Harboring genetic mutations with oncogenic potential is common, yet not everyone develops cancer. This suggests that non-genetic factors contribute to tumor initiation and progression. In epithelial cancers such as squamous cell carcinoma (SCC), stem cells exhibit plasticity, transforming from an epithelial to a mesenchymal identity through the epithelial-to-mesenchymal transition, a process linked to metastasis. The lymphatic vasculature, known for fluid balance and immune trafficking, also supports the stem cell niche. Given this dynamic, we hypothesized that lymphatic vessels may represent a non-genetic element that drives cancer progression by altering stem cell behavior. To characterize lymphatic arrangement in benign versus advanced tumors, we performed high resolution 3D whole-mount immunofluorescence imaging on optically cleared benign papillomas and progressed skin SCCs. Compared to papillomas, advanced SCCs exhibited greater lymphatic association and integration. Spatial transcriptomics showed that regions enriched for lymphatic signals aligned with domains expressing hybrid epithelial-mesenchymal states in SCCs, suggesting that lymphatic positioning helps define the spatial architecture of these transitional tumor states. To test whether lymphatic vessels are required for tumor progression, we used both chemical and genetic (SOX9-CreER; $Kras^{mut}$; $p53^{fl/fl}$; $YFP^{fl/fl}$) mouse models of skin SCC. Tumors subjected to local lymphatic dysfunction stabilized or regressed in size, while matched controls continued to progress. Immunofluorescence revealed increased epithelial identity and reduced mesenchymal identity in regressing tumors, consistent with a shift toward a more epithelial and therapeutically responsive state. These findings suggest that lymphatic cues shape the regulatory programs governing tumor cell evolution. To define these programs, we profiled papillomas and SCCs using single cell RNA sequencing. The analyses resolved distinct epithelial, hybrid, and mesenchymal states. The hybrid state emerged as a key transition point, marked by selective induction of a secreted factor with a pro-lymphatic signature, suggesting a potential role in linking lymphatic cues to tumor cell evolution and malignant progression. Using a fluorescent lentiviral reporter, we confirmed that the secreted cue becomes highly expressed in advanced tumors *in vivo*. Functionally, silencing the pro-lymphatic cue in tumors derived from tumor-initiating cells slowed progression, demonstrating its active role in driving tumorigenesis. Together, these findings reveal that lymphatic interactions with tumor-initiating cells form a central regulatory axis in SCC, positioning the lymphatic vasculature as a promising therapeutic entry point to restrain malignant progression.

#4828 Dynamic androgen signaling orchestrates epithelial-mesenchymal transitions and epigenetic memory in prostate cancer.

Zhongchi Li[1], John Blenis[2]

[1]Pharmacology, Weill Cornell Medicine, New York, NY,[2]Professor of Pharmacology, Weill Cornell Medical College, New York, NY

Prostate cancer is one of the most aging-associated malignancies, with incidence rising sharply in older men. Although hyperactivation of the androgen receptor (AR) promotes tumor growth and provides the rationale for androgen deprivation therapy (ADT), circulating androgen levels paradoxically decline with age. This contradiction underscores the need to interpret AR function in a context-dependent manner. Epithelial-mesenchymal transition (EMT) is a central driver of metastasis and a common stress-adaptation program. AR-targeted therapies, including ADT and enzalutamide, can induce partial EMT and promote aggressive tumor states, yet how prostate tumor cells dynamically modulate AR signaling during this process remains unclear. Here, we exposed androgen dependent prostate tumor cells to androgen withdrawal, enzalutamide, or TGFβ stimulation and profiled AR activity, EMT markers, and metastatic behaviors across distinct stages of stress adaptation. Both AR inhibition and TGFβ signaling triggered EMT, marked by early suppression of AR activity. This initial AR downregulation was required for tumor cells to acquire mesenchymal features and enhanced motility. After TGFβ is removed, steroidogenesis was recovered, gradually restoring AR signaling. Late-phase AR reactivation promoted mesenchymal-epithelial transition (MET), re-establishing epithelial identity and stabilizing cell state. Steroidogenesis was essential for this EMT-MET rebalancing, as its inhibition induce redox oxidative imbalance and disrupted the completion of the adaptive cycle. Cells completing this EMT-MET transition became more resistant to androgen deprivation, proliferated more rapidly in spheroid culture, and exhibited globally elevated histone propionylation, indicating the establishment of an epigenetic “memory” that reinforces tumor plasticity. Together, these findings define a dynamic AR-EMT-steroidogenesis circuit that governs prostate cancer plasticity and therapeutic adaptation. This model provides a potential explanation for the paradox of increased prostate cancer incidence despite declining androgen levels with age. It also suggests that restoring AR activity may suppress EMT and metastasis, and that targeting histone propionylation could prevent therapy-induced aggressiveness and synergize with AR-directed therapies.

#4829 The defining features of hybrid epithelial-mesenchymal state in head and neck cancer.

Po-Han Lin[1], Yu-Shuen Tsai[1], Hsing-Hsiang Wang[2], Jie-Hong Song[2], Chih-Hung Chung[1], Muh-Hwa Yang[2]

[1]Cancer and Immunology Research Center, National Yang Ming Chiao Tung University, Taipei, Taiwan,[2]Institute of Clinical Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan

Epithelial-mesenchymal plasticity represents a major axis of tumor cell adaptation, enabling cancer cells to dynamically and reversibly transition between epithelial and mesenchymal states through epithelial-mesenchymal transition (EMT) and its reverse process, mesenchymal-epithelial transition (MET). EMT is an evolutionarily conserved cellular plasticity program that allows cancer cells to adopt multiple intermediate phenotypes along an epithelial-mesenchymal spectrum. Notably, complete EMT is relatively rare in human tumors, as most cancer cells do not fully activate terminal mesenchymal markers. Instead, they adopt an intermediate or hybrid epithelial/mesenchymal (hybrid E/M) state, also referred to as partial EMT, in which epithelial traits are retained while mesenchymal features are gradually acquired. In this study, we focus on elucidating the clinical significance of the hybrid E/M state in head and neck squamous cell carcinoma (HNSCC) and investigate whether this transitional phenotype is governed by specific molecular regulators. By integrating multi-omics clinical datasets and spatial transcriptomic analyses of patient tumor tissues, we found that the tumor invasive front exhibits marked cellular heterogeneity, which strongly correlates with the hybrid epithelial/mesenchymal cell phenotype. Digital Spatial Profiling analysis revealed that epithelial markers were evenly distributed between the primary and metastatic lymph node tumor regions. In contrast, mesenchymal markers were highly expressed in outer invasive regions and metastatic tumor sites. By analyzing both TCGA datasets and our own RNA-seq cohort, we found that the hybrid E/M phenotype is significantly associated with advanced tumor stage in HNSCC patients. Through single-cell transcriptomic profiling of clinical HNSCC samples, we found that hybrid E/M cells represent a unique cell state defined by their enriched expression of adhesion-related markers. We further developed an in vitro platform to model hybrid epithelial-mesenchymal transition and performed ATAC-seq profiling. Our analysis revealed that members of the GATA transcription factor family, particularly GATA3, play a crucial role in maintaining this intermediate state. Surprisingly, depletion of GATA3 led to a disruption of the hybrid epithelial/mesenchymal phenotype. Taken together, our findings provide compelling evidence that the hybrid epithelial/mesenchymal state is not only clinically relevant in HNSCC but is also shaped by distinct molecular mechanisms. Hybrid E/M cells display a unique adhesion-related gene expression profile, suggestive of a specialized function in promoting collective invasion during tumor progression. These findings enhance our understanding of EMT plasticity and highlight hybrid E/M cells and their control mechanisms as promising targets for slowing tumor evolution and metastasis.

#4830 Mic60-low breast cancer cells activate epithelial-mesenchymal transition and support aggressive tumor growth.

Camilla Esposito[1], Michela Perego[2], Elisabetta Panza[1], Giuseppe Cirino[1], Dario Altieri[2]

[1]Department of Pharmacy, University of Naples "Federico II", Naples, Italy,[2]The Wistar Institute, Philadelphia, PA

Background & Objectives: Breast cancer (BC) is the most frequent malignancy in women and a leading cause of cancer-related mortality worldwide. Despite advances in early detection and therapy, BC heterogeneity remains a major clinical challenge. Recent evidence highlights the role of mitochondria in sustaining BC aggressiveness and metabolic reprogramming. An shRNA screen identified Mic60 (also known as Mitofilin) as a mitochondrial gene whose reduced expression is associated with enhanced tumor cell invasion and altered proliferation. Mic60, part of the MICOS multiprotein complex, ensures cristae architecture, respiratory complex organization, and outer membrane biogenesis. Notably, Mic60 loss reduces mitochondrial fitness, contributing to aggressive disease. We investigated how Mic60 influences BC phenotype with regard to epithelial-mesenchymal transition (EMT) modulation in vitro and tumorigenic potential in vivo.
Materials & Methods: Mic60 silencing was achieved using small interfering RNA (siRNA) and short hairpin RNA (shRNA) in human and murine BC cell lines. Gene expression was analyzed by RT-qPCR, protein levels by Western blotting and flow cytometry. Migration and invasion were assessed in vitro using transwell assays with and without Matrigel, quantified by microscopy. In vivo tumorigenic capacity was evaluated in immunocompetent mice injected with syngeneic AT3 cells stably silenced for Mic60.
Results: Mic60 silencing induced EMT master regulators (Twist, Snail, Lbx1, Zeb2) in both human and murine BC cell lines. This transcriptional increase was accompanied by elevated N-cadherin and reduced E-cadherin and EpCAM expression. Moreover, Mic60 silencing upregulated NF-κB signaling, a key transcription factor linking inflammation, EMT, and cancer. Functionally, silenced cells exhibited enhanced migration and invasion in vitro. When injected into immunocompetent mice, AT3 Mic60-silenced cells displayed accelerated tumor growth in vivo.
Conclusions: Mic60 downmodulation activates EMT in BC cells, promoting migratory and invasive behavior. This phenotype is accompanied by NF-κB pathway activation, linking Mic60 loss to pro-tumorigenic signaling. In vivo, Mic60 depletion drives increased tumor growth, confirming the relevance of EMT activation in cancer progression. These findings extend previous observations on Mic60 in breast cancer, directly supporting its role in tumor progression and disease aggressiveness.

#4831 Inducible models of EMT reveal dynamic changes in the tumor-immune microenvironment.

Breanna Demestichas[1], Tanvi Visal[2], Petra den Hollander[1], Nick Kuburich[1], Sendurai A. Mani[1]

[1]Brown University, Providence, RI,[2]The University of Texas MD Anderson Cancer Center, Hosuton, TX

Epithelial-to-mesenchymal transition (EMT) drives tumor cell plasticity, stemness, and metastasis, yet the dynamic consequences of EMT activation on the tumor microenvironment remain poorly defined. Doxycycline-regulated EMT-inducible systems offer a powerful strategy to study reversible EMT programs with precise temporal control in both in vitro and in vivo settings. In this study, we developed doxycycline-inducible miR-200 and ZEB1 models in the D2A1 and EMT6 breast cancer cell lines to interrogate EMT regulation across diverse contexts. Doxycycline treatment produced robust EMT inhibition in miR-200 models and EMT activation in ZEB1 models, accompanied by expected morphological changes. In vivo, doxycycline-induced miR-200 expression suppressed EMT marker expression and reshaped the tumor immune microenvironment. Specifically, miR-200 induction increased intratumoral $CD8^+$ T cells, reduced $Arg1^+$ macrophages, and decreased platelet accumulation, as confirmed by immunohistochemistry. Cytokine profiling revealed shifts in inflammatory and immune-recruiting signals, and single-cell RNA sequencing showed enhanced MHC-I antigen presentation pathways and altered immune activation states upon EMT inhibition. Together, these results demonstrate that doxycycline-inducible EMT models faithfully recapitulate epithelial-mesenchymal plasticity and uncover key EMT-dependent changes in stemness and immune composition. Ongoing studies aim to define the mechanisms through which miR-200-mediated EMT suppression drives these immune shifts. These inducible systems provide a powerful framework for dissecting how EMT dynamics shape tumor-immune interactions and may offer insight into therapy responsiveness.

#4832 Developing advanced tumoroid models driven by epithelial-to-mesenchymal transition with a novelxeno-free andbiofunctionalhydrogel system.

Alejandra I. Ferrer Diaz, John Huang

TheWell Bioscience, Inc, Monmouth Junction, NJ

Epithelial-to-mesenchymal transition (EMT) is a key biological process that facilitates cancer metastasis to distant organs. Most preclinical studies investigating EMT are conducted using traditional two-dimensional (2D) culture models, which fail to recapitulate the in vivo tumor microenvironment, limiting the translational relevance of their findings to clinical settings. Consequently, three-dimensional (3D) culture systems have emerged as a superior approach for modeling metastatic processes and evaluating therapeutic candidates. However, these models typically rely on animal-derived extracellular matrices like Matrigel, which are poorly defined, exhibit batch-to-batch variability, and lack mechanical and biochemical stability, thereby compromising experimental reproducibility and clinical translation. In this study, we developed tumoroids from two cancer types known to undergo EMT such as glioblastoma multiforme (GBM) and breast cancer using VitroGel® hydrogel, a fully synthetic and biocompatible hydrogel system. The VitroGel® hydrogel is tunable in both mechanical and biofunctional properties, making it a powerful tool for generating advanced tumoroid models that might require distinct microenvironments. The tumoroids were generated from a single spheroid formed in ultra-low attachment, u-shaped, 96-well plates, which were then embedded in VitroGel® hydrogel diluted in our xeno-free supplement. Within the first three days after adding the hydrogel, the cells began migrating from the spheroid into the matrix, developing a tube-like structure with rapidly proliferating cells. By day seven, the tumoroids exhibited an outer layer enriched with EMT marker-positive cells expressing vimentin and N-cadherin, while the spheroid core and tube-like structure were mostly composed of cells expressing the cancer stem cell–associated markers Oct4 and Sox2**.** The tumoroids were susceptible to standard chemotherapies, including temozolomide and 5-fluororacil, indicating that these structures developed in the xeno-free hydrogel are a suitable system for drug screening studies.Additionally, to enhance the physiological relevance of the tumoroid model, we aimed to mimic tumor-vasculature interactions by performing co-cultures of tumoroids with endothelial cells. The endothelial cells penetrated the matrix and migrated towards the tumoroids, enhancing their long-term survival. Altogether, these findings demonstrate that the xeno-free hydrogel system supports the development of robust 3D cancer models, providing a platform for the evaluation of therapeutic drug candidates.

#4833 Identification of protein kinase signaling networks activating partial EMT as therapeutic targets in non-small cell lung cancer.

Mohaddase Hamidi[1], Kenneth Omolo[1], Amir Yarmahmoodi[2], Margret B. Einarson[3], Yan Zhou[3], Adam Karami[4], Korrey W. Hart[1], Adrian Dizon[1], Shrey Sitaram[1], Kathy Q. Cai[3], Pedro Torres-Ayuso[2]

[1]Cancer and Cellular Biology, Temple University Lewis Katz School of Medicine, Philadelphia, PA,[2]Temple University Lewis Katz School of Medicine, Philadelphia, PA,[3]Fox Chase Cancer Center, Philadelphia, PA,[4]Fels Cancer Institute for Personalized Medicine, Lewis Katz School of Medicine, Temple University, Philadelphia, PA

Non-small cell lung cancer (NSCLC), of which one-third are lung squamous cell carcinomas (LUSC), is the leading cause of cancer-related death in the US. LUSC treatments primarily involve platinum-based chemotherapy and immune checkpoint blockade. However, only 20% of patients benefit long-term, underscoring a critical need for strategies that improve treatment efficacy. We have identified partial epithelial-to-mesenchymal transition (pEMT) as a key mechanism hindering treatment efficacy in LSCC. pEMT is a cell state in which cancer cells display epithelial and mesenchymal characteristics, and is associated with heightened cell migration/invasion, survival, and treatment resistance. Therefore, we sought to identify phosphorylation networks that could reverse pEMT and, thereby, sensitize LSCC to treatment. We have identified a STE20-family kinase network as a central signaling node sustaining pEMT in LSCC cells. RNAseq analysis of STE20-inhibited LSCC cells revealed transcriptional reprogramming of LSCC indicative of reversion to an epithelial-like phenotype. Consistently, we observed increased expression of epithelial markers (E-cadherin, EpCAM), and reduced levels of mesenchymal markers (vimentin, CD44). Furthermore, STE20 depletion or inhibition suppressed key pEMT functions, including migration, invasion, and clonogenic potential. Our current studies are aimed at identifying the underlying mechanisms of the observed phenotypes. Our initial analysis indicates that STE20 is required for the activation of the YAP/TAZ and MYC transcriptional programs. Last, to lay the groundwork for combination treatments, we conducted a high-throughput screen using a library of clinically relevant compounds in combination with STE20 inhibitors. This screen showed potential synergism with platinum-based chemotherapy, which we are investigating *in vitro* and *in vivo*. In conclusion, we have uncovered a STE20 phosphorylation module that sustains pEMT in NSCLC cells and represents an actionable vulnerability that can be targeted to sensitize NSCLCs to first-line treatments.

#4834 Keratin 17 correlates with epithelial-to-mesenchymal transition in pancreatic ductal adenocarcinoma.

Shayan Sarkar, Lyanne Delgado Coka, Robert S. Powers, Natalia Marchenko, Kenneth Shroyer

Pathology, Stony Brook University, Renaissance School of Medicine, Stony Brook, NY

Background: Pancreatic ductal adenocarcinoma (PDAC) accounts for more than 90% of all pancreatic malignancies and has a 5-year survival rate of 13%. Approximately, 80% of the patients are diagnosed at later stages with metastatic disease characterized by widespread invasion. One of the key biological pathways that lead to this metastatic spread is Epithelial to Mesenchymal Transition (EMT) - a highly plastic process that allows cancer cells to gain invasive properties by switching from an epithelial to a mesenchymal phenotype. Keratin 17 (K17), a component of the basal-like PDAC signature associated with poor prognosis, has been shown to promote pancreatic cancer metastases and induce EMT in bladder, esophageal, and lung cancers. In this study, we test the hypothesis that K17 is associated with EMT in PDAC, contributing to the poor prognosis of the disease.
Methods: We performed integrative single-cell transcriptomic analyses (scRNA-seq) of publicly available datasets comprising of 42 treatment-naïve PDACs to identify cancer-related pathways associated with K17 expression. Differential gene expression and pathway enrichment analyses were conducted in RStudio using the Hallmark gene sets from MSigDB and Gene Ontology (GO) terms. To validate the scRNA-seq results, we performed cyclic multiplex immunofluorescence imaging using the MACSima platform on FFPE tissue microarrays, along with immunohistochemistry (IHC) on whole-slide FFPE sections of human PDAC samples. These analyses were conducted to assess the spatial distribution of K17 and its correlation with the expression of top EMT-associated markers identified through scRNA-seq.
Results: scRNA-seq analysis revealed that K17-positive PDAC cells exhibited transcriptional enrichment of the EMT pathway, with ANXA1, S100A4, GPC1, LAMC2, WWTR1, and LAMA3 identified as top associated markers. Multiplex immunofluorescence image analysis confirmed that K17-positive tumor regions displayed reduced epithelial differentiation as indicated by low GATA-6 and E-cadherin score. Among the markers identified by scRNA-seq, LAMC2, an established biomarker of EMT, demonstrated the most significant positive correlation with K17 and was confirmed using IHC.
Conclusions: K17 marks a transcriptionally distinct and highly invasive PDAC subpopulation characterized by robust EMT activation. LAMC2 emerges as the EMT marker most closely associated with K17 at both transcriptomic and protein levels, suggesting a K17-LAMC2 axis that maybe a major driver of EMT in PDAC.

#4835 Morphological effects of cytokeratin 8/18 and vimentin coexpression in vulvar cancer cells.

Jani E. Lewis, Avinash Gopal, Sara M. Mongelli, Abby R. Stevenson

Biology, State University of New York at Geneseo, Geneseo, NY

Vulvar squamous cell carcinoma (VSCC) is a rare but aggressive malignancy that primarily affects women over the age of 60, with the earliest stages often obscured by vulvar lichen sclerosus (VLS). VLS is commonly treated with ultrapotent corticosteroids such as clobetasol. Our previous studies demonstrated that clobetasol treatment of A431 vulvar cancer cells results in the loss of the cell-cell junction proteins E- and P-cadherin and the subsequent gain of the intermediate filament protein vimentin. The resulting cells (referred to as A431D) do not form adherens junctions nor desmosomes. Loss of E- and P-cadherin and gain of vimentin expression is consistent with an epithelial-to-mesenchymal transition (EMT), a process associated with cancer progression and acquisition of a more aggressive phenotype. Despite these changes, A431D cells retain expression of the epithelial intermediate filaments cytokeratins 8/18. Our analyses revealed colocalization of cytokeratin 8/18 and vimentin within A431D cells. In the absence of cadherin-mediated junctions, the organization of both filament systems, and the overall morphology of the cells, resembles that of fibroblasts. It is only upon exogenous expression of an E-cadherin-plakoglobin construct, that desmosome and adherens junctions form. In the studies presented we tested the hypothesis that vimentin is driving the morphology of the A431D cells in spite of continued cytokeratin 8/18 expression even when E- and P-cadherin or E-plakoglobin were exogenously expressed in these cells. A431D cells were transfected with plasmids containing E-, P-, or a construct of E-plakoglobin and the resulting cells were examined for localization of vimentin and cytokeratin 8/18 by confocal microscopy.

#4836 High dietary cholesterol promotes epithelial-to-mesenchymal transition and invasion in colorectal cancer via the Wnt/Snai2 axis of transcriptional regulation.

Blake M. Arciga[1], Zaynab Shakkour[2], Vikas Satyananda[1], Van Nguyen[3], Jussuf T. Kaifi[1], Satyanarayana Rachagani[4]

[1]Surgery, Univ. of Missouri School of Medicine, Columbia, MO,[2]Univ. of Missouri School of Medicine, Columbia, MO,[3]Pathology and Anatomical Sciences, Univ. of Missouri School of Medicine, Columbia, MO,[4]Veterinary Medicine and Surgery, Univ. of Missouri, Columbia, MO

Introduction: Colorectal cancer (CRC) progression is frequently influenced by diet and lifestyle factors, and these variables can affect clinical outcomes. We have previously reported that modulation of cholesterol levels can facilitate epithelial-to-mesenchymal transition (EMT) and invasion in CRC. However, the exact signaling mechanisms driving this process have not yet been identified. In this study, we sought to further characterize the invasive phenotype associated with high cholesterol *in vivo*, and to investigate transcriptome-level changes that occur in response to a high cholesterol diet, in search of mechanistic insights.

Methods: We generated a variable-diet $APC^{fl/fl}CDX\text{-}Cre^{ER}$ CRC mouse model, in which the mice were fed either a high cholesterol diet (2% cholesterol), a low cholesterol diet (1% cholesterol), or a chow diet (0% cholesterol) for 6-8 weeks. Tumor growth was induced by intraperitoneal tamoxifen injection. Four weeks after injection, colon tissue samples were collected. Formalin-fixed sections were stained with hematoxylin and eosin (H+E), and examined for histological indicators of invasion by a clinical pathologist in a blinded manner. The epithelial markers claudin-1, Zo-1, and E-cadherin were stained by multiplex immunofluorescence. Frozen colon samples from chow diet-fed and high cholesterol-fed mice were submitted for bulk RNA sequencing. KEGG pathway enrichment analysis of differentially expressed genes was performed using the limma package in R.

Results: H+E-stained colon tumor sections from mice fed the high cholesterol diet showed markedly more extensive desmoplastic reactions and increased cancer invasiveness compared to the chow diet-fed mice, with low cholesterol-fed mice displaying an intermediate phenotype. Immunofluorescence revealed that expression and junctional co-localization of claudin-1, Zo-1, and E-cadherin were consistently downregulated in the tumor cells of high cholesterol-fed mice compared to mice fed either the low cholesterol or chow diet. Expression of genes involved in the Wnt signaling pathway was found to be significantly upregulated in high cholesterol-fed mice relative to chow diet-fed mice, as was expression of the EMT transcription factor Snai2 (Slug).

Conclusions: High dietary cholesterol promotes an EMT-like phenotype in CRC, which involves a loss of epithelial gene expression and activation of Wnt signaling. Notably, high cholesterol increases expression of the transcription factor Snai2 (Slug), which is known to be induced by Wnt signaling and to suppress expression of Cldn1, Zo1, and E-cadherin. These findings indicate that high cholesterol promotes EMT in CRC via a Wnt-dependent mechanism of transcriptional regulation, which could potentially increase the risk of invasion and metastasis in CRC patients affected by high cholesterol.

#4837 Mechanistic studies on the role of GABA type A ($GABA_A$) ion channel receptor in tumor invasion and metastasis in triple negative breast cancer.

Yasmeen Ahmed[1], Mark Garewal[2], Kenneth Myers[2], Isabelle Mercier[1], Asha Suryanarayanan[3]

[1]Department of Pharmaceutical Sciences, Saint Joseph's University, Philadelphia, PA,[2]Department of Biology, Saint Joseph's University, Philadelphia, PA,[3]Department of Physician Assistant Studies, Saint Joseph's University, Philadelphia, PA

Triple-negative breast cancer (TNBC) represents 15-20 percent of breast cancer cases and is associated with aggressive progression, metastasis, and limited treatment options. TNBC treatment relies on surgery, radiation, and chemotherapy, but these approaches are non-selective and highly toxic, emphasizing the need for novel molecular targets. Traditionally known for mediating inhibitory neurotransmission through chloride ion conductance, recent evidence implicates γ-aminobutyric acid type A ion channel-coupled receptors ($GABA_A$ R) in cancer cell proliferation, migration, and metastasis. Our previous studies demonstrated that β3 and α1 $GABA_A$ R subunits are overexpressed in TNBC cells, promoting chloride influx and cell survival. We also showed that pharmacological inhibition or shRNA-mediated $GABA_A$ R β3 subunit knockdown reduces proliferation and induces cell cycle arrest of TNBC cell lines. Epithelial-mesenchymal transition (EMT) drives cancer metastasis by enabling cells to lose adhesion, reorganize the cytoskeleton, degrade the extracellular matrix, and gain migratory properties. The steroid receptor coactivator and focal adhesion kinase (Src-FAK) axis plays a central role in these processes by regulating cell remodeling, promoting cell proliferation, and migration. Src-FAK activation also stimulates the PI3K/AKT pathway, enhancing cell survival and resistance to apoptosis. In addition, FAK activates Rho-GTPases, which regulate actin cytoskeleton reorganization and cell motility. In this study, we investigated whether $GABA_A$ R β3 subunit knockdown and pharmacological inhibition alter the invasive potential and EMT in TNBC. Our results showed that inhibiting $GABA_A$ R genetically and pharmacologically significantly reduced the invasive potential and reversed the EMT, as evidenced by decreased expression of mesenchymal markers (vimentin and N-cadherin) and increased expression of the epithelial marker E-cadherin as determined by Western blot analysis. Furthermore, β3 subunit knockdown decreased the expression of total Src and reduced the phosphorylation of both Src and FAK. Morphological assessment further demonstrated that β3 subunit knockdown reduced cell size, disrupted actin stress fibers, and altered actin distribution, consistent with impaired migratory capacity. To further define the molecular mechanisms downstream of $GABA_A$ R signaling, we will perform RNA sequencing on control and β3 knockdown TNBC cells to identify transcriptional pathways involved in invasion and metastasis. Collectively, these findings reveal that $GABA_A$ R β3 promotes TNBC cell proliferation, EMT, and invasion through Src-FAK signaling, highlighting GABAergic signaling as a promising therapeutic target in metastatic breast cancer.

#4838 An EMT-driven Exoc7 splicing switch controls the PRPF19-GATA3 axis to destabilize the hybrid E/M state.

Hsing-Hsiang Wang[1], Po-Han Lin[2], Yu-Shuen Tsai[2], Tsan-Jan Chen[3], Wen-Ching Wang[3], Muh-Hwa Yang[1]

[1]Institute of Clinical Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan,[2]Cancer and Immunology Research Center, National Yang Ming Chiao Tung University, Taipei, Taiwan,[3]Institute of Molecular and Cellular Biology, College of Life Sciences and Medicine, National Tsing Hua University, Hsinchu, Taiwan

The epithelial-mesenchymal transition (EMT) is a dynamic process that cancer cells exploit to gain metastatic competence, with the hybrid E/M state—co-expressing both epithelial and mesenchymal markers—being particularly critical due to its heightened plasticity and association with aggressive disease. However, the molecular mechanisms that stabilize this hybrid phenotype and govern its reversible transition to a full mesenchymal state remain a central unanswered question. Our research identified the transcription factor GATA3 as a key stabilizer of the hybrid E/M state in head and neck squamous cell carcinoma (HNSCC). Surprisingly, we found that induction of core EMT transcription factors leads to a reduction in GATA3 protein levels but does not alter its mRNA levels. This led us to explore the possibility that a post-translational mechanism drives this regulation. We analyzed the GATA3-interactome and identified PRPF19, a dual splicing factor and E3 ubiquitin ligase, as the enzyme responsible for GATA3 ubiquitination. Notably, while PRPF19 expression remains constant during EMT, its ligase activity is precisely regulated by alternative splicing. The EMT-driven loss of epithelial spliceosome switches the Exoc7 gene product from the epithelial isoform 5 (Exoc7-iso5) to the mesenchymal isoform 2 (Exoc7-iso2). Mechanistically, PRPF19 preferentially binds to Exoc7-iso5, and this interaction acts as a molecular brake by inhibiting the full cofactor assembly essential for the E3 ligase activity of PRPF19. Consequently, the EMT-associated loss of Exoc7-iso5 unleashes PRPF19, leading to unrestrained GATA3 ubiquitination and degradation. Crucially, restoring Exoc7-iso5 expression successfully rescued GATA3 protein levels and epithelial markers, formally confirming a splicing-dependent regulatory mechanism. Collectively, we propose an integrated model in which EMT-driven alternative splicing of Exoc7 serves as a functional switch to control PRPF19 E3 ligase activity, thereby targeting GATA3 for degradation to dismantle the hybrid E/M state and drive mesenchymal commitment in HNSCC, revealing this axis as a possible regulatory mechanism that controls the stability and reversibility of the hybrid E/M state.

#4839 PTPRE receptor tyrosine phosphatase in matrix-stiffness-driven EMT and breast cancer metastasis.

Calista A. Horta, Laurent Fattet, Zhimin Hu, Khoa Doan, Aida Mestre-Farrera, Qingrong Li, Dong Wang, Jing Yang

University of California, San Diego, San Diego, CA

Mechanical cues from the extracellular matrix (ECM) regulate various cellular processes in cell proliferation, migration and differentiation via distinct mechanotransduction pathways. In breast cancer patients, increase in tumor tissue stiffness is correlated with distant metastasis and poor outcome. Previous studies show that, cell invasion and metastasis. Using 3D reconstituted extracellular matrixes that recapitulate the range of physiological stiffness from normal mammary glands to breast tumors, we previously reported that increased ECM stiffness promotes Epithelial-Mesenchymal Transition (EMT) and identified the TWIST1 transcription factor as a key player driving EMT and invasion in response to increasing ECM stiffness. High ECM stiffness activates the LYN tyrosine kinase, which phosphorylates TWIST1 and promotes TWIST1 to enter the nucleus, thus triggering EMT and invasion. To understand how LYN is activated at high ECM stiffness, we performed an unbiased screen for tyrosine phosphatases that is required for high stiffness-induced EMT and invasion in basal-subtype mammary cells. This screen identified a novel role of protein tyrosine phosphatase epsilon (PTPRE) in TWIST1/LYN mechanotransduction. We show that genetic deletion of PTPRE blocked high ECM stiffness-induced EMT and invasion in human and mouse TNBC cell-derived acini as well as in patient-derived triple-negative breast cancer (TNBC) organoids, demonstrating a conserved role of PTPRE in stiffness-induced invasion. Mechanistically, knockdown or pharmacological inhibition of PTPRE blocks LYN activation, TWIST1 nuclear translocation and EMT at high stiffness. Biochemical analyses and AlphaFold modeling suggest that PTPRE bind to LYN and dephosphorylates Tyr507 to activate the LYN kinase. Functionally, treatment of mice carrying TNBC PDX tumors with a PTPRE inhibitor decreased local invasion and lung metastasis. This study identifies a novel role for PTPRE in matrix-stiffness induced EMT and metastasis in TNBC and broadens the repertoire of actionable targets implicated in breast cancer metastasis. The importance of mechanical force and tissue stiffness in regulating breast cancer invasion and metastasis has only recently been appreciated. This study raises the promise to target novel mechanotransduction pathways and mechanoregulators to combat breast tumor invasion and metastasis.

#4840 KPNA2 drives cancer stemness, which enhances drug resistance and facilitates cancer progression in lung adenocarcinoma.

Seongran Cho[1], Inyoung Cheon[1], Seoree Kim[2], Yoon Ho Ko[3], Young-Ho Ahn[4]

[1]Ewha Womans University, Seoul, Korea, Republic of,[2]Seoul St. Mary's Hospital, Seoul, Korea, Republic of,[3]Catholic University of Korea, Seoul, Korea, Republic of,[4]Molecular Medicine, Ewha Womans University School of Medicine, Seoul, Korea, Republic of

KPNA2 (Importin α1) is a nuclear transport protein that shuttles nuclear proteins into the nucleus. While its role in cancer-associated fibroblasts and the tumor microenvironment is known, its direct function in lung cancer cells remains to be fully elucidated. In this study, we found that high KPNA2 expression is associated with poor prognosis in patients with lung adenocarcinoma. KPNA2 knockdown significantly impaired cell migration and invasion and sensitized cells to anticancer drugs in vitro. In vivo, KPNA2 depletion decreased primary tumor growth and metastasis in an orthotopic model. Mechanistically, RNA sequencing revealed that KPNA2 regulates the epithelial-mesenchymal transition (EMT) pathway. Functional studies demonstrated that KPNA2 specifically increases the responsiveness of lung cancer cells to EMT-inducing factors like TGFβ, evidenced by enhanced plasticity in 3D Matrigel cultures. These findings establish KPNA2 as a critical regulator of lung cancer stemness and chemoresistance, representing a potential therapeutic target to suppress metastasis.

#4841 ZEB1 drives pro-metastatic membrane trafficking through upregulation of REEP2 in lung adenocarcinoma.

Kevin Fulp, Oluwafunminiyi Emmanuel Obaleye, Guan-Yu Xiao

University of Kentucky, Lexington, KY

Membrane trafficking governs the transport of proteins to intracellular and extracellular locations to maintain cell homeostasis. Although this process is frequently disrupted during cancer progression, the underlying mechanisms remain largely unknown. As a result, there are currently no effective drugs that target membrane trafficking. Recent evidence has demonstrated that epithelial-to-mesenchymal transition (EMT) in lung adenocarcinoma (LUAD) employs a membrane trafficking program to coordinate cancer cell invasion and immunosuppression in the tumor microenvironment (TME). To further dissect the pro-tumorigenic membrane trafficking program, we initiated an in vivo CRISPRi screen to assess more than 2,000 membrane trafficking-related genes in a syngeneic mouse LUAD model. This screen identified REEP2, an endoplasmic reticulum (ER) shaping protein, as a novel regulator of EMT-dependent membrane trafficking. High REEP2 expression is associated with poor prognosis in LUAD patients, and REEP2 depletion decreases LUAD proliferation, migration, and invasion both in vitro and in vivo. REEP2 expression is positively correlated with expression of the EMT-driver, ZEB1, which is known to regulate gene expression via miRNA regulation. Our findings show that ZEB1 upregulates REEP2 expression by silencing miR-183 and miR-193a. Pro-metastatic secretion relies on the transport of cargo from the ER to the Golgi, and then to the plasma membrane. We discovered that REEP2 is necessary for colocalization of the ER exit site (ERES) protein SEC24D with the Golgi to facilitate cargo trafficking and ultimately drive secretion of pro-tumorigenic factors. This REEP2-driven secretome promotes cancer progression by increasing LUAD proliferation, migration, and immunosuppressive tumor microenvironment. Altogether, these findings establish REEP2 as a novel mediator of the EMT-driven pro-metastatic membrane trafficking program, revealing a specific vulnerability in mesenchymal LUAD.

#4842 SNAIL2 drives the hybrid epithelial-mesenchymal transcriptional network that reveals selective, druggable anti-invasion vulnerabilities in HNSCC.

Ananya Pal[1], Fudong Wang[1], Michael Moore[2], Yi-Hsuan Chang[1], Marina Nogueira[1], Rachel Paolini[3], Robi D. Mitra[4], Sidharth V. Puram[2]

[1]Otolaryngology, Washington University School of Medicine in St. Louis, St. Louis, MO,[2]Genetics and Otolaryngology, Washington University School of Medicine in St. Louis, St. Louis, MO,[3]Medicine and Oncology, Washington University School of Medicine in St. Louis, St. Louis, MO,[4]The Edison Family Center for Genome Sciences & Systems Biology and McDonnell Genome Institute, Washington University School of Medicine in St. Louis, St. Louis, MO

In nearly all solid tumors, metastatic progression remains the major barrier to long-term disease control and is the most common reason for death. Current anticancer agents largely target proliferation, causing toxicity in normal proliferating cells and limiting their use as long-term adjuvant therapy to suppress metastatic dissemination. Notably, no FDA-approved therapy selectively inhibits invasion without impairing normal cell viability, underscoring a major gap in metastasis-directed treatment. In head and neck squamous cell carcinoma (HNSCC), invasion and metastasis are driven by hybrid epithelial-mesenchymal (E/M) states, yet the upstream regulatory circuitry governing these states remains poorly defined and therapeutically unaddressed. Here, through comprehensive correlative and loss-of-function analyses of the six canonical EMT transcription factors (TFs), we identify SNAI2 (encoding Snail2) as the dominant EMT-TF regulating hybrid-E/M states in HNSCC. Functional assays across multiple models demonstrate that SNAI2 is both necessary and sufficient to drive invasion and metastasis. We mapped genome-wide binding sites of Snail2 (via Calling Cards) and integrated this with RNA-seq to uncover the first genome scale direct Snail2 regulon in hybrid-E/M cells. To determine which genes controlled by Snail2 act as effectors for its metastatic phenotypes, we performed a large-scale functional screen to identify invasion-specific vulnerabilities and nominate druggable nodes. Remarkably, of the 48 direct SNAI2 targets we analyzed, 21 (43 percent) function as bona fide invasion drivers in multiple lines establishing the first systematic delineation of the upstream transcriptional architecture governing the hybrid-E/M invasive phenotype in HNSCC. Importantly, we identify two key downstream effectors, NID1 (basement membrane glycoprotein) and BNC2 (zinc-finger transcription factor) as actionable therapeutic targets. Pharmacologic inhibition of NID1 and BNC2 markedly reduces invasion in vitro and suppresses metastasis in vivo at doses ~10-fold lower than those associated with toxicity. Notably, BNC2 activates SNAI2 expression, forming a reinforcing SNAI2-BNC2 positive feedback transcriptional circuit that sustains the hybrid-E/M invasive program. Together, these findings position SNAI2 at the apex of the hybrid-E/M transcriptional network in HNSCC and expose selective, drug-vulnerable anti-metastatic nodes with high translational potential. This work establishes a blueprint for developing the first generation of long-term low-toxicity anti-metastatic therapies deployable in the adjuvant setting to prevent metastatic progression.

#4843 Smarca1 maintains PAX3-FOXO1 fusion oncogene and coordinates EMT networks through chromatin remodeling.

Ashwaq K. Aljabri[1], Matt Geisler[2], Marielle E. Yohe[3], Judith K. Davie[4]

[1]Independent Researcher, Columbia, MD,[2]Plant Biology, School of Biological Sciences, Southern Illinois University, Carbondale, IL,[3]Laboratory of Cell and Developmental Signaling, National Cancer Institute (NCI), Center for Cancer Research (CCR), Frederick, MD,[4]Biochemistry and Molecular Biology, Southern Illinois University School of Medicine, Carbondale, IL

Aggressive fusion positive rhabdomyosarcoma driven by the PAX3-FOXO1 oncogene remains therapeutically challenging with poor outcomes. High SMARCA1 expression marked poorer survival outcomes, indicating prognostic significance. The chromatin remodeling factor SMARCA1 shows preferential expression in fusion positive tumors, yet its functional role in sustaining oncogenic programs has not been defined. SMARCA1 function was investigated using CRISPR Cas9 knockout combined with multi-omics profiling. All detected PAX3-FOXO1 transcripts became undetectable, showing that SMARCA1 is required for fusion expression. Fusion transcript abundance showed nearly perfect quantitative correlation with downstream key oncogenic targets including FGFR4, SNAI2, MYOD1, MYCN, ALK, ID2, IGF2, and CXCR4. Fusion levels determine the magnitude of its transcriptional output. My prior findings established, SMARCA1 acts as a master coordinator of epithelial mesenchymal transition (EMT) networks. Knockout caused simultaneous suppression of all four core EMT transcription factors SNAI1, SNAI2, ZEB1, and ZEB2 which represent both direct and indirect targets of the fusion oncogene. Their upstream regulatory pathways collapsed concurrently, including complete loss of canonical SMAD dependent TGF-β signaling and multiple non canonical branches involving PI3K, AKT, RAS, MAPK, mTOR, and NF-κB pathways. WNT/β-catenin signaling was likewise dismantled. Despite the elimination of detectable PAX3-FOXO1 mRNA, suppression of EMT transcription factors, and collapse of their upstream signaling networks, EMT gene signatures paradoxically showed strong enrichment with elevated mesenchymal markers. However, this fusion independent EMT transcriptional state failed to produce functional cellular plasticity. Migration was abolished and invasion markedly impaired, indicating that transcriptional activation alone is insufficient without proper chromatin architecture. Building on our earlier observation that SMARCA1 regulates EMT pathways, our profiling indicates that YAP-TAZ-TEAD remains active as a fusion-independent EMT module despite the collapse of the canonical fusion-driven EMT network. These findings establish that SMARCA1 maintains PAX3-FOXO1 expression and governs the organization of EMT transcription factor networks together with their upstream signaling dependencies. Together, these findings show that SMARCA1 is required to maintain PAX3-FOXO1 expression, organize EMT transcription factor networks and their upstream signaling pathways, and demonstrate that chromatin architecture is essential for converting transcriptional programs into functional behavior, and reveal chromatin dependency as a targetable vulnerability in fusion driven cancers, effectively transforming the historically undruggable PAX3-FOXO1 fusion into a druggable chromatin dependent weakness.<!--EndFragment-->

#4844 Gli2 regulation of EMT in TNBC invasion.

Emily A. Jaremba[1], Erik Beadle[2], Julie Rhoades[2]

[1]Program in Cancer Biology, Vanderbilt University, Nashville, TN,[2]Division of Hematology and Oncology, Vanderbilt University Medical Center, Nashville, TN

Despite improvements in survival for patients with primary disease only, breast cancer remains a leading cause of cancer-related death for women in part due to the propensity of breast cancer to metastasize and develop therapy resistance. Triple negative breast cancer (TNBC) has high metastatic potential, and an estimated 30-50% of patients develop tumors that are resistant to chemotherapies. To metastasize, tumors undergo epithelial-to-mesenchymal transition (EMT), in which transcriptional alterations allow tumor cells to become more invasive through reduced adhesion and increased motility. In addition to facilitating the early stages of metastasis and allowing tumors to invade, EMT has been associated with a more plastic, stem-like phenotype that may lead to therapy resistance. Thus, preventing the acquisition of an EMT phenotype may offer a dual role in inhibiting metastatic potential as well as resensitizing therapy-resistant tumors in patients with TNBC. While the Hedgehog (HH) signaling pathway is primarily active during embryonic development, its aberrant activation has been observed to promote tumor growth, invasion, metastasis, and chemoresistance. Previous data have shown that components of the HH pathway are upregulated in clinical samples of breast cancer in patients with greater mesenchymal gene signatures and those with metastatic disease. Additionally, Gli2 (Glioma-associated oncogene 2), a downstream transcriptional regulator of HH signaling, correlates with poorer patient outcomes. Thus, we hypothesize that Gli2 transcriptionally regulates EMT-associated genes, therefore promoting invasive potential in TNBC. We examined the pharmacological inhibition of Gli2 and found a reduction in EMT marker expression in TNBC cell lines. Specifically, we have identified genes such as *Cldn1* (FC = 0.382, p = 0.0003), *Zeb2* (FC = 0.426, p = 0.0005), and *Spp1* (FC = 0.163, p = 0.0009) as potential targets of Gli2-mediated EMT. We will use Cleavage Under Targets & Release Using Nuclease (CUT&RUN) sequencing to identify regions of DNA bound by Gli2, followed by comparison to genes that have differentially expressed RNA transcripts upon inhibition of Gli2. Following confirmation of Gli2-regulation of EMT-associated genes, we will genetically knockdown these target genes in Gli2-overexpressing TNBC cell lines and overexpress these genes in Gli2-knockdown TNBC cell lines. We will then perform transwell migration and invasion assays as well as *ex vivo* invasion assays on decellularized extracellular matrix (dECM) scaffolds from mouse mammary fat pads using the above cell models to assess the rescue or depletion of EMT phenotypes. The proposed studies will provide insight into the mechanisms by which Gli2 regulates EMT and invasion in TNBC. Elucidating direct transcriptional regulation of Gli2 on the EMT program may provide insight into potential therapeutic targets to reduce metastatic burden and combat chemoresistance in TNBC patients.

