in vivo (immune competent and nude mice) experiments were carried out. Animals were treated with anti-VEGF antibody continuously until resistance emerged, at which point full immune profiling was performed. Based on these results, efficacy of AC708 (CSF1R inhibitor to target tumor-associated macrophages) was tested in the adaptive-resistance models. F4/80 antibody was used as a macrophage marker. Results: On the basis of full immune profiling, we detected significantly increased macrophage infiltration in tumors with anti-VEGF antibody resistance compared to tumors from sensitive mice (p<0.0001). Given the dominant role of CSF1R in macrophage function and overexpression of CSF1R in HGSC, we added AC708 following emergence of adaptive resistance to anti-VEGF antibody. Mice treated with AC708 after anti-VEGF antibody resistance demonstrated complete response upon completion of the experiment, while those that did not receive AC708 still had abundant tumor. To mimic treatment with the AURELIA regimen, we next treated mice with anti-VEGF antibody and paclitaxel until resistance emerged, and then AC708 was added. The addition of AC708 restored response to anti-angiogenesis therapy, resulting in 82% lower tumor burden compared to treatment with anti-VEGF antibody and paclitaxel alone (p < 0.0001), and a substantial decrease in macrophages (p<0.0004). Conclusions: The addition of CSF1R inhibitor to anti-VEGF therapy and taxane chemotherapy results in robust anti-tumor effects. To confirm these findings, a clinical trial at our institution is nearing activation. The REDIRECT (Randomized Induction Discontinuation Trial of EmaCTuzumab) trial will randomize patients to continue weekly paclitaxel and biweekly bevacizumab with or without a CSF1R inhibitor (emactuzumab) following an induction phase.

Establishment of an in vitro model for the study of vasogenic mimicry in ovarian and gastrointestinal cancer cells. Introduction: A key step in cancer progression is tumor irritation. The process of angiogenesis can be complemented in sub-sets of highly aggressive cancers by the process of vasogenic mimicry, which is the formation of tubular structures by tumor cells. Herein, we sought to establish an in vitro assay of vasogenic mimicry and determine the percentage of ovarian and gastrointestinal primary cultures capable of undergoing this process. Materials & Methods: From cancer cell lines, AGS and HS766T, and the ovarian cancer cell lines SKOV-3 and HEY were used in conjunction with gastrointestinal and ovarian primary cultured cancer cells extracted from peritoneal fluid. Cells were seeded on matrigel and monitored for a week. Hollow channels formation was evaluated by fluorescent dye microinjection, periodic acid Schiff staining, confocal microscopy and X-Ray microtomography (Micro-CT). Results: SKOV-3, HEY and AGS cell lines underwent the process of vasogenic mimicry. Both confocal microscopy and Micro-CT reconstruction were able to show the presence of a lumen of the structures in 3D. In 22 primary cancer cultures (Ovarian, Colon and Gastric) only 38% could undergo vasogenic mimicry. Discussion: We have standardized an in vitro assay to assay and quantify vasogenic mimicry. Regardless of origin, only a low percentage of cultures have the ability to undergo vasogenic mimicry. An understanding of this process could shed light on new therapies for this sub-set of highly aggressive cancers. Funding: FOND/EICYT 1120929, 3150028 & 1140970. Regulation of tumor angiogenesis by low dose Aspirin. Jinia Chakrabortty,1 Gargi Maitty,1 Snigdhika Banerjee,2 Sushanta K. Banerjee2. 1VA Medical Center/Blue Valley West High School, Kansas City, MO; 2VA Medical Center, Kansas City, MO.

Background and Objective: Tumor angiogenesis is a pathophysiological process in which new blood vessels are formed in the primary tumor site or distant organs for the nourishment of cancer cells and metastatic growth. Thereby, targeting tumor angiogenesis is an important area of research for cancer therapy. Studies have shown that aspirin (ASA) has the potency to inhibit breast cancer growth and metastasis, as well as reprogram the mesenchymal to epithelial transition (MET). Given the importance of ASA, we tested whether ASA may be able to regulate tumor angiogenesis. Methods: To do so, we determined the effect of low dose ASA (1mM, which is equivalent to 80mg human dose), ASA-treated (2.5mM) conditioned media (231-CMASA) or vehicle-treated conditioned media (231-CMT) of MDA-MB-231 cells on different endothelial cell lines, AGS and HS766T, and the ovarian cancer cell lines SKOV-3 and HEY were used in conjunction with gastrointestinal and ovarian primary cultured cancer cells extracted from peritoneal fluid. Cells were seeded on matrigel and monitored for a week. Hollow channels formation was evaluated by fluorescent dye microinjection, periodic acid Schiff staining, confocal microscopy and X-Ray microtomography (Micro-CT). Results: SKOV-3, HEY and AGS cell lines underwent the process of vasogenic mimicry. Both confocal microscopy and Micro-CT reconstruction were able to show the presence of a lumen of the structures in 3D. In 22 primary cancer cultures (Ovarian, Colon and Gastric) only 38% could undergo vasogenic mimicry. Discussion: We have standardized an in vitro assay to assay and quantify vasogenic mimicry. Regardless of origin, only a low percentage of cultures have the ability to undergo vasogenic mimicry. An understanding of this process could shed light on new therapies for this sub-set of highly aggressive cancers. Funding: FOND/EICYT 1120929, 3150028 & 1140970. ASA treatment blocks several angiogenic factors including VEGF-A that are associated with these three events, implicating a low dose of Aspirin is potentially therapeutic for breast cancer via blocking and normalizing tumor angiogenesis.

**#791** Inhibitory effects of teaflavin-3, 3'-digalate (TF3) on ovarian cancer cells. C. Chen,1 C. Gao,1 G. O. Rankin,1 A. Chakraborty,2 S. Singh,1 A. Mittelman,3 R. K. Tiwari,3 New York Medical College, Valhalla, NY.

Teaflavin-3, 3'-digalate (TF3) is a black tea polyphenol produced from polymerization and oxidation of green tea polyphenols epicatechin gallate and (-)-epigallocatechin-3-gallate (EGCG) during fermentation of fresh tea leaves. TF3 has been reported to have anti-cancer properties. However, the effect of TF3 on tumor angiogenesis and the underlying mechanisms are not clear. In the current research, TF3 was verified to inhibit tumor angiogenesis. Compared with EGCG, TF3 was more potent. TF3 inhibited human ovarian carcinoma OVCAR-3 cells induced angiogenesis in human umbilical vein endothelial cell model and in chick chorioallantoic membrane model. TF3 reduced tumor angiogenesis by down-regulating HIF-1α and VEGF. One of the mechanisms was TF3 inactivated Akt/mTOR/p70S6K/4E-BP1 pathway and Akt/c-Myc pathway. Besides, TF3 suppressed the cleavage of Notch-1, subsequently decreased the expression of c-Myc, HIF-1α and VEGF, and finally impaired cancer cells induced angiogenesis. Nevertheless, TF3 didn’t have any influence on MAPK pathways. Taken together, these findings suggest that TF3 might serve as a potential anti-angiogenic agent for cancer treatment.

**#792** Development of high-throughput cell-based co-culture angiogenesis assay system using hTERT immortalized cells. CHAOZHONG ZOU,1 Chiawen Hsu,2 Menghang Xia,3 Metewo S Enuameh1, ATCC, Gaithersburg, MD; 1National Institutes of Health, Bethesda, MD.

Angiogenesis is a multi-step physiological process which is involved in a large number of normal and disease state processes; In vitro angiogenesis models provide very useful tools to study these processes, one of which is the analysis of tube formation. Tubules formed in co-culture assays were significantly more heterogeneous and more closely resembled capillaries than Matrigel® tubules. Current co-culture models using primary cells have donor variability, and inconsistent results due to lot to lot variation. In this study, we established an in vitro co-culture model system consisting of an assay ready mixture of an aortic endothelial cell line and a hTERT immortalized human aortic endothelial cell line and a hTERT immortalized adipose-derived mesenchymal stem cell line (hTERT-MSCs) in a specially formulated medium containing VEGF supplement (Angio-Ready™ Angiogenesis Assay System). Both cell lines were immortalized by hTERT (human telomerase reverse transcriptase) alone and have been well-characterized showing that the cells retain the most important characteristic of their parental counterparts. The new co-culture system forms functional tubular structures in less than 7 days, and in addition, the hTERT-MSCs which surround the tubular structures have undergone transformation indicated by elevated positive oSMMA staining (a marker of smooth muscle cells), indicating that the system has physiological relevance. Notably, our results showed the co-culture system has minimal lot-to-lot variation indicated by the treatment of three lots with the anti-cancer drug, Ramucirumab (Cyramza®), which also targets the VEGF pathway. Next, we tested the new system with compounds that impact angiogenesis, results demonstrated that the angiogenesis system responds positively to elevated doses of VEGF and negatively to increasing concentrations of suramin; more importantly, the tubular formation efficiency is reduced or blocked by well-known anti-cancer drugs such as Sunitinib (SUTENT®) and Bevacizumab (Avastin®), both of which target the VEGF pathway. Finally, we used the Angio-Ready™ system validated 4 HIF-1 (hypoxia inducible factors-1) inhibitors which have anti-angiogenic properties identified by high-throughput screening methods; data showed the results of the new system match with other screening methods including a system screening time as short as 3 days. Therefore, the co-culture model developed by using hTERT-immortalized cell lines described in this report provide a consistent and robust in vitro system for studying cardiovascular biology, drug screening and cellular changes will facilitate identification of the interactive mediators and subsequent development of effective antiangiogenic therapy.

Breast cancer affects one in eight women in the USA. Early diagnosis and newer treatment modalities have rendered breast cancer manageable. However, triple negative breast cancer is still difficult to treat and warrants a search for new targets. One strategy that has emerged in cancer research involves targeting of tumor associated blood vessels which provide growing tumors with oxygenated blood and growth factors necessary for maintenance and metastasis. Antiangiogenic drug therapy is transient and has not been able to gain main-stream therapeutic modality. We discovered that endothelial progenitor cells (EPCs) are mobilized from the bone marrow to the tumor site and contribute to the development of breast tumor vessel formation in an estrogen-dependent manner. Therefore, characterization of tumor associated endothelial progenitor cells in breast cancer may provide a more specific antivascular therapy. Using the highly proliferative human umbilical cord blood derived EPCs, having the phenotype (CD133+; CD34+, VEGFR-2+), the effect of growth factor and chemokine rich EPCs conditioned medium (CM) was assessed in luminal (MCF-7), and post-EMT (MDA-MB-231) breast carcinoma cell lines. We observed an initial halt in cellular proliferation in MCF-7 followed by a significant increase in proliferation after forty eight hours of treatment. On the other hand, MDA-MB-231 showed decreased proliferation even after forty eight hours of treatment. Treating the EPCs with breast cancer conditioned medium resulted in morphological and cellular growth changes in the EPCs. MDA-MB-231 CM resulted in an increase of the EPCs proliferation and differentiation by increasing the number of spindle shaped attaching cells, and MCF-7 CM resulted only in an increase in the differentiation rate by increasing the number of cell clusters. This increase in EPCs proliferation and differentiation associated with MDA-MB-231 CM treatment might explain the invasiveness of this breast cancer cells through the increase in the tumor associated neovascularization. The analysis of the parameters of development between breast cancer cells and EPCs along with the associated cellular changes will facilitate identification of the interactive mediators and subsequent development of effective antivascular therapy.

**#794** Potential role of DLL4 in uveal melanoma vascular mimicry. Julia Escandon, Matthew G. Field, Stefan Kurtenbach, Jefim Kuznetzov, Christina L. Decatur, J William Harbour. Univ. of Miami, Miami, FL.

Uveal melanoma is the most common malignancy of the eye. Thanks to gene array analysis it is possible to classify uveal melanoma in Class 1 (low metastasis risk) and Class 2 (high metastasis risk) tumor. This classification will ultimately determine the tumor treatment, risk of metastasis and patient surveillance. Progression to metastasis remains by far the greatest problem in uveal melanoma and is associated with loss of BAP1 tumor suppressor. Bioinformatic analyses of RNA-Seq indicated that pro-angiogenic genes such as DLL4, VEGFA, VEGFC and HIF1α are overexpressed in Class 2 compared to Class 1 uveal melanoma while angiogenic inhibitors such as ZFP36L1, HIF1AN, VEGFB, VHL and HIF3A are downregulated. Further, we found that DLL4 is among the 5 most highly overexpressed genes associated with BAP1 loss in clinical specimens and in uveal melanoma cell lines induced to deplete BAP1. DLL4 is a Notch ligand known to regulate endothelial cells, bone marrow endothelial cell progenitors and angiogenesis. We hypothesize that DLL4 contributes to vascular mimicry in uveal melanoma. To test this hypothesis, we will test uveal melanoma cell lines induced to deplete BAP1 using shRNA in cell culture-based and in vivo models. The results of this research have the potential to elucidate the mechanism by which vascular mimicry occurs in uveal melanoma.

**TUMOR BIOLOGY: Angiogenesis and Vascular Biology 1**

The capacity of high-grade serous ovarian cancer cells to form spontaneous multicellular structures (SMCS) in vitro predicts their in vivo tumorigenicity. Alicia A. Boye, Chunmei Fu, Zhihui Gao, Carlos M. Telleria, McGill University, Montreal, Quebec, Canada.

High grade serous ovarian cancer (HGSOC) is the most frequent histopathological subtype among epithelial ovarian cancers (OC). While an increase in the tumor associated neovascularization. The analysis of the parameters of development between breast cancer cells and EPCs along with the associated cellular changes will facilitate identification of the interactive mediators and subsequent development of effective antivascular therapy.

**TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 1**

The capacity of high-grade serous ovarian cancer cells to form spontaneous multicellular structures (SMCS) in vitro predicts their in vivo tumorigenicity. Alicia A. Boye, Chunmei Fu, Zhihui Gao, Carlos M. Telleria, McGill University, Montreal, Quebec, Canada.

High grade serous ovarian cancer (HGSOC) is the most frequent histopathological subtype among epithelial ovarian cancers (OC). While an increase in concentration of CA125 in the blood anticipates clinical remission following standard of care, we lack biomarker/s to diagnose early disease stage or predict progression speed. In this work we question whether the capacity of HGSOC cell lines developed from the same patient’s ascites: longitudinally along disease progression—established at platinum-sensitive relapse (PEO1), from further progressive disease 10 months (mo.) later (PEO4); and after failure to respond to high-dose cisplatin 3 mo. later (PEO6). We noticed all cell types developed an adenotype that is highly overexpressed in clinical specimens and in uveal melanoma cell lines induced to deplete BAP1. DLL4 is a Notch ligand known to regulate endothelial cells, bone marrow endothelial cell progenitors and angiogenesis. We hypothesize that DLL4 contributes to vascular mimicry in uveal melanoma. To test this hypothesis, we will test uveal melanoma cell lines induced to deplete BAP1 using shRNA in cell culture-based and in vivo models. The results of this research have the potential to elucidate the mechanism by which vascular mimicry occurs in uveal melanoma.
apparent capability to form SMCs. Next, 2×10^6 PE01, PE04 or PE06 cells were implanted into the abdominal cavity of nude mice; the animals were sacrificed either after having met an end-of-wellness endpoint criterion, or after a maximum of 14 mo. if no such criteria were met. PE06-injected mice reached the humane endpoint due to accumulation of ascites 6–7 mo. following injection, and predicated by visible signs of stress in the omentum, pancreatic-spleen region, liver base and diaphragm. Animals injected with PE04 or PE01 cells, however, did not develop any apparent disease 14 mo. following injection. Yet, when a 10-fold higher load of PE04 cells but not PE01 cells (i.e., 20×10^6) were injected, animals met euthanasia criteria due to ascites accumulation 6 mo. later and displayed macroscopic disease similar to that caused by 1/10 of the load of their prepubertal (PE06) cells) within the same timeframe. The different anatomical localization and histopathological aspects of the lesions generated with PE06 cells were similar to that generated with PE04 cells, suggesting that the more aggressive PE06 cells were likely present, although in fewer quantities, within the less aggressive PE04 cell population. Our data demonstrate, then, that the in vitro SMCS forming capacity of HGSOC cells has a positive correlation to their capacity to sicken the animals. Moreover, this study suggests that the in vitro SMCS forming capacity of epithelial OC cells obtained from ascites of patients diagnosed with HGSOC may be used to predict their aggressiveness and, consequently, guide prognosis.

#796 Reproductive hormones modulate cardioprotection from doxorubicin-induced cardiomyopathy in female spontaneously hypertensive rats. Kaytie Pokrzynski,1 Elliott T. Rosen,1 Julia L. Bonanno,1 Baikuntha Aryal,1 Thomas Biel,1 Dharam Prasad,1 Steven Mog,2 Ashutosh Rao,1 FDA, Silver Spring, MD; 2FDA, College Park, MD.

Doxorubicin (Dox) causes cardiomyopathy, partially driven by the excess generation of mitochondrial reactive oxygen species (ROS). The incidence of Dox-induced cardiac stress is greater in prepubescence and postmenopausal females compared to reproductively mature women, suggesting that reproductive hormones may mediate cardioprotection. We investigated the role of exogenous estradiol (E2), progesterone (P4), Tamoxifen (Tam) or combinations thereof, and were subsequently treated with Dox. Naturally cycling animals were treated with Dox, the iron chelator Dexrazoxane (Drz), or Dox+Drz. Tumor size was used to evaluate anticancer activity. Vaginal cytologies and circulating E2 and P4 levels were obtained. Serum cardiac troponin I (cTnI), histopathology and echocardiograms were used to assess cardiac health. Dox treated animals supplemented with E2 and P4 (alone) showed cardioprotection relative to the Dox treated animals. Dox+/-Drz exhibited sustained anti-tumor activity independent of endocrine status. After 13 days with Dox, all naturally cycling animals arrested in diestrus (lowest hormone levels). These results demonstrate that E2 and P4 have a role in providing cardioprotection from Dox therapy in SHRs, and that estrous cycle stage may provide a safety treatment window, potentially reducing the risk of cardiotoxicity in reproductively normal females. We are also currently analyzing RNA sequencing data obtained from heart tissues to achieve a better understanding of the molecular mechanisms of cardioprotection.

#797 Glioblastoma animal model using CRISPR-Cas9 technology. Da Eun Jeong,1 Kee Hang Lee,1 Sung Soo Kim,1 Yoon Kyoung Bae,1 Hyun Naim,1 Ji Yoon Hwang,2 Hee Jang Pyeon,3 Hye Jin Song,3 Kyeung Min Jou1,2 SAHIST, Sungkyunkwan University, seoul, Republic of Korea; 2Samsung Medical Center, seoul, Republic of Korea.

Current in vivo model system poses limitation on fully recapitulating genomic characteristics of a tumor due to high complexity and poor understanding of the heterogeneous microenvironment conditions in cancer pathogenesis. In this respect, such as the same topic models are required. In present study, we propose that the most representative cancer models have consistent tumor microenvironments and genomic mutations. The Clustered regularly interspaced short palindromic repeats (CRISPR)-Cas9 system is a powerful genome editing tool for efficient and precise genome engineering. Here, we employed CRISPR-Cas9 system in vivo to generate Cre-dependent Cas9 knock-in mouse (B6;129-Gf(OBA)26Sortm1(CAG-cas9/EGFP/hrFtz/J, Jackson lab.). The Cre-dependent Cas9 mouse models harbor combinations of genomic alterations including well-established oncogenes such as EGFRviii, c-MET, PDGFRα, IDH1 R132H and KRAS, EGFR, ALK, BRAF in Brain and Lung cancer models, respectively. While, they also consist of tumor suppressor genes including PTEN, NF1, Ink4a/ARF, Rb, TP53 and TP53, PTEN, NKx-1, APC in both Brain and Lung models, respectively. Cre-dependent model allows us to study in-depth into the tumor initiation and progression, while able to follow up in the role of tumor microenvironment in cancer maintenance. A better understanding of cancer models for preclinical research including their uses, as well as their visible and non-visible signs may aid for future potential studies regarding the development and implementation of new immune targeted therapies and potential validation of novel therapeutic biomarkers.

#798 Label-free enrichment and detection of circulating tumor cells in metastatic breast cancer patients show 82% of cohorts have detectable targets. Yu-Jen Chang,1 Chen-Lin Chen,2 Wei-Fan Hsu,3 Meng-Ze Li,4 Wei-Yuan Ma,1 Ken-Chao Chen,1 Guan-Syuan Huang,2 Wai-Sang Wong,1 Jhan-Yu Syu,1 Thomas, Yo-Yan Huang,2 Ching-Hung Lin,2 Andrew M. Wó,3 Chuin-Sheng Huang,4 National Taiwan University, Taipei, Taiwan; 4University of California, San Diego, CA; 5National Taiwan University Hospital, Taipei, Taiwan.

Circulating tumor cells (CTC) are believed to be the culprit of metastasis and studies have shown that their enumeration has prognostic value in wide range of solid tumors. Although much progress has been made in CTC technology, their rarity in blood and their inherent heterogeneity still provide much challenge towards maturity of the technology. This paper presents semi-automated enrichment of CTC via density-based approach in a novel microfluidic disk, followed by multi-step on-disk immunofluorescence staining (pan-CK, EpCAM, Hoechst and CD45), fluorescence microscopy for image capture, and software image analysis. To characterize the performance of the system, we spiked 1 to 800 cells (five cell lines at 105, six cell lines, at 104) into the microfluidic disk. Label-free enrichment and detection of circulating tumor cells in Metastatic breast cancer patients show 82% of cohorts have detectable targets. The recovery rate of the system is 87.4% ± 3.7% (R2 = 0.958) regardless of EpCAM expression levels of the cell lines. To interrogate the limitation of the technology, this data set included ultra-low cell counts spiked of 1 to 13 cells (mean ±5, median 5) which might be indicative of CTC from metastatic breast cancer (MBC) patients. The recovery rate for this low cell count is 90±10%. Notably, one single cell was spiked into healthy whole blood, processed via the technology, and one target cell was detected. This test was repeated in triplicate with all three tests recovered one cell each. Furthermore, the microfluidic disk technology enables operation over a range of blood volume (from 2 to 7.5mL) with no statistically significant difference in recovery rate. Recovered MCF-7 cells spiked in blood were subsequently cultured for 6 days and showed good viability with cell proliferation. We tested the technology in MBC patients along with CA15-3 and CT imaging. A total 34 of blood samples were collected from 21 patients over the course of their systemic treatment. Results showed CTC were detected in 28 samples (82%). The target CTC detected ranges from 0 to 138 (mean 16, median 4 CTCs per 7.5mL). 15 out of 34 samples (44%) had CTC number > 5/7.5mL. In our patient with triple negative diagnosis, CTC count CA15-3 and CT imaging were monitored during the course of chemotherapy. The CTC count remained zero at the end of the first and second treatment course, elevated to 24 CTCs at the end of the third course, and continued its elevation to 31 by the end of the fourth treatment course. During this entire treatment course, CA15-3 did not vary significantly. However, CT image confirmed objective response within 6–9 months of the second chemo course to 8.09cm at the beginning of the fourth course. Taken together, our label-free CTC enrichment technology has high analytical sensitivity (87%) over a wide range of cancers, able to handle a flexible blood volume (2mL to 7.5mL), and amenable to detect a high percentage (82%) of CTC in MBC patients.

The presence of microlcifications on mammographic images represents a highly valuable tool in the early detection of breast cancer, often allowing radiographers to diagnose mammary tumours at an early, in-situ stage. The presence of microlcifications has also been linked to a number of unfavourable prognostic factors including decreased survival and an increased probability of relapse. Despite their long history of use in the clinic, the precise mechanisms by which microlcifications are formed remains poorly understood. Pathological soft-tissue classification is often considered the result of an imbalance between pro- and anti-calcifying factors. However, the possible impact of such an imbalance has not been studied in the context of breast calcification. We have established an in-vitro model of microlcification formation using the triple-negative adenocarcinoma cell line MDA-MB-231. When cultured in the presence of the osteogenesis-promoting reagents β-glycerophosphate, ascorbic acid and dexamethasone, calcified deposits begin to form by Day 14, as verified by Alizarin Red staining, and by 28 days calcium deposition is significant. This model will allow an understanding of the interactions that underpin microlcification formation and provide insights into the development of new anti-calcification therapies.
arin Red staining and the quantitative o-cresolphthalein assay. Following the establishment of our model, we set out to identify the underlying molecular triggers initiating the calcification process, in particular the role of micro-environmental factors. Altered magnesium homeostasis has been suggested as an important mediator of tissue calcification. We found that a slight increase in magnesium concentration resulted in almost completely blocked calcium deposition in our model. Previous studies in other tissues have shown this protective effect to be dependent on the cation channel TRPM7 which is increased in breast cancer patients with calcifications compared to those without. Unexpectedly, inhibition of the TRPM7 channel by two separate compounds (2-APB and NS-8593) not only failed to reverse the inhibition of microcalcification formation by exogenous magnesium, but actually further decreased calcium deposition by Day 28, suggesting that calcium influx via the TRPM7 channel may be promoting development of mammary calcifications. Finally, we investigated the effect of several tumor associated cytokines on the rate of calcium deposition and found that IL-1β and TNF-α blocked mineralisation whilst IL-6 and BMP2 lead to an increase. Interestingly, co-administration of IL-6 alongside a soluble form of its receptor (sIL-6R) was observed to promote mineralisation even in the absence of dexamethasone, which had previously been essential to the formation of calcifications in our model. To date, our model has yielded a number of important insights into the formation of calcifications in breast cell lines, many of which recapitulate observations from patient studies. It is hoped that this work will contribute to our understanding of the origin of these pre-invasive diagnostic clues.

#800 Enhancing tumor killing abilities of NK cells by targeting CD16 shedding, and ADAM17.

Hemant K. Mishra,1 Jiajinming Wu,1 Dan S. Kaufman,2 Bruce Walcheck.1 1University of Minnesota, St. Paul, MN; 2University of California, San Diego, CA.

CD16 consists of two isoforms (CD16a and CD16b) encoded by two highly homologous genes that differ by only 6 amino acids in their extracellular regions. CD16a is expressed by human neutrophils and CD16b by human natural killer (NK) cells. The ectodomain regions of both CD16 isoforms are cleaved proximal to the cell membrane by a proteolytic process referred to as ectodomain shedding. We demonstrate that the membrane metalloprotease ADAM17 cleaves CD16 in isolated leukocytes and in human patients. By mass spectrometry analysis, we determined 3 adjacent cleavage sites in neutrophil CD16b and one cleavage site in NK cell CD16a that occurred at the same location as the predominant cleavage site in CD16b, which is interesting considering CD16b is linked to the plasma membrane via a GPI anchor and CD16a is a transmembrane protein. Antibody-dependent cell cytotoxicity (ADCC) by NK cells is a key mechanism in the anti-cancer effects of therapeutic antibodies, and CD16a exclusively recognizes tumor-bound antibodies. Surface levels of CD16a are rapidly down-regulated upon NK cell activation by cytokines, target cell interaction, and tumor infiltration, which is associated with impaired ADCC. Thus blocking this process has important clinical significance. We contend that maintaining high surface levels of CD16a during NK cell-based immunotherapy will enhance their killing of antibody-bound tumor cells. In ongoing studies, we are examining pharmaceutical and gene-targeting means of preventing CD16a cleavage as a novel therapeutic strategy to enhance the anti-cancer effects of NK cells.

#801 A zebrafish model of NF1-mutant melanoma that lacks activating mutations of BRAF or NRAS.

Shuning He,1 Marc R. Mansour,2 Hillary M. Layden,1 Scott J. Rodig,3 E. Elizabeth Patton,4 A. Thomas Look.1 1University of Minnesota, St. Paul, MN; 2University of California, San Diego, CA.

Cutaneous melanoma is the most lethal type of skin cancer, with ~76,380 newly diagnosed melanoma and ~10,130 melanoma-associated deaths per year in the US. Thus, there is a need for improved understanding of the molecular pathogenesis and more effective targeted therapies for this devastating disease. The recent work of The Cancer Genome Atlas Network has defined melanoma as an RTK/ERK-driven solid tumor that can be classified into four tumor subtypes: BRAF-mutant, RAS-mutant, NF1-mutant, and triple-wild-type. This landmark study highlighted the important role of the previously understudied NF1 tumor suppressor in melanoma pathogenesis, especially for the 9% of melanoma patients who have acquired inactivating NF1-mutations, but lack hot-spot mutations that activate BRAF or RAS. To date, animal models have not been developed for the NF1-mutant subtype of melanoma, which has significantly impaired the development of novel therapeutic strategies for this subtype. Here we report the first zebrafish model for NF1-mutant melanoma, which we generated by combining the loss of nf1 with loss of both pten and p53. The resultant compound mutant zebrafish develop aggressive melanomas from the age of 7 weeks and the tumor penetrance is 80% by the age of 18 weeks. We demonstrate further that these high-risk zebrafish melanomas were exclusive of hotspot mutations of braf and rras. Sustained inhibition of both MEK and PI3K suppressed tumor progression in vivo, whereas inhibition of MEK or PI3K alone was insufficient to suppress the growth of these tumors. Surprisingly, single and double inactivating mutations in the tumors significantly reduced tumor growth, even further than short- and long-term suppression of tumor cell growth in nf1/pten-mutant melanomas. Thus our model appears ideal for the testing of drugs that will prove uniquely active for the significant subset of NF1-mutant, BRAF/NRAS-wildtype human melanomas.

#802 Loss of function of Arid1a synergizes with MYCN in neuroblastoma pathogenesis.

Hui Shi, Ting Tao, Cigall Kadoch, Thomas Look. Dana-Farber Cancer Inst., Boston, MA.

