Glioblastoma is an aggressive, high-grade tumor with poor prognosis due to lack of sound therapeutic options. Mesenchymal subtype GBMs are particularly difficult to treat because they tend to proliferate in the subventricular zone, an area that breeds stem-like neural cells and proves nearly impossible to access for surgical resection. They also contribute to creating a hypoxic microenvironment and switch to glycolytic metabolism in what is known as the Warburg Effect. Here, we hypothesize that strategically inhibiting the glucose transporter, GLUT1, through cytoskeletal components that traffic it to the cell membrane may reverse the Warburg Effect, attenuating further tumorigenesis and decreasing the stemness of such cells. Datamining studies and immunoblot analysis conducted on human glioblastoma patient specimens (hGBM) demonstrated that GLUT1 is highly upregulated. Limiting dilution assay conducted using GLUT1 inhibitors-fasentin and 2-Doxy-D-glucose reduced the proliferation in mesenchymal cancer stem cell (CSC) subtype in in vitro culture. Simultaneously, mass spectrometric analysis revealed significant association between GLUT1 and β-tubulin 4 (TUBB4) in mesenchymal subtyped cells. This association was further confirmed by large-scale datamining and in immunoprecipitation studies from hGBM specimens, suggesting that TUBB4 may be a viable target in deterring the trafficking of upregulated GLUT1 to the membrane. Collectively, these studies confirm that GLUT1 is associated with TUBB4, and that targeting TUBB4 via siRNA or colchicine derivatives could prove effective in reversing the Warburg Effect in GBM cells and ultimately improve patient outcomes.

**#5434 Tumor necrosis factor receptor-associated protein 1 (TRAP1) as a potential target for glutamine addicted cancer cells.**

Yu T. Vo,1 Ai N. Phan,1 Tuyen N. Hua,1 Yangaik Jeong,1 Byoung Heon Kang,2 Hyun-Won Kim,1 Jong-Whan Choe1,1 Yonsei University Wonju college of Medicine; Wonju, Republic of Korea;2 UNIST, Ulsan, Republic of Korea.

Glutamine, a non-essential amino acid, is an important nutrient which is involved in many biochemical pathways such as energy production, macromolecular synthesis, and oxidative stress scavenging. Glutamine metabolism is dysregulated in many cancers which mostly display glutamine addiction for cell proliferation, as this amino acid is a major source of energy for treating cancer. Here we report that glutamine-dependent cancer cells are more susceptible for inhibiting cell proliferation with inhibitor treatment of Tumor Necrosis Factor Receptor-Associated Protein 1 (TRAP1), a downstream factor of oncogenic c-Myc involved in glutamine metabolism. Using cell proliferation and cell viability assays, we examined growth inhibition effects of TRAP1 inhibitor, gamitrinib-triphosphophosphonin (G-TPP), on two groups of cell lines, glutamine-deprivation sensitive versus resistant cell lines. Included are cell lines for each group: HCC827 acquired gefitinib resistance and A549 for the sensitive; HuH7 for the resistant group. Glutamine-deprivation sensitive cell lines showed significant growth inhibition with TRAP1 inhibitor treatment while the corre-
were measured by qRT-PCR/Tagman analysis (in total, 1,026 analyses) and normalized by the miR16 level. miR486 levels were up-regulated (p = 0.02) and miR203 (p = 0.0005) and miR205 (p = 0.041) levels were down-regulated in Stages I and II/III adenocarcinoma. Whereas miR122 and miR29c were not detected in serum samples from the majority of healthy subjects, the miRNAs were expressed in serum samples of cancer patients of each stage. The miRNAs associated with adenocarcinoma were miR203, 205, and 16, respectively, of Stages II/III lung cancer patients. A novel label-free 90 nm (diameter) miRNA nanowell technology was developed. Electrochemical analyses of the early lung cancer biomarker candidates, miR486 and miR29c, and, an internal control, miR16, were carried out using various concentrations of miRNA standards (0 to 100 fm) with biotinylated CDNA captured by streptavidin-coated plate. The competitive electrochemical technology was capable of distinguishing isomiRs and increasing the impedance (Z‘ kohm) and sensitivity of the miRNA nanowell electrochemical technology was +1.1 mV. The impedance level obtained with miR29c in AS49 lung cancer cell media was ~2.8-fold higher (mean value ± SD, 163.9 ± 32.8 kohm) compared with ACHN kidney cancer cell media (60.8 ± 33.1 kohm) by 90 nm nanowell analysis (p = 0.000019). Electrochemical analyses of a serum sample obtained from a lung cancer patient revealed that miR486 and miR294 levels were ~2-fold (p = 0.0031) and 9-fold (p = 0.0006) higher, respectively, compared to the pooled human control sera. This result agreed with the result obtained by qRT-PCR/Tagman analysis of human serum samples. Our results suggest that miR486 and miR203 levels up- and down-regulated, respectively, in lung cancer serum samples are biomarkers for early (Stage I) lung cancer diagnosis. Supported by National SIRI Phase I contract, N268121500040C. (Topic 337).

#5437 miR-302b as adjuvant therapeutic tool to improve chemotherapy efficacy in human triple-negative breast cancer. Alessandra Cataldo,1 Ilaria Plantamura,1 Elvira D’Ippolito,1 Sandra Romero-Cordoba,2 Sara Baroni,1 Valeria Cancilla,1 Claudio Tri pode,1 Dario Palmieri,1 Marilena V. Iorio,1 Istituto Nazionale dei Tumori, Milan, Italy; 2INMGEN, Mexico City, Mexico; 3University of Palermo, Palermo, Italy; 4Ohio State University, Columbus, OH.

Introduction: Triple-negative breast cancer (TNBC) accounts for 15-20% of all breast cancer cases, with the worst outcome of all subtypes. For TNBC, still lacking targeted therapies, the only therapeutic option is currently chemotherapy, and despite a good initial response, patients often develop drug resistance. MiRNAs can modulate chemoresistance by affecting DNA repair, cell cycle progression, apoptosis and also tumor microenvironment. Macrophages constitute a major component of the immune microenvironment of cancer and pro-tumor M2 macrophages have been associated with resistance to chemotherapeutic treatments. Our previous data showed that miR-302b over-expression enhances sensitivity to cisplatin in breast cancer cell lines by targeting directly E2F1 and indirectly ATM. Here, we investigated the potential of miR-302b as a therapeutic tool to enhance cisplatin response in a TNBC mouse model and which pathways are involved in this mechanism both in tumor cells and microenvironment. Moreover, miR-302b prognostic value was assessed in a cohort of TNBC patients with available clinical outcome. Finally, we evaluated if miR-302b enhances the sensitivity to doxorubicin, another chemotherapeutic agent used as first-line therapy in TNBC patients. Material and method: MDA-MB-231 TNBC cells were injected into the mammary fat pad of female SCID mice and then treated with lipid nanoparticles containing miR-302b or cel-miR-67 control, alone or in combination with cisplatin. Gene expression profile on collected tumors was performed by microarray and tumors sections were stained with anti-arginase 1 (M2 marker) to evaluate the number of M2 macrophages. MiR-302b expression was assessed in 39 TNBC treated with chemotherapy in adjuvant setting, and associated with prognosis. Finally, MDA-MB-231 cells were transfected with miR-302b precursor or control treated with doxorubicin for 24h and then assessed for cell viability. Results: Our results show that miR-302b combination with cisplatin significantly impaired tumor growth in comparison with cel-67 control and cisplatin (p = 0.05), and reduced the number of M2 macrophages in the tumor microenvironment (p = 0.005). Moreover, gene expression profile of collected tumors confirm immune system modulation. Notably, miR-302b expression was associated with disease-free survival and overall survival in TNBC patients treated with adjuvant chemotherapy. Furthermore, we found that miR-302b also enhances sensitivity to doxorubicin in vitro, affecting cell viability and cell cycle transition through E2F1 regulation. Conclusion: Our data demonstrate that miR-302b can be exploited as a new therapeutic tool to improve the response to chemotherapy, modulating tumor microenvironment. Moreover, this miRNA has prognostic significance in TNBC patients, and might also represent an useful predictive biomarker for response to chemotherapy.

#5438 Knowledge of which miRNA isoforms are expressed in a sample can successfully discriminate amongst the 32 TCGA cancer types. Aristeidis G. Telenis, Rogan Magee, Phillipe Loher, Inna Chervoneva, Eric Londin, Isidore Rigoutsos, Thomas Jefferson University, Philadelphia, PA.

Background: Next-generation sequencing (NGS) technologies made possible the generation of large amounts of data quickly and inexpensively process. As a result, the challenge nowadays is how best to manipulate and analyze Big Data. Among non-coding RNAs, miRNAs (miRNAs) are the best studied to date. miRNAs have attracted a lot of attention because they are centrally involved in disease development, at least 70% of all protein-coding genes are targets of miRNAs. The complexity of miRNA-mediated regulation increased further with the recent discovery that miRNA isoforms (isomiRs) are produced constitutively and that isomiR expression depends on a person’s sex, population origin, race and also on tissue type, tissue state, and disease subtype. Methods: We computed and analyzed isomiR profiles across 10,271 short RNA-seq datasets from The Cancer Genome Atlas (TCGA) repository, which represent 32 cancer types. Focusing on the isomiRs of each dataset, we built a classifier that relied solely on “binarized” isomiR profiles: in a dataset, an isomiR was labeled ‘present,’ if its expression exceeded a threshold that depended on the depth of sequencing, and ‘absent’ otherwise. This differs radically from previous methods in that it attempts to classify by relying on the presence or absence of isomiRs, intentionally discarding all information about the isomiRs’ expression level. We also built a classifier that relied solely on “binarized” miRNA arm profiles: a miRNA arm was labeled ‘present’ if at least one of the isomiRs it produces is ‘present’ in the same dataset. Results: The classifier we built using binarized isomiR profiles discriminated among all 32 TCGA cancer types and classified datasets with sensitivity >90% and a false discovery rate (FDR) < 3.0%. The ability of this classifier to correctly distinguish among the 32 cancers persisted even after a 15x reduction in the number of isomiRs used. The classifier we built using binarized miRNA arm profiles could also discriminate among all 32 TCGA cancers albeit with a lower sensitivity (83%) and a slightly higher FDR (6.0%). We also examined how well the various miRNA loci have been studied over time by measuring the corresponding number of published articles. Surprisingly, the miRNAs whose isoforms have the highest ability to classify tumors are not those with the most articles in PubMed. Conclusions: The presence or absence of a specific isomiR provides adequate discriminatory power to accurately classify a sample as belonging to one of the 32 TCGA cancers. The findings suggest that isomiRs can be used as potent, novel, cancer-specific biomarkers. By ignoring the expression levels of isomiRs, we effectively show that the same miRNA produces different clouds of isoforms in each cancer type. And, since distinct isomiRs target distinct miRNAs, it follows that a miRNA locus will target different miRNAs in different cancers simply by expressing different clouds of isoforms each time.

#5439 The chronological analysis of previously-reported serum microRNA expression in colorectal cancer. Yukihito Yoshikawa,1 Mitsuko Fukunaga,1 Takaaki Masuda,2 Miwa Noda,1 Hiroko Wakiyama,1 Yuta Koyama,1 Shinya Kidogami,1 Kuniaki Sato,1 Qingjiang Hu,2 Sho Nambara,1 Tomo Saito,1 Shotaro Sakimura,1 Naoki Hayashi,1 Yohsuke Kuroda,1 Shuhei Ito,1 Koshi Mimori1.

Background: Colorectal cancer (CRC) is a major cause of cancer-associated death in the world. Although surgery, chemotherapy, and post-operative chemotherapy, recurrence is common in patients with CRC. Many studies have examined potential biomarker of recurrence in CRC in attempt to improve patients prognosis. MicroRNAs (miRNAs), the small non-coding RNAs that are associated with the development of cancer, in serum have been shown to be potential biomarkers in various type of cancers and several miRNAs have been reported in colorectal cancer. However, no miRNAs has been applied in a clinical setting because of small amount of each samples. In the present study, we evaluated the clinical effectiveness of previously-reported serum miRNAs expression in CRC using periodically gathered serum. Materials and Methods: We obtained 328 serum samples, which gathered periodically (preoperative, postoperative one month, three months, six months, one year, and two years), from 71 patients with stageI/III CRC (stageI: 31 patients, stageII: 40 patients). Thirty-three patients had a recurrence. The miRNAs were extracted from serum samples, and miRNA microarray analysis was performed. Previously-reported sixteen miRNAs (let-7a, miR-15b, miR-18a, miR-19a, miR-21, miR-23a, miR-29a, miR-31-2, miR-92a, miR-151, miR-181b, miR-203, miR-205, miR-335, miR-1229 and miR-1246) were quantified by microRNA microarray analysis. Results: In no recurrence cases, postoperative miR-1246 expression is higher than postoperative miR-1246 expression; preoperative: 5.6 ± 1.8, postoperative one month: 4.1 ± 1.6 (p < 0.05), postoperative three months: 3.4 ± 1.9 (p < 0.05), postoperative six months: 4.8 ± 1.5 (p < 0.05), postoperative one year: 4.0 ± 1.6 (p < 0.05), postoperative two years: 4.8 ± 1.5 (p < 0.05). We observed trend of miR-1246 re-elevation before recurrence. The sensitivity and specificity of miR-1246 for detection of CRC are 52.8% and 84.9% (AUC=0.746). This result is

**#5440 miRNAs as novel therapeutic adjuvants for improving the efficacy of vincristine and radiation therapy in treating medulloblastoma.**

Nourhan Abdel fattah, Subapriya Rajamanickam, Panneer dresser Subbarayalu, Santosh Timilisina, Benjamin Onyeagucha, Yidong Chen, Manjeet Rao. UT Health Science Ctr. at San Antonio, San Antonio, TX.

Medulloblastoma (MB) is the most common malignant brain tumor. Despite recent improvements in the overall survival, only a modest percentage of patients survive Myc-driven high-risk MB. The quality of life for surviving patients is substantially reduced due to the devastating and often irreversible side effects of radiation and chemotherapy. Recently, in a large unbiased genomic screen, we uncovered a group of microRNAs (miRNAs) capable of mediating drug sensitivity in c-myc amplified high-risk MB. Our functional screen of ~1900 miRNAs identified miR-584-5p as a potent candidate that uniquely sensitizes high-risk MB to radiation as well as vincristine (VCR) (20 to 25-fold dose reduction), an anti-mitotic agent routinely administered alongside radiation and in combination with other chemotherapeutic drugs to treat medulloblastoma patients. Our studies revealed that miR-584 might act as a potent tumor suppressor as it inhibited MB growth in vivo as well as migration and invasion of c-myc amplified MB. We show that miR-584 overexpression results in defective mitosis leading to mitotic catastrophe, apoptosis, DNA damage and G2-M cell-cycle arrest in high-risk MB cells without affecting normal neural stem cell growth. Notably, we discovered that miR-584 directly regulates the expression and activity of genes including histone deacetylase 1 (HDAC1), and eukaryotic translation initiation factor 4 family member 3 (EIF4E3) that are known to play important roles in microtubule dynamics, metaphase-anaphase transition and radio-resistance. Moreover, silencing either of these two target genes resulted in significant inhibition of MB growth and enhanced sensitivity to VCR and ionizing radiation. Overexpressing miR-584 or silencing either HDAC1 or EIF4E3 also inhibited the MB stem cell proliferation and self-renewal. We report that while miR-584-5p is predominately expressed in normal brain and cerebellum, its expression is significantly reduced in MB patient derived xenografts (PDx). In contrast to miR-584, EIF4E3 and HDAC1 were found to be overexpressed in medulloblastoma patients. These findings are highly significant, unexpected and innovative as this miRNA and its target genes are the first to be shown to affect the therapeutic efficacy of VCR and radiation in c-myc amplified high-risk medulloblastoma.

**#5441 Circulating exosomal microRNA-203 and microRNA-373 as non-invasive biomarkers for predicting prognosis and metastasis in human hepatoacellular carcinoma.**

Gyeonghwa Kim,1 Eunhye Lee,1 Se Young Jang,2 Won Young Tak,2 Young Oh Kweon,2 Soo Young Park,2 Keun Hur,1 1Department of Biochemistry and Cell Biology & BK21 Plus KNU Biomedical Convergence Program, Kyunggook National University School of Medicine, Daegu, Republic of Korea; 2Department of Hepatology Hospital, Daegu, Republic of Korea.

Background and Aim Hepatocellular carcinoma (HCC) is the fifth most common cancer and the most leading cause of cancer-related death worldwide. Although considerable progress has been made in treatment of HCC, early detection is still highly considered the key to improved survival. Thus, for the earlier diagnosis and accurate prediction of HCC, identification of non-invasive molecular biomarkers for HCC patients is an imperative need. Recently, cancer cell-derived extracellular vesicles (EVs) have been known to contain various intracellular biomolecules including microRNAs (miRNAs). The aim of this study was to evaluate whether exosomal miRNAs can serve as a serum-based biomarker in HCC. Materials and Methods We isolated exosome from serum samples from HCC patients as well as normal healthy controls using ultracentrifugation, and it was confirmed by expression of exosome markers (CD9, CD63, ALIX, and TSG101) based on immuno blotting. Next, the expression of 6 miRNAs (miRNA-24, -130a, -182, -203, -373, and -423) was analyzed in the exosome samples. We also investigated expression status of the 6 miRNAs in matched HCC tissues and corresponding normal liver tissues. MiRNAs expression was determined by quantitative real-time PCR (qRT-PCR), and miRNAs expression was normalized relative to cel-miR-39 and RNU5B expression for serum and tissue samples, respectively. Results We successfully purified exosome from serum clinical samples and detected miRNAs in the exosome. We observed that a subset of miRNAs from serum exosome, including miRNA-24, -130a, -182, -203, and -373 were enhanced in HCC patients than normal healthy controls. In further comparison between early stage and advanced stage of HCC patients, serum exosomal miRNA-203 (P < 0.05) and miRNA-373 (P < 0.05) were significantly up-regulated in advanced HCC patients. While no significant changes in the expression of other serum exosomal miRNAs (miRNA-24, -130a, -182, and -423) according to HCC progression. More interestingly, high serum level of miR-203 was associated with progression (P < 0.01) as well as prognosis (P < 0.05) of HCC patients. Conclusions We provided the novel evidence for usefulness of serum circulating exosomal miR-203 and miR-373 expressions as strong potential biomarkers for predicting prognosis and metastasis of HCC patients.

**#5442 Down-regulation of miRNA-214 expression by bioactive molecules mitigates invasive potential of melanoma cells through ALCAM/TAFAP2 signaling.** Ram Prasad, Santosh K. Katiyar. Univ. of Alabama at Birmingham, Birmingham, AL.

Melanoma is responsible for 80% of skin cancer related deaths in the United States and represents fifth most common neoplasia in humans. Over the past decades, the incidence of melanoma has increased by 3% to 8% per year in western countries. Therefore, it is essential to understand the molecular regulatory pathways that contribute to melanoma aggressiveness and metastatic dissemination. MicroRNAs (miRNAs) are small noncoding regulatory RNAs that contribute to tumor formation and progression, for their ability to regulate gene expression post-transcriptionally by either inhibiting protein translation or degrading target miRNAs. miR-214 is overexpressed in various types of cancers and is associated with the regulation of numerous carcinogenic processes including cell differentiation, senescence, angiogenesis and cell migration/invasion, etc. In the present study, we demonstrated that miR-214 shows distinct overexpression in melanoma cell lines (A375, Hs294t, SK-Mel11, and SK-Mel28) as compared to its expression in normal human epidermal melanocytes (NHEM), and this overexpression of miR-214 in melanoma cells was associated with the invasive potential than NHEM. Treatment of melanoma cells with an inhibitor of miR-214 (50 nM) resulted in inhibition of cell invasion ability. We also determined the effects of bioactive phychotheroxy grape seed proanthocyanidins (SPS) on the expression levels of miRNA-214 in melanoma cell lines (A375 and Hs294t) and its underlying molecular targets. Treatment of A375 and Hs294t cells with SPS resulted in suppression of the levels of miRNA-214, which leads to decrease in migration potential of melanoma cell lines. By using 3D melanoma progression model, we also verified this suppressive effect of SPSs on melanoma invasion. The transition from the non-invasive to the invasive and metastatic stage is accompanied by the loss of AP-2 transcription factors (TAFAP-2) and expression of activated leukocyte cell adhesion molecule (ALCAM) and these are associated with miRNA-214 overexpression. Here, we observed that the treatment of SPSs decreases ALCAM expression and restore TAFAP-2 levels in melanoma cell lines. Further, dietary administration of SPSs significantly reduce the metastasis potential of A375 cells in different vital organs such as lung, liver, kidney, and spleen, and this suppressive effect of SPSs on invasive potential of A375 cells was associated with the reduction in the levels of miRNA-214 and ALCAM. Our results indicate that modulation of miR-214 influences in vitro cell movement and extravasation from blood vessels in vivo. Together, these findings suggest that a dietary supplement of SPSs may provide potential diagnostic biomarkers and better understanding of the complex functions of miRNAs, as well as therapeutic targets for clinical application.

**#5443 Developing a novel miR-15a mimic as a potential therapeutic molecule to eliminate resistant colorectal cancer stem cells.**

Andrew T. Feiler, Hua Liu, Ning Wu, Jingfang Ju. Stony Brook University, Stony Brook, NY.

In the last 15 years, it has become well established that microRNA play important roles in cancer biology. Due to their ability to regulate the expression of important target genes, aberrant expression of miRNAs has been linked to cancer development and progression. Based on these important functions, there is great interest in developing miRNA based therapeutics. In colorectal cancer, treatment using 5-flourouracil (5-FU) based chemotherapy has improved patient outcomes. However, there remain challenges associated with chemoresistance and recurrence for patients with advanced stage colorectal cancer. miRNA based therapeutics may represent a potential novel therapeutic option for colorectal cancer therapy either alone or in combination with 5-FU based chemotherapy. miR-15a was of the first miRNAs identified to be associated with cancer, and has been shown to have important roles in several tumor types. miR-15a is down-regulated in colon cancer and associated with poor patient prognosis. We have identified several important cancer related targets of miR-15a in colon cancer, including YAP1, DCLK1, BM11 and BCL2. Through the regulation of these targets, miR-15a expression can be used as a potent inhibitor to reduce colon cancer cell proliferation, invasion and improve sensitivity to 5-FU, as well as...
decreasing tumor growth in vivo mouse colon tumor models using colon cancer stem cells. In the interest of developing miR-15a based colon cancer therapeutics, we have made a modified miR-15a mimic that shows enhanced abilities to disrupt resistant colon cancer cell proliferation and induction of cell cycle arrest when compared to unmodified miR-15a. Following transfection with miR-15a mimic, cell number was reduced by 84% compared to control and compared to miR-15a precursor. Cell cycle analysis showed that G1/S ratio was increased from 1.07 for control to 2.87 for precursor miR-15a and 7.07 for miR-15a mimic. This miR-15a mimic also maintains its ability to regulate these important target genes in colon cancer stem cells. In mouse models using colon cancer stem cells, miR-15a mimic has demonstrated therapeutic potential by reducing tumor growth. Based on these findings, there is potential that modified miR-15a could be adapted for treatment of patients to improve survival of advanced stage colorectal cancer patients.

#5444 Therapeutic potential of miR-195 in non-small cell lung cancer. Xiaojie Yu,1 Xiuye Ma,1 Qiyan Zhang,2 Zhenhe Zhao,2 Liqin Du,2 Alexander Pertschumlidis1. 1University of Texas Health Science Center at San Antonio, San Antonio, TX; 2 Texas State University, San Marcos, TX.

Introduction: MicroRNAs (miRNAs) play important roles in nearly all cellular physiological and pathological pathways. Dysregulated miRNAs have been shown to contribute to the tumorigenesis of most cancers, including lung cancer. We aim to modulate miRNA activity as a potential therapeutic avenue either alone or in combination with other drugs. Methods: A high throughput screen with a library of 1,239 miRNA mimics was performed in NSCLC cells to identify miRNAs that both inhibit cancer cell growth and sensitize cells to drug treatment, targeting agents (MTAs). The functions of candidate miRNA(s) were validated both in vitro and in vivo. Results: miR-195 causes G1 phase arrest by targeting CCND3. miR-195 induces apoptosis and senescence and represses migration and invasion of NSCLC cells by targeting BERCS. Conversely, over-expression of CCND3 compromises the inhibition of cell growth by miR-195; over-expression of BERCS abrogates the inhibition of cell growth, migration and invasion by miR-195. miR-195 also synergizes with MTAs paclitaxel and erubul to inhibit the growth of NSCLC cells by regulating CHEK1. Lung tumors with miR-195 over-expression grow significantly slower and respond better to erubulin treatment than tumors in control animals. Induction of miR-195 expression after tumor initiation slows tumor growth and that combination of doxorubicin with erubul shows stronger inhibition on tumor growth than erubulin. In addition, miR-195 inhibits lung tumor metastasis. Analysis of miRNA and gene expression profiles from TCGA shows that miR-195 expression is negatively correlated with that of BIRC5 and CHEK1. Clinical data from TCGA show that miR-195 is significantly down-regulated in lung tumors compared to adjacent normal tissues and that its down-regulation in lung cancer patients is associated with worse survival. TCGA data also show that BIRC5 and CHEK1 are significantly up-regulated in lung tumors compared to adjacent normal tissues and that their up-regulation is associated with worse survival. Conclusions: We report the identification of miR-195 as a tumor suppressor and chemotherapy sensitizer in NSCLC mediated by its repression of CCND3, BIRC5 and CHEK1. Mouse xenografts with miR-195 over-expression or induced miR-195 expression indicate that tumors with miR-195 expression are more sensitive to drug treatment, and that induction of miR-195 in tumors represses tumor growth and sensitizes tumors to erubicin treatment. These results highlight the potential use of miR-195 expression level as a biomarker to predict patient response to MTAs and of miR-195 mimics as a therapeutic agent or adjunct to chemotherapy. This project was supported by NIH R01 CA129632 and CPRIT Training Grant RP140105.

#5455 Inhibition of tumor suppressor function of RUNX3 by miR-301a facilitates the progression of castration resistant prostate cancer. Venkatesh Kolluru, Balaji Chandrasekhar, Collin McKenzie, Houda Alatassi, Murali Ankem, Chandil Damodaran. University of Louisville, Louisville, KY.

Treatment of prostate cancer is still clinically challenging due to lack of reliable markers for diagnosis and prognosis. Serum prostate specific antigen (PSA) is limited clinical utility due to poor sensitivity and specificity. A large number of false positives (50%) with traditional PSA testing lead many patients to undergoing unnecessary prostate biopsy and exposure to unnecessary risk of complications. So the goal of this study is to identify a reliable, non-invasive biomarker that can distinguish patients with benign, indolent and aggressive prostate cancer in various clinical settings. MicroRNAs (miRNAs) are small noncoding (18 to 28 nucleotides) RNA molecules that are present in all human cells, and their expression patterns are correlated with many cancer types, including CaP. In our results, we found a significant differential expression (p = 0.013) of miR-301a in both tumor tissues (Gleason-6 and -7) and serum samples in comparison to benign prostatic hyperplasia (BPH) or adjacent benign samples. We observed a negative correlation between miR-301a and RUNX3 expression in human CaP samples suggesting tumor suppressive role RUNX3 might be compromised in CaP. To determine MiR-301a regulation on RUNX3, we evaluated miR-301a and RUNX3 protein in panel of prostate cancer cell lines and normal prostate epithelial cells: over expression of miR-301a down regulated RUNX3 activation in prostate cancer cell lines and silencing miR-301a expression reverts RUNX3 activation in BPH cells. While evaluating the reporter activity of RUNX3 either by co-transfecting with mimic or inhibitor of RUNX3, we observed that the RUNX3 promoter activity and protein expression suggesting RUNX3 is a direct target of miR-301a in CaP cells. Silencing miR-301a reverted the pro-apoptotic function of RUNX3, results in reduced colony formation, adhesion, invasion and migration of CaP cells. Investigating the mechanistic link miR-301a and RUNX3 may explore whether it could facilitate clinical decision making such as the decision to proceed with early surgery rather than active surveillance for intermediate risk prostate cancer patients deemed to be at high risk of progression.

#5456 Tumor-derived miR-200c and 141 contribute to high levels of plasma microRNA-200c and 141 through exosomes. Lizhong Wang, Runhua Liu, Song Gao, Yicun Wang, Meng Wang, Zhi Li. University of Alabama at Birmingham, Birmingham, AL.

Circulating microRNAs (miRs) have potential as cancer biomarkers, but their regulatory mechanisms remain elusive. Here we used a breast cancer model (Fpox3 heterozygous Scurfy mutant female mice, Foxp3+/-) for identification of circulating miR biomarkers, and the formation and regulation of these miRs were investigated. Aging Foxp3+/- female mice developed spontaneous breast cancers and lung metastases. Levels of miR-200c and 141 were lower in the Foxp3+/- breast cancer cells than in normal breast epithelial cells, but plasma levels of miR-200c and 141 in the Foxp3+/- mice increased during tumor progression, especially during metastasis to the lung. Likewise, 259 participants, including patients with breast cancer or benign breast tumors, members of breast cancer families, and matched normal healthy controls, were assessed for circulating levels of candidate miRs. The results showed that: 1) the levels of miR-200c and 141 were lower in the Foxp3+/- breast cancer cells relative to those with FOXP3+/-, especially for late-stage and metastatic cancer cells; 2) the levels of miR-200c and 141 were higher in plasma of patients with metastatic breast cancer than in plasma of those with localized breast cancer, with benign breast tumors, with a family history of breast cancer, or normal healthy controls. Furthermore, in Foxp3+/- mice, plasma miR-200c and 141 were released from tumor cells through exosomes. Thus, plasma levels of miR-200c and 141 are potential biomarkers for early detection of metastases. MiR-200c and 141 appear to be released from breast cancer cells, through exosomes, into the circulation.

#5457 A microRNA signature for the classification of renal cell carcinoma subtypes. Ashley Di Meo,1 Mereet Hanna,2 Rola Saleeb,1 Samantha Wala,1 Adriana Krizova,2 Manal Gabr,3 Haiyan Zhai,2 Maria Pasic,3 Andrew Evans,5 Fadi Brimo,6 George Yousef. 1University of Toronto, Toronto, Ontario, Canada; 2The Li Ka Shing Knowledge Institute of St. Michael’s Hospital, Toronto, Ontario, Canada; 3London Health Sciences Center and Western University, London, Ontario, Canada; 4BioGenex Laboratories, Fremont, CA; 5University Health Network, Toronto, Ontario, Canada; 6McGill University Health Centre, Montreal, Quebec, Canada.

Introduction: Renal cell carcinoma (RCC) accounts for 90% of all kidney cancers. It comprises a heterogeneous group of renal tumors with distinct genetic and molecular characteristics including clear cell RCC (ccRCC), papillary RCC (pRCC) and chromophobe RCC (chRCC). The differential diagnosis of RCC subtypes relies on distinct morphology which is not always accurate. Accurate classification of RCC subtypes is critical since each exhibits different clinical behaviour, prognosis and response to therapy. The purpose of this study is to determine whether a limited number of miRNAs can classify RCC subtypes with high accuracy. Experimental Design: We extracted RNA from 90 formalin-fixed paraffin-embedded (FFPE) tissues including 27 clear cell RCC, 29 papillary RCC, 19 chromophobe RCC, 4 unclassified RCC tumors and 11 oncocytomas. We measured the absolute expression of six miRNAs by qRT-PCR. Receiver operator characteristic curves were constructed and the area under the curve (AUC) was calculated to assess diagnostic performance. We also tested miRNA expression by in situ hybridization (ISH) in an independent set of ninety-eight FFPE renal tumors. Results: We developed a two-step miRNA classifier. In the
first step, expressions of selected miRNAs were found to discriminate clear cell RCC and papillary RCC from chromophobe RCC and renal oncocytoma. Two miRNAs were able to discriminate clear cell RCC and papillary RCC from chromophobe RCC and oncocytoma. miR-221 was significantly overexpressed in chromophobe RCC and oncocytoma compared to clear cell RCC and papillary RCC (4.698-fold change, p=6.598e-05) and able to discriminate between the two groups (AUC=0.937, 95% CI: 0.913-1.04, p<0.0001). In the second step, the absolute expression of two miRNAs could distinguish clear cell RCC from papillary RCC (10.4-fold change, p=1.243e-03). Moreover, an additional two miRNAs could differentiate chromophobe RCC from renal oncocytoma (3.530-fold change, p=1.751e-006). In situ hybridization revealed that miRNAs display a nuclear staining pattern. The analysis was extended to distinguishing between RCC from papillary RCC (p<0.0001) and chromophobe RCC from renal oncocytoma (p=0.009). Conclusion: miRNA expressions were able to distinguish between RCC subtypes and renal oncocytoma. miRNA assessment by in situ hybridization is a clinically useful diagnostic tool that can complement current methods for RCC classification.

**#5449** An exosomal biomarker for prostate cancer. Divya Bhagirath, Thao Yang, Kirandep Sekhon, Nathan Bucay, Shahana Majid, Yutaka Hashimoto, Priyanka Kulkarni, Pritha Dasgupta, Marisa Shiina, Varahram Shahryari, Mit-Suho Imai-Sumida, Soichiro Yamamura, Z Laura Tabatabai, Yuichiro Tanaka, Jacob Fredsøe, 1 Jiri Sana, 1 Parwez Ahmad, 1 Natalia Anna Gablo, 1 Ondrej Slaby, 1 Michal Stanik, 2 Jan Dolezel 2. Jacob Fredsøe, 1 Anni K.Rasmussen, 2 Anni R. Thomsen, 2 Peter Mouritzen, 2 Søren Høyer, 3 Michael Borre, 4 Torben F. Ørntoft, 1 Karina D. Sørensen 1, Urology, Aarhus N, Denmark; 3 Institute of Pathology, Aarhus C, Denmark; 4 Department of Urology, Aarhus N, Denmark.

Widespread use of Prostate Specific Antigen (PSA) testing for prostate cancer (PC) detection has led to extensive overdiagnosis and overtreatment. Thus, we aimed to train and validate urine-based microRNA (miRNA) biomarkers that may assist in the diagnosis and prognosis of PC. To this end, we profiled the expression levels of 92 miRNAs by RT-qPCR in exosome-enriched, cell-free urine samples from 20 patients with benign prostatic hyperplasia (BPH) and 188 patients with clinically localized PC (cohort 1). The diagnostic potential of individual miRNAs and multi-miRNA ratio models were assessed by receiver operating characteristic (ROC) curve analysis. Prognostic potential was evaluated using Kaplan-Meier, univariate and multivariate Cox regression analyses using biochemical recurrence (BCR) after radical prostatectomy (RP) as endpoint. Our findings were validated in an independent cohort of 20 BPH patients and 197 patients with clinically localized PC (cohort 2). We identified and validated several deregulated miRNAs in urine samples from PC patients. In addition, we trained a novel diagnostic 3-miRNA model that distinguished BPH and PC patients with an area under the curve (AUC) of 0.95 in cohort 1, and which was successfully validated in cohort 2 (AUC=0.89). Furthermore, we trained a novel prognostic 3-miRNA model that predicted time to BCR after RP independently of routine clinicopathological parameters in cohort 1, and was successfully validated in cohort 2.

**#5450** Urinary microRNA as diagnostic and prognostic biomarkers for prostate cancer. Jacob Fredsøe, 1 Anni K. Rasmussen, 2 Anni R. Thomsen, 2 Peter Mouritzen, 2 Michael Borre, 3 Torben F. Ørntoft, 1 Karina D. Sørensen 1, Department of Molecular Medicine, Aarhus N, Denmark; 2 Exign A/S, Vedbaek, Denmark; 3 Institute of Pathology, Aarhus C, Denmark; 4 Department of Urology, Aarhus N, Denmark.

Our analyses suggest that identifying and validating stem cell-inhibitory in combination with current advances in nanomedicine will undoubtedly impact the development of novel therapies for targeting the CSC population and treating GBM.

**#5451** Panel of urinary cell-free microRNAs in detection of urinary bladder cancer. Jaroslav Juracek, 1 Tana Machackova, 1 Marek Vecera, 1 Kamila Soucova, 1 Jiri Sana, 1 Parwez Ahmad, 1 Natalia Anna Gablo, 1 Ondrej Slaby, 2 Michal Stanik, 3 Jan Dolezel, 3 CEITEC - Central European Institute of Technology, Brno, Czech Republic; 3 MMCi - Masaryk Memorial Cancer Institute, Brno, Czech Republic.

Bladder cancer is the most common cancer of the urinary tract. More than 90% of bladder cancers are urothelial carcinoma, which are divided into non-muscle-invasive and muscle-invasive forms. Non-muscle-invasive tumors frequently recur (50-70%) and can also progress to invasive form (10-15%). These patients are monitored by cystoscopy and may undergo cystectomy over many years. Improved monitoring method is needed, ideally via urine analysis, which could reduce the morbidity and costs associated with long follow up. Currently there are no molecular biomarkers which could diagnose or accurately predict disease progression. We aimed to develop a clinically applicable, specific and sensitive panel of urine microRNAs enabling detect bladder cancer and predict risk of progression to muscle-invasive form. Within the exploratory phase of study we have analyzed expression profiles of 1733 miRNAs in urine supernatant of 16 bladder cancer patients (6 muscle invasive, 5 high-grade muscle non-invasive, 5 low-grade muscle non-invasive), 17 controls, 10 RCC patients and 4 urinary tract infections (UTI) using Affymetrix microRNA microarrays. Diagnostic and prognostic potential of selected microRNAs was further validated on independent samples in training phase (50 bladder cancer patients, 15 controls) and validation phase (100 bladder cancer patients, 55 controls, 45 renal cancer patients) using specific TaqMan assays and qRT-PCR method. Global expression profiling identified set of 76 miRNAs able distinguish bladder cancer patients from healthy controls (P<0.01), thereof 64 highly up-regulated and 12 down-regulated. Moreover 23 miRNAs were able distinguish invasive from non-invasive forms of UCUB (P<0.01) and 18 miRNAs high-grade and low-grade non-invasive (P<0.01). Set of 12 miRNAs with highest expression level and statistical significance was validated in training phase of study. Based on the results the panel of three miRNAs (miR-31, miR-93, miR-191) was profiled. In validation phase we confirmed diagnostic potential and ability of this urine miRNA-based panel to diagnose patients with bladder cancer with high sensitivity and specificity (AUROC=0.94, sensitivity = 82%, specificity = 90%). Our data have shown that urinary microRNAs could serve as sensitive and specific biomarkers of urinary bladder cancer and could be useful tool to increase sensitivity of standard cytological examination and reduce costs associated with long-term follow-up of bladder cancer patients. This work was sup-
#5452 Antitumor activity of miR-34a in peritoneal mesothelioma relies on c-MET and AXL inhibition: Persistent activation of ERK and AKT signaling as a possible cytoprotective mechanism. Rihan El Bezawy, Michelandra De Cesare, Marzia Pennati, Marcello Deraco, Paolo Gandellini, Valentina Zuco, Nadia Zaffaroni. Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy.

The value of microRNAs (miRNAs) as novel targets for cancer therapy is now widely recognized. However, no information is currently available on the expression/functional role of miRNAs in diffuse malignant peritoneal mesothelioma (DMPM), a rapidly lethal disease, poorly responsive to conventional treatments, for which the development of new therapeutic strategies is urgently needed. Here, we evaluated the expression and biological effects of miR-34a—one of the most widely deregulated miRNAs in cancer and for which a lipid-formulated mimic is already clinically available—in a large cohort of DMPM clinical samples and a unique collection of in-house-developed DMPM preclinical models, with the aim to assess the potential of a miR-34a-based approach for disease treatment. miR-34a was found to be significantly down-regulated in forty-five DMPM clinical specimens and five established cell lines compared to normal peritoneum. miR-34a reconstitution inhibited cell proliferation in a time-dependent manner, though to a different extent and with different kinetics across individual cell lines. Such a variable antiproliferative effect was paralleled by a different kinetics of apoptosis induction. In addition, miR-34a ectopic expression significantly inhibited cell migration and invasion in two miR-34a-reconstituted cell lines was found to counteract the antiproliferative and pro-apoptotic action of DMPM xenograft models. Interestingly, an persistent activation of ERK1/2 and AKT in two miR-34a-reconstituted cell lines was found to counteract the antiproliferative and pro-apoptotic effects of miRNA, yet not affecting its anti-invasive activity. Most importantly, when three subcutaneous/orthotopic DMPM xenograft models were used to examine the impact of miR-34a on tumorigenesis, a significant reduction in tumor size and growth was consistently observed. Our preclinical data, showing impressive inhibitory effects induced by miR-34a on DMPM cell proliferation, invasion and growth in immunodeficient mice, strongly suggest the potential clinical utility of a miR-34a-replacement therapy for the treatment of such a still incurable disease. On the other hand, we provide the first evidence of a potential cytoprotective/resistance mechanism that may arise towards miRNA-based therapies through the persistent activation of receptor tyrosine kinase downstream signaling. Interestingly, a persistent activation of ERK1/2 and AKT in two miR-34a-reconstituted cell lines was found to counteract the antiproliferative and pro-apoptotic effects of miRNA, yet not affecting its anti-invasive activity. Most importantly, when three subcutaneous/orthotopic DMPM xenograft models were used to examine the impact of miR-34a on tumorigenesis, a significant reduction in tumor size and growth was consistently observed. Our preclinical data, showing impressive inhibitory effects induced by miR-34a on DMPM cell proliferation, invasion and growth in immunodeficient mice, strongly suggest the potential clinical utility of a miR-34a-replacement therapy for the treatment of such a still incurable disease. Background: Growing evidence suggests importance of aberrant microRNA (miRNA) expression in development and progression of cancer. Recent studies have demonstrated the potential of miRNA panels as promising diagnostic, prognostic and predictive biomarkers. Objective: The purpose of the present study was to evaluate the clinical and functional significance of miRNAs in esophageal cancer (EC). Methods: Herein, we evaluated the diagnostic potential of a five miRNA panel (consisting of miR-21, miR-144, miR-107, miR-93 and miR-342) in EC detection using quantitative real time PCR (qRT-PCR). To evaluate the discriminatory power of miRNA panel, receiver operating characteristic curve (ROC) curves were generated for each of the miRNAs followed by risk score analysis. Briefly, linear regression models were fitted using the cancer status and each of the risk score as input. ROC curves were then used to evaluate the diagnostic potential of the panel and to find out the appropriate cut-off point. Sensitivity and specificity of the panel were then determined. Further, pathway enrichment analysis was carried out to find the most significant pathways targeted by these miRNAs. Next, we elucidated the role of miR-144, by silencing it in KYSE-150 cells. We then evaluated the clinical and functional significance of miRNAs in EC by targeted miRNA assay and scratch assay. Potential targets of miR-144 were predicted by in silico approach followed by in vitro validation by luciferase reporter assay. Results: The ROC curve analysis indicated that the panel of five miRNAs (AUC = 0.851, p < 0.0001) constitutes a more sensitive and specific diagnostic marker as compared to any of the single miRNAs. Most importantly, panel of circulating miRNAs showed enhanced sensitivity (87.5%) and specificity (90.4%) with an AUC of 0.96 (p < 0.001) in discriminating EC patients from normal subjects. Inhibition of miR-144 significantly suppressed the proliferation of ESCC cells by 42.085 ± 1.73% at 72 h post transfection. Moreover, knockdown of miR-144 decreased (p=0.046) the migration potential of KYSE-410 cells as compared to the cells treated with negative control. In silico analysis and further validation by dual-luciferase reporter assay revealed PURA to be a direct downstream target of miR-144. Conclusion: Herein, we have demonstrated the potential diagnostic implication of five miRNA panel. Further, we have shown that mir-144 acts as an oncogenic miRNA by targeting PURA and promotes EC cell proliferation.

#5454 Serum circulating microRNAs as potential biomarkers for prostate cancer. Khamni Kasomva,1 Ignacimuthu Savarimuthu,1 Gabriel Michael Paulraj,1 Arnab Sen,2 Stephen Salio,3 Ngachan SV.3 Entomology Research Institute, Loyola College, Chennai, Chennai, India; 2ICAR Research complex for NEH region, Umiam, India; 3North Eastern Indira Gandhi Regional Institute of Health and Medical Sciences, Shillong, India.

MicroRNAs (miRNAs) are small non-coding RNA, whose differential expression has been involved in the development and progression of cancers, including prostate cancer (PCa). In recent studies circulating miRNAs have been demonstrated to have the potential as non-invasive biomarkers in various types of cancer. The aim of this study was to investigate the serum circulating miRNA-103 could be used in diagnosis of prostate cancer in North-Eastern India patient population. To evaluate this study blood samples were collected from prostate cancer patients and healthy controls following ethical approval and informed consent. The samples were reverse transcribed using stem loop primers and expression levels of miRNA-103 were determined using real time PCR. Differential expressions of miRNA-103 for each case were used to compare PCa serum with healthy serum samples. Serum circulating miR-103 levels was significantly lower in PCa patients compared with healthy controls. The serum circulating miRNA-103 could be potential for the diagnosis of PCa in North-East India Population.

Tumor suppressor p53, guardian of the genome, is frequently mutated or functionally dysregulated in more than 50% of human tumors. p53 mutation is a later event in tumorigenesis and a number of p53 mutants have “Gain of Function” (GOF) properties that have been shown to promote invasive and more aggressive phenotypes in cancer cells. Mutant p53 has been an attractive and promising therapeutic target for advanced stages of tumors. Yet, mutant p53 has proved to be one of the most undruggable targets. Thus, there is continued interest in understanding the GOF properties of mutant p53 and in designing novel strategies to target mutant p53 and/or key GOF pathways. Mature MicroRNAs (miRNAs) are ~22 nt endogenous, non-coding RNA sequences that bind to 3′UTR of their target genes and inhibit their translation. miRNA mimics are emerging therapeutics and attractive tools for mapping pathway networks. We developed a novel functional high throughput screening (HTS) assay to identify miRNAs that selectively target mutant p53-expressing cell lines. The HTS was performed in isogenic TP53+/+ (wild-type), TP53−/− (null) and TP53 R175H (mutant) HCT-116 colorectal cancer cell lines. Cell viability was used as the HTS read-out of our functional screen. Of 2754 miRNA mimics screened, we identified 56 miRNAs that selectively target TP53 R175H (mutant) cells. Our ongoing work is directed to further validating and identifying which of these miRNAs mimics selectively induce apoptosis in mutant p53-expressing cells. We are also using reporter-based assays to identify a fraction of the 56 miRNAs that can bind to the p53 3′UTR. Our long-term goal is to selectively target mutant p53-expressing cells using miRNA mimics as single agents or in combination with FDA-approved or experimental therapeutics. Our strategy is may provide a unique opportunity for development of targeted therapy for TP53 mutant tumors.

#5456 Avoiding chemotherapy resistance in squamous cell carcinomas: antitumor activities of terpenoids and their impact on the regulation of microRNAs. Camila Hernandez,1 Bruna da Silva,1 Maria de Fatima Garrido Klingbeil,2 Monica Beatriz Mathor,3 Ana Maria Soares Pereira,3 Patricia Sevigny,3 Rihan El Bezawy, Michelandrea raj,1 Arnab Sen,2 Stephen Sailo,3 Ngachan SV2. 1Universidade de Ribeirao Preto, Ribeirao Preto-SP, Brazil; 2Nu-clear and Energetic Research Institute IPEN/CNEN, Sao Paulo - SP, Brazil; 3Nu-clear and Energetic Research Institute IPEN/CNEN, Sao Paulo - SP, Brazil.

MicroRNAs are small noncoding RNAs that play important roles in cellular biology. They have been implicated in pharmacogenomics by down-regulating genes that are essential for drug function. In this work we verified the potential antitumor activity of the quinone methide triterpenes maytenin and 22β-hydroxymaytenin, as well as of a quinone methide triterpene-rich extract obtained from cultivated Maytenus ilicifolia root cells, and evaluated the associated microRNA expression following half maximal inhibitory concentration (IC50).

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
treatment. Standard selectivity index (SI) for the isolated compounds and the root cell extract was determined by the logarithmic shift in effective concentration (IC\textsubscript{50}) between cancer cell lines and oral keratinocytes. Both isolated molecules as well as the root cell extract presented pronounced antiproliferative and pro-apoptotic activities in four cell lines derived from head and neck squamous cell carcinomas, including a metastasis-derived cell line. A positive SI, with an average 2-fold increase in potency, was detected for single agents and for the extract. MicroRNA expression profiles were assessed at 24h, 48h and 72h following treatment and an average of 100 molecules presented consistent marked variation in expression levels. Considering associations of microRNAs, genes they regulate, and the drugs effects dependent on these genes, the down-regulation of hsa-miR-138 and hsa-miR-21 in treated cells was of particular interest. Both microRNAs have been involved in 5-fluorouracil and cisplatin resistance, current agents of standard chemoradiotherapy for locally advanced head and neck cancer. Squamous cell carcinoma of the head and neck is one of the most common cancer types worldwide whereas treatment options based on conventional therapies or targeted therapies under development have limited efficacy. Plant-derived products are valuable sources for the development of new therapeutic options for cancer treatment or as synergistic agents in existing regular care.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Oxidative Stress, Autophagy, and Senescence

#5457 OGT restrains the NRF2 antioxidant pathway via O-GlCNacylation of KEAP1. Po-Han Chen, Timothy J. Smith, Jianli Wu, Michael Boyce, Jen-Tsan Ashley Chi. Duke University, Durham, NC.

O-GlCNacylation is a reversible post-translational modification that adds an O-linked β-N-acetylglucosamine (O-GlcNAc) moiety onto serine/threonine residues of target proteins. This modification is regulated by only two enzymes; O-GlCNAC transferase (OGT, the writer) and O-GlCNACase (OGA, the eraser) in mammals. Recent studies have revealed that OGT expression and O-GlCNAC modifications are elevated in several cancers, but specific O-GlCNAC targets are not well defined. We conducted a global transcriptome profiling in MDA-MB-231 breast cancer cells to search for signaling events that respond to O-GlCNAC fluctuation. We found significant up-regulation of genes involved in the NRF2-dependent stress response when OGT activity is inhibited in different tumor types. We also discovered a strong positive correlation of gene signatures between low OGT activity and NRF2 activation in multiple human tumor gene expression datasets. NRF2, the primary regulator of redox balance, is usually activated by oxidative stress and repressed under basal conditions by the KEAP1-CUL3 ubiquitin ligase complex. However, we found that OGT inhibition increases NRF2 protein level through reducing poly-ubiquitination of NRF2 in the absence of oxidative stress. By chemical sugar labeling and mass spectrometry assays, we identified that KEAP1 is directly O-GlCNAcylated by OGT especially within the BTR and Kelch motifs. Of all 11 putative O-GlCNAC sites on KEAP1, we found serine 104 is responsible for regulating NRF2 activity. NRF2 protein level through reducing poly-ubiquitination of activated by oxidative stress and repressed under basal conditions by the NRF2 expression datasets. NRF2, the primary regulator of redox balance, is usually dependent stress response when OGT activity is inhibited in different tumor cell lines. Senescence is induced in normal cells by various stresses, such as aberrant oncogene signaling, and serves as a major tumour-suppressive barrier that must be bypassed for cellular transformation in vitro and tumorigenesis in vivo. Previous reports show that aberrant reactivation of EMT-inducing tran-scription factors (EMT-TFs) promotes senescence bypass. Thus, aberrant EMT may drive tumor initiation in addition to providing cancer cells with mesenchymal and stem cell properties that drive tumor progression, metastasis, and tumor recurrence. Conversely, our studies here indicate that much like aberrant oncogene signaling, aberrant EMT and CSC-properties induced by OSM may drive tumor initiation in transformed cancer cells. Senescence is induced in normal cells by various stresses, such as aberrant oncogene signaling, and serves as a major tumor-suppressive barrier that must be bypassed for cellular transformation in vitro and tumorigenesis in vivo. Previous reports show that aberrant reactivation of EMT-inducing tran-
focused on modulation of c-myc and miR34 levels and the IL1/6/8 signaling axis as potential strategies for interference with senescence and suppression of residual (dormant) tumor growth and cancer recurrence.

#5460 Targeting tumors by inhibiting mitochondrial electron transport. Arvinder Kapur, Amruta P. Nayak, Thomas Beres, Kayva Rath, Mildred Feder, Amani Gillette, Spencer Erickson, Melissa Shala, Liza Barroilhet, Manish S. Patankar. *Univ. of Wisconsin-Madison, Madison, WI.*

Recently, we demonstrated that the monopetrene, citral, is potent inhibitor of cell proliferation. Here, we are demonstrating that the α,β-unsaturated carbonyl functionality of citral is responsible for its biological activity causing substantial increase in intracellular oxygen radicals. The resulting oxidative stress activates p53. Neutralization of oxygen radicals by N-acetylcysteine attenuates the cytotoxic effect of citral and inhibits activation of p53. Inhibition of p53 by pifithrin-α inhibits citral-induced apoptosis. Oxidative stress caused by citral initiates downstream events causing apoptosis of cancer cells. With the identification of α,β-unsaturated carbonyl group as the obligatory functionality for the anti-cancer effects of citral, we surveyed other small molecule drugs that shared this chemical entity. Cinnamaldehyde, nonenal, perillaldehyde, curcumin, and plumbagin have the α,β-unsaturated carbonyl functional groups and have demonstrated anti-cancer effects. Using curcumin and plumbagin as prototypes, we were able to demonstrate similarities in the cytotoxic mechanism with citral. The oxidative stress caused by curcumin and plumbagin is the initiating step required for cancer cell apoptosis. Fluorescent Lifetime Imaging Microscopy (FLIM) showed that exposure to plumbagin results in increase in free NADH/FAD ratio. Additionally, in silico modeling showed that plumbagin and curcumin docked to the active site of complex I and III of the mitochondrial electron transport chain. Using the Seahorse analyzer, our experiments showed that plumbagin and curcumin inhibited the oxygen consumption rate in treated cells. These results indicate that the α,β-unsaturated carbonyl containing compounds produce their cytotoxic effects by interfering with the electron transport chain. The cancer cells respond to the surge in oxygen radicals by increasing the expression of Nrf-2, the transcription factor that regulates major anti-oxidant responses. This compensatory mechanism is a form of chemoresistance that allows cancer cells to evade the cytotoxic effects of agents such as citral. We will present data from strategies to inhibit the Nrf-2-mediated compensation and thereby enhance the cytotoxic activity of citral, curcumin and plumbagin. The data obtained through these experiments is providing important information that will allow designing of novel agents that can interfere with the electron transport chain and inhibit tumor growth by inducing oxidative stress.

The transcription factor p73 is a homologue of p53 that can be expressed as pro- or anti-apoptotic isoforms. Unlike p53, p73 is rarely mutated or lost in cancers and it is found to replace defective p53 inducing apoptosis. Here, we investigated the p73 involvement in anoikis, a type of apoptosis caused by inadequate cell matrix interactions. Breast cancer cells lines with different p53 status were treated with doxorubicin or docetaxel and cells detached from the extracellular matrix were analyzed. We demonstrate for the first time that doxorubicin-induced cell detachment is associated with p73 cleavage and caspase activation, independently of the p53 status. However, we did not detect p73 cleavage or caspase activation in detached cells under doxetaxel treatment. Overexpressing the apoptotic isoform of p73 led to cell detachment associated with p73 cleavage and caspase activation. Interestingly, p73 cleaved forms localize to the nucleus during the late phase of cell death indicating an increase in the transcriptional activity. Our study suggests that the cleavage of p73 on specific sites may release its pro-apoptotic function and contribute to cell death.

#5462 GTP cyclohydrolase in brain tumor stem cells is implicated in glioblastoma growth. Anh N. Tran, 1 Kiera Walker, 1 David Harrison, 2 Wei Chen, 3 James Mobley, 2 Lauren Hocevar, 1 James R. Hackney, 1 Randee S. Sedaka, 1 Jennifer S. Pollock, 1 Sara J. Cooper, 1 George Y. Gillespie, 1 Anita B. Hjelmeland. 1University of Alabama at Birmingham, Birmingham, AL; 2Vanderbilt University, Nashville, TN; 3HudsonAlpha Institute for Biotechnology, Huntsville, AL.

Glioblastomas (GBMs) are the most common primary brain tumors in adults and one of the most aggressive cancers with high rates of recurrence and therapeutic resistance. In GRMs, subpopulations of highly tumorigenic cells called brain tumor initiating cells (BTICs) have been characterized by their unique capacity to promote tumor maintenance, therapeutic resistance, and angiogenesis. BTIC maintenance is known to be regulated by reactive oxygen and nitrogen species. GTP cyclohydrolase, or GCH1, is a critical molecule regulating reactive species levels. We found that expression of GCH1 RNA and protein were upregulated in BTICs in comparison to non-BTICs. Overexpression of GCH1 in glioma cells increased cell growth in vitro and increased tumor formation and decreased survival in an intracranial GBM mouse model. In contrast, knockdown of GCH1 RNA in GBM cells led to growth inhibition in vitro as well as increased survival in animal orthotropic models. Furthermore, genetic modulation of GCH1 led to altered ROS levels in GBM xenolines. In silico analyses demonstrate that higher GCH1 levels in glioma patients correlate with higher glioma grade, recurrence and worse survival. Together, our data suggest that upregulation of GCH1 in BTICs promotes tumor maintenance and is a key regulator of reactive oxygen species in glioblastoma.

#5463 Disulfiram suppresses metastasis via induction of anoikis and calpain activation in triple-negative breast cancer. Eunhye Oh, Daeh Sung, Youngkwan Cho, Ji Young Kim, Nahyun Lee, Yoon-Jae Kim, Tae-Min Cho, Jae Hong Seo. *Korea University, Seoul, Republic of Korea.*

Triple-negative breast cancers (TNBC) exhibit aggressive phenotypes and are associated with poor clinical outcomes due to a lack of effective therapeutic strategies. Disulfiram (DSF) is a clinical therapeutic drug for the treatment of alcoholism, and has also been shown to exhibit antitumor activity in TNBC cells in a copper (Cu)-dependent manner, although how this occurs has not been clearly elucidated. We sought to investigate the mechanisms responsible for DSF/Cu-dependent induction of apoptosis and suppression of lung colonization by these cells. DSF/Cu was shown to induce a Cu-dependent increase in free NADH, as measured by NADH/FAD ratio. Additionally, exposure to DSF/Cu was found to induce a Cu-dependent decrease in cell viability and colony formation, which was associated with an increase in the cleavage of pro-caspase-3 and the upregulation of calpain, a protease involved in apoptosis. Taken together, these findings warrant further investigation of disulfiram as a potential treatment for metastatic TNBC.

#5464 Catalase mediates the survival of anchorage-independent ovarian cancer cells. Cassandra L. Libbing, Calli A. Versagli, Saint Mary’s College, Notre Dame, IN.

Among United States women, ovarian cancer is the fifth leading cause of cancer-related death and the deadliest of the female reproductive system cancers. This is due to a lack of early detection, in effect, leading to primary diagnosis in later, metastasized stages for which there are few effective treatment options. In order to metastasize, ovarian cancer cells must be able to survive detachment from the extracellular matrix (ECM). When a non-tumorigenic mammary epithelial cell detaches from the ECM, research has shown that levels of Reactive Oxygen Species (ROS) rise in the cell and inhibit cell metabolism resulting in decreased cell survival. Previous research has also shown that ECM-detached breast cancer cells are able to utilize antioxidant enzymes to neutralize ROS that Enter with N-acetyl-L-cysteine (NAC) and promote cell survival. This antioxidant activity has also been shown to bolster cancer cells’ survival in anchorage independence. Although studied in breast cancer cells, no work has been done in ovarian cancer, which exhibits a very unique mode of metastasis through the peritoneal fluid. To begin to understand the role of antioxidant enzymes in metastatic ovarian cancer cells, we have worked to characterize the role of catalase, a prominent antioxidant enzyme, in the survival of ECM-detached SKOV3 ovarian cancer cells. In order to do so, we utilized short hairpin RNA (shRNA) to engineer SKOV3 cells deficient in catalase. The catalase-deficient cells were then tested for colony formation in detachment and cell viability and proliferation in both attachment and detachment. The results show that elimination of catalase expression does not have a significant effect on proliferation in attachment or detachment, but significantly decreases both cell viability and colony formation of SKOV3 cells grown in ECM-detachment. This suggests that elimination of catalase expression may hold promise for targeted treatment in late stage ovarian cancer, calling for further investigation of the mechanisms behind these results and the role that other antioxidant enzymes play in ovarian cancer. Future studies include looking at this phenomenon in other ovarian cancer cell lines, and using mouse xenograft studies to examine the effects of antioxidant compounds on survival of metastatic ovarian cancer cells.

#5465 Persistent oxidative stress in mouse intestinal and colonic epithelial cells after exposure to 131I-iodination. Shubhankar Suman, Santosh Kumar, Albert J. Fornace, Kamal Datta. *Georgetown Univ., Washington, DC.*
Purpose: $^{12}\text{C}$-ion radiotherapy is demonstrating favorable results compared to photon radiotherapy for select cancers. While normal tissue exposure is lower with $^{12}\text{C}$-ions relative to $\gamma$-rays, it cannot be completely eliminated and therefore, late tissue toxicity, inflammation and secondary carcinogenesis cannot be ruled out. The goal of this study was to assess the extent of persistent oxidative stress (POS) after radiation exposure and compare the results through autovivary radiation exposure. Methods and Materials: Mice (C57BL/6; 6 to 8 weeks; male) were irradiated with 0.5 or 1.3 Gy of $\gamma$ or $^{12}\text{C}$-ion, and intestinal (IEC), colon (CEC) epithelial cells and tissues were collected 2 months after radiation exposure. In epithelial cells, intracellular ROS, mitochondrial superoxide, mitochondrial membrane potential (MMP), and cardiopulmonary oxidation were studied by flow-cytometry, superoxide dismutase, SOD, catalase, and NADPH oxidase activity along with lipid oxidation were also assessed in epithelial cells using biochemical assays. Results: Our results clearly showed radiation quality and dose-dependent induction of POS. Both intestine and colon showed a higher elevation of intracellular ROS, mitochondrial superoxide, NADPH oxidase activity, and mitochondrial cardiopulmonary oxidation after $^{12}\text{C}$ relative to $\gamma$ radiation. Moreover, antioxidant enzyme activities in intestine and colon was also significantly reduced in $^{12}\text{C}$-irradiated mice. Compared to $\gamma$ radiation, membrane lipid damage was remarkably higher in both intestine and colon of $^{12}\text{C}$-ion irradiated mice. At 0.5 Gy, persistent oxidative damage indicated by 4-hydroxynonenal was 3-fold in colon and 1.6 fold in intestine after $^{12}\text{C}$ relative $\gamma$ radiation. Conclusions: Mitochondrial deregulation, increased NADPH oxidase activity, and loss of SOD and catalase activities were the major contributory events in $^{12}\text{C}$-ion induced POS in mouse GI tissues. Compared to intestine, colon was more susceptible to POS induction that might be due to progressive cell turnover in intestine resulting in faster elimination of initial damage signal in a given time than colon. Taken together, our data suggest that normal tissue exposure to $^{12}\text{C}$ radiation carries higher long-term risk relative to $\gamma$-rays at comparable doses and further detail evaluation is warranted.

#5466 Mitochondrial superoxide inhibits autophagy and induces apoptosis through SQSTM1-mediated mechanism. Heather G. Hambright, Addanki P. Kumar, Rita Ghosh. UT Health Science Center at San Antonio, San Antonio, TX.

Metastatic melanoma has a dismal survival rate for patients, despite recent advances in targeted and immune-therapies. Recent studies show that elevated autophagy and reoxidation in melanoma cells contributes to chemotherapeutic resistance, making these biological processes ideal therapeutic targets. However, gaps still exist regarding the mechanism by which pro-oxidant therapies affect autophagic signaling and the ultimate impact on melanoma cell fate. We previously demonstrated that pro-oxidant compound Neuretinin (NX) selectively inhibits melanoma cell survival and autophagy. Using mass spectrometry we identified SQSTM1/p62, a substrate of the ubiquitin-proteasome system, as a possible mediator for the observed outcomes. We subsequently showed that under the stress the reduction of SQSTM1/p62 remained unknown. Thus, the primary objective of this study was to determine how p62 regulates cell fate during oxidative damage. We used a panel of primary melanocyte and melanoma cells to evaluate i) proapoptotic degradation of p62 during oxidative stress-induced autophagy blockage, ii) the requirement for p62 during NX-induced apoptosis, iii) effect of NX-induced superoxide on autophagy and cell survival, iv) association of p62 with caspase-8 during oxidative damage, and v) subcellular localization of NX. Proapoptotic degradation was evaluated using MG132 and western blotting for p62 following NX. We used genetic approaches (RNAi and overexpression using HA-p62) to determine the role of p62 in cell fate as determined by survival, apoptosis, and autophagy measurements. Fluorescence microscopy was used to determine the subcellular localization of NX. Generation of superoxide was determined using mitoSOX and mitoTEMPO pre-treatment was used to determine specificity. We found that i) NX-induced ROS inhibits p62 protein by stimulating proapoptotic degradation, ii) p62 mediates apoptosis in response to high levels of oxidative damage through caspase-8, iii) NX generates superoxide which inhibits NADPH oxidase activity along with lipid oxidation were also assessed in epithelial cells using biochemical assays. Results: Our results clearly showed radiation quality and dose-dependent induction of POS. Both intestine and colon showed a higher elevation of intracellular ROS, mitochondrial superoxide, NADPH oxidase activity, and mitochondrial cardiopulmonary oxidation after $^{12}\text{C}$ relative to $\gamma$ radiation. Moreover, antioxidant enzyme activities in intestine and colon was also significantly reduced in $^{12}\text{C}$-irradiated mice. Compared to $\gamma$ radiation, membrane lipid damage was remarkably higher in both intestine and colon of $^{12}\text{C}$-ion irradiated mice. At 0.5 Gy, persistent oxidative damage indicated by 4-hydroxynonenal was 3-fold in colon and 1.6 fold in intestine after $^{12}\text{C}$ relative $\gamma$ radiation. Conclusions: Mitochondrial deregulation, increased NADPH oxidase activity, and loss of SOD and catalase activities were the major contributory events in $^{12}\text{C}$-ion induced POS in mouse GI tissues. Compared to intestine, colon was more susceptible to POS induction that might be due to progressive cell turnover in intestine resulting in faster elimination of initial damage signal in a given time than colon. Taken together, our data suggest that normal tissue exposure to $^{12}\text{C}$ radiation carries higher long-term risk relative to $\gamma$-rays at comparable doses and further detail evaluation is warranted.

#5467 Prophosphoproteomic analysis of pyruvate dehydrogenase in response to environmental stress. Wendi O’Neill, Tereza Golias, Martin Benej, Nicholzas Denko. The Ohio State University, Columbus, OH; Slovak Academy of Sciences, Bratislava, Slovak Republic.

Pyruvate dehydrogenase is a mitochondrial enzyme that regulates the flux of carbohydrates into oxidative phosphorylation. The activity of PDH is largely regulated by reversible phosphorylation. The pyruvate dehydrogenase kinases inhibit phosphorylations to PDH on the E1α subunit at positions 232, 293, and 300. Interestingly, there is a family of 4 related PDHK genes with overlapping affinity for the 3 phosphorylation sites. PDHK1 and PDHK3 have been identified as hypoxia-inducible at the transcriptional level, and PDHK1 has been shown to be important for the growth of model tumors. This work attempts to more carefully define the functions of PDHK1 and 3 using CRISPR technology in colorectal cancer lines in vitro and genetically engineered mice in vivo. Using antibodies specific for the phosphorylated sites on E1α, we find that PDHK1 is essential for the phosphorylation of the 232 site in response to hypoxia and partially responsible for the hyperphosphorylation of 293 and 300. The level of phosphorylation in response to hypoxia is also sensitive to nutrients in the environment, with high levels of glucose enhancing E1α phosphorylation in hypoxia. Analysis of the number of phosphorylations on individual E1α molecules using isoelectric focusing shows a range of events, with some molecules having 2 or 3 phosphorylations, while a large fraction of the E1α remains un-phosphorylated in hypoxia. This type of pattern suggests a non-random phosphorylation of the multiple sites. Analysis of PDH activity supports the in vitro findings that any single phosphorylation event is sufficient to inhibit PDH complex activity. Preliminary mitochondrial oxygen consumption experiments show that colorectal cancer cells are less dependent on PDHK1 for regulating mitochondrial function compared to published data in pancreatic and head and neck cancer. Finally, analysis of PDH phosphorylation in mice supports a role for PDHK1 in the regulation of PDH activity in response to fasting and blood glucose levels. In conclusion, regulation of PDH in normal and cancerous colonicocytes appears to be sensitive to environmental oxygen and nutrients. PDHK1 is the PDHK family member with the greatest influence on the addition of non-random inhibitory phosphorylation events. These in vitro findings will be analyzed with respect to the findings obtained using the new PDHK1 f/f null mouse.

#5468 Expression of aquaporin 11 as a potential predictor of cisplatin sensitivity. Jason V. Evans, Anwar Akhtar, David P. Carbone, Mikhail M. Dikov, Elena E. Tchekeeva. West Virginia University, Morgantown, WV; Ohio State University, Columbus, OH.

Platinum-based combination is a standard of care treatment for lung cancer patients. Accumulating evidence indicates that aquaporins are emerging targets in cancer. Aquaporin 11 (AQP11), a non-ubiquitous member of aquaporins family, is an endoplasmic reticulum (ER)-specific water channel mostly present in epithelial cells and is implicated in the maintenance of ER homeostasis. In our previous studies, we demonstrated that under conditions of ER stress the reduction of AQP11 expression is a pro-apoptotic factor in normal epithelial cells. We revealed that under normal conditions AQP11 is heavily S-nitrosylated forming functionally important multimeric structures (> 1000 kDa), whereas cisplatin treatment interferes with AQP11 causing its structural and post-translational modification. We hypothesized that if tumor cells express AQP11 then cells with lower levels of AQP11 are not protected from cisplatin-associated ER stress and develop higher sensitivity to drug treatment. In normal lung AQP11 is expressed at low levels. We evaluated the expression of AQP11 in lung cancer cells to determine whether the AQP11 expression correlates with cisplatin sensitivity and whether lower AQP11 expression in lung tumor associates with positive overall survival in patients with lung adenocarcinoma. A strong link between the level of AQP11 protein expression and cell sensitivity to CP was detected using MTT assay. Screening lung cancer cell lines we found that all tested cancer cell lines expressed AQP11 protein at various levels. Western blot of stress markers showed that cisplatin-treated cells with higher AQP11 expression had lowered cellular and ER stress. Reduction of AQP11 expression using shRNA AQP11 silencing in cisplatin-resistant A549 and HCC827 cell lines, resulted in the significant increased up to 3-fold sensitivity to cisplatin compared with control shRNA transfected or parental non-transfected cells (p<0.001). In sensitive H460 cells, knocking down AQP11 did not change sensitivity to cisplatin. TCGA database analysis of previously untreated lung adenocarcinoma, detected 13% tumors with elevated AQP11 mRNA expression. Lower AQP11 expression was
significantly associated with higher OS and higher median survival rate (52.5 vs. 34.47 mo) than in patients with high AQP11 expression (p < 0.05). AQP11 gene is located within oncogenic 1q13-q14 amplicon, which is a common aberration in solid tumors associated with poor prognosis. The AQP11 is a pro-survival factor protecting tumor cells from cisplatin-induced stress. Low AQP11 expression associates with higher OS in lung adenocarcinoma patients and with higher cisplatin sensitivity in lung cancer cell. The ER stress aggravation via interference with AQP11 could become a prospective therapeutic approach in anti-tumor treatment.

#5469 Low dose ionizing radiation induces persistent activation of NA-DPH oxidase pathway in mouse colon. Santosh Kumar, Shubhankar Suman, Bo-Hyun Moon, Albert J. Fornace, Kamal Datta. Lombardi Cancer Center, Georgetown University, Washington, DC

Exposure to ionizing radiation has been linked to persistent oxidative stress. The purpose of the current study was to characterize the role of NADPH oxidase pathway in radiation-induced increased oxidant production in colon epithelial cells. Mice (C57BL/6); 6-8 weeks, male) were exposed to either sham or 0.5 Gy radiation, and NADPH oxidase pathway and oxidative stress markers were assessed in colon samples 60 d after exposure. Radiation exposure led to higher elevation of 4-HNE and 8-oxo-dG staining relative to unirradiated control. We also observed increased staining for the proliferative marker phospho-histone H3 in colon sections of irradiated mice. PCR analysis showed increased expression of two NADPH oxidase isoforms, Nox1 and Nox3, in irradiated samples. Additionally, expression of NoxA1 and Nox1 along with Hif1α were also increased after radiation. Immunoblot analysis confirmed the PCR results, and ChIP assay revealed greater binding of stress response factor GATA6 and Hif1α to Nox1 and Nox3, and Nox3 promoters respectively after radiation exposure relative to control. Co-immunoprecipitation experiments showed enhanced binding of Rac1, an activator of NADPH oxidase, to Nox1 and Nox3. In summary, we demonstrated that exposure to a low dose of γ radiation caused long-term up-regulation of NADPH oxidase isoforms as well as its regulators and activators such as NoxA1, Nox1, Hif1α, TLR4, GATA6, Doux1, and Doux2. When considered along with our results on oxidative stress and proliferative markers, our observations on NADPH oxidase pathway provides new insight into molecular events contributing to radiation-induced persistent oxidative stress and cell proliferation in colon, and have implications for colorectal carcinogenesis.

Disease recurrence at either primary or metastatic tumor sites arising from dormant tumors is largely responsible for the morbidity and mortality of many cancers. Although cellular quiescence has been proposed as a mechanism of dormancy, the nature of the growth arrest that allows tumor cells to re-emerge months or years after treatment has never been directly determined. The current work was designed to examine the hypothesis that the senescence induced by cancer chemotherapeutic drugs could be reversible, with implications for tumor dormancy and disease recurrence. Studies were performed using etoposide in models of non-small cell lung cancer (NSCLC). Exposure to etoposide at sub-lethal concentrations resulted in growth arrest accompanied by the induction of senescence and autophagy. Growth arrest transient in that proliferative recovery was evident by day 7 post-etoposide exposure. Analysis of senescence based on β-galactosidase activity demonstrated that the restoration of proliferative capacity coincided with a decline in the extent of senescence. Real-time live microscopy demonstrated heterogeneous fates of senescent cells, where the bulk of the cell population remaining in a state of stasis, a subset of cells undergoing apoptosis, and a fraction of the large, flattened, and polyploid cells spontaneously entering into mitosis. Neither genetic nor pharmacological inhibition of autophagy influenced the senescence response to etoposide, the eventual proliferative recovery, or sensitivity to etoposide. These findings indicate that the induction and resolution of senescence is independent of the accompanying autophagy, and that the autophagy induced by etoposide is non-cytotoxic in function. These observations suggest that therapy-induced senescence may ultimately be a transient process in that at least a subpopulation of tumor cells can and will regain proliferative capacity. Consequently, therapy-induced senescence could potentially be studied as a model of tumor dormancy, and the reversibility of senescence as a model of disease recurrence.

#5471 LSD1 stimulates cell survival and epigenetic homeostasis via snail in hepatocellular carcinoma. Yong Hwa Jo, Minam Nam Nguyen, Tae Gyu Choi, Sung Soo Kim. Kyung Hee Univ. - Seoul Campus, Seoul, Republic of Korea.

HCC is the fifth most common malignancy in the world. HCC generally arises in the context of chronic liver diseases, or other metabolic, dietary or toxic factors. Hypoxia is a critical microenvironment in hepatocarcinogenesis. It occurs in series of distinct steps that include tumor cell invasion and proliferation. The process of EMT required for liver cancer cell invasion is regulated by a family of E-box binding transcription repressors, which include Snail and Slug. Protein N, the first discovered histone methylase, is an epigenetic enzyme playing important role in regulation of gene expression and function by removing mono- or dimethyl moieties from H3K4 and H3K9. However, the molecular mechanisms underlying these biological behaviors have not been completely elucidated. Here, we present the first evidence that expression of Protein N was significantly associated with higher HIF1α expression. We also showed that the up-regulated Protein N enhanced HCC cell survival and sustained epigenetic homeostasis via activating Snail under hypoxic conditions in vitro/in vivo. Furthermore, we revealed that Protein N/Snail stimulated Hif1α expression by a positive feedback loop. Consequently, we elicited that Protein N is an essential mediator in epigenetic aberrances of HCC (This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MEST) NRF-2016R1D1A1B03933763).

#5472 Yeast Bax Inhibitor (BXL1) is involved in redox and calcium homeostasis of the ER in S. cerevisiae. David Eagan, Joseph Alisch, Liam McDonough, Savannah Benko, Walter Jacob, Lukas Ritter, James Mullin, John O'Reilly, Nicanor Austriaco. Providence College, Providence, RI.

In mammals, the Bax inhibitor (TMBIM) family of proteins has cytoprotective properties that are most evident in paradigms of endoplasmic reticulum (ER) stress. The canonical gene of the family called BI-1 has been linked to several human cancers. The crystal structure of a proarytometric member of the family, Bi3Tet, has revealed that the Bax inhibitor proteins are pH sensitive calcium leaks. Our published studies have shown that the yeast Bax Inhibitor, Bxl1p, is localized to the endoplasmic reticulum and is involved in the unfolded protein response (UPR) that is triggered by endoplasmic reticulum (ER) stress. We now show that cells lacking BXL1 have an altered redox microenvironment in the ER. The ER of bxl1 cells exposed to dithiothreitol (DTT) and tunicamycin, two drugs known to induce the unfolded protein response (UPR), become more reduced than their wildtype counterparts. Moreover, we also report that cells lacking BXL1 accumulate more calcium in the ER than wildtype cells. Together, our data suggests that Bxl1p is involved in regulating the ER microenvironment. Other members of the TMBIM family may have the same role in normal and cancer cells. (Our laboratory is supported by grant NIGMS R15 GM110578, awarded to N. Austriaco.)

#5473 Towards a better understanding of MTH1 as a therapeutic target in RAS-driven cancer. Govind J. Samaranayake,1 Clara J. Troccoli,1 Mai Q. Huynh,1 Andrew Win,1 Debin Ji,2 Eric T. Kool,2 Priyamvada Rai1. 1Univ. of Miami Miller School of Medicine, Miami, FL; 2Stanford University, Palo Alto, CA.

Oncogenic RAS signaling-generated reactive oxygen species (ROS) drive tumor progression by the hyperactivation of proliferative, anti-apoptotic, and metastatic pathways. Elevated ROS levels however can also cause oxidative DNA damage, leading to oncogene-induced senescence (OIS) and cell death. To avoid such tumor-suppressive outcomes, RAS-driven tumors often upregulate redox-protective proteins. The collective research from our group over the last few years has shown that oncogenic RAS elevates expression of the mammalian 8-oxo-dGTPase MutT Homolog 1 (MTH1), which in turn enables evasion of OIS, promotes transformation efficiency, and facilitates tumorigenicity. Our prior work has therefore demonstrated that MTH1 is beneficial to the spectrum of RAS-driven transformation, and that its shRNA-mediated targeting in oncogenic RAS-harboring lung cancer cells produces robust tumor-suppressive outcomes. However the first wave of chemical MTH1 inhibitors has led to controversial and conflicting results regarding MTH1 as a chemotherapeutic target. Here we evaluate the benefit of MTH1 inhibition in wildtype. vs. oncogenic KRAS expressing cells, and directly assess the effects of oncogenic KRAS as well as three recently developed inhibitors on MTH1 8-oxo-dGTPase activity. Our results support that introduction of oncogenic KRAS elevates both MTH1 expression and activity, presumably through its elevation of ROS levels, and thus sensitizes cells to MTH1 inhibitors. The degree of this sensitization has a complex dependence on residual 8-oxo-dGTPase activity in the different cells following treatment with the MTH1 inhibitors, alternate antioxidant responses, and induction of different tumor suppressor pathways. Our data therefore highlight the importance of evaluating the molecular contexts and outcomes of MTH1 inhibition when determining its utility as a chemotherapeutic target.
#5474 Sphingosine kinase 2/sphingosine 1-phosphate signaling regulates p16 mediated accelerated aging in normal somatic tissues and tcf21 mediated tumor suppression in lung cancer. Shanmugam Panneer Selvam,1 Marion Cooley,1 Kristi Helke,1 Elizabeth Garrett-Mayer,1 Charles D. Smith,2 Besim Ogtetmen,1,2 Medical University of South Carolina, Charleston, SC;2Apoee Bio- techology Corporation, Hummelstown, PA.

Sphingosine 1-phosphate (S1P), a pro-proliferative sphingolipid generated by Sphingosine Kinases is upregulated in many cancers. Telomerase (hTERT), is a ribonucleoprotein that extends the ends of chromosomes (telomeres), to promote lung cancer growth. We discovered that SK2 generated S1P binds and stabilizes telomerase in the nuclear periphery by allosterically mimicking protein phosphorylation. Mechanically, S1P binding promotes telomerase stability. MKRN1 mediated degradation thereby preventing telomere dysfunction and senescence. The objective of this study is to delineate the molecular mechanism of SK2-S1P mediated telomere dysfunction in aging and lung cancer. SK2 knockout mice tissues showed increased telomeric DNA damage and senescence associated-beta galactosidase activity. Moreover, SK2 knockout mice displayed aging phenotypes by reduced subcutaneous fat, atrophy in spleens and hypoplasia in mice testes. Also, SK2 knockout fibroblasts showed increased senescence and robust p16 expression and interestingly, p16 ablation rescued SK2 knockout fibroblasts from senescence. Importantly, we found SK2 and telomerase protein levels to be upregulated in lung cancer tumors (n=48). Mechanistically, pharmacological inhibition of SK2 by ABC294640 (in Phase II clinical trial) leads to telomere dysfunction in A549 cells and increases p16 expression and increased MKRN1 expression in H110547. SK2 inhibition showed ATM/ATR kinase mediated p-CHK1 increase and subsequent activation of caspase-3 in both in vivo hamster and in vitro experiments and stable TCF21 knockdown prevents apoptotic cell death. Importantly, p16 overexpression in p16 deficient A549 lung cancer cells prevented caspase-3 activation and leading to senescence induction following inhibition of SK2-S1P by ABC294640 or shRNA against SK2. Overall, our data suggest that SK2-S1P regulates telomere dysfunction through p16 mediated aging in normal somatic tissues and TCF21 mediated tumor suppression in lung cancer and interestingly SK2-S1P and p16 acts as a molecular switch between senescence and apoptosis in normal and cancer cells respectively.

#5475 Functional profiling of germline EPAS1 variants associated with pheochromocytoma and paraganglioma. Edward Kim, Diana E. Benn, Roderick I. Clifton-Bligh, Trisha Dwight. Kolling Institute of Medical Research, St. Leonards, Australia.

Background: Endothelial PAS domain-containing protein 1 (EPAS1), encoding hypoxia-inducible transcription factor 2-alpha (HIF2α), is involved in regulation of cellular hypoxia responses and has been shown to play a role in several cancers including renal cell cancer and pheochromocytoma/paraganglioma (PPGL). HIF2 levels are tightly regulated, being low in normoxia but increased in hypoxia. Studying heritable PPGL syndromes has uncovered diverse genetic events that lead to oxygen-independent HIF stabilization. Using massively parallel sequencing, we noted several germline EPAS1 variants that occurred in subjects also carrying pathogenic mutations in either VHL or SDHB. In addition, two distinct EPAS1 variants were identified in separate individuals who did not harbor germline mutation in other known susceptibility genes. We therefore investigated whether these variants affected EPAS1 function. Method: Six different EPAS1 variants were identified in the germline of patients with PPGL: p.His194Arg, p.Arg247Ser, p.Phe374Tyr, p.Thr766Pro, p.Pro785Thr and p.Phe374Tyr, and transfected into HEK293 cells. HEK293 cells transfected with wildtype HIF2α were also subjected to hypoxic conditions for use as a positive control. Co-immunoprecipitation followed by Western blotting analyses were performed to determine whether: a) HIF2α mutations are still able to interact with VHL and ARNT; and b) HIF2α mutations are stabilized under normoxia. Candidate target gene expression (CCND1 and SLC2A) was measured by RT-qPCR. Results: Western blot analyses showed that p.Arg247Ser, p.Phe374Tyr, p.Pro351Thr and p.Pro785Thr amino acid changes in HIF2α were all more stable than wild-type HIF2α under normoxia. Co-IP of HIF2α with VHL showed significantly reduced interaction with p.Arg247Ser and p.Pro351Thr (p<0.05). Co-IP of HIF2α with ARNT failed to show any effect on interaction occurring as a result of the HIF2α variants. Interestingly only p.Pro351Thr was able to induce CCND1 and SLC2A gene expression (p<0.05). Conclusion: Germline EPAS1 variants p.Arg247Ser and p.Phe374Tyr share some functional features in common with the known oncogenic somatic variant p.Pro351Thr. These findings are clinically relevant to developing cancers that are dependent upon pseudo-hypoxia. Whether any of these EPAS1 variants will affect response to HIF2α antagonist therapies is yet unknown and may be of importance.

#5476 CIP2A can be a therapeutic target of rapamycin in radiosensitive head and neck cancer with P53 mutation. Song Hee Kim,1 Won hyeok Lee,1 Myung Jin Lee,1 Hye Won Chang,2 Ji Won Kim,2 Mi Ra Kim,2 Jung Je Park,2 Myung Woul Han,1 Sang Yoon Kim1.1 Univ. of Ulsan, Seoul, Republic of Korea;2 Inje University College of Medicine, Busan, Republic of Korea;3 Gyeongsang National University, Jinju, Republic of Korea.

The presence of p53 mutation was associated with poor survival in various tumors. The involvement of p53 in apoptosis and cell-cycle control makes it a plausible biomarker of prognosis. Classifying TP53 mutations in HNSCC described disruptive TP53 mutation in either the L2 or L3 loop of the DNA binding domain, resulting in polarity change within the protein, or stop codon. Disruptive TP53 mutation in HNSCC tumors predicts for locoregional recurrence, due to increased radiosensitivity via the inhibition of senescence. Senescence induction contributes to cancer therapy responses and is crucial for p53-mediated tumor suppression. However, whether p53 inactivation actively suppresses senescence induction has been unclear. Here, we found that overexpression CIP2A (cancerous inhibitor of protein phosphatase 2A) positively correlated with presence of p53 mutation in head and neck cancer and mediates radiosensitization through suppression of radiation induced senescence. And we demonstrated that rapamycin could induce senescence via CIP2A downregulation and increase radiosensitivity in p53 mutant disruption cell line. This is the first investigation to analyze CIP2A resistance to the radiosensitivity of head and neck cancer. As a consequence, a greater understanding of radiosensitivity mechanisms through our results in head and neck cancer with p53 mutation will enable the rational design of combination regimens and sequential treatment algorithms to improve clinical outcomes and points to the usefulness of CIP2A as a biomarker to predict clinical response to rapamycin in head and neck cancer.

#5477 Hydrogels to study ECM-oxygen gradient interactions for sarcoma cell migration. Daniel M. Lewis,1 Sharon Gerecht,1 T. S. Karin Eisinger-Mathison,2 Johns Hopkins Univ., Baltimore, MD;2 University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.

Hypoxia is a critical factor in the progression and metastasis of many cancers, including soft tissue sarcomas. Frequently, oxygen (O2) gradients develop in tumors as they grow beyond their vascular supply, leading to heterogeneous areas of O2 depletion. Here, we report the impact of hypoxic O2 gradients and collagen fibers on sarcoma cell invasion and migration. We began with O2 gradient measurements and found that large sarcoma mouse tumors (>300 mm3) contain a severely hypoxic core (≤0.1% partial pressure of O2 (pO2)) whereas smaller tumors possessed hypoxic gradients throughout the tumor mass (0.1-6% pO2). To analyze tumor invasion, we used O2-controllable hydrogels to recreate the physiopathological O2 levels in vitro. Small tumor grafts encapsulated in the hydrogels revealed increased invasion that was both faster and extended over a longer distance in the hypoxic hydrogels compared with nonhypoxic hydrogels. To model the effect of the O2 gradient accurately, we examined individual sarcoma cells embedded in the O2-controllable hydrogel. We observed that hypoxic gradients guide sarcoma cell motility and matrix remodeling through hypoxia-inducible factor-1α (HIF-1α) activation. We further found that in the hypoxic gradient, individual cells migrate more quickly, across longer distances, and in the direction of increasing O2 tension. Treatment with minoxi- dil, an inhibitor of hypoxia-induced sarcoma metastasis, abrogated cell migration and matrix remodeling in the hypoxic gradient. Next, we have developed hydorgels to measure hypoxic gradients where we can control collagen fiber density and cross-linking density independently from oxygen gradients. Using this new platform we show that an increase in fiber density in conjunction with the hypoxic oxygen gradient leads to an increase in sarcoma cell migration. This increase in migration speed was also correlated with quicker stress relaxation times of the collagen gel and larger pore size. Using these platforms we were able to create a novel 3D experimental system with control over mechanical properties (cross-linking density, binding sight density, fiber density, stress relaxation time, and stiffness) independently from oxygen concentration. Overall, we show that O2 acts as a 3D physiologic agent during sarcoma tumor invasion and that this migration is
modulated by collagen fiber density and pore size, in the surrounding matrix. We propose the O2- controllable hydrdyes as a predictive system to study early stages of the metastatic process and therapeutic targets.

#5478 The TRPA1 Ca2+-permeable channel mediates a non-canonical redox adaptation in cancer cells. Nobuaki Takahashi,1 Hsing-Yu Chen,2 Isaac Harris,1 Daniel Stover,1 Roderick Bronson,3 Thomas Deraedt,1 Karen Cichowski,1 Alana Wehm,2 Gordon Jones,3 Joan Bruggel.1 Harvard Medical School, Boston, MA;2 University of Utah, Salt Lake City, UT;3 The University of Texas MD Anderson Cancer Center, Houston, TX.

Generation of reactive oxygen species (ROS), a natural byproduct of oxygen metabolism, occurs in all aerobic organisms at a controlled rate. Cancer cells are subjected to two sets of cellular insults, including dysregulated mitogenic/survival signaling and dissociation from their natural extracellular matrix (ECM) niches, leading to the generation of high levels of ROS. Although cancer cells possess enhanced canonical antioxidant programs that neutralize ROS, they nevertheless exhibit prominent ROS levels in response to these insults, suggesting the existence of additional programs that can allow cancer cells to tolerate elevated ROS. In this study, we provide evidence for an unconventional mechanism for redox adaptation involving the ROS-activated, Ca2+-permeable TRPA1 channel, which normally functions as an irritant receptor in sensory neurons but is highly upregulated in breast, lung, malignant neural sheath, and other tumors. We found that TRPA1 overexpression enhances survival and proliferation of MCF-10A cells under conditions of matrix-detachment and this effect was dependent on TRPA1 activation, resulting in an increase in cell survival. In MCF-10A cells overexpressing TRPA1, we observed increased Ca2+ entry in ECM-deprived cells in the luminal space and promoted their survival and proliferation. Conversely, TRPA1 knockdown inhibited Ca2+ responses to ROS generated through ECM detachment and induced clearance of cells from the luminal space in breast cancer spheroids. TRPA1 was also activated by ROS-inducing chemotherapies and drove chemoresistance in breast, lung and malignant peripheral nerve sheath tumors cells, and its downregulation suppressed breast xenograft tumor growth and enhanced chemosensitivity. TRPA1 mediated these effects independent of antioxidant responses, but through activation of cellular survival and anti-apoptotic programs involving the RAS-ERK/AKT/mTOR pathways. Together, our findings describe an unexpected mechanism whereby cancer cells co-opt the neuronal TRPA1 channel in order to adapt to oxidative environments. This TRPA1-induced response is distinct from canonical redox adaptation mechanisms that rely on antioxidant program. As TRPA1 inhibitors are currently in clinical trials for pain and respiratory therapies, these studies raise the possibility of using these inhibitors as therapeutic chemosensitizers in TRPA1-enriched tumors.

#5479 Redox stress as a therapeutic Achilles heel in castration-resistant prostate cancer. Clara L Trogcolli, Govindi J. Samarayake, Mai Q. Huynh, Karen Kage, Deukwoo Kwon, Yuqang Ban, Xi S. Chen, Enrique R. Zarco, Merce Jorda, Kerry L. Burnsnt, Priyamvada Rai. Unv. of Miami Miller School of Medicine, Miami, FL.

Androgen deprivation therapy (ADT) initially suppresses prostate cancer (PC) progression. However, castration resistant PC (CRPC) cells inevitably emerge, leading to progressive and debilitating disease. We recently demonstrated that ADT produces a form of cellular senescence leading to outgrowth of CRPC subpopulations from the AD-sensitive parental cells. Gene expression profiling studies comparing the parental LNCaP line to the senescent-resistant, early CRPC variant, LNCaP SB5, revealed an enrichment of thiol-based redox-protective proteins in the latter under AD conditions. This finding suggests that redox stress due to hyperactivated mitogenic/survival signaling or metabolic stresses may be an important and understudied Achilles heel in the progression to CRPC. Here we present the effects of inhibiting thioredoxin-1 (TRX1), a redox-protective protein that was identified as being elevated in our early CRPC LNCaP SB5 model. Suppression of TRX1 expression via siRNA led to profound growth suppression of CRPC cells, relative to their AD-sensitive counterparts, and significantly reduced CRPC xenograft tumor growth. Furthermore, under AD, TRX1 suppression promoted p53-induced cell death, which was accompanied by increased reactive oxygen species (ROS). These in vitro and in vivo results were recapitulated using a Phase II clinical trial-tested chemical TRX1 inhibitor. Thus our results point to TRX1 as a critical requirement for CRPC progression and provide a rationale for using TRX1 inhibitors in conjunction with ADT to limit CRPC.

#5480 Peroxiredoxin 2 mediates the survival of ECM-detached ovarian cancer cells. Calli A. Davison-Versagli. Saint Mary’s College, Notre Dame, IN.

Non-tumorigenic epithelial cells require anchorage to the extracellular matrix (ECM) in order to survive; however, it has been recognized that metastatic cancer cells must have the ability to survive in anchorage independence. Approximately 70% of epithelial ovarian cancer (EOC) cases are diagnosed after EOC cells have already metastasized, making EOC more difficult to treat. EOC cells shed from the primary tumor and accumulate in ascites in the peritoneal cavity before attaching and forming secondary tumors throughout the peritoneal cavity. Better understanding of the molecular mechanisms underlying survival of the non-adhesive subset of cells that survive in anchorage independence in the ascites could lead to the development of improved chemotherapeutic agents and the protection of patients from recurrent disease. The chemotherapeutic agent doxorubicin significantly decreased cell proliferation and viability in leukemia. The purpose of this study is to examine Peroxiredoxin levels in K562 cells, a human chronic myelogenous leukemia cell line, and determine if high levels of Peroxiredoxin in the ability to protect cells from chemotherapy-induced death and possibly aid in chemoresistance. We first demonstrated that serum-deprived K562 cells exhibited significant growth inhibition over a 72 hour time period, but had no significant effect on viability. We also showed that treating K562 cells with 30 nM doxorubicin significantly decreased cell proliferation and viability. Corresponding changes in Peroxiredoxin protein levels are currently being analyzed to determine the effect of both growth-inhibition and chemotherapeutics-induced cytotoxicity on the Peroxiredoxin family in K562 cells, and siRNA experiments are being conducted to examine the protective role of Peroxiredoxin in these cells. Based on previous studies on MCF-7 cells conducted in our lab, we predict that Peroxiredoxin levels will be modified under both conditions, and that suppression of Prdxs by siRNA will increase chemotherapeutics susceptibility.

#5481 Role and regulation of Peroxiredoxin antioxidant proteins in K562 leukemia cells. Elizabeth Szabo, Shelley A. Phelan. Fairfield University, Fairfield, CT.

Peroxiredoxins are a family of antioxidant proteins that have found to play a key role in many diseases, including cancer. A wide number of studies have found that Peroxiredoxin levels are elevated in several cancers, and reducing these levels can aid in inhibiting cell growth of cancer cells, suggesting that Peroxiredoxins confer resistance to reactive oxygen species (ROS)-induced cellular toxicity in cancer cells. Specific research has demonstrated that Peroxiredoxin levels are elevated in leukemia cells, and that targeting and inhibiting Peroxiredoxin in these cells can induce differentiation. Studies have also shown the use of doxorubicin as an effective chemotherapy treatment to significantly decrease cell proliferation and viability in leukemia. The purpose of this study is to examine Peroxiredoxin levels in K562 cells, a human chronic myelogenous leukemia cell line, and determine if high levels of Peroxiredoxin in the ability to protect cells from chemotherapy-induced death and possibly aid in chemoresistance. We first demonstrated that serum-deprived K562 cells exhibited significant growth inhibition over a 72 hour time period, but had no significant effect on viability. We also showed that treating K562 cells with 30 nM doxorubicin significantly decreased cell proliferation and viability. Corresponding changes in Peroxiredoxin protein levels are currently being analyzed to determine the effect of both growth-inhibition and chemotherapeutics-induced cytotoxicity on the Peroxiredoxin family in K562 cells, and siRNA experiments are being conducted to examine the protective role of Peroxiredoxin in these cells. Based on previous studies on MCF-7 cells conducted in our lab, we predict that Peroxiredoxin levels will be modified under both conditions, and that suppression of Prdxs by siRNA will increase chemotherapeutics susceptibility.

#5482 Constitutive overexpression of nrzf2 in esophageal adenocarcinoma protects cancer cells from bile salts-induced DNA damage and favors cancer cell survival. Dunfa Peng, Tianling Hu, Shoumin Zhu, Wael El-Rifai. Vanderbilt University Medical Center, Nashville, TN.

Background: Esophageal adenocarcinoma (EAC) is the major type of malignant cancer of esophagus in the USA. The incidence rate has increased 4-10% per year among men since 1976 in the USA, more rapidly than for any other type of cancer. EAC is known to originate from premalignant Barrett’s esophagus (BE) through BE-dysplasia-EAC process. Normal cells have intact anti-oxidative mechanisms, among which the key rate-limiting factor 2 (NRF2) plays a pivotal role in regulating cellular response to various stimuli. Cancer cells have high levels of reactive oxygen species and oxidative stress due to activation of oncogenes, inflammatory microenvironment, and dysfunction of anti-oxidative mechanisms. However, the role of NRF2 in Barrett’s related esophageal carcinogenesis is barely known. Methods and Results: We have found that Nrf2 protein expression is significantly upregulated in EAC cell lines as compared to BE cell lines (CPA, BAR10T) and normal esophageal squamous cell lines. We detected a similar overexpression of NRF2 in primary EAC tissue samples. Using luciferase reporter assay, we demonstrated significant induction of NRF2 transcription activity in EAC cells in response to exposure to acidic bile acids, as compared to
controls (P<.01). We detected significant increase in the expression of Heme Oxygenase 1 (HO-1) and Glutathione Reductase (GR) in these cells (P<.01). Knockdown of NRF2 by siRNA or crisp/cas9, significantly increased cellular ROS level, oxidative DNA damage (8-oxoguanine), and double strand DNA breaks (p-H2AX). Knockdown of NRF2 sensitized cells to apoptosis following exposure to reactive nitrogen species and CDDP. Concordant with the NRF2 knockdown, inhibition of NRF2 by a specific inhibitor, Brusatol, sensitized EAC cells to CDDP treatment with a significant increase in cell death, as compared to single agent treatment (P<.01).

Conclusion: These results indicate that constitutive overexpression of NRF2 in EAC cells protects cancer cells from high level of ROS and promotes cancer cell survival. Inhibition of NRF2 through its specific inhibitor may have therapeutic value in EAC.

Oncogene-induced cellular senescence is a tumor suppressor response resulting in irreversible cell cycle exit, and is dependent on the p53 and RB pathways. Loss of p53 has recently been shown to allow re-entry of senescent cells into the cell cycle. The role of the RB1 protein in maintenance of the senescent state is less well studied. We investigated whether RB1 is necessary for the induction as well as the maintenance of oncogene-induced senescence, and we also evaluated whether RB1 activation is sufficient to induce and/or maintain senescence in the absence of a functional p53 pathway. Inactivation of RB1 prior to onset of senescence led to failure of senescence induction, with impaired cell cycle exit and failure to induce senescence markers. On the other hand, loss of RB1 after cells had already entered oncogene-induced senescence was able to reverse some features of the senescence phenotype, but did not result in successful cell division and accumulation. Interestingly, in the absence of p53, constitutively active RB1 was sufficient for cells to undergo oncogene-induced senescence, and effectively prevented colony formation. Finally, while p53 inactivation was sufficient for senescent cells to re-enter the cell cycle, constitutive activation of RB1 prevented cell cycle re-entry, even in the absence of p53. Our findings show that RB1 is necessary for both the induction and maintenance of oncogene-induced senescence, and that active RB is sufficient for senescence induction as well as its maintenance, both in the presence and absence of p53. These results have direct implications on targeting RB activation as a senescence-inducing approach in both p53 wild type and p53-defective premalignant and malignant tumors.

#5484 Structural domains of βIII-Tubulin regulate multiple stress responses and influence cell growth and survival in glucose-deprived non-small cell lung cancer. Amelia L. Parker, Wee S. Teo, Joshua A. McCarror, Maria Kavalleris. Children's Cancer Institute, Randwick, Australia.

βIII-Tubulin and βIII-Tubulin III-tubulin body and tail structural domains in conferring survival advantage to glucose-starved NSCLC cells. METHODS: H460 NSCLC cells were gene-edited at the endogenous βIII-tubulin gene using zinc finger nuclease technology to replace the endogenous βIII-tubulin protein with either the full-length or truncated βIII-tubulin protein, or replacement of the βIII-tubulin body or tail with the βIII-tubulin sequence, each fused to a GFP tag. Clones expressing the modified βIII-Tubulin proteins were cultured in glucose-free conditions for 48h to 10 days and cell growth and viability were measured by Trypan Blue Dye Exclusion and Annexin-V apoptosis assay. The effect of the βIII-tubulin modifications on the endoplasmic reticulum (ER) stress response, autophagy and Akt signaling were examined by western blotting. RESULTS: Characterization of the gene-edited clones revealed that loss of the βIII-tubulin C-terminal tail or substitution of the βIII-tubulin body or tail sequence with that of the βIII-tubulin sequence did not alter the microtubule architecture, cellular proliferation rate or viability in normal growth conditions. However, loss of the βIII-tubulin C-terminal tail significantly reduced the viability of H460 cells by 37 ± 0.05% in acute glucose starvation. Inhibition of the βIII-Tubulin body with the βIII-tubulin body significantly reduced cell number by 33 ± 0.01% during prolonged glucose starvation. Loss of the βIII-tubulin C-terminal tail increased Akt activation and LC3B-II expression in glucose-rich conditions and potentiated the increase in ER stress response markers GRP78, ATF4 and CHOP in response to glucose starvation. These results indicate that the βIII-tubulin body and tail differentially confer a survival advantage to glucose-starved H460 cells and modulate multiple stress response signaling pathways in an isotype-dependent and independent manner. CONCLUSION: This study provides insight into the importance of βIII-tubulin structural domains in conferring βIII-tubulin structural importance to NSCLC cells thereby advancing our understanding of the role of tubulin isotypes in cell biology and the mechanisms contributing to poor patient outcome in this disease. Mavallaris, Nat Rev Cancer 2010 Park et al., Carcinogenesis 2016

Protein carbonylation is an irreversible modification to the side chain of amino acid residues induced by severe oxidative stress. Reactive oxygen species (ROS) are constantly produced under normal as well as stress-induced conditions, and play a role in both cancer progression and cancer suppression. Tumor tissue is known to have higher ROS levels compared to surrounding healthy tissue but ROS-induced specific protein carbonylation and its unique role in cancer progression/suppression are poorly understood. In this study we compared the relative total and specific protein carbonylation in flash frozen human breast cancer and matched adjacent normal tissue using ELISA, two-color western blot, mass spectrometry, and immunoprecipitation approaches. To understand antioxidant capacity in tumor tissue, we analyzed superoxide dismutase (SOD) for its antioxidant activity and protein level. Our results indicate that tumor tissue has greater total protein carbonylation, lower SOD activity, lower SOD protein levels, and elevated levels of autophagy compared to matched adjacent healthy tissue. We also identified three specific proteins that showed higher level of carbonylation selectively in tumor tissue compared to adjacent normal tissue. Our findings were further confirmed using the immunomortal MDA-MB-231 breast cancer cell line and MCF-12A noncancerous normal human epithelial breast cell. Identification of selectively carbonylated proteins in cancer tissue, and understanding their specific role in cancer progression may promote the development of targeted therapeutic approaches to mitigate or enhance oxidative damage of such proteins selectively in tumor tissue.
region that show dose-dependent disruption of this interaction. We also demonstrated that DOT1L mutants lacking these 10 residues did not support transformation by MLL-AF9. Encouraged by these results, we generated both genetic and chemical tools to elucidate the role of DOT1L recruitment to the MLL fusion partners and the mechanism of leukemogenic inhibition by disrupting the protein-protein interaction (PPI) between MLL-AF9 and DOT1L. FIU1 DOT1L MLL-AF9 Cre+ cell lines were generated with different constructs of DOT1L. These constructs consisted of DOT1L mutants lacking the 10 amino acid binding site, a 1867A point mutant known to block DOT1L binding, and an enzymatic mutant known to yield a catalytically inactive protein. As control cell lines, MLL-AF6, a MLL-fusion containing a cytoplasmic protein, and E2A-HLF, a non-MLL dependent fusion, were generated to demonstrate the specific effects of generated DOT1L mutant constructs. Both DOT1L PPI mutants impaired the transformation by MLL-AF9 and induced cell death by inducing apoptosis and cell cycle arrest similarly to enzymatic inhibition. These results established a foundation for discovering small-molecule inhibitors that disrupt the AF9-DOT1L as potential disease-specific therapies that target chromatin modifications in this highly aggressive leukemia. A high throughput screening was conducted identifying several different chemical classes of small molecules that bind to the AF9 C-terminal hydrophobic binding site and disrupt the PPI between DOT1L and MLL-AF9 fusion protein. Identified small molecule inhibitors were validated with series of biochemical, functional and cell-based assays. Validated compounds selectively inhibit the growth of the DOT1L dependent mutant MLL-AF9 cell line in a similar manner to the genetic approach. The small molecules also showed specificity in killing human MLL-fusion cell lines in comparison to non-MLL fusion leukemia. These results show that blocking the recruitment of DOT1L by AF9 using both genetic and chemical tools eliminate MLL-AF9 mediated immortalization emphasizing an essential function for this interaction in leukemogenesis and warrant further development of the identified small-molecule inhibitors.

#5490 Non-overlapping promoter and super-enhancer-associated dependencies in multiple myeloma. Mariateresa Fulciniti,1 Charles Y. Lin,2 Mehmet K. Samur,1 Richard Young,2 Herve Avet-Loiseau,4 Kenneth Anderson,1 James Bradner,3 Nikhil Munshi,1 Dana-Farber Cancer Institute, Boston, MA; 2Baylor College of Medicine, Houston, TX; 3Whitehead Institute for Biomedical Research, Cambridge, MA; 4Centre National de Recherche sur le Cancer, Villejuif, France; 5Novartis, Cambridge, MA

The relationship between promoter proximal transcription factor-associated gene expression and super-enhancer-driven transcriptional programs are not well-defined. We explored the transcriptional and functional interrelationship between E2F transcription factors and BET transcriptional co-activators to identify their individual contribution to eventual functional effect in multiple myeloma (MM). To better understand how E2F1 and DP1 drive proliferation, we mapped the global occupancy of E2F1/DP1 in MM. Integration of E2F1 and DP1 genomic localization to MM reference epigenome revealed specific co-occupancy of the factors at promoters of active genes marked by H3K4me3, with a strong positive correlation between E2F and RNA Polymerase II (RNA Pol II) binding at transcription start sites. In contrast, active enhancers, as defined by DNase I signal distortion (MED1) peaks and marked by H3K27ac and BRD4, showed virtually no E2F binding. Unbiased hierarchical clustering revealed distinct regulatory axes for E2F and BETs, with E2F predominantly localized to active gene promoters of growth/proliferation genes and BETs disproportionately at enhancer-regulated tissue specific genes confirming that these factors establish distinct target gene programs. At the extremes, we found less than 10% of genes were among the top 500 in BRD4 enhancer signal (i.e. SE-regulated) and top 500 E2F promoter signal. We hypothesized that the presence of BETs and E2F in distinct regulatory axes divides active genes in MM into those that can be selectively influenced by BET inhibition or E2F perturbation, but not both. In line with this we have observed that dual E2F and BET inhibition is synergistic for MM cell growth, both in vitro and in vivo. In conclusions, our results highlight the existence of distinct regulatory axes controlled by promoter and enhancer driven processes, suggesting a sequestered cellular functional control that may be perturbed in cancer with potential for development of a promising therapeutic strategy.

The majority of folate uptake into tissues and tumors involves facilitated carriers, the reduced folate carrier (RFC) and proton-coupled folate transporter (PCFT). PCFT is highly expressed in a wide range of human tumor cell lines and

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
primary tumor specimens from a variety of lineages, with modest expression in most normal tissues. PCFT transports optimally at pHs characterizing the tumor microenvironment. We discovered novel 6-substituted pyrrolo[2,3-d]pyrimidine folate analogs with substantial selectivity for PCFT over RFC, resulting in potent antitumor efficacy in vitro and in vivo. However, in some cases PCFT levels varied substantially. Studies were performed to characterize the basis for these dramatic differences in PCFT gene expression between HepG2 (elevated) and HT1080 (negligible) tumor cells. Low levels of PCFT gene expression in HT1080 cells were not likely due to methylation of CpG islands in the PCFT promoter since 5-aza-2’-deoxycytidine treatment did not restore PCFT gene expression. A PCFT promoter reporter construct -2005/+96 in pGL3 (transcription starts at +1) was generated and showed high levels of activity in HeLa cells by luciferase reporter assays. For HepG2 and HT1080 cells, wide variations in PCFT transcript levels by real-time RT-PCR were paralleled by reporter gene activities with the -2005/+96 construct, suggesting that these were primarily due to PCFT transcriptional regulation. Progressive deletion analysis of the -2005/+96 construct and reporter assays in HepG2 and HT1080 cells localized the minimal promoter region to between -50 and +96. Additional deletion constructs (-35/+96, -20/+96, -15/+96 and +10/+96) were generated and studied. Whereas the -35/+96, -20/+96, -15/+96 and +10/+96 promoters constructed retained ~50% activity for HepG2 cells and ~10-15% activity for HT1080 cells relative to the -50/+96 construct, in both cases the -10/+96 construct was essentially inactive. Two critical cis elements were identified in the PCFT minimal promoter by deletion analysis: a region between positions -50 and -35, and a region between positions -35 and -15. Informatika formatics analysis localized putative cis elements for KLF-15 (-50 to -35) and NRF1 (-15 to -10) binding. The functional importance of these elements was confirmed by mutations of core consensus sequences in the -50/+96 construct and reporter gene assays. Binding of NRF1 and KLF15 to the endogenous PCFT promoter in HepG2 and HT1080 cells was confirmed by ChiP assays which paralleled patterns of differential PCFT gene expression. Collectively, our results suggest that NRF1 and KLF15 contribute to dramatic variations in PCFT gene expression between tumor cells. Better understanding the key determinants of PCFT transcriptional control may lead to strategies for modulating PCFT levels in combination with PCFT-targeted 6-pyrrolo[2,3-d]pyrimidine folate analogs for treating solid tumors.

#5492 Comprehensive analysis of the dynamics of aberrant WNT signaling on global gene expression and nuclear structure. Markus A. Brown, National Institutes of Health, Bethesda, MD.

The organization of the genome in the nucleus is complex and dynamic. Features of the nuclear architecture, including the spatial arrangement of genomic sequences, the structure of chromatin, and the accessibility of regulatory DNA elements modulate nuclear processes such as gene transcription DNA replication, RNA repair, RNA processing, and mRNA transport. However, the interplay between nuclear architecture and gene expression is poorly understood. We propose to elucidate the impact of silencing the prominent transcription factor, TCF7L2, the major effector of the WNT signaling pathway, on the transcriptional equilibrium and nuclear architecture of the nucleus in human colorectal cancer cells. Our multidisciplinary approach combines targeted si- lencing of TCF7L2, 3D-FISH, RNA-seq, and Hi-C chromosome conformation capture, in parallel with mathematical modeling to delineate structure/function relationships in the interphase nucleus. This approach will elucidate the intricacies of a dynamic cellular signaling pathway in three-dimensional space.

Colorectal cancer (CRC) is the second leading cause of death in the United States and a truly preventive approach still remains to be developed. Men have lost during CRC progression. In colon cancer cell lines re-expression of ERbeta has anti proliferative and anti-inflammatory properties, there is however little understanding of the mechanism whereby ERbeta mediates these effects in colon cells. In order to elucidate the mechanism of ERbeta in CRC, we re-expressed this receptor using lentivirus in four different CRC cell lines. We optimize chromatin-immunoprecipitation (ChIP) with an antibody thoroughly validated for this purpose and used IgG and input as well as cell lines without ERbeta expression as controls. ChIP-seq was performed using Illumina library preparation and next generation sequencing. Alignment of sequence reads against the reference genome of version hg19 was done using Bowtie, and statistically significant peaks (FDR) were identified using MACS. Results were compared to RNA-seq analysis of the same cell lines. Key binding-sites and corresponding gene regulations were confirmed using qPCR. We present for the first time, the cistrome of ERbeta in different CRC cell lines. We identify key binding motifs, including CRE and AP-1 sites. Together, our results uncover ERbeta as an important determinant for attenuating cancer progression.

#5494 Hypoxia via HIF1alpha can regulate Wnt signaling in human colon cancer cells. Yung Lyu,1 Amber Habowski,2 Stephanie Sprow–Tanao,2 Xira Pate,2 George Chen,2 Marian L. Waterman,3 1UCI Medical Center, Orange, CA; 2University of California Irvine, Irvine, CA.

Standard-of-care treatment for metastatic colorectal cancer combines chemotherapy with bevacizumab, an angiogenesis inhibitor that depletes nutrients and triggers hypoxia. Unfortunately, this strategy extends patient survival only a few months because tumors acquire adaptive resistance, enabling resumption of angiogenesis. Adaptive resistance arises from reprogrammed metabolism, but the regulatory networks that govern reprogramming are not defined. Our studies have shown that overactive Wnt signaling, which is the most common cause of colon cancer, programs cancer metabolism by promoting glycosylation and angiogenesis. Interestingly, metabolic genes targeted by Wnt are also regulated by the hypoxia transcription factor HIF1alpha suggesting there may be crosstalk between the two pathways. Several studies suggest that HIF1alpha can influence Wnt signaling, but the reported effects are variable ranging from positive to negative. We find that HIF1alpha and LEF/TCF/beta-catenin complexes co-regulate metabolic targets including LEF1 and TCF7 (TCFI7) expression. Using luciferase reporters driven by LEF/TCF promoters, we observe significantly increased LEF1/TCF7 activity but no TCF7 activity. Expression of HIF1alpha in hypoxic colon cancer cells. We identified putative hypoxia responsive elements (HREs) in the human LEF1 promoter and deletion of these HREs reduced responsiveness to hypoxia. Furthermore, when colon cancer cells were treated with inhibitors that either inactivate or reduce HIF1alpha protein, there was a significant decrease in Wnt reporter activity. These results suggest that hypoxia and the Wnt pathway crosstalk wherein hypoxia co-regulates metabolism genes and increases Wnt signaling capacity via LEF/TCF expression. Current studies are underway to investigate the mechanisms of crosstalk and joint regulation of metabolic gene programs during adaptive resistance.

#5495 GANT61-induced cell death involves inhibition of transcription and DNA licensing at GLI sites in the promoters of GLI-dependent target genes in human colon carcinoma cells. Ruowen Zhang,1 Jiahui Wu,2 Sylvain Ferrandon,2 Katie J. Glowacki,3 Janet A. Houghton.4 Southern Research Institute, Birmingham, AL; 2Cleveland Clinic, Cleveland, OH.

The GLI genes, GLI1 and GLI2, are transcriptional regulators of the Hedgehog signaling response, binding at promoters to GACCCCAAC-like consensus sequences. From genetic and biochemical studies, GLI2 is the primary mediator of HH signaling, which activates transcription of GLI1 and GLI2-GLI3 GLI1-GLI2). In cancers both GLI1 and GLI2 are oncogenes, aberrantly and constitutively activated by oncogene-driven signaling pathways, in particular KRAS/BRAF in colon cancer. GANT61, a specific GLI inhibitor, induced extensive cytotoxicity in human models of colon cancer, indicating GLI to be a critical target in cancer cell survival. We have determined FOXM1 to be a transcriptional target of GLI at GACCCCAAC consensus sites through binding to the FOXM1 promoter by GANT61 led to inhibition of binding of the release-relaxing factors DSIF, NELF, and p-TFEB in the region of the TSS, with inhibition of binding of Pol II at both GLI and TSS sites. In R-loop regions, RNA:DNA hybrid formation was reduced at both the GLI and TSS sites in the FOXM1 promoter by GANT61, sensitive to RNaseH. Bisulfite conversion/PCR analysis showed the T to C conversion at the GACCCCAAC sites in the GLI binding region in GANT61-treated cells. Data support GANT61-induced inhibition of GLI-dependent transcription at the PIC before R-loops are formed. Pretreatment of HT29 cells with -aminan (Pol II inhibitor) reduced GANT61-induced $\gamma$H2AX foci, indicating the importance of transcription in GANT61-induced DNA damage. Co-localization of GLI1 and BrcU foci, inhibited by GANT61, indicated GLI1 and DNA replication were linked. By co-immunoprecipitation, GLI1 bound the DNA replication licensing factors ORC4, CDT1, and MCM2, decreased in the presence of GANT61. By confocal microscopy, significant co-localization of GLI1 and ORC4 foci was inhibited by GANT61, and enrichment of ORC4 occurred at the GLI binding site in the FOXM1 promoter. In addition to non-transcriptional mechanisms of interactions, GANT61 (CDT1) CDT1 foci in HT29 cells reduced GANT61-induced cell death and cleavage of caspase-3, indicating a
significant role of DNA replication licensing in the mechanism of induction of GANT61-induced cell death. In summary, we have demonstrated inhibition of GLI-dependent transcription by GANT61 at the PIC during the initiation of RNA synthesis, and the importance of inhibiting DNA replication licensing at sites in promoter regions that bind the transcription factor GLII by both non-transcriptional and transcriptional mechanisms. Supported by NCI Award 1 RO1 CA183921-01A1 and by Southern Research Institute.

#5496 Intratumor estradiol increment mediated by CtBP1/CYP19A1 decreases the proliferation of androgen insensitive prostate tumor cells. Cintia Massillo,1 Guillermo N. Dalton,1 Juliana Porretti,1 Georgina Scalsie,1 Paula L. Farré,1 Colin Clyne,2 Paola De Luca,1 Adriana Di Servi,1 1Instituto de Biologia y Medicina Experimental (IBYME-CONICET), Autonomous City of Buenos Aires, Argentina; 2Hudson Institute of Medical Research, Melbourne, Australia.

The normal growth and development of the prostate requires the action of estrogens and estrogens receptors (ER) a and β. Estrogen-related pathways are clearly important in the development and progression of hormone-dependent cancers such as prostate cancer (PCa), but the role of ERβ remains controversial. The production of estrogens from androgens is mediated by the aromatase enzyme. Aberrant expression of aromatase plays a critical role in PCa development and progression. Metabolic syndrome (MS) causes sex hormone imbalance and has been identified as a risk factor for PCa. Recently, we found that C-terminal binding protein (CtBP1), a transcriptional co-repressor of tumor suppressor genes, is a novel molecular link between MS and PCa. We developed a MS mice model that were inoculated with PC3 stable CtBP1 depleted or control cells. MS mice showed MS phenotype including increase of body weight and estradiol. Interestingly, CtBP1 strongly repressed aromatase expression in these xenografts. The aim of this study was to understand the transcriptional regulation mechanism of aromatase mediated by CtBP1 in a MS/PCa model. To fulfill our aim, PC3 cells were co-transfected with a CtBP1 expression plasmid and a panel of ten reporter vectors containing different lengths (27-1,004 bp) of CYP19A1 promoter, cloning upstream to the luciferase gene. CtBP1 significantly repressed the activity of all the studied promoters. By chromatin immunoprecipitation (ChIP) and RT-qPCR we determined that CtBP1 associated to CYP19A1 promoter and repressed its transcription. In order to identify possible CtBP1 partners in CYP19A1 expression regulation we investigated several transcription cofactors. By ChIP, we found that p300 (histone acetyl transferase) and ERβ associated to aromatase promoter in PC3 cells. Using gene reporter assays we established that CtBP1 and p300 synergistically repressed, while ERβ activated, aromatase promoter activity. Interestingly, estradiol exposure of PC3 cells, released CtBP1 from the aromatase promoter triggering its expression. Furthermore, we found that estradiol dramatically increased the viability and the S phase percentage of the androgen sensitive LNCaP and, its derivative, C4-2 cells; dramatically reducing apoptosis. Accordingly, estradiol decreased androgen insensitive PC3 cell viability and G1 phase arrest. In summary, CtBP1 represses aromatase expression in PCa. Nevertheless, MS increases intratumor estradiol, which releases CtBP1 from aromatase promoter activating aromatase expression, which in turn, modulates prostate tumor cell proliferation.

#5497 LSD1 modulates androgen receptor cistrome in prostate cancer via regulation of FOXA1 chromatin binding. Shuai Gao,1 Sujun Chen,2 Dong Han,1 Wanting Han,1 Steven P. Balk,3 Housheng Hansen He,1 Changmeng Cai1. 1University of Massachusetts-Boston, Boston, MA; 2Ontario Cancer Institute, Toronto, Ontario, Canada; 3Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA.

Patients with castration-resistant prostate cancer (PCa) benefit from CYP17A1 inhibitors and more potent AR antagonists, but still relapse with tumors expressing high levels of AR and AR regulated genes, indicating restoration of AR activity. Therefore, there remains a pressing need for further development of novel AR targeted therapies. One major mechanism that contributes to the PCa development is reprogramming of AR cistrome by transcriptional factors and chromatin modifiers. In this process, AR is recruited to a subset of newly established enhancers that can drive the expression of pro-liferation genes. FOXA1 is one such transcriptional factor that determines cell-lineage and is characterized as a “pioneer” factor to facilitate the access of additional transcription factors (such as AR or ER) to the regions with compact chromatin. A recent study by comparing the AR cistrome in normal prostate and PCa tissues suggests that FOXA1 is responsible for driving AR reprogramming. Whole genome analyses in PCa cells have revealed that FOXA1 can recognize enhancer regions with active histone marks (H3K4me1,2) and then further open up the sites to allow subsequent AR binding. However, the molecular mechanism on how FOXA1 is guided to the target region in PCa is still elusive and studying this mechanism exhibits significant translational potential on modulating AR activity in PCa. Lysine Specific Demethylase 1 (LSD1/KDM1A) is an important epigenetic modifier that can function as a repressor by demethylating H3K4me1,2. However, LSD1 also often associates with enhancers and can function as an activator in some contexts. Our previous studies showed that LSD1 binding significantly overlaps with FOXA1 and the overlapping sites that are marked by high levels of H3K4me2 enrichment for AR activated genes. LSD1 also interacts with FOXA1 and this interaction enhances binding of both proteins at AR-mediated enhancers. These findings suggest that LSD1 may regulate the availability of enhancers to AR via interaction with FOXA1 and hence may reprogram AR cistrome in PCa cells. In this study, we performed ChiP-seq analyses of FOXA1 and AR in PCa cells treated with LSD1 inhibitors. The results show that global FOXA1 binding was drastically diminished by inhibiting LSD1, indicating that its demethylase activity is required for FOXA1 binding. Importantly, inhibiting LSD1 also results in distinct AR binding patterns with the expression of many classic AR-activated genes being impaired and new AR-activated genes emerged. We are currently carrying out xenograft studies to examine the impact on tumor progression and AR cistrome by LSD1 inhibitor. Overall, our results suggest that the LSD1-FOXA1 interaction functions as an important modulator of AR cistrome and targeting LSD1 in conjunction with AR antagonists may be a promising therapeutic approach to treat PCa.

#5498 Autoregulation of protein kinase D1 (PRKD1) expression in prostate cancer. Bita Nikkhohlgh, Sittadjody Sivanandane. Wake Forest Univ., Winston Salem, NC.

Protein kinase D1 (PRKD1) is down regulated in gastric, breast and prostate cancer. Several regulatory mechanisms modulate PRKD1 activity in cancers. In colon cancer, it has been shown that PRKD1 is down regulated by nuclear beta-catenin. We explored whether beta-catenin is involved in regulation of PRKD1 expression in prostate cancer as well. A CHIP assay performed using prostate cancer LNCaP cell lysate and pull down with beta-catenin antibody, which demonstrated recruitment of beta-catenin to promoter of PRKD1 gene as well as at downstream regions in the gene suggesting that beta-catenin could be involved in PRKD1 regulation. To identify the exact binding site of beta-catenin to PRKD1 gene, we carried out CHIP sequencing. The beta-catenin protein complex was bound to a 166 bp sequence near exon 2 (chr1:29899631-29899796). Because beta-catenin is a coactivator and not a known transcription factor, we performed a transcription factor promoter array, which showed that the MYC/MAX transcription factor complex may be the mediator of the regulatory effect of beta-catenin on PRKD1 expression. We validated the results by performing CHIP assay using MYC and MAX antibodies which showed recruitment of both MYC and MAX to the same beta-catenin bindingsite to PRKD1. In order to assess the functional impact of beta-catenin regulation of PRKD1 in prostate cancer, beta-catenin mutated at threonine 120 residue (we have previously demonstrated that PRKD1 is the only known kinase to phosphorylate the site) demonstrated increased nuclear translocation of beta-catenin and increase down regulation of PRKD1 and increased androgen receptor (AR) activity (increased AR activity is well established to be associated with PC progression). Our data has identified a novel auto-regulatory mechanism of PRKD1 expression through beta-catenin phosphorylation.

#5499 The reprogramming of the steroid receptor binding landscape at active enhancers is associated with a fast DNA residence time through a mechanism termed dynamic assisted loading in breast cancer cells. Erin Swinstead, Tina Miranda, Ville Pakkinaho, Songjun Beak, Gordon Hager. NCI/NIH, Bethesda, MD.

The transcription factor (TF), FOXA1 has been described as a pioneer factor, implicated in steroid receptor (SR) binding patterns. Classically it has been proposed that the pioneer factor model is a slow and static binding event. However, it has recently been described that the estrogen and glucocorticoid receptors (ER and GR), can regulate the binding patterns of each other in a mouse mammary cell line defined as dynamic assisted loading. Further, this phenomenon has been extending demonstrating that both ER and GR can recruit FOXA1 to specific binding sites. Several targets associated with an increase in chromatin accessibility and fast DNA residence times. This was also associated with the absence of a DNasel footprint for the initiating and secondary factor supporting the assisted loading model. To further investigate the molecular mechanism behind the dynamic assisted loading model we have characterized the binding and transcriptional landscape of ER and GR in a number of breast cancer cell line models. Genome wide analysis of ChiP and DNasel hypersensitivity assays upon single and dual activation show that both SRs can recruit each other to a specific subset of binding sites associated with an increase in chromatin accessibility. Therefore, depending on the chromatin landscape, one factor functions as the initiating factor and the other the secondary factor. Further, RNA polymerase II (RNAP
Il), p300, and H3K27ac binding patterns are associated with the newly programs ER or GR binding sites. Together this suggests chromatin reorganization upon dual activation of either ER or GR (the initiating factors) and recruitment of the secondary factor (ER or GR) through an assisted loading mechanism. Further, we have demonstrated an association of the transcriptional machinery at these newly acquired binding sites at active enhancers. These results propose that many TFs in a given cell have the potential to affect the binding landscape of other TFs, depending on the chromatin context. In addition, this study has shifted our classical understanding of pioneer factors in breast cancer, demonstrating that not only can TFs alter the response of FoxA1 but also each other through highly dynamic and fast DNA interactions associated with active enhancers and transcription.

**#5500** KMT2C directs estrogen receptor activity in normal and transformed mammary cells. Kinisha Gala,1 Amit Sinha,2 Francisco Sanchez-Vega,1 Young Rock Chung,3 James Hseih,1 Michael Berger,1 Nikolaus Schultz,1 Alessandro Pastore,2 Omar Abdel-Wahab,1 Sarat Chandralapati1. *Masonic Memorial Sloan Kettering, New York, NY; 3Bayer, Inc., New York, NY.*

Estrogen receptor alpha (ERα) is a ligand-activated nuclear receptor that regulates proliferation and differentiation in mammary epithelial cells. ERα activity is likely dependent on the actions of pioneer factors and H3K4 methyltransferases which can establish a genomic landscape permissive for ERα binding. Here, we identify the H3K4 methyltransferase KMT2C as essential for ERα activity in mammary gland development and ER+ breast cancer growth. KMT2C overexpression increases estrogen-dependent gene expression and causes H3K4me1 loss at ERα target gene enhancers. Consequently, KMT2C loss selectively suppresses estrogen-driven breast cancer proliferation. Moreover, mammary-specific Kmt2c knockout mice have defects in pubertal ductal formation similar to Er1−/− deficient mice. Although KMT2C loss disrupts estrogen-driven proliferation, it conversely promotes tumor outgrowth under hormone-depleted conditions. Consistent with this, gene expression signatures of Kmt2c loss are associated with poor outcomes. We conclude that KMT2C is a key regulator of ERα activity whose loss uncouples mammary phenotypes from hormone availability.

**#5502** Functional evaluation of superenhancers as mediators of epithelial ovarian cancer risk. Kevin C. Vavra,1 Simon Coetzee,1 Janet M. Lee,1 Paul Pharaoh,2 Dennis J. Hazelet,1 Kate Lawrenson,1 Simon A. Gayther1,4 Cedars Sinai Medical Center, Los Angeles, CA; 2University of Cambridge, Cambridge, United Kingdom.

Superenhancers are master regulators of genes involved in cellular differentiation and tumorigenesis. While it is now well established that typical enhancers are key mediators of alleles associated with a mild risk of polygenic diseases including cancer, the role of superenhancers is less understood. We evaluated the role of superenhancers in mediating risk of epithelial ovarian cancer (EOC). Using FunciVar software and superenhancers defined using H3K27ac chromatin immunoprecipitation followed by next generation sequencing, performed in cell lines and tissues, we characterized the superenhancer-risk SNP intersect and identified a series of risk-associated loci where multiple candidate causal alleles overlap with ovarian superenhancers. In particular, locus 3q25, the locus most associated with epithelial ovarian cancer (EOC) risk from GWAS studies, has >70 candidate causal risk SNPs, all of which coincide with superenhancers detected in ovarian cancer precursor cells (ovarian and fallopian tube epithelia) but not in ovarian cancers. We are proposing that the presence of one or more SNPs occurring at this locus leads to a higher expression of one or more genes by modulating activation of the superenhancer region. We tested the effect of decreasing the binding affinity of BRD4, a protein that binds superenhancer regions, using a small molecule inhibitor on the expression of genes in this locus. We identified three candidate genes—LEKR1, SSR3, and TiPARP—that demonstrated a decrease expression level as a result of BRD4 binding inhibition. Preliminary results show that partial knockdown of either SSR3 or TiPARP decreases normal ovarian and fallopian cell proliferation, and knockdown of both SSR3 and TiPARP simultaneously shows an enhanced proliferation decrease compared with knockdown of a single gene. We then created stable knockout (KO) models using the CRISPR-Cas9 system to fully KO one, or two or all three of our candidate causal genes: LEKR1, SSR3, and TiPARP. Functional evaluation of these models is currently underway to test the hypothesis that risk SNPs may regulate more than one gene at this locus. In all we identify a potential role for superenhancers at a subset of EOC risk loci, and present a functional pipeline for identification of the target gene/transgenes and evaluation of their role in neoplastic transformation.

**#5503** Interplay between the transcription factors PRRX1 and FOXM1 in pancreatic cancer. Benoît Marchand,1 Maximilian Reichert,2 Meredith A. Collin1, Anil K. Rustgi1. 1University of Pennsylvania, Philadelphia, PA; 2Technical University of Munich, Munich, Germany.

Introduction: We have identified previously the Paired Related Homeobox 1 gene (PRRX1) as a key regulator of embryonic ductal development, acinar-to-ductal metaplasia (ADM) and pre-cancerous lesion (PanIN)/pancreatic ductal adenocarcinoma (PDAC) progression (Reichert M. et al Genes & Dev 2013). We discovered an isoform switch between PRRX1A and PRRX1B occurring in EMT-MET plasticity in pancreatic tumorigenesis (EMT) and metastatic colonization of the liver (MET) (Takano S. et al Genes & Dev 2016). The transcription factor FOXM1 is also implicated in ductal EMT. Located in EMT of pancreatic cancer cells, interestingly, both transcription factors, FOXM1 and PRRX1, are overexpressed in PDAC. The aim of this study was to investigate if PRRX1, specifically its isoforms, might interact with FOXM1, to regulate gene transcription in pancreatic cancer. Methods: Experiments were performed in human pancreatic cancer cells (PANC1, Mia PaCa2 and BxPC3), and HKE295T cells. Epoetipe-tagged PRRX1 and FOXM1 proteins (wild type or deletion mutants) were either transiently or stably expressed in these cells. Immunoprecipitation and western blot were performed to evaluate potential interaction between PRRX1 and FOXM1. As a functional readout, the Tnc and 6xFoxM1 luciferase reporters were used to measure Tenascin C and FOXM1 transcriptional activities. Results: Immunoprecipitation of tagged-PRRX1 or endogenous FOXM1 showed co-binding of both factors in AIP (A) with FOXM1 in pancreatic cancer cells. We further characterized this interaction using deletion mutants of PRRX1 C-terminal region, FOXM1 binds to the 200-222 amino acid region of PRRX1. Similarly, using deletion mutants of the FOXM1 N-terminal region we mapped PRRX1 binding to the winged helix DNA binding domain of FOXM1. Interestingly, we also observed co-binding of HA-tagged PRRX1A with either Flag-tagged PRRX1A or PRRX1B suggesting homo and heterodimerization of the PRRX1 isoforms. Next, we found that co-expression of PRRX1 and FOXM1 cooperatively induced transcriptional activity of a known PRRX1 target gene, Tenascin C. Furthermore, co-expression of PRRX1A and FOXM1 cooperatively induced FOXM1 transcriptional activity. FOXM1 has been reported to regulate Wnt signaling in early pancreatic carcinogenesis, we observed co-binding of PRRX1 and FOXM1 with beta-catenin. Conclusion: Our results provide new insights in the interaction of PRRX1 and FOXM1 with functional activation of FOXM1 mediated transcriptional activity, and potential regulation of the Wnt pathway.

**#5504** Regulation of the receptor for advanced glycation end products by estrogen receptor ligands in endometrial cancer. Julia Delgado,1 Dejanca Gonzalez,1 R.Steven Conlan. Swansea University, Swansea, United Kingdom.

Endometrial cancer has numerous established risk factors including excessive unopposed estrogen exposure, tamoxifen, obesity and polycystic ovary syndrome (PCOS). These risk factors may promote inflammation, an important hallmark of cancer. Since the endometrium is a site of regular and repeated inflammation during the menstrual cycle, the regulation of inflammation may be involved in endometrial cancer. The receptor for advanced glycation end products (RAGE) stimulates numerous inflammatory signalling pathways and its expression is elevated in a number of inflammatory pathologies including diabetes and more recently cancer. This work aims to investigate the regulation of RAGE by estrogen receptor ligands in endometrial cancer. RAGE and estrogen receptor isoform protein expression were examined in a patient cohort by immunohistochemistry. RAGE and ER isoform expression was assessed following estrogen receptor ligand exposure in both type I and type II endometrial cancer cell line models. ERα, ERβ, p65 and ER co-regulator recruitment to the RAGE promoter following ER ligand treatment was determined in vitro by chromatin immunoprecipitation. Data revealed (i) RAGE and ER isoform endonuclear expression is altered in endometrial cancer patients and patients receiving tamoxifen compared to postmenopausal women, (ii) RAGE is expressed in type I and II endometrial cancer cell lines and its expression can be modulated by estrogen and tamoxifen exposure, and (iii) by chromatin immunoprecipitation, estrogen receptor ligands were shown to alter ERα, ERβ and ER co-regulator binding at the RAGE promoter. To conclude, results from this work suggest RAGE is associated with endometrial cancer development. Once clinically validated, RAGE and associated targets investigated in this study could be potentially used as a panel of endometrial cancer biomarkers and may also be used to indicate if patients are at risk of the adverse agonist action of tamoxifen in the endometrium.
**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Regulation of Oncogenic Transcription**

**#5505** TERT promoter mutations in primary papillary thyroid carcinoma and matched local / distant metastases. Noa Fea Rodríguez,1 Miriam Corraliza Gómez,1 Tomás Álvarez Gago,2 Juan José Mateos Otero,2 Raquel Muñoz Martínez,1 Ginesa Maria Garcia-Rostan1, Katleen De Preter1, Fanny De Vloed,1 Geertrui Denecker,1 Suzanne Vanhauwaert,1 Jolien De Tert1.

TERT promoter (TERTp) mutations represent a common oncogenic event in sporadic thyroid follicular cell carcinomaogenesis. Though TERTp mutations have been statistically associated with aggressiveness and metastatic spreading, their involvement in lymph node metastases (LNNMs) and/or distant metastases (DMs) development among papillary thyroid carcinoma (PTC) patients remains to be elucidated. We evaluated the association of TERTp mutations with tumor expansion, primary tumors (Pt) and matched LNNMs and/or DMs were genotyped by means of PCR-direct sequencing in a cohort of 33 patients diagnosed of PTC, which had been previously analyzed for BRAF and RAS mutations. Focal changes in the growth pattern or microscopic grade within the Pt or the metastases were separately genotyped to determine the clonal/subclonal nature of TERTp mutations, their association with particular histological variants of PTC or their presence in intra-tumoral PTC-like foci. Results were correlated with clinico-pathological parameters of poor outcome and survival. The analysis of 99 tumor samples obtained from 33 PTC cases revealed that TERTp mutations were quite common (42.4%). The mutation C228T was much more common than the C250T (78.6% vs 21.4%). TERTp mutations did not correlate with specific clinico-pathological parameters (CL-PTC vs FV-PTC, CF-PTC) at diagnosis. In half of the cases, the mutations segregated to LNNM. TERTp mutations were present in all samples of DM. While 71% of the cases mutated at TERTp bore the BRAFV600E mutation, the coexistence of TERTp and RAS mutations was exceptional. TERTp mutations were found to be significantly correlated with age > 45 years old, high grade poorly differentiated PTC foci or nesting-PDC-like foci, stage at diagnosis or at last follow-up and patient status. A trend of correlation with male sex, vascular invasion, tumor recurrence and development of LNNM during the follow-up was also seen. Tumor multifocality was inversely correlated with TERTp mutations. The coexistence of TERTp and BRAFV600E mutations did not increase the prognostic power of TERTp mutations alone. All of the patients who died of disease displayed TERTp mutations. Kaplan-Meier analysis revealed that patients with Pt carrying TERTp mutations had a poor prognosis showing a higher tumor recurrence probability [p = 0.0085] and a reduced disease specific survival [p = 0.0001]. The coexistence of other mutations did not significantly increase the risk of recurrence or dying of disease. The study indicates that TERTp mutations: 1) are common in metastatic PTC; 2) are subclonal in half of the cases; 3) spread in most cases with metastatic cells to LNNM and DM but do not drive the development of LNNM; 4) identify PTCs patients with increased risk of recurrence and mortality; 5) represent “per se” a biomarker for poor outcome among PTCs.

**#5506** SOX11 acts as part of the MYCN-WEEl regulatory protein complex implicated in neuroblastoma. Bieke Decaestecker,1 Sara De Brouwer,1 Fanny De Vloed,1 Geertru Denecker,1 Suzanne Vanhauwaert,1 Jolien De Wijn,2 Geneviève Laureys,1 Bjorn Menten,1 Pauline Depuydt,1 Patrick Reynolds,2 Jo Vandorpe,3 Kris Gevaert,4 Jan Koster,1 Sara Ek,1 Frank Speelman,1 Kathleen De Preter1,1 Centre for Medical Genetics Ghent, Ghent, Belgium; 2Texas Tech University Health Sciences Center, Lubbock, TX; 3University Hospital Ghent, Ghent, Belgium; 4VIB Proteomics Expertise Center (PEC), Ghent, Belgium; 5Academic Medical Center (AMC), Amsterdam, Netherlands; 6Bieke De Vloed, Lund, Sweden.

Neuroblastoma (NB) is an aggressive lethal pediatric cancer of the developing sympatho-adrenergic nervous system and characterised by a low mutation burden while exhibiting recurrent DNA copy number alterations including chromosome 2p gain and MYCN amplification. Rare amplifications have previously allowed to identify additional oncogenes implicated in NB such as ALK and LIN28B. Here we report on three NB tumors and two NB cell lines with high level focal gain containing the SRY-related HMG-box transcription factor 11 (SOX11) as only protein-coding gene in the smallest region of overlap. The high expression levels of SOX11 in NB and the developing sympathetic nervous system, and high correlation of SOX11 mRNA and protein levels with survival outcome, suggested a role for SOX11 as oncogene and prompted us to further investigate its role in MYCN driven NB formation. SOX11 knock down in NB cells allowed to identify additional oncogenes implicated in NB such as ALK and MYCN which was confirmed by reciprocal co-ip, as well as WEE1, a tyrosine kinase critically implicated in the mitotic checkpoint control for which multiple potent and specific small molecule inhibitors are available. Furthermore, upon testing of the AZD-1775 WEE1 inhibitor in 10 NB cell lines, we observed the strongest effects in the cells with the highest SOX11 protein levels indicating that SOX11 expression levels can serve as predictive biomarker for AZD-1775 treatment response. In conclusion we identified high-level focal gain of SOX11 in NB tumors and cell lines and demonstrated the oncogenic role of SOX11 in MYCN driven neuroblastoma with therapeutic opportunities through interaction with WEE1.