#4846 Stromal MTA1 silencing reprograms mesenchymal stem cells to suppress EMT and distant metastasis in triple-negative breast cancer.

Adel Zaid I Mutahar[1], Bharathi P Salimath[2]

[1]Department of Surgery, Stanford University School of Medicine, Stanford Cancer Institute,, Palo Alto, CA,[2]Department of Studies in Biotechnology, University of Mysore, Mysore, India

Background: Metastasis-associated protein-1 (MTA1) is a chromatin regulator that drives epithelial-to-mesenchymal transition (EMT), invasion, and metastatic competence in aggressive cancers including triple-negative breast cancer (TNBC). While tumor-cell MTA1 roles are well documented, its stromal contribution within mesenchymal stem cells (MSCs)—key regulators of the tumor microenvironment—remains largely unexplored. We investigated whether genetic silencing of MTA1 in human MSCs reprograms the tumor microenvironment to restrain TNBC progression and distant metastasis.

Methods: Human MSCs were stably transfected with MTA1-shRNA or scrambled control. Knockdown was confirmed by qPCR and immunoblotting. Functional assays included MMP-2 activity, osteogenic differentiation markers (RUNX2, DMP1), endothelial tube formation, and TNBC (MDA-MB-231) 3D spheroid migration, invasion, and EMT profiling. Orthotopic MSC-TNBC spheroid co-implants were established in NSG mice (n=5-8/group) to assess tumor growth, lung and brain metastases, and histologic EMT and proliferation markers. Metastasis was quantified using macrometastatic scoring, H&E staining, IHC, and micro-CT of the lungs and whole body.

Results: MTA1 knockdown reduced MSC-MTA1 expression by >80% and suppressed MMP-2 activity by 66%. Osteogenic differentiation was markedly reduced (RUNX2 and DMP1 each ↓>60%), and angiogenic tube formation decreased by 61%. In 3D co-culture, MTA1-KD MSCs reduced TNBC migration (↓54%) and invasion (↓57%) and induced EMT reversal with increased E-cadherin and decreased Vimentin and Snail. In vivo, MTA1-KD MSCs significantly inhibited tumor growth (~48% reduction at day 56). Lung and brain metastases were profoundly reduced, with a 93% decrease in lung micrometastatic foci validated by macrometastasis scoring, H&E, IHC, and micro-CT imaging. Tumors and metastatic lesions showed reduced Ki-67, N-cadherin, and Vimentin, confirming impaired proliferation and EMT signaling.

Conclusion: Our data reveal that MTA1 acts as a master stromal determinant of metastatic competence and that its suppression in MSCs yields marked inhibition of tumor-stroma crosstalk driving EMT, invasion, and organotropic colonization. The profound reduction of lung and brain metastases—validated across macroscopic, histologic, immunophenotypic, and imaging platforms—highlights the therapeutic leverage gained by targeting stromal epigenetic programs rather than tumor cells alone. These findings nominate stromal MTA1 inhibition as a powerful, mechanistically grounded strategy to remodel the metastatic niche and provide a strong translational strategy for engineering MSC-based interventions for high-risk TNBC.

#4847 Characterisation of C6ORF15 as a marker for epithelial-mesenchymal transition and lymph node metastasis in colorectal cancer.

Dedrick Kok Hong Chan

National University of Singapore (NUS), Singapore, Singapore

Introduction Lymph node metastasis in colorectal cancer (CRC) correlates with poor prognosis, yet its molecular drivers remain unknown. This study aimed to identify novel targets associated with lymph node metastasis.

Methods Colon cancers were classified into "expanding" and "metastatic" phenotypes using TCGA data. Transcriptomic profiles were analyzed by RNA-seq and GSEA. *C6ORF15* knockout (KO) and overexpression (OE) in HCT116 and SW480 cells were achieved via CRISPR-Cas9 and lentiviral transduction, validated by Sanger sequencing and Western blot. Functional effects were assessed through proliferation, migration, and invasion assays, and Western blot for EMT markers. Immunoprecipitation-mass spectrometry (IP-MS) was performed in *C6ORF15*-OE HCT116 cells to identify potential interactors.

Results TCGA analysis identified a median CRC tumor size of 5.375 cm, enabling classification into ‘expanding’ (>5 cm, no lymph node involvement) and ‘metastatic’ (≤5 cm, early lymph node involvement) phenotypes. Kaplan-Meier analysis showed significantly poorer survival in the ‘metastatic’ group (p = 0.0145). GSEA identified epithelial-mesenchymal transition (EMT) as the top enriched Hallmark in ‘metastatic’ tumors (NES = 1.81, FDR q = 0), with *C6ORF15* highly upregulated (LogFC = 2.37, p = 2.06E-07), confirmed by immunohistochemistry in patient-derived tissue specimens.

In isogenic cell lines, *C6ORF15* KO downregulated the EMT gene set (NES = -1.44, FDR q = 0.1), reducing SNAI1/2 while preserving CDH1/2, shifting cells toward a non-metastatic epithelial phenotype with reduced proliferation, migration, and invasion. Conversely, OE cells exhibited aggravated partial EMT characteristics, marked by downregulation of CDH1 and upregulation of selected mesenchymal markers (CDH2, SLUG, and SNAI1) in a cell line-dependent manner, shifting cells toward a more aggressive metastatic phenotype with enhanced proliferation, migration, and invasion.

IP-MS identified FAT1 as one of two potential C6ORF15 interactors.

FAT1 OE is known to upregulate EMT and is associated with CRC. In isogenic cell lines, *C6ORF15* OE rescued EMT activity in *FAT1* KO cells, while *C6ORF15* KO downregulated EMT in *FAT1* OE cells, suggesting that *C6ORF15* effects on EMT may persist independent of *FAT1* expression.

Conclusion *C6ORF15* may promote EMT and early CRC metastasis involving lymph nodes, showing potential as a target for future therapies.

#4848 Multi-transcriptomics reveal the potential involvement of RAB27A in promoting epithelial-mesenchymal transition in pancreatic cancer.

Zhanghao Li, Wing Ho Chan, Huiyi Guan, Sifan Yu, Aiping Lyu, Jin Liu*

Hong Kong Baptist University, Hong Kong, China

Background: Pancreatic adenocarcinoma (PAAD) is a lethal malignancy with early metastasis, a process driven by epithelial-mesenchymal transition (EMT). Although RAB27A is implicated in cancer progression, its specific role in regulating EMT in PAAD remains unclear.
Objective: This study aims to investigate the role of RAB27A in PAAD-associated EMT and to characterize its functional impact on malignant phenotypes.Methods: RAB27A expression and its correlation with patient survival were analyzed in the TCGA-PAAD cohort. Spatial transcriptomics was used to assess its enrichment in tumor regions. Gene Set Enrichment Analysis (GSEA) was performed to link RAB27A expression to the EMT program. For functional characterization, RAB27A was knocked down via siRNA in human (PANC-1) and murine (Panc-02) PAAD cell lines. Cellular proliferation, migration, and invasion were quantified by colony formation, wound healing, and transwell assays respectively. Protein levels of key EMT markers were assessed by Western blot.
Results: Bioinformatic analysis revealed that high RAB27A expression was significantly associated with poor patient survival in PAAD. Spatial transcriptomics demonstrated a strong positive spatial correlation between RAB27A expression and tumor-annotated regions. GSEA linked high RAB27A expression to an activated EMT gene signature. Functionally, RAB27A knockdown markedly inhibited proliferation, migration, and invasion in PAAD cells. This functional suppression was accompanied by a molecular shift consistent with an attenuation of EMT, including increased E-cadherin and decreased N-cadherin levels.Conclusion: Our findings implicate the potential involvement of RAB27A in promoting EMT in pancreatic cancer.
Future Directions: Future studies will focus on elucidating the precise molecular mechanisms by which RAB27A regulates EMT and evaluate the therapeutic potential of targeting RAB27A in pancreatic cancer.

#4852 Unraveling the molecular events driving *BRCA1*-associated transformation in novel models of early müllerian cancer.

Carly A. Tompkins[1], Victoria R. Cerda[2], Marcela Haro[1], Quentin Chartreux[1], Andrew J. Li[2], Simon A. Gayther[3], B.J. Rimel[4], Fabiola Medeiros[5], Kate Lawrenson[1]

[1]Center for Inherited Oncogenesis, Department of Obstetrics and Gynecology, University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]Division of Gynecologic Oncology, Department of Obstetrics and Gynecology, Cedars-Sinai Medical Center, Los Angeles, CA,[3]Center for Inherited Oncogenesis, Department of Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX,[4]Department of Gynecologic Oncology, Fred Hutchinson Cancer Center, University of Washington, Seattle, WA,[5]Department of Pathology and Laboratory Medicine, Department of Computational Biomedicine, Cedars-Sinai Medical Center, Los Angeles, CA

Clinical and translational research studies over the last two decades have revealed that high-grade serous carcinomas (HGSCs) primarily originate from fallopian tube secretory epithelial cells (FTSECs). Germline mutations in *BRCA1/2* are the strongest risk factors associated with HGSC development, but the earliest stages of neoplastic transformation, and the precise role in increasing cancer risk in FTSECs, remains poorly understood. To address this need, novel FTSEC models were generated by harvesting epithelial cells from fallopian tube fimbria by exfoliative cytology, a protocol that allowed for the use of tissue for both clinical and research applications. The study included 4 patients with high-risk germline *BRCA1* mutations undergoing risk-reducing prophylactic salpingo-oophorectomy surgery, and 4 average risk patients undergoing salpingectomy for reasons unrelated to ovarian cancer risk. Immortalization and features of neoplastic transformation were induced by transducing cells with a cDNA encoding *TERT*, dominant negative *p53*, mutant $CDK4^{R24C}$, and *CMYC*. Transduced cells bypassed replicative senescence and maintained expression of gynecologic epithelial keratins and FTSEC lineage marker PAX8. To explore if FTSECs with high-risk *BRCA1* mutations were more prone to neoplastic transformation and DNA damage, colony formation assay, and camptothecin treatment with immunofluorescent analysis of γH2A.X, 53BP1, and Rad51, were assessed. We found that high-risk FTSECs displayed increased *MYC*-induced colony formation and DNA damage compared to average-risk FTSECs. Single cell RNA-sequencing of high-risk tubal brushings identified upregulated expression of genes encoding the electron transport chain, suggesting a metabolic alteration may characterize the precancer niche in *BRCA1*-mutant fallopian tubes. Using Agilent's Seahorse assay, we found that oxidative phosphorylation is significantly decreased in high-risk FTSECs compared to FTSECs from average risk patients. Additionally, high-risk FTSECs exhibit decreased mitochondria fission. Decreased mitochondria fission coupled with a decrease in oxidative phosphorylation, suggests metabolic defects may be occurring due to the lack of mitochondria turnover and persistence of dysfunctional mitochondria. These observations uncover a new aspect of *BRCA1* biology and give new insight into metabolic perturbations occurring in high-risk fallopian tube epithelia. This work provides new models to study early tumorigenesis in the fallopian tube of high-risk mutation carriers, and demonstrates the utility of these models to investigate mechanisms underlying elevated cancer susceptibility in high-risk mutation carriers. More importantly, they have the potential to serve as models for biomarker discovery to identify early-stage markers to aid in Stage I diagnoses in the general population.

#4853 A comprehensive endometrial cancer organoid biobank reveals subtype-specific transcriptional programs and therapeutic targets.

Mali Barbi[1], Shalini Gupta[2], Santhilal Subhash[2], Divya Gowthaman[3], Arielle Katcher[3], Megan Gorman[3], Brian Yueh[4], Erdogan Akyildiz[4], Uma Mahesh[2], Devin Gee[5], Nyasha Chambwe[5], Charlie Chung[4], Marina Frimer[3], Gary L. Goldberg[3], Semir Beyaz[4]

[1]Hematology and Medical Oncology, Northwell Health Cancer Institute, New Hyde Park, NY,[2]Department of Biosciences and Bioengineering, Indian Institute of Technology Jammu, Jammu, India,[3]Department of Obstetrics and Gynecology, Division of Gynecologic Oncology, Northwell Health, New Hyde Park, NY,[4]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY,[5]The Feinstein Institute for Medical Research, Manhasset, NY

Background: Endometrial cancer (EC) is a clinically and biologically heterogeneous disease with unequal outcomes, particularly among high-grade tumors that disproportionately affect racially diverse populations. Existing preclinical models incompletely capture this heterogeneity. We established a large, racially diverse EC patient-derived organoid (PDO) biobank with matched normal to define subtype-specific molecular programs and actionable vulnerabilities.

Methods: Tumors and matched normal endometrium were prospectively collected (n=380). Morphologic fidelity was assessed by histology and immunophenotyping. Multi-omic profiling evaluated driver retention and defined subtype-specific transcriptional states. High-throughput drug screening identified candidate vulnerabilities.

Results: A total of 319 samples were included, with a ~93% PDO establishment rate, and matched tumor-normal PDOs generated across major EC histologies. PDOs recapitulated the key architectural and protein-expression features of their parental tumors, including TP53-abnormal serous phenotypes and mixed epithelial-mesenchymal organization in carcinosarcoma (CS). PDOs also preserved the key genomic characteristics, including TP53, PTEN, and PIK3CA alterations. Transcriptomic profiling revealed distinct subtype programs. Endometrioid PDOs showed Wnt-associated epithelial renewal with reduced apoptosis, p53, mTORC1, and inflammatory signaling. Serous PDOs displayed TP53-abnormal, MYC-and cell-cycle-enriched programs with uniformly suppressed interferon signaling. CS exhibited hybrid epithelial-mesenchymal features with activation of Hedgehog and myogenic pathways and broad suppression of NF-kB and interferon signaling. Stratification by p53 stability and MSI status defined opposing hyperproliferative versus immune-active axes. High-throughput drug screening identified class I HDAC inhibitor (romidepsin, RD) as a consistent activity signal. RD-perturbation RNA-seq in CS showed extensive remodeling at 10 nM, with downregulation of core G2-M/E2F mitotic regulators and suppression of CS-associated secreted factors, accompanied by restoration of antigen-presentation and interferon-responsive genes. Pathway analysis demonstrated coordinated suppression of mitotic modules and reactivation of cytokine and immune signaling. RD inhibited the TPX2-CDK1-KIF11 mitotic module, indicating a druggable spindle-dependency circuit in CS.

Conclusions: This large, racially diverse EC PDO biobank provides a robust preclinical platform that captures EC heterogeneity and enables controlled, subtype-resolved analyses. Integrated multi-omics and functional perturbation identify a spindle-dependency axis in CS, supporting subtype-specific and ancestry-aware therapy development.

#4854 Mutational profiling of patient tumor organoids for clinical variable association and markers of therapeutic response in mucinous appendiceal cancers.

Daniel J. Gironda[1], Cecilia R. Schaaf[1], Steven D. Forsythe[2], R. Andrew Erali[3], Tiefu Liu[1], Ming Leung[1], Ashok K. Pullikuth[1], Helen R. Bernardirathgeb[3], Eleftherios Makris[3], Shay Soker[1], Edward A. Levine[3], Konstantinos I. Votanopoulos[3], Lance D. Miller[1]

[1]Cancer Biology, Wake Forest University School of Medicine, Winston Salem, NC,[2]Surgical Oncology, The University of Alabama at Birmingham, Birmingham, AL,[3]Surgical Oncology, Wake Forest University School of Medicine, Winston Salem, NC

Background: Mucinous Appendiceal Cancer (mAC) is a rare and poorly characterized malignancy with no known molecular targets and is treated using colorectal cancer protocols. In this study, we employed whole-exome sequencing (WES) on 3D cultures to investigate how mAC-specific oncogenic programming associates with patient clinical variables and therapeutic responses.
Methods: Patient-derived tumor organoids (PTOs) were generated from multiple mAC lesions from patients undergoing cytoreductive surgery and hyperthermic intraperitoneal chemotherapy under IRB approval. PTOs were treated with FOLFOX or FOLFIRI for 72 hours with response measured by Cell TiterGlo to determine a response phenotype. A subset of PTOs from 10 patients and 31 tumor deposits were treated with DMSO vehicle, FOLFOX, or FOLFIRI, after which genomic DNA was isolated and sequenced on an Illumina NextSeq 6000. GATK and DRAGEN pipelines were used for mutation calling, and alterations associated with drug response were analyzed by Ingenuity Pathway Analysis (IPA), with stratification informed by relevant patient clinical variables.
Results: Across the 10 mAC cases profiled, WES identified a total of 28,245 mutations, including therapeutically actionable KRAS G12D variants in 40% of cases. No targetable alterations were detected in BRAF, EGFR, or ALK. When pooling all pre-treated PTOs and averaging the variant allele frequency (VAF) across all 31 lesions, with a focus on mutations with an average VAF >=10% and present in at least 2/10 patients, individual gene mutations that were undetectable (i.e. VAF=0%) after FOLFIRI treatment included TAX1BP1, PDXK, ZFPM2, and H1FX-AS1. The lone genetic mutation undetectable after FOLFOX treatment was LINC01197, with mutations in SORD and ZBTB24 associated with a complete clonal loss after either FOLFIRI or FOLFOX treatment. Of note, SORD overexpression is implicated in the migration of CRC via upregulation of the mevalonate pathway. IPA canonical pathway analysis of patients progressing within 2 years revealed alterations in D-Myo-Inositol regulation associated pathways, whereas progression-free patients displayed alterations in pathways related to insulin-like growth factor uptake and iron regulation. Further pathway analysis was performed to discover mutations that differentiate pathways by sex, race, tumor grade, TNM scores, obesity status, among other clinical variables.
Conclusions: Comprehensive mutational profiling of mAC using paired PTO models via WES is feasible and clinically informative, enabling the detection of actionable oncogenic drivers and chemotherapy-sensitive clonal populations. These data provide the first integrated framework linking mAC-specific genomic alterations to patient outcomes and therapeutic responses and offers new biological insight into the molecular underpinnings of mAC.

#4855 Cystathionine beta-synthase drives transcoelomic metastasis in ovarian cancer.

Pallab Shaw[1], ARPAN DEY BHOWMIK[2], Akrit Pran Jaswal[1], Resham Bhattacharya[2], Priyabrata Mukherjee[1], Shailendra Kumar Dhar Dwivedi[2], Geeta Rao[1]

[1]Pathology, OU Health Stephenson Cancer Center, Oklahoma City, OK,[2]Obstetrics and Gynecology, OU Health Stephenson Cancer Center, Oklahoma City, OK

Ovarian cancer (OvCa) disseminates predominantly by transcoelomic metastasis, where exfoliated tumor cells survive as multicellular spheroids, adhere to the omentum, and establish peritoneal invasion. This process is largely dependent on spheroid viability (anoikis resistance) and efficient omental adhesion. We investigated whether the cystathionine β-synthase (CBS), which has been previously associated with other aspects of OvCa progression, can also functionally drive intraperitoneal metastasis. We integrated (i) publicly available multi-cohort patient data with survival analyses, (ii) an in-house HGSOC tissue microarray (TMA; n=109) scored for CBS with clinicopathologic correlation to peritoneal/omental metastasis, and (iii) mechanistic assays involving OvCa 2D monolayer and 3D spheroid models, including proteomics, to identify key players of CBS-mediated metastasis. High CBS expression was found to be positively correlated with worse patient survival and with clinically observed peritoneal/omental metastasis in the TMA cohort. Functionally, CBS maintained spheroid viability and compact architecture by stabilizing SP1 and sustaining ITGB1, a key mediator of mesothelial adherence on omentum via its interaction with fibronectin engagement. CBS silencing deteriorated spheroid structure, reduced $CD24^+$ subpopulations, downregulated EMT/stemness programs, and attenuated omental homing in vivo. Further, H_2S supplementation restored SP1 along with ITGB1, causing promulgated fibronectin adhesion, and spheroid survival, supporting a causal CBS→H_2S→SP1→ITGB1 pathway as the underlying mechanism of CBS-mediated OvCa transcoelomic metastasis. Therefore, the CBS-SP1-ITGB1 axis mechanistically facilitates the survival and omental adhesion of metastatic spheroids, underscoring CBS's candidacy as a target for anti-metastatic therapy.

#4856 Quantifying the dual effect of anti-tumor and pro-tumor human neutrophils on natural killer cell behaviors in a microphysiological system.

Shuai Shao, Caroline N. Jones

Biomedical Engineering, UT Southwestern Medical Center and UT Dallas, Dallas, TX

Neutrophils can promote tumor progression by inhibiting the antitumor activity of natural killer (NK) cells known as the first line of defense against cancer. Studies in mice show that neutrophils can be polarized toward either an anti-tumor “N1” or a pro-tumor “N2” state. However, it is unknown how N1 and N2 neutrophil subtypes influence NK cell behaviors differently in human cancer. It is also challenging to monitor neutrophil-NK cell interactions in the human tumor tissue. Here, we engineered a human cell-based microphysiological system to measure the distinct effect of N1 and N2 neutrophil subtypes on NK cell migration, motility, tumor cytotoxicity, and tumor infiltration. We fabricated a three-channel microfluidic chip using standard lithography. To model the preferential migration of NK cells toward different neutrophil subtypes (scenario 1), the two side channels of the microfluidic chip were seeded with LPS, IFN-γ, and IFN-β-polarized N1 and TGF-β-polarized N2 HL-60 neutrophils respectively and the central channel was seeded with NK-92MI cells. To model NK cell cytotoxicity against tumor (scenario 2), the side channels were seeded with a mixture of NK-92MI cells, PANC-1 pancreatic tumor spheroids, and N1 or N2 neutrophils. All cells were embedded in 3D collagen hydrogel to mimic the extracellular matrix of the pancreatic tumor tissue. Time-lapse imaging and end-point confocal imaging were performed to capture NK cell migration and motility in scenario 1 and tumor spheroid apoptosis and NK cell-tumor infiltration in scenario 2. NK-92MI cells showed both a higher percentage of migration (12.07 vs. 5.11% at t=24 h, $p<0.001$) and a higher maximum rate of migration (1.31 vs. 0.73%/h, $p<0.01$) to N1 neutrophils than to N2 neutrophils over 24 h. NK-92MI cells showed a higher motility after migration to N2 neutrophils than N1 neutrophils in speed (1.07 vs. 0.80 μm/min at t=12 h), displacement (9.89 vs. 6.89 μm at t=12 h), and directionality (0.43 vs. 0.36 at t=24 h) ($p< 0.0001$). Hence, NK-92MI cells showed preferential migration to N1 over N2 neutrophils, although they slowed down after migration to N1 compared to N2 neutrophils. Moreover, N1 neutrophils restored NK cell cytotoxicity against tumor spheroids (0.97 vs. 1.01, $p>0.99$) while N2 neutrophils suppressed it (0.97 vs. 0.54, $p<0.0001$), although both N1 and N2 neutrophils inhibited NK cell infiltration in tumor spheroids (control vs. N1 vs. N2: 8.04 vs. 5.87 vs. 5.49%, $p<0.01$). We also found that N1 neutrophils secreted a higher level of NK cell chemokine IP-10 and induced higher expressions of activation markers CD107a and IFN-γ by NK-92MI cells than N2 neutrophils. This study reveals the dual role of human neutrophils in modulating NK cell behaviors and the complex neutrophil-NK cell crosstalk, suggesting reprogramming neutrophils to reverse the immunosuppression on NK cells as a potential therapeutic strategy for cancer.

#4857 A panel of patient-derived organoid models from rare cancers for high-throughput preclinical pharmacology studies.

Nathan P. Coussens[1], Thomas S. Dexheimer[1], Zahra Davoudi[1], Thomas Silvers[1], Eric M. Jones[1], Bryce M. N. Butler[1], John R. Britt[1], Luke Stockwin[1], Dianne Newton[1], Carmen Allegra[2], James H. Doroshow[2], Beverly A. Teicher[2]

[1]Applied and Developmental Research Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD

Twenty-five patient-derived organoid models from rare cancer types were selected from the NCI's Patient-Derived Models Repository (https://pdmr.cancer.gov) to serve in a high-throughput screening panel for preclinical pharmacology studies. The models were derived from primary (16; 64%) or metastatic (9; 36%) tumors of patients (56% female, 44% male) with varied ancestries, ranging in age from 32-87 yrs, that were either previously treated (13; 52%) or treatment naïve (12; 48%). The panel included a range of cancer types, including one breast, seven digestive/gastrointestinal, one neuroendocrine, four gynecologic, seven head and neck, and five musculoskeletal. Variations were determined in microsatellite stability and genetics, including clinically relevant oncogenic variants of RAS, BRAF, and PIK3CA. A high-throughput pilot screen was conducted with a library of 166 FDA-approved oncology drugs tested at five concentrations with a 1-log dilution series ranging from 0.01 µM to 100 µM. After a seven-day drug exposure period, cell viability was determined by the CellTiter-Glo 3D endpoint assay. The overall assay performance was excellent with average Z'-factor values from nine microplates per organoid model ranging between 0.54 (0.49 - 0.63) to 0.89 (0.86 - 0.91), with an overall average of 0.67 (0.44 - 0.91). Under assay conditions, the organoid models exhibited diverse morphologies and varied growth kinetics with doubling times ranging from 48 - 363 h with an average of 129 h. Among the patients that received prior chemotherapy, four had a partial response as the best outcome, two of which were sarcoma patients treated with regimens including doxorubicin, vincristine, and etoposide. Interestingly, the organoids derived from the two patients demonstrated ≥1 log of cytotoxicity following exposure to these drugs and others at concentrations below the clinical Cmax. A patient with lip/oral cavity squamous cell carcinoma partially responded to a regimen including temozolomide and the corresponding organoid demonstrated ≥1 log of cytotoxicity following exposure to temozolomide and other drugs below the clinical Cmax. A patient with stomach adenocarcinoma partially responded to a regimen with 5-fluorouracil and cisplatin, but the organoid was minimally sensitive to these drugs. However, genomic characterizations of the tumor tissue indicated an amplification of ERBB2 and the organoid demonstrated sensitivity to the ERBB2 inhibitors neratinib, dacomitinib, and lapatinib below their respective clinical Cmax value. Altogether, these data underscore the potential utility of organoids for assessing tumor responses and exploring novel treatment modalities for underserved malignancies. Funded by NCI Contract No. 75N91019D00024 & 75N91020F00032.

#4858 Combined pan and precision targeting in extrachromosomal DNA-positive gastric cancer.

Gengyi Zou[1], Melissa Pizzi[1], Aryanasingh Bhati[1], Bansi Vanparia[1], Wei-Chieh Yu[2], Ailing Scott[1], Yibo Fan[1], Calena Brown-Abel[1], Liyong Zeng[1], Johnson Amoah[1], Tanaya Alexander Washington[1], Yuan-Hung Lo[2], Vineet Bafna[3], Shilpa Dhar[1], Jaffer Ajani[1]

[1]GI Med Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Molecular & Cellular Oncology, UT MD Anderson Cancer Center, Houston, TX,[3]University of California, San Diego, CA

Gastric adenocarcinoma (GAC) remains a major health challenge with high mortality due to late diagnosis, therapy resistance, and limited targeted options. Extrachromosomal DNA (ecDNA)—circular DNA elements carrying amplified oncogenes such as MYC, ERBB2, and EGFR—enhances transcriptional output, therapy resistance, and genomic instability. However, its role in GAC is poorly understood, and current models fail to recapitulate patient tumor complexity. Patient-derived organoids (PDOs) preserve tumor-specific features, including ecDNA, providing an ideal platform for mechanistic and therapeutic exploration.We hypothesize that ecDNA drives unique oncogenic programs in GAC that create exploitable vulnerabilities. Analysis of 221 TCGA-STAD samples with AmpliconArchitect identified ecDNA in 33.3% of primary tumors, absent in matched normal blood. ecDNA+ tumors showed distinct amplification patterns, with proteomic profiling revealing CHEK1 and TFRC enrichment, suggesting co-targetable vulnerabilities. To model these tumors, we established a PDO biobank comprising 5 primary and 9 ascites-derived PDOs. ecDNA was detected in 5/9 (55.6%) ascites-derived and 1/5 (20%) primary PDOs, consistent with ecDNA enrichment in metastatic settings. Amplified oncogenes included PTP4A3, for which inhibitors are available.RNA-seq comparison of ecDNA+ PDO 385 with ecDNA- PDOs (4666, 4601) revealed distinct transcriptional programs, with enriched expression on chromosomes 8 and 20. Transcription factor analysis identified MYC, also amplified as ecDNA. Immunofluorescence confirmed higher TFRC, CHEK1, MYC, and PRL3 (PTP4A3) expression and increased Ki67 in ecDNA+ PDO 385, supporting oncogene overexpression and aggressive growth. Drug screening predicted compounds reversing the ecDNA+ signature. Functional assays showed the TFRC inhibitor (TfR-1-IN-1) reduced proliferation of ecDNA+ PDO 385, while CHK1 inhibition had modest effects. Combined TFRC and CHK1 inhibition synergistically suppressed ecDNA+ PDO growth, with minimal effects on ecDNA- controls. These results highlight the selective vulnerability of ecDNA-driven tumors to co-targeting strategies. Using a PDO biobank, we aim to uncover and exploit vulnerabilities in ecDNA-positive GAC.

#4859 A novel sarcoma tumoroid platform preserving the tumor microenvironment to guide personalized immunotherapy.

Tony Ezzat[1], Nathaniel Ruppert[2], Elizabeth Nowak[3], Danny G. Cho[3], Masahiro Hitomi[4], Tyler E. Miller[5], Gary K. Schwartz[5], Jacob G. Scott[5], Zachary D. Burke[6]

[1]The Cleveland Clinic Lerner College of Medicine, Cleveland, OH,[2]Case Western Reserve University School of Medicine, Cleveland, OH,[3]The Cleveland Clinic, Cleveland, OH,[4]Project Staff, Dept. of Stem Cell Biology and Regenerative Medicine, The Cleveland Clinic, Cleveland, OH,[5]Case Comprehensive Cancer Center, Cleveland, OH,[6]Orthopedic Surgery, The Cleveland Clinic, Cleveland, OH

Sarcomas are rare, aggressive mesenchymal cancers with over 80 subtypes. Although they represent a small fraction of adult cancers, sarcomas comprise over 20% of pediatric solid tumors and carry poor outcomes for patients with advanced disease. Preclinical modeling remains challenging: traditional 2D cultures fail to preserve the tumor microenvironment (TME), while conventional 3D organoid platforms rely on enzymatic dissociation, which disrupts cellular interactions essential for TME integrity. Patient-derived xenografts, though more representative, are costly and low-throughput. To address these limitations, this study aims to develop reproducible 3D sarcoma tumoroids as a translational platform for functional studies and therapeutic testing that preserves the TME.

Freshly resected sarcoma specimens were mechanically cut into small fragments without enzymatic dissociation, preserving the TME in each fragment, and cultured in suspension or matrix-embedded conditions. Media formulations and growth factor combinations were evaluated across sarcoma subtypes to optimize culture performance. Tumoroid formation and growth were monitored for 14 days using brightfield microscopy, quantitative area analysis, and alamarBlue viability assay. Structural integrity and TME preservation were assessed by hematoxylin and eosin (H&E) staining and immunohistochemistry (IHC). Cytotoxic response assays were performed using standard chemotherapeutic agents, including doxorubicin and methotrexate, to evaluate drug sensitivity in 3D culture over a 5-day treatment period.

Established tumoroids maintained consistent 3D morphology and viability over 14 days, with Mammocult medium plus growth factors supporting the strongest proliferation. Quantitative growth analysis showed a progressive increase in tumoroid area and metabolic activity, indicating stable expansion under optimized conditions. H&E staining confirmed retention of tumor cells, stroma, and histologic architecture across osteosarcoma, dedifferentiated liposarcoma, and chondrosarcoma for over 10 days. IHC staining for CD45 confirmed the presence of immune and stromal cell populations within the cultures, indicating preservation of the native TME. Chemotherapeutic testing using methotrexate and doxorubicin revealed cytotoxic effects through H&E and Live/Dead staining, validating the model's responsiveness and functional relevance.

These findings demonstrate that mechanically dissociated sarcoma tissues can generate viable, subtype-representative tumoroids while maintaining key TME features. Future efforts will focus on expanding therapeutic testing, integrating immune co-culture systems to better recapitulate the sarcoma TME, and applying spatial transcriptomics and single-cell RNA sequencing to uncover cellular heterogeneity and guide precision oncology for sarcoma patients.

#4860 Predicting therapy efficacy and revealing tumor heterogeneity using patient-derived 3D bioprinted ovarian cancer models.

Jiangang Zhang[1], Huiyu Yang[2], Ying Shan[3], Zihan Zhong[4], Ziren Kong[5], Yuning Sun[1], Huayu Yang[6], Lingya Pan[3], Yilei Mao[6], Ying Jin[3]

[1]Department of Head and Neck Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[2]Department of Neurosurgery, Xuanwu Hospital, Capital Medical University, Beijing, China,[3]Department of Obstetrics and Gynecology, Peking Union Medical College Hospital, Beijing, China,[4]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[5]Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China,[6]Department of Liver Surgery, Peking Union Medical College Hospital, Beijing, China

Ovarian cancer is the most lethal gynecologic malignancy, characterized by tumor heterogeneity and a high recurrence rate. Patient-derived *in vitro* tumor models offer a promising strategy for individualized drug screening to overcome limitations of systemic therapy. Among existing modeling methodologies, 3D bioprinting exhibits advantages including high-throughput, high fidelity, and a drug screening timeline of 8 days. Here, we present experimental data of a cohort of novel 3D bioprinted patient-derived ovarian cancer (3DP-OC) models. We established 3DP-OC models by mixing primary ovarian cancer cells with Gelatin Methacryloyl (GelMA) and photoinitiator, and bioprinting in a layer-by-layer manner. In total, 3DP-OC from 79 patients were successfully established, including 61 high-grade serous ovarian cancer patients, 9 ovarian clear cell carcinoma patients, 4 ovarian sarcoma patients, 4 ovarian endometrioid carcinoma patients, and 1 ovarian neuroendocrine cancer patient. 113 3DP-OC models were constructed from different tissue origins (primary lesion and metastatic sites) with high cell viability maintained throughout bioprinting and prolonged *in vitro* culture. Bulk RNA sequencing and immunohistochemistry confirmed that key molecular markers and Ki-67 levels in 3DP-OC models closely resembled those of their paired tumor tissues, demonstrating that 3DP-OC can serve as a patient avatar for drug sensitivity testing. On days *in vitro* 5, 3DP-OC models were exposed to gradient concentrations of 15 frequently used chemotherapeutic and targeted drugs in ovarian cancer including paclitaxel, carboplatin, olaparib, *etc.* Cell viability was quantified to calculate IC_{50} values of different anti-tumor drugs. Drug sensitivity testing revealed substantial interpatient heterogeneity in therapeutic responses. To further investigate whether this response heterogeneity has clinical relevance, we conducted a prospective observational cohort study that enrolled 41 stage III/IV newly diagnosed ovarian cancer patients. Patients were divided into “3DP-OC identified sensitive group” or “3DP-OC identified resistant group” according to 3DP-OC IC_{50} values of anti-tumor drugs they received. The median follow-up time for all patients was 580.5 days. The 3DP-OC identified sensitive group exhibited significantly prolonged progression-free survival compared to the 3DP-OC identified resistant group ($P < 0.05$), with disease progression observed in 16.7% (4/24) and 52.9% (9/17) of patients, respectively. In this study, we established a 3D bioprinted patient-derived cancer model with high success rate of establishment, low intra-batch heterogeneity, and high biological fidelity. 3DP-OC model holds promise for predictive utility in precision oncology as well as the potential to serve as an innovative platform that bridges fundamental cancer research and clinical practice.

#4861 Modeling IDH-mutant low-grade astrocytoma using human embryonic stem cells.

Greta Henriette Ghita, Yanhong Yang, Viviane Tabar

Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Few existing models accurately recapitulate and sustain the phenotype of IDH-mutant low-grade gliomas (LGGs). Maintaining a stable IDH-mutant glioma line remains a major challenge, as patient-derived cultures rapidly lose mutant IDH expression due to selective pressure favoring more aggressive, IDH wild-type cells. To address this limitation, we developed an inducible human embryonic stem cell (hESC)-derived model for longitudinal studies of IDH-mutant Low-Grade Astrocytoma (LGA) pathogenesis, progression, and therapeutic response.
Methods: We engineered hESCs to carry a doxycycline-inducible IDH1-R132H mutation, with or without CRISPR/Cas9-mediated knockouts of TP53 and ATRX. These combinations generated three isogenic lines: IDH-mutant alone, IDH-mutant/TP53-null, and IDH-mutant/TP53-ATRX-null. This allows for the dissection of how common co-mutations influence glioma initiation and evolution. Cells underwent neural induction to the progenitor stage to model early gliomagenesis, with induction of mutant IDH expression being verified via Western blot. Tumorigenic potential and progression are currently being assessed both in vitro and in vivo.
Results: Upon differentiation to the neural progenitor stage, IDH1-R132H induction produced hallmark features of LGG biology, including elevated γH2AX, a marker of DNA damage response associated with IDH-mutant gliomas. Induced cells exhibited slower proliferation and limited invasiveness compared to non-induced controls, mirroring the slower growth of patient-derived LGGs. In vivo, IDH-mutant xenografts demonstrated delayed tumor expansion relative to IDH-wild-type counterparts. Ongoing studies are comparing therapeutic responses between our hESC-derived model and patient-derived lines to evaluate its translational utility for preclinical drug testing and longitudinal progression studies.
Conclusions: We established an inducible hESC-based model with the capability to recapitulate the behavior and characteristics of IDH-mutant LGA. This platform could overcome the instability of patient-derived lines, enabling controlled, long-term studies of glioma evolution and treatment response. Our model provides a powerful system to dissect how IDH and cooperating mutations drive gliomagenesis and to test targeted therapies across disease stages.

#4862 Development of a high-throughput multimodal patient-derived platform integrating autologous fibroblasts and tumor-infiltrating lymphocytes for colorectal cancer drug discovery.

Lewis Campbell, Agapitos Patakas, Athanasios Koulis, Hannah Findlay, Daria Paruzina, Cameron Fyfe, Ellen Main

RoukenBio, Motherwell, United Kingdom

Background:
Colorectal cancer (CRC) remains one of the leading causes of cancer-related mortality, driven by extensive molecular heterogeneity and the emergence of therapy-resistant subclones. Conventional *in vitro* models fail to reproduce the complexity of the tumor microenvironment (TME). To address this, we developed a high-throughput, multimodal patient-derived tumoroid (PDTO) platform incorporating autologous tumor-infiltrating lymphocytes (TILs) and / or cancer-associated fibroblasts (CAFs), enabling integrated pharmacologic, genomic, and immunologic analyses for translational drug discovery.
Methods:
Matched tumor and adjacent normal tissues were collected from CRC patients under the NHSGGC biorepository ethics approval (REC 22/WS/0020). PDTOs, CAFs, and TILs were isolated, expanded, and cryopreserved under optimised protocols that maintain molecular signature of the parental tumor. Each patient derived model was subjected to multi-omic characterisation, including whole-exome sequencing, and bulk RNA sequencing. Derived models were treated with standard-of-care drugs (SOC) to assess sensitivity/resistance, tumoroid survival and viability post treatment, which was analysed by high throughput fluorescent imaging, flow cytometry and multiplex cytokine profiling.
Results:
To date, five PDTO, CAF, TIL models, including mono-, dual-, and tri-culture formats have been successfully established from both primary and metastatic CRC samples encompassing diverse mutational backgrounds. Integrated mutational burden analysis together with transcriptional and clinical data revealed discrete transcriptional clusters associated with microsatellite status, immune infiltration, and drug response patterns. SOC regimens demonstrated expected cytotoxic profiles, confirming physiological relevance of the models. Initial experiments indicated that inclusion of immune and stromal component confirm that incorporating CAFs and TILs modifies pharmacologic response profiles.
Conclusions:
This multimodal CRC tumoroid platform recapitulates the epithelial, stromal, and immune components of the native TME. Its integration of clinical, genomic, and gene expression datasets enables high-content functional screening and predictive biomarker discovery. The platform supports translational drug development while reducing the need for large-scale expansion across heterogeneous patient cohorts by capturing most dominant CRC molecular subtypes and intratumoral complexity within each culture system.

#4863 Innovative xeno free synthetic hydrogel supports iPSC derived intestinal organoids and colorectal cancer (CRC) organoid growth, An advanced organoid platform for therapeutic screening.

Kalhara R. Menikdiwela, JOHN HUANG

Research and Development, TheWell Bioscience Inc., Monmouth Junction, NJ

Colorectal cancer (CRC) is the fourth most commonly diagnosed cancer and the second leading cause of cancer death in the United States of America. Organoids, specifically CRC organoids have emerged as a powerful preclinical model as they closely recapitulate patient-specific tumor features, including tumor morphology, genetics and treatment response. However, most organoid culture systems heavily rely on animal-based hydrogel systems, which are tumor-derived and consist of a large number of undefined components, introducing batch variability, thus limiting their translational relevance. To overcome these limitations, we developed and engineered an innovative xeno-free synthetic hydrogel system (VitroGel) to provide mechanical support and a tunable extracellular environment for advanced CRC organoid research. Human iPSCs were first cultured in synthetic hydrogel VitroGel STEM, to generate uniform spheroids. Using stepwise differentiation with endoderm-inducing and mid-gut patterning media, spheroids were guided toward intestinal lineage commitment. Immature intestinal organoids were subsequently transferred into VitroGel ORGANOID with intestine-specific medium to generate mature intestinal organoids with stable expansion. Similarly, patient-derived CRC organoids were cultured in synthetic hydrogel system, resulting in reproducible growth and structural integrity. To further evaluate the utility of the VitroGel system for modeling tumor-epithelium interactions, we established an advanced co-culture model by integrating iPSC-derived intestinal organoids with Wnt3a-overexpressing, RFP-labeled Caco-2 cells within VitroGel. Activation of the Wnt pathway induced tumor-like phenotypes within the organoid structures, enabling the development of intestinal organoids with enhanced tumor characteristics. Overall, the synthetic hydrogel VitroGel ORGANOID provides a next-generation matrix that enhances the reproducibility, scalability, and translational relevance of intestinal and CRC organoid models, including advanced tumor-epithelium co-culture. By eliminating the limitations of animal-derived extracellular matrices, VitroGel represents a significant advancement for precision oncology and drug discovery.

#4864 A leiomyosarcoma cell model based on smooth muscle-committed *TP53*-knockout iPSCs identifies novel actionable pathways..