ARID1A is a key component of the SWI/SNF-A (BAF) chromatin-remodeling complex that is known to modulate chromatin structure and gene transcription. Recent exome and whole-genome resequencing has identified SWI/SNF as the most frequently mutated chromatin remodeler in human cancers, and ARID1A is the most highly mutated component among the SWI/SNF subunits, primarily in solid tumors. In high-risk neuroblastoma, ARID1A is mutually inactivated in one allele in ~1% of patient tumors. In addition, ARID1A is deleted in one allele in at least 85% of cases with chromosome 1p deletions, which is the most common deletion found in neuroblastoma. Thus, ARID1A appears to function as a haploinsufficient tumor suppressor in a substantial fraction of high-risk neuroblastomas. The arid1a gene is disrupted in zebrafish, and the two genes are hence named arid1a and arid1ab. We targeted each allele of the two genes using CRISPR/Cas genome editing system and recovered stable lines with loss-of-function mutations in each arid1a gene. arid1ab but not arid1a homozygous mutation showed embryonic lethality. We bred these lines with a transgenic zebrafish line expressing high levels of MYCN in the peripheral sympathetic nervous system driven by the dopamine beta-hydroxylase promoter. Loss of one copy of either arid1a or arid1ab dramatically accelerated the onset and increased the penetrance of MYCN-induced neuroblastoma. Loss of additional copies of arid1a or arid1ab accelerated the tumor onset even further, with the most rapid onset in compound heterozygotes of both genes. The compound heterozygotes showed increased fraction of sympathoadrenal cells in active cell cycle compared to the MYCN transgenic fish with wild type arid1a alleles. Our long-term goal is to use the zebrafish model to elucidate the mechanisms underlying the highly dose-dependent tumor suppressor role of this component of the BAF chromatin remodeling complex in neuroblastoma, as a first step toward designing targeted therapies synthetic lethal with reduced expression levels of ARID1A.

#803 Targeting β-catenin/CBP signaling in OSCC.

Khalid Alamoud,1 Khimet Sadykov,1 Vinay Kartha,2 Stefano Monti,3 Anna Belkina,4 Jennifer Snyder-Cappione,2 Sara Pai,3 Maria Kukuruzinska1. 1Boston University Henry M. Goldman School of Dental Medicine, Boston, MA; 2Boston University School of Medicine, Boston, MA; 3Massachusetts General Hospital, Boston, MA.

Objectives: Oral squamous cell carcinoma (OSCC) is an aggressive malignant characterized by molecular heterogeneity and locoregional spread associated with high morbidity. Aggressive cancers are thought to arise from populations of cancer initiating cells (CICs) that exhibit the properties of stem cells and drive tumor development, recurrence and resistance to therapy. The transcriptional regulator, β-catenin, has been implicated in OSCC CICs. Nuclear β-catenin has been shown to recruit the chromatin remodeling CREB binding protein (CBP) to drive expression of proliferation and survival genes, as well as genes that maintain stem-like phenotypes. We hypothesized that targeting β-catenin/CBP interaction will inhibit CICs in oral tumors and restore an epithelial phenotype. Methods: To test tumor aggressive potential of OSCC CICs, we used zebrafish as a model system. We isolated CD44+CD24medCD29hi cells from aggressive HSC-3 OSCC cells by FACS and assayed their ability to drive tumor growth and metastases in zebrafish compared to unsorted and CD44+CD24medCD29med cells. In addition, we examined the role of the β-catenin/CBP axis in the aggressive phenotype of these cells. We also assessed whether the β-catenin/CBP axis affected CICs in tumors from immune competent HPV+ mice. Results: Zebrafish injected with subpopulation of cells expressing CD44+CD24medCD29med primitive cell surface markers drove rapid tumor growth and metastases, followed by sorted and sorted CD44+CD24medCD29med cells. We targeted each molecule inhibitor of the β-catenin-CBP interaction, ICG-001, interfered with tumor growth and metastases in zebrafish. Further, ICG-001 inhibited tumor growth in immunocompetent HPV+ murine model. On a cellular level, ICG-001 promoted membrane localization of β-catenin, enhanced E-cadherin adhesion and...
restored epithelial phenotype. Significantly, ICG-001 gene signatures tracked with reduced overall patient survival in the cancer genome atlas, TCGA. Conclusion: Our studies indicate that the β-catenin/β-catenin/CBP axis promotes OSCC CICs and that ICG-001 may be an effective therapeutic agent for this malignancy. #806 MGA is a potential tumor suppressor in acute myeloid leukemia. Qiaoyang Sun,1 Lingwen Ding,1 Kar-Tong Tan,1 Wenwen Chien,1 Xinyi Loh,1 Jinfen Xiao,1 Anand Mayakonda,1 Dechen Lin,1 Yanyi Jiang,1 Henry Yang,1 Sidig Gery,1 Sigal Gery,2 H. Phillip Koeffler2,1. 1Cancer Science Institute of Singapore, Singapore, Singapore; 2Cedars-Sinai Medical Center, Los Angeles, CA.

MGA is an incompletely studied gene with a high mutation frequency in MLL-PTD AML (9%) and in core bind factor AML (8%). This gene encodes a MAX-interacting protein and is believed to act as a transcription factor that suppresses MYC binding to its target. By in silico analysis, we found that MGA is expressed in normal myeloid hematopoietic cells and AML, and the expression level is comparable with TET2 or DNMT3A. Further data mining of TCGA revealed a high frequency of inactivating mutations of the MGA gene in a variety of cancers such as various adenocarcinomas. To interrogate functionally its role in leukemogenesis, lentiviral constructs containing either shRNA or CRSPR-sgRNA targeted to different regions of the MGA gene were generated. MGA expressing AML cell line EOL-1 was silenced by shRNA or CRISPR system. Silencing was confirmed by western blot (shRNA) and Sanger Sequencing (sgRNA). An increase of methylcellulose colony number (−30%) was observed in MGA silenced cell lines. Control EOL-1 cells or EOL-1 cells silenced with MGA CRISPR sgRNAs were injected into both flanks of NSG mice, and tumor masses were harvested 21 days after injection. Silencing of MGA by CRISPR was found significantly enhanced in vivo tumor growth. In addition, western blot analyses revealed silencing of MGA in EOL-1 cells increased protein levels of Cyclin E1 and phospho-RB (S807 phosphorylation inhibits the ability of RB to target protein allowing cell cycle progression), indicative of a proliferative advantage conferred by the silencing of MGA. MGA may be a potential regulator of the MYC pathway. We, therefore, examined whether silencing of MGA alters MYC transcriptional activity. Luciferase reporter assay was carried out in 293FT cells stabilized with either scramble or shRNA- targeting MGA. Luciferase activities were measured 48 h after transfection of cells with MYC activity reporter pMycE1bLuc and normalized to the corresponding co-transfected Renilla luciferase activity. A fourfold increase in luciferase activity was observed in MGA silenced cells when compared with non- targeting shRNA controls. Furthermore, Kaplan–Meier survival analysis was performed in the TCGA-AML patients by comparison of cases with highest versus lowest expression of MGA. P-values were calculated by log-rank test. MGA expression data and patient survival data were retrieved from TCGA-AML patients RNA seq, or microarray (70 AML patients). The MGA expression high and low groups were defined by 15% higher than the median or 15% lower than the median, respectively. AML patients with lower levels of MGA in their leukemic samples had worse outcome compared with those whose leukemic cells expressed higher levels of MGA. Collectively, our results suggest that MGA may function as a potential tumor-suppressor in AML.

Animal models of human cancer offer the potential to study human tumor growth kinetics, genetic variance among human cancers, and provide in vivo platforms for drug efficacy testing. In particular, immunodeficient mouse models have been invaluable in modeling a wide range of human cancers. However, some cancer lines don’t grow well in the available mouse models or show variability in growth kinetics from mouse to mouse, making drug efficacy studies difficult due to differences in tumor size at the onset of treatment. These challenges are also seen in patient derived xenograft (PDX) models, in addition to long timeframes to obtain sufficient mice with PDX tissue growth for drug efficacy studies. Mice are also limited in tumor growth potential with regard to humane endpoints and small size also limits the volume of blood that can be collected for analysis. An immunodeficient rat model would overcome some of these issues. A rat model would allow for larger tumor size, easier surgical manipulation, and greater volume of tissue and blood sampling for downstream analysis. In addition, large tumors from rats could be serially transplanted into mice for drug efficacy testing and could provide a large number of transplanted mice in a shorter period of time compared with serially transplanting from mouse to mouse. We have created an immunodeficient rat model with a functional deletion of the Rag2 gene. This knockout, created using spermato- gonial stem cells, lacks mature B and T cells. To assess the capability of the Rag2 knockout rat to accept human xenografts, we transplanted 2 commercially avail- able human cancer cell lines into our animals. The human REH acute lympho-
cytic leukemia cell line was transplanted via intravenous injection and the hu-
man glioblastoma cell line U87/MG was transplanted subcutaneously. Both cell 
lines survived in the Rag2 knockout rat and resulted in the growth of tumors comprised of human cells. Studies are underway to characterize the Rag2 knockout rat's ability to grow other human cell lines, including those that do not grow well in mice, and PDX tissues.

#808 PDGF-A overexpression and p53 depletion in rat neural precursor 
cells induces large brain tumors that resemble human glioblastoma. Nina P.

#810 Establishing patient derived preclinical in vitro and in vivo models of 
pediatric brain cancers. Sridevi Yadavilli, Madhuri Kambhampati, Jamila Git-
tens, Eshini Panditharutana, Moja Stampar, Lindsay B. Kilburn, Suresh Magge, 
Roger J. Packer, Javad Nazarian. Children’s National Health System, Washington, 
DC.

The recent surge in understanding genomic aberrations of some of the dead-
liest childhood brain cancers has highlighted the need for robust preclinical 
models. Such models will allow for robust drug screening and preclinical eval-
uation of efficacy, toxicity, and tumor penetrance in vivo. Given the rarity and 
importance of patient derived specimens, handling and processing methods are 
the most critical steps for successful establishment of viable and repro-
ducible in vitro and in vivo models. Since specimen source varies (biopsy, au-
topsy, or cryo-preserved), processing methods should be refined to allow for 
optimal extraction of maximum numbers of viable cells from each specimen 
type. We have developed standardized procedures for handling and processing of 
tissue samples obtained from biopsy, autopsy, or cryo-preserved specimens as 
well as necropsy tissue obtained from existing xenograft models. Two processing 
methods for generating viable cell suspensions are described. The first method, 
which uses collagenase-DNase mediated digestion of the tissue is efficient with 
bulky samples and can be used with tissues obtained at autopsy. The second 
method uses a commercially available enzymatic dissociation kit optimal for 
small volume samples such as biopsy, cryo-preserved and mouse necropsy spec-
imens. We show that obtaining viable cell suspension from precious tumor 
tissue by these methods results in successful generation of pre-clinical in vitro 
and in vivo models of DIPG, pilocytic astrocytoma and medulloblastoma that 
represent the exact genetic makeup of the original patient tumor. We further 
demonstrate intracranial injections of these cells into P2 mice for generating 
orthotopic xenograft models of brainstem or cortical tumors. Our methods 
and results allow for rapid establishment of preclinical models using rare and valu-
able childhood brain tumor specimens. These pre-clinical models serve as valu-
able tools for understanding the molecular mechanisms of the disease, identify-
ing targetable molecules, and screening of novel therapeutics.

TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer I

or pancreatico-duodenal artery. 4/4 success rate of a port implantation was 
achieved without mortality, but 1/4 animals suffered post-operative bleeding at 
the port head site, attributed to coagulopathy secondary to hepatic dysfunction. 
And, 4/4 animals were partially anorectic for up to 7 days post-surgery. De-
creased tumor volume and Ktrans (a measure of capillary permeability) were 
demonstrated 7 days after single HAI with CBL0137. Contralateral tumor 
cancer effect of CBL0137 on HCC was not clear because of a lack of the control 
group, we successfully implanted a VAP into the GDA of 4 woodchucks bearing 
unresectable HCC for HAI. The described woodchuck model may serve as a 
platform for identifying novel drugs and optimal conditions for the treatment of 
primary and metastatic liver tumors.
metastatic and tumorigenic cancer spheres in model cell lines is the most prominent effect in vitro. We provide preliminary evidence that sunitinib induced in vitro cancer spheres and the live tumor areas that survive within necrotic patches of the sunitinib-treated xenografts, are related. Finally, membranous expression of E-cadherin enhances the survival of ccRCC cell lines under sunitinib treatment.

#812 Multiplatform modeling of pancreatic cancer using patient-derived cells: A new approach for defining drug resistance mechanisms. Erika Maria Parasido,¹ Prathibhha Sripadhan,² George Avetian,¹ Richard Schlegel,² Jona-than Brody,² Jordan Winter,² Charles J. Yeo,³ Michael J. Pishvaian,¹ Erik Glag-gow,¹ Stephen Byers,² Christopher Albanese,¹ ¹Georgetown University, Washington, DC; ²Thomas Jefferson University, Philadelphia, PA.

Background: Pancreatic adenocarcinoma (PA) is the fourth leading cause of cancer-related death in the USA. Current treatments utilize Gemcitabine alone or in combination with other drugs, such as nab-paclitaxel, however, a growing number of patients have shown resistance to these regimes. In order to enhance clinical response, it is important to better understand the mechanisms of drug resistance. To date, one of the main limitations in PA research has been the reliance on a few commercially available PA cell lines or a limited number of genetically engineered or PDX mouse models for in vitro and in vivo studies. It was therefore imperative to develop more accurate cellular models that better represent a given patient’s tumor. In our current study, we present the use of patient-derived primary PA cells as a model system for basic and translational research, and for personalized medicine. Methods: Patients’ biopsies were collected after surgery, and long-term cultures of PA cells were established using the conditional reprogramming of cells (CRC) approach we developed. KRAS and p53 sequencing verified the PA origin of both the patient samples and the matched CRC lines. The ICCs for Gemcitabine and Abraxane were determined and used to establish drug resistant clones. Our two dimensional (2D) CRC cultures have shown to be adaptable to different platforms, such as 3D spheroid cultures as well as zebrafish- and mouse- PDX models. Results: We established KRAS-mutant primary cell lines derived from patients’ PA samples. From two different parent cell lines we created five nab-paclitaxel and two Gemcitabine resistant clones. The clones were 3-1000 times less sensitive to the drugs as compared with the parent lines. Drug resistance ratios between parent and resistant clones were confirmed both in 3D cultures and our zebrafish PDX platform.

The injection of both parent and resistant clones into NCI/nude mice induced tumor masses in 100% of the cases. Unlike the parent cell-derived tumors, the nab-paclitaxel clone-derived tumors exhibited a metastatic phenotype. Histological analyses of these PDX models recognized the presence of morphological features of human PA, including ductal acinar structures compared to the zebrafish models. Among the most significant differences were the expression of cell differentiation markers in UMSCC-49N1KO, consistent with an aggressive and invasive phenotype in the NOTCH1 deficient line. These phenotypes were validated with subsequently generated UMSCC-49 NOTCH1 knockout lines. Conclusions: NOTCH1 acts as a key tumor suppressor gene in HNSSC and regulates cell proliferation and invasion. We have created a useful genetic model to study effects NOTCH1 in tumorigenesis, proliferation and metastasis with a wildtype NOTCH1 parent (UMSCC-49) and mutant NOTCH1, otherwise syngeneic cell line (UM-SCC49N1KO). NOTCH1 mutant status correlates with worse outcome in HNSSC patients. Further characterization of the role of NOTCH1 in cell proliferation, invasion and metastasis may provide insight into treatment stratification paradigms, targetable options and predictive biomarkers for patients with NOTCH1 mutant HNSSCs.

#815 Using CRISPR/Cas9 to generate isogenic cell lines and reference standards for applications in cancer diagnostics. Xin Cheng, Nga Nguyen, Qi Zeng, Mi Shi, Andrew Hämmer, Huanyu Lin, Ruby Yuan Chong, Tsai; Ling-Jie Kong. Applied StemCell, Inc., Milpitas, CA.

We are entering an era of precision medicine, in which there are significant initiatives to employ companion diagnostics and molecular profiling to inform clinical decisions in therapeutic treatment. In order for these initiatives to work
as effectively as possible, there is a need for molecular reference materials that can help facilitate precision assay development. Cell-line based reference standards are ideal for such applications because they represent a reproducible and renewable source of control materials that can be employed for assay development, quality control, or lead compound discovery. With this in mind, we have used this cell-line approach to develop a cross-species genome that can help facilitate precision assay development. In vitro models of the disease is therefore warranted, not least because growing evidence indicates that it is sufficiently different from female breast cancer such that extrapolating knowledge from one to the other may be misleading. Here we report the establishment and characterisation of a male breast cancer cell line derived from a primary tumor arising in a 61-year old male patient. We used 3T3-j mouse fibroblast co-culture in the presence of a ROCK inhibitor to conditionally reprogram epithelial cells from freshly resected tumor tissue. Once established, the cell line showed a rapid proliferation rate and growth in full conditioned media without the support of mouse fibroblasts. Immunohistochemical profiling demonstrated expression of epithelium-specific antigens AE1/AE3, breast epithelial marker CK7 and confirmed estrogen receptor positivity in concordance with the primary tumor. Genome sequencing detected no pathogenic germline predisposition mutations in either BRCA1 or BRCA2. There was no evidence of somatic mutation in any of the established female breast cancer driver genes. Somatic whole genome sequencing of early and late passages indicated a paucity of structural aberration and little evidence for obvious accumulation of gross genetic alterations. In conclusion, we have established a novel in vitro model for studying male breast cancer that can help facilitate precision assay development.
and response to conventional therapies. Although dogs can be considered good models for translation of new cancer treatments, there is a lack of established preclinical in vitro models of canine cancers. Therefore, our aim here was to establish two canine mammary cancer cell lines and characterize their transcriptional profile to speed the translation of new cancer treatments from dogs to humans. Mammary cancer samples were obtained from female dogs that underwent surgery. Pieces of the tumors were FFPE for histopathology and the other fragments were washed with PBS, minced and dissociated with hyaluronidase and collagenase. Cells were filtered and put in culture with DMEM-F12, 5%FBS and 1% pen-strep. After 5 passages, FBS was increased to 10%. After passage 15, cells were characterized for doubling time, karyotype, immunocytochemistry for cytokeratin, vimentin and α-smooth muscle actin, and collagenase. Cells were filtered and put in culture with DMEM-F12, 5% FBS and were positive for cytokeratin, vimentin and α-smooth actin, suggesting myoepithelial origin. The doubling time was 26.0h for M5 and 42.8h for M25 cells. Karyotyping analysis showed moderate aneuploidy for both cell cultures. M25 cell line presented significant higher invasion potential than M5 cells and formed tumors in mice but the latter didn’t. Histopathology of these tumors resembled the original tumor in the dog. An average of 16.2 million paired-end 100 bp reads were sequenced per replicate (three for each cell culture) with an average of 81.1% alignment to the reference genome. A total of 11,260 and 11,476 genes with more than 1 count per million were detected in M5 and M25 cell lines. M5 cell line have 404 and 394 up- and downregulated genes in comparison to M25 cell line, respectively. Gene ontology of DE genes showed the more malignant cell (M25) significantly enriched for pathways related to drug metabolism, ECM-receptor interaction, cell cycle, DNA replication, focal adhesion and cell differentiation. In conclusion, M25 cell line is more malignant than M5 and originally from a comedocarcinoma and a mixed carcinoma, respectively. Both cell cultures showed spindle-shape cells and were positive for cytokeratin, vimentin and α-smooth actin, suggesting myoepithelial origin. The doubling time was 26.0h for M5 and 42.8h for M25 cells. Karyotyping analysis showed moderate aneuploidy for both cell cultures. M25 cell line presented significant higher invasion potential than M5 cells and formed tumors in mice but the latter didn’t. Histopathology of these tumors resembled the original tumor in the dog. An average of 16.2 million paired-end 100 bp reads were sequenced per replicate (three for each cell culture) with an average of 81.1% alignment to the reference genome. A total of 11,260 and 11,476 genes with more than 1 count per million were detected in M5 and M25 cell lines. M5 cell line have 404 and 394 up- and downregulated genes in comparison to M25 cell line, respectively. Gene ontology of DE genes showed the more malignant cell (M25) significantly enriched for pathways related to drug metabolism, ECM-receptor interaction, cell cycle, DNA replication, focal adhesion and cell differentiation. In conclusion, M25 cell line is more malignant than the M5 which is supported by their transcriptome. Thus, it is possible to use these cells as a comparative translational model for drug development especially if one wishes to work with molecular targets as described above.

**#820 Potential pro-proliferative role of SIRT6 in melanoma.** Liz Garcia-Peterson, Mary A. Ndiaye, Chandra K. Singh, Wei Huang, Nihal Ahmad. University of Madison Wisconsin, Madison, WI.

Melanoma is one of the deadliest form of skin cancer that can rapidly metastasize to become lethal, if not diagnosed early or left untreated. In 2016, approximately 76,380 new melanoma cases and 10,130 melanoma-related deaths are predicted in the United States. Current preventive and therapeutic strategies have not been sufficiently effective in the management of melanoma. Therefore, novel molecular targets and treatments are required for an effective management of this neoplasm. In our laboratory, we are assessing the role and functional and therapeutic significance of sirtuin family of proteins in melanoma. Sirtuins (SIRTs) have been conserved through evolution from prokaryotic to eukaryotic cells. SIRTs are nicotinamide adenine dinucleotide (NAD+) dependent protein deacetylases and belong to class III of the histone deacetylase (HDAC) family. Seven members of the mammalian SIRT family are known to date, and despite structural similarities, each SIRT has their own biological niche, performing unique functions via regulating critical mechanisms in the cell. The role of SIRTs in cancer is somewhat controversial, as they have exhibited conflicting functions (tumor promoter vs. tumor suppressor) depending on cell and tissue contexts. The sirtuin SIRT6, a predominantly nuclear protein, has been shown to conduct ADP-ribosyl transferase and histone deacetylase activities. SIRT6 plays key roles in DNA repair, inflammation and metabolic diseases such as cancer. Currently, the role of SIRT6 in melanoma is not known. The objective of this study was to determine the role of SIRT6 in melanoma. Using a panel of human melanoma cell lines (A375, HS 294T, G361, SK-MEL-2, SK-MEL-28, SK-MEL-31, WM115 and WM35) differing in genetic complexity and disease progression stage, and normal human epithelial melanocytes (NHEMs), we determined the endogenous expression levels of SIRT6. We found that compared to NHEMs, SIRT6 is significantly upregulated in melanoma cell lines, at mRNA as well as protein levels, as shown by quantitative Real-Time PCR and western blot analyses. Further, employing a human tissue microarray (TMA) coupled with quantitative Vectra® analysis, we determined the expression profile of SIRT6 protein in human melanoma and melanocytic nevus tissues. Our data showed that SIRT6 is significantly overexpressed in human melanoma tissues when compared to nevi. Furthermore, lentiviral short hairpin RNA-mediated knockdown of SIRT6 in human melanoma cells was found to result in a marked anti-proliferative response in melanoma cells. Taken together, our data suggest that SIRT6 overexpression could potentially be a contributing factor in melanoma progression. Further detailed studies are under way to understand the functional significance of SIRT6 in melanoma development and progression.

**#821 Loss and retention of mutations in cell culture model systems.** Pamela S. Shaw,1 Rick Nicoletti,2 Nagmahem Salimi,1 Helen L. Yang,1 Abigail E. Witt,1 Agoston T. Agoston,1 Elin S. Agoston,1 Cellaria Biosciences, Cambridge, MA; Brigham and Women’s Hospital, Boston, MA.

Although relevant, the genomic and proteomic alterations between original tumor tissue and newly established cell lines are frequently uncharacterized. In developing a novel cell model (Powder) of high grade serous carcinoma (HGSC), we followed the status of clinically relevant biomarkers to identify changes taking place between the tissue and cultured cell population. Understanding these changes enables proper utilization of new models and continued model optimization. Using a validated panel, we analyzed 592 genes in the Powder cell model and tumor from which it was derived, detecting several classes of genomic alterations. This included point mutations, indels, copy number variations, fusions, and variant transscripts. p53 mutation status of Powder was matched to a panel of previously reported HGSC cell lines. We further subvided the panel by p53 protein expression level by reanalyzing previously published reverse phase protein array (RPPA) data. Significance of differential expression between groups was determined with a Welch's t-test. A majority (14/21 or 66%) of the mutations detected in the HGSC tumor were conserved in the Powder cell model. Two additional mutations, undetected in the tumor, were found in the cell model. The tumor exhibited moderate to strong diffuse p53 staining, p53-unstainable intense staining in 79% of alleles. While the p53 mutation did not carry to the cell model, the cells were positive for CK7 and PAX8, consistent with ovarian cancer cells. In the panel of HGSC cell lines, we examined p53 mutation status and protein level, identifying 3 groups: (1) p53-mut/high protein, (2) p53-mut/low protein and (3) p53 WT/low protein. Powder identified with the p53-WT/low protein group. Previous work identifies the p53-WT/low protein group of cell models as part of a larger set of novel ovarian cell models with a stem-like molecular profile and higher drug resistance. Analysis of differential protein expression revealed upregulation in the p53 low protein group of both normal cell cycle genes and of notable cancer-related proteins. This included p21 and BAD, which are upregulated in cells with functional p53, eIF4E, a candidate cancer therapeutic target, and BOP1, which is deregulated in multiple solid cancers, including ovarian. These results underscore the need for further characterization of the Powder cell model to clarify its applications to specific research questions. Continued examination of Powder and other p53-WT cell models derived from HGSC tumors may uncover independent pathways driving disease. Additionally, understanding which mutations are underrepresented by cell models is necessary for ongoing methods development.

**#822 Simple and easy monitoring of tube formation and migration assays with the CytoSMARTTM Live Cell Imaging System.** Stefanie Buesch,1 Sabine Schaepmeermeier,1 Theresa D’Souza,2 Bodo Ortmann,1 Claudia Schwartz,1 Jenny Schroeder,1 Lonza Cologne GmbH, Cologne, Germany; 2Lonza Walkersville Inc., Walkersville, MD.

Currently, the role of SIRT6 in melanoma is not known. The objective of this study was to determine the role of SIRT6 in melanoma. Using a panel of human melanoma cell lines (A375, HS 294T, G361, SK-MEL-2, SK-MEL-28, SK-MEL-31, WM115 and WM35) differing in genetic complexity and disease progression stage, and normal human epithelial melanocytes (NHEMs), we determined the endogenous expression levels of SIRT6. We found that compared to NHEMs, SIRT6 is significantly upregulated in melanoma cell lines, at mRNA as well as protein levels, as shown by quantitative Real-Time PCR and western blot analyses. Further, employing a human tissue microarray (TMA) coupled with quantitative Vectra® analysis, we determined the expression profile of SIRT6 protein in human melanoma and melanocytic nevus tissues. Our data showed that SIRT6 is significantly overexpressed in human melanoma tissues when compared to nevi. Furthermore, lentiviral short hairpin RNA-mediated knockdown of SIRT6 in human melanoma cells was found to result in a marked anti-proliferative response in melanoma cells. Taken together, our data suggest that SIRT6 overexpression could potentially be a contribution factor in melanoma progression. Further detailed studies are under way to understand the functional significance of SIRT6 in melanoma development and progression.

The formation of new blood vessels is required to ensure sufficient nutrient and oxygen supply and to allow solid tumors to grow beyond a certain size. This process can be mimicked in cell culture models in so-called tube formation assays. In this study, Human Umbilical Vein Endothelial Cells (HUVEC) were seeded on Engelbreth-Holm Swarm Sarcoma derived Basement Membrane Extract (BME). The resulting formation of endothelial tubes was monitored with the CytoSMART™ Device. Subsequently, the average length of the formed tubes as well as the number of closed tube circles was quantitatively determined. In addition, the impact of Suramin on tube formation was evaluated as that Suramin is a tubule formation inhibiting compound. The migration of cancer cells is also required for the growth and in particular the metastasis of tumors. In a first example, the closure of a so-called wound or scratch in a confluent monolayer of cancer cells was monitored with the CytoSMART™ Device. Determining the migration speed of the cells by measuring the speed of

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
wound closure is a simple assay to determine the migration potential of cancer cells. Modifying the cancer cells, e.g. by knocking down specific genes with siRNA, can help to identify genes that play a role in cell migration. Compounds that are expected to reduce cell motility and therefore reduce the metastasis potential of cancer cells can be easily tested. In a second example, the invasion of cancer cells into a three-dimensional (3D) matrix was analyzed. Tumor cells were embedded in a cancer-relevant matrix and their invasion into the 3D matrix was documented with the CytoSMART™ Device. While this type of model is slightly more difficult in set-up and analysis compared to simple scratch assays, it may reflect better the in vivo situation where solid tumors develop within three-dimensional tissues. The images captured with the CytoSMART™ System were quantitatively assessed using appropriate software. Overall, the CytoSMART™ System is an easy-to-use, small and affordable live cell imaging system suitable for the label-free analysis of different cancer-relevant assays.

TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer I

Inhibition of focal adhesion kinase (Fak) leads to sensitization of p53 mutant head and neck cancer to genotoxic stress. Manish Kumar, Liang Yang, David Molkentine, Jeffrey Myers, Raymond Meyn, Curtis Pickering, John Heymach, Heath Skinner. UT MD Anderson Cancer Center, Houston, TX.

Head and neck squamous cell carcinoma (HNSCC) is most commonly treated with DNA-damaging therapies such as cisplatin and/or radiation. However, a significant proportion of HNSCCs are resistant to this therapy. Therefore, we have identified focal adhesion kinase (Fak) as a targetable biomarker of therapeutic resistance in this disease. Additionally, utilizing in vivo shRNA screening of druggable targets in a panel of HNSCC cell lines, Fak was one of the most significant genes related to radiosensitization. Additional investigations utilizing a combination of in vivo and in vitro assays have shown that inhibition of Fak either chemically or via shRNA leads to dramatically increased sensitivity to DNA damage. This effect is primarily found in p53-mutant tumors and cell lines, which are known to be resistant to DNA-damaging therapies. DNA damage due to radiation appears to be potentiated in p53 mutant HNSCC cell lines following Fak inhibition, but less so in matched p53 wild type HNSCC. Moreover, basal Fak activity is higher in HNSCC cell lines engineered to express missense p53 mutations compared to either wild type or p53 null cells. We also found that several forms of mutant p53 bind to Fak and may alter its activity directly. Taken together, our data suggest a targetable nexus of mutant p53 and Fak that can be directly modulated to improve the efficacy of DNA-damaging therapy.

Reduction in prostate tumor growth and induction of anti-tumor immunity after combined treatment with oncolytic VSV and radiation. Thirupandiyur S. Udayakumar, Dillon Betancourt, Glen Barber, Anis Ahmad, Brian Marples, Alan Pollack. University of Miami, Miami, FL.