**#5507** Investigation of the effects of alterations in the glutamate receptor, GRIK2 on osteosarcoma tumorigenesis. Justin G. Mayers,1 Nalan Gokcoglu,2 Jay S. Wunder,1 Irene L. Andrulis1.1University of Toronto, Toronto, Ontario, Canada; 2Lunenfeld-Tanenbaum Research Institute, Toronto, Ontario, Canada; 3Sinai Health System, Toronto, Ontario, Canada.

Osteosarcoma is a primary, malignant bone tumour mainly affecting young adults with a five-year survival rate of 60-70% depending on presentation of metastasis at diagnosis. Tumours are marked by genetic instability and heterogeneity and for this reason, molecular subtypes have yet to be characterized. Survival rates have remained consistent over the past few decades and novel molecular targets for treatment are needed. Current genomic strategies have identified recurrent copy number alterations. In a study of 44 fresh frozen osteosarcoma tumours which were obtained at the time of biopsy and 25 blood matched samples we identified recurrent copy number losses including a region at 6q16.3 in 14% of tumours. Focal deletions were observed in the 5′ intergenic space and first intron of the GRIK2 gene and do not overlap with any coding sequence. The relationship between alterations in this region and osteosarcoma tumourigenesis has yet to be explored in depth. GRIK2 encodes an ionotropic glutamate receptor that has been implicated as a tumour suppressor in gastric cancer. An interesting feature of the tumours was the overlap of focal deletions with a SETDB1 histone methyltransferase binding site indicating a potential connection with epigenetic regulation of GRIK2. The goal of this study is to examine the effects of non-coding, focal deletions on GRIK2 gene expression and function and regulation in osteosarcoma cells. GRIK2 transcript levels were measured in osteosarcoma tumours and cell lines using qRT-PCR. Functional assays were performed to characterize the role of GRIK2 in osteosarcoma cell proliferation, migration and apoptosis in vitro. Gene editing with CRISPR/Cas9 was performed to examine the link between non-coding deletions and GRIK2 expression. GRIK2 transcript levels varied in tumours; several osteosarcoma tumours with focal deletions had increased transcript levels relative to cell lines which demonstrated low expression levels. Due to the observation of low transcript levels, a gain of function approach was employed to examine GRIK2 function in vitro. Overexpression of GRIK2 decreased proliferation, migration and increased apoptosis in vitro. Osteosarcoma GRIK2 transcript levels were increased in untreated cells. This study suggests that non-coding focal deletions are linked to high expression levels of GRIK2 which may confer a less aggressive phenotype and are involved in epigenetic regulation of the gene.

Recent studies suggest p53 plays an important role in TGF-β-mediated cell signaling and migration. Previously, we showed wild-type (WT) and mutant (mt) forms of p53 differentially regulate reactive oxygen species (ROS) generation by NADPH oxidase-4 (NOX4). We found that WT-p53 suppresses TGF-β-induced NOX4, ROS production, and cell migration, whereas tumor-associated p53-mt proteins enhance NOX4 expression and cell migration by TGF-β/SMAD3-dependent mechanisms. In this study, we utilized The Cancer Genome Atlas (TCGA) to perform statistical analysis on gene expression data from primary tumor samples and found a correlation between tumors with p53 “hot-spot” mutations and increased NOX4 mRNA expression. Furthermore, we ex-
aned the basis of human NOX4 promoter regulation by p53 and SMAD3. By deletion analysis of the NOX4 promoter, we found two critical SMAD3 binding elements (SBE) are also required for p53-dependent promoter activity. Conversely, promoter activity was abolished by dose-dependent heterologous expression of p53-WT. Moreover, expression of active SMAD3 resulted in robust NOX4 promoter activity, which was abolished when co-expressed with p53-WT. Chromatin immunoprecipitation (ChIP) analysis revealed SMAD3 and p53-WT or p53-mt were associated with specific SBEs and p53 response elements (p53-RE) in a TGF-β-dependent manner. Interestingly, the repressive effect by p53-WT on NOX4 was relieved upon treatment with histone deacetylase (HDAC) inhibitors or mutation of the transactivation domain. Overexpression of p300, a known p53-mt-binding transcriptional co-activator and histone acetyltransferase (HAT), enhanced p53-mt-mediated NOX4 promoter activity, whereas the HDAC-inactive p300-mt reduced promoter activity. Furthermore, overexpression of p53-mt augmented TGF-β-mediated acetylation of histones associated with the NOX4 promoter. Finally, scratch wound assays demonstrated NOX4 and p300 promote TGF-β/mutant p53-mediated cell migration. Collectively, these data provide new insight into TGF-β/SMAD3, p53-mt-NOX4 induction involving epigenetic control of NOX4 in tumor cell migration.

#5510 Pro inflammatory cytokines induce synergistic gene expression by assisted loading of STAT3 at a subset of primed enhancers. Ido Goldstein,1 Songjoon Baek,2 Myong-Hee Sung,2 Gordon L. Hager 1.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Regulation of Oncogenic Transcription

feedback loops, contains STAT5 response element within its promoter region. In our study, we demonstrated that STAT5 preferentially binds to promoter sequence of shared STAT5 targeted genes and to distal putative enhancers of lineage-specific genes. DNase-seq demonstrated that chromatin accessibility of STAT5-based enhancers was greatly dependent on cytokine exposure, while common STAT5 promoter targets were constitutively accessible. CRIPSR/Cas9 gene editing was used to delete the generic STAT5 binding sites in Socs2 locus in mice. Prolactin induction of Socs2 was abrogated both in liver and mammary gland, and resulted in elevated STAT5 activation and precocious mammary development in mutant mice. Taken together, we demonstrated that promoter-bound STAT5 modulates cytokine responses of universal STAT5 target genes, while enhancer-bound STAT5 is necessary for lineage-specific target gene activation. This study provides new insight into the mechanism of used by a generic cytokine response element controlling lineage-specific transcription.

#5513 Notch directly represses transcription by recruitment of PRC2 to the ternary complex. Xiaojing Han, Prathibba Ranganathan, Anthony Capobianco. University of Miami, Miami, FL

It is well established that Notch functions as a transcriptional activator through the formation of a ternary complex that comprises Notch, Maml and CSL. This ternary complex then serves to recruit additional transcriptional co-factors that link to higher order transcriptional complexes. The mechanistic details of these events remain unclear. In this study, we report that the Notch ternary complex can also serve to direct the formation of a repressor complex to terminate genes expression of select target genes. Herein we demonstrate that p19Arf and Klf4 are transcriptionally repressed directly by Notch. Data indicate that Notch recruits PRC2 and Lsd1 to these promoters, which leads to changes in the state of the epigenetic landscape and repression of transcription. The de-methylase activity of Lsd1 is a pre-requisite for Notch-mediated transcriptional repression. Furthermore, we identified a stable Notch transcriptional repressor complex containing Lsd1, PRC2 and the Notch ternary complex. This study demonstrates proof of concept for a novel function of Notch and provides further insight into the mechanisms of Notch mediated tumorigenesis. This finding provides rationale for the targeting of epigenetic enzymes to inhibit Notch activity or use in combinatorial therapy to provide a more profound therapeutic response.

#5514 Loss of expression of the recycling receptor, FcRn, promotes tumor cell growth by increasing albumin consumption. Rafał Świercz, Min Mo, Priyanka Khare, Zita Schneider, Raimund Ober, Sally Ward. Texas A&M Health Science Center, College Station, TX

Tumor cells rely on high concentrations of amino acids to support their growth and proliferation. Although increased macromolecular uptake and lysosomal degradation of the most abundant serum protein, albumin, in Ras-transformed cells can meet these demands, it is not understood how the majority of tumor cells that express wild type Ras achieve this. In the current study we reveal that the neonatal Fc receptor, FcRn, regulates tumor cell proliferation through the ability to recycle its ligand, albumin. By contrast with normal epithelial cells, we show that human FcRn is present at very low or undetectable levels in the majority of tumor cell lines analyzed. Remarkably, shRNA-mediated ablation of FcRn expression in an FcRn-positive tumor cell line results in a substantial growth increase of tumor xenografts, whereas enforced expression of this receptor by lentiviral transduction has the reverse effect. Moreover, intracellular albumin and glutamate levels are increased by the loss of FcRn-mediated recycling of albumin, combined with hypoalbuminemia in tumor-bearing mice. These studies identify a novel role for FcRn as a suppressor of tumor growth and have implications for the use of this receptor as a prognostic indicator and therapeutic target.

#5515 Dicer suppresses cytoskeleton remodeling and tumorigenesis of colorectal epithelium by miR-324-5p mediated suppression of HMGB3 and WASF-2. Lina Sun, Jianming Li. Soochow University, Su Zhou, China.

Emerging evidence indicates that microRNAs, a class of small and well-conserved noncoding RNAs, participate in many physiological and pathological processes. RNase III endonuclease DICER is one of the key enzymes for mi-
croRNA (miRNA) biogenesis. However, the role of Dicer and its downstream miRNAs in colorectal cancer (CRC) remain largely unclear. Here, we found that Dicer was downregulated in tumour samples of CRC patients at both mRNA and protein levels. Importantly, more tumours were developed in mice with intestinal epithelial cells specific deletion of Dicer (Dicerlox/- & VillinCre mice) and in EGFR mutant-EGFR (AOM) and doxorubicin (DOX) administration. Interestingly, deletion of Dicer in intestinal epithelial cells led to severe chronic inflammation and cytoketone remodeling of intestinal epithelial layer in mice with or without DSS administration. Microarray analysis of 3 paired Dicer deletion CRC cell lines (RKO-WT/RKO-Dicer-/-, HCT116-WT/ HCT116-Dicer-/- and DLD-WT/DLD-Dicer-/-) showed that miR-324-5p was one of the most significantly down-regulated in the liver of Dicerlox/- & VillinCre mice, miR-324-5p was also found to be markedly downregulated. Mechanistically, miR-324-5p directly bound to the 3’ untranslated regions (3’UTRs) of HMGX3 and WASF-2, two key proteins participated in cytoketone remodeling, to suppress their expression. Intraportal injection of miR-324-5p Agomir curtailed chronic inflammation and cytoketone remodeling of colorectal epithelium and restored intestinal barrier function in Dicerlox/- & VillinCre mice induced by DSS. Therefore, our study reveals a key role of a Dicer/miR-324-5p/HMGX3/WASF-2 axis in cytoketone remodeling and maintaining integrity of intestinal barriers and as such alludes to the possibility of screening for small-molecule compounds that boost Dicer activity as a potential strategy in the treatment of colorectal cancer.

#5516 Regulation of TFPI-2 in the progression of ovarian cancer. Jacqueline Fry,1 Sumie Kato,2 Lorenza Aburaza,2 Pamela Gonzalez,2 Elisa Cumsille,2 Erasmo Bravo,2 Raimundo Correa,2 Juan E. Leiva,2 Cesar Paredes,2 Juan C. Roa,2 Carolina Ibañez,2 Mauricio Cuello,2 Garrett L. Owen,3 Maria L. Bravo,3 Pontificia Universidad Católica de Chile, Millennium Institute Immunology and Immunotherapy, Santiago, Chile; Pontificia Universidad Católica de Chile, Santiago, Chile; Hospital Gustavo Fricke, Santiago, Chile; Hospital Regional de Talca, Santiago, Chile; Pontificia Universidad Católica de Chile, Santiago, Chile; Millenium Institute Immunology and Immunotherapy, Biomedical Research Consortium Chile, Santiago, Chile.

Ovarian cancer metastasis occurs when malignant cells migrate from the primary tumor into the ascitic fluid and form a secondary tumor in the peritoneal cavity. The cells responsible for this process, Metastases Initiating Cells (MICs), suffer a series of changes in protein expression, with increased Epithelial Mesenchymal Transition and stem cell markers having been reported. Tissue Factor Pathway Inhibitor-2 (TFPI-2) is a serine protease inhibitor and potential tumor suppressor gene, whose reduction is correlated with more metastases and poor prognosis. As the exact stage of TFPI-2 loss is still unknown, the purpose of our study was to determine TFPI-2 during ovarian cancer progression. Protein and RNA levels were assessed in primary tumor and metastatic tissue from papillary serous carcinoma by immunohistochemistry and qPCR, respectively. TFPI-2 RNA and protein levels were analyzed in cancer cell lines and primary cultured cancer cells isolated from ascitic fluid of advanced ovarian cancer patients and in cancer spheres derived from these cultures. Epigenetic changes of 3 CpG were analyzed by bisulphite and plosequencing technique in ovarian cancer cell lines and cancer spheres derived from these cultures. We report that decreased TFPI-2 protein levels in metastatic tissue compared to the primary tumor, a result confirmed in matched primary and metastatic lesions from the same ovarian cancer patients. Furthermore, cancer spheres (representing potential MICs) displayed significantly lower levels of TFPI-2 than corresponding cell line and some primary cultured cancer cells. The cancer spheres showed a modest increase in methylation percentage in three specific CpG sites within the TFPI-2 promoter. Our results suggest that TFPI-2 loss plays a role in the cancer cell escape from the primary tumor. Future studies will determine the mechanism and biological consequences of the progressive loss of TFPI-2 in cancer. Funding: FONDECYT 11140657, 11140600, 11140970, 3140335, 3150028, CORFO 12 131212-1868, IMII-P09/016-F, CONICYT-FONDAP 15130011, BMRC 13CT2125-06.

Introduction: EGFR is a member of the ErbB family of tyrosine kinase receptors (RTKs) and plays important roles in the pathogenesis of certain human cancers. In non-small cell lung cancer (NSCLC), mutations in EGFR gene are commonly known as oncogenic driver mutation and targeted for treatment. Leucine rich repeat and immunoglobulin-like domain protein-1 (LRIG1) is a cell surface protein and known as a negative regulator of ErbB family. In brain tumor, LRIG1 was reported to downregulate not only wild-type EGFR, but also EGFRvIII, mutant-type EGFR. But there has been no report about the relationship between LRIG1 and EGFR mutation in the kinase domain frequently found in lung cancer. In this study, we investigate the expression of LRIG1 in lung cancer from its effect on signal transduction and cell proliferation and invasion. Method: We examined the LRIG1 expression levels in lung cancer cell lines and the surgically resected primary lung cancer tissues by quantitative PCR assay. We made stable clone of EGFR-mutant cell line (HCC827; exom19del E746-A750) overexpressing GFP tagged LRIG1, and compared with stable clone overexpressing GFP tagged EGFR. Results: The LRIG1 expression level in lung cancer cell lines and the surgically resected primary lung cancer tissues were much lower than that in normal bronchial epithelial cells and their normal tissues, respectively. The introduction of LRIG1 decreased EGFR expression and their phosphorylation in EGFR-mutant cell line. LRIG1 strongly suppressed cell proliferation, invasion and migration of EGFR-mutant cell line. In addition, a phospho-RTK array revealed that LRIG1 also downregulated the other RTKs, such as HER2, HER3, MET, and IGF-1R. Conclusion: Our findings demonstrate that LRIG1 decreases the expression and phosphorylation of mutant-EGFR protein and has strong anti-tumor effect in lung cancer harboring EGFR mutation. These findings suggest the importance of LRIG1 related studies to develop a novel strategy for EGFR mutant cancers.

#5518 Rgs8 and Rgs16 are tumor suppressor genes in mouse pancreatic ductal adenocarcinoma. Shreshi Pal Choudhuri, Yalda Zolghadri, Luke Macarenhas, Ozhan Ocal, Thomas Wilkie. UT Southwestern Medical Center, Dallas, TX.

We have identified regulators of G protein signaling (Rgs8 and Rgs16) as a new class of tumor suppressor genes in a mouse model of pancreatic ductal adenocarcinoma (PDAC). PDA is the 3rd leading cause of cancer related deaths in the United States. Kras mutations (e.g. KrasG12D) are associated with over 90% of human PDA and are an early event in the multistep process leading to PDA. Kras can be activated by protein kinase and G Protein Coupled Receptor (GPCR) signaling. Rgs proteins regulate GPCR signaling by accelerating the GTPase activity of G- and G class alpha subunits. Activating alleles of Gq that are resistant to Rgs inhibition are associated with PDA in humans. We found Rgs8 and Rgs16 are in vivo reporters of Kras activity in pancreatic intraepithelial neoplasia (PanIN), intraductal papillary mucinous neoplasm (IPMN), and PDA progression (DMM 8, 2015). Rgs8 and Rgs16 are expressed in PanIN and IPMN, precursors of PDA, in KC mice (LSL-KrasG12D; p48::Cre). To test if Rgs8-16 function as tumor suppressor genes, we crossed the Rgs8-16 double knockout into KC (termed KR8-16 mice). Compared to KC, PDA initiates earlier, is more aggressive, and KC-TR4-16 mice die earlier. Our study suggests that Rgs8 and Rgs16 control Kras-dependent PDA initiation and progression.

#5519 psiPTTE22-HERV functions as a tumor suppressor in gastric cancer and is associated with disease outcome. Jessie Qiaoyi Liang,2 Fei Xu,1 Zi Wang,3 Jun Yu1. 1The Chinese University of Hong Kong, Shatin, Hong Kong; 2Zhejiang University, Hangzhou, China.

Background and aim: The novel gene psiPTTE22-HERV identified by us previously is a human endogenous retrovirus (HERV)-related gene located adjacent to the gene psiPTTE22. With a high GC content around the promoter region, expression of psiPTTE22-HERV can be regulated epigenetically by DNA methylation. We aimed to elucidate the clinical significance of epigenetic alteration and biological function of psiPTTE22-HERV in gastric cancer. Methods and results: psiPTTE22-HERV was ubiquitously expressed in normal adult tissues including stomach, but was frequently silenced/down-regulated in gastric tumors and cancer cell lines as evidenced by RT-PCR. Bisulphite genomic sequencing results indicated that psiPTTE22-HERV was silenced by promoter DNA methylation, and its expression could be restored by demethylation treatment. In gastric cancer cell lines, Ecotropic expression of psiPTTE22-HERV significantly suppressed cell viability, clonogenicity and cell cycle progression, induced apoptosis, and inhibited migration and invasion of SGC7901 and MKN45 gastric cancer cells. In contrast, knock-down of psiPTTE22-HERV in the gastric cancer MKN1 cells significantly increased cell growth and migration ability, promoted cell cycle progress and inhibited cell apoptosis. psiPTTE22-HERV significantly suppressed subcutaneous tumorigenicity of SGC7901 cells in nude mice and metastasis (liver implantation) in tail vein injection models. Promoter methylation level of psiPTTE22-HERV was significantly higher in gastric tumors than in adjacent non-tumor tissues as revealed by bisulphite genomic sequencing (P<0.05); methylation levels in both tumors and adjacent non-tumor
tissues of gastric cancer patients were significantly higher than in normal stomach tissues (both p < 0.001). Multivariate Cox regression analysis demonstrated that promoter methylation of p53TPT2E2-HERV in primary gastric tumors was an independent risk factor for poor survival. Kaplan-Meier survival curves showed that high-methylation of p53TPT2E2-HERV promoter was significantly associated with poorer survival in gastric cancer patients (independently of other factors such as age, sex, tumor stage, and grade) and significantly increased the risk of gastric cancer recurrence (both p < 0.05). Conclusion: p53TPT2E2-HERV functions as a tumor suppressor that is commonly down-regulated by promoter methylation in gastric cancer, which may serve as a prognostic biomarker for gastric cancer patients.

#5520 CCN5/WISP-2 is a negative regulator of epithelial to mesenchymal transition and stemness in breast cancer. Gargi Maity, Amilan Das, Sandipito Sarkar, Snigdha Banerjee, Sushanta K. Banerjee. VA Medical Center, Kansas City, MO.

Background and Objective: Breast cancer is the most common cancer in women and a leading cause of cancer mortality in western countries. CCN5 (also known as Wnt-1 induced signaling protein-2 or WISP-2) is a 29-31 kDa matrix metalloproteinase that plays as a negative regulator of breast carcinoma. Our previous studies had shown the importance of CCN5/WISP-2 in the suppression of breast and pancreatic cancer progression through the regulation of the invasive phenotypes. Considering the previous report, our aim is to investigate whether human recombinant CCN5 inhibit pathological events like epithelial to mesenchymal transition (EMT), migration and stemness in triple negative breast cancer cells. Methods: To investigate the negative impact of CCN5 on EMT and stemness of TNBC, we performed several techniques like western blot, clonogenic assay, soft agar assay, sphere formation assay etc. Results and Conclusions: The exposure of triple negative human breast cancer cells (TNBC), MDA-MB-231 and HCC-70, to recombinant CCN5 (hrCCN5), resulted in a dose-dependent inhibition of cell-proliferation through the induction of apoptotic cell death. The treatment of hrCCN5 regulates various pathological events in breast cancer cells, such as reprogramming the mesenchymal to epithelial transition (MET) followed by reduction of stemness features as confirmed by sphere formation assay and delaying in vitro migration. Finally, treatment with hrCCN5 in TNBC cells significantly inhibited anchorage-dependent and independent growth of TNBC. Collectively, CCN5’s control of cancer cell physiology indicates that hrCCN5 has the potential of being used as a major therapeutic agent against triple negative breast cancer.

#5521 Loss of Lcn2 promotes development of smoking-associated Kras mutant lung cancer. Joshua Kapere Ochien1, Wenhua Lang1, Sayuri Nuno-mura-Nakamura1, Christina McDowell2, Ralph Arlinghaus1, Yuki Imaoka3, Takashi Horii4, Junya Fukuoka4, Paul Scheet1, Junya Fujimoto1, Humam Ka-dara1. 1 UT MD Anderson Cancer Ctr., Houston, TX; 2 Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; 3 Toyama University Hospi-tal, Toyama, Japan; 4 American University of Beirut, Beirut, Lebanon.

Lung adenocarcinoma (LUAD) represents the most commonly diagnosed lung cancer subtype. LUADs in smokers frequently exhibit mutations in the Kras oncogene. Relative to other LUADs, Kras mutant LUAD displays dismal lung cancer subtype. LUADs in smokers frequently exhibit mutations in the Kras oncogene. Relative to other LUADs, Kras mutant LUAD displays dismal development of Kras mutant LUAD and would thus constitute targets for early prevention and treatment. We recently found that mice with knockout of the airway lineage gene G-protein coupled receptor 5A (Gprc5a+/−), in contrast to typical WT littermates, not only developed LUADs after tobacco carcinoma (nicotine-specific nitrosamine ketone/NKNK) exposure but that these lesions harbored somatic Kras mutations, the same variants thought to act as drivers of LUAD in human smokers. We then also found by RNA-sequencing (RNA-Seq) and immunohistochemical analyses markedly elevated expression of the lipocalin 2 (Lcn2) gene in airways of Gprc5a+/− mice and preceding tumor development. While Lcn2 has been suggested to function as a putative oncogene (e.g., in mammary tissue), little is known about the role of Lcn2 in LUAD. To fill this void, we developed mice with knockout of both Gprc5a and Lcn2 (Gprc5a−/− Lcn2−/−) and examined lung tumorigenesis following NKNK exposure in these mice relative to similarly treated Gprc5a−/− littermates. We found that Gprc5a−/− Lcn2−/− mice, relative to Gprc5a−/− littermates, exhibited markedly and significantly increased lung tumor burden and growth at three and seven months following NKNK exposure. Moreover, when we injected Kras mutant Gprc5a−/− cells (MDA-F471) into the tail veins of mice, we noted a trend for increased tumor development in lungs of Gprc5a−/− Lcn2−/− relative to Gprc5a−/− littermates. To gain global insights into the impact of Lcn2 on gene expression and signaling in Kras mutant LUAD cells, we employed RNA-Seq coupled with pathways analysis to survey differentially expressed transcripts between MDA-F471 cells stably transfected with Lcn2-specific shRNA and cells with control shRNA. Pathways and gene network analysis of the differentially expressed transcripts revealed that Lcn2 knockout leads to a heightened malignant phenotype in the Kras mutant LUAD cells via the activation of various signaling nodules including Tnf, Erk1/2 and Akt. We confirmed the RNA-Seq and pathways analysis by Western blotting demonstrating increased phospho-protein levels of Tnf, Erk1/2 and Akt in cells with knockdown of Lcn2. All in all, our preliminary data suggest that Lcn2 expression plays a tumor suppressor role downstream of Gprc5a and tobacco carcinogen exposure in the pathogenesis of Kras mutant LUAD in part by inhibiting Erk1/2 and Akt oncogenic signaling.

#5522 Novel myogenic differentiation transcription factor CASZ1 suppresses rhodomysosarcoma tumor growth. Zhihui Liu1, Norris Lam1, Arnuito Mendoza1, Jun S. Wei2, John F. Shern1, Marielle Yohé3, Javed Khan2, Carol J. Thiele1, 1 NCI-CCR, Pediatric Oncology Branch, Bethesda, MD; 2 NCI-CCR, Genetics Branch, Bethesda, MD.

Disruption of muscle regulatory factors (MRFs) in muscle progenitor cells results in a failure to withdraw from cell cycle and terminal differentiation and is proposed to contribute to rhabdomyosarcoma (RMS) tumorigenesis. Zinc finger transcription factor CASZ1 is a tumor suppressor gene and regulates normal nervous system and heart development. CASZ1 is known to regulate a subset of genes that are involved in skeletal muscle development although the function of CASZ1 in normal myogenesis is not known. CASZ1 levels increase over 20-fold when C2C12 myoblasts differentiate into myotubes. To probe its role in normal myogenesis we performed genetic knockdown or overexpression experiments in C2C12 myoblasts. When CASZ1 expression is silenced using RNAi, there is a significant reduction in myotubes upon induction of differentiation. Real-time PCR shows that knockdown of CASZ1 increases Myf5, a MRF that determines early commitment of muscle precursor cells, but decreases Myogenin (2-fold, p < 0.01), a MRF required for terminal differentiation and myotube formation. Knockdown of CASZ1 also decreases late skeletal differentiation genes Acta1, Ckm, Tnt1 and Tnn1 (2-2.5-fold, p < 0.01). Over-expression of CASZ1 induces expression of Myogenin, Acta1, Ckm and Tnt1, represses Myf5 and accelerates myotube formation. This indicates that CASZ1 regulates genes important in the transition from early to late myogenic differentiation. To investigate the role of CASZ1 in RMS, we first evaluated the expression of CASZ1 in primary RMS tumors using public available microarray database. CASZ1 mRNA levels are ~1.5-fold lower in embryonal RMS (ERMS) samples compared to normal muscle (p < 0.001), while levels of CASZ1 in alveolar (ARMS) are similar to levels in normal muscle. CASZ1 levels increase over 3-fold when RD cells (ERMS) were cultured in differentiation medium (100 nm 12-O-tetradecanoylphorbol-13-acetate, TPA). Knockdown of CASZ1 in the RD cells suppressed TPA induced expression of myogenin markers TNN1 and TNN2 while CASZ1 overexpression stimulated expression of TNN1 and TNN2 (all p < 0.05). An in vivo spontaneous xenograft model showed that over-expression of CASZ1 significantly suppressed RD tumor growth (p < 0.005). In RMS patients, NexGen sequencing of 85 tumors identified 4 samples with non-synonymous single nucleotide variants (SNVs) in CASZ1 that were absent in the 1000 Genomes databases. We engineered these SNVs into C2C12 construct and transduced it into C2C12 myoblasts. When C2C12 SNV cells were silenced by shRNA and left untreated, there was no significant change in normal nuclear localization and failed to activate skeletal muscle gene transcription (p > 0.03). Taken together, our results suggest that the regulation of muscle differentiation program by CASZ1 in C2C12 is integral to proper myogenic differentiation, and genetic variants of CASZ1 disrupt early myogenesis and may contribute to ERMS tumorigenesis and progression.

#5523 Loss of RAB25 cooperates with oncogenes in the transformation of human mammary epithelial cells. Pooja Sridhar Joshi. Southern Illinois Univ. School of Medicine, Springfield, IL.

The RAB guanosine triphases (RAS-related in brain) belong to the Ras superfamily of GTPases, and loss of RAB 25 expression has been reported in a number of breast cancer cases containing H-Ras point mutations, particularly triple negative breast cancers (TNBC), one of the most aggressive subtypes of breast cancer and associated with a poor prognosis. The mechanism involved in the progression of these tumors is poorly understood. In this study, we are trying to understand if loss of RAB25 expression in Human Mammary Epithelial Cell (HMEC) lines co-operates with H-Ras mutations and contributes to tumorigenesis. HMEC were immortalized by transduction with LXSIN CDK4 R24C, a mutant form of cyclin-dependent kinase, followed by transduction with hTERT, catalytic subunit of the telomerase enzyme that permits the cells to exceed the Hayflick Limit and become immortal. We have found that with loss of RAB25 and over expression of mutant H-Ras61L, immortal HMEC undergo transformation. We have looked into the co-operativity between loss of Rab25 and...
H-Ras61L mutant by in-vitro studies to show their anchorage independent growth and increased ability to migrate. Furthermore, cells express low CD24, high CD44, and very low levels of Claudin indicating that cells acquire stem-like properties upon transformation. Loss of RAB25 and over-expression of H-ras61L resulted in increased expression of transcription markers Snail and Slug that decrease cells to lose E-cadherin and undergo Epithelial to Mesenchymal Transition (EMT). We also intend to carry out nude mice studies to look for the potential of these cells to form tumors and metastasize. This study shows that loss of RAB25 and over-expression of mutant H-Ras can transform HMEC and give rise to mesenchymal stem-like tumors. Our findings reveal that RAB25 functions as a tumor suppressor gene, and loss of RAB25 could serve as a novel biomarker in the prognosis of Claudin-low type of TNBC.

#5524 Gene 33/Mig6 regulates apoptosis and the DNA damage response through independent mechanisms. Cen Li, Soyoong Park, Xiaowen Zhang, Leonard Eisenberg, Hong Zhao, Zbigniew Darzynkiewicz, Dazhong Xu. New York Medical College, Valhalla, NY.

Gene 33 (Mig6, ERRFI1) is an inducible adaptor/scaffold protein whose expression can be induced by both stress and mitogenic signals. It contains multiple domains for protein-protein interaction and is involved in a broad spectrum of cellular functions including cell proliferation, cell migration, cell apoptosis, and cell senescence. Many functions of Gene 33 are attributable to its ability to bind to the kinase domain of the EGFR family receptor tyrosine kinases thereby inhibiting their activities. Gene 33 also binds and activates tyrosine kinase c-Abl and is involved in other signaling pathways such as NF-kB, HGF, and INK. Growing evidence at the genetic, cellular, and animal levels indicates that Gene 33 functions as a tumor suppressor in the lung. Gene 33 has been shown to promote apoptosis. A recent study has linked this protein to the DNA damage response induced by hexavalent chromium [Cr(VI)]. In the current study we find that ectopic expression of Gene 33 strongly induces apoptosis by both activating the c-Abl/p73 pathway and inhibiting the EGFR/ Akt pathways in BEAS-2B lung epithelial cells and A549 lung carcinoma cells. Surprisingly, ectopic expression of Gene 33 also triggers the DNA damage response in an ATM-dependent fashion and through pathways with and without association with apoptosis. We observed striking presence of Gene 33 in the nucleus and chromatin, which is in contrast with the belief that Gene 33 is an exclusively cytoplasmic protein. Our data show that chromatin localization of Gene 33 is partially dependent on the EBD motif of Gene 33, a domain required for interaction with EGFR and c-Abl. Our data also indicate that Gene 33 may regulate chromatin targeting of c-Abl and EGFR. Furthermore we find that both endogenous and ectopically expressed Gene 33 strongly interact with histone H2AX. Our data have revealed potential nuclear/chromatin-associated mechanisms that underlie the function of Gene 33 in apoptosis and the DNA damage response.

#5525 Induced expression of PPM1A in ER-negative breast cancer cells inhibits growth by suppressing CDK phosphorylation. Abhijit Mazumdar, Jamal Hill, Yun Zhang, Lakshmi Reddy Bolli, Anna Tsimelzon, Jenny Chang, Gordon Chang, Dazhong Xu. UT MD Anderson Cancer Ctr., Houston, TX.

Background: Estrogen receptor (ER)-negative breast cancer is a clinical subtype that is overrepresented among younger women and is associated with a poor prognosis. Current treatments for ER-negative tumors include cytotoxic chemotherapy, or for those overexpress HER2, the anti-HER2 antibody. Targeted therapy for triple-negative breast cancers is urgently needed. In this project, we investigated phosphatases that are differentially expressed in ER-negative as compared to ER-positive breast cancers. We hypothesized that: (1) specific phosphatases govern the growth of ER-negative cancers, (2) Induced expression of specific phosphatases that are under expressed in ER-negative cancers will suppress the growth of ER-negative breast cancers. Methods: Using 102 human breast tumors (57 ER-negative & 45 ER-positive) from the neo-oadjuvant studies from the Baylor Breast Center tumor bank, we isolated RNA and performed Affymetrix microarray analyses. Statistical analysis was done with dChip software, and phosphatases over (>1.5 fold; FDR <0.05) or under (<0.66-fold; FDR <0.05) expressed in ER-negative breast cancers as compared to ER-positive cancers were selected for further study. One of the phosphatases under expressed in ER-negative breast cancer was PPM1A. Regulated expression of PPM1A was achieved using a Tet-regulated vector. Cell growth in soft agar and cell cycle analyses were performed using previously published protocols. Mouse xenograft experiments were performed by injecting inducible PPM1A-clones and vector-clones in mammary fat pad of athymic mice and tumor growth was measured over time in randomized groups. To induce PPM1A expression one group was treated with doxycycline when tumor volume reached 50 mm3. Survival analyses were done using Oncomine datasets. Results: We identified 20 over-expressed and 29 under-expressed phosphatases in ER-negative breast cancers. We selected the under expressed phosphatase PPM1A, for further study. Multivariate cox regression analysis shows PPM1A is an independent predictor for breast cancer survival. Induced expression of PPM1A in ER-negative cells inhibited anchorage-dependent and independent growth but had no effect on ER-positive cell. PPM1A expression also inhibited MDA-MB 231 cells growth in vitro and growth in vivo in the presence of doxycycline. Furthermore PPM1A expression suppressed CDK6 expression at G1 phase. PPM1A interacts with CDK6 and inhibits phosphorylation of CDK and MDM2. Conclusions: We identified a set of over- and under-expressed phosphatases in ER-negative breast cancers as compared to ER-positive cancers. Overexpression of PPM1A in ER-negative breast cancer cells inhibits growth. By identifying the molecules that regulate breast cancer cell growth we aim at identifying potential new targets for the treatment of these aggressive ER-negative breast cancers. Supported by Komen Promise grant KGC08H04 & Komen SAB grant.

#5526 Tumor suppressive role of BMI-1 through inhibition of JAK-STAT signaling in leukemia. Yuk Man Lam, Stephen Se Yuen Lam, Anskar Yu Hung Leung, Ray Kit Ng. The University of Hong Kong, Hong Kong, Hong Kong.

BMI-1, which is one of the core components of polycomb repressive complex 1, is frequently found deregulated in patients with hematological disorders. In last decades, researchers concordantly agree that BMI-1 mediates tumorigenesis of leukemia stem cells through p16INK4A leukemogenic pathway. However, accumulating evidences contradict the idea that BMI-1 solely plays an oncogenic role in tumorigenesis. It has been shown BMI-1 depletion favors the development of myelofibrosis in mice; whereas high BMI-1 expression suppresses colony forming ability of MLL-ENL-transformed bone marrow cells and correlated with higher survival in some cancers. In this study, we hypothesized that BMI-1 plays a tumor suppressive role, which is independent of the regulation of INK4A-ARF locus, in human leukemia. BMI-1 was over-expressed in a panel of myeloid and lymphoid lineage leukemia cells, including HL-60, MV-4-11, MonoMac-6, SEM, Nalm-20 and RS4;11. We observed no deregulation of p16INK4A and p14ARF genes by BMI-1, suggesting the regulation of INK4A-ARF locus is independent of BMI-1 modulation in leukemia cells. Nevertheless, over-expression of BMI-1 resulted in significant reduction of leukemia cell proliferation. It is noted that constitutively active JAK-STAT signaling pathway is crucial to leukemia cell survival. By modulation of BMI-1 level, we demonstrated suppression of the activated JAK-STAT signaling pathway in most of the leukemia cell lines with the exception of MonoMac-6 and RS4;11. This is in agreement with the high sensitivity to ruxolitinib, a JAK-STAT inhibitor, in all the tested leukemia cell lines except RS4;11. Importantly, we showed that BMI-1 over-expression could sensitize RS4;11 cells to reduce cell proliferation under ruxolitinib treatment. These results suggest that higher efficacy of ruxolitinib treatment could be achieved under a condition of high cellular level of BMI-1. We further demonstrated that ruxolitinib treatment was more effective in a cohort of AML patient samples (n = 25) with a context of higher BMI-1 expression (p < 0.05). Altogether, our results suggest that BMI-1 functions as a tumor suppressor gene via inhibition of the JAK-STAT signaling pathway. The endogenous level of BMI-1 could be served as an indicator for the effective treatment of JAK-STAT-dependent leukemia cells using ruxolitinib.

#5527 Effects of PTEN localization and phosphatase activity on gene expression profiling of glioblastoma cells. Yubing Wang, Andrew M. Chan. Chinese University of Hong Kong, Shatin, Hong Kong.

PTEN possesses both protein and lipid phosphatase activities, with its tumor-suppressor function mainly depends on its lipid phosphatase activity through inhibiting the PI3K/AKT signaling pathway at the cell membrane. However, increasing evidence have demonstrated that PTEN also localizes to other intracellular organelles such as the endoplasmic reticulum, the mitochondria, or the nucleus where it plays important roles in multiple cellular processes. To further understand how PTEN localization affects the gene expression profiling in cancer cells, a PTEN null glioblastoma cell line, U87MG, was stably expressing wild-type, nuclear localization signal (NLS)-tagged, nuclear export signal (NES)-tagged and myristoylation (MYR)-tagged PTEN. Ion Torrent based whole transcriptome sequencing was used for gene expression analysis. Gene ontology enrichment analysis showed that the most common cellular component regulated by PTEN over-expression was extracellular factors, which function as growth factor-binding or fibronectin-binding molecules related to cell adhesion or organ system development. In contrast, nuclear PTEN promoted the enrichment of genes in collagen-binding and integrin-binding, which may be related to blood vessel development or cell motility. KEGG pathway enrichment also confirmed
that PTEN over-expression upregulated focal adhesion pathway, an important pathway that frequently disrupted in PTEN Hamartoma Tumor Syndrome (PHTS). Moreover, nuclear PTEN differentially regulated genes showed higher enrichment in immune response signaling pathways. This unique gene expression profiling driven by NLS-PTEN indicated that besides the membrane activities, nuclear PTEN may have additional functions than merely inhibiting the PI3K signaling pathway. The transcriptome data showed potential downstream targets of PTEN in different subcellular localizations, which may lead to unique biological functions. More functional studies will be carried out to further validate how intracellular PTEN regulates the expression of these genes, and what are the signaling pathways involved in the regulation of these processes.

3. Results and Discussion

3.1. Evidence linking aquaporin-3 loss to increased invasiveness in bladder cancer

AQP3 is involved in the invasion and metastasis of UC cells. In the present study, the expression of AQP3 resulted in increased migration in the wound-healing scratch assay. Over-expression of AQP3 plasmid resulted in reduced migration. It is known that epithelial cell polarity contributes to tumor suppression and that loss of E-cadherin is a crucial step in epithelial-to-mesenchymal transition (EMT). Our results indicate that AQP3 overexpression induced expression of E-cadherin, consistent with a role for AQP3 as a tumor suppressor by maintaining epithelial cell polarity and inhibiting EMT in BCa. Conversely, reduced AQP3 levels leading to reduced E-cadherin levels in high-grade BCa cells may result in loss of cell polarity, increased invasiveness and increased EMT.

3.2. Significance and functions of estrogen receptor beta (ESR2) isoforms in glioblastoma

Background: Glioblastoma (GBM) are the deadliest form of primary brain neoplasms. Several lines of evidence suggest tumor suppressive role of female sex hormones on brain tumors. However, mechanisms by which estrogens mediate protection against the GBM remains unknown. GBM preferentially express estrogen receptor beta (ER2). Emerging evidence suggests that ESR2 is expressed as multiple isoforms (ESR2-1 to 5, with variation at the C-terminal domain); however, much of the published information is focused primarily on ESR2-1. Little is known about the expression and functions of other ESR2 isoforms in GBM. The objective of this study is to examine the expression and determine the functions of ESR2 isoforms in GBM cells. Methods: Expression of ESR2 isoforms was profiled using 10 different patients derived and 5 established GBM cells. To study the functions of individual ESR2 isoforms in GBM cells, we have generated ESR2 knockout (ESR2-KO) cells using CRISPR/Cas9 system and then established GBM model cells expressing individual ESR2-1, 2, and 5 using lentiviral transduction in the ESR2-KO background. ESR2 isoforms was used to identify binding proteins of each ESR2 isoforms. Effect of each isoform on the growth, apoptosis, cell cycle progression, migration and invasion was analyzed using established methods. Mechanistic studies were conducted using reporter gene assays, RT-qPCR and signaling analysis. Results: RT-qPCR results demonstrated that ESR2-5 is highly expressed in majority of primary and established GBM cells compared to ESR2-1 and ESR2-2, with ESR2-4 is the least expressed. Expression of ESR2-5 significantly reduced proliferation of GBM cells. Further, ESR2-KO cells exhibited higher migratory and invasive potential compared to parental GBM cells, while ESR2-5 resulted in reduction in migratory and invasive potential of GBM cells. ESR2-KO GBM cells exhibited decreased levels of cell cycle arrest and apoptosis proteins p27, p21 and PUMA compared to parental GBM cells and re-expression of ESR2-1 or ESR2-5 in ESR2-KO cells rescued the phenotype.

IPMS studies identified several common and unique proteins that bind to each of the isoforms. Both ESR2-1 and ESR2-5 interacted with mTOR, while ESR2-5 uniquely interacted with several proteins related to DNA repair, immunomodulatory and apoptosis pathways. Overexpression of ESR2-1 reduced the activation of mTOR signaling molecules including p-mTOR, p-S6K and p-S6 in GBM cells compared to ESR2-KO cells, while ESR2-5 enhanced mTOR downstream signaling.

Conclusion: Using ESR2-KO cells, we have identified genetic evidence for the role of ESR2-1 in GBM tumor suppression. Our results also discovered that ESR2-5 is highly expressed in GBMs. Unlike ESR2-1, ESR2-5 has lesser tumor suppression ability and its interactions with mTOR, DNA repair, and apoptotic pathways may have important implications in GBM progression.

3.3. Functional role of Friend Leukemia Integration-1 (FLI1) in gastric carcinogenesis

Armando Del Portillo, Elena V. Komissarova, Anne Koehne de Gongora, Anila Bokhari, Helen Bottani, Jorge Sepulveda, Antonia Sepulveda. Columbia University, New York, NY.

Gastric adenocarcinoma (GC) is the 5th most common cancer worldwide but is the 3rd leading cause of cancer death. FLI1 (Friend leukemia integration-1) is an ETS family transcription factor that regulates genes involved in proliferation of bladder cancer (BCa) is the most common type of urothelial cancer (UC). According to American Cancer Society, in 2016, diagnoses of 76,960 new cases of bladder cancer (BCa) and 16,390 BCa associated deaths have been estimated. More than 90% of bladder cancer starts in the innermost transitional epithelium (urothelium) of the bladder. Aquaporin 3 (AQP3), one of 13 members of a transmembrane channel forming protein family (AQP0-12), has an N-terminal basolateral sorting signal and localizes to the basolateral membrane in epithelial tissues. Recent studies have shown that AQP3 expression is decreased in UC thus supporting a new hypothesis that alteration of the expression of AQP3 plays a role in the pathogenesis of UC. However, it remains to be determined whether AQP3 is involved in the invasion and metastasis of UC cells. In the present study, human bladder cancer cell lines of different grades, SW780 (G1) and TCCSUP (G4) were studied. Transcript and protein levels of AQP3 expression were significantly higher in low grade, SW780 cells when compared to the higher-grade TCCSUP cells. Expression of CuSO4 or silencing of AQP3 resulted in increased migration in the wound-healing scratch assay. Over-expression of AQP3 plasmid resulted in reduced migration. It is known that epithelial cell polarity contributes to tumor suppression and that loss of E-cadherin is a crucial step in epithelial-to-mesenchymal transition (EMT). Our results indicate that AQP3 overexpression induced expression of E-cadherin, consistent with a role for AQP3 as a tumor suppressor by maintaining epithelial cell polarity and inhibiting EMT in BCa. Conversely, reduced AQP3 levels leading to reduced E-cadherin levels in high-grade BCa cells may result in loss of cell polarity, increased invasiveness and increased EMT.
Since NUGC3 cells have low FLI1 expression, we knocked down FLI1 by using a 24 and 48 hours (P<br>support a tumor suppressor role for FLI1 in human GC and also suggest that<br>not seen when cell were subjected to CK2 inhibition after Ikaros silencing. Further<br>investigation into the mechanism of LKB1 loss and increased sensitivity to inhi-

The objective of the present study is to investigate Runx1 functional effects on cellular activities, and its contribution to inhibiting CSC-like properties in breast cancer cells. Methods: We generated Runx1 overexpression and Runx1 knock-
down stable cell lines in both malignant MCF10A-T1 and metastatic MCF10CA1a cells. Cells were analyzed for tumoursphere formation (protein (Western) and RNA (RT-qPCR) expression analysis. Cellular activity assays (cell proliferation, migration, and invasion) were performed to measure the tumorigenic potential of the cells. Xenograft studies were used to determine whether Runx1 overexpression in breast cancer cells represses tumor growth in vivo. Results: Upon overexpression of Runx1, both MCF10A-T1 and MCF10CA1a cells reduce their proliferation, migration and invasion, which support the con-
cept that Runx1 acts as a tumor suppressor in breast cancer cells. Notably, over-
expressing Runx1 inhibited the formation of tumourspheres and effectively re-
duced the stem-like population in these two breast cancer cells. These observations are consistent with the results of Runx1 knock-down in early stage ER positive MCF17 breast cancer cells which showed increased tumoursphere forma-
tion efficiency. Furthermore, Runx1 tumor suppressor activity was confirmed in mouse xenograft by showing that Runx1 overexpression inhibits tu-
mor growth. Conclusion: Our studies show that Runx1 inhibits proliferation, migration, and invasion, reflecting its tumor suppressor activity. Runx1 mediated reduction of tumoursphere formation suggests that Runx1 also contributes significantly to inhibit the population of the breast cancer stem cells. Therefore these studies offer Runx1 as a novel bio-therapeutic molecule for breast cancer intervention.

#5534 Effect of LKB1 activity on the sensitivity to PI3K/mTOR inhibitor in non-small-cell lung cancer. Takehito Shukuya,1 Tadaaki Yamada,2 Michael J. Koenig,3 Mohammad A. Rahman,4 Joseph M. Amann,5 David P. Carbone.6 1The Ohio State University, Columbus, OH; 2Kanazawa University, Kanazawa, Japan.

The serine-threonine liver kinase B1 (LKB1, also called STK11) is a tumor suppressor that functions as master regulator of cell growth, metabolism, survival and polarity. Germline mutation of LKB1 causes Peutz-Jeghers syndrome, which is an autosomal dominant disease characterized by mucocutaneous pig-
mentation and hamartomatous polyps. In non-small-cell lung cancer (NSCLC), LKB1 is frequently rendered non-functional, either through mutation or down regulation. As a tumor suppressor and a protein whose function is lost, identi-
ifying pathways that are activated with LKB1 loss may be the only way to target such tumors. Some previous studies have suggested that inhibition of mTOR, a growth promoting pathway negatively regulated by LKB1, as a potential target in LKB1 mutant NSCLC. In this study, we investigated the effect of LKB1 activity on the sensitivity to a PI3K/mTOR inhibitor using four LKB1 mutant NSCLC cell lines to which LKB1 gene was transduced and one LKB1 wild type NSCLC cell line in which LKB1 gene was knocked out by CRISPR technology. Trans-
duction of LKB1 resulted in significant resistance to a PI3K/mTOR inhibitor in two of the four LKB1 add-back cell lines, while knocking out LKB1 in the LKB1 wild type cell line induced PI3K/mTOR inhibitor sensitivity. The mechanism behind these observed results appears to be through regulation of phosphoryla-
tion of AKT. The presence of LKB1 led to a persistent AKT phosphorylation even in the presence of the PI3K/mTOR inhibitor, both in add back cell and wild type cells. Our data suggest that the identification of LKB1 activity may be a promising biomarker for the sensitivity to PI3K/mTOR inhibition. Further in-
vestigation into the mechanism of LKB1 loss and increased sensitivity to inhi-
bition of the PI3K and mTOR pathways is warranted.
#5536 The metastasis suppressor NME1 regulates stemness in melanoma
Ying Wang, David M. Kaetzel. University of Maryland Baltimore, Baltimore, MD.

Melanoma is a lethal skin cancer that is highly resistant to therapy and prone to metastasize to distant organs. The quiescence melanoma stem cells are believed to contribute to the resistance to therapy. Intraepithelial cholangiocellular carcinomas (IHCC) and liver cancer are known to have the same, overlapping, or opposing functions, and the molecular mechanisms involved are poorly characterized. To elucidate the functions of the three Lrig proteins, we generated a series of wildtype and Lrig-null (Lrig1-/-; Lrig2-/-; Lrig3-/-) mouse embryonic fibroblasts. The FLOXed Lrig genes were then deleted with CRE-recombinase, thereby creating Lrig-null MEFs. ddPCR analysis showed that the Lrig-null MEF lines were contaminated with less than 1% of cells carrying wildtype Lrig3 alleles. Lrig-null MEFs showed a higher proliferation rate and expressed more transcripts in tumor cells than the wildtype cells. These Lrig-null cells will be useful to investigate the importance of Lrig proteins for other cellular functions such as, signal transduction, lipidomics, transcriptomics, secretomics, metabonomics, and oxidative stress sensitivity. We also transduced the Lrig-null cells with individual inducible Lrig genes thus creating a powerful system for the examination of the biology of the specific Lrig proteins.

#5539 The phenotypic characterization of Lrig null mouse embryonic fibroblasts.

The LRG1 gene family consists of LRG1, LRG2 and LRG3. The most studied of these is LRG1, which is a tumor suppressor gene. The LRG1 protein is downregulated in various types of cancer and it negatively regulates receptor tyrosine kinases including the EGFR and PDGFR-receptors. Lrig1 also regulates stem cell homeostasis in mouse skin and intestine. The functions of LRG2 and LRG3 are less known, but some findings imply that they might antagonize LRG1. Intriguingly, the sole Lrig homolog in C. elegans, Sma-10, positively regulates BMP signaling. Thus, it is not known to what degree the LRG proteins have the same, overlapping, or opposing functions, and the molecular mechanisms involved are poorly characterized. To elucidate the functions of the three Lrig proteins, we generated a series of wildtype and LRG-null (Lrig1-/-; Lrig2-/-; Lrig3-/-) mouse embryonic fibroblast (MEF) lines. These cell lines were created from homozygous Lrig flox/flox;Lrig2 flox/flox;Lrig3 flox/flox mouse embryos. The FLOXed Lrig genes were then deleted with CRE-recombinase, thereby creating Lrig-null MEFs. ddPCR analysis showed that the Lrig-null MEF lines were contaminated with less than 1% of cells carrying wildtype Lrig3 alleles. Lrig-null MEFs showed a higher proliferation rate and expressed more transcripts in tumor cells than the wildtype cells. These cell lines will also be useful to investigate the importance of Lrig proteins for other cellular functions such as, signal transduction, lipidomics, transcriptomics, secretomics, metabonomics, and oxidative stress sensitivity. We also transduced the Lrig-null cells with individual inducible Lrig genes thus creating a powerful system for the examination of the biology of the specific Lrig proteins.

#5540 Transcriptional control of signaling pathways in T-cell lymphoblastic leukemia by Ikaros tumor suppressor.
Tommy Hu, Mario Soliman, Malika Kapadia, Elanora Donat, Jonathan Payne, Chunhua Song, Sinisa Donat. Penn State College of Medicine, Hershey, PA.

Cellular proliferation in T-cell acute lymphoblastic leukemia is regulated by multiple signaling pathways. The Phosphoinositide-3-kinase (PI3K)/Akt pathway is frequently dysregulated in T-ALL. Targeting the PI3K pathway has shown promise as a novel therapeutic approach for T-ALL. However, regulation of the PI3K pathway is still not well understood. Here, we report that PI3K activity in T-ALL can be controlled by transcriptional regulation of key members of this pathway, PI3KCD and PIKFYVE. DNA binding analysis of primary T-ALL lower expressed the tumor suppressor protein Ikaros, binds to the promoter regions of PI3KCD and PIKFYVE. Since Ikaros acts as a regulator of the PI3K pathway, we tested whether Ikaros binding to PI3KCD and PIKFYVE affects their expression. Overexpression of Ikaros results in reduced transcription of PI3KCD and PIKFYVE in T-ALL. Targeting Ikaros with a specific siRNA, resulted in increased transcription of PI3KCD and PIKFYVE in T-ALL. Together, these results demonstrate that Ikaros functions as a transcriptional repressor of both PI3KCD and PIKFYVE, and suggest that Ikaros can regulate the PI3K pathway in T-ALL. It has been previously shown that Ikaros function in B-cell acute lymphoblastic leukemia is regulated by oncogenic Casein Kinase II (CK2). We tested whether Ikaros ability to repress transcription of PI3KCD and

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Tumor Suppressors 2

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 • 1145
PIKfyve is regulated by CK2. Inhibition of CK2 by a specific pharmacological inhibitor, CX-4945, resulted in increased Ikaros binding to the promoters of PIK3CD and PIKfyve, as well as in transcriptional repression of both of these genes. These results suggest that Ikaros function as a repressor of PIK3CD and PIKfyve transcriptions is impaired by CK2 in T-ALL. CK2 inhibition represses Ikaros transcriptional repression of PIK3CD and PIKfyve. CK2 inhibition results in downregulation of the PI3K pathway. In conclusion, the presented data demonstrate that the PI3K signaling pathway is regulated by transcriptional repression of PIK3CD and PIKfyve by Ikaros in T-ALL. Results reveal interplay between two signaling pathways in T-ALL, CK2 and PI3K, where CK2 positively regulates the PI3K pathway by inhibiting Ikaros function. These data reveal novel mechanisms that regulate cellular proliferation in T-ALL.

**#5541 Identification of sod1 and sod2 as potential prognostic biomarkers for patients with non-small cell lung cancer.** Chen Yin, Ren Wang, Xiao-xing Li, Yang Yang, Mei-yin Zhang, Hui-Yun Wang, Steven X. Zheng. Sun Yat-sen University Cancer Center, Guangzhou, China.

Background: Reactive oxygen species (ROS) is accumulated in cancer cells related to increased metabolism, which is characteristic of cancer progression. With the rapid advance of cancer research, redox regulation has drawn more and more attentions. The superoxide dismutases SOD1 and SOD2 are essential enzymes for eliminating ROS. To date, SOD1 or SOD2 have not been well characterized in non-small cell lung cancer (NSCLC). Here we compared the expression of SOD proteins between normal and cancer tissues and investigated its prognostic significance in NSCLC patients. Method: we detected the expression of SOD1 and SOD2 in 178 NSCLC samples by immunohistochemistry and analyzed its clinical significances. Western blotting is used to confirm the protein level of SOD1 and SOD2 in the normal and cancer tissues of NSCLC patients. Results: The expression of SOD1 and SOD2 is significantly higher in both adenocarcinoma or squamous cell carcinoma (p<0.0001), compared to matched adjacent normal tissues. Correlation analysis indicates that SOD1 expression is reversely associated with TNM stage, and SOD2 is negatively correlated with tumor size, tumor number and TNM stage remarkably (all p < 0.05). Moreover, higher expression of SOD1 and SOD2 is correlated with better prognosis of NSCLC patients. Finally, Univariate and multivariate Cox regression modes further indicate that SOD1 and SOD2 can be used as independent prognostic factors in NSCLC patients. Conclusion: Higher expressions of SOD1 and SOD2 in NSCLC tissues are observed compared to adjacent tissues and indicate a subset of NSCLC harbors inactivating mutations or deletion of one allele of the IKZF1 tumor suppressor. These data suggest that IKZF1 tumor suppressor function as a regulator of transcription and a tumor suppressor in B cell acute lymphoblastic leukemia. However, the molecular mechanism of Ikaros tumor suppressor function in T-ALL is unclear. Using quantitative chromatin immunoprecipitation (qChIP), we determined that Ikaros binds to the promoter regions of the CDC2 and CDC7 cell cycle genes in primary T-ALL cells in vivo.

**#5542 Regulation of cell cycle control in T-cell acute lymphoblastic leukemia by Ikaros and Casein Kinase II.** Mario A. Soliman,1 Tommy Hu,1 Malika Kapadia,1 Elanora Dovat,1 Yali Ding,1 Chunhua Song,1 Jonathon L. Payne,1 Sinisa Dang,1,2 Penn State University College of Medicine, Hershey, PA;1 Loma Linda University School of Medicine, Loma Linda, CA.

T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive hematological malignancy that represents a therapeutic challenge. Next-generation sequencing revealed that a subset of T-ALL harbors inactivating mutations or deletion of one allele of the IKZF1 tumor suppressor. These data suggest that IKZF1 acts as a tumor suppressor in T-ALL. The IKZF1 gene encodes the Ikaros protein that functions as a regulator of transcription and a tumor suppressor in B cell acute lymphoblastic leukemia. However, the molecular mechanism of Ikaros tumor suppressor function in T-ALL is unclear. Using quantitative chromatin immunoprecipitation (qChIP), we determined that Ikaros binds to the promoter regions of the CDC2 and CDC7 cell cycle genes in primary T-ALL cells in vivo. Gain-of-function experiments showed that Ikaros overexpression in T-ALL results in reduced expression of CDC2 and CDC7, as evidenced by quantitative RT-PCR (qRT-PCR) and Western blot. The knock-down of Ikaros with siRNA in T-ALL cells resulted in increased transcription of CDC2 and CDC7 as indicated by qRT-PCR. These data suggest that Ikaros can regulate cell cycle progression in T-ALL by repressing transcription of the CDC2 and CDC7 genes. Next, we studied the mechanisms that regulate Ikaros' ability to repress CDC2 and CDC7 in T-ALL. Ikaros function as a transcriptional repressor is regulated by Casein Kinase II (CK2). CK2 is overexpressed in hematopoietic malignancies and increased expression of CK2 results in T-ALL in murine models. We tested the effect of CK2 inhibition on Ikaros' ability to regulate transcription of CDC2 and CDC7 in human T-ALL. Molecular inhibition of CK2 with shRNA against the CK2 catalytic subunit resulted in reduced transcription of CDC2 and CDC7, as evidenced by qRT-PCR. This was associated with increased DNA-binding of Ikaros to promoters of CDC2 and CDC7, as shown by ChIP. These data suggest that CK2 impairs Ikaros' ability to transcriptionally repress CDC2 and CDC7 and to regulate cell cycle progression in T-ALL. Inhibition of CK2 enhances transcriptional repression of CDC2 and CDC7 by Ikaros, resulting in improved control of cell cycle progression in T-ALL. In conclusion, our results show that control of cell cycle progression in T-ALL occurs through Ikaros-mediated transcriptional regulation of CDC2 and CDC7. Overexpression of CK2 impairs Ikaros ability to repress CDC2 and CDC7 expression, which contributes to deregulation of cell cycle control in T-ALL. Results suggest a potential mechanism of therapeutic action of CK2 inhibitors for the treatment of T-ALL.

**BIOINFORMATICS AND SYSTEMS BIOLOGY: Systems Biology Approaches to Cancer Diagnostics and Disease Management**

**#5543 Network guided modeling allows tumor type independent prediction of sensitivity to retinoic acid.** Enrico Garattini, Marco Bolis, Maddalena Fratelli, Mineko Terao. Istituto di Ricerche Farmacologiche Mario Negri, Milan, Italy.

Background: All-trans retinoic acid (ATRA) is a differentiating agent used in the treatment of acute promyelocytic leukemia and it is under-exploited in other malignancies despite its low systemic toxicity. A rational/individualized use of ATRA requires development of predictive tools allowing identification of sensitive cancer types and responsive individuals. Materials and Methods: RNA-sequencing data for 10080 patients and 33 different tumor-types were derived from the TCGA and Leucene datasets and completely re-processed. The study was performed using machine learning methods and network analysis. Results: We modeled the large panel of breast-cancer cell-lines for in vitro sensitivity to ATRA and exploited the associated basal gene-expression data to initially generate a model predicting ATRA-sensitivity in this disease. Starting from these results and using a network-guided approach, we developed a generalized model (ATRA-21) whose validity extends to tumor-types other than breast cancer. ATRA-21 predictions correlate with experimentally determined sensitivity in a large panel of cell-lines representative of numerous tumor-types. In patients, ATRA-21 correctly identifies APL as the most sensitive acute-myelogenous-leukemia subtype and indicates that uveal-melanoma and low-grade glioma are top-ranking diseases as for average predicted responsiveness to ATRA. There is a consistent number of tumor-types for which higher ATRA-21 predictions are associated with better outcomes. Conclusions: In summary, we generated a tumor-type independent ATRA-sensitivity predictor which consists of a restricted number of genes and has the potential to be applied in the clinics. Identification of the tumor-types which are likely to be generally sensitive to the action of ATRA paves the way to the design of clinical studies in the context of these diseases. In addition, ATRA-21 may represent an important diagnostic tool for the selection of individual patients who may benefit from ATRA-based therapeutic strategies also in tumors characterized by lower average sensitivity.

**#5544 New technologies to probe the systems glycobiology of cancer.** Pau-line M. Rudd, Mark Hilliard, Mohankumar Muniyappa, Roisin O’Flaherty, Radka Sal'dova. National Institute for Bioprocessing Research and Training, Dublin, Ireland.

A robotic 384 well based platform was developed to release and label the human serum N-glycome. Improved separation of the glycan pool, based on hydrophilic interaction UPLC chromatography combined with mass spectrometry (Waters Corporation) and computer assisted data interpretation (NIBRT Glycobase) enabled us to build a database after assigning the detailed structures of more than 170 N-glycans. The aim of the project was to use these technologies and databases to link glycosylation changes in individual patients’ serum with features of cancer and with changes in a range of other –omics data acquired from the same patients. Alterations in glycosylation in various breast cancers were mapped to changes in the serum glycomes and aligned with genetic, transcriptomic and proteomic data. Pathway analysis showed strong associations between these glycan changes and the –omics data. This revealed that many of the glycan changes are directly associated with pathways involved in cancer metabolism. Our next aim was to demonstrate the feasibility of collecting personalised data from individual patients from each of the –omics analyses to build up a dataset of the changing glycosylation over time. This opens up the possibility of linking these data to explore pathways of disease and, in particular, nodal points where the patient can no longer compensate for the effects of an altered pathway that is leading to disease. To this end, single glycoepitopes from 8 controls and 26 ovarian cancer patients were sequentially purified from 5ul of serum on affinity plates and the released glycans were analysed. Rather than the conventional way of looking at markers which compare a patients’ data with averages, the control can now be the blood of the patient themselves taken at an earlier time point. The
#5546 Modeling of gastric cancer with lymphovascular invasion and H. pylori: a systems approach. Samuel Perez, Penn State Univ., Phoenix, AZ

Background: Behaviors of gastric cancer system with an H. Pylori co-morbidity allows clinician-educators to describe cancer metastasis through the lens of a systems approach. Lymphovascular invasion in gastric cancer has shown to have low survival rate within a five year period. The unresolved presence of H. Pylori in the gastric chamber allows for pervasive inflammation of the mucosal lining. Lymphovascular invasion supported with extracellular membrane (ECM) detachment and anoikis suppression exhibit elements of a systems approach such as inputs, processes, output and a feedback loop. Methods: Insightmaker.com is a simulation and modeling program used to create the stock and flow models. This system based approach allows a user to create primitives such as stock and variables and add connections using link and flow elements. A simulation run provides a visualization of the defined stock against a timeline on a dynamic graph. Results: A generalized metastasis model was first generated in insightmaker.com. An organ specific model was used to model how cancer cells interact with the gastric mucosal lining and its spread to the lymphovascular system. This organ specific model will help a clinician-educator represent chemical pathways and relationships to explain the secondary growth of tumors from its original site. Conclusion: The initial instructional activity was designed with an easy to follow demo of an actual working systems model in systems biology or population ecology. This allows for the content to be familiar to the student. A team of 4 students constructed a systems model of a portion of the gastric tumor metastasis cycle such as ECM detachment or suppression of the anoikis process. An evaluation rubric was used to guide the development of the group created student model with evaluation categories such as narrative of the system model, attributes of the system, data flow and values used and a personal reflection of their experience. The successful implementation of a system approach is packaging the instructional activity and its supporting content in bite size pieces, an incremental approach and explicit description of the activity’s deliverables. The Insightmaker.com model created for the embedded systems based instructional activity is ideal for lowering the learning curve for a systems thinking instructional activity and can fit in the time constraints of an oncology course block as part of a case based instruction session in an undergraduate medical curriculum.

#5547 A computational approach to predict tissue level cell cycle regulatory network for normal proliferating and cancer cells. Tao Sheng, Sha Cao, Chi Zhang, Ying Xu. Univ. of Georgia, Athens, GA

Cell cycle control and regulation has been widely studied in terms of cyclin-dependent kinases (CDKs) activities, while only limited information are available on tissue contexts and signaling. In this study, we adopted a systems biology approach aiming to comprehensively capture how tissue level signaling events orchestrate cell cycle phases in a CDKs activities independent manner in both of normal and tumor tissues. We have applied in our house gene co-expression and bi-clustering analysis on a collection of 8 single cell transcriptomic sequencing datasets of normal proliferating human embryonic cells, 17 RNA-seq transcriptomic datasets of inflammatory tissues and 30 microarray data sets of chronic inflammatory diseases as normal proliferating reference and TCGA RNA-seq data for 20 cancer types aiming to identify cell cycle associated gene co-expression modules. Our results suggest that the tissue level signaling events are generally very active on CDKs 11022

#5548 Genomic signatures for tumor-to-treatment stratification in pancreatic cancer. Olga H. Nikolova, Laura Heiser, Adam A. Margolin. Oregon Health and Science University, Portland, OR

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is the fourth leading cause of cancer deaths. PDAC is a broadly heterogeneous disease making it difficult to treat; each patient’s tumor is unique, but it can be classified into different subtypes, and identifying the right therapeutic strategy for each subtype is key to improving patient outcomes. Three sets of transcriptional signatures for PDAC subtype classification have been proposed in the literature; however, even when the same data from our laboratory cell line models indicates that they are associated with sensitivity for only a handful of compounds. Computational methods can identify effective individual therapies by robustly analyzing genomic-scale data from multiple experimental platforms to derive molecular classifiers predictive of drug response (drug signatures). Methods: We developed a novel Bayesian framework approach called Gene-wise prior Bayesian Factor Analyses (CBGFA) for predicting drug sensitivity in a given sample from genomic data. Our approach integrates data from different omic platforms by modeling the statistical dependencies of measurements made for the same gene via a model parameter called “gene prior”. We identify gene signatures for the clinically relevant to PDAC compounds olaparib and palbociclib, leveraging data from 44 pancreatic cell lines. Using hybrid capture mutation, gene expression, and copy number data, we applied our model to score genes for their ability to predict drug response in pancreatic cell lines and compiled the top predictors into drug signatures. Results: Our results across a pan-cancer cell line collection and >100 compounds show improved ability to recapitulate known biomarkers and drug targets compared to other state of the art methods. For the MEK1/2 inhibitor selumetinib, we successfully recapitulated BRAF mutation as the top-ranked biomarker of sensitivity. In addition, we identified four genes that carry additional information that can be used to stratify samples into sensitive or resistant groups: all were wild type in the sensitive cell lines and mutated in some of the resistant lines. We hypothesize that these genes could be used in conjunction with BRAF mutation status to refine the stratification to selumetinib therapy. We also identified several highly expressed genes in the resistant cell lines, and we hypothesize that these genes may mediate drug resistance. Similar analysis are currently ongoing for olaparib and palbociclib, comparing our findings to the subtypes currently proposed in the literature. Conclusions: Our integrated approach identifies drug-specific gene signatures in PDAC cell lines. We derived genomic signatures for two clinically relevant to PDAC compounds in the con-
text of the established in the literature PDAC subtypes, and hypothesize that these signatures could be used to identify patients most likely to respond to these therapies.

#5549 Novel network predictor for drug sensitivity in cell line response data. Ana Brandusa Pavel,1 Bin Li,2 Andrew Krueger.2.1Graduate Program in Bioinformatics, Boston University, Boston, MA; 2Takeda Oncology, Cambridge, MA.

Sequencing patient tumors has enabled the design of treatment regimens that exploit sensitizing genomic alterations. Associating drugs with mutations that enhance their effect is a key component of the American Society of Clinical Oncology vision for the next two decades of cancer treatment. Methods that distinguish drug sensitizing molecular events from the millions of extraneous alterations common within a tumor will help researchers implement precision medicine strategies. Here we use molecular data from the cancer cell line encyclopedia; including mutations, copy number alterations and gene expression changes along with drug response data, to identify subnetworks of interacting proteins that contain drug sensitizing alterations. Building upon the ability of fuzzy logic models to capture gene activity from different molecular data types, we create ‘Network-FLM’, a method to identify drug sensitizing molecular markers using a subnetwork model that distinguishes a drug sensitive sample from a drug insensitive one. Because the subnetwork model incorporates the sign and direction of network edges and the magnitude of gene activity changes, biologically meaningful features are captured. We integrate protein interaction information from Metacore database with somatic mutation, copy number and gene expression data, using the expression data as a guide. Combining the expression data and mutation data, we evaluate the mean AUC of the predictor for 24 anti-cancer compounds (Barretina et al., 2012). We build subnetwork classifiers for each compound using mutation, copy number and expression data separately and in all possible combinations. We find that the Network-FLM approach performs well for targeted agents such as Sorafenib, and also for drugs with pletropic mechanisms of action. Gene expression data alone creates effective predictive subnetworks for 8 compounds (Nilotinib, Sorafenib, Ibrutinib, PLX4720, Palbitaxel, Topotecan, TAE684, and Erlotinib). Adding copy number changes to gene expression data created better predictive networks for 8 compounds (PF2341066, AZD6244, L683458, RAF265, PD0325901, ZD6474, PHA665752, and 17-AAG). Likewise, three compounds benefit from adding mutation data to expression data (Panobinostat, PD0332991, and Lapatinib). Combining all three data types created the best predictors for AEW541 and AZD0530. For three compounds, mutation data alone and together with copy number alterations is the best input for building predictive models. We identified hyper-active subnetworks in cancer cell lines and used them to predict drug sensitivity. We plan to further explore the potential of these networks to improve patient response to anti-cancer drugs.

#5550 Collaborative analyses for delineating mutation variations among different ethnic patients of prostate cancer based on genomic data integration. Qingyu Xiao,1 Yidi Sun,1 Hong Li,1 Xiyue Li,1 Guo-Ping Zhao,1 Wendy Wang,2 Sudhir Srivastava,2 1CAS-MPG Partner Institute for Computational Biology, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, China; 2National Cancer Institute, National Institutes of Health, Bethesda, MD, USA.

Emerging data support the hypothesis that both inherited and somatic alterations of genomes of African American (AA) prostate cancer (CaP) patients are significantly different from that of Caucasian American (CA) men. Recent studies from our and other groups have established that frequencies of the most common genomic alteration, TMPRSS2-ERG fusion, which apparently causes the high expression of ERG oncoprotein, is markedly lower in AA than in CA patients. Some works indicated that the frequency of CaP ERG fusion is the lowest in Asian patients, but this frequency changed from 11% to 78% in different Asian cohorts. Further analysis in Asian men is necessary. In order to systematically and comprehensively address this and related problems, Uniformed Services University of the Health Sciences-Center for Prostate Disease Research (USU-CDR), TCGA and the Chinese Prostate Cancer Consortium (CPCC), specially focusing on somatic alterations (ERG and others), microbiome, mitochondrial sequences and microRNAs. We integrated gene fusion, copy number, and gene expression data to detect potential driver genes and, as anticipated ERG alteration was one of the most commonly detected. The frequency of ERG fusion is the highest for CA, intermediate for AA and the lowest for Asian men, while its expression is significantly higher in ERG-fusion tumors than other tumors cross over all of the three ethnic groups. We did find some genes altered more frequently in Asian patients than in American patients, subject to further validations. We explored the methodology for microbiota profiling using prostate cancer WGS sequencing data. We inferred the metabolic pipeline from prostate tumor tissues and the corresponding blood samples with high confidence but inadequate sensitivity likely due to the low availability of both microbial sequences and bacterial reference genomes. Our preliminary analyses highlight the potential of international collaboration. CPDR-PICB-NCI will work on a seamless approach for data integration, particularly of the raw data to truly enhance CaP diagnosis and treatment by providing more informative biomarker and therapy targets relevant to ethnically diverse patient populations.

Non-coding genes are shown to play important roles in cancer progression with potential for serving as theranostic biomarkers. However, there is still a lack of studies to predict the biological roles of novel non-coding genes in tumorigenic pathways and associations with patient survival. Lung adenocarcinoma (LUAD) is the predominant histological subtype of lung cancer, which is the leading cause of cancer death. Nowadays, target therapies have improved LUAD patients’ survival about 6-12 months, but limited improvement of long-term survival. Suggesting new therapeutic targets are important. Therefore, here we applied weighted correlation network analysis (WGCNA) to cluster highly correlated genes of transcriptomic data to accurately investigate the functions of non-coding genes with poor prognosis in lung adenocarcinoma (LUAD). We discovered a total of 627 differential expressed coding and non-coding genes (DEGs) from 6 transcriptomic datasets derived from LUAD patients with survival information. By using WGCNA, we discovered 6 non-coding candidates (PTTG3P, MIR497HG, HSP078, TBX5-AS1, LOC100506990, and C14orf64) and their core networks of DEGs, which were highly associated with patient survival and clustered in modules functioning in cell cycle and migration. We noticed that a previously known processed pseudogene, PTTG3P (Pituitary Tumor-transforming Gene 3), is highly correlated with poor survival and associated with mitosis of the cell cycle. Up-regulated PTTG3P expression in LUAD was in silico validated of RNA-seq data from TCGA compared to normal lung tissues (fold-change = 2, p-value < 0.0001) and associated with poor 5-year survival rates (HR= 1.83, p-value = 0.012). We further confirmed PTTG3P is highly expressed and associated with poor survival outcome of LUAD patients in Taiwan (HR= 1.75, p-value = 0.037) with RNA-ISH experiment. Together the coding potential of pseudogene PTTG3P, we found that PTTG3P might encode a consensus 21 kDa novel polypeptide from a single exon by using various prediction programs of coding potential. Ectopic expression of PTTG3P in lung cancer cells indicated that PTTG3P protein can be detected resulting in shortening the process of metaphase to anaphase in cell cycle progression and promotion of cell proliferation. Knockdown experiments of PTTG3P further reversed aforementioned experiments. Together we established a powerful and systematic strategy for functional classification of non-coding genes in association with poor prognosis of LUAD patients. We revealed that commonly annotated and processed pseudogenes defined as non-coding genes for lacking of introns and promoter regions could still be translated into functional polypeptides. We found processed pseudogene PTTG3P can be translated to a protein, which might play an important role in predicted function of mitosis and impact on poor survival in LUAD patients.

#5552 Differential proteomic responses of luminal-A and basal-like breast cancer cell lines during growth inhibition induced by co-culture with agarse encapsulated murine renal adenocarcinoma (RENCA) cells. Melissa A. Laramore,1 Peter James,2 Frithy C. Martis,1 Atira Dudley,1 Lawrence S. Garda,3 Carl A. Borrebaeck,2 Barry H. Smith3.1The Rosogen Institute - Xenia Division, Xenia, OH; 2Lund University, Lund, Sweden; 3The Rosogen Institute, New York, NY.

The existence of a tumor growth regulatory network that is conserved across tumor types and species has been hypothesized. Our evidence for this regulatory network is derived from studies demonstrating tumor growth inhibition by agarse encapsulated cancer cells (cancer macrobeads). The ability of encapsulated, thus growth restricted cells, to inhibit freely growing cancer cells has been shown when the encapsulated cells are murine (RENCA) or human (e.g., M2b). Clinical trials are underway (NCT01053013, NCT02046174). We have shown that RENCA macrobeads release >10 known tumor inhibitory proteins target-
ing several signaling pathways including Akt/Pi3. To better understand the mechanism(s) of growth inhibition, we used a systems biology approach to identify protein profiles and interactions from macrobead-treated human breast carcinoma cell lines that are either mildly aggressive (MCF7) or highly aggressive (MDA-MB231 [MDA]). Target cells were co-cultured with RENCA macrobeads (5 μm) and incubated for 5 days. Lysates were run in Laemmli buffer, frozen, and sent for MS/MS. Samples were run in duplicate, protein intensities normalized, and the treated/untreated ratio log10-transformed to get a normal distribution. Protein profiles were analyzed using Key Pathway Analysis (KPA) and Metacore software. Growth inhibition by RENCA macrobeads was confirmed (MCF7 25%; MDA 57%). KPA of MCF7 proteins showed upregulation of a large number of pathways involved in aggregations of unfolded proteins. Stress induced apoptosis and DNA damage (which correlates with the growth inhibition) were the top 2 pathways upregulated using Pathway and Process Enrichment analysis. This is in line with a strong epigenetic gene deregulation (Metacore). Transcription Factor and Network analyses show up-regulation of CREB, A2MR and ATF3 networks. Also, Regulated Network analysis suggests a role for A2MR or RAGE in the inhibition of proliferation and increased apoptosis. Macrobead-treated MDA cells showed no significant changes using KPA. Pathway, Network and Process enrichment (Metacore) showed 5 of the top 10 upregulated processes were associated with cytoskeleton remodeling. Cell cycle and protein folding processes were also upregulated. Transcription factors associated with this response were similar to that of MCF7, RAGE was not upregulated in any of the pathways indicated by Network or Regulated Network analysis. The protein response to RENCA macrobeads differs for these 2 cell lines. Proteins related to apoptosis are upregulated in the MCF7 cells whereas MDA have a preference for cytoskeleton remodeling. These data support the hypothesis that distinctive tumors may respond differently to RENCA macrobead exposure at both an epigenetic and protein level, nonetheless resulting in growth inhibition.

#5553 A computational model for integrating genomic data with public datasets for molecular tumor board recommendations. R Joseph Bender,1 Edik Blais,1 Apovora Kulkarni,1 Michael J. Pishvaian,2 David Halverson,1 Jonathan R. Brody,2 Emanuel Petricoin,3 Subha Madhavan4,5 Perthera, Inc. McLean, VA;2 Georgetown University Lombardi Comprehensive Cancer Center, Washington, DC;2 Thomas Jefferson University, Philadelphia, PA.

Recent genomic profiling studies in pancreatic adenocarcinoma (PDA) have revealed actionable mutations affecting multiple signaling pathways, but in spite of these mutations, targeted inhibitors of these pathways have low success rates. A possible reason for these failures is that single-gene biomarkers (e.g., a KRAS mutation as an indicator of MEK inhibitor sensitivity) fail to account for cross-talk within and between dysregulated pathways. We have previously curated a knowledgebase of published studies as evidence to support molecular tumor board recommendations to cancer patients after multi-omic profiling. Here we present a computational framework for integrating this knowledgebase with drug response data from cancer cell lines to propose “actionable” biomarkers based on a panel of pathways instead of targeting a single gene mutation. We constructed a computational model encompassing a broad range of cancer-related pathways, including RAS/RAF/MEK/ERK, PI3K/PI2/AKT, cell cycle regulation, and DNA repair. The model consisted of a set of ordinary differential equations (ODE) with protein interactions following Hill-type kinetics and the rate of cell division and apoptosis modeled dependent on key signaling nodes, including the level of phosphorylated ERK and AKT. We integrated two sources of publicly available data: 1) published studies correlating phosphoprotein measurements and resistance pathways to targeted inhibitors in clinical development; and 2) mutation data correlated with drug-specific response metrics (e.g., IC50 values), such as CCLE and NCI-60. We systematically screened frequently observed overlapping disrupted signaling pathways (i.e., combinations of mutations) by simulating predicted IC50 values for targeted inhibitors. Based on these simulations, we found that the drug combinations involving more drugs may be best suited for inhibiting tumor growth when tumors harbor multiple mutations. We present two applications of this computational approach: a comparison of CDK4/6 inhibition in CDK2A2-mutated PDA vs. hormone receptor-positive breast cancer and a comparison of PARP inhibition in BRCA1/2-mutated PDA and ovarian cancer. The predictions generated by our simulations were consistent with clinical observations in that fewer combinations of mutations in PDA were sensitive to these inhibitors than in breast and ovarian cancer, suggesting ways to refine biomarkers for sensitivity to these drugs in PDA. The computational model presented here takes into account multiple datasets from a knowledgebase to provide a prioritized list of treatments that match a patient’s molecular profile while also providing the rationale for the recommendation. This represents a step toward incorporation of systems biology in precision oncology.

Lung cancers are among the most common invasive cancers worldwide and annually lead to high mortality and morbidity. Genomic alterations have been known to control the evolution of hallmarks of cancer in a dynamic way. These molecular alterations combined with epigenomic and post-genomic modifications contribute to formation of these neoplasms. Multiplicity of these changes has made development of personalized therapeutic regimens for these cancers a complex problem. Metabolic reprogramming is one of the main mechanisms in progression of cancers. There have been efforts to model the metabolic reprogramming in cancer using metabolic networks of cancer cells, but there has been no computational framework to model these metabolic transitions in cancer for precision and personalized medicine. We have combined computational, mathematical and experimental methodologies to develop a platform for precision oncology in non-small cell lung cancer (NSCLC) by in silico models of metabolic switches. Our integrative analysis of genomic data from NSCLC has led to discovery of genomic signatures controlling metabolic reprogramming in NSCLC with KRAS mutations. This discovery was proved in vivo and in vitro using drugs blocking different metabolic pathways. We have shown that NSCLC cells which do not carry KRAS mutations and have these genomic signatures are addicted to the pentose phosphate pathway (PPP). We have verified and proved the predictive value of these genomic signatures using Patient Derived Xenograft (PDX) tumor models of NSCLC. We are developing a mathematical and computational framework to model these metabolic switches. Our platform is capable of using genomic data from a cell line or tumor to determine the metabolic dependency of them quantitively and predict the optimized personalized treatments for modulating metabolic pathways aiming to control cancer progression.

#5555 Integrative network varioomics reveals complex genotype to phenotype relationships in cancer. Nidhi Sahni, Song Yi. UT MD Anderson Cancer Ctr., Houston, TX.

Proteins interact with other macromolecules in complex cellular networks for signal transduction and biological functions. Recently a deluge of genomic information becomes available from patients stricken by a variety of cancer types. In cancer, genetic aberrations have been traditionally thought to abolish the entire gene function. It has been increasing appreciated that each genomic mutation of a gene could have a subtle but unique effect on protein function or network rewiring, contributing to diverse phenotypic consequences across cancer patient populations. In this study, we designed an integrative multi-omics platform using systems biology approaches to functionally assess the effects of cancer genetic variants. We compared a broad spectrum of mutation classes for a wide range of mechanistic effects on gene function in the context of signaling networks. Our results reveal a functional landscape of context-specific signaling network perturbations underlying specific genetic and phenotypic variations. Such information is critical for understanding the complex pleiotropic effect of cancer genes, and it provides a possible link between genotype and phenotype in cancer. Furthermore, this study suggests new perspectives in targeted therapy and precision medicine.

#5556 Widespread protein interactome network rewiring in human cancer. Song Yi, Nidhi Sahni. UT MD Anderson Cancer Ctr., Houston, TX.

In the past decade, genome and exome sequencing projects have identified thousands of genetic variants in patients across a large number of cancer types. However, the explosion of genomic information has left many fundamental questions regarding genotype-phenotype relationships unresolved. One critical challenge is to distinguish causal disease mutations from non-pathogenic polymorphisms. Even when causal mutations are identified, the functional consequence of such mutations is often elusive. Classical “one gene, one function, one disease” models can not reconcile with the complexity that different mutations of the same gene often lead to different phenotypes. The extent to which network perturbations are involved in disease malfunction and how distinct interaction perturbation patterns can distinguish cancer mutations are largely unknown. Here we report a systematic approach to investigate genetic variant-specific effects on molecular interactions at large scale across diverse human cancers. Remarkably, in comparison to non-disease polymorphisms, disease mutations are more likely to associate with interaction perturbations. A large fraction of missense disease mutations are found to cause protein interaction alterations.
remodeling during metastases development, defining patterns of extracellular-matrix associated genes and proteins that predicted both extent of disease and tissue modulus. This allowed us to identify a core group of twenty-two matrix-associated molecules that modeled the dynamic process of tissue remodeling during tumor progression. We used these data to generate a ‘matrix index’, a quantitative measure of the mean expression of the twenty-two molecules. In cancer transcriptomic databases, this matrix index had prognostic significance in thirteen solid cancers including high-grade serous ovarian cancer, even after multivariate analysis. We conclude that there may be a common host matrix response to human solid cancers.

#5559 Using cancer dependency data to discover tumor suppressive and oncogenic functional modules. Joshua Pani,1 Robin M. Meyers,2 Brittany C. Michel,3 Ann E. Sizemore,2 Francisca Vazquez,2 Barbara A. Weir,2 William C. Hahn,1 Aviad Tsherniak,2 Cigall Kadoch1.1 Dana-Farber Cancer Institute, Boston, MA;2 Broad Institute, Boston, MA.

Efforts to define protein complexes and their functional networks are critical for systems-level understanding of the pathways involved in human cancer. Current methods to catalog human protein complexes via physical interaction are often unable to resolve functional differences between complex members or infer relationships governed by sub-stoichiometric interactions. While functional wiring maps in yeast have been generated by measuring epistatic interactions between pairs of genes, efforts to scale this concept in individual human cell lines have been met with challenges and have only been able to characterize limited numbers of genes at a time. We have developed a scalable approach that can measure functional similarity without the constraints of pairwise genetic interaction experiments. Using data from genome-wide RNAi and CRISPR dropout screens performed in hundreds of cancer cell lines, we leveraged the heterogeneity of gene dependencies across cancer types to measure functional similarity between thousands of genes at once, which in turn allowed us to recreate known inter- and intra-complex functional relationships and to uncover tumor suppressive and oncogenic functional modules in cancer-relevant pathways such as proteolysis, metabolism and transcription. Applying these approaches to the mammalian SWI/SNF (BAF) chromatin remodeling complex, which is mutated in over 20% of human cancer, revealed three functional modules that arose separately during metazoan evolution, one of which is entirely novel and uncharacterized. We then performed biochemical experiments that fully support three specialized complex configurations, each with distinct size, subunit composition, and function. These data reorganize the BAF complex into previously unrecognized modules that better explain mutational burden in human cancer. Notably, we observe that all known BAF-driven, highly penetrant rare cancers and neurodevelopmental disorders involve disruption within a single functional module we defined, underscoring the value of evaluating disease genomics through the lens of functional modularity.

#5560 Systemic map of protein phosphatase 2A (PP2A)-regulated phosphotargets and drug responses in cancer cells. Otto Kauko,1 Susumu Imanishi,1 Evgeny Kuleskij,1 Teemu D. Laajala,1 Laxmana Yetukuri,1 Artur Padzik,1 Mikael Jumppanen,1 Pekka Haapaniemij,1 Bhagwan Yadaw,1 Veronika Suni,1 Taru Varilas,1 Garry Corthals,1 Wennerberg Kristers,1 Tero Aittokallio,1 Jukka Westermarck1,1 University of Turku, Turku, Finland; 2Meijo University, Nagoya, Japan; 3University of Helsinki, Helsinki, Finland.

Despite the pivotal role of phosphatases in cancer cell signalling, systemic understanding of phosphatase targets is still at infancy. Protein phosphatase 2A (PP2A) is a human tumor suppressor complex. PP2A inhibition is a requirement for human cell transformation and PP2A regulates many cancer critical signalling pathways. Importantly, emerging data indicates that reactivation of PP2A tumor suppressor activity could provide entirely novel approach for cancer therapy. Here, we present first systemic analysis of phosphoprotein targets (dephosphorylated by PP2A) regulated by PP2A in cancer cells. Based on data, PP2A regulates cancer critical signalling pathways, including entire EGFR-RAS-RAF-MEK-ERK cascade, and functions as a master regulator of MYC function. At network level, PP2A targets critical cellular processes such as chromosome organization, RNA splicing, and nuclear envelope assembly. Surprisingly, soft clustering of PP2A dephosphorylated revealed that most phospho-target residues are subject to only unidirectional regulation in cancer cells. Moreover, targets show intracellular gradient where phosphatase inhibition dominates nuclear phosphorylation balance. Since phosphoregulation is critical for cancer drug responses, dephosphorylated was correlated with cancer cell responses to over 300 drugs. Importantly, cancer therapies could be broadly classified based on their dephosphorylome, both at quantitative and qualitative manner. Finally, we demonstrate the utility of this large dataset by validating the role of PP2A in MEK inhibitor resistance in KRAS mutant cancer cells via regulation of RAF,
Adaptation and fractional response of tumor cells to targeted inhibitors of oncogenic pathways allows a population of viable tumor cells from which fully resistant clones may arise. Thus, understanding transient drug adaptation is key for both improving the effectiveness of treatment and delaying/controlling acquired resistance. Despite the wealth of information available about feedback mechanisms associated with adaptive resistance, most of our knowledge in this area comes from studying drug response in bulk tumor cell populations. Furthermore, the phenotypic consequences of drug adaptation have been often studied at a few fixed time-points, when drug-adapted cells exhibit a high population-average activity in multiple pro-growth signaling cascades. It therefore remains unclear how the initial responses to drug relate to subsequent phenotypes such as cell death or adaptation. This is likely a key point for designing novel approaches to overcome fractional drug response in tumor cells and to achieve durable therapy. We use real-time live-cell imaging, single-cell analysis and molecular profiling to show that exposure of BRAFV600E melanoma cells to RAF/MEK inhibitors elicits a time-variable and heterogeneous response in which some cells die, some arrest and the remainder adapt to drug. Drug-adapted cells up-regulate markers of the neural crest (e.g. NGFR), a melanoma precursor, and grow slowly. The drug-induced slow growth/G0/GRHigh state is only transiently stable, reverting to the drug-naive state within two weeks of drug withdrawal as measured by the restoration of RAF/MEK inhibitor sensitivity, accelerated rate of cell division and reduced expression of NGFR. Transcriptional and biochemical profiling of cell lines and human tumors implicates a role for the c-Jun/ECM/FAK/Src cascade in driving the de-differentiation response. We identify multiple drugs targeting this cascade as well as BET bromodomain inhibitors that block this resistance program in cell lines and in a BRAFV600E melanoma xenograft model and increase sensitivity and maximal effect (E_{max}) of RAF/MEK inhibitors. Our study reveals directly how drug adaptation happens in individual tumor cells leading to emergence of heterogeneous cell sub-populations with reduced drug-sensitivity that may be targeted by drug combinations.

Harvard Medical School, Boston, MA; Dana Farber Cancer Institute, Boston, MA.

Adaptation and fractional response of tumor cells to targeted inhibitors of oncogenic pathways allows a population of viable tumor cells from which fully resistant clones may ultimately arise. Thus, understanding transient drug adaptation is key for both improving the effectiveness of treatment and delaying/controlling acquired resistance. Despite the wealth of information available about feedback mechanisms associated with adaptive resistance, most of our knowledge in this area comes from studying drug response in bulk tumor cell populations. Furthermore, the phenotypic consequences of drug adaptation have been often studied at a few fixed time-points, when drug-adapted cells exhibit a high population-average activity in multiple pro-growth signaling cascades. It therefore remains unclear how the initial responses to drug relate to subsequent phenotypes such as cell death or adaptation. This is likely a key point for designing novel approaches to overcome fractional drug response in tumor cells and to achieve durable therapy. We use real-time live-cell imaging, single-cell analysis and molecular profiling to show that exposure of BRAFV600E melanoma cells to RAF/MEK inhibitors elicits a time-variable and heterogeneous response in which some cells die, some arrest and the remainder adapt to drug. Drug-adapted cells up-regulate markers of the neural crest (e.g. NGFR), a melanoma precursor, and grow slowly. The drug-induced slow growth/G0/GRHigh state is only transiently stable, reverting to the drug-naive state within two weeks of drug withdrawal as measured by the restoration of RAF/MEK inhibitor sensitivity, accelerated rate of cell division and reduced expression of NGFR. Transcriptional and biochemical profiling of cell lines and human tumors implicates a role for the c-Jun/ECM/FAK/Src cascade in driving the de-differentiation response. We identify multiple drugs targeting this cascade as well as BET bromodomain inhibitors that block this resistance program in cell lines and in a BRAFV600E melanoma xenograft model and increase sensitivity and maximal effect (E_{max}) of RAF/MEK inhibitors. Our study reveals directly how drug adaptation happens in individual tumor cells leading to emergence of heterogeneous cell sub-populations with reduced drug-sensitivity that may be targeted by drug combinations.

Moffitt Cancer Center, Tampa, FL; University of Illinois at Chicago, Chicago, IL.

Background: Prior studies have investigated “intermittent therapy” to delay hormone resistance in prostate cancer but did not explicitly include quantitative analysis of the evolutionary dynamics. We hypothesize that evolution-informed strategies may prolong time to progression but require a multidisciplinary effort to simulate intratumoral Darwinian dynamics and design a clinically feasible treatment protocol. Methods: We investigate intratumoral evolutionary dynamics during treatment of metastatic castrate resistant prostate cancer (mCRPC) with abiraterone, which blocks CYP17A1 autostimulation of testosterone from androgen precursors. We build a mathematical model assuming three competing phenotypes: (i) TP cells express CYP17A1 and produce testosterone; (ii) T+ cells require exogenous androgen; and (iii) T- cells are androgen-independent. Model predictions were tested in a pilot clinical trial. Results: Mathematical Model: Computer simulations demonstrate continuous maximum dose abiraterone treatment produces competitive release of resistant T- cells. However, limited treatment designed to maintain residual TP and T+ populations and suppress proliferation of T- cells was predicted to prolong response while lowering the required drug dose. Clinical Trial: In a pilot clinical trial, 11 men with asymptomatic mCRPC were treated with abiraterone according to an evolution-informed, patient-specific algorithm based on the modeling results. Pre-treatment biopsies (available for 3 patients) demonstrated the predicted tumor subpopulations. Cycles of response and regrowth similar to model simulations were observed with cycle lengths varying from 3 months to > 1 year. Over a median follow-up period of 18 months, 10 subjects remained responsive to Abiraterone without PSA or radiographic progression. Median time to PSA progression significantly (P<0.001) exceeds the 11.1 months historical control. As predicted by the simulations, tumor control required significantly less abiraterone with average cumulative dose less than 40% of standard of care (P<0.001). Conclusion: Integration of mathematical models and Darwinian first principles into trial design, may allow patient-specific modifications to prolong response while lowering drug doses in mCRPC.

UT MD Anderson Cancer Center, Houston, TX; Nanostring Technologies, Inc, Seattle, WA.

Prognosis is favorable in patients with primary localized melanoma but poor in patients with metastatic disease. With more than 76,000 cases expected to be diagnosed in 2016, more precise prognostic technologies and new therapies are needed. Although targeted treatment regimens have been approved in recent years, resistance has emerged in large part due to adaptive response mechanisms and intratumoral heterogeneity. Analysis of tumor samples across multiple molecular platforms will help elucidate the complexities within and across tumors which may underlie response to therapy as well as assist in identifying predictive biomarkers; however, these approaches require significant amounts of sample, time, and resources. In order to integrate the strengths of analyzing different molecular analytes, we have modularized Nanostring Technologies’ molecular barcoding technology to perform quantitative digital measurement of DNA associated mutation variant markers, mRNA expression, and protein expression in one assay from the same sample (3D Biology). Novel nucleotide variant probes enable sensitive and specific identification of DNA mutant allele sequences down to a level of detection of ≤ 5% from 5 ng of FFPE-extracted genomic DNA. Gene expression is measured via unique digital barcoding technology to measure mRNA transcripts, and protein expression and activity (via phosphorylation) is measured by DNA-labeled antibodies. The multi-omic workflow requires only two 5-10 micron sections of FFPE tissue, whereby DNA and RNA are extracted from one section and multiplex digital protein profiling is conducted on the second. As proof of concept demonstrating the utility of this 3D Biology platform, we have simultaneously analyzed DNA variants, RNA expression, and protein expression using NanoString’s nCounter Vantage 3D+ Solid Tumor Panel on 12 FFPE melanoma tumor samples and one normal tissue from six patients. This sample set included two metastatic tumors from each patient, and in one instance multiple regions from each metastatic site (7 and 2 regions) in order to assess intratumoral heterogeneity. Importantly, this sample set has associated mRNA expression measured using the nCounter PanCancer Pathway Panel on whole human panel for a whole exome sequencing (WES) data. Somatic variants seen in this latter dataset were compared with the results from the DNA SNP Solid Tumor Panel. Samples with variants that were detected in the nCounter assay but not WES were subjected to deep sequencing for validation. Overall, we show that this multiplex and multi-omic platform has the potential for rapid and sensitive assessment of patient samples that will impact clinical care.

The evolutionary theory assumes that occurrence of mutations in cancer is random. However, recent studies suggest that passenger mutations are not randomly scattered in cancer genomes and that chromatin organization dictate mutations profiles. Hepatocellular carcinoma (HCC) serves as a model of a diverse spectrum of cancers, since it is induced by a number of well-known etiological agents, mainly Hepatitis C virus (HCV) and Hepatitis B virus (HBV). There are two distinct etiology-dependent regional mutations signature in specific genes and pathways in HCC that was not detected previously by exome sequencing of liver tumors. These observations suggest that viral infection modulate somatic mutations causing HCC. To explore the link between genomic signature and genome wide chromatin organization we studied the epigenetic

changes occur following HCV infection. Epigenetic analysis unraveled known and novel pathways that are controlled by the virus such as Hepatic lipid metabolism, cell motility, cell cycle and immunity. Invers correlation between high mutation rate and enrichment of chromatin modifications associated with active transcription provides a link between etiology and cancer genome. Our novel approach offers a perspective into the mechanisms that shape mutational signature development in cancer.

#5565 Multi-omic profiling of prostate cancer evolution in 39 patients. Qing Zhong,1 Tiannan Guo,2 Nora Toussaint,2 Ulrich Wagner,1 Konstantina Charmp1, Laurence Calzone,3 Andreas Beyer,2 Ruedi Aebersold,2 Peter J. Wild1. 1University Hospital Zurich, Zurich, Switzerland; 2ETH Zurich, Zurich, Switzerland; 3University of Cologne, Cologne, Germany; 4Institut Curie, Paris, France.

The pathological molecular events occurring during prostate cancer (PCA) progression have not been comprehensively investigated. It remains elusive how genomic aberration is transcribed into transcriptomic abnormalities that eventually influence proteins in the progression of PCA. We aimed to study the biological information flow along the central dogma and to identify critical molecular mechanisms in PCA evolution. We performed comprehensive, multi-omics analyses of 105 prostate samples, consisting of both benign prostatic hyperplasia regions and malignant tumors from 39 PCA patients. Patients were from different risk groups, including 12 low-grade (Gleason score < 7), 17 intermediate (Gleason score = 7), and 10 high-grade (Gleason score > 7) PCs.

The omics data comprised exome sequencing, copy number variation (CNV) analysis, RNAseq, quantitative proteomics, and tissue morphology. Furthermore, peripheral blood samples from each patient were genomically profiled as reference. We identified 860 somatic gene mutations from the 105 tissue samples, out of which 18 genes were mutated in three samples and 129 genes were mutated in two samples. More mutations were detected in patients with higher Gleason scores. We also found the copy numbers of 914 genes to be substantially up- or down-regulated in at least one sample. For RNAseq, we determined genes with either strictly monotonically increasing or decreasing expression from normal to intermediate and high-grade PCA per patient and per patient group, based on the regularized log-transformed read counts. Moreover, we collected tissue punches and analyzed each punch in technical duplicates by PCT-SWATH and used OpenSWATH software for data interpretation. We obtained precise quantification for several thousand proteins. The differential analysis revealed increasing and decreasing patterns of proteins of interest. Furthermore, we used network smoothing to determine overlapping molecular aberrations by comparing shortlisted DNA-mRNA-protein pathways. By integrating proteogenomics with additional omic information, we demonstrated that molecular changes in PCs at genomic level are buffered at transcriptional level, and further constrained to a few modular changes in protein networks. We also found high correlation between pathway activities with tumor progression and heterogeneity. Our multi-omic profiling further revealed PCA evolution by using molecular alterations at different layers with associated mutant allele frequencies and uncovered several protein modules as key events in the progression of prostate cancer.

#5566 African American esophageal squamous cell carcinoma expression profile reveals dysregulation of stress response and detox networks. Hayriye Verda Erkizan,1 Jack Lichy,1 Vincente Notario,2 Robert Wadleleigh2. 1Institution for Clinical Research, Veterans Affairs Medical Center DC, Washington, DC; 2Veterans Affairs Medical Center DC, Washington, DC.

Background: Esophageal squamous cell carcinoma is the third most common gastrointestinal malignancy worldwide and is largely unresponsive to therapy. African-Americans have an increased risk for esophageal squamous cell carcinoma (ESCC), this subtype that shows a marked variation in geographic incidence. So far, the molecular architecture of African-American ESCC is still poorly understood. It is unclear why African-American ESCC is more aggressive and the survival rate of these patients worse than those of other ethnic groups. Our aim is to investigate the central question of whether there is a genetic basis for the aggressive nature of ESCC among African-Americans through analysis of genetic overlaps and differences between African-American ESCC and reported Asian data. Methods: We conducted microarray expression profiling in pairs of esophageal squamous cell tumors and matched controls to define genetic alterations that occur in African American ESCC. We then utilized Ingenuity Pathway Analysis (IPA) to analyze the differentially expressed genes in African-American ESCC. We conducted a meta-analysis of differentially expressed genes of African American ESCC and those of Asian ESCC through IPA. Results: Transcriptome profiling of African-American ESCC tumors versus adja-cent normal esophageal tissues revealed significant differential expression of 756 genes. Among the most strongly up-regulated genes were keratin 17, immunoglobulin genes and ornithine decarboxylase 1. Genes that showed a great loss of expression included cysteine-rich secretory protein 3 and scelien. We performed pathway and network analysis on significantly dysregulated genes using IPA to understand the overall biological impact of the widespread transcriptional aberration in African-American ESCC. We found significant dysregulation of genes encoding drug-metabolizing enzymes and stress response components of the NRF2-mediated oxidative damage pathway, potentially representing key genes in carcinogenesis in ESCC in African Americans. Loss of activity of drug metabolizing enzymes would confer increased sensitivity of esophageal cells to xenobiotics, such as alcohol and tobacco smoke, and may account for the high incidence and aggressiveness of ESCC in this ethnic group. A meta-analysis of ESCC expression profiles in our African American sample and those of several Asian samples determined genes in the NRF2 pathway are uniquely and significantly altered in African-American ESCC. Down-regulation of TP53 pathway components represented the most common feature in ESCC of all ethnic groups. Importantly, this analysis revealed a potential distinctive molecular property of African-American ESCC a widespread and prominent involvement of NRF2 pathway. Conclusion: Taken together, these findings highlight the remarkable interplay of genetic and environmental factors in the pathogenesis of African-American ESCC.

#5567 A scalable and integrated computational and experimental workflow to identify new driver genes in cancer genome data. Heiko Horn,1 Michael S. Lawrie,2 Candace E. Housman,1 Yashavi Shrestha,2 Jessic Xin,2 Hu,1 Elizabeth Worstell,2 Emily Shea,2 Nina Illic,2 Eunjung Kim,4 Atanas Kamburov,1 Alireza Kashani,1 William C. Hahn,3 Alireza Kashani,1 William C. Hahn,3 Jesse S. Boehm,2 Gad Getz,2 Kasper Lage3. 1National Cancer Institute, Bethesda, MD; 2Broad Institute of Harvard and MIT, Cambridge, MA; 3University of Copenha-gen, Copenhagen, Denmark; 4Dana-Farber Cancer Institute, Boston, MA.

High throughput sequencing has revolutionized the study of the cancer genome, enabling numerous discoveries in basic and clinical research. However, considerable sample sizes are required to find cancer driver genes with intermediate and low mutation frequencies, and for a large proportion of patients the molecular cause (e.g. driver gene(s)) of disease is unknown. Here, we describe an integrated computational and experimental workflow that combines cancer genome data, molecular network information, multiplexed in vivo tumorigenesis assays, and reanalysis of driver-gene-negative cancer patients to predict and validate new driver genes. We develop a statistic, network mutation burden, that combines molecular network information with data from 4,742 cancer genomes to accurately classify known driver genes across 21 tumor types and predict 62 driver gene candidates. Of these, 35 gene candidates were tested in multiplexed in vivo tumorigenesis cell assays using sensitized immortalized human embryonic kidney (H1A1-M) and immortalized human lung epithelial (SALE-Y) cell lines. Tumor formation in vivo was observed for 11 genes (2 in HA1-E-M, 3 in SALE-Y, 6 in both). By reanalyzing 242 lung adenocarcinoma patients with an unknown molecular cause of disease we show that two of these candidates, TFF2 and AKT2, are significantly upregulated in metastatic samples. Overall, we describe a scalable combined computational and experimental framework to predict and validate driver genes across many tumor types. Our proof-of-concept approach should become increasingly useful as the number of cancer genomes continues to grow.

#5568 Towards decoding the interplay between glycolysis and oxidative phosphorylation in cancer. Dongyu Jia,1 Linglin Yu,1 Mingyang Lu,1 Eshel Ben-Jacob1, Jianpeng Ma,1 Herbert Levine1, Benny A. Kaipparettu2, Jose Onuchic1. 1Rice University, Houston, TX; 2Baylor College of Medicine, Houston, TX.

Abnormal metabolism is a hallmark of cancer, yet its regulatory mechanism is poorly understood. Cancer cells were considered to mostly utilize glycolysis, referred to as the Warburg effect. Recent data suggested that aerobic glycolysis, oxidative phosphorylation also plays a crucial role during cancer progression. Here we utilized a systems biology approach to decipher the regulatory principle of glycolysis and oxidative phosphorylation. Integrating information from literature, we constructed a regulatory network of genes and metabolites, from which we extracted a core circuit containing HIF-1, AMPK and ROS. Our circuit analysis showed that while normal cells have an oxidative state and a glycolytic state, cancer cells can access an additional hybrid state with both metabolic modes coexisting, due to higher ROS production and/or oncogenic activation, such as RAS, MYC and c-SRC. The anti-correlation between AMPK and HIF-1 and the association of metabolic states with oncogenes were further confirmed using
IMMUNOLOGY: Enzymes and Hormones and Metabolism in Tumor Immunity

The impact of ADI-PEG20 on PD1L expression in ASS1 deficient uveal melanoma. Ramsay S. Khadare,1 Melissa M. Phillips,1 Mandeept Singh,2 Victoria Cohen,1 Caroline Thaug,1 Peter W. Szolczer,1 Barts Cancer Institute, London, United Kingdom; 2Moorfields Eye Hospital, London, United Kingdom.

Uveal melanoma (UM), involving the iris, choroid and ciliary body, is the commonest intraocular tumor in adults. Half of patients develop metastasis with a high mortality despite currently available systemic therapies including immune checkpoint blockade. Studies show that while CTLA4 antagonism has a modest effect in UM, PD1/PD1L block in large efficacy whereas trials of combination checkpoint blockade are yet to report. We confirmed previously that deficiency of argininosuccinate synthase 1 (ASS1), a key enzyme involved in arginine synthesis, sensitizes UM cells to arginine deprivation using pegylated arginase deaminase or ADI-PEG20. Early trials of ADI-PEG20 in UM have shown safety and efficacy in the clinic and thus we tested the potential for a combined immunometabolic strategy. ASS1-deficient UM cell lines (OMM1, OMM2.5, MEL270) were analyzed for the immune checkpoint protein PD1L along with their sensitivity to arginine depletion. We also tested metastatic UM for ASS1 and PD1L expression, and the impact of ADI-PEG20 treatment using samples from a current clinical trial (NCT02029690). We showed that ASS1 and PD1L protein expression were absent in the 3 UM cell lines and in a majority of primary tumors (75/102 for ASS1 and 83/102 for PD1L: 5% threshold of expression) and all metastatic tumor biopsies (n=16/16 for both). Transfection of ASS1 in OMM1, OMM2.5, MEL270 led to an increase in PD1L expression by qPCR, western blotting and FACS, which was reversible following knockdown of ASS1. Induction of PD1L expression by ASS1 was accompanied by interferon (IFN) gene expression and arginase enzyme activity. ASS1 expression was abrogated using the pan-STAT inhibitor ruxolitinib. Next, PD1L expression was significantly increased in the 3 ASS1-negative UM cell lines with ADI-PEG20 treatment by 24hrs and was associated with Type 1 IFN signaling which waned along with PD1L expression by 48hrs. The ADI-PEG 20 induction of PD1L was abolished using ruxolitinib, indicating that the upregulation of PD1L is IFSN-dependent for the PD1L checkpoint blockade. While analysis of UM biopsies of patients progressing on ADI-PEG20 revealed upregulation of ASS1 (n=2/2), and thus resistance to ADI-PEG20 a concomitant increase in PD1L was not observed (n=0/2). Collectively, our data show that ASS1 is absent in a majority of patient biopsies of primary and metastatic UM tumors and is tightly correlated with PD1L expression. UM cell lines displayed sensitivity to ADI-PEG20, which upregulated levels of PD1L expression via Type 1 interferon signaling that may enhance the currently limited efficacy of checkpoint blockade in UM. Further studies are ongoing of the IFN-mediated signaling between ASS1 and PD1L in UM in response to arginine deprivation with ADI-PEG20.

Immune-checkpoint inhibition via enzyme-mediated degradation of kynurenine. Brett A. Fleisher, Sihem Ait-Oudhia.1

Brett A. Fleisher, Sihem Ait-Oudhia.1

Washington University in St. Louis, St. Louis, MO; 2The University of Texas MD Anderson Cancer Center, Houston, TX; 3Barts Cancer Institute, London, United Kingdom; 4The University of Texas, Austin, TX; 5Kyn Therapeutics, Cambridge, MA; 6University of Texas Austin, Austin, TX.

Checkpoint inhibitors have become the cornerstone for new innovation in immune-based oncology therapy. Several orthogonal immune pathways are currently being investigated to relieve suppression or boost activity of the innate and adaptive immune system. The IDO immune-metabolism pathway was recently clinically validated in melanoma in combination with checkpoint inhibition. This opens up a new approach to relieving suppressive mediators and lends credence to the tumor microenvironment containing small molecule metabolites that induce immune tolerance. Both indoleamine-pyrrole 2,3-dioxygenase 1 (IDO1) and Tryptophan 2,3-dioxygenase (TDO) enzymes metabolize tryptophan, forming Kynurenine which the tryphyl hydrocarbon receptor (AHR) is a innate immune and adaptive immune cells lacking a net immunosuppressive effect. Both enzymes are upregulated across many tumor types, however, only the IDO1 enzyme has thus far been addressed in the clinic with small molecule inhibitors. We have postulated that enzyme-mediated depletion of Kynurenine into safe and immunologically inert metabolites can alleviate tumor immunosuppression. We have cloned and characterized several bacterial Kynureninases (KYNase) which preferentially degrade Kynurenine with >1,000 higher kcat/KM as opposed to mammalian enzymes that cleave 3-OH Kynurenine. We show that PEGylated bacterial KYNases can deplete Kynurenine produced by IDO1 +, TDO + and IDO1/TDO + dual positive human cancer cells whereas, the IDO1 inhibitor ecadostar or TDO inhibitor 680C91 only selectivity inhibited KYNase activity in IDO1 + or TDO +, respectively.

In vivo, a single subcutaneous dose of KYNase in B16F10 tumour bearing mice was able to deplete Kynurenine in both the plasma and tumors and increase effector T-cells in the tumor. KYNase demonstrated significant tumor growth inhibition and survival benefit either as a single agent or in combination with checkpoint inhibitors (anti-PD1 or anti-CTLA4) in B16F10, CT26 and 4T1 models. Interestingly, KYNase combined with anti-PD1, showed greater efficacy than ecadostar / anti-PD1 combination in CT26 tumor bearing mice. A pharmacologically optimized human KYNase is currently moving toward clinical development for the treatment of cancers where both IDO/TDO pathways are present.
Currently, IDO-1 small molecule inhibitors in combination with checkpoint inhibitor antibodies are being evaluated in >12 clinical trials. However, whether the immune-suppressive effects of Tryptophan catabolism results from its depletion in the TME, or from the accumulation of Kynurenine, is not known. To distinguish between the effects of Trp depletion and Kyn accumulation in the TME we used an engineered Kynureninase (KYNase) enzyme that selectively degrades Kyn into immunologically inert and non-toxic metabolites. Peritumoral injection of PEGylated KYNase completely depletes serum and tumor Kyn levels for up to 72 hrs, while leaving Trp concentrations in both compartments unaffected. In the IDO-1 expressing CT26 colon carcinoma model KYNase treatment as monotherapy resulted in 16% complete and durable responses, accompanied by long-term immunity to tumor re-challenge. KYNase had no effect on tumor growth in IDO-1 mice, nor in RAG-2 or in CD8+ T cell depleted mice. Analysis of the TME demonstrated KYNase treatment resulted in increased accumulation of CD8+ cells, with a greater proportion expressing Granzyme B, undergoing proliferation and permeating the tumor interior. This effect was specific to the TME, as no detectable changes to the immune compartment occurred in other organs examined, nor overt signs of autoimmunity and toxicity. The increase in CD8+ cells was consistent with in vitro data showing that elevated concentration of Kyn directly induces apoptosis of activated CD8+ T cells partially through IL-2 suppression. No changes to the Treg percentages and phenotypes in the TME were observed, indicating that the Treg compartment is not impacted by treatment with KYNase. Cytokine analysis of tumor digest metastases compared to controls. These data show that in vivo IL-2 concentrations that hold mouse tumors after KYNase treatment. Furthermore, ex vivo stimulation of TIL after KYNase treatment demonstrated that the increase in cytokines in the TME is not solely due to an increase in TIL, but also an increased effector cytokine capacity on a per cell basis. Administration of KYNase together with either octrilA4 or qpD1 synergistically elicited complete and durable regression of multiple established tumor models. In summary, our data support the hypothesis that Kyn accumulation in the TME rather than Trp depletion is the dominant IDO-mediated immune suppressive mechanism, and that enzyme-mediated KYN deple-tiation is a promising cancer immunotherapeutic approach.

#5572 AX09: an immunotherapy candidate targeting the breast cancer stem cell protein xCT. John O’Rourke,1 Elisabetta Bolli,2 Valeria Rolih,2 Laura Conti,2 Stefania Lanzardo,3 Jayne Christen,2 Federica Pericle,1 Federica Cava-rio,2 Agilivax, Inc, Albuquerque, NM;2 University of Torino, Torino, Italy.

Triple negative breast cancer (TNBC) is an aggressive form of breast cancer that lacks the estrogen, progesterone and HER2 receptors, and accounts for 15-20% of all breast cancers in the US. The particularly aggressive features of TNBC may be due to the enrichment of breast cancer stem cells (BCSC). Due to their resistance to traditional radio- and chemotherapies, BCSC represent a reservoir for the relapse, metastatic evolution and progression of the disease after treatment. Triple negative breast cancer (TNBC) presents a major barrier towards effective cancer treatments. The ability of BCSC to resist common cytotoxic therapies relies on different mechanisms, including improved detoxification ability. The cysteine-glutamate antiporter protein xCT (SLC7A11) regulates cysteine intake, conversion to cysteine and subsequent glutathione synthesis, protecting cells against oxidative and chemical insults via the p38MAPK pathway. xCT expression is highly restricted to a few normal cell types but is upregulated in a variety of breast cancer subtypes where its expression correlates with poor prognosis. xCT is highly expressed in a variety of solid tumor CSC including BCSC where it interacts with CD44 and plays a functional role in BCSC biology. Agilivax has developed a novel immunotherapy candidate (AX09) based on our virus-like-particle technology for the treatment and prevention of metastatic breast cancer that targets the BCSC protein xCT. Immunization with AX09 elicited a strong antibody response against xCT including high levels of IgG2a antibody. Immune sera from AX09 mice bound to tumoursphere derived BCSC and impacted BCSC function and biology in vitro. To assess if AX09 immunization would decrease metastases, we employed a syngeneic transplantation model, in which purified BCSC derived from TUBO cells were injected into the tail vein of vaccinated female BALB/c mice. Multiple independent experiments showed that immunization with AX09 conferred a significant reduction in the number of pulmonary metastases compared to vaccination with control VLP alone. In a pilot study, BCSC were transplanted into the mammary fat pad and mice were treated with AX09 after primary tumors were 1.5 mm in diameter. Results indicate that AX09 immunization conferred a reduction in lung metastases compared to controls. These data suggest that an active immunization approach targeting xCT can significantly reduce metastatic progression in preclinical models. Ongoing experiments are further characterizing therapeutic mechanisms and evaluating efficacy of AX09 in combination with front line chemotherapy and checkpoint inhibitors.

#5573 A high-affinity Optide (optimized peptide) inhibitor of the Hippo pathway’s YAP-TEAD interaction. Zachary R. Crook,1 Philip Bradley,2 Gregory Sevilla,1 Della Friend,1 Chris King,2 Andrew Mhyre,1 Roland Strong,1 David Baker,3 James M. Olson3.1 Fred Hutchinson Cancer Research Center, Seattle, WA;2 University of Washington, Seattle, WA;3 University of Washington, Seattle, WA.

The Hippo pathway plays a critical role in contact inhibition, a pathway that is commonly dysregulated in many human cancers (including liver, colon, ovarian, and lung). The signaling pathway culminates in the intranuclear interaction of the transcriptional co-activator YAP and the transcription factor TEAD. This is representative of a number of cancer driving pathways that have proven nearly impossible to drug, as they are mediated by intracellular protein-protein interactions. High throughput screening campaigns with small molecule libraries have failed to provide specific, high affinity binders capable of disrupting larger protein-protein interfaces (such as YAP-TEAD), while at the same time, antibodies cannot penetrate the cell membrane to access cytosolic and nuclear targets. Optides are small disulfide-knotted peptides (knottins) that are large enough to interfere with protein-protein interactions, but small enough to access compartments beyond the reach of antibodies. Examples include the calcines, activators of sarcoplasmic reticulum ryanodine receptors, and BLZ-100, a knottin-fluorophore conjugate that is capable of accumulating in a wide range of tumor types. Using the computational design software Rosetta, we created a library of Optides designed to interact with TEAD in locations that overlap YAP binding. Mammalian surface display screening against soluble TEAD yielded a successful hit (AX09) that binds YAP with high affinity and inhibits YAP-TEAD binding. Affinity maturation, using site saturation mutagenesis, produced an improved sub-nanomolar variant (IV1) with potent YAP inhibition. This variant was also found to be highly resistant to reduction and proteolysis, crucial for a disulfide-knotted peptide with a cysteine target in the proteinase-rich tumor milieu. With this highly potent YAP inhibitor, efforts are now focused on cell penetration and biodistribution with the long-term goal of advancing a clinical development candidate.
Androgen receptor stimulation with 5α-dihydrotestosterone (DHT) decreases PD-L1 expression in androgen-responsive thyroid cancer cells. Timmy J. O’Connell,1 Melanie Jones,2 Anvita Gupta,3 Tali Lando,1 Deya Jourdy,1 Edward Shin,3 Augustine Moscatello,1 Raj Tiwari,1 Jan Gelebter1.

Thyroid cancer is the most rapidly increasing cancer in the US with 64,300 new cases expected in 2016. However, there is a disparity in the incidence of thyroid cancer between females and males, with 49,330 expected cases developing thyroid cancer three times more often than men (14,950 expected cases). Hormonal factors leading to reduced androgenic responsiveness of tumor cells is associated with suppression of the androgen receptor (AR). 84E7 is a clone of 8505C that was transfected with an AR containing plasmid resulting in constitutively expressed AR. Transcriptome analysis via RNASeq was performed on 8505C and 84E7, with and without 5α-dihydrotestosterone (DHT) treatment. Raw sequencing reads were aligned to the UCSC hg19 human reference genome with TopHat, and Cufflinks was used to perform expression analysis. Changes in expression were significant in that PD-L1 is produced by tumor cells as a strategy for immune system activation and may help eliminate nascent thyroid cancer cells. Thus, men may experience a decreased incidence of thyroid cancer due to an enhanced and less inhibited anti-tumor environment.

BPM 31510, a clinical stage candidate demonstrates potent anti-tumor effect in an immune-competent syngeneic pancreatic cancer model. Shiva Sarapaksa,1,2 Prashant Prasad,1 Shalini Garg,1 Maria Nastke,1 Tulin Dadali,1 Anne R. Diers,1 Stephane Gesta,1 Vivek K. Vishnudas,2 Rangaprasad Sarangarajan, Niven R. Nairan, BERG, LLC, Framingham, MA.

BPM 31510, a clinical stage nanodispersion of ubidecarenone, demonstrates anti-tumor effects by eliciting an anti-Warburg metabolic switch in cancer. Previous studies in an immune compromised PaCa2 xenograft model has unequivocally demonstrated significant efficacy of BPM 31510 on tumor volume and survival. The fundamental property of BPM 31510 to influence mitochondrial bioenergetics and the recognized interplay between T cell metabolism and tumor mediated killing of cancer cells (TLM) functions in eliciting anti-cancer effects. In this study BPM 31510 selectively influenced activation and maturation of T cells in murine peripheral blood mononuclear cells (PBMCs). Moreover, in addition to demonstrating changes in the CD3+ population, changes in surface expression of CD1d and CD1a along with the IFN-γ secretion were examined. Murine cancer cell lines exposed to BPM 31510 were associated with variable sensitivity with highly metabolic tumor types being most sensitive. Next, the anti-cancer activity of BPM 31510 in an in vivo immunocompetent syngeneic Pan02 rodent model was investigated. Murine Pan02 pancreatic cancer cells were implanted subcutaneously into C57BL/6 mice. Tumors with mean volume of 80 mm³ were treated twice a day with vehicle control or BPM 31510 at 25, 50, 100 mg/kg, administered intraperitoneal. Tumor volumes were measured every 4 days. At day 21 post treatment, tumors were harvested and analyzed for the level of infiltrating immune cells by immunofluorescent staining with CDB + for T cells and F4/80 for tumor macrophages. These results demonstrate a dose-dependent reduction in tumor volume following 21 days of BPM 31510 treatment. In summary, BPM 31510 exerts potent anti-tumor effects through its dual function of modulating tumor cell metabolism and potentially influencing immune check-point to improve overall survival outcomes.
the molecules from this series showed IC50 of 0.2 and 0.08 μM in the biochemical assay and 1.7 and 0.8 μM in the cell based assay against IDO1 and TDO2, respectively. In addition, another series of NCEs showed strong activation of IDO1 and TDO2 activity. As compared to untreated control, formation of kynurenine was increased in a dose-dependent manner as observed by increase in fluorescence of 8-10 fold over control. One of the compounds from this series showed an EC50 of ~20-30 μM in the biochemical assay as well as in 293T-based assay. Further mechanistic studies to understand the immune modulatory activity of these selective TDO2 modulators is underway. These tool compounds are being further optimized for potency and ADME properties to be developed as potential drug candidates. Conclusion: To our knowledge such IDO1 and TDO2 specific small molecule activators have not been reported. Therefore, these activators and inhibitors would serve as useful tool compounds in understanding the specific role(s) of IDO1 and TDO2 in disease biology and would also provide the opportunity to target this pathway for various diseases, including cancer.

**#5579 Strategic inhibition of adenosine A2A receptor (A2AR) by CPI-444 improves CD8 Treg ratios and enhances T-cell killing of a HER-2/neu expressing murine tumor.** Blake A. Scott,1 Todd Armstrong,1 Stephen Willingham,2 Ian McCaffery,2 Elizabeth M. Jaffe,1 Johns Hopkins University School of Medicine, Baltimore, MD; 2Corus Pharmaceuticals, Burlingame, CA.

It has been demonstrated that a higher CD8 T to CD4 FoxP3 T regulatory cells (Tregs) ratio coincides with improved therapeutic outcomes for patients receiving immunotherapies in the clinic. The last several years of research have drawn attention to many such therapeutics and strategies. Adenosine is an abundant extracellular signaling molecule in the tumor microenvironment (TME) of many cancers. Signal transduction through the GPCR A2AR enhances the immunosuppressive activity of Tregs while simultaneously attenuating tumor-specific CD4+ /CD8+ T cells. We have evaluated the appropriate coordination and dosing for a small-molecule inhibitor of A2AR in a Her-2/neu expressing murine model of breast cancer. We have demonstrated its capacity to augment existing therapeutic strategies in this tolerant model. To test our hypotheses on the ability of the small molecule to work in concert with existing therapeutics, we tested the role of CPI-444 when given with a T cell-inducing vaccine. Neu-expressing mammary tumor bearing HER-2/neu transgenic (Neu-N) mice were administered combinations of low-dose cyclophosphamide (Cy) to deplete Tregs, followed one day later with a granulocyte-macrophage colony-stimulating factor (GM-CSF) and neu-expressing whole cell vaccine (GVAX). The day following administration of GVAX, mice received adoptively transferred high-avidity naive specific CD8 T cells intravenously one day after vaccination. Administration of specific components in this strategy (i.e. Cy, GVAX, adoptive transfer) were altered to gain insight into the mechanistic effects of CPI-444 in vivo through analysis of tumor progression, tumor clearance, tumor infiltration and immunometabolic analysis of the TIL. Mice treated with the A2AR inhibitor or the vehicle control were administered each by oral gavage daily for 14 days (survival) or until 4 days post-adoptive transfer (TIL) at the peak infiltrate time. Of the strategies tested, Cy, followed by concomitant administration of GVAX with 100mg/kg of CPI-444 for 14 days, and a single adoptive therapy treatment provided a strong increase in tumor survival (OS) compared with 0%-20% OS in vehicle controls (P<0.05). Further, we have observed both broad and specific changes in the T cell compartment of the tumor-infiltrating leukocyte (TIL) population. Broadly, we have observed a refinement in the T cell portion of the TIL with decreased numbers of T cells overall, but an increase in specific prognostic ratios, namely a relative increase in favorability of the CD8 Treg ratio when compared to controls (P<0.05). We hypothesize that strategic combination therapy of CPI-444 with existing therapeutics can refine the local immune profile to enhance favorable outcomes in vivo. CPI-444 is currently involved in numerous clinical trials: this work may provide rationale for the expansion of these trials into new cancer types.

**#5580 Preclinical pharmacodynamics and antitumor activity of AZD4635, a novel adenosine 2A receptor inhibitor that reverses adenosine-mediated T cell suppression.** Alexandra Borodovsky,1 Yanjun Wang,1 Minwei Ye,1 Joseph C. Shaw,1 Kris F. Sachsenmeier,1 Nanhua Deng,1 Kelly J. Del-Signore,1 Adrian J. Freeland,1 James D. Clarke,1 Richard J. Goodwin,1 Nicole Strittmatter,1 Carl Hay,1 Vasu R. Sah,1 Deborah Lawson,1 Corinne Reimer,1 Miles Congreve,2 Jonathan S. Mason,1 Fiona H. Marshall,1 Paul Lyne,1 Richard Voyessa,1 AstraZeneca, Waltham, MA; 2MedImmune, Gaithersburg, MD; 3Heptares Therapeutics, London, United Kingdom.

Inhibition of extracellular adenosine within the microenvironment is a strategy exploited by tumors to escape immunosurveillance. Adenosine signaling through the high affinity adenosine 2A receptor (A2AR) on immune cells elicits a range of immunosuppressive effects which can promote tumor growth and limit the efficacy of immune checkpoint inhibitors such as anti-PD-1 or anti-PD-L1 Abs. AZD4635 (HTL-1071), an oral A2AR antagonist, binds to human A2AR with a Kᵢ of 1.7 nM and with > 30-fold selectivity over other adenosine receptors. Accumulation of intratumoral adenosine, measured by desorption with 3He/11C positron emission tomography (PET/CT), has been reported to be significantly higher in patients with advanced cancer. However, it is hypothesized that extracellular adenosine levels are spatially heterogeneous in mouse syngeneic tumors, with levels varying up to 50 fold among regions of a single tumor. To assess whether AZD4635 can reverse the inhibitory effects of different concentrations of adenosine, CHO cells stably expressing human A2AR were incubated with concentrations of adenosine ranging from 0.1 to 10 μM. In the presence of 0.1, 1 and 10 μM adenosine, the IC50 of AZD4635 for inhibition of cAMP production was 0.79, 10.0 and 14.29 nM, respectively. In an ex vivo CD8+ T cell assay, AZD4635 reversed suppression and restored IFNγ secretion in cells incubated with 5’-N-ethylcarboxamidoadenosine (NECA), a stable analog of adenosine. The therapeutic benefit of A2AR blockade was evaluated in syngeneic mouse tumor models. Inhibition of A2AR signaling led to a reduction in tumor growth alone and in combination with checkpoint inhibitors. Tumors harvested from the treated mice exhibited changes in infiltrating lymphocyte populations and increases in the functional activity of T cells. These results demonstrate that AZD4635 is a potent and selective A2AR inhibitor, and that blockade of A2AR signaling with an inhibitor such as AZD4635 can reduce tumor burden and enhance antitumor immunity. AZD4635 is currently in a Phase I clinical trial as a single agent and in combination with durvalumab (anti-PD-1 L1 Ab) in patients with solid malignancies.

**#5581 Development of 2nd generation indoleamine 2,3-dioxygenase 1 (IDO1) selective inhibitors.** Thomas Pesnot, Sachin Mahale, Philip MacFaul, John Maclean, Caroline Phillips, Matilda Bingham, Catherine Eagle, James Kelly, Abhijith Thippsewamy, Simon Armitage, Aleksandr Grisin, Sheenagh Aiken, Lucy Cartwright, Richard Armer. REDX Pharma, Macclesfield, United Kingdom.

Harnessing the immune system via immune checkpoint blockade (e.g. anti PD-1, anti PD-L1, anti CTLA4) has led to fast and long lived responses in cancer patients. Response rates however are low and new treatments that enhance these rates are needed. Recent studies have shown that the administration of immune checkpoint blockers is associated with the overexpression of indoleamine 2,3-dioxygenase 1 (IDO1). The resulting immunoregulatory phenotype counteracts immune checkpoint blockade and allows for cancer progression. The discovery of IDO1 inhibitors, and the potential to combine them with immune checkpoint blockers, therefore represents an attractive strategy to fight cancer. We carried out a ligand-based virtual screen with 1,000,000 commercially available small molecules. In vitro screening of the resulting 610 virtual hits provided us with 2 IDO1-selective, 2 TDO2-selective and 2 IDO1/TDO2-dual confirmed hits. (TDO2 is a protein with similar biochemical activity to IDO1 that is essential to tryptophan homeostasis.) A subsequent Hit to Lead campaign led to the identification of novel chemotypes that display potency similar or superior to IDO1 inhibitors currently under clinical investigation in IFNγ stimulated (i.e. IDO1) and non-stimulated (i.e. IDO1) HeLa cells, with no sign of cytotoxicity. We have demonstrated that these compounds are > 1000-fold selective for IDO1 over TDO2 using cellular assays. IDO1 upregulation by cancer cells is known to be one of the mechanisms by which cancer cells evade the immune system. In an in vitro culture assay of cancer cells and T cells we have demonstrated our compounds can rescue T cell proliferation with EC50 values between 10 and 50 nM. We have also demonstrated that our compounds inhibit IDO1 in monocyte derived human dendritic cells. Interestingly, despite this potent cellular activity demonstrated in multiple disease relevant cellular assays, this chemotype failed to inhibit recombinant IDO1 in an isolated biochemical assay performed under reducing conditions, whereas the reference compound epoxatostat provided activity comparable to literature values. In order to confirm our cellular effects were due to direct inhibition of IDO1 we set up thermal shift assays. Thermal shift assays using purified IDO1 protein have demonstrated that our compounds directly bind IDO1, and cellular thermal shift assays have confirmed direct target engagement in intact cells (stimulated for IDO1 expression). These compounds have physicochemical properties that would suggest oral dosing and dissolution in vitro CYP450 and hERG inhibition, thus reducing the risk of toxicity in the clinic. Our IDO1 inhibitors show a novel differentiated mode of action at the cellular level, and the consequences of this profile in terms of in vivo characterisation is ongoing.
**IMMUNOLOGY: Enzymes and Hormones and Metabolism in Tumor Immunity**

**#5583** Peglated adenosine deaminase 2 (PEG-ADA2) abrogates the cytotoxic effects of adenosine against chronic lymphocytic leukemia cells. Sara Serra,1 Cinzia Bologna,1 Luz Londono,2 Michael Shepard,2 Sanna Rosenberg,2 Christopher Thanos,2 Silvia Deaglio1.1 Human Genetics Foundation and University of Turin, Turin, Italy; 2Haloxy Therapeutics, San Diego, CA, USA.

Extracellular adenosine can be generated from ATP and/or ADP through the concerted action of the ectoenzymes CD39 and CD73. Adenosine can bind different type-1 purinergic receptors eliciting potent cytoprotective and immunosuppressive effects. We previously focused on chronic lymphocytic leukemia (CLL), a disease characterized by the progressive expansion of a mature B cell that is capable of expressing anti-CD73 or anti-CD39. Using these anti-CD73 or anti-CD39 antibodies, we showed that a CD73+ clone possesses a poor prognosis. This patient subset can actively generate adenosine, which favors leukemic cell survival, synthesis of immunosuppressive cytokines, while inhibiting T lymphocyte proliferation. ADA2 is a human enzyme that catalyzes the conversion of adenosine into inosine. We hypothesized that depletion of high adenosine levels from the tumor microenvironment through the administration of exogenous ADA2 could be therapeutically relevant to limit tumor protection and immunosuppression. Several engineered PEG-ADA2 variants possessed improved enzyme activity and pharmacokinetics compared to wild-type ADA2. Inhibition of adenosine receptor activation was evaluated by measuring intracellular cyclic AMP concentrations in T lymphocytes purified from healthy donors. enzyme activity was observed with increasing concentrations of PEG-ADA2-R222Q/S265N and PEG-ADA2-R222Q/S265N/K374D resulting in complete removal of high levels of adenosine, as measured by HPLC. Conversely, PEG-ADA2-E182T, which possesses significantly attenuated catalytic activity, was less effective in reducing adenosine. The functional effects of adenosine depletion on CLL cell survival were analyzed following treatment with the chemotherapeutic, DNA-damaging agent etoposide that robustly induces apoptosis within 16 hours. Addition of exogenous adenosine to cultures of purified CD73+ CLL cells significantly rescued cells from etoposide-induced apoptosis. However, when these primary leukemic cells were pretreated with PEG-ADA2-R222Q/S265N or PEG-ADA2-R222Q/S265N/K374D, the cell viability rate was significantly decreased, abrogating the cytoprotective effects of adenosine. On the contrary, PEG-ADA2-E182T had a minimal effect, suggesting enzymatic depletion of adenosine is critical to observe these effects. Similar effects were observed by the PEG-ADA2 variants on a CLL cell line expressing CD73+9. These preliminary results suggest that enzymatic depletion of extracellular adenosine following treatment with PEG-ADA2 is a relevant approach to counteract the cytoprotective effects of adenosine, warranting further development of PEG-ADA2 as a possible approach to treat CLL.

**#5584** PHY906(YIV-906), an adjuvant based on a 1800-year-old Chinese medicine, enhanced the anti-tumor activity of Immune checkpoint blockade therapy: anti-PDL1, anti-PD-1, anti-PD1/CTLA4 against melanoma. Wing Lam,1 Zaeol Jiang,1 Xue Han,2 Showo-Huey Liu,2 Lieping Chen,2 Yung-Chi Cheng1.1 Yale Univ. School of Medicine. Dept. of Pharmacology, New Haven, CT; 2Yale Univ. School of Medicine. Dept. of Immunobiology, New Haven, CT; 3Yiviva Inc, New York, NY.

Immune checkpoint blockade therapy has recently been recognized as a breakthrough in cancer treatment. Currently the FDA has approved ipilimumab (anti-CTLA4), Pembrolizumab (anti-PD-1) and Nivolumab (anti-PD-1), and Atezolizumab (anti-PD-L1) for the treatment of several types of cancers, including melanoma. However, colitis and diarrhea are commonly found in these immunotherapies, particularly in anti-PD1/CTLA4 therapy. PHY906(YIV-906) is inspired by the Huang Qin Tang, which was first described in Chinese texts 1800 years ago for the treatment of numerous gastrointestinal symptoms. Consistent preparations of PHY906 could be maintained for at least 10 years. In animal studies, PHY906 can increase the anti-tumor activity of a broad spectrum of chemotherapies while promoting damaged intestinal tissue recovery via multiple targets. Several clinical results suggest that PHY906 had potential to increase the therapeutic index of cancer treatments (chemotherapy, radiation) by prolonging life and improving patient quality of life. We hypothesize that PHY906 can reduce diarrhea caused by anti-PD-L1, anti-PD-1, and/or in combination with CTLA4 without compromising their anti-tumor activity. We studied the effect of PHY906 in combination with anti-PDL1, anti-PD1, anti-CTLA4 and anti-PD1/CTLA4, using subcutaneously implanted B16F10 melanoma in Black B16 mice. Results indicated that PHY906 enhanced the anti-tumor activity of anti-PD1, anti-PDL1, or anti-PD1/CTLA4; but not anti-CTLA4 alone, in vivo. In addition, PHY906 did not compromise the action of anti-PD-L1 in brain implanted B16 tumor. PHY906 in combination with all of the antibodies had no impact of body weight change or different type of blood cells counts. PHY906 reduced mRNA expression of several inflammation markers, including TNFa, MCP1, ICAM, PDGFB, and IL15. To assure the anti-tumor effect of PHY906, we pretreated with PEG-ADA2-R222Q/S265N or PEG-ADA2-R222Q/S265N/K374D resulting in complete removal of high levels of adenosine, as measured by HPLC. Conversely, PEG-ADA2-E182T, which possesses significantly attenuated catalytic activity, was less effective in reducing adenosine. The functional effects of adenosine depletion on CLL cell survival were analyzed following treatment with the chemotherapeutic, DNA-damaging agent etoposide that robustly induces apoptosis within 16 hours. Addition of exogenous adenosine to cultures of purified CD73+ CLL cells significantly rescued cells from etoposide-induced apoptosis. However, when these primary leukemic cells were pretreated with PEG-ADA2-R222Q/S265N or PEG-ADA2-R222Q/S265N/K374D, the cell viability rate was significantly decreased, abrogating the cytoprotective effects of adenosine. On the contrary, PEG-ADA2-E182T had a minimal effect, suggesting enzymatic depletion of adenosine is critical to observe these effects. Similar effects were observed by the PEG-ADA2 variants on a CLL cell line expressing CD73+9. These preliminary results suggest that enzymatic depletion of extracellular adenosine following treatment with PEG-ADA2 is a relevant approach to counteract the cytoprotective effects of adenosine, warranting further development of PEG-ADA2 as a possible approach to treat CLL.

**#5585** TGF-beta insensitive PSMA-specific CD8+ T cells derived from metastatic castration resistant prostate cancer (MCRPC) patients enhance the tumor killing ability. Qin Yang,1 Timothy Kuzel,2 Brian Helland,3 Ximing Li,3 Yang,1 Weijun Qin,1 Chung Lee,1 Benedetto Carneiro,3 Francis J. Giles1.1 Northwestern University, Chicago, IL; 2Rush University, Chicago, IL; 3NorthShore University Healthsystem, Evanston, IL; 4The Fourth Military Medical University, Shanghai, China.