Annalisa Astolfi[1], Livia Gozzellino[2], Alice Costa[3], Ilenia Motta[2], Margherita Nannini[1], Maria Concetta Nigro[1], Martina Lops[2], Maria Giulia Pirini[3], Antonio De Leo[1], Gianandrea Pasquinelli[1], Maria A. Pantaleo[1]

[1]University of Bologna, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,[2]University of Bologna, Bologna, Italy,[3]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy

Leiomyosarcoma (LMS) is a mesenchymal tumor of smooth muscle origin, representing one of the most common types of soft tissue sarcoma. The genetic landscape of LMS is driven by *TP53* mutation that recurs in more than 60% of patients. Leiomyosarcoma prognosis is still disappointing, since up to now no drug combination has shown relevant clinical activity in the advanced or metastatic setting and the role of adjuvant therapy remains controversial. The aim of this project was to dissect the vulnerability of the most recurrent genetic lesion in a LMS model to identify novel actionable pathways. To this end we developed a cell model system recapitulating LMS molecular and lineage phenotypes by engineering donor-derived induced pluripotent stem cells (iPSC) at the *TP53* locus using Crispr/Cas9 system. The model was then differentiated towards smooth muscle and characterized by gene expression profiling, protein and transcript biomarker expression, *in vitro* 2D and 3D cell growth and drug response testing. *TP53*-edited cell pool was subcloned to select lines carrying either homozygous or compound heterozygous frameshift mutations (*TP53* Knockout, KO). Mesoderm lineage commitment upregulated specific mesoderm markers (T, Mixl1, CD56) in both parental (iPSC WT) and *TP53* KO lines, while only *TP53* KO cells significantly downregulated p53-target genes. Differentiation towards smooth muscle showed upregulation of terminal smooth muscle markers at the transcript (ACTA2, ACTG2, TAGLN) and protein level (alpha-SMA, Cnn1) in iPSC WT and *TP53* KO clones. At the phenotypic level *TP53* loss promoted cell growth at early and late stages of smooth muscle differentiation (2 - 2.5-fold induction, $p<0.001$), and significantly induced 3D spheroid cell growth with respect to the wild type counterpart (3.6-fold, $p<0.001$). Gene expression profiling during smooth muscle differentiation uncovered the malignant phenotype driven by *TP53* knockout, shown by the upregulation of the CINSARC signature that is associated to tumor aggressiveness in sarcomas. Moreover, it identified *FBXW7* as the most significantly silenced gene immediately after *TP53* ($p<0.001$). Analysis of the TCGA Firehose Legacy dataset confirmed that *FBXW7* was significantly downregulated in *TP53*-mutant or deleted sarcomas with respect to WT tumors. Since it is known that *FBXW7*-deficient cells are more sensitive to Tigecycline, a drug that targets mitochondrial translation, we tested the drug in *TP53* KO LMS model, showing that smooth muscle-committed *TP53* KO cells are three times more sensitive to this compound than wild type cells. This study shows that *TP53* KO LMS iPSC model is an effective tool for target discovery, and that *FBXW7* pathway could be an amenable target in *TP53*-mutant LMS. The research leading to these results has received funding from AIRC under IG 2024 - ID. 30644 project - P.I. Astolfi Annalisa.

#4865 Functional assessment of patient drug sensitivity using AI-powered image analysis on patient-derived organoids and micoorganoid spheres.

Abraham Lin[1], Maxim Le Compte[2], Divya L. Dayanidhi[3], Edgar Cardenas De La Hoz[4], Rebecca Stone[5], Tyler Gilcrest[5], Geert Roeyen[6], Filip Lardon[1], Christophe Deben[1]

[1]Center for Oncological Research, University of Antwerp, Wilrijk, Belgium,[2]University of Antwerp, Wilrijk, Belgium,[3]Medical Center, Duke University, Durham, NC,[4]Industrial Vision Lab, University of Antwerp, Antwerp, Belgium,[5]Orbits Oncology, Palo Alto, CA,[6]University Hospital Antwerp, Edegem, Belgium

Lately, there has been a push for new laboratory models that more accurately represent human biology than traditional models. These include miniature tumor models such as, patient-derived organoids (PDOs) and MicorOrganoidSpheres (MOS), which act as functional avatars of patient tumors and treatment response[1,2]. While recent studies provided first evidence that patient responses to standard-of-care therapies could be recapitulated, these studies were only able to predict clinical responses in a subset of patients[3]. This limitation largely stems from the analytical methods used, namely CellTiter-Glo 3D[4], which rely on a bulk, endpoint analysis and only extracts a fraction of clinically relevant insights that PDOs provide[5]. Therefore, we hypothesized that using kinetic, higher-dimensional analysis methods, further improves the predictive performance of PDOs. We combined live-imaging techniques with AI-driven analysis to capture dynamic drug responses. Using a fully characterized a PDO panel (n=8) from patients with pancreatic ductal adenocarcinoma (PDAC) and a fully characterized MOS panel (n=43) from patients with colorectal cancer, we matched our multiparametric analysis with retrospective clinical patient response to standard of care therapies (e.g. gemcitabine-paclitaxel, FOLFIRINOX, oxaliplatin). Our PDO analysis quantified resistant and sensitive PDO clones within the patient, and identified patient-specific sensitives to therapy that were in-line with progression-free survival of matched patients ($R=0.97$)[6]. This was a significant improvement to the relative viability readouts from CellTiter-Glo3D ($R^2=0.26$). Our MOS analysis correlated with patient sensitivity and resistance to oxaliplatin. Taken together, our work highlights the importance of using sophisticated analysis methods to measure the complexity new laboratory models, such as MOS and PDOs. Our ongoing work include developing more robust predictive models, using the multiparametric readouts of our analysis platform.

#4866 Interactions between colorectal cancer cells and cancer-associated fibroblasts across desmoplastic reaction subtypes.

Wataru Kosaka[1], Keigo Murakami[2], Yota Akamori[1], Hideaki Karasawa[1], Yuki Yasuda[1], Ichiro Ise[1], Tomoyuki Ono[1], Megumi Murakami[1], Yoshihiro Sato[1], Gumpei Yoshimatsu[1], Hideyuki Suzuki[1], Takashi Kamei[1], Shinobu Ohnuma[1], Toru Furukawa[2], Michiaki Unno[1]

[1]Department of Surgery, Tohoku University Graduate School of Medicine, Sendai, Japan,[2]Department of Investigative Pathology, Tohoku University Graduate School of Medicine, Sendai, Japan

The desmoplastic reaction (DR) at the invasive front of colorectal cancer (CRC) has recently gained increasing attention as an important prognostic indicator and as a histological hallmark that reflects tumor-stroma interactions. DR is classified into mature, intermediate, and immature patterns based on stromal morphology, each representing distinct biological states of the surrounding microenvironment. Previous clinicopathological studies have demonstrated that immature and intermediate DR are associated with unfavorable outcomes; however, the biological mechanisms underlying these prognostic differences remain insufficiently understood. Because cancer-associated fibroblasts (CAFs) constitute the predominant stromal component of DR and critically influence stromal architecture, we aimed to clarify CRC-CAF interactions by combining analyses from a well-characterized clinical cohort and a three-dimensional co-culture system incorporating patient-derived CRC organoids and CAFs.We retrospectively identified 269 consecutive patients who underwent surgical resection for CRC (pT3 or higher) between 2013 and 2018 at our institution. Clinicopathological and prognostic variables were examined in detail, with a focused analysis of 191 stage II/III patients who did not receive preoperative therapy to reduce treatment-related confounding. Primary CRC organoids and CAFs were established from resected tumors under standardized culture conditions, and the DR subtype corresponding to each CAF line was determined histologically. To further explore stromal biology, proteomic profiling was performed to characterize DR subtype-specific protein expression signatures and to investigate molecular features associated with stromal phenotypes.Immature DR demonstrated significant associations with aggressive clinicopathological characteristics, including higher T (T3 66.0%, T4 34.0% P-value : 0.0011) and N (pN1-3 62.3% P-value : < 0,001) categories, vascular invasion (positive 98.1% P-value : < 0,001), and other indicators of tumor invasiveness, whereas mature DR was linked to more favorable clinical outcomes. In three-dimensional co-culture assays, CRC organoids exhibited the greatest proliferative expansion when paired with immature CAFs, emphasizing the functional relevance of stromal immaturity in promoting tumor growth (P-value : < 0.05). Proteomic analysis revealed clear segregation among DR subtypes, reflecting distinct protein expression profiles characteristic of each subtype. Notably, in immature DR, pathways related to cell adhesion centered on integrins, actin-regulation pathways, and fatty acid metabolism were among the top enriched pathways.These findings support DR classification as a clinically meaningful prognostic factor in CRC and indicate that immature CAFs play a key role in promoting CRC cell growth.

#4867 The radiosensitivity index (RSI): A patient-derived organoid platform for predicting radioresistance in cervical cancer.

Young Joo Lee[1], Ju Hee Oh[2], Eun Hye Choi[2], Kyung Jin Eoh[3], Sang Wun Kim[2], Yoo-Na Kim[2], Ji Hyun Lee[2], Eun Ji Nam[2]

[1]Department of Obstetrics and Gynecology, Kyung Hee University Hospital at Gangdong, Kyung Hee University College of Medicine, Seoul, Korea, Republic of,[2]Department of Obstetrics and Gynecology, Women's Cancer Center, Yonsei Cancer Center, Institute of Women's Life Medical Science, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Department of Obstetrics and Gynecology, Yongin Severance Hospital, Yonsei University College of Medicine, Yongin, Korea, Republic of

Purpose Radiotherapy is one of the major treatment modalities for cervical cancer; however, treatment responses vary among patients, and no reliable method currently exists to predict individual radiosensitivity. We aim to establish a radiosensitivity index (RSI) model using cervical cancer patient-derived organoids (PDOs) and to evaluate its clinical performance in relation to actual patient outcomes.

Patients and Methods Fresh cervical cancer tissues were obtained from 14 patients at diagnosis, and clinical information including stage, radiation history, histology, recurrence, and progression-free survival was retrieved from their medical records. Organoids were established from patient-derived cervical cancer tissues, and their histopathological and genomic features were compared with the original tumors to confirm reproducibility and model fidelity. Each organoid underwent irradiation assays to evaluate radiosensitivity. Radiation-response metrics including area under the survival curve (AUC-survival), growth rate-adjusted slope (GR-slope), and ΔG2/M% as well as clinical stage were standardized using z-score normalization and integrated into a composite RSI. Predictive performance of the RSI was assessed using receiver operating characteristic (ROC) curve analysis, and AUC, sensitivity, specificity, PPV, and NPV were calculated based on Youden's index. Kaplan-Meier analysis was performed to evaluate differences in survival outcomes according to RSI-predicted radiosensitivity.

Results All 14 PDOs successfully underwent irradiation assays, and multiparametric integration of AUC-survival, GR-slope, ΔG2/M%, and clinical stage yielded an individualized RSI value. The RSI effectively predicted recurrence after radiotherapy (AUC = 0.844, p = 0.039; sensitivity 80.0%, specificity 88.9%). In addition, the predicted recurrence probability was significantly higher in recurrent patients compared with non-recurrent patients. Survival analysis demonstrated a trend toward improved progression-free survival in the RSI-predicted radiosensitive group compared with the radioresistant group (median 42.3 vs. 15.5 months, p=0.257), suggesting concordance between RSI-based predictions and actual clinical outcomes.

Conclusions We successfully developed a personalized preclinical platform based on a cervical cancer PDO-derived RSI model. This is the first PDO-based approach that predicts individual radiosensitivity and validates these predictions against actual clinical outcomes. The RSI model may serve as a preclinical decision-support tool to personalize treatment decisions and guide radiotherapy optimization for cervical cancer patients.

#4868 Modelling glioblastoma sensitivity to irradiation with a patient derived xenograft-derived 3D platform.

Fu-Ju Chou[1], Annamaria Rapisarda[1], Marianna Zipeto[1], Michael Ritchie[1], Markus Hippich[1], Daniel Ciznadija[2], BanuPriya Sridharan[3], Veena Jagannathan[1], Gilad Silberberg[1], **Stefano Cairo**[1]

[1]Champions Oncology (Rockville, MD), Rockville, MD,[2]Champions Oncology, Hackensack, NJ,[3]Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

Glioblastoma (GBM) remains one of the most aggressive and treatment-refractory brain tumors, characterized by profound cellular heterogeneity, infiltrative growth, and intrinsic resistance to conventional therapies, including radiotherapy. To better understand differential tumor responses to irradiation, a series of short & long-term viability assays were conducted using glioblastoma patient-derived xenograft organoids (PDXO) to evaluate sensitivity to X-ray exposure. Multiple GBM models were included in the analysis, in a 4-day irradiation assay, & an expanded panel of ten models in a 14-day extended assay. Organoids were established in ultra-low attachment 96-well plates at defined seeding and cultured in triplicate. Following initial organoid formation, PDXOs were exposed to X-ray irradiation at doses of 2 Gray (Gy) for the short-term & 4 Gy for the extended assay. Endpoints included morphological assessment of three-dimensional structure formation, bright-field imaging, & quantitative viability measurements using the CellTiter-Glo® luminescent assay. Organoid size & integrity were monitored over time, focusing on structures measuring ≥50 µm in diameter. The 4-day assay revealed a general lack of sensitivity to irradiation across all tested models, suggesting that short-term exposure is inadequate for capturing delayed or cumulative cytotoxic effects typical of radiation-induced damage. In contrast, the 14-day assay, which incorporated both higher radiation dose & extended culture duration, successfully discriminated between irradiation-sensitive & resistant models. Several organoids displayed marked viability loss, reaching up to 92% reduction relative to control, while others displayed high viability, illustrating the broad heterogeneity of GBM responses to radiation. Analysis of molecular correlates revealed no consistent relationship between irradiation response and patient demographic variables, indicating that intrinsic tumor biology, rather than clinical factors, drives sensitivity. Notably, models harboring epidermal growth factor receptor (EGFR) amplification tended to exhibit enhanced susceptibility to irradiation, aligning with prior evidence implicating EGFR signaling in radiation response modulation. Conversely, models demonstrating resistance displayed transcriptional enrichment of mitochondrial integrity and oxidative stress-related pathways, implicating metabolic and redox homeostasis in radiotolerance. These data suggest that oxidative damage repair mechanisms and mitochondrial stress tolerance may serve as critical determinants of radiation resistance in GBM. Overall, this work underscores the importance of physiologically relevant, longitudinal preclinical models in guiding precision radiotherapy approaches for glioblastoma and in identifying novel targets to overcome therapeutic resistance.

#4870 Isolation, characterization and establishment of male breast cancer cells from male breast cancer patient-derived tumor (PDT).

Samikshya Kandel[1], Kathy Robinson[2], Ricardo Cosyleon[2], Daotai Nie[3], Krishna A. Rao[4]

[1]Medical Microbiology, Immunology and Cell Biology, Southern Illinois University School of Medicine, Springfield, IL,[2]SIU School of Medicine, Simmons Cancer Institute/Center for Clinical Research, Springfield, IL,[3]Southern Illinois University School of Medicine, Springfield, IL,[4]Professor, Internal Medicine, Medical Microbiology, Immunology and Cell Biology, Southern Illinois University School of Medicine, Springfield, IL

Breast cancer is one of the most common cancers worldwide, but it is more fatal and rarer among men. There are no male patient derived breast cancer cell lines commercially available, limiting research on breast cancers in the male patients. Consequently, most research and therapeutic approaches are largely based on female research subjects because of limited information on male mammary carcinoma. Thus, development of male breast cancer cell lines would provide an excellent biological and preclinical model to study male specific mammary carcinoma. This study aims to establish novel male breast cancer cell lines using tumors derived from male mammary carcinoma patients. Mammary tumors were obtained from three consented male breast cancer patients undergoing mastectomy at the Simmons Cancer Institute. The breast tumor tissues were minced, enzymatically digested overnight at 370c, strained using sterile strainer, and centrifuged to pellet the cells on the following day. The pellets were suspended in HUMEC Ready Mix media and cultured for several weeks until adherent epithelial cells started to grow. The epithelial cell populations were purified by positive flow sorting using EpCAM antibody (epithelial marker) and considered immortal upon reaching passage 20. Out of three tumor samples, two unique male breast cancer cell lines from two different tumor samples have been successfully cultured and named as male breast cancer cell-1(MBCC-1) and male breast cancer cell-2 (MBCC-2). During the flow sorting, MBCC-1, which is currently in passage-50, was noted to be 70% epithelial (EpCAM positive) while MBCC-2 cells, which are currently at passage-19, were 20% EpCAM positive. The average circularity and diameter of the MBCC-1 ranges between 0.6-0.8uM and 12-19 microns while the average population doubling time is forty-two hours. Further, MBCC-1 is capable of anchorage independent growth by soft agar colony formation assay and shows positive expression for Cytokeratin, CD24, CD44, ALDH1, cKIT, ki-67 but is negative for Collagen-IV and fibroblast activation protein (FAP) protein. Studies are ongoing to further characterize both the male breast cancer cell lines, including biomarkers, gene expression profiling, karyotyping, cell proliferation rate, soft agar colony formation assay, nutrient dependency tests, and tumorigenicity assays. In summary, two novel male breast cancer cell lines have been established for studying the biology of male breast cancers.

#4872 3D bioprinting of fresh NSCLC: The Lung3Dprint proof of concept study.

Aurelie Cadiou[1], Clarisse Thiollier-Schmitt[1], Gabrielle Devret[2], Raphaele Guelminger[3], Tanguy Fenouil[4], Corinne Perrin[5], Camille Leonce[1], Samantha Ballesta[6], Gaetan Pochon[6], Nicolas Alcala[7], Lars Petter Jordheim[1], Charles Dumontet[1], Michael Duruisseaux[1]

[1]Cancer Research Center of Lyon (CRCL), Lyon, France,[2]Service de chirurgie thoracique, Hopital Louis Pradel, Hospices Civils de Lyon, Lyon, France,[3]Hospices Civils de Lyon, Lyon, France,[4]Groupement Hospitalier Est, Institut de Pathologie Multisite - Site Est, Hospices Civils de Lyon, Bron, France,[5]Groupement Hospitalier Est, Tissu-Tumorotheque Est, CRB HCL, Hospices Civils de Lyon, Bron, France,[6]3D-ONCO platform, Cancer Research Center of Lyon (CRCL), Lyon, France,[7]International Agency for Research on Cancer, Lyon, France

3D bioprinted models are emerging to bridge the gap between 2D systems and animal models, advancing the efficiency and accuracy of preclinical workflows. This work aimed to (i) develop an innovative methodology to generate patient-derived bioprinted lung cancer (PDBLC) models that aim to reflect the heterogeneity of the parent tumor, and (ii) evaluate these models as a relevant ex vivo drug screening tool. Fresh Non-Small Cell Lung Cancer (NSCLC) samples were obtained from March to October 2025 at Hospices Civils de Lyon, dissociated and embedded into a fibrinogen-alginate-gelatin bioink (0.5 to 5x10^6 cells/mL of bioink). PDBLC models were obtained by extrusion-based bioprinting using a Cellink BIO X^{TM}, with post-conditioning polymerization using thrombin, transglutaminase, and calcium. PDBLC models were then placed in a dedicated lung cancer cell culture medium and analyzed at different time points, using a non-disruptive method (PrestoBlue^{TM} assay) and disruptive methods (flow cytometry and immunohistochemistry). Flow cytometry markers include EpCAM and CK-7/-8 to identify tumor cells, CD31 for endothelial cells, CD45, CD3, and CD19 for leukocyte infiltrate, and FAP, α-SMA and PDGFR-β for analysis of cancer-associated fibroblasts. Tumor and non-tumor cell contents were quantified as number of cells per object and their percentage of total live cells present. Nine samples have presently been bioprinted and analyzed. PrestoBlue^{TM} assay enabled non-specific monitoring of the model's metabolic activity over time. The median percentage of tumor cells in the bioink was estimated at 40% (range: 11 - 85). The percentage of viable tumor cells on days 7 and 14 were dependent on the initial concentration of cells in the bioink, ranging from 5 to 84%. The absolute number of tumor cells per PDBLC model tended to stabilize with time. The absolute percentage of viable tumor cells tended to increase between day 0 and day 14, with a median fold-change of 1.7-fold (range: -0.76 - 7.2). This was notably due to the decrease in the leukocyte infiltration as well as the endothelial subpopulation. Leukocyte subpopulation remaining 14 days after bioprinting was found to be T lymphocytes (CD45+ CD3+). Exposure of PDBLC models to conventional and targeted therapies used in NSCLC patients is ongoing and results will be presented. 3D bioprinting offers a relatively inexpensive and rapid means to evaluate fresh tumor samples. Our preliminary data show that our model not only supports fresh NSCLC cell survival for up to 22 days, but also maintains the primary tumor's heterogeneity over this period. The use of these 3D models as a drug-screening platform is being evaluated and would be relevant for translational research and clinical practice.

#4873 Reconstructing drug-tolerant persister (DTP) niches in iPSC-derived alveolar lung cancer organoids for spatio-temporal dissection of cell-cell interactions and ligand-receptor targets.

Toshio Suzuki[1], Harry Choi[2], Erik Johansson[2], Tetsuharu Nagamoto[2], Ayako Suzuki[3], Takuji Suzuki[1], Katsuya Tsuchihara[4], Yutaka Suzuki[3], Yuki Yamamoto[2]

[1]Department of Respirology, Chiba University, Chiba, Japan,[2]HiLung Inc., Kyoto, Japan,[3]Department of Computational Biology and Medical Sciences, Graduate School of Frontier Sciences, The University of Tokyo, Kashiwa, Japan,[4]Exploratory Oncology Research and Clinical Trial Center, National Cancer Center, Kashiwa, Japan

Purpose: TKIs and ADCs have transformed NSCLC therapy, yet most patients relapse without detectable resistant mutations due to drug-tolerant persister (DTP) cells. Although immune evasion and CAF-mediated remodeling are well recognized, the contribution of lung-specific epithelial and ECM components to protective niche formation remains unclear. Systems that recapitulate alveolar architecture are needed to reveal targetable mechanisms.
Methods: We developed a three-dimensional system, termed MicroEnvironment-Embedded Tumor in Fibroblast-integrated Organoid Alveolar MicroStructure (MEET-FOAms), by integrating human iPSC-derived alveolar organoids with NSCLC lines harboring *EGFR* exon19 deletion or *ERBB2* exon20 insertion. Organoids were exposed to osimertinib, erlotinib, or trastuzumab-deruxtecan. Longitudinal single-cell RNA-seq and Xenium 5K spatial transcriptomics mapped lineage trajectories, ligand-receptor networks, and ECM remodeling.
Results: Analysis of cancer cell clusters revealed that, even before drug exposure, a distinct subset persisted within the alveolar organoid background. These clusters lacked resistance mutations and were transcriptionally aligned with persister-like states, suggesting that the alveolar niche may inherently sustain DTP populations independently of drug pressure. Following TKI treatment, a stress-adaptive DTP subpopulation remained stable, relying on stromal-epithelial communication and ECM-receptor engagement. Under ADC exposure, an epithelium-associated DTP program was maintained via adhesion networks originating from alveolar epithelial cells, enabling protection from cytotoxic payload delivery. Spatial multi-omics profiling delineated organized multicellular interactions underpinning these responses. Intervention studies showed: (1) ADCs with bystander effect eliminated DTPs along with surrounding niche cells; (2) neutralizing CAF-derived factors suppressed DTP expansion; and (3) blocking ECM-related adhesion pathways disrupted persister maintenance.
Conclusions: With MEET-FOAms, we experimentally reconstructed lung cancer tissue architecture by introducing oncogene-driven NSCLC cells into a human iPSC-derived alveolar background, elucidating that persister-like clusters exist prior to therapy and are sustained by lung-specific niche interactions. Unlike prior models emphasizing CAFs or immune escape alone, this organoid platform highlights the underexplored role of alveolar epithelial cells and ECM in priming and maintaining DTP states. These findings suggest that such persister niches may act as reservoirs from which genetically resistant clones eventually emerge, supporting a paradigm expansion into therapeutic strategies that target multicellular remodeling in drug-tolerant NSCLC.

#4874 Preclinical assessment of HER2 CAR-T cells using tumor and GI organoid models to define therapeutic window.

Julia B. Schueler[1], Ina Rohleff[1], Tania Martianez Canales[2], Kanstantsin Lashuk[1], Youri von Elsswilk[2], Namrata Jayanth[2], Ludovico Buti[2]

[1]Charles River Laboratories, Freiburg, Germany,[2]Charles River Laboratories, Leiden, Netherlands

Anti-HER2 therapies have significantly improved outcomes for metastatic breast cancer patients with HER2+ tumors. Beyond antibody-based approaches such as trastuzumab, HER2-targeted CAR-T cells are emerging as promising options for solid tumors. However, the clinical translation of cancer therapies is often hindered by off-target toxicities, particularly in the gastrointestinal (GI) tract. CAR-T cells, can cause epithelial damage, leading to adverse events such as diarrhea and mucosal inflammation. To address this, we employed 3D iPSC-derived intestinal organoids (HIOs) as a human physiologically relevant model to assess GI toxicity. Using viability assays, cleaved caspase 3 and 7, we evaluated both direct cytotoxic and immune-mediated epithelial injury in HIOs co-cultured with PBMCs. In parallel, we investigated the efficacy of HER2-targeting CAR-T cells versus trastuzumab as positive control in HER2+ and HER2– human cancer cell lines (SK-OV3, JIMT-1, Hs578T) in 2D and 3D in vitro models. Tumor growth and invasion of the CAR-T cells was measured via fluorescence-based live cell imaging. On the last experiment day, a metabolic read-out (CellTiter-Glo, CTG assay) was performed. CAR-T cells demonstrated potent, dose-dependent cytotoxicity against HER2+ spheroids, including trastuzumab-resistant JIMT-1, while sparing HER2– Hs578T cells. Trastuzumab was effective only in SK-OV3. The un-transduced T cells proved to be ineffective. In parallel, the CAR T cells induced epithelial injury in the HIOs indicating possible safety concerns in later drug development stages. Also, in this assay the untransduced T cells from the same donor did not induce any cytotoxicity. In summary, the integration of intestinal organoid-based toxicity screening with tumor efficacy assays enabled a more precise definition of the therapeutic window for HER2 CAR-T cells. This dual-platform approach enhances preclinical evaluation by simultaneously capturing efficacy and GI safety, supporting the development of cell therapies with improved translational potential.

#4875 Modeling GBM-vasculature interaction on chip.

Promise Emeh[1], Alan Fetah[1], Jade Admiraal[1], Marleen Bokkers[1], Kevin Jimenez-Cowell[2], **Will Allen**[1], Nienke Wevers[1], Martine Lamfers[3], Clemens M. Dirven[2], Todd Burton[1], Karla Queiroz[1]

[1]MIMETAS B.V, Oegstgeest, Netherlands,[2]Department of NeuroSurgery, Erasmus MC-University Medical Center Rotterdam, Rotterdam, Netherlands,[3]Erasmus Medical Ctr., Rotterdam, Netherlands

Background: The tumor microenvironment (TME) of glioblastoma (GBM) is highly complex and dynamic, playing a pivotal role in tumor progression and therapeutic resistance. Comprising diverse components including blood vessels, immune cells, and the blood-brain barrier, the heterogeneous TME forms distinct niches that critically shape tumor behavior. Recent TME-based classification has delineated three subtypes TMELow, TMEMed, and TMEHigh distinguished by varying vascular and immune cell compositions.
Methods: This study focuses on elucidating the vascular interactions within the GBM-TME interface. To achieve this, we developed a brain-specific 3D vascular network by integrating primary human brain-derived endothelial and stromal cells within an extracellular matrix (ECM) on a microfluidic platform. Following the establishment of the brain vascular network model, GBM cell lines were incorporated to examine tumor-vasculature interactions in a 3D context. GBM integration was performed via two distinct strategies: co-seeding with vascular-forming cells within the ECM at the start of culture, or grafting tumor cells onto a pre-established vascular bed culture to facilitate invasion assays.
Results: The resulting perfusable model recapitulates key features of the brain vasculature, including the expression of adherens junction markers CD31 and VE-cadherin, tight junction marker Claudin-5, and the strategic alignment of stromal cells along vascular structures. Preliminary results from the integration of GBM in the vascular network model indicate that, irrespective of the seeding method, GBM cells preferentially localize along vascular structures, suggesting an intrinsic tropism toward the vasculature. Notably, co-cultures of GBM with vascular networks exhibited significantly higher proliferative and invasive capacity compared to GBM monocultures, highlighting the pro-tumorigenic influence of the vascular microenvironment.
Conclusion: The brain vascular network model demonstrates physiological relevance, robustness, and scalability making it suitable for medium- to high-throughput applications. This multifaceted platform offers a unique opportunity to functionally model and stratify GBM TME subtypes in vitro, with the potential to uncover novel therapeutic targets within the vascular and immune niches of the tumor ecosystem.

#4876 Cytokine supplementation for improved tumoroid-immune cell co-culture.

Shyanne Salen, **Colin D. Paul**, Sydney Hawkins, Matthew R. Dallas, David Kuninger

Thermo Fisher Scientific, Frederick, MD

Immunotherapies for solid cancers rely on robust engagement between immune and epithelial tumor cells within the tumor microenvironment. However, culture conditions that simultaneously sustain epithelial and tumor-infiltrating immune cell viability during short-term ex vivo culture remain poorly defined. Patient-derived tumoroids, multicellular organoid systems that recapitulate cancer cells in vitro but lack the immune cell component of tumors, enable interrogation of tumor-immune interactions in vitro via addback of immune cells. To explore an alternative approach, namely short-term co-culture of tumor and immune cells, we optimized OncoPro™ Tumoroid Culture Medium to promote immune cell survival and composition stability during culture of patient-derived dissociated tumor cell (DTC) digests. Initial studies showed that healthy donor PBMCs cultured in OncoPro medium alone lost approximately 80% of viable cells after 5 days. A design of experiments (DOE) screen of 13 cytokines and growth factors identified combinations that enhanced PBMC survival while maintaining balanced immune subpopulations. Among these, IL-2, GM-CSF, IL-15, IL-4, and BAFF emerged as candidates that increased PBMC cell counts relative to non-supplemented medium across multiple donors and helped preserve lymphocyte, monocyte, NK, helper T, and cytotoxic T cell proportions within 10% of baseline. Using this list of cytokine cocktails, we next assessed culture conditions supporting both immune ($CD45^+$) and epithelial ($EpCAM^+$) cell populations in colorectal cancer DTCs. Three donors were evaluated in a blocked DOE framework to control for donor variability. We evaluated both embedded culture where cells were encapsulated in Geltrex™ Flex matrix before media overlay, as well as suspension culture where cells were plated in OncoPro medium supplemented with Y-27632, 2% (v/v) Geltrex Flex matrix, and cytokines, and analyzed after 5 days by flow cytometry. Tube-based dissociation yielded ~25% higher recovery than in-plate dissociation, and bead-based enumeration cytometry using CountBright™ absolute counting beads agreed within ~25% of Trypan Blue-based counts made prior to staining samples for flow cytometry. Suspension culture favored immune cell viability, whereas embedding in Geltrex Flex matrix modestly improved tumoroid recovery but reduced $CD45^+$ cell survival. Across donors, cultures supplemented with IL-2, IL-15, GM-CSF, and BAFF achieved the highest total viable cell recovery and the lowest change in immune composition. Together, these results establish a cytokine-optimized medium that enhances immune cell viability and stability during short-term tumoroid co-culture, enabling improved modeling of the microenvironment and facilitating downstream studies of tumor-immune interactions and therapeutic response.

#4877 A high-throughput 3D tumor-immune co-culture platform for evaluating immune checkpoint inhibitors.

Laure-Anne Ligeon, Tabea Gamma, Zuzanna Kotkowska, Charlotte Veser, Irina Agarkova, Sue Grepper, Madhu Nag-LAL

Insphero, Schlieren, Switzerland

The development of immune checkpoint inhibitors (ICIs) requires preclinical models that accurately reflect interactions between human tumor and immune cells. Conventional 2D systems lack architectural and immunological relevance, and animal models often fail to capture human checkpoint regulation. There is therefore a strong need for physiologically relevant and scalable *in vitro* platforms to improve the predictive power of early-stage ICI evaluation.To address this need, we developed a high-throughput 3D tumor-immune co-culture platform to model checkpoint activity and quantify immune-mediated tumor responses. Tumor microtissues were generated in the Akura™384 format and treated to induce inhibitory ligand expression, while human immune cells were stimulated through defined co-stimulatory pathways to induce checkpoint receptor expression. After establishing the co-cultures, we applied reference ICIs or control antibodies and assessed responses using multiple assays. Apoptotic tumor cell death was quantified using Caspase-3/7 Glo®, and tumor integrity was monitored through fluorescence-based viability assays. Immune activation was evaluated using multiplex cytokine and cytolytic mediator profiling. High-content imaging was used to visualize immune-tumor interactions, spheroid structural changes, and immune infiltration depth, supported by automated segmentation workflows. Flow cytometry analysis provided phenotypic information on immune activation and checkpoint receptor modulation. To extend the platform beyond lymphoid checkpoints, we established a myeloid module in which pH-sensitive dye-labeled tumor spheroids were co-cultured with fluorescent macrophages to quantify phagocytic uptake.Checkpoint blockade enhanced immune effector function across these readouts. We observed increased caspase-3/7 activation and reduced viability of tumor spheroids. Cytokine profiling revealed elevated inflammatory and cytolytic mediator release, and imaging demonstrated deep immune penetration into the 3D architecture. Flow cytometry confirmed activation-associated immune phenotypes, while the myeloid module showed increased macrophage-tumor engagement and phagocytosis.In summary, this 3D co-culture platform provides a physiologically relevant, robust, and scalable system for characterizing human tumor-immune interactions and evaluating ICI activity. Its integration of microtissue engineering with multiparametric functional and phenotypic assays offered a translational approach for more predictive preclinical assessment and accelerated development of next-generation ICIs and biosimilars.

#4878 Modeling tumor microenvironment-mediated resistance in NSCLC using a high-throughput spheroid microarray platform.

Alireza Rahnama[1], Maddalena Arrighi[1], Ines Pulido Endrino[2], Takeshi Shimamura[2], Ian Papautsky[2]

[1]Biomedical Engineering, University of Illinois at Chicago, Chicago, IL,[2]University of Illinois at Chicago, Chicago, IL

Therapeutic resistance in EGFR- and KRAS-mutant non-small cell lung cancer (NSCLC) remains a major clinical challenge, often driven by dynamic interactions within the tumor microenvironment (TME). While third-generation EGFR inhibitors have improved outcomes, compensatory stromal signaling can undermine efficacy. Conventional models fail to capture paracrine-mediated resistance mechanisms. To investigate paracrine-mediated resistance mechanisms, a high-throughput spheroid microarray platform was developed to investigate how fibroblast- and endothelial-derived factors influence drug sensitivity across NSCLC genotypes. The platform was used to generate uniform 3D spheroids of NSCLC cell lines (H358, H1975, HCC827) harboring KRAS G12C or EGFR mutations. Agarose microwells were molded within standard 24-well plates using PDMS stamps fabricated by soft lithography. Spheroids were cultured in media conditioned by WI-38 fibroblasts, HUVEC endothelial cells, or both to simulate stromal signaling. Following a 72-hour treatment with osimertinib or adagrasib, spheroid viability was assessed using Calcein AM, Propidium Iodide, and Hoechst staining, followed by fluorescent imaging and quantitative analysis. Drug response was compared across conditions to evaluate TME-mediated resistance, with H1975 spheroids showing approximately 25% higher viability in HUVEC-conditioned media compared to control. Similarly, H358 spheroids exposed to WI-38-conditioned media showed attenuated response to adagrasib, consistent with prior findings. Combined fibroblast and endothelial conditioning further diminished drug efficacy, suggesting additive or synergistic effects. Spheroid viability remained high (>83%) across conditions, and uniformity was maintained (<22% coefficient of variance), supporting the platform's robustness for mechanistic studies. These findings highlight the role of soluble stromal factors in modulating therapeutic response and underscore the potential of this platform. Future integration with patient-derived organoids and multiplexed signaling analyses may uncover actionable targets to overcome resistance and guide combination strategies in EGFR- and KRAS-mutant NSCLC.

#4879 Bladder cancer organoids as a translational models to model disease biology and assess new therapies.

Emilie Decaup[1], Celine Rouget[1], Amandine Prioux-Quartier[1], Claire Beraud[1], Nadege Bidan[1], Xavier Game[2], Philippe Lluel[1]

[1]Urosphere, Toulouse, France,[2]CHU Toulouse, Toulouse, France

Background : Inter-patient heterogeneity in bladder cancer (BC) remains a major driver of treatment failure, highlighting the need for more personalized therapeutic approaches. Org anoids represent valuable preclinical models capturing this diversity. We established a BC organoid biobank comprising 20 models that have been extensively characterized at phenotypic, pharmacological and molecular levels. The aim of this study was to demonstrate the relevance of our biobank in terms of specifications and disease representation. In addition, we illustrated the utility of these models for evaluating targeted therapies, using Enfortumab-vedotin (EV) as a proof of concept.

Methods : Urothelial progenitors were isolated from tumor samples, seeded in Matrigel® and culture medium was added. Molecular characterization was performed by whole exome and transcriptome sequencing. Morphology of organoids was determined by optical microscopy. To evaluate targeted-therapy, organoids were treated with EV (from 0.3 to 10 µg/mL) for 5 days. Cell viability was measured with CellTiter-Glo3D® assay.

Results : All organoid models were developed following a strict quality framework: cultures were expanded beyond passage 6, cryopreserved, and demonstrated a 100% post-thaw recovery rate. The biobank captured the full pathological spectrum, from non-invasive pTa to metastatic pT4 stages. It reflected the anatomical diversity of urothelial carcinoma, with models derived from both bladder and ureteral tumors. Omics analyses revealed the presence of key molecular alterations commonly observed in BC patients, including FGFR3 and TP53 mutations. Organoid morphology, categorized as solid, hollow, or mixed, correlated with tumor stage and metastatic models exhibited features of epithelial-mesenchymal transition. For EV evaluation, we assessed Nectin-4 expression across the biobank and observed heterogeneous expression levels. Interestingly, organoid responses to EV were not strictly correlated with Nectin-4 expression with low response for models with high Nectin-4 expression.

Conclusion : Overall, our BC organoid biobank constitutes a high-quality collection of clinically annotated and comprehensively characterizes models ensuring robustness, stability, and reproducibility across experiments. It faithfully captured the pathological diversity and inter-patient heterogeneity observed in BC. These organoid models represent powerful tools for assessing novel targeted therapies, and the availability of a broad biobank enables the extrapolation of patient-specific responses, paving the way toward personalized medicine.

#4880 An in-vitro vascularized micro-tumor model of cervical cancer.

Daniela Gaebler, Christopher C. W. Hughes, Stephanie J. Hachey

University of California Irvine, Irvine, CA

Cervical cancer is a significant global health burden, ranking as the fourth most common cancer in women worldwide, with approximately 660,000 new cases each year, the majority of which occur in low- and middle-income countries. Despite the availability of preventive screening and HPV vaccination, cervical cancer remains a leading cause of cancer-related deaths, particularly in cases of advanced or recurrent disease. Current standard of care treatment approaches rely on a combination of cisplatin-based chemotherapy and radiotherapy. However, treatment resistance and disease recurrence continue to pose major challenges, underscoring the critical need for improved therapeutic strategies and more predictive preclinical models.
Currently, up to 95% of drugs that show promise in preclinical trials fail to receive FDA approval due to poor efficacy and tumor resistance. These high failure rates can be attributed to unphysiological testing conditions neglecting the tumor microenvironment, as well as poor model systems failing to predict drug-induced pharmacological responses in the human body. To address these shortcomings in cervical cancer research and reliably predict the efficacy of drugs intended for human use, we have invented a novel organ-on-a-chip platform called the vascularized micro-tumor (VMT). The VMT microfluidic device allows for the de novo formation of micro-vessels, which are cocultured with cancer cells and associated stroma. Critically, the micro-vessels enable the physiological delivery of nutrients, drugs and immune cells into the complex 3D tumor microenvironment and hence constitute a powerful tool for physiological disease modeling and drug screening approaches. Here, we present the establishment of a cervical cancer VMT model based on well-characterized, commercially available tumor cell lines and demonstrate treatment responses to standard of care cisplatin-based chemotherapy and radiotherapy.

#4881 Fabrication and characterization of echogenic microbubbles for in vitro modeling of blood-brain barrier (BBB) disruption via focused ultrasound.

Nathan Han[1], Nabhan Fakrudin[2], Frederic Zenhausern[2], Jian Gu[2]

[1]Duke University, Durham, NC,[2]University of Arizona, Phoenix, AZ

The blood-brain barrier (BBB) presents a major obstacle to the delivery of many promising pharmacological agents to the central nervous system. The BBB is composed of tightly connected endothelial cells that regulate molecular exchange to maintain brain homeostasis. While this is beneficial for protecting the brain, over 98% of small-molecule and almost 100% of large-molecule drugs are blocked by the BBB, limiting treatment options for neurological diseases. Recently, bubble-assisted focused ultrasound (BaFUS) has emerged as a non-invasive strategy to transiently disrupt the BBB and facilitate targeted drug delivery by injected gas bubbles in the bloodstream. We previously developed a custom ultrasound-transparent organ-on-chip (UST-OoC) platform for modeling BaFUS-mediated BBB disruption *in vitro*. In this study, we report on the optimization and characterization of a microbubble formulation for use in BaFUS. Microbubbles were synthesized using a phospholipid-based protocol and characterized by dynamic light scattering (DLS) and zeta potential measurements. The formulation produced ~1 µm microbubbles with a neutral zeta potential and a concentration of 2.4×10^{10} bubbles/mL. Acoustic testing showed strong, sustained bubble cavitation across flow rates of 150-300 µL/min. An acoustic dose-response sweep revealed non-linear stable cavitation and inertial cavitation thresholds to be 0.08 and 0.32 MPa. These lab-fabricated microbubbles have the advantages of low cost and easy adjustment of size and concentration. The UST-OoC platform enables human-based *in vitro* modeling for real-time visualization of barrier disruption, quantitative permeability assessment, and systematic optimization of acoustic parameters, including pressure, frequency, and duty cycle under controlled flow conditions. This integrated system provides a scalable, reproducible preclinical tool for evaluating microbubble performance and BaFUS protocols prior to *in vivo* translation. By establishing human-based BBB models, standardized methods for microbubble fabrication, acoustic characterization, and barrier disruption modeling, this platform addresses key translational gaps in developing BaFUS-enhanced drug delivery for brain disorders.

#4885 Association of an ectopic upper gastrointestinal microbiome with multiple primary lung cancers: A multi-site cross-sectional study.

Guotian Pei[1], Yaqiong Guo[2], Na Lyu[3], Yuqing Huang[1]

[1]Department of Thoracic Surgery, Beijing Haidian Hospital (Haidian Section of Peking University Third Hospital), Beijing, China,[2]Institute of Biotechnology and Health, Beijing Academy of Science and Technology, Beijing, China,[3]CAS Key Laboratory of Pathogenic Microbiology and Immunology, Chinese Academy of Sciences, Beijing, China

Background: The etiology of multiple primary lung cancers (MPLC), defined by their independent multifocal origins, remains largely unknown, particularly the contribution of the microbiome. Gastroesophageal reflux disease (GERD) is an established risk factor for lung cancer, but its specific association with MPLC and the potential for GERD-mediated translocation of upper gastrointestinal (UGI) microbiota into pulmonary nodules (PNs) has not been investigated. We hypothesized that GERD facilitates UGI-to-lung microbial translocation, contributing to a pro-carcinogenic microenvironment in MPLC.
Materials and Methods: In this prospective case-control study (NCT06973499), GERD symptom burden was assessed in 149 MPLC, 41 solitary primary lung cancer (SPLC), and 119 healthy controls using the validated GERD-Q questionnaire. For a subset of 21 MPLC patients, we performed comprehensive multi-site microbiome profiling using PacBio full-length 16S rRNA gene sequencing on samples from seven anatomical compartments, including the UGI tract and multiple resected PNs. Rigorous contamination controls were employed. Microbial source tracking (SourceTracker2) was used to quantify UGI bacterial translocation, with strain-level identity confirmed via phylogenetic analysis.
Results: MPLC patients exhibited a significantly higher prevalence of high-risk GERD symptoms (GERD-Q score >8) compared to healthy controls (26.2% vs. 16.0%; OR = 1.87, 95% CI 1.01-3.44, P=0.048); this association was not observed in SPLC patients (P=0.87). Crucially, microbial source tracking identified a significant, ectopic UGI-derived bacterial signature in 22.9% of PNs (8 of 35 nodules) from MPLC patients. Linking the symptom to the microbe, a post-hoc analysis revealed a strong trend where MPLC patients with a high GERD burden showed a greater proportional contribution of UGI microbiota to their PNs compared to those with a low GERD burden (P = 0.0692). Finally, high-resolution phylogenetic analysis confirmed shared, identical strains of *Prevotella melaninogenica* and *Gemella haemolysans* across UGI and pulmonary sites within the same individuals, providing definitive evidence of active translocation.
Conclusion: This study provides the first direct, multi-site evidence linking GERD symptom burden to the active translocation of UGI microbiota into pulmonary nodules in MPLC patients. We introduce the 'GERD-microbial translocation-multifocal carcinogenesis' axis as a novel pathogenic pathway that may contribute to the etiology and heterogeneity of MPLC. Our findings identify the UGI-lung axis as a potential target for novel diagnostic and therapeutic strategies, suggesting that managing GERD or targeting the translocated pathobiome could represent a new paradigm for MPLC prevention or interception.