Androgen deprivation therapy (ADT) is a mainstay of treatment for high-risk non metastatic and metastatic prostate cancer. Patients initially respond to ADT, but eventually develop resistance to treatment. To overcome these limitations, we have used oncolytic virotherapy which has the potential to influence both local and systemic disease through direct cytotoxic and immune mechanisms. Here, we investigated the effectiveness of radiation therapy (RT) combined with Vesicular Stomatitis Virus (VSV) vector expressing interferon-β (IFNβ) in VSV resistant prostate xenografts. In initial cell culture experiments, microarray analysis indicated that PC3 cells treated with VSV-hIFNβ and RT displayed several genes known to directly inhibit VSV replication (e.g., MX2, OA52, TRIM25, IFITM1) were downregulated compared with VSV-hIFNβ therapy alone. Additionally, many apoptotic pathway-associated genes (e.g. IL24, GADD45B, KLF4, TNF, EGFR) were upregulated several fold during combination therapy. Gene expression changes were confirmed by RT-PCR. Further, immunohistology analysis demonstrated expression levels of IFNAR, BCL-XL, phosphorylated Akt, IAK2 and STAT3 were also markedly decreased when VSV-hIFNβ was combined with RT. However, RIG-I was not significantly altered after VSV-hIFNβ+RT treatment. A marked decrease in MAVS, NFκB (p50), IRF7 and antiviral protein PKR was seen after combined treatment. The role of IFN pathway in viral response was investigated using an interferon-inducible promoter ISRE-luciferase (ISRE-Luc) reporter construct. A significant difference (>600 fold) in the ISRE-Luc activation was seen for PC3 compared to LNCAp cells, indicating that the IFN pathway is highly active in PC3 cells after VSV infection alone. The activation of ISRE-mediated transcription of luciferase was significantly attenuated (p<0.05) in both the cell lines after combined treatment with VSV-hIFNβ and RT. In subsequent in vivo studies, we determined that radiation treatment combined with intratumorally-delivered VSV-mIFNβ function synergistically to induce oncolysis in both PC3 and LnCAp xenografts and a syngeneic RM9 murine model. In the syngeneic model, combination therapy resulted in a robust anti-tumor immune response with a significantly increased CD8 T-cell expression compared to either therapy alone. These studies demonstrate that two mechanisms are involved in combined RT and VSV-mediated oncolysis. These are, (1) the attenuation of the antiviral response which increases the direct oncolytic effect of VSV on the tumor cells and (2) improved generation of an adaptive immune response earmarked by CD8+ lymphocyte expansion and anti-tumor activity. On our studies demonstrates that the combined strategy of RT plus VSV-hIFNβ affects tumor cell death that are resistant to VSV through direct and systemic mechanisms that includes a pronounced enhancement of anti-tumor immunity.

Cetuximab enhanced apoptosis effects of radiation on human prostate cancer cell line PC-3. Chia-lun Chang, Szu-Yuan Wu. Wan Fang Hospital, Taipei, Taiwan.

Prostate cancer is a leading cause of cancer death in men in developed countries. Radiotherapy is the main treatment to prostate cancer. Dose escalation of irradiation with image guide radiotherapy and intensity modulated radiotherapy were used with more and more evidences in prostate cancer patients and bring in longer PSA-free survival time. Although the evolution of radiation techniques bring better outcomes, but modern modalities were not available in non-western world. Radiation enhancement is still an imortant issue in prostate cancer in non-western world, especially in androgen independent prostate cancer. The epidermal growth factor receptor (EGFR) network has rich targets for prostate cancer killing. The chimeric monoclonal antibody Cetuximab (IMC-A12, Erbitux®) binds to EGFR and prevents its intracellular signaling. Currently, it is approved for treatment of wild-type KRAS colon and head and neck cancer. The effect and mechanisms of Erbitux and radiotherapy are still not clear. In this study, we evaluated the effects of combining the EGFR inhibition and radiation on PC-3 prostate cancer cells. PC-3 cells were treated with various doses(1,2.5,5 and 10 ug/ml) of anti-EGFR antibody (CETUXIMAB) and irradiation(5, 7, 5 Gy). The results revealed that 5 and 10ug/ml of CETUXIMAB significantly reduced the colony formation. The cell cycle analysis revealed that CETUXIMAB significantly enhanced the radiation induced G2/M phase arrest and subG1 peak increasing. The Hoechst staining and DNA ladder analysis revealed radiation and CETUXIMAB combined use will induce more apoptotic bodies or DNA fragmentation than radiation alone use. By using a apoptosis protein array, we found that several apoptosis related protein (Catalase, clAP-1, Clusterin, Fas, HIF-1α, HSP27, HSP60, HSP70, SMAC and Survivin) were significantly downregulated in radiation and CETUXIMAB combined group. Taken together, our results demonstrated that Erbitux enhanced apoptosis effects of radiation on PC-3.

Nrf2 confers radioresistance by regulating cancer stem trait in lung cancer cells. Xiaoqiao He,1 Alex Chi,2 Liying Wang,2 Yun Rianasakan,1 West Virginia Univ., Morgantown, WV; 2National Institute for Occupational Safety and Health, Morgantown, WV.

Lung cancer is the leading cause of cancer-related death accounting for more than 1.3 million deaths worldwide annually. Despite advances in treatment, the five-year survival rate is 2% if the cancer has metastasized to other organs. The major cause of poor prognosis of advanced lung cancer is multi-resistance to chemo/radio therapy. Therefore, it is crucial to understand the underlying mechanisms of chemo/radio resistance and develop therapeutic strategies to overcome the resistance. Transcription factor Nrf2 is a key regulator of cytoprotective genes which facilitate cellular defense against harmful insults. We found that Nrf2 and its downstream target NQO1 are highly upregulated in lung cancer patient tumor tissues as well as in lung cancer cell lines compared to adjacent normal tissues or normal cell lines. We hypothesized that the upregulated Nrf2 may be responsible for radio/chemo resistance and malignant in lung cancer. RNA interference studies showed that knockdown of Nrf2 substantially increased the sensitivity of human lung cancer H460 and A549 cells to radiation-induced cell death. Knockdown of Nrf2 also decreased tumor sphere formation, suggesting its role in cancer stem cell (CSC) regulation which may be responsible for the radioresistance. Analyses of CSC markers including ALDH and Oct4 in control and Nrf2-knockdown H460 and A549 cells support this finding. Together, our results indicate an essential role of Nrf2 in the control and regulation of CSCs and radioresistance. Since CSCs are widely believed to be responsible for cancer chemoresistance and relapse, our novel finding on the role of Nrf2 in radiation resistance may aid in the design of novel therapeutic strategies for resistant cancers.

#823 Inhibition of focal adhesion kinase (Fak) leads to sensitization of p53 mutant head and neck cancer to genotoxic stress.

#826 Nrf2 confers radioresistance by regulating cancer stem trait in lung cancer cells.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
Ionizing radiation (IR) can induce DNA damage in human cells and result in changes in gene expression. The changed cell behavior can be monitored by using microarray analysis. We performed in vitro gain and loss of studies with candidate miRNA transfections in human CRC cell lines and used a panel of CRC cell lines to determine the effects of miRNA expression on cellular responses to IR. We identified 17 miRs that were differentially expressed, and miR-451a, among the most upregulated miRs, inhibited proliferation and colony formation in 2D and 3D assays in the presence of radiation. Target prediction algorithms highlighted CAB39, EMSY, EREG, and MEX3C as prominent miR-451a targets in colorectal cancer and/or radiation. MiRNA subset analysis found CAB39 and EMSY protein levels were found to be upregulated in 14% and 6% of cases, respectively, and upregulated co-expression of these genes significantly reduced 3-year overall survival (69% vs 78%, p < 0.05). miR-target interaction was confirmed via the RISC-Trap assay with miR-451a mimic transfection resulting in robust 2.4-, 1.2-, and 2.8-fold enrichment of EREG, CAB39, and EMSY, respectively. In our partial responders patient cohort possessing upregulated miR-451a, the breast cancer determinant downstream of miR-451a and miR-106a was compared to non-responders. Conclusions: miRs after cell survival networks affecting radiation sensitivity and serve to identify pathways amenable to alternative therapeutic strategies.

MirRNA-106a and LITAF are novel modulators of prostate cancer radioresistance. Christianne Hoey,1 Jessica Ray,2 Paul Boutros,3 Stanley K. Liu.1 1University of Toronto, Toronto, Ontario, Canada; 2Ontario Institute for Cancer Research, University Health Network, Toronto, Ontario, Canada; 3Sunnybrook Research Institute, Toronto, Ontario, Canada. Prostate cancer (PCa) is the second most prevalent cancer affecting men worldwide, with radiotherapy being a primary treatment modality. PCa recurrence is a major clinical problem with up to a 40% biochemical recurrence rate at five years after external beam radiotherapy (ionizing radiation, IR). Therefore, there is an unmet need to characterize radioresistance in order to improve therapeutic agents and patient outcomes. MicroRNAs (miRNAs) are small non-coding RNAs that regulate gene expression. MiRNAs are aberrantly expressed in cancer, specifically, miR-106a has been found to be overexpressed in various cancer types. The purpose of this study is to determine whether miR-106a confers IR resistance and tumor aggressiveness in PCa. Utilizing The Cancer Genome Atlas (TCA) and Cancer Genome Atlas Network (TCGA) data sets, we investigated the effect of XPO1 inhibition by Selinexor in combination with radiation on GSCs. To determine whether XPO1 could serve as a target for GSC radiosensitization, we focused on the GSC cell line NSC11. Based on clonogenic survival assays, addition of Selinexor 1 h before irradiation significantly enhanced the radiosensitivity of NSC11 cells as compared to controls. To begin to investigate the mechanism behind Selinexor-mediated radiosensitivity, YH2AX foci dispersal, a surrogate marker for DNA double strand breaks (DSB) was evaluated. NSC11 cells treated with Selinexor 1 h before irradiation (2 Gy) and collected 1-24 h later for analysis of YH2AX demonstrated a significant delay in DNA DSB repair 24 h after irradiation. Because XPO1 is responsible for export of various cargo proteins out of the nucleus, including several ribosomal subunits, it is predicted to play a role in global translation. To evaluate the effects of XPO1 inhibition on GSCs, the polysome profiles of NSC11 cells treated with Selinexor were evaluated. The polysome profiles of NSC11 cells demonstrated significant attenuation of the polysome portion of the profile as early as 1 h after treatment with Selinexor. Inhibition of Selinexor treatment results in polyribosome breakdown, leading to a decrease in translational efficiency (TE) by more than half. This attenuation is not accompanied by a change in the monosomal peaks, suggesting that polyribosome breakdown to mRNA is specifically affected by radiation. Taken together, these data suggest that XPO1 plays a role in translation as well as in cellular radiosensitivity, and inhibition of XPO1 by Selinexor enhances GSC radioresistance, possibly by inhibiting global translation.
TUMOR BIOLOGY: Cellular Responses to Ionizing Radiation

Transforming growth factor β (TGFβ) is a well-documented tumor suppressor; a poorly studied aspect of TGFβ biology is its control of genomic stability. Our prior work showed that TGFβ compromises ATM (ataxia telangiectasia mutated) kinase activity, which mediates recognition and repair of DNA damage. Consequently, inhibiting TGFβ following ionizing radiation increases clonogenic survival in breast, brain, and lung cancer preclinical models. As yet unknown is how TGFβ controls ATM kinase. We recently determined that TGFβ regulates mammalian longevity commitment by post-transcriptional control of BRCA1 mRNA and protein by its suppression of miR-182 (Martinez-Ruiz et al., Science Signaling, in press). miR-182-mediated downregulation of BRCA1 impacts DNA repair sensitivity to PARP inhibitors in cancer cell lines (10.1016/j.molcel.2010.12.005) Here we used two cell culture models to investigate the effect of TGFβ regulation of BRCA1 and miR-182 on DNA damage response. Spontaneously immortalized Tgfβ1 heterozygote and wild type fibroblasts from primary mammary epithelial preparations were synchronized in S-phase and exposed to UV radiation before fixation to detect unrepaired DNA damage by quantitative immunofluorescence analysis of 53BP1 foci. Consistent with compromised BRCA1 function, more than twice as many cells with 53BP1 foci were evident in Tgfβ1 heterozygote fibroblasts compared to wild type cells (p<0.01). The second model consisted of non-malignant human breast epithelial cell line, MCF10A, stably transduced with a scrambled or miR-182 antagonist, grown under serum free conditions and treated with a small molecule inhibitor of TGFβ type I receptor and therefore, HRD. Four cell lines is target of miR-182 and thus also regulated by TGFβ and FOXD3 association with ATM is required for its kinase activity (10.1038/ncl1709). As reported, FOXD3 and ATM co-immunoprecipitated, but was eliminated by TGFβ inhibition and this effect was lost in MCF10A cells expressing a miR-182 antagonist. The impaired DNA repair phenotype induced by TGFβ inhibition can be fully rescued by antagonizing miR-182. These studies support TGFβ as stringent regulator of the DNA damage response via suppression miR-182, which directly targets BRCA1 and indirectly affects ATM activity via FOXD3. We predict that cancers that have lost TGFβ signaling capacity will be genomically unstable due to defective DNA damage control, which is consistent with our studies showing that TGFβ inhibition sensitizes cancers to radiation therapy.

#832 In vitro characterization and clinical correlation of BRCAAness as a personalized biomarker for radiosensitization with homologous recombination-directed therapies. Jennifer Ma,1 Andrew C. Bell,1 Jeremy Setton,1 Justin Baseline,1 Marcher Thompson,1 Rachna Shah,1 Benjamin H. Lok,1 Robert Deliste,1 Rebecca A,2 Nadeem Riaz,1 Simon Powell,1 Memorial Sloan Kettering Cancer Center, New York, NY; 2Washington University, School of Medicine, St. Louis, MO.

Introduction: BRCA1 and BRCA2 are involved in double-strand break (DSBs) repair via homologous recombination (HR). Clinically, BRCA1/2 mutant tumors show sensitivity to cisplatin, a cross-linking agent, but only mild sensitivity to irradiation (IR). The addition of cisplatin to IR has been one of the largest advances in improving patient outcomes with radiotherapy in the past 50 years. Recently, BRCAAness has been described wherein sporadic deficits in HR are observed in the absence of germline BRCA1/2 mutations. We hypothesize that BRCAAness tumors also exhibit sensitivity to the combination of cisplatin + IR, and are a significant driver of the observed clinical benefit of combination therapy. Methods: Sensitivity to cisplatin + IR was examined in vitro and correlated with clinical data. Functional HR deficiency (HRD) was assessed in isogenic BRCA1 (H1299; lung) and BRCA2 (DLD1; colon) knockout pairs using 3 assays: the Rad51 foci assay, a flow-based DGFP assay (DSB reporter assay) and clonogenic survival assays (CSAs) with cisplatin + IR. Cancer Cell Line Encyclopedia (CCLE) data was used to identify breast cancer cell lines with sporadic, non-BRCA1/2 mutations. Functional HRD was assessed in 4 breast cancer cell lines was assessed with the same 3 assays used for the BRCA1/2 isogenic pairs. We also examined 14 triple-negative breast cancer (TNBC) patients treated with neoadjuvant cisplatin + IR. Nine of the 14 had available tissue, which was stained for Rad51 foci. Results: Functional HRD is observed in the BRCA1/2 isogenic pairs, as demonstrated by the Rad51 foci and DGFP assay results. Increased sensitivity to cisplatin + IR is observed in the BRCA1/2 knockout lines in CSA results compared to isogenic controls. A genomic scar score, LST (large scale transition), was generated for each line based on CCLE data, with higher LST scores suggesting increased genomic instability and untreated tumors. Already 10 min p.i., the number of DNA DSB increased slightly in peripheral tumor tissue. The number peaked 8 h p.i., when the number of DNA DSB had increased 50 times in the tumor periphery and 24 times in the tumor center. The number of DNA DSB then declined, but the difference between center and periphery remained, as expected

The purpose of this study was to characterize a three-dimensional calcium alginate culture system for real-time monitoring of cancer cell metabolism and radiation response. HCT116 colorectal cancer cells were encapsulated in 2.5% calcium alginate using a custom electrostatic rig adapted from a previously published system. Bead diameter was a function of voltage and alginate concentration: 4 x 10⁶ cells/mL encapsulated at 4 and 8 kV resulted in mean diameters of 880 and 584 μm, respectively. The distribution of bead radii for all voltages showed positive excess kurtosis (4 kV = 1.6, 8 kV = 3.0) and 72.9% of 4 kV and 77.2% of 8 kV bead diameters fell within one standard deviation of the mean. Encapsulated cell viability was assessed by staining with Trypan Blue and clonogenic survival assays (CSAs). The baseline viability of cells immediately after encapsulation was 93.2%, which decreased 2 days after a single 10 Gy dose (90.7%, p<0.05). After two weeks of continuous culturing, 84.1% of non-irradiated and 73.8% of irradiated encapsulated cells remained viable (p<0.003). Pimonidazole staining demonstrated the presence of hypoxic cores proportional to bead size. CSAs of 8 kV beads showed a cell modifying factor (DMF) of 1.06 relative to cells grown in a monolayer, while larger 4 kV beads showed a DMF of 1.58. Mean oxygen consumption rate rose with increasing number of 8 kV beads/well: 1 bead, 35.5; 2 beads, 97.4; 3 beads, 175.5; 4 beads, 209.9; 2.0 x 10⁴ monolayer cells, 92.6 (all pmol/min, ~8.2 x 10⁻⁹ cells/bead, p<0.005). Hyperpolarized [1-13C]-NMR spectroscopy of 400 ul of 8 Gy beads containing 1.2 x 10⁸ cells/mL showed a detectable conversion of [1-13C]-pyruvate to [1-13C]-lactate: 1 hour after a single 10 Gy dose, the lactate-pyruvate ratio decreased by 25%. Unpaired 2-tailed Student’s t-tests were used to determine significance between and one-way ANOVA was used to determine significance among groups with α set at p<0.05. These data demonstrate the versatility of alginate hydrogels for real-time metabolic and radiation response studies which are non-invasive, higher throughput, and lower cost compared to in vivo systems. Future directions include additional metabolic flux analysis and hyperpolarized [1-13C]-NMR spectroscopy to further investigate the cancer cell metabolic response to drug and/or radiation therapy.

#834 Formation of DNA double-strand breaks in colon tumors after targeted alpha therapy with ²¹¹At-mAb. Sophie E. Eriksson,1 Erik Elgström,1 Sture Lindegren,2 Tom Bäck2.1 Lund University, Lund, Sweden; 2University of Gothenburg, Gothenburg, Sweden.

Introduction: Targeted alpha therapy has shown promising results in preclinical and clinical studies. Alpha particle irradiation gives a high fraction of DNA double-strand breaks (DSB), as shown in vitro, resulting in a high probability of cell death. We have previously examined the therapeutic effects of ²¹¹At on solid colon carcinoma tumors (diameter approximately 1 cm), with tolerable activities (5 MBq/animals) resulting in non-palpable tumors within one week p.i. The aim of the present study was to investigate the formation of DNA DSB during tumor regression after radioimmunotherapy with ²¹¹At-mAb in a syngeneic rat colon carcinoma model. Methods: 18 rats bearing solid colon tumors (1 cm in diameter) between peritoneum and the abdominal muscle were injected intravenously with 5 MBq/animal ²¹¹At-BR96. Tumors were excised and paraffin-embedded after 10 min, 2 h, 8 h, 18, 24 h, and 48 h p.i. (3 tumors per time point). 3SBP1 was stained by immunohistochemistry and used as a marker for DNA DSB. Untreated tumors were used as controls (n=9). DNA DSB were counted in central and peripheral tumor areas selected at random. Results: A few DNA DSB were detected in untreated tumors. Already 10 min p.i., the number of DNA DSB had increased slightly in peripheral tumor tissue. The number peaked 8 h p.i., when the number of DNA DSB had increased 50 times in the tumor periphery and 24 times in the tumor center. The number of DNA DSB then declined, but the difference between center and periphery remained, as expected

212 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
considering the intratumoral distribution of radioimmunoconjugate. This correlates with the 211At half-life of 7.2 h. Conclusion: DNA DSB are formed early after injection of 211At-mAb and follows the intratumoral distribution of mAbs.

#835 Sensitivity of PTEN deficient non-small cell lung cancer to ionising radiation through inhibition of ataxia telangiectasia related 3 kinase (ATR). Victoria Louise Dunne, Kelly Redmond, Caroline Coffey, Karl Butterworth, Kevin Prise, Gerard Hanna. Centre for Cancer Research and Cell Biology, Queen's University, Belfast, United Kingdom.

This study sought to determine the therapeutic efficacy of AZD6738, a small molecule inhibitor of ataxia telangiectasia related 3 kinase (ATR), in combination with ionising radiation (IR) for the treatment of PTEN deficient non-small cell lung cancer (NSCLC). An isogenic PTEN deficient cell model were generated in H460 and A549 cell lines by HuSH PTEN shRNA constructs in pGP-V-RS vectors from Origene. Radiosensitivity was determined at various concentrations of AZD6738 by clonogenic assay following IR with 225 kV X-rays. Target validation and mechanistic evaluation of the ATR radiation treatments was performed by western blotting. Cell cycle distribution was obtained using propidium iodine flow cytometry analysis which was performed 48 hours following treatment with AZD6738 alone or in combination with IR. In vivo efficacy was determined using cell line derived xenografts in female SCID mice treated with AZD6738 at a concentration of 25 mg/kg per day by oral gavage for 28 days. Animals were exposed to size fraction and hypofractionated radiation dose under CBCT image guidance using the small animal radiotherapy research platform (SARRP). Radiation induced toxicity in normal lung tissue effects was investigated in a model of radiation induced lung fibrosis in C57Bl/6 mice. A 50% or 80% i.v. doped combined treatment with AZD6738 and IR selectively targets PTEN-deficient tumour cells causing a significant reduction in clonogenic survival for both H460- and A549-PTEN KO cell models (p < 0.05 at 8 Gy). Following 2 Gy IR exposure there were significantly higher mean forci per cell in both H460-KO and A549-KO cells in comparison to WT cells (p < 0.05 at 2, 4 and 8 hours following treatment). Both PTEN-KO cell lines exhibited increased sub G0/G1 and G2/M populations in comparison to PTEN-WT cell lines when treated with AZD6738 and IR. Minimal toxicity was observed in both normal HBE and BEAS-2B cell lines. Currently in vivo tumour response experiments are underway to investigate IR and ATR kinase inhibitor AZD6738 using H460-WT and H460-PTEN KO cell models as well as determining the effects of AZD6738 in a radiation induced model of lung fibrosis. Approximately 10% of NSCLC patients have mutations in PTEN. This research therefore elucidates PTEN loss as a therapeutic target for combined IR with pharmacological inhibition of ATR in NSCLC. Targeting ATR inhibition in PTEN-deficient NSCLC may serve to increase radiation sensitivity in an in vivo model thus highlighting its clinical relevance as a potential personalised medicine approach for patients with PTEN deficient NSCLC.

#836 ATR inhibitor BAY 1895344 shows potent anti-tumor efficacy in monotherapy and strong combination potential with the targeted alpha ther-apy Radium-223 dichloride in preclinical tumor models. Antje Margret Wenger, Gerhard Siemeister, Ulrich Luecking, Julien Lefranc, Philip Lienau, Gesa Deeg, Eleni Lagkadinou, Li Liu, Sven Golifier, Christoph Schatz, Arne Scholz, Priscy, Nusbaum, Michael Brands, Dominik Mumburg, Karl Ziegeler, Bayer Pharma AG, Berlin, Germany.

The integrity of the genome of eukaryotic cells is secured by complex signal- ing pathways, known as DNA damage response (DDR). Recognition of DNA damage activates DDR pathways resulting in cell cycle arrest, induction of DNA repair, or cell death. Proteins that directly recognize aberrant DNA structures recruit and activate kinases of the DDR pathway, such as ATR (ataxia telangiectasia and Rad3-related). ATR responds to a broad spectrum of DNA damage, including double-strand breaks (DSB) and lesions derived from interference with DNA replication as well as increased replication stress. Therefore, inhibition of ATR kinase activity could be the basis for a novel anti-cancer therapy in tumors with increased DNA damage, deficiency in DNA damage repair or replication stress in a model of radiation induced fibrosis in C57Bl/6 mice. An in-vivo combined treatment with AZD6738 and IR selectively targets PTEN-deficient tumour cells causing a significant reduction in clonogenic survival for both H460- and A549-PTEN KO cell models (p < 0.05 at 8 Gy). Following 2 Gy IR exposure there were significantly higher mean forci per cell in both H460-KO and A549-KO cells in comparison to WT cells (p < 0.05 at 2, 4 and 8 hours following treatment). Both PTEN-KO cell lines exhibited increased sub G0/G1 and G2/M populations in comparison to PTEN-WT cell lines when treated with AZD6738 and IR. Minimal toxicity was observed in both normal HBE and BEAS-2B cell lines. Currently in vivo tumour response experiments are underway to investigate IR and ATR kinase inhibitor AZD6738 using H460-WT and H460-PTEN KO cell models as well as determining the effects of AZD6738 in a radiation induced model of lung fibrosis. Approximately 10% of NSCLC patients have mutations in PTEN. This research therefore elucidates PTEN loss as a therapeutic target for combined IR with pharmacological inhibition of ATR in NSCLC. Targeting ATR inhibition in PTEN-deficient NSCLC may serve to increase radiation sensitivity in an in vivo model thus highlighting its clinical relevance as a potential personalised medicine approach for patients with PTEN deficient NSCLC.

#837 PSMB8 as a candidate marker of responsiveness to preoperative radio-dia-thetapy in rectal cancer patients. Yejin Ha,1 Ka hee Tak,2 Chan wook Kim,1 Seon Ae Roh,3 Eun Kyung Cho,1 Dong Hyung Cho,2 Jeong-Hwan Kim,1 Seon-Yung Kim,2 Yong Sung Kim,3 Jin-Cheon Kim.1 Asan Medical Ctr., Seoul, Republic of Korea;2 Kyung Hee University, Yongin, Republic of Korea;3 Korea Research Institute of Bioscience & Biotechnology, Daejeon, Republic of Korea.

To predict individual responsiveness is urgently needed, specifically in locally advanced rectal cancer (LARC) patients who underwent preoperative chemoradiotherapy (CRT). The present study, RNA-Seq was used to compare the basal expression profile between responders and non-responders to preoperative CRT, in correlation with the tumor regression grade (TRG) among 22 LARC patients. Eight differentially expressed genes (B3GALT4, HSPA1B, KRBX1, PPBP, PIP1R18, PSMB8, SLCS9A7, and TAP2) associated with preoperative CRT responses were primarily identified among the 22 LARC patients by RNA-Seq (p < 0.0005 and >16-fold difference). Among these genes, PSMB8 and SLCS9A7 were upregulated in the responsive group in the other 40 LARC patients (p < 0.05). PSMB8 overexpression significantly reduced colony formation and increased apoptosis-inducing molecules like cleaved caspase-3 and cleaved PARP in irradiated CRC cells after 6 Gy irradiation. PSMB8 knockdown increased colony formation and decreased caspase-3 activation and cleaved PARP levels after irradiation. In mice treated with ionizing radiation, tumor growth suppression was significantly greater in HCT116/PSMB8-xenografts (81%) than in HCT116-vector-xenografts (53%) (p = 0.001). However, SLCS9A7 overexpression had no significant effect on irradiated CRC cells. These results suggest that PSMB8 appears to predict radiosensitivity in LARC patients with preoperative CRT, although further clinical validation is needed in a larger cohort.

#838 Effect of tumor treating fields on cell proliferation and synergistic antitumor efficacy in combination with irradiation. Eun Ho Kim,1 Yunhui Jo,2 Jiwon Sung,2 Hyo Sook Song,2 Myonggeun Yoon,2 Korea Institute of Radiological & Medical Sciences, Seoul, Republic of Korea;2 Korea University, Seoul, Republic of Korea.