Introduction: Manufacturing tumor specific CD8+ T cells has been an obstacle for developing prostate cancer (PCa) immunotherapies for men with MCRPC. We report a highly efficient method to expand human TGF-β insensitivity PSMA-specific CD8+ T cells from MCRPC patients using a FDA approved Cell Processing Work Station (CPWS, Panasonic). Methods: Peripheral blood CD8+ T cells were collected from men with MCRPC by leukapheresis, and cultured in CPWS in TexMACSTM medium with CD-3 Biotin/CD28/Anti-Biotin Beads, 5% human serum, and IL-2. We developed a TIRIIDN-TK-ires-PZ1 chimeric T cell receptor retroviral construct using an anti-PSMA IgTCR(ε) gene (PZ1) and a dominant negative TGF-β type II receptor (TIRIIDN), that could induce CD8+ T cells to be PSA reactive and insensitive to TGF-β. PC-3 cells (PSMA negative) or PSA positive PC-3-PSMA cells (PSMA positive) were exposed to TGF-β and used as target cells. Cytotoxicity assays were performed by LDH/NADH assays (target cells: CD8+ T cells at 1:20, 1:50 and 1:100 respectively). Live interactions between CD8+ T cells and PCa cells was recorded by Nikon BioStationTM. Apoptosis of PCs was evaluated by immuno-fluorescence staining for Annexin V and 7-Amino-actinomycin D (7-AAD) respectively. Results: On Day 0, 2x106 CD8+ T cells were placed in culture, infected with TIRIIDN-TK-ires-PZ1 on Day 8, and expanded 96 fold (1.9x108) by Day 36. The cellular expansion plateaued by Day 40 (1.9x108), when the ratio of CD8+ (95.2%), CD4+ (96.6%) and CD19+ (0.05%) was maintained. The cells strongly expressed PZ1 and TK gene (71.1%), and pSMAD2 was inhibited 95%. Under TGF-β treatment for 7 days, the growth of infected CD8+ T cells was not significantly changed, while the naïve CD8+ T control cells were suppressed by 44.8%. PC3-PSMA cells released 25.64 and 4.19 nmol/50ul/105 NADH when co-cultured with infected CD8+ T cells or with naïve CD8+ T cells respectively. The ratio of CD8+ T cells to PC3-PSMA cells was 7.35 or naïve CD8+ T cells (7.59). Infected CD8+ T cells induced 32.0% and 13.7% expression of Annexin V in PC3-PSMA and PC3 cells respectively, while naïve CD8+ T cells induced only 6.9% in both groups (p<0.05). Furthermore, Infected CD8+ T cells induced significantly higher expression of 7-AAD in PC3-PSMA (0.688%) compared to naïve CD8+ T cells treatment (0.03%). There were close interactions between infected CD8+ T cells and PC3-PSMA, which was not observed in other groups. Conclusion: Our study supports expansion and retroviral infection generating TGF-β insensitive PSMA-specific CD8+ T cells ex-vivo within 4 weeks in CPWS without any exogenous specific stimulation sources. These cells can enhance the PSA expressed PCs killing ability, and escape the inhibition by tumor secreted TGF-β, which have a potential to overcome many of the current barriers of immunotherapies for men with MCRPC.

**#5586** PPMX-T003, a fully human anti-TIR1 antibody with potential efficacy against hematologic malignancies. Lilin Zhang,1 Funiko Nomura,1 Yoi-ichi Aikawa,1 Yoshikazu Kuroswa,2 Kazuhiro Morishita,3 Yukio Sudo3.1 Perseus Proteomics, Inc., Tokyo, Japan; 2Fujita Health University, Nagoya, Japan; 3University of Miyazaki, Tokyo, Japan.

Transferrin receptor1 (TIR1) is a type II transmembrane glycoprotein that involves intracellular uptake of iron. TIR1 is ubiquitously expressed at low levels in normal cells except erythroblasts and placentale trophoblasts, which express high levels of TIR1 due to the need of up taking a large amount of iron. Accu-
mulating studies have shown elevated levels of TR1 in both solid tumor cells, as well as hematologic malignant cells when compared to their normal counterparts. Since TR1 is implicated in growth and survival in various cancer cells, targeting TR1 could be an attractive strategy for cancer therapeutics. To this end, we have developed a fully human antibody against TR1, PPMX-T003, which displays potent antitumor activity in vitro and in vivo in subcutaneous tumor and cell cycle arrest with EC50s of 3–200ng/ml in various tumor cell lines. Mechanistically, PPMX-T003 triggers apoptosis or cell growth arrest by inhibiting binding of TR1 to its ligand transferrin and blocking iron uptake. In addition, PPMX-T003 elicits antibody dependent cellular cytotoxicity (ADCC) activity in cancer cells. Importantly, PPMX-T003 showed potent efficacy against several blood cancer xenograft models. PPMX-T003 completely eradicated established subcutaneous tumors in two acute myeloid leukemia (AML) models generated by Kasumi-1 and HL-60, at a dose of 10 mg/kg when administrated (I.v.) once a week for 4 weeks. Moreover, PPMX-T003 completely eradicated established tumors in a lymphoma xenograft model (SU-DHL-2) at a dose of 3 mg/kg. Furthermore, PPMX-T003 greatly prolonged mice survival in a disseminated leukemia model (CCRF-CEM: acute lymphoblastic leukemia cell line). The control mice engrafted with CCRF-CEM cells (n=10) developed leukemia and died within 42 days, whereas 8 of the 10 mice treated with PPMX-T003 survived 179 days until the experiment was terminated. A preliminary toxicology study in Cynomolgus monkeys with multiple doses was also carried out. Although moderate anemia was observed at the dose of 30 mg/kg, no other adverse events were observed, indicating a tolerable safety profile. Taken together, these results indicate that PPMX-T003 could be a potent therapeutic antibody for the treatment of hematologic malignancies.

**#5587 Novel monoclonal antibodies block N-glycosylation Sites of the MUC16 ectodomain in ovarian carcinoma.** Dharmarao Thapi,1 Alberto Fernandez-Tejada,1,2 Abraham J. Axelor,3 Nestor Rosales,3 Xiujun Yan,3 Marina Stasenko,1 Sahityasri Thapi,1 Amy Wang,1 Samuel J. Danishefsky,1 David R. Spriggs,1 Jason R. Thompson,1,5 Amy Wang,1 Samuel J. Danishefsky,1 David R. Spriggs,1 Jason R. Thompson,1,5

IMMUNOLOGY: Enzymes and Hormones and Metabolism in Tumor Immunity

**#5588 Brentuximab vedotin-driven immunogenic cell death enhances antitumor immune responses, and is potentiated by PD1 inhibition in vivo.** Anthony T. Cao, Che-Leung Law, Shyra J. Gardai, Ryan A. Heiser. Seattle Genetics, Bothell, WA.

Brentuximab vedotin (BV) is an antibody-drug conjugate directed against CD30 consisting of a monoclonal antibody conjugated to monomethyl auristatin E (MMAE), a microtubule-disrupting agent. BV antitumor activity is thought to be primarily the result of intracellular payload release leading to mitotic arrest and apoptotic cell death. We have demonstrated that BV drives apoptosis in a manner consistent with immunogenic cell death (ICD) including activation of the unfolded protein/ER stress response with a concomitant increase in surface expression of calretulin and HSP70. In this study, we provide evidence that in vivo administration of BV leads to directed proinflammatory immune responses against the tumor and this activity is further potentiated by anti-PD-1 therapy. To examine the immunomodulatory effects of BV-induced ICD in vivo, we used a model in which ICD was induced in BV-treated human CD30-expressing A20P lymphoma cells in vitro. These cells were used to immunize wild-type BALB/c mice followed by live A20 challenge. Immunization with BV-treated cells, undergoing ICD, delayed tumor growth and improved survival compared to mice immunized with flash-frozen cells. Furthermore, administering anti-PD-1 to mice immunized with BV-treated cells displayed marked combinatorial effects, leading to improved tumor clearance compared to either treatment alone. Additionally, T cells isolated from mice immunized with BV-treated cells and transferred into tumor-bearing immunodeficient mice resulted in tumor regression and survival, demonstrating robust T cell memory. Lastly, we employed a humanized tumor model pairing CD30+ PDL1+ PDL2+ lymphoblastoid cell line (LCL) xenografts with adoptively transferred autologous PBMC. In this setting, mice treated with suboptimal doses of BV showed greatly enhanced antitumor responses compared to control mice with more accelerated immune-mediated tumor clearance. Tumor regression was further accelerated by treating mice with a combination of BV and a human PD1 inhibitor, demonstrating complementary modes of action for these agents. Together, these data indicate that targeted treatment with the MMAE antibody drug conjugate brentuximab vedotin drives an immunogenic form of tumor cell death that enhances innate and adaptive antitumor immunity. Combination of BV with PD1 inhibitors resulted in greater antitumor activity than either agent alone. Multiple clinical trials are ongoing to evaluate the efficacy of this treatment pairing.

**#5589 Combination of an oncokine inhibitor merestinib with anti-PD1 results in enhanced immune mediated antitumor activity in CT26 murine tumor model.** Sau-Chi Betty Yan,1 Victoria L. Peek,1 Jennifer R. Stephens,1 Um L. Um,1 Amaladas Nelusha,2 Colleen A. Burns,2 Kelly M. Credille,2 Thompson N. Doman,1 Scott W. Eastman,2 Beverly L. Falcon,3 Gerald E. Hall,2 Philip W. Iverson,3 Bruce W. Konicek,3 Jason R. Manro,3 Any T. Pappas,3 Julie A. Stewart,1 Michael B. Topper,3 Swee- Seong Wong,1 Michael Kalos,1 Ruslan D. Novosadovyi,2 Richard A. Walgren,3 David Schaefer3, Eli Lilly and Company, Indianapolis, IN; Eli Lilly and Company, New York, NY.

The combination of tumor targeted therapeutics with PD-1 checkpoint blockade has been explored as a method to increase the clinical benefits of immunotherapy, and expand response to additional cancer types. Merestinib (Mer) is a kinase inhibitor targeting several oncoproteins including MET, MRX1, AXL, METRT, and MKN1/2 that can potentially modulate immune function, angiogenesis, as well as target the tumor and immune responses that play a key role in mucin-related transformation by mediating complex cell surface interactions. These effects are mediated through MGAT5-dependent N-glycosylation of two proximal N-glycosylation sites within the 58 amino acid retained MUC16 ectodomain acting in combination with Galectin-3 and growth factor receptors. Neither N- nor O-glycosylation sites in the more distally located MUC16 regions can functionally substitute. The tumor-microenvironment promoting properties depend on co-localization of MUC16, Galectin-3, and growth factors receptors on lipid rafts. Loss of either Galectin-3 expression or the glycosylation enzyme MGAT5 completely abrogates MUC16 tumor promotion. Using synthetic glycopeptides, we have developed novel monoclonal antibodies (mAbs) directed at the crucial ecdomain N-glycosylation sites to inhibit the glycosylation-dependent effects of MUC16 on metastasis and invasion. These novel antibodies were characterized in vitro and in vivo studies using various ovarian cancer cell lines. All of the antibodies against the N-glycosylation sites closest to the cell membrane of MUC16 block Galectin-3-mediated polymerization to cell surface signaling molecules and inhibit the tumor-promoting effects of MUC16. The implications are broad: both for the biological understanding of cancer mucin biology and for potential therapeutic strategies.

**#5590 Combination of an oncokine inhibitor merestinib with anti-PD-L1 results in enhanced immune mediated antitumor activity in CT26 murine tumor model.** Sau-Chi Betty Yan,1 Victoria L. Peek,1 Jennifer R. Stephens,1 Um L. Um,1 Amaladas Nelusha,2 Colleen A. Burns,2 Kelly M. Credille,2 Thompson N. Doman,1 Scott W. Eastman,2 Beverly L. Falcon,3 Gerald E. Hall,2 Philip W. Merestinib (Mer) is a kinase inhibitor targeting several oncoproteins including MET, MRX1, AXL, METRT, and MKN1/2 that can potentially modulate immune function, angiogenesis, as well as target the tumor and immune responses that play a key role in mucin-related transformation by mediating complex cell surface interactions. These effects are mediated through MGAT5-dependent N-glycosylation of two proximal N-glycosylation sites within the 58 amino acid retained MUC16 ectodomain acting in combination with Galectin-3 and growth factor receptors. Neither N- nor O-glycosylation sites in the more distally located MUC16 regions can functionally substitute. The tumor-microenvironment promoting properties depend on co-localization of MUC16, Galectin-3, and growth factors receptors on lipid rafts. Loss of either Galectin-3 expression or the glycosylation enzyme MGAT5 completely abrogates MUC16 tumor promotion. Using synthetic glycopeptides, we have developed novel monoclonal antibodies (mAbs) directed at the crucial ecdomain N-glycosylation sites to inhibit the glycosylation-dependent effects of MUC16 on metastasis and invasion. These novel antibodies were characterized in vitro and in vivo studies using various ovarian cancer cell lines. All of the antibodies against the N-glycosylation sites closest to the cell membrane of MUC16 block Galectin-3-mediated polymerization to cell surface signaling molecules and inhibit the tumor-promoting effects of MUC16. The implications are broad: both for the biological understanding of cancer mucin biology and for potential therapeutic strategies.
pared to PD-L1 Ab monotherapy. The enhanced immune activation of the combination therapy, leading to synergistic anti-tumor efficacy, demonstrates that merestinib has the potential to augment immunotherapy while targeting the tumor directly. This preclinical data provides the rationale for the clinical investigation of merestinib in combination with checkpoint therapies targeting the PD-L1/PD-1 axis (NCT01933344).1 New data samples from healthy volunteers so far (p = 0.051).

Conclusion: Metformin treatment might be useful in reversion of exhausted CD8+ T cells in cancer-bearing patients.

#5593 Inhibition of A2AR induces anti-tumor immunity alone and in combination with anti-PD-L1 in preclinical and clinical studies. Stephen Willingham,1 Andrew Hotson,2 Po Ho,3 Carmen Choy,3 Kim Walter,2 Erik Yuval,4 Sharon Benozo,5 Gima Laport,4 Richard Miller,1 Ian McCaffrey6. Corvia Pharmaceuticals, Burlingame, CA; 7Adaptive Biotechnologies, Seattle, WA.

Adenosine signaling via A2A receptor (A2AR) on immune cells suppresses anti-tumor immunity and limits the efficacy of immunotherapy, chemotherapy, CAR-T, and vaccines. CPI-444 is a potent and selective oral A2AR antagonist. Daily treatment of mice with CPI-444 led to dose-dependent inhibition of tumor growth in multiple syngeneic tumor models. Combining CPI-444 with anti-PD-L1 treatment synergistically eliminated tumors in up to 90% of treated mice, including restoration of immune responses in models that are poorly responsive to anti-PD-1 or anti-PD-L1 monotherapy. We have initiated a Phase 1/1b clinical trial to examine safety, tolerability, biomarkers, and preliminary efficacy of CPI-444 in combination with anti-PD-L1 antibodies. In combination with atezolizumab, in patients with non-small cell lung, melanoma, renal, triple negative breast, and other (bladder, prostate, head and neck, colorectal) tumors. Step 1 of the trial focused on determining the optimal dose and schedule for CPI-444; Step 2 is currently evaluating the efficacy of optimal CPI-444 dosing alone and with atezolizumab. In 48 patients treated in Step 1, CPI-444 was well tolerated with 1 Grade 3 or 4 treatment-related adverse events. Preliminary evidence of clinical activity was observed in patients treated with single agent CPI-444, including patients who previously failed anti-PD-1 therapy. A PCaREB-based pharmacodynamic assay showed that 100 mg, BID dose of CPI-444 resulted in a complete, sustained inhibition of A2AR on circulating immune cells. CPI-444 treatment alone or in combination with atezolizumab resulted in increased frequency of circulating CD8+ PD-1+ cells and memory/effector subsets of CD4+ and CD8+ T cells. Substantial changes in TCR repertoire (Morisita Index <0.9) were observed in both anti-PD-1 naive and refractory patients and correlated to patient responses. CD73 expression, CD8+ infiltration, Treg distribution, and gene expression signatures are currently being evaluated in serial tumor biopsy specimens and will be presented. In total, this shows that CPI-444 is well tolerated in cancer patients, exhibits functional inhibition of adenosine signaling, and treatment is associated with activation of anti-tumor immunity and clinical activity.

#5594 High throughput combinatorial profiling of checkpoint inhibitor antibodies on the iQue® Screener PLUS. Tom Hasaka. IntelliCyt, Albuquerque, NM.

Checkpoint inhibitors have become valuable immuno-modulatory targets in the advancement of cancer treatment. Looking for the synergy between new checkpoint inhibitor antibodies and known inhibitors is an important aspect of this research. The iQue Screener PLUS platform is a powerful tool to simultaneously assess these interactions in a single well of a microtiter plate. ForeCyt® software provides plate-level analytics and high content visualization to generate deep insight rapidly. Using a mixed lymphocyte reaction (MLR) model, we profiled potential synergies of several known checkpoint inhibitors antibodies. Responses of PD-1, PD-L1, and CD73 inhibitors both individually, and in combination with CTLA-4 inhibitors, were assessed for proliferation, viability and cytokine secretion simultaneously in the same well. MultiCyt® cell-based and bead-based reagents were used for this analysis. Synergies ranging from 2-10 fold increase over CTLA-4 alone were observed in the secretion of TNFα and IL-1β. Results were obtained and analysis completed in a 384-well plate in 30 minutes. In conclusion, this study highlights the power of the iQue Screener PLUS platform to rapidly characterize multiple endpoints and the ForeCyt software to provide high content visualization that reveals actionable insights.

#5595 HDAC inhibitor Entinostat disrupts functions of PMN-MDSC. Ayumi Hashimoto,1 Vinit Kumar,1 Peter Ordentlich,2 Dimitry I. Gabriolovich,1 The Wistar Institute, Philadelphia, PA; 3Syndax Pharmaceuticals, Inc., Wallingford, MA.

Myeloid-derived suppressor cells (MDSCs), consisting of subpopulations of polymorphonuclear (PMN; CD11bLy6G+Ly6Cmed) and monocytic (M;
CD11b<sup>+</sup> Ly6G<sup>+</sup> Ly6C<sup>−</sup> MDSCs play a major role as immune suppressors in cancer. MDSC-targeted therapy has not been developed yet. Histone deacetylases (HDAC) are critically involved in epigenetic regulation of multiple genes and may regulate MDSC number and function. The purpose of this study was to evaluate the effect of the class I HDAC inhibitor, eninostat on differentiation and function in mouse tumor models of lung cancer (Lewis Lung Carcinoma, LLC) and colon cancer (CT26). LLC and CT26 tumor-bearing mice were treated with eninostat (10 mg/kg, p.o. daily for two weeks). Eninostat caused significant increase in the presence of CD45<sup>+</sup> CD11b<sup>+</sup> myeloid cells in bone marrow, spleen and tumors. This increase was largely due to accumulation of Ly6G<sup>+</sup>Ly6C<sup>−</sup> PMN. Unexpectedly, this was associated with a small decrease in the presence of common myeloid progenitor (CMP) and granulocyte-macrophage progenitor (GMP) cells in bone marrow. This suggests that eninostat affects differentiation of PMN downstream of GMP. Experiments in vitro demonstrated that eninostat increased differentiation of enriched hematopoietic progenitor cells (HPC) to PMN in the presence of tumor explant supernatant (TES), which supported the in vivo result. To assess the effect of eninostat on the function of PMN-MDSCs, Ly6G<sup>+</sup> cells were purified from spleen and tumors of LLC tumor-bearing mice treated with eninostat or vehicle alone and tested for their ability to suppress antigen-specific T cell. As expected Ly6G<sup>+</sup> PMN-MDSC from tumor-bearing mice treated with vehicle alone had strong suppressive activity. In contrast, Ly6G<sup>+</sup> cells from spleen and tumor of eninostat-treated LLC tumor-bearing mice show significantly reduced suppressive activity. This result was consistent with experiments with Ly6G<sup>+</sup> cells differentiated from HPC culture with/without eninostat treatment. To determine whether eninostat inhibition of PMN-MDSC immunosuppressive function could enhance immune checkpoint activity, eninostat combined with an anti-PD-1 antibody was evaluated using the LLC tumor-bearing mice. These mice were treated with eninostat (10 mg/kg, p.o., daily) and anti-mouse PD-1 rat antibody (10 mg/kg, i.p., twice a week). Eninostat or PD-1 antibody alone did not significantly inhibit the tumor growth. In striking contrast, the combination treatment blocked tumor progression. Our data demonstrate that eninostat increases a population of PMN-MDSCs that are no longer immunosuppressive leading to enhanced anti-tumor activity when combined with an immune checkpoint inhibitor. This novel phenomenon provides further rationale for combination therapy of eninostat with anti-PD-1 antibody or other checkpoint inhibitors in clinical settings.

#5596 Intratumoral administration of a TLR9-adjuvanted nanoparticle cancer vaccine stimulates more effective immunity in both injected and uninjected tumor sites compared to subcutaneous administration. Edward Naik,1 Chi Ying,1 Robert Milley,1 Carlo Calascan,1 Stewart Chipman,1 Thomas Tütting,2 Robert Coffman,1 Cristina Guiducci,1 Dynavax Technologies, Berkeley, CA;2Universitätsklinikum Magdeburg A.O.R., Magdeburg, Germany.

Therapeutic success of a cancer vaccine requires substantial expansion of vaccine-primed CTL and efficient differentiation to polyfunctional T cells capable of migrating from the site of vaccination to metastatic sites. We have evaluated the tumor itself as a potential site of vaccination, compared to vaccination at subcutaneous sites distant from the tumor. For vaccination, we have developed a highly efficient nanoparticle platform comprised of multiple copies of a CpG-rich oligonucleotide (a TLR9 agonist) and long peptide tumor antigens, both covalently linked to the succrose polymer Ficoll. Multiple peptide antigens where studied, including ovalbumin and a long peptide comprising epitopes from three melanocyte differentiation antigens. In all of these models, intratumoral vaccination was superior to subcutaneous vaccination for elimination of both injected tumors and, more importantly, distant site skin and lung metastases. Intratumoral vaccination substantially increased the magnitude of the systemic CTL response measured in the blood and in the spleen and enhanced capacity cell function to distant site tumors. A greater fraction of tumor-antigen specific CD8<sup>+</sup> T cells generated in the tumor were polyfunctional, expressing both IFN-γ and TNF-α. They were also less exhausted as measured by decreased overall PD-1 levels, increased Tbet and the increased number of PD-1<sup>−</sup> cells that retained cytotoxicity and proliferative capacity. Intratumoral vaccination also induced spread of the CD8<sup>+</sup> T cell response to tumor antigens not included in the vaccine. These results demonstrate that direct intratumoral immunization with peptide antigens combined with a strong TLR9-activating adjuvant significantly increases the magnitude and quality of vaccine-primed CTL and enhances control of metastatic disease.

#5597 Genomic profiling of syngeneic mouse cell lines and in vitro screen of the models against checkpoint inhibitors and target agents for preclinical application. Frank Xing,1 Wubin Qian,1 Chunlan Dong,1 Xiaoli Xu,2 Sheng Guo,1 Qian Shi1.1 Crown Biosciences, Taicang, China;2 Crown Biosciences, Beijing, China.

Cancer immunotherapy has provided substantial clinical benefit in a significant number of patients with advanced diseases. In pre-clinical studies, Crown-Bio has developed a large collection of syngeneic models to facilitate in vivo efficacy testing of immune-oncology agents in mice (MuScree<sup>TM</sup>). To combine the ostensibly separate therapeutic strategies of activating immune cells against tumor cells and inhibiting immune checkpoint activity, we sought to thoroughly characterize the mutation profiles of these syngeneic mouse cell lines and examine drug response profiles of these cell line models. The goal of this work was to provide an in vitro system in evaluating combination effectiveness when targeting both immune checkpoint markers and oncogenic targets in pre-clinical studies. To this end, we investigated mutation and gene expression profiles of 18 mouse cancer cell lines out of the panel of 23 syngeneic mouse models included in the MuScree<sup>TM</sup> for 50 well defined cancer-related mutations among 30,690 variants in exonic regions called by RNAseq (Illumina HiSeq X10). The somatic mutations revealed through the bioinformatics analysis include ALK (3 - frequency, same for the rest), BRAF (4), BRCA1 (7), BRCA2 (12), EGFR (3), ERBB2 (6), EGF R3 (2), FBXW7 (10), FLT3 (12), HRAS (1), KRAS (8), NRAS (1), PDGFR A (11), PTH C1 (9), PIK3CA (2), PTEN (6), RET (3), SERT (5), SMAD4 (3), SMO (13), TRP53 (13), TSC1 (3), and TSC2 (10). All of these oncogenic alterations are clinically actionable (Cancer Discovery 2, 82-93, 2012). The same set of genes was also subject to mRNA expression change analysis. We screened the 18 mouse cell lines with a few selected target therapy agents, and performed combination assays of these agents together with checkpoint inhibitors such as ipilimumab and other agents. An IncuCyte real-time imaging platform was used to distinguish activities on T cells and tumor cells. The results and the implications will be discussed.

#5598 Adenosine signaling through A2AR limits the efficacy of anti – CTLA4 and chemotherapy in preclinical models. Po Ho, Meng-Yin Hsieh, Andrew Hotson, Richard Miller, Ian McCaffrey, Stephen Willingham. Corvus Pharmaceuticals, Burlingame, CA

Elevated levels of extracellular adenosine within the tumor microenvironment create an immunosuppressive niche that promotes tumor growth and metastasis. Adenosine signaling via the A2A receptor (A2AR) on immune cells suppresses anti-tumor immunity and has been shown to limit the efficacy of immuno-therapies such as anti-PD-1 or anti-PD-1 monoclonal antibodies (mAbs). CPI-444 is a potent and selective oral A2AR antagonist that is currently being investigated in Phase 1/1b clinical trials alone and in combination with an anti-PD-1 antibody (Atezolizumab) in selected solid tumors. New preclinical data suggests that combining CPI-444 with anti-CTLA-4 mAbs as well as chemotherapy treatment are also promising therapeutic strategies in solid tumors, suggesting a broad role for adenosine as an immune suppressive mechanism. The efficacy of CPI-444 + anti-CTLA-4 mAb treatment was evaluated in MC38 and CT26 syngeneic mouse tumor models. In CT26, combination treatment eliminated established tumors in up to 90% of mice approximately 2 weeks after treatment was initiated. In MC38, combination CPI-444 and anti-CTLA-4 mAb treatment prolonged survival of 80% of mice compared to only 40% of mice that received CPI-444 or anti-CTLA-4 mAbs alone. The effect of CPI-444 + anti-CTLA-4 treatment on T-cell proliferation, T-cell activation, and Treg function will be discussed. Chemotherapy releases adenosine and ATP into the tumor microenvironment (TME). Multiple chemotherapies have also been shown to up-regulate the ecto-enzymes CD39 and CD73 that produce adenosine and further suppress immune function. In the MC38 model, CPI-444 treatment synergized with doxorubicin and eliminated established tumors 80% of treated mice. CPI-444 treatment was also synergistic with cyclophosphamides, inhibiting the growth of RENCA tumors, a model that is considered resistant to chemotherapy. Ongoing studies are evaluating the effect of CPI-444 + chemotherap y on tumor infiltrating lymphocyte localization, activation, and expression of CD73 and CD39. These results suggest that blockade of the adenosine signaling pathway may be vital for enhancing anti-tumor responses in solid tumors that show an incomplete response to anti-CTLA4 therapy or chemotherapy.

IMMUNOLOGY: IMMUNE CHECKPOINTS AND IMMUNOSURVEILLANCE

#5599 Soluble PD-L1 as a surrogate biomarker of metastatic progression and resistance to antiangiogenic therapy. Michalis Mavrili,1 Amanda Tracc,1 Yuhao Shi,2 Georg Bjarnason,1 Tran Nguyen,2 Brian Rini,4 John M.L. Ebos1.

1Roswell Park Cancer Institute, Buffalo, NY;2State University of New York, University at Buffalo, Buffalo, NY;3University of Toronto, Toronto, Ontario, Canada;4Cleveland Clinic Taussig Cancer Institute, Cleveland, OH.

Clinical studies targeting both immune checkpoint markers and oncogenic targets in preclinical studies. To this end, we investigated mutation and gene expression profiles of 18 mouse cancer cell lines out of the panel of 23 syngeneic mouse models included in the MuScree<sup>TM</sup> for 50 well defined cancer-related mutations among 30,690 variants in exonic regions called by RNAseq (Illumina HiSeq X10). The somatic mutations revealed through the bioinformatics analysis include ALK (3 - frequency, same for the rest), BRAF (4), BRCA1 (7), BRCA2 (12), EGFR (3), ERBB2 (6), EGF R3 (2), FBXW7 (10), FLT3 (12), HRAS (1), KRAS (8), NRAS (1), PDGFR A (11), PTH C1 (9), PIK3CA (2), PTEN (6), RET (3), SERT (5), SMAD4 (3), SMO (13), TRP53 (13), TSC1 (3), and TSC2 (10). All of these oncogenic alterations are clinically actionable (Cancer Discovery 2, 82-93, 2012). The same set of genes was also subject to mRNA expression change analysis. We screened the 18 mouse cell lines with a few selected target therapy agents, and performed combination assays of these agents together with checkpoint inhibitors such as ipilimumab and other agents. An IncuCyte real-time imaging platform was used to distinguish activities on T cells and tumor cells. The results and the implications will be discussed.
Immune-checkpoint inhibitors are now approved for the treatment of early- and late-stage cancers. These include agents that block the T-cell regulatory protein programmed cell death 1 (PD-1) from being activated by the PD-1 ligand 1 (PD-L1) expressed on cancer cells. There is an urgent need to identify biomarkers of PD-1 pathway inhibition that would predict patient populations responsive to treatment and/or guide drug development. While there is currently a biomarker candidate, reliable detection and quantification methodologies have proven challenging to standardize. Recently, a soluble PD-L1 (sPD-L1) fragment was identified that can derive from cell-bound PD-L1. Retrospective clinical examinations of sPD-L1 levels in cancer patients suggest a potential use as a surrogate for disease progression and response to treatment; but few preclinical data was performed to test this predictive value. We undertook in vivo experiments to evaluate plasma sPD-L1 in mouse tumor models during localized primary tumor growth (after orthotopic cell implantation) and spontaneous metastatic disease progression (after surgical removal of the primary). Mouse syngeneic and human xenograft implantation models included breast, kidney, colon, and melanoma cell systems. Our results show that circulating plasma sPD-L1 can correlate with primary and metastatic progression in a stage and model specific manner. Next, we evaluated sPD-L1 following treatment with neutralizing antibodies to PD-1 and PD-L1 in tumor-free mice and found significant dose-dependent sPD-L1 increases, suggesting systemic changes may have utility as a measurement of target saturation and dosing independent of tumor growth. Finally, with current approvals of PD-1 inhibitors in renal cell carcinoma (RCC) patients previously treated with antiangiogenic agents that block vascular endothelial growth factor (VEGF), we evaluated plasma in mouse models of sunnithressistance - a VEGF receptor tyrosine kinase inhibitor (RTKI). Our results demonstrate that VEGF pathway resistance yields changes in sPD-L1 and may be useful in predicting response to PD-1 pathway inhibition in the refractory setting. Together, these investigations suggest that circulating sPD-L1 changes during disease progression (both local and disseminated) may serve as a potential predictive biomarker for immune-checkpoint and antiangiogenic therapy.

**#5600 Simultaneous measurement and clinical significance of PD-1, LAG-3 and TIM-3 in non-small cell lung cancer (NSCLC).** Ila J. Datar,1 Jun Wang,1 Nikita Mani,1 Franz Villarroya-Espindola,2 Patrick Ryan,1 Miguel F. Sammaded,2 Kristen McCaehern,2 David Jenkins,2 David L. Rimm,1 Leiping Chen,1 Roy Herbst,1 Kurt Schalper1.

**Introduction:** The ineffective anti-tumor immune response is characterized by increased immune suppressive signals in the tumor microenvironment. In particular, T-cells recognizing tumor antigens can express diverse immune inhibitory receptors mediating lymphocyte inactivation and limiting tumor rejection. Blockade of these receptors such as PD-1 induces promising clinical benefit in patients with NSCLC. However, the expression and significance of additional potentially actionable immune inhibitory receptors in lung cancer is poorly understood. Methods: After careful validation of assays and using multiplexed quantitative immunofluorescence (QIF) we measured the levels of CD3 (rabbit polyclonal, Dako), PD-1 (clone EH33, CST), LAG-3 (Clone 17B4, Abpoorly understood. Methods: After careful validation of assays and using multiplexed quantitative immunofluorescence (QIF) we measured the levels of CD3 (rabbit polyclonal, Dako), PD-1 (clone EH33, CST), LAG-3 (Clone 17B4, Ab-poorsystematic disease progression (after surgical removal of the primary). Mouse syngeneic and human xenograft implantation models included breast, kidney, colon, and melanoma cell systems. Our results show that circulating plasma sPD-L1 can correlate with primary and metastatic progression in a stage and model specific manner. Next, we evaluated sPD-L1 following treatment with neutralizing antibodies to PD-1 and PD-L1 in tumor-free mice and found significant dose-dependent sPD-L1 increases, suggesting systemic changes may have utility as a measurement of target saturation and dosing independent of tumor growth. Finally, with current approvals of PD-1 inhibitors in renal cell carcinoma (RCC) patients previously treated with antiangiogenic agents that block vascular endothelial growth factor (VEGF), we evaluated plasma in mouse models of sunnithressistance - a VEGF receptor tyrosine kinase inhibitor (RTKI). Our results demonstrate that VEGF pathway resistance yields changes in sPD-L1 and may be useful in predicting response to PD-1 pathway inhibition in the refractory setting. Together, these investigations suggest that circulating sPD-L1 changes during disease progression (both local and disseminated) may serve as a potential predictive biomarker for immune-checkpoint and antiangiogenic therapy.

**#5602 Regulation of immune checkpoint genes revealed by a melanoma tumor genome atlas (TCGA) analysis - potential implications for improving immunotherapy.** Raya Leibowitz-Ami,1 Jason Roszik,2 Doro Avni,1 Elizabeth Grimm,3 Sheba medical center, Tel Hashomer, Israel;4 The University of Texas MD Anderson Cancer Center, TX.

**Introduction:** The interface between T lymphocytes and cancer or antigen presenting cells (C/ APCs) is multi-faceted and complex. This interface, now designated the ‘immunological synapse’, comprises of both co-inhibitory and co-stimulatory transmembrane protein pairs (‘checkpoint proteins’) that serve to modulate the signal transmitted to the T lymphocyte, leading to either activation, anergy or exhaustion. Immune checkpoint inhibitors have been successful in reactivating the T lymphocyte in a variety of malignancies, but not all patients respond to these agents. We undertook TCGA analysis of a melanoma tumor genome atlas database to identify immune-checkpoint inhibitors that may serve to be master regulators of gene expression. Our aim was to study the associations between a miRNA that was previously implicated in cancer and immune checkpoint genes. Methods: Bioinformatic analyses of the expression of mRNAs and miRNAs from 451 samples was performed using the melanoma TCGA database. Correlation coefficients between the expression of mRNAs or miRNAs/miRNAs were calculated using the Spearman rho method. Survival analysis was performed using the Kaplan-Meier method. Potential 3’UTR binding sites of miRNAs were found using the web-based tool www.targetscan.org. Results: Of 22 miRNAs of checkpoint genes assessed, the expression of 19 was highly posi-tionential correlations, TGIF was the best method to use in this predictive model. We undertook in vivo experiments to evaluate plasma sPD-L1 in mouse tumor models during localized primary tumor growth (after orthotopic cell implantation) and spontaneous metastatic disease progression (after surgical removal of the primary). Mouse syngeneic and human xenograft implantation models included breast, kidney, colon, and melanoma cell systems. Our results show that circulating plasma sPD-L1 can correlate with primary and metastatic progression in a stage and model specific manner. Next, we evaluated sPD-L1 following treatment with neutralizing antibodies to PD-1 and PD-L1 in tumor-free mice and found significant dose-dependent sPD-L1 increases, suggesting systemic changes may have utility as a measurement of target saturation and dosing independent of tumor growth. Finally, with current approvals of PD-1 inhibitors in renal cell carcinoma (RCC) patients previously treated with antiangiogenic agents that block vascular endothelial growth factor (VEGF), we evaluated plasma in mouse models of sunnithressistance - a VEGF receptor tyrosine kinase inhibitor (RTKI). Our results demonstrate that VEGF pathway resistance yields changes in sPD-L1 and may be useful in predicting response to PD-1 pathway inhibition in the refractory setting. Together, these investigations suggest that circulating sPD-L1 changes during disease progression (both local and disseminated) may serve as a potential predictive biomarker for immune-checkpoint and antiangiogenic therapy.

**Conclusion:** We also included a collection of lung adenocarcinomas with molecular annotation (cohort #4 [Yale n=106]). The targets were measured in all cells of the preparation using fluorescence co-localization with DAPI and specifically in CD3-positive T-lymphocytes. Associations between the markers and with major clinicopathological variables, driver mutations and survival were studied. Results: All the targets were detected predominantly in CD3+ T-cells with membranous staining. Expression of PD-1, LAG-3 and TIM-3 in T-cells across all NSCLC cohorts was 68.7%, 39.7% and 55.8%, respectively. Elevated levels of PD-1, LAG-3 or TIM-3 were significantly associated with increased tumor in filtrating lymphocytes and with the co-expression of one or more of the other inhibitory receptors (p < 0.05). SIMGLO and enhanced tumor cell-dependent independent antitumor action of anti-PD1 antibodies. We first explore the exact prevalence and magnitude of PD1 expression in patients and cell lines. Then we test the effect of MAPKi on its expression and explore possible immune-independent synergies with anti-PD1 antibodies. Methodology and results. Prevalence of PD1 expression by melanoma cells was explored in the Cancer Cell Line Encyclopedia (CCLE) and The Cancer Genome Atlas (TCGA) datasets. CCLE included 61 melanoma cell lines, which all expressed PD1 (Affymetrix mRNA 4.20 [3.81 - 4.65]) with values comparable to PDL1 (4.63, range 3.73 - 7.84) and PDL2 (3.73, range 3.97-8.30). The TCGA analysis included 114 melanomas, excluding those with evidence of immune infiltrate (n=236) or stromal
IMMUNOLOGY: Immune Checkpoints and Immunosurveillance
cells (n=100) potentially interfering with PD1 assessment. PD1 mRNA was expressed by all samples (median FPKM values: 64.7, range 0.4-1461.3). Next we assessed by flow-cytometry the membrane expression of PD1 in 4 melanoma cell lines and 3 patient-derived melanoma cultures, harboring BRAF and NRAS mutations. We confirmed that low rates of PD1 were expressed by all melanoma (median 1.2%, range 0.7-4.3). The median rate of viable PD1+ melanoma cells significantly increased (12.9% range 5.9-20, p=0.0180, n=7) following treatment (96h) with MAPKi (dabrafenib and trametinib) but not with chemotherapy (fotemustine). Longer treatments (8 days) further increased the rate of PD1 melanoma cells (31.8% range 15.0-50.3, n=3) and the effect was reversed by drug withdrawal. The MAPKi modulatory effect on PD1 expression was therapeutically exploited in vitro. The addition of PD1 blocking antibody enhanced the inhibitory activity of MAPKi on melanoma proliferation (mean inhibition rate: 66% vs 40%, n=2) in the absence of any immune cells. Conclusions We report a new expression pattern of PD1 receptor on melanoma and its potential therapeutic perspective. PD1 is directly expressed by a small but consistent rate of melanoma cells. Treatment with MAPKi significantly enhanced the rate of PD1+ melanoma cells and direct synergism with PD1 blockade was reported without the involvement of immune response. Our findings may be clinically relevant in settings of patients treated with MAPKi.

#5604 Novel biomarkers Ly6K/E play important role in drug resistance and tumor immune escape. Midar A. Hossiny,1 William R. Frazier,1 Noriko Steinier,1 Bhaskar Kallakury,1 Rakesh Kumar,1 Geeta Upadhyay,2 1Georgetown Univ., Washington, DC; 2Georgetown Washington, Washington, DC. Stem cell antigen Sca-1 is implicated in murine cancer stem cell biology and breast cancer models, but the role of its human homolog Ly6K and Ly6E in breast cancer is not established. Here we report increased expression of Ly6KE/E in human breast cancer specimens correlates with poor overall survival, with an additional specific role for Ly6E in poor therapeutic outcomes. Increased expression of Ly6KE/E also correlated with increased expression of the immune checkpoint molecules PD1 and CTLA4, increased tumor infiltrating T regulatory cells, and decreased natural killer (NK) cell activation. Mechanistically, Ly6K/E was required for TGFβ signaling and proliferation in breast cancer cells, where they contributed to phosphorylation of Smad1/5 and Smad2/3. Furthermore, Ly6K/E promoted cytokine-induced PD1L expression and activation and binding of NK cells to cancer cells. Finally, we found that Ly6K/E promoted drug resistance and facilitated immune escape in this setting. Overall, our results establish a pivotal role for a Ly6K/E signaling axis involving TGFβ in breast cancer pathophysiology and drug response, and highlight this signaling axis as a compelling realm for therapeutic invention.

#5605 Frequencies of HLA-Class I and II alleles between German patients with renal cell carcinoma and healthy controls can be different. Steffen Göbel,1 Astrid Kehlen,1 Karen Bluemke,1 Wolfgang Altermann,1 Gerald Schlaf,1 Kersten Fischer,1 Paolo Fornara,2 Bernd Wullich,2 Sven Wach,2 Helge W. Taubert2,1 Univ. of Halle, Halle, Germany;2 Univ. of Erlangen, Erlangen, Germany. The human leukocyte antigen (HLA) system is a major part of the human immune system and has an impact on tumor initiation, tumor progression and immunosurveillance. Renal cell carcinoma tumors are considered to be immunogenic. Therefore, we studied the allele frequencies of four gene loci (HLA-A, -B, -C and HLA-DR) in a cohort of 106 German renal cell carcinoma (RCC) patients and in 201 healthy controls. HLA-A-C were determined using serological methods, whereas HLA-C12, C14, C16, C18 and HLA-DR were characterized through the use of standard molecular biological methods. The presence of HLA-A and HLA-B alleles did not differ significantly among RCC patients and healthy controls. However, the occurrence of the HLA-C*12 allele was significantly increased in German RCC patients compared with healthy controls (P=0.0055; RR=2.3; Fisher’s exact test), whereas the occurrence of the HLA-DRB1*04 allele was significantly reduced in RCC patients compared with healthy controls (P<0.05; RR=0.7; Fisher’s exact test). But the presence of allele HLA-C*12 was not significantly associated with 10 years overall survival. We suggest that the frequency of HLA alleles can affect development of RCC and could add knowledge as predictive marker for future immunotherapies.

#5606 Fibrinogen-like protein 2 drives malignant tumor progression in glioma. Khetri Latha,1 Jun Yan,1 Yuhui Yang,1 Loyal V. Gressot,2 Lingyun Kong,1 Ganiraju Manyam,1 Ravesanker Ezhilarasan,1 Qianghu Wang,1 Erik P. Talbott,2 Kersten Fischer,1 Paolo Fornara,1 Bernd Wullich,2 Sven Wach,2 Helge W. Taubert2. 1Georgetown Univ., Washington, DC; 2Georgetown Washington, Washington, DC. Gliomas are the most common type of brain tumor in both children and adults. Several low-grade gliomas (LGG) have the ability to progress into more aggressive tumors -high-grade gliomas (HGG) including glioblastoma (GB). Although patients harboring a LGG may survive for years, after the tumor transforms to HGG, life expectancy rapidly declines to 12 to 15 months in adults and 40 months in children. A more indolent therapeutic strategy (MT) is an attractive therapeutic strategy because of the more indolent course associated with LGGs. Immune response plays a critical role in surveillance against malignant transformation. Our previous study shows that fibrinogen-like protein 2 (FGL2) acts as a hub of tumor-mediated immune suppression. Hence, we investigated the role of FGL2 in promoting tumor progression in glioma. Analysis of TCGA glioma dataset showed that the expression of FGL2 was significantly upregulated in HGG compared with LGG and GB patients. And there is a positive correlation of expression level between FGL2 and mesenchymal glioma marker CD44, and a negative correlation between FGL2 and proneural glioma marker Olig2. Engineered expression of FGL2 in a PDGFR-dependent mouse model of oligodendroglioma, a common glioma subtype, yielded a significantly higher rate of HGGs (72% vs 29%, p=0.034) and poorer-symptom free survival (63 vs 90 days, p=0.003) than PDGFR expression alone. And HGGs from FGL2 + PDGFR expressing mice exhibited a distinct mesenchymal phenotype validating TCGA data. Further, FGL2 induced high numbers of CD4+FoxP3+ cells from an early time point of tumor formation underscoring its role in tumor progression. And FGL2 overexpression induced M2-like M2-like tumor macrophages characterized by high expression of FGL2 and Arginase1 in macrophages. Finally, treatment with anti-FGL2 antibody significantly improves survival in mice, shifts the phenotype from mesenchymal HGG to neural LGG, and rescues M2 macrophage skewing. Our results show that FGL2 is critical for malignant progression of glioma by inducing immunosuppression in tumor microenvironment, and raise the potential of FGL2 to be a promising target to suppress/reverse glioma progression and provide survival benefit in clinical.
pass whole genome sequencing enables high quality genome-wide profiling of pure single cells and pools isolated from phenotypically distinct populations in FFPE tumor tissue.

**#5608 Correlation of phosphatase activity with lymphocyte infiltrates in metastatic renal cell carcinoma tissues.** Rob Kuijtenbeek,1 Liesbeuk Houkes-van Kerkhoff,1 Jeanette Oosterwijk,2 Liesbeuk Homest-Bijl,1 Riet Hildorest,1 Arie J. van den Elzen,2 Juan F. Rodriguez,3 Jesus Garcia-Domas,3 Bart Kiemeneij,2 Egbert Oosterwijk,2 VanGene International B.V., BF’s-Hertogenbosch, Netherlands; Rodaboud University Medical Center, Nijmegen, Netherlands; Centro integral oncológico Clara Campal, Madrid, Spain.

Introduction: Protein tyrosine phosphatases (PTPs) are important regulators of signal transduction in immune cells. While most analytical methods focus on the detection of these crucial enzymes at the RNA or protein level, a method was lacking to monitor multiple enzymatic activities in patient-derived materials like blood and (tumor) tissues. Such a substrate-specific assay is a new tool for biomarker discovery in immuno-oncology (I-O), because the I-O targets - checkpoint and immune receptors like PD1, CTLA4, LAG3, 4-1BB, CD40, CD20, OX40, TIGIT and GTR - are controlled by phosphatases. The aim of this study was to develop a multiplex PTP assay and investigate the phosphatase activity in metastatic renal cell carcinoma (mRCC) tissues with high and low levels of TILs (tumor-infiltrating lymphocytes). Methods: On the basis of the hema-toxyn and eosin staining of mRCC tissues, 9 tissues with high TILS-scores were selected, as well as 10 tissues without TILs, matched on basis of the percentage of viable tumor cells. The technology used is a second generation peptide microarray, which is fully automated with short turnaround times and a high throughput. Discriminating phosphosites (p<0.0002) were derived from the following 10 signaling proteins RET, ERBB2, PAXI, PGFR, CBL, FRK, DPKK1, INSR, PECAM1 and the T-cell kinase LCK. Conclusions: Proof of concept was shown in mRCC samples that high PTP activity correlates with high levels of TILs. As a TILS-score itself is already regarded to be a candidate biomarker for I-O therapy response, the observed correlation is a basis for the development of more mechanistic biomarkers predicting therapy response. This method can be a starting point for the development of an enzymatic and thus sensitive and quantitative TILs test. This study has received funding from the European Union’s Seventh Framework Programme (FP7/2007-2013) under grant agreement no 259939.

**#5609 Macrophages in secondary lymphoid organs regulate T cell tolerance and immunosurveillance in pancreatic cancer.** Fee Bengsch, Amni Liu, Kathleen Graham, Gregory L. Beatty, UPenn, Philadelphia, PA.

Pancreatic ductal adenocarcinoma (PDAC) is a deadly disease that shows striking resistance to standard therapies. Immunotherapy is an exciting new treatment strategy for PDAC, but has yet to reproducibly demonstrate clinical efficacy. This finding may reflect poor effector T cell infiltration into PDAC or mechanisms of peripheral T cell tolerance. We hypothesize that successful immunotherapy in PDAC will require strategies that reverse elements of innate immunity that regulate T cell tolerance. This hypothesis is based on our prior studies in the Kras12D12V/+/Trp53R172H/+/Pdcd1-cre (KPC) mouse model of PDAC where macrophages residing outside of the tumor microenvironment were found to regulate the efficacy of a vaccine strategy involving the combination of chemotherapy and a CD40 agonist (FGK45). Specifically, we found that depletion of peripheral phagocytes using clodronate-encapsulated liposomes (CEL) was necessary for gemicitabine chemotherapy and a CD40 agonist to induce productive anti-tumor T cell immunity against spontaneously arising PDAC tumors in the KPC model. We now investigate the mechanism by which CEL-depleted phagocytes regulate T cell tolerance in PDAC using the KPC mouse model and an orthotopic implantation model. We found that CEL depletes macrophages in the spleen and abdominal lymph nodes, thereby reversing the pathologic accumulation of macrophages in these secondary lymphoid organs that is induced by PDAC tumors. CEL targeted two macrophage subsets in the lymph node, CD11b+CD169+F4/80+ subcapsular sinus macrophages (SSM) and CD11b+CD169+F4/80+ medullary sinus macrophages (MSM). These macrophage populations may be exposed to tumor-derived antigens and apoptotic cell vesicles entering the lymph node, and have been previously identified as central orchestrators of tolerance in autoimmune models. We found that both fluorescently-labeled liposomes and OVA-FITC lipoparticle injected into the peritoneal cavity were specifically targeted to SSM and MSM with little uptake by dendritic cells (DC). In contrast, depletion of these first-line phagocytes by CEL shifted the cellular uptake of these model antigens increasing uptake by CD11b+DC11c+ DC which are more efficient in antigen presentation and show increased expression of co-stimulatory molecules after FGK45 treatment. Using an orthotopic model of PDAC, we then determined that CEL can enhance the T cell stimulatory capacity of gemcitabine chemotherapy in combination with FGK45 as seen by a significant increase in CD38, CD44, CD69 and PD-1 expression on CD4 and CD8 T cells in secondary lymphoid organs. Together, our findings suggest that tumor-derived antigens may be sequestered by tolerogenic macrophages in peritumoral lymph nodes that act to impair optimal stimulation of T cell responses. These findings strategies to disrupting the tolerogenic functions of these macrophages may offer a novel approach for improving immunotherapy in PDAC.

**#5610 Quantitative cell-based bioassays to advance individual or combination immune checkpoint immunotherapy.** Jamison Graaler, Pete Stecha, Denise Garvin, Jim Hartnett, Frank Fan, Mei Cong, Zhi-jieh Cheng, Promega Corp., Madison, WI.

Immune checkpoint receptors play a critical role in maintaining immune homeostasis and are genetically and functionally associated with autoimmune disease, cancer and persistent viral infections. Blockade of immune checkpoints (e.g., PD-1 and CTLA-4) has emerged as a promising new approach to enhance anti-tumor immune responses. While immunotherapies directed against PD-1 and CTLA-4 are showing unprecedented efficacy in the treatment of cancer, many patients and types remain refractory to these therapies. This has resulted in a broadening of immunotherapy research and development to include additional immune checkpoint receptors (e.g., LAG-3, TIGIT, CD112R) targeted individually or in combination with other immunotherapy strategies. A major challenge in the development of biologicals that target immune checkpoint proteins is access to quantitative and reproducible functional bioassays. Existing methods rely on primary cells and measurement of complex functional endpoints. These assays are cumbersome, highly variable, and fail to yield the quality of data that is required for drug development in a quality-controlled environment. To address this need, we have developed a suite of immune cell line-based bioluminescent reporter bioassays for individual and combination immune checkpoint immunotherapy targets including PD-1 (PD-L1 or PD-L2), CTLA-4, LAG-3, TIGIT, PD-1+TIGIT and more. These assays consist of stable cell lines that express luciferase reporters driven by specific response elements under the precise control of intracellular signals mediated by the T cell receptor and immune checkpoint target(s). These mechanism of action-based bioassays are available in “thaw-and-use” format and demonstrate high specificity, sensitivity and reproducibility. The bioassays are pre-qualified according to ICH guidelines and demonstrate the performance required for use in antibody screening, potency testing and stability studies.

**#5611 Use of ecto-domain vimentin to target brain cancers.** Ivan Babic,1 Rajesh Mukthavaram,1 Pengfei Jiang,1 Eric Glassy,2 Natsuko Nomura,3 Sandeep Pingle,3 Mark C. Glassy,2 Santosh Kesari,3 John Wayne Cancer Institute, Santa Monica, CA; Pathology, Inc., Torrance, CA; Nascent Biotech, Inc., San Diego, CA.

Pritumumab is a natural human IgG1 kappa antibody derived from a regional draining lymph node of a patient with cervical carcinoma. The recognized antigen is an altered form of vimentin, called ecto-domain vimentin (EDV), that is expressed on the cell surface of epithelial tumor cells. For brain cancers, immunohistological analysis showed the binding of pritumumab to EDV that was restricted to tumor cells and types remain refractory to these therapies. This has resulted in a broadening of immunotherapy research and development to include additional immune checkpoint receptors (e.g., LAG-3, TIGIT, CD112R) targeted individually or in combination with other immunotherapy strategies. A major challenge in the development of biologicals that target immune checkpoint proteins is access to quantitative and reproducible functional bioassays. Existing methods rely on primary cells and measurement of complex functional endpoints. These assays are cumbersome, highly variable, and fail to yield the quality of data that is required for drug development in a quality-controlled environment. To address this need, we have developed a suite of immune cell line-based bioluminescent reporter bioassays for individual and combination immune checkpoint immunotherapy targets including PD-1 (PD-L1 or PD-L2), CTLA-4, LAG-3, TIGIT, PD-1+TIGIT and more. These assays consist of stable cell lines that express luciferase reporters driven by specific response elements under the precise control of intracellular signals mediated by the T cell receptor and immune checkpoint target(s). These mechanism of action-based bioassays are available in “thaw-and-use” format and demonstrate high specificity, sensitivity and reproducibility. The bioassays are pre-qualified according to ICH guidelines and demonstrate the performance required for use in antibody screening, potency testing and stability studies.
binding in tumor areas of brain tissues indicating the mAb crosses the tumor brain barrier. Overall, these data together suggest that EDV is a suitable target and biomarker for brain cancers.

#5612 Cancer-immune interactions in luminal breast cancers: PIK3CA mutations, PIK3CA/akt/mTOR activation and tumor-infiltrating lymphocytes. Marcelo Sobral-Leite,1 Izhar Salomon,1 Mark Opdam,1 Karin Beelen,1 Ronald L. van Vlerken,1 Erik J. Blok,2 Hugo M. Horlings,1 Joyce Sanders,1 Koen Van de Vijver,1 Peter J. Kuppen,1 Sabine Linn,1 Marjanka J. Schmidt,1 Marleen Kok1. 1The Netherlands Cancer Institute, Amsterdam, Netherlands; 2Leiden University Medical Center, Leiden, Netherlands.

Introduction: Therapy resistance to adjuvant tamoxifen in estrogen receptor positive (ER+) breast cancer (BC) is related to activation of downstream proteins in the PI3K/akt/mTOR pathway. However, clinical activity of mTOR inhibitors has so far been modest. Growing evidence shows that this suggests a need for understanding the relationship between tumor-related immune responses and this is reflected in the presence of tumor infiltrating immune cells. This study investigated a role of tumor-related immune response.

Methods: The IAK trial recruited stage I to III postmenopausal BC patients (1982 till 1994), who were randomized to tamoxifen or no adjuvant therapy. Sequenom mass spectrometry-based genotyping was performed by PIK3CA assessment. Immunomarker and phosphorylation status of proteins in the PI3K/akt/mTOR pathway (p-akt, Thr308 and 473), p-mTOR, p-ERK1/2, p-p70S6K and p-4EBP1 were assessed by immunohistochemistry and scored by two pathologists. Expression of LAG3 and TIM3 was evaluated by using automatic scoring by image-analysis software (SlidePath® or AxioVision®) and compared with manual scoring by two pathologists. Associations were assessed using multivariable logistic regression models, including as co-variables: age, tumor grade, lymph node status, tumor size, and progesterone receptor and HER2 status. Results: We included 563 ER+ BC cases. PIK3CA mutations were found in 159 (32%) of the 486 tumors genotyped. On average, PIK3CA/akt/mTOR downstream proteins and immune markers were scored in 409 tumors (range: 366 to 438). Stromal CD8 expression, but not CD4 or FOXP3, was significantly higher in PIK3CA mutated tumors (OR = 1.11; 95%CI: 1.02-1.22). Stromal FOXP3 expression, but not CD4 or CD8, was significantly increased in tumors with activated proteins from the PI3K/akt/mTOR pathway (except p-mTOR). The largest association was with p-4EBP1 (OR = 1.34; 95%CI: 1.21-1.48) and smallest with p-70S6K (OR =1.15; 95%CI: 1.08-1.22).

Conclusion: In our dataset of ER+ BC, PIK3CA mutations are associated with higher level of CD8+ T cells. Tumors with activation of the PI3K/akt/mTOR pathway tend to have more FOXP3+ T cells. Together, our results suggest that PIK3CA mutation/activation harbor an immune-related tumor microenvironment.

#5613 PD-1 and TIGIT are major immune checkpoint receptors expressed in breast cancer-infiltrating T cells. Jee Ye Kim,1 Minsuk Kwon,2 Sung Mook Lim,1 Joo Heung Kim,1 Hyung Seok Park,1 Seho Park,1 Seung Il Kim,1 Young Up Cho,1 SooMyung Paik,2 Eui-Cheol Shin.1 1Yonsei University College of Medicine, Seoul, Republic of Korea; 2KAIST, Daejeon, Republic of Korea.

Immune checkpoint receptors, which are inhibitory receptors on T cells, have provided promising responses against various tumors. However, the expression of immune checkpoint receptors (ICRs) in BC cancers remains poorly understood. We aimed to investigate the expression pattern of multiple ICRs in tumor-infiltrating and peripheral blood (PB) lymphocytes in human BC cancer. We isolated lymphocytes from fresh breast tumor tissue and paired PB from 21 patients who underwent surgery between July 2016 and November 2016. Multi-color flow cytometry was performed primarily focusing on expression of multiple ICRs in CD8+ T cells and regulatory T cells (Tregs). In CD8+ T cell subsets, PD-1+ or TIGIT+ cells were more frequently observed in tumor-infiltrating CD8+ T cells than in PB CD8+ T cells (p<0.0001 and p=0.02, respectively). Around half of the tumor infiltrating CD8+ T cells expressed PD-1 (median 49.5%, range 0-94%). In Tregs, about 40% of tumor-infiltrating CD8+ T cells were PD-1+TIGIT+, and >70% of PD-1+ tumor-infiltrating CD8+ T cells co-expressed TIGIT, indicating that functional exhaustion of breast tumor-infiltrating CD8+ T cells might be mediated not by PD-1 alone but by multiple receptors including TIGIT. However, the expression of PD-1 and TIGIT showed different patterns in detail. PD-1 was frequently expressed by CCR7+CD45RA− effector memory T cells (TEM) (p=0.001) whereas TIGIT was frequently expressed by CCR7+CD45RA− effector memory RA T cells (TEMRA) (p=0.03), suggesting that TIGIT is expressed during terminal differentiation of CD8+ T cells. Next, we examined breast tumor-infiltrating Tregs. The frequency of CD25+ FoxP3+ Tregs among CD4+ T cells were higher in tumor than in PB (16.60% vs. 7.86%; p=0.002). In particular, CD45RA FoxP3+ activated suppressive Tregs account for 77.6% of tumor-infiltrating Tregs (vs. PB 32.2%; p=0.005). Tumor-infiltrating Tregs showed higher expression of CD39 (p=0.005), a marker of the suppressive activity of Tregs. We also examined the expression of multiple ICRs as upregulated receptors is associated with enhanced suppressive activity of Tregs. CD4+ CD25+ FoxP3+ Tregs in tumors showed higher expression levels of PD-1, TIGIT and CTLA-4 compared to PB Tregs (p<0.05). There were no noteworthy correlations between ICR expression and clinical features, such as age, stage and subtype. We show that PD-1 and TIGIT are major ICRs expressed in breast tumor-infiltrating T cells. Moreover, we found that CD4+ CD25+ FoxP3− Tregs are abundant in breast tumors and upexpress PD-1, TIGIT and CTLA-4. Our data provide an understanding of comprehensive phenotypes of immune checkpoint expression on T cells in breast cancer. Functional changes of CD8+ T cells and Tregs by blocking of single or multiple ICRs are being investigated.

Chimeric Antigen Receptor (CAR) T-cells made with mRNA offer a transient and safe alternative to viral CARs, mitigating the concern for persistent unwanted side effects from constitutively active T-cells. Previous studies have shown that mRNA CARs are transiently effective, but lack CAR persistence and survival as compared to viral CARs. The efficacy of mRNA CARs could be improved by utilizing recent advancements in RNA technology including the use of modified uracil and a novel purification method with RNaseIII to prevent double strandeding that induces toxicity. Using the established CD19 CAR model in B-cell acute lymphoblastic leukemia, we created mRNA CARs using previously described methods and compared them to mRNA CARs created using modification of uracil and/or purification to remove any aberrant double stranded mRNA. Comparing the modified and purified mRNA CAR T cells to those created using prior methods of making mRNA, both modified and purified mRNA CAR T cells showed a two-fold increase in expression of the CAR on their surface initially, as well as a two-fold improvement in cytotokic killing of leukemia cells in vitro that persisted for up to five days. Both the modified and purified mRNA CAR T cells also showed reduced expression of negative checkpoint regulators compared to original RNA CAR T cells. However, in vivo studies using a patient-derived xenograft model with a single dose of CAR T cells revealed purified RNA CAR T cells offered the most robust 2-log enhanced suppression of leukemic burden. RNaseIII is a novel purification technique that has not yet been reported in the literature for RNA manufacturing. Our results provide a time efficient purification method that can be easily incorporated into RNA production for use in clinical trials, and poise RNA CARs for increased efficacy as new CAR targets emerge and are being tested. Additional studies are ongoing investigating if the observed improved efficacy will translate to improved cytotokicity in solid tumor models.

#5615 Genomic differential expression analysis of fusion proteins incorporating the pro-apoptotic molecule Granulocyte B reveals new potential targets for treatment of breast cancer. Khalid A. Mohamedalli, Lawrence H. Cheung, Ana Alvarez-Cienfuegos, Michael G. Rosenblum. UT MD Anderson Cancer Center, Houston, TX.

Granulocyte B (GRB) is a member of the serine protease family of enzymes that play a critical role in the body’s defense against viral infection and tumor development. Cytotoxic T lymphocytes (CTL) and natural killer (NK) cells directly deliver granymes to target cells, which induces apoptosis through both caspase-dependent and caspase-independent multiple-cascade mechanisms. Anti-tumor efficacy studies have suggested that the targeted delivery of human Granyme B to tumor cells has a significant potential for cancer treatment. We had previously developed a novel fusion construct composed of the VEGF121 growth factor and human GRB. The GRB/VEGF121 construct was found to be highly cytotoxic to vascular endothelial cells expressing the R (KDR) receptor for VEGF. In this study, we examined the mechanism of GRB/VEGF121 induced cytotoxicity against cells in culture at the genomic level. The TNBC cell line MDA-MB-231 was treated with an IC50 dose of GRB/VEGF121 for 24 hours; the cells were then harvested and the effect of GRB/VEGF121 on intracellular events was examined by extraction of mRNA followed by microarray analysis. Gene level differential expression analysis revealed that a total of twenty genes were upregulated by over 3-fold, while 25 were downregulated 3-fold or more. These included genes involved in signal transduction, stress response, cell cycle control, hypoxia and metabolism. Particularly impacted were the Nuclear Receptors
Meta pathway, NRE2 pathway, nuclear receptors in lipid metabolism and toxicity, matrix metalloproteinases, and the notch signaling pathway. Validated data will be reported following complete analysis of gene level differential expression and alternative splicing. Our data suggests that Grb/VEGF121 induce expression of genes known to be induced by VEGF alone, as well as molecules previously not associated with either Granzyme B or VEGF. This data suggests a previously unsuspected impact of the serine protease Grb on various molecular pathways within the cell and may lead to a new understanding of how these agents operate at the molecular level. Research conducted, in part, by the Clayton Foundation for Research.

Background: CD137L is expressed on antigen presenting cells and CD137/CD137L interaction co-stimulates activation and proliferation of CD137 expressing T cells. CD137L expression has also been detected on various cancer cells. While signaling in immune cells showed both inhibiting and activating effects the impact of CD137L induction on tumor cells is poorly understood. In this study, the expression of CD137 and CD137L and the effects of CD137L activation were analyzed in human colorectal cancer (CRC). Methods: Expression of CD137 and CD137L was examined in human colon cancer cell lines HT29, SW480 and SW620 treated with or without hypoxia using RT-qPCR, Western blot and FACS analysis. Its differentiated expression was further analyzed by immunohistochemistry in human CRCs by immunofluorescent double-staining. To dissect the effects of CD137L activation on cancer cells, MTS proliferation assays were performed. Results: All human colon cancer cell lines demonstrated high cellular (FACS) and protein (Western Blot) CD137L expression. CD137L was found only in SW480 cells at weak expression. Additionally, both CD137L and CD137L were significantly upregulated in cells treated with hypoxia. In human CRCs both CD137 and CD137L expressing tumor cells were detected by immunofluorescent double-staining. Interestingly, activation of CD137L by immobilized CD137-Fc resulted in reduced cancer cell proliferation compared to IgG1-Fc controls. Conclusion: Our results demonstrate tumor cell mediated expression of the costimulatory molecule CD137L and its ligand CD137L in both colon cancer cell lines and human colorectal cancer. Moreover, CD137L reverse signaling was found to reduce cancer cell proliferation in vitro. Based on these data, the CD137L/CD137L signaling pathway seems to present a promising target for cancer therapy in CRC.

#5617 Combined intratumoral electroporation and allogeneic vaccina- tion of Gp96-Ig/Fc-OX40L stimulates CD8 T cell cross-priming to tumor-specific neoantigens and enhanced anti-tumor response. Sushil de Silva, Sandro Mazarati, Nandana N. Seneviratne, Li-Qi Cai, George Fromm, Anandaroop Mukhopadhyay, Jean Campbell, Robert Pierce, Taylor Schreiber. Heat Biologics, Durham, NC; Oncoselect Medical Inc., San Diego, CA.

Growing clinical evidence has unequivocally proven that combination approaches are leading the way in increasing the overall response rates in cancer immunotherapy towards tumor eradication. Most cancers are characterized by a higher likelihood of succeeding if the targeted tumor has a preexisting state of inflammation elicited by the combined presentation of shared- and neo-antigens from tumor cells. Certain cancers have been deemed to be non-immunogenic due to tumor intrinsic strategies that evade immune recognition. Thus, novel combination treatment modalities are needed to convert non-immunogenic, ‘cold’ tumors into inflamed ‘hot’ tumors that are amenable to IT. Gp96-Ig/Fc-OX40L is a re-engineered molecular chaperone, designed to export and deliver MHCI-associated antigens to APCs in context of the immunostimulatory, OX40L. Allogeneic cancer vaccine cell lines designed to co-secrete Gp96-Ig and Fc-OX40L, generate antigen-specific CD4+ and CD8+ anti-tumor responses in both highly immunogenic (CT26) and less immunogenic (B16) mouse tumor models (Fromm et al., Cancer Immunol Res, 2016). Such a strategy allows for Gp96-Ig-mediated chaperoning of antigens from the allogeneic vaccine cell line (shared antigens), which could benefit further from increased presentation of tumor-derived peptides (neo-antigens) that are only accessible if Gp96-Ig/Fc-OX40L is expressed from within the tumor. To achieve this, we have employed an in vivo electroporation-based strategy (EP) to deliver Gp96-Ig/Fc-OX40L expressing tumor cells into the flank. Herein, we set out to test whether a combination approach of intratumoral EP of Gp96-Ig/Fc-OX40L DNA and vaccination with allogeneic cells co-secreting the same effector molecules would lead to enhanced CD4+/CD8+ T cell cross-priming to tumor neo-antigens and superior anti-tumor activity over the individual monotherapies in a non-immunogenic B16 tumor model. To assess antigen-specific CD8+ T cell expansion, mice were adoptively transferred with OT-I cells after B16-ovalbumin cells were injected to generate primary and contralateral melanotic tumors. Contralateral tumors were monitored to assess whether a systemic CD8+ T cell response could be elicited following vaccination and primary tumor EP. The combination approach of intratumoral EP of Gp96-Ig/Fc-OX40L and vaccination with allogeneic cells co-secreting the same effector molecules was superior to EP alone in the peripheral blood compared to the individual monotherapies. A synergistic increase in SIINFEKLI-positive CD8+ TIL cells was also observed in treated tumors, which was associated with superior anti-tumor response in both the EP-treated primary and untreated contralateral tumors. These findings suggest that a combination approach of allogeneic vaccination and in situ tumor EP of Gp96-Ig/Fc-OX40L may have significant benefit in eliciting a potent immune response in less-immunogenic tumors.

#5618 Correlation between MET gene amplification and TP53 mutation in upregulating PD-L1 expression in EGFR wild-type lung cancer. Maher Albitar, MD, Sucha Sudarsanam, MS, Wanlong Ma, BS, Shingping, MD, Wayne Chen, MD, Vincent Funari, PhD, Steven Brodie, PhD, Sally Agerborg, MD, PhD. NeoGenomix Laboratories, Aliso Viejo, CA.

Introduction: MET gene activation has been reported to be associated with resistance to EGFR inhibitors in lung cancer. Resistance to EGFR inhibitors is also reported to be associated with upregulation of PD-L1. We studied PD-L1 expression levels with MET gene amplification and mutation in EGFR, KRAS, or TP53 in a large number of primary untreated lung cancers. Methods: Tissue samples collected from 397 core biopsies or resections from lung cancers were studied for MET gene amplification by fluorescence in-situ hybridization (FISH) and using MET (7q31) probe and centromere 7 as a control. Signals were quantified. PD-L1 expression on the same samples was evaluated using clone SP142 and standard patholohistochemistry (IHC) procedure. Samples were also sequenced using next generation sequencing (NGS) for mutations in TP53, KRAS, and EGFR. Results: PD-L1 expression was detected in 166 patients (42%). Twenty seven (7%) had expression between 1% and 5%, 61 (15%) between 1% and 20%, 92 (23%) between 1% and 50%, and 105 (26%) had PD-L1 > 50% in tumor cells. Ratio of MET: centromere signals was > 1.5 in 16 (4%) of patients. Patients with MET ratio > 1.5 had significantly higher (P = 0.004) percentage of PD-L1 as a continuous variable as well as when cut-off points of 5% (P = 0.01), 20% (P = 0.006), and 50% (P = 0.01) were used. Patients with EGFR mutation had significantly lower levels of PD-L1 expression (P = 0.003). When a cut-off point of 50% is used for PD-L1 expression, the EGFR-mutant cases had significantly less number of positive cases (P = 0.0003). There was no correlation between the presence of High MET: Ratio and EGFR mutation. There was no correlation between KRAS mutation and overall PD-L1 expression (P = 0.4). There was no correlation between MET ratio and KRAS mutation. Patients with TP53 mutation had significantly higher MET ratio as compared to patients with higher expression of PD-L1, while EGFR-mutant lung cancers had significantly lower expression of PD-L1 when clone SP142 is used and NGS is used for detecting EGFR mutations. Patients with TP53 mutation had strikingly high expression of PD-L1 using SP142 clone and higher copy number of MET gene. This data suggests that in lung cancer, both MET and TP53 genes play a direct role in regulating PD-L1 expression opposing the EGFR gene, which appears to suppress PD-L1 expression. KRAS gene may not be involved in PD-L1 expression in lung cancer.

Our current research explores the development and tumoricidal activity of chimeric antigen receptor T cells targeting a new immunotherapeutic target, thymidine kinase 1 (TK1), against non-small lung cancer (NSCLC), both in vitro and in vivo. There has been recent success utilizing CAR T-cell therapy in clinical trials, but it has been mainly focused on the treatment of haematological malignancies targeting CD19. Lung cancer is the most common cause of cancer mortality globally and is responsible for more than one million deaths every year. Moreover, NSCLC comprises approximately 85% of all lung cancers. Clinical trials against NSCLC using engineered T-cells targeting NY-ESO-1, VEGFR2, MAGE-A3, and mesothelin are currently ongoing. In spite of efforts to find new molecular targets, CAR T-cell therapy still faces several challenges in
the treatment of solid malignancies due to the lack of specific molecular targets. We have previously reported the up-regulation of TK1 in multiple malignant tissues including lung cancer tissues and the presence of TK1 on the cell surface of different NSCLC cell lines, such as H460 and A549. Flow cytometry, scanning electron microscopy and confocal microscopy showed evidence of TK1 on the surface of different NSCLC cell lines. We demonstrated TK1-CAR binding to H460 cells with lentiviral and retroviral vectors. The constructions include a single chain variable fragment for TK1, a CD28 and 4-1BB moieties connected with a CD3ζ signaling domain. Confirmation of the CAR expression on transduced human T cells was performed by flow cytometry and confocal microscopy, and approximately 50% of the transduced T-cells expressed TK1-CARs. Upon co-culturing TK1-CAR-transduced T-cells with naïve T-cells, a significant increase in the number of CD8+ T cells lysis elevated as high as 48% in comparison to negative controls. Cytokine profiles revealed a significant increase of the levels of IL-2 and IFN-γ after 24 hrs of co-culturing, indicating T-cell activation. TK1-CAR T-cells, untransduced T-cells, and transduced T-cells with empty vectors were co-cultured with H460 cells and time-lapse videos were recorded, every 5 minutes between 12 and 24 hrs post transduction. Clustering of TK1-CAR T-cells around lung cancer cells and induction of cell death after T-cell synthesis with target cells was observed. Preliminary in vitro data has shown that TK1-CAR T-cells induce specific cell lysis in NSCLC cells. In vivo experiments using xenografts models in SNG mice will be performed. Statistical differences between survival curves of mice treated with TK1 CAR T-cells, untransduced T-cells and transduced T-cells with empty vectors are expected.

#5620 Acquisition of P- and E-selectin binding capacity by effector T cells is required for the abscopal response following experimental high dose radiation therapy. Joseph W. Scarpelli, Ryan S. Lane, Joshua M. Walker, Charles R. Thomas, Jeffrey C. Nola, Amanda W. Lund. Oregon Health & Science University, Portland, OR.

High dose radiation therapy generates systemic adaptive immunity that limits distant tumor progression and synergizes with immune checkpoint blockade. Preclinical data demonstrate that ionizing radiation may sensitize otherwise refractory tumors to immunotherapy through mechanisms of lymphocyte activation and tumor cell recruitment, however, the molecular mechanisms that govern this response remain poorly understood. Selectins are critical regulators of leukocyte trafficking and migration, and facilitate the compartmentalization of naive, effector and memory T cells to their respective organ sites. Importantly, inflamed vascular endothelium expresses P- and E-selectin, which facilitate peripheral tissue infiltration of effector and memory lymphocytes. Therefore, both the acquisition of functional selectin ligands expressed by T-cells, as well as endothelial activation coordinates peripheral tissue infiltration following infection or tissue injury. In this work we test the hypothesis that the immunogenic potential of high dose radiation therapy is sufficient to stimulate synthesis of selectin ligands on T cells, which is required for their subsequent infiltration into distal tumors and the abscopal response. We have established a mouse model of the abscopal effect, where radiotherapy-induced immune-mediated tumor retardation is observed at sites distal to the primary, irradiated tumor. B16 F10 murine melanomas expressing model and endogenous antigens are implanted intradermally on opposing flanks. One day prior to radiation, naïve TCR-transgenic CD8+ T cells are transferred into tumor bearing mice and 20Gy is delivered to a single tumor by half beam block. Using this model, we demonstrate that local high dose radiation therapy is sufficient to activate and expand naive tumor-specific CD8+ T cells in the tumor draining lymph node. Following a single high dose of radiation, tumor-specific CD8+ T cells become activated and subsequently traffic to and accumulate in distal, contralateral tumors where they limit tumor growth, thus recapitulating the clinical observation of the immune-mediated abscopal effect. Importantly, we demonstrate that high dose radiation is sufficient to up-regulate selectin family of oligosaccharide binding adhesion molecules on newly activated antigen-specific CD8+ T cells. The acquisition of P- and E-selectin binding capacity by effector CD8+ T cells is required for the abscopal response as administration of selectin blocking antibodies reduced intratumoral CD8+ T cell infiltration and failed to mediate regression of distal tumors post radiation. Our data demonstrate that the acquisition of P- and E-selectin ligands requires prior antigenic stimulation and as such, these T cells represent a completely novel population of tumor-specific, homing competent CD8+ T cells that may predict response to therapy in patients.

GITR (Glucocorticoid-Induced Tumor Necrosis Factor Receptor Ligand, TNFSF18) is a member of the tumor necrosis factor (TNF) ligand superfamily. GITR binds and activates the co-stimulatory surface receptor GITR, which promotes proliferation and activation of effector T cells (Teff) and inhibits suppressive activity of regulatory T cells (Treg). It is thus hypothesized that co-stimulation of GITR by agonist agents will promote anti-tumor immunity. We generated a novel single-gene GITR chimera fused to an immunoglobulin Fc domain (GITRL-Fc) that shows robust single agent antitumor efficacy and immune effects in multiple syngeneic mouse models, suggesting its potential benefit in cancer immunotherapy. To investigate the prevalence of GITR expression in human tumors, RNA-Seq data analyses of 33 tumor types in TCGA showed GITR is highly expressed in a subset of solid tumors, including head & neck, lung, breast, esophageal, and bladder cancers. In most solid tumors, GITR expression correlated poorly with T cell markers, implying that GITR may not be exclusive to immune cells and may be expressed in tumor cells as well. Similar findings emerged from RNA-Seq data analysis of patient-derived xenograft (PDX) samples from 24 tumor types. The gene expression data was corroborated by immunohistochemistry (IHC) analysis of GITR expression in 17 tumor types which showed that in addition to immune cells, GITR was expressed on tumor cell membranes. A multi-platform approach was taken to investigate GITR-Fc pharmacodynamic (PD) biomarkers in tumors and in matched whole blood samples from mice bearing CT26 colon, 4T1 breast, and B16F10 melanoma carcinoma models. Global gene expression levels were profiled by microarray on tumors and control tissues. We also monitored the changes of immune cell populations and cytokine secretions by flow cytometry, Luminox and IHC. Immune gene changes were more robust in tumors than in blood samples. In tumor samples, GITR-Fc increased the gene expression associated with T cells, CD8 T cells, cytotoxicity, Th1 cells, interferon gamma (IFN-γ), natural killer cells, T effector cells, and T cell activation markers. These gene changes were validated by quantification of gene expression (qPCR). Similarly, flow cytometry analysis showed that GITR-Fc promoted activation of CD4+ effector cells, decreased Treg frequency, and increased the ratio of CD8+ T cell/Treg in the tumor. GITR-Fc also modulated secretion of cytokines in splenocytes, including an increase in IFN-γ. Taken together, the PD biomarker changes in immune-related gene expression, immune cell populations, and cytokine secretions observed in these preclinical tumor models are consistent with GITR-Fc mechanism of action and demonstrated target engagement of GITR-Fc. Additional approaches, including in-silico sorting, to monitor rare immune cell populations in tumor samples will be discussed.

#5622 Acquired resistance to EGFR-TKI upregulates the expression of PD-L1 and promotes immune escape in lung cancer. Shunli Peng, Qi Li, Wei Wang, Nanfang hospital, Southern medical university, Guangzhou, China, Guangzhou, China.

Background and purpose: Acquired resistance is a severe problem of EGFR inhibitors (EGFR-TKIs) therapy in lung cancer patients. Immune checkpoint therapy is a new revolution in cancer treatment with dramatic outcomes in a subset of patients. In this study, we explored the possibility of immune checkpoint therapy in lung cancers with three well-known resistant mechanisms to EGFR-TKIs, T790M, MET amplification and hepatocyte growth factor (HGF), and investigated internal regulation mechanisms. Experimental Design: PD-L1 expression and immune escape ability were evaluated in EGFR-TKIs resistant lung cancer cells by MET amplification, HGF, and T790M, as well as T790M transfected-human renal derived cells (293FT). MAPK and PI3K pathways were investigated simultaneously. PD-L1 gene deleted resistant cells were used in NOD-SCID xenograft models to evaluate immune escape in vivo. Results: All of three resistant mechanisms increased PD-L1 expression. Both MAPK and PI3K pathways are involved in MET amplification or HGF induced PD-L1 overexpression, whereas only MAPK pathway mediated it in T790M-transfected cells. The decreased cytotoxicity of lymphocytes can be restored by anti-PD-L1 antibodies. Moreover, xenograft tumors by EGFR-TKIs sensitive cells but not resistant cells responded to treatment of human lymphocytes. However, deletion of PD-L1 successfully restored cytotoxicity of lymphocytes in EGFR-TKIs resistant tumors. Conclusion: Acquired Resistance to EGFR-TKIs augments the expression of PD-L1 and promotes immune escape in EGFR mutant lung cancer. Immune checkpoint therapy might be a promising alternative therapeutic strategy for NSCLC that acquired resistant to EGFR-TKIs.

Procedures of the American Society for Cancer Research • Volume 58 • April 2017

1436
Background: Clinical trials of immune checkpoints modulators, including both programmed cell death 1 (PD-1) and programmed cell death-ligand 1 (PD-L1) inhibitors, have recently shown promising activity and tolerable toxicity in pre-treated and first line NSCLC patients. At least five PD-L1 IHC assays with custom reagents and scoring-criteria were evaluated in clinical trials. However, current assays for the prognostic and/or predictive role of tumor PD-L1 expression are not standardized and the role of PD-L1 expression as a biomarker is still controversial. Materials and Methods: Retrospectively collected formalin-fixed paraffin-embedded whole-tissue sections (WTS) from 97 NSCLC cases from Seoul National University Bundang Hospital were tested. We tested the samples divided into “training set” and “validation set”: A set of 50 NSCLC WTS (32 adenocarcinoma and 18 large cell carcinoma) resected from 2010 to 2011 was designated “training set” and the other set of 47 NSCLC WTS (32 adenocarcinoma, 14 squamous cell carcinoma, and 1 pleomorphic carcinoma) resected from 2015 to 2016 was designated “validation set”. We examined PD-L1 protein expression using different antibodies (Clone EI1LN, SP142, SP263 and 22C3) using Ventana XT platform with optiview detection kit for EI1LN, SP142 and SP263, and DAKO link 46 platform with pharmDX kit for 22C3 by immunohistochemical analysis. Staining of tumor cells (Tumor proportion score, TPS) and immune cells were evaluated. Results: PD-L1 protein expression was observed in 18 %, 16%, 11% and 12% of total tumors with EI1LN with Ventana optiview kit (5% cutoff), SP142 with Ventana optiview kit with amplification (1% cutoff), SP263 with Ventana optiview kit (25% cutoff) and 22C3 with DAKO PharmDX kit (50% cutoff), respectively. There was no different positive rate between “training” and “validation” set, which means there was no effect of the age of paraffin block on PD-L1 expression. Regarding staining proportion of tumor cells, 22C3 yields more stained tumor cells (highest TPS) and SP142 consistently labels fewer tumor cells (lowest TPS). Among 38 cases which were positive in one or more assays, 28.9% showed discrepant results for PD-L1 expression between the assays according to each criterion. When the same criterion applied for all assays, discrepant rate is higher (63.1 % with 1% cutoff, 71.0% with 5% cutoff). Conclusion: Although comparative determination of PD-L1 protein levels in NSCLC reveals inter-assay variability of tumor cell staining, positive rate is similar under each criterion. Therefore, there is a potential for different diagnostic results according to the key clinical cut-off if the assays algorithms are mismatched and we should be careful when interpret the PD-L1 expression with different assays.

Characterization of proliferation in multiple T-cell subsets in the CT26 murine colon carcinoma model by multi-color flow cytometry. Matt Thayer, Alden Wong, David Draper, Dan Sains, Scott C. Wise. MI Bioresearch, Ann Arbor, MI.

The efficacy of immune-modulating anti-cancer therapeutic antibodies that have been approved in recent years, such as anti-CTLA-4, anti-PD-1 and anti-PD-L1, has altered the paradigm of cancer treatment. Subsequently, the growing interest in the development of new single agent and combination therapies with immune-modulatory effects has generated a need for more powerful immunophenotyping techniques capable of in-depth cell characterization and proliferation assessment. To this end, using the CT26 syngeneic murine colorectal cancer model we have developed an 8 color flow cytometry antibody panel that focuses on the identification of lymphocyte subsets and analysis of proliferation within them utilizing the high-throughput-capable 4 laser, 14-color Atune NxT Flow Cytometer (Thermo Fisher Scientific). Splenocytes from tumor-naive and CT26 tumor-bearing C57Bl/6 mice were stained with CFSE (carboxyfluorescein succinimidyl ester), an amine-reactive fluorescent dye which enables generational tracking for up to seven rounds of cell division, allowing for proliferation to be quantified. Splenocytes from these mice were then stimulated with anti-CD3, anti-CD28, and IL-2. After stimulation for four days, cells were stained with antibodies against CD45, CD3, CD19, CD49b, CD335, CD4, CD8, and FoxP3. We were able to identify differential proliferative capacity between naive and tumor-bearing mice in CD4⁺ T-cell, CD8⁺ T-cell, CD19⁺ B-cell, and CD11c⁺ DC-cell populations. Furthermore, we show that the analytically-driven approach of analysis is enhanced by the use of fluorescence minus-one (FMO) controls to identify those markers that generate dim signals, as well as a viability dye used to exclude dead cells from analysis. Identification of potentially responsive immune compartments, as well as characterizing proliferation, will facilitate identification and development of potential combination therapies by expanding the depth of our ability to provide mechanistic descriptions of drug function and efficacy. Following this proof-of-concept work, we will also present data from tumor-bearing mice treated with immune checkpoint inhibitors in order to identify potential differences in proliferation after treatment with immune-modulating agents.

In recent years, immunotherapy has seen a resurgence as a promising method of treatment. Programmed Death 1 (PD-1) and its receptor, Programmed Death 1 receptor (PD-1) has been of particular interest. Many different types of tumors have been shown to overexpress PD-L1, which causes host immune cells that express the PD-1 receptor and bind PD-L1 to cease killing the tumor. Patients who have tumors exhibiting high levels of PD-L1 show poor prognosis compared to those who do not. Inhibition of the PD-L1-PD-1 binding axis has been shown to restore host immunity to the tumor, and recently many new drugs such as atezolizumab and pembrolizumab have been developed to target this interaction. Current methods of PD-L1 diagnosis have shown to vary based on the antibody, detection kit brand, antigen retrieval method, and clinically strict defined methods for use by the FDA for assessment. To refine detection of PD-L1, we have identified a PD-L1 specific peptide which can be used to detect PD-L1 expressing tumors using either conventional immunohistochemistry or flow cytometry. Immunohistochemistry using this peptide was tested against the FDA-approved PD-L1 (SP263) Rabbit monoclonal primary antibody on biopsied patient tissues. Flow cytometry was performed on both cultured cells lines and patient tissues. We have shown that our PD-L1 peptide shows specific staining in the tumor regions of FFPE tissues where the SP263 kit does not stain, and we can also detect PD-L1 expression in both cell samples and patient tissues using flow cytometry.

Investigation of T cell activation by anti-human PD-1 antibodies Nivolumab, Pembrolizumab and BGB-A317 using tumor-infiltrating lymphocytes (TILs) from colorectal cancer and colorectal liver metastasis patients. Lusong Luo, Xiaoran Wu, Tong Zhang, Chunyan Fu, Yanjuan Zhang, Amy Guo, Dongping Zhou, Lianhai Zhang, Kun Wang, Baocai Xing, Jifa Li, Lai Wang, Baocai Xing, Beihang University, Beijing, China; Peking University Cancer Hospital Institute, Beijing, China.

Blockade of the PD-1 pathway with anti-PD-1 antibody, such as nivolumab (nivo) and pembrolizumab (pembro), has led to remarkable clinical responses in patients with many different cancer types. In this study, we investigated the activation of tumor-infiltrating lymphocytes (TILs) from patients with colorectal cancer (CRC) and colorectal liver metastasis (CLM) by nivo, pembro and BGB-A317, a novel humanized IgG4 anti-PD-1 antibody under clinical development. BGB-A317 has a unique binding signature to PD-1 with high affinity. Additionally, it is engineered to remove Fc gamma receptor (FcγR) binding, including FcγRI, FcγRIIA, FcγRIIB and FcγRIIIA. In our studies, all three anti-PD-1 antibodies showed significant increases in IFN-γ and TILs proliferation in a 3D tumor spheroid and CLM patient's models. RBB-A317 treatment at concentration levels of 0.1, 1 and 10 μg/mL led to higher IFN-γ production than that in nivo and pembro treated groups. The enhanced TILs function was associated with a high density of CD8⁺ T cells, but inversely correlated with the percentage of CD11b⁺ myeloid cells in CRC tumors. Of interest, BGB-A317 showed better activation of TILs in the liver metastasis tumor microenvironment (TME) where macrophages were more abundant. This observation is consistent with the hypothesis that removal of FcγR binding might offer advantage to PD-1 mAbs in tumor microenvironment enriched with macrophages.

Uncovering novel signaling pathways that mediate tumor cell killing by T effector cells. Thomas Kuilman, David Vredevoogd, Daniel S. Peeper. Netherlands Cancer Institute, Amsterdam, Netherlands.

Recent advances in the understanding of tumor immunology have led to the development of various immunotherapeutic strategies, some of which show unprecedented clinical efficacies. Two of the most effective treatments, ipilimumab and pembrolizumab / nivolumab target the immune checkpoints factors CTLA-4 and PD-1, respectively. While not all patients respond to immunotherapy, those that do frequently show long-lasting clinical responses. These non-responding patients have led to a surge in research focusing on the question how the immune system can be stimulated for more common durable therapy responses. A current focus of tumor immunological research is the identification of mechanisms allowing cancer cells to evade recognition and/or killing by the immune system while facing immunotherapy. For example, abrogation of interferon-γ signaling pathway has been shown to result in escape of immune surveillance after pembrolizumab treatment. However, it is likely that other tumor-cell-intrinsic mechanisms play a role, too. To uncover novel pathways that are involved in resistance to immune checkpoint inhibitors, we aim to identify transcriptional changes in tumor cells that result from effector T-cell exposure. To this end, we established a co-culture platform of a panel of MART1-expressing
melanoma cell lines with primary CD8+ T cells expressing a matching TCR. The cell lines display varying degrees of sensitivity to T cells, allowing us to bioinformatically uncover differential expression depending on this range of sensitivities. Rather than concentrating on single genes, we have focused on pathways, gene sets and ontologies. These analyses have been integrated with various publicly available transcriptomic data sets to identify a set of mechanisms that may contribute to T-cell mediated killing. We will systematically abrogate key factors using CRISPR technology in our co-culture platform and assess whether this affects T-cell mediated killing. Our ultimate goal is to test whether these factors, or their signaling pathways, are involved in resistance to immunotherapy in patients, and to develop new strategies to prevent immunotherapy resistance.

**#5628** Trilaciclib (G1T28), a CDK4/6 inhibitor, enhances the efficacy of combination chemotherapy and immune checkpoint inhibitor treatment in preclinical models. Jessica A. Sorrentino, Anne Y. Lai, Jay C. Strum, Patrick J. Roberts. *G1 Therapeutics, Inc*, Research Triangle Park, NC.

While immune checkpoint inhibitors are efficacious and lead to durable responses in patients with various cancers, only a minority of patients respond. An approach to increase the response rate of immune checkpoint inhibitors is to combine them with chemotherapy in order to enhance immunogenic cell death and "prime" the immune system. However, chemotherapy itself can cause damage to various cell types of the immune system, potentially diminishing the activity of the chemotherapy/checkpoint inhibitor combination. Therefore, a targeted approach to preserve immune system function during chemotherapy would add additional efficacy of the checkpoint inhibitor therapy. Trilaciclib (G1T28), a potent and selective IV CDK4/6 inhibitor, preserves hematopoietic stem cells and enhances immune system function during chemotherapy. We and others have previously shown T lymphocytes are extremely sensitive to CDK4/6 inhibition causing a transient arrest of proliferation and protection from damage by chemotherapy. Post treatment with trilaciclib and chemotherapy, T lymphocytes are released from the transient arrest in the presence of chemotherapy-induced immunogenic cell death allowing better priming of an anti-tumor immune response. To evaluate the effect of trilaciclib combination treatments, MC38 tumor bearing mice were treated with trilaciclib, oxaliplatin, or anti-PD-L1 alone or in combination, and tumor size was measured during and post treatment for 100 days. Our results demonstrate that the addition of trilaciclib to an oxaliplatin/anti-PD-L1 combination (TOP) treatment significantly improves anti-tumor activity. Specifically, twice as many mice treated with TOP for 15 days had a complete response (CRs) when compared to oxaliplatin/anti-PD-L1 (OP); 610 CRs vs 310 CRs, respectively. In addition, the CRs were durable and without any evidence of recurrence at 100 days. Furthermore, TOP treatment caused a 60% increase in overall survival (OS) compared to mice treated with OP; median OS for TOP was 98 days compared to 61 days (HR, 0.53) for the OP treatment group. Assessment of ex-vivo stimulation of cytokine release from harvested spleenocytes to measure T-cell activation, and evaluation of immune infiltrates and T-cell receptor repertoire within the tumors are ongoing. Taken together, we demonstrate that the short-acting IV CDK4/6 inhibitor, trilaciclib, which has been shown to preserve immune function during chemotherapy, enhances the anti-tumor activity of chemotherapy/anti-PD-L1 combination therapy.

**#5629** Modeling cyclophosphamide induced ovarian toxicity in a novel translational canine model. Puja Basu,1 Rebecca Egbert,1 Evan Pasternak,1 Brian Petroff,1 Nucharin Songsasen2.

Reproductive failure following chemotherapy and/or ionizing radiation is a major adverse event, for which there are no established preventive measures. In previous studies, our laboratory has documented that the selective estrogen receptor modulator, tamoxifen (TAM) is effective in both prevention and reversal of ovarian toxicity from cyclophosphamide (CTX) in rodent models. To validate the effectiveness of this approach in a more relevant model system, we have developed a canine ovarian explant tissue model system. Dogs present with many cancers spontaneously and their pathology and treatment approaches mirror those of the human cancers. Thus, canine cancers and their treatments are excellent translational models for human diseases. Furthermore, dogs share the same environment as humans and have longer life spans than rodents. Our laboratory has recently established a dog ovarian explant tissue model system using fresh ovaries collected at the time of ovariohysterectomy. In the current study, we hypothesized that ovarian toxicity induced by CTX will be reduced by co-administration of TAM. Using this system, freshly prepared ovarian cortical tissue sections are cultured in the presence of TAM and CTX. Ovarian tissue viability is assessed by primordial and primary follicle morphology, where the number of primordial and primary follicles were counted in 9 sections of 1 mm² of ovarian cortical tissue from each dog, using CTX (0.1, 0.5, and 1μM) concentrations combined with TAM (0 and 10μM). The number and percentage of each follicle was assessed. In addition, granulosa cells proliferation is assessed using bromodeoxyuridine (BrdU) incorporation. Further, we show that, as in women, anti-mullerian hormone (AMH) may be used as an indicator of follicle response in the dog, thereby establishing the use as an in vivo monitoring system to test ovarian viability in future clinical studies. This study is intended to underpin a subsequent canine clinical trial testing TAM as a co-treatment against infertility from cancer treatment in dogs.

Despite the clinical benefit in treating ER positive breast cancer, hormone therapy resistance occurs in 40% patients leading to disease progression. Steroid receptor co-activator 1 (SRC1) enhances target gene transcription and has a critical role in breast cancer cell tumorigenicity. There is now key evidence that SRC1 is vital to the capacity of hormone-dependent tumors to adapt and overcome targeted therapy. Utilizing a genome wide CRISPRi genome sequencing of breast cancer patients and models, this study aimed to define the programs of SRC1 controlled transcriptional networks, identifying both interacting partners and downstream transcription factor (TF) targets that mediate the treatment resistant phenotype. RIME uncovered novel SRC1 interacting partners (including STAT1, PRMT1, and HDAC2) and associated TF partner networks in the hormone treatment resistant LV2 cells. In parallel, RNAseq of LV2 with SRC1 stable knockdown revealed SRC1 regulated transcriptome networks identifying 1731 up regulated genes, including 153 TFs. SRC1 cistrome, characterized by ChiP-seq analyses was combined with motif binding analysis, to further validate 40 TFs directly regulated by SRC1 and its interaction network. Dependence on SRC1 was confirmed through SRC1 siRNA and CRISPR validation. Upon this discovery, validation and functional interrogation studies we identified a cadre of 4 TFs including E2F7, DEK, TRPS1 and SMARCA1 that execute SRC1 role in hormone treatment resistance. Functional analysis of this 4 gene TF network found it to be co-operating as a driver of hormone resistant cell by coupling activation of motility with stemness. TFs can reprogram resistant cells by reversing differentiation as demonstrated in the mammosphere, 3D acinar assays and CD24/44 flow cytometry analysis. This TF gene set is a signiﬁcant predictor of poor recurrence free survival in hormone treated patients, supporting its role in increased metastatic risk in breast cancer and the clinical relevance of our ﬁndings. Furthermore, in an ER+ve PDX, established from resistant and treatment naive patient, protein expression of the TF network members co-expressed with SRC1 and were only found in the hormone treatment resistant PDX models. This study highlights SRC1 regulated disease progression and hormone treatment-resistant disease. Identified SRC1 interactome and its regulated transcriptome are active independent of its ER co-activator role. The SRC1 mediated TF network is involved in reprogramming of resistant cells, whose concerted activity is responsible for driving dedifferentiation of cells and enhancing their stem like and highly migratory tumor initiation population. This work provides key evidence on the mechanism of resistance in ER+ve hormone resistant cancer and has substantial implications both for the treatment of hormone dependent breast cancer and for identifying the mediators of metastatic potential.

**#5632** Thyroid carcinoma in The Sudan. Mohamed ElMakki Ahmed. *Univ. of Khartoum Faculty of Medicine, Khartoum, Sudan.*

Introduction: Goiter is endemic in Sudan and thyroidectomy is a daily practice in most surgical lists across the country. The most common indications are cosmones and pressure with respiratory choking. In 10% of cases a surprise histopathology on cancer is reported. This study aims to report on thyroid carcinoma on patients presenting to the surgical department in Khartoum Teaching Hospital. Methods: This study is an overview on pattern, clinical presentation a management of thyroid carcinoma in Khartoum during the period 2007 - 2014. Thyroidectomy was the standard procedure when feasible and postoperative radio iodine given. External radiotherapy was given in aggressive anaplastic carcinoma. Results: 166 patients with thyroid cancer were studied. The mean age was 51 +/- 17yrs and the age range between 15 - 85 years. Male to female ratio was 1.02:1.4. Clinical presentation was a goiter that was showing a
recent rapidly growth with either respiratory choking, pain and dysphagia. Fol-
licular carcinoma was 43%; papillary 27%, anaplastic 10% 2%medulillary. Sar-
coma and lymphoma 5% and missing data in 13%. Six per cent of patients pre-
presented with lung and bone metastasis. 20 patients had long standing goiter
before development of cancer. Different types of total thyroidectomy done in
81%, no operation done in 16% and missing data in 3%. Among patients with
active tracheotomy, 7 developed permanent hypocalcaemia, 15 recurrent nerve
palsy and a 30 days mortality was 10% and all were anaplastic carcinoma where
recurrence occurred within weeks following thyroidectomy or dubbing in most
cases. Conclusion: Patients with thyroid cancer presents late. The dominance of
follicular type indicates the significance of underlying endemic goiter in its eti-
ology. Anaplastic is very aggressive and lethal outcome.

#5633 Unique modulation of estrogen-induced apoptosis with structural
analogue of endoxifen in long-term estrogen-deprived (LTED) breast can-
cer cells. Balkees Abderrahman,1 Sean W. Fanning, 2 Daniela Quintana Rincon, 1
Geoffrey Greene, 1 Philip Y. Maximov, 1 V. Craig Jordan1. 1UT MD Anderson Cancer Center, Houston, TX; 2University of Chicago, Chicago, IL.
Endoxifen, a non-steroidal anti-estrogen is the active hydroxylated metabo-
lite of N-desmethyltamoxifen. The structure is based on a synthetic triphenyl-
ethene-type angular estrogen. Endoxifen is in clinical trials as a therapeutic
agent to treat aromatase resistant breast cancer. Paradoxically, LTED breast
 cancer is known to respond to synthetic and natural estrogens through estrogen-
induced apoptosis. A series of synthetic endoxifen analogs, were used to modu-
late estrogen-induced apoptosis in LTED breast cancer cells (MCF7/3C). X-ray
crystallography was performed on endoxifen, bisphenol, and diethylstilbestrol
(DES), bound to the ligand-binding domain (LBD) of the human estrogen re-
ceptor (ER). Cellular studies established that (MCF-7/3C) of estrogen-induced
apoptosis was dependent on the LBD of the ER. Similarly, endoxifen blocked
estrogen-induced apoptosis in a concentration and time-dependent manner.
Apoptosis triggered by DES was blocked by endoxifen and was ER-dependent.
X-ray crystallography of both endoxifen and DES illustrate the two extremes of
estrogen-induced apoptosis, which is dependent upon the closure of helix 12
over the LBD to generate estrogenic activity. Despite the fact that bisphenol,
an analog of endoxifen without the anti-estrogenic monomethylamino ethyl side
chain, is an estrogen that causes breast cancer cell replication; bisphenol initially
inhibits estrogen-induced apoptosis, but triggers estrogen-induced apoptosis
itself after 7 days of treatment of LTED breast cancer cells. X-ray crystallography
demonstrates that bisphenol can produce a unique complex with the ERLBD,
which is similar to the DES-LBD estrogenic complex. In both cases, the ligands
are sealed into the LBD by helix 12. This delay in apoptosis caused by an analog
of endoxifen, that is an angular estrogen, possess unique biological features. We
hypothesize that in LTED cells the complex passes through an anti-estrogenic
conformation to evolve into an estrogenic complex with helix 12 sealing the
LBD. We describe a unique property of a ligand-receptor complex. For the first
time we demonstrate that a ligand:receptor complex is slowly activated from
an antagonist to an agonist complex over a period of days.

#5634 Characterization of molecular mechanisms of cytoplasmic traffick-
ing and nuclear translocation of AR splice variants ARv7. Eiman Mukhtar,
Seoho Kim, Parakovi Giannakakou. Weill Cornell Medical College - Cornell
University, New York, NY.
Androgen receptor (AR) signaling is critical to not only hormone-sensitive
but also advanced castration-resistant prostate cancer. AR inhibitors (abi-
ratone and enzalutamide), the next generation of androgen deprivation ther-
apy (ADT) have been used for metastatic castration-resistant PC (mCRPC)
treatment, however, the majority of patients progress due to the development of
drug resistance. AR variants has emerged as one of the mechanisms of resistance
to these drugs. ARv7 and ARv567 splice variants that found lacking the ligand-
binding domain are constitutively active in the nucleus and thus restore AR
function despite AR inhibitors treatment. We have reported that microtubules
and dynein motor protein is required as transportation system for AR for its
nuclear translocation and activity and that taxanes inhibit AR signaling down-
stream of microtubule inhibitors. In addition, we identified that the AR hinge
region mediates binding to microtubules is present in ARv567 but missing from
ARv7. ARv7 is expressed in about 60% of CRPC patients and has been shown to
confer clinical resistance to next generation AR signaling inhibitors. Currently,
there is no therapeutic modality targeting specifically ARv7 expression or func-
tion. Using fluorescent recovery after photobleaching experiments (FRAP) we
have shown that ARv7 translocation to the nucleus occurs much faster than
AR-FL (t1/2 11s and 23 s respectively) and that its nuclear import is independent
of the importin a/b pathway utilized by AR-FL and proteins with canonical NLS.
Furthermore, transient expression of the Q69L RanGTP mutant protein, which

acts as dominant negative by occluding the nucleoporins, had minimal effect on
ARv7 nuclear import, while it completely blocked AR-FL and AR-v567. Collect-
ively, these data suggest that the nuclear import pathway for ARv7 is distinct
from that utilized by AR-FL. We believe that ARv7 undoubtedly uses facilitated
transport because of its size (75 kDa), therefore we are tackling three possibilities
of ARv7 nuclear targeting. Further, ARv7 could interact with FRAP repeat nucleoporins
(without receptor) as reported for beta catenin. We are investigating this by the use of importin B-7(1-876) mutant cell line for in vitro
studies which blocks all members of the importin family. In addition, we are
investigating the role of karyopherin transport receptors by individual knock-
down experiments coupled with live cell imaging and kinetic quantitation of
ARv7 nuclearcytoplasmic trafficking. Further, ARv7 could interact with nuclear
by utilizes a piggyback on another protein with a classical nuclear localization
signals. Overexpression of glutathione S-transferase- importin B binding do-
main fragment which will block all importin B pathways will exclude this mech-
anism. Elucidation of this mechanism will be vital to facilitate design an alter-
native therapeutic modality to halt AR signaling for CRPC treatment.

#5635 Vitamin D supplementation decreases serum 27-hydroxylaco-
terol and expression of CYP27A1 in tumors of breast cancer patients. Cat-
hrine Geising, 1 Ludmila Alexandrova, 2 Ken Lau, 1 Christine Yeh, 3 Melinda Telli, 1
Kristin Jensen, 1 David Feldman, 1 Sharon Pitteri. 1Stanford University School
of Medicine, Palo Alto, CA; 2Vincent Coates Foundation Mass Spectrometry Lab-
atory, Stanford University, Palo Alto, CA.
The goal of this study was to investigate whether vitamin D regulates the con-
version of cholesterol to 27-hydroxycholesterol (27HC), an endogenous se-
lective estrogen receptor modulator (SERM) that can act as a driver of estrogen
receptor positive (ER+) breast cancer, particularly in post-menopausal women
with low circulating estrogen levels. The hypothesis of this study was that the
active metabolite of vitamin D, calcitriol, can inhibit expression of CYP27A1,
the synthesizing enzyme for 27HC, thereby decreasing the concentration of
27HC in the blood. Both 27HC and 25-hydroxyvitamin D (25OHD) were quan-
tified by LC-MS/MS in the serum of 29 breast cancer patients, 26 of which had
ER+ cancer, pre- and post-treatment with either a low dose (control) of 400 IU
vitamin D or a high dose of 10,000 IU vitamin D per day during the neoadjuvant
period, which ranged between 7 and 37 days. In addition to these blood samples,
tissue biopsies pre-treatment and the excised tumor collected post-treatment
were tested for gene expression by microarray analysis. A significant increase
(p = 4.3E-5) was observed in serum 25OHD for patients who received the high
dose vitamin D compared to those who received the low dose, whose 25OHD
values remained stable. A greater decrease (p = 1.7E-1) was observed in serum
27HC for the high dose group compared to the low dose group, with greater
decreases in 27HC on average for those with larger increases in 25OHD concen-
tration. Gene expression showed a decrease (p = 4.5E-1) in breast cancer tissue for the high dose group compared to the low
dose group, with greater decreases in expression observed for patients on
high dose vitamin D treatment for longer times. These preliminary data show
good evidence that high dose vitamin D supplementation can decrease 27HC
levels in the body by inhibiting expression of CYP27A1 and that the longer this
administration, the greater the effect. While larger scale studies are needed, the data in
this study point to vitamin D supplementation as a possible simple method for
inhibiting ER+ breast cancer growth and suggests this reduction in CYP27A1
expression as an additional pathway by which vitamin D can mitigate risk and
improve outcomes for ER+ breast cancer patients.

#5636 Targeting of NOXA overexpression in anaplastic thyroid cancer
(ATC). Niklas K. Ffinnberg, Junaid Abdulghani, Hormoz Ehya, Wafik El-Deiry.
Fox Chase Cancer Center, Philadelphia, PA.
Anaplastic thyroid cancer (ATC) is a rare, aggressive and fatal cancer with a
median survival of 3-5 months after diagnosis. Our long-term goal is to develop
better therapies based on the biology of ATC that contributes to improved tu-
mor response and a reduced risk of potential side-effects. We recently showed
that the greater the expression of NOXA, the greater the survival advantage. We
tested for gene expression by microarray analysis. A signifıcant increase
expression by, contrast, is low. NOXA protein has previously been
shown to be subject to ubiquitination and proteasomal degradation. Indeed,
through bioinformatica, we find overexpression of several ubiquitin enzymes in

Cancer Research • Volume 58 • April 2017
1493

Proceedings of the American Association for Cancer Research
ATG suggesting that the half-life of NOXA protein may be selectively reduced in this tumor type. We are further assessing differences in the turnover of NOXA protein in ATC cells and are investigating if restoring NOXA protein expression may synergize with the pharmacologic targeting of MCL1 and other anti-apotptic BCL2 family members. Interestingly, through TCGA analysis, we discovered that expression is associated with a poor prognosis in thyroid cancer (THCA) patients. Indeed, treatment with the BCL2/BCLXL inhibitor navitoclax showed encouraging efficacy and synergized with the neddylation inhibitor MLN4924 in the ATC cell line 8505C. This was based on the expectation that MLN4924 would rescue NOXA protein expression. We are pursuing mechanistic studies in a larger panel of thyroid cancer cell lines and in vivo efficacy and toxicity studies. We conclude that restoring NOXA protein expression may together with the rational targeting of anti-apoptotic BCL2 family members may allow for the expansion of the limited ATC-selective treatment strategies currently available.

#5637 An oral Androgen Receptor PROTAC degrader for prostate cancer. Taovi K. Neklela,1 Lawrence B. Snyder,1 Mark Bookbinder,1 Xin Chen,1 Andrew P. Crew,2 Craig M. Crews,3 Hanqing Dong,1 Deborah Gordon,1 Jennifer Ma-caluso,1 Kanak Raina,1 AnnMarie Rossi,1 Ian Taylor,1 Nicholas Vitale,1 Jing Wang,1 Ryan R. Willard,1 Kurt Zimmermann1. 1Division of Cell Pathology, Lund University, Malmö, Sweden; 2Department of Transla-tional Medicine, Division of Pathology, Lund University, Malmö, Sweden; 3Department of Clinical Sciences, Division of Surgery, Lund University, Malmö, Sweden. 1

INTRODUCTION AND OBJECTIVES: Modulating the activity of eukary-otic elongation factor 2 kinase (eEF2K) has been suggested to regulate protein elongation to block autophagy in the tumor microenvironment. Among inhib-itors of eEF2K, one would also inhibit VPS34, a class III phosphatidylinositol-3 kinase, and abrogate autophagic flux to impair the survival escape mechanism. We tested the eEF2K and VPS34 inhibitors from Janssen alone or in combina-tion with anti-androgens for their effect on proliferation of prostate cancer cell lines, especially some castration resistant PC (CRPC) lines. MATERIALS AND METHODS: Cell proliferation was assessed with various concentrations of the eEF2K or VPS34 inhibitor on CRPC lines using WST-1 viability assay. Effect of combinations of eEF2K or VPS34 inhibitor with anti-androgens abiraterone (Abi) or enzalutamide (Enza) on drug-resistant CRPC cells was further ex-plored. Western blot analysis was performed to examine the response of key autophagic molecules, androgen receptor (AR) and variant. Real time RT-PCR (RT-qPCR) was used to elucidate the effect of eEF2K or VPS34 inhibitor alone or together with anti-androgens on AR, AR variant and their downstream mole-cules. RESULTS: eEF2K and VPS34 suppressed CRPC cell growth in a dose-response manner with IC50 ranging from 1 to 5 μM. These inhibitors displayed synergy with Abi and Enza against drug-resistant CRPC cells, espe-cially on the pair of enza + EF2K inhibitor with p = 0.02 for significant differ-ence when compared to enza or EF2K inhibitor alone. To our surprise, no sig-nificant autophagy was induced by these two inhibitors according to the autophagy markers detected by Western blots. VPS34 inhibitor alone and when combined with Abi and Enza showed AR/variant degrading ability. This down-regulation was at the expression level with significant change of AR and V7, together with their transactivation markers PSA, TMPRSS2, NKx3.1 and FKBPs 25 and 27. When combined with anti-androgens may solicit profound inhibitory effect on drug-resis-tant CRPC cells. Molecular delineation demonstrated the direct target might be AR and its variants. These combinations offered a new therapeutic option for advanced PC treatments.

#5639 Diagnosing indeterminate thyroid nodules: combining next gen-eration sequencing and gene expression analysis. Vivian L. Weiss,1 Robert Daber,2 Michael Moreau,2 Alisa Gaskell,2 Kim Ely,1 Alice Coogan,1 Thomas Stricker1. 1Vanderbilt University Medical Center, Nashville, TN; 2Bio-Reference Laboratories Inc., NJ. Thyroid nodules are common in the United States and are currently diag-nosed using fine needle aspiration (FNA) biopsy. FNA evaluation provides a definitive diagnosis in the majority of cases, but about 20-30% of nodules are deemed indeterminate. Targeted next generation sequencing (NGS) and gene expression analysis have been used as ancillary tests to provide additional information about the malignancy risk for indeterminate thyroid lesions. Here we develop a 31 gene NGS panel, as well as a 14 gene expression panel, and test their performance on thyroid lesions with known diagnosis. Formalin-fixed paraffin tissue from 23 rejected thyroid lesions (1 non-neoplastic, 3 follicular adenoma (FA), 1 medullary carcinoma (MC), 7 follicular carcinomas (FC), 3 papillary carcinomas (PC), 4 follicular variant of papillary carcinomas (FVPC)) was evaluated. Total nucleic acid extraction, NGS (31 genes including: NRAS, HRAS, KRAS, CTNNB1, PIK3CA, BRAF, RET, PTEN, AKT1, PTEN, FGNA, ALK, DDR2, EGRF, ERBB2, FGFR1/2/3, GNA11, GNAQ, IDH1/2, KIT, MAP2K1, MET, MTROR, NOTCH1, PDGFRα, EPHA2, ERβ1, RAC1, and ROS1) through Bio Reference Laboratories, and gene expression analysis (15 genes: KRT7, TTF-1, TG, PGK-1, CK-20, PTH, CALC, RAP2A, PLAB, HMGA2, FN-1, GAL-3, CK19, and NIS) were performed. This assay detected mutations in 14/19 malignant lesions including 4/7 FCs (NRAS, TP53), 4/4 FCs (BRAF, HRAS, NRAS, PTEN), 5/7 PCs (BRAF, NRAS), and 1/1 MC (RET). No mutations were detected in the non-neoplastic thyroid and 1/3 FAs contained a KRAS mutation. All three mutation-negative FCs were oncogenic variants and showed upregulation of ≥2 cancer-associated genes including FN-1, GAL-3, HMGA2, PLAB, and RAP2A. The two mutation-negative PCs showed upregulation of 4 cancer-associated genes including FN-1, CK-19, HMGA-3, GAL-3, and HMGA2. This upregulation was not seen in non-neoplastic thyroid and was seen in only 1 of the 3 FAs (FN-1, GAL-3, and PLAB). This small study demonstrates that a combination of NGS and gene expression increases the assay sensitivity (100% versus 74% sensitivity) and negative predictive value (100% versus <45% for NGS or gene expression alone). The positive predictive value of the combined assay was 90% versus 93% for either assay alone. The addition of gene fusions will likely further improve the assay’s diagnostic capacity. In conclusion, the addition of a gene expression assay to this thyroid NGS panel will more accurately identify the indeterminate status of thyroid nodules. The improved detection of malignant thyroid lesions will allow for better risk assess-ment for indeterminate nodules as well as improved treatment algorithms.

#5640 The prognostic role of estrogen receptor beta in a female cohort of colorectal cancer. Gerolda Topi,1 Roy Ehrnström,1 Ingrid Palmquist,2 Marie-Louise Lydstrøp,2 Anita Sjölander1. 1Department of Translational Medicine, Divi-sion of Cell Pathology, Lund University, Malmö, Sweden; 2Department of Transla-tional Medicine, Division of Pathology, Lund University, Malmö, Sweden. 1 Background: The estrogen receptor beta (ERβ) is the predominant estrogen receptor in the colon mucosa, and has been reported to have anti-proliferative and pro-apoptotic effects. However, the role of estrogen signaling in colorectal cancer (CRC) progression remains unclear. Aim: To investigate the prognostic role of ERβ in a female cohort of CRC. METHODS: A tumor tissue microarray of primary CRCs from 333 female patients was stained with a mouse monoclonal anti-ERβ antibody. The intensity of staining was evaluated using immunohis- tochemistry technique. The expression of ERβ was scored using the semi-quantita-tive method (IRS (immunoreactive score) = SI (staining intensity) × PI (percentage of positive nuclei)). Overall survival (OS) and disease-free survival (DFS) were the primary outcomes. Preliminary results are presented. Results: From 321 patients eligible for survival analysis only 315 had successful measure-ment of ERβ (141 with low expression and 174 with high expression). The
univariate analysis showed no effect of ERβ on OS, but high ERβ was associated with lower risk of cancer recurrence as indicated by DFS (HR: 0.61; CI: 0.38-1.02). Cox multivariate analysis indicated that, compared to low expression, high expression of ERβ was significantly associated with a decreased risk of cancer recurrence (HR: 0.39; CI: 0.20-0.77), after adjustment for age, tumor stage, tumor size, tumor growth, and menopause status. A possible explanation could be that most of the rectal cancer patients have undergone radiotherapy before surgery, which might affect the status of ERβ.

#5641 Effects of G1T48, a novel orally bioavailable selective estrogen receptor degrader (SERD), and the CDK4/6 inhibitor, G1T38, on tumor growth in animal models of endocrine resistant breast cancer. Suzanne E. Wardell,1 Alexander P. Villanés, Jennifer G. Baker, Robert M. Baldi,2 Taylor K. Krebs,2 Jessica Sorrentino,2 John Bisi,2 Jay Strum,2 John D. Norris1.1 Duke University, Durham, NC; 2G1 Therapeutics, Research Triangle Park, NC.

Background: The combination of targeting the CDK4/6 and ER signaling pathways with palbociclib and fulvestrant is a proven therapeutic strategy for the treatment of ER positive breast cancer. However, the poor physicochemical properties of fulvestrant require monthly intramuscular injections to patients, which limit the pharmacokinetic and pharmacodynamic activity of the compound. Therefore, an orally available compound that more rapidly reaches steady state may lead to a better clinical response in patients. Here we report the preclinical characterization of G1T48, a novel, orally bioavailable, non-steroidal small molecule inhibitor of ERα, which is a potent, selective antagonist that down regulates ERα in vitro and vivo in ER-positive models of breast cancer.

Methods: Breast cancer cells expressing clinically relevant ESR1 mutations (ER-Y537S, ER-D538G) were treated with G1T38, G1T48, and mechanistically distinct SERMs/SERDs and cellular proliferation was assessed by measuring DNA content (Hoechst dye). Overexpressed nnu/nnu mice bearing xenograft tumors of clinically relevant tamoxifen (TamR) and aromatase (long term estrogen deprived) resistant ER+ breast cancer were treated with G1T38 and G1T48, alone or in combination, with clinically relevant comparators. Time to progression and tumor volume were assessed over a 4 week dosing period. Results: G1T38 and G1T48 significantly inhibited cellular proliferation of MCF7 breast cancer cells bearing endocrine resistant ER mutations, ER-Y537S and ER-D538G. G1T48 treatment led to dramatic reductions in ER protein levels. Importantly, tumor growth inhibition was observed in mouse models of sensitive and resistant human breast cancer when G1T48 was dosed as a single agent or in combination with G1T38, a potent, selective CDK4/6 inhibitor. Conclusions: G1T38, a novel CDK4/6 inhibitor, and G1T48, a novel SERD, either alone or in combination, demonstrated highly potent inhibition of tumor growth in animal models of tamoxifen and aromatase resistance. G1T48 also demonstrated activity in models of endocrine resistance mediated by ER mutation. G1T48 is currently completing IND enabling studies.

#5642 Quantitative comparison of hydrocortisone and prednisone in the postoperative hormone therapy of hypercortisolism. Kunlong Tang,1 Yuting Huang,1 Shangdong Dong,1 Peng Gao,2 Tianjin Medical University General Hospital, Tianjin, China; 2Tianjin Medical University Cancer Institute and Hospital, Tianjin, China.

Tumors and several types of malignancies including lung cancer, pancreatic cancer, pituitary tumor, and most often adrenal adenoma, may cause hypercortisolism, which requires glucocorticoid (GC) replacement following adrenalectomy and/or surgical resection of the tumor. Based on our previous report of a simplified GC therapy scheme and the perioperative observation, we further investigated its efficacy and safety up to 6 months post-surgery in this retrospective cohort study. All patients received no GC before surgery. The i.v. doses of hydrocortisone (HC) were 100 mg during surgery, 100 mg bid on day 0 and day 1, followed by 100 mg qd on the morning of day 2 post-surgery. Patients were grouped by oral reception of either HC or prednisone since day 2. The doses and the withdrawal schedule are shown in Table. We found in adrenal adenoma patients, the adrenocorticotrophic hormone (ACTH) levels were normal, and sufficient to stimulate the recovery of the dystrophic adrenal cortex, thus exogenous supplemental ACTH might not be necessary. By 6 months post-surgery, prednisone and HC exhibited similar efficacy in correcting hypertension, hyperglycemia, and hypokalemia (p>0.05). Most patients lost weight. Both groups reported significant improvement in a subjective evaluation questionnaire. HC showed advantages over prednisone in improving liver function (p=0.035), but also caused significant leg edema (p=0.034). Both groups developed adrenal insufficiency (AI) during GC withdrawal, with no significant difference regarding the incidence rate or severity. Most AI symptoms were relieved by resuming the prior oral doses, while the severe cases were treated in hospital. No particular variable was identified as risk factor for AI. The withdrawal process may last longer time for HC than prednisone. HC may be prioritized for patients with hyperglycemia or abnormal liver function, while prednisone may reduce the incidence of leg edema.

#5643 Physical and functional interactions of exon-skipping variants of androgen receptor with the full-length counterpart. Takuma Uo,1 Cynthia C. Sprenger,1 Shihua Sun,1 Robert K. Bradley,2 Peter S. Nelson,3 Stephen R. Plymale,4 Univ. of Washington Medical Ctr., Seattle, WA; 2Fred Hutchinson Cancer Research Center, Seattle, WA.

The androgen receptor (AR) is arguably the critical driver of not only early but also advanced prostate cancer. The recent comprehensive splicing landscapes revealed that metastatic castration resistant prostate cancer harbors multiple forms of AR variants (AR-Vs), many of which have diverse patterns of inclusion/exclusion of exons (E4-E8) corresponding to the ligand-binding domain. We had used AR-negative M12 prostate cancer cell line and recently reported characteristics of AR-Vs with respect to their subcellular localization and transcriptional activation on luciferase reporter driven by probasin-based promoter (AR2PB-luc)(1). While ARVs6es is predominantly nuclear and constitutively active like well documented ARV5es (v7es and v6es), many of others are castration –induced variants that are inactive. As many AR-Vs and the full-length AR (AR-FL) are co-expressed in the same cell, it is important to determine how these inactive AR-Vs interact with active AR including AR-FL. To this end, we examined two inactive AR-Vs namely v7es and v6es in relation to AR-FL. ARV7es, which skips exon 7, is predominantly localized in cytoplasm. ARV6/7es physically interacted with AR-FL. Moreover, nuclear accumulation of ARV7es was promoted by the addition of 17α-androstenediol hydrocarboxylic acid (DHT) only in the presence of AR-FL, suggesting that ARV7es and AR-FL heterodimerize in the nuclear compartment. However, DHT-dependent transactivation of AR-FL was not affected by the presence of ARV7es. More specifically, in M12 cells, AR2PB-luc was transactivated by AR-FL to the similar extents either in the presence or absence of ARV7es. In addition, in doxycycline (Dox)-inducible ARV7es stable LNCaP cell line (LNCaP/ARV7es), the presence of ARV7es did not affect DHT-induced expression of endogenous PSA and NKKX3.1 transcripts as well as transactivation of AR2PB-luc. In the similar setting, when we examined ARV5es6es which also physically interacted with AR-FL, Dox-induced expression of ARV5es6es in LNCaP/ARV5es6es was sufficient to induce expression of endogenous PSA and NKKX3.1 transcripts. Further, DHT-induced expression of these transcripts was enhanced by ARV7es6es in LNCaP/ARV5es6es. Accordingly, we propose that AR-Vs display differential modes of action on AR-FL as exemplified by ARV7es as the bystander and v6es6es as the effector. 1. Oncogene (PMID: 27694897).

#5644 The emergence of resistance to tamoxifen in relation to menopausal status, HER-2 status, status of steroid receptor and lymph nodes metastases status. Sima Maksimovic,1 Suzil Health Institute Hospital 'Sveti Vračev' in Bijeljina, Bijeljina, Bosnia and Herzegovina.

Background: The study used data from medical and counselling of patients who were diagnosed with hormone-dependent breast cancer. Aim: The objective of the paper is to identify within a group of patients diagnosed with hormone
sensitive breast cancer and those who have received adjuvant tamoxifen, and then to isolate the patients with whom the therapeutic effect of tamoxifen stopped. Methods: The study analyzed 153 patients in the period from 2005 to 2011, at the Public Health Institution Hospital, Sveti Vračevi in Bijeljina. Resistance to tamoxifen was developed by 60 patients (39.2%) and 93 patients (60.8%) did not develop resistance to it. Results: It was observed a statistically significant difference in frequency of resistance to tamoxifen was observed in the group of patients with ER/PgR+ status of steroid receptors (p<0.001). In relation to HER-2 status of diagnosed cancer, a statistically significant difference in frequency of resistance emergence during tamoxifen therapy in patients with HER2-positive status (p<0.001) was observed. We found that there is a statistically significant difference between patients with metastatic in lymph nodes compared to patients who had no metastases in lymph nodes (X2=39.494; p<0.001). Conclusions: The analysis of menopausal status of patients, status of ER/PgR receptors status, HER-2 status of diagnosed cancer and status of lymph nodes trying to sort out the parameters on the basis of which a group of patients who can be expected to develop resistance to tamoxifen could be differentiated.

**#5645 Associations between biomarkers and outcome in a patient cohort with invasive lobular carcinoma.** Rachel C. Jankowitz,2 Kevin Levine,1 Maryam Zamanian,1 Matthew Sikora,2 Nilgun Tasdemir,1 Priscilla McAluriff,1 David Dabbs,3 Nancy Davidson,1 Brenda Diergaarde,1 Steffi Oesterreich1.

**#5646** Germline activating mutations in the proto-oncogene GCM2 in primary hyperparathyroidism. Bin Guan,1 James M. Welch,1 Julie C. Sapp,3 Hua Ling,3 Meghana Vemulapalli,1 Yulong Li,1 Jennifer J. Johnston,1 Electron Kebebew,1 Leslie G. Biecker,1 William F. Simonds,1 Stephen J. Marx,1 Sunita K. Agrawal,1 \*NII. Bethesda, MD;2Johns Hopkins University, Baltimore, MD; and 3Boston Medical Center, Boston, MA.

Primary hyperparathyroidism (PHPT) is a common endocrine disease caused by parathyroid tumors (adenoma or hyperplasia). The hypersecreting parathyroid tumor elevates serum parathyroid hormone level, which causes hypercalcemia and the classical symptoms of PHPT, including kidney stones, osteoporosis, and neuromuscular symptoms associated with hypercalcemia, such as muscle weakness, drowsiness, and depression. Familial PHPT occurs in an isolated nonsyndromal form, termed familial isolated hyperparathyroidism (FIHP), or as part of a syndrome, such as multiple endocrine neoplasia type 1 or hyperparathyroidism-jaw tumor syndrome. We performed exome sequencing on germline DNA of eight index cases from eight unrelated kindreds with FIHP. Rare variants were identified (minor allele frequency <1%), and selected variants were assessed for co-segregation in affected family members by Sanger sequencing. Candidate genes were then screened in an additional 32 kindreds with FIHP. The functional consequence of variants in one FIHP candidate gene (GCM2, a parathyroid tissue-specific transcription factor) was analyzed in a cell culture model. In eight kindreds with FIHP, we identified three rare GCM2 missense variants. Functional characterization of GCM2 variants and deletion analyses revealed a small C-terminal Conserved Inhibitory Domain (CCID). Two of the three rare variants were recurrent, located in the CCID that enhanced the transcriptional activity of GCM2, and found in seven of 40 (18%) kindreds with FIHP. Functional assays for transcriptional activity demonstrated that these two variants were gain-of-function mutations, suggesting that GCM2 is a parathyroid proto-oncogene. We further investigated the ethnicity of individuals with GCM2 CCID activating variants in PHPT patient samples and in genome survey datasets. Our results demonstrate that germline activating mutations in the GCM2 CCID can cause FIHP, and specific activating mutations expose a large population at risk for PHPT. Our findings for the first gene with mutations specific for FIHP are expected to have an important impact on clinical practice, including treatment decisions and genetic testing of individuals with PHPT and family members.

**#5647** Intron retention as a novel source of tumor neoantigens associated with response to checkpoint inhibitor therapy. Alicia C. #5648 Combined immune checkpoint targeting with anti-PD-1 plus anti-CD40 antibodies as the most effective approach to eradicate head and neck squamous cell carcinomas (HNSCCs) in mouse models. Jose Augusto Monte de Oliveira Novaes, Alissa R. Poteete, Marlesse A. Pisegue, Uma Giri, Fahao Zhang, Patrick Hwu, John V. Heymach, William N. William. The University of Texas MD Anderson Cancer Center, Houston, TX, USA.

Introduction: Immunotheapy with single agent anti-PD-1 antibody confers modest overall survival benefits in patients with recurrent/metastatic HNSCCs. Combined immune checkpoint targeting has shown promising results for melanomas and other solid tumors. Thus, evaluation of combination immunotherapies in animal models specific to HNSCCs could inform prioritization and design of future clinical trials for this disease. We conducted this pre-clinical study to test the hypothesis that combining anti-PD-1 with either anti-CTLA-4 or co-stimulatory immune checkpoint agonist antibodies would be more effective than anti-PD-1 monotherapy in a mouse model of oral carcinoma. We also aimed at identifying the combination regimen with highest anti-tumor activity. Methods: CS7BL/6 mice were subcutaneously grafted with 2106 mouse oral cancer 1 (MOC1) cells derived from a carcinogen-induced tumor molecularly similar to human HNSCC. After 25 days, mice were randomized into one of 12 treatment groups (IgG, or antibodies targeting PD-1, CTLA-4, CD40, OX-40, GITR, 4-1BB, PD-1+CTLA-4, PD-1+CD40, PD-1+OX-40, PD-1+GITR, or PD-1+4-1BB), N=8-9 mice/group. Antibodies were administered every 4 days for 3 doses. Tumors were measured twice per week. The primary endpoint was overall survival. Mice bearing tumors >3 mm2 in diameter (at ulceration) were used in the study. At the end of the study, tumors were harvested and stained for CD45+ cells by flow cytometry. Results: In a preliminary human clinical trial, anti-PD-1 therapy led to a modest improvement in survival compared to IgG [HR=0.41; 95%CI 0.06-0.53; P=0.015], indicating that this model recapitulates, in part, the effects of immunotherapies in HNSCC patients; none of the animals survived long term. Monotherapy with anti-CTLA-4, anti-CD40, anti-OX-40, or anti-4-1BB also improved survival compared to IgG (P=0.0001, 0.003, 0.02, and 0.003, respectively), but were not more effective than anti-PD-1 alone (P=0.09, 0.12, 0.72, and 0.77, respectively). Combination therapy did not prolong survival compared to anti-PD-1 alone, with the exception of anti-PD-1+anti-CTLA4 [HR=0.36; 95% CI 0.07-0.6; P=0.016], and anti-PD-1+anti-CD40 [HR=0.125; 95% CI 0.02-0.24; P=0.0003]. Notably, 50% of mice receiving anti-PD-1+anti-CD40 antibodies had complete tumor eradication and are alive and disease-free 120 days after tumor grafting. Conclusion: Single immunotherapeutic targeting PD-1, CTLA-4, CD40, OX-40 and 4-1BB modestly improved survival in a mouse model of oral cancer. Combination with anti-PD-1+anti-CTLA4 and anti-PD-1+anti-CD40 antibodies outperformed anti-PD-1 monotherapy. Complete responses were exclusively seen with PD-1+CD40 dual targeting. This regimen should be prioritized for evaluation in HNSCC clinical trials.

Tumor initiating cells (TIC) foster treatment resistance and tumor relapse. We show here that in mouse B16 (melanoma) and ID8agg (ovarian carcinoma), and human ovarian cancer ES2, PD-L1 knockdown (shRNA) reduced TIC numbers and functions. Data shown are from 2 PD-L1sh clones/cell type. Sorted control CD44+CD133+CD24- (B16), CD44+CD24+ (ID8agg) and ALDH+ (ES2) TIC formed 50-73% more and bigger spheres vs. PD-L1+ TIC in vitro, consistent with reduced TIC self-renewal in PD-L1+. In vivo, PD-L1sh B16 and ID8agg TIC exhibited reduced tumorigenicity in wild type mice, consistent with poor TIC function, but immune effects could not be excluded. B16 and ES2 PD-L1sh TIC had significantly reduced tumorigenicity versus control TIC in immune deficient NSG mice consistent with cell-autonomous, immune-independent TIC promotion by PD-L1. In further confirmation, we found reduced adhesive interactions of PD-L1sh B16 TIC versus PD-L1+ TIC (B16) [n=10]. PD-L1sh ES2 TIC versus PD-L1+ ES2 TIC. The corresponding stemness gene SOX2 was significantly higher in control vs. PD-L1sh ES2 TIC. Altogether, these data validate effects in human cells, and are consistent with PD-L1 driving TIC through stemness gene control, although specific genes differed in distinct tumors (likely due to differing mutational landscapes). mTORC1 signaling linked to stemness (assessed by raptor depletion) was lower but mTORC2 was unaffected (rictor) in PD-L1sh versus control TIC from all 3 tumors, suggesting mTORC1 control of PD-L1-mediated TIC generation. In support, the mTORC1 inhibitor rapamycin reduced control TIC significantly (>30% vs. untreated). Strikingly, rapamycin significantly increased PD-L1sh TIC in all 3 tumors, suggesting mTORC1 effects differ by tumor PD-L1 status. Interferon (IFN)-γ similarly reduced control TIC and augmented PD-L1+ TIC numbers, suggesting the novel concept that PD-L1 alters IFN-γ signals. PD-L1 sensitization of TIC to IFN-γ and rapamycin is the first example of a molecule enhancing TIC treatment response to our knowledge. We recently showed that self-deliverable RNAi (sd-rxRNA) directly reduces B16 and ID8agg proliferation in vitro and in vivo (accession no. 27617647). Preliminary data now show that anti-PD-1 (and anti-CD8) directly reduce TIC proliferation, and these effects differ from non-TIC. We challenge the paradigm that tumor PD-L1 is primarily an immune escape molecule and that anti-PD-1 works primarily to block T cell PD-1 interactions.

#5650 Enhancement of CAR-T cell activity via PD-1 knockdown by self-deliverable RNAi. Alexander Wolfson,1 Alexey Eliseev,1 Taisiya Shumskikhov,2 Monica Betancur-Boissel,2 Monica Betancur-Boissel,2 Nathalie Scholler,3 Mir-Mo, Immune, Boston, MA; Adirna, Cambridge, MA; 3SRI International, Menlo Park, CA.

Background: A growing body of evidence indicates that the blockade of PD-1 and other immunosuppressive receptors can increase the efficacy of adoptively transferred cells in immunotherapy for cancer. The expression of PD-1 can be suppressed by ex vivo treatment of transferred lymphocytes by self-deliverable RNAi (sd-rxRNA) compounds. sd-rxRNAs are based on proprietary chemical modifications of siRNA compounds making them stable to nuclease degradation and capable of penetration into target cells without the use of transfection reagents. Experimental methods: Aim: To determine whether the reduction of PD-1 by ex vivo treatment of mesothelin-targeting CAR-T cells with sd-rxRNA will improve the efficacy of meso-CAR-T cells in a mouse model of ovarian cancer. Methods: Second-generation human CAR-T cells expressing P4 antibody fragments targeting mesothelin (meso-CAR-T) were treated ex vivo with PD-78, a self-deliverable siRNA silencing the PD-1 gene. The meso-CAR-T cells were then injected into tumors in a xenograft mouse model of human ovarian cancer (A1847 cell line expressing mesothelin and PD-L1) in NSG mice. The tumor volumes were monitored over the course of one month. After the animals were sacrificed, human CD45-containing cells extracted from the tumor were analyzed for PD-1 expression by flow cytometry. Results: We observed a statistically significant reduction in tumor growth in the group of mice injected with meso-CAR-T cells pretreated ex vivo with PD-78. The post-mortem tumor analysis by flow cytometry showed that the expression of PD-1 in meso-CAR-T cells was significantly suppressed for the full duration of the experiment (one month). Conclusion: Our results suggest that the silencing of immunosuppressive genes by ex vivo treatment with sd-rxRNA may improve efficacy of CAR-T cells in the treatment of solid tumors. A similar approach may be applied to other types of adoptive cell transfer.

Combining immunotherapeutic antibodies in cancer treatment has shown benefits over single agents. An alternative to combining two antibodies is the development of bispecific antibodies that not only bring two biologics together but may result in novel mechanisms of action that are impossible to attain with combinations. Lymphocyte Activation Gene-3 Gene-3 (LAG-3) is a member of the Ig superfamily expressed on activated T cells, NK cells, pDCs, B cells, y T cells and participates in immune suppression. Programmed Cell Death receptor (PD-1) binds to its ligand PD-L1, expressed not only on activated immune cells to inhibit cellular immune responses but also on tumor cells. Expression of both these surface molecules therefore leads to T cell exhaustion allowing the tumor to escape immune surveillance. A mAb 2738 (bispecific antibody) was engineered which binds murine LAG-3 and PD-L1 simultaneously and with nanomolar affinities. The anti-LAG-3/PD-1 mAb2 inhibits LAG-3 binding to MHCIId and PD-L1 binding to PD-1 and CD80, resulting in T cell activation in vitro. This translates into in vivo efficacy, where the mAb2 decreased tumor burden in the MC38 colon carcinoma tumor model. At the end of the study tumor-free animals were more numerous in the LAG-3/PD-L1 bispecific group than in the group given a combination of individual anti-LAG-3 and PD-L1 antibodies. The results were recapitulated in the CT26 murine colon cancer model, where the mAb2 showed an increase of antitumor activity as compared to the antibodies given in combination. Thus, the preclinical data supports developing an anti-human LAG-3/PD-1 mAb2 for the treatment of cancer patients.
CLINICAL RESEARCH: Innate Immunity to Generate Adaptive Immunity

#5652  Translational evidence of reactivated innate and adaptive immunity with intratumoral IMO-2125 in combination with systemic checkpoint inhibitors from a Phase I/II study in patients with anti-PD-1 refractory metastatic melanoma. Cara Saymak, 1 Marc Uemura, 1 Ravi Murthy, 1 Marihella James, 1 Daqing Wang, 2 Julie Brevard, 2 Suzanne Swann, 3 James Geib, 4 Mark Cornfeld, 5 John C. Krizan, 5 Joshua Gimotty, 5 Suchi Khanna, 5 Oddvar Vawgo, 6 Rodabe Amaria, 7 Sapna Patel, 1 Hussein Tawbi, 1 Isabella Glitza, 1 Scott Woodman, 6 Wen-Jen Hwu, 7 Michael A. Davies, 1 Patrick Hwu, 1 Willem Overwijk, 1 Chantale Bernatchez, 1 Adi Diab, 1 UT MD Anderson Cancer Center, Houston, TX; 2Idera Pharmaceuticals, Inc., Cambridge, MA.

Background: While checkpoint inhibitor (CPI) therapy has transformed metastatic melanoma (MM) treatment, many patients remain refractory. We reasoned that combining CPI with an agent that activates antigen presenting cells and improves T-cell priming may result in improved response. Our hypothesis is that this will result in dendritic cell (DC) activation and induction of tumor-specific CD8+ T-cells which will synergize with ipilimumab or pembrolizumab to overcome immune-escape. Based on this rationale we initiated a phase I/II clinical trial. Study Design/Methods: Adults with refractory MM that have had prior PD-1 blockade therapy (with or without a BRAF inhibitor) are eligible. IMO-2125, in doses escalating from 4mg to 60mg q.d., is given subcutaneously. Along with administration of ipilimumab or pembrolizumab. Primary endpoints are safety, tumor response, and PK. Multiple biopsies are obtained in both the injected and distant tumor pre- and on-treatment. Immune analyses include DC subsets and their activation status as well as T cell activation, function and proliferation. T-cell repertoire diversity is evaluated by high-throughput CDR3 sequencing. Changes in circulating cytokines are also being assessed during therapy. Results: Enrollment is proceeding on both the IMO-ipilimumab and IMO-pembrolizumab dose-escalation arms of the trial. Safety is acceptable with no DLT recorded to date. Durability and efficacy data will be presented in our oral presentation.

Pancreatic cancer is an aggressive malignancy with a 5 year survival rate of less than five percent. The predominant immune cells infiltrating the tumor microenvironment are monocytes/macrophages, which are reported to support tumor growth by suppressing host immune responses to the tumor. Recruitment of monocytes to various tissues, including tumors, is dependent upon activation of the chemokine receptor CCR2 by one or more of the chemokines CCL2, CCL8 and CCL13. In preclinical and clinical studies, inhibition of CCR2 in pancreatic cancer has shown to decrease tumor progression by blocking recruitment and accumulation of monocytes/macrophages in the tumor microenvironment. Analysis of human pancreatic tumors revealed elevated levels of both CCL2 and CCL8, which recruits monocytes, and the monocyte marker CD14, in advanced pancreatic cancers. Current immunotherapy using checkpoint inhibitors are ineffective in some tumors, but lack efficacy in immune insensitive cancers, including pancreatic cancer. Here, we report that the inhibition of CCR2 using a small molecule antagonist potentiates anti-PD-1 immunotherapy in a syngeneic, orthotopic mouse model of pancreatic cancer. Our data reveal that CCR2 blockade decreases tumor burden and increases immune infiltration and creating a microenvironment more favorable for CD8 T cell activity, and provide a mechanistic rationale for investigating the combination of a CCR2 antagonist and an immune checkpoint inhibitor in pancreatic cancer.