#4886 Integrative analysis reveals bacterial load as a determinant of molecular and immune phenotypes in colorectal cancer.

Subha Singh[1], Travis D. Kerr[1], Melissa Lumish[2], Ying Ni[1], Natalie Silver[1], Daniel McGrail[1]

[1]Cancer Sciences, Cleveland Clinic Research, Cleveland, OH,[2]Department of Hematology and Oncology, University Hospitals Seidman Cancer Center, Cleveland, OH

Colorectal cancer (CRC) ranks as the third most frequently diagnosed cancer and the second leading cause of cancer deaths globally. The incidence and mortality rates vary widely across regions, being highest in developed countries but it is increasing rapidly in low- and middle-income nations due to aging population, urbanization and adoption of Western lifestyles. Phenotypically, CRC can broadly be divided into tumors with microsatellite instability (MSI) and those that are microsatellite stable (MSS). MSI tumors typically arise in the right colon and are driven by hypermutation from loss of function in DNA mismatch repair (MMR) genes, such as *MLH1* or *MSH2*. We recently found that the overall bacterial load in a tumor, rather than relative abundance of any specific taxa, is the primary driver of microbial-based immunosuppression in head and neck squamous cell carcinoma. However, how bacterial load is associated with clinicopathological features and molecular phenotypes of CRC remains unknown. To address this, we performed a comprehensive analysis of bacterial load in CRC tumors. We found that bacterial load was independently enriched in both MSI tumors and tumors with lymphatic invasion. After controlling for MSI status, tumors with high bacteria were more likely to be *TP53* and *APC* wildtype and exhibited elevated inflammatory signaling at both the gene and protein level. Further analysis of systems-level metabolic rewiring indicated elevated levels of glycoprotein metabolism in high bacterial tumors, which have previously been associated with bacteria adhesion to tumor cells. Together, these findings offer the first landscape of how the bacterial load is associated with clinicopathological and molecular alterations, which may have implications for patient prognosis and treatment strategies.

#4887 Mapping the cellular landscape of intratumoral bacteria in colorectal cancer using single-cell transcriptomics.

Ian Wesley Folkert[1], Abderrahman Day[2], Ashish Damania[2], Matthew C. Wong[2], Taylor Neilson[3], Ryan Morgan[3], Scott Kopetz[4], Joshua Smith[5], Jennifer A. Wargo[4], Nadim J. Ajami[2], John P. Shen[6], Michael Geoffrey White[4]

[1]Department of Surgery, Penn Medicine, Philadelphia, PA,[2]Department of Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Surgical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]UT MD Anderson Cancer Center, Houston, TX,[5]Department of Colon & Rectal Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX,[6]Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Tumor-associated microbes are increasingly investigated across cancer types. In CRC, intratumoral microbes are associated with detrimental treatment responses and clinical outcomes. However, critical gaps remain in understanding how individual cells within the TME respond to microbial presence. Defining these cellular responses could provide mechanistic insights into microbe-host interactions in cancer and reveal novel therapeutic targets.

To map the cellular landscape of intratumoral bacteria in CRC, we developed a custom analytical pipeline integrating single-cell transcriptomics with metagenomic profiling. We performed scRNA-seq on 150 samples from 146 CRC patients across 85 primary tumors, 60 liver metastases, and 5 peritoneal metastases. Unsupervised clustering was performed using Seurat 5.1.0, with cells annotated using PanglaoDB and canonical markers. Single-cell reads were aggregated and mapped against NCBI and SILVA databases.

Starting with $1.09x10^9$ reads from 650,485 cells, we applied stringent quality filters including trimming, human genome filtering (removing 98.7% of reads), and a custom k-mer diversity filter to exclude likely contaminants. This final filter eliminated 96% of remaining reads and 92% of initially identified taxonomies, addressing the challenge of ambient contamination in scRNA-seq data. Our pipeline ultimately retained 18,115 high-confidence bacterial reads (<0.001% of total) from 4,888 cells (0.8%), representing 1,237 unique taxa. After contaminant exclusion, we identified 89 species across 48 genera, including Bacteroides fragilis, Parvimonas micra, Gemella morbillorum, and Fusobacterium nucleatum. Bacterial reads were mapped to cells using barcodes. Clustering identified 16 cell populations with bacterial signals across all major cell types and tumor sites. In this exploratory single-cell analysis, cells from primary colon tumors exhibited increased bacterial diversity compared to cells from liver metastases ($p<0.01$). Within primary colon tumors, cells from MSI-H tumors (n=15) demonstrated significantly higher bacterial reads than cells from MSS tumors (n=67, 95% CI [2.425, 12.691], $p = 0.006$). Furthermore, the presence of bacteria-positive cells in primary colon tumors was associated with significantly worse patient survival compared to tumors without detectable intracellular bacteria (HR 4.90, 95% CI [1.08, 22.2], $p = 0.039$).

Our findings demonstrate that bacterial reads, although present at extremely low abundance, can be retrieved from scRNA-seq data when stringent contamination controls are applied. The taxonomic resolution achieved provides proof-of-concept for investigating microbe-host interactions at single-cell resolution. This study establishes a methodological foundation for leveraging single-cell technologies to probe the complex interplay between tumors and their microbiome.

#4888 Association of intratumoral *Fusobacterium nucleatum* with stromal remodeling and immune exclusion in esophageal squamous cell carcinoma.

Takashi Ofuchi[1], Qingjiang Hu[2], Kosuke Kanemitsu[1], Koshi Mimori[2], Masaaki Iwatsuki[1]

[1]Kumamoto University Hospital, Kumamoto, Japan,[2]Kyushu University Beppu Hospital, Beppu, Japan

Background: *Fusobacterium nucleatum* (*F. nucleatum*), an oral anaerobe, has been linked to tumor progression and immune suppression in esophageal squamous cell carcinoma (ESCC). However, its relationship with stromal remodeling and immune exclusion within the tumor microenvironment (TME) remains unclear.

Methods: We performed integrated analyses combining metagenomic profiling, transcriptomic deconvolution, and histopathologic validation in 93 TCGA-ESCC cases and 126 resected tumors. *F. nucleatum* status was determined using Centrifuge and quantitative PCR. Immune and stromal cell fractions were estimated by CIBERSORT and EPIC. Immunohistochemistry (IHC) for α-smooth muscle actin (α-SMA) and NF-κB p65 (RelA) assessed cancer-associated fibroblast (CAF) activation and inflammatory signaling, and fluorescence in situ hybridization (FISH) visualized *F. nucleatum* within tumors. Clinicopathologic variables, including ECOG performance status, were compared between *F. nucleatum*-positive and -negative cases.

Results: Twenty-three of 93 TCGA-ESCC tumors (25%) were *F. nucleatum*-positive (≥0.02% relative abundance). Gene set enrichment analysis revealed activation of TNFα/NF-κB and epithelial-mesenchymal transition pathways in *F. nucleatum*-positive tumors. CIBERSORT showed reduced $CD8^+$ T-cell infiltration, while EPIC demonstrated a higher CAF fraction (0.72 vs. 0.45, $P < 0.01$). In the validation cohort, IHC confirmed increased α-SMA expression in *F. nucleatum*-positive tumors, consistent with transcriptomic results. FISH identified *F. nucleatum* signals within tumor cells adjacent to α-SMA-positive fibroblasts, suggesting spatial proximity between infection and stromal activation. Nuclear RelA localization was significantly more frequent in *F. nucleatum*-positive tumors, indicating NF-κB activation. Cases with both strong α-SMA expression and nuclear RelA were markedly enriched in the *F. nucleatum*-positive group ($P < 0.01$). These findings support a model in which *F. nucleatum* activates NF-κB-mediated cytokine signaling that promotes fibroblast recruitment and stromal expansion, contributing to immune exclusion. Clinically, *F. nucleatum* positivity was associated with poorer performance status despite similar tumor stages, suggesting colonization may reflect systemic vulnerability or impaired oral hygiene.

Conclusions: Intratumoral *F. nucleatum* is associated with an NF-κB-activated, fibroblast-rich, and $CD8^+$ T-cell-poor TME in ESCC. By promoting stromal remodeling and immune exclusion, *F. nucleatum* may enhance tumor aggressiveness. These findings highlight the interplay between microbial colonization, stromal activation, and host condition, offering insight into potential microbiome-stroma-immune interactions in ESCC.

#4889 Distinct tumor microbiome profiles in triple negative breast cancer compared to other breast cancer subtypes: A pilot study.

Yangbo Sun, Chi-Yang Chiu, Jay H. Fowke, Karen Johnson

University of Tennessee Health Science Center, Memphis, TN

Background: Emerging evidence suggests that the tumor microbiome may influence breast cancer biology and therapeutic responses. However, few studies have characterized microbial differences across breast cancer subtypes, particularly triple-negative breast cancer (TNBC), which tends to have poor prognosis and limited targeted therapies, compared with other subtypes. We conducted a pilot study to compare the microbiome in TNBC versus other subtypes.

Methods: DNA was extracted from 25 formalin-fixed paraffin-embedded (FFPE) tumor tissues, including 4 TNBC cases and 21 non-TNBC cases. 16S rRNA gene sequencing was performed to characterize bacterial composition. Relative abundance was analyzed at multiple taxonomic levels. Differential abundance between TNBC and other subtypes was evaluated using linear regression.

Results: Distinct microbial signatures were observed between TNBC and other subtypes. At the phylum level, TNBC tissues were enriched in *Fusobacteriota* compared with non-TNBC tissues (*p* value=0.03). At the family level, TNBC tissues showed higher relative abundance of *Dermacoccaceae*, *Fusobacteriaceae*, and *Rikenellaceae*, and lower abundance of *Oscillospiraceae (p* values<0.05*)*. At the genus level, TNBC tumors were enriched in *Dermacoccus*, *Rothia*, and *Alistipes*, while *UCG-002* was reduced compared to other subtypes (*p* values <0.05).

Conclusions: This pilot study reveals distinct microbial composition in TNBC tissues compared with other breast cancer subtypes, characterized by enrichment of *Fusobacteriota* and specific genera such as *Dermacoccus* and *Rothia*. These findings suggest potential microbiome-mediated mechanisms contributing to TNBC biology and warrant validation in larger, well-annotated cohorts.

#4890 Patients with high body mass index share tumor microbial profiles with CpG island methylator phenotype-high or early-onset colorectal cancers.

KuoHsing Chen[1], Jyh-Shiuan Hsu[2], Yu-Li Su[3], Shih-Chiang Lin[4], Been-Ren Lin[5], Kai-Lung Tsai[6], Li-Ming Tseng[7], Yi-Hsin Liang[8], Jia-Huei Tsai[9], Chien-Chen Tsai[10], Ting-Ting Liu[11], Mong-Hsun Tsai[12], Kun-Huei Yeh[13]

[1]Medical Oncology, National Taiwan University Cancer Center (NTUCC), Taipei City, Taiwan,[2]Institute of Biotechnology, National Taiwan University, Taipei, Taiwan., Taipei City, Taiwan,[3]Division of Hematology Oncology, Department of Internal Medicine, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan,[4]Oncology and Hematology, Far Eastern Memorial Hospital, New Taipei City, Taiwan,[5]Surgery, National Taiwan University Cancer Center, Taipei, Taiwan,[6]Division of Colon & Rectal Surgery, Kaohsiung Chang Gung Memorial Hospital,, Kaohsiung, Taiwan,[7]Division of Colorectal Surgery, Far Eastern Memorial Hospital, New Taipei City, Taiwan,[8]National Taiwan University College of Medicine, Taipei, Taiwan,[9]Department of Pathology, National Taiwan University Hospital, Taipei, Taiwan,[10]Department of Anatomical pathology, Far Eastern Memorial Hospital, New Taipei City, Taiwan,[11]Department of Anatomic Pathology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan,[12]Institute of Biotechnology, National Taiwan University, Taipei, Taiwan,[13]Dept. of Oncology, National Taiwan University Hospital, Taipei, Taiwan

BackgroundTumor microbiota plays a significant role in colorectal cancer (CRC) by influencing tumor development and progression. Our previous study demonstrated a significant association between high body mass index (high BMI, BMI ≥ 27.5 kg/m^2) and CpG island methylator phenotype-high (CIMP-high) in early-onset CRC (EOCRC, age < 50y). The present study investigates whether tumor microbiota may mediate this association in CRC.

Materials and methods We enrolled 140 patients with CRC and 30 patients with polyps from the biobank of National Taiwan University Hospital, respectively. The tumor and adjacent normal part in each tumor or polyp were collected. V3-V4 regions of bacterial 16S ribosomal RNA gene were amplified and then amplicons were sequenced on the MiSeq system. Patients' clinicopathological characteristics were also recorded. CIMP status was defined by using a 5-gene panel (*p16, MINT1, MINT2, MINT31 and MLH1*) and MethyLight assay. Analysis of diversity and LefSe (Linear discriminant analysis Effect Size) of tumor microbiota were performed and the results were compared between each subgroup.

ResultsIn total, 121 CRC tumors (CRC-T), 115 adjacent normal (CRC-N) and 26 polyps (polyp-T and polyp-N) passed the quality control (sequencing depth > 5000 reads). Microbiota α diversity is significantly lower in CRC compared to that in polyps (p = 1.3 x 10^{-11}). Microbiota α diversity is also reduced in CRC patients with high BMI compared to those with low BMI (p = 0.042). LefSe analyses revealed specific microbiota enriched in each subgroup, including EOCRC, high BMI, and CIMP-high. The Venn diagram revealed multiple overlapping bacteria taxa between the high BMI and the CIMP-high or EOCRC subgroups.

ConclusionWe found the diversity of microbiota in CRC with high BMI is significantly lower than that in CRC with low BMI and identified specific bacteria taxa shared between high BMI and CIMP-high or EOCRC tumors. The clinical applications of these bacterial taxa warrant further exploration.

#4891 Paired metagenomic profiling reveals site-specific microbial composition and conserved diversity in the oral cavity of head and neck cancer patients.

Jada Tschetter[1], Rachel Elsey[2], McKenna Perrin[2], David Starks[2], Benjamin Solomon[2], William Spanos[2], Sarah Viet[3], Cody Silvernail[3], Jason L. Petersen[3], Erik A. Ehli[3], Tobias Meissner[2], Casey T. Finnicum[3]

[1]Sanford School of Medecine, University of South Dakota, Vermillion, SD,[2]Avera Cancer Institute, Sioux Falls, SD,[3]Genetics, Avera McKennan, Sioux Falls, SD

Background: The extent to which microbial diversity and composition vary across oral subsites within an individual remains poorly defined, limiting the reproducibility of microbiome-based biomarkers and the standardization of sampling strategies. We investigated compositional and diversity differences between paired tonsil and saliva samples to characterize microbial ecology across oral compartments in HNC patients.

Methods: Paired tonsil and saliva samples were collected from 25 patients diagnosed with head and neck squamous cell carcinoma (NCT05142033) (median age = 63 years [IQR 53-73]; 76% male, 96% White). The cohort included 68% oral cavity, 20% oropharyngeal, 8% laryngeal, and 4% cutaneous primaries. Shotgun metagenomic sequencing was performed on all samples. Beta diversity was assessed using paired permutational multivariate analysis of variance (PERMANOVA) on Bray-Curtis dissimilarity matrices with restricted permutations to account for individual variation. Species-level differential abundance was tested using paired Wilcoxon signed-rank tests with false discovery rate (FDR) correction. Additionally, alpha diversity metrics were compared between sites.

Results: Microbial composition differed significantly between tonsil and saliva samples (PERMANOVA: $F=1.00$, $R^2=2.0\%$, $p=0.001$). Twenty species showed significant abundance differences after FDR correction ($q<0.05$). Fifteen species were increased in saliva versus tonsils, including *Rothia aeria* (FDR=0.004), *Actinomyces naeslundii* (FDR=0.008), and *Streptococcus sanguinis* (FDR=0.009). Five species decreased in saliva, including *Prevotella scopos*, *Prevotella jejuni*, and *Campylobacter concisus*. Despite compositional differences, alpha diversity metrics were equivalent between sites (Shannon index: tonsil 3.73±0.59 vs saliva 3.71±0.70, $p=0.565$; observed species: 3135±1567 vs 3251±1228, $p=0.708$). Individual-level differences in evenness significantly correlated with compositional dissimilarity (Spearman rho=0.450, $p=0.024$), indicating that diversity and composition co-vary within individuals.

Conclusions: Tonsil and saliva harbor distinct microbial communities yet maintain equivalent species diversity levels. This pattern demonstrates niche conservatism in the oral cavity. The paired study design was essential for detecting these differences, as massive individual variation dominated over site-specific effects. These findings have implications for understanding oral microbiome ecology in head and neck cancer and suggest that sampling site selection is critical for microbiome-based biomarker discovery.

#4892 Janus villus chip identifies an anaerobic probiotic that suppresses tumor growth in mice.

Saeyeon Shin[1], **Jaeyoung SHIN**[2], Gwan Myeong Seo[3], Hyungji Jo[4], Sejong Oh[1], Sungsu Park[3]

[1]Animal Science, Chonnam National University, Gwangju, Korea, Republic of,[2]OrganoPlus, Suwon, Korea, Republic of,[3]Mechanical Engineering, Sungkyunkwan University, Suwon, Korea, Republic of,[4]Metabiohealth, Sungkyunkwan University, Suwon, Korea, Republic of

Chronic intestinal inflammation disrupts epithelial integrity and reshapes the tumor immune microenvironment (TIME), accelerating colorectal cancer progression. We investigated how the strict anaerobic mucin-binding probiotic *Bifidobacterium adolescentis* OP820 modulates inflammation-driven epithelial and immune dysfunction using a Janus oxygen-gradient villus chip and in vivo models. Because *Bifidobacterium* requires strict anaerobic conditions for viability and physiological activity, the villus chip—engineered with an anaerobic apex and oxygenated base to reproduce the native villus oxygen gradient—was essential for accurately modeling OP820-epithelium interactions. Under these conditions, epithelial cells upregulated *MUC13* and *MUC17*, generating a mucin-rich glycocalyx to which OP820 adhered strongly, reflecting its natural niche preference. Transcriptomic profiling revealed that OP820 modulates inflammatory signaling by elevating CCL8, TGFA, and MMP12—genes linked to epithelial repair and immunoregulatory remodeling—while suppressing TSLP, FLT3LG, and IL18, which are typically associated with heightened inflammatory stress. These coordinated shifts indicate that OP820 promotes a resolution-oriented immune state rather than amplifying inflammation. The effects were consistent across monolayer, spheroid, and villus-chip models, underscoring the robustness of OP820's immunomodulatory activity under strict anaerobic conditions that reflect its physiological habitat. In vivo, OP820 demonstrated dual therapeutic activity. In the DSS-induced colitis model, it attenuated mucosal injury and preserved epithelial structure, supporting its inflammation-resolving function. In the colorectal cancer xenograft model, intravenous OP820 administration significantly reduced tumor burden, and OP820 cells were detected within the tumor microenvironment, suggesting that intratumoral localization may underlie its immune-modulating and tumor-suppressive activity. The presence of a strict anaerobe within tumors implies the existence of permissive micro-niches and points to direct modulation of local cytokine or stromal networks. Collectively, these findings identify OP820 as a microbiome-derived therapeutic capable of reinforcing epithelial barrier recovery and reprogramming inflammation-driven tumor microenvironments. By integrating villus-chip modeling with in vivo validation, this study highlights OP820's potential as a mechanism-based intervention for inflammation-associated colorectal cancer.

#4893 Profiling the ovarian cancer-specific intratumoral microbiome.

Ryosuke Sonobe, Miho Suzuki, Keiko Shinjo, Yutaka Kondo

Division of Cancer Biology, Graduate School of Medicine, Nagoya University, Nagoya, Japan

Interactions between tumors and their associated microbiota have recently emerged as a novel dimension of cancer biology. These microbes can influence tumor initiation, immune evasion, and therapeutic response. Although several cancers, such as colorectal and esophageal cancer, harbor distinct microbial communities that shape their tumor microenvironment, the presence and functional relevance of intratumoral bacteria in ovarian cancer, the most lethal gynecologic malignancy, remain largely unexplored. Using pan-bacterial 16S rRNA fluorescence in situ hybridization (FISH), we detected bacterial signals in approximately 60% of ovarian cancer specimens, whereas benign ovarian tissues were nearly negative. The signals were predominantly localized (>80%) within the tumor stroma. To further characterize the bacterial composition, 16S rRNA sequencing identified a unique intratumoral microbiota dominated by *Phyllobacterium, Rhodococcus* and *Fusobacterium*. To assess the biological impact of these bacteria, we established an in vivo mouse model by introducing the ovarian cancer-resident bacteria via intraperitoneal injection, followed by transplantation of mouse ovarian cancer cells. Tumor growth was approximately 3-fold higher in bacteria-exposed mice than in controls. These findings demonstrate that bacterial exposure can enhance tumor progression, potentially through remodeling of the tumor microenvironment. Collectively, our results reveal that ovarian cancer harbors a distinct, stromal-localized intratumoral microbiota that contributes to tumor progression. We propose that bacterial colonization of the tumor stroma may act as a chronic inflammatory niche, promoting fibroblast activation, angiogenesis, and immune modulation.

#4894 *Pseudomonas*-derived LPS promotes metastatic behavior in papillary thyroid cancer metastasis is attenuated by Hashimoto's thyroiditis.

Yue Che, Wei Kou, Haoran Feng, Qiwu Zhao, Zhuoran Liu, Jie Kuang, Weihua Qiu

Department of General Surgery, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Intratumoral microbiota can influence cancer progression through immune and metabolic interactions. Papillary thyroid cancer (PTC) frequently coexists with Hashimoto's thyroiditis (HT), an autoimmune condition that remodels the tumor immune microenvironment. However, how microbe-derived molecules contribute to PTC metastasis, and how autoimmune cytokines modulate these effects, remains poorly understood.

Methods: Tumor and matched adjacent tissues from 75 PTC patients were analyzed using 16S rRNA sequencing, and microbial functional pathways were inferred with PICRUSt2. The pro-metastatic activity of *Pseudomonas*-derived lipopolysaccharide (LPS) was evaluated using wound-healing and Transwell assays, with polymyxin B to confirm LPS specificity. NF-κB activation and EMT markers were analyzed by Western blotting. To model the autoimmune cytokine milieu of HT, PTC cells were treated with recombinant IFN-γ. For *in vivo* validation, LPS-stimulated PTC cells were injected intravenously into NCG mice to establish a spontaneous lung metastasis model.

Results: Patients with lymph node metastasis (LNM) exhibited increased *Pseudomonas* abundance and enhanced predicted LPS biosynthetic activity. In contrast, HT^+ tumors showed reduced *Pseudomonas* levels and diminished LPS pathway activity compared with HT^- tumors. After adjusting for age and TNM stage, *Pseudomonas* abundance remained positively associated with LNM within the HT subgroup. Propensity score-matched mediation analysis further indicated that HT conferred a protective effect against LNM, whereas the pro-metastatic effect of *Pseudomonas* partially counteracted this protection. *In vitro*, *Pseudomonas*-derived LPS promoted PTC cell migration and invasion in a dose- and time-dependent manner through TLR4-NF-κB activation, accompanied by increased phosphorylated NF-κB and N-cadherin; these effects were substantially diminished by polymyxin B. Under an HT-like cytokine environment, IFN-γ markedly attenuated both LPS-induced NF-κB activation and invasive behavior. *In vivo*, mice receiving LPS-pretreated PTC cells developed significantly more pulmonary metastatic foci.

Conclusions: *Pseudomonas* functions as a potential pro-metastatic bacterium in PTC with its LPS promoting PTC cell invasiveness through TLR4-NF-κB-EMT pathway. HT is associated with reduced *Pseudomonas* abundance, weakening this pro-metastatic signaling and contributing to the lower LNM risk observed in HT patients. These findings highlight the importance of microbial-immune interactions in PTC metastasis and suggest potential therapeutic targets for PTC prevention and treatment.

#4895 *Helicobacter pylori*-driven T cell stress in tumors as a mediator of resistance to immune checkpoint blockade in gastric cancer.

Donghyeok Seol[1], Jieun Lee[1], Junwoo Jo[2], Chanmi Bang[1], Hyeon Jeong Oh[1], Sejoon Lee[1], Mira Yoo[1], Duyeong Hwang[1], So Hyun Kang[1], Young Suk Park[1], Sang-Hoon Ahn[1], Masami Yamamoto[3], Tetsuya Tsukamoto[4], Sachiyo Nomura[5], Qi Su[6], Seong-Ho Kong[7], Do Joong Park[7], Hyuk-Joon Lee[7], Hyung-Ho Kim[1], Charles Lee[8], Han-Kwang Yang[7], Sunjae Lee[9], Yun-Suhk Suh[1]

[1]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of,[2]Gwangju Institute of Science and Technology, Gwangju, Korea, Republic of,[3]Nippon Veterinary and Life Science University, Tokyo, Japan,[4]Fujita Health University, Toyoake, Aichi, Japan,[5]Hoshi University, Tokyo, Japan,[6]The Chinese University of Hong Kong, Hong Kong SAR, China,[7]Seoul National University College of Medicine, Seoul, Korea, Republic of,[8]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[9]Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of

The influence of microbiota residing within tumors on patient response to immunotherapies for gastric cancer (GC) is not yet fully understood. We aim to define the characteristics and functional role of tumor-resident microbiota in the context of immune checkpoint inhibitor (ICI) efficacy in GC. A comprehensive multi-omics analysis was performed on samples from 137 GC patients, all of whom were treatment-naïve regarding chemo- or antibiotics. This extensive dataset included both metagenomes and host transcriptomes, with single-cell RNA sequencing data. To achieve accurate quantification, we developed a novel tumor-resident microbial index (TM index) that compared taxon-level load between tumor tissue and matched normal tissue. Treatment responses were subsequently validated using syngeneic mouse models with a cancer-bacteria co-culture platform. Abundance analyses consistently highlighted *Helicobacter pylori* as the only species significantly decreased in tumor tissue compared to paired normal tissue. Metagenome-assembled genomes showed patient-specific *H. pylori* strains, maintaining over 99% genomic identity across the paired samples. The TM_{HP} index indicated that high levels of *H. pylori* were predominantly found in the genomically stable (GS) subtype, characterized by a partially preserved normal physiology. Single-cell RNA sequencing data showed that *H. pylori*-infected cells exhibit a signature of elevated T cell stress, correlating with the overexpression of *HSPA1A*. Critically, *H. pylori* significantly compromised the therapeutic effectiveness of anti-PD-L1 by reducing the infiltration of T cells in mouse models. However, a negative effect was not observed with standard 5-fluorouracil or oxaliplatin treatments. Our findings implicate *H. pylori* as a mediator of immunotherapy resistance and a therapeutically actionable target for overcoming ICI resistance in GC.

#4896 *Sphingomonas*-driven sphingosine signalling enhances neoadjuvant therapy responses in digestive system cancers.

Bin Wang, Xiuchao Wang, Jihui Hao

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Neoadjuvant therapy (NAT) is becoming an essential component in the management of digestive system malignancies, yet whether the microbiome modulates NAT efficacy remains unclear. Here, we profile the intratumoral microbiome of patients with digestive system cancers following NAT and identify *Sphingomonas* as markedly enriched in pancreatic ductal adenocarcinoma (PDAC) tumors from responders. *Sphingomonas* was likewise detected in gastric and colorectal cancers with favourable NAT responses. Using mouse models, we show that *Sphingomonas* stably colonizes pancreatic, gastric, and colorectal tumors and augments NAT efficacy through secretion of sphingosine. Mechanistically, *Sphingomonas*-derived sphingosine binds lipid raft structures on the plasma membrane and is preferentially internalized by immune cells, where it selectively activates the ceramide-sphingomyelin synthetic pathway rather than the Sphingosine-1-Phosphate (S1P) pathway. This process amplifies lipid raft organization, promotes immune synapse formation, and enhances immune-mediated tumor cell killing. We further develop a lipid-raft-targeted sphingosine delivery system that boosts immune activation and sensitizes tumors to NAT. Together, these findings uncover a previously unrecognized microbial determinant of NAT responsiveness in digestive system cancers and provide a conceptual and translational framework for microbiome-based patient stratification and therapeutic sensitization.

#4897 Characterization of the intratumoral microbiota in non endemic EBV associated nasopharyngeal carcinoma.

Deborah Lenoci[1], Federico Rossignoli[1], Armando Giuseppe Licata[1], Marta Lucchetta[1], Ilenia Rolli[1], Marica Ficorilli[1], Antonello Manocchio[2], Noemi Crippa[2], Walter Ferrari Bravo[2], Federica Manoni[2], Monica Zucchini[3], Francesca Taverna[3], Stefano Cavalieri[2], Lisa Licitra[2], Loris De Cecco[1], Salvatore Alfieri[2]

[1]Integrated Biology of Rare Tumors, Department of Experimental Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[2]Head and Neck Medical Oncology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[3]Department of Immunohematology and Transfusion Medicine Service, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Epstein-Barr virus (EBV) related nasopharyngeal carcinoma (NPC) is an epithelial malignancy arising from the nasopharyngeal mucosal lining. A high incidence of EBV related NPC is recorded in endemic areas (EA), East and Southeast Asia. Microbiota resides the upper respiratory tract including nasopharynx. Thus, intratumoral microbiota (ITM) in EA EBV related NPC has been characterized with Corynebacterium and Staphylococcus being the most predominant taxa. Currently, ITM profile in NPC remain unexplored in non endemic area (NEA). We hypothesized that the ITM in NEA NPC is associated to tumor biology. In our previously NEA EBV related NPC study, we stratified patients into three transcriptional clusters (Cl1: immune active; Cl2: defense response; Cl3: proliferative), with Cl3 displaying the poorest prognosis. Hence, the present work investigates the ITM composition according to our clusters' model. Formalin-fixed paraffin embedded (FFPE) samples from 94 NEA NPC EBV related cases were collected. Total RNA was extracted using miRneasy kit (Qiagen) and libraries were generated using QuantSeq 3' mRNA (Lexogen) and sequenced on the NextSeq500 (Illumina). The ITM composition and immune cell deconvolution (xCell) were inferred from RNAseq data. Differential abundance analyses (LEfSe) among clusters and correlation analyses between immune cells populations and differentially abundant taxa were conducted. To validate the RNAseq findings and assess spatial colocalization patterns, spatial and metatranscriptomics (SMT) (Stereoseq OMNI for FFPE, STOmics) was performed on one representative case per cluster. 297 bacterial taxa were detected in our NEA cohort. LEfSe comparisons showed that Bacteroidota and Pseudomonadota were enriched in Cl1 vs Cl2, while Bacillaceae dominated in Cl2. Actinomycetota was more prevalent in Cl1 vs Cl3. Correlation analyses showed that most differentially abundant taxa, found in clusters' comparison, were positively associated with fibroblast and stroma score and inversely correlated with CD8+ and CD4+ T cell populations. SMT profiling confirmed intratumoral bacteria expression: Cl1 and Cl2 exhibited higher bacterial proportion in respect to EBV (the latter expressed in 14.6% and 23.6%, respectively), while Cl3 displayed both bacterial and EBV signals, with a predominant EBV expression (52.5%). SMT analyses is ongoing to disclose co expression patterns between immune cells, intratumoral bacteria and EBV. This study provides the first characterization of the ITM in NEA EBV related NPC. Higher EBV expression was detected in Cl3, the subgroup associated with the poorest prognosis, suggesting a possible synergistic interplay between EBV and specific bacterial taxa in the NPC pathogenesis. These findings highlight the impact of the microbiome on the tumor microenvironment and support its potential as biomarker in NEA EBV related NPC.

#4898 Gut virus shapes distal tumor immunity: fecal phage transfer from long-term pancreatic cancer survivors delays tumor progression.

Xiaoqing Wang, Jiakun Wang, Hongji Dai, Bin Wang

Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Gut bacteria and fungi have been implicated in promoting tumor progression in patients with pancreatic ductal adenocarcinoma (PDAC). However, the role of the gut virus in PDAC pathogenesis remains poorly defined. Here, we systematically compared the fecal virus of long-term survivors (LTS) and short-term survivors (STS) of PDAC, and identified striking compositional differences between the two groups. Through fecal virus transplantation into murine orthotopic PDAC models, we demonstrated that the LTS-derived virus significantly delayed tumor progression. Mechanistically, LTS samples were characterized by a reduced abundance of Akkermansia muciniphila-targeting phages (Akkermannviridae), leading to significantly increased intestinal *Akkermansia* following transplantation compared to STS. *Akkermansia*-derived metabolite 2-PMPA exerted tumor-suppressive effects by promoting migration of intestinal group 3 innate lymphoid cells (ILC3s) into the tumor, where they modulated IL-17 signaling and enhanced $CD8^+$ T cell infiltration, thereby orchestrating an anti-tumor immune response. Our study provides the first causal evidence that the gut virus can regulate the progression of pancreatic cancers through a bacteriophage-microbiota-metabolite-innate/adaptive immunity axis, offering new insights into microbiome-targeted interventions and immunotherapeutic strategies for distal tumors.

#4899 A dysbiotic polymicrobial signature characterized by oral pathogens links the oral-gastric axis to gastric carcinogenesis in a high-risk Chilean cohort.

Javier Figueroa[1], Marcelo Garrido[2], Arnoldo Riquelme[3], Matias Munoz Medel[4], Franz Villaroel-Espindola[2], Fernan Gomez-Valenzuela[2], **Ignacio Retamal**[2]

[1]Universidad Adofo Ibanez, Santiago, Chile,[2]Universidad Mayor, Santiago, Chile,[3]Pontificia Universidad Catolica de Chile, Santiago, Chile,[4]Celerity Clinical Research, Santiago, Chile

Objectives:Gastric cancer (GC) remains a formidable global health challenge, particularly in high-risk regions like Chile. The traditional etiological model centered on *Helicobacter pylori* is insufficient to explain the full spectrum of disease. This study aimed to identify a robust, polymicrobial signature in GC tissue and test the hypothesis that the Oral-Gastric Axis drives the carcinogenic process via chronic colonization by translocated oral pathogens.
Methods: We employed high-throughput 16S rRNA amplicon sequencing to profile the gastric microbiome in tissue samples from a Chilean cohort (15 GC patients [CAN], 15 healthy controls [NOC]). Microbial composition, alpha diversity (richness, evenness), and differential abundance were assessed using non-parametric tests (Mann-Whitney U) and statistically validated through supervised machine learning approaches, including Random Forest and penalized regression models (Lasso/Ridge), to ensure robust biomarker selection.
ResultsThe GC microbiome showed a profound dysbiotic shift, characterized by a significant increase in species richness (Observed ASVs, ACE, Chao1; $p<0.001$) but marked ecological unevenness. A core four-genus signature consistently differentiated CAN from NOC tissue: *Fusobacterium* (MWU $p=0.024$), *Lactobacillus* (MWU $p=0.038$), *Neisseria* (MWU $p=0.005$), and *Prevotella* (MWU $p=0.023$). The oral pathogens *Neisseria* (Random Forest Rank 1) and Fusobacterium (enriched in CAN) were identified as the top predictive features. Mechanistic insights suggest Fusobacterium contributes to immune evasion by promoting the recruitment of PD-L1-expressing tumor-associated neutrophils, linking this signature directly to immunotherapy targets.
Conclusions: Gastric cancer is associated with a distinct, pathologically unstable polymicrobial signature dominated by known oral pathogens. This robust signature provides compelling quantitative evidence supporting the Oral-Gastric Axis Hypothesis. The identified microbial community offers promising candidates for novel non-invasive diagnostic biomarkers and suggests new therapeutic strategies, such as targeted depletion of pro-tumorigenic oral microbes to sensitize tumors to immune checkpoint blockade therapy in gastric cancer.

#4900 Microbiome derived lactate promotes immunosuppression and radiation resistance.

Christy Charles, David Lo, Jennifer L. Anderson, Ratna Veeramachaneni, Francisco Saenz, Anastasios Maniakas, MIchael T. Spiotto, Andrew G. Sikora, Lauren Elizabeth Colbert

UT MD Anderson Cancer Center, Houston, TX

The cervical microbiome plays a pivotal role in shaping vaginal health and influencing tumor prognosis. Tumor associated microbes secrete bioactive metabolites that modulate both tumor behavior and its surrounding microenvironment. Our lab previously identified a species of L-Lactate producing *Lactobacillus* (LAB), *Lactobacillus iners* (*L. iners*), to be associated with poor chemoradiation response. In vitro experiments revealed that conditioned media from *L. iners* enhances radiation resistance in cervical cancer cells—a phenomenon replicated by direct lactate supplementation. This study aims to characterize the impact of microbiome-derived lactate on the tumor microenvironment.

Hypothesis: We propose that L-lactate produced by cancer-derived LAB supports tumor progression by fostering an immunosuppressive niche.

Methods: LAB strains were isolated via targeted culture from cervical, vaginal, vulvar, and oral cavity cancers. These isolates were used in co-culture systems and to generate cell-free bacterial conditioned media (CFS) to assess their capacity to interact with cancer cells and promote tumor-supportive conditions. For initial studies, we focused on cervical cancer isolates. To evaluate LAB-derived lactate's role in radiation resistance, we performed cell viability assays (CyQUANT) on HeLa, SiHa, and CaSki cervical cancer lines exposed to CFS from patient-derived LAB and radiation. Lactate production was quantified using the Diazyme D-/L-Lactate rapid test kit, enabling precise source attribution between bacterial and tumor origins. We developed a syngeneic lactate exposure model using mEER (mouse oral line) xenografts in C57BL/6 mice, administering weekly intratumoral lactate injections. The tumors were radiated after the tumors reached ~75mm^3. To evaluate the immune landscape, multiplex immunofluorescence using the Lunaphore COMET microfluidic platform was performed on mEER tumors.

Results: Cervical cancer cells exhibited increased radiation resistance when co-cultured with L-lactate-producing LAB, the isoform preferentially metabolized by human cells. LAB emerged as the dominant source of lactate in co-culture, confirming its role in driving lactate accumulation within the tumor microenvironment. In vivo, lactate-treated tumors grew significantly larger post-radiation (mean volume 48 mm³ vs. 74 mm³, $p < 0.0001$). Immune profiling revealed elevated T-cell infiltration, with a skew toward regulatory T cells and reduced CD8$^+$ populations. The lactate-rich microenvironment showed marked upregulation of immune checkpoint proteins CTLA4 and PD-L1, suggesting functional exhaustion of infiltrating immune cells.

#4901 Biodiversity and biogeography of the multi-kingdom cancer microbiome.

Anders B. Dohlman[1], Robin Mjelle[2], Henry M. Wood[3], Alaina Shumate[1], Iris T.-h. Lee[1], Gianmarco Piccinno[4], Phil Quirke[3], Curtis Huttenhower[5], Nicola Segata[6], Matthew L. Meyerson[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Norwegian University of Science and Technology, Trondheim, Norway,[3]Leeds Institute of Molecular Medicine, Leeds, United Kingdom,[4]University of Trento, Trento, Italy,[5]Harvard T.H. Chan School of Public Health, Boston, MA,[6]Computational Metagenomics Lab, University of Trento, Trento, Italy

There is growing evidence that microorganisms represent an important component of the tumor microenvironment. However, conflicting reports regarding the cancer microbiome have left the extent of microbial presence across cancer types unclear, highlighting the need for more robust methods for identifying tumor-associated microorganisms. Leveraging the completed human reference genome, we built a host-subtraction and microbial classification pipeline to accurately identify tumor-associated microorganisms in whole-genome sequencing data, which we validated and benchmarked on *in silico* and *in vitro* mixtures of human and microbial DNA. We used this pipeline to perform the largest pan-cancer microbiome analysis to date, spanning 16,369 high-depth tumor whole genomes from the UK 100,000 Genomes Project. After decontamination, microbial signatures were indistinguishable from background in most cancer types. However, in oral, esophageal, gastric, and colorectal cancers, we detected multi-kingdom polymicrobial communities, including bacteria, fungi, viruses, and archaea. In some oral and colorectal cancers, we also detected the parasite *Trichomonas vaginalis*. These microbial communities varied by tumor site and subtype, with increased microbial colonization of microsatellite-instable and POLE/POLD1-mutated tumors. This pattern was driven by a correlation between microbial load and tumor mutation burden across cancer types that was independent of genomic subtype. Additionally, we observed an over tenfold depletion of *Akkermansia muciniphila* in early-onset colorectal cancer. Together, our analysis helps resolve the microbial landscape of cancer and provides a new tumor microbiome atlas for future studies.

#4902 Gut bacteria as hidden architects of stemness maintenance in the progression of pancreatic cancer.

Kirtana Arikath, Seoung Ryoung Choi, Annant Bir Kaur, Nivedeta Krishna Kumar, Venkatesh Varadharaj, Zahraa Wajih Alsafwani, Neelanjana Gayen, Poompozhil Mathivanan, Wyatt Petersen, Prabagaran Narayanasamy, Surinder K. Batra, Moorthy P. Ponnusamy

University of Nebraska Medical Center, Omaha, NE

Background: Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest cancers, defined by an aggressive tumor microenvironment (TME) and a small pool of cancer stem cells (CSCs) that fuel recurrence and therapy resistance. Evidence suggests that bacteria migrating from the gut to the pancreas reshape the TME to sustain these CSCs. Although microbial imbalance is linked to other cancers, its role in PDAC stemness remains unclear. This study investigates how gut-derived microbes and their metabolites reprogram the tumor niche to enrich CSCs and accelerate PDAC progression.

Methodology: Clinical profiling of PDAC patient samples was performed to identify diverse microbial species that contribute to dysbiosis. We performed tissue validation using 16S rRNA FISH (fluorescent *In-situ* hybridization) and lipopolysaccharide (LPS) staining to localize these bacteria in human and murine PDAC tissues. To define microbial effects, we exposed PDAC and normal pancreatic cell lines to bacterial supernatants, live bacteria, or purified LPS, followed by functional validation through tumor sphere, serial dilution, and colony assays with CSC markers assessed by immunofluorescence, western blotting, and qPCR. We next applied Omics Integration using LC-MS of bacterial supernatants and RNA sequencing of Antibiotics (Abx) treated mice to identify microbial metabolites and signaling pathways linked to CSC enrichment. In our *In-Vivo* studies using $Kras^{LSL\text{-}G12D/+}$;Pdx1-Cre (KC), $Kras^{LSL\text{-}G12D/+}$;$Trp53^{R172H/+}$;Pdx1-Cre (KPC), and C57BL/6J (C57) mice treated with Abx, we evaluated how microbiome depletion reshapes CSC dynamics and PDAC progression.

Results: Clinical Profiling of 62 resected PDAC samples showed that the basal-like subtype is enriched with *Pseudomonas aeruginosa, Acinetobacter baumannii*, and *Sphingopyxis macrogoltabida*, linking microbial dysbiosis to tumor aggressiveness. *In-situ* hybridization and LPS staining revealed stage-dependent bacterial accumulation in human PDAC and in KC and KPC tumors. LPS or bacterial supernatants elevated CSC and proliferation markers including SOX2, SOX9, NANOG, Cyclin A, and p-ERK, while normal pancreatic cells remained unchanged. Co-culture with *P.aeruginosa* and *S.macrogoltabida* produced the strongest stemness induction with LPS-CD44 co-localization. Functional assays and KPC organoids confirmed enhanced self-renewal and growth, most pronounced with *S.macrogoltabida* supernatant. Abx treatment in xenograft tumors altered tumor growth, and KC and KPC mice showed reduced PanIN lesions with decreased CD44 and Ki67 expression, consistent with loss of CSC maintenance.

Conclusion:A dysbiotic microbiome within the PDAC microenvironment sustains CSC-driven aggressiveness through metabolite-mediated signaling. Targeting this microbiome-stemness axis may offer a therapeutic approach to limit PDAC progression and improve patient outcomes.

#4903 Explore the effects of *Fusobacterium nucleatum* on chemotherapy response in colorectal cancer at spatial and single-cell resolution.

Yuting Shan[1], Lilin Wang[1], Matthew Jeon[1], R. Stephanie Huang[2]

[1]University of Minnesota, College of Pharmacy, Minneapolis, MN,[2]Asst. Professor, Dept. of Medicine, University of Minnesota, Minneapolis, MN

Introduction: Emerging evidence implicates intratumoral microbiota such as Fusobacterium nucleatum (Fn) in modulating therapeutic response and clinical outcomes in colorectal cancer (CRC). Here, we leveraged tumor transcriptomic data to predict the efficacy of hundreds of chemotherapies at single-cell resolution in the presence or absence of Fn, aiming to identify drugs with differential efficacy under each condition.