Alternating electric fields at an intermediate frequency (100–300 kHz), called tumor treating fields (TTFs), are reported to interrupt the process of mitosis via apoptosis and to act as an inhibitor of cell proliferation. Although the presence of an antimotic effect of TTFS has been widely reported, the efficacy of TTFS is still controversial issue among medical experts. To resolve this controversial issue, the comparison study between the effects of TTFS and the effect of other conventional cancer treatments(Xevo) is the first and only attempted targeted alpha therapy so far. It is indicated for the treatment of patients with castration-resistant prostate cancer (CRPC), symptomatic bone metastases and no known visceral metastatic disease, based on improvement of overall survival. It exhibits strong cytotoxic effects on adjacent cells via the induction of DNA DSB. Here, we disclose for the first time the structure and functional characterization of the novel ATR kinase inhibitor BAY 1895344. In vitro, BAY 1895344 is a selective low-nanomolar inhibitor of ATR kinase activity, potently inhibiting proliferation of a broad spectrum of human tumor cell lines (median IC50 of 78 nM). A clear separation between highly sensitive (IC50 < 10 nM) and less sensitive cell lines was observed. The majority of the sensitive cell lines are characterized by mutations affecting the ATM (ataxia telangiectasia mutated) pathway. In cellular mechanistic assays BAY 1895344 inhibited hydroxyurea-induced H2AX phosphorylation demonstrating the anticipated mode of action. BAY 1895344 is an ATR inhibitor that exhibits strong in vivo anti-tumor efficacy in monotherapy in a variety of xenograft models of different indications that are modeled by DDR deficiencies, inducing stable disease in castration-resistant prostate cancer or even complete tumor remission in mantle cell lymphoma models. In addition, we could demonstrate that combination treatment with BAY 1895344 and Radium-223 exhibits clear synergistic anti-tumor activity in a bone metastases xenograft model of CRPC. Our findings validate the concept of synthetic lethality of genetically determined DNA repair deficiency and ATR blockade by demonstrating strong monotherapy efficacy of the highly potent ATR inhibitor BAY 1895344 in a variety of tumor indications. Furthermore, the mechanism-based combination potential of DNA damage induction by Radium-223 with BAY 1895344 creates a powerful new treatment option for CRPC patients with bone metastases. The start of clinical investigation of BAY 1895344 is planned early 2017.
#839  Network-driven analytics of published tissue-based biomarkers to predict response to neoadjuvant therapy in rectal cancer. Lian R. Poynter,1 Kirill Veselkov,1 Dieter Galea,2 James Kinross,1 Alexander Mirnezami,2 Jeremy Nicholson,2 Zoltan Takats,3 Reza Mirnezami,1 Ara Darzi1. Imperial College London, London, United Kingdom; 2University of Southampton, United Kingdom

Introduction Neoadjuvant chemoradiotherapy (nCRT) plays a central role in the management of locally advanced rectal cancer. For many, nCRT leads to clinically meaningful tumour regression. However, up to 20% exhibit little to no response and, in this group, nCRT results in unnecessary delays to definitive treatment. There is a critical need for development of robust molecular methods to predict response to nCRT, to allow for more precise treatment stratification. Although numerous molecular pathways and biomarkers have been implicated in radiosensitivity, the lack of a unifying interpretation of these findings has restricted translational deployment. The aim of the current study was to develop a ‘knowledge network’ with which to visualise and interpret published, quantitative, biomarker data relating to radiosensitivity in rectal cancer, beyond the conventional format of a systematic review. Methods Existing data on predictive biomarkers were retrieved by way of a systematic review of electronic bibliographic databases. Biomarkers were classified according to biological function and built into a hierarchical Gene Ontology tree. Significance was binarized based on p-values or multivariate statistics. An interactive, direct acyclic graph was developed using the Dagre-D3 JavaScript library. Nodes were sized by number of cited publications and color-coded according to their significance scores. The scores reflect the ratio of significant versus non-significant evidence across studied biomarkers. A negative score range indicates more non-significant biomarker findings for that ontological term (node). Weightings were applied to reflect those biomarkers confirmed as significant across two or more studies. p-values of 0.05 or less (adjusted for multiple comparative analysis where appropriate) were considered to be statistically significant. Results 72 individual biomarkers were identified through review. On highest order classification, the domains of response to stress and factors inhibiting apoptosis were found to be most significant (aggregate significance scores across identified biomarkers, 0.75 and 0.714 respectively). A predictive power was not reached for the majority of prognostic biomarkers; rather, the levels of their statistical significance were assessed. Conclusions Building a knowledge-based network analysis of published data identifies promising areas for further research into cellular mechanisms, which may aid in biomarker discovery. Regarding significant node clusters within a network of published data on predictive biomarkers, modifications in cellular metabolic responses to the insult posed by nCRT appear to hold promise in developing a panel of biomarkers with a predictive capacity for response. Network-based analytics takes into account the complex nature of response to therapy, and is a novel way of presenting results obtained from a systematic review.

#840  Polymorphism in DNA repair gene XRCC1 leading to nonconservative amino acid substitution and its role in susceptibility to lung cancer risk. Gh Rasool Bhat, Rakesh Kumar. Shri Mata Vaishno Devi University, Katra, India

Lung cancer is a heterogeneous disease and major global health concern, accounting for more than a million annual deaths worldwide. Historically, 85% of lung cancers are non-small cell lung cancer (NSCLC) and the other 15% are small cell lung cancer (SCLC). In India, it is the most common cause of cancer-related mortality in both men and women. According to the Indian Council of Medical Research cancer registry, 57,795 new cases were reported in 2010, which is projected to increase up to 67,000 new cases annually by the year 2020. Studies revealed that in Srinagar (Jammu and Kashmir) the incidence of lung cancer among males is highest and recent investigation by Global Adult Tobacco Survey (GATS) declared Jammu and Kashmir as the lung cancer capital of India with 26.6% smokers. Lung cancer remains the biggest health concern and challenge for society. Various factors being responsible for lung cancer, but among them smoking is the main cause of lung cancer. However, not all of cigarette smokers develop lung cancer. This differential susceptibility to developing lung cancer can be predicted individually by smoking history, age, genetic factors etc., but the exact mechanisms underlying this modulation are not completely described. To address this problem, we identified a SNP in the XRCC1 gene, codon 399 (Arg/Gln), which was found to be associated with susceptibility to lung cancer risk. However, such studies are completely lacking in the region of Jammu and Kashmir. With this background, we elected to screen these functional variations in Patients and Healthy Individuals in a case-control based study design in population group from Jammu and Kashmir. In the pilot study, we have observed that both the variations are present in the population group of Jammu and Kashmir and hence can be screened for the case-control association. Further, preliminary analysis showed a difference in the frequency distribution of the variations in cases vs. controls. However, a larger sample size is required to reach a conclusion regarding the association. We are working on increasing the sample size of the patient and double the number of controls, from where a real picture of the association can emerge.

#841  UTR analysis identifies Musashi1 as a translational regulator of radiation-induced Golgi-related gene expression. Stacey L. Lehman, John W. O’Neill, Kevin Camphausen, Philip J. Tofilon. National Cancer Institute, Bethesda, MD.

The cellular radioresponse is regulated by post-translational modification of constitutively expressed proteins and by changes in gene expression. Although the role of constitutively expressed proteins, such as those involved in the DNA damage response and cell cycle checkpoints, is well-understood in the context of the radioresponse, radiation-induced changes in gene expression are not as clearly defined. We have previously demonstrated that globlastoma stem-like cells (GSCs) alter their gene expression at the translational level in response to ionizing radiation (IR). In particular, the NSC11 GSC line demonstrated thousands of genes differentially regulated at one hour after a dose of 2 Gy, while considerably fewer were modified at the transcriptome level. Furthermore, there was little overlap between the transcriptome and the proteome. Genes undergoing translational regulation in response to IR fell into distinct functional categories, including mitochondrial structure and function, Golgi function, and translational regulation. Here, we aimed to elucidate the mechanism by which IR induces translational changes in the NSC11 GSC line. NSC11 cells were either exposed to 2 Gy or mock irradiated and polysomes were isolated by sucrose gradient fractionation one hour later. Polysome-bound mRNA was purified and analyzed by microarray. The 5’ and 3’ untranslated regions (UTRs) of the top 75 up- and down-regulated genes were analyzed for the presence of regulatory elements. The most frequently occurring element in the UTRs of both the top up- and down-regulated genes was the Musashi1 binding site. Musashi1 is an RNA binding protein that typically binds to 3’ UTRs to regulate mRNA translation. It is a neural stem cell marker, and its expression is correlated with the grade of malignancy in glioma. GO term analysis of known Musashi1 target genes that were translationally regulated in response to IR revealed an enrichment of genes involved in Golgi function and vesicular trafficking. Knockdown of Musashi1 prevented IR-induced Golgi dispersal in NSC11 cells. Musashi1 knockdown also radiosensitized NSC11 cells, indicating a role for the protein in the cellular radioresponse. Together, these data demonstrate that in the NSC11 GSC line, Musashi1 contributes to radiation-induced translational regulation, specifically in the context of Golgi-related genes, and suggests that Musashi1 is a novel target for radiosensitization.

#842  Breast cancer: Relationship between GPC3 and EMT process. Lilian F. Castillo, Gisela V. Novack, Elisa Bal de Kier Joffé, Maria G. Peters. Instituto de Oncología Angel H. Roffo, CABA, Argentina.

Epithelial-mesenchymal transition (EMT) is a process whereby epithelial cells acquire mesenchymal fibroblast-like properties and display reduced intracellular adhesion and increased motility. Glicp3- (GPC3) is a heparan sulfate proteoglycan associated with cancer. We have established that GPC3 regulates the EMT process underwent by breast cancer cells. However, cellular and molecular events underlying this modulation are not completely described. At the present work we analyzed the effect of GPC3 on cell adhesion and on the expression of molecules associated with this property. We have confirmed that GPC3 regulates the EMT process underwent by breast cancer cells. However, cellular and molecular events underlying this modulation are not completely described. At the present work we analyzed the effect of GPC3 on cell adhesion and on the expression of molecules associated with this property. In addition, molecular regulators of EMT were also studied. We employed a murine breast cancer cell line (LM3; GPC3-) as well as human lines (MDA-MB231; GPC3+ and MCF-7; GPC3+). We have blocked GPC3 expression in MCF-7 cells, while it was over-expressed in MDA-MB231 and LM3 ones. It is known that EMT depends on a reduction in cell adhesion. We determined that GPC3 over-expression induced an increase in the homotypic adhesion of MDA-MB231 and LM3 cells, although GPC3 silencing did not lead significant changes in the organization of MCF-7

TUMOR BIOLOGY: Epithelial to Mesenchymal Transitions in Metastasis

TUMOR BIOLOGY: Cellular Responses to Ionizing Radiation

214 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
spheroids. GPC3 was also able to modulate the adhesion to extracellular matrix components. GPC3 overexpressing cells were more adherent to fibronectin than controls, but no changes were observed in their adhesion to laminin. E-Cadherin, a molecule involved in homotypic adhesion, is considered a suppressor of invasion and growth of many epithelial cancers. Here, we have corroborated by WB that GPC3 overexpression inhibits the E-Cadherin regulation in L3M and MDA-MB231 cells, whereas GPC3 silencing inhibits the expression of this epithelial marker in MCF-7 cells. We also confirmed the called ‘cadherin switch’, since N-Cadherin was downregulated in GPC3 overexpressing cells and upregulated in GPC3 silenced ones. β-Catenin is a key downstream effector in the Wnt pathway. We confirmed that GPC3 expressing breast cancer cells exhibit a canonical Wnt signaling inhibition, β-Catenin also activates Slug. Similar to SMAD2, Slug binds to the E-Cadherin promoter to repress transcription. By WB and qPCR we demonstrated that GPC3 induces a decrease in Slug and Snail levels. Surprisingly, Twist expression was higher in GPC3 expressing cells. It was reported that Slug is able to repress integrin expression. However, β1-Integrin levels were decreased in GPC3 overexpressing MDA-MB231 cells, while they were increased in GPC3 blocked MCF-7 sublines. Our results suggest the key role of GPC3 in the EMT regulation. GPC3 would modulate cell adhesion and expression of E-Cadherin, N-Cadherin and β1-Integrin. In addition, GPC3 would regulate the expression of different EMT molecules (as Slug, Snail and Twist) as well as signaling pathways involved in that process (like canonical Wnt). The set and balance of these regulations would result in the reversal of EMT, reinforcing the function of GPC3 as an inhibitor of mammmary tumor progression.

**#843 CLDN1 mediates tumor invasion in HNSCC by regulation of EMT through AMPK/TGF-β signaling**

Jae Won Chang,1 Seung-Nam Jung,1 Lihua Liu,1 Jin Man Kim,1 Myung Jin Ban,2 Yeon Soo Kim,3 Bok-Soon Lee,4 Yang Butcher,4 Susan Holbeck,4 Apurva K. Srivastava,4 Robert J. Kinders,5 Donald P. Bottaro,5 Shivaani Kumar,5 Alice Chen,5 James H. Doroshow,5 Ralph E. Parchment.1 1Clinical Pharmacodynamics Program, Applied/Developmental Directorate, Leidos Biomedical Research, Frederick National Laboratories, Frederick, MD; 2Biological Testing Branch, Developmental Therapeutics Program Directorate, NCI-Frederick, Frederick, MD; 3Biological Testing Branch, Developmental Therapeutics Program Directorate, NCI-Frederick, Frederick, MD; 4Pathology/Histotechnology Laboratory, Animal Sciences Program, Leidos Biomedical Research, Frederick National Laboratories, Frederick, MD; 5Division of Cancer Treatment and Diagnosis and Center for Cancer Research, NCI, Bethesda, MD; 6Urologic Oncology Branch, Center for Cancer Research, NCI, Bethesda, MD.

Epithelial-mesenchymal transition (EMT) is a critical process implicated in metastasis. Despite extensive research, the clinical significance of EMT remains unclear, and a quantitative evaluation of this process in human tumors has yet to be demonstrated. We previously reported a validated EMT immunofluorescence assay (EMT-IFA), that utilizes β-catenin as a tumor segmentation marker to delineate tumor tissue from surrounding stroma in FFPE tumor biopsies. The assay accurately quantifies individual expression and co-localization of E-cadherin (E) and vimentin (V) in tumor cells (Navas et al. NCI-EORTC 2015). We used this assay to measure changes in both the total number and the corresponding EMT phenotypes of tumor cells in xenograft tissues following treatment with various anticancer agents currently in clinical trials at the NCI. Daily treatment for 14 days with the multikinase inhibitor pazopanib caused significant tumor regression and delayed regrowth in the epithelial (E) / gastric cancer xenograft model MKN45, and the tumor cells remaining after treatment were significantly shifted toward a mesenchymal (V+) phenotype. In contrast, pazopanib (Qdx15) had less anti-tumor efficacy in the mesenchymal gastric cancer xenograft model SN55. In another instance, daily treatment of the MDA-MB-468 breast cancer xenograft model with the BCR-Ab1 kinase inhibitor nilotinib for 19 days did not demonstrate any significant anti-tumor efficacy or change in the predominance of the E+ phenotype, whereas a cycle of treatment with the tubulin agent paclitaxel (Q3Dx4) led to MDA-MB-468 tumor regression and delayed tumor regrowth after completion of the treatment cycle. Furthermore, the EMT-IFA was also able to detect changes in the total MDA-MB-468 tumor cell number compared to single-agent arms, but also effectively transformed the EMT phenotype of the tumor, with only a subset of cancer cells surviving by the last day of treatment, which were mostly CD44+/CD133+ mesenchymal cells and potential cancer stem cells. The changes in EMT phenotype brought on by effective drug treatments occurred via preferential killing of cells with E+ phenotype, suggesting that V+ and E+ tumor cells may be more resistant to therapy. The EMT-IFA provides a much-needed analysis tool suitable for clinical investigation of the proposed role of EMT in tumor progression, metastasis, and acquired drug resistance, and is able to detect changes in EMT signature which may serve as early indicators of treatment efficacy and tumor resistance. Funded by NCI Contract No. HHSN26120080001E.

**#846 A novel high-throughput 3D screening system for EMT inhibitors.**

Kazuya Arai,1 M Mamunur Rahman,2 Manabu Itoh,1 Norio Masuda,1 Takano Eguchi,1 Tetsuya Nakatsura,1 Stuart K. Calderwood.4 1ORGANOGENIX, Inc., Kanagawa, Japan; 2MBL International, Woburn, MA; 3Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; 4National Cancer Center, Chiba, Japan; 5Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.

EMT (epithelial-mesenchymal transition) is a significant event in tumor metastasis and malignancy. Therefore, inhibition of EMT is considered to enable controlling of malignant transformation. In this study, we introduce an innova-
tive three-dimensional (3D) high-throughput (HTS) system that leads to an identification of EMT inhibitors. At first, we established 3D-HTS EMT model with NanoCulture Plate (NCP) that provided a gel-free micro-patterned scaffold for cells forming spheroids naturally. In the NCP-based 3D cell culture system, A549 lung cancer cells migrated, gathered, and then formed multiple spheroids with an epithelial phenotype for screening for EMT inducers. Live cell imaging and fluorescent intensity, expression and proliferation assays were performed for screening for EMT inducers. Using this 3D NCP-based HTS system, we showed that this 3D NCP-based HTS system was useful for screening of EMT inhibitors. SU9516 was a cyclin-dependent kinase 2 (CDK2) inhibitor, which is a tumor suppressor. In this paper, we showed that SU9516 is a promising inhibitor for EMT inhibitors.

#847 Anti-cancer effects of selective Cox-2 and EP2 inhibition through suppression of EMT and the clinical implications of overexpression of Cox-2 and downregulation of E-cadherin in pharyngeal squamous cell carcinoma. Yoshihiro Watanabe,1 Yorihisa Imanishi,2 Hiroyuki Ozawa,3 Kaori Kamayama,4 Koji Sakamoto,5 Ryoichi Fujii,6 Seiji Shigemi,7 Noboru Habu,8 Kuninori Otsuka,1 Yoichi Sato,9 Mariko Sekimizu,10 Fumihiro Ito,11 Yuichi Iki,12 Shin Saito,13 Kaoru Ogawa14.1 Keio University, School of Medicine/Tokyo Saiseikai Central Hospital, Tokyo, Japan; 2Keio University, School of Medicine/Kawasaki Municipal Kawasaki Hospital, Tokyo/Kawasaki, Japan; 3Keio University, School of Medicine, Tokyo, Japan.

Background: Overexpression of cyclooxygenase 2 (Cox-2), an inducible prostaglandin (PG) synthetase, is assumed to promote cancer progression through its multifaceted function, including induction of angiogenesis, stimulation of cell proliferation, restraint on apoptosis, and immunosuppression. Furthermore, recently its inverse relationship with E-cadherin expression was reported. The epithelial-to-mesenchymal transition (EMT) accompanied by the downregulation of E-cadherin is supposed to promote metastasis. However, neither the anti-cancer effect of selective Cox-2 inhibitors nor the EMT-inhibitory small molecule compounds. In a pilot screening, 9 of 1,330 compounds were above the thresholds of the SEMTIN activity and cell viability. Finally, two compounds SB-525334 and SU9516 showed SEMTIN activities in a dose dependent manner. SB-525334 was a known TGF-β receptor I (TGFβRI) inhibitor. SU9516 was a cyclin-dependent kinase 2 (CDK2) inhibitor, which we showed also had an EMT-inhibitory activity. Taken together, it was shown that this 3D NCP-based HTS system was useful for screening of EMT-regulatory drugs.

#848 Netropsin blocks EMT of murine BRAF mutated melanoma cells. Juliano Freitas, Fenfei Leng, Lidia Kos. Florida International University, Miami, FL.

Melanoma is the most aggressive and deadliest type of skin cancer due to its high propensity to metastasize. Despite current progress in the identification of potential drug targets for melanoma, drug resistance remains a major issue indicating that novel therapeutic strategies may be required. It is well documented that the process of converting the epithelial tumorigenic cell to a mesenchymal phenotype, the epithelial-mesenchymal transition (EMT), is responsible for conferring an invasive phenotype to cancer cells. An EMT-like process has been shown to occur during melanoma progression. High-mobility group A-1 (HMGA2) is a multi-functional transcription factor for oncogenesis and EMT in a variety of cancers. HMGA2 is a small DNA-binding protein with three “AT-hook” DNA-binding motifs that specifically recognize the minor groove of AT-rich DNA sequences. HMGA2 is significantly upregulated in human primary melanoma and metastases, including those with BRAF mutations. We accessed the potential application of netropsin, a potent inhibitor of HMGA2-DNA interactions, as an EMT blocking agent of BRAF mutated melanoma cells. Three murine melanoma cell lines that carry mutations in the BRAF gene and show resistance to vemurafenib (D4M, YUMM1.1, and YUMM1.7) were used. Cells were treated with EMT Inducing Media Supplement along with Netropsin and the expression of E-cadherin as well as their migratory behavior were evaluated. Netropsin treatment of EMT induced cells showed a 10-25% increase in cell morphology levels. With E-cadherin expression and decreased migratory behavior. All three cell lines express HMGA2 which continues to be expressed in the tumors resulting from subcutaneous injections in mice. YUMM1.1 cells showed the highest levels of expression of HMGA2 amongst the three cell lines. Interestingly, in our preliminary study only YUMM1.1-derived tumors generated overt metastasis in the lung 30 days after the injections. Altogether our data showed that Netropsin is capable of blocking EMT of murine BRAF mutated melanoma cells. The results of this study will contribute to the development of strategies to prevent EMT that may result in the implementation of more effective therapies to treat melanoma.

#849 Molecular characterization of primary tumor & the paired liver metastatic biopsies of colorectal cancer reveals a critical role of immunosuppression, EMT & angiogenesis in cancer metastasis. Jiangang Liu,1 Yong Beom Cho,2 Hye kyung Hong,3 Song Wu,4 Philip J. Ebert,5 Steven M. Bray,6 Swee Seong Wong,1 Jason C. Ting,1 John N. Calley,1 Catherine F. Whittington,7 Shripad Bhagwat1, Emma Bowden,1 Arun Aggarwal,1 Christoph Reinhard,1 Robert Wild,1 Do-Hyun Nam,2 woo Yong Lee,3 Sheng-Bin Peng,2 Eli Lilly and Company, Indianapolis, IN; 3Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; 2Samsung Biomedical Research Institute, Seoul, Republic of Korea.

Colorectal cancer (CRC) is one of the leading causes of cancer-related mortality worldwide. In United States alone, it was estimated that nearly 137,000 people were diagnosed, and more than 50,000 were dead from the disease each year. CRC primary tumors often metastasize to liver which accounts for most of CRC death. The molecular mechanism of tumor metastasis is complex and remains poorly understood. In this study, we have collected 79 human CRC primary and their matched liver metastatic tumors. To further characterize the molecular mechanism of metastatic progression, we have assembled gene correlation networks based on RNA sequencing data of these CRC samples. Computational analysis of these correlation networks has identified gene signatures of immune-suppression, epithelial-mesenchymal transition (EMT) and angiogenesis as the key events and potentially synergistic drivers associated with CRC metastasis. Further independent cohort validation using published datasets verified that these specific gene networks of tumor microenvironment were progressively up-regulated throughout the carcinogenesis, and represented distinct biological processes. These gene networks were capable of discriminating the previously categorized CRC molecular subclasses. In addition, we also showed an association of type 1 interferon network with good clinical outcome of CRC, and gene network of EMT-suppression, immunosuppression and cell exhaustion are closely associated with the poor patient outcome. We further demonstrated that the networks of EMT and angiogenesis were related to innate anti-PD-1 resistance, and the networks of immunosuppression and T cell exhaustion were associated with resistance to radiation and checkpoint blockade. Overall, we
conclude that a genome-wide interrogation of co-regulated networks utilized in this study represents a valuable strategy to identify molecular mechanisms of cancer metastasis, and gene networks of immune-suppression, EMT and angiogenesis are among the key events associated with CRC metastasis.

The Pi3K/Akt pathway mediates epithelial-mesenchymal transition (EMT) and malignant progression in BRCA-defective epithelial ovarian cancer.

**#850**

**Conclusion:** The Pi3K/Akt pathway mediates epithelial-mesenchymal transition (EMT) and malignant progression in BRCA-defective epithelial ovarian cancer. Methods: BRCA2-mutated POEO and BRCA2-wild type PEOP epithelial ovarian cancer cell lines were derived from the same patient at first and second relapse, respectively, following platinum-based chemotherapy. Non-targeted siRNA control (NTC) and BRCA1 knockdown (BRCA1-kd) SKOV3 cell lines were previously established in our laboratory. Western blot analysis and luciferase reporter assay were performed to determine EMT markers (snail, slug, fibronectin) in BRCA defective ovarian cancer cells. Scratch wound assays were conducted to determine the ability of cells to migrate. Clonogenic and apoptosis assays were carried out to determine cell survival in response to various concentrations of carboplatin and olaparib with or without MK-2206, a small molecule inhibitor of AKT. Results: PE01 cells exhibited an increase in mesenchymal markers Snail and fibronectin, whereas PE04 cells exhibited an increase in the epithelial marker E-cadherin. POE1 cells also exhibited an increase in cell migration compared with PE04 cells. In the luciferase reporter assay, BRCA2-mutated PE01 and BRCA1-kd SKOV3 cells exhibited lower levels of the epithelial marker E-cadherin compared to their BRCA2-wild type counterparts, POEO and SKOV3 NTC, respectively. Treatment with MK-2206 caused increased susceptibility of BRCA1-kd SKOV3 cells to olaparib compared with BRCA1-kd wild type SKOV3-NTC cells. Conclusions: BRCA2-mutated PE01 cells manifested an increase in mesenchymal markers and invasive phenotypes. BRCA1-kd SKOV3 cells manifested a decrease in the epithelial trait, E-cadherin activity. In addition, AKT inhibition heightened susceptibility of BRCA1-kd SKOV3 cells to DNA damaging agents such as olaparib. These findings suggest that BRCA2-defective cells rely on the induction of EMT via activation of AKT to survive DNA damage and develop therapeutic resistance during malignant progression.

Reversion of epithelial to mesenchymal transition under androgen deprived conditions promotes chemoresistance in prostate cancer.

**#851**

**Conclusion:** Reversion of epithelial to mesenchymal transition (EMT) under androgen deprived conditions promotes chemoresistance in prostate cancer. Akanksha Upadhyay,1 Anthera Medical, Miami, FL; Sarah Louis Ryan,2 Boston, MA; G. Hollier,1 Elizabeth D. Williams1. 1Australian Prostate Cancer Research Centre – Queensland, Institute of Health and Biomedical Innovation, School of Biomedical Sciences, Queensland University of Technology and Translational Research Institute, Australia, Brisbane, Australia; 2Australian Prostate Cancer Research Centre – Queensland, IHBI, School of Biomedical Sciences, Queensland University of Technology and Translational Research Institute, Australia, Translational Cell Imaging – Queensland, Brisbane, Australia.

Introduction: Metastatic prostate cancer (PC) is one of the leading causes of cancer related male deaths in Australia. Radical prostatectomy followed by androgen deprivation therapy (ADT) upon recurrence of disease is the conventional form of treatment. Upon relapse, administration of androgen targeted therapy (ATT) and subsequent chemotherapy improves quality of life and increases overall survival of patients. However, it is not curative and the disease ultimately progresses. Epithelial to mesenchymal transition (EMT) is a process that can facilitate tumour growth and progression to metastasis and has also been associated with chemoresistance. We therefore aim to determine how EMT and resultant reversal of this state (MET) influences the chemoresistance profile of PC cells and further determine if and how specific genetic regulators are involved in this process. Methods: Doxycycline hydolate (Dox) inducible Snail and Zeb1, lncAP EMT models were used to determine the effect of the EMT status in response to a clinically relevant panel of drugs using cellular and molecular assays. All assays were performed in both lethal bovine serum (FBS) and charcoal stripped serum (CSS) supplemented culture media. CSS media was used to mimic an ADT-like environment. Using 2D monolayer and 3D spheroid [Happy Cell©] formats. Cells were induced for 5 days of EMT in the presence of Dox and were allowed to revert for 14 days of MET (absence of Dox) before the drug assays were carried out over a period of 72 hours. Live/dead cell staining and morphological and gene expression viabilities in both spheroid and monolayer cultures were used for 2D assays and 3D assays were analysed using either a GE IN Cell Analyzer live cell imaging system or confocal microscopy. Results: Induction of Snai1 and Zeb1 induced an elongated cell shape and increased mRNA and protein expression of mesenchymal markers such as vimentin during EMT. This was associated with a decrease in expression of epithelial markers E-cadherin and N-cadherin. An apoptotic response was observed in 14 days of dox removal along with an increase in epithelial markers was observed. These changes were also associated with a gradual reversal in the phenotype of these cells. However, this reversal in phenotype and expression of EMT markers was not as striking in cells grown in CSS compared to cells in FBS media (both 2D and 3D). Mitoxantrone concentration-response assays in a 2D format showed that cells that undergo a subsequent MET are more chemoresistant than uninduced or EMT cells when grown in CSS media. This was however, not observed in cells undergoing similar transitions in the FBS media. Conclusions: The chemoresistance profile of prostate cancer cells is altered by their EMT status. This effect is enhanced in the context of ADT. Cells that revert back to a more epithelial phenotype after undergoing an EMT exhibit higher resistance towards chemotherapy drugs.

Bromodomain and extraterminal proteins regulate the epithelial-mesenchymal transition in breast cancer.

**#852**

**Conclusion:** Bromodomain and extraterminal proteins regulate the epithelial-mesenchymal transition in breast cancer. Guillaume Andrieu, Gerald V. Dienes. Boston Univ. School of Medicine, Boston, MA.

The epithelial-mesenchymal transition (EMT) is a developmental program that cancer cells often activate to acquire a highly plastic phenotype that promotes invasion, metastasis, but also chemoresistance and cancer stem cell generation. As readers of epigenetic marks, bromodomain and extra-terminal (BET) proteins BRD2, BRD3 and BRD4 participate in the regulation of multiple transcriptional programs implicated in cancer progression. We sought to unravel the roles of BET proteins in EMT in breast cancer. Despite their homology, we report that BET proteins differentially regulate EMT. Based on an EMT PCR array, we identify a BRD2-specific transcriptional profile that promotes EMT, whereas BRD3 and BRD4 signatures repress this program. These individual signatures are unidentifiable upon pan-BET inhibition using JQ1, reinforcing the necessity to target each BET member separately to better understand their functions. Upon BRD2 depletion, basal-like breast cancer cells, which present a mesenchymal phenotype, exhibit a reduced expression of mesenchymal markers (N-cadherin, vimentin) and re-express epithelial markers (E-cadherin, cytokeratins). Moreover, a large panel of EMT master transcription factors is down-regulated in BRD2-depleted cells, including the Snai and ZEB families or Twist. Interestingly, we found that BRD3 or BRD4 depletion leads to the opposite phenotype: an increase of mesenchymal marker expression and repression of the epithelial markers. In luminal A breast cancer cells which present an epithelial phenotype, BRD2 overexpression leads to the expression of mesenchymal markers (N-cadherin, vimentin) and re-express epithelial markers (E-cadherin, cytokeratins). Moreover, a large panel of EMT master transcription factors is down-regulated in BRD2-depleted cells, including the Snai and ZEB families or Twist. Confirming the differential roles of BET proteins in EMT regulation. Taken together, our results establish that BRD2 positively regulates EMT, whereas BRD3 and BRD4 repress this program. BET proteins possess separate and opposite biological functions, reinforcing the relevance of an individual targeting instead of a pan-BET inhibition using JQ1. We hypothesize that BET proteins modulate EMT through the regulation of its master transcription factors. We propose that the balance of BET proteins presence at the promoters of the EMT genes is a novel mechanism of regulation of this program in breast cancer cells.

Cisplatin, a gene with unknown function, is a novel driver of epithelial-mesenchymal transition in human cancer.

**#853**

**Conclusion:** Cisplatin, a gene with unknown function, is a novel driver of epithelial-mesenchymal transition in human cancer. Sarah R. Amend, James Hernandez, Princy Parsana, Kenneth J. Pienta. Johns Hopkins Univ., Baltimore, MD.