#5656  Quantitative measurement of PDL1 expression across tumor types using laser capture microdissection and reverse phase protein microarray. Elisa Baldelli, 1 Valerie Calvert, 1 Alex Hodge, 2 Maria Isabella Sereni, 2 Guido Gambara, 1 Eric B. Haura, 3 Lucio Crino, 3 Bryant Dunetz, 3 Sergio Pecorelli, 2 David J. Perry, 4 Stephen P. Anthony, 5 Nicholas Robert, 5 Donald W. Northfelt, 5 Mohammad Jahanghez, 5 Emanuel F. Petricoin, 1 Mariaelena Pierobon, 1 George Mason University, Manassas, VA; 2H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL; 3’S. Maria della Misericordia Hospital, Perugia, Italy; 4The Side Out Foundation, Fairfax, VA; 5University of Brescia, Brescia, Italy; 6MedStar Washington Hospital Center, Washington DC, DC; 7Evergreen Hematology & Oncology, Spokane, WA; 8Virginia Cancer Specialists, Fairfax, VA; 9Mayo Clinic, Scottsdale, AZ; 10University of Miami, Miami, FL.

Background: The efficacy of immunotherapy, including therapeutic strategies capable of modulating innate/adaptive immune resistance, varies greatly across tumor types. As the number of available immunotherapies accelerates, the study of predictive markers by IHC (e.g. PDL1 expression) is under intense investigation. However, staining protocol inconsistency, variation across scoring systems, and subjective interpretation of the immunostaining have produced conflicting results thus far. This work explored the role of Laser Capture Microdissection (LCM) coupled with Reverse Phase Protein Microarray (RPPA) as an alternative high throughput, quantitative, operator independent platform for measuring PDL1 expression across tumor types. Material and Methods: Pure epithelial cells were isolated via LCM from 178 samples including: 72 ovarian cancers (OC), 57 lung adenocarcinomas (LC), 30 metastatic breast cancers (MBC), and 19 pancreatic cancers (PC). PDL1 expression was measured on a continuous scale using quantitation of CCL2 and CSF1, which recruit monocytes, as well as the monocyte marker CD14, in advanced pancreatic cancers. Current immunotherapy using checkpoint inhibitors are ineffective in some tumors, but lack efficacy in immune insensitive cancers, including pancreatic cancer. Here, we report that the inhibition of CCR2 using a small molecule antagonist potentiates anti-PD-1 immunotherapy in a syngeneic, orthotopic mouse model of pancreatic cancer. Our data reveal that CCR2 blockade decreases tumor burden and increases immune infiltration and creating a microenvironment more favorable for CD8 T cell activity, and provide a mechanistic rationale for investigating the combination of a CCR2 antagonist and an immune checkpoint inhibitor in pancreatic cancer.

#5654  Lymphodepletion induces T cell homeostatic proliferation and augments antitumor effects of PD-1/PD-L1 blockade therapy. Massashi Arita, Satoshi Watanabe, Takahashi Miho, Miyuki Sato, Aya Ohtsubo, Kosuke Ichikawa, Rie Kondo, Tetsuya Abe, Junta Tanaka, Toshiyuki Koya, Toshiaki Kikuchi. Niigata University, Niigata City, Japan.

Programmed death receptor-1 (PD-1)/programmed death receptor ligand-1 (PD-L1) blockade therapy has demonstrated to enhance antitumor immunity. Recent evidence has shown that anti-PD-1/PD-L1 therapy restores the function of exhausted effector T cells and augments antitumor immune responses. The expression of PD-L1 has been best studied as a biomarker for the anti-PD-1/ PD-L1 therapy. Because PD-L1 expression on tumor cells is induced by IFN-γ which is mainly produced by effector T cells, induction of antitumor effector T cells in patients treated with the anti-PD-1/PD-L1 therapy may be an important factor. Indeed, previous studies have suggested that the increase of tumor-infiltrating lymphocytes is the predictive biomarker for PD-1/PD-L1 blockade therapy. We and others have demonstrated that lymphodepletive therapies, such as chemotherapy and radiotherapy, induce tumor-specific effector T cells from naïve T cells. Naïve T cells rapidly proliferate and elicit memory-like functions after lymphodepletive regimens could augment the antitumor efficacies of the anti-PD-1/ PD-L1 therapy. In the current study, we transferred naïve T cells into mice after whole-body irradiation or chemotherapy. These mice were inoculated s.c. with PD-L1+ B16F10 melanoma cells or PD-L1+ MCA205 fibrosarcoma and then were treated with anti-PD-1 mAbs. Lymphodepletion by whole body irradiation, but not cytotoxic agents following the transfer of naïve T cells significantly enhanced antitumor immunity of anti-PD-1 mAbs. This augmentation required both of CD4+ and CD8+ T cells, but not NK cells. Further experiments revealed that immune cells infiltrating MCA205 expressed PD-L1. Transfer of CFSE-labeled immune cells from naïve mice to tumor-bearing mice augmented antitumor effects of anti-PD-1 mAb therapy by lymphodepletion. These results suggest that lymphodepletion induces homeostatic proliferation of T cells and augments antitumor effects of PD-1/PD-L1 blockade therapy.
sion of PD-L1 with only 2/19 (10.5%) cases been above the population median and none within the top quartile of the population. Conclusions: The LCM-RPPA workflow has the unique ability to capture immune checkpoint expression on a continuous quantitative scale as well as capture its broad dynamic range. Because RPPA is unconstrained by antigen retrieval issues as well as subjectivity of IHC interpretation, this approach may generate more accurate cut-point of therapeutic response prediction. Overall the dynamic range of PD-L1 was broader in LC compared to other solid tumors, and LC had a much higher proportion of patients with tumors expressing high levels of PD-L1. These quantitative differences may explain therapeutic efficacy of PD-L1 inhibition across tumor types. Such speculative hypothesis should be further validated in prospective clinical trials. Finally, these preliminary data suggest that organ specific microenvironments more than specific driving mutations (e.g. KRAS) may strongly influence PD-L1 expression in malignant lesions.

#5657 Objective measurement and significance of VISTA (PD-1H) expression in non-small cell lung cancer (NSCLC). Franz Villarroel-Espindola,1 Ilia J. Datar,1 Vamsidhar Velcheti,2 David L. Rimm,3 Roy S. Herbst,4 Kurt A. Schalper5.1Yale School of Medicine, New Haven, CT; 2Cleveland Clinic, Cleveland, OH; 3Medical Oncology Yale Cancer Center, New Haven, CT.

Introduction: VISTA (PD-1H) is a member of the B7 family of immune co-modulatory molecules and has been proposed as a novel anti-cancer immunotherapy target. The intra- and extracellular domains of VISTA show homology to PD-1 and PD-L1, respectively, suggesting a role in anti-tumor immune evaluation. The expression of VISTA, its association with PD-1 axis components and biological role in human NSCLC are unknown. Methods: Using multiplex quantitative immunofluorescence (QIF), we simultaneously measured the levels of VISTA (clone D1L2G, CST). PD-L1 (clone 405.9/A11, CST) and PD-1 (clone EH33, CST) protein in 732 stage I-IV NSCLCs from 3 retrospective collections represented in tissue microarray format (cohort #1 [n=237, Yale], cohort #2 [n=329, Greece]; and cohort #3 [n=106, Yale]). To evaluate the tumor tissue distribution, VISTA was also selectively measured in cytokeratin + tumor cells, CD3+ T-cells, CD4+ T-helper cells, CD8+ cytotoxic T-cells and CD20+ B-lymphocytes. Associations between the marker levels, clinicopathological-molecular variables and survival were studied. Results: VISTA protein was detected in all NSCLCs, showed a membranous staining pattern and was localized predominantly in the tumor cells in 27.4% of cases; and in the stromal compartment in 98.5%. Although VISTA was detected in all major tumor infiltrating lymphocyte (TIL) subsets, the signal was higher in CD20+ B-cells than in CD3+ T-lymphocytes (P<0.05); and in CD4+ helper than in CD8+ cytotoxic T-cells (P<0.0001). Using the median score as cut point, elevated VISTA in tumor and/or stromal cells was significantly associated with high PD-L1, PD-1 protein expression and increased CD8+ TILs in the cohorts (P<0.001 – P<0.05). No consistent association between VISTA levels and age, gender, smoking status, specific NSCLC histology, stage, EGFR/KRAS mutations and overall survival was found. Conclusion: VISTA is expressed in the majority of NSCLCs and shows differential distribution in tumor/stromal cells and TIL subsets, suggesting a complex functional as a ligand and receptor. Elevated expression of VISTA in NSCLC is associated with increased PD-1 axis targets and cytotoxic T-cell density, indicating its possible modulation by pro-inflammatory signals. Our results support VISTA as a candidate target for anti-cancer immunotherapy in NSCLC alone or in combination with PD-1 axis blockers.

Pancreatic cancer remains a serious unmet medical need. The majority of pancreatic tumors are composed of stromal cells that make tumors resistant to conventional therapies. We are developing an approach in which a TLR9 agonist, IMO-2125, is administered intratumorally, which induces local Th1 response and modulates the tumor microenvironment. This approach has shown promising antitumor activity in preclinical models of multiple tumor types in combination with checkpoint inhibitors. We are employing a similar approach to the treatment of pancreatic cancer. We evaluated the local therapeutic effect of IMO-2125 in a murine syngeneic pancreatic ductal adenocarcinoma (Pan02) cancer models. In the first study, C57BL/6 mice were intraperitoneally (i.p.) implanted with Pan02 cells to generate peritoneal metastatic cancer. Tumor-bearing mice (n=10 per group) were then treated with 2.5 mg/kg IMO-2125 either by i.p. or subcutaneous (s.c.) injections for six times in two weeks. In the second study, to establish dual solid tumors in C57BL/6 mice, Pan02 cells were subcutaneously implanted in both the right and left flanks of the animals. When tumors reached to 50-150 mm³, we started the intratumoral (i.t.) administration of IMO-2125 in right tumors at doses of either 0.25 mg/kg, 1 mg/kg or 2.5 mg/kg, or PBS (n=10 per group), 3x/week for three weeks. In the peritoneal metastatic pancreatic tumor model, 80% of IMO-2125 intraperitoneally treated mice survived for more than 88 days, while 90% of the control group died within 29 days. Conversely, the IMO-2125 treatment group survived for only 36 days. Tumor-free mice from the IMO-2125 i.p treatment group (n=7) rejected the same tumor rechallenge, suggesting establishment of durable tumor-specific immune response. In the dual solid pancreatic tumor model, intratumoral IMO-2125 treatment led to a dose dependent antitumor activity in both injected and distant tumors. Tumors treated with 0.25, 1 and 2.5 mg/kg doses of IMO-2125 showed reductions in tumor volume by 66% (p = 0.004), 74% (p = 0.002) and 95% (p = 0.003), respectively. Moreover, the distant tumors exhibited a reduction of 0% (p = 0.65), 64% (p = 0.006) and 69% (p = 0.001), respectively. Antitumor activity was associated with increased T-cell infiltration and upregulation of the gene expression of various checkpoint in both treated and distant tumors. In an independent study, treatment with a control IMO showed minimal antitumor activity. All treatments were well tolerated. In summary, local treatment with IMO-2125 exerts antitumor activity in preclinical pancreatic cancer models, associated with an increase in T-cell infiltration in the tumor microenvironment, providing a novel approach to the treatment of pancreatic cancer. The clinical trial of intratumoral IMO-2125 is in progress in patients with melanoma.

#5660 Tumor cell death caused by INT230-6 induces protective T cell immunity. Anja C. Bloom,1 Lewis H. Bender,2 Ian B. Walters,2 Katharine T. Clark,1 Masaki Terabe,1 Jay A. Berzofsky 1.1National Cancer Institute, Bethesda, MD; 2Intensity Therapeutics Ltd, Westport, CT.

Standard care for many types of cancer involves systemic administration of cytotoxic agents. This may result in low drug concentration at tumor sites, which limits cell killing. More recently it has been shown that cytotoxic formulations designed for intratumoral delivery improve drug efficacy presumably by increasing drug concentration at the tumor site. Furthermore, it has been discovered that the mechanisms of anticancer agents extend beyond direct tumor cell lysis. One major aspect is that cell death often induces an immune response. Different types of cell death such as necrosis, apoptosis and auto-phagic cell death induced by cytotoxic agents trigger immune responses with varying degrees of inflammation and involving different types of immune cells. The ideal immune responses that may give maximum benefit to patients would be strong and long lasting anti-tumor T cell responses. In this study, a novel, tissue and cell diffusive cytotoxic formulation, INT230-6, was administered intratumorally over 5 sequential days into subcutaneous 300 mm³ murine Colon26 tumors. Treatment resulted in regression from baseline of 100% of the tumors and up to 80% complete regression (CR). We then analyzed the T cell responses induced by INT230-6. No animals achieved a CR after CD8 or CD8/CD4 double depletion at treatment onset, indicating a critical T-cell role in tumor regression. Mice with CRs were protected from re-challenge by either subcutaneous or intravenous re-inoculation of the Colon26. The protection was abrogated by CD4/CD8 double depletion prior to the re-challenge, indicating that immunological T-cell memory areas was not necessary for protection. Hence, INT230-6 given locally to treat tumors induces tumor-specific protective T cell immunity. Colon26 tumors express the endogenous retroviral protein gp70 containing the AH-1 CTL epitope. AH-1-specific CD8 T cells were detected in tumors of mice without treatment. However, these highly expressed PD-1. This was consistent with the observation that the PD-1 blockade enhanced the efficacy of INT230-6. Conversely, INT230-6 enhances the efficacy of checkpoint inhibitors.

#5661 Targeting CD47 expression on macrophages regulates immunomodulation enhancing tumoricidal activity against cancer cells. Ashley A. Smith, Adam S. Wilson, David R. Soto-Pantoja. Wake Forest School of Medicine, Winston Salem, NC.

Macrophage mediated elimination of cancer cells is critical for control of tumor growth. Cancer cells evade immune recognition by expressing receptors that send inhibitory signals to prevent macrophage mediated cytotoxicity. Clinical studies show that overexpression of the cell surface receptor CD47 is a poor prognostic factor in cancer, allowing tumors to bypass immunosurveillance and activation pro-growth pathways. Prior studies have described that CD47 cell surface expression on cancer cells inhibits phagocytic activity through engagement of its counter receptor SIRPα on macrophages. However, the role of CD47 expression on macrophage function is not known. Here, we show that CD47 is expressed on primary mouse macrophages, RAW 264.7 and the U937 cell lines. Moreover, knockdown of CD47 on macrophages enhanced the tumoricidal ca.
with progression free survival (PFS) after autoSCT in multiple myeloma (MM), and showed that there was an inverse correlation between NKG2A expression on CD56bright NK cells and PFS. Therefore, we aimed to investigate a potential role for NKG2A modulation, especially in the post-transplant setting with maintenance chemotherapy. We performed immunophenotypic analyses of NK cells from patients in the immediate post-transplant setting as well as from patients at various time points after transplant on lenalidomide maintenance therapy. In the immediate post-transplant setting (mean time since transplant = 13 days) NKG2A was upregulated on NK cells when compared with KIR2DL1 (p = 0.001) and KIR2DL2 (p = 0.002). Additionally, in immunophenotypic analyses of PBMC from MM patients on various treatments, patients receiving lenalidomide maintenance therapy that recently underwent stem cell transplant (mean time since transplant = 0.53 years) had elevated NKG2A expression compared to patients receiving no treatment (p = 0.029). Conversely, patients receiving lenalidomide maintenance therapy over years (mean time since transplant = 4.21 years) after transplant showed reduced NKG2A expression compared to patients receiving no treatment (p = 0.0161). In bone marrow aspirates from patients with MM, primary CD138-positive myeloma cells in the bone marrow express HLA-E, the cognate antigen for NKG2A, which makes the overexpression of NKG2A biologically relevant. These data suggest that the NKG2A/HLA-E checkpoint axis may be more biologically relevant than KIR in myeloma, particularly in the post-transplant setting. This has important potential implications for treatment, as it demonstrates that NKG2A could serve as a potential target for modulation in the immediate post-transplant setting to improve survival, especially in the setting of maintenance chemotherapy. Further investigation should be aimed delineating the potential effect of NKG2A modulation on immune recovery and tumor surveillance to increase survival in the post-transplant setting.

#5664 PLAG prevents the loss of circulating neutrophils in the chemotherapy-induced neutropenia model. Yong-Jae Kim, Jinsung Jung, Ha-Reun Lee, Ki-Young Sohn, Heung-Jae Kim, Sun Young Yoon, Jae Wha Kim.

PLAG on excessive neutrophil extravasation by chemotherapy via attenuating the key role to regulate on neutrophil migration. Collectively, modulating effect of PLAG on excessive neutrophil extravasation by chemotherapy via attenuating STAT3/CXCL2(8) pathway could be used as very powerful regimen for preventing of neutropenia during diverse chemotherapy.

#5665 Physical crosstalk between CD8+ T and natural killer cells elicits antitumor effector response. Roman V. Uzhachenko, Ashutosh Singhal, Shawn J. Goodwin, William H. Hofmeister, Anil Shanker.

The interaction between the innate and adaptive immune components is fundamental for an effective antitumor immunity. Our studies in murine solid tumor models showed that productive antitumor effector response relies on functional crosstalk between innate immune effectors—natural killers (NK) and adaptive immune effectors—cytolytic CD8+ T lymphocytes. We found that this lymphocyte cooperativity between CD8+ T and NK cells can prevent the development of antigen-escape tumor variants. In this study, we first investigated the role of physical contacts in during the functional crosstalk between...
CD8+ T and NK cells. Since, studying dynamic lymphocyte interactions present extreme challenges, in this study, we engineered a 3D nanoﬁbre matrix to provide lymphocytes a 3D culture environment for a controlled interaction. Con-focal imaging showed that CD3/CD28-activated CD8+ T cells (CD69+/CD25−) formed multiple intercellular contacts with several naïve NK cells upon cocul-ture, whereas T cells made signiﬁcantly more contacts with NK cells. Lymphocyte coculture (physical contact possible) found that activated CD8+ T and NK cells cross-regulate each other phenotype wherein NK cells polarize activated CD8+ T cells towards “T central memory phenotype” and activated CD8+ T lymphocytes induce acquisition of “effector/regulatory phenotype” by naïve NK cells. This cross-regulation of lymphocytes disappeared in trans-well co-culture (no physical contact) indicating the necessity of cell-to-cell physical inter-action during CD8+ T–NK crosstalk. Notably, intercellular physical interac-tion led to cross regulation of mitoCa2+ oscillations in both activated CD8+ T and NK cells. Inhibition of mitochondrial Ca2+ uptake or Na+/Ca2+ exchanger with Ru360 and CGP37157, respectively, mimicked observed alterations in both lymphocytes. Further, NK cells displayed increased oxidative signaling, Tyk2, Jak1 and 3, Stat2 and Stat6 phosphorylation while inhibiting TCR- and various cytokine receptors-mediated signaling. In turn, NK cells selectively restrain IL-2 signaling in CD8+ T cells by dampening activation-induced up-regulation of CD25, Stat5 phosphorylation, IL-2 synthesis and elevation in IL-2 uptake. These data underscore a novel mitochondrial Ca2+ transport-regulated activation/ regulatory phenotype by NK and CD8+ T cells upon their interaction. Understanding the mechanism of the synergistic interaction between CD8+ T cells and NK cell-lymphocyte synapse allowing their functional remodeling with the intact tissues in tumor settings will lead to novel strategies for effective cancer immunotherapies, with a potential of relapse-free survival in cancer patients.

**#5666 Safety of the first-in-class anti-NKG2A monoclonal antibody monalizumab in combination with cetuximab: a phase Ib/II study in recurrent or metastatic squamous cell carcinoma of the head and neck (R/M SCCHN), Roger B. Cohen,1 Sébastien Salas,1 Caroline Ewen,1 Nuria Kotecki,2 Antonio Jimeno,3,4 Anne-Marie Souléa,5 Anne Thirouzan-Jiménez,5 Robert Zerbib,6 Pascale André,6 Agnès Boyer-Chammard,6 Jérôme Fayette,7 1Abrams-on Cancer Center, Philadelphia, PA; 2Assistance Publique-Hôpitaux de Mar-seille, Marseille, France; 3Gustave Roussy, Villejuif, France; 4Centre Oscar Lam-bret, Lille, France; 5University of Colorado Cancer Center, Aurora, Denver, CO; 6Innate Pharma, Marseille, France; 7Centre Léon Bérard, Lyon, France.**

Monalizumab (IPH2201) is a first-in-class immune checkpoint inhibitor targeting CD94-NKG2A receptors expressed on tumor infiltrating cy-totoxic CD8+ T lymphocytes and NK cells. HLA-E, the ligand of this inhibitory checkpoint receptor is up-regulated in SCCHN, protecting cancer from killing by CD94-NKG2A+ cells. Monalizumab blocks binding of CD94-NKG2A to HLA-E, reducing inhibitory signaling and thereby enhancing NK and T cell anti-tumor responses. Cetuximab is an anti-EGFR monoclonal antibody block-ing oncogenic signaling and inducing Fcγ receptor-mediated antibody depen-dent cellular cytotoxicity (ADCC). In vitro cetuximab-mediated ADCC is inhibited by HLA-E expression on target cells and this inhibition can be circumvented with CD94-NKG2A blockade. Combination of monalizumab and cetuximab might provide greater antitumor activity than either drug alone. Methods: A multicenter, non-randomized dose-escalation and expansion study is evaluating monalizumab plus cetuximab in patients with R/M SCCHN (NCT02643550). Patients ≥ 18 years who progressed after platinum-based chemotherapy (regardless of the number of previous lines of treatment) were enrolled, without regard to HLA-E or human papilloma virus status. Using a 3+3 design, 5 dose levels of monalizumab (0.4, 1.2, 4 or 10 mg/kg every 2 weeks) were explored with ﬁxed doses of cetuximab (400 mg/m² load followed by 250 mg/m² weekly). Patients were treated until disease progression or unacceptable toxicity. The primary objective was to evaluate safety and Dose Limitation Toxicity (DLT). The secondary objectives were to estimate the Maximum Tolerated Dose (MTD) and the Recommended Phase II Dose (RP2D), and to determine the pharmacokinetics, pharmacodynamics and immune responses. The enrollment began in December, 2015. As of October 11, 2016, 13 patients with R/M SCCHN were enrolled at dose levels 0, 1, 2 and 4 mg/kg. Median age was 60 years (range: 40-74); 92% were male; PS was 0 or 1; all patients had received prior systemic therapy (1 prior line in 1 patient and > 2 lines in 12 patients) for R/M SCCHN including platinum based chemotherapy (100% of the patients) and cetuximab (12% in 10 patients). First dose was no DLT. There were no DLTs or immune-related disorders or deaths related to treatment. No discontinuation attributable to treatment-related adverse events and no treatment-related grade 3 and 4 adverse events were reported, except fatigue (grade 3) in one patient. Updated data including pharmacodynamics and pharmacokinetics on the full dose escalation part will be presented. Conclusion: Monalizumab + cetuximab were well tolerat-ed with no additional safety concerns compared to monalizumab or cetuximab alone. The dose-expansion phase of the study will be initiated in the near future.

**#5667 Exposure of tumor-associated macrophages to apoptotic pancreatic cancer cells promotes cancer stem cell chemoresistance.** Gabrielle D’Errico, Mirėia Vallespinos, Sonia Alcala, Sandra Valle, Laura Martin-Hijano, Bruno Sainz, Antonio D’Errico, A. University of Madrid, Spain. Pancreatic ductal adenocarcinoma (PDAC) is the fourth leading cause of cancer related deaths worldwide. This is largely due to the existence of a subpopulation of stem-like cells present within the tumor, known as cancer stem cells (CSCs) that drive metastasis and chemoresistance. In addition, we have now come to realize that the tumor-associated microenvironment not only provides structural support for tumor development, but more importantly the microenviron-ment provides cues to CSCs that regulate their biological properties. Chemotherapy often leads to apoptosis of cancer cells, and in previous studies we have shown that tumor-associated macrophages (TAMs) exponentially increase following chemotherapy. We hypothesized that TAMs, in response to chemo-therapy-induced apoptosis, secrete factors that potentiate PDAC chemoresis-tance. In line with this hypothesis, we show that monocyte-derived macrophages cultured in the presence of apoptotic PDAC cells polarize towards an M2 pro-tumor phenotype and secrete factors that render naïve PDAC cells, speciﬁcally CSCs, resistant to Gemcitabine- or Abraxane-induced apoptosis, irrespective of mutations in p53. Importantly, chemoresistant cells showed increased microRNA capacity and increased tumorigenesis as measured in an extreme limiting dilution assay in nude mice, conﬁrming an enrichment in CSCs. Moreover, using a syngeneic orthotopic in vivo model of PDAC, we were able to signiﬁcantly augment the anti-tumor potential of Gemcitabine by pharmacologically eliminating TAMs using clodronate liposomes. To determine the mecha-nism by which TAMs promote PDAC chemoresistance, we performed proteomic analyses on macrophage conditioned media and identiﬁed several proteins speciﬁcally induced and secreted when macrophages were co-cultured with apoptotic PDAC cells, including 14-3-3 protein zeta/delta (14-3-3ζ), a ma-jor regulator of apoptotic cellular pathways. We present additional data to show that TAM-secreted 14-3-3ζ promotes CSC chemoresistance. Taken together, the sum of these data highlight a unique regulatory mechanism by which chemotherapyme-induced apoptosis acts as a switch to initiate a pro-tumor/anti-ap-o-totic mechanism in PDAC, challenging the idea that apoptosis of tumor cell is therapeutically beneﬁcial, at least when immune sensor cells, such as macrophages, are present.

**#5668 CCL2/CCR2-driven monocyte recruitment to the tumor following radiotherapy inﬂuences the outcome of the treatment of head and neck cancer.** Michele Mondini,1 Pierre L. Loyher,2 Kevin Berthelot,3 Celine Clemenson,1 Alessio Ingrassias,2 Giuseppina Cannistraci,2 Eric Deutsch.1 1Gustave Roussy, Villejuif, France; 22INERM U1135, Paris, France. Local radiotherapy is the major treatment to control locally advanced head and neck cancer. Evidence supporting the importance of immune response in the response to radiation therapy is growing and the possibility to potentiate the effects of radiotherapy by modulating the function of the immune system offers new exciting therapeutic perspectives. Monocytes/macrophages are immunomodulatory agents that can amplify the effects of radiotherapy on the immune system. We have recently developed a model of human papillomavirus (HPV)-related head and neck cancer using immunocompetent mice and validated its usefulness to evaluate the tumor response to radiotherapy. Using the same model, based on the injection of TC1/luciferase cells in the inner lip of C57Bl/6 mice, we show that local radiotherapy induces an increase of CCL2 levels in the bloodstream and intratumorally accompanied by a neo-infiltration of monocytes in the tu-mor that subsequently differentiate into tumor-associated macrophages (TAM). When TC1/Luc cells were engrafed in CCL2−/- or CCR2−/- mice, the tumor response to radiotherapy and survival were improved. This was accompanied by an impaired infiltration of inflammatory monocytes, and a subsequent decrease of TAM levels at later time points. In vitro, exposure to ionizing radiation in-creased the secretion of CCL2 by TC1/Luc cells, and such increase was signifi-cantly enhanced, in tumor cells were co-cultured with irradiated RAW 264.7 macrophage-derived cells. This data suggests interplay between tumor and TAM that can amplify the effects of radiotherapy on the immune system. We propose that reducing radiation-induced monocyte recruitment may yield improved results in the treatment of HPV-related head and neck squamous cell

Breast cancer is the most common cancer in Canadian women and the second leading cause of cancer deaths. Given that most mammary tumors are surgically resectable and over 90% of breast cancer-associated deaths are due to metastasis, new therapeutic strategies targeting metastasis are required. Natural killer T (NKT) cells are a rare population of immune cells that have been shown to limit primary tumor growth and target distant metastatic disease in various animal models. We have shown that NKT cell activation improves survival in a model of post-surgical metastatic breast cancer. We are now expanding this work to determine whether NKT cell activation can be combined with chemotherapies to improve outcomes. In our model, 4T1 mammary carcinoma cells were injected into the mammary fatpad of syngeneic BALB/c mice. Tumors were resected at day 12, and mice were treated with cyclophosphamide or gemcitabine. On day 17, NKT cells were activated by transfer of dendritic cells loaded with the glycolipid antigen α-GalCer. We also examined whether gemcitabine or mafosfamide (active component of cyclophosphamide) would induce immunogenic cell death of 4T1 cells in culture. Chemotherapeutics did not affect NKT cell activation as measured by serum IFNγ levels. Treatment with cyclophosphamide or gemcitabine significantly enhanced survival as measured by serum IFNγ levels. Combined treatments significantly enhanced survival. NKT cell activation decreased the frequency and immunosuppressive function of myeloid derived suppressor cells (MDSCs). Treatments resulted in enhanced tumor specific immunity as surviving mice exhibited slower tumor growth following secondary tumor challenge. Gemcitabine and mafosfamide also increase the immunogenicity of cancer cells in vitro by increasing the expression/release of MHC I, MHC II, CD1d, Calreticulin, HMGB1 and ATP. NKT cell activation therapy can successfully be combined with low doses of gemcitabine or cyclophosphamide to enhance protection against tumor metastasis and reoccurrence. This work provides a clear rationale for combining chemotherapy with NKT cell immunotherapy to target metastatic disease in the clinical setting.

Multiple myeloma (MM) is the second most common haematological cancer and is characterized by the accumulation of neoplastic plasma cells in the bone marrow and is characterized by limited survival. Effective treatment is constrained by treatment-resistant clones, drug resistance and high levels of immunosuppressive molecules (e.g., IL-6, IL-10). Therefore, novel immunotherapeutic approaches are needed to improve treatment options to MM patients. Among the currently explored targets, B-cell maturation antigen (BCMA, CD269) is considered to be particularly attractive due to its limited expression on normal B-cells and high expression on MM cells (MM). While historically considered incurable, recent approvals and ongoing clinical trials with monoclonal antibodies (mAbs) targeting surface antigens promise greatly improved outcomes and have heralded a new era of MM treatment in which immunotherapies are expected to take center stage. However, an unmet need remains as patients eventually relapse and/or become refractory to currently available treatments. Consequently, novel immunotherapeutic approaches are needed to provide improved treatment options to MM patients. Among the currently explored targets, B-cell maturation antigen (BCMA, CD269) is considered to be particularly attractive due to its limited expression on healthy tissues and almost universal expression on myeloma cells in the majority of patients. Natural killer (NK) cells are cytotoxic effectors of the innate immune system capable of rapidly eradicating infected and transformed cells. The cytolytic activity of NK-cells can be used therapeutically to induce tumor cell lysis by direct engagement of the activating receptor CD16A (FcγRIIIa) using mAbs (ADCC). Despite similar mechanisms of target cell lysis, activation of NK-cells is not associated with the systemic symptoms of high level cytokine release as seen with direct T-cell engagement. Hence, it is considered a potent immunotherapeutic approach with reduced toxicities compared to traditional (M protein). The human immune system is regulated by a broad network of co-inhibitory and co-stimulatory receptors that control the type, scale, and duration of immune responses. These receptors are now recognized as promising immunotherapy targets for the treatment of many cancers and autoimmune diseases. Immunotherapies that block co-inhibitory receptors such as PD-1 and CTLA-4 are showing unprecedented efficacy in the treatment of some tumors, and have generated interest in the characterization of additional immunotherapy targets that may broaden the number of patients who can be helped by these drugs. Immunotherapy research programs are now exploring a wide range of both co-inhibitory (e.g. LAG-3, TIGIT, Tim-3) and co-stimulatory (e.g. GITR, 4-1BB, OX40) receptors, individually and in combination. Quantitative and reproducible functional bioassays are essential tools in the development of biologics for cancer immunotherapy. Most existing assays rely on primary cells and suffer from lengthy protocols and high day-to-day and donor-to-donor variability. These approaches are cumbersome, error-prone, and do not produce data of the quality required for drug development in a quality control environment. To address this, we have developed a suite of cell-based reporter bioassays for co-stimulatory immune checkpoint targets including GITR, 4-1BB, OX40, and CD40. In these assays, stable cell lines express luciferase reporters driven by response elements under the precise control of intracellular signals mediated by each co-stimulatory receptor. These bioassays reflect mechanisms of action for drug candidates designed for each co-stimulatory receptor and demonstrate high specificity, sensitivity and reproducibility. Reporter-based bioassays can serve as powerful tools in immunotherapy drug development for antibody screening, potency testing and stability studies.

#5673 Large established B16 tumors in mice are eradicated by ZVexα (dendritic cell-targeting lentiviral vector) and G100 (TLR4 agonist) combination immunotherapy through increasing tumor-infiltrating effector T cells and inducing antigen spreading. Tina C. Albershardt, Andrea J. Parsons, Jardin Leleux, Peter Berglund, Jan ter Meulen. Immune Design, Seattle, WA.

INTRODUCTION: Effective immunotherapy requires the presence of effector T cells penetrating the tumor. ZVexα is a hybrid lentiviral vector platform that targets dendritic cells in vivo to express genes of tumor-associated antigen (TAA)-of-interest and activate TAA-specific CD8 T cells. G100 is the intratumoral (IT) injection of formulated glucopyranosyl lipid A (a synthetic TLR4 agonist) and has been shown to induce T cell homing chemokines, CXCL9 and CXCL10. We report here that G100 promoted an inflamed tumor microenvironment (TME) and improved infiltration of ZVexα-induced TAA-specific CD8 T cells to the TME, thereby eradicating large established B16 tumors. This was previously achieved only with a complex vaccine/anti-tumor antibody/checkpoint inhibitor/IL-2 regimen (Moynihan, Nature, 2016). RESULTS: B16-OVA tumor-bearing mice were randomized into 4 treatment cohorts: 1) untreated; 2) ZVex expressing ovalbumin (ZVex/OVA), subcutaneously (SC); 3) G100 (IT); 4) ZVex/OVA (SC) and G100 (IT) combination. While mice in Cohorts 2 and 3 exhibited delayed tumor growth, nearly all mice (16/18) from Cohort 4 had completely regressed tumors and survived tumor-free until end of study (109 days). CD8+ T cell depletion abrogated this anti-tumor response. Cohort 4 mice with regressed tumors were then randomized and re-challenged with either a) B16-OVA or b) parental B16 (lacking expression of the ZVexα-targeted antigen, OVA); a) B16-OVA re-challenge was rejected by 100% of recipient mice - consistent with induction of T cell memory; and b) B16 re-challenge was rejected by 30%-50% of recipient mice - demonstrating functional antigen spreading. T cell receptor deep sequencing showed that ZVex/OVA alone increased tumor-infiltrating T cell clones specific for OVA, validated by mHHC-multimer staining. ZVex/OVA and G100 combination expanded additional T cell clones, further evidence of antigen spreading. Lastly, the TME of Cohort 4 mice showed the most profound pro-inflammatory changes, as assessed by RNA transcriptional profiling. CONCLUSIONS: These data collectively demonstrate that anti-tumor efficacy observed in Cohort 4 mice was mediated largely by ZVex/OVA-induced
effector T cells and that TME modulation with G100 drastically shifted the TME to a more inflamed milieu, promoting T cell proliferation, antigen spreading, and generation of immunological memory. To our knowledge, this is the first time that large established B16 tumors have been completely eradicated using a combination of systemic and in situ immunizations, potentially effective for cancer immunotherapy.

**#5674 Cancer immunogenomics for the development of personalized ovarian cancer vaccine.**
Muzamil Y. Want, Takemasa Tsuiji, Richard Koya, Sebastiano Battaglia, Roswell Park Cancer Institute, Buffalo, NY.

Ovarian cancer (OC) is the fifth leading cause of cancer death in the United States with approximately 20,000 women being diagnosed every year. Since OC development is mainly asymptomatic, patients are often diagnosed at late stage and present local and distal metastases. This offers a clinical challenge, as roughly 70% of the patients develop chemoresistant disease. With the advent of cancer immunogenomics it is now possible to identify tumor specific mutations, or neoantigens/neoepitopes, that can be exploited for the development of personalized T cell therapies via DC vaccines or adoptive cell therapy (ACT). We therefore hypothesize that tumor cells isolated from malignant ascites reflect the genomic landscape of the primary tumor, offering a unique opportunity to identify clinically actionable tumor neoantigens. We utilized primary tumor, tumor cells isolated from malignant ascites and metastatic samples to create patient-derived xenografts (PDX) mice and to interrogate the tumor mutational landscape. Somatic mutations were identified by whole exome sequencing (WES) and RNAseq analysis in tumor samples, using PBMCs as germline control. In parallel 20 PDX of ovarian cancer were established in NSG mice by injecting $2 \times 10^6$ cells/mouse subcutaneously (SQ, n = 10) and intraperitoneally (IP, n = 10). Tumor growth was monitored weekly via caliper measurement for mice injected SQ and via abdominal circumference change injected IP. Mutational analysis and prediction of high affinity peptides was done using bioinformatics approach. We have utilized different algorithms that are based on Artificial Neural Networks or published motifs for predicting binding of 8-11 mer peptides to number of Human MHC alleles (HLA) and out of 168 mutated peptides identified, 30 were found to have high affinity for different HLAs compared to wild type peptide. Mutated and wild type peptides were pulsed into dendritic cells and co-cultured with CD8 T cells for 20 days. Validation of stimulated CD8 T cells by these mutated peptides using ELISPOT is underway. TCR specific for neoantigen from CD8 T cells will be identified and cloned using retroviral vectors. Transfected CD8 T cells with neoantigen specific TCR will be confirmed by co-culturing them with dendritic cells pulsed with wild type and mutated peptides. Further engineered CD8 + T cells specific for neoantigens will be tested for adoptive cell therapy in the established PDX models of ovarian cancer.

**#5675 A novel PI3K inhibitor suppresses tumor progression by immune modulation.**
Zusheng Xu,1 Yangtong Lou,1 Yingying Qu,1 Wei Wang,1 Xiaoxi Wang,1 Bing Ji,1 Ying Gu,2 Yingxia Zhang,2 He Zhou,2 Shanghai Yingshi Pharmaceuticals Co. Ltd., Shanghai, China; Shanghai ChemPartner Co., Ltd., Shanghai, China.

Phosphoinositide 3-kinase delta (PI3Kδ) inhibitors have shown anti-tumor efficacy in the clinic and one such compound, idelalisib, was approved by the FDA for the treatment of relapsed chronic lymphocytic leukemia (CLL) in 2014. A novel PI3Kδ inhibitor, YY-20394, was developed with specific selectivity against PI3Kδ and inhibited PI3Kδ expressing human tumor cells growth both in vitro and in vivo. In addition, our previous data have shown YY-20394 significantly inhibited primary tumor growth in immune-competent mice with 4T1 and CT26 tumors, as well as 4T1 lung metastasis with dose dependency. The anti-tumor efficacy of YY-20394 was largely mediated by T cells. More importantly, YY-20394 synergistically enhanced the anti-tumor efficacy of anti-PD-L1 antibody in CT26 model and achieved long-term immune memory which is specific for CT26 tumors, but not for unrelated A20 tumors. In vitro mechanistic studies showed YY-20394 significantly inhibited T cell differentiation into Treg both in mouse splenocyte and in human primary CD4+ T cells, and was especially potent inhibiting their IL-10 secretion in vitro. Analyses of tumors treated with YY-20394 reviewed that YY-20394 decreased the percentage of Treg in the tumor infiltrating leukocytes, as well as IL-10 secretion. It also showed some effects on the myeloid populations in the tumors. These data suggest the YY-20394, a novel PI3Kδ inhibitor, represents a promising and safe immune modulator and shows great potential as a cancer immune-therapeutics.

**#5676 Functional pairing of immunomodulatory targets in anaplastic thyroid cancer.**

Thyroid cancer is the most common type of endocrine malignancy that has an excellent overall survival frequency. Although most well differentiated thyroid cancers (WDTC) are manageable and respond to current therapeutic modalities, undifferentiated anaplastic thyroid cancers (ATC) exhibit a dramatically different clinical behavior and poor prognosis. With the recent development of immunotherapies, targeted, well-defined treatment plans can demonstrate promising treatment outcomes in ATC patients. Precise immunological targets in ATCs with potential clinical relevance are unknown. Major progress has been made in last 5 years toward development of immune checkpoint inhibitors using anti-CTLA-4 and anti-PD-1/PD-L1 antibodies for cancer treatment which has made immunotherapies one of the mainstream treatment choices. Few additional members of the immunoglobulin superfamily of receptors, like LAG3, TIM3 and VISTA have recently been identified as potential checkpoint targets. Interestingly some of these molecules including TIM3 and PD-L1 promote tumor progression and immune escape. Identification of specific immunotherapeutic targets require a better understanding of the immune microenvironment in ATC. To this end we evaluated the expression of prominent co-stimulatory and co-inhibitory cell surface molecules by RT-PCR in three thyroid cancer cell lines - TPC-1 (papillary), CGTH-W1 (follicular) and 8505C (anaplastic). We observed that majority co-inhibitory molecules were upregulated in all three tumor cell lines. CTLA4, interestingly, had the highest expression in 8505C. Additionally we observed differential expression of BTLA, LAIR1, TIM3 and VISTA between TPC-1 and 8505C. LAG3, PD-1 and PD-L1 were also upregulated in 8505C compared to TPC-1. Similar pattern was observed with the expression of co-stimulatory molecules, CD40L and GITR. GITR has been shown to have a tumor suppressor function in multiple myeloma. Another co-stimulatory molecule OK40, which has shown promise in tumor regression when targeted, was upregulated in all three cell lines and 8505C showed the highest expression. Our findings suggest that the aggressive and less immunogenic phenotype of ATC might be attributed to the differential expression of these molecules. Targeting these immunomodulatory molecules in ATC warrants a better understanding of the crosstalk between them and it might provide an efficient means for the disease management.

**CLINICAL RESEARCH: Liquid Biopsies 5: cfDNA, MicroRNA, and Protein**

**#5677 Performance of a robust and sensitive liquid biopsy workflow for mutation detection in plasma.**
Jonathan Choi, Cindy Choi, Jorge Dinis, Jingchuan Li, Sean Chien, Bosun Min, Abraham Munoz, Janet Jin, Amrita Pati, Liang Feng, Johnny Wu, Ashla Singh, Fergal Casey. Roche Sequencing Solutions, Pleasanton, CA.

The discovery of circulating tumor DNA (ctDNA) and the development of highly sensitive technologies have made the utility of liquid biopsies in clinical practice more feasible. Potential applications for liquid biopsies include early cancer detection, tumor genotyping in the absence of tissue biopsies, disease monitoring, and identification of drug resistance markers. However, there is a multitude of technical challenges to accurately detect ctDNA with high sensitivity and reproducibility. Various methods have been established by research centers and companies, each with its advantages and limitations. We have developed a sensitive NGS-based liquid biopsy assay, called the AVENIO ctDNA Analysis Kits (research use only), which includes three panels targeting biomarkers for solid tumors. The AVENIO ctDNA Analysis Kits include cfDNA extraction from up to 5ml plasma input, optimized reagents and workflow for NGS library preparation and target enrichment. It is accompanied with an intuitive software and data analysis package to easily obtain results. The assay sensitivity detects 4 cancer relevant mutation classes – single nucleotide variations (SNVs), insertions/deletions, copy number variations and structural rearrangements. We conducted a study with 200+ samples of plasma-derived cfDNA, cell line blends containing relevant cancer mutations, and clinical samples, with which we demonstrated the analytical sensitivity of the three distinct AVENIO gene panels (covering 17, 77 and 197 genes). We demonstrate >95% sensitivity for SNVs at 0.5% mutant allele frequency; >95% specificity for 1% indels; >95% specificity for 1% structural variants. We also demonstrate assay robustness through multiple replicates, day-to-day, and operator-to-operator reproducibility. In conclusion, the AVENIO ctDNA Analysis Kits for solid tu
nors encompasses a comprehensive assay and analysis workflow aimed to provide researchers with robust, reliable, highly sensitive and easy to use liquid biopsy assays to conduct the necessary studies to demonstrate the utility of circulating biomarkers in routine clinical testing.

**#5678** Novel serum microRNAs that enable liquid biopsy for colorectal cancer: validation study of large cohort. Hirayuki Takamur, 1 Yutaka Saito, 1 Taku Sakamoto, 2 Seiichiro Abe, 3 Masayoshi Yamada, 1 Takashi Nakajima, 1 Kazuki Sudo, 2 Ken Kato, 1 Junpei Kawauchi, 1 Satoko Takizawa, 1 Hiromi Sakamoto, 1 Motohiro Kojima, 1 Atsushi Ochiai, 1 Shumpei Niida, 2 Hideshi Ishii, 3 Tomoko Takamur, 1 Juntaro Matsuaki, 2 Takahisa Matsuoka, 2 Takahiro Ochiai, 1 National Cancer Center Hospital, Tokyo, Japan; 1Toray Industries, Inc., Tokyo, Japan; 1National Cancer Center Research Institute, Tokyo, Japan; 2National Cancer Center Hospital East, Tokyo, Japan; 3National Center for Geriatrics and Gerontology, Tokyo, Japan; 4Osaka University Graduate School of Medicine, Osaka, Japan; 5Showa University, Tokyo, Japan.

Introduction: Recent studies have reported that serum microRNAs (miRNAs) are potentially useful biomarkers for cancer. However, the detection system using serum miRNAs is not established in colorectal cancer (CRC). The aims of this study are 1) to identify specific serum miRNAs and establish the discriminant model for CRC detection and 2) to validate the miRNAs and the discriminant model using a large cohort. Methods: First, we identified serum miRNAs related with the presence of CRC and constructed the discriminant model for CRC detection using the publicly-released serum miRNA database including 50 patients with CRC and 90 healthy individuals (GSE39016). Comparing serum miRNA levels between patients with CRC and healthy individuals, we picked up miRNAs (p<0.05 by t-test and fold change > 2). Using these miRNAs, Fisher’s linear discriminant analysis was performed and the diagnostic models were constructed using less than 7 miRNAs. Subsequently, 1117 patients of National Cancer Center Hospital with CRC were enrolled as a validation cohort. Patients with the following criteria were excluded: (i) patients simultaneously or previously diagnosed as the other cancers, (ii) patients who were treated for CRC previously and (iii) patients with familial adenomatous polyposis or Lynch syndrome. Control blood samples were obtained from patients without any history of cancer who were admitted or referred to National Center for Geriatrics and Gerontology or Yokohama Minoura Clinic between 2010 and 2015. A total of 1013 CRC patients and 4384 non-cancerous patients were analyzed. Total RNA was extracted from 300 micro L of serum and comprehensive miRNA expression analysis was performed using a 3D-Gene microarray. ROC analysis was performed to evaluate the previous discriminant models. The sensitivity in each pathological stage and location of CRC was also investigated. This research is partially supported by the “Development of Diagnostic Technology for Detection of miRNA in Bodily Fluid” from the Japan Agency for Medical Research and Development (AMED). Results: First we picked up 30 miRNAs for CRC diagnosis. Fisher’s analysis revealed 107611 candidates of numerical formulas, that showed > 80% of sensitivity and specificity. We could narrow these candidates to 43 formulas with validation analysis. By ROC analysis, the AUC, sensitivity and specificity of the discriminant formula with best performance was 0.904; 79.6% and 86.5% respectively. The sensitivities of each pathological stage were as follows; pStage 0: 79.0%, pStage I: 90.7%, pStage II: 85.1%, pStage III: 73.7%, pStage IV: 62.2%. The sensitivity of CRC in the right side of the colon was 79.4%, whereas in the left side was 79.7%. Conclusions: We identified novel serum miRNAs for CRC detection. Our discriminant using these miRNAs can diagnose CRC including early stage. Furthermore, the sensitivity was high irrespective of the tumor location.

**#5679** Using droplet digital PCR to analyze MYCN copy number in plasma from patients with high-risk neuroblastoma. Marco Lodrini, 1 Annika Sprüssel, 1 Annika Atrash, 1 Solna, Sweden; 2Robert Kochschak, 1 Holger Lode, 2Matthias Fischer, 3Johannes H. Schulte, 1 Angelika Eggert, 1 Hedwig Debeer 1Charité, Berlin, Germany; 2Greifswald University Hospital, Greifswald, Germany; 3University Hospital Cologne, Cologne, Germany.

The invasive nature of surgical biopsies most often prevents their sequential application to monitor disease in patients with high-risk neuroblastoma. Even when available, single biopsies often fail to reflect neuroblastoma dynamics, intratumor heterogeneity and drug sensitivities likely to change during neuroblastoma evolution and treatment. Implementing molecular characterization of cell-free neuroblastoma-derived DNA (cfDNA) isolated from blood plasma would improve outcome prediction, patient monitoring and treatment selection for high-risk neuroblastoma patients, by providing a method to follow clonal evolution in tumor subpopulations and treatment response as well as capture the molecular landscape of all tumor clones. As a first step, we established a digital droplet PCR (ddPCR) protocol to analyze the MYCN copy number status. Analyzing the dilution series of a synthetic MYCN template consisting of 70 nucleotides demonstrated a strong correlation between theoretically calculated MYCN copy number and the MYCN copy number measured using our ddPCR protocol in these patients. The MYCN copy number status in a large panel of neuroblastoma cell lines with MYCN copy number determined from cfDNA isolated from cell culture media from the corresponding cell lines. Our ddPCR protocol reliably detected MYCN status in the cell line using cfDNA analysis. Next, we analyzed cfDNA copy number status in primary neuroblastoma samples from 10 patients and compared these values to the MYCN copy number determined from cfDNA isolated from 200 µL of blood plasma collected from the corresponding patients. These final validation steps demonstrated that our ddPCR protocol for cfDNA from patient blood plasma reliably detects MYCN copy number status in the tumor. Our data justify the further development of molecular neuroblastoma characterization from cfDNA in patient blood plasma. An expanded molecular diagnostic monitoring palette will improve monitoring of disease progression including relapse and metastatic events as well as therapy success or failure in high-risk neuroblastoma patients.

**#5680** Clinical significance of low frequency EGFR and KRAS mutations of cell free DNA using Ion AmpliSeq Cancer Hotspot Panel in lung cancer patients. Jae Sook Sung, 1 Jong Won Lee, 2 Boyeon Kim, 3 Saet Byeol Lee, 2 Chang Won Park, 2 Ha Mi Kim, 2 Nak-Jung Kwon, 2 Won Jin Jang, 2 Yoon Ji Choi, 2 Jung Yoon Choi, 2 Eun Joo Kang, 2 Kyung Hwa Park, 2 Sung Yong Lee, 2 Yeol Hong Kim, 1 Cancer Research Institute, Korea University, Seoul, Republic of Korea; 2Division of Pulmonary Medicine, Department of Internal Medicine, Korea University Anam Hospital, Korea University College of Medicine, Seoul, Republic of Korea; 3Department of Internal Medicine, Korea University Guro Hospital, Seoul, Republic of Korea.

Cell free DNA (cfDNA) present in the bloodstream shows great potential as a useful cancer marker for molecular diagnosis and cancer progression monitoring. Especially, the cfDNA with Next Generation Sequencing (NGS) technology allows high through put examination of various genes concurrently at a low cost. However, there are still debates regarding clinically meaningful variant frequency to identify mutations in cfDNA, especially with ultra-deep sequencing. In this study, we examined the clinical utility of Ion AmpliSeq Cancer Hotspot Panel v2 (ICP; Ion Torrent) with Proton platform for cfDNA. We compared 2800 COSMIC mutations from 50 cancer genes was used to analyze cfDNA of 125 serum samples from lung cancer patients. The percentage of on target was 92% with mean depth of 22,868X. We identified aberrations of TP53 (72%), EGFR (43%), PSEN (26%), PIK3CA (26%), BRF (16%), KRAS (14%), KIT (10%) and RET (10%) with the cut-off criteria of variant frequency >0.1% and p<0.01. To validate the results, we analyzed EGFR gene status by direct sequencing in available 100 FFPE tumor tissues (tDNA). Out of 17 patients with EGFR mutations in tDNA, 9 patients showed very low frequency (<0.05%) of same EGFR mutation in cfDNA. To validate the results of ICP, droplet digital PCR (ddPCR) was carried out with same cfDNA. From those 9 patients, EGFR mutations in cfDNA were detected in 5 patients (minimum frequency 0.01%) by ddPCR. From the patients with wild type EGFR in tDNA, EGFR exon 19 deletion or exon 21 point mutation were detected by ICP in 19 patients using cfDNA. Again, ddPCR was carried out with same cfDNA to confirm the result. EGFR mutations were confirmed in nine patients (47.4%) by cfDNA ddPCR and among the 6 patients treated with EGFR TKI, 4 patients showed response or stabilization of disease. Also, we identified 18 patients with KRAS mutations in tDNA. The result of ddPCR was matched in 80% of patients. Interestingly, 2 patients had multiple KRAS mutations in cfDNA with ICP as well as ddPCR. In our study, we demonstrated that ICP with Proton system is a useful assay to identify somatic mutations using cfDNA in lung cancer patients. Also, we suggest that even EGFR mutation of very low frequency (<0.05%) might have clinical significance in NGS analysis using cfDNA. In future studies, we will be reanalyzed the 2800 COSMIC mutations in cfDNA with ddPCR. CLINICAL RESEARCH: Liquid Biopsies 5: cfDNA, MicroRNA, and Protein

Many studies have been conducted investigating cell-free DNA (cfDNA) for disease diagnosis. To prevent cellular DNA release into the plasma, plasma separation within 2 hours of blood collection is required, utilizing the most commonly used type of tube (BD Vacutainer® CPT™; CPT). These temporal restrictions render operations requiring plasma separation a laborious task. It has been noted that Cell-Free Plasma BCT tubes (Streck Inc. BCTs) prevented nucleated cell disruption. The use of BCTs may enable us to separate plasma without temporal restrictions. The aim of this study was to evaluate changes in DNA levels in plasma after preservation using two types of collection tubes. Samples were drawn from 7 healthy donors into CPTs and BCTs, and stored at room temperature. Plasma was separated immediately (d0), and on days 3, 6, 9, 12, and 14 after blood collection. The concentrations of DNA in the extracted plasma samples were measured. Blood stored in CPTs showed increases in plasma DNA concentrations over time. The mean DNA concentrations at each time-point were 0.39 (d0), 2.96 (d3), 40.44 (d6), 84.94 (d9), 91.41 (d12), and 94.94 (d14). However, plasma DNA levels remained stable in BCTs from 6 days. There were significant differences between the DNA concentrations in BCTs on d0 (0.74 [0.43-1.44] ng/µl) and d14 (1.78 [0.63-4.20] ng/µl) (p = 0.0378). Although significant differences were only observed between d0 and d14 in BCTs, the amount of plasma DNA gradually increased after d6. Furthermore, obvious color changes in the plasma were observed, and the boundary between plasma and PBMCs became unclear over time. These results indicate that BCTs may yield stable cfDNA samples for up to 6 days after blood collection. BCTs may be a novel collection tube for cfDNA research, including liquid biopsies in cancer patients.

#5684 NSABP FC-7 correlative study: HER2 amplification (amp) in circulating cfDNA (cfdNA) in metastatic colorectal cancer (mCRC) resistant to anti-EGFR therapy (tx) (S. Kim, Ashok Srinivasan, Carmen J. Allegra, Samuel Jacobs, Rebecca J. Nagy, Richard B. Lanman, AmirAli Tala- vaz, Patrick Gavin, Rekha Pal, Peter C. Lucas, Kay Pogue-GeIle, NSABP, Pittsburgh, PA; NSABP, and UF Health, Gainesville, FL; Guardant Health, Redwood City, CA; University of Pittsburgh School of Medicine, Pittsburgh, PA.

Background. FC-7 is a phase Ib study hypothesizing that dual ERBB blockade (neratinib and cetuximab) could overcome an acquired resistance mechanism to anti-EGFR tx in KRAS/NNAS/BRAF/PiK3CA wild type (wt) mCRC patients (pts).

Previously we demonstrated a 36% rate of HER2 amp in post-anti-EGFR biopsies (bxs). Assay of plasma cfDNA is minimally invasive and may provide comprehensive genomic profiling. We tested the accuracy of a cfDNA assay for HER2 amp, comparing results from matched bxs to evaluate molecular changes in HER2 copy number. Methods: 23 pts with mCRC resistant to anti-EGFR tx were enrolled and treated with cetuximab and neratinib. 17 paired bxs (6 post-tx bxs had insufficient tumor) were assessed for HER2 amp using chromogenic in situ hybridization (CISH) (Dako PharmDx™). HER2 was considered amplified when HER2/CEP17 ratio ≥ 2. cfDNA was extracted from plasma of 11 pts after 1st line anti-EGFR tx but before addition of cetuximab and neratinib. 5-30 ng of DNA was sequenced across S12 exons in 24 genes with Hiseq (Illumina). Copy number variants (CNV) were quantified using a customized pipeline (Guardant 360). One plasma sample failed to yield sufficient cfDNA. 10 pts had comparison of cfDNA with pre- or post-anti-EGFR bx. Results: 4 of 9 plasma samples (1 non evaluable) had HER2 amp, all concordant with pre- or post-anti-EGFR bx tissue. 3 pts converted to HER2 amp after anti-EGFR tx (pts 3, 5, 7), and for 2 of these conversions (pts 5, 7), the amplification was evident in cfDNA.

#5683 Evaluation of the utilization of blood collection tubes for cell-free DNA research. Fumitaka Endo, Takeshi Iwaya, Takeshi Chiba, Mizunori Yae-gashi, Kei Sato, Kohei Kume, Atsuhiro Arisue, Yutaka Nishinari, Ryoko Kawagi-shi, Takenori Segawa, Satoshi Nishizuka, Akira Sasaki. Department of Surgery, Iwate Medical University School of Medicine, Morioka, Iwate prefecture, Japan.

Many studies have been conducted investigating cell-free DNA (cfDNA) for disease diagnosis. To prevent cellular DNA release into the plasma, plasma separation within 2 hours of blood collection is required, utilizing the most commonly used type of tube (BD Vacutainer® CPT™; CPT). These temporal restrictions render operations requiring plasma separation a laborious task. It has been noted that Cell-Free Plasma BCT tubes (Streck Inc. BCTs) prevented nucleated cell disruption. The use of BCTs may enable us to separate plasma without temporal restrictions. The aim of this study was to evaluate changes in DNA levels in plasma after preservation using two types of collection tubes. Samples were drawn from 7 healthy donors into CPTs and BCTs, and stored at room temperature. Plasma was separated immediately (d0), and on days 3, 6, 9, 12, and 14 after blood collection. The concentrations of DNA in the extracted plasma samples were measured. Blood stored in CPTs showed increases in plasma DNA concentrations over time. The mean DNA concentrations at each time-point were 0.39 (d0), 2.96 (d3), 40.44 (d6), 84.94 (d9), 91.41 (d12), and 94.94 (d14). However, plasma DNA levels remained stable in BCTs from 6 days. There were significant differences between the DNA concentrations in BCTs on d0 (0.74 [0.43-1.44] ng/µl) and d14 (1.78 [0.63-4.20] ng/µl) (p = 0.0378). Although significant differences were only observed between d0 and d14 in BCTs, the amount of plasma DNA gradually increased after d6. Furthermore, obvious color changes in the plasma were observed, and the boundary between plasma and PBMCs became unclear over time. These results indicate that BCTs may yield stable cfDNA samples for up to 6 days after blood collection. BCTs may be a novel collection tube for cfDNA research, including liquid biopsies in cancer patients.

Conclusion: In this sample set, HER2 amp detected in plasma-derived cfDNA from mCRC pts resistant to anti-EGFR tx is comparable to amp assessed in primary or metastatic tissue. Given advantages of liquid bx relative to repeated tissue bx, mea-

#5685 An evaluation of DNA and RNA based blood biomarkers in prostate cancer. Jenny Antonello,1 Jakub Chudziak,1 Alan Redfern,1 Victoria Foyle,1 Shambhavi Srivastava,2 Adnan Syed,1 Deborah Burt,1 Mahmood Ayub,1 Bedirhan Kileri,1 Marina Parry,1 Richard Marais,2 Esther Baena,1 Crispin Miller,1 Dominic Rothwell,1 Noel Clarke,2 Caroline Dive,1 Ged Brady1.1 CRUK Manchester, Manchester, United Kingdom; 2Christie NHS Foundation Trust Manchester, Manchester, United Kingdom.

Background: Prostate cancer (CaP) is the second-leading cause of male cancer-related mortality in Western societies. Localised prostate cancer (Loc-CaP) can be classified into low-, intermediate-, or high-risk groups. Active surveillance is recommended for low-risk patients, whereas radiotherapy or surgery is often indicated in intermediate- and high-risk patients, with possible intensification using hormone therapy treatment. Despite advances in radiation delivery and surgery, ~20% of patients will not be cured with local treatment and require androgen deprivation therapy (ADT). The majority will develop resistance to ADT resulting in castration resistant prostate cancer (CRPC), with poor prognosis and increased risk of metastatic disease (mCRPC). Biomarkers are being developed based on tumour biopsies which may help stratify patients and allow more effective treatment. However tumour biomarkers are invasive, demanding for patients and surgeons as well as challenging for longitudinal sampling. Here we evaluate a range of blood biomarkers suitable for longitudinal sampling including circulating tumour cells (CTCs), circulating tumour DNA (ctDNA) and Tumour educated platelet mRNA (TEP-RNA). Methods: A blood sampling, processing and banking pipeline has been established for CaP patients providing ctDNA, enriched and single CTCs as well as TEP-RNA. Following ctDNA isolation, next generation sequencing (NGS) libraries are prepared to generate copy number alteration (CNA) data and mutation profiles. CTCs are enriched using both the epitope independent Parsertix (P-CTC) (Chudziak J. et al, 2016) and the epitope dependent (EPACM and KRT19) CellSearch (CS-CTC) platforms. Genomic analysis of CTCs is carried out by NGS of whole genome amplified (WGA) single and pooled CTCs. CTC and TEP-RNA mRNA profiles are established using both the Fluidigm RT qPCR (Fluidigm Biomark™ HD system) and RNA-Seq. Results: Over 160 Loc-CaP and 100 mCRPC blood samples have been collected, processed and banked. In keeping with published data 53% of the 100 mCRPC patients have ≥50% CTCs (a poor prognostic indicator) compared to 100% of Loc-CaP having <2 CTCs. Control cell “spike in” RNA data showed ≥1000 fold enrichment of epithelial mRNAs post Parsertix CTC enrichment indicate an equivalent enrichment of the “spiked in” cells. Similar epithelial mRNAs enrichment was seen in 3/5 mCRPC patients. Using a CNA “spiked in” RNA-Seq data showed that exosomes only carry short fragments of mRNA and ncRNA. To address this, we have developed a novel platform specifically designed to perform RNASeq on long RNA from exosomes to efficiently interrogate these as RNA biomarkers. Paired-end sequencing revealed the presence of a wider diversity of annotated mRNA and ncRNAs than previously recognized in exosomes. Employing our whole transcriptome unique molecular indexing strategy, we were able to accurately quantify the number of unique RNA molecules. We detected a total of over 1.4 million unique RNA molecules in our libraries, with 271,308 mapped to protein-coding regions from as little as 2 ml of plasma. We observed that even at a shallow sequencing depth (15 million read pairs), we could detect more than 10,000 genes, composed of 40,000 mRNA and 37,000 ncRNA annotated transcripts. ERCC spike-in analysis indicates that our RNASeq platform is highly sensitive, detecting as few as 8 copies of RNA. Long non-coding RNAs dominated the ncRNA classes and accounted for over 95% of all uniquely detected ncRNAs. We also observed a broad distribution of transcript lengths in the liquid biopsy space has been limited to variant detection in cell-free DNA and circulating tumor cells but transcriptional dysregulation is also an important feature of cancer. Our results shed new light on the biology of exosomes and indicate that, in addition to well-recognized small RNA cargo, plasma exosomes carry an abundance of long RNAs that can be interrogated by our optimized workflow. As exosomes provide a rich and protected source of RNA in biofluids, sequencing both long and small RNA from exosomes has the potential to identify biomarkers without the need for invasive tissue biopsies and allow us to have a more complete picture of how the RNA transcriptome in plasma changes in health and disease.

#5687 Detection and monitoring of IDH mutations in unamplified plasma cell-free DNA in patients with advanced cancers treated with IDH inhibitors. Filip Janjigian1, Anthony P. Conley1, Anjali Raina1, Verónica R. Holmes1, Aung Naing1, Daniel D. Karp1, David Fogelman1, Ahmed O. Kaseb1, Rajyalakshmi Luthra2, George A. Karlin-Neumann3, Funda Meric-Bernstam4, Jenny Antonello1, Jakub Chudziak1, Alan Redfern1, Victoria Foyle1, Sunita Badola1, Graham Miller1, Dominic Rothwell1, Noel Clarke2, Caroline Dive1, Ged Brady1. 1ExosomeDiagnostics,Inc.,Cambridge,MA; 2TakedaPhar- maceticals International Co. Translational and Biomarker Research, Cam- bridge, MA; 3Sagrat Cor Hospital-Quirónsalud Group, Barcelona, Spain; 4OncologyInstitutDrRosell,DexeusUniversityHospital-Quirónsalud Group, Barcelona, Spain; 5CRUK Manchester, Manchester, United Kingdom; 6Christie NHS Foundation Trust Manchester, Manchester, United Kingdom.

Background: Cell-free (cf) DNA from plasma of patients with advanced cancers offers an easily obtainable material for detection of IDH mutations, which can be used for diagnostics and monitoring purposes. Methods: Plasma was serially collected from patients with advanced cancers with IDH1 R132 or IDH2 R172 mutations, who were enrolled to clinical trials with IDH1, IDH2 or pan-IDH inhibitors. cfDNA was purified and up to 16 ng of each DNA was tested for mutations in the R132 hotspot of IDH1 and R172 hotspot of IDH2 using the QX200 Droplet Digital PCR™ platform (Bio-Rad). Results (mutation allele fre- quency [MAF] in the wild-type background or the number of IDH-mutant copies/mL of plasma) were compared both to treatment outcomes and to the results of mutation analysis of either archival primary or metastatic tumor tissue obtained at different points of clinical care from a CLIA-certified laboratory. Results: Of the 28 patients (cholangiocarcinoma, 24; other cancers, 4) with IDH1 or IDH2 mutations (N=25) or IDH2 R172 mutations (N=3) in the tumor tissue, IDH mutations were detected in 26 (93%) of plasma cfDNA samples even though median time from tissue to plasma sampling was 16.5 months (3.5-71.1 months). Quantity (< median vs. > median cfDNA or copies/mL) of IDH-mu- tant cfDNA was not associated with survival (median not reached vs. 11.1 months, P=0.26). The best radiological response to treatment with IDH inhibit- ors was achieved in patients with disease for >18 months in 28 (19.8% of patients). Median progression-free survival was 1.8 months (95% CI 1.4-2.2). The median quantity of IDH- mutant cfDNA (MAF and copies/mL) at baseline, on therapy and at disease progression did not differ (P=0.16). Changes in quantity (MAF and copies/mL) of IDH-mutant cfDNA within first 3 weeks of therapy were not associated with response on radiographic imaging (P<0.05) or progression-free survival (P=0.12). Conclusions: Detection of IDH mutations in a small amount of unamplified plasma cfDNA using ddPCR has excellent sensitivity compared to conventional clinical IDH mutation testing of archival specimens. Quantity and change in IDH-mutant cfDNA did not correspond with treatment outcomes.

#5688 Routine testing for KRAS mutations in cfDNA from blood of advanced cancer patients. Mónica Garzón Ibáñez1, Clara Mayo de las Casas1, Víctor Gil de Laraniva2, Filip Janjigian3, Avelino Escudero4, Beatriz Gracia5, Sergi Vilàtoro6, Jordi Bertrán-Alamillo7, Alejandro Martínez-Bueno8, Santiago Viteri Ramírez2, Ana Pérez Rosado1, Daniela Morales Espinoza1, María José Catalán,1 Niki Karachalios,4 Miguel Ángel Molina-Vila9, Rafael Rosell3,9.1 Pauengiae Oncology, Barcelona, Spain; 2Oncology Institut Dr Rosell, Dexeus University Hospital-Quiron- Salud Group, Barcelona, Spain; 3Sagrat Cor Hospital-Quironsalud Group, Barcelona, Spain.

Background: Mutations in the KRAS proto-oncogene, GTPase (KRAS) are driver alterations in several tumors, such as non-small-cell lung (NSCLC) and colorectal cancer (CRC). However, their role as a prognostic marker in liquid biopsies is unclear. We studied the status of KRAS mutations in the peripheral blood of advanced
NSCLC and colorectal cancer patients visited in our hospital and evaluated its potential value as a monitoring marker in the clinical practice. Methods: We developed a sensitive TaqMan assay, in the presence of a PNA clamp, for the determination of KRAS mutations (codons 12, 13 and 61) in circulating-free DNA (cfDNA). The assay detected 2.5 pg mutated DNA/µL and a ratio of KRAS mutated versus wild type allele of 1:2000, and was validated in 80 cancer patients previously genotyped in tumor tissue showing a clinical sensitivity of 72.5% and specificity of 100%. cfDNA was isolated from serum and plasma specimens, using an automatic extractor and mutational analyses were performed in quadruplicates samples. Serum and plasma samples were drawn at diagnosis, during follow-up and progression. Results: 239 NSCLC and 11 colorectal cancer patients were screened for KRAS mutations in cfDNA at presentation in the period of 2013 to 2016. In addition, 160 cfDNA samples collected during disease monitoring of 61 patients were analyzed. Paired biopsies were available from 110/250 pts at diagnosis (60 positive for KRAS in FFP and 50 WT). The KRAS mutation was detected in the cfDNA of 76.6% (46/60) p positive in tumor tissue vs. only in 1/50 WT patients where a GI2C was detected in cfDNA in a consistent manner, probably associated with a heterogeneity of the tumor. In patients with no biopsy available, we detected KRAS mutations in cfDNA in 14.3% (20/140) cases at diagnosis. The most prevalent mutations observed in cfDNA were GI2C (44.7 %), GI2V (22.4%) and GI2D (10.4%) for NSCLC patients and GI3D (5.9%) for colorectal patients. The Q61H mutation was detected in the cfDNA of one NSCLC and one CRC p. Of the 67 patient’s positive in cfDNA at presentation, KRAS mutations were detected in serum and plasma in 38 patients, only in plasma in 24 and only in serum in 5. Regarding the 61 patients with serial blood samples, we observed a correlation between the KRAS mutation load in cfDNA and the course of the disease, with a decrease in patients responding to chemotherapy and an increase during disease progression. Conclusions: Our results demonstrate the feasibility of KRAS mutation analysis in the cfDNA of advanced NSCLC and colorectal patients. Analysis of KRAS mutations in the blood of mutated patients can have a value in patients with no biopsy available and to monitor the course of the disease.

#5689 Identify tissue-of-origin in cancer cfDNA by whole genome sequencing. Yaping Liu,3 Sarah Reed,4 Atish D. Choudhury,4 Heather A. Parsons,5 Daniel G. Stover,5 Gavin Ha,5 Gregory Gyudosh,5 Justin Rhoades,5 Denisse Rotem,5 Samuel Freeman,2 Viktor Adalsteinsson,5 Manolis Kellis1,5, MIT, Cambridge, MA; 2Dana-Farber Cancer Institute, Boston, MA.

Cell free DNA (cfDNA) has been shown to be an emerging non-invasive biomarker to monitor tumor progression in cancer patients. Elevated cfDNA has been found not only from tumors, but also from normal tissues. Thus, the identification of cfDNA’s tissue-of-origin is critical to understand the mechanism of cfDNA release and tumor progression. Recent efforts to identify cfDNA’s tissue-of-origin begin to utilize cfDNA’s epigenetic status, such as DNA methylation and nucleosome spacing. However, both of these methods have limitations: (1) for nucleosome positioning, lack of reference nucleosome maps in different tumor and normal tissues has limited its application to tissue-of-origin deconvolution; (2) For DNA methylation, large DNA degradation during whole genome bisulfite sequencing (WGBS) library preparation, even with current low-input DNA technology, is still the major hurdle for its clinical application, although extensive DNA methylation studies by WGBS in tumor and normal tissues have been reported. Along the histone modification maps. Very recently, a pioneer study showed significant differences between DNA fragment lengths of methylated and unmethylated cfDNA. Taking advantage of this experimental observation, we developed a machine learning approach to infer the base pair resolution DNA methylation level from fragment size information in whole genome sequencing (WGS). The predicted DNA methylation, from not only high coverage but also dozens of ultra-low pass WGS (ULP-WGS), showed high concordance with the ground truth DNA methylation level from WGS in the same cancer patients. Furthermore, by using hundreds of WGS datasets from different tumor and normal tissues/cells as the reference map, we deconvoluted cfDNA’s tissue-of-origin status by inferred DNA methylation level at ULP-WGS from thousands of breast/prostate tumor samples and healthy individuals. The cfDNA’s tissue-of-origin status in cancer patients showed high concordance with confirmed metastasis tissues from physicians. Interestingly, some clinical information, such as cancer grades/stages, seemed to be correlated with cfDNA’s tissue-of-origin status. Overall, our methods here pave the road for cfDNA’s application in clinical diagnosis and monitoring.

The evaluation of cfDNA allows novel approaches to noninvasive detection of actionable alterations, resistance mechanisms, and tumor monitoring in patients with cancer. Importantly, tumor-specific DNA fragments represent a small minority of the cfDNA and can be obscured by false positive (FP) variants introduced by chemical damage and sequencer error. To address this, we improved key processes in the design of NGS libraries, including a new molecular barcoding approach, that maximize molecular recovery while eliminating spurious variants. We engineered a type all-1:2000 mutant and was validated in 80 cancer patients previously genotyped in tumor tissue showing a clinical sensitivity of 72.5% and specificity of 100%. cfDNA was isolated from serum and plasma specimens, using an automatic extractor and mutational analyses were performed in quadruplicates samples. Serum and plasma samples were drawn at diagnosis, during follow-up and progression. Results: 239 NSCLC and 11 colorectal cancer patients were screened for KRAS mutations in cfDNA at presentation in the period of 2013 to 2016. In addition, 160 cfDNA samples collected during disease monitoring of 61 patients were analyzed. Paired biopsies were available from 110/250 pts at diagnosis (60 positive for KRAS in FFP and 50 WT). The KRAS mutation was detected in the cfDNA of 76.6% (46/60) p positive in tumor tissue vs. only in 1/50 WT patients where a GI2C was detected in cfDNA in a consistent manner, probably associated with a heterogeneity of the tumor. In patients with no biopsy available, we detected KRAS mutations in cfDNA in 14.3% (20/140) cases at diagnosis. The most prevalent mutations observed in cfDNA were GI2C (44.7 %), GI2V (22.4%) and GI2D (10.4%) for NSCLC patients and GI3D (5.9%) for colorectal patients. The Q61H mutation was detected in the cfDNA of one NSCLC and one CRC p. Of the 67 patient’s positive in cfDNA at presentation, KRAS mutations were detected in serum and plasma in 38 patients, only in plasma in 24 and only in serum in 5. Pascale”, Naples, Italy.

Introduction: The detection of actionable mutations in lung cancer is still a major challenge due to the lack of tissue specimens for molecular profiling of the tumor in approximately 25% of patients. The circulating cell-free tumor DNA (cfDNA) isolated from plasma of cancer patients is an alternative, minimally invasive source of tumor DNA that also allows rapid determination of the mutations present in the tumor. Moreover, the initial information provided in cfDNA makes their detection and quantification in plasma a challenging task. Here we report a multi-institutional validation of the Oncomine cfDNA Lung Cancer assay for the analyses of cfDNA in molecular pathology laboratories. Methods: The Oncomine cfDNA Lung assays is a multiplexed sequencing assay for liquid biopsy that generates reads containing targeted cfDNA regions along with a molecular tag. In order to allow an initial uniform evaluation of the assay, the Multiplex 1 cfDNA Reference Standard (Horizon Dx) derived from human cell lines, and fragmented to an average size of 160bp±10% (144bp–176bp) to closely resemble cfDNA extracted from human plasma, was used. The reference sample covers 8 mutations in the EGFR, KRAS, NRAS and PIK3CA genes at 5%, 1%, 0.1% allelic frequencies and wildtype allele. The same lot of control sample was distributed to the participating laboratories within the OncoNetwork Consortium. Samples were sequenced twice in each laboratory either using the Ion PGM system or the Ion S5 system. Libraries were templated using the Ion Chef and multiplexed as four libraries on a 318/520 chip or eight libraries on a 530 chip. A bioinformatics pipeline within the Torrent Server software allowed for automated variant calling. Results: The laboratories involved in the study were able to detect the 8 hotspot base changes and indels present in the control samples at allelic frequencies from 0.1% to 5% with an average 94.05% sensitivity (range 87.50% - 97.92%) and an average 99.87% specificity (range 99.53% - 100%). When only considering variants at the 0.1% allelic frequency, the average sensitivity was 83.04% (range 68.75% - 99.95%) and the average specificity was 99.95% (range 99.68% - 99.95%). Notably, at the 0.1% allelic frequency, all the pathological laboratories were able to detect the challenging EGFR T790M variant that is a marker of sensitivity to EGFR tyrosine kinase inhibitors. Con-11clusion: These preliminary data confirm the potential of the Oncomine cfDNA lung assay for plasma genotyping to allow for the noninvasive, multiplexed detection of complex, targetable genomic alterations in lung cancer.

#5695 Increased sensitivity for detection of oncogenic mutations present in circulating cell-free tumor DNA. Aaron R. Thorner, Michael K. Slevin, Andrea Clapp, Haley A. Coleman, Suzanne R. McShane, Samantha D. Drinan, Edwin Thai, Bruce M. Wollison, Robert T. Burns, Alex Frieden, Matthew D. Ducas, Anwesha Nag, Laura E. MacConaill, Matthew L. Meyerson, Dana-Farber Cancer Institute, Boston, MA.

Molecular pathways involved in tumor survival and progression are often activated by genetic alterations, and anticancer agents specifically targeting many oncogenic pathways have entered clinical trials. Precision cancer medi-3cation relies on the accurate identification of oncogenic pathways of interest or the specific targeting of mutant alleles of interest. Liquid biopsy, in particular circulating cell-free tumor DNA (cfDNA) derived from plasma represents a convenient assay material that has been effectively
analyzed for oncogenic mutations in specific forms of cancer such as non-small cell lung cancer. However, introduction cfDNA for clinical genotyping is limited by sensitivity requirements. cfDNA is typically present at 20-100 ng/mL of plasma, of which the cancer fraction can be below 1%. Error rates associated with PCR amplification and base calling (Illumina HiSeq platform) are approximately 5%. The presence in replicate assays of low sequence reads indicative of rare variants with allele fractions (AF) at or below that percentage. We conducted an evaluation of commercially available kits to determine 1) kit sensitivity and if necessary 2) modify the protocol to achieve sensitivity of < 1% AF. To evaluate kit sensitivity cfDNA from a translocation positive cell line was mixed at 5% and 20% with normal cell line cell gDNA. Libraries were prepared for each percent mix using 10 ng of input. Raw mean target coverage (MTC) was similar for evaluated kits (MTC, 250–300X); Percent Duplication, ~34%. Comparison of 20% and 100% translocation samples showed similar levels of unique single nucleotide variant (SNV) detection. However, 5% mixtures showed a ~10 fold reduction in SNV detection compared to both 20% and 100% translocation samples. Furthermore, translocation rearrangement was only detectable in one third of the 5% translocation samples. Increased sensitivity requires unique molecular barcodes coupled with improvements in bioinformatics analysis for clinical implementation of these assays.

#5696 Emerging KRAS mutation can play a considerable role to get acquired resistance to EGFR blockade. Takeshi Yamada, Goro Takahashi, Takuma Iwai, Kouki Takeda, Michihiro Koizumi, Akihisa Matsuda, Seiichi Shini, Yasuyuki Yokoyama, Masahiro Hotta, Keisuke Hara, Satoshi Matsumoto, Fujita, 2 Kengo Horie, 1 Koji Kameyama, 1 Masafumi Ito, 2 Takashi Deguchi 1.

Background: Epidermal growth factor receptor (EGFR) blockade can achieve considerable tumor shrinkage in patients with metastatic colorectal cancer (CRC). However, most patients who benefit from EGFR blockade acquire resistance within a year. It was previously reported that nine of 24 (38%) patients whose tumors initially exhibited wild type KRAS developed detectable mutations in KRAS in their sera after acquiring resistance to EGFR blockade. However, the mechanisms of this acquired resistance remain unclear. In this study, we aimed to identify the mechanisms underlying acquired resistance to EGFR blockade by using circulating-cell-free (ccf)DNA to track emerging KRAS, BRAF and S492R mutations during chemotherapy. Methods: We enrolled 29 patients with metastatic CRC and no mutations in their primary tumors. Patients were treated with first-line systemic chemotherapy that included EGFR blockade. We purified ccfDNA from 1 mL of serum from each patient before they started chemotherapy, and every 2-3 months during chemotherapy until disease progression. We detected KRAS (codons 12, 13, 61, and 146), BRAF (V600E) and S492R mutations using digital polymerase chain reaction. Results: KRAS mutations were detected in the ccfDNA of three of the 29 patients (10%) before chemotherapy. The response rate was 86% (25/29); the four non-responders were the three patients with KRAS mutations, and another who exhibited ccfDNA BRAF mutations before starting chemotherapy. All patients with no KRAS or BRAF mutations in their ccfDNA before chemotherapy responded to the chemotherapy (25/25). Of these 25 initially responsive patients, 13 (52%) acquired resistance. We detected emerging KRAS mutations in the ccfDNA of 11 of these 13 patients (84%); eight of these patients had multiple mutations. We also detected S492R mutations in six patients (16%), four of whom had isolated S492R mutations. Five patients (38%) had S492R; one had mutations in S492R only. Only one patient had no KRAS, BRAF or S492R mutations. Discussion: EGFR blockade has no beneficial effect in patients with KRAS or BRAF mutations in their ccfDNA prior to starting chemotherapy; Emergence of KRAS, BRAF or S492R mutations that were undetectable before the start of chemotherapy may be a mechanism underlying acquisition of resistance to EGFR blockade. Notably, emerging KRAS mutations were detected in most of the patients (84%) who acquired resistance. This indicates that the emergence of KRAS mutations may play a considerable role in the acquisition of resistance to EGFR blockade.

#5697 Proteomic analysis of prostate cancer-related exosomes isolated by anti-PSMA antibody beads. Kosuke Mizutani, 1 Kyojiro Kawakami, 1 Yasunori lasCasas, 1 Mónica Garzón, 2 Nuria Jordana Ariza, 1 Aridasa Balada, 2 Jordi Ber- tez Garcia, 1 Sergio Villatoro, 1 Erika Aldegue, 1 Sonia Rodri-

guez, 1 Raquel Campos, 1 Santiago Viteri Ramirez, 2 Maria Gonzalez-Cao, 2 Niki Karachaliou, 3 Rafael Rosell Costa, 1 Miguel Angel Molina-Vila 1.

Aim: In order to get more detailed understanding cancer-derived exosome, their proteomic analysis is necessary. The aim of this study is to establish the method for isolation and analysis of prostate cancer-related exosomes. Experimental procedures: Total exosomes were isolated from the conditioned media of LNCaP cells by ultra centrifugation. Then, exosomes positive for CD9 or prostate specific membrane antigen (PSMA) were isolated by magnetic beads conjugated with anti-CD9 or -PSMA antibody, respectively. Isolated exosomes were subjected to proteomic analysis. The PSMA positive fraction was also collected by anti-PSMA beads from diluted serum of 3 prostate cancer patients and analyzed by proteomics. Results: A total of 126, 139 and 13 proteins were detected in the LNCaP exosome fractions that were isolated by anti-PSMA beads, respectively. Out of 126 proteins identified in ultracentrifuged isolated exosome, 56 and 6 protein were found in exosomes that were isolated by anti-CD9 beads and anti-PSMA beads, respectively. Seven proteins were commonly detected in exosomes that were isolated by both beads. Fifty, 34 and 48 proteins were identified in the PSMA positive fraction from serum of 3 prostate cancer patients (P1: localized prostate cancer, P2: advanced prostate cancer and P3: castration resis-
tant prostate cancer). Thirty-three proteins were detected in one patient, 22 in two patients and 25 in three patients. Most proteins detected in all patients were serum- or immunoglobulin-related proteins. The numbers of proteins that were detected only in P2 and P3 were 16 and 8, respectively. Six proteins were found in both P2 and P3 patients. Conclusion: In the present study, we analyzed pros-
tate cancer-related exosomes that were isolated by immunoaffinity-based method. Although most proteins were serum- or immunoglobulin-related proteins, proteins that had been reported as a cancer marker were also detected, which could be candidates for exosomal marker of prostate cancer.

#5698 Next generation sequencing of circulating-free DNA from advanced non small cell lung cancer patients using Gene Reader. Clara Mayo de las Casas, 1 Mónica Garzón, 2 Nuria Jordana Ariza, 1 Aridasa Balada, 2 Jordi Ber-tez Garcia, 1 Sergio Villatoro, 1 Erika Aldegue, 1 Sonia Rodri-

guez, 1 Raquel Campos, 1 Santiago Viteri Ramirez, 2 Maria Gonzalez-Cao, 2 Niki Karachaliou, 3 Rafael Rosell Costa, 1 Miguel Angel Molina-Vila 1.

Background: Stand-alone tests such as PCR-derived techniques, FISH or IHC are usually employed to determine clinically relevant alterations in non-small cell lung cancer (NSCLC). However, they target single genes and proteins. Multiplex techniques can reduce the turnaround time and quantity of sample in this setting, but require a careful validation. Methods: A total of 41 cfdNA samples from serum and plasma from advanced NSCLC p were analyzed with the Ac-
toenable Insights TumorPanel, which covers mutations in 15 clinically relevant genes, using the Gene Reader platform (Qiagen). The samples had been previously genotyped for EGFR, KRAS and BRAF mutations by stand-alone, PNA-Taqman assays. Paired biopsies were available in 37 cases. The remaining 4 corresponded to p.T790M-positive blood samples of p progressing to EGFR TKIs. Results: Of the 41 samples taken into the GeneReader workflow, some had a DNA input concentration below specifications, in spite of this limitation, good results were obtained. 14 mutations were fully concordant between tissue, Taq-
man and GeneReader and the four p.T790M mutations were concordant be-
tween Taqman and GeneReader. Five mutations present in tissue were detected by GeneReader and not by Taqman and 11 mutations detected by Taqman were below the 1% detection threshold of GeneReader. Finally, 12 mutations present in tissue were not detected in cfdNA by any of the assays. Concordance between tissue and cfdNA was 97.5%. Conclusion: Application of NGS to liquid biopsies is challenging and requires a careful validation. However, once fully validated, NGS will probably become the methodology of choice for cfdNA analysis in NSCLC patients at presentation and at progression.

#5699 Detection of genetic and epigenetic DNA markers in urine for the early detection of liver cancer. Surbhi Jain, 1 Janin D. Steffen, 2 Yih-Ping Su, 2 Jeremy Wang, 1 Ting-Tsung Chang, 1 Chi-Tan Hu, 2 Wei Song, 1 Ying-Hsiu Su 1.

Aim: In order to get more detailed understanding cancer-derived exosome, their proteomic analysis is necessary. The aim of this study is to establish the method for isolation and analysis of prostate cancer-related exosomes. Experimental procedures: Total exosomes were isolated from the conditioned media of LNCaP cells by ultra centrifugation. Then, exosomes positive for CD9 or prostate specific membrane antigen (PSMA) were isolated by magnetic beads conjugated with anti-CD9 or -PSMA antibody, respectively. Isolated exosomes were subjected to proteomic analysis. The PSMA positive fraction was also collected by anti-PSMA beads from diluted serum of 3 prostate cancer patients and analyzed by proteomics. Results: A total of 126, 139 and 13 proteins were detected in the LNCaP exosome fractions that were isolated by anti-PSMA beads, respectively. tant prostate cancer). Thirty-three proteins were detected in one patient, 22 in two patients and 25 in three patients. Most proteins detected in all patients were serum- or immunoglobulin-related proteins. The numbers of proteins that were detected only in P2 and P3 were 16 and 8, respectively. Six proteins were found in both P2 and P3 patients. Conclusion: In the present study, we analyzed pros-
tate cancer-related exosomes that were isolated by immunoaffinity-based method. Although most proteins were serum- or immunoglobulin-related proteins, proteins that had been reported as a cancer marker were also detected, which could be candidates for exosomal marker of prostate cancer.

CLINICAL RESEARCH: Liquid Biopsies 5: cfDNA, MicroRNA, and Protein
CDKN2A, SFRP1, TPFI, and MGMT). In this present study, we developed specialized short amplicon PCR assays optimized to detect these biomarkers from the urine of patients with cancer and tested the panel of biomarkers in urine of hepatitis, cirrhosis and HCC patients to demonstrate the feasibility of a breakthrough urine DNA test for HCC screening and early detection. Our evaluation indicated that the 4-marker DNA marker panel without combining DNA biomarkers were significantly higher in HCC than in non-HCC population. A correlation analysis indicated that these three markers do not correlate with each other and are suitable to be combined in a panel of biomarkers for the early detection of HCC. The 3-marker HCC urine DNA panel had an AUROC of 0.880 for distinguishing HCC from cirrhosis and hepatitis. By logistic regression, the AUROC for the DNA marker panel was 0.925 with specificity of 84.5% and 89.5% respectively, with a specificity of 90% for detecting HCC with AUROC of 0.951. Furthermore, these 3-DNA markers scored 43 of the 49 (87.8%) AFP-negative (less than 20 ng/mL) HCC urine samples ‘positive’ in this study population. A novel statistic model was build by using Random Forest machine learning method as compared to full logistic regression in both open labeled urine samples and 242 blinded urine validation samples. A sensitivity of 92.3% at a specificity of 87% was obtained by applying the random forest algorithm generated from the open labeled data (at 90% specificity cutoff) to the validation study, where as a sensitivity of 76.9% at a specificity of 84.7% was obtained from the full logistic regression derived from the open labeled data set. In conclusion, HCC DNA markers can be detected in urine of patients with HCC by short-amplicon, PCR-based assays and this urine test has the potential to become the first line of screening for HCC in high risk populations.

#5700 CircSarc: Disease monitoring by liquid biopsies in sarcomas. Heidi M. Namlos,1 Seyed Hossein Moosavi,2 Bodil Bjerkhagen,1 Olga Zaikova,1 Synnove Granlien,1 Stine Næss,1 Nina Louise Jelsøn,2,3 Skyler Mishkin,1 Eva W. Strafford,1 Else Munthe,1 Kirsten S. Hall,1 Lars B. Asheim,3 Eivind Hovig,4 Brian Kudlow,5 Ola Myklebost,4 Kjetil Boye,4 Leonardo A. Meza-Zepeda4 1. Oslo University Hospital, Oslo, Norway; 2Haukeland University Hospital, Bergen, Norway; 3Archer, Boulder, CO; 4University of Bergen, Bergen, Norway; 5Capital Biosciences, Gaithersburg, MD; 6Russian State Center of Radiology and Surgery Technologies, Saint Petersburg, Russian Federation.

We developed a new approach for isolation of circulating cell-free DNA (cfDNA) from liquid biopsies (plasma or serum). Our technology is based on using the proprietary bi-functional substance X (SubX®) that binds DNA under physiological conditions (e.g. directly in biological liquids), followed by adsorption of DNA - SubX® complex on a solid phase matrix. Since SubX® captures DNA via the phosphate groups it allows for elimination of bias related to both AT/CG content and DNA fragments length, thus improving extraction efficacy and accuracy of downstream applications. All currently available commercial kits are [silica-chaoietic salt]-based and exhibit bias for either short or long DNA fragments, as well as for the GC content. In addition, such systems require at least 4-fold dilution of starting volume of bio liquid with concentrated (5-10 M) guanidinium thiocyanate (GTc) to keep resulted GTc concentration at about 1 M, which in turns reduces concentration of DNA to at least 3.0 M. Thus, already low concentrations of cfDNA are significantly reduced and may negatively influence extraction efficacy of low abundance DNA fragments. Since our method does not require chaoietic salt for DNA capture, no dilution of starting material (and thus cfDNA) takes place. DNA-binding matrix SubX® allows either scaling the procedure to either large volumes of starting material or extra low volumes and adaptation of the protocol for 96/384 well format. Separation of cfDNA from the bulk of proteins occurs in a single vortex-spin step without employing chaoietic agents thus speeding-up isolation procedure and reducing the costs. The whole procedure can be completed within an hour and cfDNA is eluted in small volume of TE buffer. Average DNA yield from 0.2 ml of double centrifuged blood plasma from normal donors, cancer and multiple sclerosis patients was 7.5±4.2 ng (n=96).

#5701 Innovative approach for isolation of circulating cell-free DNA from liquid biopsies. Andrei Malychy,1 Vladimir Evtushenko2,3 2Capital Biosciences, Inc., Gaithersburg, MD; 3Russian State Center of Radiology and Surgery Technologies, Saint Petersburg, Russian Federation.

We developed a new approach for isolation of circulating cell-free DNA (cfDNA) from liquid biopsies (plasma or serum). Our technology is based on using the proprietary bi-functional substance X (SubX®) that binds DNA under physiological conditions (e.g. directly in biological liquids), followed by adsorption of DNA - SubX® complex on a solid phase matrix. Since SubX® captures DNA via the phosphate groups it allows for elimination of bias related to both AT/CG content and DNA fragments length, thus improving extraction efficacy and accuracy of downstream applications. All currently available commercial kits are [silica-chaoietic salt]-based and exhibit bias for either short or long DNA fragments, as well as for the GC content. In addition, such systems require at least 4-fold dilution of starting volume of bio liquid with concentrated (5-10 M) guanidinium thiocyanate (GTc) to keep resulted GTc concentration at about 1 M, which in turns reduces concentration of DNA to at least 3.0 M. Thus, already low concentrations of cfDNA are significantly reduced and may negatively influence extraction efficacy of low abundance DNA fragments. Since our method does not require chaoietic salt for DNA capture, no dilution of starting material (and thus cfDNA) takes place. DNA-binding matrix SubX® allows either scaling the procedure to either large volumes of starting material or extra low volumes and adaptation of the protocol for 96/384 well format. Separation of cfDNA from the bulk of proteins occurs in a single vortex-spin step without employing chaoietic agents thus speeding-up isolation procedure and reducing the costs. The whole procedure can be completed within an hour and cfDNA is eluted in small volume of TE buffer. Average DNA yield from 0.2 ml of double centrifuged blood plasma from normal donors, cancer and multiple sclerosis patients was 7.5±4.2 ng (n=96).

#5702 A targeted re-sequencing assay for molecular profiling of somatic mutations from plasma cell-free dna (cfDNA) for bladder cancers. Liqin Dong,1 Pramit Khetrapal,2 Simon Rodney,3 Wei Shen Tan,1 Sheida Rezaee,1 Patricia de Winter,1 John Kelly,2 Andrew Feber1. 1University College London, Cancer Institute, London, United Kingdom; 2Division of Surgery & Interventional Science, UCL Medical School, UCL, London, United Kingdom.

Bladder cancer (BC) is the 5th most common cancer in Western societies with a rising global incidence. The major challenge to improving patient outcomes is to better identify patients at risk for recurrence, progression, and metastasis, and to monitor treatment response. A non-invasive monitoring assay is needed in order to interrogate the molecular features and clinical tumor heterogeneity of bladder cancers, which will potentially lead to better stratified patient management. We developed a targeted amplicon-based re-sequencing workflow for detecting and tracking genomic mutations in cfDNA using dual molecular indexed primers for specific amplification of a panel of 20 of known (TERT, FGFR3, PIK3CA, HRAS) and novel BC mutations. Only 3hr time is needed for the total workflow for the library generation and followed by next generation sequencing (NGS) performed on Illumina MiSeq sequencing platform. Data analysis and variants calling was performed. After a thorough test, optimization, and validation of the targeted panel and the workflow on selected samples of matched bladder tumor-blood pairs and controls, 45 samples were included for testing the workflow, which includes samples of 16 matched bladder tumor-blood pairs, technical duplicates of cfDNA DNA Reference Standards (Horizon Discovery) with mutations at known allelic frequencies. Technical duplicates of cfDNA were included in this study. Somatic variants from matched tumor-blood pairs were detected. We showed that detection sensitivity at 1.0% allele frequency was achieved. Our preliminary results demonstrated that we were able to detect mutation burden from cfDNA samples and track mutation burden change in response to chemotherapy for patients with metastatic BC. Here we developed a sensitive, non-invasive targeted NGS workflow to detect somatic mutations for bladder cancers from both tumor DNA and cfDNA samples. Our early results demonstrated that we can detect and track mutational changes from patients with metastatic BC.

#5703 An ultra-sensitive multiplex allele-specific real-time PCR (Udx-PCR) assay for detection of ESR1 mutations in metastatic breast cancer. Jiaaa Liu,1 Yashouai Wen,2 Shengrong Sun,2 Dehua Derek Yu1. 1USK Bioscience, Shenzhen, China; 2Wuhan University Renmin Hospital, Wuhan, China.

Activating mutations of estrogen receptor α (ESR1) are attributed to acquired resistance to estrogen-deprivation therapy in patients with metastatic breast cancer (MBC). Thus, detection of these mutations is clinically critical for monitoring early progression and effective therapeutic options in treatment of BC patients under hormonal therapy. However, current investigations for detection ESR1 mutations mainly focus on digital PCR technology due to low abundance of the cfDNA in plasma samples, which is not a currently feasible method for clinical diagnosis. Herein, we developed a multiplex allele-specific real-time (ARMS) PCR assay for detection of ESR1 four mutations (Y537S, Y537C,
y537N, and D538G) in a single tube reaction. In this real-time PCR system, the wild-type ESR1 DNA is completely blocked by a modified probe with a higher annealing temperature, and the mutant gene is selectively amplified by the modified ARMS primers. The assay was found to be highly specific and sensitive. With this assay, as low as 0.1% mutant DNA template in the background of a total of 10ng wild-type genomic DNA could be detected. By using this assay, we analyzed the ESR1 mutations in 50 Chinese MBC FFPE and plasma samples. The ESR1 mutations were detected in 3 FFPE and 6 plasma samples, which were confirmed by pyrophosphate sequencing. The multiplex allele-specific real-time PCR assay provides a rapid and reliable diagnostic tool for accurate detection of ESR1 mutations with potential for clinical application.

Circulating cell-free DNA (cfDNA) in plasma offers a non-invasive approach to monitor tumor molecular profiling in real-time at multiple time-points, detection of emerging genomic alterations associated with drug resistance and clarifying cancer prognosis and diagnosis of cancer recurrence or progression. Therefore, it is crucial to improve our current NGS technology to detect low frequency alleles in cfDNA. There are many technical challenges in NGS technology, including base errors generated from library preparation and sequencing, making it hard to distinguish real mutations from false positives produced from amplification sequencing and base-calling processes. We have adopted a more sensitive approach to overcome this challenge. We used short, random DNA sequences called unique molecular tags (UMTs) during library preparation to label input DNA. This technique can remove background errors, false positives during data analysis, providing high confident mutation calls with better sensitivity down to 0.1% (depends on DNA input amount). We will present data showing validation of this NGS platform using commercially available DNA control, archival FFPE tissue and cfDNA matched samples and demonstrate robust sensitivity and specificity by using the off-the-shelf Archer Reveal ctDNA panel for Illumina covers 28 oncogenes. This molecular-tagged NGS panel can detect mutations down to 0.1% allelic frequency. This robust NGS platform is being used in our lab to analyze cfDNA samples, enabling the development of a non-invasive method to overcome existing challenges to provide molecular understanding of patient’s tumor evolution in real-time, and aid in the development of personalized therapies for cancer patients.

#5705 Analytical validation of Guardant360 v2.10. James Vowels,1 Justin Odegaard,2 Stefanie Mortimer,2 Stephen Fairclough,2 Marcin Sikora,2 Diana Abdueva,2 Reza Mokhtari,2 Arthur Baca,2 Amir Ali Talasaz,1,2 Guardian Health, Redwood City, CA; 3Guardian Health, San Jose, CA.

Guardant360 is a cell-free circulating tumor DNA (cfDNA) test that genotypes all guideline-recommended solid tumor somatic genomic treatment targets from a single non-invasive blood draw. The new version, v2.10, was redesigned to enhance sensitivity and specificity across 73 cancer-related genes. It detects all four major variant classes (single nucleotide variants, SNVs, indels in all 73 genes; indels in 23 genes; gene amplifications, CNAs, in 18 genes; and fusions in 6 genes). Analytical performance was assessed throughout the reportable range via multiple serial dilution studies of orthogonally-characterized contrived and patient samples. Analytical specificity was assessed by calculating the false positive rate in pre-characterized healthy donor sample mixtures serially diluted. Positive predictive value (PPV) was estimated as a function of allelic fraction/ copy number from pre-characterized samples and prevalence-adjusted using a cohort of 2,585 consecutive clinical samples. Confirmation was performed using ddPCR. Analytical sensitivity was 100% for SNVs, fusions, and CNAs and 96% for indels across 25 defined samples. Relative to Guardian360 v2.9, v2.10 demonstrated 20-50% increase in fusion molecule recovery. Retrospective in silico analysis of 2,585 consecutive clinical samples demonstrated a 15% increase in actionable fusion detection, a 6%-15% increase in actionable indel detection (excluding newly reportable indels), and a 3%-6% increase in actionable SVN detection.

### CLINICAL RESEARCH: Liquid Biopsies 5: cfDNA, MicroRNA, and Protein

Guaridan360 analytical performance characteristics based on standard cfDNA input (30ng). Analytical sensitivity/limit of detection estimates are provided for clinically actionable variants and may vary by sequence context and cfDNA input. PPV is estimated across entire reportable panel space (PPV was 100% for clinically actionable variants). Conclusion: Guardian360 v2.10 comprehensively detects all adult solid tumor guideline-recommended somatic genomic variants with unparalleled sensitivity, accuracy, and specificity.

#5706 Gene expression profile of peripheral blood mononuclear cells in breast cancer patients may be contribute to the identification and the immunological classification of breast cancer patients by blood test. Eiji Suzuki,1 Kosuke Kawaguchi,1 Masahiro Sugimoto,1 Fengling Pu,1 Ruiyi Uozumi,1 Ayane Yamaguchi,1 Mariko Nishie,1 Moe Tsuda,1 Takeshi Kotake,1 Satoshi Morita,2 Masakazu Toi1,3 Kyoto Univ. Hospital, Kyoto, Japan; 4Massachusetts General Hospital, Harvard Medical School, Boston, MA; 5Keio University, Yamagata, Japan; Kyoto University, Kyoto, Japan.

It is reported that gene expression profile of peripheral blood mononuclear cells (PBMCs) exhibits unique gene expression signature in cancer patients including renal cell carcinoma, pancreatic cancer and lung cancer. Since pancreatic cancer diagnosis is difficult in not only early detection of the disease but also in the diagnosis itself, development of novel diagnostic tools in addition to conventional diagnostic strategy has been awaited. On the other hand, in breast cancer, breast cancer, because early diagnosis by mammography and ultrasound examination on breast is established successfully, exploration of gene expression profile of PBMCs may be important in terms of insight to host antitumor immune response aspects. In the current study, we performed RNA sequencing (RNA-Seq) analysis on RNA of PBMCs from 3 healthy volunteers, 6 early and 7 metastatic breast cancer patients including all phenotypes defined by ER, PgR and HER2. Genes that showed FDR<0.05 and fold change of <0.5 and 2.0 in comparison of healthy volunteers and breast cancer patients were applied to clustering analysis by Ward method. We found significant unique gene expression signature between healthy volunteers and breast cancer patients. Furthermore, it was shown that HER2 overexpressing breast cancer patients, which breast cancer patients were divided into 3 clusters including HER2 type and other 2 different groups, seemed to be classified into healthy group different from other phenotypes of breast cancer patients. These findings suggested that evaluation of gene expression patterns of PBMCs of breast cancer patients might distinguish breast cancer patients from healthy subjects and the gene expression signature of PBMCs which divided breast cancer patients into 3 groups might reveal immunologically important biologic properties such as response prediction of cancer immunotherapy including immune checkpoint inhibition treatment.

### CLINICAL RESEARCH: Prognostic Biomarkers 2

#5707 STAT3 and STAT5a are potential therapeutic targets in castration-resistant prostate cancer. Sambit K. Mohanty,1 Kader Yagiz,2 Luthringer R.,1 Mahul B. Amin,1 Serhan Alkan,1 Bekir Cinar4, Cedars Sinai Medical Center, Los Angeles, CA; 2Clark Atlanta University, Atlanta, GA.

Background: Currently, there is no effective pharmacotherapy for metastatic castration-resistant prostate cancer (mCRPC). The mechanisms underlying mCRPC are not clearly understood, thus hindering rational-based drug design. Evidence suggests that signal transducer and activator of transcription 3 (STAT3) and 5a/b (STAT5a/b), key components of the JAK/STAT pathway, play a significant role in aggressive PC. However, expression of STAT3/5 in prostate tumor samples have not been studied. Here, we evaluated the possible role of STAT3/5a in aggressive PC. Materials and Methods: Expression of STAT3 and STAT5a in high grade PC (HGPC, n=15) and in benign prostatic hyperplasia (BPH, n=15) tissue sections were evaluated by immunohistochemistry (IHC) according to the protocol approved by Institutional Review Board.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 1457
CLINICAL RESEARCH: Prognostic Biomarkers 2

Age ranged from 59 to 95 years (median = 81) in the former and 57 years to 86 years (median = 68 years) in the latter category. In addition, the effects of STAT inhibitor, Pimozide, on androgen-sensitive LNCaP and its castration-resistant subtype C4-2 PC cell growth were assessed in vitro. Results: A strong nuclear immunoreactivity for STAT3 and STAT5α in 93% (n = 140) and 80% (n = 12) of HGPGC patients was observed. HGPGC patients showed increased expression of STAT3 and STAT5α may serve as a predictive biomarker for efficacy of the JAK/STAT targeted therapy. Since JAK/STAT and androgen receptor signaling are functionally synergistic in contributing PC progression, the inhibition of JAK/STAT-alone or in combination with AR may lead to a novel treatment modality for mCRPC. #5708 HOXA4 and HOXB3 gene expression signature as a biomarker of tumor recurrence in patients with high-grade serous ovarian cancer (HG-SOC) following primary cytoreductive surgery and first-line adjuvant chemotherapy. Jai N. Patel,1 Katherine Miller,1 James Symanowski,1 Jalid Sehoulii,2 Chad Michener,3 Ioana Braicu,4 Darla DestePhan,5 Ashley P. Sutker,6 Eric J. Norris,7 David Tait,7 Wendell Jones,8 Qing Zhang,1 Chad Livasy,1 Charles Bisscotti,9 Ram N. Ganapathi,10 Mehruki K. Ganapathi11. Levine Cancer Institute, Charlotte, NC; 2Charite Medical University of Berlin, Berlin, Germany; 3Cleveland Clinic, Cleveland, OH; 4EA Genomics, Morrisville, NC; 5Carolinas Healthcare System, Charlotte, NC; 6University of Pennsylvania, Philadelphia, PA.

Background: Aberrant HOX gene expression has been observed in various malignancies; however, their role as a biomarker for recurrence in patients with HG-SOC is unknown. We tested the hypothesis that a HOX gene signature is a biomarker for disease-free survival (DFS) in HGPGC patients following primary cytoreductive surgery and adjuvant platinum-based chemotherapy. Methods: A panel of HOX genes associated with DFS in a discovery cohort of 19 HGPGC patients with available RNA-Seq data, and/or previously reported as associated with survival endpoints in the literature, were selected for testing by qPCR using the Fluidigm platform in an independent training cohort of primary tumors from 73 HG-SOC patients. Cox proportional hazards regression while controlling for the optimal cutoff was used to identify HOX genes significantly associated with DFS. A prognostic gene signature was developed based on the combined linear predictor from the final multivariable Cox model. Patients were stratified into risk groups using the optimal cutoff of the linear predictor risk score, whereby the optimal cutoff was defined as the value that maximized the log-rank test statistic. Risk group stratification was further tested for association with DFS in a larger HG-SOC dataset (N = 414) with similar clinical characteristics from The Cancer Genome Atlas (TCGA). The role of the identified HOX genes in influencing drug sensitivity was examined by overexpressing these genes in a HG-SOC cell line, PEO1. Results: Of 23 HOX genes selected for testing in the training cohort, overexpression of HOXA4 (HR = 1.21, 95% CI = 1.08-1.35, P = 0.001) and HOXB3 (HR = 1.19, 95% CI = 1.02-1.17, P = 0.016) were significantly associated with decreased DFS in multivariate analysis. The median DFS in patients with a HOXA4/HOXB3 risk score ≤ the optimal cutoff was > 80 months (not yet reached), whereas the median DFS in patients with a HOXA4/HOXB3 risk score > the optimal cutoff was 16.9 months (HR = 7.85, 95% CI = 4.19-14.69, P < 0.001). The HOXA4/HOXB3 risk score remained significantly associated with DFS in the HG-SOC dataset from the TCGA (P < 0.02). In vitro studies demonstrated that PEO1 cells overexpressing either HOXA4 or HOXB3 were significantly (P < 0.05) more resistant to cisplatin and carboplatin, but not to paclitaxel, as compared to empty vector transfected cells. Conclusion: The HOXA4/HOXB3 risk score was significantly associated with DFS in a training cohort of HG-SOC patients, and remained significantly associated in a larger independent HG-SOC dataset from the TCGA. Further, in vitro studies suggest that HOXA4 and HOXB3 overexpression is associated with platinum resistance. Thus, overexpression of HOXA4 and HOXB3 in primary HG-SOC may serve as a potential biomarker for recurrence and the risk score model developed warrants prospective validation in HG-SOC patients.

Introduction: Malignant Pleural Mesothelioma (MPM) is an aggressive cancer with overall survival (OS) of about 8 months. Prognostic biomarkers allowing for biology-driven individualized therapies are lacking in MPM. Alterations in a tumor suppressor gene NF-2 are seen in 20–40% of MPM. NF-2 encodes for Merlin, which suppresses tumorigenesis by regulating pathways like mTOR and Hippo. Merlin status has been proposed as a predictive biomarker for treatment with the focal adhesion kinase (FAK) inhibitor. The purpose of our study is to examine differences in Merlin expression among histologic subtypes of MPM and its prognostic impact on clinical outcome. Materials and Method: 48 cases of MPM from 1993-2013 with available archival tissues were identified. H/E stained sections were reviewed by a pathologist and categorized into 3 histologic subtypes namely epitheliod (E), sarcomatoid (S) and biphasic (B). Immunohistochemistry-based Merlin expression score from 0 to 3 were given to the samples, accounting for both intensity and frequency of staining. Chart review was performed to obtain clinical data. Kruskal-Wallis Test was used to compare mean Merlin scores, and Logrank test was used to compare OS between low Merlin (LM, <3) and high Merlin (HM, ≥3) groups. Results: Mean age of patients was 66.75 years (HM 64.58, LM 68.92). Other demographic profile (HM%, LM%) included male sex 89.5% (51, 49), current or past smokers 66.6% (47, 53), current or past Asbestos exposure 71% (35, 65), resectable disease 89% (51, 49), stages 3 or 4 disease 64% (56, 44), and 85% (56, 44) received surgery. Mean Merlin score of 3 among histologic types were different (Mean, Std. Dev: B 2.25, 0.48; E 2.74, 0.54; S 2.56, 0.53; p = 0.0037). Mean Merlin score of E component was significantly higher than that of S component within B MPM (E 2.75, 0.45; S 1.75, 0.68; p<0.001). Interestingly, mean Merlin score of S was significantly higher than that of S component of B MPM (S 2.56, 0.53; B 1.75, 0.68; p = 0.005) making S component of B MPM least Merlin expresser. There was no significant difference in response rate to platinum and in progression-free survival between LM and HM. Median OS (months) for LM was 8.8 compared to 12.9 for HM (p = 0.15), however among different variables analyzed (age, sex, smoking history, histology, and upfront treatment modalities), age was associated with OS. For controlling age, there was no statistically significant difference in OS between LM and HM (p = 0.11). Conclusion: Merlin expression level is different among E, S and B MPMs. Moreover, it is significantly lower in S component of B MPM than S. Its prognostic ability appears to be confounded by the association with age in our cohort. A larger study is needed to further explore the prognostic impact of this biomarker. #5710 PGRMC1 is a biomarker for breast cancer cell proliferation and early relapse. Elizabeth S. McDonald, Dhruv K. Pant, Tien-chi Pan, David A. Mankoff, Robert H. Mach, Lewis A. Chodosh. University of Pennsylvania, Philadelphia, PA.

Background: Breast cancers may recur following a long latency period, implying a dormant or quiescent phase, however little is known about the biology of cellular quiescence and few markers exist for this clinically important state. The purpose of this study was to investigate whether progesterone receptor membrane component family 1 (PGRMC1), which is expressed in both cycling and quiescent tumor cells, is a prognostic biomarker in human breast cancer and to define its expression in breast cancer subtypes. Methods: Seventeen publicly available data sets were combined to analyze PGRMC1 expression in 4,463 invasive breast cancers as a function of established molecular and phenotypic markers, estimates of cellular proliferation, and recurrence-free survival data. A gene expression signature-based assay was utilized to estimate cellular proliferation. Association between gene expression and relapse-free survival was assessed using Cox proportional hazards regression while controlling for the effect of proliferation. Results: PGRMC1 expression was analyzed stratified by immunohistochemical and molecular subtype, tumor grade and size and compared with a known triple negative breast cancer biomarker, BCL11a. PGRMC1 and BCL11a each exhibited a robust positive correlation of comparable magnitude with proliferation across all breast cancer subtypes (r = 0.27, p = 6.5x10^-17 and r = 0.29, 1.7x10^-15, respectively), and PGRMC1 was strongly associated with proliferation within the basal subtype (r = 0.42, p = 2.4x10^-17 PGRMC1 versus 0.31, p = 1.1x10^-15 BCL11a). PGRMC1 expression was associated with a higher risk of early breast cancer recurrence (HR = 1.25, 95% CI [1.12,1.39], p = 6.4x10^-5) and this association was dependent upon its association with proliferation. Conclusions: PGRMC1 is a breast cancer proliferation biomarker. Further study of the function of this protein is warranted.

#5711 Gene expression profiles in BRAF V600E mutant colorectal cancer and association with SREBP2 methylation status. Kazuya Yasui,1 Takeshi Naganaka,1 Toshiaki Toshima,1 Takashi Kawai,1 Kunitoshi Shigeyasu,1 Yoshiko Mori,1 Junko Haraga,1 Keiichiro Nakamura,1 Yuzo Umeda,1 Hiroshi Tazawa,1 Ayao Goel,2 Toshiyoshi Fujiwara1,2,3,4 Okayama Univ. Graduate School of Med., Okayama, Japan; 5 Baylor University Medical Center, Dallas, TX.
Background: Classification of colorectal cancer (CRC) according to gene expression profiling remains controversial with regards to their ability to stratify patients for precision therapy. Several studies have suggested that ‘stem cell like’ or ‘epithelial-mesenchymal transition (EMT)’ signature associates with poor prognosis. Meanwhile CRCs with BRAF V600E mutation have shown poor outcomes in clinical trials, but the biological roles of BRAF mutation have not been fully elucidated. Materials and Methods: To evaluate biological roles of BRAF mutations in CRC, we performed mRNA microarray analysis in the following three subsets; eight BRAF-mutant CRC tissues without MSI, six BRAF-mutant CRCs with MSI and five BRAF-wild type CRCs with MSI. Pathway analyses were performed by Gene Set Enrichment Analysis (GSEA). Following identification of candidate biomarkers that in significance poor outcomes and associate with BRAF V600E mutation, we examined these candidate biomarkers in a cohort of 1068 CRC patients who underwent surgical resection of their primary tumor and/or metastatic lesions from 1994 to 2015 at the Okayama University Hospital. Results: By the GSEA, prominent signatures enriched in CRCs with BRAF V600E mutation vs. wild-type were EMT-related processes (EMT and myogenesis). Additionally, CRC with BRAF V600E mutation strongly associated with inactivation of Wnt signaling and secreted frizzled-related proteins (SFRPs) which normally support activation of the pathway: RAF1 (9%), MAPK1 (3%) and RPS6KA1 (1.9%) was found to be significantly associated with poor DFS (P = 0.0286) and disease free survival (DFS) in HNSCC (0.00150; median progression time = 38.11 vs. 71.22 months in DUSP4-unaltered patients) which can potentially be explained by activation of oncogenic MAPK pathway upon DUSP4 underexpression. Interestingly, we identified four unmethylated CRCs with genetic mutation in the KRAS/BRCA genes demonstrated significantly poorer outcome in RFS compared with SFRP2 methylated CRCs with genetic mutations in the KRAS/BRCA genes (5-years RFS rate were 46.8% vs 72.1%; P = 0.015, Hazard ratio 2.06 [95% CI, 1.12 to 3.69]; P = 0.021). Conclusion: Our results suggest that SFRP2 methylation status could be a potential prognostic biomarker for stage II-IV CRCs, especially with genetic mutations in the KRAS/BRCA genes.

#5712 Potential clinical significance of downregulation of MAPK pathway components mRNA expression in head and neck squamous cell carcinoma (HNSCC). Hoi Lam Ngan,1 Vivian W.Y. Lui2. The University of Hong Kong, Hong Kong; 2The Chinese University of Hong Kong, Hong Kong, Hong Kong.

We previously showed the MAPK pathway can be mutationally activated, and may implicate drug sensitivity in HNSCC [1]. Here, we report that RNA expression of several MAPK pathway components may be associated with HNSCC patients’ outcome based on the US-TCGA Provisional data. We found that loss of DUSP4, a negative regulator of MAPK pathway, was correlated with poor overall survival (OS; P = 0.0286) and disease free survival (DFS) in HNSCC (0.00150; median progression time = 38.11 vs. 71.22 months in DUSP4-unaltered patients) which can potentially be explained by activation of oncogenic MAPK pathway upon DUSP4 underexpression. Interestingly, we identified a group of HNSCC patients with homogenous loss and mRNA downregulation of MAPK pathway scaffold protein components (GRB2, SHC2 and SHC3) with significantly poorer DFS (P = 0.000871). RPPA analysis showed a trend of decreased protein expression level of phospho-RAFs, downstream of scaffold proteins, decreased MEKs and MAPKs, supportive of an overall decreased MAPK pathway signaling in this subset of patients. Unexpectedly, downregulation (homogenous deletion/ RNA expression less than 2 SD) of multiple MAPK pathway components which normally support activation of the pathway: RAF1 (9%), MAPK1 (3%) and RPS6KA1 (1.9%) was found to be significantly associated with poorer DFS (P = 6.643x10^-5) with median time to progression of 18.17 months vs. 71.22 months in the unaltered group. Subsequent proteomic analysis of the respective patient tumors from the TCGA cohort (N = 357 with RPPA data) showed that these patient tumors had elevated levels of E2F1 protein expression (P = 0.0146), along with increase FOXM1 expression (P = 8.499x10^-4), which is known to drive cell cycle progression [2]. As E2F1 is involved in cell survival upon DNA damage [3], it is likely that upregulation of E2F1 protein expression may enable cancer cells to survive after DNA insults by radiotherapy or chemotherapy, and contributes to disease relapse. #5713 PIGN gene expression aberration weakens chromosomal stability via altering its interaction with the spindle assembly checkpoint protein complex during leukemogenesis. Jeffrey J. Pu,1 Emmanuel K. Teye,1 Abigail Sido,1 Yukia I. Kawasawa,1 Ping Xin,1 Niklas K. Finnberg,2 Wafik S. El-Deiry,2 Sara Shimko1,1 Penn State Hershey Cancer Institute, Hershey, PA; 2Fox Chase Cancer Center, Philadelphia, PA.

Several studies have linked increased frequency of glycosylphosphatidylinositol-anchor protein (GPI-AP) deficiency with genomic instability and the risk of carcinogenesis. Recently, Phosphatidylinositol Glycan Anchor Biosynthesis Class N (PIGN), a gene participating in GPI-AP synthesis, was suggested as a cancer chromosomal instability suppressor in a colon cancer model. We investigated the association of PIGN with genomic instability and leukemogenesis. A Random Forest analysis of the gene expression array data from 55 MDS patients (GSE4619) demonstrated a significant (p = 0.0007) correlation (P = 0.04068) between PIGN-biosynthesis expression and genomic instability, in which PIGN was ranked as the third most important in predicting risk of MDS progression. We observed that PIGN gene expression aberrations (increased transcriptional activity but diminished to no protein production) were associated with increased frequency of GPI-AP deficiencies among leukemic cells during leukemic transformation/progression. The PIGN gene expression aberrations were attributed to partial intron retrictions between exons 14 and 15 resulting in frame shifts and premature termination which were confirmed by examining the RNA-seq data from a group of AML patients (phs001027.v1.p1). PIGN gene expression aberration correlated with the elevation of genomic instability marker expression that was independent of the TP53 regulatory pathway. PIGN protein expression suppression/elimination caused a similar pattern of genomic instability that was rescued by PIGN restoration. Furthermore, PIGN bound to the spindle assembly checkpoint proteins and regulated their expression during the cell cycle. In conclusion, PIGN gene is crucial in the regulation of mitotic integrity to maintain chromosomal stability and prevents leukemic transformation/progression.

#5714 AXL and GAS6 Co-expression in lung adenocarcinoma as a prognostic classifier. Masahiro Seike, Ritaro Noro, Cheol-Hong Kim, Fenfei Zou, Kaoru Kubota, Akihiko Gemma. Nippon Medical School, Tokyo, Japan. AXL, a receptor tyrosine kinase implicated in cell survival, proliferation, and migration, is also associated with acquired resistance to epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor therapy. However, its prognostic significance in lung adenocarcinoma (AD) remains unclear. We therefore evaluated the prognostic significance of the expression of AXL and/or its ligand, growth arrest-specific 6 (GAS6), in completely resected lung AD. We evaluated the relationship between AXL, GAS6, and vimentin expression, as determined by immunohistochemistry (IHC) analysis, with overall survival and disease-free survival in 113 patients with stages I-III lung AD. Protein expression was also assayed using western blot analysis in 10 lung AD cell lines. AXL-positive (AXL+), GAS6-positive (GAS6+), or AXL+/GAS6+ staining was significantly associated with vimentin-positive (vimentin+) expression. AXL+/GAS6+ and vimentin+ showed a negative tendency toward an association with EGFR muta- tion. AXL+, GAS6+, or AXL+/GAS6+ statuses significantly correlated with poor overall survival. In stage I cases, an AXL+/GAS6+ status significantly correlated with poor overall survival and disease-free survival, especially in cases with wild-type EGFR. In multivariate analysis, AXL/GAS6 classifications in stage I as well as in stages I-III lung AD were found to be independent factors for poor patient outcomes. Unlike lung AD cell lines with mutant EGFR, those with wild-type EGFR closely correlated with AXL and vimentin expression by western blotting. AXL+ and GAS6+ expression is relevant to a poor prognosis in resected lung AD patients at stage I. AXL/GAS6 might serve as crucial predictive and prognostic biomarkers and targets to identify individuals at high risk of post-operative death.

#5715 Gene body methylation and expression of SHOX2 gene are potent prognostic markers for survival in intermediate grade gliomas and renal cancer. Yanyun Zhou,1 Xinyun Zhen,1 Xian Luo,1 Guanghua Xiong,1 Ali F. Gazzaniga1,2 UT Southwestern Medical Ctr., Dallas, TX, 1University of Mississippi Medical Ctr., Jackson, TX.

Background: Previous data indicated that low level of promoter methylation of the SHOX2 gene was a prognostic marker for worse progression-free survival

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 1459
CLINICAL RESEARCH: Prognostic Biomarkers

for non-small cell lung cancer. Purpose: (a) to determine the relationship between SHOX2 gene methylation and expression; (b) to determine whether SHOX2 gene methylation and expression were prognostic markers for other cancers. Methods: We examined multiple methylation and expression datasets available from The Cancer Genome Atlas (TCGA) and other previously published studies of multiple tumor types. A total of more than 1100 renal cancer cases were examined, along with smaller number of corresponding non-malignant tissues. We performed Kaplan-Meier survival analyses and univariate and multivariate Cox regression model analyses. Results: SHOX2 gene contains three CpG islands encompassing the promoter region and body. Methylation of various regions of SHOX2 gene body was significantly positively correlated with its expression in gliomas and renal cancer. Abnormally high methylation and expression of SHOX2 gene, which were significantly higher than the corresponding nonmalignant tissues, were identified in subsets of gliomas and renal cancers. Survival analysis of patients indicated that the methylation and expression of SHOX2 gene in gliomas and renal cancer (both clear cell and papillary cell carcinomas) were highly potent markers for poor survival. We further investigated the combination of SHOX2 with other known clinically relevant glioma markers (IDH genotype status, TERT expression, 1p/19q chromosome co-deletion, MGMT methylation, ATRX mutation and NES expression). When combined with SHOX2 expression, we identified subsets of glioma patients with significantly favorable survival outcomes, especially in the subgroup (i.e., IDH wild-type) associated with worse prognosis for each individual marker. Multivariate analysis demonstrated that SHOX2 was a potent independent survival marker for gliomas. Conclusion: Gene body methylation and expression of SHOX2 gene are tightly positively correlated and are potent new markers for overall survival prognosis for intermediate grade gliomas and renal cancer. The combination of IDH or other relevant prognostic markers with SHOX2 identified intermediate grade glioma subsets with improved survival outcomes.

#5716 Tristetraprolin is a prognostic biomarker for biochemical recurrence in low Gleason score patients. Anders E. Berglund, Travis Gerke, Shivanshu Awasthi, G. Daniel Grass, Hyun Y. Park, John L. Cleveland, Jong Y. Park, Koji Yamashita, Robert J. Rounbehler. H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL.

PURPOSE: Most prostate cancer patients currently classified as having a low-risk of disease-specific death are overtreated in the United States, resulting in hundreds of thousands of men to have debilitating side effects from unnecessary treatment. However, ~30% of low-risk patients on active surveillance are later reclassified and require therapeutic intervention. Thus, there is a dire need for biomarkers that can discriminate which prostate tumors currently classified as low-risk will progress into aggressive disease. EXPERIMENTAL DESIGN: Retrospective analyses of two independent prostate cancer expression datasets were performed to determine the relationship between the expression levels of the tumor suppressor Tristetraprolin (TPP, ZFP36) and biochemical recurrence (BCR). Further, TTP expression levels were measured by quantitative real-time PCR (qRT-PCR) in a cohort of prostate tumors from Moffitt Cancer Center patients having long-term follow-up (n = 382), and will be correlated to associated clinical data, including BCR. Finally, the Cancer of the Prostate Risk Assessment Posturgical (CAPRA-S) scores, a clinical tool used to predict prostate cancer outcomes following radical prostatectomy, were calculated along with BCR for the patients in one of the prostate cancer datasets. RESULTS: Analysis of The Cancer Genome Atlas (TCGA) prostate adenocarcinoma dataset revealed that tumors with low TTP expression have an increased rate of BCR compared to those with high TTP levels (p = 0.0096). Further, assessment of the GEO dataset GSE21034 (Taylor et al., Cancer Cell, 2010) established that prostate cancer patients with low Gleason scores (6 and 3+4) have an increased chance of BCR if their tumors express low levels of TTP compared to men with high TTP expressing tumors (p = 0.0001). To validate these findings, patients with low Gleason score tumors and decreased levels of TTP in the Moffitt Cancer Center cohort are being analyzed to determine their rate of BCR. In contrast, CAPRA-S scores for low Gleason score tumors in the GSE20134 dataset failed to distinguish if a patient would have BCR (p = 0.0511). CONCLUSIONS: Prostate cancer patients with Gleason score 6 or 3+4, which are currently classified as having a low-risk of dying from prostate cancer, have an increased risk of BCR if their tumors express low levels of the tumor suppressor TTP. Our data suggests that TTP may be a biomarker that clearly discriminates which low Gleason score tumors will progress into aggressive disease.

#5717 PKR promotes EphA2 and other proteins degradation and is predictor of survival in lung cancer. Apar Pataer, Ruping Shao, Bulent Ozpolat, Bingliang Fang, Stephen G. Swisher. UT MD Anderson Cancer Ctr., Houston, TX.

Relative expression of PKR and EphA2 was a significant predictor of survival in non-small cell lung cancer. To study the PKR-regulated protein, we evaluated expression of 149 proteins in lung cancer cells by reverse-phase protein assay (RPPA) after induction of PKR. Expression of several proteins (EphA2, IRSI, Chk1 and c-Raf and paxillin) was inhibited by PKR. In validating the downregulated proteins by western blot analysis, we observed that PKR reduced EphA2, IRS1, Chk1 and paxillin protein expression. We next investigated the involvement of the proteasomes and lysosomes in PKR-induced protein degradation. Human lung cancer H1299 and A549 cells were transfected with Ad-PKR for 48 h in the presence or absence of the proteasome inhibitor MG132 or lysosome inhibitor (3MA: 3-methyladenine). We observed that MG132 prevented PKR-induced EphA2 and paxillin degradation in these cells. However, we found that 3MA prevented PKR-induced EphA2 and paxillin degradation in these cells. These data suggest that PKR is involved in proteasome as well as lysosome function. To study the involvement of autophagy pathway in PKR mediated protein degradation, we evaluated proteins which known involved in autophagy by Western blotting after induction of PKR on these cancer cells. We observed slightly decrease of LC-3, ATG5 and Beclin1 in these cancer cells after induction of PKR. Our data suggest that PKR may directly involve in in lysosome function.

Additional prognostic stratification of colorectal cancer patients is needed to improve management of patients. Using microfluidic array chip (Miacarta) approach of tumor samples remains the standard method for disease subtyping. However, visual analysis is subjective and weakly reproducible due to intra- and intra-observer variations. Recent progress within machine learning, especially its novel branch called deep learning, enables accurate evaluation of complex patterns observed in microscopic tissue images. Here, we combined deep learning techniques to evaluate a set of digitized formalin fixed paraffin embedded hematoxylin-eosin stained tumor tissue microarray (TMA) samples from 420 randomly selected patients with colorectal cancer. For each patient a set of clinicopathological characteristics including histological grade, Dukes stage and age at diagnosis are available as well as outcome data. Using convolutional neural networks and Long Short-Term Memory networks we validated the predictive power of the colorectal TMA with regards to patient outcome. Univariate Cox proportional hazard regression analysis demonstrated that the prognostic accuracy of the deep learning algorithm on TMAs (hazard ratio 2.3; CI 95% 1.79–3.03) outperforms visual histological grading performed by a certified pathologist on a whole slide level (hazard ratio 1.65; CI 95% 1.30–2.15). In multivariate Cox proportional hazard regression, the deep learning based model was a prognostic factor, independent of histological grade, Dukes stage and age at diagnosis (Wald p-value < 0.001). Thus, we demonstrate that novel deep learning models can serve as digital prognostic biomarkers in colorectal cancer.

#5719 Long intergenic non-coding RNAs: a new independent risk predictors in multiple myeloma. Mehmet K. Samur, Annamaria Guilla, Mariateresa Fulciniti, Anil Aktas Samur, Raphael Szalat, Masood Shamas, Florence Magrangeas, Stephane Minvielle, Kenneth Anderson, Giovanni Parmigiani, Hervé Avet-Loiseau, Nikhil Munshi, Dana Farber Cancer Institute, Boston, MA; 1Centre Hospitalier Universitaire de Nantes, France; 2Université de Nantes Institut de Recherche Thérapeutique, France; 3Unité de Génomique du Myélome, University Hospital; CRCT, INSERM U 1037; Université Paul Sabatier, France.

RNA has diverse sets of regulatory functions and a recent analysis of RNA repertoire has identified a large numbers of non-coding transcripts. One of which, long intergenic non-coding RNA (lincRNA) with transcripts longer than 200 nucleotides, are located between the protein coding genes and do not overlap exons of either protein-coding or other non-lincRNA genes. lincRNAs have been considered to provide regulatory functions, however, their precise role in cellular processes of patients. We studied lincRNAs using uniformly treated patients to show their impact on survival outcome in MM. We performed RNA-seq on CD138 + MM cells from 360 newly-diagnosed patients and 18 normal plasma cells (NPM) and analyzed for lincRNA and protein coding genes. MM patient data for clinical characteristics, cytogenetic and FISH as well as clinical survival outcomes were also analyzed and correlated with lincRNA data. Our data showed expression of 951 lincRNAs (median TPM > 1) with 351 lincRNAs differentially expressed between MM and normal plasma cells. Using only the expresed lincRNAs, we applied log rank tests for quartile 1 (Q1) versus Q2 through Q4 and Q4 versus Q3 in order to identify under- and overexpressed prog-
nastic genes, respectively. Four under and seven overexpressed genes were selected for final model. We used Más-o-menos for final predictive model, which simply calculates the risk score, by using expression values. The Kaplan-Meier estimates of EFS at 4 years were 53.3% (95% CI, 45.1% to 63.1%) and 32.6% (95% CI, 25.1% to 42.2%), and OS at 4 years were 93.2% (95% CI, 88.9% to 100%), and 69.0% (95% CI 56.7% to 79.4%). The Relative risk score was associated with a low or high risk score. When applied to patient cohort separated by other risk categorization including minimal residual disease status (MRD), cytogenetic risk status (del17p, t(4;14) and t(14;16)) and International Staging System (ISS), lncRNA signature was able to further identify patients with significant differential survival outcomes. In summary, we report that lncRNAs have an independent effect on survival outcome in MM and provides rationale for its use in risk stratification as well as to understand biological impact.

#5720 Serum interleukin-18 and metalloproteinase-1 predict long-term prognosis of breast cancer. Ji-Yeon Kim,1 Kyunghee Park,2 Eunjin Lee,2 Hae Hyun Jung,3 Seok Jin Nam,4 Jeong Eon Lee,3 Seok Won Kim,1 Jung Han Yoo,1 Se Kyung Lee,3 Soo Yoon Bae,1 Jin Seok Ahn,1 Young-Hyuck Im,1 Yeon Hee Park1,2

1Samsung Medical Center, Seoul, Republic of Korea; 2Samsung Genome Institute, Seoul, Republic of Korea; 3Samsung Advanced Institute for Health Sciences and Technology, Seoul, Republic of Korea.

Introduction: Intrinsic subtyping and twenty-one gene expression assay using tumor tissue indicates gene expression profile had advantage to predict breast cancer (BC) patients’ prognosis. However, these tumor biomarker assays had limitations as high as high cost, demand for large amount of tumor sample and limited use for specific subtype of BC. Therefore, we conducted this study to find serum biomarker predicting BC prognosis. Materials and Methods: This study was conducted by retrospective analysis of patients with stage I to IIIC invasive breast cancer who received curative surgery at Samsung Medical Center between 2003 and 2004. We performed multiplex immunoassay using 45 cytokine and 8 MMP multiplex immunoassay panels (Bio-Rad Laboratories Inc, Irvine, CA, USA). Among clinical factors, operational stage was re-categorized into stage I II/III vs. stage III and Hormone receptor (HR) status was grouped into HR positive vs. negative. For each protein, proteins significantly associated with overall survival (OS) in univariate analyses were candidates for the multivariate analysis. Results: In total, 246 patients who received curative surgery for breast cancer were enrolled. Of 246 patients, serum cytokine analyses were performed in 229 patients. Of clinical characteristics, ten year OS of BC with stage III was 76.2% compared to 92.7% of stage I and 88.6% of stage II (hazard ratio (Stage III vs. stage I/II): 2.62 (95% CI: 1.26-5.38), p-value = 0.016) and HR expressed BC had 91.1% of 10 year OS, compared to 81.9% of HR negative BC (hazard ratio (HR positive): 0.47 (95% CI: 0.23-0.95), p-value = 0.035). In terms of serum biomarker, high expression of IL-18 was associated with good prognosis (hazard ratio: 0.45 (95% CI: 0.21-0.96), p-value = 0.033) in contrast with poor prognosis of MMP-1 expression (hazard ratio: 1.96 (95% CI: 0.94-4.08), p-value = 0.067). Multivariate analysis showed that BC stage, HR positivity, serum IL-18 and MMP-1 affected patients’ OS. Stage I/II HR positive BC with low MMP-1 and high IL-18 increased OS about 5 times compared to stage III HR negative BC with high MMP-1 (hazard ratio: 5.08 (95% CI: 1.01-25.46), c-index = 0.731, p-value < 0.0001). Internal validation using 10,000 times of bootstrapping showed that this prediction model was suitable for BC prognosis prediction (c-index: 0.705, p-value = 0.041). Conclusion: Our research suggested that the level of serum IL-18 and MMP-1 would help to predict BC patients’ prognosis. Further external validation of these biomarkers would be warranted.

#5721 Genome-wide discovery and identification of a novel mirRNA signature for recurrence prediction in colorectal cancer. Raju Kandimalla,1 Feng Gao,2 Naoki Takahashi,3 Yasuhide Yamada,4 Takatoshi Matsuyama,5 Toshiyuki Ishikawa,6 Xin Wang,7 Ayaj Goel8. 1Baylor University Medical Center, Dallas, TX; 2City University of Hong Kong, Hong Kong; 3National Cancer Center Hospital, Tokyo, Japan; 4Tokyo Medical and Dental University Graduate School of Medicine, Tokyo, Japan.

Purpose: Colorectal cancer (CRC) is one of the leading causes of cancer-related deaths worldwide. In 2016, there were estimated 95,270 newly diagnosed CRC cases, and 49,190 deaths from this disease in the United States. Survival of patients is closely associated with the tumor stage at the time of diagnosis as 5-year relative survival rates range from 65% for all stages, 90% for localized primary tumor, 71% for regional metastasis and 13% for distant metastasis. Post-surgery, adjuvant therapy is only recommended to those with high risk stage II, as well as stage III and IV tumors. However, approximately 40-50% of the patients undergo curative surgery only and 20-30% that are treated with adjuvant chemotherapy, eventually relapse and experience a metastatic disease and eventual death. The current gold standard TNM (Tumor, Node, Metastasis) staging for determining the prognosis of CRC patients remains inadequate at identification of high-risk stage II and III patients that have a high potential of developing tumor recurrence. MicroRNAs (miRNAs) play an important role in CRC development and are emerging as important disease biomarkers. Therefore, in this study we sought to determine the prognostic potential of the eight gene miRNA signature discovered from the genome-wide analysis was validated in two independent patient cohorts (n=127 and n=96) using Taqman-based RT-PCR assays. Results: The genome-wide comprehensive analysis led to the identification of an eight gene miRNA classifier that significantly predicted recurrence free survival (RFS) in training (log-rank p=0.003) and two independent validation cohorts (log-rank p<0.0001 and p=0.002). The RT-PCR based training and validation of the eight gene classifier in two independent clinical cohorts significantly associated with poor prognosis in stage II and III CRC patients (log-rank p<0.004 and p<0.0001). Multivariate analyses performed in these two patient cohorts revealed that the eight gene miRNA classifier served as an independent predictor of poor prognosis in stage II and III. CRC patients. Conclusively, our study revealed that these novel miRNA based classifier, which is robustly predictive of poor prognosis in patients with stage II/III CRC, and might facilitate identification and stratification of high-risk patients that are candidates for adjuvant chemotherapy and clinical surveillance.
Pathway mutations in head and neck cancer and its clinical significance. Vivain W.Y. Lui,1 Hoi Lam Ngan2. 1The Chinese University of Hong Kong, Hong Kong, Hong Kong; 2The University of Hong Kong, Hong Kong, Hong Kong.

The PI3K pathway is the most frequently mutated mitogenic pathway in head and neck squamous cell carcinoma (HNSCC) tumors. Mutations in PIK3CA and PIK3R1 genes are the most common type of mutations (in 16% (83/510 cases) of HNSCC primary tumors (TCGA, Provisional), with the pathway components defined as: GRB2 SHC1 SHC2 SHC3 HRAS KRAS NRAS ARAF BRAF RAF1 DUSP1 DUSP4 MAP2K1 MAP2K2 MAPK1 MAPK3 RPS6KA1 RPS6KA4 RPS6KA5. Mutations of the entire MAPK pathway gene components are not associated with patient overall survival (OS) and disease-free survival (DFS) (p=n.s.). With HRAS, MAPK1, BRAF and RPS6KA1 gene mutations being most commonly mutated in 6%, 1.7%, 1.7% and 1.7% in the US-TCGA cohort, we conducted survival analyses of each of the mutated gene component alone to examine their individual correlation based on the available clinical data. Our results show that HRAS mutation, BRAF mutation and RPS6KA1 mutation do not associate with patient OS nor DFS (OS: P=0.285, DFS: 0.300 and P=0.197, respectively; DFS: 0.216). Lastly, we note that except for MAP2K2, patients with somatic mutations of multiple positive regulators of the MAPK pathway (RAF1 MAP2K1 MAPK1 HRAS BRAF) are associated with significant better OS (P=0.0293). Prognostic analysis suggests that these mutations of these MAPK pathway positive regulators are associated with downregulation of snai1 (P=0.0786). Mismatch repair gene mutations correlated with OS and DFS (p=n.s.).

#5723 MAPK pathway mutations in head and neck cancer and its clinical significance. Vivain W.Y. Lui,1 Hoi Lam Ngan2. 1The Chinese University of Hong Kong, Hong Kong, Hong Kong; 2The University of Hong Kong, Hong Kong, Hong Kong.