Methods: Two CRC cell lines (HT29 and HCT116) were co-cultured with or without Fn and sequenced using the 10x Genomics platform. In parallel, a CRC patient tumor was profiled using 10x Genomics Visium spatial transcriptomics. Raw sequencing data from both the cell lines and the patient sample were obtained from published sources and aligned to references to generate single-cell RNA and Fn count matrices. Drug sensitivity for each cell was predicted using scIDUC, a previously validated single-cell level transcriptome-based drug response prediction model. This enables prediction of >350 drugs for their likelihood of response in each cell derived from either cell line or patient sample. We then compared the predicted drug sensitivity between Fn-positive and Fn-negative cells for each drug. Differential expression and gene set enrichment analyses were conducted to identify Fn-associated molecular pathways.

Results: After quality control, 11,624 cells from the CRC cell lines and 3,105 spatial spots from the patient sample were retained, each with >20,000 genes quantified. Among standard-of-care agents used to treat CRC, oxaliplatin was consistently predicted to have reduced efficacy in Fn-positive cells ($P < 2.2 \times 10^{-16}$ for HT29 and HCT116; $P < 0.01$ for the CRC sample). In contrast, 5-fluorouracil was predicted to be less effective in Fn-positive cells in the patient sample but more effective in cell lines. Notably, dasatinib, a BCR-ABL inhibitor, was consistently predicted to exhibit enhanced efficacy in Fn-positive cells. Transcriptomic analyses revealed upregulation of tumor growth and drug-resistance genes, including JUN, DDIT4, and BIRC3, in Fn-enriched CRC cells.

Discussion: This study provides one of the first spatial and single-cell perspectives on how intratumoral microbiota shape chemotherapy response in CRC. Our findings suggest that F. nucleatum status may serve as a predictive biomarker for chemotherapy efficacy and a potential guide for drug repurposing and treatment stratification in colorectal cancer.

#4904 Reprogramming of the non-pathogenic *E. coli* surface architecture to create next-generation immune engagers for potent cancer therapies.

Shaobo Yang[1], Anna Clara Bader[1], Stephanie Sendker[1], Ashley Hu[1], Alice Chen[1], Daniel Chen[1], Hetal Nath[1], Eden Bobilev[1], Michal Sheffer[1], Veronica W. Hui[1], Tereza Kochs[1], Andreia Maia[1], Fuguo Liu[1], Xingyu Deng[1], Maily Nguyen[1], Mila Stanojevic[1], Mubin Tarannum[2], Alaa Ali[1], Roman Shapiro[1], Young Rock Chung[1], Erin M. Parry[1], Julissa G. Tello[1], Stephanie K. Dougan[3], Marco Campisi[1], David A. Barbie[1], John Koreth[3], Robert J. Soiffer[1], Catherine J. Wu[4], Jerome Ritz[5], Rizwan Romee[3]

[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]DFCI/Harvard Medical School, Boston, MA,[3]Dana-Farber Cancer Institute, Boston, MA,[4]Dana-Farber Cancer Institute, Brookline, MA,[5]Professor of Medicine, Dana-Farber Cancer Institute, Boston, MA

Background: Multi-specific immune engagers show therapeutic promise but are limited by systemic toxicities (e.g., cytokine release syndrome, CRS), short half-lives, and poor infiltration into the immunosuppressive tumor microenvironment (TME). Tumor-homing bacteria offer a targeted delivery strategy capable of overcoming restricted infiltration and TME-mediated suppression. Building on our *E. coli* K-12 surface display platform for localized cytokine delivery (Yang et al., *Nat Biotechnol*, 2024), we developed *Live Immune Modulating Engagers* (LIME), engineered *E. coli* co-displaying scFvs against tumor-associated antigens and effector-cell receptors (T or NK). We hypothesize that dual-display LIME enhances anti-tumor immunity by enabling localized effector-cell activation and precise tumor-immune cell bridging.

Methods: *E. coli* was engineered to display scFvs targeting TAAs (CD19, Mesothelin, DLL3, etc.) and immune receptors (CD3, NKG2D, etc.) using optimized outer-membrane scaffolds, confirmed by flow cytometry. In vitro co-cultures with primary human T or NK cells assessed binding, activation (CD25/CD69), and cytotoxicity (7-AAD/Annexin V). In syngeneic A20 and KPC tumor models, mice received intravenous LIME ± anti-PD-1 (i.p.) or RMC-7977 (oral). In DLL3$^+$ H69 xenografts, NSG mice were infused with human CD3$^+$ T cells followed by LIME, benchmarked against the FDA-approved engager Tarlatamab. Tumor growth was monitored and analyzed by flow cytometry, multiplex ELISA, and CFU quantification.

Results: In vitro, LIME activated T or NK cells and enhanced killing across a broad panel of tumor cell lines, including Small cell lung cancer, Glioblastoma, Pancreatic ductal adenocarcinoma, etc. In vivo, CD19 LIME cured ~34% of A20-bearing mice and achieved ~80% cures when combined with anti-PD-1, generating durable immune memory. Mesothelin LIME significantly inhibited KPC tumor progression, with extended survival upon RMC-7977 co-treatment. DLL3 LIME provided superior tumor control compared with Tarlatamab in H69 xenografts. Mechanistically, LIME reprogrammed the TME by activating T and NK cells, driving macrophage repolarization toward an M1 state, and enhancing DC activation in draining lymph nodes. Bacteria remained enriched in tumors, and no evidence of CRS was observed in plasma.

Conclusions: LIME represents a versatile platform that enables localized, immune engagement, overcomes major barriers in solid tumors, and outperforms existing immune engagers while maintaining a favorable safety profile.

#4905 Microbiome-wide association study identifies crosstalk between tumor-associated microbes and the human tumor microenvironment.

Nathan O. Siemers, Naouel El Asri, Corinne Danan, Karen L. Abbott

Theralytica, Inc., Mountain View, CA

Summary: Using recently refined measures of microbiome abundance in TCGA samples, we use quantitative models, in combination with human RNA-seq and RNA signatures, to identify microbial strains associated with functional modulation of the tumor microenvironment (TME), with implications for prognosis and therapy.

Methods: Determining the influence of intra- and peri-tumoral microbes on cancer outcomes is an active area of investigation. Progress has been limited in part by technical challenges to accurate quantitation of microbial species across large clinical cohorts, such as The Cancer Genome Atlas (TCGA). Recent advances in this area have produced refined tumor microbiome estimates across thousands of TCGA samples (Ge et al. 2025). We exploited the refined microbiome information to perform associative modeling between strain abundances and TME signals in human TCGA RNA-seq and -signature data. We reasoned that identifying direct associations between microbe abundances and tumor transcription might add support to a given microbe's importance. Linear models were constructed based on these data and selected technical and clinical covariates across 25 distinct human tumor types. Human RNA abundances and RNA signatures were selected based on potential to identify mechanistic and regulatory elements associated with microbial presence, as well as to infer differences in abundance of human TME cell types.

Results: We observed associations between microbe abundances and human transcription, confirming previously reported findings and identifying novel associations. In some cases, these associations were both specific to limited microbial strains and tumor type. For example, the relationships between an alpha-interferon-based RNA signature and microbial strains in serous ovarian carcinoma revealed only a small number of microbes in association, most of which were specific to ovarian cancer.

Conclusion: By exploiting advances in microbiome quantitation, a large clinical cancer cohort, and an associative study framework, we identified a subset of microbial species in association with human tumor transcriptional profiles. Although limited by the associative nature of the study, these species are candidates for future efforts that evaluate their mechanistic roles in the TME. The analysis adds to the body of evidence from preclinical models and early clinical observations that microbial elements in patient tumors can modulate tumor and TME function, influencing prognosis and response to therapy.

#4907 Obligate anaerobes in the gut drive pancreatic cancer metastasis.

Adriana Zingone[1], Senthil K. Muthuswamy[2], **Norihiro Yamaguchi**[1]

[1]National Cancer Institute, Bethesda, MD,[2]National Cancer Institute Center for Cancer Research, Bethesda, MD

Introduction: Tumoral microbiota is a strong predictor of gastrointestinal cancer outcome. However, our efforts to identify bacterial molecular drivers of cancer progression are hindered by 1) the lack of an efficient anaerobic bacterial culturing system and 2) the fact that >90% of the human gut microbiota are anaerobes. This predicament limits our capability to conduct mechanistic studies in tumor microbiota research. To fill this gap, we sought to establish a novel experimental system to propagate metastasis-associated tumoral microbiota by leveraging a curated, culturable human gut microbiota library. **Methods:** We established a gnotobiotic system by sequentially administering the curated human gut microbiota library via oral gavage in germ-free C57BL/6 mice. Subsequently, the mice underwent intrapancreatic injections of syngeneic KPC pancreatic cancer cells. Liver metastatic foci, primary pancreatic cancer, and the duodenum with their associated bacteria were subject to 16s sequencing and direct culture-based propagation. **Results:** To validate the feasibility of our experimental platform in identifying bacterial species despite the expected low biomass, we conducted proof-of-concept experiments by intrapancreatically injecting KPC cancer cell lines in wild-type C57BL/6 mice. Liver metastatic foci, primary pancreas tumors, and the duodenum were subject to 16S sequencing and direct culture. A Bray-Curtis dissimilarity matrix-based PCoA plot revealed apparent dissimilarity between tumor-bearing mouse samples and corresponding mock-surgery non-tumor-bearing samples, in a sample-site-agnostic manner, suggesting a systemic impact of the tumor-bearing state. Clostridium species were particularly enriched in primary pancreatic tumors and liver metastatic samples, suggesting biological pressure in hypoxic tumors and the hypoxic liver microenvironment that favors obligate anaerobes. Co-injections of KPC cancer cells and Clostridium species promoted liver metastasis more than 10-fold. Moreover, Clostridium-conditioned media also enhanced liver metastasis, suggesting a critical role for bacteria-derived soluble factors in regulating metastasis. **Conclusion:** The observed symbiosis between metastasizing pancreatic cancer cells and obligate anaerobes warrants further searches of similar co-opted bacteria-cancer interactions in other cancers. Our discovery of pro-metastatic bacteria-derived soluble factors paves the way for developing bacteria-derived, yet live microorganism-free, scalable therapeutics by blocking their interactions with host cells. In summary, we identified novel bacteria-derived soluble factors that strongly drive cancer metastasis.

#4908 Functional interrogation of pancreatic cancer resident microbes reveals their role in host modulation.

Vidhi Chandra[1], Le Li[1], Seyda Baydogan[1], Fuduan Peng[1], Thais Bartelli[1], Haoyue Liu[1], Fernando Jimenez-Arancon[1], David Romanin[1], Javier A. Gomez[1], Steven Maron[2], Erick M. Riquelme[3], Mark Hurd[1], Anirban Maitra[1], Luis A. Diaz[2], Ismet Sahin[4], Adriana Paulucci-Holthauzen[1], Jared K. Burks[1], Huamin Wang[1], Jay Kolls[5], James R. White[6], Linghua Wang[1], Michael P. Kim[1], Florencia McAllister[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Pontificia Universidad Catolica de Chile, Santiago, Chile,[4]Texas Southern University, Houston, TX,[5]Tulane University, New Orleans, LA,[6]Resphera Biosciences, Baltimore, MD

Tumor resident microbes are a well-recognized component of the tumor microenvironment. Microbial subcellular location across tumors along with their functionality remains to be determined. Bulk microbial profiling techniques lack subcellular and spatial resolution and ultimately cannot distinguish between microbial signals or live microbial presence. To address these limitations, we performed orthogonal methods for functional microbial-host characterization. We first developed advanced quantitative fluorescent imaging methodologies that allows visualization of microbial cellular compartmentalization across three different tumor types (total n=30). Using this methodology, we performed spatial microbial transcriptomics at the regional and single cell levels to determine microbial distribution and to interrogate microbial regulation of tumor cell signaling in human pancreatic tumors (n=55). To confirm presence of viable microbes, we performed multiplexed culturomics of patient tumors and normal adjacent tissue specimens (n=80), followed by Whole Genomic Sequencing (WGS) analysis. We tested the effect of the isolated clinical strains on tumor cell signaling pathways with *in vitro* co-culture assays, and upon genetic fluorescent labelling we defined their role on *in vivo* tumor growth in murine models. These experiments confirmed their role in promoting tumors, driving resistance to therapeutics and modulation of host signaling mechanisms. Overall, our results identified several pathways under microbial regulation within cancer cells that can drive immune evasion through impaired antigen presentation. In summary, using multiple complimentary novel methodologies we characterize the microbial niche of tumors (MiNT) that uncover microbial regulation of host cell signaling and patient outcomes. Microbial modulatory approaches may be needed to reverse resistance to therapies in pancreatic cancer.

#4909 Microbial stimuli differentially regulate astrocyte and glioblastoma cell phenotypes.

Ariana N. De Jesus-Carrasquillo[1], Claudia M. Ramos-Lugo[1], Aliaha Serpa-Figueroa[1], Alondra Soto-Nieves[2], Alexander Y. Morla-Sevilla[2], Yaraliz Corchado-Vargas[1], Joseph M. Torres-Cruz[3], Yisel M. Cantres-Rosario[4]

[1]University of Puerto Rico - Comprehensive Cancer Center, San Juan, PR,[2]University of Puerto Rico - Rio Piedras Campus, San Juan, PR,[3]University of Puerto Rico - Medical Sciences Campus, San Juan, PR,[4]Microbiology and Medical Zoology, University of Puerto Rico - Medical Sciences Campus, San Juan, PR

Glioblastoma multiforme (GBM), an astrocytoma, is the most prevalent and aggressive primary brain tumor. These tumors present with an intricate molecular profile and resistance to treatment, thus resulting in poor prognosis. Astrocytes, the most abundant cells in the brain, maintain the blood-brain barrier (BBB) and support metabolic homeostasis. Studies have shown that, when exposed to inflammation, they can acquire a reactive phenotype, possibly contributing brain carcinogenesis. However, the mechanisms behind their role in tumor development remain unclear, highlighting the need to further understand the phenotype of astrocytes in GBM. Lipopolysaccharides (LPS) from periodontal disease-causing pathogen *Porphyromonas gingivalis* (Pg) are known endotoxins capable of crossing the BBB, inducing strong inflammatory responses. Thus, understanding the role of common microbial products in the brain microenvironment, and their influence on GBM pathogenesis is key. To assess this response, astrocytes and U87-GBM cells were cultured and exposed directly to Pg-LPS, *Staphylococcus aureus* lipoteichoic acids (Sa-LTA) and *Escherichia coli* lipopolysaccharides (Ec-LPS). Indirect treatments were also performed using astrocyte-conditioned media (ACM) primed with Pg-LPS, Sa-LTA and Ec-LPC. After 24- and 48-hour exposures, cytokine and protein expression were measured by ELLA assays and immunofluorescence (IF) respectively. Viability was assessed via MTT Assay. At 24 hours, exposure to Pg-LPS significantly increased astrocyte metabolic activity when compared to other treatments ($p = 0.042$), though this effect was not observed at 48 hours. IF staining of proliferation marker Ki67 in astrocytes revealed a significant increase when treated with Pg-LPS ($p = 0.033$) for 24H. In contrast, Pg-LPS-primed ACM for 48H, decreased proliferation in GBM cells compared to untreated ($p = 0.007$), directly treated U87-GBM cells with Pg-LPS ($p = 0.003$), and not-primed astrocyte-conditioned media ($p = 0.024$). GBM cells expressed consistently higher levels of Ki67 than all astrocyte treatments and viability remained unchanged across treatments. Moreover, Pg-LPS-primed ACM presented detectable levels of IL-10, IFN-a2, IL-4 and TGF-beta. Our results suggest that Pg-LPS promotes a shift toward an anti-inflammatory phenotype and may reduce proliferation in GBM cells. Further studies are needed to elucidate how Pg-LPS-conditioned astrocytes modulate GBM progression.

#4913 Single-cell intercellular CRISPR screen reveals stromal regulators of colorectal cancer plasticity.

Corinne Molyneux, Rhianna O'Sullivan, Alistair Wilkinson, Nick Li, Shauna Crampsie, Petra Vlckova, Aurelie Dobric, Chris Tape

Cancer Institute, University College London, London, United Kingdom

Colorectal cancer (CRC) displays high levels of non-genetic phenotypic plasticity, enabling cancer cells to dynamically shift between distinct functional states, resulting in therapy evasion and disease progression. This plasticity is driven by both intrinsic transcriptional programmes within epithelial cancer cells and extrinsic cues from the tumour microenvironment.
To explore the molecular mechanisms underlying this process, we performed single-cell transcriptomic profiling of ten CRC patient-derived organoid (PDO) models co-cultured with or without cancer-associated fibroblasts (CAFs). Across all CRC PDOs, we observed varying admixtures of proliferative colonic stem cells (proCSC) and slow-cycling, onco-foetal, revival colonic stem cells (revCSC). In response to stromal cues some PDOs underwent pronounced transcriptional reprogramming towards the chemoresistant revCSC state. However, this CAF-induced epithelial plasticity was highly patient-specific with some PDOs maintaining an intrinsic stem cell equilibrium. We identified the transcriptional regulator DACH1 as a defining marker of CRC cells with high stromal responsiveness and this factor was consistently downregulated upon CAF interaction.
To functionally identify the stromal signals mediating this stem cell reprogramming, we developed an arrayed CRISPR screening platform to systematically perturb the CAF secretome during direct PDO-CAF co-culture. Perturbed co-cultures were assessed via multiplexed mass cytometry to capture the PDO response to the genetically-edited CAF population at single cell resolution. This approach revealed the key regulators of proCSC-to-revCSC transdetermination with prostaglandin E2 (PGE_2) emerging as the primary effector of stromal-induced CRC plasticity changes.
These findings demonstrate that CRC phenotypic plasticity is regulated by cell-intrinsic transcriptional states and stromal-derived signals, provide new mechanistic insight into therapy failure and describe a potential therapeutic intervention strategy to overcome plasticity driven chemoresistance.

#4914 Defining the immunoregulatory molecular drivers of dendritic cells using CRISPR screens in ex-vivo modelsvivo models.

Mukta Asnani, Jiekun Yang

Rutgers University - New Brunswick, New Brunswick, NJ

Conventional dendritic cell type 1 (cDC1) plays a central and indispensable role in coordinating antitumor T-cell responses by producing cytokines such as IL-12 and expressing key regulatory molecules including PD-L1. Despite their importance in shaping antitumor immunity and influencing responses to modern immunotherapies, the molecular mechanisms controlling cDC1 activation and maturation remain poorly defined. This gap in knowledge is compounded by the extremely low abundance of cDC1 within the tumor microenvironment (TME), which limits the ability to experimentally interrogate their biology and apply genetic perturbation tools at scale. To address these challenges, we developed, optimized, and compared robust ex vivo differentiation systems capable of generating physiologically relevant cDC1-like cells from both murine and human hematopoietic stem cells (HSCs).Using a carefully designed two-stage culture platform incorporating Fms-like tyrosine kinase 3 ligand (Flt3L), DLL1-mediated Notch signaling, and granulocyte-macrophage colony-stimulating factor (GM-CSF), we efficiently produced $CD103^+$ cDC1-like populations from mouse bone marrow progenitors and $Clec9a^+CD141^+$ cDC1-like cells from G-CSF-mobilized human peripheral blood $CD34^+$ HSCs. These ex-vivo derived cells closely mirrored their in-vivo counterparts, exhibiting the expected surface immunophenotypes, high IL-12 secretion upon stimulation measured by ELISA, and strong functional responsiveness to TLR agonists and cell-associated antigens. Upon activation, cells consistently upregulated classical maturation markers including PD-L1, MHCII, and CD40, demonstrating their ability to undergo appropriate immune stimulation-driven maturation.To support downstream genetic studies, we optimized viral transduction strategies for primary HSCs, a major technical barrier in the field. An ecotropic retroviral system combined with retronectin substantially improved gene delivery efficiency in murine cells, while an amphotropic pseudotyped retroviral approach enhanced transduction of human $CD34^+$ HSCs. These advances enable reliable introduction of CRISPR-based perturbations into precursor cells prior to differentiation.Together, this scalable, high-yield differentiation and gene-delivery platform provides a powerful foundation for conducting CRISPR-based genetic screens aimed at identifying the molecular regulators orchestrating cDC1 activation and maturation. These insights have the potential to inform the development of next-generation immunotherapies that harness or enhance dendritic cell-driven antitumor immunity.Defining the immunoregulatory molecular drivers of dendritic cells using CRISPR screens in ex-vivo models

#4915 Using functional CRISPR screening to investigate metabolic genes in lung squamous cell carcinoma adoptive T cell therapy.

Verra Ngwa, Jin Chen

Vanderbilt University Medical Center, Nashville, TN

Lung squamous cell carcinoma (LUSC) represents 30% of non-small cell lung cancer (NSCLC) cases and has a high mortality rate with limited targeted therapies. Unlike lung adenocarcinoma (LUAD), which has seen advancements in targeted therapies, LUSC has not benefited from similar breakthroughs despite having similar genetic abnormalities. While immune checkpoint inhibitor therapies have shown promise in some LUSC patients, a significant portion does not respond effectively, leaving limited treatment options. The metabolic landscape of tumors plays a crucial role in shaping the efficacy of immunotherapies, especially adoptive T cell therapies. However, identifying actionable metabolic vulnerabilities involved in T cell therapy is poorly understood. Here, we performed a high-throughput CRISPR-Cas9 screen targeting metabolic genes in an orthotopic LUSC mouse model to identify key metabolic enzymes that would sensitize the tumors to adoptive $CD8^+$ T cell therapy. By comparing sgRNA enrichment and depletion between tumors treated with adoptive T cells and those receiving PBS, we identified genes that are involved in the fatty acid biosynthesis pathway as potential suppressors of T cell-mediated killing in this tumor model. Moreover, pilot experiments indicate that loss of these genes promote invitro cytotoxic killing when tumor cells were co-cultured with T cells. Additionally, in vivo studies showed a decrease in tumor growth. Experiments are underway to evaluate the effect of adoptive T cell therapy in vivo.

#4916 StromaBlast™: A novel CRISPR-based functional genomics platform to identify therapeutic targets within the tumor microenvironment.

Abdullah Al Emran[1], Lu Gong[1], Nick Patsoukis[1], Yi Yang[1], Ruth Fekade[1], Fen Ma[1], Jahnavi Tatineni[1], Renhong Tang[2], Amin Al-Shami[1], Pankaj Seth[1], Tamas Oravecz[1]

[1]Simcere Zaiming, Cambridge, MA,[2]Simcere Zaiming, Shanghai, China

Background: The solid tumor microenvironment (TME) plays a critical role in regulating tumor progression, metastasis, and therapeutic resistance. It is a complex network of cancer-associated fibroblasts (CAFs), immune cells, endothelial cells, extracellular matrix (ECM), and soluble mediators. Recent advances in oncology have shifted the therapeutic paradigm from a cancer cell-centric to a TME-centric model, underscoring the importance of stromal components in shaping tumor behavior. Among these, CAFs represent the functionally dominant stromal population, driving resistance through multifaceted mechanisms including ECM remodeling, paracrine signaling, and metabolic reprogramming. These processes collectively create a protective niche that fosters drug tolerance and immune evasion.

Methods: To overcome the limitations of traditional discovery screens that rely solely on monoculture cancer models, we developed StromaBlast™, a next-generation CRISPR screening platform which incorporates co-cultures of cancer cells, CAFs, and immune cells. Using both Cas9-mediated knockout and dCas9-based activation approaches, we performed a comprehensive CRISPR surfaceome screen in lung cancer cells under conditions that simulate therapeutic antibody exposure and T-cell mediated killing in fibrotic tumors. Our screen was optimized to identify essential interaction networks and novel therapeutic targets involved in CAF-cancer-immune cell crosstalk.

Results: The StromaBlast™ screen uncovered several novel and known targets that are essential for cancer cell survival and communication within a CAF-rich microenvironment. Comparative analyses distinguished targets exhibiting CAF dependency from those functioning independently of stromal interactions. Functional validation confirmed the critical role of select targets in sustaining cancer cell viability in the presence of CAFs. These findings nominate actionable targets amenable to development as biologics, including T-cell engagers and antibody-drug conjugates, designed to disrupt CAF-cancer cell interactions and restore anti-tumor immune activity.

Conclusion: Fibrotic, CAF-enriched tumors are notoriously resistant to immunotherapy and antibody-based treatments due to CAF-ECM-mediated physical barriers and immune suppression. StromaBlast™ represents a transformative platform for discovering therapeutic targets that can overcome this resistance. Targeting CAF-dependent vulnerabilities identified through this approach holds the potential to convert immune-cold, fibrotic tumors into immune-active, therapy-sensitive states - advancing precision oncology and improving patient outcomes.

#4917 Establishment of patient-derived lung epithelial progenitor lines as a foundation for autologous immune and tumor modeling.

Sanaz Keshavarz Shahbaz[1], Florentina Marches[1], Te-Chia Wu[1], Mohammed Toufiq[1], Andrew Salner[2], Peter Yu[2], Adolfo Garcia-Sastre[3], Karolina Palucka[1]

[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[2]Hartford HealthCare Cancer Institute, Hartford, CT,[3]Department of Microbiology, Icahn School of Medicine at Mount Sinai, New York, NY

Lung cancer is the leading cause of cancer-related mortality worldwide. Resistance to immunotherapy significantly limits durable clinical benefit. Elucidating the interactions between epithelial and immune compartments within the lung tumor microenvironment is critical for the development of effective interventions. However, most preclinical systems do not preserve patient-specific epithelial programs or support autologous immune modeling.The purpose of this study was to generate and characterize patient-derived lung epithelial progenitor lines from uninvolved tissues of lung cancer patients as a foundation for future immune and tumor co-culture platforms. Epithelial progenitor organoids were established from uninvolved lung tissues of adenocarcinoma and squamous cell carcinoma patients and maintained to passage 5 (P5) under defined, growth factor–optimized conditions. Identity and quality were verified by pan-cytokeratin immunostaining and fibronectin. Progenitor lines were expanded and cryopreserved to create a biobank supporting downstream air–liquid interface (ALI) and immune co-culture assays. Parallel spatial imaging of matched tumor and uninvolved tissues, along with RNA sequencing of progenitor cell lines, will be performed to analyze the immune and stromal architecture, providing integrative context for model development.Sixteen stable progenitor lines were generated (7 female, 9 males; 9 adenocarcinoma, 7 squamous cell carcinoma) with consistent morphology and long-term viability. Cryopreserved stocks and associated patient-matched materials (tumor blocks, uninvolved tissues, PBMCs, and serum) are now being integrated into functional ALI and immune co-culture assays.In conclusion, this work establishes a comprehensive biobank of lung epithelial progenitor lines derived from cancer-adjacent tissues, enabling next-generation autologous models to explore immune regulation, aging, and therapeutic resistance in lung cancer.

#4918 Bioprinted multicellular microenvironments to accelerate immunotherapy discovery in pancreatic cancer.

Aji Istadi[1], **Ali McCorkindale**[2], Silvia Lombardi[1], Inna Navarro[1], Diego Chacon Fajardo[1], Henry Barraclough-Franks[1], David Hermann[1], Sean Porazinski[2], Marco J. Herold[3], Paul Timpson[1], Greg Neely[4], Marina Pajic[1]

[1]Garvan Institute of Medical Research, Darlinghurst, Australia,[2]Inventia Life Science, Alexandria, Australia,[3]Olivia Newton-John Cancer Research Institute, Victoria, Australia,[4]Charles Perkins Centre, The University of Sydney, Camperdown, Australia

90% of pancreatic cancer (PC) patients succumb to the disease [1], necessitating development of more effective treatments. PC tumors are characterized by dense fibrotic stromal regions that contain complex, highly remodelled extracellular matrices. These fibrotic regions create protective niches promoting growth and shielding cancer cells from therapies [2]. These regions, along with other immunosuppressive elements within the tumor, prevent robust immune responses against the cancer cells, limiting immunotherapy efficacy.

Accurately modeling fibrotic microenvironments in preclinical settings remains challenging. Two-dimensional models can incorporate multiple cell types and extracellular matrices, but fail to replicate nutrient and drug gradients that exist in tumors. These architectural features are particularly important when studying immune interactions, as T cells are often spatially excluded from tumor niches in patients [3]. Furthermore, in vivo models can lack sufficient immune components, make dissecting causal effects of therapies difficult and are limited by throughput costs.

We present development and characterization of 3D in vitro co-culture models incorporating cancer, stroma, immune and microenvironment components using the RASTRUM^{TM} Allegro bioprinter from Inventia Life Science. We investigate the role of CAFs in supporting immune evasion and analyze cancer-T cell dynamics in various contexts. Using single-cell RNA sequencing we show this physiologically-relevant system better mimics native PC tumors while maintaining scalability for drug screening. The modular design facilitates combinatorial drug testing and mechanistic dissection of therapy effects across distinct cell populations. This model will be utilised to identify combination therapies that are more effective in vivo, streamlining preclinical testing, particularly for immunotherapies and immunomodulators.

Neurofibromatosis Type I (NF1) is a tumor-predisposing genetic syndrome driven by germline variants in the tumor suppressor gene *NF1*. Patients with NF1 frequently develop benign peripheral nerve sheath tumors, including cutaneous and plexiform neurofibromas (cNFs, pNFs), which are associated with significant comorbidities. Notably, a proportion of pNFs can progress to malignant peripheral nerve sheath tumors (MPNSTs), aggressive soft tissue sarcomas, in approximately 15% of patients. Current therapies for NF1 associated tumors are extremely limited, being the MEK 1/2 inhibitors selumetinib and mirdametinib the only FDA-approved drugs for patients with symptomatic inoperable pNFs. However, both treatments are not curative and require continuous administration, with associated toxicities that highlight the need for alternative therapies. NF1 tumors present a complex microenvironment comprising different cell types including Schwann cells, fibroblasts, and mast cells embedded in a dense extracellular matrix (ECM). Efforts to identify effective non-surgical treatments are constrained by the rarity of these tumors, their marked cellular heterogeneity, their abundant ECM deposition, and the lack of patient-derived models that accurately recapitulate these complex features. We have developed patient-derived organoids of both neurofibromas (*Nguyen et al, Cell Reports Methods* 2024) and MPNSTs (*Al Shihabi et al, Cell Stem Cell* 2024) that preserve the cellular and molecular characteristics of parental tumors, providing robust tractable models for drug discovery studies. Here, we are developing a single-cell typing, image-based assay, integrating multiplex immunofluorescence with computational techniques, to evaluate the impact of drugs on individual cell subpopulations within NF1 organoids. This methodology will be coupled with our high throughput mini-ring organoid screening platform (*Phan et al, Communications Biology 2019; Al Shihabi et al, Science Advances 2022*), to rapidly screen FDA-approved drugs, along with a modified 3D-compatible Cell Painting assay for providing unbiased phenotypic readouts of the impact of therapeutic agents on each cell type as well as proteomics approaches. By integrating these methods, we aim to address the challenges posed by the cellular heterogeneity of NF1-associated tumors and to identify precision therapeutic strategies for NF1 patients.

#4920 Decoding phenotypic and functional states of *in vivo*-mimetic 3D human pancreatic CAF/ECM units through sequential high-plex IF.

Mariia Dmitrieva, Edna Cukierman, Janusz Franco-Barraza

Dr. Edna Cukierman's laboratory, Fox Chase Cancer Center, Philadelphia, PA

Background: Pancreatic ductal adenocarcinoma (PDAC) is characterized by extensive desmoplasia, with cancer-associated fibroblasts (CAFs) dominating the tumor microenvironment (TME) and driving collagen-rich extracellular matrix (ECM) deposition. While resident pancreatic fibroblasts exert natural tumor-restrictive functions, CAF/ECM units adopt both tumor-promoting and tumor-suppressive phenotypes, critically shaping tumor progression, therapeutic response, and patient outcomes. Defining inter-patient heterogeneity in CAF/ECM phenotypic traits and understanding their functional shifts in response to therapy is essential for predicting clinical outcomes, predicting therapy responses, and identifying new TME-targeting strategies.
Methods: We developed a human PDAC TME-within-a-chip integrating fresh tissue-derived 3D CAF/ECM units cultured in customized microfluidic chambers on glass slides. High-plex sequential immunofluorescence (seqIF™) on the COMET™ platform standardized ~20 mesenchymal biomarkers to distinguish tumor-supportive from tumor-restrictive CAF phenotypes. Automated image analysis (HORIZON™ software) quantified single-cell, subcellular, and extracellular marker expression patterns.
Results: CAF activation-state interventions revealed marked alterations in canonical TGFβ signaling, reduced Ki67-positive cell proliferation, and changes in ECM architecture and composition, reflecting shifts in stromal functional states. This integrated platform effectively resolved CAF/ECM unit heterogeneity and tracked TME adaptations in response to therapeutic perturbation.
Conclusions: This technological advancement provides a robust, medium-throughput framework for dissecting CAF heterogeneity and exploring stromal biology in PDAC (and other cancers). The platform enables comprehensive profiling from minimal starting material while substantially reducing antibody consumption and processing time compared to conventional methods, establishing a scalable foundation for functional screening and evaluating therapeutic interventions in complex TMEs.

#4921 An advanced 3D vascularized tumor immune microenvironment on a chip for predictive efficacy and toxicity testing of IO therapeutics.

Junfeng Wang, Byungjun Lee, Delaney Donnelly, Sabrina Figueroa Buezo, Bushra Rajput, Jihye Baek, Hyeon-geun Park, Eunjeong Kim, Joseph Harris, Aneesh Sathe, Tsung-Li Liu, Branka Mitrovic, Kyusuk Baek, Sanghee Yoo

Qureator, Inc., San Diego, CA

Introduction: Conventional pre-clinical models for immuno-oncology (IO) therapeutics, such as animal models, suffer from irrelevant biology and ecosystems, while simple 2D/3D *in vitro* assays lack the complexity of the human tumor microenvironment. These gaps lead to poor prediction of clinical outcomes, including immune-related toxicities. To address this translational gap, we developed and validated an advanced, patient-relevant 3D vascularized tumor immune microenvironment (vTIME) on-a-chip model for the predictive assessment of IO drug efficacy and toxicity—a platform now proven to generate data packages supporting Investigational New Drug (IND) approval.

Methods: Within proprietary microfluidic CurioChips, we established the vTIME model by co-culturing patient-derived organoids in hydrogel with stromal cells and endothelial cells (HUVECs). In this co-culture, endothelial cells are self-assembled into a perfusable vascular network. We subsequently introduced human monocytes, which migrated into the tumor bed and differentiated to build an immunosuppressive microenvironment. The transformation of immune microenvironment was characterized by multiple cytokine changes. We then validated the model's predictive utility using a clinical stage T-cell engager (TCE) for dual efficacy and toxicity evaluation. The tumor killing and T cell activations are measured by immunofluorescent images, immune cell profiling and secretome analysis.

Results: The model successfully recapitulated a clinically relevant, immunosuppressive TME: monocytes differentiated into tumor-promoting macrophages, fibroblasts converted to CAF-like cells, and metastatic organoids demonstrated vascular invasion. For efficacy testing, TCE-mediated cancer-killing was observed in a dose-dependent manner; however, this efficacy was significantly diminished in the presence of immunosuppressive macrophages, demonstrating the model's ability to avoid the overestimation of efficacy seen in simpler systems. For toxicity assessment, the complete vTIME model captured the key cascade of cytokine release syndrome (CRS). TCE treatment induced a characteristic kinetic, with an initial IFNγ peak followed by a substantial IL-6 elevation. Critically, we also captured significant, CRS-linked vessel toxicity post-TCE treatment, a key initiating event of organ failure in patients.

Conclusion: These findings demonstrate that our advanced 3D vTIME-on-a-chip platform represents one of the powerful New Approach Methodologies (NAMs), which is reliable and predictive for the dual assessment of novel IO therapeutics. It is capable of capturing complex immune-mediated responses, identifying the therapeutic "sweet spot" balancing efficacy and toxicity, and modeling CRS-driven vascular damage not seen in conventional systems.

#4922 Development of vascularized 3D tumoroid models using microphysiological systems.

Geetika Sahni[1], Hooi Linn Loo[1], **Colin D. Paul**[2], Matthew R. Dallas[2], Sei Hien Lim[1], Kuan Chee Mun[1]

[1]AIM Biotech Pte Ltd, Singapore, Singapore,[2]Thermo Fisher Scientific, Frederick, MD

The adoption of New Approach Methodologies (NAMs) in drug discovery and toxicology is accelerating as the field seeks human-relevant predictive models to replace animal testing. Microphysiological systems (MPS) are leading this transition by enabling physiologically relevant, reproducible in vitro models. Here, we demonstrate construction of vascularized tumoroid models using AIM Biotech's VasQ Kit and organiX™ platform and Thermo Fisher Scientific patient-derived OncoPro™ Tumoroid Cell Lines. These models combine a microfluidic system optimized for complex three-dimensional (3D) co-cultures with physiologically-relevant tumoroid (cancer organoid) lines. Endothelial cells and fibroblasts, which came pre-validated in the VasQ Kit, were co-cultured with OncoPro tumoroid models in hydrogel matrices to generate perfusable vascular networks. Tumoroids derived from colorectal (HuCo1044-GFP) and lung (HuLu051421) cancers were integrated into organiX devices to assess tumor-vasculature interactions. Fluorescent and confocal imaging with Texas Red-dextran, anti-CD31, and CellEvent™ Caspase-3/7 reagents were used to visualize perfusion, vascular architecture, and apoptosis within tumoroids.

Perfusable vascular networks reproducibly formed around patient-derived tumoroids, recapitulating critical features of the tumor microenvironment (TME). Confocal imaging revealed active vasculature-tumoroid interfaces, with endothelial networks penetrating hydrogel matrices and surrounding tumor masses. Quantification of apoptotic markers and spatial analysis of immune or stromal cell compartments demonstrated the model's capability for assessing drug response and cellular infiltration.

This method establishes a standardized and human-relevant MPS model for vascularized tumoroids, enabling mechanistic studies of tumor biology, immune cell trafficking, and therapeutic efficacy. This integrated approach supports the broader transition toward NAMs and offers a translationally relevant platform for immuno-oncology and precision medicine research.

#4923 A micro-vascularized pancreatic ductal adenocarcinoma-on-chip model recapitulates immune exclusion and altered T cell polarization.

Thomas Sommermann[1], Amelie Paillereau[1], Alina Deipenbrock[2], Nicole Teusch[2], Martin Raasch[1], Knut Rennert[1]

[1]Dynamic42, Jena, Germany,[2]Institute of Pharmaceutical Biology and Biotechnology, Heinrich-Heine-University Dusseldorf, Dusseldorf, Germany

Pancreatic ductal adenocarcinoma (PDAC) demonstrates strong immune evasion by reshaping the tumor microenvironment (TME) into an anti-inflammatory, immunosuppressive niche. This process involves creating chemokine gradients and physical barriers that hinder the recruitment and infiltration of immune effector cells.To study these interactions under physiologically relevant conditions, we developed a PDAC-on-chip model using a microfluidic three-channel biochip. The system was based on PDAC co-spheroids composed of primary cancer-associated fibroblasts (CAFs) and Panc1 tumor cells embedded in an extracellular matrix within a dedicated chip channel. Over 10 days, fibroblasts generated a fibrotic barrier exceeding 100 µm around the tumor core. Concurrently, endothelial cells integrated into the matrix formed a perfusable microvascular network directly interfacing with the TME. Various immune cell populations were introduced into the vascular channel, and their transmigration across a porous membrane through the microvasculature into the complex TME was tracked over time using live-cell imaging and flow cytometry.Our findings show that PDAC-on-chip models effectively restrict T cell infiltration, reinforcing the concept of active immune exclusion by the tumor. Moreover, activated CD8 T cells recovered from the chip exhibited an altered activation phenotype characterized by HLA-DR downregulation and 4.1BB upregulation. This microvascularized PDAC-on-chip platform faithfully reproduces key features of PDAC immune evasion observed in vivo and provides a promising tool for evaluating immunotherapeutic strategies in a controlled microphysiological setting.

#4924 Decellularized lung biomatrix models to investigate microenvironmental regulation of organ-selective tropism in metastatic breast cancer.

Kasra Goodarzi[1], Yi Yin[1], Maureen Aliru[2], Andrew Z. Wang[1]

[1]University of Texas Southwestern Medical Center, Dallas, TX,[2]Harold C. Simmons Comprehensive Cancer Center, Dallas, TX

Background: Breast cancer is the most frequently diagnosed malignancy and a leading cause of cancer-related death in women. Metastatic disease is the main cause of breast cancer mortality, with lung as a key metastatic organ. Although a variety of tumor models, ranging from conventional two-dimensional (2D) systems to in vivo models, have been used to study breast cancer lung metastasis, they do not fully recapitulate lung specific microenvironment.
Methods: To study the role and impact of organ microenvironment on the tropism of breast cancer cells, we used parental and lung-metastatic variants of MDA-MB-231cells by seeding the various cell densities (25 k, 15 k, 5 k, 2.5 k, 1 k, and 0.5 k cell/cm²) on decellularized lung matrices. The decellularized lung biomatrix scaffolds were harvested from rats using perfusion protocol. To assess cell activity, ATP-based luminescence assays were performed for all conditions and normalized to the corresponding control condition (cells cultured in the absence of lung biomatrix).
Results: Normalized ATP measurements showed that decellularized lung biomatrix differentially modulated the metabolic activity of parental and lung-metastatic MDA-MB-231 cells. Across almost all seeding densities and biomatrix concentrations, the lung-metastatic variant generally exhibited higher growth velocity than the parental line, suggesting that the lung-derived matrix provides a more favorable microenvironment for the metastatic cells through enhanced cell-matrix interactions that activate proliferative signaling pathways. This difference was most evident at higher cell seeding densities and higher protein concentrations of decellularized lung biomatrix. At 25 k, 15 k, and 5 k cells/cm², the lung-metastatic cells displayed a clear increase in normalized metabolic activity relative to the parental cells at 200 and 300 µg/cm². In contrast, at cell densities of 2.5 k, 1 k, and 0.5 k cells/cm², normalized ATP values for parental and metastatic cells were comparable across all matrix protein densities within 5 days culture period. Ongoing work aims to further characterize cellular activities and cell-matrix signaling pathways in the lung-mimetic scaffolds.
Conclusion: Our ex vivo model based on decellularized lung biomatrix scaffolds demonstrates that lung specific microenvironmental cues selectively enhance the metabolic activity of lung-metastatic breast cancer cells relative to parental cells, supporting microenvironmental regulation of organ specific metastatic preference.

#4925 Unlocking the extracellular matrix as a source of novel targets: A matrisome-based platform to characterize the tumor microenvironment.

Edward Long, Cecilia Pennica, Lisa Sassi, Seyed Mahfouzi, Filippo Prestinoni, Luca Frenguelli, Gareth Muirhead, Kovilen Sawmynaden, Athiva Shankar, Tu Vinh, Matthew J. Edwards, Chris Stevenson, Emma Huang, **Sam Cooper**, Giuseppe Mazza

Engitix Therapeutics, London, United Kingdom

Background:
The extracellular matrix (ECM) is a bioactive environment key to tumorigenesis and disease progression. Yet despite evidence that multiple ultra-selective ECM targets exist, efforts to leverage the ECM for therapeutic targeting have remained centered on fibronectin isoforms.
Methods:
We leveraged a decellularization protocol focused on preserving stable ECM targets to characterize the matrisome in three cancer indications, including moderately to poorly differentiated pancreatic ductal adenocarcinoma (PDAC) tumors (n = 5; stage IA-IIB), moderately differentiated primary colorectal cancer (CRC) tumors (n = 5; stages I-IIIB), and CRC liver metastases (CRC-LM; n = 5; stage IV). For each indication, we decellularized tumor and background whole-tissue samples using mechanical and chemical approaches. This method enables the removal of cells while preserving 3D ECM structure and composition. Decellularized ECM was then analyzed histologically and with proteomics via TMT DDA mass spectrometry (MS).
Results:
Analysis of CRC and CRC-LM tumor and adjacent non-tumor tissue samples identified 1,080 commonly expressed proteins, 79 of which were core matrix proteins and 67 matrix-associated. Tumor-specific matrisome signatures clearly differentiated tumor from non-tumor adjacent tissue samples for both indications—83 and 96 ECM proteins were differentially expressed in CRC and CRC-LM, respectively (FDR < 0.05). Analysis of PDAC tumors and adjacent non-tumor tissue samples detected 854 proteins, including 103 core matrisome and 77 matrisome-associated proteins. In addition, we identified a PDAC signature of 109 ECM proteins differentially regulated between tumor and background. Critically, comparison of highly enriched targets identified by this study with both bulk and single-cell RNA data indicated that a number of these targets are ultra-selective and could thus serve as valuable ECM-stable candidates for therapeutic targeting.
Conclusions:
TMT-MS analysis of decellularized tumors and adjacent non-tumor tissues defined a novel, tumor-specific matrisome signature enriched for stably bound proteins. Integration of this dataset with transcriptomic data identified specific ECM pathways and targets that may be valuable for therapeutic targeting.