Metastatic prostate cancer is an incurable lethal disease and is the cause of death for 28,000 men in the US annually. In order for a cancer cell to metastasize from the primary tumor, it must move. In a critical early event of metastasis, a rare population of cells in the primary tumor undergoes a phenotype switch from a proliferating epithelial cell to gaining the migratory capacity of a mesenchymal cell, a process termed epithelial-to-mesenchymal transition (EMT). To identify previously overlooked regulators of EMT, we undertook a multi-study gene expression array analysis (15 published gene expression studies; 95 total samples; 6 cancer types) and identified Clorf116 as a candidate driver of the epithelial phenotype in EMT across multiple cancer types. Of note, Clorf116 is
an unnamed gene of unknown function that is largely uncharacterized in any setting, including in cancer biology or in EMT. To substantiate its potential role in EMT, we queried the NCi-60 cell line collection gene expression dataset and found that C1orf116 shared a similar expression pattern with epithelial marker genes (ESRP1, ESRP2, OVOL1, OVOL2) and a converse expression pattern to mesenchymal markers (CDH2, ZEB1, VIM). This suggests a role as a driver of the epithelial phenotype. Interestingly, the sole publication specifically studying C1orf116 describes it as Specifically Androgen Regulated Gene (SARG). The authors demonstrate the presence of an androgen response element upstream of the C1orf116 start site in the androgen-responsive prostate cancer cell line LNCap. Our data indicate a role for C1orf116 in the androgen receptor-negative prostate cancer cell line PC3, suggesting a non-androgen-mediated role for C1orf116 in prostate cancer. In addition to elucidating its role in EMT, work is underway to characterize the RNA and protein products of C1orf116. Alternative splicing transcripts of varying length that likely give rise to at least two protein product sizes. RNA sequencing and mass spectrometry will reveal transcript and protein identity and provide insight into potential isoform switching regulating EMT and other processes.

**#854** Human tissue Kallikrein 6 enzyme activity regulates epithelial-mesenchymal transition and metastasis in colon cancer. Huan Liu, Iurin Chen, Earlaphia Sells, Haidan Cui, Ritu Pandey, George Pampalakis, Georgia Sotiropoulou, Thomas Doetschman, Natalia A. Ignatenko. 1Univ. of Arizona Cancer Ctr., Tucson, AZ; 2Univ. of Arizona, Tucson, AZ; 3Univ. of Patras, Patras, Greece.

Background: Kallikrein-related peptidase 6 (KLK6) belongs to the family of human tissue kallikrein genes, majority of which are shown to be differentially expressed in cancers. Clinical studies have demonstrated that upregulation of KLK6 in primary colorectal tumors and lymph nodes correlates with serosal invasion, liver metastasis and indicative of poor prognosis in patients. It has been reported that KLK6 protein is involved in regulation of the epithelial-mesenchymal transition (EMT) program in an organ-specific context. The aim in this study was to investigate contribution of KLK6 enzyme in the EMT during neoplastic transformation in the colon. Results: We expressed enzymatically active or inactive KLK6, using pcDNA3.1(+) preproKLK6 and pcDNA3.1(+) preproKLK6 Ser197Ala mutant plasmids, in Caco-2 colon cancer cell line, which has been characterized before as a very low KLK6 expresser with an undetectable secreted KLK6. Stable isogenic clones were selected and further evaluated for their ability to migrate and invade using in vitro assays and to metastasize in vivo using SCID orthotopic mouse model. We found no effect of KLK6 enzyme activity on migration of Caco-2 cells, expressing the empty vector (Caco-2 mock), and Caco-2 cells, expressing an enzymatically active KLK6 (Caco-2 KLK6 wt) or inactive KLK6 (Caco-2 KLK6 mut). But Caco-2 KLK6 wt cells demonstrated the invasive phenotype in Matrigel invasion assays (p<0.001, compared to Caco-2 mock and Caco-2 KLK6 mut cells). The Caco-2 mock and Caco-2 KLK6 mut cells, injected in SCID mice orthotopically, developed primary colon tumors but no metastatic lesions were identified. In contrast, Caco-2 KLK6 wt cells formed primary colon tumors and metastasized locally, although they failed to form the distant metastasis (lung and mesentery). Animals, growing the Caco-2 KLK6 wt tumors, displayed a significant decrease in their survival rates, compared to other groups (p=0.02). In Caco-2 KLK6 wt cells, TGF-β signaling pathway was induced and activation of SMAD2/3 signaling pathway was associated with the elevated expression of known regulator of the EMT, zinc-finger protein Snail. In addition, the expression of a high-mobility group AT-hook 2 (HMGA2) protein was induced in Caco-2 KLK6 wt cells. The HMGA2 expression is implicated in the EMT program, acting through the TGF-β signaling pathway and is associated with cancer progression and metastasis. Western blot analysis demonstrated that Caco-2 KLK6 wt cells expressed constitutively active TGF-β. These findings demonstrate that KLK6 enzyme activity is required for colon cancer progression via induction of the EMT program. We identified the TGF-β signaling pathway as a mechanism driving the EMT in colon cancer cells expressing KLK6 enzyme.

**#855** Ube2v1 promotes epithelial mesenchymal transition and metastasis in colorectal cancer by epigenetically transcriptional suppression of autophagy. Tong Shen, Dong Ling Cai, Hong Yu Lan, Juan Wen Gan, Ming Li, Ru Jing Wang, Da Peng Guo, Qun Zhou, Xing Xing Lu, Shi Li, Na Li Sun, Ming Jian Li, Soochow University Medical School, Suzhou, China; “Baoan Hospital of Shenzhen,” Shenzhen, China.

Ubiquitination is one of the basic post-translational modifications for cellular homeostasis. The conjugating enzyme (E2) family plays as a bridge linking the first step mediated by E1 with the final step mediated by E3 in the ubiquitin-proteasome system. However, the role of Ube2v1, one of Ubiquitin-conjugating E2 enzyme variant proteins (Ube2v1), in colorectal cancer (CRC) and autophagy is currently unknown. Here, we found that Ube2v1 is elevated in tumor samples of CRC patients and correlated with poorer survival of CRC patients. Furthermore, Ube2v1 promotes migration and invasion of CRC cells in vitro and boosts tumor growth and metastasis of CRC cells in vivo. Interestingly, Ube2v1 suppresses autophagy program and promotes EMT and metastasis of CRC cells in an autophagy dependent pattern in vitro and in vivo. Moreover, Rapamycin attenuates the enhanced in vitro migration and invasion in vivo and metastasis of Ube2v1 overexpression by inducing the autophagy pathway. Mechanistically, Ube2v1 increases histone H4 lysine 16 acetylation by down-regulating expression of Sirt1 and epigenetically suppresses gene expression of autophagy genes in colorectal cancer. In conclusion, Ube2v1 functions as a global regulator for autophagy by epigenetically transcriptional suppression of autophagy, and consequently sensitizes to chemotherapy treatment than the parental HCT-116/ICN1 cell line. Ube2v1, one member of E2 family in the ubiquitin-proteasome system, regulates the EMT and autophagy program in CRC progression and metastasis.

**#856** Notch-1 promotes a mesenchymal phenotype in colon cancer cells via Notch-3 and Smad-3 activation. George Sigounas, Fred E. Bertrand, Douglas A. Weidner, Kaitlyn E. Vinson, Alexander G. Clark, Azeem Khan. 1East Carolina Univ, School of Medicine, Greenville, NC; 2University of Alabama at Birmingham, Birmingham, AL.

A role for cancer initiating cells (CIC) in tumor growth, drug resistance, relapse, and metastasis via epithelial to mesenchymal transition (EMT) has been supported by experimental evidence. It is well-documented that Notch-1 receptor signaling participates in stem cell maintenance and lineage commitment in various organs, including the colon, and can regulate EMT. The function of Notch signaling in colorectal cancer (CRC) is not clear. We have reported that Notch-1 activation in the human colon tumor cell line HCT-116 resulted in upregulation of Jagged-1, Smad-3, CD44, and Slug proteins. These changes were accompanied by acquisition of a mesenchymal cell phenotype that included increased anchorage independent growth and migratory activity. Experiments with a γ-secretase inhibitor (DAPT) and soluble Jagged1-Fc protein demonstrated that Notch-1 signaling activates CD44 and Slug via other Notch receptors. In subsequent experiments, we observed an increase in Notch-3 expression in the presence of activated Notch-1. Herein, we tested the hypothesis that the stem cell-like mesenchymal phenotype induced by Notch-1 signaling in colon cancer cells is mediated by the Notch-3 receptor and Smad-3. The human colon tumor cell line HCT-116 was transduced with constitutively active Notch-1, and a Notch-3 shRNA to produce a Notch-3 null cell line with activated Notch-1 (ICN1-shN3 cells). ICN1-shN3 cells exhibited a 2.5-fold lower plating efficiency than the HCT-116/ICN1 cell line (p<0.01) that expresses constitutively active Notch-1 in the presence of Notch-3. In addition, Notch-3 null cells with constitutively active Notch-1 (ICN1-shN3 cells) were slower by 29% in completing wound healing as compared with the HCT-116/ICN1 cell line (p<0.05). Consistent with the lower plating efficiency, a 37% decrease in colosphere formation was observed with ICN1-shN3 cells as compared with the HCT-116/ICN1 cell line (p<0.001). These data indicated that loss of Notch-3 abrogated the Notch-1 induced mesenchymal cell phenotype. Western blot analysis demonstrated that the HCT-116/ICN1 cells with intact Notch-3 exhibited increased levels of the EMT markers E-cadherin and vimentin, and a converse expression pattern to the parental HCT-116 cell line. Expression of CD44 and Slug in Notch-3 receptor null ICN1-shN3 cells was highly reduced compared with HCT-116/ICN1 cells and was similar to that detected in the parental HCT-116 cells. Treatment of HCT-116/ICN1 cells with a Smad-3 inhibitor resulted in significant reduction of the CD44 and Slug proteins. Meanwhile, Notch-3 receptor null ICN1-shN3 cells were also more sensitive to chemotherapy treatment than the parental HCT-116/ICN1 cell line (p<0.05). Collectively, our data provide evidence for a novel pathway in which Notch-1 signaling in colon tumor cells promotes a mesenchymal phenotype via activation of Jagged-1, Notch-3 and Smad-3, followed by expression of CD44 and Slug.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
ELF3 modulates mesenchymal to epithelial transition through regulation of CD44 variant isoform expression in pancreatic cancer cells. Ayano Kabashima-Niibe,1 Hiromasa Takaishi,2 Takonari Kanai,2 Hideyuki Saya,2 Gregory J. Gores,3 Hajime Higuchi4,5 Mayo Clinic, Rochester, MN; 6Keio University School of Medicine, Tokyo, Japan; 7International University of Health and Welfare, Tokyo, Japan.

BACKGROUND: Epithelial to Mesenchymal Transition (EMT) and Mesenchymal to Epithelial Transition (MET) may participate in pancreatic ductal adenocarcinoma (PDAC) metastasis. CD44 proteins are cell membrane proteins which function as co-receptors regulating many cellular functions. Some reports have shown that isoform switching from CD44 variant form (CD44v) to CD44 standard form (CD44s) can take place during the EMT (Brown et al., Clin. Cancer Res, 2011, Yae et al., Nat. Commun., 2012). The AIM of this study was to explore the regulation of CD44 isoform switching in PDAC cells. METHODS: The expression levels of CD44v and CD44s in PDAC cell lines were assessed by immunohistochemistry and immunoblot analysis. PDAC cell lines were implanted into immunodeficient mice and treated with sulfasalazine for 14 days. Sulfasalazine, which inhibits glutamate-cysteine transport, reduces CD44v-dependent cell growth. CD44v or CD44s positive cells were isolated using flow cytometry and induced to undergo the EMT by TGF-β treatment (7.5ng/mL) for 72 hours. A doxycycline inducible system was employed to overexpress Slug, which promotes the EMT phenotype. To induce MET, the cells were released from TGF-β treatment and cultured for an additional 72 hours. EMT-like ETS Transcription Factor (ETFS) was knoowed to be transduced by siRNA transfection. RESULTS: Immunohistochemistry analysis revealed that CD44v protein is expressed specifically by PDAC with ductal structures within the complex tumor environment of these cancers. However, in contrast, CD44v expression was not observed in solitary infiltrating cancer cells. PAN-C-1, AsPC-1 and SUT-2 PDAC cell lines expressed both CD44v and CD44s isoforms. Tumor mass in implanted PAN-C-1, AsPC-1 and SUT-2 cells were reduced 69%, 50% and 36%, respectively by sulfasalazine treatment following 2 weeks of therapy. However, CD44v null HPAC cells were resistant to sulfasalazine therapy following implantation. E-cadherin was expressed in CD44v positive cells but not in CD44s positive cells, and both CD44v and E-cadherin protein were reduced by TGF-β treatment. Slug over expressed cells were resistant to sulfasalazine treatment compared to non-Slug-induced cells. Removal of TGF-β restored both CD44v and E-cadherin expression levels which consistently occurs with MET. However, restoration of CD44v expression was diminished when ELF3 expression was reduced by siRNA transfection. CONCLUSION: The isoform switching between CD44v and CD44s was reversible. The expression of CD44v isoform appears to be controlled by ELF3 during MET.

The circadian clock of glioma cells undergoing epithelial-mesenchymal transition. Arpan De, Dilshan Harshajith Beligala, Vishal Premdev Sharma, Benjamin R. Fry, Michael Eric Geusz. Bowling Green State University, Bowling Green, OH.

Highly invasive gliomas contain many cells that have changed to an enhanced migratory state through an epithelial-mesenchymal transition (EMT). These cells have the phenotype of glioma stem cells (GSCs). Similar to GSCs, glioma cells undergoing EMT show phenotypic heterogeneity, altered gene expression, and resistance to anticancer drugs along with increased invasiveness. Circadian rhythms in tumor cells influence the progression and severity of cancer and appear to regulate cell division cycles. Increased cancer incidence and progression have often been linked to disruption or deregulation of the molecular mechanisms of the circadian clock. One of the major clock proteins, PER2, has been shown to play a regulatory role as a tumor and EMT suppressor in metastatic breast cancer cell lines. GSCs in tumorsphere cultures contain circadian clocks that may regulate their cancer properties. The possibility of a regulatory role for circadian rhythms in EMT was examined here. We used a standard method to induce EMT in the C6 rat glioma cell line that has known circadian rhythms in gene expression generated by the circadian clocks within its cells. EMT was induced by withdrawing the cell culture medium with a serum-free stem cell medium (SCM) containing growth factors (EGF, FGF2, PDGF-alpha-beta). Cell cultures were imaged continuously with a microscope and digital camera in a cell incubator to monitor cell shape, cell death, migration, and apoptosis. During EMT, cells changed from an extended flat state to rounded and spindle shapes, ceased proliferating, and expressed EMT markers ZEB1 and vimentin. At the end of two days in SCM, 33.4% of the cells were ZEB1-positive and only 1.26% were GFAP-positive (n = 3 cultures). Cell diameters after EMT were within the size range of C6 GSCs described as Hoechst-negative cells positive for stem cell markers nestin and CD133. Following EMT, small tumorspheres began to form. After initiating EMT, the rounded cells were counted at hourly intervals for up to four days after the medium exchange. As the number of post-EMT cells increased, the population size oscillated, and when examined by Lomb-Scargle periodogram analysis, four cultures had a significant period within the circadian range, 19-29 hours, (average 22.20 ± 2.45 SD, p <0.05). One had a 16-hour period and one lacked a consistent time period. There were no significant rhythmic patterns in the cultures that were not synchronized with an initial forskolin treatment. We conclude that EMT may be timed by endogenous circadian oscillators in gliomas that favor larger numbers of post-EMT cells at a particular time of day. These results suggest that pharmacological treatments that suppress EMT or target GSCs would be more effective when delivered at particular times during the circadian cycle of the tumor.

Epigenetic regulation of epithelial-mesenchymal transition in esophageal squamous cell carcinoma. Chen Chen,1 Ming Zhao,1 Xiaojie Huang,2 Xiang Wang,2 Wenlian Liu,1 Mengjiu Chen,1 Bangliang Yin,1 Zhi Li,1 Yunchang Yuan,1 Qianjin Li,1 Fengei Yu2. The Second Xiangya Hospital of Central South University, Changsha, China; 3Beijing Genomics Institute at Shenzhen, Shenzhen, China.

Epithelial-mesenchymal transition (EMT), which is associated with tumor progression and metastasis. Here, we investigated the correlation and potential modifications in the regulation of EMT in esophageal squamous cell carcinoma (ESCC). The RNA-Seq analysis identified a total of 6150 differentially expressed genes (3423 up-regulated and 2727 down-regulated). The GO terms showed that these genes belonged to several molecular functions and biological pathways. The abnormal expression of key EMT genes, some of Sox family genes and Ezh2 significantly related to patient survival. The MeDIP-Seq analysis identified histone modifications in the regulation of EMT in the whole genome level with focal hypermethylated and widespread global DNA hypomethylation. The gene ontology analysis showed that the DMRs related genes belonged to different ontological domains, such as EMT progression, cell cycle, adhesion, proliferation, and apoptosis. The results of the bisulfite-sequencing confirmed the gene EMTs DMRs identified by MeDIP-Seq. However, further analyses showed that the EMT gene DMRs only related to gene expression, but not the patient survival. ChiP-Seq was then performed to test the relationship between histone methylation and gene expression. A total of 295 genes were found to correlate with H3K27 tri-methylation (H3K27me3), and a certain number of key EMT genes, such as ZEB1/2, AREG, GATA4, and CDH18 were identified. Further study showed that Ezh2-mediated H3K27me3 regulate the expression of key EMT genes. Ablation of Ezh2 expression prevents EMT, whereas forced expression of Ezh2 restores EMT. Sox4 gene could directly regulate Ezh2 expression, tri-methylated H3K27me3 for EMT gene repression. Taken together, our results suggest that both of the DNA methylation and H3K27me3 modification involved in the regulation of EMT in ESCC. Sox4-Ezh2-mediated H3K27me3 marks associate with key EMT gene regulation, representing an important epigenetic EMT signature.
and may play a critical role in regulating the EMT program during the progression of cancer. They also suggest that modulation of OLFM4 expression might be a novel molecular target for advancing prostate-cancer therapies.

**#862** Atypical protein kinase c inhibitors can repress epithelial to mesenchymal transition (type III) in malignant melanoma. Warnhawan Sarathi Ratnayake, Mildred Acevedo-Duncan. Unv. of South Florida, Tampa, FL.

Melanoma is a type of cancer occurring in melanocytes. Approximately 90% of melanoma occurs in skin (cutaneous melanoma) but can rarely arise from the mucosal surfaces or areas where neural cells migrate. Examples are eye, intestine and mouth [Eur. J. Cancer, 69, 39-42 (2016)]. 76,380 of new cases and 10,130 number of deaths are expected in 2016 in the USA due to melanoma [http://seer.cancer.gov/statfacts/html/melan.html (11/05/2016)]. Atypical PKC inhibitors contain two structurally and functionally distinct isoforms in human which are PKC-α in (iota) and PKC-ζ (zeta). They are believed to be involved in cell cycle progression, tumorigenesis, cell survival and cell migration. We believe that atypical PKCs play an important role in cell motility of melanoma by involving the signaling pathways which induces EMT-type III (Epithelial to Mesenchymal Transition). In normal melanocytes, PKC-ζ was found in low levels and PKC-α was not detected. But both proteins are detected in very high levels in malignant melanoma [Melenoma Res. 12:201-209 (2002)]. In the current study, we have investigated the effects of novel atypical PKC inhibitors [4-(5-amino-4-carbamoylimidazol-1-yl)-2, 3-dihydroxy(cyclopentyl) methyl dihydrogen phosphate (ICA-1)] which is specific to PKC-ζ and 8-hydroxy-1, 3, 6-naphthalenetrisulfonic acid (Compound-50) which is specific to PKC-α on all the proliferation, apoptosis and cell migration of two malignant melanoma cell lines (SK-MEL-2 and MeWo) compared to normal melanocyte cell line (PCS-200-013). We showed that both inhibitors can decrease the levels of total and phosphorylated levels of PKC-ζ and PKC-α. Furthermore, both inhibitors increased the levels of E-cadherin and decreased the levels of Vimentin which is a mesenchymal marker associated with EMT. Treatments with inhibitors altered the levels of CD44, a cell-surface glycoprotein involved in cell-cell interactions, cell adhesion, migration and tumor cell homing during metastasis. These results suggest that both PKC-α and PKC-ζ are involved in signaling pathways which upregulate EMT and which can be effectively suppress using ICA-1 and Compound-50. Furthermore we established that treatment with ICA-1/Compound-50 induced apoptosis as shown by increasing Caspase-3 levels and decreasing Bcl-2 levels.

**#863** Neuronal splicing regulatory factors are upregulated in models of epithelial-mesenchymal transition. Yevenia L. Khodor, Julia Froese, Frank Gertler, Robert A. Weinberg, Christopher B. Burge. MIT, Cambridge, MA; Whitehead Institute, Cambridge, MA.

Epithelial-mesenchymal transition (EMT) is an essential developmental program through which epithelial cells lose their polarity and junctions with neighboring cells and acquire migratory and invasive properties. Cancer cells hijack at least a portion of the EMT program to increase their invasive properties, acquire resistance to senescence, and metastasize. Major changes in cell signaling, transcriptional and post-transcriptional regulation occur during EMT. To study post-transcriptional changes we characterized gene expression and splicing across EMT in 3 cell culture models of EMT: the luminal epithelial MCF7ras breast cancer cell line with EMT induced by SUGL+SOX9 and in basal mammary epithelial (HMLEras) cells, with EMT induced by either SNA1 or ZEB1. RNA-seq was performed at 2-day intervals across these transitions. We observed broad overlaps between these systems, with 821 genes that changed significantly in all three. In all three time courses, genes associated with cell cycle and growth decreased in expression, while genes associated with signaling, cell movement, adhesion, extracellular matrix organization, and differentiation increased. Intriguingly, genes associated with neurogenesis and angiogenesis were also induced in the MCF7 and HMLE-Sna1 time courses. Those include known axon guidance and angiogenic factors in the Robo and Slit families. We also found that CPEB2B is essential to establish anoikis resistance (AnR), and promotes metastasis in vivo in orthotopic models. In contrast, CPEB2A decreases AnR and metastatic transformation. In the current studies, we examined the function of CPEB2 isoforms using next generation sequencing analysis of downstream signaling pathways. We found that CPEB2 expression upregulated AnR in breast cancer cells and induced key genes/proteins in the epithelial to mesenchymal transition (EMT) and hypoxic response (hypoxia inducible factor 1α (HIF1α)-dependent) pathways. Inhibition of either TWIST1 or HIF1α reduced the CPEB2B-mediated AnR in cells ectopically expressing CPEB2B, confirming a link between CPEB2B alternative splicing and the induction of the EMT/hypoxia pathways. We then extended our findings, and demonstrated that CPEB2 alternative splicing induced de novo translation of both HIF1α and TWIST1, whereas CPEB2A decreased translation of these factors. Furthermore, CPEB2 isoforms were found to modulate differential polyadenylation site selection of the TWIST1 3'UTR and differential expression of CPEB2 isoforms using next generation sequencing analysis of downstream signaling pathways. We found that CPEB2B expression upregulated AnR in breast cancer cells and induced key genes/proteins in the epithelial to mesenchymal transition (EMT) and hypoxic response (hypoxia inducible factor 1α (HIF1α)-dependent) pathways. Inhibition of either TWIST1 or HIF1α reduced the CPEB2B-mediated AnR in cells ectopically expressing CPEB2B, confirming a link between CPEB2B alternative splicing and the induction of the EMT/hypoxia pathways. We then extended our findings, and demonstrated that CPEB2B alternative splicing induced de novo translation of both HIF1α and TWIST1, whereas CPEB2A decreased translation of these factors. Furthermore, CPEB2B isoforms were found to modulate differential polyadenylation site selection of the TWIST1 3'UTR and competed for binding to HIF1α and TWIST1 3'UTR cytoplasmic polyadenylation element (CPE) site sequences. These results demonstrate that CPEB2 and CPEB2B isoforms in breast cancer cells.
address this issue, immunohistochemistry and E-selectin microsphere dynamic adhesion assays were initially used to assay 110 cases of breast cancer for EMT biomarkers and E-selectin ligand activity. The expression of E-cadherin, but not N-cadherin or vimentin, directly correlated with E-selectin ligand activity. Thus, it was hypothesized that the EMT, and in turn the mesenchymal-to-epithelial transition (MET), regulate expression of functional E-selectin ligands in breast cancer cells. The ectopic expression or shRNA knockdown of transcription factors (i.e., Snail and Twist) in target cell lines were used to induce EMT or MET, respectively. Shear flow adhesion assays and flow cytometry demonstrated that cells with epithelial phenotypes had greater E-selectin ligand activities and greater expression of sialofucosylated carbohydrates compared to cells with mesenchymal phenotypes. Moreover, glycoprotein E-selectin ligand activities of breast cancer cells were more affected by the EMT compared to glycolipid E-selectin ligand activities. Assessing expression of α1,3- and α1,4- fucosyltransferases (FUT) at the RNA level using qRT-PCR revealed that FUT3 and FUT6 gene expression were decreased via the EMT, corresponding to the lowered E-selectin ligand activities observed in mesenchymal phenotype cells. Altogether, the results of this investigation demonstrate that the EMT, as well as MET, mechanistically regulate the expression of functional E-selectin ligands expressed by breast cancer cells.

TUMOR BIOLOGY: Epithelial to Mesenchymal Transitions in Metastasis

#867 Circulating lung tumor cells capture extracellular vesicles conferring resistance phenotype by the occurrence of epithelial-mesenchymal transition reprogramming. Josephine Zangari, 1,2 Marius Ilie, 1,2 Simon Heeke, 1,2 Véronique Hofman, 3 Baharia Mograbi, 1 Sophie Raynaud, 1 Salome Lalve, 1 Nathalie Yazbeck, 1 Charles-Hugo Marquette, 1 Sylvie Leroy, 3 Patrick Bulte, 4 Université Côte d’Azur, Nice, France; 2Université Côte d’Azur/FHU Oncogene, Nice, France; 3CHU Nice, Nice, France.

Background: The overall prognosis of lung cancer patients remains dismal, particularly in advanced stages. Only complete surgical resection of early-stage tumors improves the prognosis of certain non-small cell lung cancer (NSCLC) patients. However, migration of circulating tumor cells (CTCs) into the blood stream is probably an early event of carcinogenesis inducing metastases. The fact that some of these CTCs could survive within this “liquid environment” suggest that they acquire phenotypic changes that would confer them improved resistance against anoxia. In this context, we looked if immune blood cells could transfer to CTCs some factors associated with this increased resistance. Materials and Methods: Lung cancer cells (A549 cell line) were incubated with different sub-population of blood cells (PBMCs, granulocytes, platelets) and serum to look for potential transfer of extracellular vesicles (EVs) into the cancer cells. To assess the inter-cell transfer we looked for the presence of a validated blood cell specific marker the miR-223 that should not be expressed in lung cancer cells. By using a direct method for CTCs detection and characterization, we looked for these biomarkers within CTCs of lung cancer patients with early and late stages. Moreover the quantification of these biomarkers was correlated with the expression of vimentin, cytokeratin and E-cadherin Results: First, A549 cells were able to quickly capture microRNA (in particular miR-223) within the control blood samples. We then identified neutrophils as a major source of these miRNA. The inter-cell transfer was EVs dependent and promoted increased resistance and survival for cancer cells. In NSCLC patients with different stages, the presence of some specific miRNAs for blood cells was detected in a subpopulation of CTCs showing epithelial to mesenchymal phenotype, in particular an increase of vimentin expression and loss of E-cadherin expression. Conclusion: These results tend to prove that CTCs may capture extracellular vesicles from immune blood cells within the bloodstream and this phenomenon may be associated with a more aggressive phenotype. Inhibition of specific EVs transfer could be of interest for development of new targeted immunotherapies.

Locally advanced and metastatic prostate cancer is incurable, despite decades of research. The activity of the androgen receptor (AR), a Paul lab previously identified G protein-coupled receptor 5 (GRK5) for its ability to regulate PCa progression, independent of AR activity. GRK5 partially partitions to the nucleus, wherein it has been shown to regulate the transcriptionome in non-PCa models. To globally elucidate the mechanistic impact of GRK5 on PCa progression, we are investigating the impact of GRK5 on the PCa transcriptome. We hypothesize that GRK5’s regulation of the PCa transcriptome promotes tumor progression. To assay the effect of GRK5 on the PCa transcriptome, RNA sequencing was performed in two cell lines: PC3 Control (PC3 shGFP) and PC3 GRK5 Knockdown (PC3 shGRK5). Ontologic analysis identified the epithelial-mesenchymal transition (EMT) as being affected when GRK5 is depleted. The epithelial–mesenchymal transition (EMT) is highly associated with promoting PCa progression and chemoresistance, thus we selected this pathway for further investigation. Confirmatory western blot analysis and quantitative PCR (qPCR) validated that depleting GRK5 suppresses the expression of the mesenchymal markers Vimentin and N-Cadherin. Similarly, overexpression of GRK5 in prostate cancer models reprogrammed the mesenchymal markers. Stable overexpression of GRK5 promotes cells to develop a spindle-like morphology, indicative of a mesenchymal state. GRK5 mediates this mesenchymal transition through increasing the expression of the EMT transcription factor, Twist1. Further analysis identifies that GRK5 activity promotes in vitro invasion. Cell lines overexpressing GRK5 demonstrate an increase in resistance to docetaxel, the mainstay chemotherapy for advanced PCa. Overexpression of mutated forms of GRK5 that are retained to the nucleus are able recapitulated all aforesaid changes, arguing that the nuclear activity of GRK5 mediates this effect. Collectively, this data presents a novel mechanism promoting PCa progression, independent of AR activity. Future work seeks to assay the ability of GRK5 to promote metastasis in vivo in mouse models.