The PI3K pathway is the most frequently mutated mitogenic pathway in head and neck squamous cell carcinoma (HNSCC) tumors. Mutations in PIK3CA and PIK3R1 genes are the most common type of mutations (in 16% (83/510 cases) of HNSCC primary tumors (TCGA, Provisional), with the pathway components defined as: GRB2 SHC1 SHC2 SHC3 HRAS KRAS NRAS ARAF BRAF RAF1 DUSP1 DUSP4 MAP2K1 MAP2K2 MAPK1 MAPK3 RPS6KA1 RPS6KA4 RPS6KA5. Similar to the PI3K pathway, mutations of the entire MAPK pathway gene components are not associated with patient overall survival (OS) and disease-free survival (DFS) (p=n.s.). With HRAS, MAPK1, BRAF and RPS6KA1 gene mutations being most commonly mutated in 6%, 1.7%, 1.7% and 1.7% in the US-TCGA cohort, we conducted survival analyses of each of the mutated gene component alone to examine their individual correlation based on the available clinical data. Our results show that HRAS mutation, BRAF mutation and RPS6KA1 mutation do not associate with patient OS nor DFS (OS: P=0.285, DFS: 0.300 and P=0.197, respectively; DFS: 0.216). Lastly, we note that except for MAP2K2, patients with somatic mutations of multiple positive regulators of the MAPK pathway (RAF1 MAP2K1 MAPK1 HRAS BRAF) are associated with significant better OS (P=0.0293). Prognostic analysis suggests that these mutations of these MAPK pathway positive regulators are associated with downregulation of snai1 (P=0.0786). #5724 Circulatory microRNA expression profiling between HCV-infected African & Caucasian Americans: implications for racial health disparities. Pradip Devhare,1 Robert Steele,1 Adrián M. Di Bisceglie,1 David E. Kaplan,2 Ratna B. Ray1. 1St Louis University, St Louis, MO; 2University of Pennsylvania, Philadelphia, PA.

The purpose of the study: Hepatocellular carcinoma (HCC) is a global problem and incidence of HCC is increasing in last several years. Hepatitis C virus (HCV) infection is one of the major cause towards development of HCC. HCV infection is highly prevalent in African American population compared to other ethnic groups and these people are less likely to naturally clear HCV. Higher incidence of HCC and mortality was noted in HCV infected African Americans as compared to Caucasians. However, the explanation for this disparity and the molecular mechanisms behind this are currently unknown. Circulating microRNAs in the blood are emerging as biomarkers for pathological conditions. Differential expression of miRNAs among ethnic groups would be important for optimizing personalized treatment strategies. Experimental procedures: In this study, we assessed the differential expression of circulatory miRNAs from HCV infected African Americans and Caucasians by specific miRNA array profiling. Expression of significantly altered miRNAs was validated by qRT-PCR. Results: We identified increased expression of miR-146a, miR-150 and miR-155 in HCV infected African Americans patient sera as compared to sera of Caucasians. Further analysis demonstrated that these miRNAs were significantly elevated in African Americans diagnosed with HCV-mediated HCC. Higher expression of miR-150 was also noted in cirrhosis and HCC in African Americans, which may serve as a predictor of liver disease progression in this population. Conclusion: The differential expression of miRNAs suggests that these miRNAs and their target genes could be useful to gain further mechanistic insight of racial disparity associated with HCV pathogenesis.
A functional polymorphism in DTX1 gene of Notch pathway was found to predict the prognosis of surgically resected non-small cell lung cancer. Shin Yup Lee,1 Janghyuck Lee,1 Kyung Min Shin,1 Ji Woong Son,2 Jae Yong Park.1
1Kyoungpook National Univ. School of Med., Daegu, Republic of Korea; 2Konyang University of Turku, Turku, Finland; 4Institute for Molecular Medicine Finland, Helsinki, Finland; 3Institute for Molecular Medicine Finland and Helsinki University Hospital (HUSLAB), Helsinki, Finland. Prostate cancer (PCa) is the most diagnosed cancer in men in developed countries. Fibroblast growth factor receptors (FGFRs) have been demonstrated to play an important role in PCA initiation and progression. Fibroblast growth factor receptor factor like 1 (FGFR1) is the most recently identified member of the FGFR family. Its extracellular domain shares high similarity to FGFR1-4 but it is specifically expressed in normal prostate and PCa, tissue microarrays containing different types of benign and malignant prostate tissue were used. Altered FGFRL1 protein in normal prostate and PCa, tissue microarrays were constructed using formalin-fixed paraffin-embedded specimen. 70 (35.9%) out of 195 patients showed immunoreactivity for USP10 and 124 (63.6 %) showed loss of immunoreactivity for USP10. 120 (61.5 %) of 195 patients were immunopositive for p14ARF and 75 (38.5 %) patients showed loss of immunoreactivity for p14ARF. Loss of USP10 was associated with male predominiency (p = 0.014), higher stage (p = 0.044), presence of lymphatic invasion (p = 0.033), absence of sporadic adenoma (p = 0.024) and absence of peri-tumoral dysplasia (p = 0.019). On multivariate survival analysis, loss of USP10 expression was independent poor prognostic factor (HR = 3.04, 95% CI = 1.79-5.18, p < 0.001) and also both loss of USP10 and p14ARF expressions showed similar result (HR = 3.76, 95% CI = 1.52-9.43, p < 0.005). Loss of USP10 and p14ARF was an independent prognostic factor (p = 0.587). Our findings indicate that loss of USP10, associated with loss of p14ARF protein expression, could be poor prognostic factors in small intestine adenocarcinoma.
function of membranous FGFR1. However, knock-down of FGFR1 in PC3M cells resulted in reduced cell growth in tumor xenografts. Additionally, mRNA sequencing on PC3M cells with FGFR1 knock-down revealed differential expression of about 250 molecules, including several metalloproteinases and FGFR1, compared to control cells (FDR<0.1 and |logFC|>1). In conclusion, we suggest that FGFR1 knock-down and alternations in PI3K/Akt activity result in smaller, spindle-shaped cells, whereas FGFR1 knock-down increased AR nuclear expression and resulted in smaller, round-shaped cells. These data suggest that PI3K and Akt have different roles in sustaining AR activity in PCa as perturbations of the two components leads to differential responses in terms of AR nuclear expression and cell morphology. In conclusion, activated Akt associates with AR expression and predicts poor overall survival in prostate cancer patients. Therefore, targeting PI3K/Akt, especially when the inhibitors are administered in combination with anti-androgens, may have implications in the design of PCa therapy targeting PI3K/Akt, especially when the inhibitors are administered in combination with anti-androgens.

#5733 Expression levels of UL16 binding protein 1 and natural killer group 2 member D in patients with gastric cancer. Kiyoshi Yoshimura,1 Moeko Inoue,1 Tetsuhiiko Asan,1 Masanori Fuse,1 Satoshi Wada,2 Atsuo Kurama1,3,1 National Cancer Center, Chuo-ku, Tokyo, Japan; 2Kanagawa Cancer Center, Yokohama, Kanagawa, Japan; 3Yamaguchi University Graduate School of Medicine, Ube, Yamaguchi, Japan.

UL16 binding protein 1 (ULBP1) expressed on the tumor cell surface binds to the natural killer group 2 member D (NKG2D) receptor present on natural killer (NK) cells, CD8+ T cells, and gamma delta T cells. However, the role of ULBP1 and NKG2D expression and associated immune responses in gastric cancer is unclear. Here, we investigated the relationships between ULBP1 and NKG2D expression and clinical outcomes in patients with gastric cancer. The expression levels of ULBP1 and NKG2D were examined in human gastric cancer cell lines and gastric cancer tissues from 98 patients who underwent surgery from 2004 to 2008. MKS-72 cells expressed ULBP1 with ULBP2, -3, or -6. NKG2D was expressed at a higher level after activation on T cells and NK cells. Among tissue sections positive for NKG2D expression, six cases were positive for CD8 and CD56. In all tissues, NKG2D-expressing cells were typically cD8+ T cells. Patients with NKG2D expression in tumors had significantly longer overall survival (OS) than patients without NKG2D expression in tumors (p = 0.0217). The longest OS was observed in patients positive for both ULBP1 and NKG2D, whereas the shortest OS was observed in patients negative for both ULBP1 and NKG2D. The interaction between ULBP1 and NKG2D may improve OS in patients with gastric cancer and may have applications in immunotherapy for induction of adaptive immunity in patients with cancer. Moreover, ULBP1 and NKG2D may be useful as prognostic biomarkers in gastric cancer.

#5734 The influence of body mass index on overall survival following surgical resection of non-small cell lung cancer. Xi Liu,1 Boris Sepesi,1 Kathryn A. Gold,2 Arlene M. Correa,1 John V. Heymach,1 Ara A. Vapourcyian,1 Jason Roznik,1,2 Ethan Dmitrovsky,1,2 UT MD Anderson Cancer Ctr., Houston, TX; 3UC San Diego Health, San Diego, CA.

Prior work implicated an association between increased body mass index (BMI) and lower risk of mortality from lung cancer. The aim of our study was to comprehensively evaluate the influence of BMI on long-term overall survival in patients with non-small cell lung cancer. This study investigated 1935 patients who underwent surgical resection for non-small cell lung cancer from 2000 - 2014. Study variables included both patient and treatment related characteristics. Univariate and multivariate Cox regression analyses were performed to identify variables associated with overall survival. By univariate analysis, significant predictors of better survival were higher BMI, pathologic tumor stage (stage I versus stages II, III, or IV), type of surgery (lobectomy/pneumonectomy versus wedge resection/segmentectomy), younger age, female gender, and adenosquamous histology (versus squamous) (all p < 0.05). Patients considered morbidly obese (BMI ≥ 35) had a trend towards better outcomes than those classified as obese (BMI ≥ 30 and <35) (p = 0.05), overweight (BMI ≥ 25 and <30) (p = 0.13), or healthy weight (BMI < 25) (p = 0.37) (HR 0.727, 0.848, 0.926, and 1, respectively). By multivariate analysis, BMI remained an independent predictor of survival (p = 0.02). Propensity matching analysis showed significantly better overall survival (p = 0.008) in patients with BMI ≥ 30 compared to BMI < 25. For exploratory analysis of expressed mRNAs associated with obesity in lung cancer, the association between obesity-related species (LEP, LEPR, PCSK1, POMC, MC4R, BMIQ1, BMIQ2, UCP2, BMIQ5, BMIQ6, INSL2, FTO, TME1M18, GNPD2A1, NEGR1, BDNF, KCTD15, SH2B1, MTH2, and NPC1) and survival was explored using The Cancer Genome Atlas (TCGA). Kaplan-Meier analyses demonstrated significantly improved overall survival in patients with high BMI.
lun cancer patients with higher Uncoupling Protein 2 (UCP2) expression, as will be presented. In summary, this large, single center series, after controlling for disease stage and other variables found higher BMI was associated with improved overall survival following surgical resection of non-small cell lung cancer. Studies are underway to elucidate the underlying mechanisms responsible for this association between BMI and lung cancer survival.

#5735 Comprehensive analysis of serum levels of VEGF and its receptors in patients with uterine cervical cancer. Daiken Osaku,1 Tetsuro Oishi,1 Mayumi Sawada,1 Hiroki Koamata,1 Jun Chikuni,1 Akiko Kudoh,1 Michiko Nonaka,1 Shinya Sat0,1 Muneaki Shimada,1 Hiroki Itamochi,2 Tasuku Harada,3 Tottori Univ. School of Medicine, Yonago, Japan; 4Iwate Medical University, Morioka, Japan.

Objective: Angiogenesis is one of the processes that is critical for the growth, invasion and metastasis of solid tumors, including uterine cervical cancer (CC). The vascular endothelial growth factor (VEGF) family is one of the major pathways involved in tumor angiogenesis. The aim of this study was to determine whether serum levels of these angiogenic factors could be used as biomarkers in patients with CC. Methods: A total of 107 patients with International Federation of Gynecology and Obstetrics (FIGO) stage IB to IIB CC who were treated at Tottori University Hospital between 2006 and 2015 were enrolled in this study. The study was approved by the Institutional Review Board of the School of Medicine of Tottori University. All patients gave written informed consent before the collection of specimens according to institutional guidelines. Serum samples were collected before initial surgery and levels of VEGF-A, -C, VEGFR-1, and VEGFR-2 were analyzed by enzyme-linked immunosorbent assay (ELISA). We evaluated the association between the levels of these angiogenic factors and clinicopathologic variables. With a median follow-up duration of 1743 days, survival analysis of 93 patients treated between 2006 and 2013 was performed. We also determined the mRNA expression of VEGF-A by real-time RT-PCR in fresh frozen tumors and the protein expression by immunohistochemical staining in paraffin-embedded tumors from CC patients. The mRNA levels of VEGF-A relative to GAPDH were used for the analysis. Results: Median levels of serum VEGF-A, -C, VEGFR-1, and VEGFR-2 were 313, 8122, 68, and 6210 pg/ml, respectively. We found a significant positive correlation between VEGF-A levels and the maximum tumor diameter (P = 0.010). Patients with pelvic lymph node involvement (PLNI) showed significantly higher levels of VEGF-A and VEGFR-2 than those without PLNI. Patients with bulky tumor or parametrial infiltration (PI) also showed significantly higher levels of VEGF-A. In contrast, patients with a bulky tumor or PLNI showed significantly lower levels of VEGFR-1. Both histological types and FIGO stage were not related to levels of these angiogenic factors. We set the cutoff values of these factors at the median levels of the angiogenic factors. The 5-year overall survival rate (OS) for patients with high VEGF-A levels was significantly lower than those with low levels (92.9% vs. 72.8%, P = 0.014). The 5-year OS for patients with high VEGFR-2 levels was significantly lower than those with low levels (94.7% vs. 73.8%, P = 0.012). PLNI and PI were prognostic factors for overall survival. Multivariate analysis revealed that PLNI, VEGF-A, and VEGFR-2 levels were independent prognostic factors. The mRNA and protein expressions of VEGF-A and VEGFR-2 were observed in the cancer cells. There was no correlation between mRNA levels and serum levels of VEGF-A. Conclusion: These results suggest that serum VEGF-A may be a promising prognostic biomarker for CC.

#5736 Clinical impact of high serum hepatocyte growth factor in advanced non-small cell lung cancer. Takahiro Tsuji, Hiroaki Ozasa, Yuichi Sakamori, Takashi Nomizo, Tomoko Funazo, Yuto Yasuda, Hironori Yoshida, Hirotoki Nagai, Young Hak Kim. Kyoto Univ. Graduate School of Medicine, Kyoto, Japan.

Activation of c-MET through hepatocyte growth factor (HGF) increases tumorigenesis, induces resistance, and is associated with poor prognosis in various solid tumors. We previously reported that lung cancer cell lines had increased expression of c-MET due to gene amplification-induced cytotoxic drug resistance, and that resistant cells paracrine HGF and promote its resistance. However, the clinical significance of sHGF in patients with advanced or recurrent NSCLC, especially in patients treated with cytotoxic chemotherapy, is yet to be identified. Here, we present sHGF may be useful to predict tumor response and PFS in patients with advanced NSCLC. A total of 81 patients with 101 treatment regimens were investigated; 53 patients received first-line therapy and 48 patients received second-line therapy during the observation period. sHGF levels were evaluated using ELISA at 4 time-points: at pre-treatment, at response-evaluation (1-2 months after treatment initiation), at the best tumor response, and at the disease progression. As a control biomarker, serum carcinomembrioncy antigen (CEA) was also evaluated. sHGF at response-evaluation in patients with progressive disease was higher compared with that of disease controls in both first-line and second-line treatment (median value (MV); under the limited of detection (LOD) vs. 0.40; P = 0.0086 and MV; under the LOD vs. 0.41; P = 0.0035, respectively). Positive-sHGF at response-evaluation predicts poor progression-free survival (PFS) compared with negative-sHGF in both first-line (median, 6.1 vs. 11.2; P = 0.047) and second-line treatment (8.7 vs. 21.9; P = 0.014). Lung adenocarcinoma subgroup analysis showed that in patients receiving second- line cytotoxic chemotherapy, there were no significant differences in PFS or HR between patients with low-CEA compared with those with high-CEA, but positive-sHGF at pre-treatment or at response-evaluation predicts poor PFS (35 vs. 132; P = 0.0045, 50 vs. 215; P = 0.0647, respectively). Simple and repeatable marker-based monitoring of the HGF/c-MET pathway would provide rationale for future research investigating the merit of sHGF as a potential clinical biomarker to indicate administration of MET inhibitors.

TUMOR BIOLOGY: Carcinogenesis and Human Tumors

#5737 YAP1 and COX2 converge to regulate SOX2 and urothelial cancer stem cells. Akira Oki,1 Noah Hahn, Mohammad Hoque. Johns Hopkins Univ. School of Medicine, Baltimore, MD.

Since cancer stem cell (CSC) are resistant to conventional chemotherapies that efficiently eliminate bulk tumor cells, the elimination is indispensable in treating malignant diseases. However, the underlying mechanisms responsible for the urothelial CSC traits remain elusive. The tumor microenvironment reinforces a chronic inflammatory state to support tumor progression by triggering CSCs. In addition, chemotherapy-induced apoptotic cells release COX2-derived PGE2, which in turn promotes CSC expansion. Environmental risk factors, such as arsenic (As), cause chronic inflammation and have been linked to urothelial carcinoma incidence. We previously developed an in vitro stepwise model for urothelial malignant transformation by As exposure in normal urothelial cells line (HUC1), which may reveal the intimate connections between carcinogenesis, chronic inflammation, and CSCs and provide clues to develop novel therapeutic strategies. As-exposed cells displayed more aggressive phenotype than As-unexposed cells in a time dependent manner. In gene set enrichment analysis of expression array of chronic As-exposed and unexposed cells; EGFR, COX2 and YAP1 were top-ranked oncogenic signature in As-exposed cells. Moreover, As exposure induced malignant stemness properties. In stem cell-specific RT-PCR array, SOX2 has been gradually overexpressed in line with acquired spheron formation and self-renewal capacities. SOX2 is frequently overexpressed in numerous Urothelial carcinoma (UC) cell lines as well as in As-exposed cells, especially in the spheroid cells. Stable knockdown of SOX2 reduces in vitro CSCs properties and also in vivo tumorigenicity. COX2/PGES1 and YAP1 signaling pathways are required to accelerate SOX2 activity. Mechanistically, COX2/PGE2 secreted induces promoter methylation of let-7 host gene via inducing DNA methyltransferases, resulting in downregulated let-7 expression and subsequent SOX2 expression. On the other hand, YAP1 induces COX2/PGE2 signaling inde- pendently SOX2 expression, and these signaling mutually compensate via negative feedback mechanism of SOX2, indicating that dual blockade of these signaling is indispensable to eradicate urothelial CSCs. The pharmacological inhibition of COX2 and YAP1 elicited long-lasting therapeutic response by subverting CSCs expansion following chemotherapy in both UC cells-derived and patient-derived xenograft models. In basal type UC, EGFR-targeted therapy was effective in line with previous reports, but the acquired resistance is inevitable. We reveal that COX2 and YAP1 signaling determine acquired resistance to treatment with the EGFR inhibitor via SOX2. Thus, our findings indicate that the combined inhibition of YAP1 and COX2/PGE2 signaling could be an effective therapeutic strategy to slow CSC expansion and UC progression.

#5738 Tracking the genetic relationship between first and late-onset second urothelial cancers by mutational signature analysis. Xavier Castells,1 Maude Ardín,1 Sandrine Rorive,2 Nilufer Broeders,3 Yan Song,1 Stephanie Vilardell,1 Christine Carreira,1 Pierre-Paul Bringuier,5 Adriana Heguy,6 Thierry Roumeguere,7 Joelle Nortier,3 Jiri Zavadil1.

Since cancer stem cell (CSC) are resistant to conventional chemotherapies that efficiently eliminate bulk tumor cells, the elimination is indispensable in treating malignant diseases. However, the underlying mechanisms responsible for the urothelial CSC traits remain elusive. The tumor microenvironment reinforces a chronic inflammatory state to support tumor progression by triggering CSCs. In addition, chemotherapy-induced apoptotic cells release COX2-derived PGE2, which in turn promotes CSC expansion. Environmental risk factors, such as arsenic (As), cause chronic inflammation and have been linked to urothelial carcinoma incidence. We previously developed an in vitro stepwise model for urothelial malignant transformation by As exposure in normal urothelial cells line (HUC1), which may reveal the intimate connections between carcinogenesis, chronic inflammation, and CSCs and provide clues to develop novel therapeutic strategies. As-exposed cells displayed more aggressive phenotype than As-unexposed cells in a time dependent manner. In gene set enrichment analysis of expression array of chronic As-exposed and unexposed cells; EGFR, COX2 and YAP1 were top-ranked oncogenic signature in As-exposed cells. Moreover, As exposure induced malignant stemness properties. In stem cell-specific RT-PCR array, SOX2 has been gradually overexpressed in line with acquired spheron formation and self-renewal capacities. SOX2 is frequently overexpressed in numerous Urothelial carcinoma (UC) cell lines as well as in As-exposed cells, especially in the spheroid cells. Stable knockdown of SOX2 reduces in vitro CSCs properties and also in vivo tumorigenicity. COX2/PGES1 and YAP1 signaling pathways are required to accelerate SOX2 activity. Mechanistically, COX2/PGE2 secreted induces promoter methylation of let-7 host gene via inducing DNA methyltransferases, resulting in downregulated let-7 expression and subsequent SOX2 expression. On the other hand, YAP1 induces COX2/PGE2 signaling independently SOX2 expression, and these signaling mutually compensate via negative feedback mechanism of SOX2, indicating that dual blockade of these signaling is indispensable to eradicate urothelial CSCs. The pharmacological inhibition of COX2 and YAP1 elicited long-lasting therapeutic response by subverting CSCs expansion following chemotherapy in both UC cells-derived and patient-derived xenograft models. In basal type UC, EGFR-targeted therapy was effective in line with previous reports, but the acquired resistance is inevitable. We reveal that COX2 and YAP1 signaling determine acquired resistance to treatment with the EGFR inhibitor via SOX2. Thus, our findings indicate that the combined inhibition of YAP1 and COX2/PGE2 signaling could be an effective therapeutic strategy to slow CSC expansion and UC progression.
TUMOR BIOLOGY: Carcinogenesis and Human Tumors

Exposure to aristolochic acid (AA, IARC Group 1 carcinogenic) present in some traditional herbal medicines leads to aristolochic acid nephropathy (AN), often complicated by development of multiple urothelial carcinomas of sequential onset. We used genome-scale mutational signature analysis of multiple urinary tract tumors of AA cases from a unique patient group to determine the mechanism and significance of the late-onset cancers and their associations with AA exposure as well as to the first cancers. Aristolactam-DNA adduct-positive AAN patients (n=4) who developed cancer within 8 years following the initial exposure to AA were chosen for analysis of their first cancers (upper tract urothelial carcinomas, UTUC) and second cancers of delayed onset (1-9 years after first-cancer diagnosis, involving the bladder or ureteral meatus). All patients had received a kidney transplant before developing the first cancers and harbored considerable overlap in exposure-specific (A>1T) somatic mutations. This finding suggests that the development of bladder urothelial carcinomas in AAN patients is likely due to distal seeding of cancer cells originating from the primary UTUC tumors. Our first-of-its-kind study addresses the risk as well as mechanistic factors leading to the second, late-onset bladder urothelial carcinomas following kidney transplantation and primary UTUC development. Our results underline the importance of long-term bladder follow-up in high-risk populations with established or suspected AA exposure. Funding: IARC NYU Genome Technology Center is partially supported by the NIH/NCI (P30CA16087) grant.

#5739 Nicotine promotes stemness-related properties and cell migration/metastasis through IGF-1R regulation in triple negative breast cancer. Yung-Chie Kuo,1 Jan-Show Chu,2 Kha-Liang Lee,3 Victor James Drew,2 Wei-Zhan Zhuang,4 Chi-Long Chen,5 Yuan-Soon Ho,6 Yen-Hua Huang,6 1Department of Biochemistry and Molecular Cell Biology, School of Medicine, Taipei Medical University, Taipei, Taiwan; 2Department of Pathology, School of Medicine, Taipei Medical University, Taipei, Taiwan; 3Graduate Institute of Medical Sciences, College of Medicine, Taipei Medical University, Taipei, Taiwan.

Purpose: To determine the role of insulin-like growth factor (IGF)-I receptor (IGF-IR) in alpha 9 nicotinic acetylcholine receptor (α9-nAChR)-induced stemness-related properties and to assess the therapeutic potential for preventing early tumor relapse and metastasis of TNBCs. Experimental Design: Expression levels of stemness-related genes, α9-nAChR and IGF-IR in tissues (n = 67) were analyzed by real-time Q-PCR and the correlation of different gene levels were calculated by the Pearson correlation analysis. The effects of either α9-nAChR activation or IGF-IR transactivation on stemness expression in TNBC were examined using α9-nAChR overexpressing or E2-E10 overexpressing cells, which were treated with nicotine and IGF-IR antibody, wound closure, invasion/migration assay, and annexin-V. The α9-nAChR, OCT4 and IGF-IR protein, p-IGF-IR in tissues were detected by immunohistochemical staining. Results: A high positive correlation between the gene expression levels of OCT4/NANOG/CD24/CD44 and α9-nAChR/IGF-IR in human breast cancer tissues was observed. Nicotine induced α9-nAChR activation-trans-activates an IGF-IR expression and a phosphorylation of STAT3, which stimulated stemness-related properties in both the cell lines and the xenografted mouse. The inhibition of either α9-nAChR or IGF-IR activation by RNA interference significantly suppressed the nicotine-induced stemness-related properties and cell metastasis both in vitro and in vivo. Conclusions: IGF-1R signal regulates the nicotine/α9-nAChR-induced stemness properties and cell metastasis therefore cannot prevent poor prognosis in TNBCs.

#5740 Aberration of (pro)rein receptor induces genomic instability in human pancreatic ductal epithelial cells. Yuki Shibayama,1 Jun Yasuda,2 Daisuke Yamazaki,3 Asadar Rahman,2 Shinichi Yachida,2 Akira Nishiyama,1 Kagawa University, Kagawa, Japan; 2Tohoku University, Sendai, Japan; 3National Cancer Center Research Institute, Tokyo, Japan.

Background: We have recently shown the potential contribution of (pro)rein receptor (P)RR to tumorigenesis of pancreatic ductal adenocarcinoma (PDAC) through an activation of Wnt/β-catenin signaling pathway (Sci. Rep., 2015). We also found that significant (P)RR expression was synchronized with an appearance of atypical nuclei in PanIN-2 of PDAC tissues. Furthermore, (P)RR knockdown reduced a total of DNA amount in human PDAC cell lines. Based on our findings, we have hypothesized that an aberration of (P)RR leads to a failure of genome homeostasis. Accordingly, we explored whether an aberrant expression of (P)RR induces genomic instability in human pancreatic ductal epithelial (HPDE) cells which are capable of developing to the PDAC. Methods: HPDE cells were infected with either an empty vector or (P)RR-expressing vector. The effects of (P)RR expression on genomic instability were evaluated by high coverage comparative genomic hybridization (CGH) analysis. Results: (P)RR overexpression induced genomic instability in PDAC cell lines. HPDE cells transfected by vector without the insertion of ATTPaP2 was noted as Mock. We also performed a comet assay to evaluate the defects of DNA repair capacity, flow-FISH to measure the length of telomere and western blotting to confirm the activation of DNA damage pathway by measuring protein levels of γ-H2AX and p53. Then, comparative analyses of human whole exome sequenced PDAC and (P)RR expressing HPDE cells were examined. Furthermore, we implanted 14-passage HPDE cells expressed by either Mock or (P)RR into the renal subcapsules of immunodeficient mice to investigate whether (P)RR-expressing HPDE cells show a precancerous status in vivo. Results: (P)RR overexpression led to inactivation of γ-H2AX and p53 as the components of DNA damage pathway, which were associated with a disappearance of comet tail and shorten telomere length. Substantial structural variations, e.g., inter- and intra-chromosomal translocations throughout all the chromosomes were observed in HPDE cells expressed by (P)RR under the analysis by BreakDancer. Analyses with Bctool showed that the number of all the somatic mutations was approximately 2-fold greater in HPDE cells expressed by (P)RR than those expressed by Mock (Mock: 124,579 vs. (P)RR: 239,860). (P)RR overexpression led to a failure of genome homeostasis by resulting in several genes which were commonly detected in PDAC tissues. The area occupied by (P)RR-expressing HPDE cell population remarkably expanded after the implantation to renal subcapsules of all the immunodeficient mice. However, there were no KRAS 12 codon mutations which are prevalent in PDAC patients. Conclusion: We have demonstrated that (P)RR overexpression induces genomic instability on global genome level in HPDE cells. These data are consistent with our hypothesis that (P)RR is essentially involved in the early carcinogenesis of PDAC.

#5741 Evaluating the role of recurrent ESR1-CCDC170 fusion in breast cancer endocrine resistance. Yiheng Hu,1 Jamunaranir Veeraraghavan,2 Jian Wang,3 Yin Tan,1 Jin-Ah Kim,2 Rachel Schiff,3 Xiaosong Wang.1 University of Pittsburgh, Pittsburgh, PA; 2Baylor College of Medicine, Houston, TX.

Background: Recurrent gene fusions resulting from chromosome rearrangements are central to the formation of cancer. Previously, our lab identified recurrent rearrangements between the estrogen receptor α (ERα) gene ESR1 and its neighbor gene CCDC170 in ~6-8% of luminal B tumors, a more aggressive form of ER+ breast cancer that has worse clinical outcome after endocrine therapy. ESR1-CCDC170 fusions enable expression of different-sized N-terminally truncated CCDC170 (ΔCCDC170) under ERα promoter, which is associated with the potential for estrogen receptor α (ERα) and ERβ interactions with its neighbor gene CCDC170, in breast cancer cellstransformedcellstoa potentially high-affinity ATP-binding pocket at its C-terminus, physically interacting with ERα and HER2, and forms homodimers. RPPA analysis showed that silencing of ESR1-CCDC170 repressed ERα and BCL2 protein levels, as well as total/phospho-HER2 levels, consistent with the findings of ΔCCDC170 interactions with ERα and HER2. Importantly, analysis of ΔCCDC170 protein sequence revealed a potential high-affinity ATP binding pocket at its C-terminus, suggesting that ΔCCDC170 may be directly druggable. Conclusion: These data suggest a potential role of ESR1-CCDC170 in mediating breast cancer endocrine resistance, which may possibly through cytoplasmic mislocalization of ΔCCDC170 and interactions with ERα and HER2. Further studies will clarify and elucidate the role of overexpressed or endogenous ESR1-CCDC170 in breast cancer endo-
The role of atypical protein kinase C in colorectal cancer cell growth and proliferation. S M Anisul Islam, Mildred Acevedo Duncan. Univ. of South Florida, Tampa, FL.

Colorectal cancer (CRC) is the second most common cancer in men and women from colorectal cancer accounts for 8% of all cancer deaths both in men and women in the United States. CRC is life threatening disease due to therapy resistant cancers cells. The exact mechanisms of cell growth, survival, metastasis and inter & intracellular signaling pathways involved in colon cancer are still a major challenge for scientists. Hence, investigating the signaling pathways that lead to colon carcinogenesis may give insight into the therapeutic target. In this study, the role of atypical Protein kinase C (aPKC) on colon cancer was identified by using four inhibitors of that particular protein class: 1) ACPD (2-acetyl-1,3-cyclopentanediene and 2) DNDA (3,4-diamino-2,7-naphthalene-disulfonic acid) are non-specific inhibitors of aPKCs; 3) 3-\(\beta\)-stilbene glucuronide; methyl dihydroxyphenyl phosphate is a PKC-\(\varepsilon\) specific inhibitor; and 4) ICA-1 (4, 9-amino-4-carbamoylmethylidazol-1-y-2, 3-dihydroxycyclopentanylmethyl dihydroxyphenyl phosphate) is a PKC-\(\gamma\) specific inhibitor. The cell lines tested were HT-29 colon cancer and CDB18CO normal colon epithelium. Additionally, the inhibition of aPKCs did not bring any significant toxicity on CDB18CO normal colon cell line. These results suggest the potentiality of utilizing aPKC-\(\gamma\) inhibitors to block colon cancer cell growth and proliferation.

#5745 Study on telomere shelterin component TPP1 in esophageal squamous cell carcinoma. Lihuia Yao,1 Jiang Zou,1 Ru Sun,1 Jiaying Cai,1 Guangcheng Huang,1 Qiang Ma,2 Lei Xu,1 Mayong Fu,2 Xiaolian Guo2, North Sichuan Medical College. Nanchong, China; 2Affiliated Hospital of North Sichuan Medical College, Nanchong, China.

Esophageal cancer (EC) is one of the most aggressive cancer and ranks the sixth leading cause of cancer-related mortality worldwide, approximately 70% of global esophageal carcinoma cases occur in China and esophageal squamous cell carcinoma (ESCC) is the most frequent histological subtype of EC. Lacking of reliable early diagnostic markers and efficient medical and surgical treatment approaches, the five-year survival rate of ESCC is only about 4.4%. Therefore exploration of the genetic mechanism that most ESCC patients in China could be beneficial to improve the diagnosis, therapy, and prevention of this disease. As an important telomere binding protein, TPP1 protects the ends of telomeres and maintains the genomic stability and integrity of chromosomes in eukaryotes. Previous investigation discovered that TPP1 might play an important role in the carcinogenesis and progression of some cancers. However, whether and/or how TPP1 participates in ESCC remains unclear. Here TPP1 was studied in 65 ESCC patients’ specimens including tumor tissue, the adjacent tissue, and the peripheral blood leukocytes, also the ESCC cell lines were employed to further explore the molecular mechanisms of TPP1 involved in the tumorigenesis of ESCC. In this study, TPP1 mRNA and protein were measured in the ESCC tissue specimens, peripheral blood leukocytes and also in ESCC cell lines using real time RT-PCR and Western Blot. The results showed that TPP1 mRNA level was significantly higher in ESCC tumor tissues compared with the adjacent tissues (P<0.05); the same trend was observed in ESCC cells (Eca109, Kyse150) vs human esophageal epithelial cells (HET-1A), respectively. However, in peripheral blood leukocytes, the expression of TPP1 did not show any difference between the cancer patients and the healthy controls. Among the 65 ESCC patients, TPP1 expression in 46 patients was obvious higher in tumor tissues than that in the matched adjacent tissues, although there were 19 patients in exception. Moreover, the TPP1 expression was correlated with the lymph nodes metastasis and CYF2, which is one of the potential tumor markers for diagnosis of esophageal carcinoma. To further explore the potential biological function of TPP1 in ESCC, stably transfecting shRNA-TPP1 (sh-TPP1) and shRNA-Negative Control (sh-NC) cells were performed to study TPP1’s roles in ESCC. The colonicogenic assay showed that depletion of TPP1 decreased ESCC cells proliferation and cell growth, and the wound healing experiment and cell invasion transwell chamber test demonstrated that down-regulation of TPP1 suppressed the cell migration and inva...
sion capabilities in vitro. Taken together, our findings revealed that TPF1 might play crucial roles in the pathogenesis of ESCC and targeting TPF1 could be a valuable potential for ESCC early diagnosis, intervention and therapeutics.

#5746 TRAF1 is required for solar UV-induced skin carcinogenesis. Hiroyuki Yamamoto,1 JooHyun Ryu,2 Eli Min,1 Naomi Oi,1 Ruhua Bai,1 Tatayana A. Zykov1,2 Dong Hoon Yu1,3 Margarita Malakhova,1 Kenji Moriyma,12 Ann M. Bode,1 Zigang Dong4,1 University of Minnesota, Austin, MN;1 Mukogawa Women’s University, Nishinomiya, Japan.

Tumor necrosis factor receptor-associated factor 1 (TRAF1) is a member of the TRAF protein family, which regulates the canonical and non-canonical NF-κB signaling cascades. Although aberrant TRAF1 expression in tumors is reported, the role of TRAF1 remains elusive. Here, we report that TRAF1 is required for skin carcinogenesis induced by chronic solar UV radiation. In vivo studies with solar UV exposure indicate that the deletion of TRAF1 results in the inhibition of AP-1 activity by down-regulating the induction of c-Fos and c-Jun by regulating ERK5 activation. Furthermore, we show that TRAF1 is required for solar UV-induced ERK5 activation. Mechanistic studies revealed that TRAF1 expression enhances the ubiquitination of ERK5 on K184, which is necessary for AP-1 activation. Altogether, our results suggest that TRAF1 mediates ERK5 activity by regulating the upstream effectors of ERK5 and also by modulating its ubiquitination status. Targeting TRAF1 function might lead to strategies for preventing and treating skin cancer.

#5747 Influence of air carcinogenic pollution on oncological morbidity. Olya Ostash,1 Igor Chernichenko,1 Olga Litvichenko,1 Sergei Tsymbaliuk,2 preventivemeasurestoundercompoundshazardinfluenceonpopulation.

In the present study, we investigated whether VCAN expression was associated with the pathogenesis of cccRCC. Methods: VCAN expression was analyzed in 3 RCC and normal kidney cell lines, as well as 84 matched cccRCC and normal renal tissues. We also performed various functional analyses of growth and progression properties using VCAN-depleted cccRCC cells. Microarray analysis was then employed to identify the target genes of the pathway involved in cccRCC tumorigenesis and development. Results: There are 4 isoforms of VCAN containing the N-terminal globular (G1 domain) and C-terminal globular (G3 domain) domains, each of which was found to be over-expressed in the cccRCC samples as compared to the controls. Higher VCAN expression was significantly correlated with metastasis (p<0.001) and worse 5-year overall survival after a radical nephrectomy (p=0.014). In vitro, VCAN knockdown by siRNA in Caki-2 and 786-O cells significantly decreased cell proliferation and increased apoptosis, and was also found to be associated with alteration of several TNF signaling-related genes, such as TNF-α, BID, and BAK. Furthermore, VCAN deletion markedly decreased cell migration and invasion associated with reduced MMP7 and CCN2 levels. Consequently, our results demonstrate that VCAN promotes cccRCC tumorigenesis and metastasis, showing it to be an attractive novel target for diagnostic, prognostic, and therapeutic strategies for affected patients.

#5750 USP15 inhibits HPV16 E6 degradation and catalytically inactive USP15 has reduced inhibitory activity. Aoi Tokuda, Masafumi Yoshimoto, Yuji Yaginuma. Kumamoto Univ. Graduate School of Health Sci., Kumamoto, Japan.

HPV’s can be classified as either high-risk or low-risk depending on the transforming potential of the virus. Most cervical cancers and a significant proportion of other anogenital cancers have been associated with infection by a small number of high-risk genital HPV types. Tumorigenesis induced by high-risk genital HPVs has been linked to the expression of two viral oncoproteins, E6 and E7, which cooperate in cellular immortalization and transformation processes. HPV16 E6 is an oncoprotein that causes the development of high-risk type human papilloma virus (HPV) and induces cancers, including oropharyngeal, anal, and cervical cancers. The stability of E6 is essential for its complete function as an oncoprotein. Using the yeast two-hybrid system, we identified ubiquitin-specific protease 15 (USP15) as an HPV16 E6-interacting protein. USP15 encodes a protein that consist of 952 amino acids and functions as a deubiquitinating enzyme. Deubiquitination is an essential process that releases ubiquitin chains from ubiquitin-protein conjugates. Aberrations in the ubiquitin-proteasome some system have been recently connected to the pathogenesis of several human protein degradation disorders, including cancer and neurodegenerative diseases; as
such, the proteasome is now considered to be important in the mechanism of carcinogenesis. USP15 cleaves polyubiquitin chains of HPV16 E6 and/or ubiquitin precursors. Immunohistochemical analysis showed that USP15 was highly expressed in normal cervical squamous cells, and cervical cancer cells. Our results indicated that USP15 can increase the level of HPV16 E6 by inhibiting E6 degradation. USP15 dose-dependently inhibited the degradation of HPV16 E6. In contrast, catalytically inactive mutants of USP15 had a reduced inhibitory effect on E6 degradation. In particular, USP15 mutants of all three cysteine boxes and the NHL mutant of the KRF box had a drastically reduced inhibitory effect on HPV16 E6 degradation. In addition, HPV16 E6 mRNA was not induced by USP15; therefore, HPV16 E6 appears to be post-translationally regulated. These results suggest that USP15 has the ability to stabilize E6 as a deubiquitinating enzyme, and HPV16 E6 can affect biological functions as an oncprotein in infected human cells.

**#5751 Induction of cancer stem cell like characteristics by overexpression of CDX1.**  
SANG IL CHOI, Kyoung-Ok Hong, Mi Ree Park, Yun Hee Na, Soo-Jeong Cho.  
National Cancer Center, Korea, Goyang-si, Gyeonggi-do, Republic of Korea.

Intestinal metaplasia (IM) has been regarded as the most significant risk factor for gastric cancer (GC). However, the molecular mechanisms of the pathogenesis of IM and the progression of GC remain unclear. The aim of this study was to evaluate the role of CDX1 in IM and GC using stable CDX1 overexpression in HFE145 gastric epithelial cells, and its expression in patient samples. For CDX1 overexpression, we generated lentiviral CDX1 and infected it to HFE145 cells. We found that CDX1 overexpression increased the expression of differentiation markers such as villin and SI and a decrease of gastric epithelial marker such as MUC5AC. Overexpression of CDX1 in HFE145 cells caused an increase in cell proliferation (P<0.05) and showed 2.7-fold higher clonogenic ability than that of control cells. The expression of CDX1 induced in vitro invasiveness 1.9-fold higher compared to HFE145 control cells with statistical significance (P=0.004), augmented the expression of MMP-9 and phosphorylation of FAK and paxillin. Overexpression of CDX1 also induced anchorage-independent colony formation and spheroid formation, and enhanced the expression of stem cell markers including SOX2, Oct3/4, NANOG and c-Myc in HFE145 cells, suggesting CDX1-induced stem cell like phenotype of gastric epithelial cells. HFE145 cells infected with CagA-positive Helicobacter pylori (G27 wild type) caused an increase in expression of CDX1 compared to HFE145 cells infected with CagA-negative H. pylori (G27 ΔCagE). Using luciferase promoter assay, we confirmed that the expression of CDX1 was regulated by the CagA secreted from H. pylori. In clinical practice, the Operative Link on Gastric Intestinal Metaplasia Assessment (OLGIM) staging system is often used to evaluate the degree of IM in biopsy samples or surgical specimen. We measured expression of CDX1, SI, and villin adjusted by glyceraldehyde 3-phosphate dehydrogenase expression using densitometry in 9 patients with various OLGIM stage (2 in stage 0, 1 in stage 1, 2 in stage 2, 1 in stage 3, 3 in stage 4). We were able to find out that the patients with higher OLGIM stage (stage 3-4) tended to have higher expression of CDX1 (3.935 vs. 0.416, p=0.100), SI (9.739 vs. 0.311, p=0.088), and villin (7.785 vs. 0.866, p=0.119) compared to patients with lower OLGIM stage (stage 0). These results suggest that CDX1 overexpression could be one of the causes of GC tumorigenesis and progression. Further investigation on CDX1 would encourage development of specific target for cancer treatment.

**#5752 Susceptibility of cells from cervical transformation zone to HPV-16 induced immortalization and dysplastic differentiation.**  
HAN Deng, Eric Hill, Pholimana Yenoboa, Sumona Mondal, Craig D. Woodworth.  
Clarkson University, Potsdam, NY.

Persistent infection of high-risk human papillomavirus (HPV) is a major risk factor for cervical cancer. Greater than 90% of these cancers originate in the cervical transformation zone (CTZ), a narrow band of squamous metaplastic epithelium between ectocervix and endocervix. It is unclear why the CTZ has high susceptibility to malignant transformation and few studies have specifically examined cells from this region. We hypothesized cells cultured from human CTZ are uniquely susceptible to cellular immortalization and dysplastic differentiation, two alterations that contribute to malignant development. Primary epithelial cells were cultured from each region of human cervix (ectocervix, endocervix and CTZ) and characterized for expression of differentiation markers to assess their origin. We examined susceptibility of cells from each region to immortalization after transfection with the complete HPV-16 genome or infection of HPV-16 E6/E7 retroviruses. In addition, we evaluated the extent of dysplastic epithelial differentiation in organotypic cultures of HPV16-immortalized cell lines derived from each region of cervix. Our results showed that cells from the CTZ express specific keratin markers (keratin 14 and 18) that confirm their origin. Primary cell cultures from CTZ and ectocervix are more susceptible to immortalization by the HPV16 complete genome or E6/E7 retroviruses. In contrast, preliminary results indicate that HPV-immortalized CTZ and endocervical cells are more susceptible to dysplastic differentiation when compared to cells from other regions. Although results are preliminary, our studies may serve to identify important signal pathways or biomarkers that are unique to cells from CTZ and that can be targeted for improved screening, prevention or therapy.

**#5753 Inhibition of CCAR1, a coactivator of β-catenin, suppresses the proliferation and migration of gastric cancer cells.**  
Te-Sheng Chang,1 Chung-Kuang Lu,1 Kuo-Liang Wei,1 Yi-Hsing Chen,1 Ying-Tung Cheng,2 Shui-Yi Tung,1 Cheng-Shyong Wu,1 Ming-Ko Chiang3.  
Chung Gung Memorial Hospital, Chiayi, Taiwan; National Chung Cheng University, Chiayi, Taiwan.

Given a current hypothesis that cancer arises from cancer stem cells (CSCs), targeting key signaling pathways that support CSC self-renewal appears to be a useful approach to cancer therapy. Deregulated expression of Wnt signaling is among the major pathways implicated in regulating the stemness properties of a variety of human cancers, including gastric cancer. Cell cycle and apoptosis regulator 1 (CCAR1) is a transcriptional coactivator which has been shown to be a component of Wnt/β-catenin signaling, and plays an important role in transcriptional regulation by β-catenin. However, the function and clinical significance of CCAR1 in gastric cancer have not been elucidated. Here we show the elevated CCAR1 nuclear expression correlates with the occurrence of gastric cancer. In addition, RNAi-mediated CCAR1 reduction not only suppressed the cell growth and increased apoptosis in gastric cell lines AGS and MKN28, but also reduced the migration and invasion ability of these cells. Furthermore, in vivo xenograft assay showed that the expression level of CCAR1 was critical for tumorigenesis. Our data demonstrates that CCAR1 contributes to carcinogenesis in gastric cancer and is required for the survival of gastric cancer cells. Moreover, CCAR1 may serve as a diagnostic marker and a potential therapeutic target.

**#5754 The genetic aberrations in carcinogenic sequence of colitis-associated cancer.**  
Nobuyuki Kakiuchi,1 Kenichi Yoshida,1 Yusuke Shiozawa,1 Akira Yokoyama,1 Keiseke Katoaka,1 Yoshikage Inoue,1 Yasuhiko Takeuchi,1 Yasunori Kogure,1 Ayana Kon,1 Masahiro Nakagawa,1 Kenichi Chiba,1 Hiroko Tanaka,1 Yuichi Shirashi,1 Satoru Miyano,1 Kenji Kawada,1 Hideaki Okajima,1 Yoshiharu Sakai,1 Takaki Sakurai,1 Hironori Haga,1 Hiroshi Nakase,3 Motoi Kuwahara,1 Hiroki Ikeuchi,1 Takako Kihara,1 Seichi Hirota,1 Takahiro Horimoto,1 Minoru Matsuura,1 Hiroyuki Marusawa,1 Hiroshi Seno,1 Seishi Ogawa,1 Kyoto University, Kyoto, Japan; The University of Tokyo, Tokyo, Japan; 2Sapporo Medical University, Sapporo, Japan; 3Hyougo College of Medicine, Nishinomiya, Japan.

Colitis-associated cancer (CAC) is a common complication among patients with a long history of ulcerative colitis (UC). Previous studies revealed that dysplasia precedes CAC development, and more than 20% of CAGs are multicentric, suggesting the presence of a field effect on colorectal carcinogenesis in UC patients. However, the genetic basis of the field effect in UC patients is poorly understood. To address this issue, we isolated single crypts from non-tumorous colon mucosa from 6 UC patients, as well as those from apparently normal mucosa from non-UC patients, and "single crypt-derived WES" was analyzed for somatic mutations using whole-exome sequencing (WES). In total, 19 crypts from histologically non-dysplastic, but inflamed mucosa, and 2 from apparently normal mucosa were isolated from 6 UC patients, including 4 with pancolitis, 1 with left-sided colitis and 1 with proctitis, while 32 crypts were obtained from normal mucosa from 20 non-UC patients, including 10 with colorectal cancer, 6 with adenoma and 4 healthy volunteers. Regardless of the disease status, mutations were detected in all crypts analyzed with the median of 43/crypt (3–121), showing high variant allele frequencies (VAFs) (~0.5), suggesting that these mutations were shared by all cells within single crypts and therefore by crypt-maintaining stem cells. The number of mutations increased with age, in crypts from both UC and non-UC patients (P < 10^-3), showing clear age-related C to T transition in both normal and UC-inflamed crypts. Strikingly, however, the age-adjusted number of mutations was significantly higher in UC-derived crypts than in those from non-UC individuals (P < 10^-3). KRAS and TP53 mutations were reported to be the most prevalent alterations in UC-associated CAC, but only rarely seen in UC-derived normal crypts. Next, to evaluate clonal expansion of mutated clones, we performed WES for the bulk specimens composed of 20-30 mutually adjacent crypts. However, this time, mutations and copy number alterations (CNAs) with high VAFs were detected only in UC-inflamed mucosa, suggesting that clonal crypt expansion

TUMOR BIOLOGY: Carcinogenesis and Human Tumors
occurred only in UC-derived mucosa. WES was also performed for 14 CACs. The number of non-synonymous mutations (101/sample) in CAC were significantly higher than that in UC-derived normal crypts (38/sample) and recurrently involved known driver genes, such as TP53 (71%) and KRAS (36%). CNAs were also more frequent in CAC than UC-derived, normal crypts (36%). This study revealed that specific clonal expansion events in UC were also present in CAC. This would indicate that mechanisms such as clonal expansion in UC and clonal selection in CAC are more prevalent in UC than in CAC. Although the significance of clonal expansion in UC is still unclear, it is possible that clonal selection in CAC may be the result of the interaction between the host and the tumor microenvironment. This study provides new insights into the pathogenesis of UC and CAC, and may help to develop new therapeutic strategies for these diseases.

#5755 In vitro reconstitution of high-grade serous ovarian carcinoma from primary fallopian tube secretory epithelial cells. Kohei Nakamura, Kentaro Nakayama, Tohru Kiyono, Narisawa Ishihara, Toshikazu Minamoto, Tomoka Ishibashi, Kaori Sanuki, Hitomi Yamashita, Ruriko Ono, Kouji Iida, Hiroki Sasamoto, Rayna Suzuki, Mohammad Mahmoud Hossain, Tsukasa Ishihara, Satoko Kyo, Shion University Faculty of Medicine, Izu, Japan; National Cancer Center Research Institute, Tsukiji, Chuo, Japan.

Purpose: Recent studies suggest that fallopian tube secretory epithelial cells (FTSECs) are potential cells-of-origin for high-grade serous ovarian carcinoma (HGSOCC). Several genetic alterations are involved in HGSOCC carcinogenesis, but the minimal requirement for tumor initiation remains unclear. Therefore, we sought to identify oncogenic mutations indispensable for HGSOCC carcinogenesis in a stepwise in vitro model using immortalized FTSECs, over-expressing etiologic drivers. We established an in vitro stepwise carcinogenesis model using immortalized FTSECs over-expressing cyclin D1, CDK4/6 and hTERT, and mimicked select genetic abnormalities identified as gene alterations essential for carcinogenesis, including p53, c-Myc, or RAS/PI3K/AKT pathway mutations. Results: Our analyses revealed two distinct patterns of gene alterations essential for HGSOCC carcinogenesis: p53/KRASV12 and p53/KRASV12/c-Myc. Dominant-negative p53 expression alone or in combination with oncogenic KRAS (KRASV12) constitutively active AKT (CA-AKT), or c-Myc in immortalized cells failed to induce a tumorigenic phenotype; however, overexpression of either CA-AKT or c-Myc in combination with dominant-negative p53 and KRASV12 was sufficient to confer tumorigenic potential. Importantly, all transformed FTSECs formed tumors in xenograft mice, which were grossly, histologically, and immunohistochemically similar to human HGSOCC. Interestingly, mice harboring tumors with c-Myc amplifications displayed extensive metastases, consistent with the increased dissemination observed in their human counterparts. c-Myc is associated with cell proliferation in vitro; therefore, this genetic abnormality may promote HGSOCC progression. Conclusions: Collectively, our data showed that aberrant p53/KRASV12/c-Myc or p53/KRASV12/PI3K-AKT signaling is the minimal requirement for FTSEC carcinogenesis. Moreover, the model generated with this evidence will likely facilitate analysis of early events in HGSOCC carcinogenesis.

#5756 Effects of Epstein-Barr virus latent membrane protein 1 (LMP1) on cell invasiveness and expression of endogenous microRNAs in human cells in vitro. Bárbara Grasiele Müller-Coan, Ethel Cesmaran, Deilson Elgui De Oliveira, Universidade Estadual Paulista (UNESP), Botucatu, SP, Brazil; Weill Medical School at Cornell University, New York, NY.

Infection by the Epstein-Barr virus (EBV) is associated with a variety of human cancers, notably Burkitt lymphoma and nasopharyngeal carcinoma (NPC). Most malignant cells within EBV-associated cancers are latently infected, and some viral products expressed during the latent phase of the viral cycle have well-described carcinogenicity, including the EBV latent membrane protein 1 (LMP1). Distinct viral genomes described so far include the B95.8, the most studied viral strain originally found in an elderly patient with transfusion-induced infectious mononucleosis, and the M81 strain, isolated from a NPC case from a Chinese patient. Compared to B95.8, the EBV M81 strain infects epithelial cells more readily, and it is more likely to induce spontaneous viral lytic reactivation. However, whether these EBV strains have distinct biological features relevant for the progression of EBV-associated cancers remains to be elucidated. Thus, this study aimed to evaluate whether the expression of B95.1 and M81 variants of EBV LMP1 have different impact on cell migration and invasiveness of human cells lines in vitro, as well as on the expression of selected endogenous microRNAs (miRs) that were previously reported to have a role on cancer progression. Expression of EBV LMP1 was achieved in 293 and NPE9 cells transfected with vectors encoding its B95.8 or M81 variants. In vitro migration and invasion rates were assessed by the scratch wound healing assay and the Boyden chamber assay, respectively. The expression of 91 selected miRs were evaluated by a customized qPCR-array approach. Cells expressing EBV LMP1 showed increased migration and invasion rates compared with mock-transformed cells. However, the differences observed between B95.8 and M81 variants did not achieve statistical significance. Conversely, 293 cells expressing the M81 variant of LMP1 showed hyperexpression of human miRs 497-5p, 17-3p, and 34a-5p, compared to B95.8. The in silico target prediction for these miRs showed enrichment of gene targets involved in the MAPK, NF-kB, and PI3K/AKT in cellular signaling pathways. This would indicate that EBV LMP1 could promote proliferation and cell motility/adhesion, as well as higher levels of apoptosis. Based on these data, it is plausible to suggest that EBV LMP1 from M81 viral strain is somewhat less effective in terms of carcinogenicity, and this might be a reflection of the improved ability of EBV M81 to induce lytic viral infection compared to the B95.8 strain, as previously reported. In conclusion, the results indicate that cells expressing LMP1 from EBV isolates B95.8 and M81 showed differences in terms of miRNA expression signatures, which ultimately might impact the pathogenesis and progression of EBV-associated cancers.

#5757 Study of human mammary tumor virus (HMTV) in human breast cancer by NanoString nCounter and FISH analysis. Stella M. Melana, Joseph Tripodi, Digna Nosike, Jaffer Shahnab, Polly Etkind, Beatriz GT Pogo, James F. Holland, The Fish Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY; Department of Pathology, Icahn School of Medicine at Mount Sinai, New York, NY.

Human Mammary Tumor Virus (HMTV), a retrovirus 90-98% homologous to Mouse Mammary Tumor Virus (MMTV), the etiological agent of mammary tumorigenesis, has been detected by PCR in 40% of American women's breast cancers, but not in healthy tissues of the same breast (Cancer Research 1995, 55:5173-79; Clin. Cancer Research 2001, 7:283-9). A complete 9.9 kb HMTV proviral sequence has been detected in breast cancer genomic DNA (Cancer Res 2001,61:1754-9). HMTV viral particles with betaretrovirus characteristics have been isolated from metastatic breast cancer cells in effusions (MSSM cells). Expression of HMTV proteins has been detected in MSSM cells by western blot, fluorescence-activated cell sorting analysis, and immunofluorescence assays but not in normal mammary epithelial cells (J Virol Methods 2010,163(1):157-61). PCR is a sensitive technique susceptible of contamination, which due to amplification, could result in false positive detection. Although murine DNA was not found by PCR, the possibility still exists that HMTV in human DNA could be a result of laboratory contamination. Despite the substantial evidence supporting the presence of HMTV in breast cancer the controversy continues because the chance of contamination has led to doubt that murine-like viruses are human pathogens. We now report additional analyses of breast cancer specimens employing other methods for HMTV detection that reinforce previous findings. NanoString nCounter, a new technology using specific 100 mer oligonucleotides as probes bound to reporter molecules that can detect HMTV gag, env andLTRsequencesastwellastumour specific probes in a single reaction without amplification. Fluorescence in situ hybridization (FISH) assays with a HMTV probe is a technology that permits visualization of HMTV proviral DNA in the nuclei of surgical samples of breast cancer as well as in MSSM cells. Results from Nanostring nCounter, and FISH analysis show the presence of HMTV DNA in surgical cancer specimens and in MSSM cells. The data exclude contamination and confirm the authenticity of HMTV in human breast cancer. Next-generation sequencing and other studies are in progress to further understand the role of HMTV in the pathogenesis of breast carcinoma.

#5758 Elevated level of estrogen enhances chemotherapeutic efficacy potentially through epigenetic mechanism in human breast cancer cells. Yu-Wei Chang, Kamaleshwar Singh, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY; Department of Pathology, Icahn School of Medicine at Mount Sinai, New York, NY.

Effectiveness of chemotherapy depends on the age of breast cancer patients. Breast tissues are estrogen sensitive and the levels of ovarian estrogen are age-dependent variable among the breast cancer patients. Whether this variation in estrogen levels influences the chemotherapeutic efficacy in breast cancer patients is unclear. Therefore, the objective of this study was to determine the effects of natural estrogen 17 beta-estradiol on the efficacy of chemotherapy in breast cancer cells. Estrone responsive MCF-7 breast cancer cells were long-term exposed to 100 pg/ml estrogen for three months. Using these exposed MCF-7 cells, the efficacy of chemotherapeutic drugs doxorubicin and cisplatin were determined. The result of cell viability and cell cycle analysis revealed increased efficacy of doxorubicin and cisplatin in estrogen-exposed MCF-7 cells as compared to control MCF-7 cells. Gene expression analysis of marker genes for cell cycle, anti-apoptosis, DNA repair, and drug transporter genes further confirmed the increased efficacy of chemotherapeutic drugs in estrogen-exposed cells at molecular level. To further understand the role of epigenetic mechanism in enhanced chemotherapeutic efficacy by estrogen, cells were pre-treated with epigenetic drugs,
5-Aza-2-deoxycytidine and Trichostatin A before doxorubicin and cisplatin treatments. The enhanced efficacy of doxorubicin and cisplatin in estrogen-treated cells was significantly decreased by 5-aza-2-deoxycytidine pre-treatment, suggesting the role of estrogen-induced hypermethylation in enhanced sensitivity of these drugs in estrogen-exposed cells. In conclusion, results of this study demonstrate that estrogen cells induce hypermethylation on the levels of estrogen in breast cancer cells. Findings of this study will have clinical implications in selecting the type and dose of chemotherapy in breast cancer patients depending on the serum estrogen levels that varies in between pre- and post-menopausal age of the patients.

#5759 Histopathologic patterns of nasopharyngeal malignancy in Lagos, Nigeria and its association with Epstein-Barr virus (EBV): a 10-year retrospective study. Oladipo Omosebi,1 Olakanni Akinde,1 Omobolade Obadahun,1 Nzechukwu Ikeri,1 Gabriel Ogun,2 Adekumbiola Banjo,1 1Lagos University Teaching Hospital, Lagos, Nigeria; 2University College Hospital, Ibadan, Nigeria.

Background: Nasopharyngeal cancer (NPC) is a rare cancer worldwide. It is now found to be increasing in incidence in Nigeria, though the incidence is lower when compared to countries in the Mediterranean basin, North Africa and Southeast Asia. NPC is frequently associated with Epstein-Barr virus (EBV), but no previous study has been done in Lagos to document the association. Objective: To determine the prevalence, histologic types and age distribution of nasopharyngeal malignancy in Lagos University Teaching Hospital (LUTH) and its association with EBV over a period of 10 years, between January 2003 to December 2012. Methods and Materials: Slides and formalin-fixed paraffin-embedded (FFPE) tissue blocks, hospital request forms, referral cards, patients' case notes and duplicate copies of histopathology reports of cases of histologically diagnosed nasopharyngeal malignancy in the Anatomical and Molecular Pathology department of LUTH within the study period were retrieved. The cases were reclassified into epithelial and non-epithelial malignancies. The epithelial malignancies were reclassified according to WHO classification. Immunohistochemistry (IHC) for EBV latent membrane protein-1 (LMP-1) was carried out on cases with viable FFPE to evaluate the prevalence of the virus in Nasopharyngeal malignancy. Results: A total of 75 histologically confirmed cases of nasopharyngeal malignancy were seen during the study period, which constituted 1.1% of the total cancer recorded in this center. There were 47 males (63%) and 28 females (37%) with a male to female ratio of 1.7:1. The age ranged from 3 to 75 years, mean age was 44.1 years, the peak age group was 40-49 years for males and 50 - 59 years for females. On histological classification, undifferentiated carcinoma (WHO type III) was the commonest (49.3%), differentiated non-keratinizing squamous cell carcinoma, SCC (WHO type II) and keratinizing SCC (WHO type I) accounted for 24% and 9.3% respectively. Thus, NPC accounted for 82.6% of the total cases of nasopharyngeal malignancy seen. Other histological types seen were non-Hodgkin lymphoma (NHL) 13.3%, well differentiated adenocarcinoma 2.7% and low grade mucoepidermoid carcinoma 1.1%. EBV LMP-1 IHC was positive in 30 (86%) out of the 35 cases studied. These consisted of 14 undifferentiated carcinoma, 5 NHL, 2 adenocarcinoma, 7differentiated non-keratinizing SCC (WHO type II) and the 2 cases of keratinizing SCC. Conclusion: Nasopharyngeal malignancy is not uncommon in this environment. It occurred more frequently in males than females with the peak age of incidence at 5th decade of life, undifferentiated carcinoma (WHO type III) is the commonest histologic type and it is highly associated with EBV.

#5760 Identifying cell of origin for Group 3 medulloblastoma. Ran Tao, Najiba Murad, Zhenhua Xu, Yansin Pei. Children’s National Medical Center, Washington, DC.

Medulloblastoma (MB) is the most common malignant pediatric brain tumor. Although surgery, radiation and high-dose chemotherapy have led to increased survival rates, many patients still die from their disease and those who survive often suffer severe long-term side effects. Group 3 MB is the most aggressive subtype of MB, which is often resistant to therapy, and patients with this tumor have an extremely poor prognosis. Thus, developing novel and more effective therapeutic approaches is desperately needed for treating this disease. Improved approaches are likely to come from a deeper understanding of the molecular and cellular basis of the disease. Group 3 MB is characterized by large cell/anaplastic histology with a high proliferative index and is associated with MYC amplification or overexpression. Our previous studies suggest that MYC-driven MB can be generated by infecting granule neuron progenitors (GNPs, Math1+) or neonatal cerebellar stem cells/progenitors (CD133+) with viruses encoding MYC and dominant negative p53 (DNp53) and transplanting these cells into the cerebella of immunocompromised mice (NSG). Although this model resembles Group 3 MB in terms of histology and gene expression, it most likely does not faithfully recapitulate human MB because mutation and deletion of p53 are rarely detected in human Group 3 MB at diagnosis. This observation prompted us to ask whether there might be a cell type in which the MYC oncogene alone is sufficient to induce MB. Sox2 expression has been found in neural stem cells and the tumor cells in cerebellum. Moreover, it has been reported that ~70% human Group 3 MB express Sox2, and that its expression is correlated with poor prognosis. Thus we hypothesize that Sox2-positive cells with MYC overexpression can develop tumors. We FACS-sorted Sox2+/−, positive or Sox2−/− negative cells from Sox2+/− mice at P5, infected these cells with MYC virus and transplanted them into the cerebella of NSG mice. Animals (n = 10) receiving Sox2−/− positive cells developed highly aggressive tumors and died within 3-6 weeks. In contrast, only one of the animals (n = 10) that received Sox2−negative cells developed a tumor at 8 weeks. These results suggest that the MYC oncogene alone is sufficient to induce tumorigenesis in Sox2−positive cells, without requiring loss of p53. Further studies demonstrate that the tumors that were generated from Sox2−positive cells resemble Group 3 MB at a histological, immunohistochemical and molecular level, indicating that Group 3 MB may originate from Sox2-positive cells during cerebellar development. We will use this model to investigate the mechanisms that make these cells sensitive to transformation. These studies will pave the way for the development of novel approaches to treating this devastating tumor.

#5761 C-Fos drives non-tumorigenic head and neck squamous cell carcinoma cells to tumorigenic by promoting cancer stem cells like properties. Naoshad Muhammad, Sourav Bhattacharya, Robert Steele, Nancy Phillips, Ratna B. Ray. Saint Louis University, Saint Louis, MO.

Objectives: The head and neck squamous cell carcinoma (HNSCC) is the sixth most widespread cancer and leading cause of cancer related death world widely. Regardless of the advancement in treatment processes the overall survival rate of patients having this cancer has not substantially improved in the past few decades. Development of tumor progression is due to emergence of CSCs in a small population of cancer cells, termed as cancer stem cells (CSCs). This population of cells can self-renew and re-form the ordered organization of tumors. CSCs contribute to HNSCC and may offer prominent therapeutic strategy for the management of HNSCC. We previously observed that c-Fos was highly up-regulated in the HNSCC sphere forming cells. In the present study, we explored the role of c-Fos in the tumor initiation in relation with cancer stemness and EMT. Experimental procedures: We examined whether overexpression of c-Fos has an effect on tumorigenicity and stemness. For this, c-Fos was overexpressed in non-tumorigenic HNSCC cell lines and tumor growth was investigated. We also examined the expression of different CSC marker genes expression by Western blot analysis. Summary: Our results demonstrated that exogenous expression of c-Fos in non-tumorigenic MDA1386Tu cells makes the cells tumorigenic in nude mice. Mechanistic investigations showed that c-Fos overexpression in MDA1386Tu cells enhanced epithelial-mesenchymal transition (EMT)/CSC properties and increased numbers of oralspheres when grown in ultra-low binding plate. Conclusions: Collectively, our data strongly demonstrate that c-Fos plays a critical role in the modulation of EMT and cancer stem cell reprogramming in HNSCC cells and enhance tumor growth.

#5762 PR55α alpha associated PP2A promotes pancreatic tumorigenesis. Ying Yan, Ashley L. Hein, Parthasarathy Seshacharyulu, Satyanarayana Rachagani, Yuri M. Sheinin, Michel M. Ouellette, Moorothy P. Ponnusamy, Surinder K. Batra. University of Nebraska Medical Center, Omaha, NE.

PP2A holoenzyme consists of a catalytic subunit, a scaffold subunit, and a regulatory subunit. Loss of function analysis using PP2A catalytic inhibitors or inhibition via tumor viral proteins suggest PP2A as a putative tumor suppressor. However, PP2A has also been shown to facilitate the activation of oncogenic signaling pathways when associated with specific regulatory subunits. In this study, we investigated the possible oncogenic role of PP2A in pancreatic cancer. We found a striking increase in the expression of PR55α, a PP2A regulatory subunit, in compared to normal pancreatic epithelial cells. Consistently, PR55α expression was markedly elevated in pancreatic ductal adenocarcinoma tissues compared to adjacent normal pancreatic tissues (P<0.0001) and correlated with poor survival of pancreatic cancer patients (P<0.0003). DNA-mediated depletion of PR55α in pancreatic cancer cells resulted in diminished phosphorylation of both AKT and ERK1/2 and decreased protein levels of β-catenin. Accordingly, pancreatic cancer cells with reduced PR55α expression exhibited significantly impaired properties of transformation, including attenuated cell growth, clonogenicity, mobility, and anchorage-independent growth. Moreover, orthotopic implantation of PR55α-depleted pancreatic cancer cells into nude mice showed a marked reduction in tumori-
TUMOR BIOLOGY: Carcinogenesis and Human Tumors

#5763 Investigating the carcinogenic potential of various types of mineral fibers in the development of mesothelioma. David Larson, Mika Tanji, Andrea Napolitano, Sandra Pastorino, Michele Carbone, Haining Yang. Univ. of Hawaii Cancer Ctr., Honolulu, HI.

Malignant mesothelioma is a very aggressive tumor and has been linked to occupational and environmental exposure to carcinogenic mineral fibers such as asbestos. It was discovered recently that individuals carrying germ-line BAP1 mutations are predisposed to mesothelioma in presence of even minimal exposure to carcinogenic mineral fibers. Mesothelioma causes about 3,200 deaths per year in the U.S. and over 40,000 deaths per worldwide. Most malignant mesothelioma studies have focused on carcinogenesis due to occupational exposure to the six regulated industrial mineral fibers collectively called ‘asbestos’. Besides this family of six regulated asbestos minerals, there are other non-regulated fibers that possess physical and chemical structures that are similar to industrial asbestos, and may also be carcinogenic. However, many of those mineral fibers are unknown for their carcinogenicity. We conducted serious studies on this topic and established in vitro and in vivo assays to help determine the carcinogenesis of various types of mineral fibers. We found that high mobility box 1 protein (HMGB1) is a key initiator of asbestos-induced inflammation, which plays critical roles in the development and growth of mesothelioma, and that HMGB1 may be a good indicator for fiber carcinogenesis and a biomarker for fibers exposure. Moreover, we found that specific immune system changes that occur after exposure to carcinogenic fibers, which may be a useful tool to help intero-gate the carcinogenic potential of mineral fibers. In particular, the ability to induce an M2 macrophage response appears related to the potent tumor-inducing capacity of carcinogenic mineral fibers.

TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 6

#5765 Noninvasive characterization of 3D morphology and pathophysi-ology of multicellular tumor spheroids using optical coherence tomography. Yongyang Huang,1 Shunqiang Wang,1 Sarah Kessel,1 Ian Rubinioff,1 Leo Li-Ying Chan,2 Peter Li,2 Yaling Liu,1 Jean Qiu,2 Chao Zhou,1 Lehigh University, Bethlehem, PA; 2Nexelom Bioscience LLC, Lawrence, MA.

Screening of anti-cancer drug candidates follows a step-by-step testing procedure on different models, involving in vitro cell cultures, in vivo animal models and humans. Traditionally, in vitro 2D cell cultures are frequently used to evaluate cytotoxic effects of drug candidates on tumors. Although simple and efficient, 2D tumor cultures do not accurately reflect drug responses in a 3D environment, which hampers the use of these models for in vivo studies. Multicellular tumor spheroids (MCTSs), a 3D model, has attracted much attention in cancer research due to their physiological similarities with in vivo tumors, such as their structures, oxygen and nutrient gradients, and drug resistances. Therefore, they can serve as a more predictive model for the cancer drug discovery. High-throughput screening (HTS) systems employ various imaging approaches, e.g. bright-field microscopy, fluorescence microscopy or confocal mi-croscopy, have been employed to perform routine imaging and analyses of structures and functions of MCTSs. One drawback of the current HTS systems is that they do not readily provide a 3D view of the entire MCTS, especially for large spheroids (>500μm), due to limited imaging penetration, which hampers accurate characterization of the spheroid volumetric changes. In this work, we developed a new screening system to visualize the entire 3D structure of MCTSs using 96-well ultra-low attachment (ULA) plates combined with optical coherence tomography (OCT), a high resolution and 3D imaging modality. We showed that this imaging system was able to perform longitudinal tracking of 3D structural changes, e.g. sizes, shapes and volumes, for individual MCTSs. In particular, we demonstrated that spheroid volume measured based on 3D OCT imaging data provided a more accurate and robust result as compared to volume calculated based barely on the spheroid size (diameter). Furthermore, we demonstrated that this system could perform non-invasive, label-free monitoring of pathophysiological status of MCTSs over time. The 3D distribution of a spher-oid’s necrotic core could be assessed based on intrinsic optical contrast. This OCT-based screening system would open up new opportunities for accurate 3D characterization of morphological and pathophysiological features of MCTSs, and benefit the development of the state-of-the-art 3D HTS system for cancer drug discovery.

#5766 High-content microscopy-based screening of colorectal organoids. Niklas T. Rindtorff,1 Bettina Jette,1 Jan Sauer,1 Thilo Miersch,1 Tianzuo Zhan,1 Florian Heigwer,2 Claudia Scholl,2 Matthias Ebert,2 Bernd Fischer,1 Michael Boutros1.1 DKFZ Heidelberg, Heidelberg, Germany; 2University Hospital Mannheim, Mannheim, Germany.

High-content screening of cells has become a widespread approach for cellular assays due to its capacity to capture complex biological processes. However, conventional cell culture is limited with respect to cell and tissue architecture. Organoids are a unique model system for the intact and diseased intestinal epithelium. The 3D model can be used for the functional study of cancer development, and, potentially, prospective therapeutics testing of drugs in patient derived tumor organoids. Here, we present a high-content microscopy based screening workflow to study organoid self-organization and growth with up to single cell resolution. After seeding of organoid fragments in a basal membrane extract, screening plates are incubated to allow for organoid formation. Subsequent treatment and incubation is followed by staining and imaging on a high-throughput microscopy platform followed by automated image analysis using open-source software. Profiling of both complete organoids and their individual architecture enables the quantitative description of population and tissue heterogeneity in the context of various perturbations. We generated four distinct colon organoid lines from mice carrying mutations of APC and KRAS in different combinations. These are profiled for differential phenotypic responses to a library of ~1000 drug-like compounds. Also, this methodology is used to screen for clinically relevant differential treatment responses in patient derived tumor and normal colon organoids. Hence, based on this work we are able to analyze gene-drug interactions in early colon cancer development and drug response of patient derived colorectal cancer organoids.

#5767 Ex vivo three-dimensional tumor growth assay: 3DX-TGA. Praveen Nair,1 Dileep Nair,1 Kaede Hinata,1 Cyrus Mirdsadi,1 Junjie Wu,2 Yong Hu,2 Brett M. Hall.1 1Molecular Response, San Diego, CA; 2Bioduro, San Diego, CA.

With a 7% likelihood of regulatory approval, oncology drug registration failure rates lead all therapeutic areas. Further complicating the drug development...
To realize the promise of precision medicine, it is important to integrate phenotypic assessment of cell populations to genomic data. The analysis of invading leader cells at the tumor invasion front is of interest as they may be guided by a targetable molecular phenotype. However, there is a lack of suitable platforms on which to analyze the tumor invasion front. In this study, we have designed and constructed a fluidic device for long-term (several days to weeks) 3-dimensional tumoroid culture of diverse cancer cells. Using this device, we can recapitulate the tumor invasion front and at the same time quantify the invasive potential of different breast cancer cell line models. Analyses of the tumor invasion front indicated a region of higher proliferation and suggest that the leader cells possess a different molecular phenotype from the tumoroid mass. Interestingly, some of the invasion front cells can be targeted using a combination of strategies indicating that there could be: 1) the presence of multiple subpopulations of invasive cells, each with a different clonal genetic signature; and/or 2) reversible phenotypic switching occurring among invading cells due to phenotypic plasticity. These results obtained using this innovative device highlight and present a promising solution to the challenges developing adequate therapeutics accounting for tumor phenotypic heterogeneity. There is potential for the device for use in personalized medicine at diagnosis, allowing for both the quantification of disease progression risk as well as the molecular characterization of the invasive subpopulations from patient samples and their response to tailored therapies.

#5770 in vitro PDX models: 3D cultured patient-derived tumors for compound evaluation. Sander Bästén,1 Bram Herpers,2 Julia Schueler,2 Torsten Giesemann,2 Leo S. Price,1 Ocelli B.V., Leiden, Netherlands; Charles River Laboratories, Breburg, Germany.

Background. Patient-derived xenograft (PDX) models in immune-compromised mice allow propagation of and compound testing in human-derived tumors in vivo. To expand the potential of these human-relevant PDX models, we sought to develop 3D in vitro culture methods for PDX-derived tumor cells that show in vivo-like growth characteristics, invasion and responses to therapeutics. In combination with advanced 3D image analysis methods, we created a unique high throughput in vitro PDX screening platform that not only allows efficient identification of active and selective molecules but also enables selection of the optimal PDX tumor models for subsequent validation of candidates in vivo. Results. Each PDX model has its own unique growth characteristics. Hydrogel and growth media composition were optimized to support growth of tumor tissues in vitro from cells derived from bladder, stomach, breast, pancreas, colon and lung cancer PDX tumors. Tumor tissues were cultured in a 384-well format and used to test chemotherapeutics (e.g. 5FU, doxorubicin, paclitaxel, cisplatin), small molecules (e.g. erlotinib, lapatinib, trametinib, everolimus), antibodies (e.g. cetuximab, trastuzumab) and antibody-drug-conjugate (ADC, T-DM1) dose ranges. Using Ocelli’s 3D image analysis platform, Omixer, tumoroid growth, cell proliferation, apoptosis, invasion, cell polarity, differentiation and other aspects of cell and tissue architecture were analyzed and the effects of compound exposure on tumoroids was determined. By performing feature training based on reference compounds, we selected ±10 morphological features (out of more than 500) to generate a phenotypic signature that described the unique phenotypic change induced by each compound. Different compounds that target the same molecule were found to induce a similar morphological change whereas compounds with off-target effects could be discriminated. This approach enabled a high resolution evaluation and comparison of compound activity in an automated manner. Conclusions. We established several PDX model-derived 3D tumor cultures in which standard-of-care and novel therapeutic agents (small molecules, antibodies and ADCs) can efficiently be screened, based on therapeutically relevant parameters and their changing morphological profile. This method enables both the in vitro selection of promising compounds in a pre-clinically relevant setting and the selection of optimum PDX tumor models for follow-up in vivo studies. This highly translational in vitro-in vivo PDX pipeline is expected to reduce attrition and increase efficiency in early drug discovery.

#5772 Developing a patient derived 3D co-culture model of prostate organoids to examine biological mechanisms involved in prostate cancer disparities. Joseph Marsili,1 Zachary Richards,2 Jason Garcia,3 Cindy Voisin,4 Larisa Nunn,5,6 Northeastern Illinois University, Chicago, IL; Northwestern University, Chicago, IL.

The prostate is composed of a fibro-muscular stromal and glandular epithelial cell population. The prostate cell population is essential for normal prostate development and is involved in carcinogenesis. In the past year, an estimated 220,800 new cases of prostate cancer (PCA) were diagnosed and 27,540 died of PCa. PCa in African American men occurs more frequently, develops at a much earlier age, and is more aggressive and lethal compared to men of European origin.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 1473
**TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 6**

Descent. Both biological and socioeconomic factors likely contribute to this disparity. There is currently a paucity of relevant preclinical models in which to examine biological mechanisms in African American PCa. Patient-derived organoids are a recently developed in vitro preclinical model which facilitate examination of underling mechanisms of disease etiology. However, current models of epithelial organoid growth lack the prostate stroma. To address this unmet need, we began development of a 3D organoid model that incorporated both primary human prostatic epithelial (PrE) and stromal (PrS) cells to better mimic the microenvironment of the organ. Prostate organoids were derived from cells collected from radical prostatectomy tissues from patients (UICC IRBs: 2006-0679 (PI Behm), (2013-0341(PI Nomm). Mixtures of single PrE-derived and single PrS-derived cells were seeded on matrigel. Bright-field microscopy of live organoids and histological examination of fixed organoids showed that the addition of PrS cells to the culture altered the shape of the organoids compared to the spherical phenotype observed in PrE only cultures. Immunofluorescent analysis of the basal cell marker p63 showed increased epithelial differentiation in the co-culture organoids. In summary, these data suggest that inclusion of prostate stroma in co-culture organoid models influences prostatic epithelial organoid development in vitro. Ongoing studies are focused on molecular analysis or organoid phenotypes and comparison of AA and EA-derived organoids.

**#5773 Automation and miniaturization of 3D tumor models for compound screens.** Michael Kowalski,1 Kayla Hill,2 Vipat Raksakulthai,3 Kristin Prasaukas,4 Tara Jones-Roe1. Beckman Coulter, Indianapolis, IN; 1Molecular Devices, Sunnyvale, CA

Three-dimensional (3D) systems of cell culture can provide a more representative model of solid tumors and more physiologically relevant outputs from drug screens than two-dimensional cell cultures. A diverse array of 3D models have been used to investigate tumor physiology and susceptibility to chemotherapeutics but all of these models present challenges to establish and manipulate at the high throughputs required for screens. Cancer spheroids are large clusters of cancer cells formed in suspension to replicate the gradients of gases, nutrients, and drugs seen by solid tumors. In contrast, Matrigel® or other hydrogel cultures are often used to replicate native cell morphology and polarity or to enable studies of 3D structure formation or cell migration. To overcome manual challenges and improve reliability, we automated the plating, drug treatment, and analysis of these 3D models. We were able to form consistent cancer spheroids in both hanging drop and low attachment plates and used imaging and flow cytometry to gain a more complete understanding of the cytotoxic drug response in this model. Cells were also plated on top of and embedded within Matrigel and cell growth and apoptosis induction was measured with standard and confocal imaging approaches. Both 3D models were miniaturized to 384-well format, thereby enabling the throughput required for large-scale screens to identify novel cancer treatments.

**#5774 Effect of extrinsic and intrinsic solid stress on tumor spheroid growth.** Ludivine Guillaume, Anaïs Desmaison, Bernard Ducommun, Valérie Lobjois. Univ. of Toulouse, Toulouse, France.

Growth-induced solid stress and adaptive response to extrinsic mechanical cues have been recognized as major hurdles to overcome in cancer treatment and any approach that could significantly modulate these parameters would have an impact in improving therapies. An attracting in vitro model to explore this issue is the Multicellular Tumor Spheroid, a 3D culture model reproducing the non-vascularized microtumor environment, proliferation gradient and cellular interactions. To explore and assess spheroid growth-induced solid stress, we couple biological approach to the application of mechanics and modeling. We adapted a method, which consist in partial sectioning of the microtumor and measuring tissue relaxation parameters. Using this strategy, we showed that cell proliferation induced the accumulation of intrinsic mechanical constraint. To investigate the consequence of the accumulation of solid stress at the cell scale, we analyzed 3D cellular organization within spheroids. Using 3D light sheets microscopy (LIS) visualization in 3D optically cleared spheroids combined with 3D reconstruction and automatic algorithms, we were able to determine cell density, nuclear orientation and nuclear shape in whole 3D spheroids. We found that stress accumulation is associated with an increase in cell density and a regionalization of nuclei organization. We also explored the impact of extrinsic stress in 3D culture condition under constraint. We found that mechanical constraint and cytoskeleton control nucleus orientation and using live 3D LSM microscopy we show that mechanical constraint induces an actin cytoskeleton-dependent prometaphase delay. We anticipate that this work will provide key information and parameters to improve our knowledge of the cross-talk between mechanical parameters and tumor growth.

**#5775 A unique 3D tissue-engineered human melanoma model combining lymphatic and blood microvasculature to study cancer cell dissemination.** Jennifer Bourland, Julie Fradette, François A. Auger. Centre de recherche en Organogénèse Expérimentale de l’Université Laval/LOEX, CRCHU de Québec Université Laval, Quebec, Quebec, Canada.

INTRODUCTION: Melanoma is amongst malignancies with constantly increasing incidence in developed countries. One of the underlying causes of death for patients diagnosed with melanoma is metastasis, which can spread through lymphatic or blood vessels. Mechanisms controlling the dissemination path are poorly understood and relevant models for studying metastasis physiopathology are often inadequate. To address this, we hypothesized that the human tumor microenvironment can be mimicked in vitro by combining tissue-engineered microvascularized skin and melanoma microtissues. METHODS: Tissue-engineered skin was produced using primary dermal, epidermal and microvascular endothelial cells by the self-assembly technique without any exogenous biomaterial. Tumor microtissues were produced using the hanging drop method. Six melanoma cell lines were used originating from primary tumor sites (A375, SK-MEL 28 and WM983a) and from metastatic sites (RP11-7951, Malme 3M and WM983b). Tumor development and growth were assessed by histology, immunofluorescence and confocal microscopy, while cytokine secretion profiles were determined by ELISA. WM983a and WM983b models were treated for 11 days with vemurafenib. Response to treatment was assessed by counting the ratio of tumor cells positive for Ki67, representative of the tumor proliferation. RESULTS: We obtained three-dimensional skin microvascular networks: a VE-cadherin+CD31+ blood network, and a PDLP1+LYVE-1+CD31+ lymphatic network. Blood capillaries were thin and highly connected whereas lymphatic capillaries were larger and presented a distinct morphology. Histological analyses revealed tumor microtissue integration at the dermoepidermal junction within the reconstructed skin. The pro-lymphangiogenic factor and tumor-secreted VEGF-C was detected in conditioned medium from the melanoma microtissues (662 pg/ml). Furthermore, CCL21, a chemottractant known to be secreted by lymphatic endothelial cells, displayed secretion levels that were 10-fold higher in microvascularized tissues compared to the non-microvascularized skin (P ≤ 0.001). Both of these cytokines are involved in the cross-talk between tumor cells and capillaries, and thus in tumor dissemination. The 3D melanoma model responded to vemurafenib with up to a 5-fold decrease of tumor cell proliferation and a partial pigmentation of the tumor. CONCLUSION: This unique 3D in vitro melanoma model mimics tumor microenvironment by combining blood and lymphatic capillaries with melanoma microtissues in a reconstructed skin. Being responsive to treatment such as vemurafenib, it represents a valuable tool for studying mechanisms of metastasis and drug response in a fully human cell and matrix microenvironment, and thus testing anti-metastatic compounds could better predict their safety and efficacy.

**#5776 Glioblastoma tumor model to analyze the mechanisms of resistance to tyrosine kinase inhibitors.** Sara Pedron,1 Gabrielle L. Wolter,1 Emily Chen,1 Jann N. Sarkaria,2 Brendan A. Harley,1 1University of Illinois at Urbana-Champaign, Urbana, IL; 2Mayo Clinic, Rochester, MN

The extracellular matrix (ECM) is increasingly recognized as having a key role in cancer development. We have developed a biomaterial tumor mimic that recapitulates systematically the main characteristics and heterogeneities of glioblastoma ECM. With the use of these 3D in vitro platforms we seek to understand the key features that make this cancer so challenging to treat. We are using this device in three different ways: (1) to further understand how particularities of brain tumor ECM affect cancer cells and assist in the diagnostic of different glioblastoma (GBM) tumor types, (2) provide new models for drug screening to afford more personalized therapies and (3) study the mechanisms of resistance to current therapies in order to identify more effective combinatorial treatments and new therapeutic targets. Hyaluronic acid (HA), is the main component of the brain ECM and GBM is associated with aberrant HA secretion and overexpression of receptors associated with HA, such as CD44 and EGFR. We cultured GBM patient-derived xenograft (PDX) cells within gelatin based hydrogels that are composed of HA. Cell proliferation and cell phenotype analyses demonstrate that biomimetic hydrogels support xenograft culture and cells upregulate matrix remodeling genes and others related to tumor growth in response to matrix biophysical properties. We also used these platforms to evaluate the mechanisms of cell resistance to tyrosine kinase inhibitors. For this purpose, we first focused on the epidermal growth factor receptor (EGFR), which has been identified as a molecular target and associated with worse clinical outcomes. We characterized the 3D in vitro behavior of 3 PDX that represent these EGFR variants: GBM10 (EGFR, wild type), GBM12 (EGFR+) and GBM6 (EGFRVIII). We studied the relationship between the HA contained in the surrounding matrix and response of GBM cells to a tyrosine kinase inhibitor (TKI),...
erlotinib. Results indicate that while EGFR+ cells are sensitive to TKI in HA hydrogels, HA seems to collaborate with EGFR/III signaling to stir cell activity. Immunoblots demonstrate that this enhanced cell activity is related to a significant increase in PDGFR concentration. Blockade of the CD44 receptor, in combination with erlotinib treatment, does not affect phosphorylation rates of PI3K or ERK. Yet, this suggests that this biotactic tumor model can be used as a valuable tool in the mechanistic studies of tumor development and prediction of tyrosine kinase inhibitors efficacy.

Finally, we show that, patient-derived xenograft cells resistant to erlotinib in vivo (GBM10), become sensitive when CD44 is blocked in HA-containing matrices, as demonstrated by a decrease of phosphorylated PI3K. In summary, we highlight the importance of extracellular HA in EGFR inhibition efficiency. We demonstrate that this biomaterial tumor model can be used as a valuable tool in the mechanistic studies of tumor development and prediction of tyrosine kinase inhibitors efficacy.

#5777 Translation of HPV mediated immortalization to cancer precision medicine. Aleksandra Dakic, Nancy Palechor-Ceron, Ewa Krawczyk, Hang Yuan, Frank Suprynowicz, Seema Agarwal, Richard Schlegel, Vera Simic, Prathibha Sripadhan, Chen Chen, Jie Lu, Tung-Wei Hou, Sujata Choudhury, Xuefeng Liu. Georgetown Univ. School of Medicine, Washington, DC.

The E6/E7 oncogenes of the high-risk HPV’s are both necessary and sufficient to immortalize HFKs and their presence and expression is required for the continued proliferation of HPV-positive cervical cancer cells. We and others have shown previously that hTERT induced by E6 and cytoskeleton alteration by E7 are critical. Both E6 and feeder cells activate telomerase, while both E7 and Rock inhibitors (Y-27632) disrupt the actin cytoskeleton and inactivate Rho. Feeder and Y-27632 to induce unlimited cell proliferation of human keratinocytes. Unexpectedly, we observed that feeders and Y-27632 could be used to establish both normal and tumor cell cultures from non-keratinocyte tissues. This culture has been termed as “conditional reprogramming”, since CR cultures stop proliferating or terminally differentiate after its removal, depending on culture conditions. The combination of CR and Organoids (Matrigel, air-liquid interface (ALI)) cultures represents next generation human cancer models and functional diagnostics for cancer precision medicine as described in August 2015 in the NCI precision medicine initiative and three nature review articles (Nat Rev Cancer. 2015 Dec; Nat Rev Genet. 2015 Jul; Nat Rev Clin Oncol. 2014 Nov.). The technique is relatively simple and has been reproduced in more than 50 laboratories (including an original and independent article in Science from Massachusetts General Hospital) (Science. 2014, 346(6216):1480-6.). Importantly, the CR technology can generate 2x10^6–6cells in a week from small biopsies, and can generate cultures from cryopreserved tissue and small biopsies. We therefore initiated studies to examine whether CR cultures reflected the biology and genotype of the original tumor and whether cultures might be used to predict clinical responses. Moreover, the epithelial cells can be propagated indefinitely in vitro, yet retain the capacity to become fully differentiated when placed into conditions that mimic their natural environment. Thus, the CR method significantly advances applications for regenerative medicine.

#5778 A three-dimensional RAFT™ co-culture as advanced model for breast cancer drug discovery. Ying Nie, Krista L. Garner, Theresa D’Souza, Lonza Walkersville Inc., Walkersville, MD.

High-throughput screening (HTS) using two-dimensional (2D) cell culture models (2D HTS) is essential for rapid identification of drug candidates from chemical libraries. However, it often results in a large number of poorly qualified leads that exert extra burden on the downstream, preclinical animal studies and that cannot be translated into clinical success, because 2D culture cannot represent the complexity of the tumor microenvironment in vivo. The progression of tumors and their response to drugs in vivo are regulated by their interactions with neighboring cells, and the natural gradients of nutrients, cytokines, wastes, oxygen, which can be better mimicked with three-dimensional (3D) cell–culture models. We constructed a breast cancer model using the RAFT™ 3D Cell Culture System. The essential component of this system is a collagen matrix condensed to the physiologically-relevant collagen density by removing the majority of the liquid from the collagen hydrogel with specialized absorbers. Our 3D model is a co-culture of human mammary fibroblasts (HMFs), embedded in the RAFT™ Collagen matrix, and the MCF7 human breast cancer epithelial cells, overlaying on top of the matrix, to model the interaction of breast cancer cells and stromal cells in vivo. As non-tumorulent control, human mammary epithelial cells (nHMECs), isolated from normal breast tissue, were used to replace MCF7 cells in such a co-culture. A medium formulation combining fibroblast medium FGM2™ and mammary epithelial cell medium MEGM™ was optimized to grow both cell types in the co-culture. The RAFT™ co-cultures were stained with standard immunocytochemistry protocol to reveal the morphology of the cells. After three days in culture, the HMFs, evenly interspersed in the matrix, fully stretched out on the collagen matrix, and the nHMECs grew to reach above 90% confluence on the collagen matrix. The cell proliferation in the co-culture was quantified with the ViaLight™ Plus Cell Proliferation and Cytotoxicity BioAssay, which measures cell viability with bioluminescent detection of cellular proliferation and vital dye based on the Raman signature of single cells. We demonstrate here the feasibility of co-culturing HMFs and mammary epithelial cells, in the RAFT™ System, as a 3D breast cancer model. The efficacy of anti-cancer drugs can be assessed by measuring the cell viability with the ViaLight™ Assay. This enables us to bridge the gap between 2D HTS and pre-clinical animal studies. It may provide physiologically-relevant data and better prediction of the in vivo efficacy and dosage of the drug candidates identified in HTS, and reduce the burden of animal studies in breast cancer drug discovery.

#5779 Building a novel 3D hyaluronan-based tri-culture model of the bone metastatic microenvironment for cancer studies. Lindsey K. Sablatura, Daniel A. Harrington, Mary C. Farach-Carson, Rice University, Houston, TX; University of Texas Health Science Center at Houston School of Dentistry, Houston, TX.

The high attrition rate of potential anti-cancer drugs entering clinical trials predicates a need for more predictive pre-clinical model systems. Three-dimensional (3D) culture systems provide cells a more physiological microenvironment than traditional cell culture methods—including relevant extracellular matrix (ECM) cues and cell-cell interactions while allowing for experimental control and higher-throughput studies than animal models. Prevalent cancers, including breast and prostate cancer, metastasize preferentially to bone, where they become incurable. The bone marrow microenvironment is a complex network of interacting bone homeostatic and hematopoietic niches that contribute to osteotropic cancer homing, proliferation, and treatment resistance. We created a 3D in vitro tri-culture model of the bone metastatic microenvironment to serve as a new platform to study the “trialogue” between bone metastatic cancer, bone marrow stroma, and bone marrow endothelial cells. This tool can be used to inform drug discovery and to combat treatment resistance. Within the present study, the utility of peptide-functionalized hyaluronan hydrogels for supporting the self-organization of 3D bone marrow microvascular networks was explored. Gel crosslinking density was varied to examine the effect of matrix porosity on cell migration and organization over time. Tubule length and diameter were quantified and the endothelial structures were assessed for indicators of mature vasculature, including lumen formation, basement membrane production, and the recruitment of supporting stromal cells. Breast/prostate cancer cell growth, survival, and physical association with bone marrow stromal and bone marrow microvascular endothelial cells was assessed in tri-culture models. Ongoing studies seek to identify and disrupt key cell signaling pathways that mediate cell–cell interaction and promote cancer cell proliferation and survival, providing new tools to combat bone metastatic disease.

#5780 3D ex-vivo assay platform using primary lung cancer cells in malignant pleural effusions as predictor for clinical outcome of personalized chemotherapy. Cheng-guang Wu, Francesca Chiovaro, Tamara Tanos, Alex Soltermann, Sumeer Dhar, University of Zurich, Zurich, Switzerland; In-Sphero AG, Zurich, Switzerland.

Background: Despite advances in therapeutic programs to treat various cancer types, dismal overall response rates for several entities has posed dilemma for oncologists and researchers alike. Therefore, there is immense need in accelerating therapeutic programs towards clinical success in cancer patients. It is well established that patients suffering from same cancer type may respond very differently to a given chemotherapeutic regimen. We propose the development of a unique patient-derived 3D ex-vivo drug testing platform as a valid decision making tool for 2D or 3D line treatment regimens. Materials and Methods: In this ex-vivo platform freshly collected malignant pleural effusions from patients were processed for cytological diagnosis on cell blocks, using respective immune-histochemical markers. Effusions were prepared for a 96 well based 3D ex-vivo assay format using the hanging drop method and a parallel 2D cell culture format. Subsequently, we compared the original cell composition of the malignant effusion with respective microtumors generated in the 3D format. Microtumors were then breast embedded in paraffin and processed like original cell blocks. IHC including respective markers for tumour cells such as TTF1, CD2 and oestrogen receptor and for non-tumour cellular fractions like calretinin, CD45, and MPO were processed. Results: The microtumors generated (ranging from 300 to 500μm) retained the native tumor morphology and cellular com-
position, thereby presenting tumour microenvironment like conditions in this ex vivo system. These cultures contain all cellular components of a malignant effusion at the beginning. Next to cancer cells, mesothelial cells, lymphocytes and granulocytes were main constituents. Cellular ratios were measured by computerized image analysis. Both cell sediments and supernatants are amenable to profiling strategies by next generation sequencing and mass spectrometry.

Conclusion: Our model presents an optimal condition to conduct chemosensitivity/resistance profiling in individual cancer patients using standard drug combinations. Furthermore, we are currently developing an immune competent 3D model to access cancer cell interaction with surrounding immune cells. We expect that original immune cells will be quenched out during culture, thus these micro-environments are thus created, easily transplanted method to perform high-throughput drug screenings. In 3D organoids and PDTo and demonstrate its utility in determining drug sensitivities and optimizing multi-drug combinations in vitro.

#5781 Establishment of a 3D ex vivo assay as a preclinical drug testing platform for personalized cancer therapy

Sumeer Dharia,1 Francesca Chiovoro,2 Tamara Tanos,3 Tomas Hejhal,1 Seife Heilemariam,1 Jens Kelm,1 Anja Irmisch,1 Mitchell Levesque1.

In vitro cell based drug testing tools have been widely used in drug discovery and early development to evaluate novel drug entities for further evaluation in preclinical in vivo models. However, a poor correspondence with in vivo models has compelled oncologists to pursue complementary in vitro strategies with better outcomes. Within this realm, a 3D ex vivo platform is being extensively used to evaluate efficacy of cytotoxic drugs, targeted molecules and antibodies. To increase the translational value of this model, maintenance of the tumor microenvironment (immune and other stromal cells) is highly pertinent. We have established a 3D ex vivo assay as a patient drug testing platform for personalized medicine therapies in collaboration with our clinical partners. In this study we setup the protocols for obtaining single cell suspensions from biopsy and/or tumor resection samples from patients presenting with Urothelial cancers, Renal cell carcinoma, Pancreatic, NSCLC, Ovarian, and Melanomas to generate 3D microtumors in 96 well format cultured over a period of 7-15 days. The microtumors were monitored for growth characteristics, biomarker phenotype and drug activity profile. As expected the growth characteristics for each tumor varied, corresponding very well with clinical disease progression. Subsequently, these microtumors were assessed using a standard clinical immunohistochemistry diagnostics approach to evaluate disease specific biomarkers and were compared to the clinical diagnostics profile of the patients. The biomarker profile from 3D derived tumor samples showed concordance with the patient diagnostics profile. In the instances where clinical information and treatment regimens were available, the microtumors were tested and followed with single and pairwise drug treatments. The ex vivo 3D treatments clearly reflected the clinical outcome. Currently, this platform is being used to develop 3D ex vivo immune-competent models to study immunomodulatory therapies. Based on the overall data we conclude that the 3D ex vivo assay system offers a highly pertinent platform to perform chemosensitivity testing providing predictive information on the clinical outcome, which enables oncologists to redefined individualized chemosensitive targeted treatments.

#5782 A novel method for high-throughput drug screening in 3D tumor organoids

Nhan Phan, Jessica Huang, David Eisenberg, Sanaz Memarzadeh, Alice Soragni.

UCLA, Los Angeles, CA.

3D tumor organoids are pivotal tools to study tumor development, propagation and invasive properties (Tanner and Gottesman, 2015). They closely recapitulate many characteristics of the tumor of origin in terms of structure, heterogeneity, complexity and response to drug treatment. As such, they are considered an accurate pre-clinical model for drug discovery and development (Nyga et al, 2011; Tanner and Gottesman, 2015; Shroyer, 2016). Nevertheless, reliable methods to perform high-throughput drug screenings using tumor organoids are limited and require extensive manipulation such as sample transfer from plate to plate. In addition, thick 3D matrix supports may hinder drug penetration. Here we introduce a robust method to generate, treat and assay 3D tumor organoids in standard, uncoated 96- or 384-well plates. By plating cells around the rim of the wells we generate an ultrathin layer of Matrigel that allows penetration of small molecules and bulkier peptide drugs. Media change is easily performed from the center of the well without perturbing the organoids. After a 2-day treatment course, organoids are released by dispase treatment and assayed in the same well by performing a CellTiter-Glo assay (Promega). The method exhibits low plate-to-plate, experiment-to-experiment and operator-to-operator variability. In addition, it can be extended to patient-derived tumor organoids (PDTo) generated from primary tumors. We show how PDTo from high-grade serous ovarian carcinoma (HGSOC) specimens are generated with a success rate >95%. Given the low number of cells required and high assay sensitivity, we can seed 200 wells from 1Mio cells derived from a tumor biopsy, and test over 60 different drugs/concentrations in triplicates. Moreover, we show how drug combination studies are feasible and allow assessing treatment synergies. As an example we perform a peptidic inhibitor of p53 and an EGFR inhibitor, ReAPc53 (Soragni et al, 2016), with carboplatin in PDTo HGSOC established from a panel of patients harboring different p53 mutations. Drug interaction studies are performed across a range of ReAPc53 and carboplatin concentrations and cell viability assessed at day 2 is used to compute drug-response curves, EC50 values and combination indexes. In conclusion, we are introducing an ex vivo treatment and easy to implement method to perform high-throughput drug screenings in 3D organoids and PDTo and demonstrate its utility in determining drug sensitivities and optimizing multi-drug combinations in vitro.

#5783 In vitro modeling of patient derived bladder cancer cell lines in 3D culture systems

May Ellbana,1 Sreenivasulu Chintala,2 Eric Ciampi,3,4 Remi Adelayie,1 Ashley Orillion,1 Sreevani Arisa,5 Nur Damayanti,1 Michelle Grimmer,1 TJ Puls,1 Sherry Harbin,1 Melissa Fishel,1 Roberto Pili,1 Indiana University School of Medicine, Indianapolis, IN, 1,2,3,4,5The Janssen Pharmaceutical Companies of Johnson & Johnson, Antwerp, Belgium; 3Purdue University, West Lafayette, IN.

Background: Drug screening is a key component for drug development and optimizing anti-tumor therapies. Traditionally, in vitro drug testing has been conducted in monolayer systems that are not capable of recapitulating the tumor microenvironment. Recently, the field has witnessed the rise of interest in developing 3D culture systems which are capable of reproducing tumor complexity while circumventing the cost associated with in vivo drug testing. Our access to fresh patient samples has enabled us to establish a novel 3D culture system consisting of bladder cancer patient derived cell lines. Using a wide range of matrices and co-culture conditions with tumor associated stromal cells we were able to establish a unique high throughput drug testing tool. Methods: Matrigel and collagen based matrices were used to establish 3D culture systems of bladder cancer patient derived cells. Tumor cells were cultured in 3D conditions either alone or in coculture with tumor associated stromal cells. Response to Cisplatin and PI3K pathway targeted agents (i.e. LY2900454) was tested in both conditions. High throughput imaging via Thermo ArrayScan XTI was used to assess the biological behavior of spheroids as well as their response to therapies overtime. Confocal microscopy was used to validate the biological mimicry of tumor derived spheroids to the original patient tumors. Integration of RNA-seq data from the patient-derived tumor cells with the biological behavior and therapeutic response in 3D culture is ongoing for the purpose of characterizing the 3D model Results: In 3D culture conditions; bladder cancer derived cells were able to re-express E-cadherin that was suppressed upon propagation in monolayer. The re-expression of the epithelial marker (E-cadherin) observed in 3D accurately mirrors the original tumors; which are of epithelial origin. Phenotypic differences were observed across different matrix conditions and also among different tumor derived cells. Bladder 3D organoids of luminal origin were more sensitive to both cisplatin and PI3K pathway inhibitors as compared to those of basal origin. This drug response profile was remarkably consistent of what we observed with our patient derived xenograft (PDx) models derived from the same tumors. The phenotypic as well as the drug response variations observed in our 3D culture correlated with variable gene expression profiles (luminal vs basal) that were detected in our RNA-seq data. Conclusion: As compared to monolayer, 3D culture is more capable of recapitulating tumor complexity and accurately reflects the drug resistance / sensitivity profiles that are observed in PDX models in vivo. Therefore, a 3D culture system provides an invaluable tool for high throughput screening of drugs in bladder cancer and providing a better understanding of tumor biology in the search of more effective treatments for bladder cancer patients.

#5785 Characterization of a novel microfluidic in vitro model of the blood-tumor and blood-brain barrier

Jessica Griffith, Tori Terrell-Hall, Amanda Ammer, Paul Lockman.

West Virginia University, Morgantown, WV.

Background: There is a need for a cost-effective and reliable in vitro model of the blood-tumor barrier (BBB) and blood-brain barrier (BBT) for primary and metastatic lesions in brain. Current models do not accurately recapitulate physiological conditions and are unreliable with up to a 100-fold variance in predicting drug permeability into brain tumors. Methods: Human umbilical vein endothelial cells (HUVECs) were cultured with either CTX-TRD2 rat astrocytes (BBB) or Met-1 murine breast cancer cells (BBT) in a microfluidic chip, which contained chambers separated by a porous wall. Shear stress was induced on HUVECs by perfusion of media through the apical chamber, and permeability was characterized by the diffusion of fluorescent tracers, one of which is subject
to P-gp efflux. Data was compared to in-vivo work. Results: Permeability of free Texas Red was significantly higher (p < 0.05) in BTB chips (Kp = 13.1 ± 1.3 X 10⁻⁴) than in the BBB chips (Kp = 2.5 ± 0.3 X 10⁻¹). There was a similar trend observed in larger markers, but these were not significantly different. The movement of Rhodamine 123 was also restricted, indicating functional P-gp efflux in vitro, similar to data published in vivo studies. In the BBB model, diffusion of Rh123 increased 14-fold in the presence of verapamil (Kp = 14.7 ± 7.5 X 10⁻⁴) and eight fold with the addition of Cyclosporine A (Kp = 8.8 ± 1.8 X 10⁻⁴). In the BTB model, this increase was also observed, but to a lesser extent, as only 3 and 2-fold increases in permeability were observed, respectively. The magnitude of permeability changes were not significantly different from in-vivo models in both parameters, indicating active efflux phenomena. Conclusion: The novel microfluidic chip is a cost-effective in vitro model which recapitulates the BTB and BBB physiology and can predict permeability more reliably than current in-vitro models.

Patient derived organoids are becoming a popular 3D in vitro model that more accurately recapitulate in vivo conditions compared to standard 2D culture systems. Organoids consist of epithelial cells and lack stroma and mesenchyme, allowing cells of interest to be studied as an isolated system. However, the tunability of the organoid model also permits the re-addition of microenvironmental factors, i.e. cancer associated fibroblasts (CAFs), resulting in a wide range of experimental capabilities. Organoids are easily scalable, making them more efficient and cost-effective than traditional animal models. Despite the popularity of animal models for pre-clinical drug testing, there still remain issues with translating results from animal testing to patient outcomes; even patient-derived xenograft models experience non-physiological mouse-human interactions. Therefore, studying the impact of microenvironmental perturbations, such as the presence of CAFs, or nutrient and drug gradients, on organoids may reduce translational error. Using our biorepository of patient derived colon cancer (primary- and liver metastases) organoids, we can observe changes in tumor architecture and cell growth or death, allowing us to more accurately assess the efficacy of drug therapies and observe how interpatient heterogeneity impacts their efficacy. Here we focus on the histopathology of different patient derived organoids to quantitatively study cell growth or death under drug treatments (+/- CAFs) which could ultimately become a standard procedure for drug screening. Here we investigate the effects of CAF co-culture in patient derived organoids in response to standard chemotherapies such as Irinotecan and Oxaliplatin. Following treatment, the organoids are paraffin fixed to retain their structural integrity, then sectioned. The samples are stained with H&E to show the tumor architecture, and immunofluorescent antibodies (IF) to identify cells that are proliferating (Ki67) or apoptotic (TUNEL). As a result, we are able to investigate how tumor microenvironmental factors affect the tumor architecture of an individual patient tumor. We also examine the cytotoxic or cytostatic effects of standard chemotherapies by quantitating the number of proliferative and apoptotic cells, as well as their location within the tumor, in response to the presence of both CAFs and therapy. Ultimately, we envision the method outlined here will further personalize medicine by allowing physicians to more rapidly assess an individual patient’s response to therapy and adjust treatment accordingly. Additionally, this method could prove to be a more inexpensive and faster means of screening new drug compounds. By creating a system that more closely recapitulates patient outcomes, we hope to move therapies forwards faster approval while still retaining results representative of in vivo outcomes.

The OncoPanel™ service has established 100 genomically-characterized human tumor cell lines as targets for the screening of compounds in 3D spheroid models. We sought to (1) expand the cell line capability of the service and (2) validate the cell lines in a long-term (10-day) assay. For the cell line expansion, cells were plated at two densities in 384-well spheroid-promoting plates, and were incubated for 3 days to allow formation of spheroids. The growth media were then removed and replaced with media containing the hypoxia probe, Lox-1. Twenty-four hours later, the ability to form spheroids was determined by bright-field, high-content imaging, and fluorescent detection of the Lox-1 probe in the hypoxic core of the spheroids. Cells were then seeded in assay plates at pre-determined densities, along with a time zero (T₀) plate, and were incubated for 4 days to allow spheroid formation. Spheroid formation was verified by bright-field, high-content imaging, as previously mentioned. The growth media were removed and replaced with fresh media, followed by the addition of staurosporine over a range of 10 concentrations, using acoustic liquid transfer. At 2 days post-stimulation, the cell lines were re-plated with fresh media, for each cell line to pass quality control. Based on our tests of spheroid formation in the expansion cell lines, we have added 36 cell lines to the spheroid- or loose aggregate-forming cell line panel, with 20 cell lines validated in the long-term assay. Through the use of high-throughput screening and high-content imaging, we can verify and validate spheroid formation and growth in a 384-well format, with which we can test agents for drug discovery projects and provide value for potentially greater therapeutic outcomes.

#5788 Development of cellular morphology-based separation system for three-dimensional culture. Hirofumi Matsui,1 Shinji Sugiuira,2 Masato Tamura,3 Toshiyuki Kamonari,4 Toshiyuki Takagi,5 Taku Satou,4 Ryuji Kato,6 Kei Kanie,5 Mayu Shibuta5. 1University of Tsukuba, Tsukuba, Japan; 2National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan; 3Nagoya University, Nagoya, Japan.

The present study includes proof concept of morphology-based cell separation and development of automatic cell separation system. 3D culture environment with a specific extracellular matrix regulates cellular function and phenotype. In addition, cancer cell morphology changes depending on its malignancy in 3D culture environment. The cell separation system in 3D culture environment should need to obtain the cells according to its morphology, which includes cell phenotypes. Recently, we developed gelatin-based photodegradable hydrogels, and applied this hydrogels to optical cell separation. The target cells in the photodegradable hydrogels were successfully separated by the optical cell separation, the separated cells was growth on another dish. On the other hand, we recently developed the predication model of stem cell differentiation by image analysis. The image analysis technique and the photodegradable gelatin hydrogels are included in the automated morphology-based cell separation system in the 3D culture environment. For forming cell encapsulated-photodegradable hydrogels, suspension of cells including heterogeneous population is mixed with pregel solutions and cells are encapsulated in the gelatin-based photodegradable hydrogels. After the culture in 3D environment, microscopic images of the 6 cells are captured. The captured images are analyzed to distinguish the target cells from the other cells by using the image analysis algorithm, which we previously developed for analyzing stem cells. The hydrogels around the target area is irradiated with light (365nm). The cells in the irradiated area are collected by automated pipetting system. We developed automated system for this optical cell separation procedure, including cultivation, image acquisition, image analysis, light irradiation, and pipetting for cell collection. We demonstrated automated optical cell separation using the model culture system. Normal gastric mucosal cells were cultured in the photodegradable hydrogels. After cultivation for 1 week, the cells were irradiated the light for 5 to 20 min. The cells in the irradiated area were collected by automated pipetting and transferred into a collection dish. The collected cells were viable and attached in the collection dish after collection. We are currently developing an automated image analysis algorithm to distinguish cancer cells from normal cells under 3D environment. The automated optical cell separation system with image analysis algorithm will be applied to the establishment of novel cancer-cell lines from clinical samples such as biopsy tissue.

Interaction between cancer cells and stromal components in the tumor microenvironment is well known for their significant roles in tumor progression and subsequent treatment failure. Hepatic stellate cells (HSCs), as a predominant cell type in the microenvironment of hepatocellular carcinoma (HCC), are involved in creating desmoplastic and chemoresistance-inducing microenvironment. HSCs secrete various paracrine factors that modify the HCC tumor

Proceedings of the American Association for Cancer Research. Volume 58. April 2017
TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 6

microenvironment leading to tumor growth, drug resistance and metastasis via promoting epithelial-to-mesenchymal transition (EMT). Although several studies using 2D co-culture system have shown bidirectional cross-talk between cancer cells and HSCs, data obtained remain limited in their clinical relevance due to lack of in vivo tumor-like characteristics. We developed a mixed-cell spheroid model which recapitulates direct 3D tumor-HSC interactions in parallel and contact-mediated manners. Huh-7, human HCC cells, were mixed co-cultured with LX-2 cells, immortalized human HSC at 1:3 ratio using liquid overlay technique in 96-well plates. Electron microscopy was used to examine subcellular structural changes. Cellular distribution within spheroids was observed by labeling LX-2 cells with fluorescent tracer. The expression of pro-fibrotic and EMT markers was detected by immunofluorescence staining on paraffin embedded sections. Invasion ability was served by labeling LX-2 cells with fluorescent tracer. The expression of pro-fibrotic and EMT markers was detected by immunohistochemistry or immunosubstitutes, after which their development was followed by fluorescence microscopy. RESULTS: Both of the cancer cell lines used were able to form compact spheroids and grow on bladder equivalents. The invasive behaviour of spheroids varied depending on the nature of the cells used. The non-invasive RT4 cell line was unable to cross the basal lamina whereas the invasive T24 cell line was able to do so. CONCLUSION: The establishment of such a model for studying cancer biology in a physiological environment will help bridge the gap between overly simple cell culture models and more complex transgenic mice models. This new model offers a unique opportunity to study separately the players involved in the development of BCA and thus represents a powerful tool for the mechanistic analysis of this complex pathology.

#5790 Assessing the effects of TIMP2 knockout on lung cancer cell lines cultured in 3D. David Feeney. NCI, Bethesda, MD.

Tissue inhibitor of matrix metalloproteinases (TIMPs) are a small family of endogenous proteins that classically function to inhibit metalloproteinase activity. Since the original description of this protein family in the 80s and 90s, various MMP-independent biological functions of TIMPs have been described. This built the impression that MMP/TIMP ratios may play an important role in tissue homeostasis, an idea which is supported by the observation that altered MMP/TIMP expression ratios are often associated with a number of human conditions such as cancer, cardiovascular and CNS disease. TIMP2 is the most abundantly expressed protein in this family and has previously been shown to interact with several membrane proteins including MT1-MMP, insulin-like growth factor-1 receptor (IGF-1-R) and alphabeta3 integrin (αβ3) to mediate downstream signaling. In addition, TIMP2 has been shown to inhibit growth factor stimulated proliferation, angiogenesis and tumor cell invasion and metastasis, highlighting the potential for TIMP2-based cancer bio-therapies that can be used in conjunction with conventional treatments. Recent studies in our lab highlight that syngeneic lung tumors (LL2 cells; Lewis lung carcinoma) developed in C57BL mice harboring a loss-of-function mutation in TIMP2 are significantly larger than tumors grown in their WT counterparts. To gain a deeper understanding of the role of TIMP2 in tumor initiation and progression we have used CRISPR-Cas9 to develop stable TIMP2 knockout (T2KO) human lung cancer cell lines. Although indistinguishable in 2D culture, T2KO tumor cells display a morphologically distinct phenotype when grown in spheroids. Preliminary data show that, when grown in spheroids, T2KO cells exhibit enhanced EGFR activation in comparison to WT cells. By assessing the functional characteristics and gene expression of T2KO cells grown in 3D culture conditions we hope to gain further insight into the biological functions of TIMP2 and to provide a mechanistic link between the loss of TIMP2 activity and enhanced tumor formation that is observed in our mouse model.

#5791 3D tissue engineering bladder model for cancer invasion study. Cassandra Ringuette Goulet, Geneviève Bernard, Stéphane Chabaud, Frédéric Pouliot, Stéphane Bolduc. Université Laval, Quebec, Quebec, Canada.

INTRODUCTION: Our understanding of the biological processes involved in bladder cancer (BCa) is greatly limited by the models currently available. In fact, the combination of in vitro and in vivo models of BCa has failed to elucidate all the fundamental aspects of the disease. The eighth most commonly diagnosed cancer in Western societies, BCa has become a growing public health concern, and more realistic models are needed to reveal the mechanisms involved in tumor initiation and progression. METHODS: Bladder substitutes have been constructed by tissue engineering with healthy human fibroblasts and urothelial cells, using the self-assembly method. Meanwhile, spheroids have been produced from non-invasive (RT4) and invasive (T24) BCa cell lines expressing DsRed fluorescent protein. The invasive potential of these spheroids was characterized in a type-I collagen gel invasion assay. Following this, the invasion spheroid model was used to investigate the effect of TGF-beta on cell invasion. CONCLUSION: The establishment of such a model for studying cancer biology in a physiological environment will help bridge the gap between overly simple cell culture models and more complex transgenic mice models. This new model offers a unique opportunity to study separately the players involved in the development of BCA and thus represents a powerful tool for the mechanistic analysis of this complex pathology.

#5792 Development of cell line derived organoids to evaluate stroma targeted therapies in pancreatic cancer. Bradley Hall,1 Bindu Santhamma,2 Andrew Cannon,1 Rakesh Bhatia,1 Sushil Kumar,1 Chandranakarathe,1 Harree Nair,2 Klaus Nickisch,3 Surinder Batra.1 University of Nebraska Medical Center, Omaha, NE; 2Evestra, Inc, San Antonio, TX.

Background: Most solid tumors have extensive stroma that not only facilitates the tumor progression but also impedes the delivery of the chemotherapeutic agents. Due to lack of any in-vitro system, presently it is difficult to evaluate any stroma-targeted therapies. Therefore, we developed an organoid system using labeled pancreatic cancer and stellate cell lines. Methods: Murine (FC 1295 and imPSCc-2) cell lines cultured in different combinations were grown as an organoid system using matrigel. The organoids, starting day four were treated with either gemcitabine or EC359, a novel mifepristone derived steroidcytotoxic agent that targets stroma, or both in combination. qRT-PCR analysis of activated stroma signature genes was performed on the mRNA isolated from different treatment groups. H&E, immunohistochemistry, and western blot analysis were performed to further validate our findings. Results: Histologically, these cell line derived organoids develop ductal structures surrounded by fibroblast as seen in the pancreatic tumors. Immunohistochemistry demonstrated elevated level in the mixed-cellspheroids compared to that of cancer cell-alone invasion. CTGF showed similar patterns of distribution to that of LX-2 cells, but at an increased level. CONCLUSION: The establishment of such a model for studying cancer biology in a physiological environment will help bridge the gap between overly simple cell culture models and more complex transgenic mice models. This new model offers a unique opportunity to study separately the players involved in the development of BCA and thus represents a powerful tool for the mechanistic analysis of this complex pathology.

#5793 Comparison of EMT biomarker expression in 2D monolayer and 3D spheroid cultures in a prostate cancer cell model. Jan Carlstrom, Jeanne M. Hintermender, Lindsay Nelson, Stephen Hurt, PerkinElmer, Hopkinton, MA.

The purpose of this study was to examine the induction of epithelial to mesenchymal transition (EMT) in a prostate cancer cell line by measuring classical biomarker expression in three-dimensional (3D) spheroid cultures compared to traditional 2D monolayers in an effort to develop a more biologically relevant assay. Using Ultra-Low Attachment (ULA) microplates, we grew spheroids from a human prostate cancer cell line (DU 145). Numerous studies have implicated a role for EMT in carcinoma invasion and metastasis. EMT is characterized by rearrangement of the extracellular matrix (ECM) and differential regulation of ECM proteins. We induced EMT using TGF-beta and phorbol-12-myristate-13-acetate (PMA) and compared expression levels of specific biomarkers, such as E-cadherin, fibronectin, and IL-6, using AlphaLISA and LANCE (TR-FRET) assay technologies. We confirmed that treatment of DU 145 cells with TGF-beta is sufficient for inducing changes in both EMT biomarker expression and characteristic cellular morphology in monolayer cultures. However, in 3D spheroid cultures, we observed only a partial EMT response to the same TGF-beta treatment as demonstrated by changes in the expected bio-
marker expression pattern. Using the small molecule, PMA, we see significant differences in the levels of IL-6 secretion after EMT induction between cells grown in monolayer and those grown in spheroids. Cellular proliferation, growth and vitality were assessed using ATPFite luminescence assays and confocal microscopy of live-stained cells with a high content imaging system. Though we observed increased proliferation in monolayer cultures compared to 3D spheroids, the changes observed in protein expression patterns cannot be sufficiently explained by differences in cell number or viability. These data illustrate the differences in protein expression levels and in cellular tolerance for compound treatment between a human prostate cancer cell line grown in monolayers and those same cells grown in 3D spheroids.

TUMOR BIOLOGY: Effects of Tumor-Microenvironment Cross-talk on Metastasis

#5794 TrkB-mediated signaling contributes to malignant phenotypes of gallbladder cancer. Makoto Kawamoto, Hideya Onishi, Keigo Ozono, Akio Yamasaki, Akira Imazuymi, Masafumi Nakamura. Kyushu University, Fukuoka, Japan.

Background: Brain derived neurotrophic factor (BDNF)/ Tropomyosin-related kinase B (TrkB) signaling has been shown to be associated with aggressive phenotype in some cancers. However, the contribution of BDNF/TrkB signaling to gallbladder cancer (GBC), one of refractory malignancies, still remains unclear. This study aims to analyze the biological significance of BDNF/TrkB signaling in GBC. Methods: 1) Clinical experiment: 69 patients with primary GBC who underwent curative surgical resection were enrolled in this study. We investigated TrkB expression by immunohistochemistry and analyzed the correlation between TrkB expression and clinicopathological findings. 2) In vitro experiment: BDNF/TrkB signaling was inhibited using 1TRDA or siRNA, and was activated by recombinant human BDNF (rhBDNF). Then, whether BDNF/TrkB signaling contributes to the biological function was estimated by proliferation assay and Matrigel invasion assay, using TrkB-expressing 5 GBC cell lines (NOZ, TGBB2TK, DBs15, TYGBK-1, TYGBK-8). Furthermore, we determined the mechanisms of invasion in terms of epithelial mesenchymal transition (EMT) and matrix metalloproteinases (MMPs). We also examined the relationship between TrkB expression and the level of vascular endothelial growth factors (VEGFs) and hypoxia-inducible factor-1α (HIF-1α) in GBC. 3) In vivo experiment: Tumorigenesis and tumor growth of TrkB siRNA-transfected GBC cells were analyzed, using xenograft mice model. Results: 1) Clinical results; TrkB expression was detected in 63 (91.3%) GBC specimens. TrkB expression in the invasive front correlated with T factor (p=0.0391) and clinical staging (p=0.0391). Overall survival was lower in patients with high TrkB expression in the invasive front than in those with low TrkB expression (p=0.0363). 2) In vitro results; Proliferation was unaffected by rhBDNF treatment; however, K252a treatment and TrkB siRNA transfection decreased proliferation. rhBDNF treatment increased invasiveness by inducing EMT and activating MMP-2/MMP-9, whereas K252a treatment abrogated these effects. TrkB or BDNF siRNA transfection suppressed invasiveness. TrkB siRNA transfection decreased HIF-1α, VEGF-A, and VEGF-C/D expressions. 3) In vivo results; TrkB siRNA transfection decreased tumorigenicity and tumor growth in NOZ and TYGBK-1. Conclusion: These findings demonstrate that TrkB-mediated signaling contributes to the induction of malignant phenotypes (proliferation, invasiveness, angiogenesis, lymphangiogenesis, and tumorigenesis) in GBC.

#5795 Loss of CDCP1 in patient prostate cancer metastasis leads to uncoupling of beta-1 integrin from its cytosplasmic signaling through FAK. Sara G. Pollan,1 Fangjin Huang,1 Joshua M. Lang,2 Jamie M. Sperger,1 Kavita Shah,3

Proceedings of the American Association for Cancer Research. Volume 58 • April 2017 1479

model system of CTCs. In this system, CDCP1 silenced cells exhibit 3-fold higher proliferation, 4-fold greater anchorage independent growth with colonies exceeding 5 microns in diameter, and a 2-fold reduction in migration ability. In 10% human plasma, these cells up-regulate p-FAK, p-SRC, p-AKT and p-MAPK expression, and at the same time loose expression of activated β1-integrin. The loss of β1-integrin occurs through prevention of TALIN phosphorylation. Upon loss of CDCP1, Talin is no longer phosphorylated by CDK5 and this causes the disassembly of the β1 integrin - Talin complex. In addition, β1-integrin dissociates from CDK5 and from the CDK5-regulatory subunit, p35, but remains bound to p-FAK. We determined the pathway by which the loss of CDCP1 arrests CDK5 kinase activity. Upon loss of CDCP1, siRNA phosphorlylates p35. This generates a binding site for the C2 domain of PKCα and phosphorylation of CDK5-T777 by PKCα. The subsequent dissociation of the regulatory subunit abolishes the activity of β1-integrin. Altogether we discovered a new mechanism of regulation of CDK5 in prostate cancer cells, which leads to the uncoupling of β1-integrin and FAK. The potential biological and clinical consequences of this mechanism are (1) a switch from cell-matrix to cell-cell adhesion, (2) increased sensitivity of CTCs to FAK inhibitors and (3) improved adaptation and survival of cancer cells in the circulation and at the metastatic sites.

#5796 Heparan sulfate proteoglycans mediate tumor cell invasion and metastasis. Henry Qazi,1 Zhong-Dong Shi,2 Jonathan W. Song,1 Limary M. Cancel,1 Lance L. Munn,1 John M. Tarbell2

The Cub-Domain Containing Protein - 1, CDCP1, is a transmembrane glycoprotein that shares a characteristic domain with the core protein for heparan sulfate proteoglycans. Previous studies suggest that heparan sulfate (HS) in the glycocalyx plays an important role in the invasion and metastasis of renal cell carcinoma cells. We demonstrated that loss of CDCP1 facilitates PCA metastasis, we determined the consequences of CDCP1 loss in non-adherent cancer cells, which provide an experimental model system of CTCs. In this system, CDCP1 silenced cells exhibit 3-fold higher proliferation, 4-fold greater anchorage independent growth with colonies exceeding 5 microns in diameter, and a 2-fold reduction in migration ability. In 10% human plasma, these cells up-regulate p-FAK, p-SRC, p-AKT and p-MAPK expression, and at the same time loose expression of activated β1-integrin. The loss of β1-integrin occurs through prevention of TALIN phosphorylation. Upon loss of CDCP1, Talin is no longer phosphorylated by CDK5 and this causes the disassembly of the β1 integrin - Talin complex. In addition, β1-integrin dissociates from CDK5 and from the CDK5-regulatory subunit, p35, but remains bound to p-FAK. We determined the pathway by which the loss of CDCP1 arrests CDK5 kinase activity. Upon loss of CDCP1, siRNA phosphorlylates p35. This generates a binding site for the C2 domain of PKCα and phosphorylation of CDK5-T777 by PKCα. The subsequent dissociation of the regulatory subunit abolishes the activity of β1-integrin. Altogether we discovered a new mechanism of regulation of CDK5 in prostate cancer cells, which leads to the uncoupling of β1-integrin and FAK. The potential biological and clinical consequences of this mechanism are (1) a switch from cell-matrix to cell-cell adhesion, (2) increased sensitivity of CTCs to FAK inhibitors and (3) improved adaptation and survival of cancer cells in the circulation and at the metastatic sites.

#5797 Semaphorin 5A preserves epithelial phenotype in pancreatic cancer cells by regulating cross-talk between Wnt and TGF-β signaling. Sugandha Saxena,1 Abhilasha Purohit,2 Surinder K. Batra,1 Rakesh K. Singh3

Pancreatic cancer (PC) is one of the deadliest forms of cancers. In spite of recent advances, minimal progress has been made in our understanding of PC progression, metastasis, and treatment of PC patients with advanced disease. Striking similarity between the process of cancer metastasis and guidance of neuronal cells to their target sites has generated interest in pharmacologically targeting guidance cue molecules for treatment of metastasis. Among the guidance cue family members, Semaphorin5A (SEMA5A), was found to be involved in organ-specific homing during PC metastasis. With an interest to delineate the function of SEMA5A in PC, we generated SEMA5A knockdown in metastatic PC cell lines. Knock down of SEMA5A expression resulted in loss of cellular differentiation and epithelial phenotype with higher motility as compared to vector. This observation is in line with our previous finding that SEMA5A expression was higher in well-differentiated tumors in comparison with undifferentiated pancreatic tumors. Loss of SEMA5A increased TGF-β2 production, decreased expression of E-cadherin, and nuclear translocation of β-catenin. Furthermore, we observed higher Wnt activity and increased expression of the transcription factor SNAIL in SEMA5A knockdown cells in comparison with vector control cells. Higher Wnt signaling along with increased TGF-β2 production explains the loss of differentiation and epithelial markers. Moreover, we observed that non-canonical TGF-β2/AKT mediated inhibition of GSK3-β is responsible for increased stability of β-catenin and SNAIL, thereby activating Wnt signaling in SEMA5A knockdown cells. Our
observations demonstrate that SEMA5A has a potential role in maintaining the epithelial phenotype in PC cells by keeping cross-talk between Wnt and TGF-β signaling under check.

#5798 Exosomal oncogenic proteins promote tumor progression, metastasis and chemoresistance in ovarian cancer. Kalpana Deepa Priya Dorayapan, Ross A. Wanner, Roman A. Zingarelli, Uksha Saini, Selvendiran Karuppaiah, David E. Cohn. The Ohio State University, Columbus, OH.

Introduction: Ovarian cancer is the most lethal gynecological malignancy. Despite its clinical significance, the factors that regulate the development and tumor progression and metastasis are among the least understood of all major human malignancies. In this study we show that the oncogenic proteins which are specifically packed in the cargo of the exosomes released from the ovarian cancer cells play a role in tumor progression, metastasis and chemoresistance.

Methods: The exosomes were isolated using ExoQuick solution from different primary ovarian cancer cells (POCC), HGSOc cell lines, normal ovarian epithelial cells (OSE) and patient ascites. Further quantified by NTA and morphologically characterized by TEM, their purity was validated by the presence of exosome specific markers and absence of golgi matrix protein. Protein profiling in exosomes was done using Capillary LCMS/MS analysis. Proteomic data sets were analyzed by (http://www.qiagen.com/ingenuity) Ingenuity Pathway Analysis (IPA) to gain biological insight in disease mechanisms, associated to the observed expression changes. Cell proliferation assay and cell migration assay were carried out in normal and ovarian cancer cell lines with and without exosome co-culture, STAT3 and Hepatocyte growth factor (HGF) expression in exosomes and Matrix (ECM) proteins in different cell lines were analyzed using Western Blotting. Also in-vivo studies were carried out using orthotopic tumor model in mice. In addition cisplatin accumulation studies were done using ICP-MS. Results: The exosome concentration from POCC and HGSOc cells was much higher (2-10 fold times) than from the OSE cells. Expression of CD9, CD63, TSG101 and EpCam confirmed the exosomes. HGF, Complement factor H (CFH) and Lysyl oxidase- 2 (LOX2) were selected from the top 25 proteins identified by IPA based on their expression ratio and disease relevance. IPA scored STAT3 as the top regulator effect network and further more HGF was activated in our data set. The expression of activated STAT3 and HGF were confirmed in the exosomes from HGSOc cells and patient ascites. Cell proliferation and migration was significantly increased with concurrent increased expression of MMP-2 and -9 in-vitro favoring the role of exosomal oncogenic proteins in tumor progression and metastasis as evidenced in in-vivo orthotopic tumor mouse. The decrease in cisplatin accumulation in OVCAR8 cells observed, when co-cultured with exosomes from cisplatin resistant cell line suggests its role in chemo-resistance as well. In addition, blocking exosome function inhibits cell proliferation and increases the cytotoxicity to cisplatin. Conclusion: The results conclude that the tumor exosomes of ovarian cancer cells are enriched in highly elevated oncogenic proteins that play a very important role in mediating tumor progression and metastasis while inducing chemo-resistance as well and are evident from our in-vitro and in-vivo studies.

#5799 Targeting CX3CR1 impairs the reseeding of cancer cells recirculating from metastatic tumors. Chen Qian, 1 Asuraya Worrede-Mahdi, 1 Raman- gopal Kaur, 2 Fei Song, 2 Joseph Salvino, 1 Olimpia Meucci, 1 Alessandra Stattus, 1 Drexel University, Philadelphia, PA; 2University of pennsylvania, Philadelphia, PA.

Cancer cells re-enter systemic blood from established metastatic tumors. Recent evidence indicates that these recirculating cancer cells further seed and colonize skeleton and soft tissues to expand metastatic dissemination, thus precipitating the clinical progression to terminal disease. We have previously shown that the chemokine receptor CX3CR1 is implicated in the metastatic seedling of breast cancer cells and that novel small-molecule antagonists for this receptor effectively contains the number and size of secondary tumors in animal models. Using the same models, we now report that targeting CX3CR1 also restrains the re-seeding of skeleton and soft-tissue by circulating cancer cells (CTCs) in the blood, we sought to assess whether these compounds could synergize with docetaxel by extending bioavailability and its cytotoxic effects. Thus, we tested this paradigm on CTCs departing from skeletal and soft-tissue lesions generated by breast and prostate cancer cells in mice. Based on the results obtained from these experiments, it can be concluded that implementing the development of CX3CR1 antagonists and promoting their clinical use will provide novel and effective tools to contain the progression of metastatic disease in cancer patients.

#5800 Epidermal growth factor-induced ANGPTL4 enhances anoikis resistance and tumor metastasis in head and neck squamous cell carcinoma. Yu-Han Liao, National Cheng Kung University, Tainan, Taiwan.

Epidermal growth factor (EGF) is important for cancer cell proliferation, angiogenesis and metastasis in many types of cancer. However, the mechanisms involved in EGF-induced head and neck squamous cell carcinoma (HNSCC) metastasis remain largely unknown. In this study, we reveal that angiotensin-like 4 (ANGPTL4) plays an important role in the regulation of EGF-induced cancer metastasis. We showed that EGF-induced ANGPTL4 expression promoted anoikis resistance and cancer cell migration and invasion in head and neck squamous cell carcinoma (HNSCC). In addition, depletion of ANGPTL4 inhibited EGF-induced cancer cell invasion. Autocrine production of EGF-induced ANGPTL4 regulated the expression of MMPs. The induction of MMP-1 gene expression by ANGPTL4-activated integrin β1 signaling occurred through the AP-1 binding site in the MMP-1 gene promoter. Furthermore, down-regulation of MMP-1 led EGF- and recombinant ANGPTL4-enhanced HNSCC cell migration and invasion. Depletion of ANGPTL4 significantly blocked EGF-primed anoikis resistance and extravasation. Moreover, depletion of ANGPTL4 significantly blocked EGF-primed metastatic seeding of tumor cells and MMP-1 expression in vitro. HNSCC xenografts formed in vivo were not observed in the depletion of ANGPTL4. These results suggest that EGF-induced expression and autocrine production of ANGPTL4 enhances HNSCC metastasis via up-regulation of MMP-1 expression. Inhibition of ANGPTL4 expression may be a potential strategy for the treatment of EGF-mediated HNSCC metastasis.

#5801 Loss of core 1,3-galactosyltransferase (C1GALT1) in pancreatic cancer leads to altered mucin glycosylation and increased tumor aggressiveness. Seema Chugh, 1 Satyaranayana Rachagani, Xinhe Yu, 2 Sirram Neelamgeham, 2 Lijun Xia, 1 Michel O. Ouellette, 1 Moorthy P. Ponnusamy, 1 Su-rinder K. Batra. 1 University of Nebraska Medical Center, Nebraska, NE; 2State University of New York, NY; 1University of Oklahoma Health Sciences Center, OK; 2Internal Medicine Division of Gastroenterology-Hepatology, NE.

Background: Aberrant expression of mucins underlie pancreatic cancer (PC) progression and metastasis. Mucin type O-glycosylation is the principal post-translational modification on mucins and is regulated by myriad of glycosyltransferases. Not much has been investigated about the specific glycosyltransferases involved in increased PC aggressiveness. We found that core 1,3-galactosyltransferase (C1GALT1), which is essential for O-glycosylation, is not expressed in a subset of the PC patients. C1GALT1 adds galactose in O-glycosylation pathway that forms core 1 structure, which is usually elongated to several carbohydrate structures. Loss of C1GALT1 is accompanied by incomplete O-glycosylation that results in increased expression of truncated carbohydrate antigens (Tn and sTn). Increased expression of these truncated carbohydrate antigens on mucins has been associated with augmented aggressiveness in several malignancies. Based on these results, we hypothesized that loss of C1GALT1 in PC patients is associated with altered mucin O-glycosylation and increased aggressiveness. Methods: Expression of C1GALT1 was examined in HPNE (human pancreatic nestin expressing cells) and oncogenic transformed HPNE cells. To understand the role of C1GALT1 in PC, CRISPR/Cas9 mediated knockout of C1GALT1 was performed in PC cells. Impact of C1GALT1 knockout on glycosylation profile and mucin glycosylation was evaluated using lectin blotting and lectin pull down assay. Wound-healing assay was performed to examine the effect of C1GALT1 knockout on migration. To gain mechanistic insight, protein expression of signaling molecules involved in growth and motility was evaluated using western blotting. Orthotopic implantation of C1GALT1 knockout cells was carried in pancreas of nude mice to study its role in tumor growth and metastasis. Results: Knockout of C1GALT1 displayed increased tumor promotions which was associated with significantly increased migration. Western blotting demonstrated increased expression of proteins involved in growth and motility. Lectin-pull down assay revealed altered MUC16 glycosylation in C1GALT1 knockout cells. In vivo studies using orthotopic implantation and KPC mouse...
model demonstrated increased tumor weight and metastasis with knockout of CIGAL1T. Conclusion: Overall, our results indicate that loss of CIGAL1T in PC is associated with altered MUC16 glycosylation and increased PC aggressiveness.

**#5802 Role of mesenchymal stem cells in acquisition of metaplasia in AKU-BC42 breast metastatic carcinoma cell line.** Nazia Riaz,1 Sadia Habib,2 Azhar Hussain,2 El-Nasir Lalani,3 *Centre for Regenerative Medicine and Department of Surgery, Aga Khan University, Karachi, Pakistan; 3Centre for Regenerative Medicine, Aga Khan University, Karachi, Pakistan.*

Introduction: Metaplastic carcinoma (MCa) is a rare and aggressive subtype of invasive breast carcinoma exhibiting epithelial to mesenchymal transition (EMT) where tumor of epithelial origin manifests differentiation into non-glandular, mesenchymal phenotypes such as spindle, chondroid or osseous components. Acquisition of EMT is associated with low expression of e-cadherin, claudins and high expression of vimentin. Biological mechanisms for acquisition of metaplastic components within MCa are not well understood. The present study was undertaken to establish and characterize a cell line from a patient diagnosed with MCa and to evaluate the role of mesenchymal stem cells (MSC) in attainment of metaplastic phenotype. Methodology: AKU-BC42 was established from a 65 years old Pakistani female patient diagnosed with T4N1M0 MCa. Specimen was procured and processed under sterile conditions and cultured in DMEM supplemented with 10% FBS. Epithelial colonies were visualized after 3 weeks of culture, which were passaged and propagated. AKU-BC42 was phenotypically and genetically characterized using karyotyping, gene expression analysis, immunocytochemistry and florescent in situ hybridization. MSC marker expression was assessed by flow-cytometry. AKU-BC42 was cultured under appropriate conditions for assessment of differentiation along osteogenic, adipogenic and chondrogenic pathways. Lineage differentiation was evaluated by special immunohistochemical stains and induction of lineage differentiation genes was assessed by Q-PCR. Results: AKU-BC42 was found to have a human karyotype with multiploidy and population doubling time of 60 hours. Gene expression profiling revealed negative expression for estrogen and progesterone receptors and positive expression of androgen receptor (AR) and HER-2/neu. FISH analysis was negative for HER-2/neu amplification. Basal (5, 14 & 19) and luminal cytokeratins (8 & 18) were expressed at mRNA level along with mesothelial markers (CD10, 100A7, p-cadherin, desmin, s100A4, s100A2 & α-SMA). AKU-BC42 demonstrated MSC pool with expression of CD73 (79.2%), CD90 (10.3%) and CD105 (30.2%) as revealed by flow-cytometry. Osteogenic differentiation was assessed by von kossa stain for mineralization with up-regulation of ALPL and OPN genes. Similarly, differentiation of AKU-BC42 into mature adipocytes was evaluated with Oil red O staining of lipid droplets and expression of FABP4 gene. Chondrogenic induction was achieved by performing pellet cultures. Colla-gen synthesis in extracellular matrix of chondroblasts was assessed by mason trichrome staining with up-regulation of ACAN, COL10A1 and COMP. Conclusions: We report a novel MCa cell line containing a MSC pool. MSC pool within MCa may be responsible for acquisition of metaplasia in this rare subtype of breast cancer. Further studies on this cell line may reveal the biological mechanisms of MCa of the breast.