#4926 Modeling the metaplastic triple negative breast cancer matrix.

Elizabeth Martin[1], Katherine Hebert[2], Mackenzie Hawes[2], Thomas Cheng[2], Delia Carlino[3], Matthew E. Burow[4], Bridgette M. Collins-Burow[2], Jorge Belgodere[2]

[1]Tulane Univ. Health Sciences Ctr., New Orleans, LA,[2]Tulane University School of Medicine, New Orleans, LA,[3]Tulane Cancer Center, New Orleans, LA,[4]Associate Professor of Medicine & Surgery, Tulane University School of Medicine, New Orleans, LA

Metaplastic breast cancer accounts for >1% of all breast cancers and is marked by an aggressive phenotype with poor patient survival. Individuals diagnosed with metaplastic breast cancer have higher rates of recurrence, metastasis, and limited therapeutics options. Further the five-year survival rate of metaplastic breast cancer is 55%. Metaplastic breast cancer is characterized by unique histological features and recent evidence suggests that metaplastic breast tumors have extensive extracellular matrix (ECM) remodeling, including altered protein expression and increased ECM stiffness. Due to the scarcity of this tumor type, accurate modeling of the metaplastic ECM would provide enhanced *in vitro* testing and ultimately guide the discovery of novel targeted treatments for this rare disease. Here we demonstrate changes in the metaplastic TNBC tumor microenvironment and preliminary modeling of the metaplastic matrix *in vitro*. Specifically, SEM imaging revealed enhanced pore size and stiffness in the metaplastic tumor compared to matched distal breast adipose tissue. Further, metaplastic TNBC had significant enrichment for ECM proteins, notably glycoproteins (MFAP2, POSTN, FN1), compared to distal adipose. The enhanced expression of the glycoprotein MFAP2 in primary metaplastic and non-metaplastic TNBC breast cancer cell lines demonstrated enrichment of genes associated with the biological process: epithelial-to-mesenchymal transition. In depth analysis of genes elevated with MFAP2 expression in metaplastic TNBC demonstrated elevated expression of genes associated with a cancer stem like phenotype and ECM remodeling. Overall, our results establish an extracellular signature and onco-architecture for the metaplastic triple-negative tumor type.

#4927 Expression profiles of TCF-4 variants across digestive system cancers quantified by a novel PNA-directed qPCR assay.

Hironori Koga, Yasuko Imamura, Tomoya Sudo

Kurume University Research Center for Innovative Cancer Therapy, Kurume-shi, Japan

Background: TCF-4, a key transcription factor in the Wnt/β-catenin pathway, produces multiple splice variants with distinct functions. Although our group previously identified 14 variants in liver cancer cells, quantitative assessment across digestive system cancers has been limited by the low resolution of conventional assays. To address this unmet need, we developed a peptide nucleic acid (PNA)-directed PCR clamping-based quantitative RT-PCR system enabling precise discrimination of individual TCF-4 splice variants.
Purpose: To establish a robust quantitative framework for variant-level TCF-4 expression analysis and delineate organ-specific expression patterns across digestive cancer cell lines and colorectal cancer (CRC) tissues, with emphasis on the functionally distinct variants TCF-4J (SxxSS–) and TCF-4K (SxxSS+). Methods: A PNA-qPCR platform was constructed for sensitive discrimination of closely related TCF-4 splice variants. Sixteen cell lines representing liver, stomach, colorectum, pancreas, and pancreatic neuroendocrine tumors were analyzed. TCF-4J and TCF-4K expression levels were further quantified in 39 paired CRC tissues and adjacent mucosa (IRB-approved). An exploratory subgroup analysis was performed using quartile-based stratification of tumor TCF-4J expression.
Results: The PNA-qPCR system enabled specific quantification of 14 TCF-4 variants. Distinct organ-dependent expression signatures were observed: liver cancer cell lines showed a predominantly TCF-4B-dominant pattern, whereas gastric, colorectal, and pancreatic cancer lines exhibited TCF-4J-dominant profiles, indicating lineage-specific variant usage rather than differentiation-dependent changes. In CRC tissues, TCF-4J was significantly upregulated relative to noncancerous mucosa, whereas TCF-4K expression remained low. Exploratory quartile analysis revealed that patients in the lowest 25% of tumor TCF-4J expression had no distant metastasis, and this subgroup showed a trend toward longer overall survival compared with higher-expression cases (51 vs. 23 months).
Conclusions: This study establishes a sensitive quantitative platform for TCF-4 variant profiling and reveals striking organ-specific differences in variant usage across digestive system malignancies. The inverse relationship between low TCF-4J expression and metastatic progression in CRC suggests potential biological relevance. Integration of this bulk RNA-based framework with single-cell and spatial transcriptomic approaches will be essential to elucidate variant-specific regulation and intratumoral heterogeneity.

#4928 Immune signaling reporter cell lines enable quantitative monitoring of crosstalk among cancer, innate, and adaptive immune cells in tumor microenvironment model.

Hyeyoun Chang, John G. Foulke, Luping Chen, Meghan Sikes, Catherine McManus, Fang Tian

ATCC, Manassas, VA

Background: T cell-targeted immunotherapies have led to major clinical gains, yet many patients fail to respond or develop resistance due to the immunosuppressive tumor microenvironment (TME). Increasing evidence shows that B cells and myeloid cells also influence antitumor immunity, but accessible models capable of capturing interactions among cancer cells and multiple immune cell types remain limited. To address this gap, we developed immune signaling reporter cell lines that allow real-time, quantitative monitoring of NFAT- and NF-κB-driven activation pathways. These models enable capturing dynamic interactions among multiple immune cell lineages and cancer cells relevant to immunotherapy response.

Methods: Six luciferase-based reporter lines derived from T cells, B cells, or myeloid cells were engineered with NFAT or NF-κB response elements driving luciferase expression. The models retain high endogenous expression of checkpoint receptors, including PD-1, TIGIT, and GITR in T cell reporters and SIRPα, Siglec-10, LILRB1, and B7-1 in myeloid reporters. Reporter activation was assessed following pathway-specific stimulation: PMA and ionomycin for NFAT and TNF-α or T cell-conditioned media for NF-κB. The B cell NF-κB reporter with elevated basal activity was further tested with an NF-κB inhibitor. In addition, all reporters were evaluated in co-culture with primary immune and cancer cells.

Results: Stimuli activating NFAT or NF-κB signaling produced strong, dose-dependent increases in luciferase activity, while pathway inhibition reduced signal as expected. Co-culture with primary immune and cancer cells generated diverse activation patterns, reflecting context-dependent signaling shaped by interactions within the TME.

Conclusions: These reporter cell lines provide a scalable platform for monitoring NFAT- and NF-κB-driven immune activation across T, B, and myeloid lineages. They support sensitive, reproducible evaluation of immune responses, enable mechanistic studies of dynamic immune crosstalk, and evaluation of combinatorial immunotherapy strategies within the TME.

#4929 CAR-Tmigration andcytotoxicity in atumor-vasculature-on-chipmodel.

Luuk de Haan, Aleksandra Olczyk, Thomas Olivier, Joris Wesselius, **Will Allen**, Johnny Suiker, Todd Burton, Lenie van den Broek, Karla Queiroz

MIMETAS B.V, Oegstgeest, Netherlands

CAR-T cell therapies have shown remarkable success in hematologic malignancies; however, their efficacy in solid tumors remains limited. This is primarily due to the complex tumor microenvironment (TME), which creates immunosuppressive conditions and physical barriers that hinder CAR-T infiltration and function. Current in vitro models fail to replicate these critical parameters, limiting the ability to predict clinical performance. To address this gap, we developed a tumor-vasculature-on-chip model using the OrganoPlate platform, enabling perfusion of CAR-T cells through a functional endothelial vessel adjacent to a tumor compartment. This setup allows assessment of key processes such as extravasation, migration, and killing kinetics in a physiologically relevant context. EpCAM-positive HT-29 colorectal cancer cells and EpCAM-negative A375 melanoma cells were co-cultured with an endothelial tubule to evaluate EpCAM-targeting CAR-T cells. CAR-T cells selectively killed EpCAM-positive HT-29 cells while sparing EpCAM-negative A375 cells, demonstrating antigen-specific activity. Killing was dose-dependent, and endothelial integrity was maintained at most CAR-T concentrations but disrupted at the highest doses, revealing a therapeutic window. We further compared CAR-T constructs with different co-stimulatory domains (CD28 vs. 4-1BB) and observed reduced potency with 4-1BB. Addition of IL-2 enhanced CAR-T cytotoxicity. Cytokine profiling showed increased IFN-γ, TNF-α, and IL-6 over time, and morphometric analysis confirmed endothelial disruption at high effector-to-target ratios. The platform was also used to study combination strategies, including immune checkpoint inhibitors and temozolomide. This modular, scalable organ-on-chip system enables phenotypic and functional characterization of CAR-T cells under relevant conditions.

#4930 Cell Avidity: The Next-Gen cell binding assay to understand therapeutic mechanism of action through quantifying cell-cell and cell-protein interaction strength.

Keith Bailey[1], Riley Pihl[1], Michael SAVAGE[2], Trey Simpson[3]

[1]LUMICKS, Amsterdam, Netherlands,[2]LUMICKS, New York, NY,[3]LUMICKS, Boston, MA

While conventional assays such as affinity, cytokine secretion, and cytotoxicity provide valuable data at a molecular level, this information is insufficient to fully characterize and select the best cellular therapies. There is still a lack of understanding about the biophysical cell-cell interactions that drive functional processes.

Methods: Cell avidity, the integrated strength of multivalent interactions between an effector cell and its target, can help elucidate the mechanism of action for therapeutic candidates. Our Cell Avidity platform challenges these interacting pairs using contactless force and quantifies the strength of binding between effector and target cells to distinguish productive from unproductive cell binding in a physiological context. This biophysical metric provides a unique view into cell binding characteristics to interrogate binding potency, selectivity, sensitivity, and kinetics.

Results: Here, we review recent publications highlighting how researchers have used Cell Avidity to: • Fine-tune the affinity/cell avidity of CAR-T cells to mitigate on-target off-tumor toxicity in renal cell carcinoma. • Assess the impact of Venetoclax treatment on NK cells, finding improvements to cytoskeleton remodeling and lytic granule polarization, which contributed to a more efficient IS, enhancing NK cell-mediated killing of AML cells. • Format-tune bispecific T cell engagers to enhance efficacy against renal cell carcinoma • Validate binding mechanism of tandem CAR-T cells to overcome tumor heterogeneity • Engineer CAR-T cells secreting a T-cell engaging molecule to overcome a challenging tumor microenvironment in pancreatic adenocarcinoma. • Elucidate mechanism of action of tandem CAR-T targeting heterogenous solid tumors • Phenotype the tumor-primed NK cells for cell binding and function.

Conclusions: We developed a Cell Avidity platform that enables the characterization and screening of molecular binders and cellular products, including antibodies, small molecules, and cell therapies. Cell Avidity provides comprehensive information on potency, selectivity, sensitivity, and kinetics, offering key insights into the mechanism of action for cell therapies.

#4931 Development of a CyTOF panel for macrophage polarization and functional assessment under treatment conditions.

Poornima Gourabathini[1], Rachel Weil[2], **Kimberly Q. McKinney**[3], Jeffrey S. Huo[1], Kenzie Wells[4], Kaitlyn Smith[5], David M. Loeb[2], Javier Oesterheld[4]

[1]Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Charlotte, NC,[2]Albert Einstein College of Medicine, Bronx, NY,[3]Pediatric Oncology Research Laboratory, Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Charlotte, NC,[4]Atrium Health Levine, Charlotte, NC,[5]Wake Forest Baptist Health, Winston Salem, NC

Purpose: Tumor associated macrophages (TAMs) are prevalent in the sarcoma tumor microenvironment, and often contribute to immune suppression, angiogenesis, and tumor progression. TAMs exhibit a spectrum of polarization states, ranging from anti-tumor (M1) to tumor-supportive (M2) functions. Mass cytometry (CyTOF) enables high-dimensional single-cell profiling, making it ideal for dissecting the presence and abundance of various macrophage phenotypes within a tumor. This study aimed to design and validate a CyTOF panel targeting macrophages and associated immune markers, to characterize macrophage polarization states and evaluate treatment induced changes in macrophage subtypes.

Methods: A mouse macrophage-focused CyTOF panel was developed comprised of 40 markers, including lineage markers, activation markers, and cytokine-associated proteins relevant to M1/M2 phenotypes and other immune cell populations. For optimization of antibody titration and staining conditions, macrophage polarization was performed *in vitro* using the commercially available mouse-derived macrophage cell line RAW 264.7. Macrophage polarization states were induced under standard conditions: M1: LPS + IFN-γ and M2a: IL-4 + IL-13, M2b- OVA, Anti-OVA IgG, M2c- IL-10, and M2d-NECA stimuli. Following validation, the panel was applied to a mouse model of orthotopically implanted osteosarcoma cells treated with a novel compound to quantify the TAM polarization and associated immune networks. Tumor tissue samples were dissociated into single cell suspensions, stained using the CyTOF panel, and analyzed using dimensionality reduction (UMAP) and clustering algorithms.

Results: The 40-marker CyTOF panel was successfully used to identify and characterize macrophage subtype populations in vitro as well as in mouse xenograft tumors. In vitro polarization of mouse RAW264.7 cells showed distinct phenotypic clusters corresponding to M1 and M2 subtypes. These results also enabled effective antibody titration. Treatment of orthotopically implanted osteosarcoma tumors with the novel compound resulted in increased expression of M1 markers and a reduction in M2-associated markers compared to vehicle control, indicating a shift in macrophage polarization induced by this compound.

Conclusion: The developed CyTOF panel provides a robust platform for high-resolution analysis of macrophage polarization and treatment-induced phenotypic changes, offering more detailed investigation of immune modulation strategies. This panel could be applied as a tool for future investigations focused on macrophage subpopulations and their functional roles and will allow for further dissection of the tumor immune microenvironment, advancing the understanding of immunological variability in response to treatment.

#4932 Establishment and characterisation of PDTOs and CAFs for the development of a co-culture system in pancreatic periampullary adenocarcinoma.

Panagiotis Sarametidis[1], Jojanneke Stoof[1], Laura Ivers[2], Jean Murphy[3], Niall Swan[3], Luca Benigno[3], Fiona Hand[3], Kevin C. Conlon[3], Paul B. Mullan[4], Maeve Lowery[5], Naomi P. Walsh[1]

[1]Dublin City University, Dublin, Ireland,[2]Life Sciences Institute, Dublin City University, Dublin, Ireland,[3]St. Vincent's University Hospital, Dublin, Ireland,[4]Postdoctoral Fellow, Dept. of Oncology, Queen's University Belfast, Belfast,[5]Trinity St James Cancer Institute, Dublin, Ireland

Periampullary adenocarcinoma (PAC) constitutes a diverse group of malignancies originating from the pancreatic head (60%), the ampulla of Vater (20%), the distal common bile duct (10%), and the duodenum (10%). The pancreatic tumour microenvironment (TME) is a major driver of tumour progression and therapeutic resistance, with cancer-associated fibroblasts (CAFs) emerging as central contributors. Representing a heterogeneous population within the TME, CAFs actively mediate stromal remodelling through complex interactions with tumour cells as well as with immune and stromal components. Detailed characterisation of CAF phenotypes is essential to define their impact to PAC pathobiology and to facilitate the design of novel therapeutic strategies against this highly aggressive malignancy.Patient-derived tumour organoids (PDTOs) and CAFs were isolated from freshly obtained primary PAC specimens. CAFs subtypes were characterised by immunofluorescence staining for key CAF proteins and transcriptomic sequencing. PDTOs were characterised by genomic sequencing. Drug screening of PDTOs with talazoparib and olaparib was conducted to examine the correlation between an HRD mutation and sensitivity to PARP inhibitors.4 PDTOs and 4 CAFs were successfully derived and cultured from PAC specimens. CAF cell lines showed positive expression of fibroblast markers α-SMA and vimentin, and showed heterogeneous intensity and expression of CAF markers such as PDGFR and FAP. They were categorised into antigen-presenting (apCAFs), inflammatory (iCAFs) and myofibroblastic (myCAFs) subgroups based on the RNA expression of key genes. MyCAFs were grouped based on the expression levels of CTGF, COL1A1, POSTN and ACTA2 genes. CD74 and HLA genes were chosen for the characterisation of apCAFs, while iCAFs were characterised based on the expression of IL-1/6/11, FAP and CXCL1/2 genes. Mutational profiling of the PDTOs identified a missense ATM variant c.5558A>T (p.Asp1853Val) in an intestinal-type adenocarcinoma, which was sensitive to olaparib (1.66 μM) and talazoparib (0.45 μM).PDTOs and CAFs serve as a useful model for studying the cellular architecture and heterogeneity of PAC in vitro. Building on this, defined CAF heterogeneity will be assessed for its association with immunosuppressive versus immunostimulatory profiles, and T cells, along with immunotherapeutic agents, will be incorporated into the co-cultures. These models will provide valuable insights into PAC tumour-stroma-immune biology and form the basis for advanced co-cultures to test strategies targeting the TME.

#4934 Identifying molecular regulators of ovarian tumor cell attachment to peritoneal mesothelial cells under shear stress using an *ex-vivo* microfluidic model.

Jillian A. Martin[1], Breanna Baker[2], Vasilios Morikis[1], Alessandra DiMauro[1], Gregory D. Longmore[1], Whitney R. Grither[3]

[1]Medical Oncology, Washington University School of Medicine, St. Louis, MO,[2]Hematology, Washington University School of Medicine, St. Louis, MO,[3]Obstetrics and Gynecology, Washington University School of Medicine in St. Louis, St. Louis, MO

Ovarian cancer metastasis is unique in that the primary tumor and the initial metastatic site, the peritoneal mesothelial layer, share the same cavity. Early spread of ovarian cancer involves tumor cell shedding from primary ovarian tumors, which then circulate throughout the abdominal cavity to attach and invade mesothelium covering the abdominal organs. During peritoneal migration, ovarian tumor cells are also exposed to ascitic fluid, and the influence of this fluid flow on tumor cell attachment to mesothelium is poorly understood. To address this problem, we developed and characterized a robust microfluidic device incorporating ovarian tumor cell attachment to mesothelial cells in the presence of fluid flow. Mesothelial cells are cultured within the microfluidic device for 48 hours, and ovarian cancer cells are introduced at fixed flow rates for 7 minutes. Using live cell video imaging and analysis, we can quantify the extent of tumor cell adhesion. We find that factor(s) secreted by ovarian tumor cells significantly increase tumor cell adhesion to mesothelium. To identify candidate molecules modulating this cell-cell communication, we performed bulk mRNA sequencing of mesothelial cells treated with ovarian tumor cell culture supernatant and proteomics of the ovarian tumor cell secreted media. From these analyses, we have identified numerous potential candidate molecules. One of these molecules, cadherin-12, is downregulated in mesothelial cells in response to tumor cell culture supernatant exposure both in vitro and in vivo. Genetic depletion of cadherin-12 in mouse peritoneal mesothelial cells results in altered mesothelial barrier function, fibroblastic differentiation, and increased tumor cell adhesion to mesothelium. Our results suggest that cadherin-12 plays a role in maintaining peritoneal mesothelial integrity and is manipulated by some factor(s) secreted by ovarian tumor cells during early ovarian cancer metastasis.

#4935 Cell cycle regulation by PAX3-FOXO1 via WEE1 kinase in fusion-positive rhabdomyosarcoma.

Chandra Kaladhar Vemula, JinSeok Park

Hematology and oncology, Children's Hospital Los Angeles, Los Angeles, CA

IntroductionFusion-positive rhabdomyosarcoma (FPRMS) is a highly aggressive form of the most common childhood muscle cancer, rhabdomyosarcoma. A distinct genetic signature, the PAX3-FOXO1 (P3F) fusion gene, characterizes a subtype of the most common pediatric soft tissue sarcoma. We aim to understand the collective cell invasion by determining how leader-follower cellular cooperation, P3F signaling, and the cell-cycle checkpoint kinase WEE1 drive tumor growth and invasion, and whether inhibiting WEE1 can blunt these behaviors.
Brief Experimental Procedures To understand the collective cell invasion of FPRMS, we utilize a 3D "mini-tumor" (spheroid) model that recapitulates leader cells at the invasive front and rapidly proliferating follower cells behind them. We paired this with live-cell reporters of cell-cycle checkpoint activity and proliferation. We analyzed the transcriptome of FPRMS cells with P3F knockdown (PFKD) to confirm whether P3F regulates cell cycle checkpoints and DNA replication. Additionally, we employ ChIP-seq to identify the P3F-regulated genes and pharmacological WEE1 inhibition.
ResultsOur preliminary data show that follower cells exhibit higher P3F expression, increased proliferation, and elevated WEE1 activity relative to other regions, consistent with a fast-cycling compartment that mechanically supports leader-directed invasion. These findings suggest that P3F upregulates WEE1-dependent programs, which fuel follower growth and cooperative invasion. Additionally, we use P3F knockdown to demonstrate, via RNA-seq, the Negative enrichment of gene sets associated with the G1/S transition and DNA replication in PFKD FPRMS cells. PAX3-FOXO1 regulates cell cycle progression by S-phase arrest. Furthermore, P3F regulates cell cycle progression by reducing the expression of pCDK2 and the double-strand break regulatory gene γH2A.X.
ConclusionsTogether, the data support a model in which P3F-driven WEE1 signaling sustains the follower population that powers collective invasion in FPRMS. Targeting WEE1 slows growth and invasion in our 3D model, suggesting that WEE1 inhibition is a therapeutic strategy worthy of further evaluation in patient-derived specimens and preclinical studies.

#4936 Dissecting tumor microenvironment and cellular adaptation in ovarian cancer models using Bio-Rad ddSEQ Single-Cell 3' RNA-Seq technology.

Errile Pusod[1], Madison Uyemura[2], Patricia Schnepp[1], Aqila Ahmed[1], Angelica P. Olcott[3], Adnan Chowdhury[3], Michelle Racey[3], Elizabeth Dreskin[3], Zhen Ni Zhou[4], Analisa DiFeo[2]

[1]Bio-Rad Laboratories, Ann Arbor, MI,[2]Department of Pathology, University of Michigan, Ann Arbor, MI,[3]Bio-Rad Laboratories, Hercules, CA,[4]Department of Obstetrics and Gynecology, University of Michigan, Ann Arbor, MI

Ovarian cancer remains one of the most lethal gynecologic malignancies due to its complex biology and the challenges associated with early detection and effective treatment. Advances in single-cell RNA sequencing technologies have enabled researchers to dissect cellular heterogeneity within tumors and gain deeper insight into the dynamic interactions between cancer cells and their microenvironment. By leveraging innovative single-cell analysis tools, analysis of gene expression profiles at single-cell resolution can be performed across various cancer models, providing valuable information on tumor evolution, therapeutic response, and mechanisms driving tumorigenesis.Single-cell and single-nucleus RNA sequencing were performed using the Bio-Rad ddSEQ 3’ Single-Cell RNA-Seq Kit on multiple cancer models—including a primary high-grade serous ovarian tumor, a patient-derived cancer cell line (PDCC), and a patient-derived xenograft (PDX)—all originating from the same patient. The objective of this study is to investigate the role of the tumor microenvironment in modulating gene expression patterns that support the persistence and adaptation of cancer cells in various patient-derived models. By comparing single-cell transcriptomic profiles across these models, we aim to identify key regulatory pathways and microenvironmental signals that influence cellular behavior. These insights may advance our understanding of tumor cell adaptation mechanisms and facilitate the development of more physiologically relevant models for cancer research. Integration of single-cell data from various cancer models showed concordance of distinct clusters suggesting changes in gene expression specific to the cancer model utilized. We identified cancer cells as well as fibroblasts, endothelial cells, T and B cells, and myeloid cells in the primary tumor sample. Additionally, enrichment of cancer cells expressing increased levels of *PHGDH* and *PSAT1*, genes associated in serine metabolism pathway that is crucial in tumorigenesis was observed in PDCC samples - data which were previously confirmed with bulk RNA-Seq. The Bio-Rad ddSEQ 3’ RNA-Seq kit enables robust analysis of various *in vitro* and *in vivo* cancer models due to the capability of running many samples simultaneously, generating high-quality single-cell data. The observed concordance of distinct expression profiles—particularly the upregulation of serine metabolism genes in enriched cancer cell populations—highlights the power of single-cell approaches to uncover both cellular diversity and model-specific molecular features. These findings underscore the value of high-throughput single-cell technologies for advancing our understanding of ovarian cancer biology, with implications for improving cancer models and identifying potential therapeutic targets.

#4937 Enabling transcriptome-wide single cell RNA sequencing from FFPE tissues with Evercode WT combinatorial barcoding.

Aisling Sinclair, Ajay Sapre, Alec Salvino, Guillermo Gallareta-Olivares, Vuong Tran, Joey Pangallo, Gokhan Demirkan, Sam You, Charles Roco, Alexander Rosenberg

Parse Biosciences, Inc., Seattle, WA

Formalin-fixed, paraffin-embedded (FFPE) tissues represent a vast and underutilized resource of patient data for retrospective and translational research. While FFPE enables long-term preservation of valuable clinical specimens, RNA degradation and fragmentation have historically hindered its compatibility with single cell RNA sequencing (scRNA seq). Currently, researchers have relied on probe-based FFPE profiling approaches and are limited to predefined target sets, restricting transcriptome coverage and discovery potential.

Here, we introduce a novel split-pool combinatorial barcoding method for FFPE tissue that captures the full transcriptome through dual priming with both poly dT and random hexamer reverse transcription primers. This workflow extends the scalability of Parse's single-cell technology to FFPE tissues, enabling unbiased transcriptome-wide analysis of millions of cells and hundreds of samples within a single experiment. By capturing a broad range of RNA biotypes, this approach delivers deeper insights into cellular function and disease mechanisms.

As a proof of concept, FFPE tissues from multiple organs, including kidney, brain, lymph node, liver, and breast tumor, were processed using our novel Evercode Whole Transcriptome (WT) for FFPE assay. The resulting single cell datasets demonstrated high-resolution identification of cell types across diverse tissue types. Comparative analyses between FFPE and matched fresh frozen samples revealed concordance in gene expression patterns and cell type proportions, validating the approach's complete capture of sample biology. In cancer samples, complex cellular biology was captured from the detection of tumor infiltrating lymphocytes to cancer associated fibroblasts.

By enabling transcriptome wide scRNA-seq from thousands to millions of cells from FFPE-preserved tissues across hundreds of samples simultaneously, this method greatly expands access to single cell analyses of archival specimens, offering a powerful platform for translational oncology, biomarker discovery, and precision medicine research.

#4938 Elucidation and pharmacologic targeting of master regulator proteins representing mechanistic determinants of macrophage state and immunoevasive potential.

Gaetano Viscido[1], Mikko Turunen[1], Zhouzerui Liu[2], Justyn Chang[2], Meghna S. Raman[2], Leo B. Dupire[1], Hanrui Zhang[3], Tim Olsen[2], Jeremy Worley[4], Aleksandar Obradovic[5], Andrea Califano[6]

[1]Systems Biology Department, Columbia University, New York, NY,[2]Chan Zuckerberg Biohub, New York, NY,[3]Cardiovascular Genomics Program, Department of Medicine, Columbia University Irving Medical Center, New York, NY,[4]Columbia University and Chan Zuckerberg Biohub, New York, NY,[5]Columbia University, New York, NY,[6]Dept. of Systems Biology and Dept. of Medicine and Dept. of Biomedical Informatics and Dept. of Biochemistry & Molecular Biophysics, and HICCC, Columbia University Irving Medical Center; Chan Zuckerberg Biohub, New York, NY

PURPOSE: Macrophages (mΦ) exhibit extensive transcriptional plasticity within the tumor microenvironment (TME). While M1 mΦ promote anti-tumor immunity, regulatory M2 mΦ drive tumor progression and resistance to immune checkpoint therapy. In a recent study, Obradovic et al. (Cell 2021) used VIPER, a network-based algorithm that infers protein activity from transcriptomic data, to identify a highly immunosuppressive TAM subset in clear cell renal carcinoma (ccRCC) characterized by TREM2$^+$/C1Q$^+$/APOE$^+$ (TCA$^+$) expression. TCA$^+$ mΦ were associated with poor prognosis, metastasis, and immune evasion. We aim to identify Master Regulator (MR) proteins that mechanistically control the TCA$^+$ program and may serve as actionable targets for selective depletion or reprogramming of these cells toward neutral, antitumor or pro-inflammatory states.

METHODS: We performed pooled single-cell CRISPR interference (CRISPRi) via Perturb-seq targeting 50 candidate MRs identified by VIPER from genes differentially expressed in TCA$^+$ versus M0/M1 mΦs, followed by time-resolved scRNA-seq. THP-1 monocytes were differentiated and polarized to the M2 state using IL-4 and IL-13 for 48 hours, then profiled across seven time points spanning M2 polarization (0, 6, 12, 24, 48, 96, 192 hr). Approximately 100,000 cells per time point were analyzed, along with ~10,000 unperturbed THP-1-derived M0, M1, and M2 mΦs as references. We aim to generate perturbational RNA-seq profiles of TCA$^+$ mΦs with >350 drugs using PLATE-seq to identify compounds that either target individual MRs (OncoTarget) or invert the global MR-activity signature (OncoTreat), thus phenocopying validated genetic perturbations.

UNPUBLISHED DATA: We generated a comprehensive dataset comprising ~700,000 time-resolved (~100,000 cells per time point), genetically perturbed mΦs, enabling high-resolution characterization of MR-specific transcriptional responses across the full course of M2/TCA$^+$ polarization. The dataset captures early, intermediate, and late transcriptional changes induced by targeted repression of candidate MRs, providing a dynamic view of the regulatory architecture underlying the acquisition and maintenance of the TCA$^+$ state. We will integrate with >350 drug-perturbation profiles to establish a matched pharmacologic resource for downstream identification of compounds capable of modulating MR activity or globally shifting the TCA$^+$ transcriptional program.

CONCLUSION: This study provides a large-scale, time-resolved map of regulatory programs in immunosuppressive TCA$^+$ mΦs, with the aim of identifying and targeting Master Regulators to invert their immunosuppressive phenotype. This framework offers a path to neutralize mΦ-mediated immunosuppression and improve responses to immune checkpoint therapy.

#4939 Quantifying tumor immune escape through immunogenic tension mapping.

June-Young Koh[1], Ludmil B. Alexandrov[2]

[1]UCSD, San Diego, CA,[2]UC San Diego Health, San Diego, CA

Predicting response to immunotherapy remains challenging because biomarkers such as TMB, PD-L1 expression, and bulk immune infiltration offer only static snapshots of tumor biology and fail to capture the cumulative influence of immune pressure over time. Immune pressure leaves discernible footprints on tumor evolution, and characterizing these signatures may help distinguish tumors shaped by immune editing from those that have escaped immune surveillance. Comparing observed tumor genomes with patient-specific neutral expectations provides a direct framework for revealing such evolutionary deviations. Using TCGA colorectal cancers, we generated mutational-signature-matched neutral simulations and quantified how far each tumor diverged across multiple evolutionary metrics. Observed coding mutations showed substantially greater dispersion than neutral simulations. Although the cohort appeared near-neutral overall, tumors showing strong deviation in one metric consistently deviated across others, revealing a coherent subset under stronger selective pressure. These strongly deviated tumors aligned with well-established hypermutated categories—including POLE-mutated hypermutated tumors and MSI-H/indel-rich tumors—and displayed steep TMB gradients (44.8 vs 5.3 mut/Mb across quartiles). They also exhibited stronger immune-associated features, including significant higher CD8-related infiltration and elevated CD103 ratios in extreme cases, suggesting that immune activity contributes to the observed evolutionary divergence. To evaluate whether broader mutation patterns capture deeper evolutionary structure, we embedded observed and simulated mutation catalogs into a genomic foundation model. The resulting latent space clearly distinguished strongly deviated tumors from near-neutral cases, and also separated molecular subtypes and each sample's mutational-signature composition. These findings suggest that zero-shot sequence representations capture contextual patterns linked to immune-driven tumor evolution. Because these embeddings encode mutation context at a finer resolution than classical summaries, they can recover evolutionary trajectories and underlying mechanisms that remain obscured in low-dimensional metrics. Together, these results show that immune-linked evolutionary divergence is detectable even when cohort-level averages appear neutral. Tumors that diverge most strongly from neutral expectation correspond to hypermutated biology and increased CD8-driven immune activity. Evolution-based approaches—especially when combined with foundation-model embeddings—offer a scalable framework for quantifying historical immune pressure and refining immunologic stratification beyond conventional biomarkers.

#4940 A hybrid mathematical model: Emergent CAF structures and their impact on cancer progression.

Junho Lee, Eunjung Kim

Center for Natural Product Systems Biology, Korea Institute of Science and Technology, Gangneung, Korea, Republic of

Cancer-associated fibroblasts (CAFs) are key regulators of the tumor microenvironment (TME), exhibiting diverse phenotypes that exert both anti- and pro-tumorigenic effects. To investigate how this heterogeneity shapes cancer progression and therapy response, we first developed an ordinary differential equation (ODE) model, which assumes a well-mixed, homogeneous, and non-spatial TME. This mean-field framework captures cancer-immune-CAF interactions and predicts that CAF composition strongly influences treatment outcomes sometimes making single-agent therapies as effective as multi-drug combinations, or conversely rendering even triple-combination therapies ineffective. These results highlight CAF composition as a potential biomarker for guiding less invasive, CAF-informed therapeutic strategies.

To overcome the limitations of non-spatial ODE models, we developed a hybrid Agent-Based Model-Partial Differential Equation-Ordinary Differential Equation (ABM-PDE-ODE) framework. In this spatial model, cancer cells, T cells, and CAFs are represented as individual agents that migrate, proliferate, or die based on local environmental cues. Diffusible factors including oxygen, CXCL, IFN-gamma, and TGF-beta are modeled by PDEs to generate spatial gradients, while each T cell independently solves an ODE-based PD-1/PD-L1 binding equation to determine its activation or exhaustion state. This multiscale model resolves spatial heterogeneity, local immunosuppressive niches, and CAF-driven barriers to immune infiltration phenomena that cannot be captured in the well-mixed ODE system.

Together, these complementary modeling approaches provide a unified multiscale framework to evaluate how CAF phenotypic diversity shapes cancer dynamics and treatment response, and they offer new opportunities for CAF-informed, spatially guided personalized therapy design.

#4944 Chromogenic triplex characterization of breast and gastrointestinal cancers for biomarker discovery and spatial image analysis.

Andrew Fuller[1], Stacey Margerrison[1], **Scott J. Anderson**[1], Anne Hellebust[2]

[1]Leica Biosystems, Buffalo Grove, IL,[2]Indica Labs, Albuquerque, NM

Background: HER2 and PD-L1 expression serve as key biomarkers in breast and gastrointestinal (GI) cancer research. The tumor immune microenvironment, particularly the presence of tumor-infiltrating lymphocytes (TILs), also plays a critical role in these cancers, with mounting evidence of the importance of the signaling between the tumor and its environment. In this study, we evaluated two multiplex chromogenic immunohistochemistry (IHC) assays, HER2/PD-L1/CD3 and HER2/PD-L1/CD8, to assess the relationships among their expressions and related signaling pathways.
Methods: Formalin-fixed, paraffin-embedded (FFPE)tissue sections from HER2-expressing and/orPD-L1-positive breast and GI cancers were stained using CD3/HER2/PD-L1 andCD8/HER2/PD-L1 chromogenic multiplex IHC assays on the BOND RX RUO automated stainer from Leica Biosystems. The assays employed the Chromoplex III Triple Detection RUO system from LeicaBiosystems. Whole-slide imaging was performed on the Aperio GT 450 DX scanner, and HALO® digital image analysis from Indica Labs was used to quantify biomarker expression with the Multiplex IHC module leveraging HALO AI nuclear and membrane segmentation. Relationships between identified tumor cells and immune infiltrates were further interrogated with the Spatial Analysis module
Results: In HER2-positive breast cancer, expression of PD-L1and TIL markers (CD3, CD8) varied, with a subset of cases showing high CD8+ T-cell infiltration, potentially indicative of a more immunogenic phenotype.HALO AI analysis provides insights into proximity ofCD3, CD8 and PDL1 positive infiltrating cells to HER2positive carcinoma cells within breast and stomach carcinoma cases providing valuable spatial analysis using chromogenic multiplexing.Visualization of 3 markers simultaneously using ChromoPlex III Triple Detection RUO allows automated spatial analysis of tumor samples.In HER2 positive breast cancer and stomach cancer cases higher density of CD3+ cells and CD8+ cells shown to be in closer proximity to HER2 positive cells with the highest number of CD3 or CD8+ cells seen within 10uM of a HER2+ cell.
Conclusions: ChromoPlex III Triple Detection RUO can be used as a tool to identify 3 simultaneous markers in FFPE tissue using automated staining (BOND RX). As an example -multiplex chromogenic IHC staining of HER2, PD-L1,and CD3/CD8 provides valuable insights into the interplay between the tumor and the immune cell microenvironment in breast and GI cancers. The use of whole-slide digital pathology (Aperio GT 450 DX) and HALO AI Image Analysis, enables high-throughput assessment of multiplex chromogenic stained slides. HALO AI Image Analysis is a powerful tool for automated quantification of marker expression and proximity analysis.

#4945 Distinct colorectal cancer tumor cell subtypes revealed by single-cell and spatial transcriptomics.

Ji Hye Choi[1], Yeong Hak Bang[2], Kyung Yeon Han[3], Woong-Yang Park[4]

[1]Sungkyunkwan University, Seoul, Korea, Republic of,[2]University of Ulsan College of Medicine, Seoul,[3]Translational Genomics Center, Seoul, Korea, Republic of,[4]GENINUS, Seoul, Korea, Republic of

Background: Colorectal cancer is highly heterogeneous, exhibiting diverse tumor characteristics. However, studies focusing on the epithelial cell compartment remain limited. Here, we aimed to comprehensively profile CRC epithelial cells, define tumor-specific subtypes, and explore their spatial distributions and prognostic implications.
Method: We performed single-cell RNA sequencing of 65 primary CRC samples, along with 13 liver metastasis, 33 colon normal, and 8 liver normal controls. Epithelial cell clusters were classified using non-negative matrix factorization. After characterizing their transcriptional and developmental features, we mapped the subtypes to spatial transcriptomic data to assess spatial localization patterns within the tumor.
Results: We analyzed a total of 273,711 cells including 64,911 epithelial cells. Among these epithelial cells, 14 tumor-associated epithelial clusters were identified after excluding low-quality and normal-like clusters. Of these, seven clusters consistently abundant across multiple samples were selected for further analyses: C1 (inflamed), C2 (ribosomal), C3 (epithelial-mesenchymal transition; EMT), C4 (goblet-like), C5 (MHC II), C6 (oxidative phosphorylation), and C8 (proliferating). C1 and C3 were enriched in advanced-stage tumors and associated with poor prognosis in TCGA data. Trajectory inference suggested a developmental continuum from C8 toward C1 and C3, indicating potential tumor cell evolution toward EMT and inflamed states. Spatial transcriptomic analysis using both Visium and Xenium datasets revealed distinct localization patterns: C2, C6 and C8 were concentrated in the tumor core, whereas C1 and C3 were predominantly enriched at the tumor margin. Interestingly, tumor budding regions were predominantly composed of these C3 clusters, consistent with the EMT-like characteristics of tumor buds. Notably, co-localization analysis revealed subtype-specific epithelial-immune-stromal niches, in which myofibroblastic cancer-associated fibroblasts and *SPP1*$^{+}$ macrophages were spatially associated with C3 clusters, suggesting potential crosstalk that may promote tumor invasion and immune modulation.
Conclusions: We profiled colorectal cancer epithelial cells and identified distinct tumor cell subtypes with unique transcriptional and spatial characteristics. These subtypes exhibited dynamic interactions with the surrounding tumor microenvironment, suggesting that epithelial plasticity and spatial crosstalk may collectively drive tumor progression and immune evasion.

#4946 Osteopontin spatially rewires tumor-immune niches to promote colon cancer liver metastasis.

Patrick Czabala[1], Yang Zhao[1], John Klement[1], Dafeng Yang[1], Dakota Poschel[1], Kendra Fick[1], Zainab Tiamiyu[1], Martina Zoccheddu[1], Kristen Carver[1], Priscilla Redd[1], Patricia Schoenlein[1], Jennifer Waller[2], Huidong Shi[1], Kebin Liu[1]

[1]Biochemistry and Molecular Biology, Augusta University, Augusta, GA,[2]Biostatistics, Data Science, and Epidemiology, School of Public Health, Augusta University, Augusta, GA

Osteopontin (OPN) is a secreted extracellular matrix protein that regulates T cells, myeloid cells, and tumor cells. Although OPN is a known biomarker of colorectal cancer (CRC) progression and liver metastasis, the cellular circuitry linking OPN-producing and OPN-responsive cells in the metastatic liver microenvironment remains poorly defined. Here, we investigated how tumor-derived and host-derived OPN remodel this microenvironment to promote disease progression. Using orthotopic mouse models, we found that deleting OPN in either tumor cells or host cells was sufficient to increase T cell infiltration and suppress liver metastasis, whereas dual deletion produced an even greater reduction in metastatic burden. To define niche-specific programs, we applied COSMX spatial transcriptomics to mouse liver metastasis tissues, profiling 1,000 signature genes across 1,179,351 cells. We determined that tumor-derived OPN reprograms immune-inactive niches enriched for highly proliferative cancer cells, and that host-derived OPN rewires niches characterized by low monocyte and T cell abundance and enriched stem-like cancer cells. Mechanistically, tumor-derived OPN activates the MEK/ERK pathway to promote tumor cell proliferation. To translate these findings, we tested OPN blockade immunotherapy in mouse models. OPN blockade immunotherapy significantly suppressed tumor growth and increased immune cell infiltration in both syngeneic models and humanized mouse models of CRC liver metastasis. Together, these data identify tumor- and host-derived OPN as nonredundant, pro-metastatic drivers of proliferation, immune suppression, and niche remodeling, and support OPN inhibition as a promising immunomodulatory strategy for CRC liver metastasis.

#4947 Spatially organized transcriptional programs and tumor-stroma interfaces shape immunotherapy response in microsatellite instability-high gastrointestinal cancers.

Xueshuai Han[1], Kohei Yamashita[1], Melissa Pool Pizzi[2], Kyung Serk Cho[1], Enyu Dai[1], Kai Yu[1], Yunhe Liu[1], Yibo Dai[1], Tian Chu[1], Matheus Sewastjanow-Silva[1], Hiro Yoshimura[1], Yibo Fan[1], Rebecca Waters[1], Qiong Gan[1], Feng Yin[1], Shilpa S. [1]UT MD Anderson Cancer Center, Houston, TX,[2]Gastrointestinal Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

Background: Immune checkpoint blockade (ICB) has significantly improved outcomes in microsatellite instability-high (MSI-H) gastrointestinal cancers, yet more than half of patients do not achieve durable remission despite initial tumor regression. Clinical decisions guided solely by MSI status and radiographic response provide limited ability to anticipate long-term benefit or inform choices regarding surgery and treatment modification. The development of spatially informed molecular predictors of sustained response would therefore address a critical unmet need in the management of MSI-H tumors.

Methods: Spatial transcriptomic profiling was performed on 18 tumor specimens from 13 patients with gastric, colorectal, or esophageal cancers, including 11 MSI-H and 2 MSS tumors, collected before and after ICB therapy. All tissues were assayed using the 10x Genomics Visium platform. Pathology-guided spot annotation was combined with transcriptional Meta-program analysis, spatial deconvolution, niche interaction mapping, and ligand-receptor modeling to characterize tumor-immune-stromal organization across sustained complete responders (CR) and non-sustained responders (NR).