TUMOR BIOLOGY: Imaging Cancer Immunotherapy, Tumor Microenvironment, and Other Aspects of Tumor Biology

Background: Radiation therapy (RT) can induce upregulation of programmed death ligand 1 (PD-L1) on tumor cells or myeloid cells, which might affect the response to RT with or without anti-PD-1/PD-L1 blockade. RT-induced PD-L1 expression during therapy could be a predictive marker for the therapy response, however, serial biopsies to monitor its distribution may be unreliable because its expression is heterogeneous. Therefore, non-invasive imaging of tumor PD-L1 expression could be more helpful. Materials and Methods: Two different murine tumor models (MEER and B16F10) were established in two locations, at the back of the neck and at the right flank of C57BL/6 mouse. Then fractionated RT (2Gy x 4 or 2Gy x 10) with or without anti-PD-1 therapy was delivered only to the neck tumor. PD-L1 expression was measured by PET/CT imaging and biodistribution with Zr-89-DFO-anti-mouse PD-L1 monoclonal Ab (clone 1H9G2) and the results were corroborated by flow cytometric analysis and immunohistochemistry. PET/CT imaging and biodistributions were performed 48 or 96 hours after tracer-injection. The change of PD-L1 expression on irradiated neck tumor was evaluated using non-irradiated flank tumor as a control. Endothelial cell morphology in tumor vessels was also analyzed by CD31 stain-
TUMOR BIOLOGY: Imaging Cancer Immunotherapy, Tumor Microenvironment, and Other Aspects of Tumor Biology

ing to determine whether RT-induced increased permeability of tumor vessels might result in increased non-specific tracer accumulations in the irradiated tumors. Results: PET/CT imaging and biodistribution study of ex-vivo tracer uptake values demonstrated significant increased tracer uptake in irradiated tumor compared to non-irradiated flank tumor in either case of MEER and B16F10. Tracer uptakes in the spleens were significantly decreased if high dose of non-labeled anti-mouse PD-L1 monoclonal Ab was given in advance before tracer-injection, which indicates the tracer is fully functional. Flow cytometry and immunohistochemistry showed PD-L1 upregulation in both irradiated tumors corroborating PET/CT imaging of RT-induced PD-L1 upregulation. Flow cytometry also revealed RT-induced PD-L1 upregulation on myeloid cells is more prominent than that of tumor cells, while positive staining in the irradiated tumors was not different from that of non-irradiated tumors, which shows RT did not induce alterations in tumor blood vessels. PD-L1 upregulation of MEER was not seen unless it was performed 2 Gy X10 RT, however, that of B16F10 could be seen at an earlier time-point of 2 Gy X4. Combination therapy of anti-PD-1 with RT did not show further PD-L1 upregulation compared to RT without anti-PD-1 therapy. Conclusion: RT-induced PD-L1 upregulation in different tumor models of MEER and B16F10 was identified by PET/CT using Zr-89 labeled PD-L1 monoclonal Ab and its validity was corroborated by flow cytometric analysis and immunohistochemistry.

#871 [18F]BMS-986192 as a novel PET imaging agent for assessment of PD-L1 expression in vivo. Ralph A. Smith,1 David Donnelly,1 Paul E. Morin,1 Dana Lipovsek,2 Jochem Gokejemeier,3 Daniel Cohen,4 Joonyoung Kim,5 Adrienne Pena,1 Xi-Tao Wang,1 Patrick Chow,1 Samuel J. Boscia,1 Xi-Tao Wang,1 Martin L. Boscia,1 Wendy Hayes1. 1Bristol-Myers Squibb, Waltham, MA; 2NIH, Bethesda, MD; 3Scripps, La Jolla, CA; 4Yale University, New Haven, CT; 5Scripps, San Diego, CA.

Objections Inhibition of the Programmed Death Ligand-1 (PD-L1)/PD-1 interaction allows for potent anti-tumor activity and antibodies that disrupt this interaction have been approved for the treatment of multiple cancer types. PD-L1 expression has been investigated clinically as a potential biomarker to predict response to anti-PD-1/PD-L1 therapy. BMS-986192, an Adnectin with high affinity and specificity for human PD-L1, was selected in vitro from a phage display library and characterized further in cell culture before labeling with SPIO for adoptive cell transfer into mice receiving scans. PET/MRI Data: Anatomical and qualitative SPIO data is collected using a balanced steady-state free precession (bSSFP) sequence. Iron quantification is done using R2* maps from a multi-echo single point imaging sequence (TurboSPI). Iron nanoparticle (SPIO) labeled tumor cells were observed after exposure to ionizing radiation or IFN-gamma, which has been reported to upregulate the expression of PD-L1. In vivo, we were able to observe radiation induced increase in bioluminescence signals from tumor established by use of the reporter cells. Our study therefore provided proof of principle for the use of our endogenous PD-L1 reporter imaging system to monitor the expression levels of PD-L1 in vitro and in vivo noninvasively and serially.

#872 Noninvasive monitoring of endogenous PD1 expression by using a dual reporter system. Min Zhou, Xinjian Liu, Fang Li, Chuan-Yuan Li. Duke University Medical Center, DURHAM, NC.

Programmed death-ligand 1 (PD1) is a key immune checkpoint protein facilitating tumor escape from host immune system. Clinical approval of anti-PD1 and anti-PDL1 antibodies for the treatment of a variety of malignancies underscores the promise of immune checkpoint therapy. Further progress in this promising area of research is likely to come from better understanding of the mechanisms for regulation of immune checkpoint proteins such as PD-L1. In the present study, we designed a dual reporter imaging system to monitor PD1 with PET/CT and SPIO with MRI. The expression of PD-L1 in both MEER and B16F10. CD31-positive staining in the irradiated tumors was not different from that of non-irradiated tumors, which shows RT did not induce alterations in tumor blood vessels. PD-L1 upregulation of MEER was not seen unless it was performed 2 Gy X10 RT, however, that of B16F10 could be seen at an earlier time-point of 2 Gy X4. Combination therapy of anti-PD-1 with RT did not show further PD-L1 upregulation compared to RT without anti-PD-1 therapy. Conclusion: RT-induced PD-L1 upregulation in different tumor models of MEER and B16F10 was identified by PET/CT using Zr-89 labeled PD-L1 monoclonal Ab and its validity was corroborated by flow cytometric analysis and immunohistochemistry.

#873 Evaluating immunotherapy effects using preclinical molecular imaging tools for quantitative immune cell tracking. Marie-Laurence Tremblay,1 Zombie O’Brien-Moran,2 Christa Davis,1 Kimberly Brewer1. 1WK Health Center, Halifax, Nova Scotia, Canada; 2Dalhousie University, Halifax, Nova Scotia, Canada.

Immunotherapies are a promising class of cancer therapeutics, but clinical translation is often impeded by a lack of understanding regarding optimal therapy administration, combination, and reliable biomarkers of success. Traditional metrics such as RECIST, and modern metrics like irRC and PERCIST used for monitoring cancer therapy outcome, have limitations for immunotherapy evaluation and are not always reflective of the underlying immune mechanisms. We aim to better characterize and monitor these immunotherapies, with focus on combination therapy optimization, by tracking immune cell migration in response to these therapies using preclinical magnetic resonance imaging (MRI). MRI is used to obtain anatomical tumor changes, detect and quantify superparamagnetic iron oxide (SPIO)-labeled cells in vivo. Goal: To link immune cell migration to early prognostic biomarkers for immunotherapy success. Methods: C57BL/6 mice (n = 40) received an implant of 5x10⁶ C3 cancer cells in the left flank. Mice (n = 10/group) were i) untreated or treated with ii) 200 μg of anti-PD1/day on days 7, 9, 11, 21 and 23, and iii) the peptide-based vaccine DepoVaxTM on day 15, or iv) with anti-PD1 and DTX. CD8+ cytotoxic T cells (CD8) and suppressive regulatory T cells (Tregs) were isolated from diseased-matched & treated donor mice for expansion in culture before labeling with SPIO for adoptive cell transfer into mice receiving scans. PET/MRI Data: Anatomical and qualitative SPIO data is collected using a balanced steady-state free precession (bSSFP) sequence. Iron quantification is done using R₂ maps from a multi-echo single point imaging sequence (TurboSPI). Tumor metabolism was assessed by ¹⁸F-fluorodeoxyglucose uptake during simultaneous acquisition of positron emission tomography (PET) with MRI. Imaging was done 21 and 28 days post-implant. Results: CD8 and Treg cells are consistently recruited to both the tumor and vaccine draining inguinal lymph nodes. CD8 T cells are primarily recruited to the tumor periphery and do not always penetrate the tumor core. Positive therapy outcomes are correlated with an increasing CD8/Treg ratio in the tumor, particularly at earlier time points (21 vs 28 days). In certain cases, CD8 T cells were found within the fat pad between the tumor and lymph node. As expected, DTX & anti-PD1 combination therapy resulted in the best prognosis. Simultaneous acquisition of PET/MRI demonstrated large areas of necrosis in tumor cores. Using TurboSPI, we have begun quantifying CD8 and Tregs cells, evaluating if volumetric tumor changes due to pseudo-progression correlate with Treg or CD8 T cell migration and comparing areas of necrosis in tumor cores. Using TurboSPI, we have begun quantifying CD8 and Tregs cells, evaluating if volumetric tumor changes due to pseudo-progression correlate with Treg or CD8 T cell migration and comparing areas of necrosis in tumor cores.

#874 Lifting the iron curtain: Imaging cellular barriers to combination chelation-immune checkpoint therapy. Avildor Leftin, Suresh Vearappan, Huiyong Zhao, Sadina Budhlu, Elisa de Stanchina, Jedd Wolchok, Taha Merghoub, Jason Koutcher. Memorial Sloan Kettering Cancer Center, New York, NY.

Iron accumulation in cancer cells and macrophages can result in tumor microenvironment that is unfavorable for checkpoint immune therapy. Chelation is a safe approach of reducing cellular iron accumulation that while...
TUMOR BIOLOGY: Imaging Cancer Immunotherapy, Tumor Microenvironment, and Other Aspects of Tumor Biology

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 223

Ying Du, Yue Tian. Institute of Automation, Chinese Academy of Sciences, Beijing, China.

Purpose: An intraoperative technique to accurately identify microscopic tumor residuals could be applied to decrease the risk of positive surgical margins. Several lines of evidence support the expression and immunotherapeutic effect of PD-1 in breast cancer. Here, we sought to develop a fluorescent labeled PD-1 probe for in vivo breast tumor imaging and image-guided surgery. The efficacy of PD-1 monoclonal antibody (mAb) as adjuvant immunotherapy after surgery was also assessed.

Experimental Design: A near-infrared dye labeled PD-1-IRDye800CW probe was developed and examined for its application in tumor imaging and image-guided tumor resection in an immunocompetent 4T1 mammary mouse tumor model that recapitulates clinical breast cancer. Fluorescence molecular imaging (FMI) was performed to monitor probe biodistribution and intraoperative imaging. Bioluminescence imaging (BLI) was carried out concurrently to monitor tumor growth and evaluate post-surgical tumor residuals, recurrences, and metastases. Results: The PD-1-IRDye800CW probe exhibited a specific and stable signal at the tumor region compared to the IgG control, and exhibited the highest tumor-to-background ratio (TBR) 8 h post-injection (11.62 ± 0.79), approximately 5 fold higher than the IgG control (2.13 ± 0.30). Furthermore, PD-1-IRDye800CW guided surgery combined with PD-1 adjuvant immunotherapy inhibited tumor growth and microtumor metastases, as determined by BLI imaging, and thus improved survival rate with notable side effects. Conclusion: Our study demonstrates the feasibility of using PD-1-IRDye800CW for breast tumor imaging and image-guided tumor resection. Moreover, we found that PD-1 mAb adjuvant immunotherapy reduces cancer recurrences and metastases emanating from minimal tumor residuals.

#876 Imaging the interaction of leukemia and bone marrow microenvironment in murine model of ALL. Karine G. Harutyunyan,1 Saradhi Mallam-pati,1 Anna Zal,3 Mateusz Bytelewski,1 Michael C. Gurkin,2 Jason M. Butler,2 Tomasz Zal,1 Marina Konopleva,1 MD Anderson Cancer Ceter, Houston, TX; 2Weill Cornell Medical College, New York, NY.

Interactions of leukemia and the bone marrow (BM) microenvironment are known to play a key role in the survival and growth of leukemic cells, and we have shown that HIF-1α stabilization in BM stromal cells facilitates leukemia homing and progression (Chen et al. Blood 2012, 119:4971). Leukemic cells have been shown to hijack the homeostatic mechanisms of normal hematopoietic stem cells (HSCs) and take refuge within the BM niche. This mechanism is pivotal during chemotherapy and contributes to disease relapse. In this study, we investigated the time-dependent progression of BM in murine leukemia model involving both acute lymphocytic leukemia (ALL) cells and components of the BM niche, using multiphoton intravital microscopy (MP-IVM). We generated a transplantable, fluorescence leukemia model by retrovirally transducing C57Bl6-Ai4 murine BM cells that express red fluorescing tdTomato with the p190-Bcr/Abl oncogene (KG Harutyunyan et al, Blood 2014 124:2396). The resulting BM Abl tdTomato cells caused rapid development of ALL in non-irradiated C57Bl6 immunocompetent mice, manifested by infiltration of multiple organ and BM sites, followed by death within 14-18 days. We utilized C02.3-GFPemd transgenic mice as recipients of leukemia to highlight the osteoblastic niche, and visualized vasculature by injection of TRITC-dextran. We showed the dynamic of homing and engraftment of ALL leukemic B cells (MLC) in OB-GFP recipient mice, with homing in the vicinity of blood vessels visualized by MP-IVM, followed by proliferation and leukemia progression. This was accompanied by invasion of both vascular and osteoblastic components of BM microenvironment. Longitudinal assessment of hypoxia utilizing pimonidazole staining showed progressive development of BM hypoxia starting from Day 10 p.i., paralleling leukemia progression, despite the abundant vascularity of the BM. Moreover, we showed that tumors in cases of complete tumor growth inhibition, systemic iron-load was not consequently confirmed in MMTV-PyMT orthotopic breast cancer models. Even being observed in low-iron C57BL6 model backgrounds; a result subsequently confirmed in MMTV-PyMT orthotopic breast cancer models and quantitative voxelation (11.62 ± 0.79), approximately 5 fold higher than the IgG control (2.13 ± 0.30). Furthermore, PD-1-IRDye800CW guided surgery combined with PD-1 adjuvant immunotherapy inhibited tumor growth and microtumor metastases, as determined by BLI imaging, and thus improved survival rate with notable side effects. Conclusion: Our study demonstrates the feasibility of using PD-1-IRDye800CW for breast tumor imaging and image-guided tumor resection. Moreover, we found that PD-1 mAb adjuvant immunotherapy reduces cancer recurrences and metastases emanating from minimal tumor residuals.

#877 Real-time imaging of adherent and non-adherent cell interactions: utility of an automated microfluidic trap platform to recapitulate in vivo cell culture microenvironment. Rikka Kannan, Victor Yeh, James Helton, Amedeo Cappione. Millipore Sigma, Hayward, CA.

The study of dynamic cell processes and their interactions is of crucial importance to understand the complexities of tissue microenvironments. Simulation of in vivo cell culture microenvironments can greatly improve biologic relevance of cell-cell interaction studies, and so there is an ongoing demand for heuristic screening in tumor microenvironments, and temperature control for long-term cell culture. Each chamber within the plate can be addressed by programmable and on-demand perturbation of up to 10 reagents, enabling uninterrupted real-time live cell imaging assays. We present here the use of this microfluidic platform to replicate tumor microenvironment by maintaining adjacent co-cultures of cancer and immune cells. We have successfully imaged and cultured monolayers of tumor cell lines for 7 days followed by subsequent loading and trapping of immune (non-adherent) cells. In conclusion, the microfluidic platform enables unique co-cultures with environmental control and real-time imaging to facilitate the investigation of cell-cell interactions in a wide range of applications such as drug response and screening in tumor microenvironments, invasion, evasion pathways and other mechanisms governing cell-cell interactions.

#878 Imaging the interaction of leukemia and bone marrow microenvironment in murine model of ALL. Karine G. Harutyunyan,1 Saradhi Mallampati,1 Anna Zal,3 Mateusz Bytelewski,1 Michael C. Gurkin,2 Jason M. Butler,2 Tomasz Zal,1 Marina Konopleva,1 MD Anderson Cancer Ceter, Houston, TX; 2Weill Cornell Medical College, New York, NY.

Interactions of leukemia and the bone marrow (BM) microenvironment are known to play a key role in the survival and growth of leukemic cells, and we have shown that HIF-1α stabilization in BM stromal cells facilitates leukemia homing and progression (Chen et al. Blood 2012, 119:4971). Leukemic cells have been shown to hijack the homeostatic mechanisms of normal hematopoietic stem cells (HSCs) and take refuge within the BM niche. #878 A new SOX2/OCT4 stem cell biosensor reveals the mechanism of cancer stem cell dissemination in human breast cancer. 

Ved P. Sharma, 1 Sonia Voiculescu, 1 Yarong Wang, 1 George S. Karagiannis, 1 Binwu Tang, 2 Lalage Wakefield, 2 David Entenberg, 1 Sumanta Goswami, 1 Maja Oktay, 1 John Condeelis, 1 Albert Einstein College of Medicine, Bronx, NY; 2National Cancer Institute, Bethesda, MD.

There is increasing consensus that cancer stem cells (CSC) play an important role during metastatic progression of breast cancer. Previous studies have shown that stem cells display a pro-invasive phenotype in breast cancer. However, the phenotypes specific to breast cancer stem cells have not been evaluated at single cell resolution in vivo. Here, we employ high-resolution intravital two-photon microscopy in cells with orthotopic xenograft tumors and their metastases from human breast cancer cell lines expressing a previously characterized SOX2/OCT4 transcription-based fluorescent stem cell biosensor (SORE6). Using this high resolution imaging technology we found that SORE6+ stem cells: (a) constitute a minority population of the primary mammary tumors, (b) move approximately ten times slower than non-stem breast cancer cells (0.1 vs 1.1 μm/min, respectively), (c) are migratory toward blood vessels and, (d) compared to non-stem cells, they are enriched for invasive cellular protrusions called invadopodia. This is important because we have shown that these phenotypes are specifically associated with the disseminating population of tumor cells in the primary tumor site and, in addition, invadopodia are required for transendothelial migration during intravasation. Stem cells also have a three-fold higher incidence of cell death compared with macrophages compared to non-stem cells. In fact, stem cells were frequently seen to be part of the tripartite macrophage-tumor cell-endothelial cell complex called TME, which was previously shown to be the doorway for intravasation of tumor cells in primary mammary tumors and is validated as a prognostic of metastasis in human breast cancer patients. Furthermore, we followed breast cancer stem cell dissemination to the lung by using a novel lung window for high resolution imaging of the lung (WHRIL), which allows visualization of the same lung tissue in a single mouse, serially, over days to weeks. Using WHRIL, in combination with intravital multiphoton microscopy and the above biosensor, we visualized the arrival, extravasation and outgrowth of spontaneously arriving breast cancer tumors in the lung. We report here for the first time, the kinetics and stemness state of the spontaneously metastasizing tumor cells and, the record at single cell resolution, of their fate and metastasis outgrowth in the lung over time.

#879 Multi-scale time-lapse intravital imaging of soft tissues to map single cell behavior. 

Jessica M. Pastoriza, 1 Maria Soledad Sosa, 3 Kathryn Harper, 4 Julio Aguirre-Ghiso, 1 Maja H. Oktay, 1 David Entenberg, 1 Yarong Wang, 1 John S. Condeelis, 1 Aviv Bergman, 1 Mihaela Skobe, 1 Benedicte Lenoir, 1 Albert Einstein College of Medicine, Bronx, NY; 2Icahn School of Medicine at Mount Sinai, New York, NY.

After more than 10 years of research into the tumor micro-environment and the sources of tumor micro-heterogeneity, it is becoming increasingly clear that in addition to driver mutations, the tumor microenvironment determines tumor metastatic phenotype. This research has led to a new understanding of the impact of tumor micro-environments and their heterogeneity upon tumor cell proliferation, dissemination, dormancy, and survival. A full understanding of this heterogeneity, both temporally and spatially, how it supports tumor cell dissemination, dormancy and eventual further metastatic growth, and how it responds to therapeutic interventions, is crucial. Traditional single parameter studies have not been as productive as hoped in revealing the above relationships and have highlighted the need to understand tumors as integrated systems of genes, gene networks, and intracellular interactions, particularly with regard to the interplay between cells and their immediate microenvironment. To accomplish this, we have developed a new technology in the form of large volume intravital imaging using multiphoton intravital microscopy (MIVM) where images of large tumor volumes are stitched together to form a comprehensive record of the genes, gene networks, and intracellular interactions that occur throughout many tumor microenvironments at single cell resolution. Here, we report a protocol to obtain large numbers of high-resolution multiphoton images from living animals. The protocol is composed of surgical techniques for the stabilization of soft tissues including mammary gland, lymph node, liver, and lung and the acquisition of multiple high-magnification tiles that are stitched together to form a large-area low-magnification image. We have developed specific protocols for the surgery as well as tools for tissue stabilization and the acquisition and stitching of the images to generate very large MIVM data sets. We have interfaced these very large MIVM image data sets with support vector machine (SVM) classification, a nonlinear, multiparametric classification algorithm suitable for analysis of systems with arbitrary distributions and/or non-linear parameter’s correlations. To define the combinations of microenvironment parameters where tumor cell phenotypes of interest are likely to occur, we used these microenvironment parameters as an “input” for the SVM classifier to identify associated tumor cell phenotypes as the classifier’s “output”. Using this approach at widely varying temporal and spatial scales (from minutes to weeks and from sub-cellular to tissue wide) and at different stages (early carcinoma on to advanced metastatic disease), we have made inroads into the heterogeneity of tumor microenvironments and tumor cell phenotypes associated with progression. These results were noted in new insights into the mechanisms of metastasis.

#880 A computational and statistical approach for interpreting real-time in-vitro gene reporter data. 

Alexander T. Pearson, 1 Dan Sun, 2 Zhengli Li, 3 Jacques Nor, 2 Qiong Yang, 2 Laura Buttitta, 3 Univ. of Michigan Health System, Ann Arbor, MI; 2Univ. of Michigan, Ann Arbor, MI; 3Univ. of Michigan Dental School, Ann Arbor, MI.

We have developed a new computational approach to track and analyze data from cells engineered with fluorescent cell cycle gene reporters. Gene reporters are a rapidly growing tool to gather information captured with time-lapse imaging, and can give insights to real-time metabolic conditions, cell cycle state, cancer stem cell state, and many other applications. Gene reporters may reflect cellular conditions that are cyclical rather than monotonic. Currently, the primary mechanism for interpretation of time lapse gene reporter data is reporting the mean fluorescence of imaging over time. This simplistic analysis discards information such as the cycle length and variation between gene reporters between cells, and can be biased due to the overall fluorescence shift from population growth. More nuanced data acquisition and analysis approaches have been reported to require large amounts of laborious hand-on data analysis. We have implemented a high-throughput computational pipeline for interpretation of cell cycle information using a combination of commercial and newly developed software to partition the activities of individual cells. The fluorescence information for each cell is smoothed and the cycle states for each cell are assigned adaptively. Our approach captures and quantifies the total time each individual cell spends in each presumptive state, and then analyzes state information from the cohort of observed cells using censored survival time data methods such as the Cox Proportional Hazards Model to account for death or movement out of the observed area. As a proof of concept for our pipeline, we engineered T3T fibroblast cells with a cell cycle reporter construct including mCherry-CDT1 and mVenus-p27K- reporters which can discriminate cells in G0 phase from G1 phase. We calculated the sample size required for statistical power of 80% to detect a hazard ratio (HR) of 0.8 between groups at α = 0.05 and 386 tracked cells per group. As our treatment model, we used the Protein Phosphatase 2A inhibitor Okadaic Acid (OA) an agent known to promote departure from G0. We captured a distinct total of 601 vehicle cells and 479 treatment cells in a 24 hour monitoring period with 20 minute capture intervals. We were able to discern significant differences between conditions and treatment G0 time, including a subtle statistically significant decrease in G0 time after treatment with OA (p = 0.0166, HR = 0.84). Here we have developed a computational pipeline with the capability for high-throughput image-stack data processing and nuanced quantification. Our approach assigns cycling cell states adaptively and the time until each cell departs its current state is tallied and interpreted statistically with survival analysis. The cell-level analysis affords a high degree of statistical power to discriminate group differences. Our pipeline is highly adaptable and has a multitude of applications in cancer biology research.

#881 CD44-specific supramolecular hydrogels for fluorescence molecular imaging of EMT induced BRAF <V600E> mutant thyroid cancer cells. 

Hyung Kwon Byeon, 1 Minhee Ku, 1 Yeon Ju Yang, 1 Min Hee Cho, 1 Yoojung Oh, 1 Jae Wook Kim, 2 Myung Jin Ban, 2 Ji-Hoon Kim, 3 Da Hee Kim, 1 Joo Hyun Kim, 1 Jaemon Yang, 1 Yoon Woo Koh 1, 2 1Yonsei University College of Medicine, Seoul, Republic of Korea; 3Sochunhyang University College of Medicine, Seoul, Republic of Korea; 1Yonsei University Wonju College of Medicine, Wonju, Republic of Korea.

Previously, the authors have identified that the acquired drug resistance to BRAF inhibitor, PLX4032 in BRAF (V600E) mutant anaplastic thyroid cancer promotes not only tumor progression and proliferation, but also migration and invasion of cancer limited upregulated epithelial-to-mesenchymal transition (EMT). The underlying mechanism to the acquired resistance to BRAF inhibition involves c-Met mediated reactivation of PI3K/ AKT pathway. Therefore combinatorial dual targeted therapy of BRAF and c-Met inhibition has shown to reverse EMT and show maximal antitumor effect. Previously, the authors have developed a novel in vivo imaging strategy using CD44-targetable near-infrared (NIR)-sensitive supramolecular hydrogels (NIRSHs) for the recognition of CD44 expressing cancer cells. In the present study, we applied this NIR-sensitive molecular imaging probe in detecting the upregulated EMT changes in PLX4032-treated 8505C cells. The CD44-tar-
getable NIRSHs were fabricated by polyplexing Cy5.5-conjugated polyethyleneimine and hyaluronic acid in an aqueous medium. Ectopic xenograft mouse models were prepared by injecting 8505C cells at the flank of male athymic nude BALB/c mice, aged 6 weeks. After confirming tumor formation at 3 weeks post-injection, the mice were randomly divided into four groups and were each treated under different conditions: DMSO, PLX4032, PHA665752, PLX4032 and PHA665752. After 3 weeks, tumors were validated by MRI which showed correlations with the NIRSH fluorescence. The injected NIRSH probes showed highest uptake in the PLX4032 single treatment group and lowest uptake in the PLX4032 and PHA665752 combination group. Sizes of tumor were verified by MRI which showed correlations with the NIRSH fluorescence. The results suggest that CD44-targetable NIRSHs imaging shows potential as a non-invasive in vivo imaging tool in detecting the increased invasion potential of cancer cells and monitoring appropriate therapeutic effects.

**#882 Interpreting glioma MR imaging and somatic mutations in a cancer hallmark context.** John Graf,1 Mirabela Rusu,1 Yunxia Sui,1 Dattesh Shannbag,2 Uday Patil,3 Jeffrey Kiefer,3 Jill Barnholtz-Sloan,4 Michael Berens,3 Fiona Ginty,3 Sandeep Gupta,1 Chinmappa Kodira,1 Lee Newberg,1 Anup Sood1. GE Global Research, Niskayuna, NY; 2GE Global Research, Bangalore, India; 3Translational Genomics Research Institute, Phoenix, AZ; 4Case Comprehensive Cancer Center, Cleveland, OH.

Extracting biologically relevant data from radiology images can enable better monitoring of disease progression and therapy response. The field of radiogenomics is providing new approaches for such genomic/radiology correlations. However, there are several challenges in validation and clinical translation in that few DNA mutations are shared between tumors from different individuals and the differences in scale between imaging and genomic features can limit interpretation of underlying mechanisms. The goals of this work were to i) analyze correlations between low grade glioma (LGG) DNA somatic mutations, using a novel DNA impact scoring approach, and MRI derived imaging features; and ii) to interpret results in context of cancer hallmarks. Multi-parametric MRI and corresponding DNA data from 32 LGG patients were extracted from The Cancer Genome Atlas (TCGA) and The Cancer Imaging Archive (TCIA). The cohort included 18 males (56%), with mean age of 44 years (range: 21-74 years). An expert radiologist outlined the normal and tumor regions of interest using ITK-Snap tool. The normal region was used as a reference to normalize image intensities in the tumor region. Tumor mean intensity and mean variance were computed from Apparent Diffusion Coefficient (ADC), T1 enhancement, T2/T1 ratio (derived from T1 pre- and post-contract MRI), and Fluid-Ablated Inversion Recovery (FLAIR) images. A novel algorithm was used to compute DNA impact scores for each somatic mutation. The score represents the probability of a DNA variant being pathogenic vs. non-pathogenic. First, the scoring algorithm computes a score for nucleotide base insertions, deletions, or single base changes and then computes the consequence of such changes on amino acid coding, binding sites, splice sites and protein phosphorylation sites. An impact score was then computed based on the individual DNA impact scores of mutations within the gene. Finally, an average DNA impact score was computed at the Cancer Hallmark level using a gene-cancer hallmark map. At gene level, significant positive correlations were found between the ATRX (p<0.0002), TP53 (p<0.00001) mean intensity, T1 mean intensity and T1 T2/T1 ratio (p<0.0002). After combining the T2 and T1 impact scores, positive correlations were significant between the T1 T2/T1 ratio and TP53 expression and degradation, and DNA damage response, signal transduction by p53 class mediator, and DNA translocase activity were found to be enriched with genes that correlated with ADC and FLAIR. These pathways also contained genes that were enriched in the following cancer hallmarks: replicative immortality, evading growth suppression and genome instability. The ATRX gene is a member of all three hallmarks and TP53 a member of two. Since ADC is a measure of water diffusion and hence an indirect measure of cellularity, these findings demonstrate that mutations in replication and repair pathways are contributing to imaging features at the tumor level. Hanahan, D. and Weinberg, R.A. (2011). Hallmarks of cancer: the next generation. Cell 144(5):646-74.