**#5803 Role of Neurophilin 2 in osteoclasts promoting prostate cancer bone metastasis.** Navath Shree Polavaram, Arup Bag, Sohini Roy, Samiksham Dutta, Kaustabh Datta. *University of Nebraska at Medical Center, Omaha, NE.*

Background: Bone metastases is one of the major clinical concerns that causes skeletal related malignancies and increased mortality. Bone is one of the preferred sites for metastatic prostate cancer. The tumor cells interact with bone cells (osteoblasts and osteoclasts) resulting in an imbalance in the bone homeostasis causing metastatic bone disease. Unlike other cancers, the bone maturation promoted by metastatic prostate cancer (PCa) leads to increased osteoclastic activity resulting in osteoblastic bone lesions. However, bone matrix response to osteoclasts leads to release of growth factors that aid PCa cells to develop into an overt metastasis. Our preliminary data indicated a non-tyrosine kinase receptor Neurophilin 2 (NRP2) is expressed in osteoclasts (OC) induced by PCa cells. The objective of our current study is to study the role of NRP2 in PCa-induced OCs. We hypothesize that PCa-induced NRP2 expression in OC is necessary for low osteoclastic activity and that it negatively regulates the OCs leading to PCa bone metastasis. Methods: Mouse OC precursors were isolated from bone marrow of C57BL/6 mice and differentiated into OCs under conditions of RANKL and M-CSF and in conditioned medium (CM) collected from PCa cell line LNCaP C4-2B (promotes high osteoclastic and low osteoclastic activity) and PC3 (predominantly osteoclastic activity) to mimic the conditions in normal bone and PCa bone metastasis. NRP2 expression at protein and mRNA was evaluated. TRAP staining and activity were conducted to confirm the differentiation of OCs. Results & Discussion: We observed that NRP2 was expressed in OCs induced under standard conditions (C57BL/6 and C4-2B). TRAP staining and activity confirmed the differentiation of OCs under these conditions. Interestingly, depletion of NRP2 and treatment either in standard conditions or C4-2B CM exhibited a drastic increase in osteoclastogenesis. However, NRP2-depleted OC precursors when treated with PC3 CM showed no change in osteoclastogenesis. These findings advocate a role of NRP2 in inhibiting osteoclastic activity in PCa. Conclusion: This study established that osteoclastic activity in PCa evades NRP2 inhibition. Protein analysis of the time course of NRP2 in OC in PC3 CM and C4-2B CM showed a differential NRP2 expression. This difference in the NRP2 levels can be impacted at either transcription or post-translational level. No change was observed in the NRP2 expression at transcriptional level in both the conditions suggesting that this difference can be due to either translation or rapid degradation of NRP2. Using in-vitro and transgenic mice, we examine how PC3 CM-induced OCs escapes the inhibition of NRP2. We will also determine whether NRP2 expression regulates the transcription of genes involved in OC differentiation and activation. Together, this approach will elucidate the role of NRP2 axis on OCs in promoting PCa-induced bone metastasis and will aid in determining whether NRP2 axis can be a therapeutic target.

**TUMOR BIOLOGY: Effects of Tumor-Microenvironment Crosstalk on Metastasis**

**#5804 Heterogeneity in androgen receptor and IL-1beta expression by prostate cancer cells in skeletal metastases.** Asurayya A. Worrede-Mahdi,1 Melisa Diaz,2 Alessandro Fatatis1.1Drexel University College of Medicine, Philadelphia, PA; 2Drexel University, Philadelphia, PA.

Bone metastases are a prevalent complication of advanced prostate cancer (PCa). The current standard of care for advanced PCa patients is androgen deprivation therapy (ADT), which fails within approximately two years and patients progress to castration resistant prostate cancer (CRPC). CRPC presents with additional metastasis in soft tissues and is incurable. We have found that in PCa patients, bone metastases have heterogeneous Androgen Receptor (AR) expression, and that cells lacking AR are the only PCa cell type that secretes the cytokine Interleukin-1 beta (IL-1β). Furthermore, pre-clinical work in our lab has revealed the role for IL-1β in promoting bone colonization by AR+ PCa cells and generation of heterogeneous skeletal metastases. A significant barrier to studying tumor heterogeneity in PCa metastasis has been the lack of an animal model to study the interaction between multiple PCa phenotypes in the bone microenvironment. By engrafting a suspension containing both AR+ and AR- cells directly into the left cardiac ventricle of mice, our lab has developed an in vivo model that allows us to study the progression of both AR- and AR+ cells in skeletal and soft tissue metastases. AR- and AR+ cells were genetically engineered to express two different Luciferase constructs (630 nm Red-shifted Luc and 540 nm Luc2 respectively) thereby allowing the progression of AR- and AR+ cells to be independently tracked and quantified. We used this model in combination with histological and radiographic analyses to assimilate the pathological features of our in vivo mixed AR+/AR- metastases to the human clinical scenario. Finally, we used castrated mice to determine whether IL-1β secreting PCa cells could support the growth and survival of IL-1β/AR+ cells in androgen deprived conditions. Co-injection of AR- (PC3-ML) and AR+ cells (LNCaP, VCAp, and 22Rv1) led to increased establishment of soft tissue metastases as compared to injecting AR- cells alone. Unlike the metastases generated by PC3-ML cells alone, which show exclusively osteolytic activity, AR-/AR+ mixed metastases are both osteosclerotic and osteolytic, thereby recapitulating clinical pathology. Finally, preliminary results suggest that co-injection with IL-1β-secreting AR- cells enables the growth of androgen-dependent AR- cells in castrated mice. This animal model of metastasis heterogeneity recapitulates human pathology and enables further interrogation of the mechanisms by which IL-1β supports survival of AR+ cells and the potential role for AR- in evading AR-targeted therapy during castration resistant prostate cancer (CRPC).

**#5805 Myosin 1e colocalization with β1-intergin and association with tumor progression in colorectal cancer.** Jeffrey Pfannenstein,1 Filippo Bori,2 Alessandro Bombonati,3 David Zuzga.1 La Salle University, Philadelphia, PA; Einstein Medical Center, Philadelphia, PA.

For colorectal cancer (CRC), the risk of relapse among stage II and stage III a/b patients is 20-30% and the benefit of treating these patients with chemotherapy is uncertain. As a result, many patients are untreated, putting them at increased risk for disease relapse, or overtreated, exposing them to unnecessary
and harmful chemotherapy with little potential benefit. Therefore, defining prognostic biomarkers to more accurately determine each person’s risk of relapse and need for chemotherapy is a priority in CRC research. Promising targets for biomarker discovery are actin-binding proteins. As a broad class, these proteins regulate the actin cytoskeleton and serve as direct, proximal regulators of invasiveness and metastatic phenotypes. Further, the prognostic utility of several of these proteins has recently been reported in the literature. Myosin Ie (Myo1e) a long-tailed, class I myosin, is one such protein with proposed clinical utility as a prognostic biomarker. In kidney podocyte cells, Myo1e regulates endocytosis, adhesion, migration, and invasiveness dynamics. Despite its expression in numerous cancers, the functional role of Myo1e specifically in cancer cells and its association with tumor progression remains elusive. To define a role in cancer cells, the localization of Myo1e was examined in vitro by immunofluorescence in T84 human CRC cells. Myo1e co-localized with actin, cortactin and β1 integrin at membrane ruffles, which regulate integrin endocytosis and trafficking. Interestingly, both Myo1e and β1 integrin also co-localized with caveolin-1, a regulator of integrin endocytosis, suggesting Myo1e expression may regulate caveola-dependent integrin endocytosis and trafficking. To evaluate potential prognostic utility, Myo1e expression in colorectal tumors and matched normal adjacent tissue (NAT) was examined by immunochemistry in a tissue microarray constructed from duplicate tissue cores from 119 CRC patients. The patient cohort was well balanced across TNM stage: stage 0 (10.1%), stage 1 (20.2%), stage 2 (26.9%), stage 3 (31.1%), and stage 4 (12.6%), and the majority (68.8%) of the tumors examined were rectal. The ratio of Myo1e expression in tumors compared to NAT was significantly correlated with clinicopathologic indicators of disease progression, including clinical stage, depth of invasion at the primary tumor (T-score), and lymph node metastasis. Together, these data suggest Myo1e expression correlates with tumor progression and may regulate invasive phenotypes through integrin trafficking pathways. Examining the prognostic utility and biologic function of Myo1e may define a novel biomarker with translational utility for improved clinical management of colorectal cancer patients.

Copper is an enzymatic cofactor required for cellular respiration, iron homoeostasis, melanogenesis, neurotransmitter biosynthesis, and connective tissue formation. Copper deficiency in humans is evidenced by Menkes disease, a lethal pediatric disorder caused by mutations in the ATP7A copper transporter. ATP7A, a ubiquitously expressed copper transporting P-type ATPase, transports copper from the cytoplasm into the Golgi complex to supply copper to secreted copper-dependent enzymes. Copper requirement for lysoxydase (LOX) proteins in tumor metastasis is further illustrative of copper’s role in cancer biology. Copper-dependent LOX proteins catalyze the oxidation of lysine residues within collagen and/or elastin, stabilizing crosslinks between these fibrous proteins during the formation or remodeling of the extracellular matrix. While research implicates a direct role for LOX proteins in many types of cancer, the use of copper chelators or other strategies to starve LOX enzymes of copper as a therapeutic strategy has been largely overlooked. LOX family members acquire copper in the secretory pathway via the ATP7A protein. Consistent with this requirement, LOX activity is reduced in cultured fibroblasts derived from patients with Menkes disease that lack functional ATP7A protein. As the cancer promoting properties of LOX enzymes have been shown to require catalytic activity, we hypothesize that blocking the ATP7A protein could be a powerful approach to inhibit LOX-dependent tumorogenic and pro-metastatic pathways. In this study, we have found that genetic ablation of ATP7A using CRISPR/Cas9 inhibits the tumorogenic and metastatic potential of a multiple cancer cell lines in vivo. These findings could be attributed to a variety of copper functions or those of copper-dependent enzymes, such as LOX. In this study, we investigate the role of copper-dependent enzymes, such as LOX, using in vitro and in vivo methods. While others have implicated lysyl oxidase secreted by cancer cells in tumorigenesis and metastasis, the contributions of lysyl oxidase at the metastatic site have not been evaluated. Here, I describe a novel conditional mouse model that we use to explore this question.

#5807 Disseminated tumor cell clearance by the immune system. Raziye Piranloung, Eun Mi Lee, Maria Ouzunova, Ali S. Arbab, Paulo C. Rodriguez, Asm L. Iskander, Hasan Korkaya. Augusta University, Augusta, GA.

The classical model of metastasis suggests that the tumor cell dissemination occurs late in tumor development, however accumulating evidence coming from in vitro and in vivo studies indicate that tumor cells with early dissemination signal to the immune system and start to disseminate during the initial steps of tumor development. However, the dissemination from the primary area does not always result in metastasis. Due to the non-permissive nature of microenvironment in distant sites, these early disseminated tumor cells might be cleared or maintained in a non-proliferative/dormant state. The mechanism by which some early disseminated tumor cells escape immune surveillance while some remain dormant is not well known. In order to understand the underlying factors that may contribute to the metastatic growth, we performed time course experiments by utilizing murine mammary tumors (4T1 as metastatic and 4T6 as less metastatic) in a syngeneic mouse model. Luciferase expressing 4T1 or 4T6 tumor cells were orthotopically implanted into the fat pads and tumor cell dissemination was analyzed over 3-week time points. We determined that both 4T1 and EMT6 tumors disseminated as early as one to two-week post implantation, however only 4T1 tumor develop metastasis in distant organs. Moreover, we also resected primary tumors 1, 2 and 3-week post implantation of EMT6-Luci or 4T1-Luci tumors and observed distant metastasis via optical imaging of luciferase expression in live animals. Although the majority of 4T1 tumor-bearing mice (>80%) developed the expression of TIMP-1 and 4T1 tumors resected 2 and 3-weeks post implantation only 10% of mice developed metastasis when primary tumor resected one-week post implantation. In contrast, EMT6 tumors following resection only relapsed in the primary tumor site but failed to develop metastasis. Furthermore, EMT6 tumor-bearing mice efficiently cleared tail vein injected EMT6-luci cells in the lungs. We investigated the possible mechanism by which EMT6 tumor-bearing mice clears disseminated tumor cells in the lung. We provide evidence that pulmonary infiltrated mMDSCs mediate tumor cell killing via secretion of high levels of cytotoxic granules, granzyme A, granzyme B, perforin. This was confirmed by mouse transcriptome and qPCR analyses as well as biochemistry using in vivo samples and in vitro co-culture samples. Our studies provide a new paradigm in the understanding of the fate of disseminated tumor cells in secondary organs and the role of the immune system in this process.

#5808 The role of breast cancer-derived exosomes in breast metastasis. Gohran Morad, Jiang Yang, Marsha A. Moses. Boston Children’s Hospital, Harvard Medical School, Boston, MA

The development of breast metastasis is associated with a significant reduction in the survival rate of breast cancer patients. Improving the prognosis of women with breast metastasis from breast cancer relies on the elucidation of the mechanisms underlying this process. Our group and others have shown that the formation of brain metastases occurs along the abluminal side of brain vessels, a process called “vessel co-option”. These observations prompted our hypothesis that the cellular and extracellular matrix (ECM) components of the blood-brain barrier (BBB) can serve as a pre-metastatic niche for breast cancer brain metastases. The role of tumor-derived exosomes (TEX) in the preparation of a pre-metastatic niche in distant organs has been shown in a number of cancers. To investigate the mechanisms driving the vessel co-option of breast cancer brain metastases, we studied the role of breast cancer-derived exosomes in preparation of the BBB for metastasis formation. Exosomes were isolated from the MDA-MB-231 breast cancer cell line, a brain-seeking variant of these cells, and a bone-seeking variant as a non-brain metastatic control. Brain endothelial cells, astrocytes, and brain vascular pericytes, the three components of the BBB, were treated with exosomes for 3 days to recapitulate the continuous exposure of cells to the circulating TEX in vivo. The treated cells were analyzed for cellular activities relevant to pre-metastatic niche preparation in the brain such as the integrity of the BBB, expression of cytokines, and modulation of the ECM. An initial screen was performed using cytokine antibody arrays and PCR arrays for ECM and adhesion molecules and results were validated in three separate experiments using western blots, ELISA, and Multiplex assays. Exosomes derived from breast cancer-seeking cells significantly increased astrocyte migration and decreased the expression of Integrin β1 in brain endothelial cells, both of which can lead to the disruption of the BBB integrity. Moreover, the expression of Interleukin 8 was increased by TEX in astrocytes. TEX also increased the expression of MMP-3 and -9 (Matrix Metalloproteinases) from an undetectable baseline level and decreased the expression of TGF-β and -3 (Tissue Inhibitors of MMPs) in astrocytes. While the importance of these two MMPs for brain metastasis from breast cancer has been previously reported, our study is the first to demonstrate that secretion of these MMPs is triggered by TEX. Surprisingly, we did not observe any significant TEX-derived modulations in the expression of cytokines, ECM, Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
and adhesion molecules in brain pericytes. These findings indicate that within the BBB, astrocytes and endothelial cells, but not pericytes, can be affected by breast cancer-derived exosomes in such a way that can potentially lead to progression of a suitable niche for future metastasis formation along the brain vasculature. (This work is supported by the Breast Cancer Research Foundation.)

#5809 Fluorescence-guided spatiotemporal dynamics of epithelial-mesenchymal transition under inflammatory microenvironment during colorectal cancer progression. Takeshi Ieda,1 Hiroshi Tazawa,2 Satoru Kikuchi,3 Shinji Kuroda,1 Toshiaki Ohara,1 Kazuhiro Noma,1 Hiroyuki Kishimoto,1 Takeshi Nagasaki,1 Masahiko Nishizaki,1 Shunsuke Kagawa,1 Takeshi Imamura,2 Toshiyoshi Fujiwara1.1Okayama University, Okayama, Japan;2Ehime University, Ehime, Japan;3Daiichi Medical Center, Okayama, Japan.

Background: Epithelial-mesenchymal transition (EMT) is a biological process, by which epithelial cancer cells acquire mesenchymal phenotype with malignant properties for invasion and metastasis, leading to poor prognosis. Inflammatory microenvironment has been shown to be responsible for the development and progression of colorectal cancer. However, the role of inflammatory microenvironment in the EMT-related tumor progression remains unclear. To explore the relationship between inflammatory microenvironment and EMT, a live imaging system for EMT is a promising strategy on the in vitro and in vivo experiments. In this study, we developed a fluorescence-guided live cell imaging system for the assessment of spatiotemporal dynamics of EMT, and investigated the potential of inflammatory microenvironment for the induction of EMT phenotype in human colorectal cancer cell lines. Methods: Two human colorectal cancer cell lines, HCT116 and RKO, were stably transfected with vimentin promoter-driven red fluorescence protein TurboFP635 expression vector. Both cell lines were treated with inflammatory cytokines, IL-1β (1 ng/ml) and TNF-α (20 ng/ml), or co-cultured with mouse macrophage cell line RAW264.7 in the presence of lipopolysaccharide (LPS) (200 ng/ml). The time-lapse live imaging was observed by confocal laser scanning microscope. Migration and invasion properties were examined by transwell chamber assays. The fluorescence intensity was measured by microplate reader and flow cytometric analysis. The expression of EMT-related markers was assessed by Western blot analysis and q-PCR. EMT-induced HCT116 and RKO cells were treated with anti-inflammatory agents, aspirin (1 mM) and salicylic acid (1 mM), for the suppression of EMT. Results: Inflammatory cytokines (IL-1β and TNF-α) induced red fluorescence intensity and morphological change like mesenchymal phenotype in HCT116 and RKO cells. Removal of inflammatory cytokines attenuated red fluorescence intensity and morphological change in both cells. Inflammatory cytokines also induced the migration and invasion properties in association with EMT-related markers. Moreover, co-culture with LPS-stimulated macrophages also induced red fluorescence intensity and morphological change as well as inflammatory cytokines. Anti-inflammatory agents significantly suppressed the fluorescence-related EMT phenotype under inflammatory microenvironment. Conclusions: These results suggest that inflammatory microenvironment has a great potential for the induction of EMT process during colorectal cancer progression. Moreover, we found that the fluorescence-guided EMT imaging system is useful method for the exploration of inflammation-mediated tumor progression.

#5810 microRNAs targeting EMT transcription factors may be associated to lymph node metastasis in breast cancer tumors. Elisa Pérez-Moreno,1 Gabriela Valarezo,2 Valentina Zavala,1 Wanda Fernández,1 Pilar Carvallo1.1Pontificia Universidad Católica de Chile, Santiago, Chile;2Hospital San Borja Arriarán, Santiago, Chile.

Breast cancer is the leading cause of cancer-associated deaths in women. Lymph node near to the primary breast tumor have a high chance of developing a secondary tumor, representing one of the first signs of metastasis in breast cancer. Metastasis is promoted by epithelial-mesenchymal transition (EMT), process lead by the transcription factors SNAIL, SLUG, ZEB and TWIST. MicroRNAs are small non-coding RNAs, whose expression has been demonstrated to be altered in different cancer types. Because of their ability to regulate large sets of genes involved in cancer growth and metastasis, microRNAs have emerged as candidate molecular biomarkers and novel therapeutic targets. The aim of this study is to identify microRNAs differentially expressed in breast tumors in relation to EMT-transcription factor expression and lymph node metastasis, and that are involved in epithelial-mesenchymal transition. For this purpose, we used microRNA microarray data from 50 fresh frozen breast tumors with different tumor grades (1 to 3), 28 from patients with lymph node metastasis. Microarray data analysis using RankProd (R package) revealed approximately 40 microRNAs down-regulated in breast tumors with expression of EMT-transcription factors (p < 0.05). Several of the identified microRNAs have been previously described to regulate early steps of metastasis in different cancer types, like members of the miR-200 family (miR-200c and miR-141), miR-205 and miR-30a. In addition we found other microRNAs not previously associated to breast cancer metastasis. Our results demonstrate that down regulation of microRNAs, and up regulation of their targets, may induce a metastatic behavior of tumor cells of the primary breast tumors, promoting invasion and colonization of the lymph nodes. In this sense, the changes in the expression of microRNAs may serve as biomarkers of breast cancer prognosis in patients.

#5811 HMP19, a pancreatic cancer metastasis suppressor, is secreted in extracellular vesicles and inhibits EGFR activity. Sharon Manley, Gada Al-Ani, Danny Welch. University of Kansas Medical Center, Kansas City, KS.

Pancreatic cancer is usually diagnosed when the cancer is already at an advanced stage. The presence of metastases contributes to the poor prognosis as do the limited treatment options, resulting in an urgent need for early detection methods and novel treatments. HMP19 was identified as a metastasis suppressor in pancreatic duct adenocarcinoma (PDAC) using unbiased genome wide shRNA screen assay (Kurahara et al. 2016). HMP19 is localized to the membrane of Golgi apparatus and has been implicated in the vesicular trafficking in neurons (Saberan-Djoneidi et al. 1994). HMP19 is a predicted type II, single-pass transmembrane protein with protein binding domains at the N- and C- terminals, although, the physiological function of HMP19 remains undefined. Our lab showed that HMP19 attenuates nuclear ERK1/2 activity in PDAC cells. Furthermore, we found that ectopic HMP19 is secreted in the extracellular vesicles (EVs) in non-metastatic PDAC cell line, Suit2 subclone 028 (S2-028), but not in metastatic PDAC cell line, S2-007. Furthermore, silver staining and mass spectrometry showed that the EVs protein profiles between S2-028 and S2-007 EVs are distinct. We hypothesize that secreted HMP19 regulates cell migration and proliferation, and also negatively regulates signaling pathway(s) upstream of ERK. To examine effects of HMP19-containing EVs on parental cells, HMP19-containing EVs were incubated with parental cells and proliferation and migration then were quantified. HMP19-containing EVs treatment inhibited migration but not proliferation of metastatic S2-007 cells, but not non-metastatic S2-028 cells. We identified several proteins as HMP19 binding partners in the co-immunoprecipitation followed by mass spectrometry study and were subsequently validated by co-immunoprecipitation followed by immunoblot. HMP19 was found to interact with multiple proteins, including ERK regulators such as MET and epithelial growth factor receptor (EGFR). We then investigate the role of HMP19 on the MET and EGFR signaling pathway. Intriguingly, HMP19 down regulates EGFR phosphorylation and protein expression in metastatic S2-007, but not non-metastatic S2-028 PDAC cells. Moreover, HMP19 expression had no effect on phosphorylated and total MET and Janus kinase (JAK) total protein levels. Altogether, the data suggest that HMP19 may inhibit metastasis through down regulation of EGFR signaling pathway. In conclusion, we showed that HMP19 is secreted in EVs and these EVs attenuate PDAC cell migration, and mechanistically, HMP19 down regulates the EGFR signaling pathway. Future studies will further bridge the effects of HMP19 on the EGFR signaling cascade and the extracellular HMP19-mediated inhibition of migration.

#5812 MIEN1 promotes breast cancer cell migration and invasion by regulating cytoskeletal dynamics via focal adhesion kinase and N-WASP. Pankaj Chaudhary, Marilyne Kpetemey, Timothy Van Treuren, Jamboor K. Vishwa-natha. University of North Texas Health Science Center, Fort Worth, TX.

Short Description: Migration and invasion enhancer 1 (MIEN1) is an important regulator of cell migration and invasion. MIEN1 overexpression represents an oncogenic event that promotes tumor cell dissemination and metastasis. The underlying mechanism by which MIEN1 regulates migration and invasion has yet to be deciphered. Methods: Immunofluorescence, actin polymerization, Immunoprecipitation, migration, invasion, and adhesion assays were performed using breast cancer cell lines, MDA-MB-231 and MCF10CA1a to investigate the mechanisms by which MIEN1 potentiates cell motility. Results: Our results show that MIEN1 acts as a cytoskeletal-signaling adapter protein to drive breast cancer cell migration. Knockdown of MIEN1 led to the loss of actin-protrusive structures whereas the overexpression of MIEN1 resulted in rich and thick membrane extensions. Knockdown of MIEN1 also decreased the cell-substratum adhesion, suggesting a role for MIEN1 in actin cytoskeletal dynamics. Our results show that MIEN1 supports the transition of G-actin to F-actin polymerization and stabilizes F-actin polymers. Additionally, MIEN1 promotes cellular adhesion and actin dynamics by inducing phosphorylation of FAK at Tyr-925.
and reducing phosphorylation of cofilin at Ser-3, which results in breast cancer cell migration. Furthermore, we found that MEN1 associates with cytoskeletal proteins involved in motility processes. Conclusion: Our results show that MEN1 plays an essential role in maintaining the plasticity of the dynamic membrane-associated actin cytoskeleton, which leads to an increase in cell motility. Hence, targeting MEN1 might represent a promising means to prevent breast tumor metastasis.

#5813 Rab GTPase 3C promotes colon cancer metastasis via regulation of IL-6 secretion and STAT3 signaling pathway, Chi-Long Chen. Taipei Medical Univ., Taipei, Taiwan.

RAB GTases are involved in membrane trafficking vesicle formation and cell motility. Recently, exocytotic RABs received growing attention in cancer research. However, the molecular mechanism of exocytotic RABs in colorectal tumorigenesis remains unclear. In this study, we found RAB GTPase 3C (RAB3C) has the most significant association with higher pathological stage, tumor recurrence, frequent distant metastasis, and poor prognosis in 215 colorectal adenocarcinoma cohort using tissue microarray (TMA) analysis. In multivariate analyses, high RAB3C expression retained its independently prognostic significance for both overall survival (p = 0.001) and disease-free survival (p < 0.001). Further experimental results showed increased migration and invasion ability in RAB3C overexpressing colon cancer cells compared with control group in vitro and in vivo. The cell culture medium collected from RAB3C overexpressing model could promote parental colon cancer cells further indicated that the metastasis-promoting role of RAB3C is exocytosis dependent. We then integrated the results from previously microarray and proteomics datasets and discovered that increased production of multiple cytoxines in RAB3C overexpressing cell lines. Of these cytoxines, IL-6 pathway is the top pathway corresponding to gene expression changes after RAB3C overexpression. Blocking of IL-6 function with IL-6 antibody or IL-6 knockdown significantly reduced the migration ability in RAB3C overexpressing colon cancer cells. Furthermore, secretion of IL-6 after RAB3C overexpression promoted the JAK2-STAT3 signaling with increased STAT3 phosphorylation levels to promote migration. In addition, Ruxolitinib, a JAK2 inhibitor, was found to significantly inhibited RAB3C induced colon cancer cell migration through blocking STAT3 phosphorylation. In conclusion, our study showed that RAB3C overexpression promoted tumor metastasis and is associated with poor prognosis of colon cancer patients through modulating the IL6 exocytosis of cancer cells to activate JAK2-STAT3 pathway. These findings suggest a new therapeutic strategy through the inhibition of STAT3 signaling pathway in RAB3C-IL-6 axis by Ruxolitinib to prevent metastasis of colon cancer.

#5814 Engineered microfluidic 3D human microvasculature identifies Talin-1-dependent adhesion and FAK activation as the key promoter of cancer cell ex-vivo endothelial migration. Mara Gallardi,1 Simone Bersini,2 Rosa Maria Moresco,3 Marco Vanoni,1 Roger D. Kamm,1 Matteo Moretti1. 1BCCS Galeazzi Institute, Milano, Milan, Italy; 2San Raffaele Hospital, Milan, Italy; 3University of Bicocca - Milano, Milan, Italy; 4Massachusetts Institute of Technology, Cambridge, MA.

In extravasation cancer cells and vascular niche are involved in a tight cross talk which is the rate limiting step in cancer progression [1]. Recent, animal studies support the hypothesis that metastatic deficiency lies in focal adhesion complex alterations, however, it still needs to be elucidated which are the specific regulators of each event composing extravasation. Focal adhesion proteins Talin-1 (TLN-1) and Focal Adhesion Kinase (FAK) are up-regulated in breast cancer. Both targets due to their structural and functional role, dramatically influence cancer mechanotransduction leading to endothelial junction disruption, critical in extravasation process [2]. Here, we generated a doxycycline engineered models for each extravasation step allowing single cell behavior analyses through high resolution real time imaging in a reliable and quantitative way in a physiological environment. Through this novel approach we analyzed the effect of TLN-1 and FAK and their genetic and chemical inhibition in breast cancer extravasation. The 3D-microfluidic vasculature displayed maturation markers and physiological permeability (1.5–2.0*10^-6 cm/s) and allowed cancer cell injection through the hollow vessels. Western blot confirmed TLN-1 and FAK knock down (KD) in MDA-MB231. Both targets significantly affected morphology and proliferation (p<0.001). We demonstrated the involvement of both targets in adhesion to the endothelium (p<0.001). Transendothelial migration (TEM) was decreased in TLN-1 KD (p=0.05) and in FAK KD (p=0.01). Both TLN-1 and FAK KD cells were trapped into the vessels and were not able to extend pseudopodia. Cancer migration tracking in 3D matrix was statistically lower in both KD (p<0.001). The calculated ratios of adhesion/TEM and invasion/TEM were lower in TLN-1 compared to FAK KD, demonstrating that TLN-1 plays a major role in adhesion to endothelium and early invasion while FAK was identified as the main driver in TEM. Additive (TLN-1 and FAK) KD did not show significant difference respect to the target that mostly affected adhesion and invasion demonstrating TLN-1 role in these events. Additive KD was statistically lower compared to TLN-1 KD (P<0.05), supporting FAK crucial role in TEM. Inhibition of TLN-1 and FAK phosphorylation revealed that actin polymerization and pseudopodia formation (required for extravasation) were dependent by their structural role and were independent by their phosphorylation. However, the inhibition of FAK activity showed FAK phosphorylation as the key driver of TEM mechanism (p<0.01). Concluding, our results supported by in vivo data (p<0.05) showed that TLN-1 and FAK inhibition may represent novel strategies challenging mechanisms leading to metastatic establishment. 1. Cell, 2011. 147(2):p.275-92; 2. Proc Natl Acad Sci USA, 2015. 112(1):p.214-9.

#5815 The HBP1 tumor suppressor is a negative epigenetic regulator of MYCN driven neuroblastoma through interaction with the PR2 complex. Geerttui Denecker,1 Shana Claeyes,1 Irma Lambertz,1 Els Janssens,1 Suzanne Vanhaeustert,2 Bieke Decaestecker,2 Tom Van Maerkert,2 Bram De Wilde,1 Genieve Laureys,2 Kristina Althoff,3 Johannes Schulte,3 Jean-Baptiste Demoulin,3 Sara M. Roberts,3 Laure D'Hyver,1 Eline J. Molenaar,4 Frank Wernsteeman,5 Katleen De Preter,1 Frank Speleman1. 1Center for Medical Genetics, Ghent, Belgium; 2Ghent University Hospital, Ghent, Belgium; 3University Children’s Hospital Essen, Essen, Germany; 4Université catholique de Louvain, Woluwesaint-Lambert, Belgium; 5Memorial Sloan Kettering Cancer Center, New York, NY; 6Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; 7German Cancer Research Center, Heidelberg, Germany.

MYCN is a key driver in initiation and progression of neuroblastoma (NB) and represents a major target for novel drug strategies. We previously reported that the MYC repressor gene HBP1 was down regulated by mutant ALK via the P3K-AKT-FOXO3 signaling axis [1]. Here, we further demonstrate that HBP1 upregulation suppresses proliferation of neuroblastoma cells by decreasing the MYCN signaling pathway. HBP1 levels were also shown to be repressed in neuroblastoma cells through MYCN/MYCN driven upregulation of the miR-17-92 cluster, indicating that MYCN and mutant ALK both act to inhibit HBP1 expression in NB. Next, we tested the green tea polyphenol epigallocatechin gallate (EGCG), known to upregulate HBP1, and the BET inhibitor JQ1, which represses MYCN activity in neuroblastoma cells, and showed in vitro and in vivo synergistic effects on cell viability and tumor growth. Treatment with the PI3K/mTOR dual inhibitor BEZ-235 together with JQ1 also showed very strong synergistic effects. Further dissection of the HBP1 regulome using Gene Set Enrichment Analysis (GSEA) and iRegulon analysis (http://iregulon.aertslab.org) allowed identification of the PRC2 component SUZ12 as a central node in HBP1 regulated signaling, mainly through controlling the repression of MYCN regulated genes. In keeping with this finding, GSEA analysis of our HBP1 overexpression data set revealed also strong enrichment for genes that are differentially expressed upon EZH2 inhibition in neuroblastoma cells. Because HBP1 has previously been shown to interact with HDAC, we tested the effects of the HDAC inhibitors vorinostat and panobinostat as single agents and in combination with BEZ-235. Both combinations showed a strong synergistic effect on cell viability. The molecular mechanism of this synergism will be explored through RNAseq expression analysis. We conclude that HBP1 is a crucial component in MYCN controlled repression of gene activity through PRC2 interaction and demonstrate novel opportunities for precision drugging of MYCN overexpressing NB cells. 1Lambertz et al. Clin Cancer Res. (2015).

#5816 Ablation of oncogenic MYCN expression by hTERT-driven oncogenic lymphedonic adenosine induces cell death in MYCN-amplified neuroblastoma. Terutaka Tanimoto,1 Hiroshi Tazawa,1 Hiroshi Nosu,2 Takanori Oyama,1 Yasuo Urata,2 Shunsuke Kagawa,2 Takuo Noda,2 Toshiyoshi Fujisawa2. 1Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; 2Oncolys Biopharma, Inc., Okayama, Japan.

Background: Neuroblastoma (NB) is a primary malignant tumor of the peripheral sympathetic nervous system. Amplification and overexpression of the MYCN proto-oncogene occur in approximately 20% of NB. Since MYCN amplification is highly associated with poor prognosis, MYCN is an attractive target for the treatment of MYCN-amplified NB. MYCN is a transcriptional activator that...
induces the expression of many down-stream target genes including human telomerase reverse transcriptase (hTERT). We developed two types of hTERT-driven oncolytic adenoviruses, OBP-301 and OBP-702, in which the hTERT promoter drives the expression of the viral E1A and E1B genes for tumor-specific virus replication, and OBP-702 further expresses tumor suppressor p53 protein. Both adenoviruses show tumor selectivity against MYCN-amplified NB with hTERT activation, the therapeutic potential of these viruses in MYCN-amplified NB remains unclear. In this study, we investigated whether OBP-301 and OBP-702 induce cell death and modulate MYCN expression in MYCN-amplified NB cells. Methods: We used 3 human NB cell lines with MYCN amplification, including IMR-32, CHP-134 and LA-N-5, to assess the effect of OBP-301 and OBP-702 on cell death by XTT assay. Virus-mediated cell death and modulation of MYCN and E2F1 expression were analyzed by Western blot analysis. The mRNA expression of hTERT and MYCN was analyzed by real-time RT-PCR analysis. To explore the role of E2F1 in the virus-mediated MYCN modulation, Ad-E2F1, a replication-defective adenovirus expressing E2F1 gene, was further used. Results: All NB cell lines showed high hTERT mRNA expression. OBP-301 and OBP-702 showed profound antitumor effect through autophagy-related cell death in all NB cell lines. Both viruses induced E1A and its target mediator E2F1 expression in these cell lines. Expression of MYCN mRNA and protein was downregulated by these viruses. Replication-deficient Ad-E2F1 infection also downregulated the expression of MYCN. Conclusions: These results suggest that hTERT-driven oncolytic adenoviruses are safe and effective antitumor agents for treatment of MYCN-amplified NB. These viruses induce profound autophagy through hTERT-dependent viral replication. E2F1 upregulation by viral infection is supposed to be one of the causes for MYCN downregulation and autophagy-related cell death. In vivo experiments are underway to investigate the antitumor effect of these viruses against xenograft NB tumors.

#5817 Protein phosphatase 1 regulatory subunit 1A promotes tumorigenesis and metastasis in Ewing sarcoma. Wen Luo,1 Changxin Xu,1 Janet Ayello,1 Filemon, De La Cruz,2 Jerey Rosenblum,1 Stephen L. Lessnick,4 Mitchell S. Cairo1. 1New York Medical College, Valhalla, NY; 2James J. Peters Veterans Affairs Medical Center, Bronx, NY; 3Memorial Sloan Kettering Cancer Center, New York, NY; 4Nationwide Children’s Hospital, Columbus, OH.

Background: Ewing sarcoma (ES) is a highly invasive and metastatic pediatric soft tissue and bone tumor. Children with metastatic ES have a cure rate of less than 30% (De Ioris MA et al, 2013). Novel and specific therapeutic targets are urgently needed. ES is characterized by the oncogenic fusions, mostly EWS/FLI which functions as an aberrant transcription factor to deregulate downstream targets and mediate ES pathogenesis. By comparing genes dysregulated by EWS/FLI across multiple model systems (Niedan S et al, 2014; Sankar S et al, 2013; Sankar S et al, 2015; Niedan S et al, 2015), we identified protein phosphatase 1 regulatory subunit 1A (PPP1R1A), a potent protein phosphatase 1 (PP1) inhibitor upon PKA phosphorylation, as one of the core EWS/FLI targets (Luo W et al, 2016). Objective: In the current study, we seek to define the role of PPP1R1A in ES pathogenesis. Methods: Quantitative reverse transcription polymerase chain reaction and luciferase reporter assays were performed to investigate transcriptional regulation of PPP1R1A in regulatory subunit 1A (PPP1R1A), a potent protein phosphatase 1 (PP1) inhibitor upon PKA phosphorylation, as one of the core EWS/FLI targets (Luo W et al, 2016). Objective: In the current study, we seek to define the role of PPP1R1A in ES pathogenesis. Methods: Quantitative reverse transcription polymerase chain reaction and luciferase reporter assays were performed to investigate transcriptional regulation of PPP1R1A in Ewing sarcoma (ES).

#5818 Disrupting the Aurora kinase A interactome in pediatric cancer. Sucheta Mukherjee, Carolyn Tu, Clay Gustafson. UCSF, San Francisco, CA.

Neuroblastoma is the most common extra-cranial solid tumor of childhood. Amplification of the MYCN proto-oncogene occurs in 50% of the high-risk neuroblastoma and indicates an aggressive and lethal form of the disease. As a transcription factor with no apparent small-molecule surface, direct inhibition of MYCN remains a challenging. Prophylactic cleavage of MYCN is regulated in part by an activity-independent scaffold function of Aurora Kinase A (AURKA). The dynamic expression and activation of AURKA allows for precise cell cycle regulation of several substrates identified by protein-protein interaction studies that are also viable anti-cancer targets, such as the aforementioned MYCN oncoprotein. Utilizing co-immunoprecipitation, flow cytometry, and other perturbation techniques, we aim to delineate a novel mechanism of targeting the AURKA interactome by disruption of MYCN. We have recently described a neoteric class of confirmation disrupting "amphosteric" inhibitors of AURKA (CD-AURKA) that orthogradially inhibit the ATP-binding pocket to dramatically disrupt the active confirmation of AURKA to associate with downstream oncogenic drivers of the neuroblastoma. In addition to MYCN, our preliminary results show CDS52 will also dissociate other oncogenic proteins that interact with AURKA. We hypothesize that confirmation disruption of AURKA and subsequent blockade of an array of protein-protein interactions will delineate the roles of AURKA, MYC, and MYCN in the cell cycle and expand the clinical applications for CD-AURKA in cancer to include non-MYCN-driven diseases.

#5820 Targeting the PIM protein kinases for the treatment of a T-cell acute lymphoblastic leukemia subset. Satish Kumar Reddy Padi,1 Libia Lu,ovo,2 Neha Singh,2 Jin Song,3 Ritu Pandey,4 Jon C. Aster,3 Xue-Zhong Yu,4 Shikhar Mehrotra,4 Andrew Kraft1. 1University of Arizona Cancer Center, Tucson, AZ; 2University of Arizona, Tucson, AZ; 3Harvard Medical School, Boston, MA; 4Medical University of South Carolina, Charleston, SC.

While intensive chemotherapy regimens result in remission in approximately 80% of pediatric and 45% of adult ALL patients, new approaches are needed for the treatment of patients with T-cell acute lymphoblastic leukemia (T-ALL) who fail to achieve remission with chemotherapy. Early T-cell precursor (ETP) ALL, a subset of T-ALL associated with a higher rate of relapse and induction failure, with a 10-year overall survival of 19% as compared with 84% for all other T-ALLs. PIM protein kinases are overexpressed in a number of hematopoietic malignancies, including ALL, with its overexpression being associated with poor prognosis. Pan-PIM inhibitors (PIMi) are being tested in clinical trials in pediatric leukemia and adult acute myeloid leukemia. Analysis of the effects of PIMi (AZD1210/LGB321) on human T-ALL cell lines demonstrated that the sensitive cell lines expressed higher PIM1 levels, whereas T-ALL cell lines with NOTCH mutations tended to have lower levels of PIM1 kinase and were insensitive to these inhibitors. NOTCH-mutant cells selected for resistance to gamma secretase inhibitors developed elevated PIM1 kinase levels and increased sensitivity to PIM inhibitors. Immunophenotype of all the PIMi insensitive cells lines was consistent with a more mature T-ALL phenotype. In contrast, sensitive cells had an immature or ETP-ALL phenotype. Bioinformatics analysis of three independent T-ALL patient datasets (GSE28703, E-MEXP-313, and GSE62156) demonstrated overexpression of PIM1 in the majority of ETP-ALLs and in a small subset of non-ETP-ALL. We also identified 58 genes changing significantly between PIMi sensitive versus insensitive cell lines that were common to the differential genes between ETP versus non-ETP ALL cases from GSE28703, suggesting that high PIM1 expression along with 58 gene signature could be a driver of the ETP phenotype. Importantly, we have made the novel observation that, combination of Ponatinib, a tyrosine kinase inhibitor (TKI) with the PIMi is synergistically lethal to T-ALL cells with ETP phenotype. These agents appear to work together by inducing PARP and Caspase cleavage, sufficient to drive apoptosis. Following engraftment of NSG mice with H-SB2-Luc cells, three weeks of dual therapy with AZD1210 (30mg/kg/day) and Ponatinib (3mg/kg/day) significantly abrogated leukemia as evidenced by optical scanning for luciferase cells, and reduced number of hCD45+ leukemia cells in the peripheral blood and bone marrow.

Also, the dual therapy significantly prolonged the survival of the treated mice. In summary, our work demonstrates a strong preclinical rationale for a novel treatment strategy of combining PIMi and TKI to treat T-ALL patients with high PIM expression.
Hedgehog-driven medulloblastoma demonstrate that the loss of Pin1 impairs vivofunctional analyses of Pin1 in the GFAP-tTA;TRE-SmoA1 mouse model of molecular model in which PIN1 promotes GLI1 protein abundance, thus conferring a growth advantage to the cells. The GLI1/PIN1 interaction was validated by reciprocal pulldowns using epitope-tagged proteins in HEK293T cells as well as by co-immunoprecipitations of the endogenous proteins in a medulloblastoma cell line. Our results support a molecular model in which PIN1 promotes GLI1 protein abundance, thus contributing to the positive regulation of Hedgehog signals. Most importantly, in vivo functional analyses of Pin1 in the GFAP-βGal;TRE-SmoA1 mouse model of Hedgehog-driven medulloblastoma demonstrate that the loss of Pin1 impairs tumor development and dramatically increases survival. In summary, the discovery of the GLI1/PIN1 interaction uncovers PIN1 as a novel therapeutic target in Hedgehog-driven medulloblastoma tumorigenesis.

In summary, the discovery of the GLI1/PIN1 interaction uncovers PIN1 as a novel therapeutic target in Hedgehog-driven medulloblastoma tumorigenesis.

Increase in protein expression and copy number drives the activation of NPY/YSR pro-survival loop in chemotherapy-treated neuroblastoma.

Neuroblastoma (NB) is a tumor derived from neural crest cells, primitive progenitors of sympathetic ganglia. It accounts for 6–10% of all pediatric cancers with approximately 700 new cases per year throughout the US. Although there are highly effective therapies for patients with low-risk and intermediate-risk disease who have local relapses, recurrent disease in patients with high-risk NB is mostly refractory to therapy. Neurotide Y (NPY) is a sympathetic neurotransmitter highly expressed in NB. Its elevated release from tumor tissue is associated with unfavorable clinical outcome. NPY, acting via its Y5 receptor (Y5R), stimulates NB cell survival and chemoresistance, however the mechanisms underlying NPY/YSR axis activation in these tumors remain unclear. The aim of this work was to investigate the correlation between the expression of NPY and NPY5R proteins and the copy number status of the NPY and NPY5R genes in pre- and post-chemotherapy NR. Eighty-five tissue samples, including specimens from the primary tumors, distant metastases and local relapses, pre- and post-chemotherapy, were collected from the Hospital Pequeno Principe, Parana, Brazil. Protein expression was investigated by immunohistochemistry. COPY number alterations (CNAs) for NPY and NPY5R genes were determined using TaqMan copy number assay. Additionally, FISH analysis was performed to assess MYCN amplification status, a genetic marker of high risk NB. Our results show that elevated extracellular NPY staining, which reflects peptide release, correlates with patients’ age above 18 months, relapse and poor clinical outcome. Moreover, the intensity of NPY staining was increased in chemotherapytreated NBs, as compared to tumors at diagnosis. However, the differences in NPY CNAs between these samples were not statistically significant. Thus, chemotherapymediated increase in NPY levels observed in post-chemotherapy NB is driven by its elevated expression rather than genomic changes. FOR NPY5R, significantly higher level of CNAs was observed in the post-chemotherapy samples (P<0.05), independently of the MYCN status. These findings are in line with previous studies reporting elevated NPY5R expression in chemotherapytreated NB tumors and cell lines. Therefore, for this receptor genomic changes may play an important role in conferring chemotherapymediated YSR up-regulation. Altogether, our results confirm activation of NPY/YSR pro-survival loop in chemotherapy-treated NB tumors. However, these coordinated increases in the NPY and NPY5R expression levels are driven by different molecular mechanisms.

Modulation of the Hippo pathway protein YAP as a mechanism of resistance to MEK inhibition in MAPK hyperactivated neuroblastoma.

Background: Current therapies for high-risk neuroblastoma are highly toxic and ineffective, as a majority of patients will face therapy-resistant relapses. Our recent whole genome sequencing analysis revealed that a majority of relapsed tumors had mutations causing RAS-MAPK pathway activation. Recent studies have implicated the Hippo pathway transcriptional coactivator protein YAP in relapsed neuroblastoma as well as resistance to MEK inhibition in other cancer models. Based on these findings, we hypothesized that YAP activity may lead to acquired resistance to MEK inhibition, and that dual inhibition of these two pathways may have synergistic therapeutic efficacy. Methods: We selected the neuroblastoma cell line SKNAS (NRAS Q61K), which acquires resistance and undergoes NF1 loss. NLF cell were treated with MEK inhibitor trametinib (20 nM) over a 72-hour period and whole cell lysates and nuclear lysates were collected for immunoblot. Effects of YAP knockdown via siRNA transfection with and without trametinib co-treatment on survival were assessed by CellTiter-Glo and RT-CES. Cell signaling analyses of tumor lysates from mouse SKNAS (NRAS Q61K) xenografts treated with vehicle, 0.3 mg/kg, 1 mg/kg, or 3 mg/kg for YAP, pERK, and apoptosis pathways were performed via immunoblot. Results: Immunoblots of 72-hour time course treatments of trametinib in NLF showed decreased pYAP, the cytosolic inactive form of the YAP protein, indicating increased YAP capable of translocating to the nucleus, which was confirmed by analyses of nuclear extracts. siRNA-mediated knockdown of YAP alone in NLF cells had a modest effect on survival, while combination inhibition of MEK and YAP signaling caused a significant reduction in cellular proliferation and survival. Immunoblotting of trametinib-treated SKNAS xenografts indicated decreased pYAP and pERK in response to increasing trametinib dose, while total YAP levels remained constant. Conclusion: Our results demonstrate that prolonged trametinib exposure causes a marked nuclear enrichment of unphosphorylated YAP. We show that co-inhibition of MEK and YAP effectively reduces proliferation and survival. We are currently investigating the effects of MEK inhibition on the expression of YAP target genes and on cellular proliferation upon modulation of YAP protein expression.

MHC class I immunogenicity and novel tumor antigen discovery in neuroblastoma.

Background: Neuroblastoma is a childhood neuroblastocytic tumor characterized by a high incidence of both early childhood and late relapse disease. The incidence of neuroblastoma is estimated at approximately 1419 new cases per year throughout the US. Although there are effective therapies for patients with low-risk and intermediate-risk disease who have local relapses, recurrent disease in patients with high-risk disease is mostly refractory to therapy. Neurotide Y (NPY) is a sympathetic neurotransmitter highly expressed in NB. Its elevated release from tumor tissue is associated with unfavorable clinical outcome. NPY, acting via its Y5 receptor (Y5R), stimulates NB cell survival and chemoresistance, however the mechanisms underlying NPY/YSR axis activation in these tumors remain unclear. The aim of this work was to investigate the correlation between the expression of NPY and NPY5R proteins and the copy number status of the NPY and NPY5R genes in pre- and post-chemotherapy NR. Eighty-five tissue samples, including specimens from the primary tumors, distant metastases and local relapses, pre- and post-chemotherapy, were collected from the Hospital Pequeno Principe, Parana, Brazil. Protein expression was investigated by immunohistochemistry. Copy number alterations (CNAs) for NPY and NPY5R genes were determined using TaqMan copy number assay. Additionally, FISH analysis was performed to assess MYCN amplification status, a genetic marker of high risk NB. Our results show that elevated extracellular NPY staining, which reflects peptide release, correlates with patients’ age above 18 months, relapse and poor clinical outcome. Moreover, the intensity of NPY staining was increased in chemotherapytreated NBs, as compared to tumors at diagnosis. However, the differences in NPY CNAs between these samples were not statistically significant. Thus, chemotherapymediated increase in NPY levels observed in post-chemotherapy NB is driven by its elevated expression rather than genomic changes. FOR NPY5R, significantly higher level of CNAs was observed in the post-chemotherapy samples (P<0.05), independently of the MYCN status. These findings are in line with previous studies reporting elevated NPY5R expression in chemotherapytreated NB tumors and cell lines. Therefore, for this receptor genomic changes may play an important role in conferring chemotherapymediated YSR up-regulation. Altogether, our results confirm activation of NPY/YSR pro-survival loop in chemotherapy-treated NB tumors. However, these coordinated increases in the NPY and NPY5R expression levels are driven by different molecular mechanisms.

Modulation of the Hippo pathway protein YAP as a mechanism of resistance to MEK inhibition in MAPK hyperactivated neuroblastoma.

Mechanisms of intrinsic and acquired resistance to antibodies targeting IGFR-1 in pediatric sarcoma cell lines. Terry J. Shankleford,1 Seethalakshmi Hariran,2 Doris Phelps,2 Hemant Bd,2 Hiahong Zhong,2 Peter Houghton3,4. Greehey Children’s Cancer Research Institute, UT Health San Antonio, San Antonio, TX; 3Resonant Therapeutics, Inc., University of Michigan, Ann Arbor, MI; 4MedImmune, Inc., Gaithersburg, MD.

Background: Pediatric bone and soft tissue sarcomas are heavily dependent on the Type 1 insulin-like growth factor receptor (IGF-1R) signaling axis, which promotes tumorogenic properties such as proliferation, survival, angiogenesis and metastasis. While a substantial proportion of patients demonstrate intrinsic resistance to monoclonal antibodies targeting IGFR-1, a strong and sustained response has been observed in a smaller number of patients, with overall survival rates about 30% of patients. Understanding these resistance mechanisms may identify combinations of targeted therapies that optimize therapeutic efficiency of IGFR-1-targeted antibodies. Methods: For intrinsic resistance, we used a panel of Ewing sarcoma (ES, n = 10) and rhabdomyosarcoma (RMS, n = 10) cell lines that, with the exception of Rh41, are all intrinsically resistant to TZ-1, a monoclonal antibody that targets IGF-1R. For acquired resistance, we developed a TZ-1 resistant RMS cell line, Rh41/TZ-1. We utilized Receptor Tyrosine Kinase (RTK) Arrays to analyze the phosphorylation status of 49 RTKs. The cell lines were treated with TZ-1 and changes in RTK expression were assessed by quantitative PCR. Results: RMS cells intrinsically resistant to TZ-1 treatment expressed multiple activated RTKs including EGFR family of receptors, IGF-1R, IR, PDGFR, CREBBP, EP300, BRD4, ERBB4, AXL, DTK, HGF, FGFR4, and AK. Increased expression of these receptors was confirmed by qPCR. In contrast, Rh41/TZ-1 cells selected for acquired resistance to TZ-1 constitutively expressed activated RTKs (PDGFRB, FGFR4, AXL, DTK, VEGFR1). In Rh41 cells treated with TZ-1, the BRD4 inhibitor, IQ1 (300 nM, 24 Hr), blocked the induction of IGF-1R, IR, HGF, ERBB4, AXL, DTK, VEGFR1 and AK. However, it had less effect on the induction of FGFR 2/3/4 receptors. Further, combined treatment of TZ-1 and IQ1 reduced cellular proliferation of Rh41 cells more than TZ-1 treatment alone. Conclusions: We demonstrate that intrinsic resistance to the IGFR-1 targeted antibody TZ-1 is characterized by constitutive activation of multiple RTKs. In response to TZ-1 treatment in a sensitive cell line there is rapid induction of multiple RTKs indicating a dynamic response to inhibition of IGF-1R. Our data suggests that BRD4 is involved in induction of these signaling molecules and that combined inhibition of BRD4 along with the IGF-1R-targeted therapy can overcome this resistance and warrants further investigation.

Ewing sarcoma remains the second most common form of bone and cartilage cancer in children. Although EWS/FLI1 fusion protein (derived by chromosomal translocation) is known to induce aberrant transcription in the patient cells, why and how this molecule leads to tumorigenesis specifically in skeletal cell lineage is not understood. We previously reported a novel role of EWS/FLI1, which leads to constitutive activation defects through inhibition of EWS function. We further demonstrated that EWS interacts with Aurora B and relocates from inner centromere to the midzone (a midline structure that is composed spindles called the central spindle) during anaphase of mitosis. Disruption of EWS-directed Aurora B-relocation leads to defects in cytokinesis, and to induction of chromosome instability (CIN). EWS is an abundant molecule that is localized throughout the entire cytoplasm of anaphase, but how EWS specifically regulates midzone formation is not understood. A potential candidate mechanism is post-translational modification of EWS to modulate its activity in a spatial-temporal manner. Because previous studies showed that EWS/FLI1-T79 is a potential modification site of O-GlcNAcylation and phosphorylation, we hypothesized that the O-GlcNAcylated EWS/FLI1 contributes to the impairment of Aurora B relocation. Our study shows that high expression of O-GlcNAc increases the level of O-GlcNAcylated EWS/FLI1 accompanied by the impairment of the Aurora B relocation and of central spindle formation. Contrary, EWS/FLI1-T79A and EWS/FLI1-T79D (phospho-mimic mutant) does not impair the mislocation of Aurora B at the midzone, suggesting that the O-GlcNAcylation of EWS/FLI1 is responsible for mislocation of Aurora B at the midzone. The O-GlcNAc-dependent impairment of midzone formation by EWS/FLI1 may lead to the identification of therapeutic targets for Ewing sarcoma patients.

Essential role for cyclic-AMP responsive element binding protein 1 (CREB1) phosphorylation in the survival of medulloblastoma patients. Walderik W. Zomerman,1,2 Sabine L. Plasschaert,1 Frank J. Scherpen,1 Harm Jan J. Houghton1. 1Greehey Children’s Cancer Research Institute, UT Health San Antonio, San Antonio, TX; 2Grand Valley State University, Allendale, MI.

Our preclinical work showed that EWS/FLI1-T79 is a potential modification site of O-GlcNAcylation and phosphorylation, we hypothesized that the O-GlcNAcylated EWS/FLI1 contributes to the impairment of Aurora B relocation. Our study shows that high expression of O-GlcNAc increases the level of O-GlcNAcylated EWS/FLI1 accompanied by the impairment of the Aurora B relocation and of central spindle formation. Contrary, EWS/FLI1-T79A and EWS/FLI1-T79D (phospho-mimic mutant) does not impair the mislocation of Aurora B at the midzone, suggesting that the O-GlcNAcylation of EWS/FLI1 is responsible for mislocation of Aurora B at the midzone. The O-GlcNAc-dependent impairment of midzone formation by EWS/FLI1 may lead to the identification of therapeutic targets for Ewing sarcoma patients.

Targeting the polyamine-hypusine nexus for the treatment of neuroblastoma. Andre S. Bachmann,1,2 Raid El-Khawaja,3 Chad Schultz2. 1Michigan State Univ., Grand Rapids, MI; 2Grand Valley State University, Allendale, MI.

The highly conserved and unique post-translational hypusine modification is essential for the activation of a single cellular protein called eukaryotic initiation factor 5A (eIF5A). Hypusination of eIF5A represents an essential mechanism in the control of cell proliferation and has been linked to cancer. The hypusine modification of eIF5A requires the enzymes deoxyhypusine synthase (DHPS) and deoxyhypusine hydroxylase (DOHH) and, importantly, uniquely depends on the polyamine spermidine as a selectivte substrate. Polymamines including spermidine are frequently dysregulated in neoplastic disease and are critical for cell proliferation. Ornithine decarboxylase (ODC) is the sentinel enzyme in polyamine biosynthesis. We pioneered the repurposing of the irreversible ODC inhibitor alpha-difluoromethylornithine (DFMO) for neuroblastoma (NB), a devastating pediatric cancer of the sympathetic nervous system. Our preclinical work was confirmed by other groups and spurred two consortia (NMTRC and NANT) to test DFMO in independent phase I/II NB clinical trials. The oncogene MYCN is commonly amplified in high-risk NB patients and predicts poor prognosis. MYCN directly activates ODC (and eIF5A) and drives NB tumor progression, presumably through the activation of polyamines, but the precise molecular mechanisms are not fully understood. Since spermidine is the only molecule that can activate eIF5A through hypusine modification, we hypothesized that the polyamine-hypusine nexus provides a rational target site to identify new drug combinations that trigger synergistic anti-tumor effects. In this study we found that DFMO combined with DHPS inhibitor GC7 induced synergistic drug reactions in NB at concentrations that are not lethal on their own. While
each drug alone at higher concentrations induced p21/Rb-mediated G1/S cell cycle arrest, the combination of both drugs resulted in the induction of programmed cell death (apoptosis). The intracellular free polyamine levels (putrescine, spermidine, and spermine) were quantified by C-18 RP-HPLC and responded directly to drug treatments, suggesting specific drug targeting effects. This dual-drug combination approach that co-targets the blockade of the unique polyamine/spermidine-dependent hypusine-eIF5A signaling circuit known to be involved in cell proliferation might lead to more effective DFO treatment options by reducing high DFO doses currently needed while achieving better therapeutic outcomes in NB.

**#5829 Targeting TSLP-induce upregulation of Mcl-1 for the treatment of Ph-like ALL with CRLF2 alterations.** Cornelio Stojan, 1 Nathaniel George Mambo, 2 Pierce McCarthy, 2 Veritha Vidalis, 1 Jacqueline S. Coats, 1 Ineavely Baes, 1 Sinisa Dovat, 1 Shadi Farzin Gohar, 1 Dhimant Desai, 1 Muhammad Kamal, 1 Kimberly J. Payne, 1 Loma Linda Univ., Loma Linda, CA; 2California State University San Bernardino, CA; 3Pennsylvania State University, PA; 4Pennsylvania State University–Hershey, Hershey, PA.

B cell precursor acute lymphoblastic leukemia (B-ALL) is the most common childhood cancer. The subset of pediatric B-ALL patients at greatest risk for relapse and death have a gene expression profile similar to Philadelphia chromosome positive ALL. Approximately half of these Ph-like B-ALL are defined by genetic alterations that result in overexpression of the cytokine receptor, CRLF2. Stimulation of the CRLF2 receptor by the cytokine, TSLP, causes downstream activation of the Jak/Stat5 and PI3/AKT/MTOR pathways. Activation of these pathways has been associated with one prognosis and chemoresistance. A gene target of activated STAT5 in B cell precursors is Mcl-1, a Bcl family pro-survival molecule. Further, Mcl-1 protein levels are increased through post-transcriptional mechanisms induced by activation of the mTOR pathway. We hypothesized that circulating TSLP cytokine contributes to chemoresistance by increasing CRLF2 activation leading to increased Mcl-1 expression and that targeting Mcl-1 could be an effective strategy for treating Ph-like B-ALL with overexpression of CRLF2 (CRLF2 B-ALL). To test this hypothesis we cultured human CRLF2 B-ALL cell lines (MUTZ5 and CALL4) with and without TSLP for 3 days and evaluated expression of Mcl-1 by flow cytometry. We found that TSLP induced significant increases in Mcl-1 proteins in both cell lines. To determine if these results are reflective of what happens in patients, primary CRLF2 B-ALL cells from pediatric patients were cultured with physiological levels of TSLP (~20 pg/ml) and similarly evaluated. Physiological TSLP significantly increased Mcl-1 protein in primary CRLF2 B-ALL cells, including those with activating Jak mutations. Our next question was whether TSLP-induced increases in Mcl-1 could be effectively targeted with Mcl-1 inhibitors (MIM-1 or MIM-2). CRLF2 B-ALL cells were incubated with and without TSLP and treated with increasing doses of Mcl-1 inhibitors. The dose response curve achieved plateau by flow cytometry after 2 or 3 days. Mcl-1 inhibitors induced dose-dependent decreases in cell count and increases in caspase-3 activation and apoptosis (Annexin V/7-AAD). These corresponded with dose-dependent decreases in Mcl-1 protein, suggesting that both inhibitors target Mcl-1 for degradation. MIM-1 and Maritoclax showed efficacy against both CRLF2 B-ALL cell lines and primary patient specimens, including those with activating Jak mutations, although these responses were associated with decreased Mcl-1 expression levels in cells cultured with TSLP. Typically required twice the dose of Mcl-1 inhibitor to achieve the same effect observed without TSLP. These data provide evidence that TSLP can contribute to leukemia cell survival and identify Mcl-1 inhibitor as a candidate therapy for CRLF2 B-ALL. Ongoing studies are evaluating the efficacy of the Mcl-1 inhibitor, Maritoclax, in novel patient-derived xenograft models of CRLF2 B-ALL that provide physiological levels of human TSLP.

**#5830 A novel Notch-YAP circuit drives stemness and tumorigenesis in embryonal rhabdomyosarcoma.** Katherine K. Slemmons, Lisa E.S. Crose, Stefan Riedel, Manuela Sushmitha, Brian Belyea, Corinne M. Linardic. Duke University, Durham, NC.

Introduction: Rhabdomyosarcoma (RMS), a tumor characterized by skeletal muscle features, is the most common soft tissue sarcoma in children and adolescents. The standard of care treatment has not changed in over 40 years, resulting in a stagnant survival rate of less than 30% for high risk groups. Previous studies have identified the developmental pathways Notch and YAP as potent oncogenic signals in the embryonal subtype of RMS (eRMS). Understanding the signaling between Notch and YAP in cancers driven by these pathways, such as other cancers, will be crucial to designing rational combination therapies. Experimental Procedures: For in vitro assays, we utilized 3D sphere cell culture methods that permit the study of stem cell behavior. To analyze signaling, we performed genetic gain and loss-of-function (dox-inducible shRNAs and constitutively active constructs), and pharmacologic inhibition. Target validation was assessed by qPCR and immunoblot, and mechanism was determined by ChIP and limiting dilution assays. For in vivo experiments, we performed subcutaneous xenografts in immunocompromised mice. Immunohistochemistry was used to analyze protein expression in human and murine tumors. Statistical analysis was performed to assess significant differences. Results: We have discovered a novel signaling circuit, the Notch-YAP circuit, that is functional in eRMS. Inhibition of the circuit in eRMS xenografts does not reduce or cure tumors. Overexpression of the core Notch ligand Jagged1 (JAG1) and the core Notch transcription factor RBPJ can provide partial efficacy in vivo. In YAP knockdown tumors, Notch signaling is increased, while YAP transcriptional activity is decreased. Inhibition of Notch and YAP is necessary to silence the circuit’s signaling and growth. Importantly, nuclear Notch and YAP protein expression correlates in eRMS patient tumor samples, suggesting this circuit is intact in human eRMS tumors. Conclusions: While unidirectional signaling between the two pathways has been reported in metazoan development and rarely in human malignancy, this is the first finding of an intact bidirectional circuit between Notch and YAP that supports cancer cell stemness and tumorigenesis. This study provides mechanistic insight into the long-standing question of how eRMS cancer stem cells maintain plasticity. Additionally, while this signaling is identified in other RMSs, it may also be applicable to the well described eRMS tumor circuit, for example through Notch pharmacologic blockade, is not sufficient to shut down the circuit, as stemness and cell growth can be rescued by ectopic YAP. Rather, dual inhibition of Notch and YAP is necessary to silence the circuit’s signaling and sphere growth. Importantly, nuclear Notch and YAP protein expression correlates in eRMS patient tumor samples, suggesting this circuit is intact in human eRMS tumors. Conclusions: While unidirectional signaling between the two pathways has been reported in metazoan development and rarely in human malignancy.
Rho-associated kinase is a therapeutic target in neuroblastoma. Cecilia H. Dyberg, Susanne Fransson, Teodora Andonova, Baldur Sveinbjörnsson, Jessica Lännerholm-Palm, David Forsberg, Eric Herlenius, Tommy Martinsson, Per Kogner, John Inge Johnsen, Malin Wickstrom, Karolinska Institute, Stockholm, Sweden; Department of Medical and Clinical Genetics, Västerbotten Institute, Umeå, Sweden; University of Tromsø, Norway, Norway.

Background: Neuroblastoma is a peripheral neural system tumor that originates from the neural crest and is the most common and deadly tumor of infancy. The non-canonical Wnt/planar cell polarity (PCP) signaling pathway regulates cytoskeletal organization, migration and maturation of neural crest cell-derived neuroepithelial tumors. Here we show that neuroblastoma harbors frequent mutations of genes controlling the PCP signaling pathway and Rac/Rho signaling cascade important for proper migration and differentiation of neural crest cells during neurogenesis. The majority of these mutations were detected in GTPase activating proteins and guanine nucleotide exchange factors genes, which may result in inhibition of Rho and activation of Rho and was associated with aggressive high-stage neuroblastomas. Methods: We performed whole-exome sequencing of neuroblastoma samples of all clinical subgroups to search for mutations and genetic aberrations. Cytotoxic activity of Rho-associated kinases (ROCK) inhibitors was studied in cell viability assays. Morphology and invasion were studied with microscopy. The molecular mechanisms were characterized using cell- and molecular biology techniques. In vivo studies (xenografts and the transgenic mouse model TH-MYCN) in mice were carried out to validate the therapeutic effects and toxicity. Results: Exome sequencing detected frequent mutations and gene aberrations in genes controlling the activity of PCP signaling. Analysis of gene signatures and immunohistochemistry showed that high expression of ROCK1 and ROCK2 correlated with poor patient survival. Several mediators of Rac/Rho were differentially expressed in cell lines and patient samples. Pharmacological or genetic inhibition of ROCK, a key molecule in Rac/Rho signaling resulted in differentiation, inhibition of neuroblastoma cell growth and migration and degradation of MYCN protein. Finally, ROCK inhibition reduced the growth of established neuroblastoma xenografts in nude mice and repressed tumor progression in a MYCN-driven mouse model of neuroblastoma (T-MYCN) Conclusions: These results provide evidence that inhibition of the non-canonical/PCP signaling cascade using ROCK inhibitors suppresses the growth of neuroblastoma in preclinical models and suggest possibilities for improved treatment of high-risk neuroblastomas.

Targeting the transcription co-activator TAZ inhibits MYC-driven medulloblastoma. Yingchao Xue, Mingyao Ying. Kennedy Krieger Research Inst, Baltimore, MD.

Medulloblastoma (MB), the most common malignant pediatric brain tumor, results in significant neurological, intellectual and physical disability or death. Four major molecular subtypes (WNT, SHH, Group 3 and Group 4) have recently been described. The Group 3 MB, the most aggressive subtype, is more frequently associated with gene amplification and/or protein overexpression of the MYC (c-Myc) oncogene, hereby referred to as MYC-driven MBs. It is still unclear how MB cells activate and maintain high MYC expression, as only a small portion of MYC-high MBs is caused by MYC genomic amplification. MYC-targeted MB therapies are also lacking. Targeting MYC upstream activators is a promising strategy for inhibiting MYC-driven MBs, when compared to direct MYC inhibition that is still challenging. Here, we focus on the transcription co-activator TAZ, a novel MYC upstream activator and a potential therapeutic target for inhibiting MYC-driven MBs. TAZ (transcriptional co-activator with PDZ-binding motif) is an oncogenic driver in multiple human cancers. TAZ and its paralog YAP form complexes with other transcription factors, such as TEAD, to activate downstream gene targets. TAZ and YAP are transcriptional effectors of various signaling pathways, such as the Hippo pathway. We found for the first time that TAZ is an essential MYC activator in MB cells. TAZ but not its paralog YAP is highly expressed in MYC-amplified MB cells and their xenografts. TAZ silencing downregulates MYC and inhibits MB cell proliferation. Enforced TAZ expression in neuroblastoma cells indicates that TAZ-driven expression of ROCK inhibitors further showed that TAZ forms complex with transcription activator TEAD to bind to and transactivate MYC enhancers. For pharmacological TAZ targeting, we found that the FDA-approved drug Verteporfin (VP) inhibits TAZ-TEAD interaction, suppresses MYC expression and inhibits MB cell tumor propagation in vivo. We have also developed a nanoparticle formulation by using DSPED-PEG2000 micelles to achieve VP delivery across the blood-brain barrier in mice bearing brain tumor xenografts. In summary, our results provide novel insights into MYC upstream activators in MB, and also identify TAZ as a potential therapeutic target for inhibiting MYC-driven MBs. This knowledge may also be widely applicable to other TAZ/MYC-expressing human cancers, such as glioblastoma. Moreover, our studies support the effectiveness of VP treatment in pre-clinical MB models. These results and also the nanocarrier system for systemic VP delivery provide a solid foundation for VP clinical trials in patients with MB and likely other MYC-driven cancers.

Background: Cancer cell lines have traditionally been established in serum-containing medium though it has been questioned whether serum-grown cell lines faithfully represent the tumors they are derived from. Potential serum-driven induction of in vitro cultured cells could partly explain why xenografted cell lines often lack invasive growth and robust metastasis. Direct implantation of patient tumor material into mice, i.e. patient derived xenografts (PDXs), has shown to more closely mimic the original tumor growth pattern. By isolating cells from neuroblastoma PDXs and culturing the PDX cells under serum-free conditions, we expect to preserve a less differentiated phenotype, enabling us to use PDX cells as a source for identifying potential neuroblastoma stem-like cells. Moreover, to facilitate future drug screening, we investigated conditions that would allow us to grow neuroblastoma PDX cells adherently, without compromising their tumorigenic or metastatic capacity. Materials & Methods: PDX cells were cultured in stem cell medium or serum-containing medium for up to 7 days. RT-qPCR and WB were used to investigate the expression of sympathetic neuronal differentiation markers. For monolayer culture, cells were grown on laminin. Results: PDX cells can routinely be established as neurospheres in serum-free medium with retained tumorigenic and metastatic capacity. Addition of serum induces loss of sphere formation, adherent growth and a robust increase in sympathetic differentiation markers, both at mRNA and protein level. Serum-cultured cells also showed a decreased cell proliferation (without increased apoptotic rate, as determined by sub-G0/G1 analyses). The serum-induced differentiation was not irreversible since transferring serum-grown cells back to serum-free medium resulted in a phenotypic switch, with recovered proliferation and decreased expression of differentiation markers. Growing cells on laminin achieved adherent culture of PDX cells. This resulted only in slight morphological differentiation but did not affect growth rate or the cells tumorigenic and metastatic capacity. Conclusion: Culturing neuroblastoma PDX cells in serum-containing medium results in a more differentiated phenotype. Thus, avoiding serum appears to be a key strategy in order to preserve the phenotypic origin of these cells. The phenotypic effects of serum on tumor cells have largely been overlooked and might be a general effect on cancer cells explaining why serum-established cell lines do not metastasize and grow invasively.

Oncogenic activation of the serine synthesis pathway by the scaffolding protein menin. Laurie Kathleen Svoboda, Selina Shiqing Teh, Sudha Sud, Armand Bankhead, Brian Magnuson, Mats Ljungman, Costas Lyssiotis, Tomasz Cierpicki, Jolanta Grembecka, Elizabeth R. Lawlor. Univ. of Michigan, Ann Arbor, MI.

Developmental transcription programs are epigenetically regulated by multi-protein complexes including the DLL-containing trithorax (TrxG) complexes, which methylate H3K4 to promote gene transcription. We recently reported that the TrxG protein MLL1 and its binding partner menin are overexpressed by and function as oncogenes in Ewing sarcoma. Moreover, small molecule inhibition of the menin-MLL protein–protein interaction leads to loss of menin and MLL1 protein expression and to inhibition of growth and tumorigenicity. For the current study we investigated the mechanistic basis of menin-MLL1 mediated oncogenic activity in Ewing sarcoma. Bru-seq analysis was performed to identify changes in nascent gene transcription in Ewing sarcoma cells following exposure to the menin-MLL1 interaction inhibitor MI-503. Identiﬁed targets were validated by qRT-PCR, western blot, immunocytochemistry and by interrogation of published databases. Loss of function was achieved by lentiviral shRNAs and by inhibitor treatment. Exposure of three independent Ewing sarcoma cell lines to MI-503 resulted in significant and reproducible modulation of nearly 100 genes. Bioinformatics analysis of MI-503-regulated genes revealed that the serine synthesis pathway (SSP) was the most signiﬁcantly impacted pathway downstream of MI-503 treatment. The SSP has recently emerged as a major mediator of tumorigenicity in multiple human cancers. qRT-PCR confirmed reduced expression of SSP enzyme–encoding genes PHGDH, PSAT1 and PSPH in MI-503 treated cells. To determine if the SSP contributes to Ewing sarcoma pathogenesis we evaluated expression of SSP genes and proteins in
tumors and cell lines. Our findings showed that Ewing sarcomas express high levels of PHGDH, PSAT1, and PSPH and interrogation of the Cancer Cell Line Encyclopedia revealed that PHGDH expression is higher in Ewing sarcoma than in any other cancer in the database. Studies of Ewing sarcoma cells in serine and glycine free media showed that cells retain viability but that exposure to the PHGDH inhibitor, CBR-8844, inhibits ADPRT and arrests cells in both standard and glycine-free conditions, confirming the importance of the pathway to tumor pathogenesis. To determine how menin-MLL1 promotes SSP activation we performed loss of function studies and discovered that knockdown of menin, but not of MLL1, leads to a significant reduction in SSP gene expression, implicating menin as the primary mediator of SSP gene activation. Transcriptional up-regulation of Wnt/β-catenin signaling has been linked to ATP3 knockdown in both small cell lung cancer (SCLC) and multiple pediatric/adolescent and young adult (AYA); synovial sarcoma (SS), Ewing sarcoma (ES) and rhabdomyosarcoma (RMS) sarcomas, as well as soft-tissue sarcomas (STS) and bone sarcomas. We specifically included cell lines and SS and AS subtypes that were never phosphoprophored before, to reveal completely novel molecular insights into sarcoma pathology. Validations were performed in vitro, in vivo, and in patient tumor material. Our unique tyrosine phosphorylation data revealed a novel subclassification of sarcoma, and showed that particularly the pediatric/AYA sarcoma models did not cluster within their histological subgroup. Particular tyrosine kinases exhibited enhanced phosphorylation in particular subtypes, and we identified driver kinases with outlier levels of activation. ALK was identified as a completely novel and unexpected driver in the Aska-SS SS cell line, which was explained by an underlying ALK translocation.

Functional ALK dependency was confirmed with in vitro proliferation assays, showing high sensitivity for the ALK inhibitor TAE684 (IC_{50} 26.3 ± 3 nM) and the ALK/MET inhibitor crizotinib (IC_{50} 46.7 ± 5 nM). Patient specimens confirmed a clinical role for ALK in SS, with ALK immunopositivity in 14% (6/43) of patients and one 16y old patient harboring an ALK translocation, present in both adult (gastrointestinal stromal tumor as in 4 metastases. Other SS cell lines and sarcoma subtypes exhibited multiple activated tyrosine kinases, providing a rationale for combined targeting approaches. Indeed, high MET and PDGFRα phosphorylation in Yamato-SS SS cells predicted sensitivity to crizotinib and pazopanib (PDGFR) in vitro and in vivo. The clinical significance was again confirmed in a cohort of SS patients, in which MET or PDGFRα expression was detected in 58% and 84% of SS patients, respectively, with co-expression in 56%. Altogether, this is the first study to provide a deep insight into activated networks and molecular clustering patterns in sarcoma. Our integrated approach systematically identified and validated ALK and MET as novel and actionable drivers in SS.

**TUMOR BIOLOGY: Radioprotectors, Radiosensitizers, and Radiation Resistance**

#5838 Adhesion- and stress-related adaptation mechanisms eliciting glioblastoma radioresistance can be effectively circumvented by betal integrin/JNK co-targeting. Anne Vehlow,1 Erik Klapprath,2 Katja Storch,1 Ellen Dickreuter, Michael Seifert,3 Antje Dietrich,2 Rebecca Bütot,1 Achim Tonn,11 Thomas Silber,2 Markos Tzartos,2 and Yvonne Vorsatz,11

1OncoRay - National Center for Radiation Research in Oncology, Dresden, Germany; 2Institute for Medical Informatics and Biometry, Dresden, Germany; 3Department of Neurosurgery, Dresden, Germany.

Glioblastoma multiforme (GBM) is the most common brain tumor in adults and characterized by poor clinical outcome due to genetic and epigenetic alterations in resistance-mediated genes and destructive infiltration into the normal brain. Upon therapy, malignant tumors show adaptation to maintain their homoeostasis. Two critical determinants of this adaptation process are cell adhesion by betal integrins and stress signaling via c-Jun N-terminal kinases (JNK). Here, we evaluated the potential of simultaneous betal integrin/JNK targeting to overcome GBM adaption controlling radioresistance and invasion. Comparative Oncomine data base analysis was performed on the expression of JNK1/2/3 in GBM, betal integrin and its ligands in GBM with normal brain. Different human GBM cell populations (patient-derived, stem-like, established) were analyzed for sphere formation, clonogenicity, 3D collagen type-1 invasion, and cell cycling, chromatin organization, DNA double strand break (DSB) repair (γH2AX foci assay), broad-spectrum phosphoproteome analysis, FACS analysis and protein expression/phosphorylation upon irradiation (0-6 Gy x-rays) and chromotherapy (Temozolomide) with and without single and simultaneous inhibition of betal integrin (AIIB2) and JNK (SP600125, JNKi). The radiochemoresistant potential of AIIB2/JNKi was also investigated in an orthotopic GBM mouse model using stem-like cells. In contrast to JNK isoforms, betal integrin and col1 showed significant overexpression in GBM compared with normal brain. While single inhibition of betal integrin and JNK mediated cytotoxicity, only combined targeting resulted in radioresistance sensitization. Intriguingly, double AIIB2/JNKi treatment abrogated GBM cell invasion. Importantly, dual betal integrin/JNK inhibition elicited a significant reduction in tumor growth and longer survival of mice concomitantly treated with radiotherapy/Temozolomide. Mechanistically, JNK blocking induced betal integrin expression for
stabilizing diverse signaling pathways controlling cell cycling, invasion and radiochemoresistance. Radio sensitization by AIIB2/JNKii is caused by enhanced ATM phosphorylation and prolonged G2/M cell cycle arrest as well as impaired DNA double strand break repair in the context of elevated levels of eukratin. In summary, our data reveal that both beta1 integrin/JNK targeting efficiently impairs cancer cell radiosensitivity and radioresistance. In addition, our studies determine the intrinsically radiosensitive regions of the tumor are impacted by the radiochemoresistance and invasion. More in-depth evaluation is warranted to clarify the potential of this kind of beta1 integrin/JNK multimodal-targeting strategy administered concomitantly to standard radiochemotherapy in patients suffering from GBM.

#5839 Androgen receptor (AR): A novel target for radiosensitization in triple-negative breast cancers (TNBC). Benjamin C. Chandler,1 Corey W. Speers,1 Shuang G. Zhao,2 Melan Liu,2 Kari Wilder-Romans,3 Eric Olsen,3 Shiyam Nyati,1 Daniel Spratt,1 Daniel Wahl,1 Daniel Hayes,1 Felix Y. Feng,2 Lori J. Pierce1.1University of Michigan, Ann Arbor, MI; 2University of California, San Francisco, San Francisco, CA.

Purpose: Increased rates of local recurrence (LR) have been observed in TNBC despite chemotherapy and radiation (RT). Thus, approaches that result in radiosensitization in TNBC are critically needed. We characterized the RT response of 21 breast cancer cell (BCC) lines using clonogenic survival assays and paired this with high-throughput drug screen data, identifying AR as a top target for radiosensitization. We demonstrate that AR inhibition confers radiosensitization in vitro and in vivo, identified a biomarker of response, and characterize the mechanism of AR-mediated radiosensitization in TNBC. Materials/Methods: Clonogenic survival assays determined the intrinsic RT sensitivity of 21 BCC lines. IC50 values were determined for 130 clinical compounds and correlation coefficients were calculated using IC50 values and SF-2Gy. Gene and protein expression was measured using RNA Seq and RPPA arrays, respectively, in tumor samples (n=2,061) and BCC lines (n=51). AR function was assessed using gene knockdown (KD) or functional inhibition with anti-androgen drugs. We measured in vivo tumor growth with varying control and treatment groups (16-20 tumors/group). Kaplan-Meier analysis was performed to estimate local control. A Cox proportional hazards model and MVA were used to determine significant correlations with LR from GBM.

#5840 Radiosensitization with the c-MET inhibitor crizotinib in KRAS mutant colorectal cancer. Kyle C. Cuneo, Himabindu Kurupati, Ranjit Mehta, Theodore S. Lawrence, Mukesh K. Nyati. University of Michigan, Ann Arbor, MI.

Background: KRAS mutant colorectal cancers (CRC) are resistant to many targeted therapies including cetuximab. Novel molecular targets for KRAS mutant tumors may enhance the efficacy of chemoradiation. C-MET plays important roles in treatment resistance, tumor invasion, and metastasis. In this study, we used a small molecule inhibitor of c-MET, crizotinib in cetuximab resistant mutant KRAS driven CRC cell lines and assessed radiosensitization. Methods: To test the effect of c-MET inhibition on CRC cells we used the KRAS mutant cell lines HCT116, DLD1, and LoVo. Colony formation assays were performed to assess the effects of crizotinib and cetuximab in combination. Immunoblot analysis was used to determine the effect of crizotinib on c-MET and downstream pathways including ERK and AKT phosphorylation. We then selected doses of crizotinib below the IC50 and assessed clonogenic survival with radiation. To study potential mechanisms of radiosensitization cell cycle analysis was performed using flow cytometry. The effect of c-MET inhibition on cellular function was assessed using cell migration assays. Results: We first performed a series of clonogenic survival assays with crizotinib and cetuximab to determine the IC50 for each cell line. As expected, the KRAS mutant cell lines LoVo, HCT116, and DLD1 were resistant to cetuximab (surviving fraction greater than 95% at 100 µg/mL). These results were consistent with c-MET being radiosensitive to c-MET inhibitor crizotinib with IC50 values of 14.4 nM for LoVo, 316 nM for HCT116, and 217 nM for DLD1. Immunoblot analysis showed that crizotinib at concentrations near the IC50 for each cell line attenuated c-MET phosphorylation and downstream signaling pathways including ERK and AKT. Crizotinib further blocked radiation induced c-MET phosphorylation and attenuated activation of downstream signaling pathways. We then performed a series of clonogenic survival assays to test the radiosensitizing potential of crizotinib. Pretreatment with crizotinib for 24 hours radiosensitized LoVo and DLD1 cell lines with enhancement ratios of 1.66 and 1.25, respectively. Interestingly, treatment with crizotinib for 1 hour prior to radiation had only modest dose enhancement, suggesting that prolonged exposure to crizotinib is required for optimal radiosensitization. Cell cycle analysis revealed minimal G1 arrest with crizotinib. Additionally, crizotinib completely blocked HGF and EGF induced cell migration. Conclusions: Inhibition of c-MET with crizotinib effectively sensitizes cetuximab resistant KRAS mutant CRC cell lines to radiation. Given the important role c-MET plays in treatment resistance, crizotinib has the potential to improve the outcome of patients with locally advanced rectal cancer undergoing radiation therapy.

#5841 Hypoxic tumors can be sensitized to radiation therapy by repurposing papaverine as an inhibitor of mitochondrial respiration. Martin Bence,1 Joanna Papandreu,2 Xiangqian Hong,2 Bing Yu,2 Nicholas Denko1.1Ohio State University Wexner Medical Center, Columbus, OH; 2The University of Akron, Akron, OH.

Tumor hypoxia is a characteristic feature of solid tumors. Low oxygen tension represents a barrier to effective radiation therapy because oxygen is required to fix the DNA damage induced by ionizing radiation. Many strategies have been proposed as a means to increase the radiosensitivity of hypoxic tumors but the clinical benefits have been disappointing. Finding an effective way to radiosensitize hypoxic tumors thus represents a major challenge for improving the current protocols for clinical radiation therapy. Decreasing the demand for oxygen within the tumor has been proposed as a way to reduce hypoxia, as reduced demand could lead to increased tumor oxygenation prior to delivery of radiation. Although several compounds have been proposed based on this approach, the toxicity and/or required dose have proven to be a limitation of their potential clinical benefit. Papaverine is an opiate alkaloid that has been used in clinical practice for over 70 years as a smooth muscle relaxant. The drug has a long history in its off-target effect limiting mitochondrial oxygen consumption. We therefore hypothesized that papaverine could effectively radiosensitize hypoxic tumors by decreasing tumor hypoxia. At clinically achievable concentrations in the low micromolar range, papaverine efficiently reduced the rate of oxygen consumption (OCR) in all tested cell lines in vitro. Within the first 30 minutes, 10 µM of the drug reduced the OCR by 30-40%. We identified the mechanism of action as OCR reduction as direct binding and inhibition of mitochondrial complex I, II, and III. 10 µM of the drug reduced the OCR by 30-40%. We identified the mechanism of action as OCR reduction as direct binding and inhibition of mitochondrial complex I, II, and III. Importantly, a single dose of 2 mg/kg papaverine injected I.V. significantly increased tumor oxygenation in vivo by 1.2-1.3 fold in nude mice harboring E0771 and A549 xenografts. Because normal tissue is fully oxygenated, we found muscle oxygenation remained unchanged after drug delivery. Finally, 2 mg/kg papaverine injected 35 minutes prior to a single dose of irradiation resulted in a 2.0 fold relative growth delay in E0771 tumors compared to irradiation alone. In addition, in the more hypoxic A549 xenografts, the benefit provided by papaverine was a 3.0 fold relative growth delay. In conclusion, according to our data a single, clinically relevant dose of papaverine administered shortly before irradiation reduces tumor hypoxia and thus provides significant benefit over irradiation alone, strongly highlighting its potential to improve current strategies to enhance response to radiation therapy.

Photodynamic therapy (PDT) involves the combination of a photosensitizer and light of a specific wavelength. Upon light activation in the presence of oxygen, photosensitizer molecules generate reactive oxygen species that cause cytotoxicity by inducing oxidative stress. Aminolevulinic acid (ALA) is a pro-drug used for the diagnosis and PDT treatment of various solid tumors based on
endogenous production of heme precursor protoporphyrin IX (PpIX). Although all human cells express heme biosynthesis enzymes and produce PpIX, tumor cells are often found to have higher PpIX production and accumulation than normal cells, allowing for the detection and treatment of solid tumors. In exploring ALA-based tumor detection and therapy in breast cancer, we have reported that high ALA-PpIX was accumulated in triple negative breast cancer cells (TNBC) contributes to reduced PpIX levels in tumor cells, causing cell resistance to ALA-PDT. The administration of an ARBG2 inhibitor Ko143 was able to reverse cell resistance to ALA-PDT by increasing PpIX levels. In this study, we showed that some kinase inhibitors were able to increase ALA-mediated PpIX by inhibiting ARBG2 activity. Particularly, our results demonstrate that lapatinib, a inhibitor of EGF/Her2, increased ALA-PpIX and cell sensitivity to ALA-PDT in the MDA-MB-231 TNBC cells. Lapatinib treatment had little effect on MCF10A breast epithelial cells. These results indicate that small molecule kinase inhibitors such as lapatinib can be used for enhancing ALA-based tumor detection and PDT in tumors with high ARBG2 activity.

**#5843 Role of CDK9 inhibition as a sensitizer to radiation in esophageal adenocarcinoma:** In vitro and in vivo efficacy study. Omkara Lakshmi M, Veeranki, Rashmi Dokey, Alicia Mejia, Zhimin Tong, Jianhu Zhang, Yawei Qiao, Pankaj Kumar Singh, Rithvik Kathakadha, Barbara Minoo, Jaime Rodriguez Canales, Steven Lin, Sunil Krishnan, Dipen Maru. UT MD Anderson Cancer Ctr., Houston, TX.

Preoperative chemoradiation in neoadjuvant setting is the standard of care for pre-region esophageal adenocarcinoma (EAC). However, less than 30% of patients develop complete pathological response indicating need for newer therapeutic strategies. Cyclin dependent kinase 9 (CDK9) is found to be over expressed in EAC compared to Barrett’s esophagus. Our previous studies demonstrated strong antitumor effects on inhibition of CDK9 in EAC both in vitro and in vivo. Here we report augmented tumor regression in irradiated xenografts on combination with Flavopiridol, a well-established clinically used CDK inhibitor, compared to single modality treatments. In vitro studies indicate that Flavopiridol could radiosensitize FLO-1 and SKGT4 EAC cells with sustained 53BP1 foci especially in SKGT4 cells. Flavopiridol and BAY1143572, a more selective inhibitor of CDK9, could radiosensitize additional EAC radiation sensitive and resistant cell lines (SKTG4-R, OE-33 and OE-33-R) as analyzed by MTT assay, apoptosis, formation of 53BP1 foci and clonogenic assay. Flavopiridol and BAY1143572 showed a radio-synergistic action by downregulating MCL-1 and Axl. In conclusion, the radio-sensitizing capacities of CDK9 inhibitors presented here suggest that their adjuvant administration might improve EAC therapy.

**#5844 Suberylnolide hydroxamic acid, a histone deacetylase inhibitor, improved radiosensitivity of human hepatocellular carcinoma.** Fang-Esin Chen,1 Ching-Fang Yu,2 Ji-Hong Hong,2,3 Chang Guang University, Taoyuan City, Taiwan; 3Chang Guang Memorial Hospital, Taoyuan City, Taiwan.

Hepatocellular carcinoma (HCC) is a leading cause of cancer–related death worldwide. Radiotherapy (RT) is one of modalities for HCC therapy in clinics, but the therapeutic effect is unsatisfactory due to high radiosensitivity of normal liver tissues that limits the optimal dose. This study is to develop a new therapeutic approach to enhance the efficiency of RT on HCC tumors. Suberylnolide hydroxamic acid (SAHA), a FDA approved chemotherapeutical drug, is an inhibitor of histone deacetylase (HDACs) and has been reported to enhance radiosensitivity in many cell lines. This study hypothesized that combination of SAHA and RT could improve tumor control on HCC tumors. HCC-834 cell, a primary culture of human HCC, had a dose-dependent response to RT when analyzed by clonogenic assay. SAHA had mild cytotoxicity to HCC-834 cell (IC50 = 16.0 μM). Combination of SAHA and RT reached a synergistic effect to prevent colony formation. In detailed, the radio-sensitizing capacities of CDK9 inhibitors presented here suggest that their adjuvant administration might improve EAC therapy.

**#5845 Identification of proteasome pathway and a novel serine threonine kinase DCLK3:** Potential therapeutic targets for innately radiation resistant glioblastoma cells. Jacinth Rajendra, 1Keshava Dutta, 1Sheikh Burhan Ud Din Faroquee, 1Raja Reddy, 1Nilesh Guality, 2Ektok Kantak, 1Atilash Moiyadi, 1Prassana Venkataraman, 1Kakoli Bose, 1 Amit Dutt, 1 Harsha Gowda, 2Shilpee Dut, 1Advanced Centre for Treatment Research and Education In Cancer, Khagr, Navi Mumbai, India; 2Institute Of Bioinformatics, Bangalore, India.

INTRODUCTION: Glioblastoma resistance and recurrence is attributed to the presence of innately Radiation Resistant (RR) cells present in the heterogeneous parent tumour. However, targeting these cells has been impossible due to inaccessibility of these cells. METHODOLOGY We therefore recapitulated clinical scenario of resistance in a cellular model developed from fresh primary GBM patient samples and cell lines. The model allowed us to capture 1) Parent cells 2) innately Radiation Resistant cells - less than 10% of the parent population and 3) Relapse (R) cells. To identify the targetable proteins governing the survival of RR cells, we performed iTRAQ based quantitative proteomic analysis on all the three populations from GBM cell line (SF268). RESULTS The proteomic data analysis identified 34 proteins as differentially present in RR population of which 22 were upregulated and 12 were downregulated. A GENE STRING analysis of all the different proteins in RR population revealed putative interaction of a novel serine threonine kinase DCLK3 with 14-3-3 zeta. The increased expression of DCLK3 and 14-3-3 zeta was confirmed by western blots in RR cells of two GBM cell lines and 8 patient samples. Meta-analysis of 242 tumor samples from COSMIC database showed DCLK3 overexpression in 232 tumors. Furthermore, it harbours 8 missense deleterious mutations, 6 of which were in the kinase domain, indicating towards an important kinase function of this protein. We hypothesized that DCLK3 mediated interaction and phosphorylation of 14-3-3 zeta modulated 14-3-3 zeta functions facilitating RR cell survival. For this, first we wanted to see if DCLK3 and 14-3-3 zeta can interact together. In silico docking of DCLK3 with 14-3-3 zeta did show interaction. This interaction was confirmed by in vitro immunoprecipitation studies. Further studies are ongoing to understand the importance of these proteins and their interaction in GBM recurrence. Additionally, pathway analysis of differentially upregulated proteins in RR cells revealed deregulation of the proteins involved in Ubiquitin-Proteosome System. Indeed, proteasome activity assay showed increased proteasome activity in the RR population of GBM cell lines and Patient samples. Accordingly, Bortezomib, a proteosome inhibitor induced significant apoptosis in the RR population at a concentration significantly lower than that required for inducing apoptosis in the parent cells. SIGNIFICANCE In conclusion this is the first study to identify a proteome signature of innately radiation resistant cells of GBM and identify proteasome pathway and a novel serine-threonine kinase DCLK3 in RR cells as a potential therapeutic target to inhibit GBM radioresistance and recurrence.

**#5846 The use of sodium sulfide, a hydrogen sulfide donor, to sensitize glioblastoma multiforme to photon and proton radiotherapy.** Adam Xiao,1 Rajesh Pidikiti,1 Matthew Maynard,1 Nader Sheibani,1 Lynn Harrison1, J. Louisiana State University Health Sciences Center Shreveport, LA; 2Willis-Knighton Cancer Center, Shreveport, LA; 3University of Wisconsin School of Medicine and Public Health, Madison, WI.

Glioblastoma multiforme (GBM) is the most common glial tumor accounting for 12-15% of all brain tumors worldwide. It is a rapidly progressing, life-threatening disease with a median survival of 3-6 months when left untreated. Minimal advancements in the treatment of GBM have limited its management. Conventional treatment with surgical resection of the primary tumor followed by photon radiation (60 Gy in 2 Gy fractions) in combination with adjuvant chemotherapy can limit recurrence and prolong median survival to 15 months. Proton radiotherapy has received increased attention in recent years due to its more precise energy deposition and 10% higher relative biological effectiveness (RBE) when compared to photon therapy. Several clinical trials have shown that high dose photon/proton therapy reduces central recurrence rate and extends median survival of GBM patients to 21-6 months. Unfortunately, the high rate of radioresistance has limited its widespread adoption. Radiosensitization agents may overcome this problem by allowing for the use of lower radiation doses to achieve comparable cytotoxic effects; however, no radiosensitizers are currently approved for the treatment of GBM. The current study supported our hypothesis and demonstrated that SAHA combined with local RT was effective on inhibiting DNA repair and anti-tumor growth. This study provided a new strategy on HCC tumor therapy that SAHA could act as a radiosensitizer to improve the therapeutic efficiency of RT on HCC tumors.
examines the use of sodium sulfide (Na2S), a hydrogen sulfide donor, as a radiosensitizing agent for both photon and proton therapy in two human glioblastoma cell lines, T98G and U87-MG. Survival curves were generated for T98G cells using a colony forming assay. Protons had an increased RBE of 1.18, which is in close agreement to the accepted RBE of 1.1. Na2S (0 μM, 10 μM, 100 μM, 500 μM, 1000 μM) was given as a pre-treatment in two 2-hour incubations: 2 hours prior to radiation and again immediately before radiation. Na2S alone exhibited a concentration dependent cytotoxic effect with maximal killing of approximately 50% at 500 μM. Further increases in sodium sulfide up to 1000 μM had no effect on cell survival. Similar killing was not observed in a non-cancer mouse retinal endothelial cell line even at extremely high doses of 1000 μM suggesting that Na2S cytotoxicity is specific and limited to cancer cells. Na2S increased killing in both photons and protons at 6 Gy by decreasing the surviving fraction from 27.7% to 20% and 16% to 3% respectively. Initial studies into the mechanism of radiosensitization using bleomycin as a radiomimetic agent have suggested Na2S increases the number of DNA double strand breaks (DSB), a highly cytotoxic form of DNA damage, as seen by γH2AX staining in both T98G and U87-MG cells. The benefits of high dose radiation therapy, particularly with proton boost, in the treatment of high grade central nervous system tumors such as GBM are apparent, but the increased risk of radionecrosis has limited its use. While further studies need to be conducted to elucidate the exact mechanism, preliminary results strongly suggest that sodium sulfide can act as a radiosensitizing agent by increasing DNA DSB formation.

We also investigate the inflammatory -cytokine profiles in the irradiated lung tissue by protein array. The results revealed that fucoidan administration changes the inflammatory -cytokine expression pattern in in the irradiated lung tissue. Conclusions: This study demonstrated that inflammatory -cytokine expression after whole lung irradiation is correlated with neutrophil accumulation and can be influenced by fucoidan supplementation. Further studies might prove that fucoidan can modulate the inflammatory -cytokine expression pattern which may lead to attenuates radiation pneumonitis and fibrosis. It is potential to be a therapeutic molecular to attenuate or prevent radiation pneumonitis.

#5847 SIRT1 protects against radiation-induced lung injury via de-acetylating the Ku70 and P65. Xianxin Xue, Lin Zhou, Feifei Na, Lei Deng, Jie Liu, Bo Li. 1 Adam Dicker, 2 You Lu. 1 West China hospital, Sichuan university, Chengdu, China; 2 Thomas Jefferson University, Philadelphia, PA.

Radiotherapy-induced lung injury (RILI) is a common and serious complication in the radiation therapy of thoracic cancer, which significantly restricts the radiation doses of tumor. The prevention and treatment of RILI have long been clinical challenges. SIRT1 is a NAD+-dependent protein deacetylase and the exact role of SIRT1 in RILI remains unclear. The aim of this study is to investigate the prevention and repairing efficacy of RILI by adenosine-mediated SIRT1 gene overexpression in a mice model. Our studies confirmed that the protein expression and activity of SIRT1 in lung tissues were decreased in RILI mice models in a time-dependent manner, but the mRNA expression level was not obviously changed. The activity of SIRT1 was elevated by orally given resveratrol, an agonist of SIRT1. The extent of RILI could be evidently alleviated by orally given resveratrol, as assayed by histopathology, malondialdehyde (MDA) and plasma cytokines (IL-1β, TNF-α and active TGF-β1). Overexpressing SIRT1 could obviously mitigate the extent of RILI (H&E staining and CT scan), the concentration of MDA and ROS in lung, IL-1β and active TGF-β1 in plasma; as well as improve the mice survival. Moreover, SIRT1 could inhibit the radiation-induced DNA damage in vitro. In vitro Co-IP experiment showed that the expression of SIRT1 in irradiated cells was reduced and the acetylated-Ku70 was increased; over-expressing SIRT1 promoted the de-acetylation of Ku70; interference of Ku70 could reverse the effect of SIRT1 in DNA repair. Furthermore, overexpressing SIRT1 could inhibit the acetylation level of NF-κB subunit RELA (P65) in lung tissue; in vitro gene expression showed the SIRT1 inhibited the NF-κB transcriptional activity. In conclusion, our results suggest that SIRT1 could evidently mitigate the RILI, repair the irradiation-induced DNA damage and inflammation via de-acetylating the Ku70 and P65. Our study may provide new avenue for the prevention and treatment of RILI in clinic.

#5848 Fucoidan administration attenuates radiation pneumonitis and fibrosis through reducing inflammatory cytokine expression in lung tissue. Szu-Yuan Wu, Taipei Medical University - Wan Fang Medical Center, Taipei, Taiwan.

Purpose: There is no well-known compound to prevent radiation pneumonitis (RP) or prophylactically use to attenuate the toxicity of RP. RP is one of major complications in chest part irradiation and limitations of radiation dose. Fucoidan is a natural sulfated polysaccharide found in the brown algae and brown seaweed. Recent studies have demonstrated its anti-inflammation effect. Since RP is an radiation induced inflammatory and fibrosis related complication, we investigated the effect of fucoidan administration on radiation pneumonitis and fibrosis. Materials and Methods: In this study, we compared the pneumonitis and fibrosis in lung tissue specimen between the lungs irradiated (10Gy/one shot) C57BL/6 mice with or without Fucoidan administration (200mg/kg/day, oral gavage for 14 days). Results: The results demonstrated that fucoidan administration attenuates pneumonitis and fibrosis in lung tissue. We found the accumulation of neutrophils in irradiated lung tissue was decreased, and the radiation induced Masson trichrome staining fibrosis was decreased.

#5849 Exosomes promote survival and migration in squamous head and neck cancer cells after ionizing radiation: Evidence for a bystander effect. Lisa Mutschelknaus,1 Omid Azimzadeh,2 Theresa Heider,1 Claudia Winkler,1 Marcus Vetter,2 Soile Tapio,1 Janine Merle-Pham,1 Rosemarie Kell,2,3 Stephan Huber,2 Lena Edalat,2 Vanja Radulovic,2 Natasa Anastasov,3 Carsten Michael,2 Michael John Atkinson,1 Simone Moertl1. 1 Helmholtz Zentrum München, Neurherberg, Germany; 2 Independent Scientist, Germany; 3 University of Tübingen, Tübingen, Germany; 4 Technical University of Munich, Munich, Germany.

Exosomes are important intercellular communicators in the acute radiation stress-response. Here we show that exosomes from head and neck tumor cells confer protective signals to their neighboring cells. This promotes the tumorigenic and radiosensitive phenotype of head and neck cancer cells. Isolation of exosomes was performed by serial ultracentrifugation of conditioned medium collected from irradiated or non-irradiated head and neck cancer cell lines M Byrne and FaDu. Quantification by NanoSight technology indicated an increased exosome release from irradiated compared to non-irradiated cells 24 hours after radiation treatment. To test whether the released exosomes influence the radiation response, exosomes isolated from non-irradiated and irradiated donor cells were transferred to non-irradiated and irradiated recipient cells. We found an enhanced uptake of exosomes, when transferred to irradiated recipient cells compared to the transfer to non-irradiated cells. Functional analyses indicate increased survival of irradiated recipient cells after exosome transfer. These findings mesh with increased DNA double strand break repair that we found after the transfer of exosomes isolated from irradiated cells. Moreover we observed an increased migration and enhanced chemotaxis induced motility after the transfer of exosomes isolated from irradiated cells. To investigate whether differential protein loading into exosomes is responsible for the functional differences we performed proteome analysis of the exosomes. We have identified 679 proteins, of which 39 were up- and 36 were downregulated by irradiation of the donor cells. In a good agreement with our functional assays, the proteome profiling showed that exosomal proteins were mainly involved in wound healing. Exosomes are functional components of the response of tumor cells to therapeutic radiation exposure. In a clinical context these results suggest that radiotherapy modified exosomes may influence the cancer progression, metastasis and therapeutic success.

#5850 Salicylate sensitizes prostate cancer (PrCa) to radiotherapy; activation of AMPK and suppression of lipogenesis. Theodoros Tsakiridis,1 Karolina Marcinko,2 Lindsay Broadfield,2 Linda Villani,2 Carrie Gerdes,1 Danitra Maharaj,3 Tom Farell,1 James Wright,1 Gregory Steinberg2.

Radiotherapy (RT) is a key therapeutic modality for PrCa that achieves reasonable disease control rates in localized disease. However, this requires dose-escalated RT, which is associated with increased toxicity to surrounding tissues and leads to deterioration of patient quality of life. Improving the therapeutic ratio in PrCa RT is of high clinical importance. Aspirin has an established role in cancer prevention and studies suggested association with improved PrCa outcomes. It was shown that its metabolite salicylate (SAL) binds directly and activates the metabolic stress sensor AMP-activated kinase (AMPK). This is likely achieved through direct binding to the AMPK β1 subunit, leading to enhanced AMPK activity through suppression of AMPK α-subunit T172 de-phosphorylation. In this study we examined the ability of SAL to sensitize PrCa to RT. Hormone insensitive (PC3) and sensitive (LnCap) human PrCa cells, as well as PC3 xenografts grown in immunocompromised nude mice were subjected to SAL and RT treatments. SAL mediated a dose-dependent inhibition of proliferation and donogenic survival in both PrCa cell lines and suppressed de novo lipogenesis (DNL). This was detected at μM concentrations of the drug, which can be safely achieved in human circulation. SAL (100-500 μM) radio-sensitized PC3 and LnCap cells, and reduced the ability of SAL to inhibit DNL. In animals treated with conformational RT (10Gy) to the tumor xenografts, Salazole feeding (chow diet containing 2.5 gr/kg) enhanced the cytotoxicity of RT detected as reduced tumor growth kinetics and weight and volume at sacrifice. Salicylate treatment of cells or salazate feeding of mice led to increased AMPK activity in cells and tumors,
inhibitory phosphorylation of Acetyl-CoA Carboxylase and reduction of Akt-Thr308 phosphorylation. These results indicate that SAL could improve radiation response in PrC through a mechanism involving the suppression of DNL. This is achieved at clinically attainable doses of SAL. This work supports prospective investigation of SAL as a radio-sensitizer in early phase clinical trials of localized PrC.

Brain tumor xenografts initiated from human glioblastoma (GBM) stem-like cells (GSCs) simulate many of the characteristics of GBMs in situ including extensive invasiveness, phenotypic heterogeneity and radiosensitivity. As an approach to investigating the relationship between these aspects of GBM biology and tumor cell proliferation, we used the halogenated thymidine analog CldU (5-chloro-2'-deoxyuridine), which is incorporated into DNA during S-phase, to identify proliferating cells in orthotopic brain tumor xenografts. Specifically, CD133+ NSC11 GSCs were implanted into the right striatum of nude mice; at various times after tumor cell implantation CldU was delivered in a series of daily intraperitoneal (IP) injections. Subsequent immunohistochemical analyses of CldU incorporation along with the GSC marker SOX2 was then used to determine the percentage of proliferating tumor cells in the mouse brain. NSC11 tumors are first detectable using bioluminescent imaging (BLI) at day 21 post-implantation. After 4 daily injections of CldU beginning on Day 21, approximately 60% and 30% of tumor cells were CldU positive in the white matter (corpus callosum) and grey matter (striatum), respectively. However, when CldU injections were initiated on Day 28 post-implantation, approximately 80% of cells were positive in both tissue locations after 4 doses, which corresponds to a rapid tumor growth phase according to bioluminescent imaging. Tumor cells were also detected in the left hemisphere and had lower percentages of CldU positive cells as compared to the right hemisphere (site of implantation), which illustrates the extensive invasive capacity of this GSC line and is consistent with the "grow or go" concept whereby GBM cells switch between proliferative and non-proliferative states.

2% of tumors cell were CldU positive in the white matter of the 3x12Gy-treated tumors and no proliferating cells were detected in the grey matter. These values can be compared to 50% and 40% CldU positive cells in the white and grey matter, respectively, of the sham irradiated tumors. Our data indicates that the unexpected membrane-to-nuclear trafficking of DUOX2 significantly reduces the levels of serum protein oxidation. Taken together these data suggest that DUOX2 could potentially be used as a biomarker to stratify patients and follow the efficacy of clinical application of chemopotentiation by LDFRT.

#5853 Peroxiredoxin I-targeted AMRI-59 has a role of radiosensitizer by promoting induction of ROS/h2AX/caspase pathway and suppression of ERK. Wan Gi Hong,1 Jeong Hyun Cho,2 Ju Yeon Kim,1 Eun Ah Lee,2 Sang Gu Hwang,1 Yong Shin Chang,1 Hong Duck Um,1 Jong Kuk Park1,2. KIRAMS, Seoul, Republic of Korea;1 Kyung Hee University Hospital, Seoul, Republic of Korea;2 Ewha Womans University, Seoul, Republic of Korea.

We have identified AMRI-59, one of small molecule, is specific pharmaceutical inhibitor of peroxiredoxin (PRX) I enzyme activity in our previous study. In this study, we tried to prove whether AMRI-59 has role of radiosensitizer against non-small cell lung cancer cells - NCi-H460 and NCi-H1299. The radiosensitizer effects of AMRI-59 was tested with MTS assays. The in silico and in vitro results suggest that induction of mitochondrial potential via enhancement of PrxI oxidation, which subsequently induced one of DNA damage markers - phospho-h2AX, and suppressed phospho-ERK of ERK, and, finally, activated caspase-3. Notably, inhibition of ROS production prevented ERK suppression, and inhibition of ERK in addition of combination with AMRI-59 and IR increased caspase activation and apoptosis. In a xenograft assay, combination with AMRI-59 and IR delayed tumor growth by 11.4 days compared with controls, yielding an enhancement factor of 1.48. Collectively, these results indicate that AMRI-59 functions as a Prx1 - targeted radiosensitizer by induction of apoptosis through activation of a ROS/h2AX/caspase pathway and suppression of ERK.

#5854 TIE2-mediated epigenetic marks regulate therapeutic resistance of glioblastoma. Mohammad Belayat Hossain,1 Renuhuma Shifat,1 Jingyi Li,1 Yisel Rivera-Mokina,1 Francisco Puerta Martinez,2 David G. Johnson,3 Mark T. Bedford,4 Mien-Chie Hung,1 Erik P. Sulfman,1 Frederick Lang,1 Raymond Sawaya,4 Candelaria Gomez-Manzano1. 1UT MD Anderson Cancer Center, Houston, TX; 2UTMD Anderson Cancer Center, Smithville, TX.

Glioblastomas (GBs), the most common subtype of primary brain tumors in adults, are resistant to current strategies of surgery, irradiation and chemotherapy with a median survival that ranges from 9 to 15 months. GBs invariably recur after therapy due to the presence of cells exhibiting a multidrug-resistance phenotype in the core of the tumor. There is an urgent need of developing the new therapeutic strategies for brain tumor treatment including the identification of novel molecular pathways regulating this resistant phenotype. One of the key phenomena of GB is that tyrosine kinase receptors (TKRs) are abnormally regulated and related to poor treatment outcomes. We have previously reported the expression of TIE2 in human surgical glioma specimens in relation to malignancy, and the role of TIE2 in endothelial-glia adhesion, tumor invasion and multi-drug resistance of gliomas. Recently, we have identified that the unexpected membrane-to-nuclear trafficking of TIE2 is related to radiosensitivity of brain tumor stem cells. Interestingly, TIE2 binds, upon irradiation stress, to DNA/protein complexes and directly phosphorylates histones. Specifically we discovered a new histone H4 mark (H4pY31) that is read by ABL1. TIE2/H4pY31/ABL1 complex binds to DNA repair proteins, such as ATM, DNA-PK, and pCHK2, activating a NHEJ DNA repair mechanism. In an effort to find the molecular mechanisms underlying TIE2 nuclear translocation, we identified that TIE2 binds and directly phosphorylates cavelin-1 (CAV1) at Tyr14 residue in vitro and in vivo. Importantly, CAV1-pTyr14 is necessary for the translocation of both TIE2 and CAV1 to the nucleus. We also uncovered new TIE2-mediated epigenetic marks. Thus, TIE2 binds and phosphorylates histone H2B at Tyr37 and this modification enhance the recruitment of DNA repair proteins to the DNA damage site. Our results summarize that upon irradiation TIE2 localizes to the nucleus where it is involved in key cellular functions by directly phosphorylating core histones, and recruiting SH2 domain proteins to the DNA damage sites, that are complexing to the DNA repair machinery. Our discovery related to tyrosine modifica-
tion of core histones might be of high significance to understand the resistance of cancer to DNA-damage inducers, which eventually might result in the design of TIE2-targeting combinational therapies for patients with GBs.

#5855 Radiosensitization of cervical cancer cells by HDAC inhibitors. Ima Paydar,1 Alfredo Velena,2 Scott Grindrod,3 Mira Jung,3 1MedStar Georgetown University Hospital, Washington, DC; 2Georgetown University, Washington, DC; 3Shuttle Pharmaceuticals, Inc, Rockville, MD.

Introduction: While histone deacetylase (HDAC) inhibitors have demonstrated in vitro and in vivo radiosensitization in several human cancer cell lines, the efficacy and mechanism of action of HDAC inhibitors in HPV-positive cancers are poorly understood. We hypothesize that HDAC inhibitors can be used to treat HPV-positive squamous cell carcinomas by enhancing radiosensitivity.

Methods: The cellular cytotoxicity of ten HDAC inhibitors was examined in HPV-positive (CaSkï, SiHa, HeLa) and HPV-negative (C33a) cervical cancer cell lines by the WST-8 [2-(2-methoxy-4-nitrophenyl)-3-(4-nitrophenyl)-5-(2,4-disulfophenyl)-2H-tetrazolium, monosodium salt] assay, and the drug with the highest cytotoxicity (pan-HDAC inhibitor SP-1-161) was selected for further analysis. SAHA was used as a control. Evaluation of the cell cycle phase distribution was performed by flow cytometry using FACS analysis following treatment with drugs at 24, 48, and 72 hours as well as in combination with radiation in CaSkï cells (HPV-16 positive). The extent of radiation sensitization was confirmed by cellular clonogenic assays in CaSkï cells. Results: Of all drugs tested, cytotoxicity was demonstrated in a dose-dependent manner. The values of IC50 were at 1.071, 1.567, 1.71, and 0.929, respectively. SP-1-161 conferred significant cytotoxicity (0.054, 0.353, 0.0994, and 0.095 μM (SP-1-161) for CaSkï, SiHa, HeLa, and C33a cell lines, respectively. SP-1-161 conferred significant cytotoxicity (0.054 μM) in CaSkï cells. Cellular radiation sensitivity is tightly associated with cell cycle phases and varies as a function of the position in the cell cycle. To assess the effects of HDAC inhibitors on the cell cycle, CaSkï cells were treated with IC50 dosage (SP-1-161 at 0.054 μM, SAHA at 1 μM) for 24 hours, 48 hours, and 72 hours and then treated with radiation. The drugs alone arrested cells primarily in the G1 phase of cell cycle (77.3% for SP-1-161, 84% for SAHA), in a relatively radiation-sensitive phase. Pre-treatment of SP-1-161 for 24 hours prior to radiation (5 Gy) increased cell cycle arrest in the G1 phase as well. To determine the radiosensitization property of SP-1-161, the radiation clonogenic survival assay was performed following pre-treatment of SP-1-161 for 24 hours. Cells were exposed to graded doses of γ-irradiation, and the data were fitted using the single-hit multitarget and the linear-quadratic models. Comparisons of survival curves revealed smaller D0 (D0 ratio 1.43) for cells irradiated in the presence of SP-1-161 (D0 = 1.4) than for controls (D0 = 2.0). Interestingly, treatment with SAHA did not impact radiosensitization (D0 = 1.9, D0 ratio 1.05). Conclusion: SP-1-161 conferred significant toxicity in CaSkï cells and primarily arrested cells in the G1 phase of cell cycle. Furthermore, treatment with SP-1-161 enhanced radiosensitization, while SAHA showed little change despite cell cycle arrest primarily in the G1 phase. Together, our results support SP-1-161 as a new therapeutic agent with potential for cervical cancer.

#5856 Molecular mechanism underlying breast cancer cell radioresistance: role of radiation-induced NF-κB self-sustenance. Hui Yu,1 Natarajan Aravindan,1 Ji Xu,3 Mohan Natarajan1. 1UT Health Science Ctr. at San Antonio, San Antonio, TX; 3University of Oklahoma Health Sciences Center, Oklahoma City, OK; 4Basic Medical College, Zhengzhou University, Henan, China.

Understanding the mechanism of breast cancer cell radioresistance and the associated selection pressure, tumor recurrence, would help us to develop molecular interventions and achieve disease/progression-free survival in patients with cancer. In the present study, we investigated the molecular mechanisms prompted in breast cancer cells in response to clinical radiation and the associated coordination of intra- and inter-cellular signaling that orchestrate radioresistance and tumor relapse/recurrence. Our findings showed that clinical doses of radiation increase NF-κB transcription and DNA-binding activity. Further, radiation exposure resulted in de novo TNF-α synthesis and secretion. An NF-κB gene manipulation approach revealed that NF-κB regulated NF-κB-mediated TNF-α transcriptional activity. NF-κB DNA binding kinetic analysis demonstrated that both sustained and dual phase NF-κB activation with radiation. Radiation prompted NF-κB-dependent synthesis/secretion of TNF-α, a requisite for the second phase of NF-κB activation and maintenance.

Radiation-associated NF-κB-dependent secretion of TNF-α from irradiated cells also activated NF-κB in radiation-irradiated, non-targeted bystander cells. Together, these findings demonstrated that radiation-triggered NF-κB-dependent TNFα secretion is critical for self-sustenance of NF-κB (through autocrine positive feedback signaling) and for coordinating bystander response (through intercellular signaling of de novo activation of NF-κB in bystander cells) after radiation exposure. Further, the data suggest that this NF-κB→TNF-α→NF-κB feedback-dependent self-sustenance of NF-κB could drive the selection pressure (proliferation, clonal expansion) of surviving breast cancer cells and subsequent tumor relapse/recurrence.

#5857 HER2-targeted thorium-227 conjugate (HER2-TTC): Efficacy in a HER2 positive orthotopic bone model. Jenny Karlsson,1 Urs B. Hagemann,1 Christoph Schatz,2 Derek Grant,1 Christine Ellisengo,1 Alexander Kristian,1 Dessislava Mihaylova,1 Steinar R. Uan,1 Mari Suominen,2 Roger M. Bjerke,1 Olav B. Ryan,1 Carl F. Nising,1 Dominik Mumberg,3 Alan Cuthbertson,4 Bayer AS, Oslo, Norway; 5Bayer AG, Berlin, Germany; 6Pharmacist Services Ltd, Turku, Finland.

In 2015, the estimated incidence of new breast cancer (Ca) cases in the US was 234,190 and number of deaths 40,730. Human epidermal growth factor receptor 2 (HER2) is encoded by the proto-oncogene c-erbB-2 and initiates downstream signaling pathways leading to cell proliferation and tumorigenesis. HER2 is overexpressed in several cancer types and has emerged as one of the most strongly validated targets for the treatment of breast and gastric cancer serving as both a prognostic and predictive biomarker. Given that 20% of breast Ca patients are HER2 positive and 70% of patients with metastatic disease will develop bone metastases and associated morbidities, there is still an unmet medical need for improved therapies targeting HER2. Radium-223 (Ra-223) is a novel targeted alpha therapeutic for treatment of patients with castration-resistant prostate cancer and bone metastases. Localized high energy alpha particle emission from alpha-emitting radiolabeled therapeutic antibodies enables efficient radio-labeling with the alpha particle emitting radionuclide Th-227. Anonymized samples of breast cancer patients were analyzed by Immunochemistry (IHC). The IHC data demonstrated HER2 positive expression in breast tumor and matched bone metastases, supporting the preclinical evaluation of the anti-tumor efficacy of HER2-TTC in the BT-474 orthotopic bone mouse model. HER2-TTC was prepared at high radiochemical yield and purity. When tested for binding to recombinant HER2, HER2-TTC was shown to retain comparable binding affinity to trastuzumab. In vitro cytotoxicity experiment of HER2-TTC demonstrated target mediated in vitro cytotoxicity in the m4-range on breast cancer cell line BT-474 (430 000 mAbs bound/ cell as determined by FACS).

Anti-tumor efficacy of HER2-TTC was evaluated at 250 and 500 kBq/kg at a protein dose level of 7.4 mg/kg. Using imaging, serum biomarker analysis (PINP on micro CT 3D reconstruction imaging and histological analysis demonstrated significantly reduced bone lesions and tumor induced bone remodeling. The promising preclinical anti-tumor activity supports the development of the HER2-TTC as a novel targeted alpha therapeutic for the treatment of patients with HER2 positive bone metastatic disease.

Radioresistance is a challenge in the treatment of esophageal squamous cell carcinoma (ESCC). MicroRNAs (miRNAs) are known to play an important role in the functional modification of cancer cells and recent studies have reported the miRNA-mediated radiotherapy resistance. However, further research would be necessary to reveal the regulation mechanisms and the treatment strategies using miRNA have yet to be established in ESCC. We compared the miRNA expression profile in ESCC parental (TE-4) and acquired radioresistant (TE-4R) cell line using miRNA microarray and qRT-PCR. Our data showed that miR-338-5p, one of the target miRNA biomarkers, was significantly downregulated in TE-4R. Ectopic overexpression of the miR-338-5p induced apoptosis and sensitivity to radiation treatment by interfering the survivin, which is known to play an inhibitor of apoptosis. Over expression of survivin using plasmid vector reversed non-338-5p induced apoptosis. From tumor xenograft experiments, we found that therapeutic delivery of the miR-338-5p mimics via direct injection to tumor mass increased sensitivity to radiation therapy. In conclusion, these findings suggested that miR-338-5p is a potential radiosensitizer and may be one of the therapeutic biomarkers for radiosensitive in ESCC.
HER2-targeted thorium-227 conjugate (HER2-TTC): Efficacy in preclinical models of trastuzumab and T-DM1 resistance. Jenny Karlsson,1 Urs B. Hagemann,1 Christoph Schatz,2 Derek Grant,1 Alexander Kristian,1 Christine Ellingsen,1 Dessislava Mihaylova1, Solene Geraudie,2 Bard Indreidel,2 Uta Wirnitzer,2 Roger M. Bjerve,1 Olav B. Ryan,1 Carl F. Nising,1 Dominik Mumbow,1 Gunilla Roland,1,3 Bayer AS, Oslo, Norway; 2Bayer AG, Berlin, Germany; 3Bayer AG, Wuppertal, Germany.

The human epidermal growth factor receptor 2 (HER2) is encoded by the proto-oncogene c-erbB-2 and initiates downstream signaling pathways leading to cell proliferation and tumorogenesis. HER2 is overexpressed in several cancer (Ca) types and is one of the most strongly validated targets for the treatment of breast and gastric cancer. Here we report a prognostic and predictive biomarker. HER2-targeting antibodies as well as antibody-drug conjugates are either approved or are in clinical development. Prolonged treatment with monoclonal antibodies and antibody drug conjugates have resulted in development of resistance and so there is still an unmet medical need for drugs of new mechanism of action targeting this important receptor system. We describe herein the development of a high energy, alpha particle emitting HER2-targeted thorium-227 antibody-chelator conjugate at Th-227. HER2-TTC consists of the humanized HER2 targeting IgG1 antibody (trastuzumab) covalently linked via an amide bond to a 3.2-hydroxypropyridine-based chelator moiety, enabling efficient radiolabeling with the alpha particle emitting radionuclide thorium-227 (Th-227). HER2-TTC was prepared at high radiochemical yield and purity. When tested for binding to recombinant HER2, HER2-TTC was shown to retain full affinity to the same degree as trastuzumab. In vitro cytotoxicity experiments were performed on 8 cell lines with different HER2 expression levels (from 7000-227,000 mAbs bound/ cell as determined by FACS) of breast, ovarian, gastric and prostate cancer. Tumor cell lines were tested for binding to recombinant HER2, HER2-TTC was shown to interact with HER2-expressing cells in a dose-dependent fashion. HER2-TTC demonstrated target mediated in vitro cytotoxicity in the P3 range. In vivo biodistribution and anti-tumor efficacy of HER2-TTC was evaluated in the dose range 100-500 kBq/kg at a protein dose of 0.14 mg/kg i.v. and showed a dose-dependent antitumor effect. Significant antitumor activity was observed in the HER2-TTC in the JIMT-1 s.c. breast cancer xenograft model. HER2-TTC demonstrated target-mediated in vivo cytotoxicity in the P3 range. In vivo biodistribution and anti-tumor efficacy of HER2-TTC was evaluated in the dose range 100-500 kBq/kg at a protein dose of 0.14 mg/kg i.v. and showed a dose-dependent antitumor effect. Significant antitumor activity was observed in the HER2-TTC in the JIMT-1 s.c. breast cancer xenograft model.

TUMOR BIOLOGY: Radioprotectors, Radiosensitizers, and Radiation Resistance

Melvin L.K. Chua,1 Erle Holgersen,2 Veronica Sabelnykova,1 Paul C. Boutros,2 Robert G. Bristow1.

Radiotherapy is an effective and integral part of cancer treatment in many solid tumors. However, tumor resistance to radiation is a major clinical challenge. The use of radiotherapy is closely related to the expression of the p16 (INK4a)-CyclinD-CDK4/6-Rb pathway in prostate cancer cells. Overexpression of the CDK4/6 kinase regulates expression of cyclin D1 and E, which is essential for the G1/S transition. Inactivation of Rb leads to the derepression of cyclin D1 and E, which in turn activates the cell cycle. The CDK4/6-Rb pathway is also important for the regulation of cell proliferation, differentiation, and apoptosis. Alterations in the CDK4/6-Rb pathway have been observed in many cancer types, including prostate cancer, and are associated with poor prognosis.

Copy number aberration (CNA) profiling was performed on 33 anatomically distinct prostate cancer samples at the time of recurrence following high dose precision radiotherapy. The aim of the study was to investigate if clonal selection or adaptation of new clones dominates in prostate cancer at the time of recurrence following high dose precision radiotherapy. Here, we investigated if clonal selection or adaptation of new clones dominates in prostate cancer at the time of recurrence following high dose precision radiotherapy. We identified 11 patients with biopsy-proven multi-focal recurrent prostate cancer following definitive image-guided radiotherapy/brachytherapy. Copy number aberration (CNA) profiling was performed on 33 anatomically distinct tumour foci with 11 matched-normals in the radio-resistant cohort. To assess clonality, 4 cases had matched pre-radiotherapy tumours for copy number profiling. We evaluated for recurrent driver amplifications and deletions, and genomic instability as measured by percent genome aberration (PGA). We also compared these genomic indices against 373 comprehensively profiled sporadic prostate cancers from the Canadian Prostate Cancer Gene Network [Fraser, et al., Nature, 2016]. Results: Independent of Gleason grade, we observed large intra-patient (COV of 0.66-1.13) and inter-patient heterogeneity (p <0.001, one-way ANOVA) in the levels of genomic instability, as judged by PGA scores, among the radioresistant tumours. Interestingly, although total CNA cancer scored as both non-recurrent and recurrent between the two datasets (PGC/GENE) cohorts (median CNAs of 40, radioresistant vs 33, sporadic, p = 0.20), we observed a trend for increased genomic instability in the radioresistant cohort (median PGA of 8.8 vs 4.9, p = 0.059). This concurs with the findings on intra-tumoural spatial CNA analyses, which revealed the acquisition of CNAs that were both common and non-recurrent in the multi-focal radioresistant tumours, thus suggesting a common origin with subsequent divergent evolution. Importantly, we observed a mixture of CNAs, including known drivers of aggressive prostate cancer, namely NKX3-1, Pten, TP53, CDKN1B, and CDH1, that was shared between pre-radiotherapy and radioresistant tumours, supporting a clonal selection process. We also discovered a novel deleted region on Chr3p, consisting of RAD18 and FANCD2, which was unique only in the radioresistant tumours. Conclusions: Our novel observations in a small cohort of radioresistant prostate cancers favour the model of selection of radioresistant clones, as opposed to new-onset tumours. These results support the current approach of discovering biomarkers a priori, and molecular therapeutic targets for these radioresistant clones, so as to improve the therapeutic ratio and precision radiotherapy.

Dysregulation of the p16INK4a-CyclinD-CDK4/6-Rb pathway in patients with NSCLC (Non-Small Cell Lung Cancer) is a rational therapeutic target. The current study investigated the radiosensitizing potential of a novel CDK4/6 inhibitor, LY2835219 (LY, Abemaciclib) in NSCLC cell lines with varied genomic context to identify genomic and metabolic biomarkers that are predictive of a response over conventional EGFR/tyrosine kinase inhibitor (EGRF-TKI) therapy. NSCLC cell lines were exposed to LY (0-10uM) for 24 hr immediately after 0-10 Gy radiation. Cell survival was assessed by clonogenic assay and cell cycle distribution was quantified by flow cytometry. Dose modifying factors (DMF) were calculated at 10% survival from radiation survival curves. Altered DNA repair pathways and metabolic profiling of cells post LY treatment was assessed by immunoblot and LC/MS mass spectrometry analysis. LY treatment enhanced radiosensitivity of EGRF-TKI sensitive (HCC827, PC9) and EGRF-TKI resistant (H820 and H1975) cell lines with DMF of 1.3 (±0.06), 1.4 (±0.30), 1.5 (±0.51) and 1.3 (±0.02), respectively. Values in the parenthesis indicates standard deviation. Wild type EGRF expressing cells (A549 and H460) also showed enhanced radiosensitivity by LY with DMF of 1.6 (±0.09) and 1.75(±0.15), respectively. Interestingly, no radiation enhancement by LY was observed for cells deficient in functional PTEN (H1650, RB (H82) and p53 (H460 DNP53 and H1975) protein. Radiosensitization was also observed for cells made resistant to third generation EGRF-TKI, AZD9291. Flow cytometry analysis of majority of cell types exposed to LY exhibited 55% to 94% GI arrest (depending on cell type). Mechanistically, the combinatorial treatment in radiosensitive cells showed elevated phosphorylated-Rb/A2. Combination treatment also reduced expression of ATR, ATM, DNA-PK, Rad51 and Chk2 suggestive of reduced DNA double strand break repair compared to radiation alone. LY treatment brought major changes in the glycolysis/TC/A/ total amino acids. LY increased significantly Acetyl-CoA, fumarate and malate, indicating enhanced oxidative phosphorylation. LY significantly elevated Uracil acid levels suggestive of oxidative stress and elevated nucleotide degradation. Finally, administration of 100mg/kg LY2835219 for five days in combination with fractionated dose of radiation (3 Gy) significantly delayed tumor regrowth in H640 xenograft (p< 0.014). Collectively, our pre-clinical data indicates altered Rb, p53 and PTEN status are distinct predictive biomarkers of response for LY mediated radiosensitization and provides an alternative therapeutic option in overcoming EGRF-TKI resistance in NSCLC.

YAP1 mediated CDK4/6 activation confers radiation resistance in esophageal cancer: rationale for the combination of YAP1 and CDK4/6 inhibitors in EC. Fan Li, Xiaoqiong Dong, Hai Tao Zhu, Ailing W. Scott, Lang Ma, Jiankang Jin, Jeannelln Santiano Estrella, Heath Skinner, Randy L. Johnson, Shumei Song, Jaffer A. Ajani. UT M.D. Anderson Cancer Ctr., Houston, TX.

Background: Esophageal carcinoma (EC) is a lethal disease with high incidence globally and often exist therapy resistance. Alterations (either overexpression or amplification) of YAP1 and CDK4/6 were found frequently in esophageal cancer. Deregulation of these pathways may represent key elements for resistance in esophageal cancer. Methods: Expression of YAP1 and CDK4/6 were examined in esophageal tumor tissues as well as cell lines using immunochemistry and immunoblotting. Inducible YAP1 overexpression in EC cells by lentivirus system was performed to test YAP1 mediated CDK4/6 expression and activation and association with radiation resistance. YAP inhibitor CA3 and CDK4/6 inhibitor Lee011 were used to test their antitumor activities in vitro and in vivo. Cell proliferation assay (MTS), Flow cytometry and immunofluorescence and tumor sphere formation assay were performed to test cell cycle distribution, cancer stem cell (CSC) population maintenance and over growth and therapy resistance. Results: We demonstrate that overexpressed YAP1 is positively associated with CDK4/6 expression in resistant tumor tissues and EC cell lines. Overexpression YAP1 by inducible lentivirus system in EC cells up-regulates expression of CDK4/6 at level of its transcription, while knock down YAP1 in HESEO EC cells dramatically decreased CDK6 expression as well as its transcription. CA3, a novel YAP1 inhibitor, was able to decrease activation of
CDK4/6 and phosphorylation RB and cell cycle progression induced by YAP1. Interestingly, we found that inducible YAP1 high EC cells are resistant to radiati
on resistance and CDK6 knockout by Lenti-Crisp sensitize radiation resistance in EC cells induced by YAP1. Further, we demonstrated radiation resistant cells are enriched CSC population and demonstrated increased level of both YAP1 and CDK4/6 in vitro and in vivo. Conclusions: Our data provide evidence that YAP1 mediated CDK4/6 up-regulation plays an important role in conferring radiation resistance in esophageal cancer cells. Targeting both YAP1 and CDK4/6 may provide novel therapeutic strategies in EC. Corresponding Authors: Shumei Song. Tel: 733-834-6144; Email: ssong@mdanderson.org; or Jaffer A. #5863 Identifying the radiosensitizing effects of PARP inhibitor in ovarian cancer. Yue Bi,1 Ioannis Verginidias,1 Souvik Dey,2 Imlang Guo,2 Lilie Lin,2 Yanfang Zheng,2 Constantinos Koumenis1. 1University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA; 2Zhongshan Hospital of Southern Medical University, Guangzhou, China.

Ovarian cancer is the seventh-most common cancer with a high mortality rate among women. Radiation therapy (RT) is used in ovarian cancer for local re-lapse, but doses are limited due to concern for small bowel obstruction in pa-tients who have had multiple surgeries and chemotherapeutic regimens. There-fore, it’s an ideal setting to improve therapeutic window by combining RT and a radiosensitizer. Poly (ADP-ribose) polymerase-1 (PARP-1) is involved in the recognition of DNA damage and the facilitation of DNA repair by recognizing DNA single-strand breaks (SSB). Inhibition of PARP1, especially in tumors driven by BRCA1 or 2 mutations, has been shown to potentiate the DNA-damaging effects of radiation in vitro and in vivo and to increase tumor vasculature perfusion and oxygenation. Approximately half of ovarian cancers have germ-line or somatic BRCA gene mutation, epigenetic silencing or other mutations that affect homologous recombination (HR) competency resulting in DNA repair defects, making this tumor particularly susceptible to the radiation-sensi-tizing effects of PARP inhibitors. Here, we investigated the therapeutic effects of the PARP inhibitor olaparib in preclinical models of ovarian cancer. Basic BRCA1 and PARP1 protein and mRNA levels were characterized in a panel of ovarian cancer cell lines. The radiosensitizing effects of olaparib were tested on both HR-proficient and HR-deficient ovarian cancer cells by evaluating the colo-ny formation, DNA damage, apoptosis, and PARP1 activity. Survival benefit of olaparib was also examined in xenograft models of ovarian cancer. Our results demonstrate that combination of olaparib with IR decreased colony formation, inhibited DNA damage (γH2AX) repair, and induced more apoptosis compared to olaparib or IR alone. In addition, HR-deficient cells were more sensitive to IR than HR-proficient cells in the presence of olaparib. Furthermore, olaparib inhibited PARP1 activity in vivo, significantly decreased tumor growth and in-creased overall survival when combined with IR in mice bearing subcutaneous xenografts of HR-deficient OVCAR8 cells while producing a relative modest increased overall survival when combined with IR in mice bearing subcutaneous xenografts of HR-proficient SKOV3 cells. These results provide a preclinical rationale for improved treatment mo-dalities using olaparib as an effective radiosensitizer in ovarian cancer, particu-larly in tumors with HR-deficiencies.

#5864 Targeting brain cancer stem cells by potentiating radiation-in-duced ER stress. Regina M. Graham, Suneetha S. Shah, Alexis J. Musick, Win-ston Walters, Ricardo J. Komotar, Jeffery S. Prince, Steven Vann, Univ. of Miami Miller School of Medicine, Miami, FL.

Background. Glioblastoma (GBM) is one of the most malignant brain tumors occurring in both children and adults. Despite an aggressive treatment regimen consisting of surgical resection, radiation therapy and chemotherapy the five-year survival rate is less than 5%. This poor outcome has been attributed to the existence oftherapy-resistant GBM stem-like cells (GSCs), which are believed to be responsible for tumor recurrence and patient relapse. Understanding the resistance mechanisms employed by brain tumor stem cells and developing novel methods to target these cells is necessary for prolonged patient survival. Recent evidence suggests that the endoplasmic reticulum stress response path-way may mediate therapeutic resistance in cancer. Here we sought to examine the ER stress response pathway of GSCs in response to ionizing radiation and to increase the extent of ER stress in an effort to promote cell death using the glycolytic inhibitor, 2-deoxy glucose (2-DG). Methods. GSC lines were derived from resected tumor sections. GSCs were irradiated using the Rad Source 2000 Series Biological Irradiator. Transmission Electron Microscopy (TEM) was used to investigate the ultra-structural alterations of GSCs following exposure to 8 Gy radiation. Viability was determined using trypan blue exclusion, MTS and LDH assays. Cell signaling pathways were investigated by western blot analysis. Results. Consistent with previous findings, minimal cell death was observed in GSCs exposed to 2-20 Gy radiation. TEM analysis revealed that exposure to 8 Gy significantly increased ER luminal dilution, suggestive of ER stress. Western blot analysis indicated an increase in ER stress markers GRP78, GRP94 and CHOP, confirming that radiation induces ER stress in GSCs. Treatment with 2-DG induced an increase in ER luminal diameter and ER stress markers. Combined 2-DG (0.5mM and 2mM) and radiotherapy (8 Gy) significantly increased ER luminal diameter and ER stress marker expression over radiation or 2-DG alone. Furthermore, the combination of 2-DG (0.1-2mM) significantly reduced GSC viability compared to radiation or 2-DG alone. Conclusion. The ER stress response pathway is an adaptive mechanism and thought to mediate therapeutic resistance. Here we demonstrate that radiation induces ER stress response pathway including ER luminal dilution and an increase in molecular chaperone ex-pression in GSCs. Potentiating ER stress can switch the pathway from one of adaptation to cell death. 2-DG increased radiation-induced ER stress and pro-moted cell death. Our data suggests that targeting this adaptive response could increase the efficacy of radiotherapy and prolong patient survival.

#5865 The role of t-Darpp in radiation sensitivity and resistance. Santosh K. Singh, James W. Lillard, Rajesh Singh. Baltimore Research Institute of the City of Hope, Duarte, CA; University of California Los Angeles, Los Angeles, CA, CA.

t-DARPP, one of two protein isoforms encoded by the PPP1R1B gene, is overex-pressed in gastric, esophageal, colon, prostate, and breast cancers; and confers resistance to trastuzumab in Her2++ breast cancer cells. To gain insight into the trastuzumab-resistance mechanism of t-Darpp, we studied its structure, oligo-gomerization status, metal-binding properties, and sites of phosphorylation. Circular dichroism spectroscopy analysis showed that recombinant t-Darpp ex-hibits 12% alpha helix, 29% beta strand, 24% beta turn and 35% random coil character at 25°C. Upon mild heat treatment (50°C for five min) the secondary structure does not appreciably change. Metal ion-binding analyses through in-ductively coupled plasma-mass spectrometry and graphite furnace-atomic ab-sorption indicated that t-Darpp co-purifies with calcium, but not other metals commonly found in biological systems. The T75 site, critical for t-Darpp activa-tion of the Akt signaling pathway, is a substrate for phosphorylation by cyclin-dependent kinase 1 (CDK1) and cyclin-dependent kinase 5 (CDK5). Gel filtration chromatography, sedentation equilibrium analysis, native blue gel electrophoresis, and glutaraldehyde-mediated crosslinking experiments showed that the majority of t-Darpp (calculated mass = 19 kDa) exists as a monomeric protein but forms low levels (<3%) of hetero-oligomers with its longer isoform Darpp-32. t-Darpp has a relatively large Stokes radius of 4.4 nm, suggesting an elongated structure. In summary, this study indicates that t-Darpp is an elongated, mild-heat-stable, and monomeric calcium-binding protein that is capable of being phosphorylated at T75 by CDK1 and CDK5. Blockage of t-Darpp calcium binding capacity or T75 phosphorylation may therefore help sustain Her2++ breast cancer sensitivity to trastuzumab therapy.
affinity folate receptors presents on PCa cells. The resulting PBM nanoparticles were shown to be rapidly internalized and induce significant cancer cell apoptosis at lower doses compared to unformulated resveratrol and/or docetaxel. Our data showed that resveratrol potently synergizes with docetaxel to inhibit proliferation and induce cell death in resistance PCa cells. The up-regulation of serotoninergic transporter (SERT), p53 and p21 were induced in response to resveratrol-docetaxel treatment. These results suggest that the co-delivery of resveratrol, and a cytotoxic agent in a PBM nanoparticle might potentially improve the treatment of drug-resistant tumors. #5868 Role of STAT3 vs AKT in cellular survival. Maximilian Niti, Joshua Rosen, Rozanne Arulananandam, Victoria Hoskin, Bruce Elliott, Leda Raptis. Queen’s University, Kingston, Ontario, Canada.