Results: We found that tumor cell meta-programs (MPs) exhibited distinct spatial gradients across different response groups. The epithelial-mesenchymal transition MPs was enriched at the invasive margin of pre-treatment NR (pre-NR) tumor tissue and diminished toward the core, while the Cycling-high-Interferon MPs peaked at the periphery of pre-CR tumor tissue. These findings indicate that transcriptional programs are spatially compartmentalized within the tumor. Next, we investigated how the spatial organization of the tumor microenvironment (TME) differed between response groups. In pre-CR tumors, malignant cells colocalized with B cells and T follicular helper cells within tertiary lymphoid structures (TLSs), whereas in pre-NR tumors, they were associated with macrophages and cancer-associated fibroblasts. Notably, TLSs from CR tumors exhibited stronger immune activation signatures irrespective of their maturation state. Cell-cell communication analysis further revealed immune activation at the tumor-stroma interface in sustained-CR tumors, contrasting with immunosuppressive signaling in NR tumors.

Conclusions: Our study reveals distinct spatial and transcriptional programs underlying differential responses to ICB in MSI-H gastrointestinal cancers, highlighting the pivotal role of tumor-immune-stromal organization in shaping therapeutic outcomes and guiding future strategies to enhance immunotherapy efficacy.

#4948 Spatial architectures of colorectal cancer microenvironment underlying immune checkpoint inhibitor response.

Chuyan Liu[1], Hang Yin[2], Joon Sang Lee[3], Julien Tessier[4], Junbum Kim[2], Donald Jackson[3], Angela Hadjipanayis[4], Olivier Elemento[5]

[1]Graduate School of Medical Sciences, Weill Cornell Medicine, New York, NY,[2]Department of Systems and Computational Biomedicine, Weill Cornell Medicine, New York, NY,[3]Precision Oncology, Sanofi, Cambridge, MA,[4]Precision Medicine and Computational Biology, Sanofi, Cambridge, MA,[5]Caryl and Israel Englander Institute for Precision Medicine, Weill Cornell Medicine, New York, NY

Colorectal cancer (CRC) remains a leading cause of cancer mortality. Immune checkpoint inhibitors (ICI) are among the most effective systemic therapies, yet they benefit only a subset of MSI-H/MMRd patients. To investigate how spatial tumor-immune-stromal organization contributes to heterogeneous treatment responses, we profiled FFPE CRC tissues from PD-1 inhibitor pembrolizumab-treated (n=10) and treatment-naïve (n=14) patients using the CosMx Spatial Molecular Imager (SMI) with a 1,000-gene single-cell panel. After image processing and cell segmentation, cell states were annotated through unsupervised Leiden clustering, gene-module scoring, and supervised InsituType prediction using a public CRC single-cell atlas, followed by spatial analyses including niche identification, neighborhood enrichment, distance-based metrics, and ligand-receptor inference. Across 24 patients (balanced sex distribution; stages I-IV; median age 66.5), ICI-treated tumors exhibited markedly higher frequencies of all $CD8^+$ T cell subsets, $CXCL8^+$ cancer-associated fibroblasts (CAFs), myofibroblasts, and diverse macrophage and neutrophil populations compared with treatment-naïve tumors, alongside higher proportions of CMS1-like malignant cells. *De novo* nonnegative matrix factorization (NMF) revealed eight tumor-intrinsic programs, with Inflammatory/MHC-II, Type I IFN/Antigen Presentation, and Innate Inflammatory programs enriched in ICI-exposed tumors, whereas Invasion/Angiogenesis, Proliferation/Stress, and CEA-high programs characterized untreated tumors. Spatial mapping uncovered two recurrent architectures: immune-infiltrated tumors enriched for tertiary lymphoid structures (TLSs) marked by T-B lymphocyte aggregates and focal LTB and CXCL13 expression, as well as fibroblast-dominated tumors demonstrating stromal encapsulation, limited immune intermixing, and preliminary enrichment of CAF-immune suppressive ligand-receptor circuits. Together, these findings delineate inflamed versus fibrotic CRC microenvironments with distinct tumor-immune communication states. Integration of spatial features with clinical response will support refined stratification for ICI-based therapy and nominate TLS density, CAF patterning, and specific ligand-receptor modules as candidate spatial biomarkers for predicting or modulating treatment responsiveness.

#4949 High resolution spatial transcriptomics reveals dynamic remodeling of the tumor microenvironment during prostate cancer progression.

Jiayi Zhou, Gabriel Cruz, Somnath Mahapatra, Radha Paturu, Hanbyul Cho, Xuhong Cao, Fengyun Su, Rui Wang, Dan Robinson, Yi-Mi Wu, Rohit Mehra, Kayla Muschong, Christine Caldwell Smith, Chelsea Decker, Chandan Kumar-Sinha, Saravana Mohan Dhanasekaran, Rahul Mannan, Yuping Zhang, Arul Chinnaiyan

University of Michigan, Ann Arbor, MI

Prostate cancer exhibits diverse cellular composition, and the interaction between the tumor epithelial and tumor microenvironment (TME) cell types plays a crucial role in disease progression. However, due to technical limitations, systematic characterization of microenvironmental influences on prostate cancer progression remains insufficient. This study combined an assembled single-cell transcriptomic data (163 prostate samples; 756,000 high-quality cells) with the spatial data we obtained from 20 primary prostate tumors using the Visium HD platform to create high-resolution spatial profiles of the TME in prostate cancer. Our approach enabled detailed investigation of the dynamic remodeling of TME during prostate cancer progression from benign to low- and high-grade lesions. Our spatial transcriptomics data cohort includes 13 high-grade (grade group>=2) and 7 low-grade cases (grade group 1). We used the single cell clustering results as a reference and applied robust cell type decomposition (RCTD) to annotate the Visium HD data. In total, we identified 15 major cell types within the microenvironment and observed significant differences in the distribution of TME cell types and their frequency across benign, low-grade, and high-grade prostate cancers areas. Inflammatory fibroblasts and their gene signature were more prevalent in benign and low-grade microenvironments, whereas they decreased in high-grade TME. Conversely, myofibroblasts and their gene signature were enriched in high-grade TMEs. Within the smooth muscle populations, the more proliferative and migratory synthetic type (THY1-high) is increased in high-grade TMEs, while the contractile type (RERGL-high) was enriched in benign and low-grade microenvironments. Among endothelial cells, the abundant pro-angiogenesis subpopulation (EDNRB-high) was noted in high-grade TMEs, in contrast to the preferential enrichment of anti-angiogenesis subpopulation (RGS16-high), in localized to benign and low-grade microenvironments. Our findings uncover variations in the TME across tumor stages and implicate several important cell types that may influence prostate cancer progression, offering clues for future therapeutic exploration.

#4950 Spatially resolved multiomic profiling of cancer tissue with DISS enables variant mapping across tissue landscape.

Vivian Tran Dien, Tyler Lopez, Connor Thompson, Ben Krajacich, Adeline Mah, Andrew Altomare, Mariam Dawood, Neam Dawood, Keerthana Elango, Daniel Honigfort, Ryan Kelley, Michael Kim, Jean Kwon, Seana Lymer, Kyle Metcalfe, Jacob Moreno, Duuluu Naranbat, Evan O'Brien, Tristin Rammel, Carlos Ruiz Perez, Ramreddy Tippana, David White, Kelly Wiseman, Jennifer Wong, Jane Yao, Grace Yeo, Matthew Kellinger, Sinan Arslan, Michael Previte

Element Biosciences, Inc., San Diego, CA

Clonal evolution within the tumor microenvironment is central to understanding disease initiation, progression, and therapeutic response and resistance. Resolving these dynamics requires high accuracy spatial transcriptomics that can map driver mutations and cellular phenotypes directly in intact tissue. Direct in Sample Sequencing (DISS) on AVITI24™ enables the measurement of transcriptome and targeted gene expression directly in intact tissues sections without library preparation, linking genotype and phenotype at high resolution to resolve the complex clonal architecture in the tumor microenvironment. AVITI24™ utilizes two complementary approaches for spatial profiling with DISS: a 3' transcriptome method using poly-T probes to capture polyadenylated mRNA, and a targeted strategy employing custom probes designed against expressed variants or a panel of hundreds of RNA markers. The AVITI24™ system automatically performs probe hybridization, cDNA extension, probe circularization, and rolling-circle amplification onboard. DISS chemistry is designed for flexibility, using single-ended probes and supporting up to 100 sequencing cycles with >80% Q30, enabling sensitive detection of a broad range of expressed variants including SNPs, indels, and fusions through long, high quality reads of the transcriptome, not currently capable with dual-sided probe or padlock-based detection methods. To demonstrate variant detection in cancer with DISS, we profiled somatic driver mutations expressed in fresh frozen and FFPE colorectal cancer sections, including multiple hot-spot SNVs in KRAS and TP53, TGFBR2 and APC indels, and ALK gene fusions. Targeted DISS achieved sensitive detection of mutations with variant allele frequency (VAF) down to 5% for genes of diverse expression levels. Utilizing unbi2ased transcriptomic profiling, we accurately resolved major cell types within the tumor microenvironment, with results from sequential tissue sections demonstrating high concordance with RNA seq ($R^2 = 0.7$). Spatial mapping of these alterations onto tissue morphology uncovered regional clonal architecture and mutational heterogeneity within intact tumor microenvironments. Using DISS chemistry in tissue, transcriptomics from the same tissue section across a panel of custom genomic targets enabled a highly personalized and sensitive approach to identify both cell types and their associated oncogenic mutations with spatial precision.

#4951 Unraveling the role of APOE/APOC1/SPP1/TREM2-positive lipid-Associated macrophages in destructive venous invasion and metastasis of colorectal cancer.

Sanha Hwang

Seoul National University, Seoul, Korea, Republic of

Background/Objective
Venous invasion (VI) is strongly linked to recurrence and poor outcomes in colorectal cancer, especially when the vessel wall is breached (destructive VI). The cellular programs that distinguish destructive VI from intraluminal VI remain unclear. We hypothesized that lipid-associated macrophages (LAMs) co-expressing APOE, APOC1, SPP1 and TREM2 remodel the VI niche via lipid metabolic reprogramming, immune suppression and matrix/vascular remodelling, thereby driving metastatic spread.
Methods
We analysed 103 metastatic colorectal cancer patients across three platforms. Using GeoMx Digital Spatial Profiler on 67 samples we compared regions of destructive VI tumours, VI-negative tumours and control vessels. We re-analysed published single-cell RNA-seq data from 60 matched primary-liver-metastasis pairs for myeloid re-clustering, differential expression and pathway analysis. We applied Xenium in situ sequencing (5k panel) on 36 tissues to spatially map macrophage states around VI boundaries. Standard normalization, batch correction, multiple-testing control and ring-based spatial enrichment around destructive VI edges were applied, with primary contrasts of destructive VI versus VI-negative/control regions.
Results
Across platforms we found a convergent myeloid program. In GeoMx data, tumour microenvironments adjacent to destructive VI exhibited consistent up-regulation of APOE, APOC1 and SPP1, along with cathepsins (eg CTSB/CTSL), and enrichment of protein secretion, glycolysis and complement/coagulation pathways compared to VI-negative tumours and control vessels. The single-cell dataset revealed a distinct TREM2$^+$ TAM cluster co-expressing APOE/APOC1/SPP1 with lipid-oxidative signatures, matching LAM-like macrophages. In Xenium spatial data these macrophages preferentially accumulated at destructive VI boundaries, aligning exactly with suppressed T-cell activity at sites of vascular breach and tumour escape. Our data confirm a functional interaction between APOE and LRP1, supporting a Jun-APOE-LRP1 axis in colorectal cancer invasion and metastasis.
Conclusions
Our multi-platform study nominates APOE/APOC1/SPP1/TREM2$^+$ LAMs as central players in the destructive VI niche in colorectal cancer, integrating lipid-metabolic rewiring with matrix/vascular remodelling and immune suppression at vascular breach sites. The confirmed involvement of the Jun-APOE-LRP1 axis points to this pathway as a therapeutic target. These findings support translational efforts to target TREM2 and the APOE-LRP1 axis to intercept metastatic seeding via venous invasion. Functional validation is underway.

#4952 Spatial Transcriptomics reveals core resistance niches distinguishing non-MPR from MPR in NSCLC after neoadjuvant chemoimmunotherapy.

Seo Hye Park[1], Jeongbin Park[1], Hongyoon Choi[1], Jaemoon Koh[2], Taeyoung Yun[3], Jihyeon Park[3], Bubse Na[3], Samina Park[3], In Kyu Park[3], Chang Hyun Kang[3], Young Tae Kim[3], Kwon Joong Na[1]

[1]Portrai, Inc., Seoul, Korea, Republic of,[2]Department of Pathology, Seoul National University Hospital, Seoul, Korea, Republic of,[3]Department of Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul, Korea, Republic of

Background

Neoadjuvant chemoimmunotherapy (nCIT) is increasingly used in NSCLC. Major pathologic response (MPR) is a robust prognostic marker, yet bulk or single-cell assessments of residual tumor do not capture how spatially heterogeneous TMEs yield non-MPR. Using FFPE Visium CytAssist spatial transcriptomics, we defined tissue-scale core resistance niches distinguishing MPR from non-MPR after nCIT and asked whether these niches delineate spatially targetable compartments.

Methods

FFPE resections from 10 nCIT-treated patients were profiled; MPR status followed IASLC criteria. Blocks were selected by residual tumor burden (MPR 5-10%; non-MPR 70-90%). We compared global programs (DEG, GSEA/Reactome, cell-cycle), inferred cell composition (cell2location), analyzed context-specific ligand-receptor and metabolic states, and spatially mapped resistance axes (DDR, NRF2/ferroptosis, MDR/ABC) and TACSTD2 (TROP2).

Results

Non-MPR activated cell-cycle/transcription/DNA-repair programs and showed a proliferative landscape, whereas MPR was ECM/immune-enriched and quiescent. Deconvolution mapped deep T-cell/myeloid infiltration into MPR cores/borders, while non-MPR cores remained epithelial-dense. Ligand-receptor mapping showed immune-recruiting ECM-integrin/syndecan and CX3CL1-ITGAV at MPR boundaries but LGALS9-HAVCR2, MIF-CD74, and TIMP1-CD63 within non-MPR cores, extending into peritumor tissue. Non-MPR exhibited hyper-metabolic, antioxidant-buffered states (glycolysis, OXPHOS/TCA, glutathione), with differences attenuating in cancer-only analyses, implicating TME contribution; resistance axes were higher in non-MPR and formed contiguous core hotspots. TROP2 was core-enriched in a subset and often overlapped NRF2/MDR-high niches with low signal in adjacent non-tumor, although TROP2-independent resistant cores were also observed.

Conclusion

Spatial transcriptomics defined non-MPR by a core-centered, resistance-rich TME that is proliferative, immune-suppressive, and metabolically flexible, contrasting with the immune-permissive, quiescent landscape of MPR. Dismantling core resistance niches, restoring immune access, and tempering metabolic buffering emerge as organizing principles for overcoming residual disease. TROP2-aligned cores represent a compartment-selective subset, whereas TROP2-independent cores argue for complementary strategies.

#4953 Spatial tissue architecture as a unifying principle of tumor and microenvironmental states in adult gliomas.

Anna Mathioudaki[1], Zaira Seferbekova[1], Samuel P. Rutz[1], Michael Ritter[1], Domenico Calafato[1], Gleb Rukhovich[1], Felix Hinz[2], Philipp Mahlknecht[2], Franziska M. Ippen[2], Ekaterina Popova[3], Sophia Schinkewitsch[4], Nela Runa Koeberer[4], Nina Wilhelm[1], Pooja Sant[5], Jan-Philipp Malm[5], Sascha Dietrich[3], Christel Herold-Mende[6], Nima Etminan[7], Antje Wick[8], Sandro Krieg[9], Michael Platten[10], Andreas von Deimling[2], Felix Sahm[2], Abigail Suwala[2], Moritz Gerstung[1]

Adult gliomas exhibit substantial molecular and pathological variation. Prior single-cell studies have characterized intratumoral heterogeneity; in glioblastoma, tumor cells adopt lineage-associated programs—such as oligodendrocyte- and neuro- progenitor (OPC, NPC), astrocyte (AC) and mesenchymal (MES) like states. However, how these states recur across other gliomas remains unclear. Given their shared environment, defining conserved versus entity-specific tumor characteristics is essential for understanding glioma heterogeneity.

Here, we analyzed 310 tumor cores from 284 patients spanning oligodendroglioma, astrocytoma, glioblastoma, and ependymoma, using single-cell spatial transcriptomics with a 344-gene panel (10x Xenium). This approach yielded a dataset of 2.8 million cells, including 18 tumor microenvironment (TME) cell types. To further probe local interactions, we profiled a validation cohort of astrocytomas using a 5,096-genes panel and multiplexed immunofluorescence (57 proteins).

Our data revealed 9 recurrent tumor states across gliomas, organized into neighborhoods shaped by local cellular interactions. These formed structured layers, with OPC-/NPC-like tumors near cortical interfaces and AC-like regions forming a continuum with MES1-gliosis. Neighborhoods were largely subtype-specific suggesting that tissue organization and not cell composition alone, underlies glioma heterogeneity. Consistently, methylation classification—central to subtype definition in gliomas—stratified the cohort into 13 classes with distinct neighborhood profiles, including characteristic architectures in RTK1, RTK2, and MES glioblastomas.

Neighborhoods also showed distinct TME variation: $P2RY12^{+}$ microglia were enriched in AC-like and MES1-gliosis regions, while $CD163^{+}$ myeloid cells concentrated in MES1-gliosis and MES2-hypoxia niches. These immune patterns corresponded to neighborhood-specific inflammatory programs and at the entity level to myeloid-dominated inflammation in ependymoma and low inflammation in oligodendroglioma.

Beyond neighborhood definition, we evaluated their diagnostic potential. In astrocytoma, AC-like enrichment marked favorable prognosis, whereas MES1-like prevalence defined high-risk patients. Given this, we asked whether neighborhoods show histopathological correlates in routine H&E. Morphology embeddings extracted with histopathology foundation models recovered clusters mirroring niche composition, indicating that neighborhoods can be inferred from H&E morphology and incorporated into diagnostic workflows.

Collectively, these findings link glioma microanatomy heterogeneity by connecting tumor states to their TME. By capturing spatially dependent programs, our work provides a framework for integrating spatial architecture into biological understanding, diagnosis, and risk stratification.

#4954 Integrated scRNAseq andspatial RNAseq analysis of aggressive prostatic adenocarcinoma identifies *TIGIT-NECTIN 2/3* and *TIGIT/PVR*immunosuppressive interactions.

Jerry A. Ombor[1], Anurendra Kumar[2], Jatin Gandhi[1], Rakesh Shiradkar[3], Tilak Pathak[1], Cynthia L. Winham[1], Ismaheel O. Lawal[1], Olayinka A. Abiodun-Ojo[1], Lara Harik[1], Saurabh Sinha[2], Martin G. Sanda[1], David M. Schuster[1], Adeboye O. Osunkoya[1], **Carlos S. Moreno**[1]

[1]Emory University, Atlanta, GA,[2]Georgia Institute of Technology, Atlanta, GA,[3]Indiana University, Indianapolis, IN

Background: Our understanding of the mechanisms of tumor immunosuppression in the tumor microenvironment (TME) of aggressive prostatic adenocarcinoma (PCa) at the single-cell level is limited. Integrated Visium-HD Spatial RNAseq analysis and 10X Flex sequencing of formalin-fixed paraffin-embedded (FFPE) tissue can provide unique insights into the mechanisms of immunosuppression in the 'immune cold' TME of PCa.

Design: Visium-HD Spatial RNAseq analysis was performed on FFPE blocks from radical prostatectomy specimens of 12 patients of which six had lymph node metastases (LNM) and six did not. All specimens were also analyzed by 10X Flex sequencing, and data from each scRNAseq dataset were integrated with spatial RNAseq data. VisiumHD bins were processed with H&E images to generate cell-level expression data using the bin2cell package, and cell types were annotated. Ligand-receptor interactions were identified using the CellWhisper algorithm.

Results: Mean patient age was 63 years (range: 50-77 years). Gleason scores ranged from 7-10 (Grade group 3-5). Patients with LNM had more significant enrichment for gene signatures associated with inflammation and immune responses and high numbers of naïve regulatory T cells (Naïve Treg) near the invasive front of the aggressive tumor foci. The inflamed stroma adjacent to PCa in patients with LNM was enriched in expression of antigen-presenting genes, but also in immunosuppressive gene signatures. In addition, there was significant enrichment for spatial co-expression of the immunosuppressive receptor *TIGIT* and the *NECTIN2, NECTIN3,* and *PVR* ligands. *TIGIT* was expressed in CD4 and CD8 expressing cells and CD14+ monocytes, while *NECTIN2, NECTIN3,* and *PVR* were expressed in tumor cells, suggesting that this is one of the mechanisms of immunosuppression in aggressive PCa.

Conclusions: High-definition spatial RNAseq analysis with integrated 10X Flex scRNAseq enabled identification of mechanisms of immunosuppression in the TME of PCa. Targeting *TIGIT-NECTIN2/3* and/or *TIGIT/PVR* interactions may be a potential immunotherapeutic strategy for the management of patients with aggressive PCa.

#4955 Basescope™ duplex assay enables same-slide detection of short RNA targets including isoforms.

Sonali A. Deshpande, **Alvin J. Y. Ling**, Julia Yu, Anushka Dikhshit, Li-Chong Wang

Bio-Techne, Newark, CA

Background Genetic changes in mammalian genes including exon skipping and point mutations play a crucial role in oncogenesis and predicting patient survival and disease prognosis. Studies have shown that cancer cell lines can be distinguished from non-cancer cell line based on gene transcript isoform. As example, MET (receptor tyrosine kinase) exon 14 skipping mutation and EGFR exon 19, 21 deletion or exon 20 insertion mutation have emerged as a biomarker in various cancer types. Additionally, alternative-splicing plays a crucial role in disease progression and therapeutic response. Spatial visualization of gene isoform holds the potential of providing better understanding of tumor microenvironment.

Methods We developed a next-generation, manual and fully automated fluorescent assays on the Leica platform that enables specific and simultaneous detection of highly similar RNA targets - isoform-specific exon-exon junctions. The assay utilizes specificity and sensitivity of RNAscope™ technology to visualize single RNA molecule on formalin fixed paraffin embedded (FFPE) tissue and cell pellets. To validate the new workflow, endogenous control genes were detected using 1zz probes on HeLa cell pellets and Mouse multi tissue array. Signal and background were quantitatively compared to original BaseScope 1zz probes. To visualize MET exon 14 skipping (METΔ14), MET WT exon and exon 14-15 junction specific probes were detected on the WT and variant positive cell pellets. Further, exon 13-15 or exon 14-15 junction probe and exon 15 probes were duplexed and co-detected in MET WT and Δ14 cell pellets, respectively using BaseScope duplex assay that utilizes streamlined RNAscope chemistry to potentially co-detect mRNAs, proteins and protein-protein interactions.

Results Signal (as determined by dot counts/cell) from control gene using new BaseScope technology was comparable to signal generated using original BaseScope assay. Next, we visualized specific signal from METΔ14 exon junction probe on MET mutant pellet and WT MET probe on WT cell pellet, using dual fluorophores to identify both isoforms on the same slide. No signal was observed from mutant probe in WT pellet indicating specificity of the assay. Similarly, MET exon 14-15 junction probe and exon 15 probes were duplexed in the assay and visualized using two distinct fluorophores on wild-type cell pellet. Exon 13-15 junction probe and exon 15 probe were duplexed and co-detected using two fluorophores on mutant cell pellet. These results demonstrate the assay's efficacy in same-slide detection of cells expressing two short targets.

Conclusions This BaseScope Duplex assay provides spatial resolution of isoform and point mutation-specific gene expression, offering a powerful tool for exploring cell-specific transcript variants within the tumor microenvironment and potentially advancing precision oncology research.

#4956 Spatial and vascular microenvironmental features predict tumor-infiltrating lymphocyte expansion in glioblastoma.

Jodie Jepson[1], Kenan Zhang[2], Anna Corcoran[2], Elizabeth Owens[1], Kelly M. Hotchkiss[2], Beth H. Shaz[2], Kyra Van Batavia[2], Jose R. Conejo-Garcia[1], John Hickey[2], Mustafa Khasraw[3]

[1]Duke University School of Medicine, Durham, NC,[2]Duke University, Durham, NC,[3]Duke Cancer Institute, Durham, NC

Introduction/Rationale: Adoptive transfer of tumor-infiltrating lymphocytes (TILs) has demonstrated meaningful clinical activity in several solid tumors, yet its application in glioblastoma is challenged by profound immune dysfunction, sparse T-cell infiltration, and spatially restricted immune niches that constrain the outgrowth of tumor-reactive lymphocytes ex vivo. A deeper understanding of the spatial, cellular, and vascular features that distinguish tumors capable of yielding TIL cultures from those that fail may identify microenvironmental determinants of successful expansion and guide patient selection or microenvironment-modifying strategies for future TIL-based therapies.

Methods: TIL expansion was attempted in 40 tumors, 24 (60%) yielded successful yield in an optimized rapid expansion protocol (REP). Expanded products were characterized by spectral flow cytometry and TCRseq. A subset of TIL-positive (TIL^+; n = 5) and TIL-negative (TIL^-; n = 6) tumors underwent bulk RNA and TCRseq, single-cell RNAseq, CODEX multiplex spatial proteomics, and Xenium in situ spatial transcriptomics to define immune cell states, spatially organized niches, receptor-ligand communication networks, and vascular architecture.

Results: Expanded TILs proliferated 100-1000-fold from pre-REP to REP and were enriched for $CD4^+$ cells, with both $CD4^+$ and $CD8^+$ compartments dominated by effector-memory phenotypes and containing minimal naïve or regulatory subsets. Although overall T-cell infiltration in tumors was low (<3% of all cells), TIL^+ tumors contained more stem-like $TCF7^+$ $CD8^+$ T cells and exhibited lower expression of HAVCR2 and TOX, consistent with reduced terminal exhaustion. Spatial analysis demonstrated 2.3-fold higher $CD31^+$ endothelial density and significantly shorter T cell-endothelium distances in TIL^+ tumors ($p < 0.05$), indicating more accessible vascular niches. In contrast, TIL^- tumors exhibited 1.6-fold stronger inhibitory TAM-microglia signaling, whereas TIL^+ regions were enriched for T cell-endothelial and TAM-macrophage interactions, reflecting a more permissive immune architecture.

Conclusion: Our data highlight vascular accessibility, immune spatial organization, and reduced inhibitory myeloid signaling as key determinants of successful TIL expansion in glioblastoma. The integration of spatial transcriptomics, multiplex proteomics, and single-cell sequencing identifies microenvironmental hallmarks associated with TIL outgrowth and suggests that modulating vascular or myeloid niches may enhance the feasibility and effectiveness of TIL-based therapies in glioblastoma. These insights support microenvironment-guided patient selection and inform the development of combination approaches aimed at reconditioning the glioblastoma tumor microenvironment to improve responsiveness to cell-based immunotherapy.

#4957 Spatially resolved profiling of the tumor microenvironment and therapeutic response in SMARCB1-deficient epithelioid sarcoma.

Jiayi Fan, Jeffrey Quinn, Wesley Tansey

Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Epithelioid sarcoma (ES) is a rare, aggressive soft-tissue sarcoma driven by biallelic loss of SMARCB1. It primarily affects adolescents and young adults and has poor clinical outcomes. The EZH2 inhibitor tazemetostat is the only FDA-approved targeted therapy for ES, yet most tumors show primary resistance or relapse after treatment. How the ES tumor microenvironment (TME) is spatially organized, and how it is reshaped by therapy, remains poorly understood. Here, we profiled 64 tumor tissue microassay (TMA) samples from 19 patients using the 10X Xenium 5k platform. An analysis pipeline integrating automated cell-type annotation, spatial neighborhood characterization, and ligand-receptor interaction (LRI) inference, and therapy response was established. Spatial niche analysis identified tumor associated M2 like macrophages that limit effector T cell development in the early lymphoid aggregates. Further, LRI analysis identified a detailed communication network involving immune suppression, tumor proliferation and angiogenesis in the TME. Comparative analyses using paired pre and post tazemetostat samples further revealed consistent treatment associated transcriptional shifts. Most post treatment tumors showed up regulation of inflammatory and mesenchymal transition pathways. Notably, patients who responded clinically displayed the opposite features. Together, the genes and pathways that become activated after tazemetostat exposure may highlight potential targets that could be explored in combination with EZH2 inhibition. Moreover, cancer-associated fibroblasts (CAFs) were highly abundant in ES. Distal and proximal tumors exhibited divergent CAF subgroups, with distal tumors showing a higher prevalence of CAF programs associated with matrix remodeling and migratory signaling that may facilitate tumor dissemination. These findings provide one of the first large-scale spatially resolved maps of ES.

#4958 Spatial transcriptomic profiling reveals heterogeneity in desmoplastic small round cell tumor.

Elana Sverdlik[1], Jeffrey Quinn[2], Jiayi Fan[2], Christopher Tosh[2], Tamar Feinberg[2], Melania Franchini[3], Jovana Pavisic[2], Shanita Li[2], Andoyo Ndengu[2], Glorymar Ibanez Sanchez[2], Emily Stockfisch[2], Filemon Dela Cruz[2], Andrew L. Kung[4], Joshua Honeyman[2], Emily Slotkin[2], Wesley Tansey[2]

[1]Gerstner Sloan Kettering - Graduate School of Biomedical Sciences, New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Herbert Irving Comprehensive Cancer Ctr., New York, NY,[4]Chief, Division of Pediatric Hematology/, Memorial Sloan Kettering Cancer Center, New York, NY

Desmoplastic small round cell tumor (DSRCT) is a rare, aggressive soft tissue sarcoma driven by the chimeric fusion protein EWSR1-WT1 that modulates oncogenic gene expression programs in DSRCT tumor cells. Despite this defined molecular driver, treatment response and survival outcomes vary substantially between DSRCT patients (5-year survival ~ 15%). We hypothesize that treatment outcome variability reflects heterogeneity in tumor cell phenotypic states, microenvironmental architecture, and signaling networks. Here we profiled seven peritoneal and lymph node metastatic tumor sites across four DSRCT patients using Xenium 5K spatial transcriptomics on tissue microarrays (1,383,406 cells). We integrated snRNA-seq data from 15 DSRCT samples (251,087 cells) for cell type annotation, identifying patient-specific tumor subtypes through per-patient Leiden clustering (resolution=0.2) and CAF subtypes through marker gene scoring. This revealed 14 patient-specific tumor subtypes (3-4 per patient), three CAF subtypes (apCAFs, myCAFs, iCAFs), macrophages, T cells, and endothelial cells.

#4959 Trekker enables high-sensitivity, single-cell spatial profiling of the FFPE lung SCC tumor microenvironment without segmentation or deconvolution.

Cedric R. Uytingco, Alec Barret, Julie Wilhelmy, Bryant Ngo, Chenglong Xia, Jonathan Sakkos, Diksha Kool, Wanxin Wang, Christina Chang, Christina Fan, Andrew Farmer

Spatial Genomics R&D, Takara Bio USA, San Jose, CA

Squamous cell carcinoma (SCC) is a highly heterogeneous malignancy characterized by complex cellular architecture, variable patterns of immune infiltration, and diverse stromal interactions that influence progression, metastatic potential, and therapeutic response. A detailed understanding of the SCC tumor microenvironment (TME) is therefore essential for identifying biomarkers, resolving resistant niches, and guiding precision oncology strategies. Although single-cell sequencing captures cellular diversity, it lacks spatial context, while most spatial transcriptomics platforms depend on complex protocols, proprietary reagents, and computationally intensive segmentation, deconvolution, or binning steps that limit true single-cell resolution—especially in FFPE clinical samples. To address these challenges, we present Trekker, a flexible, next-generation single-cell spatial transcriptomics platform that delivers spatial context with the simplicity of standard snRNA-seq. Using a Slide-tag-inspired spatial tagging approach (Russel et al., 2023), Trekker™ indexes nuclei directly within intact tissue sections and is compatible with same-section H&E staining for direct histopathological correlation. The workflow requires no specialized instrumentation and integrates seamlessly with a fixed snRNA-seq protocol, enabling high-sensitivity, single-nucleus expression and spatial data without modifying established laboratory practices. By applying Trekker to FFPE human lung squamous cell carcinoma specimens, we generated high-resolution spatial maps of malignant cells, stromal elements, and diverse immune populations. Because each nucleus carries its own spatial barcode, downstream analysis bypasses cell segmentation, unmixing, and binning, allowing users to analyze the data using familiar single-cell bioinformatics pipelines. This streamlined approach supports robust characterization of SCC architecture, tumor-immune interaction zones, and spatially informed differential gene expression. By combining ease of implementation, FFPE flexibility, reduced computational complexity, and high-sensitivity single-cell spatial resolution, Trekker provides an accessible and powerful platform for cancer researchers. This technology enables deeper, more intuitive exploration of SCC tumor ecosystems and has the potential to accelerate biomarker discovery and therapeutic development.

#4960 Cross-platform comparison of spatial transcriptomics technologies in an FFPE lung squamous cell carcinoma sample.

Bryan Bell, Cedric Uytingco, Alec Barrett, Bryant Ngo, Jonathan Sakkos, Diksha Kool, Wanxin Wang, Melissa del Rosario, Christina Chang, Christina Fan, Andrew Farmer

Takara Bio USA, San Jose, CA

Spatial transcriptomics technologies vary widely in methodology, spatial resolution, sensitivity, and compatibility with FFPE tissues, yet comparative data generated from the same clinical specimen remain limited. We conducted a benchmarking study using a single FFPE lung squamous cell carcinoma block to evaluate Takara Trekker™ alongside Visium, Visium HD, and Xenium. Sections from the same block were processed with each platform following standard workflows. Trekker employs a unique spatial-tagging strategy that preserves the positional identity of intact nuclei and integrates seamlessly with the 10x Flex assay, enabling true single-cell–resolution spatial profiling. Visium HD and Visium provide array-based mRNA capture and Xenium enabled targeted in situ detection. Data were processed with platform-specific pipelines.Within the same tumor region, Trekker delivered higher gene recovery and captured malignant, immune, and stromal populations with spatial patterns broadly aligned with histopathology. Comparisons with Visium HD showed overall spatial concordance in major tumor and stromal features. Trekker's increased sensitivity relative to Visium HD and Visium resulted in deeper transcriptome coverage and clearer separation of transcriptionally distinct tumor states. The nuclei-based workflow also supported reliable detection of lower expressing genes. Xenium offered high-resolution, targeted measurements that aligned with Trekker's major spatial features, though its panel limited unbiased transcriptome-wide discovery.Across platforms, integrated analysis showed that Trekker provided strong concordance with both high-resolution imaging-based signals and array-level structure while preserving the advantages of whole-transcriptome profiling from FFPE. These findings demonstrate that Trekker enables high-resolution, scalable, and unbiased spatial characterization of archival lung cancer tissue and complements existing spatial technologies by combining flexible FFPE compatibility with comprehensive molecular detection.

#4961 Cell type-specific adipokine signaling networks in the breast tumor microenvironment uncovered by high-plex spatial imaging.

Samarth Singhal[1], Amber Rockson[2], Hanina Hibshoosh[3], Parin Shah[3], Fatemeh Derakhshan[3], Diane Chen[3], Alireza Salem[3], Benjamin Izar[3], Kevin L. Gardner[4], Coral O. Omene[5], Daniel Fernandez[6], Adrienne L. Castillo[6], Emma Armstrong[6], Ijeamaka Anyene Fumagalli[6], Elizabeth M. Cespedes Feliciano[7], Sandeep K. Singhal[8], **Adana A. M. Llanos**[2]

[1]University of North Dakota,[2]Epidemiology, Columbia University Mailman School of Public Health, New York, NY,[3]Columbia University Irving Medical Center, New York, NY,[4]Vagelos College of Physicians & Surgeons, New York, NY,[5]Clinical Instructor, Dept. of Medicine, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[6]Kaiser Permanente Northern California, Oakland, CA,[7]Kaiser Permanente, Oakland, CA,[8]University of North Dakota, Grand Forks, ND

Background Adiposity is linked to adverse breast cancer outcomes, but mechanisms connecting adipose signaling to tumor progression remain unclear. Adipokines like leptin and adiponectin, and their receptors, may influence tumor behavior via paracrine and autocrine interactions across tumor, stromal, and immune cells in the breast tumor microenvironment (TME). Using high-plex spatial molecular imaging, we mapped adipokine expression and cell type-specific signaling networks to reveal adiposity-related differences in tumor biology.
Methods Single-cell spatial transcriptomics was performed using the CosMx Spatial Molecular Imager (Human 6K Panel) on breast tumors and matched adjacent tissues. Cells were segmented and classified into tumor epithelium, stroma, and immune compartments via an AI framework. LEP, LEPR, ADIPOQ, ADIPOR1, and ADIPOR2 were quantified to derive compartment-specific positivity rates, mean/very high expression, potential 5-gene co-expression, and composite adipokine signature scores and expression was compared with non-tumor cells and cells from adjacent tissues, and correlated with select clinical variables.
Results In 259 women with stage II-III breast cancer (49% postmenopausal, 47% Black, 53% Hispanic, 62% ER-positive, 17% HER2-positive), adipokine and receptor expression was consistently higher in tumor cells than stromal or immune cells. All five adiposity genes showed elevated expression in tumor cells versus stroma and immune cells. In the tumor epithelial compartment, ADIPOR1, ADIPOR2, and LEPR exhibited markedly high-end expression versus adjacent epithelium ($P < 10^{-16}$), defining a tumor-intrinsic adipokine receptor program. Tumor epithelial 5-gene signature scores and co-expression of ≥2 adipokine genes were enriched in a subset of tumors and modestly inversely associated with tumor size. In stroma, ADIPOR1, ADIPOR2, and LEPR formed a tightly coordinated module; stromal ADIPOR1 positivity and higher stromal adipokine signature scores were enriched in higher-grade and ER-negative tumors, indicating a grade- and subtype-linked stromal adipokine phenotype. In the immune compartment, ADIPOR1 and ADIPOR2 were broadly detectable at lower intensity, correlated with LEPR and immune-specific adipokine scores, consistent with a distinct immune-focused axis. Across compartments, 5-gene signatures captured coherent TME-wide adipokine programs remodeled in tumor versus adjacent tissue and showing compartment-specific associations with BMI, grade, ER status, and tumor size.
Conclusion Single-cell spatial profiling reveals a compartmentalized adipokine architecture in the breast TME, including a heightened tumor epithelial receptor program, a grade-linked stromal module, and an immune-associated axis that together form integrated adipokine signatures strongly connected to clinicopathologic features.

#4962 Spatial transcriptomics reveals distinct ASCL1 and ASCL2 gene expression patterns in advanced prostate cancer.

Fan Wei[1], Joy C. Yang[1], Kenneth Iczkowski[2], Marc A. Dall'Era[1], Chengfei Liu[1]

[1]Department of Urologic Surgery, University of California Davis, Sacramento, CA,[2]Department of Pathology and Laboratory Medicine, University of California Davis, Sacramento, CA

Background: ASCL1 and ASCL2 are bHLH transcription factors aberrantly reactivated in advanced prostate cancer. ASCL1 drives neuroendocrine differentiation by activating neuronal genes to promote androgen receptor (AR) independence. ASCL2, regulated by Wnt/β-catenin signaling, maintains stem-like programs and facilitates epithelial to neuroendocrine transition under androgen deprivation. Both factors promote lineage plasticity leading to castration-resistant and neuroendocrine prostate cancer (NEPC). This study examines their distinct gene expression patterns to elucidate how ASCL1 and ASCL2 contribute to lineage transitions and identify potential targets to block transdifferentiation.
Methods: Spatial transcriptomic profiling was performed on a Gleason 10 prostate cancer specimen using the 10x Genomics Visium platform. Regions with ASCL1-high, ASCL2-high, or ASCL1/ASCL2-low expression were analyzed for differential gene expression using Loupe Browser, heatmaps, volcano and violin plots, and pathway enrichment via Gene Set Enrichment Assay (GSEA). A patient derived (PDX) model derived from the same patient was subjected to castration, and intact (n=4) and relapsed (n=6) tumors underwent RNA-seq and GSEA. A spontaneously immortalized prostate cancer cell line, UCDCaP, was derived from the same patient, and its castration-resistant derivative, UCDCaP-CR, was established through serial castration-relapse cycles in mouse passages. Key genes were validated by qRT-PCR and Western blotting.
Results: ASCL1 and ASCL2 were expressed in a mutually exclusive manner in prostate cancer patient tissues. Compared with ASCL2-high regions, ASCL1-high areas showed higher expression of WNT5A, FOLH1 (PSMA), KRT15, and PROX1, but lower levels of AR, AKR1C3, MAOA, and MET. GSEA indicated enrichment of E2F, Myc, DNA repair, translation, and neural lineage pathways in ASCL1-high regions, while interferon signaling, androgen response, extracellular matrix, and epithelial-mesenchymal transition (EMT) pathways were enriched in ASCL2-high regions. Castration-relapsed PDX tumors exhibited increased AR, AKR1C3, ASCL1, and ASCL2, with reduced FOXA1, FOXJ1, DUSP1, and ALDH1A3. Parallel analyses in UCDCaP-CR cells showed upregulated ASCL2 and neuroendocrine markers, and downregulated ASCL1, PTEN, AR response, and P53 pathways.
Conclusions: ASCL1 and ASCL2 define distinct molecular states in prostate cancer. ASCL1 is linked to neural lineage and proliferative pathways, whereas ASCL2 is associated with androgen response and EMT programs. Their mutual exclusivity suggests divergent mechanisms of lineage plasticity. The transition toward ASCL2 dominance in castration-relapsed models, accompanied by neuroendocrine marker upregulation and loss of AR and P53 signaling, highlights their dynamic interplay in driving therapy resistance and neuroendocrine differentiation.

#4963 Cross platform validation of spatial domain identification reveals concordant tumor microenvironment architecture in NSCLC using integrated spatial transcriptomics and multiplex immunofluorescence.

Zeinab Mokhtari[1], Mint Htun[2], Debayan Mukherjee[2], Nima Vakili[1], Deon Hildebrand[2], Crysthiane Ishiy[2], Anna Pasto[2], Sue Griffin[2], **Paul Barber**[2], Tony NG[2]

[1]GSK, Heidelberg, Germany,[2]GSK, Stevenage, United Kingdom

Background: Spatial organization of the tumor microenvironment (TME) in non-small cell lung cancer (NSCLC) influences therapeutic response, yet the reproducibility of spatial domain identification across platforms remains unclear. We performed spatial transcriptomics (STx) and multiplex immunofluorescence (mIF) on surgically resected NSCLC specimens to validate spatial domain identification and characterize TME architecture between lung adenocarcinoma (LUAD) and squamous cell carcinoma (LUSC).
Methods: Formalin-fixed paraffin-embedded NSCLC tissue was analyzed using spatial profiling platforms. STx was performed using Xenium platform with cell type annotation via TACCO optimal transport-based label transfer from public NSCLC single-cell RNA sequencing data. mIF was performed using Leica Cell Dive platform. Spatial domain identification was achieved independently on both platforms: foundational deep learning models identified tissue domains in STx data, while Cell Charter method with transfer variational autoencoder (trVAE) determined cellular architecture in mIF images. Cross-platform validation assessed concordance of spatial domain boundaries and composition between STx and mIF based modalities.
Results: Spatial domain identification revealed strong concordance between STx and mIF platforms across multiple tissue compartments. Tumor epithelial domains identified transcriptomically overlapped with EpCAM-defined regions in mIF. Cancer-associated fibroblast (CAF)-enriched stromal and tertiary lymphoid structure (TLS) domains showed consistent boundaries and composition across modalities. Computationally-defined spatial domains accurately reflected histological features without manual annotation. LUSC samples exhibited expanded CAF-enriched stromal domains with reduced T-cell infiltration compared to LUAD, indicating distinct immune-stromal organization between subtypes.
Conclusions: We demonstrate robust cross-platform validation of spatial domain identification in NSCLC tissue, with computational methods accurately recapitulating biological compartments across transcriptomic and proteomic modalities. The strong concordance between STx and mIF spatial domains establishes confidence in automated tissue segmentation approaches for TME characterization. Spatial domain analyses reveal distinct microenvironmental architectures between LUAD and LUSC, with differential organization of stromal and immune compartments. This validated spatial domain framework provides a reproducible approach for high-resolution TME mapping and may enable identification of spatially-defined biomarkers for precision therapy selection in NSCLC.

#4964 Spatial interaction between Gli1 high tumor cells and M2 macrophages predicts survival and recurrence in gastric cancer.