**#883 Elucidating cancer hallmark context from glioma MR imaging and RNA expression data.** Yunxia Sui,1 Mirabela Rusu,1 Dattesh Shannbag,2 Uday Patil,3 Jeffrey Kiefer,3 Jill Barnholtz-Sloan,4 Michael Berens,3 Fiona Ginty,3 Graf John,1 Sandeep Gupta,1 Chinmappa Kodira,1 Lee Newberg,1 Anup Sood1. GE Global Research, Niskayuna, NY; 2GE Global Research, Bangalore, India; 3Translational Genomics Research Institute, Phoenix, AZ; 4Case Comprehensive Cancer Center, Cleveland, OH.

Radiogenomics or radiomics is an emerging field where tumor genomic data is correlated with radiology image features, thereby potentially providing more biological information about the tumor phenotype. A central challenge is the potential for model over-fitting due to analysis of many thousands of genomic data-points with hundreds of corresponding patient image features. Biological interpretation of the imaging feature correlations is also challenged by overlapping pathways and common gene effects. Our goals were: i) to explore correlations between gene expression and corresponding Magnetic Resonance (MR) Apparent Diffusion Coefficient (ADC) derived imaging features in low grade glioma (LGG); ii) to classify significant gene and imaging correlates by cancer hallmark. RNA expression data from 32 LGG patients were matched with corresponding MR image data from The Cancer Imaging Archive (TCIA). Among 32 patients, 18 were males (56%), and ages ranged from 21 to 74 years (mean age 44). Tumor and normal regions in the MR images were annotated by an expert radiologist using ITK-Snap. The normal reference region was used to normalize image intensities in corresponding tumor regions. Tumor texture features were extracted on voxel level in the tumor region including first and second order statistics, Run Length and co-occurrence matrix derived measures features. The voxel features were finally aggregated within the tumor region using statistical measures of mean, variance, median, kurtosis, and skewness. ADC imaging features (n=310) were correlated with each single gene expression value (11641 genes after MAD>0.4 filtering). Only image features and genes with pairwise correlations higher than 0.68 (0.68 is the 3-standard deviation above average correlation) and FDR (False Discovery Rate) <0.1 were used for follow-up analyses. Significant genes and MR image features were aggregated into 3 groups based on gene expression and correlated with cancer hallmarks. Seven Haralick image features (reflecting the average level of image intensity heterogeneity) were independently, significantly correlated with the Angiogenesis Hallmark (FDR<0.05). Three Haralick image features reflecting asymmetry features may be useful in limiting cancer progression. Studies have shown that melatonin can affect tumor metabolism and we hypothesize that this may be a mechanism by which the disruption of circadian melatonin production by light exposure at night (LAN) promotes breast cancer initiation and progression. The aim of this study was to evaluate the effect of melatonin on intratumoral heterogeneity measured by non-invasive MR imaging in a syngeneic mouse model of breast cancer (4T1). To visualize habitats, clusters were generated from combined MR images generated by different pulse sequences. These were co-registered with histology using tumor specific 3-D printed cradles to classify these tumor habitats. Methods: Mice were exposed to LAN (Control) or LAN plus melatonin. The melatonin metabolite 6-sulfotyramelatonin (6-SMT) was assessed in urine as a measure of melatonin production. Mice were imaged in a 7T MRI system with: 1) anatomical T2 images, 2) T2*, 3) diffusion-weighted MRI (DWI); and 4) T1 weighted dynamic contrast enhanced (DCE). DCE maps were obtained through semi-quantitative analysis of the pre- and post-contrast agent bolus time-series on a pixel-by-pixel basis. These were combined to the corresponding T2*, T1 and Apparent Diffusion Coefficient (ADC) values to generate parameter maps. Parameter maps were used to classify multiple clusters, based on a Gaussian mixture model. Following euthanasia, a 3D printed mold based on the T2 tumor isosurface was created in order to co-register the MRI and histology. Tumors were stained with H&E and for pimonidazole (hypoxia) by immunohistochemistry. Results: Melatonin treatment increased the 6-SMT in urine of mice exposed to LAN and statistically reduced tumor growth by day 15 (p<0.05). Distinct hypoxic habitats were observed with corresponding patient image features. Biological interpretation of these features was needed to reach statistical significance. Conclusion: These data indicate that...
TUMOR BIOLOGY: Imaging Cancer Immunotherapy, Tumor Microenvironment, and Other Aspects of Tumor Biology

#885 Live-imaging reveals the correction of skin deformities within two tumor-associated mutational models. Cristiana Pineda, Samara Brown, Valentina Greco. Yale University, New Haven, CT.

Healthy tissues are frequently subject to oncogenic mutations that fail to produce malignancy. Such mutations can lead to aberrant cellular behaviors such as increased proliferation or invasion and have been shown to be associated with the formation of aberrant tissue growths and cancer. However, it remains unclear how phenotypically normal tissue is capable of harboring mutations and raises the question as to how the switch from normal to malignant is initiated. One challenge to understanding the initiating events towards malignancy is the inability to follow the same cells over time in an intact mammal. Specifically, this roadblock hinders the ability to understand both the role of specific cells and how their location contributes to their growth, whether that growth be normal or cancerous. To overcome this, we have established a novel live imaging approach to perform in vivo lineage tracing of the same mutant cells over time within two distinct mutational systems in the skin epithelium. To begin, we turned to the pro-differentiation pathway Wnt/β-catenin, which when mutated is known to drive benign growths in the skin, and activated this mutant form in skin stem cells. We show that the resulting growths that deform the skin tissue architecture spontaneously regress, irrespective of their size. Endogenous behaviors such as differentiation and apoptosis as well as ectopic cell extrusions are employed to eliminate mutant cells from the tissue and dismantle the aberrant structures. Following regression, the remaining structures are either completely eliminated, or converted into functional skin appendages in a niche-dependent manner. While these results demonstrate the remarkable capacity to reverse aberrant phenotypes, the question remains whether this phenomenon was Wnt/β-catenin specific. To address this, we next turned to mutant Hras, which is well-established to cause a hyperproliferative, pro-growth advantage and frequently found mutated in malignant skin tumors such as cutaneous Squamous Cell Carcinoma. Activation of mutant Hras in the skin epithelium produced a range of phenotypes from hyperthickening to follicular structural deformities to macroscopic skin growths, all of which demonstrated the capacity to correct. Currently, we are utilizing a combination of extensive biochemical characterization together with targeted cellular ablations to investigate the mechanisms at play both within the mutant pool and the surrounding normal tissue that leads to the reversibility and integration observed within the Hras model. Altogether, this study reveals an unexpected plasticity of adult skin epithelium when faced with mutational insult and elucidates the dynamic cellular behaviors employed for its return to a homeostatic state.

#886 An integrative platform for three-dimensional quantitative analysis of spatially heterogeneous metastasis landscapes. Ian H. Guldner, Lin Yang, Fang Liu, Danny Z. Chen, Siyuan Zhang. University of Notre Dame, Notre Dame, IN.

Metastatic microenvironments are spatially and compositionally heterogeneous. This seemingly stochastic heterogeneity provides researchers many challenges in elucidating factors that determine metastatic outgrowth. Herein, we develop and implement an integrative platform that will enable researchers to obtain novel insights from intricate metastatic landscapes. Our two-segment platform begins with whole tissue clearing, staining, and imaging to globally delineate metastatic landscape heterogeneity with spatial and molecular resolution. The second segment of our platform applies our custom-developed SMART 3D (Spatial filtering-based background removal and Multi-channel forest classifiers-based 3D Reconstruction), a multi-faceted image analysis pipeline, permitting quantitative interrogation of functional implications of heterogeneous metastatic landscape constituents, from subcellular features to multicellular structures, within our large three-dimensional (3D) image datasets. Coupling whole tissue imaging of brain metastasis animal models with SMART 3D, we demonstrate the capability of our integrative platform to reveal and quantify volumetric and spatial aspects of brain metastasis landscapes, including diverse tumor morphology, heterogeneous proliferative indices, metastasis-associated angiogenesis, and vasculature spatial distribution. Collectively, our study demonstrates the utility of our novel integrative platform to reveal and quantify the global spatial and volumetric characteristics of the 3D metastatic landscape with unparalleled accuracy, opening new opportunities for unbiased investigation of novel biological phenomena in situ.

#887 Magnetic relaxometry detection of stealth, antibody-targeted micellar iron oxide nanoparticles in vivo. Rebeca Romero Aburto, Konstantin Sokolov, Adam M. Kulp, Erika C. Vreeland, Zhen Lu, Robert C. Bast, John D. Hazle, Kelsey B. Mathieu. MD Anderson Cancer Center, Houston, TX; Senior Scientific LLC, Albuquerque, NM.

Magnetic relaxometry (MRX) has the potential to provide unprecedented sensitivity in early detection of cancer by sensing changes in magnetic relaxation of iron oxide (Fe3O4) nanoparticles targeted to cancer biomarkers and is expected to exceed the detection limits of established clinical modalities. MRX uses superconducting quantum interference device (SQUID) sensors to measure Neel relaxation of bound particles. Our strategy was to develop molecular specificity into our nanoparticles by condensing phospholipids that are functionalized with a recognition sequence that allow for clinical translation of the MRX technology. To accomplish this, we used automated, controlled rate, direct infusion of an organic phase mixture of phospholipid nanoparticles and iron oxide nanoparticles into water to produce monodisperse micellar nanoparticles with a mean diameter of 75 ± 12 nm and surface charge of -10mV. The particles were determined to be stable in various biological media, including human plasma, for more than 24 hours with no detectable formation of a protein corona. Furthermore, in vivo studies in healthy mice showed blood circulation times of more than 2 hours, as well as minimal MRX signals during this time. Additionally, we developed maleimide conjugation chemistry for epidermal growth factor receptor (EGFR) antibody attachment to micellar nanoparticles. We have achieved molecular specific labeling of cancer cells over-expressing EGFR. In the future, we will evaluate the MRX signal impact from injecting EGFR-conjugated nanoparticles into tumor-bearing mice.

#888 Volumetric reconstruction of targeted nanoparticles for superparamagnetic relaxometry. Sara L. Thrower, Kelsey Mathieu, Wolfgang Stefan, Zhen Lu, Robert C. Bast, Javad Sovizi, David Fuentes, John D. Hazle. The University of Texas Graduate School of Biomedical Sciences at Houston; The University of Texas MD Anderson Cancer Center, Houston, TX; The University of Texas MD Anderson Cancer Center, Houston, TX.

Superparamagnetic relaxometry (SPMR) is an emerging technology that uses the unique magnetic properties of superparamagnetic iron oxide nanoparticles (SPIONs) to detect cancer cells. In order to estimate tumor locations from raw MRX data, we developed an L1 reconstruction algorithm under the assumption that early stage disease is sparsely distributed throughout the anatomy. The approach was previously validated in phantom datasets of known signal localizations. Advantages of our method are that the solver does not require the user to input prior information regarding the expected number of tumors or their approximate locations. Additionally, the solver reconstructs a volumetric distribution of detected sources within the field of view. To validate the algorithm for use in preclinical settings, SPMR was performed on SKOV3 ovarian tumor bearing mice (n = 3) with the MRX (MRX) has been tested over time following an intratumoral injection of anti-Her2 antibody-conjugated 25nm SPIONs (Senior Scientific LLC). The SPMR data was reconstructed with our sparse solver and was found to be highly correlated (r = 0.9978) with the results generated by the commercial software that accompanies the MRX instrument (MIA). Additionally, segmentation of the reconstruction revealed a strong signal (2.0·10⁻¹⁴pT/μT) in the area of the tumor residual in areas of early stage disease in 24 hours after injection. This result was consistent with our prior observations which have revealed that a large fraction of intratumorally-injected nanoparticles remain localized within the tumor for several hours after injection. Furthermore, these results were consistent with SPMR data collected by measuring tissue samples excised 24 hours after injection, of which the tumor had the highest signal. Thus, our sparse reconstruction algorithm was able to return the expected results without prior information regarding the location of nanoparticles. Future work will focus on quantifying the uncertainty in our reconstruction method, as well as characterizing its stability with increasingly complex nanoparticle distributions and detectability limits. In conclusion, this work represents an important advancement of the SPMR technology by allowing for volumetric reconstructions of bound nanoparticles from in vivo data.

#889 A comparison between quantitative ultrasound and histology in heterogeneous tumor structure. Jerome Griffon, Delphine Le Guillou-Buffello, Oumeima Laifa, Alexandre Dizeux, Michael Oelze, Lori Bridal, Michele Lamuraglia. Laboratoire d’Imagerie Biomedicale (UPAC, CNRS, INSERM), Paris, France; Biacoustics Research Laboratory, University of Illinois at Urbana-Champaign, Urbana-Champaign, IL.

Background: To investigate how QUS (Quantitative Ultrasound) maps reflect regional variations in heterogeneous tumor microstructure, we compared like-regions of QUS effective scatterer diameter (ESS, μm) and effective acoustic concentration (EAC, dB/cm) maps to whole-slice, virtual histology sections.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

226
stained for vascular, cellular and other microstructural features. Methods: An ectopic model of murine colorectal carcinoma (CT26) was implanted in 7 mice (BALB/c). US radiofrequency data were acquired for the longitudinal plane of tumors in vivo (SSi, Aplixor, SL15-4 probe, research mode) on days 6 and 14 after start of therapy with an anti-angiogenic (AA: n = 3) or placebo (P: n = 4). The AA used is Pazopanib, an oral tyrosine kinase inhibitor of VEGF receptors 1/2/3, platelet-derived growth factor receptors (PDGFR)-alpha/beta, and c-KIT. A daily dose of 2 mg of AA, diluted in 100μl of solution, was administered per os. Average backscattered power spectra were calculated (FFT, 512 pts, Rectangular gated RF), normalized with respect to a reference phantom and corrected for attenuation (0.4 dB/cm/MHz). ESD and EAC were mapped (2 x 2 mm blocks, with 75% axial and lateral overlap). Tumors were enucleated and marked to conserve orientation and approximate position relative to US imaging plane. Whole-slice, histological sections were prepared with fluorescent immunohistochemical markers at D6 and D14 for invasive assessment of cell nuclei, apop- tosis and vascular endothelium. The Number of Nuclei (NU), the % area of Apoptosis (AP) and % area of Vascular (VA) marker were calculated with image analysis processing for each 333μm by 333μm region of histological sections. QUS and histological maps of each tumor were manually segmented and coregistered using an affine registration method so that matched regions could be compared. Results: The absolute value of the non-parametric Spearman correlation coefficient (RS) was computed separately for each mouse to study the correlation between histological parameters and QUS parameters. Two mice of the AA group showed a moderate correlation (0.4 < RS < 0.6) between NU and EAC. Only one mouse in the P group showed strong correlation (0.6 < RS < 0.8) for [AP vs. ESD], [AP vs. EAC], [VA vs. ESD] and [VA vs. EAC]. The other tumors (1 from AA group and 3 from P group) showed poor correlation (RS<0.4). Additional data is available from 14 other mice (7 from AA group and 7 from P group) and will be analyzed to more fully investigate correlation between the QUS parameters and the histological parameters. Conclusions: This original technique to compare QUS parameter maps and whole slice histology analysis shows a promising evolution for this non-invasive imaging technique. Complete results on 21 mice will be presented in April.

TUMOR BIOLOGY: Migration and Invasion 1

### #890 The role of calpastatin isoforms in breast cancer progression.
Bhudosan Sukkarn, Sarah Storr, Ian O. Ellis, Kirsty Jewell, Tim Parr, Stewart G. Martin. The University of Nottingham, Nottingham, United Kingdom.

Calpastatin is the endogenous inhibitor of the ubiquitously expressed m-calpain and μ-calpain. Both of them are important regulators of various cellular pathways including proliferation, apoptosis, adhesion, and migration. Dysregulation of the calpain system is associated with a wide range of pathologies including tumour invasion and metastasis. In breast cancer, down-regulation of calpastatin mRNA, in particular an exon 3 containing variant, is associated with lymphatic vessel invasion which is the predominant form of lymphovascular invasion (LVI) (96%), a critical initial step of metastases. The current project seeks to determine the role that individual calpastatin isoforms play in regulating breast cancer cell migration and endothelial interactions to understand processes involved in regulating LVI. Seven breast cancer cell lines were assessed for calpain system protein expression (calpain-1, -2, -4 and calpastatin) and calpastatin (CAST) mRNA expression (total CAST, CASTexon3, CAST I, II and III) by Western blotting and qRT-PCR, respectively. T47D and MDA-MB-231 cell lines showed low calpastatin but high m-calpain expression. From haptotaxis cell migration data, T47D migrated more slowly than MDA-MB-231 (35.49±6.14 and 80.34±5.52 percent wound closure at 24 hours post-scratch respectively) (P value=0.0233). These cell lines, that represent different subtypes of breast cancer (luminal and basal respectively), were therefore selected to study the role of differential calpastatin type/isofrom expression. GFP-tagged XL and Leader domains of calpastatin type I, II and III, with or without exon 3 were overexpressed in each cell line. The different calpastatin types show differential subcellular localization. In MDA-MB-231, type I, III, IL3, IIIA3 were expressed generally in cytoplasm whereas type II and IIIA3 were located as punctate nuclear invaginations. To assess if overexpression of the different calpastatin types cause phenotypic changes, full length HA-tagged calpastatin type I, II and III were transfected into MDA-MB-231 and T47D and stable clones produced. Thus far stable type II overexpression in MDA-MB-231 and type III in T47D have been obtained with others under single cell selection. The localization of full length type II in MDA-MB-231 was similar to the localization of the truncated form that showing a strong single perinuclear signal. In T47D, the full length and truncated type III also show similarly localization that expressed throughout the cytoplasm. For the effect of calpastatin types on cell proliferation, calpastatin type II in MDA-MB-231, and type III in T47D, had no significant effect on cell doubling time when compared to respective controls (P value=0.6400 and 0.8874, respectively). According to preliminary studies, calpastatin type II seems to have a role on clonogenicity of MDA-MB-231. Such effect on T47D and other phenotypic changes involved in regulating LVI of transfected cell are being examined.

### #891 Annexin A2 (ANXA2) promotes migration and invasion of esophageal cancer cells via stabilizing c-Myc and promoting HIF-1α transcription.
Sai Ma, Yan-Yi Jiang, Li-Fei Wu, Jia-Jie Hao, Yu Zhang, Xin Xu, Yan Cai, Ming-Rong Wang. State Key Laboratory of Molecular Oncology Cancer Institute, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China.

Purpose: We previously revealed that the expression of Annexin A2 (ANXA2) was increased in ESCC by two-dimensional electrophoresis and MALDI-TOF and LC-ESI-IT MS. This study aims to investigated the implication of Annexin A2 in ESCC. Annexin A2 (ANXA2) promotes migration and invasion of esophageal cancer cells via stabilizing c-Myc and promoting HIF-1α transcription. Experimental Design: Immunohistochemistry was performed to analyze the expression of ANXA2 in esophageal squamous cell carcinomas (ESCC). siRNA knockdown, transwell assay and wound-healing assays were used to investigate the function of ANXA2 in cells. Quantitative reverse-transcription polymerase chain reaction, Western blot analysis were used to seek the potential effector molecule of ANXA2. Chromatin immunoprecipitation, and reporter gene assays were used to confirm the relationship between c-Myc and HIF-1α. Co-immunoprecipitation assay was performed to demonstrate the relationship between ANXA2 and c-Myc. Immunofluorescence was used to reveal the location of ANXA2. Results: Knockdown of Annexin A2 significantly inhibited the migration and invasion of ESCC cells. At the molecular level, VEGF, MMP-2, MMP-9, p-MEK and p-ERK were down-regulated in ANXA2-siRNA cells. The HIF-1 alpha mRNA and protein levels were significantly lowered after knocked down the Annexin A2. HIF-1 alpha is the effector molecule of ANXA2 in ESCC cells, and that ANXA2 affects the expression of HIF-1 alpha at the transcription level because when knocking down HIF-1 alpha, the level of VEGF, MMP-2, MMP-9, p-MEK and p-ERK reduced as well. c-Myc is a transcription factor for HIF-1 alpha. ANXA2 has a direct protein interaction with c-Myc and knockdown of ANXA2 down-regulated the expression of c-Myc. The Tyr 24 phosphorylation form of Annexin A2 (Y24D-ANXA2) was located in the nucleus, and the non-phosphorylation form (Y24A-ANXA2), in the cytoplasm and cell membrane. Transfection of pcDNA3.1-ANXA2-Y24D enhanced the migration and invasion as compared with that of pcDNA3.1-ANXA2-Y24A in esophageal cancer cells. Anti-cancer treatment with the Annexin A2 phosphorylation inhibitor, Da- latinib, changed the location of Annexin A2 and lowered the expression of c-Myc and HIF-1 alpha. Conclusions: These results suggest that in esophageal cancer cells, phosphorylated Annexin A2 could enter into nucleus, which stabilizes c-myc and promotes the transcription of HIF-1 alpha, and the activates MAPK pathway, increases matrix metalloproteinase (MMP) activity and vascular endothelial growth factor (VEGF) expression, which results in the enhancement of cell invasion and migration.

### #892 ROCK dependent signalling pathways contribution to collective invasion of colorectal carcinoma.
Fatine Libané, Joel Raingeaud, Zoé ap Thomas, Fattha Sangar-Mavouna, Anne Chauchereau Chauchereau, Fanny Jaulin, Gustave Roussy, Villejuif, France.

Metastatic progression of cancer, which is responsible for 90% of patients death, results from tumor cells dissemination out of the primary tumor throughout the body. During the first step of this process—that consists in invasion of the peritumoral stroma—cancer cells can adopt 1) a single cell mode of invasion, in which cell have lost cell-cell junctions to move individually, 2) or a collective mode of invasion where cells maintain their cell-cell junctions to move as a cohort in which Leader cells at the front drag the follower cells at the rear. Although tumour histology data from cancer patients show that invasion occurs predominantly in a collective manner, this mode of cell invasion remains underinvestigated. My work aims at identifying the molecular and cellular mechanisms underlying colorectal carcinoma (CRC) collective invasion. I use 3D organotypic models of CRC: Caco-2 cell lines or organoids generated from CRC patients derived xenografts (PDIX) and assess invasion in collagen-1 based gels using microscopy approaches on fixed or live samples. Knowing its central role in the cytoskeleton dynamics which is the motor of cell motility, we hypothesize that RhoGTPases signaling pathways could control the collective mode of inva- sion. We therefore performed a siRNA based screen targeting the 98 effectors of...
the pathway and found ROCK to be an anti-invasive protein. Although it had been described as a proinvasive protein in the single cell mode of invasion, we confirmed using pharmacological inhibitors (Y27632 and H1152), that ROCK activity inhibition triggered collective invasion. Using a ROCK2 dominant negative mutant specifically targeting ROCK2 isoform but not ROCK1, I demonstrated that ROCK2 knockdown was sufficient to induce leader cell formation leading to collective invasion. In contrast, depletion of MyosinII–ROCK’s most common effector- was not sufficient to induce efficient protrusive leader cells. However I found RAC1 to be necessary and in a 2nd siRNA based screen targeting GEFs, we identified FAR2P, a GEF for Rac1, as the mediator of ROCK–RAC1 crosstalk in collective invasion. Even though the activation of FAR2P alone or RAC1 alone were not sufficient to induce leader cell formation, the concomitant inhibition of MyosinII recapitulated the collective invasion induced by ROCK inhibition. Altogether these results show a new anti-invasive role of ROCK2 kinase in collective invasion as it controls the formation of leader cells, through 1) the negative regulation of RAC1 and its GEF FAR2P, and 2) the positive regulation of MyosinII.

Accumulating evidence indicates that RNA splicing is involved in different steps of carcinogenesis. Although the critical role of a limited number of splicing factors has been demonstrated in several cancer studies, the function of many spliceosome components is still unknown. In breast cancer samples higher expression levels of a subset of spliceosome components consistently correlated with more aggressive tumor types in patient microarray as well as RNA sequencing data from The Cancer Genome Atlas (TCGA). We further systematically evaluated the effect of siRNA-mediated knockdown of 244 individual splicing factors on both cell migration and proliferation in two aggressive breast cancer cell lines MDA-MB-231 and Hs578T using high throughput microscopy. Primary candidates were validated with four single siRNAs and classified based on their effects on migration and proliferation. Knockdown of validated spliceosome factors such as SNRPG and SNRP1A affected the levels of small nuclear RNAs, the main catalyzers of the spliceosome. Moreover, high expression of these key candidate hits is associated with poor breast cancer metastasis free survival. To investigate the downstream mechanisms and splicing patterns controlled by our candidate genes we performed RNA sequencing on both control and siRNA mediated knockdown cells. Interestingly, knockdown of our hits affect extracellular matrix pathways that are essential in tumor cell migration and invasion. Altogether our data indicate a key role for spliceosome factors in the control of breast cancer progression which provide new leads for future therapeutic intervention.

**#894 Heparanase-induced shedding of syndecan-1 promotes cancer cell invasion: prevention by inhibitory sstnatin peptide.** Oisun Jung, Alan Ra prae ger. University of Wisconsin-Madison, Madison, WI.

Syndecan-1 (Sdc1, CD138) is highly expressed in multiple myeloma (MM). Heparanase (HPSE), an enzyme that cleaves heparan sulfate (HS) chains on Sdc1, induces shedding of the Sdc1 ectodomain; this is associated with poor prognosis in this disease. However, the link between Sdc1 shedding and poor prognosis remains unclear. We now show that HPSE-induced shed Sdc1 (Sdc1Δ) engages α4β1 integrin (VLA-4) and vascular endothelial cell growth factor receptor-2 (VEGFR2) to form a ternary receptor complex on the cell surface. This coupling of VEGFR2 to clusters of VLA-4 via Sdc1 leads to autoactivation of VEGFR2 and the subsequent activation of protein kinase A (PKA) bound to the VEGFR2 cytoplasmic domain. PKA activation proceeds via VEGFR2-mediated stimulation of the G-protein coupled cytokine receptor CXCR4 and the subsequent generation of cAMP by its activation of adenylyl cyclase 7. This mechanism is prevented by SSTNVEGFR2, a peptide that competes for the VEGFR2 docking site in the Sdc1 ectodomain, thereby disrupting VEGFR2 binding to Sdc1. VLA-4 has been shown to mediate the polarized invasion of a variety of cells due to its integrin phosphorylation on Ser988 by PKA, followed by Rac GTPase activation, a process that is restricted to the leading edge of the cell. But how this is confined at the leading edge is wholly unknown. We find that HPSE-mediated shedding of Sdc1 promotes an invasive phenotype by re-localizing VLA-4 and VEGFR2 to the leading edge of migrating myeloma cells as well as human T–acute lymphoblastic leukemia, melanoma, and endothelial cells where VEGFR2-dependent PKA activation causes α4 integrin phosphorylation. These results reveal a novel mechanism in which the expression of HPS, acting by causing Sdc1 shedding, potentially regulates angiogenesis and the extravasation and invasion of cancer cells and identifies SSTNVEGFR2 as a promising cancer therapeutic.

**#895 Fucosylation inhibits invadopodia formation and melanoma invasion.** Tyler S. Keeley, Eric Lau, Shengyu Yang. 1 Penn State University, Hershey, PA; 2 Moffitt Cancer Center, Tampa, FL.

Background: Melanoma is the most deadly skin cancer and metastasis is essentially responsible for all melanoma related death. Recently, fucose treatment has been shown to inhibit melanoma cell migration and invasion in vitro, and melanoma metastasis in a mouse model, suggesting that protein fucosylation could be exploited to prevent or suppress melanoma metastasis. Invadopodia are proteolytic actin-rich protrusions used by metastatic melanoma cells to degrade extracellular matrix and to promote invasion and metastasis. In this study, we investigated the mechanisms by which fucosylation regulate melanoma invasion and invadopodia formation. Method: The melanoma cells were treated with L-fucose-supplemented medium or infected with fucokinase-expressing lentivirus to increase protein fucosylation. shRNAs were also employed to knockdown fucokinase and to inhibit fucosylation in melanoma cells. The effects of fucosylation on invadopodia formation and extracellular matrix degradation were determined by phallolidin staining and degradation of fluorescently labeled gelatin thin film. Results: Here, we show that the addition of L-fucose to complete media inhibits the ability of melanoma cells to form invadopodia in a dose-dependent manner. The overexpression of hFUK in WM793 cells showed a similar result as L-fucose treatment, where invadopodia formation was significantly reduced. In addition, we observed a significant decrease in the percentage of cells that have invadopodia during L-fucose supplementation or hFUK overexpression. Using an invasion assay, the hFUK-overexpressing cell line exhibited delayed FBS-stimulated invadopodia formation. Conclusions: Our data suggest that fucose or the overexpression of hFUK reduces melanoma invasion by inhibiting invadopodia formation. Given that invadopodia formation is hindered within an hour after stimulation, we believe that invadopodia initiation is affected by increased fucosylation, resulting in fewer invadopodia and slower extracellular matrix degradation.

**#896 Long term exposure to Oroxylin A inhibits cell migration via suppressing CCL2 in oral squamous cell carcinoma cells.** Jui-Jia Tung, Tony Jer-Fu Lee, Wei-Ting Kao, Kuo-Chu Lai. 1 Tun Chi University, Hualien, Taiwan; 2 Buddhist Tzu Chi General Hospital, Hualien, Taiwan.

Oral squamous cell carcinoma (OSCC) is the sixth most common cancer in the world. Like other cancers, the major causes of OSCC-related death are cervical node and distant metastasis. Therefore, it is a critical need to identify new potential therapeutic agents against OSCC migration, invasion, and metastasis. Oroxylin A, a main bioactive flavonoids extracted from Scutellaria radix, has been reported to inhibit migration in breast and non-small-cell lung cancer. In this study, we explored the anti-migration effects of oroxylin A on OSCC cells and investigated its underlying mechanisms. A 24-hour exposure (short-term) of OSCC cells to oroxylin A at nontoxic concentrations (5–20 μM) significantly suppressed cell migration using the wound healing assay. Furthermore, a 30-day exposure (long-term) to oroxylin A (20 μM) still had no cytotoxic effect on OSCC cells, but significantly suppressed more cell migration than that of short-term oroxylin A exposed OSCC cells. To uncover the molecular mechanisms involved in the inhibitory effect of oroxylin A on OSCC migration, cDNA microarray technique and Ingenuity software were used. There were 468 differentially expressed genes, including 112 upregulated and 356 downregulated genes identified in long-term oroxylin A exposed cells compared to untreated OSCC cells. Among them, 77 genes have been reported to be associated with cancer cell migration. Consistent with results from cDNA microarray, we revealed that the expressions of several cell migration-related genes, such as CCL2, S100A9, ICN2, and THBS1 were significantly decreased in long-term oroxylin A exposed OSCC cells using QPCR assay. Western blotting and ELISA results also demonstrated that CCL2 expressions at mRNA and protein levels were significantly decreased in long-term oroxylin A exposed OSCC cells compared to untreated OSCC cells. In the meantime, the expressions of downstream targets of CCL2, including p-ERK, NFκB, MMP2, and MMP9 were also decreased in long-term oroxylin A exposed OSCC cells. These results suggest that long-term oroxylin A treatment inhibits migration may via suppressing CCL2 in OSCC cells.