Cell-to-cell adhesion is mediated by the cadherin family of proteins. We previously demonstrated that cadherin engagement (which is favored under conditions of confluence) triggers a dramatic increase in Rac protein levels, followed by an increase in IL6 secretion and Stat3 (Signal Transducer and Activator of Transcription-3) activation. This is critical for survival of both normal and neoplastic cells. On the other hand, cell adhesion to the substratum, ie the extracellular matrix at the focal adhesion sites, is mediated by the integrin receptors. The focal adhesion kinase (FAK) binds beta-integrins and this forces FAK in an open conformation. Autophosphorylation of tyrosine at Y576 phosphorylates Src to affect cell fate. Bosutinib inhibited the growth of both parental cells and HR cells, and induced apoptosis and G1 arrest in HR cells. Bosutinib suppressed HR cell migration more effectively compared with parental cells. Bosutinib exhibited potent tumor growth inhibition in both SNU2670 and SNU2670HR xenograft models and more significantly suppressed tumor growth in HR models. Conclusion: Src activation may contribute to tumor cell adhesion resistance in part to HER2-positive gastric and biliary tract cancer cells. Targeting Src might be a candidate strategy to overcome trastuzumab resistance in HER2-positive cancers.

#5870 Epigenetic drug treatment overcomes osteoblast-induced chemoresistance by suppressing cell adhesion and related signaling. Anthony Quaglino, Sonali Barwe, Anilkumar Gopalakrishnapillai. Nemours/A.I. duPont Hospital for Children, Wilmington, DE.

Acute lymphoblastic leukemia (ALL) is the most commonly diagnosed cancer in pediatric patients. Recent advances have allowed for improved efficacy of treatment allowing 95% of patients to achieve remission following chemotherapy. However, nearly 20% will have a second recurrence that is often more aggressive and difficult to treat. One reason for this high rate of relapse may be due to the role of the bone marrow microenvironment (BM) consisting of osteoblasts, endothelial cells, adipocytes, and stromal cells as well as extracellular matrix proteins. Interaction between leukemic cells and BM elements activates intracellular signaling pathways that protect ALL cells from chemotherapy. Many of these pathways can be aberrantly activated due to changes in methylation patterns during leukemogenesis. Therefore, utilizing epigenetic modifiers offers a unique approach to overcoming the chemoprotective effects of the BM. The aim of our study is to identify if the combination of the epigenetic drugs azacitidine (DNA methyltransferase inhibitor) and panobinostat (histone deacetylase inhibitor) is successful in overcoming these effects. We demonstrated that azacitidine and panobinostat are more effective in killing ALL cells in coculture with osteoblasts than chemotherapy alone. This required direct interaction between ALL cells and osteoblasts and could not be replicated when ALL cells were suspended in Transwells above the osteoblast monolayer. Additionally, ALL cells pretreated with non-killing concentrations of azacitidine and panobinostat were sensitized to chemotherapy even in the presence of osteoblasts. These effects were replicated ex vivo in primary ALL patient samples with a variety of cytogenetic characteristics. These patient samples have been xenografted in mice to observe the efficacy of this combination with chemotherapy in comparison to chemotherapy alone. We also observed that treatment with azacitidine and panobinostat decreases the ability of ALL cells to effectively adhere to osteoblasts, suggesting a role that down-regulation of cell adhesion molecules (CAMs) may play in mediating this response. Due to the need for direct contact of ALL cells with osteoblasts for the chemoprotective effects, we investigated how treatment with azacitidine and panobinostat could affect the expression levels of certain CAMs. We found that N-cadherin was induced in ALL cells in coculture with osteoblasts and that increase was partially reversed by azacitidine and panobinostat. Beta-catenin, which is known to interact with N-cadherin, was also up-regulated in ALL cells cocultured with osteoblasts and was reversed by azacitidine and panobinostat. These data suggest that azacitidine and panobinostat may overcome microenvironment-induced chemoprotection by decreasing the expression of certain CAMs like N-cadherin and interfering with their downstream signaling pathways.

#5871 Characterizing hormone therapy-resistance phenotypes in metastatic breast cancer conferred by estrogen receptor (ER) mutations. Shanhang Jia,1 Ryan Hennesius,2 Marilyn Ngo,2 Peiui Wang,3 Amir Bahreini,2 Ning Chen,2 Zhiye Ding,4 Tongying Shun,2 Lansing Taylor,2 Shannon Puhalla,2 Adrian Lee,2 Steff Oesterreich,3 Andrew M. Stern,2 Mark T. Miedel2. Tsinghua University, China;1 UPDDI, Pittsburgh, PA; 2UPMC, Pittsburgh, PA.

232,000 new cases of invasive breast cancer will be diagnosed in 2016. 40,300 patients will die primarily from metastatic disease. Mortality results from the ability of cancer to evolve and evade therapy. Estrogen receptor (ER+) breast cancer accounts for 70% of invasive breast cancer. The mainstay treatment of ER+ breast cancer involves estrogen deprivation therapy using aromatase inhibitors as well as estrogen receptor antagonists and degraders. We and others have shown that patients treated with aromatase inhibitors often (14-54%) acquire ESR1 mutations in their metastases in contrast to only a 0.5% ESR1 mutation frequency detectable in their primary tumors. We hypothesize that ESR1
Gateways of evolution and represent targetable dependencies for ER+ metastatic disease. We reasoned that characterization of the phenotype engendered by ESR1 mutations under physiologically relevant conditions will help us understand the mechanism of ER+ metastatic cancer. To achieve this objective we have stably expressed the two most common independent (constitutive) ERE transactivation in contrast to the parental and wild type control cells. Furthermore, partial and potently clinically relevant resistance of these ESR1 mutant-expressing cells to ER antagonists such as fulvestrant and 4-hydroxytamoxifen was evident. In addition, using this reporter assay, mutant ESR1-expressing cell lines show similar resistance in the absence of estrogen. We are using a human microphysiologymodel of liver metastasis as a complementary approach to patient-derived xenograft models to investigate metastatic associated phenotypes conferred by these mutations. Since our previous studies indicated the existence of polyclonal mutations within individual patients (P.Wang, A. Bahreini et al., CCR 2016), we are testing the hypothesis that the persistence of this heterogeneity results from cooperation among these mutant-expressing clones. These studies form the basis for our continuing efforts to understand ER+ metastatic disease and use this knowledge to identify more effective therapies.

Targeted cancer therapies can effectively promote tumor regression in clinical responses. Eventually, most tumors develop resistance to these drugs. Stat3 activation has been suggested as one of the mechanisms that cause acquired resistance to EGFR-tyrosin kinase inhibitor (TKI) in non-small cell lung cancer (NSCLC). However, the underlying molecular mechanisms are not well studied. In this study, we found that treatment of gefitinib (EGFR-TKI) in NSCLC cell lines harboring EGFR-TKI sensitive mutation induced feedback activation of Stat3 in a time- and dose-dependent manner. High levels of IL-6 were detected in the conditioned medium of gefitinib-treated cells by cytokine array and were confirmed by ELISA. We demonstrated that IL-6 treatment could induce Stat3 activation and conditioned medium treatment-induced Stat3 activation was suppressed by IL-6 neutralizing antibody. We also demonstrated that gefitinib treatment-induced IL-6 secretion could be inhibited by knockdown of Stat3 expression. Moreover, pharmacochemical inhibition and genetic inhibition of Stat3 activation increased cell cytotoxicity of gefitinib in both PC9 and HCC827 cells that harboring EGFR-TKI sensitive mutation. Our data suggested that gefitinib treatment could induce activation of IL-6/Stat3 signaling loop and modulate cell cytotoxicity of gefitinib. Microarray and Ingenuity Pathway Analysis (IPA) analysis revealed prostaglandin D2 synthase (PTGIS) as a downstream target gene of IL-6/Stat3 signaling and PTGIS was up-regulated by gefitinib treatment. The induction of PTGIS by gefitinib via Stat3 feedback activation was confirmed in vitro genetically and pharmacologically. Moreover, we showed that cotreatment with PTGIS inhibitor improves the efficacy of EGFR inhibition in PC9 and HCC827 cells. Importantly, high expression of PTGIS was found in gefitinib-resistant PC9 cells (PC9/gef) compared with gefitinib-sensitive PC9 cells. Targeting PTGIS was also effect in decreasing viability of cells with acquired resistance to gefitinib in PC9/gef cells. Taken together, our study indicated that Stat3 feedback activation-induced PTGIS expression participates in modulating gefitinib efficacy and Stat3/PTGIS inhibition could potentially overcome acquired resistance to gefitinib in NSCLC.

#5873 Chaetocin sensitizes GBM cells to TRAIL and BH3 mimetics induced apoptosis. Ezgi Özverli, Zeynep Kahya Yeşil, Udo Oppermann, Tuğba Bağcı Önder1. Koç Univ., İstanbul, Turkey; 2University of Oxford, Oxford, United Kingdom.

Glioblastoma Multiforme (GBM) is the most common and aggressive brain tumor, which lacks efficient therapy. TRAIL is an antitumor agent that triggers apoptosis selectively on tumor cells, thus can be utilized as therapeutic approach for GBM. However, most GBM cells confer TRAIL resistance and how this resistance is regulated at a molecular level is not completely clear. Epigenetic deregulation has been increasingly recognized as a hallmark of cancer. In this study, we conducted a drug screen against selected chemotaxis modifiers in U87MG GBM cells and identified Belinostat, Trichostatin A and Chaetocin as potential apoptosis regulators. While Belinostat and Trichostatin A are well-characterized histone deacetylase inhibitors in the context of malignancies, Chaetocin’s role in cancers is less well-known and its relation to TRAIL is novel. Chaetocin is a fungal mycotoxin that inhibits Suv39H1, a histone methyltransferase (HMT) that catalyzes H3K9 methylation. In this study, we investigated whether Chaetocin increases sensitivity of GBM cells to TRAIL.

To this end, GBM cell lines U87MG and U373 are treated with varying dose of Chaetocin and cells’ viability and apoptosis responses to varying doses of TRAIL are analyzed. Chaetocin decreased viability down to 11% of control in U87MG cells upon TRAIL treatment, without inducing cellular toxicity and apoptosis by itself. Chaetocin was shown to upregulate the expression of proapoptotic genes while downregulating antiapoptotic gene expression. In addition, elevated Caspase3/7, Caspase8 and Caspase9 activities were detected in U87MG upon Chaetocin treatment together with PARP cleavage as indicator of apoptosis. Chaetocin also sensitized GBM cells to BH3 mimetic ABT263 which indicates that sensitization of GBM cells by Chaetocin is not limited to TRAIL but is rather a general phenomenon for apoptosis. We infer from these findings that Chaeto- cin plays critical and specific role in apoptotic pathway. Our future work is directed towards examining the changes in gene expression profiling of GBM cells upon Chaetocin treatment and understanding the functional role of H3K9 Methylation in GBM cell apoptosis. To this end, RNAseq analysis is currently being performed and expected to enlighten Chaetocin’s mechanism of action. These findings support our motivation that identifying epigenetic modifier drugs as apoptosis sensitizer may be a promising therapeutic approach for GBM treatment.

#5874 Cdk4/6 kinase inhibitor resistance in prostate cancer. Renee de Leeuw, Matthew J. Schierer, Christopher McNair, Michael A. Augello, Akihiro Yoshida, Edward S. Hazzard, Sean Courtney, Gerard T. Hardiman, Justin Drake, Felix Y. Feng, Scott Tomlins, Maha H. Hussain, Alan Dighil, William K. Kelly, Karen E. Knudsen. Thomas Jefferson University, Philadelphia, PA; Medical University of South Carolina, Charleston, SC; Rutgers University, New Brunswick, NJ; University of California San Francisco, San Francisco, CA; University of Michigan, Ann Arbor, MI; Northwestern University, Chicago, IL.

Non-organ confined prostate cancer (PCA) is often effectively, but only transiently treated by targeting the androgen receptor (AR) signaling axis through androgen depletion strategies, often coupled with AR antagonists. Unfortunately, disease recurs within a median of 3-4 years, presenting as castration resistant PCA (CRPC), for which there are limited therapeutic options. This emphasizes the need for more efficacious drugs and a patient-tailored approach towards cancer therapy to improve disease outcome. One class of drugs currently tested clinically, Cdk4/6 kinase inhibitors, blocks phosphorylation of the retinoblastoma (RB) tumor suppressor, thereby blocking its function, and likely preventing castration resistance. As Cdk4/6 inhibitor resistance has already been reported in other cancers, some PCA patients are anticipated to develop drug resistance. Here, we created palbociclib-resistant PCA cell models by continuously culturing them in presence of the drug to unravel mechanisms of drug resistance. Here, we created palbociclib-resistant PCA cell models by continuously culturing them in presence of the drug to unravel mechanisms of drug resistance. Here, we created palbociclib-resistant PCA cell models by continuously culturing them in presence of the drug to unravel mechanisms of drug resistance. Here, we created palbociclib-resistant PCA cell models by continuously culturing them in presence of the drug to unravel mechanisms of drug resistance.

The putative DNA/RNA helicase, Scheflin 11 (SLFN11), is a recently discovered determinant of sensitivity to DNA damaging agents such as platinum, topoisomerase I and II inhibitors (camptothecins, etoposide, doxorubicin), cisplatin, gemcitabine (1-3) and PARP inhibitors (olaparib, talazoparib) (4). Because SLFN11 expression is suppressed in ~45% cancer cell lines, SLFN11 inactivation is potentially one of the most prevalent mechanisms of resistance to DNA damaging agents. However, the molecular mechanisms of SLFN11 action in the DNA damage response have not been solved. Using isogenic cell lines of SLFN11-knockout and SLFN11-overexpression, we will show that SLFN11 binds to chromatin in response to camptothecin within 2 hours. ChiP-seq analysis reveals that SLFN11 preferentially binds to replication origins under camp-

#5876 Osimertinib (AZD9291), a mutant-selective EGFR inhibitor, reverses ABCB1-mediated drug resistance in cancer cells. Xiao-Yu Zhang,1 Zi-Ning Lei,2 Yun-Kai Zhang,1 Yi-Jun Wang,2 Pranav Gupta,1 Leli Zeng,1 Megan Xu,2 Xi-Qi Wang,2 Dong-Hua Yang,2 Zhe-Sheng Chen1. "St John's University, Queens, NY; 2John L. Miller Great Neck North High School, Great Neck, NY; 3South China Agricultural University, Guangzhou, China.

In recent years, tyrosine kinase inhibitors (TKIs) have been shown capable of inhibiting the ATP-binding cassette (ABC) transporter-mediated multidrug resistance (MDR). In this study, we determine whether osimertinib, a novel selective, irreversible EGFR (epidermal growth factor receptor) TKI inhibitor, could reverse ABCB1-mediated MDR. The results showed that at non-toxic concentrations, osimertinib significantly sensitized both ABCB1-transfected and drug-selected cell lines to substrate anticancer drugs colchicine, paclitaxel, and vincristine. Osimertinib significantly increased the accumulation of [3H]-paclitaxel in ABCB1 overexpressing cells by blocking the efflux function of ABCB1 transporter. In contrast, no significant alteration in the expression levels and localization pattern of ABCB1 was observed when ABCB1 overexpressing cells were exposed to 0.3μM osimertinib for 72 h. In addition, ATPase assay showed osimertinib stimulated ABCB1 ATPase activity. Molecular docking and molecular dynamic simulations showed osimertinib has strong and stable interactions at transmembrane domain of human homology ABCB1. Taken together, our findings suggest that osimertinib, a clinically approved third-generation EGFR TKI, can reverse ABCB1-mediated MDR, which supports the combination therapy with osimertinib and ABCB1 substrates may potentially be a novel therapeutic treatment in ABCB1-positive drug resistant cancers.

#5877 The functional role(s) of serum amyloid A1 (SAA1) polymorphisms in integrin-mediated cell adhesion in nasopharyngeal carcinoma (NPC) cells. OnYing Man, HongLokLung. BaptistUniversityofHongKong, Hong Kong, China.

Serum amyloid A1 (SAA1) was previously identified as a tumor suppressor gene with anti-angiogenic activities in nasopharyngeal carcinoma (NPC). Three SAA1 isoforms (SAA1.1, SAA1.3, and L.5) were observed with disproportionate frequencies among the NPC patients and healthy people. SAA1.1 and 1.3 are the functional isoforms to inhibit angiogenesis whereas SAA1.5 was the defective gene. Our immunohistochemical results showed that the loss of SAA1 staining in the metastatic NPC tissues was significantly associated with tumor progression. We aim to investigate the functional roles of the three SAA1 isoforms in NPC mediated by SAA1.1 knockout cell study. We tested the ability of SAA1.1 and 1.3 isoforms to suppress tumor metastasis by antagonizing the integrin-FAK signaling pathway in the NPC tumor cells. The focal adhesion assay was performed by seeding the tumor cells with or without the integrin alphaVbeta3/beta5 ligand vitronectin. Both the vector-alone control and the SAA1.5-expressing NPC cells began to spread out and adhered to the bottom of the culture dish in the presence of vitronectin from 7 to 9 hours, whereas the functional SAA1.1 and 1.3 isoforms can suppress tumor metastasis by antagonizing the integrin-FAK signaling pathway in the NPC tumor cells. The focal adhesion assay was performed by seeding the tumor cells with or without the integrin alphaVbeta3/beta5 ligand vitronectin. Both the vector-alone control and the SAA1.5-expressing NPC cells began to spread out and adhered to the bottom of the culture dish in the presence of vitronectin from 7 to 9 hours, whereas the functional SAA1.1 and 1.3 isoforms remained in the round-up morphology with minimal attachment. Interestingly, after 48 hours the SAA1.1 and SAA1.3-expressing cells formed adherent junctions among the cells. In order to study the viability of the effects of the three SAA1 isoforms on NPC cells, MTT viability assay was performed. The results showed that the viability of the SAA1.1 and SAA1.3-expressing cells were around 50 % lower than both the vector-alone and the SAA1.5-expressing cells. It is likely that the loss of focal adhesion after seeding of the SAA1.1 and SAA1.3-expressing cells will affect the survival of NPC cells. Furthermore, we found that the presence of the recombinant SAA1.1 and SAA1.3 proteins could reduce the number of viable NPC cells compared with the solvent control and the SAA1.5 protein. We previously reported that the SAA1 proteins can physically interact with the integrin alphaVbeta3. Taken together, we suggested that the secreted SAA1 proteins from the NPC cells could directly affect the NPC focal adhesion as well as the cell viability by blocking the integrin on the NPC cell surface. We acknowledge the financial support of the General Research Fund (grant number HKU717115114 to HLL) of the Research Grants Council of the Hong Kong Special Administrative Region.

#5878 Trichostatin A overcomes chemotherapy resistance of urothelial carcinoma cells through the inactivation of c-Raf/ERK pathway. Kuan-Lin Kuo,1 Chung-Sheng Shi,2 Ju-Tong Hsieh,1 Shiang-Peng Chen,1 Wei-Chou Lin,3 Shih-Ming Liao,3 Shing-Hwa Liu,4 Kuo-Hsiao Huang.1 National Taiwan University College of Medicine, Taipei, Taiwan; 2Chang Gung University College of Medicine, Taoyuan, Taiwan; 3National Taiwan University Hospital, Taipei, Taiwan.

Trichostatin A (TSA), a potent histone deacetylase (HDAC) inhibitor, has been reported to elicit anti-proliferative response in various tumors. Here, we investigated antitumor effect of TSA alone or in combination with conventional chemotherapeutic agents on urothelial carcinoma (UC) cells. We use one high-grade UC cell line (T24) and another UC cells (NTUUC) obtained by primary culture from the surgical specimen of a women with high-grade and metastatic bladder UC. The cytotoxicity and apoptosis induced by TSA alone , chemotherapeutic agents (cisplatin, gemcitabine and doxorubicin) and combined treatment were assessed by MTT assay and fluorescence-activated cell sorting and flow cytometry. The expression of phosphor c-Raf, phosphor-MEK1/2, and phosphor-ERK1/2 were measured by Western blot. Further elucidation on the role of Raf/MEK/ERK pathway on the TSA-enhanced cytotoxicity were examined by using ERK1 siRNA knockdown and the specific MEK inhibitor (PD98059). Our results showed TSA markedly enhances the cytotoxicity and apoptosis of three chemotherapeutic agents in UC cells with concurrent suppression of Raf/MEK/ERK signaling pathway. Consistently, inhibition of Dox-regulation of ERK by MEK inhibitor or by ERK 1 siRNA knockdown potentiated the chemotherapeutic agent-induced cytotoxicity of TSA in UC cells. We concluded that TSA potentiates the therapeutic efficacy of cisplatin, gemcitabine and doxorubicin in human UC cells through Raf/MEK/ERK signaling pathway. These findings provide a new treatment strategy against UC.

#5879 Establishing doxorubicin resistant HCC1806 triple negative breast cancer cell lines result in the differential expression of let7a and miR34a. Checo J. Rorie, Malcolm M. Moses, Mohammed K. Musa, Sherette S. Godfrey. North Carolina A&T State Univ., Greensboro, NC.

Resistance to chemotherapy is one of the major difficulties in the treatment of triple negative breast cancer. Besides the typical known causes of drug resistance, tumor microenvironment can also promote resistance by preventing the drug from accumulating in tumor cells in order to elicit a cytotoxic response. TNBC is characterized by the loss or low expression of estrogen receptor, progesterone receptor, and HER2 proteins that have been targeted and established as some of the main therapeutic targets for disabling, or combating resistance to chemotherapy. However, resistance may have as high as an 80% p53 tumor suppressor gene mutation rate which may also play a role in the ability of TNBC to recur as a result of the inability to kill all remaining TNBC cells leading to chemotherapy resistance. In these studies, we hope to mimic TNBC recurrence by establishing doxorubicin resistant HCC1806 TNBC cell lines. Here we show that we were able to sustain TNBC cell growth after pulse treatments with increasing concentrations of doxorubicin, and we revealed that p53-related miRNAs, let7a and miR34a, were differentially expressed after pulse treating the HCC1806 cells. Understanding the molecular and mechanistic factors related to recurrence and doxorubicin-resistance in TNBC cells may help to develop a list of possible targets for molecular therapy to overcome tumor drug resistance in triple negative breast cancer and may develop or establish a list of potential targets for disabling, or combating resistance to doxorubicin treatment in TNBC patients.
#5880 Acquired chemotherapeutic drug resistance in colorectal cancer is regulated by epithelial-to-mesenchymal transition and altered cellular pathways. Lahiri Gangoda,1 Nidhi Mathew,1 Michael Liem,1 Shahei Keerti Kumar,1 Ching-Seng Ang,2 John Mariadason,2 Suresh Mathivanan,1 La Trobe Institute for Molecular Science, La Trobe University, Bundoora, Australia;1The Bio21 Molecular Science and Biotechnology Institute, University of Melbourne, Parkville, Australia;2Olivia Newton John Cancer Research Institute, Heidelberg, Australia.

Colorectal cancer (CRC) is the third most common cancer and the second leading cause of cancer-related death in the western world. Chemotherapy is the mainstay in the treatment of metastasized CRC. However, cancer cells acquire resistance to treatment by various mechanisms resulting in treatment failure. Even though various molecular mechanisms regulating drug resistance is critical to overcome chemoresistance, it is poorly understood. We developed a panel of seven CRC cells resistant to 5-FU. The parental and 5-FU resistant CRC cells were assayed for proteins known for their involvement in chemotherapeutic resistance. In addition, an unbiased quantitative proteomics and DNA methylation analysis was performed on the panel of seven parental and 5-FU resistant CRC cells. The integrated analysis revealed multiple mechanisms contributing to chemotherapeutic drug resistance including epithelial-to-mesenchymal transition (EMT), deregulation of apoptosis, increased survival autophagy and epigenetic modifications resulting in altered drug metabolism potency. Inhibitors of EMT and autophagy sensitized the 5-FU resistant CRC cells. Furthermore, CCRISPR-based gene knockouts of these candidate genes (both up and downregulated) enriched or rendered them resistant to 5-FU. As a follow up, PDX models were established and made resistant to 5-FU. Follow up quantitative proteomics and biochemical validations of 5-FU resistant PDX tissue lysates confirmed the role of EMT in acquired chemoresistance. Overall, this project unravelled multiple mechanisms by which CRC cells may become resistant to 5-FU. Importantly, some of these mechanisms are also conserved in many cancer types and hence targeting these mechanisms can overcome chemoresistance and increase patient survival rates.

#5881 Identification of resistance mechanisms to IGF-IR targeting in triple negative breast cancer. Jennifer Tsui,1 Whitney Petrosky,1 Maria Celeia Fernandez, Pnina Brodt. McGill University, Montreal, Quebec, Canada.

The triple negative subtypes of breast cancer (TNBC) are associated with poor prognosis. Unlike HER2+ and hormone receptor-positive BC, TNBC do not respond to targeted therapy and chemotherapy remains the primary treatment option. There is therefore an unmet need to develop effective therapy for TNBC. The insulin-like growth factor 1 (IGF-1) axis plays a critical role in BC progression by conveying survival and growth signals. Our laboratory reported on the production of a soluble fusion protein comprised of the extracellular domain of human IGF-IR fused to the Fc portion of human IgG (the IGF-Trap). The IGF-Trap reduces the bioavailability of circulating and locally produced IGF-I, thereby limiting tumor growth. When human TNBC MDA-MB-231 cells were xenografted into nude mice and treated with the IGF-Trap, we observed variability in the response as it ranged from complete tumor regression to disease stabilization and tumor progression in some mice. This suggested that MDA-MB-231 cells are heterogeneous in respect to their sensitivity to IGF-IR signaling blockade. The aim of the present study was to identify resistance mechanisms that allow the cells to progress in the face of IGF-IR signaling blockade by the IGF-Trap. We first analyzed the tyrosine kinase receptor profile of these cells and confirmed by PCR that in addition to IGF-IR, they express epidermal growth factor receptor (EGFR), c-Met, and fibroblast growth factor receptor 1 (FGFR1). They also produce IGF-I, EGF and relatively high level of FGF1 that could provide potential autocrine signaling to compensate for IGF signaling blockade. Using limiting dilution cloning, we isolated MDA-MB-231 cell lines and NT2. Reduction in extracellular matrix and adhesion molecules and altered morphology of CHD1 KO cells were as compared to parents and NT2 cells suggest that loss of CHD1 would cell-cell and cell-matrix adhesion. These results suggest that in the absence of PTEN loss in Ets negative tumors, deletion of CHD1 gene could change cell adhesion dynamics ascribing a new role for CHD1 in the development and progression of PCa.

#5882 FAK is required for the survival of tumor cells in MMTV-Wnt1 driven basal-like mammary tumors. Ritama Paul,1 Syn K. Yeo,1 Ming Luo,2 Susan Waltz,2 Jun-Lin Guan,1 University of Cincinnati, Cincinnati, OH;2University of Michigan, Ann Arbor, MI.

Breast cancer is a heterogeneous disease. Stratification of patients based on the subtypes of breast cancer is integral to successful treatment. Focal Adhesion Kinase (FAK), a cytoplasmic tyrosine kinase is over expressed and activated in several cancers including breast cancer. Our earlier studies have shown inhibition of FAK in MMTV-PyMT mouse mammary tumors that are classified as Luminal B subtype, delays tumor onset and reduces tumor growth. To address whether inhibition of FAK would be beneficial in basal-like mammary tumors, we used a conditional deletion of FAK and a knock-in mutation of FAK lacking its kinase activity, in MMTV-WNT1 mouse model, which classifies as basal-like. Similar to PyMT mammary tumors we found that loss of FAK or its kinase function delays tumor onset and tumor growth of basal like WNT1 mammary tumors. However unlike the PyMT tumors, the reduced tumor growth in WNT1 model is not due to decreased proliferation. Interestingly loss of FAK activity in WNT1 tumors results in accumulation of cleaved caspase 3, suggesting that loss of FAK activity results in compromised tumor cell survival. When we investigated the pathways through which FAK could affect survival, we found that loss of FAK activity reduces activation of AKT. Reduced AKT activation reduces the expression of pro-apoptotic genes. In summary our studies show that in a basal-like tumor model, FAK is required for survival of the tumor cells. Hence inhibition of FAK could be beneficial for elimination of basa-like tumor cells.

#5883 CHD1 as regulator of cell adhesion in Ets fusion negative prostate cancer. Aparna Kareddula,1 Whitney Petrosky,1 Irina Tershchenko,1 Daniel Medina,1 Hana Aviv,2 Eric Singer,1 Robert S. DiPaola,3 Kim M. Hirshfield,1 Rutgers Cancer Institute of New Jersey, New Brunswick, NJ;2Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; 3School of Medicine, University of Kentucky, Lexington, KY.

Prostate cancer (PCa) develops into lethal disease in about 10% of men diagnosed with this malignancy. Common genomic changes are seen in PCa such as alterations in CSDK181, TP53, PTEN, NKX3-1, MYC and androgon receptor. Oncogenic fusions involving the Ets family are seen in 50-70% PCa patients, the most common of which is TMPRSS2-ERG. TMPRSS2-ERG influences cell migration, particularly when PTEN is co-deleted or PIK3CA activating mutations are present. However, in the absence of ERG fusions, molecular drivers of the PCa phenotype are less clear but include alterations in SPOP (6-15% of PCa), SPINK1 (10%), MAP3K7 (18-38%) and CHD1 (15-27%). CHD1 (Chromodomain Helicase DNA Binding Protein-1) is a chromatin remodeling factor with many roles including homologous recombination mediated DNA repair of double strand breaks and maintenance of genomic stability and therefore it is hypothesized to cause the predominant intrachromosomal rearrangements observed in Ets fusion negative tumors. This study was undertaken to evaluate the cellular effects that follow CHD1 deletion that could aid PCa initiation and progression. CHD1 was knocked out in the non tumorigenic, HPV16 immortalized prostate epithelial cell line, RWPE-1, using CRISPR/Cas9. Compared to control, CHD1-KO cells were less migratory and non tumorigenic in vivo. In contrast, the C-terminus of CHD1, a smaller and rod domain morphology were less adherent to tissue culture plates. To study expression of extracellular matrix and adhesion molecules, RT profiler assay was performed using RWPE-1 parental and CHD1 KO cells. CHD1 KO cells showed a decrease in the expression of SPARC, MMP2, ITGA2, ITGA5, ITGA6, FN1, LAMB3, collagen, tenasin and vitronectin as compared to parental and NT2. Reduction in extracellular matrix and adhesion molecules and altered morphology of CHD1 KO cells as compared to parents and NT2 cells suggest that loss of CHD1 reduces cell-cell and cell-matrix adhesion. These results suggest that in the absence of PTEN loss in Ets negative tumors, deletion of CHD1 gene could change cell adhesion dynamics ascribing a new role for CHD1 in the development and progression of PCa.
us. In this study, many TFSs, including krüppel-like factor 4 (KLF4), were found to preferentially bind to mCpG-containing motifs and transactivate gene expression. Using a site-specific KLF4 mutant (R458A) that abolishes its binding activity to mCpG, but has no impact on binding to its canonical unmethylated motif, we investigated biological function of mCpG-dependent gene regulation by KLF4 in glioblastoma cells. Our study revealed that KLF4-mediated cell adhesion, migration, and morphological changes, all of which are abolished by R458A mutation. We identified over a 100 genes were directly activated via mCpG-dependent KLF4 binding activity. These targets were associated with multiple pathways including pathways involved in cytoskeletal organization, cell adhesion, cytokine, and extracellular matrix. Genes such as NGEF, UGDH, PHLD1R2, LIMS2, LM607 and Rabex-5/RABGEF1 involved in migration and cytoskeletal organization were highly induced. We validated these targets by Bisulfite Sequencing, ChIP-PCR, RT-PCR and western blot to confirm they are indeed KLF4-mCpG direct targets. To understand the biological implication of KLF4-mCpG activity and broaden the current understanding of the role of DNA methylation in transcriptional regulation, we utilized one of the direct KLF4-mCpG targets UGDH to investigate this novel epigenetic regulation. UGDH (UDP-α-D-glucose 6-dehydrogenase) is involved in the biosynthesis of the glycosaminoglycan precursor UDP-α-D-glucuronic. Glycosaminoglycans (GAGs) are one of the major components of the cellular environment. Certain GAGs such as Hyaluronic acid (HA) participate in numerous cellular phenomena, including adhesion, motility, angiogenesis and wound healing. UGDH, although regulated in GBMs has not been implicated in GBM tumor biology. We show that UGDH is required for KLF4-mCpG dependent increase in migration and UGDH knockdown decreases GBM cell proliferation, migration and the abundance of GAGs. Elevated glycosaminoglycan formation is implicated in a variety of human diseases, including the progression of tumors. The inhibition of synthesis of UDP-α-D-glucuronic acid using UGDH antagonists might therefore be a useful strategy for therapy.

#5887 The role of FAK in tumor microenvironment. Hsin-Jung Wu, Syn Kok Yeo, Megan Wilson. University of Cincinnati, Cincinnati, OH.

Focal Adhesion Kinase (FAK) is a cytoplasmic non-receptor tyrosine kinase important in mediating signal transduction in cell migration, survival and proliferation. In the regulation of cell adhesion, migration and cytoskeletal organization in tumors, FAK has been implicated in impacting tumor microenvironment, including endothelial cells and fibroblasts. However, much less is known about how FAK behaves in the tumor stroma affects tumor progression, or how stromal FAK cross-talks with cancer cells. Here we use an inducible Col1α2-creERT; FAK 

#5888 Tmem 205-mediated cisplatin resistance in ovarian clear cell carcinoma (OCCC) is overcome by herpes simplex virus (oHSV)/cisplatin combination therapy. Uksha Saini,1 Maria Riley,2 Kalpana Deepa Doryappan,1 Chelsey Bolyard,1 Balveen Kaur,1 Roman Zingarelli,1 Ikko Konishi,2 Periannan Kuppusamy,3 George Larry Maxwell,4 David E. Cohn,1 Karuppaiyah Selvendiran1.

TUMOR BIOLOGY: Tumor Cell Adhesion and Drug Resistance

Tumor biology is one of the major challenges for the treatment of ovarian cancer. Unlike other solid tumors, ovarian cancer primarily disseminates within the peritoneal cavity. A crucial step in metastasis formation is the adhesion of ovarian cancer cells onto the peritoneal mesothelium under ascitic shear flow. However, the adhesion mechanisms engaged in this tumor-mesothelium interaction remain elusive due to a lack of physiologically relevant model to manipulate and investigate this dynamic process. In this study, using a 3D microfluidic platform, we found that the metastatic population of cancer stem cells (M-CSCs) exhibited slower rolling velocity and higher binding affinity to the peritoneal mesothelium than non-metastatic (NM)-CSCs under flow condition. This adhesion cascade was mediated by P-selectin which expressed on the peritoneal mesothelium. The key carbohydrate determinant on M-CSCs was a glycoprotein, but not a glycolipid, with its recognition as sialyl-Lewis X (sLeX) in a sialic acid- and fucose-dependent manner. Moreover, several glycosyltransferase genes including B4GALT4, ST3GAL3, ST3GAL4 and LIM101 were upregulated in M-CSCs. The upregulation of sLeX and sLeA were significantly inhibited by siRNA targeting TMEM205. Overall, our findings revealed that a distinct sLeX-P-selectin axis of ovarian tumor-mesothelium interaction in early metastasis and may offer the possibility of new therapeutic targets. (This work is supported by RGC grant 1712014.)

Kinase inhibitors are integral for the treatment of certain cancers, but the emergence of drug resistance limits their long-term effectiveness. Resistance can arise through several routes, including the selection of mutants that render it insensitive to drug. Although some resistance mutations for a few inhibitors are well characterized, most remain uncharacterized or even unidentifiable, particularly in new or emerging kinase targets. Ideally, we could characterize every possible resistance mutation that could arise during treatment with each inhibitor. The resulting comprehensive data could improve clinical decision-making for patients with drug-resistant tumors. However, current experimental methods for discovering resistance mutations cannot achieve the required scale, preventing us from realizing this goal. We developed a method for parallel assessment of the degree of inhibitor resistance of nearly all possible single mutants of the promising drug target Src kinase. We generated a comprehensive single mutant library of Src and subjected it to selection for Src activity either alone or in the presence of the inhibitor dasatinib. Then, we measured the change in frequency of each mutant during selection by deep sequencing. Using this data, we classified the impact of each Src mutant, both in terms of activity and resistance to dasatinib. Our method identified dozens of previously uncharacterized dasatinib-resistance mutations in Src. As expected, some of these novel resistance mutations cluster near the ATP-binding cleft of the catalytic domain. However, a surprisingly large number occur at residues distant to dasatinib’s binding site. Biochemical validations of a subset of these newly identified resistance mutations are ongoing. Although dasatinib is not currently approved for Src inhibition, these results could be useful to direct treatment for those patients currently enrolled in dasatinib clinical trials. Our results demonstrate the power of our method for the characterization of resistance mutations in drug targets. In contrast with previous low-throughput and retrospective methods, our approach enables the comprehensive and prospective identification of resistance mutations. The approach can reveal resistance mechanisms, even before a drug is clinically approved. Importantly, our method allows for the rapid profiling of other Src inhibitors and potentially the discovery of inhibitors for resistance mutations. Finally, we are using our data to explore hypotheses regarding the structure, function, or regulation of Src kinase.
Breast cancer has a predilection for bone metastasis, where the five-year survival rate is bleak. Disseminated breast cancer cells invade bone and can remain undetectable and untreatable for decades during a period of reduced proliferation. Our work reveals that osteoblasts are educated into a tumor-associated stromal cell by disseminated breast cancer cells and alter their production of these factors in the tumor microenvironment. Osteoblasts undergo an inflammatory stress response and secrete factors suggestive of the epithelial to mesenchymal transition that significantly inhibit tumor colony formation. In contrast, the overexpression of FAK and SMA expression. Since activated CAFs are known to secrete extracellular matrix proteins, we examined the activation of FAK downstream of integrin signaling and found increased phosphorylation of FAK at Y397. To determine the importance of FAK activation on the interaction between CAFs and PDAC cells, cells were treated with the FAK inhibitor PF573228 and increased activation of TRAP was mediated by crosstalk via gap junction intercellular communication (connexin 43) and cross-exosome exchange that occurred between TAO cells and breast cancer cells. TAO-derived exosomes were found to contain increased amounts of microRNAs 320a and 193b compared to normal osteoblasts or breast cancer cells. microRNA 320a is associated with decreased cellular proliferation and induction of G0 phase of the cell cycle. miR193b has been shown to regulate cyclin D1 expression and repress cellular proliferation. Knock-down of miR320a and 193b in breast cancer cells resulted in a reduced number of cancer cells in G0 and increased numbers of cancer cells in G1/S/G2/M phases of the cell cycle. Furthermore, TAO cell CM led to decreased activation of TRAP+ osteoclasts. We hypothesized that TAO cells induced CAF activation and cocultured or treated with the CM of human breast cancer cells, tumors grew more slowly and were at least 50% smaller than tumors composed of normal osteoblasts plus breast cancer cells, or breast cancer cells inoculated alone. Mice inoculated with an admix of TAO cells plus human metastatic breast cancer cells lived ~20 days longer than mice inoculated with an admix of normal osteoblasts plus metastatic breast cancer cells, or breast cancer cells alone. These data also suggest that TAO cells regulate the proliferation of metastatic breast cancer cells in the tumor microenvironment. Overall, these date suggest that osteoblasts are an important source of factors, specifically exosomal microRNAs, in breast cancer bone metastasis. The nature of these factors suggest their importance for facilitating disseminated breast cancer cell proliferation, as well as osteoclast activation in the bone microenvironment. TUMOR BIOLOGY: Tumor Cell Adhesion and Drug Resistance

5890 Osteoblasts are educated into a tumor-associated stromal cell by disseminated breast cancer cells and mediate breast cancer cell proliferation in the bone microenvironment. Frank Marinj, Julia Chifman, Janet Toones, Candela Garcia-Manzano, Karen M. Bussard. Wake Forest Comprehensive Cancer Center, Winston-Salem, NC; *American University, Washington, DC; 4The University of Texas MD Anderson Cancer Center, Houston, TX; 5Thomas Jefferson Univ Kimmel Cancer Ctr., Philadelphia, PA.

5891 DCIS to invasive progression in breast cancer is delayed by restoring CCN5. Sandipto Sarkar, Arnab Ghosh, Gargi Maity, Snigdha Banerjee, Shashanta Banerjee, University of Kansas Medical Center/ VA Medical Center, Kansas City, KS.

Malignant progression of breast cancer from pre-invasive to invasive lesions remains a mechanistically unknown event and a major challenge in medical research. By revealing the mechanism of action, our new and substantially different approach aims to demonstrate that CCN5/WISP2 might play a role in negative regulation of progression of pre-invasive lesion ductal carcinoma in situ (DCIS) to invasive carcinoma (IC). DCIS to IC transition results primarily from the loss of the myoepithelial cell (MEC) layer surrounding the breast ducts & lobules and basement membrane (BM) degradation followed by invasion of cancer cells into the surrounding stromal tissue and vasculature. It has been recently discovered that CCN5, a matricellular protein, is highly expressed in DCIS patient specimens and facilitates regression of aggressive phenotypes. Our in-vitro studies with myoepithelial cell lines (MECs) indicate that CCN5 may prevent the DCIS to IC transition through the protection of the MEC layer. CCN5 performs its protective role by regulating sonic hedgehog (SHH) expression in MECs. It has been previously shown in separate studies that Neuripin1 (Nrp1) positively regulates expression of SHH and Nrp1 is exclusively expressed in MEC layer in breast tissues. An extension of our studies indicate that CCN5 might regulate the integrity of the mammary ductal architecture by protecting the MEC layer through a non-Nrp1-SHH signaling. In our studies, our studies indicate that regulating CCN5 expression level in breast cancer tissues might help us controlling the rate of progression of the disease from DCIS to an invasive stage.

5892 Induction of stromal fibrosis accelerates tumorigenesis in NeuT mice. Robert I. Glazer, Hongyan Yuan, Lu Jin. Georgetown University Medical Center, Washington, DC.

Background: One of the central challenges in cancer prevention is the identification of factors in the tumor microenvironment (TME) that increase breast cancer susceptibility. The stromal composition of the breast is largely adipose and fibroblast tissue, and thus it is important to understand how alterations in these constituents affect in the onset of stromal fibrosis (SF) and cancer progres-

sion. To address these questions, MMTV-NeuT mice were crossed into the FAT-ATTAC (fat apoptosis through targeted activation of caspase 8) background (NeuT/ATTAC), wherein conditional dimerization of the FKBPs-caspase 8 fusion transgene in female mice results in mammary fat ablation and its replacement with fibrotic tissue. Results: Induction of mammary fat ablation in NeuT/ATTAC mice over 4 weeks resulted in increased ductal proliferation and SF as denoted by increased collagen deposition and expression of Fibroblast Activation Protein and α-smooth muscle actin. Maintaining SF over 3-5 months resulted in a 40% reduction in tumor onset and a 2.5-fold increase in tumor multiplicity, which was associated with increased infiltration by myeloid-derived suppressor cells. Gene expression profiling of tumors from mice with and without mammary fat ablation confirmed increased expression of the immune-related genes Cxcl1, Ly6d and CD14, as well as acute phase proteins Saa1 and S100a6 in NeuT/ATTAC mice with SF. Conclusion: Induction of SF in an erbB2-dependent breast cancer model resulted in a tumor microenvironment more conducive to tumor progression and immune tolerance. These results suggest alternative therapeutic approaches that could be taken, eg, chemokine receptor antagonists, to increase the effectiveness of immunotherapy and chemotherapy. Supported by a grant from the Avon Foundation for Women and Award IP30CA051008 from the National Cancer Institute, NIH, to the Lombardi Comprehensive Cancer Center.

#5893 Bioenergetic signature from cocultures of pancreatic tumor cell lines and fibroblasts. Mª Teresa Agulló-Ortuño,1 Elena Prieto-Garcia,2 C. Vanesa Díaz-García,1 Irene Otero Blas,2 Inmaculada García-Ruíz,1 José A. López-Martin1,3. 1Instituto de Investigación Sanitaria 12 de Octubre, Madrid, Spain; 2Hospital Universitario 12 de Octubre, Madrid, Spain; 3Hospital Universitario 12 de Octubre, Madrid, Spain.

Pancreatic ductal adenocarcinoma (PDAC) is one of the tumors with greater invasiveness and metastasis. PDAC is associated with a large desmoplastic reaction, characterized by fibroblastic proliferation and extracellular matrix secretion. Besides, cellular bioenergetics has become a central issue in investigation of cancer biology, because the altered energy metabolism of cancer cells has been proposed as a potential target for cancer treatment. We have established cocultures between PDAC cell lines (Capan-1 or PL-45) and fibroblasts (LCS). A reverse phase protein microarray (RPMA) approach has been applied to quantify proteins of energy metabolism in theses co-cultures, with the aim of identifying potential biomarkers in PDACs. The fifteen proteins of energy metabolism studied included members of the mitochondrial oxidation of pyruvate, the tri-carboxylic acid cycle, β-oxidation of fatty acids, electron transport and oxidative phosphorylation, glycogen metabolism, glycolysis and oxidative stress using highly specific antibodies. Co-cultures modified proteins expression of energy metabolism, respect to monocultures. Capan-1 in co-culture increased several proteins belonging to OXPHOS (NDUFS3, SDHB, CORE2 and COXII), the antioxidant SOD2, the mitochondrial HSP90, and G6PDH. The expression of the glycolytic PKM2 decreased. Their fibroblasts partners increased the expression of SDHB and also decreased PKM2. PL-45 in co-culture, experimented an increase in HADHA. Their fibroblasts partners showed a decrease in PKM2, LDHA, IF1, PDHe and HSP90.Capann-1 and PL-45 in co-culture with fibroblast, differ in their energy metabolism phenotype. Overall, the results indicate that the quantification of bioenergetic signature offers potential biomarkers that could be implemented to refine the understanding of the biological principles of PDAC and, eventually, the management of patients with these tumors.

#5894 Stromal fibroblasts from metastatic breast cancer promote proliferation and migration of breast cancer cell and regulate its stemness. Yirui Gui, Adriana Aguilar-Mahecha, Marguerite Buchanan, Mark Basil. Ladi Davis Institute for Medical Research, Jewish General Hospital, McGill University, Montreal, Quebec, Canada.

Breast cancer is one of the most common causes of cancer-related death in women in the world. Although most research is focused on the tumor cells, it is important to elucidate the molecular nature of the tumor-stromal relationship to truly understand the biology of breast tumor growth. Cancer-associated fibroblasts (CAFS) are the major cellular constituents of the tumor microenvironment. CAFs are in direct contact with the adjacent cancer cells and crosstalk with them through soluble cytokines, growth factors and exosomes during carcinogenesis in human breast cancer. To determine for the first time the function of CAFs in metastatic sites of breast cancer, we collected CAFs from human patients of metastatic sites (m-CAFs) and compared them with CAFs from primary tumor (p-CAFs) and normal fibroblasts (NFs). We found that m-CAFs expressed higher levels of α-smooth muscle actin (SMA) compared with p-CAFs and NFs. The proliferation of MDA-MB-436 breast cancer cells was significantly increased by treatment with conditioned medium (CM) from m-CAFs compared with p-CAFs in vitro. Also, CM by m-CAFs induced paclitaxel resistance in MDA-MB-436 cells, suggesting that soluble factors produced by m-CAFs promote chemoresistance, to a greater extent than CM from p-CAFs. The migration and invasion ability of MDA-MB-436 cells co-cultured with m-CAFs CM was significantly greater than that of the p-CAFs CM. m-CAFs outperformed the p-CAFs and NFs. Furthermore, CM by m-CAFs induced a 3D in vitro culture model. Furthermore, m-CAFs protected MDA-MB-436 cells from the cytotoxic effects of doxorubicin more than p-CAFs in this spheroid 3-D culture. When MDA-MB-436 cells were sorted from these spheroids and grew in the respective CMs, they showed higher expression of the stemness markers of CD44 /CD24 compared with cells obtained from p-CAFs/MDA-MB-436 spheroids. To these cells from the co-culture with m-CAFs experienced with the cadherin switch. Nanog has been demonstrated to promote chemoresistant and epithelial-mesenchymal transition (EMT). The results displayed that MDA-MB-436 cells incubated with the CM from the m-CAFs had a higher expression of Nanog compared with that of p-CAFs. RNA-seq results showed that IFG2 is one of the most different genes between m-CAFs and p-CAFs, its expression was more significant in m-CAFs co-cultured with MDA-MB-436 cells than p-CAFs. The signaling pathway in MDA-MB-436 cells were comparable between co-cultured with m-CAFs CM and the IFG2 stimulation at 2 hours. All these data illustrates that fibroblasts isolated from metastatic site differed in terms of their ability to promote breast cancer cells progression compared to p-CAFs. Our data suggests that m-CAFs are more potent than p-CAFs in inducing the proliferation, migration, drug resistance and cancer stemness of breast cancer cells in an in vitro model.

#5895 Circulating CAF and cCAF circulating tumor cell co-clusters are associated with metastatic breast cancer. Utsav Sharma, Philip Miller, Kelsie Medina-Saenz, Pedro Ferrer, Svetlana Speransky, Toni Yeasky, Dorraya El-Ashry, University of Miami, Miami, FL.

Background: Breast cancer metastasis is the cause of breast cancer-related mortality. The tumor microenvironment (TME) plays a critical role in governing tumor initiation, progression and metastasis. In breast cancer, cancer associated fibroblasts (CAFs) are master regulators of the TME. Cancer metastasis occurs in part by transport of circulating tumor cells (CTCs) in the circulation. CTCs in clusters, rather than individual CTCs, have a greater capacity to establish metastases. We recently demonstrated that CAFs also circulate (cCAFs), both in clusters with CTCs and individually, in the blood of the majority of breast cancer patients with metastases, some patients without overt metastases, and in no patients with no evidence of disease. Our lab has also established primary breast cancer and primary CAF cell lines from dissociated breast tumors of different molecular subtypes; these are ideal models to dissect tumor–stromal interactions, both in vitro and in vivo. We hypothesize that cCAFs originate from the primary tumor, and further, that cCAFs cluster with CTCs to facilitate metastatic seeding. Methods: We used separately labeled CAFs and primary breast cancer cells (DT28) co-injected into NSG mice and followed by a novel 2-color IVIS. We also modeled the ability of CAFs and breast cancer cells to form clusters in culture and used our microfluidic filter technology to evaluate the composition of clusters. Conclusions: CAFs of breast cancer cells of the metastatic capacity – metastatic DT28 and non-metastatic MCF-7. Results: Through sequential dual-color IVIS we demonstrate that we can monitor the presence of CAFs and breast cancer cells at orthotopic tumor injection sites and to sites of distant metastasis, indicating that cCAFs originate from the primary tumor. Evaluation of cCAFs and CTCs in tumor bearing mice indicates that breast cancer cells with high metastatic potential mobilize greater numbers of cCAFs. CAFs formed robust clusters with metastatic DT28 cells, while non-metastatic MCF-7 cells clustered with each other but not with CAFs suggesting that the ability of breast cancer cells to form clusters with CAFs, both in vitro and in vivo, is reflective of the metastatic capability of the breast cancer cells. Conclusions: The intrinsic metastatic capacities of breast cancer cells are augmented by contact and clustering with cCAFs. In turn, the ability of CAFs to mobilize into circulation is in part conferred by properties of aggressive breast cancer cells. These data corroborate observations from our pilot clinical study that indicated the presence of cCAFs is overwhelmingly associated with the presence of metastatic breast cancer.

#5896 IL-8 signaling enhances TNBC growth and metastasis via crosstalk with stromal components. Kideok Jin, Niranjan B. Pandey, Aleksander S. Podobed, Utsav Sharma, Philip Miller, Kelsie Medina-Saenz, Johns Hopkins Univ. School of Medicine, Baltimore, MD.

Triple negative breast cancer (TNBC) as a metastatic disease is currently incurable. Reliable and reproducible methods for testing drugs against metastasis are not available. We have previously developed a robust metastatic model in
which mice are pretreated with tumor cell-conditioned media (TCM) from hu-
man TNBC cells (MDA-MB-231 and SUM149) for 2 weeks prior to tumor cell
inoculation. In this model we found reproducible spontaneous metastases in
lymph nodes (LN) and lungs within 4-5 weeks after orthotopic tumor inocula-

tion. We have discovered that the TNBC tumor cells secrete large amounts of inter-
eukins (IL-11, IL-6) that "educates" lymphatic endothelial cells (LEC) in theLN
and lungs. Stat3, a transcription factor, gets activated and induces the synthesis of
CCL5 and VEGF among other factors. CCL5 recruits the tumor cells to the LN
and lungs; VEGF helps build blood vessels in the LN to facilitate tumor cell
survival; VEGF produced in the lung helps the tumor cells extravasate into the
lung. We have confirmed the importance of these factors by showing that inhib-
itors of the VEGF and Stat3 pathways significantly inhibit metastasis. In this context using a hu-
man antibody array, we identified factors secreted by fibroblasts and macro-
phages upon induction by MDA-MB-231 TCM. We ranked the expression level of
each factor by real time qRT-PCR and determined that interleukin 8 (IL-8) was the top candidate. We confirmed by ELISA that IL-8 secreted from either fibroblasts or macrophages treated with MDA-MB-231 TCM was upregulated compared to treatment with serum free media (SFM). Our data showed that the proliferation of MDA-MB-231 cells co-cultured with fibroblasts or macro-
phages was enhanced compared to monoculture. Furthermore, MDA-MB-231 cell
migration, a key step in tumor metastasis, was promoted by CM from TCM-
induced fibroblasts or macrophages. Knockdown of CXCR2, IL-8 receptor, ex-
pression by CRISPR-Cas9 system reduces MB231 cell proliferation and migra-
tion compared to wild type. In a mouse xenograft tumor model, the growth of MB231-CXCR2-/- cell was significantly decreased. In addition, the incidence of thoracic metastasis of MB231-CXCR2+/- tumor was reduced com-
pared to WT. We found that the auto- and paracrine loop of IL-8 exists between
TNBC cells and stroma, which results in enhanced IL-8 secretion from the stromal
components. Significantly, inhibition of the IL-8 signaling pathway by Re-
partin, an inhibitor of the IL-8 receptor CXCR1/2, abrogated MDA-MB-231 tumor
growth and metastasis. These findings implicate IL-8 signaling as a crit-
ical event in TNBC tumor growth and metastasis via crosstalk with stromal
components. Further, these studies suggest that IL-8 acts as a key regulator
orchestrating TNBC metastatic breast cancer. Therefore, we have provided ev-
idence that supports the hypothesis that functional antagonism of the IL-8 sig-
naling pathway has the potential to circumvent TNBC breast cancer growth and
metastasis.

#5897 Single cell-derived analysis of desmoid tumors for studying tumor-
stroma interactions. Mushrik Al-Jazawi,1 Steven Xu,2 Qingxia Wei,2 Ray-
mond Poon,2 Benjamin Alman1,1 University of Toronto, Toronto, Ontario, Can-
ada; 2Hospital for Sick Children, Toronto, Ontario, Canada; 3Duke University,
Durham, NC.

Cancer associated fibroblasts play an important role in the maintenance and re-
modeling of the tumor microenvironment, providing the appropriate condi-
tions for neoplastic cell growth and invasion. Desmoid tumors (DT), also
called aggressive fibromatosis, are rare, locally invasive soft tissue tumors that consist of
fibroblastic cells embedded in extracellular matrix. Identification of the stro-
mal cells to study tumor-stroma interactions is difficult due to both populations
displaying a fibroblastic phenotype, and no cell marker exists that reliably dif-
ferrante between the two populations. Majority of DT arise sporadically due
to somatic activating mutations in beta-catenin (CTNNBN1), a major effect-
or of canonical Wnt signaling. We established single cell derived colonies from
multiple DT samples and characterized the beta-catenin mutation status of
each clone by Sanger sequencing. Indeed, we were able to establish both mutant
and non-mutant colonies from DT samples. Quantitative PCR for beta-catenin
targets AXIN2 and LEF1 confirmed differential activity between the mutant and
non-mutant colonies. The specific CTNNB1 codon mutation had no difference
on-beta-catenin transcriptional activity. We next performed a high throughput
surface antigen screen to identify cell markers that can distinguish between the
two subpopulations. Our screen found CD142 to be uniquely expressed by the
mutant colonies, while the non-mutant colonies uniquely expressed Podopla-
nin. Quantitative PCR confirmed the differential expression of these markers.
Furthermore, the CD142-positive population in heterogeneous DT samples cor-
related with their mutation frequency. Importantly, CD142-based cell sorting
allowed the isolation of the mutant subpopulation even in samples that appeared
as wild-type by Sanger sequencing. We also studied the expression of secreted
factors in our mutant and non-mutant populations. We observed that CTHRC1,
a ligand related to the Wnt/PCP pathway, is highly elevated exclusively in the
mutant subpopulations. Recombinant CTHRC1 increased the proliferation rate
of DT primary cultures, as measured by BrdU incorporation, while neutralizing
antibodies against CTHRC1 decreased cell proliferation. The importance of

#5988 The consomic xenograft model identifies genetic changes in the tumor microenvironment that alter the growth and metastasis of head and neck cancers. Michael W. Straza,1 Amy Rymaszewska,2 Kwangok P. Nickel,2 Anne Frei,1 Anirban Chatterjee,2 Rachel Schlaak,1 Amit Joshi,1 Michael Flister,1 Randy J. Kimple,2 Carmen Bergom,1 Medical College of Wisconsin, Milwaukee, WI; 2University of Wisconsin, Madison, WI.

Background: The tumor microenvironment (TME) is known to impact tu-

mor growth, metastatic potential, and treatment response. Nearly all studies of
head and neck cancer (HNC) have focused on somatic mutations in the
malignant genomes. We hypothesized that genetic determinants limited to the microen-
vironment would influence HNC growth and metastatic potential. Approach:
To demonstrate the impact of genetic differences in the TME on HNC cell line in vivo growth we utilized a novel tool, the consomic xenograft model (CXM). A
consomic rat has an entire chromosome substituted into the isogenic back-
ground of another inbred strain by selective breeding. Use of immunodeficient
(IL2Rγ-/-) consomic allows one to study the influence of stromal genetics on tumor biology without the confounding effect of differences in the immune
system through the orthotopic implantation of cancer cells into different con-
sonomic genetic environments. In this system, any disparities in metastatic phenotypes are due to differences in the TME rather than cancer cells or immune response.
We utilized SS and SS.BN3 consomic rat strains, previously shown to affect the growth of breast tumors, to study the effects of the TME on HNC tumor growth using two well-characterized HPV negative HNC cell lines, SCC-6 (base of tongue derived) and SCC-22b (derived from a hypopharyngeal cancer that had metastasized to lymph nodes). Both cell lines were modified to stably express
luciferase. HNC cells were inoculated into the tongue of SS and SS.BN3 animals and tumor growth was monitored by biophotonic imaging after luciferin injec-
tion. Results: A significant difference in the tumor growth was seen between rat
strains for both cell lines, with the SS.BN3 rats exhibiting less tumor growth and metastasis. Median luciferase activity from baseline increased by 4.1-fold vs. 1.1
fold in SCC-6 tumors in SS vs SS.BN3 rats, respectively (p<0.05). A significant differences in lung metastases was also seen between strains. Lung metastases were seen in 88% of SS and 0% of SS.BN3 rats (n=6 per group) inoculated with SCC-6 (p<0.02) and in 75% of SS and 30% of SS.BN3 rats (n=10 per group) inoculated with SCC-22b (p<0.1). Despite a
non-statistically significant difference in the number of SCC-22b inoculated animals with lung metastases, there was a significantly higher metastatic burden as measured by luciferase signal, with the median signal 6.8 fold higher in SS as compared to SS.BN3 (p<0.03). Conclusions: The use of the CXM model dem-
onstrates an important role for the TME in the growth and metastatic spread of HNC tumors. The short term differences in TME between tumoral and stromal samples for both cell lines allow us to investigate the contribut-
ing causal genetic variants in the TME mediating the HNC changes in tumor
growth and metastasis.

#5899 Compartment-resolved proteomics reveal NNMT as a master met-
abolic regulator of cancer associated fibroblasts. Mark A. Eckert,1 Fabian
Coscia,1 Shawn Pan,1 Samantha M. Tienda,1 Agnieszka A. Chryplewicz,1
Chun-Yi Chiang,1 Anthony Montag,1 S. Diane Yamada,1 Matthias Mann,2 Ernst
R. Lengyel1,1 University of Chicago, Chicago, IL; 2Max Planck Institute for Bio-
chemistry, Martinsried, Germany.

The poor outcome of ovarian cancer patients is due to late detection and the ability
of ovarian cancer cells to metastasize quickly throughout the abdominal

cavity. Recent research, including histopathological studies and experiments
with mouse models, suggest that ovarian cancer may actually arise in the fallo-
opian tube as serous tubal intraepithelial carcinomas (STIC). Lesions of the ovary
would, therefore, represent metastases from the fallopian tube. To better under-
stand the molecular events that occur in both the tumor and stromal compart-
ment during ovarian cancer progression, we performed shotgun proteomics on

laser-microdissected tumor and stromal compartments from anatomic sites
representing the hypophyseal progression series for ovarian cancer (STIC →
fallopian tube → ovary → omentum). With an optimized sample preparation
technique, we successfully quantified 4-5000 proteins per anatomic site with
high reproducibility and with as few as several thousand microdissected cells
derived from formalin-fixed and paraffin-embedded (FFPE) biobank speci-

TUMOR BIOLOGY: Tumor Microenvironment

Men. Proteomics of the tumor compartments revealed high inter-patient heterogeneity, with no conserved protein signatures associated with invasion or metastasis. In strong contrast, a highly conserved molecular signature of stromal proteins associated with metastasis to the omentum was identified. In particular, nicotinamide N-methyl transferase (NNMT) was highly upregulated in the stroma of aggressive pancreatic cancer cells. Independent analysis of more than 17,000 proteins in a mouse model of peritoneal metastasis demonstrated that NNMT is expressed in cancer stroma and is associated with gene expression changes in the tumor stroma. This work supports the use of ultra-low input proteomics for compartment-resolved identification of candidate drivers of disease phenotypes and identifies NNMT as a central, metabolic regulator of CAF differentiation.

#5900 Transforming growth factor-beta (TGF-β) inhibitor modulates cancer stroma in a pancreatic cancer orthotopic mouse model. Takashi Murakami,1 Yukiko Hiroshima,2 Kentaro Miyake,1 Tasuku Kiyuna,1 Ho Kyoung Hwang,1 Kei Kawaguchi,1 Jonathan C. DeLong,1 Thinner M. Lwin,1 Kentaro Igarashi,1 Ryusei Matsuyama,2 Ryutaro Mori,3 Takafumi Kumamoto,7 Takashi Chishima,5 Kuniya Tanaka,6 Michael Bouvet,2 Itaru Endo,2 Robert M. Hoffman,1 1University of California, San Diego, San Diego, CA; 2Yokohama City University Graduate School of Medicine, Japan.

Background: The tumor microenvironment (TME) contributes to the recapitulation of this disease. Cancer-associated fibroblasts (CAFs) are thought to be important for the pancreatic cancer TME. Transforming growth factor-beta (TGF-β) has an important role for CAF induction. The present report describes the efficacy of a TGF-β inhibitor to modulate pancreatic cancer stroma in an orthotopic mouse model. Materials and methods: BxPC-3 human pancreatic adenocarcinoma cells expressing green fluorescent protein (GFP) were implanted subcutaneously in athymic nude mice expressing red fluorescent protein (RFP). Established dual-color tumors, with GFP cancer cells and RFP stroma, were cut into small fragments and then implanted orthotopically onto the tail of the pancreatic RFP-expressing nude mice. Fourteen mice were randomized into control group (n = 7, vehicle, i.p., weekly, for 3 weeks) and treated group (n = 7, SB431542 (TGF-β inhibitor) 0.3 mg i.p., weekly, for 3 weeks) when tumor diameters reached to 7 mm. Pancreatic cancer stroma was evaluated weekly for 3 weeks by real-time intravital imaging with the FV-1000 confocal microscope. Stromal ratio, the percentage of the RFP fluorescence area from the stromal cells relative to the total fluorescence area, was calculated with ImageJ. Tumors were resected on the 21st day from the initial treatment for histological evaluation. Results: Microvessel density using anti-CD31 antibody and expression of CD31-antibody and expression of TGF-β were examined by immunohistochemical staining. Results: The GFP cancer cells and RFP stromal cells were distinctly imaged. The stroma ratio significantly decreased in the TGF-β inhibitor treated mice compared to control untreated mice from day 7 to 21. TGF-β expression and microvessel density were reduced in the treated mice. Conclusions: The present study demonstrated that TGF-β inhibitor treated mice have a decreased cancer stroma, indicating that TGF-β inhibitor treatment may be an option to modulate pancreatic cancer stroma. However, more studies are required to fully understand the role of TGF-β in pancreatic cancer stroma.

#5901 Involvement of VEGF-A signaling in the acquisition and maintenance of human prostate carcinoma-associated fibroblast phenotype. Javier Cerda Infante, Marianela Sanchez, Paola Conejerios, Alejandra Alarcón, Alejandra Godoy, Enrique Brandan, Viviana P. Montecinos. P. Catholic University of Chile, Santiago, Chile.

Introduction: Progression of prostate cancer (CaP) is modulated by the carcinoma-associated fibroblasts (CAFs) within the tumor microenvironment. However, little is known about the specific mechanisms involved in the activation of the benign prostate fibroblasts (BAFs) to CAFs in CaP and the specific signaling altered in CAFs that are needed to maintain its activated phenotype. Vascular endothelial growth factor-A (VEGF-A) is overexpressed in CaP and, additionally to the angiogenic effect, a non-angiogenic effects of VEGF-A on cancer cells have been recently reported. This study seeks to evaluate the potential role of VEGF-A signaling in the activation of BAFs and/or in the maintenance of the activated phenotype presented in CAFs. Methods and Method. Primary cultures of BAFs and CAFs were characterized by gene expression profile, qPCR, WB and ELISA for the expression and/or secretion of VEGF-A and its receptors. Dose-response and time course analysis for the effect of exogenoux VEGF-A, TGF-β1 and conditioned medium from CAFs (CM-CAFs) were analyzed by RT-qPCR, immunocytochemistry and WB for the stroma cell markers: Vimentin, Pro-collagen, α-SMA, Tenascin, Fibronectin and FSP-1. The contribution of VEGF-A signaling to the phenotype of CAFs was determined by siRNA assays for the VEGFRs and the functional effect of CAFs on cancer progression was studied using CM-CAFs or CM from VEGFR siRNA-CAFs over PC3 cancer cell lines, in vitro and in vivo. Results: Exposure of primary cultures of BAFs to exogenous VEGF-A, TGF-β1 and CM-CAFs upregulate stroma cell markers associated with the appearance of CAFs phenotype and it is reversed with the pre-treatment of the VEGF-A antibody Bevacizumab. Furthermore, CAFs, but not BAFs, produced massive levels of VEGF-A and over-express its cognate receptors. siRNA studies demonstrated that knock down of VEGFRs in CAFs results in the activated phenotype and CM from VEGFRsiRNA-CAFs failed to increase the migration and invasion potential of PC3 cells in vitro and tumor growth in vivo. Discussion: Our data indicate that VEGF-A signaling plays a key role in the activation of human prostate fibroblasts. Furthermore, VEGF-A and TGF-β1 interactions may cooperatively regulate activation of fibroblasts within the tumor microenvironment in CaP. These findings also suggest that blockade of this signaling cascade in the activated fibroblasts could be a potential therapeutic target designed to prevent disease progression.  1506 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
signal activation by CAFs co-operates for promoting FAK phosphorylation and enhances the invasiveness of GC cells in extracellular matrix (ECM). On the other hand, a previous study presented that CXCR4 and integrin signaling co-operates in mediating adhesion and chemoresistance in small cell lung cancer cells. Therefore, we hypothesized that CXCL12-CXCR4 and integrin signal activation by CAFs and CXCL12-CXCR4 integrin related signaling by western blotting analysis. Furthermore, we investigated the critical molecule for chemoresistance by silencing CXCR4 or integrin beta1 in GC cells. Results: ROS-sensitive assay and chemo-sensitive assays revealed that GC cells cultured with CAF-CM showed more resistant to ROS and cisplatin than those cultured with fresh medium. Moreover, GC cells with CAF-CM on Matrigel-coated plates exhibited remarkable resistance in these assays. On the other hand, western blotting analysis showed that Akt activity in GC cells cultured with CAF-CM was up-regulated in concurrence with FAK phosphorylation. Finally, the chemoresistance induced by CAFs was significantly suppressed by CXCR4 or integrin beta1 silencing. Conclusions: These results suggest that interaction with ECM is important for enhance chemoresistance mediated by CXCL12-CXCR4 and integrin beta1 signal activation by CAFs in GCs. This mechanism underlying the chemoresistance may provide a novel therapeutic target in advanced GCs.

**#5904** Stiffness of extracellular matrix regulates breast cancer progression by stimulating mesenchymal stem cells. Seiichiro Ishihara, David R. Inman, Wan-Ju Li, Suzanne M. Ponik, Patricia J. Keely. *University of Wisconsin-Madison, Madison, WI.*

The tumor microenvironment contains cancer cells, non-cancerous cells, and extracellular components such as extracellular matrix (ECM). Previous studies have demonstrated that interactions between the cells and the microenvironment contribute to cancer progression via chemical stimuli, such as growth factors, and mechanical stimuli, such as stiffness of the ECM. Recently, it has been reported that mesenchymal stem cells (MSCs) differentiates into cancer associated fibroblasts (CAFs) in response to chemical stimuli from cancer cells and thereby promote cancer progression. However, the contribution of mechanical stimuli to MSCs in cancer is poorly understood. In this study, we revealed that MSCs showed CAF phenotypes and promote mammary cancer progression in response to mechanical stimuli. On a stiff substrate, MSCs treated with conditioned media from cancer cell culture expressed increased levels of alpha smooth muscle actin (alpha-SMA), a marker of CAFs, compared to the MSCs cultured on a soft substrate. MSCs grown on a stiff substrate displayed higher expression and activity of YAP and increased phosphorylation of myosin light chain (MLC) compared to MSCs grown on a soft substrate. In addition, knockdown of YAP by shRNA decreased the expression of alpha-SMA and phosphorylation of MLC in MSCs on a stiff substrate. Pharmacological inhibition of MLC phosphorylation by H1122 treatment also reduced expression of alpha-SMA and activity of YAP in MSCs. Cell-cell communication between MSCs and carcinoma cells was unidirectional, as conditioned medium from MSCs cultured on a stiff substrate, but not a soft substrate, increased growth of mammary carcinoma cells. The soluble factor prosaposin was highly secreted by the MSCs on a stiff substrate, and the addition of recombinant prosaposin increased proliferation and survival of mammary carcinoma cells. Furthermore, secretion of prosaposin was promoted in YAP-overexpressed MSCs on a soft substrate. Mammary carcinoma cells treated with prosaposin showed increased level of phosphorylation in Akt at T308. In addition, inhibition of phosphorylation of Akt at T308 prevented proliferation and survival in mammary carcinoma cells. These results suggest that increased stiffness of the ECM in the tumor microenvironment induces differentiation of MSCs to CAFs via YAP and actomyosin contractility, secretion of prosaposin from MSCs, and as a result, trigger progression of mammary cancer via phosphorylation of Akt at T308.

Background: Cancer associated fibroblasts (CAFs) are activated fibroblasts and an important player in the tumor microenvironment. Their activity promotes cancer cell proliferation, migration, and invasion, and metastasis. The most prognostic factor in tumor progression is metastasis. Cancer metastasis is a multi-step process that tumor cells detach from primary site, survive in the bloodstream, and seed in target organ. Although previous studies have focused on the interaction between CAFs and cancer cells in primary tumor site, the roles of CAFs in blood circulation remain largely unknown. We investigated the effect of CAFs coexisting with cancer cells in bloodstream on tumor metastasis in vivo mouse model, and also examined the effect of CAFs in subcutaneous tumor. Methods: We used female BALB/c-nu/nu mice and BALB/c mice in the experiments. Cancer cells were mouse mammary carcinoma cell lines 4T1 transfected with luciferase, colon cancer cell lines Colon 26 transfected with luciferase. Fibroblast cell lines were mouse embryonic fibroblast MEF and NIH-3T3. In vivo injection mouse model, we injected 1 × 10⁶ cancer cells alone or the same number of cancer cells and fibroblast co-cultured together. When we injected cancer cells transfected with luciferase, the mice were subjected to in vivo imaging system (IVIS) and measured luminescence intensity of metastatic sites. We have also harvested lung and compared its weight and metastatic nodules under microscopy. Furthermore, in subcutaneous tumor metastatic mouse model, cancer cells alone or mixed with cancer cells and CAFs were subcutaneously inoculated into the mice. Results: In the group of mice injected with cancer cells and fibroblasts, luminescent intensity of each lungs were higher than cancer cell alone. Harvested lung weight and the number of metastatic nodules were also higher in the group with cancer cells and fibroblasts. In subcutaneous model, mice inoculated with cancer cells and fibroblast had much more metastatic sites than cancer cells alone. Conclusions: Our data indicate that CAFs promote tumor metastasis by stimulating cells in blood circulation, and regulate metastatic site. These findings suggest that CAFs in both bloodstream and primary site could be a promising therapeutic target. CAF-targeted therapy could reduce tumor metastasis and improve the prognosis of cancer patients.

**#5906** TIMP-1 expression is inversely correlated with miRNA125a-5p and let-7e in non-small-cell lung carcinoma. Ammar Kutiyawanalla, Sampa Ghoshal-Gupta, Byung R. Lee, Ashis Mondal, Ravindra Kolhe, Amy M. Rojiani, Mantuz V. Rojiani. *Medical College of Georgia- Augusta University, Augusta, GA.*

Epigenetic alterations are emerging as significant elements in our understanding the biology of lung cancer which remains the leading cause of cancer deaths worldwide. In earlier studies we have shown that tissue inhibitor of metalloproteinase 1 (TIMP-1) overexpression in NSCLC cells results in aggressive tumors in mice. We have also demonstrated TIMP-1’s anti-apoptotic activity in these cells. It is well documented that miRNAs are involved in many physiological and neoplastic processes, including apoptosis. We have previously shown that knocking down TIMP-1 in A549 NSCLC cells alters the miRNA profile in these cells with upregulation of miR-125a-5p. Subsequently, we have identified that miR let-7e is also upregulated in TIMP-1 KD clones. The present study is focused on confirming the involvement of miR-125a-5p with TIMP-1 by using mimics and antagonoms of 125a-5p. Furthermore, we have sought to validate this relationship in vivo by examining these patterns in clinical samples. We have added mimics of miR-125a-5p into the parental A549 cells, which resulted in down expression of TIMP-1 levels. We were then able to rescue TIMP-1 downregulation by adding antagonoms of miR-125a-5p to the same cells. MiR-125a-5p binding sites were identified in TIMP-1 3’ UTR and using luciferase assay, we have confirmed that TIMP-1 is indeed a bona fide target of miR-125a-5p. Translational studies were carried out using archived NSCLC adenocarcinoma tissues from the Surgical Pathology archives at AU Medical Center. We first measured expression level of TIMP-1 by RT-PCR in 20 tumors and paired normal adjacent tissues and divided the samples into 2 groups, those with low and high TIMP-1 expression levels. Tissues were then interrogated for miR-125a-5p and let-7e miRNA expression using chromogenic in situ hybridization. We identified negative correlation pattern between tumor and paired normal adjacent tissue samples. Generally, TIMP-1 was highly expressed in the tumor region, while miRNA expression was relatively decreased when compared with adjacent normal tissues. miRNA125a-5p and let-7e are known tumor suppressors in NSCLC. Analyzing secondary data (adenocarcinoma) by KM plotter we found that high TIMP1 correlated with lower patient survival with a hazard ratio of 3.17 (2.34-3.7) and a log rank p value of 8.1e-14. These studies provide additional clarity and further extend our understanding of the relationship between these miRNA families and TIMP-1 expression.

**#5907** Radiotherapy-induced damage to cancer-associated fibroblasts and its reciprocal influence on cancer progression: Impact of soluble factors. Olivier De Bever, Joke Tommelein, Marc Bracke, Tom Boterberg, Pieter Demetter, Laurin Verset, Ghent Univ. Hospital, Ghent, Belgium; Université Libre de Bruxelles, Brussels, Belgium.

Epigenetic alterations are emerging as significant elements in our understanding the biology of lung cancer which remains the leading cause of cancer deaths worldwide. In earlier studies we have shown that tissue inhibitor of metalloproteinase 1 (TIMP-1) overexpression in NSCLC cells results in aggressive tumors in mice. We have also demonstrated TIMP-1’s anti-apoptotic activity in these cells. It is well documented that miRNAs are involved in many physiological and neoplastic processes, including apoptosis. We have previously shown that knocking down TIMP-1 in A549 NSCLC cells alters the miRNA profile in these cells with upregulation of miR-125a-5p. Subsequently, we have identified that miR let-7e is also upregulated in TIMP-1 KD clones. The present study is focused on confirming the involvement of miR-125a-5p with TIMP-1 by using mimics and antagonons of 125a-5p. Furthermore, we have sought to validate this relationship in vivo by examining these patterns in clinical samples. We have added mimics of miR-125a-5p into the parental A549 cells, which resulted in down expression of TIMP-1 levels. We were then able to rescue TIMP-1 downregulation by adding antagonons of miR-125a-5p to the same cells. MiR-125a-5p binding sites were identified in TIMP-1 3’ UTR and using luciferase assay, we have confirmed that TIMP-1 is indeed a bona fide target of miR-125a-5p. We identified negative correlation pattern between tumor and paired normal adjacent tissue samples. Generally, TIMP-1 was highly expressed in the tumor region, while miRNA expression was relatively decreased when compared with adjacent normal tissues. miRNA125a-5p and let-7e are known tumor suppressors in NSCLC. Analyzing secondary data (adenocarcinoma) by KM plotter we found that high TIMP1 correlated with lower patient survival with a hazard ratio of 3.17 (2.34-3.7) and a log rank p value of 8.1e-14. These studies provide additional clarity and further extend our understanding of the relationship between these miRNA families and TIMP-1 expression.
Preoperative radiotherapy is a mainstay in current management of colorectal cancer. Several tumor types, including colorectal cancer, show an abundant desmoplastic stroma, characterized by cancer-associated fibroblasts (CAFs). Nevertheless the effects of radiation to the CAFs in the stroma and its reciprocal impact on the response of CRC cells to irradiation have not been studied. We investigated the functional (cell number, morphology) and biochemical (transcriptomics, metabolomics and kinomics) phenotype of CRC cells in response to paracrine signals from irradiated CAFs. Using neutralizing antibodies and small molecule inhibitors, we analysed the role of tyrosine-kinase receptor activation in CRC cells in response to supernatants from irradiated CAFs. Furthermore, the impact of tyrosine-kinase receptor neutralization in combination with RT was evaluated by an orthotopic CRC model. The level of TKO activation, a downstream tyrosine-kinase receptor intermediate, was analysed in response to neoadjuvant treatment in human CRC specimens. Further work will reveal which soluble factor(s) are implicated in the communication between irradiated CAFs and colorectal cancer cells.

Drug resistance remains a major problem in the treatment of most cancers. For example, KRAS wild-type colorectal cancers (CRCs) are typically treated with the anti-epidermal growth factor receptor (EGFR) therapy cetuximab in combination with standard chemotherapy; however, of the 40% of patients that do respond, virtually all relapse within 3-12 months. Additionally, around 25% of non-responders are not treatable. This suggests that it is not just cell-intrinsic mechanisms that result in resistance, but that extrinsic factors play a role. The purpose of this study was to investigate how the dynamics of the tumor microenvironment, specifically cancer-associated fibroblasts (CAFs) and hypoxia, modify the response of CRC cells to cetuximab. We used a novel high-content imaging platform to generate quantitative phenotypic data (i.e. morphology, birth/death rates) of cellular co-cultures perturbed by multiple, co-occurring microenvironmental conditions. Preliminary data demonstrated reduced sensitivity of tumor cells to cetuximab in the presence of CAFs, which was dependent on patient specifics and time scale of co-culture. Additionally, we found that low oxygen conditions altered the effect of CAFs on tumor cell phenotypes, which highlights the importance of studying co-occurring micro-environmental factors. This work underlies the importance of considering not just the genetic makeup of patient tumors, but also the heterogeneity of the surrounding microenvironment when designing personalized treatment strategies.

Considerable evidence suggests that cancer-stem cells (CSCs) play critical roles in tumorigenesis and metastasis. Although surface marker expression or enzymatic activity of CSC has proven useful, variability of expression highlights the need for the development of high throughput functional CSC assays. One such approach utilizes the capability of CSC’s to form single-cell-derived spheres in suspension environments (functional CSCs). Microfluidic tools are suitable for handling and monitoring a large number of single cells in suspension as well as for examining the interaction of these cells with those in the tumor micro-environment including cancer associated fibroblasts (CAF’s). In order to accomplish this, we have developed a high-throughput (10,000-well), simple-to-use, vertical platform for CSC/CAF co-culture. The platform consists of a non-adherent substrate having 10,000 micro wells for single-cell-derived sphere formation and a porous trans well for CAF adherent co-culture. As predicted by Poisson’s distribution, approximately 30% of micro wells capture single cells when T47D breast cancer cells are loaded at a concentration of 200k/μL. After cell seeding, trans wells containing CAF’s are placed onto the substrate. 0.4μm pores on the trans well allow for secretion-based cellular interaction while preventing direct CSC/CAF cell contact. This cell separation facilitates sample cell retrieval without cell cross contamination. Utilizing this device, we determined that co-culture of tumor cells with CAF’s doubled the frequency of sphere formation. Spheres derived from individual CSCs were then retrieved and dissociated for single-cell transcriptome analysis utilizing RNA barcoding followed by RNAseq. Molecular analysis revealed significant cellular heterogeneity among sphere derived cells. In addition, principal component analysis of single cell RNAseq, revealed significant differences in gene expression between mono-cultured and CAF co-cultured cells isolated from tumor spheres. These genes represent potential therapeutic targets for interfering with CSC stromal cell inter-actions in the tumor microenvironment. The vertical adhesion suspension co-culture platform provides a system to identify and evaluate novel CSC targeted therapeutics.

#5910 Influence of 3D-cultured prostate cancer and stromal cells on drug response. Dominique N. Gales, Sonni Miller, Temesgen Samuel, Clayton Yates. Tuskegee University, Tuskegee, AL.

Background: Response to chemotherapeutic drugs presents a significant challenge to effective treatment of advanced prostate cancer. Exploration of therapeutic response has focused largely on the tumor cell. However, evidence suggests mechanisms that involve the tumor microenvironment mediate response to therapeutics. Therefore, it is imperative to mimic the in vivo tumor microenvironment, to bridge the gap between in vitro studies and the development of therapeutics. The concept of three-dimensional (3D) cell culture and co-culture of multiple cell types is critical to predict therapeutic efficacy and outcome. Thus, these studies sought to determine the distinct responses to anti-cancer drugs in 3D cell spheroids. Methods: In this study, we utilized metastatic prostate cancer cells (PC3) and freshly cultured prostate bone stromal cell line (HS27a) to generate tumor spheroids. Tumor spheroid viability was measured at 72 and 120 h using the CellTiter-Glo 3D assay after treatment with three common anti-cancer drugs, Docetaxel (4μM), Enzalutamide (30μM), and Bicalutamide (30μM). Treatments were compared with spheroids originated from HS27a and HS27a PC3 cells (cell lines in which omentin induced glucose uptake was normalized using the untreated cells as 100% cell survival. Results: Spheroid formation increased resistance to Docetaxel, Enzalutamide, and Bicalutamide. However, PC3 spheroid cells were significantly higher compared to HS27a and co-culture spheroids. For all three spheroids, as the size of the spheroids increase, cellular resistance to anti-cancer and hormone drugs increased. Conclusion: The findings in this study demonstrated that the use for 3D-cell cultures influence many aspects of PCA behavior including, proliferation rates, and response to chemotherapeutics.

#5911 Omentin drives metabolic shift in ovarian cancer cells in the omental tumor microenvironment. Chi Lam Au Yeung,1 Abhinav Achreja,2 Hongyuen Zhao,2 Tsz-Lun Yeung,1 Rosemarie Schmandt,1 Daniel K. Yip,3 Karen H. Lu,1 Deepak Nagrath,1 Samuel C. Mok1. 1UT MD Anderson Cancer Center, Houston, TX; 2Rice University, Houston, TX; 3University of South Florida, Tampa, FL.

Advanced stage high grade serous ovarian cancer (HGSOC) metastasizes preferentially to the omentum, which is a well-vascularized fold of peritoneal tissue and is a major site of adipose tissue accumulation. The mechanisms by which omental adipose tissue interact with ovarian cancer cells and promotes tumor growth and disease progression are not entirely clear. We previously showed that a novel adipokine called omentin (Intestinal Lactoferrin Receptor ITLN1) produced by the omental adipose tissue was significantly down-regulated in patients with HGSOC compared to healthy individuals and omentin suppressed ovarian cancer cell growth only in the presence of adipocytes in vitro. Since we and others demonstrated that omentin induced insulin-dependent glucose uptake exclusively in adipocytes, we therefore hypothesized that omentin may suppress ovarian cancer growth via driving metabolic shift in ovarian cancer cells in the omental microenvironment. Using a cancer cell/adipocyte co-culture model, we demonstrated that omentin reduced both glucose uptake and lactate secretion in ovarian cancer cells when they were co-cultured with adipocytes but not with other stromal cell types, suggesting that omentin-induced glucose uptake in adipocytes may deplete the surrounding glucose that fuels the glucose-addicted ovarian cancer cells in the omental microenvironment and thus drive metabolic shift in ovarian cancer cells. To delineate the mechanism by which omentin suppressed ovarian cancer cell glucose uptake in adipocytes, expression levels of the adipocyte-specific glucose transporter GLUT4 induced by omentin in adipocytes and the effect of GLUT4 silencing in adipocytes using GLUT4 specific siRNAs on ovarian cancer growth were examined. The results showed that omentin up-regulated GLUT4 in adipocytes and GLUT4 silencing in adipocytes abrogated the effects of omentin on glucose uptake in cocultured ovarian cancer cells compared to controls. Taken together, this study shows that omentin plays an important role in driving metabolic shift in ovarian cancer cells in the omental microenvironment. Therapeutic strategies based on up-regulating omentin in ovarian cancer patients may inhibit ovarian cancer progression and improve patient survival rates.

#5912 Tumor microenvironment modulates RTK signaling. Dhruv Thakar,1 Shali T. Low-Nam,2 Jay T. Groves,1 Valerie M. Weaver1.1 University of California San Francisco, San Francisco, CA; 2University of California Berkeley, Berkeley, CA.

Receptor tyrosine kinases (RTKs) and their associated signaling molecules are mutated or dysregulated in many aggressive cancers such as non-small cell lung carcinoma (NSCLC), breast cancer, and colorectal cancer. Despite therapeutic interventions such as tyrosine kinase inhibitors (TKI) that target RTKs, majority of patients develop resistance even after initial tumor regression. Although clinical studies suggest sequential treatments with TKI, chemotherapy, and radiation can eliminate most cancer cells, resistance inevitably emerges (Sequist, et al., Sci Trans Med, 2011). We demonstrated that alterations in the extracellular matrix (ECM) correlate with cancer progression and that RTK signaling is subject to spatiotemporal regulation (Paszek, et al., Cancer Cell, 2005; Salaita, et al., Science, 2010). Thus, geometric and mechanical properties of the ECM may directly modulate RTK signaling. Here, we use silicone gel substrates that exhibit tunable stiffness in the physiological range (100s Pa – 10s kPa) to measure RTK-adaptor protein interactions in mammary epithelial cells (MECs; MCF10A) (Ou, et al. Integr. Biol., 2016). These gels are compatible with total internal reflection fluorescence (TIRF) imaging and enable single molecule detection of activated RTK phosphoryrosine residues via recruitment of Grb2 tagged with the fluorescent protein mEos3.2. We demonstrate a spectrum of Grb2 behaviors that are determined by the stiffness of the substrate. This indicates that the same receptor is capable of different signaling activities that are dictated by material properties. These new insights create opportunities to target the tumor microenvironment to address RTK inhibitor resistance and metastasis in cancer patients and to develop effective therapeutic strategies for better prognosis and prolonged patient survival.

#5913 The impact of daily exercise on tumor perfusion. Jennifer M. Wiggins,1 Sharon Lepler,1 Christine Pampol,1 Lori Rice,1 Jennifer A. Lee,2 Dietmar Siemann1.1 University of Florida, Gainesville, FL; 2National Cancer Institute, Bethesda, MD.

Ablative blood vessel networks in solid tumors lead to impaired tissue perfusion and areas of hypoxia (pO2 < 10 mmHg). Tumor hypoxia is associated with aggressive progression, dissemination, and therapeutic resistance. It is found in 40% of breast cancers, and can constitute a major obstacle to anticancer therapy. Exercise is associated with improvements in cardiovascular and respiratory function, aerobic capacity and overall health. In cancer patients undergoing chemotherapy and radiation, exercise has been shown to decrease treatment related side effects and general fatigue. The goal of the present investigation was to determine whether aerobic exercise could be applied to improve tumor perfusion and oxygenation in a breast cancer model. Such modulation of the tumor physiology and host environment would be expected to lead to enhanced antitumor efficacy when combined with radiotherapy or chemotherapy. The effects of a single and daily bouts of moderate intensity treadmill running were studied in mice bearing the syngeneic murine mammary carcinoma 4T1. The exercise intensity was determined by measuring the anaerobic threshold, which was assessed by measuring the steady rise in blood lactate during exercise. Initial studies examined the effect of a single moderate bout of exercise (18 m/min) in mice bearing ~500 mm3 orthotopic tumors. In subsequent experiments mice were exercised at 18 m/min, 5 days a week, for 8 weeks prior to orthotopic injection of tumor cells and continued exercise (5 days a week) for 2 weeks during tumor growth. Controls for each treatment consisted of sedentary mice exposed to a stationary treadmill for the equivalent amount of time. At the end of each of the exercise regimen, tumors were harvested, sectioned, stained, and tile mapped to assess physiological changes by immunofluorescence. The detection of open blood vessels (Hoechst-33342) was used as an indirect indicator of perfusion. Tumor hypoxia was determined using the 2-nitroimidazole (EF5). Blood vessels were stained using the endothelial cell marker CD-31. All markers were quantified using Photoshop and ImageJ NIH software. Our results indicate that in the 4T1 breast cancer model moderate intensity exercise did not significantly alter tumor growth, oxygenation or blood vessel number. However, daily bouts of exercise did significantly increase the number of open tumor vessels indicating improved tumor perfusion. These results suggest that a daily exercise regimen may have the potential to improve drug delivery to mammmary tumors.

#5914 A soft microenvironment protects from failure of midbody abscission and multinucleation downstream of EMT initiators. Allison K. Simi,1 Alisya A. Anlas,1 Sherry X. Zhang,1 Tiffany Hsaia,1 Derek C. Radisky,1 Celeste M. Nelson.1 1Princeton University, Princeton, NJ; 2Mayo Clinic Cancer Center, Jacksonville, FL.

This study investigates how increased stiffness of the tumor microenvironment can induce cellular multinucleation, an easily observable marker of polyplody. Up to 37% percent of tumors exhibit whole-genome doubling, which typically precedes other somatic copy number alterations. Additionally, induction of tetraploidy in human cells promotes increased tolerance for mutation, tumor growth and tumor transformation. Tumor cells are inherently stiffer than normal tissue, and this property has been shown to affect cell growth and proliferation. Similarly, cell cycle errors have long been linked to chromosomal abnormalities. Here, we used engineered two-dimensional substrata that mimic the stiffness of tumor and normal microenvironments to investigate how matrix stiffness regulates multinucleation in mammary epithelial cells. Multinucleation was quantified by staining with Hoechst to visualize the nuclei. Timelapse microscopy enabled visualization of the process by which cells become multinucleated. Changes in gene expression were determined by quantitative RT-PCR. Cells cultured on “soft” substrata, representing tumor tissue, showed a nearly 14-fold increase in multinucleation compared to cells cultured on “hard” substrata, representing normal tissue. We found that multinucleation was induced in part by signaling downstream of matrix metalloproteinase-3 (MMP3), which is commonly upregulated in cancer and known to induce epithelial-mesenchymal transition (EMT). This signaling depended on expression of the Rac1 splice variant, Rac1b, production of ROS, and expression of Snail. Under all conditions, cells cultured on soft substrata maintained a low frequency of multinucleation. Multinucleation on stiff substrata was not seen without previous treatment. A soft tumor microenvironment protected the stability of the genome in epithelial cells by preventing midbody resorption, which depended on septin 4, a novel target of Snail. Importantly, we found that transforming growth factor-β (TGFβ), another EMT-inducer, also caused multinucleation downstream of Snail, which was prevented by culture on soft substrata. Our data thus suggest that tissue stiffening during tumorigenesis and bioengineered tumor microenvironments in preclinical and clinical cancer applications. Methods: We utilized a novel method CLARITY that has been shown to transform intact rodent tissues into an optically transparent and permeable hybridized-hydrogel form that can undergo immunostaining followed by 3-D imaging of nucleic acids and proteins markers, without the need to separately analyze hundreds of conventional FFPE sections. In this study, human breast and lung cancer excision biopsy samples were obtained commercially. Murine orthotopic MCF-7 xenograft and patient-derived xenograft (PDX) breast tumors were explanted and prepared as fresh samples. The intact tissues were incubated in a mixture of 4% paraformaldehyde/4% acrylamide/0.05% bis-acrylamide for 48 hours, and polymerized in the presence of a thermal initiator, VA-044, for 3 hours at 37°C to form an intact hydrogel/tissue matrix. The tissues were then lipid-cleared in a solution of 0.2M borate buffer containing 8% SDS, pH 8.5 at 45–55°C from 5–35 days, depending on sample size. The cleared tissues were then stained with two multiplex antibody panels that were selected to highlight the microenvironment of the tissue including, immune cells (CD-3 or CD-8), vasculature (Lectin-Texas Red or CD-31), and tumor (cytokeratin[8 + 18] or PD-L1, directly conjugated to Alexa Fluor® 647®). For non-directly conjugated antibodies, the tissues were then subjected to a secondary goat anti-mouse or goat anti-rabbit antibody conjugated to either Alexa Fluor® 568 or 700 followed by a nuclear counterstain, Sytox Blue. Samples were then placed in an appropriate refractive index solution for imaging on a laser scanning confocal microscope. Results: The tissues remained intact throughout the procedure and the cellular morphology of the tissue was well preserved. The individual components of the microenvironment could be identified, demonstrating that the tissues could be successfully interrogated with a multiplex of indirect and directly conjugated commercially available antibodies. These preliminary studies, provide evidence for the use of this novel technology for detecting the heterogeneity of biomarker expression within the tumor microenvironment. Most notably, the analysis of a lymph node from a patient with metastatic breast cancer revealed variation across the tissue which may have implications for the detection of micro-metastasis in patients with early stage disease when using conventional thin section histological methods. Conclusion: These results implicate CLARITY as a powerful next generation tissue process.
TUMOR BIOLOGY: Tumor Microenvironment 8

ing technology for profiling the intact tumor microenvironment, eliminating the need to recapitulate this spatial and quantitative information with standard thin section techniques.

#5916 Proton-sensor GPR4 potentiates intestinal inflammation in the DSS-induced colitis mouse model. Edward J. Sanderlin,1 Nancy R. Leffler,3 Stephen Finn,3 Raymond McDermott,3 Sharon Anneve Glynn1. University of California, San Francisco.

Proton-sensor GPR4 potentiates intestinal inflammation in the DSS-induced colitis mouse model. We observed that GPR4 mRNA expression was increased in mouse and human IBD tissues when compared to control intestinal tissues. To determine the function of GPR4 in intestinal inflammation, wild-type and GPR4-deficient mice were treated with 3% DSS for acute and chronic time points for the induction of colitis. Our results showed that the severity of colitis was decreased in GPR4-deficient DSS-treated mice in comparison to wild-type DSS-treated mice. Clinical parameters, macroscopic disease indicators, and histopathological features were less severe in the DSS-treated GPR4-deficient mice than the DSS-treated wild-type mice. Inflammation gene expression, endothelial adhesion molecule expression, leukocyte infiltration, and isolated lymphoid follicle (ILF) formation were reduced in intestinal tissues of DSS-treated GPR4-null mice. In summary, our results suggest GPR4 potentiates intestinal inflammation as the absence of GPR4 ameliorates intestinal inflammation in the DSS-induced colitis mouse model. Use of GPR4 inhibitors could prove a valuable therapeutic in the reduction of intestinal inflammation and subsequent CRC development.

#5918 Collagen enhances tumorigenicity of papillary thyroid cancer. Anna Sharabura, Laura MacDonald. Hendrix College, Conway, AR.

While the mutations associated with thyroid cancer are well defined, less is known about how the tumor microenvironment contributes to thyroid cancer progression. Papillary thyroid cancer is most common and is associated with activating BRAFV600E mutations. Jolly et al. recently found that murine papillary thyroid cancers with constitutively active BRAF and a PTEN deletion recruit cancer-associated fibroblasts that enrich the tumor with collagen, a component of the extracellular matrix. Our study addresses how collagen impacts tumorigenicity of papillary thy-roid cancer cells. Cell lines derived from mouse models of papillary thyroid cancer with BRAFV600E and PTEN deletions were grown in the presence of or absence of collagen and assessed for cellular proliferation, altered cellular morphology, secretion of microvesicles, and altered cellular signaling. Our results show that papillary thyroid cancer cells increase microvesicle secretion and have increased growth rates. Collectively, our study suggests that collagen enhances tumorigenic characteristics of papillary thyroid cancer cells.

#5919 Identification of a novel molecular interaction, targeted by Metformin, between breast cancer and white adipose tissue progenitors. Francesca Reggiani, Valentina Labanca, Patrizia Mancuso, Andrea Manconi, Francesco Bertolini. European Inst. of Oncology, Milan, Italy.

The white adipose tissue (WAT) contains a resident population of progenitors with mesenchymal- or endothelial-like phenotype, able to promote breast cancer (BC) progression (Orecchioni et al., 2013). We recently characterized a novel molecular axis underneath the interaction between BC and WAT progenitors, possibly explaining the acquisition of a cancer-associated phenotype by WAT progenitors cells and the establishment of a permissive tumor microenvironment. GM-CSF balance was identified to be the principal regulator of the transcriptional alteration occurring in WAT progenitors exposed to BC: GM-CSF, produced by BC cells, dramatically changed the secretion profile of progenitors, enhancing its own production through a positive regulatory loop and inducing the expression of several factors involved in inflammation (IL-1β), ECM remodeling and angiogenesis (MMPI). IL-1β was strongly down-regulated by GM-CSF neutralization in WAT progenitors in vitro and in preclinical models. Induction of IL-1β by GM-CSF was able, in turn, to up-regulate MMPI in the same cells. The markedly increased expression of IL-1β was already observed in BC-associated WAT progenitors, being addressed to increased local and metastatic tumor growth in obese mice. GM-CSF production was significantly enhanced in the presence of concomitant obesity in preclinical models of BC, both in orthotopic models (MMTV-neu/ErbB2; 4T1) and in spontaneous tumor-bearing mice (MMTV-PyMT). GM-CSF neutralization in several obese syngeneic models of BC significantly reduced immunosuppressive cells in tumors and in the surrounding WAT, including Tregs (CD4+ CD25+PD1+CD127low), regulatory T cells, and proinflammatory cells (CD4+PD1+CD127high). In preclinical models of BC, the absence of GPR4 ameliorates intestinal inflammation in the DSS-treated wild-type mice. In summary, our results suggest GPR4 potentiates intestinal inflammation as the absence of GPR4 ameliorates intestinal inflammation in the DSS-induced colitis mouse model. Use of GPR4 inhibitors could prove a valuable therapeutic in the reduction of intestinal inflammation and subsequent CRC development. GM-CSF has been shown to be activated by acidosis and can increase the expression of numerous inflammatory and stress response genes in vascular endothelial cells (ECs) and has functionally increased EC-leukocyte adhesion. Subsequently, genetic and small molecule approaches for the inhibition of GPR4 activity have been reported in other contexts.

#5920 Paraendocrine interactions between bone marrow mesenchymal stem cells and prostate cancer cells: impact on tumor cell invasive and proliferative capacity. Karen O’Leary,1 Sarah Ridge,1 William Watson,2 Antoinette Perry,2 Stephen Finn,3 Raymond McDermott,3 Sharon Anneve Glynn1. National University of Ireland Galway, Galway, Ireland; National University of Ireland Dublin, Dublin, Ireland; Trinity College Dublin, Dublin, Ireland.

Introduction: The primary site of prostate cancer metastasis is to the bone. Bone marrow derived mesenchymal stem cells (BM-MSCs) are multipotent stem cells resident in the bone with the potential to differentiate into osteoblasts, chondrocytes and adipocytes. They have been shown to home to sites of inflammation, including prostate cancer, contributing to tumor growth and progression. This study aims to explore the impact of metastatic prostate cancer patient derived BM-MSCs on prostate cancer cell proliferation and invasive capacity. Methodologies: BM-MSCs were isolated from bone marrow aspirates from patients diagnosed with metastatic prostate cancer (both androgen deprivation treatment naive and commenced). Co-culture models were used to examine the impact on patient BM-MSCs versus healthy donor BM-MSCs on prostate cancer cell proliferation, PSA and cytokine secretion, and induction of cell migration and invasion. The impact of metastatic prostate cancer cells on healthy donor BM-MSCs was also examined. Results: Here we show that metastatic prostate cancer cells (PC-3 and DU145), reprogram normal donor BM-MSCs to a pro-inflammatory secretory phenotype that in turn induces prostate cancer cell invasion using a 3D spheroid model of invasion into a matrigel-collagen gel, while restricting BM-MSCs with the 3D spheroid. Additionally we isolated a series of BM-MSCs from metastatic prostate cancer patients (n = 10). Results show that a proportion of prostate cancer patient derived BM-MSCs patients have a reduced differentiation capacity to osteocytes while maintaining normal adipocyte capacity. Additionally patient derived BM-MSCs increase prostate cancer cell (MDA-PCa-2B) secretion of PSA and display increased expression of inflammation associated enzymes including the immunosuppressive enzyme indoleamine-2,3-dioxygenase and its metabolite kynurenine. Conclusions: Ultimately, we seek to decipher the role of BM-MSCs in metastatic prostate cancer, in the context of impact on androgen receptor signaling, chemotherapeutic drug response, and the maintenance and promotion of metastatic lesions. Future directions will use 3D co-culture models to identify the key regulatory networks co-activated in prostate cancer and BM-MSCs that facilitate chemotherapeutic drug resistance and metastatic progression.
Introduction: Lepidic predominant adenocarcinoma of the lung was classified into adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA), and invasive lepidic predominant adenocarcinoma (LPA) in current WHO classification, 4th edition. Furthermore, LPA is thought to progress in a stepwise fashion from AIS and MIA. However, these classifications were diagnosed histologically and therefore failed to identify intermediate stages. Thus, the aim of this study was to investigate the microenvironmental changes in the process of development from AIS to MIA and LPA, and subjective marker of stepwise progression. We have published a part of data in this study in Lung Cancer (100:53-62, 2016), and we believe that this study makes a contribution to elucidate the mechanism of development of LPA of the lung. Materials and Methods: Cliquen pathological characteristics of AIS (n=51), MIA (n=59), LPA smaller than 3 cm (S-LPA, n=113), and LPA larger than 3 cm (L-LPA, n=47) were analyzed. We then immunohistochemically evaluated the expression levels of epithelium-mesenchymal transition (EMT)-related molecules (E-cadherin, S100A4), invasion-related molecules (laminin-5, ezrin), and growth factor receptors (EGFR) in cancer cells of each group (n=20). The number of tumor-promoting stromal cells, including podoplanin-positive cancer-associated fibroblasts (PDPN+CAFs), CD204-positive tumor-associated macrophages (CD204+ TAMs), and CD34+ microvessel cells, were also analyzed. Results: LPA-S showed significantly frequent vascular and pleural invasion than MIA (p<0.05); however, no significant difference in those factors was found between S-LPA and L-LPA. Laminin-5 expression in the non-invasive component of MIA was significantly higher than that of that of AIS (p<0.001). During the progression from MIA to S-LPA, the expression level of laminin-5 in the invasive component was significantly elevated (p<0.01). Moreover, tumor-promoting stromal cells were more frequently recruited in the invasive area of LPA-S (PDPN+CAF; p<0.05, CD204+ TAM; p<0.001, CD34+ microvessel; p<0.05). Ezrin expression in the invasive component of LPA was significantly increased (p<0.05) compared to S-LPA; however, the number of tumor-promoting stromal cells were not different between these two groups. Conclusion: Our current study indicated that microenvironmental molecular changes occur during the progression from MIA to S-LPA. Thus, it was suggested that this process may play an important role in disease progression from AIS to LPA of the lung.

Tumor microenvironment such as neangiogenesis, stroma and tumor immunoactivity has recently gained much attention because it is significantly involved in tumor progression. Pancreatic adenocarcinoma (PAC; pancreatic invasive ductal carcinoma) is recognized as one of the most intractable malignancies and required to disclose a key biological characteristics to provide a clue for its diagnosis and therapeutics. Here we focus on the biological role of bone marrow-derived human mesenchymal stem cells (MSCs) in PAC, which were reported to be accumulated in various cancer tissues such as colon, breast cancers. We detected small numbers of MSCs in the stroma of PAC in human pathological tissues using double immunofluorescence in combination with several MSC markers including CD73, 105, 34, 45, SMA and so on. Then, in in vitro coculture system, we found that MSCs significantly facilitated invasion of BXPC3 cells, a human PAC cell line, in comparison with the culture of BXPC3 cell alone by transwell chamber assay. Proteome profiling of the cocultured supernatant revealed augmented production of soluble molecules including CXCL7, CCL7 as a cytokine, integrin beta1, transferrin R, ALCAM, and Amphiregulin (AREG) as a soluble receptor and ligand, metalloprotease (MMP), ADAMTS-1 as a soluble protease-related molecule, all which were significantly increased comparing to the culture sup. of BXPC3 alone or MSC alone. Based on the result of proteome profiling, we further examined mRNA upregulation on the cells of each culture by real-time PCR (qPCR) to identify which molecule would be more specifically upregulated by the coculture sample of PAC cells and MSCs. Consequently, upregulation of AREG and MMP-3, in addition to downregulation of MMP-9 was observed by qPCR, and knockdown of AREG using the specific siRNA on the cocultured cells corroborated marked decrease of PAC invasion in transwell chamber assay. Interestingly, AREG expression on the tumor cells of tissue specimens of the patient with PAC was observed especially on the cells at invasive front, which suggests stromal MSCs may interact with PAC cells and facilitate invasion of cancer cells by regulating expression of the specific genes such as AREG and MMPs.

Cancer pancreatic (PDA) has a dismal prognosis and responds poorly to all existing therapies. This is largely attributed to the existence of dense stroma and lack of T cell infiltration. PDA exhibits heterogeneous tumor microenvironments that are composed of various stromal cells. Human PDA has been shown to have various levels of T cell infiltration. The mechanisms underlying the inter-tumor heterogeneity of immune microenvironment in PDA and its effects on distinct responses of PDA to therapies, especially immune-modulating therapies, remain largely unknown. Our lab has demonstrated that there is no difference in somatic mutation burden or neo-epitope load between human PDA tumors with high or low amount of cytolytic T cells. We hypothesize that tumor-cell-intrinsic determinants, transcriptional and/or epigenetic factors, shape the heterogeneous tumor microenvironment, and lead to different responses to therapies. For the reason that tumor cellularity of PDA is very low, the profiling of bulk tumor samples cannot provide enough information for understanding tumor-cell-intrinsic molecular events associated with differential immune microenvironment. Therefore, we developed a panel of ~60 cell lines (diversity-cell-panel) from PDA tumors derived from inbred C57BL/6 KPC mouse model, which recapitulates the major histopathological and molecular features of human PDA. Our preliminary results have demonstrated that the diversity-cell-panel recapitulates the immune microenvironments heterogeneity in PDA. Tumor cells mainly fell into two subgroups: T-cell-high and T-cell-low. Tumors resulted from T-cell-high tumor cells also possess less amount of immune-suppressive myeloid cells. To study whether this difference is caused by various amount of mutations, we performed exome-sequencing for 8 cell lines within this cell-panel, and showed that T cell-high and T-cell-low tumor cells have similar amount of mutations and neo-epitopes. To further study the distinct molecular features of T-cell-high and T-cell-low tumor cells, we will perform RNA-seq and ATAC-seq on tumor cells sorted from resulting tumors. To understand whether T cell infiltration affects the response of PDA tumors to immune-modulating therapies, I have been testing the response of T-cell-high and T-cell-low tumors to a group of therapies, including chemotherapy, CD40 therapy and immune checkpoint blockade therapy. Utilizing this novel system, the cell-panel, this study will delineate in unprecedented detail the novel molecular determinants of immune heterogeneity in PDA and the implication of the heterogeneity to therapies. This diversity-cell-panel will also be useful for understanding other aspects of tumor heterogeneity, including angiogenesis, drug resistance and metastatic disease.

Necrotic cells promote microglia infiltration in glioblastoma through regulating MCP-1 and MIP-3α expression. Yieun Jung, So-Hee Ahn, Hyunja Park, Iwoo Lim, Jiihee Lee Kang, Youn-Hee Choi, Eun Ju Kim. 1Department of Physiology, Tissue Injury Defense Research Center, Ewha Woman’s University School of Medicine, Seoul, Republic of Korea; 2Department of Molecular Medicine, Tissue Injury Defense Research Center, Ewha Woman’s University School of Medicine, Seoul, Republic of Korea.

Glioblastoma multiform (GBM), a grade IV astrocytoma, is most lethal and common adult primary intracranial tumor. GBM is characterized by diffuse infiltration into normal brain parenchyma, rapid growth and the presence of necrosis and microglia/macrophage infiltration. Among these properties of GBM, necrosis has been implicated to be a strong predictor of poor prognosis; however, the effect of necrosis on GBM progression is poorly understood at present. In this study, we examined the effect of necrosis on glioblastoma cells by exploring molecular mechanisms underlying gene expression and chemokine expression. Data obtained from chemokine array and ELISA showed that CTR-MG human glioblastoma cells secreted several chemokines including MCP-1 and MIP-3α in response to necrotic cells. Expression levels of mRNA and protein of MCP-1 and MIP-3α were also increased by treatment with necrotic cells in CTR-MG in a dose-dependent manner. Necrotic cells induced NF-kB/AP-1 activation and their binding to the MCP-1 and MIP-3α promoter, leading to enhanced MCP-1 and MIP-3α production in GBM cells. Finally, by cell migration assay, we observed increased migration of necrotic cells significantly enhanced the migration of microglia. Our data demonstrate that when GBM cells are exposed to and stimulated by necrotic cells, the expression and secretion of MCP-1 and MIP-3α are increased in GBM cells and microglia infiltration/migration to the tumor site are facilitated.

Mapping the molecular communication within the tumor microenvironment of pancreatic cancer as well as between tumor and peritumoral tissues. Mohamed S. Alwan, Yvonne C. Meisinger, Dorothea H. Hoheisel. German Cancer Research Center (DKFZ), Heidelberg, Germany.

We are analyzing in detail the molecular communication between the different cell types in the microenvironment of pancreatic ductal adenocarcinomas (PDAC). Also, its regulation is being investigated, looking at aspects such as the
kind and mixture of molecules needed for triggering a particular regulative function, and unraveling the inter- and intracellular processes utilized to transmet a molecular message. Although a rare tumor entity, adding up to only about 3% of all cancer cases in the Western world, PDAC is the fourth most frequent cause of cancer-related death; mortality is nearly identical to incidence. There is no real remedy apart from surgery, which can be applied to only 10 to 20% of patients. Even then, basically all patients will experience tumor recurrence. Our study is based on a large basic set of data at the levels of DNA, RNA and protein that was generated from some 1000 pancreatic tumor samples [1], supplemented with information from studies that aim at an elucidation of functional molecules and comparative analyses in other tumors. This has already led to the creation of basic functional knowledge about metastasis [e.g., 2], the establishment of means for diagnosis [3, 4], an accurate disease prognosis [1], the characterization of communication processes [5] and the identification of new therapeutic avenues [6]. At the conference, we will report about the status of mapping particularly the protein-mediated communication between the different cell types in the tumor microenvironment. Also, we will show results about the effect that PDAC tissue has on the wider peritumoral environment and vice versa. The peritumoral tissue is exhibiting a field defect that does not seem to be dependent on DNA-methylation. A comparison of PDAC and cystic pancreatic tumors revealed that differences in communicating with the peritumoral tissue could actually be more important to the known pathological difference between the two cancer entities than the molecular variations in the tumor cells. 1. Introduction: Esophageal squamous cell carcinoma (ESCC), which is the most common type of esophageal cancer, is one of the most common cancers in eastern Asia and one of the leading causes of cancer-related death worldwide. This unsatisfactory outcome in ESCC is thought to mainly result from late diagnosis, the aggressiveness of this disease, and the lack of the understanding in the molecular and pathological aspects of disease. Therefore, new targeted agents are needed to be investigated and developed in order to improve treatment strategies. The discoind domain receptors (DDRs) are a set of receptor tyrosine kinases (RTKs) that are activated by collagen and crucial role in key regulators in cancer progression by controlling the interactions of tumor cells with their surrounding collagen. DDR1 is expected to be involved in ESCC, which demonstrates aggressive tumor proliferation and devastating prognosis. However, there have been only a few reports about DDR1 in ESCC. We retrospectively investigated DDR1 in ESCC. Methods: A total of 60 formalin-fixed paraffin-embedded (FFPE) primary tumor samples were collected from patients with ESCC who underwent surgery with curative intent. DDR1 immunohistochemistry (IHC) was conducted on ESCC FFPE tissue specimens. Clinicopathological factors, DDR1 immunohistochemistry (IHC) and survival data were analyzed in this study. Results: When compared the clinicopathological factors between the weak and the strong group in the intensity of DDR1 IHC, in univariate analysis there were significant differences between the two groups in age (P = 0.007), histological grade (P = 0.04), invasion depth (P = 0.0001), stage (P < 0.0001). There were no significant differences between the two groups with respect to the other clinicopathological factors. In the multivariate analysis, DDR1 overexpression was recognized with respect to invasion depth (T3, 4) (P = 0.007), lymph node metastasis (LNM) (N2, 3) (P = 0.0005) and DDR1 IHC expression (strong) (P = 0.0009). When these clinicopathological factors were used as co-variables for the multivariate analysis, LNM and DDR1 IHC expression were found to be significantly independent prognostic factors (LNM, P = 0.04, HR = 4.20, DDR1; P = 0.03, HR = 4.27). Conclusion: DDR1 IHC expression was found to be useful as a biomarker to predict long-term outcome.

TUMOR BIOLOGY: Tumor Microenvironment 9

#5927 Eribulin modulates tumor vascular remodeling through vascular re-modeling for antitumor effect in multiple mouse xenograft models. Ken Itô,1 Shusei Hamamichi,1 Takano Abe,1 Tsuyoshi Akagi,1 Hiroshi Shirota,1 Satoshi Kawano,1 Makoto Asano,1 Osamu Asano,1 Akira Yokoi,1 Junji Matsui,1 Izumi Sugimoto,1 Tomoaki Ito,2 Hajime Orita,3 Koichi Sato,3 Kazuhiro Sakamoto,1 Kiichi Umeda,2 Hirofumi Fujishita,1 Eisai Co., Ltd., Tsukuba, Japan; 2National Cancer Center Research Institute, Tokyo, Japan; 3Juntendo University, Faculty of Medicine, Shizuoka, Japan.

Since eribulin treatment increased accumulation of 111In-labeled PEGylated liposomes (Eribulin), a first-in-class halichondrin B-based microtubule dynamics inhibitor, has been reported to remodel tumor vasculature (i.e., improvement of tumor vessels and perfusion) in human breast cancer xenograft models; however, the role of this vascular remodeling in anti-tumor effects is not fully understood. Here, we investigated the effects of eribulin-induced vascular remodeling on anti-tumor activities in multiple human cancer xenograft models. Microvessel densities (MVDs) were evaluated by immunohistochemistry (CD31 staining), and anti-tumor effects were examined in 10 human cancer xenograft models treated with eribulin. Eribulin treatment significantly increased MVDs compared to the corresponding control groups in 7 out of 10 models with a correlation between enhanced MVD and anti-tumor effects (R² = 0.55). Because of observed increases in MVDs, we next utilized 11In-labeled PEGylated liposomes to examine if eribulin treatment would result in increased tumoral accumulation levels of such liposomes, and indeed, we found that eribulin, unlike vinorelbine another tubulin inhibitor, enhanced them. Since eribulin treatment increased accumulation of 11In-labeled PEGylated liposomes, we postulated that this treatment might enhance anti-tumor effect of Doxil (a liposomal anti-cancer agent). As expected, eribulin enhanced anti-tumor activity of Doxil in the PE-H11650 xenograft model. Then, we evaluated whether eribulin facilitated the recruitment of immune cells into the tumor. Infiltrating CD11b-positive immune cells were significantly increased in the multiple eribulin-treated xenografted tumors, and natural killer (NK) cell depletion reduced anti-tumor effects of eribulin. Collectively, these findings suggested a contribution of the immune cells for anti-tumor activities of eribulin. Taken together, our results obtained from multiple human cancer xenograft models suggested that vascular remodeling induced by eribulin therapy would act as a microenvironment modulator, and contributed to show anti-tumor effects of eribulin.

#5928 Discoidin domain receptor-1 (DDR1) is an independent prognostic marker of poor prognosis in esophageal squamous cell carcinoma. Kiichi Sugimoto,1 Tomoaki Itô,2 Hajime Orita,1 Koichi Sato,1 Kazuhiro Sakamoto,1 Mutsumi Sakurada,1 Tomoyuki Kushida,1 Hiroshi Maekawa,1 Ellen Tully,1 Jiyungh Woo,2 Edward Gabrielson2.1 Juntendo University, Faculty of Medicine, Tokyo, Japan; 2Johns Hopkins University, Sydney Kimmel Comprehensive Cancer Center, Baltimore, MD; 3Juntendo University, Faculty of Medicine, Shizuoka, Japan.

#5929 A novel image cytometric analysis method for T-cell-mediated cytotoxicy of 3D tumor spheroids. Le Li Ying Chan,1 Laure Humbert,2 Scott Cribbes.1 Nexcelom Bioscience LLC, Lawrence, MA; 2Immunoconcern Limited, London, United Kingdom.

Cell-mediated cytotoxicity assays have frequently been performed to characterize cancer cytotoxic potential of immune cells, antibodies, and drug compounds. Traditionally, these assays are performed using release assays such as Cr51 (radioactivity), Calcein (fluorescence), or LDH (enzymatic). However, release assays have limitations such as the handling of hazardous material, the indirect measurement of cell death leading to an under estimation of cytotoxicity, the requirement for a large volume of cell sample, and the inability to visually confirm, image and track the assay kinetically. In the recent years, Celigo image cytometry has been used to perform high throughput cell-mediated cytotoxicity assays using a direct cell counting method where cancer cells (Target) are stained with Calcein AM. Upon the addition of effector immune cells with the fluorescently stained Target cells in the presence or absence of antibody or drug compounds, the Celigo image cytometer is used to capture bright-field and fluorescent images and analyze the change in Target cell count over time to determine the cytotoxicity percentage. In general, these assays are performed in a 2D culture. The 2D assays for cancer drug discovery have had some difficulty in identifying more qualified drug candidates for clinical testing, thus there has been an increase in interest of performing cytotoxicity assays in 3D tumor models. Traditional 3D spheroid analysis methods require the use of standard microscopy, which is time-consuming and subjective. Celigo imaging cytometer has also been used to rapidly analyze drug effects on 3D tumor spheroids. In this work, we demonstrate a novel method of analyzing T-cell mediated cytotoxicity on 3D tumor spheroids in the presence of absence of ImmTAC molecules, which can promote higher T cell killing. In this experiment, MDA-MB-453 GFP expressing breast cancer cells are used to form tumor spheroids in an ultra-low attachment plate. The spheroids are then treated with primary T cells at 1:10 and 1:50 E:T ratios, as well as 10, 1, 0.1, 0.01, and 0.001 nM ImmTAC. The results showed a dose response effect of T cell killing with the addition of ImmTAC molecules by measuring spheroid size in GFP fluorescence and viability using propidium iodide. The image cytometry method was able to monitor changes in spheroid size and fluorescence over time and rapidly quantify T cell killing, which was as high as 75%. The captured bright-field and fluorescent images also clearly showed the activated T cells in the combination of T cell and ImmTAC. The ability to screen cytotoxic effects of immune cells, antibody, and drug compounds on 3D tumor spheroids can provide an alternative tumor model for identifying more qualified cancer drug candidates for drug discovery campaigns.
Prior work by us and others has demonstrated that the extracellular pH (pHe) of solid tumors is acidic, due to a combination of increased fermentative metabolism, resulting in lactic acid production and poor perfusion. This acidity promotes tumor progression and metastasis formation. Recently we have shown in melanoma and pancreatic cancer models that acidic pH is a central player in promoting T-cell exhaustion in the setting of predesigned mAbs targeting PD-1 or PD-L1. We thus hypothesized that targeting Tumor associated fibroblasts (TAFs) for depletion or acidification with buffer therapy (200mM NaHCO₃), synergized with checkpoint blockade (anti-CTLA4 and anti-PD1) and adoptive T-cell therapy has resulted in cures. While this is promising, concerns are high regarding the ingestion of such large amounts of sodium bicarbonate, which makes clinical translation a challenge. Hence, we hypothesize that alternative pharmacological interventions and neutralization of pHe of tumors and removal of this immunosuppressive effect. To study this we first investigated a series of agents for their ability to inhibit metastasis in the PC3 prostate cancer model, which is exquisitely sensitive to inhibition with buffer therapy. In this study, male SCID mice were grouped in to 6 groups (n=5) and treated with tap water, 200mM bicarbonate ad lib, 30 mg/kg daily (q.d) intraperitoneal (i.p) Acetazolamide (CA inhibitor), 1.2 mg/kg q.d.i.p. Furosemide (diuretic), 10 mg/kg q.d.i.p. DH348 (selective CAIX inhibitor) or 2.1 mg/kg q.d.i.p. FX-11 (LDHA inhibitor). Mice were intravenously injected with 5x10⁶ 6-PC3-MLuc cells and ventral bioluminescence images were acquired at time 0 and weekly thereafter. Our results showed that FX-11, acetazolamide, DH348 and bicarbonate were able to effectively (p<0.004) suppress metastasis formation in the setting of TLAx1, whereas furosemide was not. Based on these results, a subsequent study investigated the combination of bicarbonate, FX-11 or DH348 with immune checkpoint blockade in a Panc02 mouse model of pancreatic cancer. Animals were inoculated orthotopically with Panc02 cells and randomized into 8 groups (n=10). Once tumors reached 0.3 cc in size, mice were treated with either 15 mg/kg anti-PD-1 antibody or normal rat IgG controls twice weekly alone or in combination with bicarbonate; FX-11 or DH348 and tumor response was evaluated using US 3D-Mode imaging and volume analysis (FUJI FLM VisualSonics) and histopathology. Anti-PD-1 antibody was ineffective as a monotherapy in this system. Both bicarbonate and DH348 neutralized tumor acidity and reduced tumor growth as monotherapies. Notably, despite the fact that FX-11 was shown to inhibit LDH-A in pancreatic cancer models, it did not affect pH and had no effect on tumor growth as monotherapy. However, FX-11 significantly reduced tumor growth (p<0.001) and metastasis formation in combination with anti-PD-1 antibody, suggesting that inhibition of LDH-A might be effective in combination with checkpoint blockade.
responders of those checkpoint inhibitors are limited. Recently, it is considered that tumor immunosuppression may be caused by not only cancer cells but also tumor microenvironments (TME). Cancer-associated fibroblasts (CAFs) are one of the major components and have a central role for tumor progression in TME. It has been hypothesized that they can also play an essential role in tumor immunosuppression. In this study, a correlation between CAFs and TILs in clinical samples and further in vivo study. Materials and methods: Total 140 cases of esophageal cancer were evaluated for the presence of CAFs and TILs by immunohistochemistry (IHC). CAFs were defined as fibroblasts expressing alpha smooth muscle actin. CD8+ cytotoxic CD8+ T lymphocytes and FoxP3+ regulatory T cells were investigated as TILs in each specimen’s intratumoral and peritumoral tissues. The outcome was set as the correlation between CAFs and TILs, and Overall survival. In vivo experiments, we used a mouse-derived cancer cell (colon26-Luc) and mouse embryonic fibroblasts (NIH/3T3). BALB/c or BALB/c-nu/nu mice were inoculated with only cancer cells (control) or cancer cells with CAFs by co-CAFs into right flank to examine the immunosuppression affected by CAFs. The proliferation was examined by in vivo imaging system. Result: In clinical analysis, CD8+ TILs and CAFs demonstrated strong relations, which were significantly “negative” correlation and showed moderate correlation coefficient in intratumoral tissues (P<0.001, r=-0.416). In FoxP3+ TILs, “positive” correlation was detected significantly (P<0.001, r=0.484). In terms of prognosis, high group of CD8+ TILs had a good prognosis significantly (P<0.001), whereas high group of FoxP3+ TILs had a poor prognosis significantly (P<0.001) in intratumoral tissues. However, there was no difference of the correlation and the prognosis in peritumoral tissues. In vivo experiments demonstrated that promoted ratio of tumor progression by co-CAFs was more strongly demonstrated in BALB/c mice rather than BALB/c-nu/nu mice, suggesting that the group co-CAFs showed inducing immunosuppression in TME. IHC analysis of those tumors showed that accumulation of CD8+ TILs was decreased in tumors of co-CAFs as compared with tumors of control. On the other hand, accumulation of FoxP3+ TIL was increased, showing the same trends as clinical analysis. Conclusion: Our results suggest that Both CD8+ and FoxP3+ TILs in intratumoral tissues are independent prognostic factors, and CAFs have a significant correlation to those TILs. We consider that CAFs may affect tumor immunosuppression by regulating the migration of TILs.

#5935 Higher tumor mutation burden (TMB) is associated with the presence of DNA repair gene mutations, T-cell infiltration, and favorable survival outcome in ovarian carcinoma. Young Kwang Chae,1 William H. Bae,2 Sobina Khan F. Anwar,3 Yoon Pak Kim,3 Mario J. Pineda,1 Sabina Murshudova,1 Jonathan F. Anker,1 Young Suk Kim,3 Mario J. Pineda,1 Yonsei University College of Medicine, Seoul, Republic of Korea; 2Carnegie Mellon University, Pittsburgh, PA. Immunotherapy is being explored as a promising therapeutic option in ovarian cancer. However, little progress has been made in our understanding of the immune cell landscape in the tumor microenvironment and its association with genomic features in ovarian cancer. The RNA-seq values of the immune “metagene” markers that are specific to each of 28 cell types (Angelova et al, 2015) from the TCGA database were analyzed to determine the tumor infiltration by immune cells in 307 patient samples (185 sequenced) with ovarian carcinoma. Tumor tissues were most frequently infiltrated by all T cells (46.91%), activated CD4 T (19.87%) and activated CD8 T (16.94%) cells. Activated CD8 T cells were significantly co-infiltred by NK56 bright, effector memory CD4 T, activated CD4 T, myeloid dendritic cell (DC) and plasmacytoid DC. The tumors with mutated homologous recombination (HR) genes, including ATM, ATR, CHEK1, CHEK2, BRCA1, BRCA2, BAP1, BRD1, FANCD2, FANCE, FANCC, FANCA, RAD50, RAD51, and PALB2, demonstrated a significant 1.36-fold increase in average mutation counts compared to the wild-type (p < 0.01). Mutations in mismatch repair genes had no statistically significant association with the average mutation counts. Tumors with high mutation counts showed a significantly increased infiltration by activated CD8 T cells and immature DCs (Table 1, p < 0.05). The highest quartile in tumor mutation burden (TMB) was associated with a significant 16.7 months longer overall survival (OS) compared to the lowest quartile (p < 0.01). Our study demonstrated that higher TMB is associated with the presence of DNA repair gene mutations, activated CD8 T cell infiltration, and favorable survival outcome in ovarian carcinoma.

#5936 Comparison of carbonic anhydrase and activity between triple-negative & luminal breast cancer cells. Zhijuan Chen, Chan M. Mboge, Ching-kuang Tu, Lingbao Ai, Coy Heldermon, Susan C. Frost. Univ. of Florida, Gainesville, FL. Tumor microenvironment substantially influences the process of tumorigenesis. Extracellular acidification within the tumor microenvironment is an indicator of an aggressive cancer and a marker for poor patient outcome. In solid tumors, hypoxia leads to extracellular acidosis. Carbonic anhydrases (CA) are thought to regulate intracellular and extracellular pH (pHi and pHe, respectively). To explore the effect of CAs in breast cancer, we compared the expression and activity of two membrane bound CAs, CAIX and CAXII, between triple negative breast cancer cells (TNBCs) and luminal breast cancer cells (LBCs). We chose five different TNBC and LBC lines. Our data show that, among the TNBC lines, CAIX expression increased in three of the five lines: HBL100, SUM159, and the new UFH-001 cells under hypoxic condition. UFH-001 cells also showed strong constitutive expression. None of these TNBC lines expressed CAXII or estrogen receptor (ER). In LBC lines, four of the five lines constitutively expressed CAXII: T47D, MCF7, SKBR and SUM52 cells. CAXII expression was not hypoxia-dependent. Each of the five luminal lines expressed ER. We also examined CA expression in a tumor graft model. In tumors grown from cells derived from TNBC patients, we observed CAIX expression in four of six sample sets. In tumors derived from ER-positive LBC patients, all five expressed CAXII. We also used the 18O exchange method to assess CA activity. Two TNBC lines: UFH-001 and HBL100 cells showed that CAIX activity increased in hypoxic conditions which was blocked by an impermeant sulfonamide CA inhibitor (N3500). In the luminal lines, we detected CAXII activity in T47D and MCF7 cells that was also inhibited by N3500. Like CAXII protein expression in these cells, CAXII activity was not affected by hypoxia. We also evaluated the effect of pH on CA activity in TNBC and LBC lines. Both CAIX and CAXII showed increased activity in response to reduced pH, which is expected in a bicarbonate-based system. However, UFH-001 cells also exhibited a hypoxic-dependent increase in CAIX activity which is associated with increased protein expression. In conclusion, these observations demonstrate that CAIX expression is associated with the TNBC phenotype. Based on our activity data, we would predict that CA activity in TNBC tumors will be sensitive to both hypoxia (based on enhanced expression) and reduced pH. This change in activity may serve to regulate pH in the tumor microenvironment favoring an aggressive phenotype. On the other hand, LBC tumors, which are ER-positive, are only associated with CAIXII expression. In luminal cells, we expect that only pH and not hypoxia will affect CAIXII activity. This may, in part, explain the more positive prognosis in patients with CAIXII expression.
#5937 Obesity-induced destabilization of p16INK4A promotes the procarcinogenic effects of breast stromal adipocytes through miR-141/miR-146b-5p-dependent inhibition of leptin. Huda H. Alkhalfa,1 Abdellah Aboussékra,2,1 KACST, Riyadh, Saudi Arabia; 2KFSHRC, Riyadh, Saudi Arabia.

Despite increased obesity, a disease linked to increased number of adipocytes in various tissues, is increasingly recognized as a risk factor for the development of breast cancer. However, the molecular basis of adipocyte-related breast carcinogenesis remains elusive. In this study, we established and characterized normal stromal adipocytes from post-plastic surgery of breast tissues from obese and lean women. We have shown that adipocytes from obese women express low level of the tumor suppressor p16 protein, have higher secretion of various adipokines and higher invasion and migration capabilities as compared to adipocytes from lean women. In addition, down-regulation of p16INK4A by shRNA in adipocytes from lean women increased the expression/secretion levels of various adipokines including leptin, activated breast adipocytes and enhanced their migration/invasion abilities. Consequently, media conditioned with p16-deficient adipocytes or adipocytes from obese women promote epithelial-to-mesenchymal-transition in normal breast luminal cells in a leptin-dependent manner and induced tumor growth in vivo. Indeed, p16INK4A suppresses Leptin at the mRNA level through miR-141 and miR-146b-5p, which inhibits Leptin expression through a specific sequence at the Leptin 3’UTR. These results show the existence of active adipocytes in the mammary gland of obese women in absence of breast cancer that may contribute to the development of breast cancer. Adipokines such as leptin are potent angiogenic agents and contribute to aggressiveness of the cancer and resistance to therapy. Increased density of collagen (Col1) fibers, a major structural component of the ECM in solid tumors, and their alignment in tumors frequently result in increased invasion and metastasis of cancer cells. To understand the role of COX-2 at the lung metastatic site, and its relationship with Col1 fibers, COX-2 overexpressing triple negative SUM-149 human breast cancer cells (SUM-149-COX2) or empty vector SUM-149 cells (EV) were injected through tail vein in SCID mice to compare Col1 fiber patterns in metastatic lesions. We isolated the lungs, processed the tissue, and imaged for Col1 fiber by second harmonic generation microscopy on H&E stained sections. The number of cancer associated fibroblasts (CAFs) were detected in adjacent sections by immunostaining for α-SMA. COX-2 overexpression did not change the size of the blood vessels or the size of pulmonary metastases formed in the lungs. However, COX-2 overexpression did significantly increase the number of pulmonary metastases. Significantly higher Col1 fiber volume was observed in emboli compared to pulmonary metastases independent of COX-2 overexpression. Interestingly, the Col1 fibers were significantly more aligned in the COX-2 overexpressing pulmonary metastases compared to COX-2 overexpressing and EV emboli. The COX-2 overexpressing emboli had significantly higher amounts of CAFs detected by α-SMA expression compared to the EV emboli and the EV and COX-2 overexpressing pulmonary metastases. Pulmonary metastases from COX-2 overexpressing cells were detected further away from the nearest blood vessel compared to the metastases from EV cells suggesting that COX-2 may facilitate cancer cell extravasation. These insights provide important new insight into the role of COX-2, Col1 fibers, and CAFs in enabling emboli to extravasate to form pulmonary metastatic foci. These insights are important as COX-2 up-regulation during treatment may potentiate metastasis. This work was supported by NIH R01 CA23377.

#5938 In vivo targeting of laminin-411/B1 integrin-Notch signaling pathway using nanobiocjugate alters glioma microenvironment for effective treatment. Julia T. Ljubicicova, Cedars-Sinai Medical Center, Los Angeles, CA.

Introduction: Brain gliomas have been extensively characterized by genomic and molecular level analysis. These studies have underscored glioblastoma multiforme (GBM) heterogeneity, which may underlie failure of even the newest drugs to improve patient survival. For this reason, we turned to genetic modulation of glioma microenvironment using a novel nanobiocjugate. Methods/ Results: Clinical material from 107 GBM patients was analyzed, and tumors with overexpression of "malignant" tumor vascular basement membrane laminin-411 were found to have higher recurrence rate and shorter patient survival. In 92% of human GBM samples, overexpression of laminin-411 was associated with high expression of cancer stem cell (CSC) markers. To examine the interaction between GBM cells and their extracellular matrix microenvironment, blood-brain barrier (BBB) passing nanobiocjugates based on poly(β-L-malic acid) (PMLA) were synthesized that specifically inhibit α4 and β1 chains of trimeric laminin-411. In vitro. Normal brain endothelial cells and astrocytes had higher expression of β1 integrin, Notch-1, and Notch ligands when seeded on "malignant" laminin-411 as compared with "normal" laminin-421. All these markers were downregulated in two GBM cell lines treated with anti-β1/α5 oligonucleotides against laminin α4 and β1 Chains, suggesting regulation of Notch pathway by laminin-411 through integrin β1. In vivo. In GBM xenograft mouse models increased expression of laminin-411 correlated with overexpression of integrin β1 and Notch signaling pathway members. In two mouse models with intracranial human LN229 and U87MG GBMs, treatment with PMLA-based nanobiocjugate against tumor microenvironment protein laminin-411 led to significantly increased animal survival, associated with marked suppression of laminin-411/B1 integrin-Dll4-Notch axis and CSC markers CD133, Nestin, and c-Myc. Conclusion: BBB crossing and brain tumor-targeted nanodrug therapy using laminin-411 suppression provided a unique tool to study mechanistic interactions between tumor microenvironment and signaling pathways, and showed promise for efficient GBM treatment affecting both the bulk of tumor cells and CSC. Support: NIH grants U01 CA151815, R01 CA136841, R01 CA188743, R01 CA209921.

#5939 Dissemination of breast cancer. Samata Kakkad, Mikayla Hanna, Desmond Jacob, Balaji Krishnamachary, Zaver M. Bhujwalla. Johns Hopkins University School of Medicine, Baltimore, MD.

Breast cancer is the second leading cause of death in US women. Despite advances in early detection, diagnosis and treatment of breast cancer, metastasis and tumor recurrence persist leading to continued morbidity and mortality. Several breast cancer studies have highlighted the role of cyclooxygenase-2 (COX-2) and its interaction with the tumor microenvironment (TME) in breast cancer progression. The TME consists of stromal cells that include fibroblasts, macrophages, the extracellular matrix (ECM), and several secreted factors that contribute to aggressiveness of the cancer and resistance to therapy. Increased density of collagen (Col1) fibers, a major structural component of the ECM in solid tumors, and their alignment in tumors frequently result in increased invasion and metastasis of cancer cells. To understand the role of COX-2 at the lung metastatic site, and its relationship with Col1 fibers, COX-2 overexpressing triple negative SUM-149 human breast cancer cells (SUM-149-COX2) or empty vector SUM-149 cells (EV) were injected through tail vein in SCID mice to compare Col1 fiber patterns in metastatic lesions. We isolated the lungs, processed the tissue, and imaged for Col1 fiber by second harmonic generation microscopy on H&E stained sections. The number of cancer associated fibroblasts (CAFs) were detected in adjacent sections by immunostaining for α-SMA. COX-2 overexpression did not change the size of the blood vessels or the size of pulmonary metastases formed in the lungs. However, COX-2 overexpression did significantly increase the number of pulmonary metastases. Significantly higher Col1 fiber volume was observed in emboli compared to pulmonary metastases independent of COX-2 overexpression. Interestingly, the Col1 fibers were significantly more aligned in the COX-2 overexpressing pulmonary metastases compared to COX-2 overexpressing and EV emboli. The COX-2 overexpressing emboli had significantly higher amounts of CAFs detected by α-SMA expression compared to the EV emboli and the EV and COX-2 overexpressing pulmonary metastases. Pulmonary metastases from COX-2 overexpressing cells were detected further away from the nearest blood vessel compared to the metastases from EV cells suggesting that COX-2 may facilitate cancer cell extravasation. These insights provide important new insight into the role of COX-2, Col1 fibers, and CAFs in enabling emboli to extravasate to form pulmonary metastatic foci. These insights are important as COX-2 up-regulation during treatment may potentiate metastasis. This work was supported by NIH R01 CA23377.

#5940 The HU177 collagen neo-epitope regulates nuclear YAP accumulation and melanoma tumor growth and metastasis in vivo. Xiaohua Han, Jennifer M. Caron, Peter C. Brooks. Maine Medical Center, Scarborough, ME.

The extracellular matrix (ECM) plays a central role in controlling cellular behavior and integrin receptors play key roles in this process. Significant molecular insight is available on how structurally intact forms of collagen regulate integrin-signaling; however unique collagen neo-epitopes can be generated during tumor development and these neo-epitopes may differentially bind to integrin receptors. These findings raise an interesting question as to whether signaling initiated by collagen neo-epitopes as compared to intact collagen, differentially modify the final signaling out put. Integrin A10B1 is a receptor for the HU177 collagen neo-epitope, however, little is known about the down stream signaling events stimulated by this receptor-ligand interaction. We provide evidence that melanoma cell interaction with denatured collagen results in enhanced adhesion and migration. Talin is a molecule that facilitates integrin-associated linkages to the cytoskeleton and helps govern adhesive cellular processes. Melanoma cell interactions with denatured as compared to intact collagen, resulted in enhanced Talin phosphorylation and surprisingly increased the levels of Cyclin Dependent Kinase 5 (CDK5), a molecule implicated in Talin phosphorylation and motility. Melanoma cell interactions with denatured collagen also led to elevated nuclear accumulation of the Yes-associated protein YAP. Given these results, we examined the effects of anti-HU177 antibody on adhesion and migration. Targeting the HU177 neo-epitope inhibited cell adhesion and migration on denatured collagen and also inhibited YAP nuclear accumulation. Knocking down YAP in melanoma cells resulted in the generation of cells that were resistant to the inhibitory effects of anti-HU177 antibody, suggesting that part of the inhibitory activity of anti-HU177 antibody may be associated with its ability to alter YAP activity. We next examined the role of the HU177 neo-epitope and its receptor, A10B1, on melanoma tumor growth and metastasis. Targeting the HU177 neo-epitope inhibited tumor angiogenesis, accumulation of ASMA positive stromal cells in melanomas and tumor growth in vivo. Importantly, knock down of A10B1, or direct targeting of the HU177 neo-epitope inhibited experimental metastasis of melanoma cells. Taken together, these studies provide new insight into the role of the HU177 collagen neo-epitope in melanoma tumor growth and metastasis and provide a novel strategy to inhibit melanoma progression through selective targeting of a A10B1 ligand, rather than the integrin itself.

#5941 Integrin signaling modulation demonstrates potential therapeutic strategy in bladder cancer using three-dimensional organoid culture. LaMont Barlow, Rebecca Meyer, Ethan Shelkey, Bishoy Faltas, Mark Rubin. Weill Cornell Medical Center, New York, NY.

Introduction: Integrin signaling plays an important role in cellular proliferation and migration via interactions with extracellular matrix proteins. Prior
studies indicate that integrin signaling facilitates tumor invasion and metastasis, and there are several ongoing clinical trials using agents that modulate this pathway. We recently identified clonal enrichment in missense mutations in the integrin cell surface interactions pathways in advanced chemotherapy-resistant urothelial carcinoma. An ideal strategy for investigating integrin signaling is via 3D organoid cultures containing intercellular interactions that mimic the epithelial microenvironment. We hypothesize that pharmacologic integrin signaling modulation will impair organoid growth in human bladder cancer cells and demonstrate a potential therapeutic utility for this approach. Methods: RT4 human bladder cancer cell line was used as well as a second cell line established from a patient-derived bladder cancer sample (PM748). Cells were grown in 3D organoid culture as previously described. For in vitro integrin modulation, defactinib (VS-6063), an orally bioavailable selective inhibitor of focal adhesion kinase (FAK, a convergent and conserved enzyme activated by integrin ligand binding), was used. SDS-PAGE and immunoblotting were performed to show in vitro FAK inhibition. Single-cell suspensions and formed organoids were plated in the presence of various concentrations of defactinib to determine the impact on organoid formation and regression. Results: Both RT4 and PM748 bladder cancer cell lines demonstrated consistent organoid growth in three-dimensional culturing conditions. Addition of defactinib to cultured cells showed a dose-dependent decrease in autophosphorylation of FAK for both cell lines, demonstrating effective FAK inhibition. 3D culture of single cells in the presence of defactinib produced a dose-dependent decrease in organoid size after 96 hours (mean size for DMSO, 100nM, 1uM, and 10uM were 128um, 75um, and 26um, respectively; p<0.0001 versus DMSO for all dilutions). Established bladder cancer organoids showed a dose-dependent reduction in size after 72 hours of defactinib exposure (mean size for DMSO, 100nM, 1uM, and 10uM were 225um, 96um, 70um, and 34um, respectively; p<0.0001 versus DMSO). Experiments utilizing Crispr-Cas9-mediated FAK knock-out as well as in vivo studies with FAK inhibitors in mouse xenograft models are currently underway. Conclusions: Integrin modulation via FAK inhibition with defactinib causes both inhibition of organoid formation as well as regression of formed organoids, and the effects are seen at concentrations well below the cytotoxic range for the drug. This study suggests a utility for these agents in bladder cancer treatment.

Collagen prolyl-hydroxylase regulates breast cancer progression and chemoresistance. Gaofeng Xiong, Ren Xu. Univ. of Kentucky Markey Cancer Ctr., Lexington, KY.

Collagen prolyl hydroxylation (P4H), an enzyme hydroxylylating proline residues in X-Pro-Gly-sequences, is a potential therapeutic target for the disorders associated with increased collagen deposition. Upregulation of collagen prolyl-4-hydroxylase in cancer cells is required for breast cancer promotion. P4H1 mRNA levels were significantly upregulated in triple-negative breast cancer (TNBC) compared to other cancer subtypes. Increased mRNA levels of P4H1 correlated with poor clinical outcome in breast cancer patients. Silencing P4H1 expression or treatment with the P4H1 inhibitor significantly inhibited cell proliferation and suppressed aggressive phenotypes of breast cancer cells in 3D culture, accompanied by reduced deposition of collagen. We found that activation of the P4H1 in TNBC cells enhanced cancer cell stemness. We also found that P4H1 inhibition inhibited tumor growth and metastasis to lungs in xenograft models. Inhibition of P4H1 activity with the P4H1 inhibitor sensitized TNBC to the docetaxel treatment in the patient-derived organoid (PDO) and xenograft models. Therefore, these results suggest the crucial role of P4H1 in breast cancer progression and that targeting collagen P4H1 is a promising strategy to inhibit tumor progression and to sensitize TNBC to the docetaxel treatment in the patient-derived organoid model.

Role of tissue stiffness and oxygen tension in promoting breast cancer stem cells. Mei-Fong Pang, 1 Derek C. Radisky, 2 Celeste M. Nelson. 1Princeton Univ., Princeton, NJ; 2Mayo Clinic Cancer Center, Jacksonville, FL.

Breast tumors are stiff and hypoxic. Nevertheless, it remains unclear how stiff and hypoxic conditions within the tumor microenvironment promote breast cancer progression. Using an innovative engineered culture model to recapitulate these features, we found that, under stiff and hypoxic conditions, breast cancer cells have enhanced integrin-linked kinase (ILK) expression and acquire cancer stem cell (CSC)-like traits, suggesting tissue stiffness and oxygen tension can modulate ILK expression to induce breast CSC formation. Knocking down ILK impairs the mechanosensing of invasive breast cancer cells on stiff microenvironments, inhibits CSC markers and properties. In contrast, ectopic expression of ILK promotes breast CSC formation. In addition to promoting CSC-like phenotype, microarray analysis reveals that stiff and hypoxic microenvironments also regulate genes involved in mRNA processing, splicing and the spliceosome. These data suggest that the non-cellular compartment of the tumor microenvironment, namely tissue mechanics and oxygen tension, can promote breast cancer progression by controlling mechanotransduction and post-transcriptional regulation of breast cancer cells.

Matrilysin/MMP-7 compromises a novel border interaction between perlecain/HSPIG2 and semaphorin 3A to support prostate cancer invasion. Brian J. Grindel, 1 Daniel A. Harrington, 2 Ieland Chung, 1 Mary C. Farach-Carson. 1 Rice University, Houston, TX; 2University of Texas Health Science Center at Houston School of Dentistry, Houston, TX, 3Cedars-Sinai, Los Angeles, CA.

Prostate cancer (PCa) cells interact with the stroma and extracellular matrix (ECM) during tumor expansion and invasion during metastasis. Dissecting the complex matrix-cancer interplay is essential to halting tumor progression. A vital component of the ECM is perlecain/heparan sulfate proteoglycan 2 (HSPG2). As a large extracellular proteoglycan, perlecain helps orchestrate tumor angiogenesis, proliferation, differentiation and invasion. Actively metastasizing cancer cells must proteolytically degrade several tissue borders which perlecain patrols, including the basement membrane, vasculature, reactive stromal matrix and bone marrow. Investigating the effects of perlecain on metastatic PCa cells showed full length perlecain and specifically conserved domain IV of perlecain triggers clustering of PCa cells. Perlecain cleavage by the pro-tumor protease matrilysin/matrix metalloproteinase (MMP-7) reverses this, favoring cell dispersion and tumor dyscohesion. Network analysis of a reverse phase protein array and subsequent western blots revealed clustered cells on intact perlecain/Dm IV induced a strong focal adhesion kinase (FAK) dephosphorylation/reactivation. Alternatively, FAK was highly phosphorylated/activated on MMP-7 cleaved perlecain/Dm IV consistent with an adhesive and dispersive/metastatic phenotype. Several lines of evidence indicate Dm IV interacts with the classically known axon guidance protein semaphorin 3A (Sema3A), to shut off pro-metastatic FAK activation. Notably, a C-terminus directed Sema3A antibody mimics the clustering activity of Dm IV. We showed Dm IV binds to Sema3A in ELISA and crystal quartz microbalance experiments and the interaction is abrogated by the Sema3A antibody. Interestingly, Sema3A also is sensitive to MMP-7 proteolytic activity. Finally, transient knockdown of Sema3A in PCa cells inhibits the clustering effect by a Dm IV substrate. This work shows that perlecain is an effective border molecule because it coordinates with Sema3A to repulse and cluster cells by switching off FAK activity. However, PCa cells expressing active MMPs, such as MMP-7, can destroy this Sema3A/perlecain complex to develop an invasive, metastatic phenotype associated with lethal disease.

CRISPR-Cas9 dissection of heparan sulfate. Ryan J. Weiss, Philipp N. Spahn, Nathaniel E. Lewis, Jeffrey D. Esko. University of California, San Diego, La Jolla, CA.

Heparan sulfate proteoglycans (HSPGs) are expressed on virtually all animal cells and play important roles in tumor growth and metastasis. Each HSPG consists of a core protein with one or more covalently attached linear heparan sulfate (HS) chains composed of alternating glucosamine and uronic acids that are heterogeneously N- and O-sulfated. These complex cell surface carbohydrates regulate important biological processes including cell adhesion, proliferation, and development and maintain intracellular stores that number in the billions. Together, these modifications contribute to a large number of matrix proteins and growth factors. The arrangement and orientation of the sulfated sugar residues of HS specify the location of distinct ligand binding sites on the cell surface, and these modifications can vary temporally during development and spatially across tissues. Previous studies have shown that HSPGs can modulate tumor growth kinetics and are abundantly expressed on the cell surface of many types of cancer. Additionally, genetically reducing the sulfation of HS has been shown to selectively inhibit tumor angiogenesis and lymph node metastasis. While most of the enzymes involved in HS biosynthesis have been studied extensively, much less information exists regarding the specific mechanisms that give rise to the variable composition and binding properties of HS. The overall goal of this project is to uncover and characterize novel genes whose expression influences HS-mediated regulatory networks in tumor growth and metastasis. A genomewide CRISPR/Cas9-mediated screen was developed to uncover and characterize novel genes other than those encoding known HS biosynthetic enzymes. A lentiviral single guide RNA (sgRNA) library was utilized to knock down gene expression across the entire genome in a human malignant melanoma cell line. Subsequently, a high-throughput screening assay was adapted to identify lentiviral-encoded sgRNAs that induce resistance to cytotoxins whose action depends on HSPGs. Parallel screens using alternative HS-dependent toxins or plant lectins that cause cytotoxicity dependent on other types of glycosylation were performed in order to sort genes that se-
lectively affect HS biosynthesis. From the toxin screens, we identified previously studied genes essential for HS formation and factors involved in the intoxication of cells by diphtheria toxin, an HS-dependent exotoxin. Furthermore, we uncovered potential candidate genes whose function is unknown relative to HS biosynthesis. Top hits from the screens were characterized and categorized based on their predicted gene functions and are currently being individually validated and examined for their potential involvement in the regulation of HS biosynthesis. Overall, these studies will provide a better understanding of the genetic regulatory factors involved in HS biogenesis. Additionally, the factors we identify could reveal novel targets for anti-cancer therapies, as well as lead us to methods to manipulate HS and its activities in other cellular processes that go awry in human diseases.

REGULATORY SCIENCE AND POLICY: Recent Trends in Regulatory Science

#5946 Universal consent for biospecimens: a novel electronic/video consent. Arash Naeim,1 Neil Wenger,1 Antonia Petruse,1 Liliana Sanchez,1 Azita Sharif,2 Sarah Dry1. 1David Geffen UCLA School of Medicine, CA; 2Daedalus Software, Inc., MA.

Background: Developing innovative, efficient and institutionally scalable bio-specimen consent for remnant tissue that meets the NIH consent guidelines for genomic and molecular analysis is essential for precision medicine efforts in cancer. Solutions in this arena need to satisfy the needs of patients, researchers, ethicists, IRB and compliance leadership, while fitting as seamlessly as possible into existing clinical workflows. Methods: UCLA developed a video-application kiosk-based approach for providing universal consent to repurpose clinical remnant bio-specimen for research. The process was designed to be self-service, comprehensive yet fast (mean shorter than 5 minute for completion). The consent additionally asked the patient if they were willing to be contacted directly for future research projects. This approach was piloted with 474 patients who were coming in for routine services in laboratory medicine, radiology, oncology, and hospital admissions. Of the pilot population, 175 individuals had targeted surveys to evaluate drivers for opting-in or opting-out of the consent for allowing the collection and use of their remnant tissue for research. The cognitive survey was online and presented immediately after the consent process was completed. Results: The opt-in rate for the pilot was 90.7%, and 56% agreed to direct contact for future research. Only 7% needed help navigating the online consent process. Of the subgroup of pilot population who completed the targeted survey, there was no difference between individuals who opted in and out regarding ease of use, of the consent application with about 75% stating it provided mostly or very useful information, 90% stating it was mostly or very easy to understand, and 85% stating they trusted the information. However, there were significant differences between those that opted-in and opted-out in their beliefs concerning usefulness of tissue, trusting researchers, importance of contributing to science and privacy risk with those opting in strongly supporting these beliefs (≥90%) compared to those that opted out (<40%), p<0.001. Conclusions: Video-application approach for allowing individuals to consent for remnant specimens to be collected and used for research, including cancer research, can be efficient, patient-centric and meet the NIH requirements. This method could increase the availability of blood and tissue for cancer research and should be tested for scalability as an enterprise solution.

#5947 The NCI Best Practices for Biospecimen Resources: 2016 revised recommendations. Abhi Rao, Jim Vaught, Ping Guan, Carol Weil, Helen M. Moore. NIH, Bethesda, MD.

Improved biospecimen handling practices are increasingly important for cancer research as advanced molecular analysis becomes routine in clinical trials and more frequently available in standard of care medicine. Biospecimens and associated clinical data collected in a consistent, established fashion can greatly facilitate cancer biomarker validation and development and validation of clinical diagnostic assays. In order to establish a set of guidelines to improve the quality of biospecimen-related research, the NCI’s Biorepositories and Biospecimen Research Branch developed the NCI Best Practices for Biospecimen Resources which includes technical recommendations on biospecimen handling as well as ethical and regulatory best practices. The 3rd, 2016 revised version of these Best Practices focused on updating technical and operational best practices with recommendations based on more recent research, guidance and standards for collecting, processing and storing biospecimens; revised informatics best practices; and updated ethical, legal and policy sections describing new developments on return of research results, informed consent for genomics research, data sharing, and community engagement. These Best Practices aim to help patients by improving the reproducibility of cancer research data. The NCI Best Practices are also foundational to the NIH Precision Medicine Initiative, part of which aims to establish the world’s largest research biobank that will support studies that utilize biospecimens from a cohort of one million individuals in the United States.
findings indicate that patient-derived T cells recognized the eliminated neoantigens and suggest that these neoantigens were relevant targets for the achievement of initial therapeutic response to checkpoint blockade. Conceptually, neoantigen loss occurs through elimination of tumor subclones or through deletion of chromosomal regions containing such alterations. To estimate the contribution of these mechanisms to the loss of neoantigens, we analyzed the tumors both before and after therapy using the SCHISM pipeline and incorporating mutation frequency, tumor purity, and copy number variation to infer the fraction of cells containing a specific mutation (mutation calling). Consistent with other studies, we observed both loss of neoantigen elimination: loss of truncal changes through genetic events involving chromosomal deletions and loss of heterozygosity (LOH) and loss of subclonal neoantigens either by LOH or through elimination of tumor subclones. Both truncal and subclonal changes were among the eliminated neoantigens that were functionally validated.

To evaluate the impact of neoantigen loss on cytotoxic T-cell receptor repertoire, we analyzed serially collected PBMCs, prior to immunotherapy initiation, at clinical response, and at resistance. We hypothesized that loss of neoantigens would lead to a decrease in clonality of cytotoxic TCR clonotypes, thus reflecting tumor immune evasion at the time of emergence of resistance. We observed peripheral T-cell expansion of a subset of the top 100 most frequent intratumoral clonotypes, with the most frequent clones reaching up to a 44-fold increase in abundance in the blood at the time of response, followed by a decrease to pretreatment levels at the time of resistance. As a comparison, such decreases in TCR frequencies were not observed in a NSCLC patient with durable response to PD-1 blockade and no change in intratumoral TCR frequencies was seen in a NSCLC patient with primary resistance to PD-1 blockade. Taken together, these observations suggest that TCR expansion may be both a useful measure of response to checkpoint blockade and an indicator of acquired therapeutic resistance through neoantigen loss.

As immune checkpoint therapy has become standard of care for many cancer types, the development of acquired resistance is being recognized more commonly. Through our comprehensive genomic analyses, we have identified changes in the genomic landscape of truncal immune response that have remained elusive. To examine mechanisms of resistance to immunotherapy, we performed genome-wide sequence analysis of protein coding genes and T-cell receptor (TCR) clonotype analysis, followed by functional assays of autologous T-cell activation of patients who demonstrated initial response to immune checkpoint blockade but ultimately developed progressive disease. Of a cohort of 42 NSCLC patients treated with single-agent PD-1 or combined PD-1 and CTLA4 blockade, we identified all consecutive cases that at the time of the analysis developed acquired resistance (two subjects treated with nivolumab and two with ipilimumab and nivolumab) and who had paired tumor samples available both before and after therapy. To examine the landscape of genomic alterations and associated neoantigens, we performed whole exome sequencing of tumors from these patients. Pretreatment and postprogression specimens were obtained from the same anatomic location or from sites in close anatomic proximity. We examined multiple immune-related pathways, identified peptides stemming from somatic alterations using a computational multidimensional neoantigen prediction platform. This approach allowed for identification of peptides within mutated genes that were predicted to be processed and presented by MHC class I proteins and therefore had the potential to elicit an immune response. The algorithm evaluated the binding of mutant peptides (8-11mers) to patient-specific HLA class 1 alleles and ranked the neoantigens according to MHC binding affinity, antigen processing, and self-similarity.

Analyses of matched pretreatment and resistant tumors identified genomic changes resulting in loss of 7 to 18 putative mutation-associated neoantigens in resistant clones. While algorithm-based predictions of antigenicity are valuable in narrowing the large number of peptides capable of being generated by a mutation to a set of potential antigenic peptides presented by self-MHC alleles, functional T cell recognition is critical to evaluate immune responsiveness. To this end, we developed a sensitive approach for assessing T-cell response to candidate MANAs (cMANAs) that utilized next-generation sequencing of TCR-Vb CDR3 regions as a measure of T-cell clonality. To evaluate T-cell recognition of eliminated neoantigens, purified peripheral blood T cells from the patients described above were stimulated with autologous peripheral blood mononuclear cells (PBMCs) loaded with CMANA peptides in a ten-day culture system. We subsequently used TCR next-generation sequencing to assess the T-cell recognition of eliminated neoantigens, purified peripheral blood T cells from the patients described above were stimulated with autologous peripheral blood mononuclear cells (PBMCs) loaded with CMANA peptides in a ten-day culture system. We subsequently used TCR next-generation sequencing to assess the T-cell recognition of eliminated neoantigens, purified peripheral blood T cells from the patients described above were stimulated with autologous peripheral blood mononuclear cells (PBMCs) loaded with CMANA peptides in a ten-day culture system. We subsequently used TCR next-generation sequencing to assess the T-cell recognition of eliminated neoantigens, purified peripheral blood T cells from the patients described above were stimulated with autologous peripheral blood mononuclear cells (PBMCs) loaded with CMANA peptides in a ten-day culture system. The Effects of Tumor Microenvironment on Metastasis and Therapy Resistance

#NG02 Lymphatic vessels: Balancing immune priming and immune evasion in melanoma. Ryan S. Lane, Julia Fernel, Jamie Booth, Christopher Loo, Nathan M. Nelson, Takahiro Tsujiyak, Guillaume Thibault, Amanda W. Lund. Oregon Health & Science University, Portland, OR. Lymphatic vessel remodeling and lymphangiogenesis is correlated with melanoma progression and lymph node metastasis. While lymphatic vessels provide an important route for disseminating tumor cells, they are also a crucial interface between a developing malignancy and the host immune response. Rather than acting as passive conduits, lymphatic vessels directly regulate their transport function and facilitate leukocyte trafficking for efficient induction of adaptive immunity in downstream draining lymph nodes. We recently published that in the absence of dermal lymphatic vessels, the tumor...
microenvironment of murine melanoma remains completely uninflamed and fails to induce a robust T-cell response (1). Consistently, TCGA analysis of human cutaneous metastatic melanoma identified positive correlations between LEC gene expression and immune status, including a T-cell-inflamed signature, indicating a relationship between lymphatic vessel remodeling and local immunity. Furthermore, others have recently demonstrated that lymphatic vessel density (LVD) in combination with intratumoral T cell function stratified best overall survival in nonmetastatic and metastatic colorectal cancer (2). In contrast to this, however, many reports independently correlate high LVD with lymph node metastasis and some poor prognosis (3). Furthermore, our previous work demonstrated that vascular endothelial growth factor C (VEGFC)-driven lymphangiogenesis in the context of murine melanoma drove increased leukocyte infiltration but associated with poor CD8+ T cell priming in draining lymph nodes (4). Therefore, we hypothesize that lymphatic vessels are (A) required for induction of adaptive immunity but (B) acquire immunosuppressive activity as a function of the accumulation of local cytotoxic immunity. Furthermore, we predict that LVD may be a relevant biomarker of in situ immune responsiveness and response to therapy (5).

To test the first part of this hypothesis (A), we have continued our published work and used a cutaneous model of viral infection to demonstrate the requirement for lymphatic vessel drainage in cutaneous immunopathology. Following cutaneous virus infection we demonstrate that the absence of lymphatic vessel transport both cellular and humoral adaptive immune responses fail to initiate, leading to enhanced cutaneous immunopathology and persistent viral load. The complete absence of primary CD8+ and CD4+ T cells in cutaneous tissue following challenge mirrors our observations in melanoma and is consistent with correlations of intratumoral lymphocytes and LVD both by our group in cutaneous metastatic melanoma as well as others. This unequivocal requirement for a functional lymphatic vasculature in the setting of cutaneous immunity further supports the prediction that LVD may be a novel biomarker of immune reactivity within tumor parenchyma. To test this, we simultaneously evaluated immune and vascular components in human primary melanoma samples using a multiplex-immunohistochemistry-based approach. Tissue regions that have tumultuous lymphatic borders and show infiltrates are selected for analysis, followed by tissue segmentation, and automated detection of cell populations within intratumoral regions and bordering stroma. Interestingly, those tumors with enhanced hematopoietic infiltrate (CD68 and CD8) also appear to demonstrate increased vasculature, both blood (CD31 and CD34) and lymphatic (D2-40 and Prox1). Preliminary data demonstrate that lymphatic vessels, blood vessels, and CD8+ T cells are significantly enriched at the tumor-stroma border in primary melanoma and positively correlate with one another, indicating that lymphatic vessels may be a dynamic component of the immune-microenvironment.

While we demonstrate that lymphatic vessels are necessary for immune induction, we further hypothesized (B) that in the context of an ongoing immune response lymphatic vessels adapt their function to promote immune resolution. The adaptive resistance hypothesis proposes that upon accumulation of local cytotoxic immunity, both tumors as well as stromal components adapt and acquire therapeutically relevant immunosuppressive function. We demonstrate that peripheral, tumor-associated lymphatic endothelial cells (LEC) (LymphoCyt™, CD45−CD31+gp38+) acquire expression of immunoregulatory proteins, most notably programmed death receptor ligand-1 (PD-L1) and major histocompatibility complex II (MHCII), coincident with CD8+ T-cell infiltration in an interferon gamma (IFNg)-dependent manner. Adoptive transfer of activated CD8+ T cells induced higher expression of PD-L1 by LECs in B16 F10 tumors, while neutralization of IFNg reduced levels to that of naïve skin. Furthermore, conditional deletion of IFNg in tumor-associated LECs constitutively expresses PD-L1 and this neutralization of IFNg reduced levels to that of naïve skin. Furthermore, conditional deletion of IFNg in tumor-associated LECs constituting indicates that IFNg is critical for the induction of PD-L1 in tumor-associated LECs. Notably, lymph node LECs constitutively express PD-L1 and this expression is increased further in IFNg-deficient cohorts attributable to a lack of IFNg-induced PD-L1 transcription. Importantly, in the absence of IFNg on peripheral LECs we observed significantly enhanced accumulation of antigen-specific CD8+ T cells in cutaneous tissue. Thus, cutaneous lymphatic vessels, which necessary for immune induction, acquire immunosuppressive activity in a dynamic manner and may participate in immune evasion within tumor microenvironments.

In conclusion, our work across multiple model systems provides strong experimental evidence to indicate that the lymphatic vasculature is an important, active component of the antitumor immune response and may represent a biomarker to stratify patient response and survival for effective clinical immunotherapy. These data indicate a need to revisit the paradigm of lymphatic vessel involvement in tumor progression and metastasis to a more active component of the immune microenvironment. These data indicate a need to revisit the passive evidence to indicate that the lymphatic vasculature is an important, active component of the immune microenvironment.

Diet and Precision Medicine in Cancer Prevention: The Role of Genetic Background, the Microbiome, and Epigenetic Mechanisms

NG03 Marine Omega-3 polysaturated fatty acid and colorectal cancer prevention and treatment, Mingyang Song,1 Kana Wu,2 Shuji Ogino,3 Jeffrey A. Meyerhardt,4 Charles S. Fuchs, Wendy Garrett, Edward L. Giovannucci, Andrew T. Chan. 1Massachusetts General Hospital, Harvard Medical School, Boston, MA; 2Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; 3Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA.

Background: Lifestyle factors are important determinants for the development and progression of colorectal cancer (CRC). An estimated 50-60% of new CRC cases and deaths in the U.S. could be potentially prevented through modification of lifestyle, including diet (2). Fish oil, a rich source of marine omega-3 polysaturated fatty acid (OM3PUFA), is one of the most popular natural dietary supplements used by U.S. adults (3). OM3PUFA has potent anti-inflammatory activity, and substantial experimental data support its beneficial effect for CRC prevention and treatment (4). However, the relevance of these findings to human cancer has been largely unknown. I have led a series of studies linking OM3PUFA to CRC, leveraging data from two large prospective cohort studies, the Nurses’ Health Study (NHS) and the Health Professionals Follow-up Study (HPFS) that have provided detailed information on lifestyle and diet in relation to CRC.

Study setting: The NHS cohort enrolled 121,701 female nurses aged 30-55 years in 1976, and the HPFS cohort enrolled 40,507 men aged 40-75 years in 1986. Over 30 years of follow-up, we have followed up participants through a biennial questionnaire to collect their updated lifestyle and medical information. We have also collected dietary data every 4 years through the food frequency questionnaire, which has been validated for OM3PUFA intake. Moreover, we have followed up patients through a biennial questionnaire to collect their updated lifestyle and medical information.

Study design: We conducted a matched case-control study nested within each cohort, with CRC cases identified through centralized medical record linkage and death certificate verification. We excluded participants who did not complete at least 10 years of follow-up data. We used conditional logistic regression to estimate hazard ratios (HR) and 95% confidence intervals (CI) for the association of overall and dietary OM3PUFA intake with CRC risk. We have also investigated interactions with age, body mass index (BMI), physical activity, and other potential modulators of CRC risk.

Main findings: In our main analysis, we found that CRC risk was lower by 20% in the highest quintile of dietary OM3PUFA intake compared to the lowest quintile (HR: 0.80, 95% CI: 0.70-0.93). This finding was consistent with the inverse association of OM3PUFA with CRC risk reported in prior observational studies (3). Furthermore, among individuals with a family history of CRC, the inverse association of OM3PUFA with CRC risk was stronger (HR: 0.66, 95% CI: 0.47-0.95). These findings are consistent with results from prior studies and support the potential role of OM3PUFA in CRC prevention.

Implications: Our study provides strong evidence for the potential role of OM3PUFA in CRC prevention and highlights the potential for lifestyle modification to reduce CRC risk.

Invited Abstracts

Given the increasing data linking the tumor immune response to cancer prognosis, I led further studies assessing the relationship of MOPUFA intake with CRC survival. We found that patients with high MOPUFA intake after CRC diagnosis had a significantly longer survival compared to those with low intake, suggesting that MOPUFA may exert a beneficial effect across the continuum of colorectal carcinogenesis. We have recently validated these findings in the cohort of CALGB 89803 (Van Blarigan EL et al., manuscript in preparation).

Future plan: Based on this work, I now propose to better understand the intricate relationship between MOPUFA, immune response, and CRC through the development of an independent research program. First, given the increasing data supporting a pivotal role of gut microbes in integrating dietary cues with host immunity and potentially mediating the therapeutic efficacy of cancer therapy, we have proposed to study how MOPUFA modulates the gut microbial composition and function, thereby shaping the gut immune response and suppressing CRC. The findings from this study will provide translational insights into novel dietary and microbial strategies for CRC prevention. Second, to better understand the immunomodulatory effect of MOPUFA in the tumor microenvironment, I plan to characterize the MOPUFA-associated tumor immune signature and study whether MOPUFA improves CRC survival by ameliorating the immunosuppressive microenvironment. Because the immunosuppressive mechanisms have been implicated in the development of resistance to powerful cancer immunotherapeutic agents, our findings may open new avenues for incorporating natural products into existing cancer immunotherapy paradigms for optimizing clinical benefit. In both these areas, I will take an integrated approach that combines the power of population science and clinical research to establish causality and facilitate clinical translation. This approach will also provide a foundation for my research program as I transition into independence.

Mechanisms of Primary and Acquired Resistance to Immunotherapy

NG04 Mechanisms of resistance to anti-PD-1 immunotherapy through interferon pathway mutations

checkpoint blockade immunotherapy can produce dramatic, durable tumor regression, is now being deployed or tested in a growing list of cancer types, and has received FDA approval for the treatment of metastatic melanoma, Hodgkin’s lymphoma, and lung, renal, and head and neck carcinomas. Depending on cancer type, higher CD8 infiltration, PD-L1 expression, and mutational load in tumors may potentiate immune responses to tumors expressing PD-1 ligand (PD-L1). In a cohort of 55 patients from centers in the US and Australia with advanced desmoplastic melanoma (a rare subtype, less than 4% of patients). Our analyses further highlight the relationship between clinical benefit from immune checkpoint blockade therapy and higher mutational load and PD-L1 expression. Objective tumor responses were noted in 39 patients (71%), with most being long lasting. Our analyses reveal that baseline tumor biopsies have significantly higher tumor parenchymal PD-L1 expression than nondesmoplastic skin melanomas that is highly correlated with PD-L1 in the invasive margins. Desmoplastic melanoma has a known relationship to ultraviolet light radiation damage, resulting in one of the highest mutational burdens among all cancer types. Whole-exome sequencing in this cohort confirms this finding and demonstrates a non-random distribution of nonsynonymous mutations per tumor, as compared with a median of 485 mutations per tumor in nondesmoplastic melanomas (P = 0.01).

However, accumulating data from cutaneous melanoma suggest that primary and secondary resistance to anti-PD-1 therapy is a rare event. Recent pooled data from 65% patients on a clinical trial of the anti-programmed death 1 (PD-1) therapy antibody pembrolizumab reported that ~60% of patients with metastatic melanoma had no response to therapy (primary resistance), while ~25% of those with initial objective tumor response had progressed as much as two years later despite continuous therapy (secondary or acquired resistance). Potential mechanisms of resistance conceptually stratify into either T-cell dysfunction (lack of recognition, trafficking, intrinsic exhaustion, or extrinsic suppression) or tumor-based escape (loss of antigen presentation, resistance to killing, or upregulation of suppressive factors).

We have recently reported two genetic mechanisms of acquired resistance to anti-PD-1 therapy (1). In this study, we analyzed melanoma cases with late acquired resistance after strong initial response to anti-PD1 therapy, with the hypothesis that changes from baseline would be mechanistically meaningful in this setting, particularly with respect to immune function or mutations acquired by surviving clones. To investigate this, we performed whole exome sequencing and immunohistochemistry on tumors from cases with paired pre- and post-tumor samples, followed by in vitro modeling with primary tumor cell lines.

First, we studied the local immune environment at relapse to rule out a lack of tumor-specific T-cell effectors. Immunohistochemistry revealed that CD8 T cells were present in the early tumors and at relapse in the majority of the tumors. This is a pattern that our lab and others have shown would otherwise be predictive of response to PD1 therapy. Further studies using targeted sequencing of the T-cell receptor population in biopsies from the four reported cases showed that the top T-cell clones at baseline or during active response were detected at similar frequencies in the relapsing tumors, indicating that the local T-cell repertoire had not changed. Additionally, clones that significantly increased in frequency in the peripheral blood during active response were highly enriched among the top clones in the relapsing tumor. Together, these data indicate the T cells present at relapse are the same T-cell specific clones that mediated the original response. Multiplexed immunofluorescence showed that stromal cells in the tumor microenvironment at progression were strongly positive for PD-L1 expression in areas of high T-cell density. PD-L1 is often upregulated in response to the interferon gamma produced by activated T cells, raising the possibility that these T cells were currently or had recently been active.

With evidence that T cells were still present and possibly active in the resistant lesions, we investigated relapse-specific changes within the tumors themselves by whole exome sequencing. We identified new homozygous loss-of-function mutations in the interferon receptor pathway-associated kinases in the relapse biopsies of two separate cases (JAK1 Q503* and JAK2 F547_splice-site). In addition to the clinical radiographic evidence of relapse in situ, we found strong genetic evidence that the progressing lesions were directly descended from the baseline lesions by clonal selection and oligoclonal expansion. Over two years between biopsies, the resistant tumor shared >92% of nonsynonymous mutations originally identified at baseline. The relapsing tumors also contained the same initial somatic mutations and loss of heterozygosity observed for the invasive margin. We have become homozygous as part of additional LOH events. Neither JAK mutation was detected pretherapy, either in the exome sequencing reads or by targeted amplicon sequencing, suggesting these represent a de novo mutation or extremely rare preexisting clone.

While the JAK kinases are known to associate with growth factor, cytokine, and interferon receptors, in the context of immune resistance we focused on their role in interferon sensitivity. Interferons cause phosphorylation of the STAT transcription factors, and upregulate expression of chemokines, antigen presentation machinery, and PD-L1. In vitro western blot, RNA (Nanosigntm), and flow cytometry studies using primary cell lines derived from pre- and postprogression biopsies from the JAK2 mutated case showed that the JAK2 mutated cells were entirely insensitive to interferon gamma. Other melanoma cell lines with JAK1 or JAK2 deleted by CRISPR-Cas9 approach produced similar results. We also found the JAK mutant cell lines to be resistant to interferon-gamma induced growth inhibition, while the baseline and JAK wild-type cell lines remained sensitive. Notably, the JAK2 mutant cell lines were still sensitive to growth inhibition by interferon-alpha/beta or a STENG agonist (all of which are JAK2-independent), showing the lack of growth arrest was specific to interferon gamma resistance and not a generalized phenomenon.

In a third case, we also identified a new truncating mutation in the antigen presentation gene beta-2 microglobulin (B2M), which led to loss of surface expression of major histocompatibility complex (MHC), with the potential to mechanically implicate in immune evasion. Since the publication of this work we have gathered seven additional biopsies of late secondary progression from patients with advanced melanoma (four of them with a paired baseline) in order to assess the frequency of acquired genetic events in the interferon gamma and antigen presentation pathways, as well as define other potential mechanisms.

Our studies of primary resistance to anti-PD-1 therapy provide further support that loss of function mutations in the interferon pathway genes JAK1 or JAK2 are of high relevance for resistance to antiprogrammed death protein 1 (PD-1) therapy. Immune selection may lead to similar mutations
Dysregulation of MicroRNAs Leads to Target Therapy

#NG05 TP53-mediated human cancer susceptibility is defined by genomic dysregulation of microRNA-34A. Nardin Samuel,1 Gavin Wilson,2 Genevieve Deblois,3 Bade Id 3.1x10^4,4 Niu 1.1x10^4,4 and validated in an independent patient cohort (n=76, 1.9x10^8). Targeted sequencing demonstrated that miR-34A is inactivated by hypermethylation across many different histologic types of primary tumors from LFS patients, such as brain tumors, osteosarcomas, rhabdomyosarcomas, and adrenocortical carcinomas. miR-34A promoter hypermethylation also occurs in lymph node metastases from a cohort of 29 patients with choroid plexus carcinomas, a characteristic LFS tumor (p<0.05). The relationship between miR-34A hypermethylation and TP53 mutation was further validated in sporadic cancers, using the publicly available TCGA dataset. This demonstrates the robustness of this correlation and the applicability of these findings to other cancer contexts.

This study refines the role of epigenetic in a cancer predisposition syndrome and is the first to implicate a microRNA, miR-34A, in human cancer susceptibility and provides a repository of genomic regions of deregulated methylation in the context of dysfunctional TP53. These findings suggest that deregulated DNA methylation at defined genomic loci may be an important hallmark of TP53-mediated cancer susceptibility. The most striking finding from this study is the relative miR-34A promoter hypermethylation at two adjacent CpG sites in peripheral blood from TP53 mutation carriers, confirmed in two independent cohorts and shown to cosegregate with TP53 mutations in LFS families. This result is remarkable since miR-34A is a central microRNA in the p53 network and the first microRNA identified as a direct proapoptotic target of the p53 pathway.

The detection of miR-34A promoter hypermethylation in TP53 mutant cells that have not undergone malignant transformation supports a putative model whereby wild-type p53 may influence methylation patterns at this locus. In particular, in nontransformed cells that do not harbor mutations in TP53, wild-type p53 may be recruited to the miR-34A locus and sustain hypermethylation. We have performed a series of in vitro studies on primary prostate and colon epithelial cell lines to corroborate this model. Conversely, in the setting of loss-of-function or deleterious mutations in TP53, mutant p53 may be able to maintain hypermethylation of the miR-34A promoter, leading to upregulation of miR-34A. Owing to the known redundant cellular roles of p53 and miR-34A, upregulation of miR-34A may be beneficial to cells harboring mutant p53 by supplementing the basal tumor suppressive function that is lost when p53 is mutated. This mechanism may serve to guard against mutant p53, even when the wild-type allele remains. Accordingly, this may explain why miR-34A promoter hypermethylation is characteristic of TP53 mutant tumors that lack wild-type p53 because this microRNA serves a critical role in cell maintenance, and its loss may cooperate with other genetic and/or epigenetic events to drive malignancy.

It is therefore not surprising that, akin to p53, somatic miR-34A deregulation is pervasive in human cancer and miR-34A inactivation by focal deletion or promoter hypermethylation has been reported in the literature to occur in a multitude of human malignancies. The precise mechanisms of how the miR-34A promoter undergoes somatic epimutation in tissues remains to be elucidated, and likely various pathways may converge to yield this outcome in different tissues. Given the high frequency of TP53 mutation in human malignancies, the relationship between mutant p53 and miR-34A has strong implications for the targeting of miR-34A in cancer. Encouragingly, studies have demonstrated in vivo the utility of miR-34A-based therapies in cancer, including intratumor or systemic delivery of lipid-formulated synthetic miR-34A.

To further probe these intriguing findings, we conducted mechanistic studies aimed at functionally interrogating the the miR-34A-p53 axis. We utilized in vitro-based assays to modulate miR-34A levels in primary-derived fibroblast cell lines, and subsequently performed by RNA-seq of the transcriptional responses. Our results uncover a number of novel cellular roles for miR-34A in cell maintenance. Significantly, the transcriptional response to miR-34A inhibition revealed that this microRNA may be a crucial switch that can lead to numerous changes to noncoding RNA networks as well as known p53 pathways. Markedly increased expression of key components of the U12 spliceosome occurs when miR-34A expression is diminished, thereby identifying the miR-34A-p53 axis as a potential driver of transcriptome regulation. The most striking manifestation of this regulatory network is the distinct transcriptional signature of miR-34A in LFS. These findings suggest that deregulated DNA methylation at defined genomic loci may be an important hallmark of TP53-mediated cancer susceptibility. The most striking finding from this study is the relative miR-34A promoter hypermethylation at two adjacent CpG sites in peripheral blood from TP53 mutation carriers, confirmed in two independent cohorts and shown to cosegregate with TP53 mutations in LFS families. Invited Abstracts

Introduction: Chemotherapy-resistant urothelial carcinoma (UC) has no uniformly curative therapy. Understanding how selective pressure from chemotherapy directs UC’s evolution and shapes its clonal architecture is a central biologic question with important clinical implications.

Methods: To address this question, we performed whole-exome sequencing and clonality analysis of 72 UCs including 16 matched sets of primary and advanced tumors prospectively collected before and after chemotherapy.

Results: Our analysis provided several important insights. Our findings show that chemotherapy-treated UC is characterized by significant intrapatient mutational heterogeneity. The majority of mutations were not shared. On average, only 28.4% (range 0.2%-76.4%) of mutations were shared between pre- and postchemotherapy samples. This effect was consistent across primary-primary tumor pairs and primary-metastatic tumor pairs (p=0.17, Wilcoxon test). Surprisingly, even mutations in previously reported driver genes, including PIK3CA, KMT2D (MLL2), ATM, and TP53, were not consistently shared between matched prechemotherapy and postchemotherapy tumors. We confirmed these findings with targeted sequencing of 250 common driver genes achieving an average coverage of 400x and an excellent concordance with variant allele frequencies obtained from whole exome sequencing (Pearson correlation coefficient = 0.93, P<10^-171). Phylogenetic analysis revealed that both clonal evolution and metastatic spread were very early events in the natural history of UC. At the copy number level, our analysis revealed limited intrapatient heterogeneity with respect to interpatient heterogeneity, suggesting that each patient’s cancer is relatively stable during evolution at the copy number level. We discovered two distinct copy-number-based clusters. Cluster A was defined by 9p21 (CDKN2A, CDKN2B, and MTAP) deletions in the setting of euploid copy number background. Cluster B was characterized by several enriched amplifications, including 1q21.1 (SETDB1 and MLLT11) amplifications (P=0.0002, Fisher’s exact test) and 6p22.3 (E2F3) amplifications (P=0.001, Fisher’s exact test). This cluster was also enriched with TP53 mutations (P=0.0001, Fisher’s exact test). We validated the presence of these clusters in the TCGA dataset of untreated UC and confirmed that these copy-number alterations persisted as a relatively static feature during the lifetime of UC tumors. On the other hand, the mutational landscape of UC tumors evolved significantly after chemotherapy. We observed a significant increase in the number of clonal mutations in the postchemotherapy samples across the study cohort (P=0.0134, Fisher’s exact test). Chemotherapy-treated UC was enriched with clonal mutations involving L1-cell adhesion molecule (LICAM) and integrin-signaling pathways. To understand the mutational mechanisms driving the evolution of UC, we compared the patterns of single base transitions between chemotherapy-naive and chemotherapy-treated tumor samples. We observed a significant increase in C to A nucleotide substitutions in tumors treated with cisplatin-based chemotherapy consistent with previously described specific mutagenesis signature induced in C. elegans genome after cisplatin treatment. Further analysis of context motifs of various base substitutions showed enrichment of C>T or G changes at the TCW motifs (where W=A or T), which is highly suggestive of APOBEC-induced mutagenesis. APOBEC-induced mutations were clonally enriched in chemotherapy-treated UC and continued to shape UC’s evolution throughout its lifetime.

Conclusions: Our findings have several potential clinical implications: First, genomic divergence between untreated and treated clones suggests that clinically actionable molecular targets in metastatic chemotherapy-treated tumors will be potentially missed when relying only on analyses of untreated primary tumors at the time of diagnosis, and that repeat mutative biopsies during the course of clinical care would be needed to detect the most recent version of the rapidly changing molecular landscape of a given patient’s UC. Second, further study of the functional role of LICAM and integrin signaling in mediating chemotherapy resistance in UC could lead to a potential strategy for reversing or preventing chemotherapy resistance by targeting these pathways. Third, despite its initial effectiveness in eliminating cancer cells, platinum-based chemotherapy is associated with unintended significant mutagenic editing of the genomic landscape of postchemotherapy tumors. Our insight into the nature of these edits is crucial towards a complete understanding of the basis of chemotherapy resistance in advanced UC, which lays the foundation for the development of rational therapeutic strategies for preventing the emergence or reversing the chemotherapy-resistant state of UC. In summary, our results demonstrate that adjuvant chemotherapy-treated UC undergoes extensive and dynamic clonal evolution throughout the lifetime of the tumor with significant genetic editing that continues during and after chemotherapy. Our findings lay the foundation for an evolutionary understanding of advanced chemotherapy-treated UC and present opportunities for advancing cancer precision medicine.

Drug Development Sessions

New Drugs on the Horizon

#DDT01-02 AZD5991: A potent and selective macrocytic inhibitor of Mcl-1 for treatment of hematologic malignancies, Alexander W. Hirud,1 J. Paul Secrist,1 Annmar Adam,1 Matthew E. Belmonte,1 Eric Gang,1 Frank Gibbons,1 David Hargreaves,1 Jeffrey W. Johannes,1 Stephen L. Kazmirk,1 Jason G. Kettle,1 Stephen E. Kurtz,1 Michelle L. Lamb,1 Martin J. Packer,1 Bo Peng,1 Craig R. Stewart,1 Jeffrey W. Tyner,1 Wenzhan Yang,1 Qing Ye,1 XiaoLan Zheng,1 Edwin A. Clark 1, AstraZeneca, Cambridge, United Kingdom; 2AstraZeneca, Macclesfield, United Kingdom.

Mcl-1, a member of the Bcl/Mcl family, is a key protein involved in evasion of apoptosis in a wide variety of tumors. Its amplification and overexpression have also been implicated in innate and acquired resistance to anticancer drugs. Mcl-1 is capable of preventing induction of apoptosis, both by binding and inactivating the pro-apoptotic executioner Bcl-2 protein, Bak, as well as by sequestering other pro-apoptotic Bcl-3-only proteins. Given the role of Mcl-1 in hematologic malignancies, such as multiple myeloma, acute myeloid leukemia, and non-Hodgkin lymphoma, are particularly sensitive to Mcl-1 inhibition with the expression of an Mcl-1 inhibitor. In addition, cell line profiling data revealed an activity profile distinct from a selective Bcl-2 inhibitor, further underscoring the unique therapeutic opportunity for an Mcl-1 inhibitor. Synergistic combinations were identified with therapies selectively targeting Bcl-2, the MAPK pathway, and proteasome inhibitors. In vivo, AZD5991 demonstrated robust inhibition of tumor xenograft growth with a clear PK/PD relationship, exhibiting on-mechanism activity as measured by Bak and caspase activation on a discontinuous dosing schedule of once or twice weekly. An ongoing phase 1 clinical trial is currently evaluating AZD5991 in multiple myeloma.

#DDT01-03 ABBV-621: A best-in-class TRAIL-receptor agonist fusion protein that enhances optimal clustering for the treatment of solid and hematologic tumors, Susan E. Morgan-Lappe. AbbVie, North Chicago, IL.

Tumor necrosis factor (TNF)-related apoptosis-inducing ligand (TRAIL) is a member of the TNF superfamily of proteins that play diverse roles in the activation of several intracellular signaling pathways that control cell proliferation, survival, and apoptosis. Activation of the TRAIL pathway has been viewed as an attractive therapeutic approach for the treatment of cancer because of its distinct role in the induction of tumor cell apoptosis. TRAIL can bind as a trimmer to membrane-bound or soluble receptors, and only the two closely related cell surface death receptors TRAIL-R1 (DR4) and TRAIL-R2 (DR5) can preferentially trigger the extrinsic pathway of tumor cells, leading to apoptotic cell death. The BCL-2 family member Mcl-1 is an essential component of the extrinsic apoptotic pathway since Mcl-1 acts as a gatekeeper to cell death signaling. The BCL-2 family member Mcl-1 is a key player in the extrinsic apoptotic pathway, serving to amplify the extrinsic pathway through further downstream activation of caspases. Given the crossstalk between the extrinsic and intrinsic cell death pathways, several resistance mechanisms have emerged to escape TRAIL-induced apoptosis. These include altered receptor regulation, overexpression of cellular FLICE-like inhibitory protein (cFLIP) that inhibits the proapoptotic activity of the DISC, overexpression of the prosurvival BCL-2 family member proteins, and the inhibitor of apoptosis proteins (IAPs) that directly inhibit caspases. In addition, TRAIL can induce non–cell death signaling pathways (e.g., NF-κB, MAPK, P38) to promote tumor cell growth as a potential resistance mechanism. Results of several clinical trials that targeted DR4 and DR5 with first-generation agonistic anti-TRAIL antibodies or human recombinant TRAIL indicated that these agents failed to demonstrate significant improvement in patient progression-free survival compared to standard-of-care therapy. The major contributing factor in this lack of clinical activity is believed to be the suboptimal TRAIL receptor clustering by these agonists.
ABBV-621 is a novel, second-generation TRAIL receptor agonist comprising a human IgG1Fc linked to native single-chain TRAIL-receptor binding domain (sc-TRAIL-RBD) monomers that are covalently connected by glycosylated linkers, resulting in a plethora of trimeric RBDs. ABBV-621 is designed to maximize receptor clustering but does not require FCyR-mediated crosslinking for optimal in vivo efficacy, which has been deemed an activity-limiting step for the competitor anti-DR4 and anti-DR5 antibodies in the clinic. In-house studies have demonstrated the requirement for enhanced caspase-8 aggregation into the death-inducing signaling complex (DISC) to induce potent tumor cell death, providing mechanistic insights as to why death receptor agonists originally failed and further distinguishing ABBV-621 from the first-generation agents.

ABBV-621 induces dose-dependent apoptotic cell death at sub- to single-digit nanomolar potencies across a large panel (>100) of human hematologic and solid tumor cell lines in vitro. ABBV-621 activity is on-target and mechanism-based as demonstrated by a rapid activation of downstream apoptotic signaling events (cleavage of caspase-3, caspase-8, and PARP). In human tumor xenograft models, ABBV-621 exhibits potent antitumor activity in vivo as a monotherapy and in combination with targeted agents or chemotherapy using xenograft tumors derived from colorectal, lung, leukemia, and lymphoma cell lines. This activity is on-target, mechanism-based, and dose-dependent as indicated by rapid activation of tumor caspase-8 and caspase-3 after a single ascending dose of ABBV-621 in a colorectal carcinoma xenograft model. ABBV-621 exhibits a dose-proportional pharmacokinetic (PK) profile in mice and cynomolgus monkeys, and the projected human half-life is estimated to be ~2 days. PK/pharmacodynamic (PD) assessments estimate that achieving exposure above an efficacious concentration for 4-7 days is sufficient to maintain tumor regressions up to 4-7 weeks.

Screening of 55 patient-derived xenograft (PDx) models comprising 12 different solid tumor types uncovered single-agent activity (regressions) in >50% of all PDx tested. PDx models can be more reflective of human disease by providing estimation of effects of tumor heterogeneity on ABBV-621 activity. Models that were partially sensitive or completely resistant were also identified. These responses are being utilized with associated pre- and post-treatment genomic/proteomic information to further inform potential patient stratification markers. To demonstrate on-target biologic activity in the clinic, proximal and distal target engagement markers will be pursued. In a GLP nonmonkey toxicity study, ABBV-621 was well tolerated with no adverse test item–related findings. The first-in-human (FIH) phase 1/1b study with ABBV-621 will enroll subjects with previously treated advanced solid tumors and hematologic malignancies. The phase 1 objectives will be to establish the safety and tolerability of ABBV-621, as well as to understand the PK properties. Secondary objectives will be to explore target engagement and efficacy biomarkers and to evaluate clinical activity.

**#DIT01-04 Discovery and development of H3B-6545: A novel, oral, selective estrogen receptor covalent antagonist (SERCA) for the treatment of breast cancer.**

Peter G. Smith, Xiaolong Puyang, Craig Furman, Guangzhong Zheng, Deepti Alley, Megan O’Meara, Shyra J. Gardai, Nicole M. Okeye. Seattle Genetics, Inc., Bothell, WA

H3B-6545 is being developed for the treatment of breast cancer. In preclinical studies H3B-6545 demonstrated several key properties, including: (a) a high degree of selective activity, with robust antitumor activity in xenograft models of estrogen receptor (ER) positive breast cancer including models carrying ER mutations; (b) high intrinsic cell potency in biochemical and cell-based assays. In vitro H3B-6545 shows potent activity and superior efficacy to fulvestrant in the MCF-7 xenograft model with maximal antitumor activity at doses >10x below the maximum tolerated dose in mice. In addition, H3B-6545 shows superior antitumor activity to tamoxifen and fulvestrant in patient derived xenograft models of estrogen receptor positive breast cancer including models carrying ER mutations. In a clinical safety study in both humans and monkeys, H3B-6545 is well tolerated across a broad dose range and at exposures that significantly exceed those required for efficacy in mouse xenograft models.

In summary, H3B-6545 is a first-in-class, orally available and potent selective estrogen receptor covalent antagonist with a compelling pre-clinical efficacy and safety profile that is being developed for the treatment of breast cancer.
advances, however, and the knowledge gap between cultured cell models and in vitro (2). The relevance of these reprogrammed pathways to bona fide human cancer is an essential component of malignancy (1). In particular, pathologic differences between human and rodent models of cancer—such as the NIH or the Food and Drug Administration. is solely the responsibility of the authors and does not necessarily represent the official views of the NIH or the Food and Drug Administration. Cancer Development and Outcomes Related to Tobacco Use

#SY01-03 Reducing harm by targeting the addictiveness of combusted tobacco products through regulated reductions in nicotine content. Eric Donny. University of Pittsburgh, Pittsburgh, PA.

Nicotine is the primary addictive constituent in cigarettes, driving chronic dependence in smokers. New tobacco products are marketed in the US with approximately half the nicotine content of traditional cigarettes. The impact of such reductions on smoking behavior and harm reduction potential is unclear. In this study, we compared smoking behavior and harm reduction potential in human smokers before and after using reduced nicotine content cigarettes compared to standard nicotine content cigarettes. Cigarettes were delivered in a double-blind, randomized design to 30 smokers in a factorial 2 x 2 x 2 design (2 nicotine content x 2 delivery methods x 2 orders of presentation). The results showed that smokers who received standard nicotine content cigarettes smoked significantly more cigarettes per day, which is associated with reduced harm reduction potential. These findings suggest that reduced nicotine content cigarettes may not be an effective harm reduction strategy.

Cancer Metabolism: Moving towards the Clinic

#SY02-02 Exploring the lung cancer metabolism, in vivo and ex vivo, for individualized cancer. Teresa W. Fan, 1 Ramon Sun, 2 Marc Warwomes, 1 Qiushi Sun, 1 Yuan Song, 1 Angela Mahan, 1 Jeremiah Martin, 2 RIchard M. Higashi, 2 Andrew N. Lane, 1

1Univ. of Kentucky, Lexington, KY; 2Richard M. Higashi, Lexington, KY; 3Andrew N. Lane, Lexington, KY.

Lung cancer is a leading cause of cancer death worldwide. This disease is of serious concern in Kentucky, which leads the nation in both lung cancer incidence and mortality. The past decade of cancer research has focused on the downstream value of exploring human metabolism for the discovery of novel therapeutic and diagnostic biomarkers for human cancers and other diseases. To better understand metabolic reprogramming in individual tumors of lung cancer patients, we have developed stable isotope tracers (e.g., [13 C]glucose) coupled with NMR and MS-based stable isotope-resolved metabolomics (SIRM) analysis directly in patients and in patient-derived ex vivo and in vivo models. In the in vivo patient study, we mapped differential metabolic network between paired cancerous (CA) and noncancerous (NC) tissues procured from non–small cell lung cancer (NSCLC) patients infused with [13 C]-glucose and snap-frozen immediately after resection. In particular, we uncovered elevated anaplerotic pyruvate carboxylase (PC) activity in CA versus paired NC tissues. Proliferating cancer cells require active Krebs cycle for generating metabolic fuels, intermediates for anaplerotic intermediates to meet anabolic demands cannot be sustained without anaplerotic. Pyruvate carboxylation represents one of the two major anaplerotic pathways that...
replenish the Krebs cycle intermediates; the other involves glutaminolysis as a feature of more aggressive, less differentiated tumors (5,6).

At the same time, the variability of tumor FDG uptake seen in clinical imaging has driven applications of aberrant glycolysis as a feature of more aggressive, less differentiated tumors (5,6). This has been most widely exploited using the elevated rate of glycolysis observed in most tumors as a target for imaging (2)–in particular, positron emission tomography (PET) imaging of glucose analog \(^{18}F\)-fluorodeoxyglucose (FDG). PET, now combined with anatomic imaging in the form of PET/CT, has become an important tool for cancer detection, staging, and response assessment, widely used in oncologic clinical practices around the world (3,4). Clinical use of FDG PET has increased our appreciation of aberrant glycolysis as a feature of more aggressive, less differentiated tumors (5,6). At the same time, the variability of tumor FDG uptake seen in clinical imaging has heightened opportunities to exploit cancer metabolism as a target for diagnosis. This has been most widely exploited using the elevated rate of glycolysis observed in most tumors as a target for imaging (2)–in particular, positron emission tomography (PET) imaging of glucose analog \(^{18}F\)-fluorodeoxyglucose (FDG). Emerging Targets in Immunotherapy

##SY03-02 Preclinical assessment of JTX-2011, an agonist antibody targeting ICOS, supports evaluation in ICONIC clinical trial. Jennifer S. Michaelson,1 Chiron Harvey,1 Katlu Elpjo,1 Ellen Doong,1 Lindsay Shulberg,1 Matthew Wallace,1 Robert Mabry,1 Jennifer Sho,1 Amit Dey,1 Tom Foss,1 Stephen Safzinsky,1 Joshua Aggar,2 Barbara Mouhou-Zamora,3 Michael Briskin,4 Elizabeth Trehu,1 Jason Reeves,1 Heather Hirsch,2 Siriram Sathyanarayanan,1 Deborah Law1,7. 1Sounce Therapeutics, Cambridge, MA; 2Applied Biome, MA; 3ToxStrategies, CA.

ICOS (the inducible T-cell co-stimulator) is a co-stimulatory molecule expressed on the surface of T cells and a member of the CD28 family, which includes clinically validated targets of cancer immunotherapies, such as PD-1 and CTLA-4. Clinical data identified ICOS as a potentially key molecule in providing optimal antitumor benefit following anti-CTLA-4 therapy. We have developed a species cross-reactive humanized IgG1 agonist antibody, JTX-2011, that binds ICOS and is designed to induce an antitumor immune response. Our preclinical data suggest that JTX-2011 functions through a dual mechanism of action, by stimulating T effector cells (Teff) and by depleting intratumoral T regulatory cells (Tregs). The ICOS antibody is efficacious as a single agent in mouse syngeneic tumor models and demonstrates enhanced activity when administered in combination with anti-PD-1. Single-agent activity in the preclinical models appears to correlate with ICOS expression, with greater efficacy observed in tumor models that exhibit a higher percentage of ICOS-expressing immune cell infiltrate. An integrated expression analysis of human tumors identified non-small cell lung cancer (NSCLC) and head and neck squamous cell carcinoma (HNSCC) as indications with higher percentages of ICOS-expressing cell infiltrate. Preclinical studies performed in rodent and monkeys evaluated safety, pharmacokinetics, and pharmacodynamics of JTX-2011 to inform the first in-human study. The ICONIC phase I/I clinical trial is currently ongoing for evaluation of JTX-2011 alone or in combination with the anti-PD-1 antibody Nivolumab in patients with advanced solid tumors and incorporates a patient enrichment strategy design based on the preclinical and translational findings.
Inherited risk for cancer has been well established from twin studies and family studies. For example, a large, population-based study in Scandinavian countries of more than 200,000 same-sex twin pairs found that heritability was 33% for overall cancer and 57% for prostate cancer (1). To determine, family history is the most commonly used method for evaluating an individual’s inherited risk for cancer. For those individuals with a strong family history, typically defined as multiple affected relatives or relatives who died of cancer at an early age, genetic testing of specific genes may also be recommended. However, recent data suggest that this standard of care is insufficient and inadequate for identifying individuals with higher inherited risk.

Several recent studies suggest that inherited mutations in a number of high-penetration genes (HPGs) are more common in cancer patients than previously estimated. In one study based on The Cancer Genome Atlas (TCGA) data, 4-19% of cancer patients harbored an HPG mutation, with 8% of prostate cancer patients found to be HPG mutation carriers (2). Furthermore, mutation carriers do not have a positive family history. In our recent study of patients with prostate cancer, 60% of pathogenic mutation carriers of BRCA1/2 and ATM had a negative family history of prostate cancer (3). Therefore, it is necessary and relevant to include HPGs in cancer risk assessment among all subjects, regardless of family history.

Another major component of inherited risk is cancer risk-associated SNPs. Many cancer risk-associated SNPs have been identified through genome-wide association studies. The validity of these SNPs has been well established, as they are statistically significant (P<5E-08) and have been replicated among independent study populations. Although each SNP has a small individual effect on cancer risk, they have a strong cumulative effect. The cumulative effect of these SNPs can be measured using several methods, including genetic risk score (GRS) (4). Because GRS is based on individuals’ genotypes and is a continuous variable, it is objective and informative in stratifying inherited risk of developing specific cancers. More importantly, GRS can identify considerably more high-risk subjects in the general population than family history.

For example, in the Prostate Cancer Prevention Trial (PCPT), 24% of men in the study population had a GRS >1.4 and the prostate cancer detection rate during the 7 years of follow-up in these men was 33% (5). In contrast, 17% of men in the cohort had a positive family history and the prostate cancer detection rate in these men was 29%.

Taken together, the latest data suggest that a comprehensive assessment of inherited cancer risk should include family history, HPGs, and GRS. These measures are complementary and, used together, can better identify subjects in the general population at elevated inherited risk for cancer. Using prostate cancer as an example, approximately 7-17% of men in the U.S. population have a positive family history of the disease and are therefore considered to have elevated inherited risk for prostate cancer (6,7). In addition, approximately 2% of men in the general population have a considerably higher inherited risk for prostate cancer due to harboring at least one pathogenic mutation in an HPG for prostate cancer (8). Many of these men do not have a positive family history. Finally, approximately 24% of men in the general population have higher GRSs (>1.4) and have an estimated prostate cancer risk equivalent to or even higher than a positive family history (5). Considering all three risk factors, approximately 56% of men in the general population are estimated to be at higher inherited risk for prostate cancer using this comprehensive risk assessment strategy, more than twice that of the current standard of care risk assessment.

The more comprehensive assessment of inherited cancer risk has important clinical implications, both for asymptomatic subjects in the general population as well as for cancer patients. The most notable clinical utility is for developing individualized cancer screening strategies. A personalized cancer screening approach can maximize benefits and minimize harms associated with cancer screening. For example, offering PSA screening among men with higher inherited risk based on family history, HPGs, and GRS is a rational approach to address the current debate on prostate cancer screening. It is important to note that individualizing cancer screening is the most impactful component of precision medicine, as it can effectively reduce cancer-related mortality and improve quality of life.

Myelomonocytic Cells and Stroma as Therapeutic Targets

The tumor microenvironment (TME) is a complex network, which includes soluble factors and components of the extracellular matrix as well as stromal, endothelial, and immune cells. Immune cells and, among them, myeloid cells play important roles in cancer development and can promote or inhibit cancer initiation and progression (4).

Among tumor-infiltrating immune cells, macrophages are well-known determinants of cancer-related inflammation and are typically characterized by their remarkable plasticity. This consists of the ability to acquire a wide spectrum of activation states in response to various signals derived from the microenvironment. Classical M1 and alternative M2 macrophages represent the paradigm of this property. Tumor-associated macrophages (TAMs) usually display a so-called “M2-like” phenotype that can foster tumor progression in different ways, namely by promoting genetic instability, angiogenesis, and metastasis and by restraining antitumor adaptive immunity. Notably, TAMs can also play a dual role in the response to conventional antitumor therapies: they can enhance the antineoplastic effect or, in contrast, they can sustain a tumor-promoting response and so foil the antitumor power of these drugs (5).

Given their roles in tumor development and the number of macrophage-targeted anticancer approaches are currently being evaluated. They include inhibition of macrophage recruitment and/or survival at tumor sites, functional reprogramming of TAMs to the antitumor M1-like phenotype, and enhancement of killing and/or phagocytosis of cancer cells. Moreover, TAMs express checkpoint proteins that modulate T-cell activation in such a way that they can be targeted by checkpoint blockade immuno-therapies. Also, neutrophils can affect the TME. However, unlike macrophages, they do so by releasing stored and newly synthesized inflammatory mediators. In the “classic,” albeit now obsolete, point of view, neutrophils were viewed as terminally differentiated effector cells that play major roles in the acute inflammatory response and antimicrobial defense. This limited standpoint was challenged by the finding that neutrophils can infiltrate tumors, interact with a number of microvascular sprouts, and produce a wide array of cytokines and effector molecules that exert a plethora of effects on tumor behavior (6,7). Therefore, macrophages and neutrophils are both involved in the regulation of the innate and adaptive immune responses in various inflammatory situations, including cancer.

Besides immune cells, innate immunity comprises a humoral arm that includes a variety of molecules, namely complement components, collectins, ficolins, and pentraxins. The role of the humoral arm of the innate immune system in cancer-related inflammation is still being evaluated. PTX3 deficiency was recently found to increase susceptibility to mesenchymal and epithelial carcinogenesis in mice (8). In detail, tumor-infiltrating leukocytes and endothelial cells were found to be a major source of PTX3 and to contribute to PTX3-mediated protection against carcinogenesis. PTX3 deficiency was associated with enhanced macrophage recruitment, profibrogenic cytokine production, angiogenesis, complement C3 deposition, and C5a levels, which suggests exacerbated cancer-related inflammation. Moreover, genetic inactivation of...
C reverts the increased susceptibility to 3-MCA-induced carcinogenesis and macrophage recruitment. PTX3 regulated C3 deposition on sarcoma cells by recruiting the negative complement regulator factor H. In addition, CCL2 inhibition was sufficient to revert this increased susceptibility to PTX3 deficiency in mice to the M2-like phenotype of TAMs. Thus, in 3-MCA sarcomas, unleashed complement activation and increased C5a production associated with PTX3 deficiency is likely to increase the production of CCL2, which in turn recruits tumor-promoting macrophages and favors M2-like polarization. PTX3 deficiency was also associated with increased DNA damage, which is in accordance with the theory that cancer-related inflammation contributes to the genetic instability of tumors. Moreover, the PTX3 gene was found to be highly methylated in some human mesenchymal and epithelial tumors, and its demethylation might sensitize TAMs to therapeutic intervention. Thus, an essential component of the humoral arm of innate immunity and regulator of complement activation works as an extrinsic oncosuppressor gene in mice and humans by modulating complement-mediated, macrophage-enhanced, tumor-promoting inflammation (8).

In an increasingly more personalized treatment approach, the more accurate understanding of cancer-related inflammation has led to new therapeutic options that target the TME. These strategies include inhibition of inflammatory mediators or of their downstream signaling molecules, blockage of recruitment/activation of myeloid cells, modulation of their immunosuppressive properties, and re-education of TME. These novel therapeutic strategies could synergize with conventional anticancer treatment and so significantly improve the patient’s clinical outcome and follow-up.

Mechanisms Regulating Immune Checkpoint Therapies

**#SY09-01 Next-generation anti-CTLA-4 antibodies.** Alan J. Korman,1 John Engelhardt,1 John Loffredo,2 Jose Valle,1 Rahima Akter,1 Raja Vayyuru,2 Natalie Bezman,1 Paula So,1 Robert Graziano,1 Kimberly Tipton,1 James West,1 Bryan Irving,1 Mark Schulz,2 Bristol-Myers Squibb Co, Redwood City, CA; Bristol-Myers Squibb Co, Lawrenceville, NJ; CytomX Therapeutics, South San Francisco, CA.

The activity of ipilimumab as a single agent and in combination with nivolumab (anti-PD-1) in melanoma, as well as the use of ipilimumab/nivolumab combinations in other malignancies, has confirmed the importance of CT-L cell blockade in immunotherapy. The antitumor effect of this treatment also results in significant immune-related adverse events that limit dosing and result in patient discontinuation. We have taken two approaches to alter the activity of ipilimumab so as to improve its potency and its safety profile. One approach is to enhance the antibody-dependent cellular cytotoxicity (ADCC) activity of ipilimumab in order to increase the potential for Treg depletion at the tumor site; this would be expected to increase the activity of the antibody. The second approach is to produce a produg form of ipilimumab (an anti-CTLA-4 Probody therapeutic) that will have reduced activity systemically, but will become proteolytically cleaved at the tumor site to produce the fully functional antibody; the goal of this approach is to reduce the adverse event profile while retaining the antitumor activity of ipilimumab. It has previously been shown that antitumor activity of anti-CTLA-4 antibodies in mouse models of cancer is dependent on the ability of the antibody to bind activating FcγRs and mediate ADCC against Tregs at the tumor site (1, 2). Although human IgG1 Abs have been shown to be effective mediators of ADCC in patients with hematologic malignancies, it is still unclear whether ipilimumab mediates Treg depletion in solid tumors. Using in vitro ADCC assays, we have found that a nonfucosylated (NF) version of ipilimumab (ipilimumab-NF) has increased activity compared to ipilimumab. Ipilimumab-NF also demonstrates fucosylated IL-2- and IL-15-independent ADCC activity.

In addition, ipilimumab-NF was tested for its ability to enhance a vaccine response in 3-MCA sarcoma-bearing mice. As previously demonstrated, the vaccination of mice with SIV antigens has been shown to induce a CD4+ T-cell response. In colorectal cancer patients coexpression of human CSF1R and CD40 on TAMs was detected, providing the basis to explore this combination in the clinic.

**#SY06-03 Reprogramming the tumor microenvironment to improve responses to therapy.** David G. Denardo. Washington Univ. School of Medicine, Saint Louis, MO.

Immunotherapeutics represent highly promising agents with the potential to improve patient outcomes in a variety of cancer types. Unfortunately, single-agent immunotherapy has achieved limited clinical benefit to date in patients suffering from pancreatic ductal adenocarcinoma (PDAC). This may be due to the presence of a uniquely immunosuppressive tumor microenvironment (TME) present in PDACs, which creates a barrier to effective immune surveillance. Critical obstacles to immuno-therapy in PDAC tumors include the dense desmoplastic stroma that acts as a barrier to T-cell infiltration and the high numbers of tumor-associated immunosuppressive cells. We have identified hyperactivated focal adhesion kinase (FAK) activity in neoplastic PDAC cells as a significant regulator of the fibrotic and immunosuppressive TME. We found that FAK activity was elevated in human PDAC tissues and correlates with high levels of fibrosis and poor CD8+ cytotoxic T-cell infiltration. Single-agent FAK inhibition (VS-4718) significantly limited tumor progression, resulting in a doubling of survival in the p53-Cre/LSL-KrasG12D/;P53Flox;LoxPTX mouse model of human PDAC. This alteration in tumor progression was associated with dramatically reduced tumor fibrosis, decreased numbers of tumor-infiltrating immature myeloid cells, and immunosuppressive macrophages. We postulated that these beneficial effects of FAK inhibition in the TME might render PDAC tumors more sensitive to immunotherapy. Accordingly, we found that FAK inhibition rendered the previously unresponsive KPC mouse model responsive to anti-PD1 and anti-CTLA4 antagonists, leading to a near tripling of survival times. These data suggest that FAK inhibition increases immune surveillance by overcoming the fibrotic and immunosuppressive PDAC TME and thus renders tumors responsive to immu

# Obesity, Inflammation, and the Adipose Microenvironment in Cancer

Prostate cancer (PCa) is promoted by white adipose tissue (WAT) overgrowth in obesity, and underlying mechanisms for this enhancement have been discovered in the recruitment of adipose stromal cells (ASC) by tumors. We reported that CXC1L1 expressed by cancer cells chemotacticlly activates CXC1R1, a candidate upstream mechanism in which we identified interleukin 22 secreted by WAT-infiltrating leukocytes and signaling through IL-22R in cancer cells. Our findings in Hi-Myc mice indicate that obesity promotes epithelial-mesenchymal transition (EMT). We show that ASC directly induce EMT in adenocarcinoma cells. To test whether cancer progression can be blocked by ASC targeting, we have used a human-killed peptide D-WAT composed of an ASC-homing and a pro-apoptotic domain. D-WAT administration depleted prostate stromal cells expressing a chemokine SDF-1α and suppressed the EMT. These results indicate that ASC promote the EMT, at least in part, via SDF-1α paracrine signaling and validate ASC as a therapeutic target.

**#SY07-02 Adipose stromal cells: A player in cancer progression and a therapeutic target.** Mikhail Kolonin. The University of Texas Health Science Center at Houston, TX.

Prostate cancer (PCa) is promoted by white adipose tissue (WAT) overgrowth in obesity, and underlying mechanisms for this enhancement have been discovered in the recruitment of adipose stromal cells (ASC) by tumors. We reported that CXC1L1 expressed by cancer cells chemotactically activates CXC1R1, a candidate upstream mechanism in which we identified interleukin 22 secreted by WAT-infiltrating leukocytes and signaling through IL-22R in cancer cells. Our findings in Hi-Myc mice indicate that obesity promotes epithelial-mesenchymal transition (EMT). We show that ASC directly induce EMT in adenocarcinoma cells. To test whether cancer progression can be blocked by ASC targeting, we have used a human-killed peptide D-WAT composed of an ASC-homing and a pro-apoptotic domain. D-WAT administration depleted prostate stromal cells expressing a chemokine SDF-1α and suppressed the EMT. These results indicate that ASC promote the EMT, at least in part, via SDF-1α paracrine signaling and validate ASC as a therapeutic target.
Invited Abstracts

reduced activity of the Probody Tx outside the tumor microenvironment. The development of next-generation anti-PD-L1 antibodies holds promise for improving the utility of ipilimumab for single-agent or combination therapy. The two improvements to ipilimumab outlined above could each lead to a superior therapeutic outcome and merit further investigation.

#SV09-02 A novel genetic mechanism of evading antitumor immunity in multiple human cancers. Seishi Ogawa. Kyoto Univ. Graduate School of Medicine, Kyoto-shi Sakyoku-Ka, Japan.

Immune checkpoint blockade therapy using antibodies against programmed cell death 1 (PD-1) and PD-L1 ligands (PD-L1) is revolutionizing cancer treatment. Surprising therapeutic responses to these agents are obtained in many advanced cancer patients with different tumor types, such as melanoma, non-small-cell lung cancer, kidney cancer, and Hodgkin lymphoma, suggesting that cancer cells depend critically on evading immune surveillance for their malignant growth. Accumulating evidence suggests that various modulatory factors and molecular pathways contribute to modulating the PD-1/PD-L1 immune checkpoint to unleash antitumor immune responses. However, the genetic basis for the PD-1/PD-L1-mediated immune escape has not been fully elucidated, with the exception of enhanced PD-L1 expression by gene amplification and utilization of an ectopic promoter by translocation, which were reported in Hodgkin and other B-cell lymphomas as well as stomach adenocarcinoma. Only a few genetic markers are currently available to reliably predict response to anti-PD-1/ PD-L1 therapy as well. I will show a unique genetic mechanism of immune escape caused by terminal variations (SVs) commonly disrupting the 3′-UTR region of the PD-L1 gene. Widely affecting multiple common human cancer types, including adult T-cell leukemia/lymphoma (27%), diffuse large B-cell lymphoma (8%), and stomach adenocarcinoma (2%), these SVs invariably lead to a marked elevation of aberrant PD-L1 transcripts that are stabilized by truncation of the 3′-untranslated region (UTR). Disruption of PD-L1 3′-UTR in mice enables immune evasion of EG7-OVA tumor cells with elevated PD-L1 expression in vivo, which is effectively inhibited by PD-1/PD-L1 blockade, supporting the role of relevant SVs in clonal selection through immune evasion. Our findings not only unmask a novel regulatory mechanism of PD-L1 expression, but also suggest that PD-L1 3′-UTR disruption could serve as a genetic marker to identify cancers that actively evade antitumor immunity through PD-L1 overexpression.

Pan-cancer Genomic Analysis

#SY10-02 Pan-cancer study of recurrent and heterogeneous RNA aberrations and association with whole-genome variants. Samikumar Amin, Philip Awadalla, Andrew Biemond, Paul Boutros, Alviz Brazma, Angela Norie Brooks, Claudia Calabrese, David Chang, Aurélien Chateligne, Ken Chen, Zichen Chong, Brian Craft, Chad Creighton, Deniz Demircioğlu, Nuno Fonseca, Mihalya Frenkel-Morgenstern, Gad Geit, Jonathan Goe, Mary Goldman, Liliana Gregor, Syed Haider, Yao He, Katherine Hoadley, Yuan Ji, Andre Kahles, Jan Korbel, Katherine Hoadley, Yau He, Andre Kahles, Jan Korbel, Kjong Lehmann, Han Liang, Fenglin Liu, Maximillian Marin, Matthew Meyerson, Akinyemi Ojesina, Francis Ouellette, Chandra Pedamallu, Marc Perry, Gunnar Rathsch, Roland Schwarz, Yuichi Shiraishi, Cameron Soulouli, Olivier Stegle, Patrick Tan, Alfonso Valencica, Linda Xiang, Christina Yung, Junjun Zhang, Fan Zhang, Zemin Zhang, Jinchun Zhu. To more comprehensively catalogue cancer-associated gene alterations, we have extended our catalog of recurrent somatic mutations that contribute to cancer pathogenesis; however, these studies limit our ability to identify cancer-associated mutations to those that cause protein-coding changes. To more comprehensively catalogue cancer-associated gene alterations, we have extensively characterized tumor transcriptions from 1,200 donors with matched whole-genome sequence data to identify recurrent RNA-level aberrations. Specifically, we created a unified RNA-Seq analysis pipeline including sequence alignment and quality control and subsequently identified gene alterations through outlier detection from estimated gene expression levels, alternative splicing, alternative transcription start, and allele-specific expression and through identified RNA-edited sites and gene fusions. Our data represent an extensive catalog of RNA aberrations for each gene across 27 cancer types. We have also provided genetic associations with these RNA phenotypes. Using an integrative analysis approach, we have mapped genome-wide cis and trans effects on individual RNA phenotypes, considering both common germline variants as well as somatic SVs in gene promoters, enhancers, and intronic and intergenic regions. Many of the regulatory associations we identify are not accessible by exome sequencing, underlining the importance of whole-genome sequence data. Utilizing this RNA-centric view, we have identified genes that are recurrently altered, yet have not been previously characterized as cancer genes or identified through DNA-level driver gene analysis. To identify further supporting evidence that these recurrent alterations are potential drivers, we identified genes with mutually exclusive RNA-level alterations. Our findings reveal new insights into selective advantages of somatic changes and molecular mechanisms of cancer. This work is by the Transcriptome Working Group of the Pan-Cancer Analysis of Whole Genomes (PCAWG) consortium and authors are listed in alphabetical order.

The Unfolded Protein Response in Tumor Biology

#SY13-03 GRP78/BiP: Cancer’s aide in crime. Amy S. Lee, Jeli Shen, Daisy Rangel, Chun-Chih Tseng, Yuan Li Tsai, Dat P. Hu, He Zhao, Louis Dubeau. USC Norris Comprehensive Cancer Center, Los Angeles, CA.

The 78 kDa glucose-regulated protein (GRP78), also referred to as BiP/HSIP5, is a major endoplasmic reticulum (ER) chaperone with antiapoptotic properties and also serves as a regulator of ER stress signaling (1). Tumor cells are subjected to ER stress due to intrinsic factors such as genetic mutations, altered metabolism and hyperproliferation, as well as extrinsic factors in the tumor microenvironment including oxygen and nutrient deprivation (2). As an adaptive measure, cancer cells turn on the unfolded protein response (UPR), and ER stress induction of GRP78 in cancer cells represents a major prosurvival response, suppressing apoptosis while promoting proliferation and invasive-ness. Thus, GRP78 is an emerging target for therapy to blunt cancer development, progression, and drug resistance (3). GRP78 conditional knockout mouse models further established the requirement of GRP78 in solid and blood tumorigenesis driven by mutation of the tumor suppressor gene PTEN and that GRP78 is an upstream regulator of the P38/ERK/S6 pathway (3,4). KRAS is commonly mutated in various cancers, including pancreatic adenocarcinoma (PDAC) and lung cancer, and thus far is deemed “undruggable”. We discovered that haploinsufficiency of a single moiety, GRP78, while having no effect on the normal pancreas, is sufficient to impede acinar-to-ductal metaplasia, block oncogenic signaling, curb PDAC progression, and prolong survival. Similarly, GRP78 haploinsufficiency is able to suppress mutant KRAS-driven lung cancer development. Further, we recently established that ER stress can actively promote cell surface localization of GRP78, where it assumes novel co-receptor functions with cell surface protein partners in regulating signal transduction pathways (5). Our studies uncover that cGRP78 interacts with specific cell surface signaling partner proteins and through those interactions impacts cancer cell adherence, polarity, migration, and survival.

Presidential Select Symposium: Cancer Health Disparities

#SY14-01 Colon cancer screening and genomics. John M. Carethers. Univ. of Michigan, Ann Arbor, MI.

Colon cancer (CRC) is the third most prevalent and second deadliest cancer in the U.S. in 134,490 cases and 49,190 deaths in 2016. Its pathogenesis stems from genetic...
susceptibility coupled with environmental interactions in the colon that synergize ideal conditions for neoplastic growth, initially from benign adenomatous polyps that might progress to carcinoma over several years. Adenoma initiation and progression to carci-
mona may take one of a few identified genetic pathways that determine the tempo of progression as well as morbidity and mortality of the patient. Each patient’s CRC is genetically unique with variable numbers of passenger mutations and propelled by 2-8 driver mutations. CRC’s can be classified as hypermutated, possessing hundreds to thousands of somatic mutations and including CRCs driven by defects in DNA mismatch repair and POLE mutations; and non-hypermutated, with tens of somatic mutations containing multiple copy number alterations and aneuploidy with oncogenic activation of KRAS and PIK3CA coupled with mutations and loss of heterozygosity of tumor suppressors APC and TP53. Epigenetic events as well as inflammatory cellular alterations in DNA mismatch repair further contribute to CRC pathogenesis and metastasis. Because CRC is deadly, prevention through screening (and/or surveillance in high-risk patients) is an ideal and effective approach. Screening provides the opportunity to identify and remove the adenoma precursor before it becomes CRC, and can also utilize the somatic genetic knowledge to effectively screen patients noninvasively. There are seven CRC screening tests suggested by the USPSTF and a Multi-society Task Force for effective screening, with varying abilities to detect significant colonic neoplasia and various specificities; even the most noninvasive and least sensitive test has shown a durable reduction in CRC mortality and is cost effective. Thus, any of the seven CRC screening tests is better than no test. Noninvasive strategies include guaiac-based fecal occult blood testing, fecal immunochemical testing, fecal DNA testing, and CT colonog-
raphy. Luminol-immunoassay tests include flexible sigmoidoscopy and colonoscopy and their combinations with a noninvasive test. If any of the noninvasive tests shows a positive result, a colonoscopy should be performed to identify the cause of the positive test. For high-risk populations, or if there is a chance of patients who have a poor prognosis, it may be used. Knowledge of the patient’s age and family history and personal adenoma or CRC history can influence when to commence screening; additionally, multiple lines of evidence suggest that race should be included in the algorithm influencing the timing and tempo of screening and/or surveillance.

#SY14-04 Cancer health disparities in American Indian and Alaskan Native pop-
ulations, Cheryl L. Willman. University of New Mexico School of Medicine and University of New Mexico NCI Comprehensive Cancer Center, Albuquerque, NM.

American Indian and Alaskan Native communities constitute 562 federally recognized independent sovereign nations within the United States, including 229 located in Alaska and the remainder in 33 other states. These tribal nations and communities are highly diverse in ethnicity, language, customs, modes of tribal governance, and cultural perspec-
tives regarding cancer and health care. American Indian and Alaskan Natives are a diverse group with varying experiences of colonization, contact, and the conduct of health care or community interventions. These nations have very significant cancer health disparities, disproportionately low rates of cancer screening, and more limited access to state of the art cancer diagnosis and treatment and cancer clinical trials when compared to other Americans. Cancer incidence and mortality rates vary, often dramatically, among different tribal nations in different geographic regions of the U.S. (see American Indian and Alaskan Native Cancer Profiles at surveillance.cancer.gov and http://statecancerpro-
files.cancer.gov). These variations may result from differing cancer etiologies, environ-
mental exposures, social behaviors (including diet and tobacco use), spectra of cancers associated with somatic mutations and genetic susceptibilities to cancer and pre-cancerous conditions (such as diabetes), limited rates of community-based cancer screening, and limited access to health care. American Indian and Alaska Natives are often diagnosed at later stages of disease. Disparities may have a poorer prognosis as compared to other racial/ethnic groups. Regional variations in cancer staging and survival within specific cancers are also observed. Highlighting specific examples of cancer health disparities, lung cancer incidence rates for American Indians and Alaska Natives in the Northern Plains and Alaska are currently among the highest in the world. In contrast, lung cancer rates in American Indians in the Western United States are among the lowest in the country. Kidney and hepatobiliary cancers are increasing in incidence in many tribal communities and occur at a significantly higher frequency than observed in other racial and ethnic groups. American Indians and Hispanics, particularly in the Southwest, have the nation’s highest rates of hepatocellular carcinoma, gall bladder cancer, and cholan-
giocarcinoma. Colorectal cancers are also seen at higher rates in American Indian and Alaska Native communities, which may be a result of exceedingly low rates of colorectal cancer screening. Tribal women and girls are also disproportionately impacted by higher rates of cervical cancer, despite implementation of more robust cervical cancer screening programs. Hispanic and American Indian children and adolescents affected by acute lymphoblastic leukemia (ALL) also have significantly poorer survival compared to non-Hispanic and ethnic groups in the U.S. Strikingly, Hispanic children now have the highest ALL incidence in the United States, increasing from 8% of all pediatric ALL cases reported in 1990 to nearly 25% in 2005. Our genomic studies, supported by the NCI TARGET / TCGA (cancer.gov) programs, discovered that American Indian children affected by ALL, and Hispanics with a significant degree of American Indian genetic ancestry, have a high frequency of unique leukemia-causing mutations compared to other racial/ethnic groups (such as those in CRLF2/JAK signaling pathways or novel fusions involving genes encoding epigenetic modifiers and tyrosine kinase signaling pathways (2)). These mutations can be targeted by tyrosine kinase inhibitors (TKIs) or novel therapeutic strategies that are now being tested in national clinical trials, focused on improving overall outcomes in these diseases.

In recognition and respect of the sovereign nation status of American Indian and Alaska Native communities, of tribal laws, of requirements for tribal membership, and of unique cultural perspectives and beliefs, meeting and overcoming cancer care delivery challenges and significant cancer health disparities through research and engagement requires unique, sustained, collaborative, community-engaging, partnership models. Such partnerships must address the concerns of American Indian and Alaska native communities regarding cancer health research and care intervention, including joint oversight of collaborative projects; regular communication of data and results; genetic privacy; appropriate and potentially more limited informed consent for specific studies; appropriate oversight of biospecimen acquisition and utilization of samples collected and stored for specific research projects; intellectual property; and access to data and modes of data sharing and utilization. The National Cancer Institute, The Centers for Disease Control, and the Indian Health Service have supported several projects within tribal communities, largely focused on cancer control. Such activities include the provision of educational materials (such as Native Circle) to communities, the development of high quality cancer registries for American Indians and Alaska Natives including 12 Tribal Epidemiology Centers (tribealpecenter-
s.org), and training and education programs targeted to American Indian and Alaska Native students. The NCI SEER/New Mexico Tumor Registry at the University of New Mexico Comprehensive Cancer Center, which holds cancer registry data from American Indian communities in New Mexico and Arizona and supports the Cherokee Native Cancer Registry and the Alaska Native Tumor Registry, is working with the NCI to leverage the American Indian Cancer Registry and facilitate the registries to collection to allow American Indian and Alaska Native communities to track their cancer data and monitor the incidence and outcome of cancers in their communities. New collaborative partnership models (such as The Southcentral Foundation of Alaska, the TGEN/Pima Indian Nation Partnership in Arizona, and evolving partnerships in New Mexico, Utah, and other regions of the U.S.) with full engagement of tribal nations and collaborating universities, research entities, and health systems are providing new opportu-
nities for American Indians, can and Alaska Native communities to engage in and benefit from cancer research focused on gene-environment interactions and cancer causation, cancer precision medicine and discovery of the spectrum of cancer-associated mutations in cancers disproportionately affecting these communities, cancer education and screening interventions, and cancer clinical trials.

#SY17-03 Can a change in diet change your cancer risk? Stephen J. O’Keefe. University of Pittsburgh, Pittsburgh, PA.

There is a remarkable variation in gastrointestinal cancer risks around the world, best illustrated by colon cancer, where the incidence varies 20-fold between Westernized and less-developed countries. Overwhelming experimental and human study evidence shows that the variation can be accounted for by environmental factors rather than genetic constitution. For example, studies have shown that migration from a low-incidence country to a high-incidence country results in a change in risk to that of the host country population. This is in contrast to the genetic mutation theory for the etiology of colon cancer. Less than 10% of cancers are due to inherited genetic aberrations, and GWAS studies have struggled to identify mutations that strongly influence risk for developing sporadic colon cancer. On the other hand, there is convincing evidence, based on observation and interventions, that cancer risk is increased by consuming加工和/or processing meat and suppressed by the consumption of fiber-rich foods, suggesting that the primary environmental factor that drives risk is what we eat. Recent studies of ours in African Americans, who suffer the highest rates of colon cancer incidence and death in the U.S., showed that a change to a traditional ‘African’ high-fiber (55 gm/day), low-meat diet suppressed mucosal biomarkers of colon cancer risk in their colons within 2 weeks (1). Furthermore, these biomarkers were increased when rural Africans were given a ‘Western’ diet for only 2 weeks. We obtained evidence that these diet effects were mediated by the American microbiota, which break down undiseged food into metabolites that either support mucosal health and are anti-neoplastic, for example short-chain fatty acids such as butyrate, or are inflammatory and carcinogenic, such as conjugated bile acids (which increase in a high-fat diet) and nitroso-compounds (which increase with a high-meat diet). Butyrate has a remarkable array of colonic health-

Diet, Microbiome, and Cancer

Large-scale genomic and transcriptomic interrogation of cancer has underscored the complexity of its genetic landscape, revealing a massive number of genetic alterations that results in the impossibility of distinguishing “driver” from “passenger” mutations. This understanding has sparked unprecedented interest in pursuing strategies to achieve the preferential targeting of cancer cells. This talk will focus on recent advances in the field of metabolic reprogramming of cancer metabolism.

Invited Abstracts

Inflammation and Cancer

Michael Karin, UCSD, La Jolla, CA

The majority of sporadic human colorectal cancer is initiated by genetic loss or inactivation of tumor suppressor genes like APC (Aberrant in Polyposis Colon). In addition to activation of beta-catenin signaling, we found that loss of APC results in upregulation of IL-6 signal transducer (IL6/gp130), thereby leading to activation of STAT3 and YAP, two transcription factors that make important contributions to colorectal tumorigenesis. In addition, APC loss results in deterioration of the intestinal epithelial barrier and immune homeostasis, barrier loss due to downregulation of genes encoding tight junction proteins, and suppression of mucin production. Together, such changes promote the invasion of inflammation-inducing colitogenic bacteria and their products. Loss of immune homeostasis is due to defective luminal transport of IgA dimers caused by loss of polymunoglobin receptor (PlgR) and CCL28, a chemokine responsible for recruitment of IgA-producing plasma cells. Defective luminal transport of IgA results in dysbiosis and over-representation of inflammation-causing bacteria that can accelerate colorectal tumor genesis through upregulation of IL-17 production.

Kingdom et al. (2011) observed that germ-free mice treated with intraperitoneal Lactobacillus reuteri elicited lower levels of colonic IL-17 production than conventional mice. Inflammation-driven cancer: Host and microbial pathways. Fiona Powrie, Sarah McCuaig, Nathan West, Grigory Ryzhakov, University of Oxford, Oxford, United Kingdom

The gastrointestinal (GI) tract is home to a large number and vast array of bacteria that play an important role in nutrition, immune system development, and host defense. In inflammatory bowel disease (IBD) there is a breakdown in this mutualistic relationship, resulting in aberrant inflammatory responses that can progress to colon cancer. Our studies in model systems have implicated innate lymphoid cells and production of IL-22 as key drivers of neoplasia and cancer in the intestine. In this presentation I will discuss new checkpoints that control bacteria-driven innate inflammation in the intestine as well as the functional effects of IL-22 on intestinal epithelial cells and interactions between host genetics, gut microbiota, and deranged inflammatory pathways will yield new approaches to patient stratification and personalized therapy.

Targeting Residual Disease

Alberto Bardelli, Univ. of Turin School of Medicine, Candiolo, Italy

When metastatic cancers are challenged with targeted agents, almost invariably a subset of cells insensitive to the drug emerges. As a result, in most instances targeted therapies are only transiently effective in patients. Strategies to prevent or overcome resistance are therefore needed to delay the next generation of resistance. How can we overcome the near-certainty of disease recurrence following treatment with targeted agents? Addressing this question means considering as a target not “only” individual oncogenes but also the evolving nature of human tumors. We used colorectal cancer (CRC) as a model system to test the hypothesis that by understanding tumor evolution, the emergence of drug resistance can be controlled. We find that clonal dynamics can be monitored in real time in the blood of patients, and liquid biopsies can be used to intercept the emergence of resistant clones before relapses are clinically manifest. We discovered that a multiphase clonal evolution process driven by progressive increases in drug fitness underlies the development of resistance in cells and patient avatars. To have long-term efficacy, the use of targeted therapies must take into account the continuous evolution of cancer cells; that is to say, therapies must adapt to tumor evolution. One possibility is to anticipate the changes the tumors will make. For example, by knowing in advance how CRC cells overcome resistance to EGFR blockade, we devised further rounds of therapy. Another approach is to unleash the ability of the immune system to recognize drug-resistant cells. We tested this possibility in syngeneic mouse models of CRC sensitive to targeted therapies. Our findings indicate that manipulation of the mutational loads can trigger prolonged therapeutic responses that are not observed when cancer cells are challenged with targeted drugs alone. We postulate that rationally combined targeted therapies and immunotherapies can restrain tumor evolution and can limit the emergence of drug resistance, thus leading to long-term responses.

AACC-JCA Joint Symposium: Cancer Metabolomics

Sofia M. Settimi, University of Turin, Turin, Italy

AIB1 is required for the viability of tumor-suppressor hepatocellular carcinoma (HCC) cells in culture. AIB1 knockdown reduces the viability of HCC cells, not only by apoptosis but also by autophagy. AIB1 is a pleiotropic regulator of metabolism; however, its role in the metabolic regulation of HCC cells remains to be fully elucidated. In this study, we aimed to investigate the role of AIB1 in the metabolic regulation of HCC cells. We found that AIB1 knockdown decreased the viability of HCC cells by inducing autophagy and apoptosis. AIB1 knockdown also decreased the expression of ATF4, a key transcription factor in the regulation of autophagy, indicating that AIB1 knockdown induced autophagy by inhibiting the expression of ATF4. These findings suggest that AIB1 knockdown may be a novel strategy for the treatment of HCC by inducing autophagy and apoptosis.
levels of most metabolites were unaltered in tumor tissues. This raises the question of which molecules contribute to the regulation of metabolic reprogramming of colorectal cancer metabolism.

Host Immunity to Oncogenic Viruses

#SY23-01 KSHV: Immune evasion and oncogenesis. Blossom A. Damania. Univ. of North Carolina at Chapel Hill, Chapel Hill, NC.

Infection of cells with oncogenic DNA viruses, including herpesviruses, triggers innate immune responses mediated by DNA sensors. Cyclic GMP-AMP synthase (cGAS) is a key DNA sensor that upon activation produces the cyclic dinucleotide cGAMP, which binds and activates Stimulator of Interferon Genes (STING), leading to interferon production and an antiviral response. Kaposi’s sarcoma-associated herpesvirus (KSHV) is an oncogenic herpesvirus that is linked to several human malignancies including Kaposi’s sarcoma (KS), primary effusion lymphoma (PEL), and multicentric Castleman’s disease (MCD). We have found that KSHV infection activates the cGAS-STING pathway and that cGAS and STING also play an important role in regulating KSHV reactivation from latency. Furthermore, we have identified several KSHV viral proteins that inhibit the cGAS-STING pathway. It appears that modulation of this pathway is important for viral transmission and the lifelong persistence of oncogenic herpesviruses in the human population.

#SY23-02 Host immune responses to HPV and HPV vaccines. Lrigia Pinto. Leidos Biomedical Research, Inc., Frederick National Laboratory, Frederick, MD.

Human papillomavirus (HPV) infection is the cause of multiple cancers in both women and men. There are three different licensed HPV prophylactic vaccines. Currently licensed L1 virus-like particles (VLP)–based HPV vaccines target two to nine different HPV types and have demonstrated excellent efficacy against the targeted HPV types and associated disease. Host immune responses to HPV vaccines and infection will be presented and discussed. Briefly, HPV vaccines induce nearly 100% seroconversion to all HPV types included in the vaccine. High titers of high-affinity L1 IgG antibodies, to the HPV types included in the vaccine, are generated after vaccination, and these persist for several years after vaccination at levels considerably higher than those observed in natural infection. Although correlates of vaccine protection have not been identified, neutralizing antibodies are believed to be the main effectors of protection against HPV infection. Vaccine-induced antibodies are detectable not only in serum but also at mucosal sites of infection, such as the cervix and oral cavity. Local HPV-specific antibody levels, although lower, correlate well with circulating levels. Immunogenicity data have shown noninferiority of antibody responses after two doses of HPV vaccine, and the recommended number of vaccine doses was recently reduced from three to two. There is some evidence suggesting that even one dose of the bivalent HPV vaccine may provide similar protection to the recommended dose regimens. Antibody levels following one dose of the bivalent vaccine, although lower, have been shown to be stable over 4 years of follow-up and vaccine recipients remained HPV16/18 seropositive, suggesting that a single dose of the bivalent vaccine may provide durable protection against infection. The robust immunogenicity of the HPV vaccines contrasts with the immune responses observed after natural infection, in which seroconversion has been shown in only a percentage of individuals with incident HPV infection. Furthermore, levels of antibodies induced by vaccination are much higher than the levels observed after infection and appear to be preserved over time. A better understanding of long-term protection of the vaccine as well as a more comprehensive evaluation of correlates of immune protection against HPV infection are still needed.

Liquid Biopsies: Emerging Technologies to Monitor Cancer Progression and Guide Immunotherapy

#SY24-01 High throughput CTC detection for noninvasive cancer monitoring. Shyamala Maheswaran, Mark Kalinich, Irun Bhan, David Miyamoto, Yu Zheng, Xin Hong, Tanya Todorova Kwan, Ravi Kapur, Lecia Sequist, Ryan Sullivan, Aditya Bardia, Richard Lee, David Ting, Mehmet Toner, Daniel A. Haber. Massachusetts General Hospital, Charlestown, MA.

Circulating tumor cells (CTCs) provide a noninvasive source of patient-derived material to repeatedly sample cancer cells during the course of therapy, assessing changes in tumor burden, genetic composition, and transcriptional and RNA-based abnormalities. While some CTCs are viable and tumorigenic ex vivo, the majority of these cells die in the circulation, and some localized cancers with vascular invasion appear to shed CTCs long before the initiation of metastatic lesions. CTC detection therefore also offers an opportunity for early cancer detection. Two major technologic hurdles have limited the broad clinical application of CTC analyses: 1) the capture of these rare cells, estimated at approximately one tumor cell per billion normal blood cells in the circulation; and 2) the stringent criteria required for scoring rare tumor cells against a genomically identical T cell using antibody-dependent staining. To address the primary challenge of capturing rare CTCs admixed with large numbers of normal blood cells, we have previously described a microfluidic device, the CTC-Chip, capable of high throughput depletion of normal hematopoietic cells, producing an output that is highly enriched for CTCs. This negative depletion strategy enables isolation of CTCs across most types of cancer, independent of cell surface markers, and it ensures the highest quality of cellular RNA for downstream molecular analyses. To address the secondary challenge of imaging CTCs using accurate and high throughput platforms, we took advantage of the intact cancer cell-derived transcriptome within microfluidically enriched cancer cells to establish digital PCR platforms, capable of highly sensitive, reliable, and robust detection of CTCs from different cancer types. As proof of principle, we tested the application of such a digital CTC detection in patients with hepatocellular cancer, prostate cancer, and melanoma, demonstrating accurate measurement of tumor burden and associated RNA-based alterations and genotypes, as well as cancer cell–derived predictive markers of drug response. Taken together, the digital scoring of CTCs from microfluidically enriched cancer cell populations provides a high throughput and highly quantitative platform for serial noninvasive monitoring of cancer. For future early cancer detection applications, the use of intact cancer cells in the circulation as a source of molecular markers may help distinguish invasive from indolent cancers.

Mechanisms of Primary and Acquired Resistance to Immunotherapy

We evaluated immune surveillance in pancreatic ductal adenocarcinoma (PDA), which exhibits far fewer missense mutations and potential neoepitopes than classically described carcinogen-induced, highly mutated tumors. In contrast to these immunogenic tumor models from which the theory of elimination-equilibrium-escape was determined, we found no evidence for immunoeediting in a mutant Kras-driven murine model of PDA. These tumors progress the same with or without a functional adaptive immune system, similar to other mouse tumors that have also been shown to grow independently of T cells. Thus, the manifestations of cancer immune surveillance in the KPC model depend on tumor antigenic strength; the lack of neoepitopes is not a consequence of immunoeediting in this model. These findings suggest an alternative biologic mechanism in which tumor outgrowth reflects immune quiescence, which is linked to, and regulated by, poor tumor antigenicity—a conclusion with potential relevance to human cancers with a low burden of mutations and minimal neoepitopes.
Targeting DNA Damage/Repair in the Genome

Prostatic adenocarcinoma (PCA) is the third leading cause of cancer death in U.S. men. Organ-confined PCAs can be effectively managed, but there is no durable treatment for advanced disease. Advanced PCAs is treated through androgen deprivation therapy, often coupled with direct androgen receptor (AR) antagonists, as PCAs is exquisitely dependent on AR activity for cell survival and proliferation. Unfortunately, relapse is common; recurrent disease arises largely due to resurgent AR activity with 2-3 years, and there is no cure for this castration-resistant phase (castration-resistant PCAs, CRPC). Thus, there is a significant need to develop new targets for targeting recurrent AR activity or to develop adjuvant therapies in advanced PCAs. Emerging data from our laboratory and others strongly support the concept that alterations in DNA damage repair (DDR) pathways are more common than previously thought in sporadic PCAs, and that alterations in these pathways may afford new, more effective means of therapeutic intervention. New studies to be discussed will address underlying mechanisms of action with regard to the therapy and identify clinically actionable ramifications of DNA repair dysfunction. Major concepts to be considered include 1) new findings implicating differential functions of p53 somatic mutations on PCAs behavior and response to therapeutic intervention and 2) differential roles of DNA-dependent protein kinase (DNA-PK) in controlling PCAs progression. Findings to be discussed strongly support a model wherein selected DDR pathways can be developed as therapeutic targets to tailor treatment for prostate cancer and improve outcome for advanced disease.

#SY28-09 Novel mechanisms of PARP inhibitor resistance. Alan D. Andreea. Center for DNA Damage and Repair, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA.

Ovarian and breast cancers are the most common forms of gynecologic malignancy. Persistent genome instability is a hallmark of these cancers and likely important for their development and maintenance. The most commonly used targeted therapies are poly (ADP-ribose) polymerase (PARP) inhibitors, which are utilized to exploit the DNA repair deficiency that is associated with these tumors. Due to the high prevalence of these mutations, PARP inhibitors are now in clinical use for these diseases. However, PARP inhibitors also induce cell death in normal cells, and the development of resistance to PARP inhibitors presents an important clinical challenge. In breast and ovarian cancers, the most common forms of resistance to PARP inhibitors are defects in homologous recombination repair (HRR) pathway genes. The most commonly altered HRR genes in serous ovarian cancers (HGSOCs) harbor genetic and epigenetic alterations in homologous recombination repair (HRR) pathway genes.

Systemic Metabolic Dysfunction and Cancer

#SY28-01 Stromal contributions of adipocytes to cancer. Philipp E. Scherer. UT Southwestern Medical Ctr., Dallas, TX.

The past few years have provided substantial evidence for the vital role of the local tumor microenvironment and obese postmenopausal women: a randomized controlled trial. Cancer Res 2012;72(9):2314-26.

Targeting DNA Damage/Repair in the Genome

#SY28-09 Novel mechanisms of PARP inhibitor resistance. Alan D. Andreea. Center for DNA Damage and Repair, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA.

Ovarian and breast cancers are the most common forms of gynecologic malignancy. Persistent genome instability is a hallmark of these cancers and likely important for their development and maintenance. The most commonly used targeted therapies are poly (ADP-ribose) polymerase (PARP) inhibitors, which are utilized to exploit the DNA repair deficiency that is associated with these tumors. Due to the high prevalence of these mutations, PARP inhibitors are now in clinical use for these diseases. However, PARP inhibitors also induce cell death in normal cells, and the development of resistance to PARP inhibitors presents an important clinical challenge. In breast and ovarian cancers, the most common forms of resistance to PARP inhibitors are defects in homologous recombination repair (HRR) pathway genes. The most commonly altered HRR genes in serous ovarian cancers (HGSOCs) harbor genetic and epigenetic alterations in homologous recombination repair (HRR) pathway genes.
are BRCA1 and BRCA2, followed by other Fanconi anemia genes including FANCN/PALB2, FANCO/RAD51, FANCI/BRIP, and FANCA. Loss of HR causes genomic instability, hyperdependence on alternative DNA repair mechanisms, and enhanced sensitivity to PARP analogues, topoisomerase inhibitors, and PARP-inhibitors (PARPi). The synthetic lethal interaction with PARPi is being exploited therapeutically in diverse clinical contexts and most notably in ovarian cancer, where the PARPi olaparib is FDA approved for use in patients with germline BRCA1/2 mutations. PARPi inhibitor resistance has already emerged as a vexing clinical problem for the treatment of BRCA1/2-deficient tumors. The most prevalent mechanism of PARPi resistance is secondary events that cancel the original HRR alteration and restore HRR proficiency. However, PARPi resistance may still develop without restoration of HRR proficiency via disruption of multiple pathways, such as PTIP or CHD4, that leads to replication fork (RF) stabilization. Importantly, this latter mechanism—namely, the restoration of RF-stability—appears to be a highly prevalent mechanism of PARPi inhibitor resistance in vitro and in vivo, particularly in tumor cells with an underlying BRCA2 deficiency. Due to their underlying deficiency in BRCA2 and inability to generate RAD51 nucleofilaments, these tumor cells are unable to restore HRR mechanisms. Instead, these cells acquire PARPi inhibitor resistance by limiting the nucleolytic degradation of their stalled replication forks. We have recently made the surprising observation that BRCA2-deficient tumors can become resistant to PARPi by downregulating the expression of the polycomb repressive complex PRC2, a methyltransferase complex containing EZH2, SUZ12, EED, and RbAp48. Importantly, downregulation of PRC2 results in the reduced recruitment of the nuclease MUS81 to the RF, thereby providing a novel mechanism of RF protection and PARPi resistance. A molecular understanding of PARPi inhibitor resistance mechanisms may allow the generation of a new class of drugs or a repurposing of existing drugs, which may reverse this resistance and extend the use of PARPi inhibitors to more tumor types.

Biology of Metastasis: Mechanisms, Models, and Medicine

#SY31-02 Macrophages—evildoers in cancer. Jeffrey W. Pollard, MRC Centre for Reproductive Health, University of Edinburgh, Edinburgh, United Kingdom.

Tumor evolution to malignancy requires manipulation of its tissue microenvironment to be promiscuous. This is particularly true for the immune microenvironment that is biased away from responding to the tumor to effect control and instead actively promotes progression. The tumor immune response thus downregulates cytotoxic T-cell responses and promotes tissue repair and morphogenic activities of the infiltrating immune cells (1). Thus the environment tends to be dominated by innate immune cells, particularly macrophages and neutrophils, while cytotoxic T cells are often excluded. Our interest has been in macrophages as these, in many different mouse models of cancer, promote tumor progression and enhance metastasis. In fact, macrophages appear to be involved in every step of tumor progression. They stimulate tumor initiation, enhance angiogenesis, promote tumor cell migration and intravasation, increase stem cell viability, suppress immune responses, and, at the metastatic site, promote extravasation and persistent growth. Consequently, macrophage ablation results in inhibition of tumor progression and metastasis (2). These macrophage biologic activities are induced through a dynamic interplay with tumor cells that often involves reciprocal signaling. We have been particularly interested in the involvement of macrophages in enhancing metastasis since it is metastatic disease that is responsible for most cancer deaths. We have demonstrated a chemokine-signaling cascade that results in the recruitment of the progenitor monocytes and their retention in the tissue (3, 4). This results in differentiation of what we termed metastasis-associated macrophages (MAMs) that confer survival signals and growth advantage to metastatic cells. These MAMs in term respond to local signals to upregulate an inflammatory gene signature through the tyrosine kinase transmembrane receptors, vascular endothelial growth factor receptor 1 (VEGFR1 or FLT1) and colony stimulating factor 1 receptor (5). Importantly, downregulation of VEGFR1 can lead to inhibition of metastasis (6). We have demonstrated a chemokine-signaling cascade that results in the recruitment of the progenitor monocytes and their retention in the tissue (3, 4). This results in differentiation of what we termed metastasis-associated macrophages (MAMs) that confer survival signals and growth advantage to metastatic cells. These MAMs in term respond to local signals to upregulate an inflammatory gene signature through the tyrosine kinase transmembrane receptors, vascular endothelial growth factor receptor 1 (VEGFR1 or FLT1) and colony stimulating factor 1 receptor (CSF1R) (5). Furthermore, monocytes appear to be preadapted by the primary tumor to promote metastasis by the generation of preferred sites known as premetastatic niches (6). Thus, understanding monocyte biology, the mechanisms of their recruitment, and differentiation is of central importance to the fundamental appreciation of the role of macrophages in the tumor. My talk will focus on these questions.

Dysregulation of MicroRNAs Leads to Target Therapy

#SY32-01 The new genetics and treatment of CLL. Carlo M. Croce. Ohio State University Comprehensive Cancer Center, Columbus, OH

Loss of miR-15/16 on chromosome 13q14 is the most common genetic alteration in CLL. Recently, we discovered that miR-15/16 target BCL2, an antipapotic gene we discovered and named in 1984. Thus, loss of miR-15/16 leads to overexpression of BCL2 (the driver) and causes sensitivity of CLL cells to the antiBcl2 drug venetoclax that is capable of inducing complete remission of CLL in patients and was approved by the FDA in April 2016. The discovery of the involvement of miR-15/16 in CLL also indicated that alterations in genes not encoding proteins can cause cancer. Before our publication of 2002, the dogma was that alterations in protein coding genes, oncogenes, and suppressor genes, cause cancer. We speculate that by looking at other targets of miR-15/16 we might discover other biomarkers that are overexpressed because of miR-15/16 loss, providing novel opportunities to discover treatable targets. Since it seems likely that among the billions of leukemic cells in patients, there are a few that do not respond to the drug—for example, because of mutations in the Bcl2 pocket binding the drug—it is important to develop other drugs capable of killing CLL cells because they have lost miR-15/16. We propose to define whether loss of miR-15/16 may lead to overexpression of specific surface markers that can be targeted by specific monoclonal antibodies. The availability of cancer our probing (PALB2, FANCO/RAD51, FANCJ/BRIP, and FANCA). Loss of HRR causes genomic instability in BRCA1 and BRCA2, followed by other Fanconi anemia genes including FANCN/PALB2, FANCO/RAD51, FANCI/BRIP, and FANCA. Loss of HR causes genomic instability, hyperdependence on alternative DNA repair mechanisms, and enhanced sensitivity to PARP analogues, topoisomerase inhibitors, and PARP-inhibitors (PARPi). The synthetic lethal interaction with PARPi is being exploited therapeutically in diverse clinical contexts and most notably in ovarian cancer, where the PARPi olaparib is FDA approved for use in patients with germline BRCA1/2 mutations. PARPi inhibitor resistance has already emerged as a vexing clinical problem for the treatment of BRCA1/2-deficient tumors. The most prevalent mechanism of PARPi resistance is secondary events that cancel the original HRR alteration and restore HRR proficiency. However, PARPi resistance may still develop without restoration of HRR proficiency via disruption of multiple pathways, such as PTIP or CHD4, that leads to replication fork (RF) stabilization. Importantly, this latter mechanism—namely, the restoration of RF-stability—appears to be a highly prevalent mechanism of PARPi inhibitor resistance in vitro and in vivo, particularly in tumor cells with an underlying BRCA2 deficiency. Due to their underlying deficiency in BRCA2 and inability to generate RAD51 nucleofilaments, these tumor cells are unable to restore HRR mechanisms. Instead, these cells acquire PARPi inhibitor resistance by limiting the nucleolytic degradation of their stalled replication forks. We have recently made the surprising observation that BRCA2-deficient tumors can become resistant to PARPi by downregulating the expression of the polycomb repressive complex PRC2, a methyltransferase complex containing EZH2, SUZ12, EED, and RbAp48. Importantly, downregulation of PRC2 results in the reduced recruitment of the nuclease MUS81 to the RF, thereby providing a novel mechanism of RF protection and PARPi resistance. A molecular understanding of PARPi inhibitor resistance mechanisms may allow the generation of a new class of drugs or a repurposing of existing drugs, which may reverse this resistance and extend the use of PARPi inhibitors to more tumor types.

Immunometabolism in Immunotherapy

The extraordinary proliferative capacity of cancer necessitates specialized metabolic programming on the part of cancer cells. Indeed, this specialized metabolism not only facilitates growth but also creates a hypoxic, acidic, nutrient-deprived tumor microenvironment able to thwart immune destruction. We hypothesized that by targeting tumor metabolism we could not only slow down tumor growth but also “condition” tumors to be more susceptible to immunotherapy. Inherently to the specialized metabolism of tumor cells is a markedly increased requirement for glutamine. To this end we have devised a novel glutamine antagonist that is delivered as an inert prodrug that is converted to the active drug by enzymatic activity, which is enriched in tumors. In syngeneic mouse models of cancer our drug (JHU-083) markedly inhibited tumor growth, led to cure of mice after only 14 days of monotherapy. Importantly, targeting glutamine metabolism led to a decreased extracellular acidification rate (ECAR), decreased hypoxia, and increased nutrient availability. Furthermore, we observed decreases in MDSC and fibrocytes with a concomitant increase in inflammatory (TNF-producing) tumor-associated macrophages (TAMs). Likewise, there was an increase in the CD8:Treg ratio and in some tumors a decrease in PD1 expression on both tumors and infiltrating immune cells. Most importantly, JHU-083 markedly enhanced the efficacy of immunotherapy in the form of checkpoint blockade, adoptive cellular therapy (ACT), and A2ar blockade. Overall, our studies define a novel compound for targeting metabolism as a means of enhancing immunotherapy for cancer.
Surgery in the 21st Century: Convergence of Genes, Imaging, and Robots

#SY33-02 Fuelling T cells and antitumor immunity, Jeffrey C. Rathmell. Vanderbilt University School of Medicine, Nashville, TN

Lymphocyte activation leads to rapid proliferation and differentiation, and we have shown that T cells with Treg regulatory distinct metabolic properties can fuel T cell fates (Th1, Th2, Th17) activate a highly glycolytic program. Regulatory CD4 T cells (Treg), in contrast, utilize a more oxidative metabolism and utilize lipids as a major fuel. These metabolic distinctions may allow new understanding of T-cell function in tumors and approaches to manipulate immunity. We have now examined the metabolism of Treg in detail and found that FoxP3 itself can promote oxidative metabolism characteristic of Treg and that this is critical to maximize Treg suppressive capacity. Treg can be glycolytic and proliferative in vivo. We found, however, that glucose uptake and glycolysis impaired Treg stability. Thus, Treg regulate glycolytic and oxidative metabolism to balance fates (Th1, Th2, Th17) activate a highly glycolytic program. Regulatory CD4 T cells shown that T-cell subsets require distinct metabolic programs. The effector CD4 T-cell University School of Medicine, Nashville, TN is useful when patient material is available but usually cannot be used to develop response to identify the profile and a second independent clinical trial to validate it. This strategy double-negative tumors exhibiting a response rate of 82%.

In conclusion, surgery, the oldest type of cancer therapy, when used in combination with neoadjuvant chemotherapy (NAC) prior to bladder cancer surgery as a model applicable to other cancer types of how this is being used to develop biomarkers of therapy prediction while identifying novel therapeutic targets.

Bladder cancer is the second most common cancer of the genitourinary tract, and primary treatment consists of transurethral resection of the tumor. At diagnosis, 30% of patients present with muscle-invasive disease (MIBC), in which case standard of care consists of removal of the bladder (radical cystectomy; RC) and pelvic lymph node dissection. Despite this extensive surgery, 5-year survival rates do not exceed 60%, due to the presence of occult nodal or visceral micrometastases at the time of surgery. The use of platinum-based NAC has improved outcome in MIBC patients, with the most commonly used regimen being gemcitabine/cisplatin. The benefit of NAC is 14% in the risk of death. Importantly, pathologic complete response (i.e., stage pT0) at RC is associated with an excellent 5-year survival rate of 85%, but only 25% of patients experience this. The resolution of 75% of patients are exposed to chemotherapy as adjuvant therapy in the form of neutropenia (70-80%), neutropenic sepsis (2-14%), mucositis (1-22%), and death (1-3%), without an improved outcome. These patients are also subjected to a delay in RC, which might negatively affect their prognosis.

Given this information, the search for tools that can predict which patients benefit from NAC has been a focus of investigation. The NAC approach has two major advantages for biomarker discovery: 1) robust surrogate outcomes of survival (i.e., stage pT0 at RC) and 2) ability to examine pre- and post-samples collected during standard of care, which greatly facilitates biomarker discovery both practically and scientifically. Gene expression analysis has been used in an attempt to predict response to NAC. An early study has shown that gene expression can be used to build predictive models of the response to a single drug as well as to combination regimens. In this study, baseline gene expression profiles from a panel of 40 bladder cancer cell lines were used to develop chemotherapy response prediction models, which showed highly significant concordance with empirical patient responses. In another study by Takaga and colleagues, gene expression was measured in tumor samples from 27 patients with MIBC prior to neoadjuvant treatment with methotrexate vinblastine, Adriamycin, and cisplatin (MVAC) chemotherapy. The authors identified a set of 50 genes that significantly differed between 14 responders and 13 nonresponders. The same investigators have subsequently validated their predictive signature on 22 additional patients, showing that their gene expression signature could predict MVAC response in 19 out of 22 cases. Ails and colleagues analyzed gene expression in 30 patients with locally advanced or metastatic bladder cancer, identifying 55 genes that proved to be expressed at lower levels in patients with longer survival. Two genes that discriminated patients by their survival—EMMPRIN and survivin—were further investigated by immunostaining, which showed they were significantly associated with overall survival, with double-positive tumors exhibiting a response rate of 27% and double-negative tumors exhibiting a response rate of 69%.

The use of molecular profiles to predict treatment outcomes requires a training dataset to identify the profile and a second independent clinical trial to validate it. This strategy is useful when patient material is available but usually cannot be used to develop response biomarkers to regimens before clinical studies are carried out. A new strategy was proposed by our group that extrapolates in vitro drug response data to make in vivo predictions based on the gene expression profiles that are common to both. This approach, called Orthogonal Exploration (OxPe), uses extra data as a “Rosetta stone” for translating between drug activities in a cancer cell line panel and drug activities in a set of clinical tumors. Using a variety of cancer cell lines and their gene expression profiles and drug sensitivity, Lee et al. used COXEN to predict sensitivity to cisplatin and docetaxel in bladder cancer cell lines and sensitivity to docetaxel and tamoxifen in breast cancer patients, and also demonstrate the utility of COXEN in drug screening. This approach was used to identify a promising new agent in bladder cancer, called C1311, while predicting the response of bladder cancer patients to chemotherapy both in the neoadjuvant and treatment settings.

In conclusion, surgery, the oldest type of cancer therapy, when used in combination with systemic therapy guided by discoveries made with molecular tools, promises to not only advance our understanding of cancer but also lead to a quantum improvement in patient outcome. There is every expectation that, given their effects on metastatic disease, the use of neoadjuvant and adjuvant immunotherapy with surgery will also have a significant impact and can be studied using the same tools described here.

Transformative Small Molecule Therapies

#SY37-02 Lindig-directed degradation of GSP1 by a novel cereblon modulator drives potent anti-tumor effects, Mary Matysikela,1 Gang Lu,2 Takumi Ito,3 Barbra Pagarian,1 Chin-Chu Lu,2 Karen Miller,2 Wei Fang,1 Nai-Yu Wang,1 Derek Nguyen,1 Jack Houston,1 Gilles Carmel,1 Tam Tran,1 Mariko Riley,1 Lyn‘Al Nosaka,1 Gabriel Pagarigan,1 Chin-Chu Lu,1 Karen Miller,1 Wei Fang,1 Nai-Yu Wang,1 Derek Nguyen,1 Jack Houston,1 Gilles Carmel,1 Tam Tran,1 Mariko Riley,1 Lyn‘Al Nosaka,1 Gabriel Pagarigan,1 Chin-Chu Lu,1 Karen Miller,1 Wei Fang,1 Nai-Yu Wang,1 Derek Nguyen,1 Jack Houston,1 Gilles Carmel,1 Tam Tran,1 Mariko Riley,1 Lyn‘Al Nosaka,1 Gabriel
the surface of cereblon. The principal molecular feature on GSPT1 that binds to cereblon is a beta-hairpin incorporating a glycine residue that docks against CC-885. Surprisingly, we found evidence that a similar molecular feature mediates Ikaros recruitment, even though there is no common structural fold or sequence homology other than the key glycine residue. We thereby define the common molecular feature, or degron, shared by the known cereblon neomorphic substrates. We further describe a novel therapeutic target, GSPT1, with promise in cancer such as AML. These results further show that cereblon-mediated protein degradation can be directed against new proteins and that this mechanism enables the targeting of multiple protein classes that may be considered undruggable with conventional approaches.

Convergence, Computation, and Cancer

#PL04-04 Novel vapproaches for personalizing treatments: From nutrition to cancer. Eran Segal. Weizman Institute of Science, Rehovot, Israel, Israel.

Elevated blood glucose levels are rapidly increasing in the general population, resulting in a sharp incline in the prevalence of prediabetes and impaired glucose tolerance and eventual development of type 2 diabetes mellitus. Dietary intake is considered a central determinant of glucose levels, with high postmeal glucose levels affecting weight gain, obesity, hunger, and energy dips and being associated with increased risk of cardiovascular disease, cancer, and overall mortality. However, despite their importance, existing dietary methods for controlling postmeal glucose levels have limited efficacy. By continuously monitoring week-long glucose levels in over 1,000 people, we found high variability in the response of different people to identical meals, suggesting that generic population-wide dietary recommendations have limited utility and are ineffective in achieving proper glycemic control. We devised a machine-learning algorithm that integrates blood parameters, dietary habits, anthropometrics, physical activity, and gut microbiota measured in this cohort and showed that it accurately predicts personalized postmeal glucose responses to real-life meals. Moreover, a blinded nation-wide controlled dietary intervention based on this algorithm resulted in significantly lower postprandial responses in a cohort of prediabetics and consistent alterations to gut microbiota configuration. These results suggest that personalized diets may successfully modify elevated postprandial glucose levels and its metabolic consequences. As another example of personalized medicine approaches that we are developing, I present our work on functional profiling of a library of over 10,000 variants that we generated for the tumor suppressor p53, the most frequently mutated gene in human cancers. Remarkably, the mutational effects observed in large-scale in-vitro assays with this library correspond to p53 mutation recurrence in patients and provide many novel insights on adverse and benign variants, protein structure, and evolutionary conservation. Apart from gaining comprehensive insights into the effects of the p53 “mutome,” our results may lead to better understanding of patients’ response to treatment based on their p53 sequence, potentially contributing to the development of novel patient-specific therapeutics. Finally, I also present our studies of the mechanisms driving recurrent postdieting obesity in which we identified an intestinal microbiome signature that persists after successful dieting of obese mice. This signature was associated with faster weight regain and metabolic aberrations upon re-exposure to obesity-promoting conditions and transmits the accelerated weight regain phenotype upon interanimal transfer. Notably, a microbiome-based machine-learning algorithm enabled personalized prediction of the extent of postdieting weight regain. We further find that the microbiome contributes to diminished postdieting flavonoid levels and reduced energy expenditure and demonstrate that flavonoid-based ‘probiotic’ intervention ameliorates excessive secondary weight gain. These results thus highlight a possible microbiome contribution to accelerated postdieting weight regain and suggest that microbiome-targeting approaches may help to diagnose and treat this common disorder.

Plenary Sessions

Opening Plenary: The Road to Cancer Cures—Discover, Predict, Prevent, and Treat

#PL01-03 Earlier detection as a key to lower cancer death rates. Bert Vogelstein. Johns Hopkins Kimmel Comp. Cancer Ctr., Baltimore, MD.

Two disciplines within cancer research—secondary prevention and cancer therapeutics—have historically been viewed as distinct. I will argue that these two disciplines are intertwined and that their joint pursuit is the optimal way to reduce cancer deaths. At present, the preferred way to treat cancers, in fact the only way that generally cures patients, is surgery. It is therefore widely recognized that the detection of cancers prior to the onset of metastasis is vital to reducing cancer deaths. What is less widely recognized is that the detection of metastatic cancers can also be life-saving—as long as this detection occurs prior to the formation of bulky metastatic disease. Therapies that only modestly extend life when administered to patients with measurable metastases can be curative when administered to patients with metastatic disease that is present but undetectable by imaging. Such therapies include conventional cytotoxic drugs as well as genome-targeted agents and immunotherapeutics. A new paradigm for designing clinical trials to test such agents in a cancer-specific setting will be described. Genome-based diagnostic approaches for detecting cancers earlier will be discussed, as these are integral to the design of the next generation of adjuvant trials. In aggregate, these issues support the importance of modulating the focus of cancer research and treatment from patients with advanced disease towards patients with less-advanced disease. They also highlight the importance of developing novel diagnostic approaches that will allow the detection of smaller tumors.

Author Index

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
Multiple endocrine neoplasia
Genetic mechanisms in pediatric MTIC
Mutagenesis
Muscreen
Musashi1
Multiregional analysis
Multiple myeloma
N-121
N-121 PK and antitumor activity 4042
N-AK-ATPass
Nanoparticle
Namavirone
Natrium
Navagard sequencing
Highbrightness single-nuclei RNAseq
Nanomaterial
Osteosarcoma & TRA/GO
Nanomaterial
Ovarian cancer and BRCA1

**Subject Index**

**Multiple myeloma**
- ESR1 D538G mutation in CTCs
- Elevated RNA vs DNA mutation signal
- Deep learning for the biosciences
- CTC DNA sequencing
- BAP1 mutations
- Porcine model of pancreatic cancer
- Genetic load in cancer cell population
- Epi-mutation-positioning
- Cysteine-mediated functional change
- APOBEC3A in pancreatic cancer
- APOBEC mutational signatures
- MuScreen: Syngeneic model screening
- MSI1 controls Golgi gene expression
- Multitarget fecal miRNA test
- Heterogeneity in bladder cancer
- B7–H1/PD–L1 expression levels
- Tracking evolution in myeloma
- Tazemetostat in myeloma models
- Targeting BCMA with ACTR
- Selectivity/specifıcity of KITE-585
- Purine analog for plasma cell tumor
- Preclinincal evaluation of AMG 176
- PERK inhibitor in multiple myeloma
- NIK kinase inhibitor TRC694
- MT-4019: a CD38-targeted ETB
- Melphalan/XPO1 inhibitors
- KITE-585: a fully human BCMA CAR
- Genetic profiling of human cancers
- ETC activity regulates BIM
- Drugs synergistic effect on MM cell
- Copanlisib in multiple myeloma
- APRIL blocking BION-1301 in MM
- Myxofıbrosarcoma
- Myeloma
- Myeloid cells
- Myelodysplastic syndrome
- MYB
- MV-4-11
- Immune-microenvironment&metastasis
- Hypoxia causes MDSC accumulation
- Compounds that target S100A8/S100A9
- A zebrafısh model of neuroblastoma
- MYC and MYCN driven neuroblastoma
- HBP1 is regulator of MYCN in NB
- Adenoviral MYCN ablation
- Targeting c-MYC and hTERT genes
- MYC oncogene promotes NK exclusion
- MYC inhibition by JQ1
- MYC and p53 inhibitors
- MSI2-bound LncRNAs and MYC regulation
- IGF1 mediate tumor dormancy in PDAC
- HDACi resistance in CRC
- BETP-PROTAC activity in sAML cells
- BCL-2 targeting in DH lymphoma
- Mutations drive oncogene activation
- VariED
- TSC1/2 mutations in HCC
- TMB for TST170 gene panel
- T cells responses to neoantigens
- A survey of mutations in literature
- SRSF2 and EZH2 gene mutations
- Somatic mutation caller
- Solid tumor actionable gene test
- Regression of metBrCa after TIL
- N-121
- N-121 PK and antitumor activity 4042
- N-AK-ATPass
- Nantavigo
- Namavirone
- Natrium
- Navagard sequencing
- Highbrightness single-nuclei RNAseq
- Nanomaterial
- Osteosarcoma & TRA/GO
- Nanoparticle
- ACN-APs improve abscess effect 3685
- Au-HgMn1-R808 for antitumor activity 538
- AR427-AP as PARP inhibitor
- Binary classification of SPAR data 564
- Cancer cell membrane coated NPs 2198
- Cancer nanotherapy
- Carboplatin and doxorubicin 396
- Cancer cell cycle arrest 1701
- Combretastatin A4 phosphate 3195
- Combination therapy nanoparticles
- Combretastatin A4 phosphate conjugates 3195
- Curcin analog in prostate cancer
- Disrupting immunosuppressive TME
- Doxil®/ADV immunomodulation
- Doxorubicin loaded nanoparticle 3176
- DSNF
- Dual-profilng of CTC and eosinophil 7191
- EGRF mapping in single cells
- EGRF inhibitor in KY
- Ovarian cancer and BRCA1
- EMT CTC capture by magnetic cubes
- Enhanced nano tumor delivery by MET
- Enhancing the efficacy of Temodar 1907
- Ewing sarcoma associated IncRNA
- FGF2 Chimeric gene for thermal therapy
- FUS-mediateded NP brain delivery 3199
- GA/Gm-Comandereded tumor active 1601
- Giloma microenvironment
- Hyperthermia at the single-cell
- IL-13 QD01 glioma stem cells-eosinophils
- In vivo NFTX38 efficacy 3193
- LHERs PNs for breast cancer MRI
- Ligand-conjugated nanoparticles
- Magnetically-induced trastion 3104
- Manipulating magnetic fields 3105
- Math modeling of Nano-Drug delivery 2185
- MED1 in breast cancer
- MENS treatment for cancer 1900
- MMPE nanomaterial-drug conjugate 4065
- MMP-sensitive therapeutic nanoparticles
- Multisite responsive nanogels
- N-121
- Nano/mils inhibit GBM stem cells 449
- Nanocogiates overcome resistance
- Nanodrug delivery strategy
- NanoXan for cancer treatment 3193
- Nanoparticle delivery of ONX0912
- Nanoparticle mediated delivery of Ribo 4250
- Nanoparticles and lung metastasis
- Nanoparticles for breast cancer
- Nanoparticles for pancreatic cancer
- Neutrophin-2 and TGR7 discovery 1914
- NIRF imaging of tumor imaging 1867
- Novel composite pro-nanodrug 2187
- Novel CTC tool for oligometastasis 1735
- Osi-004 and ABx for tumor growth 1915
- PARP inhibitor nanoflamologies
- Peptide nanoparticles for GBM 178
- PET imaging of photothermal therapy 2869
- Prostate cancer target for gene therapy 1067
- PSMA-targeted NPs against PCA
- Raman imaging of tumor cells
- Sensitivity of magnetic relaxometry
- siRNA delivery by DNA nanoparticle 1907
- SIRPα to test NPs for breast cancer 1317
- ST1926 nanoparticles in AMD
- Strategies for photodynamic TD 2185
- Targeted delivery
- Targeted nanomengineered MSCs
- Targeted nanomedicine 3105
- Targeted nanoparticles for GBM 3105
- Theranostic nanoparticles
- Tissue-penetrating photodynamic nanoparticles
- TL99 targeted SNA for immunotherapy 2476
- Tumor cell growth response 2476
- Tumor imaging using CICD-HSA 2864
- Tumor-specific PIIIK inhibition 412
- Ultrasensitive nanotherapeutics
- Verteportin on endometrial cancer 117

**Proceedings of the American Association for Cancer Research**

**Volume 58** • April 2017
Influence of IncRNA lncRNA 4397
L1TD1 regulates genome stability 2490
Late-stage BC in lncRNA 2547
LINC00152 in lung cancer 3444
lncRNAs in a new risk model for m sm a lncRNA biomarker for lung cancer 3501
lncRNA GATA3 in BC 3125
lncRNA in Bcr-Abl transformation 3450
LncRNA in drug-resistant melanomas 3493
lncRNA in squamous cell cancer 3503
LncRNA PANC1 activates p52 2572
lncRNA promoter methylation 717
lncRNA regulation in RMS tumors 3873
lncRNA signature in human lung 5405
lncRNA Wnt16B and HIF-1α 1895
Long-non-coding RNAs in CRC 3496
Long-non-coding RNA in lung cancer 5406
Lung cancer associated lncRNA 3498
MALL-2 lncRNA in LUAD metastasis 3447
MEG3 inhibits proliferation of CRC 1980
miR-1207-3p regulates c-Myc 1473
miS2 bound-lncRNAs and miRNA in regulation 2534
miRNA regulation in drug resistance 3066
Non-coding RNAs as biomarkers 3504
Novel cluster analysis of lncRNA 2523
Oncogenic activity of H19 in CRC 3489
Oncogenic Inc-CHD1-1 in HCC 3443
P251 in cancer 3446
PIWIRE regulates genome stability 1398
Prognosis of non-Hodgkin’s lung cancer 5501
Repeat enterprising DNA damage 70
Role of G8H in lncRNA stability 4257
The role of IncRNA HAND2-AS1 in EEC 3448
Small ncRNAs in breast cancer 3492
Small noncoding RNAs in CRC 4447
Small RNA sequence mapping 4423
sncRNAs expression in TNBC 3506
Targeting of H19 in pancreatic cancer 2500
Urinary microRNAs in bladder cancer 4431
Xiap BIR domain regulated 250a 393
ZFAS affects GBC cells 3445
Non-Hodgkin’s lymphoma
Anti-C70D9-A for T cell lymphoma 4589
Application of G13129 beyond NHL 1173
ASNS02, a SYK and JAK inhibitor 4204
ATG regulates BCL-2 in DLBCL 2565
Bc-2 antagonist in lymphoma 5091
BGL-21 regulates HD in lymphoma 2422
C-ATK cell polarization 2974
CDK6 inhibitor, AZD9291 in NHL 2974
Chemically induced B6C6l deregulation 2526
Coplaspin in lymphoma models 154
Cytotoxic lncRNA cell treatment 3132
CXC4B and MYC targeting in DLBCL 2619
Efficiency of Hu-anti-CD79b-vc-MMAE 2656
Expression of SU11897 beyond NHL 2565
Expression of lncRNA in NHL 5072
Methyltransferase inhibitor in FL 4195
Modulation of the sensitivity 1479
MT-3724 inhibits tumor xenografts reduces A2a 1644
Mutations in a large FL cohort 2444
novel anti-C19D4 in NHL 2509
Novel BTK inhibitors in DLBCL 4182
Osteovalpin regulates the tumor microenvironment 1164
PAX4 inhibitor for NHL therapy 1358
PD-L1 blockade in cancer 2657
PyroXane non-Hodgkin’s lymphoma 2133
Pre-clinical toxicolgy and safety 4079
Pixantrone non-Hodgkin’s lymphoma 2113
PD-L1 blockade in PMBL 2657
PAK4 inhibitor for NHL therapy 4059
NRF2 binds to E2F7, antidyneal 1213
Nuclear translocation
ALK mediates mGFR translocation 3333
Breast cancer motility and nucleus 1883
CD38 inhibits AR signaling 2080
DUOX1 loss promotes nuclear EGF 1434
EGFR nuclear translocation 3527
Nuclear Aurora-A kinase 2974
Nuclear NF-kB by fly cytometry 823
Nuclear translocation of Avb7 2974
ROS-induced MIT nuclear trafficking 3034
SINE plus Dev disrupts mTORC1 529
Nuclear-cyttoplasmic transport
NFAT nuclear transport and NF-κB 259
Novel anticancer agents
Id2 PM2 inhibits colon cancer 2992
Epithelium and cancer stem cells 2997
Mutations in normal epithelial organs 4169
Notch and Pi4ka in HCC model 1850
Notch1 in head and neck cancer 814
Novel drug for breast cancer treatment 2903
Nottingham prognostic index
Uracil incorporation expression 111
Novel agent
AS-10 ASACa for PCs chemoprevention 2237
Novel anticancer targets
Id2 PM2 inhibits colon cancer 2992
Epithelium and cancer stem cells 2997
Mutations in normal epithelial organs 4169
Notch and Pi4ka in HCC model 1850
Notch1 in head and neck cancer 814
Novel drug for breast cancer treatment 2903
Novel chemoimmunotherapy
BMSCs and tumor microenvironment 558
Novel cytokine and DDR
SINE plus Dex disrupts mTORC1 329
Notch1 and Numb in SCLC 4735
Epinephrine and cancer stem cells 2894
Oncogenic function of Notch 1163
Notch-YAP circuit in eRMS 5830
Notch-1-induced EMT in colon cancer 856
MET/Notch in Rhabdomyosarcoma 2465
Leukemia and lymphoma 2177
Novel receptor
JAK2 regulates in breast cancer cells 5010
Notch in tumor stromal cells 5010
Notch inactivation in CRC 4624
Notch ligand-based therapeutics 1624
Notch recruits PRC2 5513
Notch signaling and tissue renewal 1629
Notch-1-induced EMT in colon cancer 856
Notch-YAP circuit in EMT 5830
Notch4 and HEY induction in EMT 1332
Novel inhibitor of Notch 1164
Notch4 expression function of 1164
Resistance to bevacizumab therapy 774
Role of Hes in the internalizing 1975
Notch receptor
Biomechanic for PEJK pathway in HNSCC 2992
Epithelium and cancer stem cells 2997
Mutations in normal epithelial organs 4169
Notch and Pi4ka in HCC model 1850
Notch1 in head and neck cancer 814
Novel drug for breast cancer treatment 2903
Nucleolar stress factors in DDR 497
SINE plus Dex disrupts mTORC1 329
Selinexor and palbociclib synergy 1089
TPR-0005 overcomes drug resistance 3168
Nucleolin
Cancerous and metaplastic adenocarcinoma 2149
Nuclear stress factors in DDR 497
Nucleolin RNA binding domain 1587
Nuclear translocation and endocytosis 1587
Tumor neoantigen-induced therapies 2617
Novel DNMT inhibitor
Molecular profiles and SGI-110 rep 1068
Novel molecular targets
POPDCl1 (BVES) and breast cancer 4124
Novel target
New glucose transporter inhibitors 117
Novel therapeutic strategies
Potential drugs in CRC 3122
Novel therapeutic targets
Novel function mutations in RTKs 380
Novel treatments
TTFfields arrays for pancreas 1569
NP2-SHD13
Thymic precursor and AML 2463
O6-alkylguanine adducts detection 4242
Chemoprevention of SSG 3862
AM RF EMF inhibits brain metastasis 5207
5-Fu resistance mtp53 DPYD 96
Nuclear PAK4 in OvCa 2419
Human CRL4 E3 regulates H3K56ac 1381
UCK2 as a biomarker of RX-3117 1790
AR XPO1 PSA 1587
Allele-specific targeting of NPM1c 1031
AXL mediates nEGFR translocation 3333
Epithelial and stromal cells 2997
Novel nuclear translocation
ALK mediates mGFR translocation 3333
Breast cancer motility and nucleus 1883
CD38 inhibits AR signaling 2080
DUOX1 loss promotes nuclear EGF 1434
EGFR nuclear translocation 3527
Nuclear Aurora-A kinase 2974
Nuclear NF-kB by fly cytometry 823
Nuclear translocation of Avb7 2974
ROS-induced MIT nuclear trafficking 3034
SINE plus Dev disrupts mTORC1 529
Nuclear-cyttoplasmic transport
NFAT nuclear transport and NF-κB 259
Novel anticancer targets
Id2 PM2 inhibits colon cancer 2992
Epithelium and cancer stem cells 2997
Mutations in normal epithelial organs 4169
Notch and Pi4ka in HCC model 1850
Notch1 in head and neck cancer 814
Novel drug for breast cancer treatment 2903
Nucleolar stress factors in DDR 497
SINE plus Dex disrupts mTORC1 329
Selinexor and palbociclib synergy 1089
TPR-0005 overcomes drug resistance 3168
Nucleosome
HELLS in HCC 1022
Nucleotide excision repair
Active mutant BRAF in canine tumor 324
Allele-specific targeting of NPM1c 1031
AR XPO1 PSA 1587
Allele-specific targeting of NPM1c 1031
AXL mediates nEGFR translocation 3333
Epithelial and stromal cells 2997
Novel molecular targets
POPDCl1 (BVES) and breast cancer 4124
Novel target
New glucose transporter inhibitors 117
Novel therapeutic strategies
Potential drugs in CRC 3122
Novel therapeutic targets
Novel function mutations in RTKs 380
Novel treatments
TTFfields arrays for pancreas 1569
NP2-SHD13
Thymic precursor and AML 2463
Must-Have Content
Anytime, Anywhere

AACR’S ESTEEMED JOURNAL COLLECTION

CANCER DISCOVERY
The essential information source to serve the diverse professional community in cancer science and medicine
Impact Factor: 19.783

Cancer Epidemiology, Biomarkers & Prevention
Translating science to populations
Impact Factor: 3.622

Cancer Immunology Research
Illuminating the interplay of cancer and the immune system
Impact Factor: 6.665

Cancer Prevention Research
The forefront of prevention science
Impact Factor: 3.887

Cancer Research
Driving innovation to prevent and cure cancer
Impact Factor: 8.556

Clinical Cancer Research
The journal of clinical and translational research
Impact Factor: 8.738

Molecular Cancer Research
Defining the molecular basis of malignancy and progression
Impact Factor: 4.51

Molecular Cancer Therapeutics
The journal of cancer drug discovery & preclinical development
Impact Factor: 5.579