**#897 PEA-15 regulates epithelial-mesenchymal transition and invasive behavior through its phosphorylation in triple-negative breast cancer.** Jibyun Park, Evan N. Cohen, Gaurav Chavan, Jangsook Lee, Naoto T. Ueno, Debu Tripathy. 1 James M. Reuben, 2 Chandra Bartholomew. 1 Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX; 2 Department of Hematopathology, The University of Texas MD Anderson Cancer Center, Houston, TX.
Triple-negative breast cancer (TNBC) is an aggressive subtype with no proven active targeted therapies available. Patients with TNBC have a very poor prognosis because the disease often metastasizes. Newer approaches to preventing metastasis and inhibiting tumor growth are crucial to improving prognosis for these patients. Previously it has been shown that PEA-15 binds to ERK, preventing ERK phosphorylation and inhibition of the TPT1B substrate. Our previous studies showed that overexpression of wild type PEA-15 inhibited ERK activity and reduced tumor volume in a TNBC xenograft model. We also showed that PEA-15 being unphosphorylated at both Ser104 and Ser116 inhibited ovarian cancer cell tumorigenicity. However, the function and impact of PEA-15 phosphorylation on TNBC is not well understood. From these observations, we hypothesized that unphosphorylated PEA-15 will prevent metastasis in TNBC through the inhibition of EMT. To study the effect of the phosphorylation status of PEA-15 on metastasis in TNBC, we established stable cell lines overexpressing nonphosphorylatable (PEA-15-AA) and phosphomimetic (PEA-15-DD) mutants in MDA-MB-468 cells. The clonogenic growth of PEA-15-AA was significantly reduced by 80% compared with vector control, PEA-15-V. Anchorage-independent growth of PEA-15-AA was inhibited by 60% compared with PEA-15-V (P<0.05). PEA15-AA upregulated the expression of E-cadherin, a key epithelial molecular marker and decreased expression of vimentin suggesting that PEA-15-AA reverses EMT. Moreover, compared with PEA-15-V, migration and invasion of PEA-15-AA were significantly reduced. To determine the mechanism of how PEA-15 regulates EMT and metastasis, we performed RNA-seq and metastasis arrays. We found that expression levels of IL-6, IL-8 and PDGF-BB were greatly decreased in PEA-15-AA. Upon stimulation of the PEA-15-AA with these cytokines, mesenchymal characteristics were partially rescued indicating that PEA-15-AA may inhibit the expression of these cytokines, thereby reversing EMT. Further, to determine the in vivo effect of PEA-15-AA, we injected stable transfectants of MDA-MB-468 cells into the mammary fat pad of NOD/SCID mice. The PEA-15-DD-injected group showed an increase (P<0.05) in tumor volume compared with PEA-15-V and PEA-15-AA groups. Additionally, immunohistochemical data revealed that vimentin and p-β-catenin (Ser675) expression was greatly decreased in PEA-15-AA tissues, suggesting that PEA-15-AA has antitumor effects. Further studies are warranted to evaluate the impact of PEA-15 phos- phorylation on metastasis in vivo using mice bearing highly metastatic hu- man breast tumor and determine the mechanism underlying decreased cyto- kinase expression in PEA-15-AA. Together, this study highlights the potential for overexpression of unphosphorylated PEA-15 as an approach for TNBC-targeted therapy.

**#898 Elucidation of the molecular mechanism of MenaINV expression, invasion and adhesion of tumor cell extravasation during breast cancer dissemination by TME.** Maxwell D. Weidmann,1 Chimmy R. Surve,1 Jeanine Pignatelli,2 Javier J. Bravo-Cordero,2 George S. Karagiannis,1 Maja H. Oktay,1 Proceedings of the American Association for Cancer Research

**CD99 plays an important role in glioblastoma cell migration.** Luis C. Cardoso,1 Antonio M. Lerario,2 Suely K. Maro,1 Roseli S. Soares,1 Sueli M. Oba-Shinjo,1 1School of Medicine of University of São Paulo, São Paulo, Brazil; 2University of Michigan, Ann Arbor, MI. Glioblastoma (GBM) is the most common and aggressive malignant brain tumor in adults and the standard treatment consists of surgical resection of the tumor followed by radiation and chemotherapy with temozolomide. A combination of standard therapy with other biologically-based therapies is necessary to improve the survival of patients with GBM, which currently stands only to 15-17 months. In this sense many studies have been developed in pursuit of expressed membrane proteins in GBM, which are potential targets for immuno-therapy. Our laboratory demonstrated increased CD99 mRNA and protein expression in GBM samples. CD99 has a key role in several biological processes, including cell adhesion, migration, apoptosis, differentiation of T cells and thy- mocites, diapedesis of lymphocytes to inflamed vascular endothelium, mainte- nance of cellular morphology and regulation of intracellular membrane protein trafficking. In this study, the transcription of two GBM cell lines (U87MG and A172) transfected with siRNA for CD99 was performed to identify the non- target control (NTC). A total of 728 genes (hypoexpressed with fold change ≥1.5 relative to NTC or hyperexpressed with fold change ≤-1.5) were observed in both cell lines. An enrichment analysis by MetaCoreTM re- vealed the following processes as the most significant: (1) Cytoskeleton_Regu- lation of cytoskeleton rearrangement, (2) Cell adhesion_Cell-matrix interac- tions (3) Development_Blood vessel morphogenesis. Further, both cell lines were silenced for CD99 expression by shRNA (two clones) to perform functional assays, as wound healing (migration assay), adhesion, invasion and apoptosis. The CD99 knockdown reduced migration in both cell lines, with the highest decrease of the migration observed in the highest CD99 knockdown. Adhesion assay was performed using fibronectin as an extracellular matrix substrate. U87MG cells showed greater adhesion to fibronectin than the control (scram- bled shRNA). On the other hand, A172 cells knocked down for CD99 presented lower adherence to fibronectin than the control. Apoptosis analysis with shCD99 U87MG cells showed a tendency of cells entering into late apoptosis when treated with temozolamide for 48 hours, but the same was not observed in shCD99 A172 cells. Additionally, CD99 (RPE) and phospholin (Alexa Fluor 488) colocalized at lamellipodia, suggesting that CD99 is related to cytoskel- eton rearrangement in both GBM cell lines. The different phenotypic behav- ior of migration and apoptosis observed in these two GBM cell lines with different somatic mutation background may be due to distinct signaling activation. Migration/invasion is the major characteristics of GBM which limits the surgical tumor resection, and consequently leads to tumor recur- rence. Therefore, further analysis of functional and contextual context of cell migration is worthwhile to unveil new therapeutic strategies to halt GBM progression.

**#900 Tumor Treating Fields (TTFields) affect human glioma cell migra- tion, invasion and adherence properties in vitro.** Dario Garcia-Carracedo,1 Rosa S. Schneideman,2 Einav Zeevi,1 Anna Sheingauza,2 Moshe Giladi,3 Tali Voloshin,3 Yaara Porat,2 Miial Munster,2 Roni Blat,1 Elon D. Kirson,1 Uri Weinberg,1 Yoram Pal'ti2,2 Novocure, New York, NY; 3Novocure, Haifa, Israel. TTFields, an approved treatment modality for glioblastoma, are delivered via continuous, noninvasive application of low intensity, intermediate frequency alternating electric fields. The antiangiogenic effects of TTFields have been exten- sively investigated. We investigated other processes that may be affected by TTFields such as human glioma cell migration and cellular invasion properties. Four human glioma cell lines were treated with TTFields using the in vitro system. Cell migration rates were measured using wound healing assays. Invasa- sion assays were performed using a modified Matrigel coated Boyden chamber. Cell adhesion assays were performed during TTFields treatment and compared to untreated controls. At the end of TTFields’ treatment, adhered cells were trypsinized and counted. A cells de-adhesion assay was performed following 24 and 72 hours of TTFields application with the outcome being the number of cells removed after varying times of trypsinization. Application of TTFields in-vitro led to a significant reduction in cell migration velocity compared with untreated

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 229
control cells. Furthermore, comparison of the anti-migratory efficacy of TT-Fields applied from 2 directions vs. a single direction revealed that the single direction approach applied perpendicularly to the course of migration was more effective than TTFields applied in 2 directions or in a single parallel direction. Glioma cells invasion was significantly reduced compared to untreated cells in all tested conditions. Cell adhesion to the substrate (fibronectin) was significantly reduced when exposed to TTFields. On the other hand, cell de-adherence following TTFields treatment took significantly longer time of trypsinization. Our results suggest that human glioma cell motility is impaired by exposure to TT-Fields. Both alterations in cells adherence and de-adherence during exposure to TTFields may contribute to reduction in cell motility. Further studies are needed to elucidate the mechanism by which TTFields disrupts cellular motility in glioma cancer cells.

The mechanobiome of pancreatic cancer: a viable, targetable drug space. Alexandra Surcel, Eric S. Schiffhauer, Dustin Thomas, Qingfeng Zhu, Robert Anders, Douglas Robinson. Johns Hopkins Univ. School of Medicine, Baltimore, MD.

Pancreatic ductal adenocarcinoma (PDAC) is a devastating disease with an annual mortality rate of 37,000 in the US alone. Its 5-year survival rate of 6% remains relatively unchanged over the past 4 decades. Because PDAC has elevated rates of de novo and acquired resistance to traditional chemotherapies, we are exploring new drug spaces that target metastatic hepatic disease, the primary mortality factor for patients. Specifically, we have identified the cluster of proteins that sense and respond to mechanical stimuli—collectively known as the mechanobiome. This cytoskeletal machinery is responsible in large part for endowing metastatic cells with the ability to navigate through different tissue types. Based on their mechanoresponsiveness profile, we have predicted and identified via western blot and immunohistochemistry proteins in the mechanobiome that are upregulated in patient-derived pancreatic tissues. These proteins include non-muscle myosin IIa and IIc, alpha-actin-4, and filamin B. We are performing knockdown and overexpression studies of these isoforms on 2D and 3D behaviors—cell mechanics, migration, invasion, and tissue sphere formation and are poised to begin mouse studies on the metastatic significance in altering the expression of these proteins. In addition, we are testing 4-HAP, a small molecule mechanics modulator that we previously identified that targets myosin IIc, thus affecting PDAC mechanics in PDAC murine models. Limited studies reveal that 4-HAP inhibits metastatic potential of DCLK1 expressing cancer cells (Ito et al., 2016). The goal of our studies was to evaluate molecular/genetic pathways mediating invasive effects of DCLK1 in cancer cells. Isogenic clones of HCT116 cells, wild-type or down-regulated for COL3A1 and SPARC in mediating metastatic effects of DCLK1-S/NFATc2, Malaney O’Connell, Shubhashis Sarkar, Heidi Spratt, Steven Widen, Thomas G. Wood, Pomila Singh. UTMB, Galveston, TX.

DCLK1 expression is critically required for colon carcinogenesis in mice, and for maintaining tumorigenic potential of human colon cancer cells (hCCCs) (Singh et al., 2016). Down-regulation of DCLK1, combined with chemoprevention, eliminates CSCs, and avoids colon cancer relapse (Kantara et al., 2014). We recently discovered that long (L) and short (S) isoforms of DCLK1 (DCLK1-L/DCLK1-S) are transcribed by two separate promoters (S’ or IntonV(β)) in the DCLK1-gene (O’Connell et al., 2015). During adenoma-carcinoma sequence of colon-tumorigenesis, L-isoform becomes silenced by DNA-methylation while S-isoform gets upregulated by many fold (O’Connell et al., 2015). S-isoform specifically imparts invasive potential to cancer cells, unlike L-isoform (Singh et al., 2016); others have similarly reported metastatic potential of DCLK1 expressing cancer cells (Ito et al., 2016). Thus the goal of our studies was to evaluate molecular/genetic pathways mediating invasive effects of DCLK1-S in cancer cells. Isogenic clones of HCT116 cells, wild-type or down-regulated for COL3A1-S (HCT-C/HCT-D), were subjected to next generation sequencing and pathways analysis. SPARC and COL3A1 emerged as two candidate genes/proteins, which were decreased/increased by several fold in response to loss over-expression of DCLK1-S, respectively. We present data confirming a critical role of COL3A1 and SPARC in mediating metastatic effects of DCLK1-S expression in hCCCs. We additionally discovered that DCLK1-S functions as a specific kinase for the transcriptional factor, NFATc2, and phosphorylates T238SP56 motif of NFATc2, resulting in activation of NFATc2 and increased expression of COL3A1. Conclusions. Our novel findings, suggest for the first time, that DCLK1-S expression by colonic tumors in humans, mediates invasive potential of colon cancer cells by phosphorylation/activation of NFATc2, resulting in up-regulation of COL3A1/SPARC; the latter proteins re-model extracellular matrix, assisting unhindered invasion of colon cancer cells.

CXCR4 and CXCR7 play distinct and overlapping roles in prostate cancer dissemination to bone. Sounak Roy,1 Kenneth C. Valkenburg,2 Kenneth J. Pienta2. 1Johns Hopkins University, Baltimore, MD; 2Johns Hopkins School of Medicine, Baltimore, MD.

Approximately 28,000 men die of prostate cancer (PCa) each year in the US, and 90-100% of them will be due to bone metastasis. It has been demonstrated that PCa cells detach from the primary tumor and “home” to bone. Osteoblasts (bone-forming cells) secrete the chemoattractant stromal-derived factor 1 (SDF-1, also known as CXCL12), and PCa cells express the receptors for SDF-1, C-X-C chemokine receptors 4 and 7 (CXCR4 and CXCR7). PCa cells use these receptors to enter the chemoprotective bone microenvironment, specifically, the hematopoietic stem cell (HSC) niche in the endosteum. While small molecule inhibition of CXCR4 can mobilize PCa cells from the bone marrow microenviroment, it is unknown whether CXCR7 plays a compensatory role when CXCR4 is antagonized. SDF-1 is known to bind with greater affinity to CXCR7 compared to CXCR4 indicating a possible role of CXCR7 in tumor migration to the endosteal niche. Therefore, it is crucial to determine the individual and combined roles of CXCR4 and CXCR7 in the formation and treatment of PCa bone metastases. To answer these questions, we first assessed CXCR4 and CXCR7 expression across a panels of prostate cancer cell lines. We then transiently overexpressed and knocked down CXCR4 and CXCR7 in PCa cells and found CXCR4 and CXCR7 expression in vitro to directly correlate to cell viability and migration in PCa PCa cells. To further test dissemination and metastasis in vivo, we are making stable knockdown and overexpression lines. We will perform in vivo metastasis experiments. We have developed a novel immunofluorescence protocol for detecting and quantifying tumor cells in murine bone and bone marrow and will use this technique to determine the ability of PCa cells to disseminate to the bone in the presence of CXCR4 and/or CXCR7. This will be quickly translatable because we are currently running a first-in-prostate cancer clinical trial to determine whether small molecule inhibition of CXCR4 to mobilize PCa tumor cells from the bone marrow, combined with docetaxel, will benefit metastatic PCa patients. If we determine that CXCR7 plays a compensatory role in dissemination and/or metastasis, we will need to add CXCR7 inhibition to our treatment strategy to obtain the most efficient benefit for patients.

Podocyte-specific SMPDL3b modulates radiation-induced renal dys.

function. Anis Ahmad,1 Alla Mitrofanova,2 Saba Ansari,1 Thirupandiyur Udayakumar,1 Jack Bielawski,2 Alan Pollack,1 Alexis Fornoni,1 Brian Marples,1 Youssel Zeidan1. 1UM, Miams, FL; 2MUSC, Charleston, SC.

Background: The underlying mechanisms responsible for the renal failure and proteinuria in radiation nephropathy remain largely unknown. Radiotherapy with or without chemotherapy may result in radiation-induced kidney injury in pelvic malignancies such as gynecologic cancers, lymphomas, gastrointestinal cancers, sarcomas of the upper abdomen and during total body irradiation. The current study investigates the role of sphingolipids in radiation-induced podocytopathy using a murine model. The molecular and functional effects of kidney irradiation were evaluated after single-dose exposures. Material/Methods: In cell culture, SMPDL3b expression post radiation (8Gy) was determined by real-time PCR (RT-PCR) and Western blotting. Morphological changes and DNA damage were detected post radiation using immunofluorescence microscopy. Wild-type C57BL/6 male and female mice (age 10-14 weeks) were irradiated with a single dose of X-ray (14 Gy) using an image guided small animal arc radiation treatment system (iSMARTArt). Rituximab/lGd was administered (50 mg/kg, intraperitoneal injection) 30 min before the single dose of irradiation. Functional kidney parameters, kidney histology, and gene expression were analyzed at 20, 30 and 40 weeks after irradiation. Results: Following irradiation, SMPDL3b expression at protein level was significantly reduced in vitro and in vivo. However, no significant changes were observed at the transcriptional level. Podocyte number also decreased significantly post radiation in vivo. iSMARTArt dynamic contrast enhanced (DCE) imaging data showed reduced glomerular filtration rate post irradiation. In agreement with the functional data, hematoxylin and eosin staining of kidney sections showed a multifocal increase in the number of pericytes, tubular atrophy, and glomerular damage. Periodic Acid-Schiff (PAS) staining showed an increased in glomerular mesangial matrix accumulation post irradiation. Sirius red staining showed diffuse intertubular fibrosis, especially in the renal cortex post radiation. These histological changes were paralleled by the change in serum Creatinine, urine albumin. Rituximab pretreatment to mice, improved kidney functional parameter in comparison with radiation-only mice. Rituximab pretreatment to mice, suppress the development of fibrosis and tubular damage post irradiation. Conclusion: This study shows that rituximab pretreatment protects mice against radiation-induced nephrotoxicity, which may have therapeutic implications for radiation-induced injuries in cancer patients.
Lysyl oxidase is required for chemotaxis. Haoran Tang, Nathalie Dhomen, Richard Marais. CRUK Manchester Institute, Manchester, United Kingdom.

Purpose: Lysyl oxidase (LOX) increases extracellular matrix stiffness by cross-linking collagen. A stiffer matrix drives integrin activation, and therefore LOX is believed to promote cancer cell invasion through enhanced integrin signaling. However increased matrix stiffness does not necessarily lead to a more permissive environment for invasion. Fibrillar collagen matrix orientation, density and porosity also determine how well cells can invade. Assays based on collagen gel-covered transwell systems have previously been used to show that LOX is required for invasion. These systems are driven by a chemoattractant gradient, and thus LOX for chemotaxis could not be excluded. In this study we aimed to clarify whether LOX was required for matrix invasion or chemotaxis.

Experimental procedures: To set up a 3D invasion assay that was not driven by a chemoattractant gradient, spheroids from multiple LOX expressing cancer cell lines were embedded into a thick 3D collagen gel. Cells were then allowed to randomly invade into the surrounding collagen. Alternatively, cancer cells were allowed to invade a fibrinostabilized 3D collagen gel in an organotypic assay. In this assay the invasion was driven by a strong chemoattractant gradient through a dense collagen gel, with cancer cells cultured atop the collagen gel at the air-medium interface. A Dunn chemotaxis chamber or a transwell culture insert was used to investigate chemotaxis towards serum or EGF. Small interfering RNA (siRNA) or short hairpin RNA (shRNA) specific to human LOX was used to deplete LOX expression in the cancer cell lines, to assess LOX functions in the above assays. Results: LOX depletion in parental MDA-MB-231 cells, MDA-MB-231 brain or bone metastatic sub-population cells, U87 and U118 cells did not impact 3D collagen gel invasion. LOX inhibition by BAPN also did not impact collagen gel invasion in MDA-MB-231, LN229, U87, U118 and U118 cells. The data indicated that LOX was not required for invasion through a thick 3D collagen gel in vitro. However, in the chemotactic-driven organotypic assay, loss of LOX in MDA-MB-231 cells completely abolished invasion. When the chemotactic potential towards serum and EGF of LOX depleted MDA-MB-231 and U87 cells was tested using Dunn chemotaxis chambers, we observed strong chemotactic defects in both cell lines. The chemotactic defects of these cells were also observed when a transwell based chemotaxis assay was used. Random cell migration of MDA-MB-231 and U87 cells were otherwise not affected by LOX depletion. Conclusions: LOX is not required for collagen matrix invasion per se. Instead LOX is important for cells to sense chemoattractants and to maintain directional cell migration. The molecular mechanisms underlying these observations are now the subject of further investigation.

PATZ1 promotes migration and invasion of thyroid cancer cells through upregulation of the activity of plasminogen activator-inhibitor type 1 matrix metalloproteinases. Asumi Isato,1 Teruo Nakamura,2 Tuyoshi Uehara,1 Hi-ruto Izumi,1 Ken-ichi Ito1. Shinshu University School of Medicine, Matsumoto-city, Nagano-Prefecture, Japan; 2University of Occupational and Environmental Health, Kitakyusyu-city, Japan.

Background: PATZ1, a transcription regulator, has been reported to function as oncogene or tumor suppressor in several human malignant neoplasms. The aim of the study was to examine involvement of PATZ1 in carcinogenesis and progression of thyroid cancer. Materials and methods: PATZ1 expression in 165 clinical thyroid specimens obtained from 87 patients were evaluated by IHC. We examined the function of PATZ1 using an immortalized normal thyroid follicular epithelial cell line (Nthy-or1-31), and four thyroid cancer cell lines; TPC-1 (papillary cancer), FTC-133 (follicular cancer), FRO and ACT-1 (anaplastic cancer). Knockdown of PATZ1 in Nthy-or1-31 and differentiated thyroid cancer cell lines (TPC-1, FTC-133) induced morphological change of the cells and significant increase of cell proliferation and migration as well as moderate increase of invasion. Furthermore, the expression of u-PA, MMP2 and MMP11 was increased by inhibition of PATZ1 in TPC-1 and FTC-133. On the other hand, overexpression of PATZ1 in anaplastic cancer cell lines (FRO and ACT-1) decreased proliferation and migration of the cells along with the decreased expression of u-PA, MMP2, MMP9 and MMP11. Conclusion: Our study suggests that PATZ1 might play an important role as a tumor suppressor in thyroid follicular epithelial cells and might be involved in progression of thyroid cancer.

Expression of nuclear PATZ1 in thyroid tumor type Normal thyroid/ goiter (N=68) Follicular adenoma (N=5) Papillary adenoma (N=39) Follicular differentiated carcinoma (N=84) Anaplastic Medullary thyroid cancer (N=28)

Tracking of migration using digital holography to monitor drug-induced phenotypic shifts in breast cancer cells. Sofia Kamlund, Stina Oredsson. Lund University, Lund, Sweden

This study aims to investigate the migration behaviour of individual JIMT-1 breast cancer cells during the cell cycle. Mechanisms behind cell migration are important at the tumor level to understand the context by which cancer release occurs. Pull-down with ADAM9 and interactive proteins in malignant phenotypic progression. The aim is to clarify the association between ADAM9 expression and cancer progression. The results indicate possible to use ADAM9 as a biomarker for metastatic breast cancer.

Phosphorilidocisocoxaeoxoate (PZ-DHA) inhibits breast cancer cell invasion and angiogenesis. Wasundara Fernando, Emma MacLean, Krysta Coyle, Paola Marcato, David W. Hoskin, H. P. Vasantha Rupasinghe, Dalhousie University, Halifax, Nova Scotia, Canada; Dalhousie University, Truro, Nova Scotia, Canada.

In our in vitro and in vivo studies, we showed the selective cytotoxicity, in vitro anti-proliferative and anti-metastatic activities of phosphorilidocisocoxaeoxoate (PZ-DHA). PZ-DHA combines phosphorilid (PZ), a dihydrochalcone found in apple peels, and phosphorilidocisoxaeoxoic acid (DHA), an ω-3 fatty acid found in fish oil, through an acylation reaction. Significant suppression of tumor growth resulted from the in vitro administration of PZ-DHA to non-obese diabetic severe combined immunodeficient (NOD-SCID) female mice xenografted with MDA-MB-231 breast cancer cells. Examination of hematoxylin and eosin-stained tumor sections confirmed that PZ-DHA caused tumor cell death. PZ-DHA also suppressed the invasion of MDA-MB-231 cells through membranes coated with extra cellular matrix proteins, fibronectin and gelatin, in a Boyden chamber assay. The effect of PZ-DHA on the mRNA transcription of the gelatinase, extracellular matrix proteins, fibronectin and gelatin, in a Boyden chamber assay. The effect of PZ-DHA on the mRNA transcription of the gelatinase, extracellular matrix proteins, fibronectin and gelatin, in a Boyden chamber assay. The effect of PZ-DHA on the mRNA transcription of the gelatinase, extracellular matrix proteins, fibronectin and gelatin, in a Boyden chamber assay.

INTRODUCTION In cancers with β-catenin and Ras signaling pathways by APC (90%) and K-Ras (40-50%) mutations are closely interacted and accelerate CRC tumorigenesis. Protein level of β-catenin as well as Ras is increased by APC loss via inhibiting GSK3B-mediated poly-ubiquitination dependent Ras degradation through recruitment of β-TrCP E3 linker. Moreover, additional K-Ras mutation results in the liver metastasis by secondary activation of the Wnt/β-catenin signaling pathways via Ras-ERK and -AKT pathways in addition to the initial activation by APC loss. Consequently, both β-catenin and Ras were highly increased in human CRC patient tissues, especially in metastatic tumor. EXPERIMENT PROCEDURES To investigate the synergistic effects of aberrant Wnt/β-catenin and Ras signaling pathways on tumor development to metastasis, we established the APCMin/−/K-RasG12DLA2 compound mouse that harbors APCMin and K-Ras mutations in and normal tissues. Tumor-specific, tumor-specific Ras protein level using human CRC patient tissues of normal mucosa and adenocarcinoma (N=24) and metastatic adenocarcinoma (N=26) and tumor budding (N=10). To recapitulate the metastatic tumor environment which have enriched receptor tyrosine kinases (RTKs), we maintained and experimented with EGF (20ng/ml) in every in vitro studies. RESULTS We observed that β-catenin and Ras were increased in adenocarcinoma and metastatic adenocarcinoma of human CRC compared with normal mucosa. Interestingly, both β-catenin and Ras were most significantly increased in tumor budding regions which histopathologically represent epithelial mesenchymal transition (EMT). In murine model, the EMT phenomenon was effectively induced and invasion of small intestinal tumors were occurred in APCMin/−/K-RasG12DLA2 with increased level of β-catenin and Ras compared with APCMin/+. However, EMT phenomenon and its following events such as migration and invasion of CRC cells induced by APC and K-Ras mutations were abolished by distalization of β-catenin and Ras. CONCLUSION Our results show that distalizing β-catenin and Ras could be effective therapeutic targets for inhibiting metastasis in the early stage of CRC development.

ADAM9-plectin interaction involved in prostate cancer malignancy progression. Che-Ming Liu, Chia-Ling Hsieh, Shian-Ying Sung. China Medical University, Taichung, Taiwan.

Introduction: To identify a specific biomarker for malignant prostate cancer progression and therapeutic target, we had demonstrated the correlation of ADAM9 expression and cancer progression. The aim is to clarify the association of ADAM9 and interactive proteins in malignant phenotype progression. Methods: Knockdown of ADAM9 expression was conducted to explore its role in cell motility and metastasis activities. Pull-down assays were performed to identify the proteins that interact with ADAM9 during cancer cell migration. Proximity ligation assay (PLA) was carried out to validate the protein-protein interaction. Transmission electron microscope (TEM) analysis to confirm ADAM9 and plectin interaction. Protein degradation test was conducted to determine the regulation pathway. Results: Our study demonstrated that ADAM9 play an important role in the regulation of prostate cancer migration, invasion and metastasis in the in vitro assay and xenograft animal models. The combination of ADAM9 pull-down assays and mass spectrum analysis demonstrated hemidesmosome components, plectin, ladinin, and cytoskeleton were pull-down with ADAM9. However, the key element of hemidesmosome, z-catenin and Ras could be an ideal therapy for treating metastatic colorectal cancer. Consequently, both β-catenin and Ras were highly increased in human CRC patient tissues, especially in metastatic tumor. EXPERIMENT PROCEDURES To investigate the synergistic effects of aberrant Wnt/β-catenin and Ras signaling pathways on tumor development to metastasis, we established the APCMin/−/K-RasG12DLA2 compound mouse that harbors APCMin and K-Ras mutations in and normal tissues. Tumor-specific, tumor-specific Ras protein level using human CRC patient tissues of normal mucosa and adenocarcinoma (N=24) and metastatic adenocarcinoma (N=26) and tumor budding (N=10). To recapitulate the metastatic tumor environment which have enriched receptor tyrosine kinases (RTKs), we maintained and experimented with EGF (20ng/ml) in every in vitro studies. RESULTS We observed that β-catenin and Ras were increased in adenocarcinoma and metastatic adenocarcinoma of human CRC compared with normal mucosa. Interestingly, both β-catenin and Ras were most significantly increased in tumor budding regions which histopathologically represent epithelial mesenchymal transition (EMT). In murine model, the EMT phenomenon was effectively induced and invasion of small intestinal tumors were occurred in APCMin/−/K-RasG12DLA2 with increased level of β-catenin and Ras compared with APCMin/+. However, EMT phenomenon and its following events such as migration and invasion of CRC cells induced by APC and K-Ras mutations were abolished by distalization of β-catenin and Ras. CONCLUSION Our results show that distalizing β-catenin and Ras could be effective therapeutic targets for inhibiting metastasis in the early stage of CRC development.