Dae Yeong Kim[1], Dae-Hee Lee[2], Sang Cheul Oh[3]

[1]Institute of Convergence New Drug Development, Korea University College of Medicine, Seoul, Korea, Republic of,[2]Gangneung-Wonju National University, Gangneung, Korea, Republic of,[3]Dept. of Oncology, Korea University, UT MD Anderson Cancer Center, Seoul, Korea, Republic of

Purpose: This study investigated the prognostic significance of GLI1 expression in gastric cancer by analyzing its association with the infiltration and spatial proximity of tumor-associated M2 macrophages identified by CD163 and CD206. We evaluated how the combined GLI1-M2 macrophage spatial phenotype influences clinical outcomes, including survival and recurrence patterns.
Methods: GLI1 expression and M2 macrophage infiltration were assessed using immunohistochemistry and spatial biology approaches, including multiplex immunofluorescence and machine-learning-based digital pathology. CD163 and CD206 defined M2 macrophage populations. Spatial metrics included GLI1 expression intensity, M2 macrophage density, and the intercellular distance between GLI1-positive tumor cells and CD163/CD206-positive macrophages. Associations with clinical outcomes were analyzed using Kaplan-Meier survival curves and multivariate Cox regression.
Results: High GLI1 expression demonstrated a strong correlation with increased infiltration of CD163/CD206-positive M2 macrophages ($p=0.001$) and reduced spatial distance between tumor cells and M2 macrophages ($p=0.01$). The GLI1-high and M2-close phenotype was associated with markedly reduced overall survival, higher recurrence rates including early relapse, and a microenvironment enriched with immunosuppressive and tumor-promoting signals. In contrast, tumors with lower GLI1 expression and greater separation from M2 macrophages showed improved survival outcomes and reduced recurrence.
Conclusions: GLI1 expression and the spatial proximity of CD163/CD206-positive M2 macrophages serve as strong prognostic indicators in gastric cancer. The GLI1-high and M2-close phenotype identifies a clinically vulnerable subgroup with significantly poorer outcomes. These findings highlight the biological relevance of the GLI1-M2 macrophage axis and suggest that targeting GLI1 signaling or reprogramming M2 macrophages may provide therapeutic benefit and reduce recurrence risk in gastric cancer.

#4965 Sarcomatoid transformation rewires the immune spatial landscape and checkpoint regulation in chromophobe renal cell carcinoma.

Wafaa Bzeih[1], Yan Tang[1], Tiegang Han[1], Andrew J. Sedgewick[2], Nathan D. Maulding[2], Carmen Priolo[1], Katrina Collins[3], Hadi Mansour[1], Joelle Chami[1], Michelle M. Stein[2], Justin Guinney[2], Michel Alchoueiry[1], Jessica F. Williams[4], Michelle S. Hirsch[4], Pavlos Msaouel[5], Elizabeth P. Henske[1]

[1]Department of Medicine, Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[2]Tempus AI, Inc., Chigaco, IL,[3]Indiana University School of Medicine, Indianapolis, IN,[4]Department of Pathology, Harvard Medical School / Brigham and Women's Hospital, Boston, MA,[5]Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Chromophobe renal cell carcinoma (ChRCC) is the second most common non-clear cell RCC. Patients with metastatic ChRCC have a poor prognosis with a median overall survival of ~2 years. Sarcomatoid transformation occurs in ~5% of ChRCC and is associated with increased metastatic risk and reduced survival. In clear cell RCC, the sarcomatoid phenotype is associated with an immune-inflamed state and enhanced responsiveness to immunotherapy. The immune landscape of sarcomatoid ChRCC and how it differs from classic ChRCC remain poorly defined. To address this, we performed a spatial comparison of the immune microenvironment in classic versus sarcomatoid ChRCC.

Results: The 10x Genomics Xenium Prime Assay with 5k-plex target panels was performed on 10 ChRCC tumors (5 classic and 5 sarcomatoid). Hallmark pathway enrichment and differential expression analysis of pseudo-bulk data showed that sarcomatoid transformation is associated with activation of epithelial-mesenchymal transition, proliferation, and inflammatory response pathways ($p < 0.05$). Examining the spatial distribution of single cells, classic tumors showed an immune-excluded microenvironment, with T cells and macrophages localized to the tumor periphery. In contrast, sarcomatoid tumors exhibited an immune-infiltrated microenvironment, with T cells and macrophages present within the tumor bed. Sarcomatoid tumors showed an upregulation of CTLA4 across multiple T cell subsets, including cytotoxic $CD8^+$ T cells, naïve T cells, and regulatory T cells, compared to classic tumors. Additionally, in sarcomatoid tumors, cytotoxic $CD8^+$ T cells exhibited increased expression of LAG3 compared to classic tumors. Using metastasis as a proxy for sarcomatoid transformation, we compared 113 primary ChRCC tumors and 27 metastatic ChRCC tumors using bulk RNA-seq (Tempus xR). Expression profiles and immune deconvolution showed a shift from the immune-excluded, indolent primary state to an immune-modulated metastatic state marked by increased gamma delta T-cell abundance, higher LAG3 expression and decreased T cell exhaustion score (FDR < 0.05).

Conclusion: By generating the first spatially resolved immune map of ChRCC, we showed that sarcomatoid ChRCC exhibits an immune-infiltrated microenvironment with intra-tumoral T cells and macrophages, accompanied by increased expression of immune checkpoint genes including, but not limited to CTLA4 and LAG3. This higher CTLA4 is of interest given the SUNNIFORECAST trial result, where combined CTLA4 and PD1 blockade achieved a 27% objective response rate in ChRCC. We also show that metastatic progression is associated with a shift toward a gamma delta T cell-enriched immune state. Together, these findings reveal potential therapeutic vulnerabilities and support further evaluation of immune checkpoint blockade in ChRCC.

#4966 A single-cell spatial proteomic analysis of the TNBC microenvironment defines genotype-specific features.

Dana Pueschl[1], Danielle Bragen[1], Jia-Ren Lin[2], Anupma Nayak[1], Derek A. Oldridge[3], Kate Bennett[1], Victoria Fang[1], kConFab Investigators, Kenneth Offit[4], Andrew K. Godwin[5], Paul A. James[6], Phuong L. Mai[7], Soo Hwang Teo[8], Antonis Antoniou[9], Georgia Chenevix-Trench[10], E. John Wherry[1], Susan M. Domchek[1], Katherine L. Nathanson[1]

[1]University of Pennsylvania, Philadelphia, PA,[2]Harvard Medical School, Boston, MA,[3]The Children's Hospital of Philadelphia, Philadelphia, PA,[4]Memorial Sloan Kettering Cancer Center, New York, NY,[5]University of Kansas Cancer Center, Kansas City, KS,[6]Peter MacCallum Cancer Center, Melbourne, Australia,[7]University of Pittsburgh, Pittsburgh, PA,[8]Cancer Research Malaysia, Subang Jaya, Malaysia,[9]University of Cambridge, Cambridge, United Kingdom,[10]QIMR Berghofer Medical Research Institute, Brisbane, Australia

Breast cancer in women with germline BRCA1/2 pathogenic variants (g*BRCA1/2*) are generally treated with platinum-based therapies and PARP inhibitors (PARPi) with resistance commonly emerging. As the tumor microenvironment (TME) in *gBRCA1* triple-negative breast cancer (TNBC) is enriched with tumor-infiltrating lymphocytes (TILs) and CD8 T cells, treatment trials have been done combining PARPi and immune checkpoint inhibitors (ICIs) in *BRCA1* TNBC. This combination has not been shown to be more effective than PARPi alone. Evaluating the TME in *gBRCA1/2* TNBC may help identify tumors most likely to benefit from PARPi/ICI therapy. We performed a detailed spatial proteomic analysis to characterize tumor-immune cell interactions in patients with *gBRCA1/2* and wild-type (WT) TNBC with spatial tissue multiplexing (PhenoCycler) in 101 g*BRCA1*, 24 g*BRCA2*, and 30 WT TNBCs with matched RNAseq for 34 g*BRCA1*, 8 g*BRCA2*, and 16 WT TNBCs. A 43-plex antibody panel was developed featuring markers of DNA damage and repair, immune subtypes and exhaustion. We detected single tumor cells (PANCK+) in S/G2 phase (Geminin+) with double-stranded DNA breaks (γH2AX+) and DNA repair capacity (RAD51+) across all three cohorts. g*BRCA1/2* TNBC patients exhibited a significantly lower proportion of tumor cells with homologous recombination proficiency (HRP) (g*BRCA1* p = 0.006; g*BRCA2* p = 0.007) compared to WT TNBC. CD4 & CD8 T cells, and CD20 B cells had intact DNA repair in WT and g*BRCA1/2* TNBC. The frequency of CD8+ T (p=0.016) and CD20 B (p=0.003) cells was significantly higher in g *BRCA1* compared to WT TNBC; BRCA2 and WT TNBC showed no differences. A detailed characterization of CD8 T cells revealed significantly increased numbers of potentially dysfunctional CD8 T cells in BRCA1 (TOX, p<0.0001; LAG-3, p=0.028; PD-1, p=0.033) and BRCA2 (LAG-3, p=0.033) compared to WT TNBC. We observed two types of TMEs in g*BRCA1* TNBC: 1) CD8 low (mean<9.38%) with 1.4-fold increased immune checkpoint (PD-1) expression (mean: 15.4%) and high DNA damage in tumor cells; and 2) CD8 high (>9.38%) with reduced PD-1 and low DNA damage in tumor cells. Our findings suggest that although g*BRCA1/2* variants lead to DNA damage and impaired repair in tumor cells, T cells (CD4, CD8) and B cells (CD20) retain intact DNA repair mechanisms. We also found that g*BRCA1/2* TNBCs exhibit higher levels of immune checkpoint proteins LAG-3 and PD-1 on CD8 T cells compared to WT TNBC. This finding suggests the potential utility of additional ICI (LAG-3, PD-1) beyond PD-L1 blockade. Importantly, patients with g*BRCA1*-associated TNBC exhibit two different TMEs, suggesting that the response to ICI- and DNA-damaging-based therapies may differ between tumors, and anticipated prior to treatment. Defining treatment-naïve TME is crucial for designing personalized, targeted ICI strategies for individuals with *BRCA*-mutated TNBC.

#4967 Spatial divergence across glioblastoma multi-regional biopsies and corresponding neurosphere cultures.

Roberto Salatino[1], Jacob Geisberg[2], Arantxa Romero Toledo[1], Benjamin Oakes[1], Dobeen Hwang[1], Cristina Vincentelli[3], Oszkar Szentirmai[4], Thomas O. McDonald[2], Franziska Michor[2], **Michalina Janiszewska**[1]

[1]The Wertheim UF Scripps Institute, Jupiter, FL,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Mount Sinai Medical Center, Miami Beach, FL,[4]Cleveland Clininc Martin Health, Port St. Lucie, FL

Glioblastoma (GBM), the most aggressive brain tumor, remains an unmet medical need, as only 6.8% of patients survive 5 years post diagnosis. Lack of effective treatment for GBM is largely driven by high level of intratumor heterogeneity, which is poorly captured by the current models of the disease used for drug discovery. Several recent studies demonstrated that spatial organization of the GBM tumor tissue is another highly heterogeneous aspect of this disease. Despite these observations, and availability of imaging-guided surgical navigation that allows for tumor-wide sampling to account for variation between distant regions of the tumor, typical drug screening is performed on cell lines derived from a single biopsy and does not account for GBM heterogeneity.

Here, we profiled matching MRI-guided multi-region primary tumor biopsies from 6 GBM cases (n=40 biopsies) and corresponding neurosphere cultures (n=30) derived from these spatially distinct tumor samples. The tumors represented all three GBM subtypes, with some biopsies classifying as a different subtype than the rest. Whole exome sequencing-based clonal analysis of the tumor samples confirmed their heterogenous nature, with 3-5 clones found in each biopsy.

Interestingly, the neurosphere cultures derived from different areas of the same tumor retained their diversity with respect to metabolism of 5-ALA, used in fluorescence-guided tumor resection, varying proliferative capacity and distinct transcriptional programs. Tumor periphery, which is thought to harbor cells driving local recurrence after surgery, gave rise to neurospheres with higher expression of cell cycle and DNA repair genes. The lines representing tumor periphery and not accumulating 5-ALA had high levels of MYC activity.

Since these cells are thought to drive local recurrence, targeting these tumor subpopulations could have a significant clinical benefit. To inhibit these pathways, we selected a panel of 7 drugs based on their recent evaluation in clinical trials for GBM patients, and tested their ability to affect proliferation of our neurosphere lines. We found that the responses to these drugs were variable between the neurospheres derived from distinct regions of the same tumor. Unexpectedly, we found that the cellular composition of the original tumor sample, predicted based on bulk transcriptomic data, can be linked to drug response outcomes derived from respective neurosphere line.

Our study demonstrates that the tumor-wide diversity of phenotypes of GBM can be propagated *in vitro*. Our results suggest that, at least in part, the transcriptional programs retained by GBM cells in vitro reflect their history of selection in distinct microenvironments in the tumor.

#4968 Comprehensive multi-omic profiling of the tumor-immune microenvironment using Xenium transcriptomics and Hyperion XTi Imaging Mass Cytometry.

Wendell Smith[1], Elim Cheung[2], JingHao Tian[2], Qanber Raza[1], Toby Astill[1], Daniel Zangrando[1], Nina Lane[1], Tommy Tran[2], Rikita Gakhar[2], Vidyodhaya Sundaram[2]

[1]Standard BioTools Inc., South San Francisco, CA,[2]BioChain Institute Inc., Newark, CA

Spatial multi-omics has become a powerful strategy for resolving cellular heterogeneity and precisely characterizing the tissue microenvironment, surpassing the biological resolution achievable with RNA-only or protein-only spatial assays. To address the limitations of single-modality profiling, we established an integrated workflow that combines Xenium in situ transcriptomics with Standard BioTools' Hyperion XTi Imaging Mass Cytometry (IMC) system. This approach is designed to enable coordinated, high-parameter analysis of transcriptomic and proteomic features within the same tissue regions, supporting deeper investigation of microenvironmental structure and function. Using a human primary FFPE multi-tissue panel comprising stomach large cell carcinoma, colon adenocarcinoma, invasive ductal carcinoma, and lung squamous cell carcinoma, BioChain generated spatially resolved Xenium transcriptomic data and mapped cell populations using lineage-defining markers. Major epithelial, stromal, endothelial, lymphoid, and myeloid compartments were identified, and architectural features—including tumor nests, stromal boundaries, tertiary lymphoid structures, and mixed immune aggregates—were delineated. For each region of interest, transcriptomic readouts were distilled into concise microenvironmental summaries reflecting immune infiltration intensity, lymphoid organization, cytotoxic activity, stromal composition, and checkpoint-associated transcriptional programs. These region-level profiles enabled cross-tissue comparison of microenvironmental classes across heterogeneous tumor types. Hyperion XTi IMC profiling of the same tissue regions provided a complementary proteomic view with high spatial and phenotypic resolution. The expanded protein panel resolved functional states associated with immune activation, suppression, proliferation, and tissue remodeling. Overlapping immune and stromal markers supported alignment of proteomic signals with the Xenium transcriptomic map, allowing corresponding cellular neighborhoods to be referenced across modalities. Together, these datasets established a multi-omic spatial framework that links cellular identity to protein-level functional dynamics within shared tissue coordinates. Overall, this combined transcriptomic-proteomic strategy establishes a scalable and practical template for comprehensive spatial profiling using limited FFPE material. The workflow is compatible with existing analysis tools, readily adaptable to new panels or tissue types, and well positioned for future development of spatially informed biomarkers and mechanistic insights into complex tissue ecosystems.

#4969 Automated multiomics assay with over 100 biomarkers for in-depth spatial profiling of the tumor microenvironment in multiple cancer types.

Marion Bonnet[1], Cansaran Saygili-Demir[1], Kim Handel[1], Pedro Machado[1], **Alix Failletaz**[1], Debia Wakhloo[2], Anushka Dikshit[2], Maria Giuseppina Procopio[1], Saska Brajkovic[1]

[1]Lunaphore, a Bio-Techne brand, Tolochenaz, Switzerland,[2]Advanced Cell Diagnostics, a Bio-Techne brand, Newark, CA

Background

The tumor microenvironment (TME) plays a pivotal role in cancer progression, immune evasion, and therapeutic response. Understanding the spatial organization and functional states of cells within the TME is essential for advancing immuno-oncology and precision medicine [PMID: 40102282]. However, simultaneous visualization of secreted molecules and cellular phenotypes in situ remains a major challenge in the spatial biology field [PMID: 39930476]. Here, we employed an automated hyperplex multiomics assay to simultaneously detect RNA and protein expressions to spatially map cell phenotypes and their functional states in the TME of multiple cancer types.

Methods

We examined a formalin-fixed paraffin-embedded tissue microarray (TMA) comprising various human cancer types: prostate, lung, breast, colorectal, melanoma, and lymphoma. A TMA section was stained and imaged on the COMET™ platform, integrating RNAscope™ HiPlex Pro for transcript detection and sequential immunofluorescence (seqIF™) for proteomic analysis [PMID: 22166544; 37813886; 41065276]. Image was analyzed using HORIZON™ software to extract single-cell and spatial features.

Results

The automated multiomics approach enabled the concomitant in situ detection of over 100 biomolecular targets, including 12 transcripts and more than 90 proteins on the same section. High-resolution spatial profiling of the TME allowed accurate mapping of cancer, stromal, vascular and diverse immune cell subsets. It further revealed key molecular features associated with tumor-suppressor or proto-oncogene activity, including markers of proliferation, apoptosis, and immune checkpoint regulation. Concurrent detection of cytokine and chemokine transcripts highlighted localized immune signaling and cell-cell communication within tumor and stromal compartments.

Conclusions

This multiomics workflow offers a powerful tool for in-depth characterization of the TME across multiple cancer types, while significantly reducing sample consumption. Spatial profiling provides new opportunities to dissect the tissue architecture and immune dynamics to identify functional cell states and interactions to be exploited in immunotherapy and personalized medicine.

#4970 Transcriptomic analysis reveals myoepithelial cell reprogramming in invasive breast cancer.

Mohamed M. Haq[1], Curtis Benson[2], Meik Kunz[2], Elim Cheung[3]

[1]HCA Houston Healthcare Southeast, Pasadena, TX,[2]The Bioinformatics CRO, Sanford, FL,[3]BioChain Institute Inc., Newark, CA

INTRODUCTION: Myoepithelial cells (MECs) in ductal carcinoma in situ (DCIS), although morphologically similar to normal MECs, exhibit distinct functional properties that promote progression to invasive breast cancer. To investigate MEC alterations in invasive disease (IDC), we performed a transcriptomic comparison of MECs within IDC and adjacent normal breast tissues from the same patient specimens.

METHODS: Breast cancer tissue specimens were obtained from HCA Houston Healthcare Southeast (Pasadena, TX). MEC presence within invasive ductal carcinoma (IDC) was validated by α-smooth muscle actin (αSMA) staining and confirmed by a pathologist. Seven untreated, loco-regional invasive breast carcinoma FFPE blocks were sent to BioChain Institute for spatial transcriptomic profiling using the GeoMx Digital Spatial Profiler (DSP, NanoString). H&E staining was used to identify suitable regions, and a 3 mm core tissue microarray (TMA) was constructed using both tumor and adjacent normal tissues. MEC transcriptomes were profiled on 5 µm TMA sections, with ROIs selected based on αSMA, PanCK, and Syto13 staining to distinguish MECs from stroma, and indexing oligonucleotides were collected for sequencing. Libraries were prepared and sequenced on an Illumina NextSeq2000 platform. Bioinformatics analyses were conducted in R by The Bioinformatics CRO using EdgeR, fgsea, and clusterProfiler, with normalization, differential expression, gene set enrichment analysis and functional pathway analysis revealing molecular distinctions between tumor-associated and adjacent normal MECs.

RESULTS: Our analysis revealed profound molecular reprogramming across three principal domains: extracellular matrix interactions, epithelial-mesenchymal transition, and cellular signaling. Key molecular alterations included (1) widespread upregulation of 17 distinct collagen isoform genes, indicating active stromal remodeling; (2) increased expression of matrix metalloproteinases (*MMP2*, *MMP9*, *MMP11*, and *MMP14*), suggesting compromised basement membrane integrity; and (3) significant dysregulation of epithelial markers (*KRT5*, *KRT7*, and *KRT14*), characteristic of a transitional phenotype resembling cancer-associated fibroblasts. Additional findings included elevated expression of pro-tumorigenic genes (*SPARC*, *POSTN*) and integrin subunits, alongside alterations in growth factor signaling pathways. These findings, although limited by the sample size and the transcriptomic approach, align with previously reported molecular alterations associated with myoepithelial reprogramming in DCIS-associated MECs.

CONCLUSION: This comprehensive transcriptomic analysis demonstrates significant molecular plasticity of myoepithelial cells within the IDC microenvironment, consistent with a phenotypic transition from tumor-suppressive to tumor-promoting function.

#4972 KIT exon 9 versus exon 11 mutations imprint distinct spatial and phenotypic immune microenvironments in gastrointestinal stromal tumors.

Jean-Philippe Guegan[1], Jean-Michel Coindre[2], Carine Ngo[3], Antoine Bougouin[4], Christophe Rey[5], Catherine SAUTES-FRIDMAN[6], Wolf Herve Fridman[6], Armelle Dufresne[7], Alban Bessede[5], **Antoine Italiano**[8]

[1]Immunospot, Cleveland, OH,[2]Institute Bergonie, Bordeaux, France,[3]Carine Ngo (Individual),[4]Sorbonne University, Paris, France,[5]ImmuSmol, Pessac, France,[6]INSERM U1138 (Centre de Recherche des Cordeliers), Paris, France,[7]Leon Berard Center, Lyon, France,[8]Institute Bergonie, Bordeaux cedex, France

Background:
The tumor microenvironment (TME) is a key determinant of progression and treatment response in gastrointestinal stromal tumors (GIST). Oncogenic KIT mutations in different exons (exon 9 vs exon 11) are clinically relevant, but their impact on immune and stromal architecture in situ remains insufficiently understood. We hypothesized that KIT exon 9 and exon 11 mutations drive distinct spatial transcriptional programs and immune cell compositions.

Methods:
FFPE samples from KIT-mutated GIST (exon 9 and exon 11) were profiled using the NanoString GeoMx® Whole Transcriptome Atlas (18,695 protein-coding genes). Eleven areas of illumination per case were selected in tumor and peritumoral regions and segmented into $CD45^+$ (immune-enriched) and $CD45^-$ (tumor/stromal) compartments. Cell-type abundances in $CD45^+$ segments were estimated with SpatialDecon. In parallel, three multiplex immunofluorescence (mIF) panels (DOG1/CD11c/CD11b/CD68/CD45/HLA-DR; DOG1/CD45RO/CD56/CD4/CD8/CD20; DOG1/CD45/CD16/CD56) were applied to independent retrospective GIST cohorts (n=170), and cell densities were quantified in tumor and stromal compartments using QuPath-based segmentation and FACS-like phenotyping.

Results:
GeoMx analysis identified 2315 differentially expressed genes in $CD45^+$ tumor regions between exon 9 and exon 11 tumors, indicating exon-specific immune transcriptional programs. SpatialDecon deconvolution revealed that exon 11-mutant tumors exhibited higher NK-cell scores (adjusted $p \approx 6\times10^{-6}$), whereas exon 9-mutant tumors showed higher fibroblast (adjusted $p \approx 6\times10^{-6}$) and $CD8^+$ memory T-cell signals (adjusted $p \approx 1.9\times10^{-4}$). In the large mIF cohorts, unsupervised analyses of DOG1-gated tumor regions confirmed robust technical performance of all three panels and demonstrated genotype-segregated TME patterns KIT-mutant cases, and within them exon 9 vs exon 11 tumors, occupied distinct regions in PCA space, with exon 11 tumors showing higher $CD56^+$ (NK/NKT) and myeloid ($CD11b^+$/$CD68^+$/HLA-DR^+) densities, whereas $CD8^+CD45RO^+$ memory T cells were more abundant in exon 9 tumors, independently of PDGFRA-mutant GIST. Across panels, these phenotypic differences aligned with the GeoMx-derived enrichment of NK cells in exon 11 tumors and of and $CD8^+$ memory T cells in exon 9 tumors.

Conclusions:
Integrated spatial transcriptomics and multiplex IF demonstrate that KIT exon 9 and exon 11 mutations are associated with distinct immune and stromal microenvironments in GIST, characterized by an NK-cell-enriched, myeloid cells , less fibroblast- and $CD8^+$ memory T-cell-dense niche in exon 11 tumors and the converse pattern in exon 9 tumors. These data support the concept that the precise KIT exon mutated imprints the TME and should be considered when designing genotype-adapted combinations of kinase inhibition and immunotherapy.

#4976 Upregulation of a B7 family protein drives immune escape in therapy-induced senescent cancer cells.

Donghee Kang[1], Min-Ji Kim[1], Hyung Jung Hwang[1], Jeong Minwoo[2], Jong-Ho Cha[2], Jae-Seon Lee[2]

[1]Research Center for Controlling Intercellular Communication, Inha University, Incheon, Korea, Republic of,[2]Program in Biomedical Science and Engineering, Inha University, Incheon, Korea, Republic of

Background: Conventional cancer therapies, including ionizing radiation (IR) and chemotherapy, often drive tumor cells into a cellular senescence state. Accumulating evidence suggests that senescent tumor cells contribute to the establishment of an immunosuppressive tumor microenvironment (TME) and promote tumor recurrence. A B7 family protein, an immune checkpoint protein, is frequently overexpressed across various tumor types and is known to suppress T-cell activity, thereby facilitating immune evasion and resistance to immunotherapy. However, the molecular mechanisms underlying the role of this B7 family protein in therapy-induced senescent (TIS) cancer cells remain poorly understood.
Methods: To elucidate the molecular mechanisms and immunoregulatory roles of the B7 family protein in TIS, we analyzed The Cancer Genome Atlas (TCGA) database to assess its expression across multiple cancer types. We further examined changes in its expression following IR or doxorubicin treatment in several human cancer cell lines, including A549 (lung), HCT116 wild-type (colon), HepG2 (liver), MIA PaCa-2 (pancreas), DU145 (prostate), and U2OS (bone). The role of the B7 family protein in cellular senescence was evaluated through gene knockdown experiments, and its impact on immune function was investigated using T cell-mediated cytotoxicity assays.
Results: TCGA analysis revealed that the B7 family protein is highly expressed across diverse cancer types. Following IR or doxorubicin treatment, its expression was significantly upregulated in senescent cancer cells across multiple cell lines. Depletion of the B7 family protein did not alter the senescence phenotype, indicating that it is not directly involved in regulating cellular senescence. Mechanistically, its upregulation in IR-induced senescent cancer cells occurred predominantly at the transcriptional level rather than through post-transcriptional or post-translational mechanisms. Notably, depletion of the B7 family protein markedly enhanced T-cell infiltration and cytotoxic activity against senescent cancer cells, demonstrating that its upregulation impairs antitumor immunity in TIS.
Conclusions: Our findings reveal the B7 family protein acts as a key regulator of immune suppression during therapy-induced senescence. This upregulation enables senescent cancer cells to evade T-cell mediated immune attack. Thus, inhibiting B7 family protein may offer a strategy to restore anti-improve immunity and improve therapeutic outcomes.

#4977 Programmed cell death ligand 1 (PD-L1) expression across molecular subtypes of human high-grade ductal carcinoma in situ (DCIS) of the breast.

Hossein Schandiz[1], Lorant Farkas[2], Berit Gravdehaug[3], Elin Edda Seland Agustsdottir[3], Torill Sauer[4], Jurgen Geisler[1]

[1]Department of Oncology, Akershus University Hospital, Lorenskog, Norway,[2]Department of Pathology, Oslo University Hospital, Oslo, Norway,[3]Department of Breast and Endocrine Surgery, Akershus University Hospital, Lorenskog, Norway,[4]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway

Background: The expression of PD-L1 in tumor-infiltrating lymphocytes (TILs) in tumor microenvironment (TME) of high-grade breast DCIS is currently unknown.
Methods: Formalin-fixed paraffin-embedded specimens from 494 female patients diagnosed with DCIS between 1996-2018 were available to routine diagnostic immunohistochemical (IHC) staining. ER and PR IHC positivity was defined as ≥1% positive tumor cells, and HER2 IHC was scored based on the updated guidelines of the American Society of Clinical Oncology and the College of American Pathologists, as in routine diagnostic procedures. HER2 silver in situ hybridization was performed when the IHC score was 2+. We calculated the Ki67 ratio by counting 200 intraductal epithelial cells in two separate hotspot foci. DCIS cases were classified as Luminal A (LumA), LumB HER2$^-$, LumB HER2$^+$, HER2-enriched, or triple-negative (TPN) subtypes according to the 2013 St. Gallen guidelines, which is used for molecular subtyping of invasive breast carcinoma. Each subtype was sorted into “Pure”: without an invasive component and “W/invasive”: with an invasive component. We calculated the PD-L1 IHC ratio by counting (up to) 1000 immune cells divided by positive PD-L1 cells. PD-L1 expression was dichotomized at a threshold of 1%. We assessed the associations between PD-L1 status, subtype, and other variables, including age, Ki67, DCIS extension, and invasiveness.
Results: We identified a significant proportion of TILs in 149/484 (31%) cases. 100% of these cases were high-grade DCIS. We successfully stained 118/149 cases with PD-L1 IHC, and 73/118 (63%) expressed PD-L1 ≥1%. In 92/149 (62%) cases with TILs, strong membrane-positive HER2 overexpression was observed (25% LumB HER2$^+$ and 37% HER2-enriched subtype, $p < 0.0001$). A significant number (31/60; 52%) of the “W/invasive” cases contained TILs, compared to “Pure” (118/362; 32%) ($p < 0.0055$). PD-L1 ≥1% was most prevalent in HER2-enriched (48.6%) and LumB HER2$^+$ (25%) subtypes, with lower representation in LumA (12.5%), LumB HER2$^-$ (9.7%), and TPN (4.2%) subtypes. However, comparison of the PD-L1 ≥1% status across subtypes yielded a non-significant chi-square result ($p = 0.2734$). PD-L1 expression was not significantly associated with “W/invasive” cases ($p = 0.0765$). Significant differences were observed across subtypes among cases expressing PD-L1 ≥1% for Ki67 ($p = 0.0325$) and DCIS extension ($p = 0.0323$), but not for age ($p = 0.4329$) or invasive status ($p = 0.6722$).
Conclusions: PD-L1 ≥1% was more common in HER2-driven subtypes, but its distribution was not subtype-dependent. PD-L1 expression also lacked a significant association with invasiveness. These findings demonstrated strong PD-L1 expression in high-grade DCIS, although the utility of PD-L1 as a standalone biomarker for subtype stratification or prediction of invasive potential in DCIS patients could be limited.

#4978 MHC class 1 expression and distribution of multiple immune cells in chemotherapy-naïve triple-negative breast cancers: lack of antigen-presentation can bring high TILs and good prognosis, possibly via decreased regulatory T-cell composition.

Makiko Yamashita[1], Akira I. Hida[2], Naomi Gondo[3], Yasuyo Ohi[4], Shigehisa Kitano[1]

[1]Department of Advanced Medical Development, Cancer Institute Hospital, Tokyo, Japan,[2]Department of Pathology, Matsuyama Shimin Hospital, Ehime, Japan,[3]Department of Breast Surgery, Sagara Hospital, Kagoshima, Japan,[4]Department of Pathology, Sagara Hospital, Kagoshima, Japan

Triple-negative breast cancers (TNBCs) have not been candidates for targeted therapies because they are negative for ER, PgR, and HER2. In addition, the aggressive nature of TNBCs makes their treatment challenging. However, recent advances include immune checkpoint inhibitors (ICIs), which are effective against some TNBCs. The abundance of tumor-infiltrating lymphocytes (TILs) in the cancer microenvironment correlates with better prognosis, and improved efficacy of chemotherapy and ICIs. We don't know yet in detail what makes the difference, high or low TIL, and wanted to investigate cancer immunity cycles.

We retrospectively recruited 153 consecutive TNBC patients from a single institution, all of whom had primary curative surgery and standard adjuvant chemotherapy. Representative surgical samples were immunohistochemically stained for MHC class 1 and evaluated by a pathologist in a score of 3 (diffusely positive) to 0 (almost negative). Heterogeneous staining was scored as 2 (positive area>50%) or 1 (positive area<50%). TILs were estimated after hematoxylin & eosin staining, and relapse-free survival was recorded. Thirty cases with different levels of MHC expression were stained for CD3, CD4, CD8, CD20, CD56, CD204, FoxP3, and pan-cytokeratin using a multi-fluorescence technique. Six-hundred small areas of interest were selected and assigned to one of four categories according to tumoral MHC (positive/negative) and stromal TILs (high/low). Staining signals were calculated on the images, and clustered to determine the distribution of cells in areas of tumor or stroma.

TIL abundance was an independent prognostic factor (HR: 2.52, p=0.013). MHC class 1 expression was diffusely positive in many cases (score 3 in 88 of 153 cases), and four cases were negative (score 0). MHC positivity correlated with higher TILs; nevertheless, the four cases with an MHC score of 0 had high TILs (42.5% on average) and showed no recurrence or death during the mean follow-up period of 14.5 years. Detailed composition of immune cells in areas of high TIL showed infiltration by many CD3+ and CD20+ cells, while CD204+ cells were numerous in areas of low TIL. MHC class 1-negative areas had fewer FoxP3+ cells than positive areas, even in areas of high TIL. There was no significant difference in CD56+ cell number between MHC-positive and -negative areas. Cluster analysis of immune cells revealed CD204 to be a major divider of the population.

MHC class 1-negative TNBCs contained relatively high TILs, the main components of which were CD3+ and CD20+ cells. The presence of FoxP3+ cells seems to require HMC class 1, and the lack of negative regulation by FoxP3 might have resulted in high TIL and better prognosis. Our findings indicate a missing link between antigen presentation and T-cell recruitment.

#4979 CD155- binding peptide enhances antitumor activity of T cells and cytotoxic activity of a lytic peptide in colon tumor.

Gunassekaran Gowri Rangaswamy[1], Poongkavithai Vadevoo Sri Murugan[2], Byungheon Lee[2]

[1]Biochemistry, Kyungpook National University, Daegu, Korea, Republic of,[2]Kyungpook National University, Daegu, Korea, Republic of

CD155 is an immunoglobulin-like protein overexpressed in most tumor cells and promotes the proliferation, adhesion, and migration/invasion of tumor cells. CD155 has multiple immune checkpoint receptors, including CD226, TIGIT, CD96, CD112R (PVRIG) and KIR2DL5. These ligands bind with different affinities to PVR-like protein receptors, thus exerting immune-activating or immunosuppressive functions.CD155 binds to TIGIT with far higher affinity than binds to CD96 or CD226. Moreover, the CD155 immunosuppressive target TIGIT, CD96 competes with the immune activation target CD226 to inhibit immune system activation. As a result, TIGIT exerts an immunosuppressive impact on immune cells by preventing CD226-mediated co-stimulation. Upregulation of CD155 in colon tumor is associated with poor patient outcomes, which highlights its potential as therapeutic target. Using a phage-displayed peptide library, we identified a peptide that binds CD155 with a high affinity (CD155pep). Treatment of CT26 colon tumor cells with CD155pep during co-cultures with CD8+ T cells down-regulated CD155 expression of the tumor cells and enhanced antitumor activity of T cells, including the release of granzyme B, interferon-γ, and tumor necrosis factor-α, and the increase of tumor cells lysis. In addition, treatment of tumor-associated macrophages with CD155pep during co-cultures with CD8+ T cells decreased anti-inflammatory IL-10 production while increasing pro-inflammatory IL-12 secretion of macrophages. Furthermore, CD155pep-linked lytic peptide showed a selective toxicity in tumor cells over normal cells and inhibited tumor growth in mice. These results highlight the therapeutic potential of CD155pep and CD155pep-linked lytic peptide for targeted therapy of CD155-high tumors.

#4980 Clinical and prognostic significance of spatial distribution of CD163-positive tumor-associated macrophages in pleural mesothelioma.

Ryota Sumitomo[1], Tetsuya Fukui[1], Masashi Kobayashi[2], Hiroaki Sakai[3], Toshi Menju[1]

[1]Kyoto University Hospital, Kyoto, Japan,[2]Department of Thoracic Surgery, SHOWA Medical University, Tokyo, Japan,[3]Hyogo Prefectural Amagasaki General Medical Center, Hyogo, Japan

Objectives: Pleural mesothelioma (PM) remains a fatal malignancy despite multimodal therapy. Macrophages activated by asbestos and tumor-derived factors may develop into tumor-associated macrophages (TAMs) with tumor-promoting properties. However, the spatial distribution and clinical impact of these TAMs in PM remain poorly defined.

Methods: We retrospectively analyzed 101 consecutive patients with PM treated at Kyoto University Hospital and Hyogo Prefectural Amagasaki General Medical Center between 1998 and 2010. CD163 immunohistochemistry was performed to quantify pro-tumoral TAMs in intratumoral and peritumoral regions, while Ki-67 staining assessed tumor proliferation. The intratumoral region was defined as an area within the tumor or, if not feasible, as a field containing ≥70% tumor tissue. The peritumoral region was defined as an adjacent stromal area containing >70% stroma. Optimal cutoffs for TAM densities were determined using the minimum p-value method with pretreatment C-reactive protein (CRP). Overall survival (OS) was estimated using the Kaplan-Meier method, and the Cox regression model was employed for univariable and multivariable analyses to examine factors influencing survival.

Results: Intratumoral and peritumoral CD163-positive TAM densities were 660.8 ± 565.9 and 223.1 ± 195.6 cells/mm², respectively, and were moderately correlated ($r = 0.505$, $p < 0.001$). Both intratumoral and peritumoral TAM densities correlated with CRP ($r = 0.283$ and 0.255, $p < 0.05$) and Ki-67 ($r = 0.498$ and 0.435, $p < 0.001$). Intratumoral TAMs were more abundant in sarcomatoid histology ($p < 0.001$) and in advanced stage ($p = 0.043$), whereas peritumoral TAMs showed no significant associations with clinicopathologic factors. High CD163-positive TAM density predicted poorer OS in both regions: intratumoral high versus low groups showed 5-year OS rates of 13.3% and 23.2% ($p = 0.044$), and peritumoral high versus low groups showed 5-year OS rates of 13.2% and 24.1% ($p = 0.046$). In multivariable analysis, peritumoral CD163-positive TAM-high status (HR = 1.700, 95% CI 1.034-2.796, $p = 0.037$) remained an independent prognostic factor along with stage and histology.

Conclusions: In PM, high densities of CD163-positive TAMs were associated with systemic inflammation and tumor proliferation. The spatial distribution of these TAMs may indicate a prognostically relevant tumor immune microenvironment, and peritumoral TAMs in particular showed independent prognostic significance. These findings suggest that TAM spatial profiling may serve as a practical biomarker for risk stratification.

#4981 New thought and strategy of liver cancer immunotherapy.

Gen-Sheng Feng

UC San Diego School of Medicine, La Jolla, CA

This study is to explore new strategy of liver cancer immunotherapy. Despite the great success of immunotherapy in a broad range of cancers, the vast majority of cancer patients showed poor response. Approximately 17% liver cancer patients responded to monotherapy of pembrolizumab and 20% responded to nivolumab. A combination of nivolumab and ipilimumab increased the response rate to 30% in HCC. Simultaneous blockade of PD-L1 and VEGF signaling using atezolizumab and bevacizumab achieved better overall and progression-free survival than sorafenib in HCC.

Our previous data showed that monotherapy with anti-PD-L1 antibody exhibited no inhibitory effect in primary liver cancer driven by classical oncogenes in mice. Given a robust induction of PD-L1 expression by polyIC in the liver, we reasoned that the synthetic dsRNA could sensitize hepatic response to αPD-L1 treatment. Indeed, combined treatment of polyIC and anti-PD-L1 showed markedly improved efficacy in mouse HCC models.

A combinatorial therapy of polyIC and anti-PD-L1 exhibited an intriguing synergistic effect in liver tumors. We interrogated the compositions and changes of immune cell subtypes infiltrated into the tumors grown subcutaneously or in the liver, as well as the whole liver of tumor-bearing mice. The data suggest that it is the tumor microenvironment, rather than the tumor cells, that determine the response to immunotherapy.

We have also found that the polyIC+antiPD-L1 combination exhibited more potent anti-tumor effect than antiPD-L1+antiVEGFA. Further, we demonstrate that a monotherapy of liver-targeting lipid nanoparticles that encapsulate polyIC (polyIC-LNP) is sufficient to suppress both primary and metastasized liver tumor progression in mouse models.

Current working address: Institute of Cancer Research, Shenzhen Bay Laboratory

#4982 Targeting collagen receptor CD49b enhances PD-L1 blockade by promoting CD8⁺ T-cell immunity in breast cancer.

Ibrahim R. Eissa[1], Kenneth K. Tanabe[2]

[1]Massachusetts General Hospital, Boston, MA,[2]Massachusettes General Hospital, Boston, MA

Background: Immune checkpoints blockade (ICB) have improved cancer outcomes, but its efficacy in breast cancer remain limited by an immunosuppressive tumor microenvironment and dense extracellular matrix (ECM). Collagen, the main ECM component, supports tumor progression and immune evasion via integrin-mediated signaling and DDRs receptors. The collagen receptor CD49b (integrin α2) promotes tumor adhesion. This study evaluated whether CD49b targeting enhances PD-L1 blockade to overcome ECM-driven resistance.
Methods: Expression of CD49b, CD29, and DDR1 were profiled in breast cancer cell lines by flow cytometry, along with MHC-I and PD-L1. Collagen adhesion assays followed CD49b inhibition using Vatelizumab (anti-human CD49b), HMα2 (anti-mouse CD49b), or CRISPR/Cas9 knockout in 4T1 cells. Transcriptomic datasets (CCLE, scRNA-seq, spatial transcriptomics) were analyzed to define collagen receptor localization in breast cancer TME. In vivo, 4T1-bearing mice were treated with anti-PD-L1, anti-CD49b, or the combination, followed by analysis of tumor growth and tumor immune infiltration.
Results: CD49b and CD29 were highly expressed in MCF7, T47D, and 4T1 cells, while MDA-MB-231 cells showed low levels and weak collagen adhesion. CD49b blockade or knockout impaired adhesion and delayed tumor growth in vivo without affecting proliferation. Transcriptomic analysis confirmed CD49b enrichment in malignant cells. Dual CD49b and PD-L1 inhibition showed a synergistic antitumor activity, significantly reducing tumor burden and increasing $CD8^+$ T-cell infiltration and IFN-γ expression, consistent with enhanced cytotoxic immunity.
Conclusions: CD49b mediates tumor-ECM interaction in breast cancer. Combined CD49b and PD-L1 blockade remodels the TME, enhances $CD8^+$ T-cell-driven responses, and represents a promising therapeutic strategy to overcome ICB resistance in collagen enriched tumors.

#4984 Dissociative, spatial, and functional single-cell profiling reveals antigen-driven exhaustion and chemotactic failure of tumor-reactive T cells in HPV-negative HNSCC.

Joseph Zenga[1], Musaddiq Awan[1], Fumou Sun[1], Stuart J. Wong[1], Abdullah Memon[1], Tyce Kearl[1], Ean Norenberg[1], Margaret L. Hoang[2], Joseph M. Beechem[3], Eric Hobbs[4], Ashley Heck[2], Rachel Liu[2], Daniel McGuire[2], Erin Piazza[2], Peiman Hematti[1], Heather Himburg[1]

[1]Medical College of Wisconsin, Milwaukee, WI,[2]Bruker Spatial Biology, Seattle, WA,[3]Bruker Spatial Biology, Piedmont, CA,[4]Bruker Cellular Analysis, Emeryville, CA

Introduction: HPV-negative head and neck squamous cell carcinoma (HNSCC) remains highly lethal, and even the recent KEYNOTE-689 trial showed limited response to PD-1 blockade. To clarify mechanisms of immunoresistance, we performed multi-omic single-cell profiling of HPV-negative HNSCC to define the states, clonotypes, and spatial niches of tumor-reactive T cells.
Methods: Two patients with untreated HPV-negative HNSCC underwent surgical tumor sampling. Biopsies were allocated for dissociative single-cell RNA and TCR sequencing, for single-cell spatial whole transcriptome imaging with TCR add-in on the Bruker CosMx platform, and for functional co-culture of autologous tumor cells and tumor-infiltrating lymphocytes (TILs) on the Bruker Beacon system with robotic retrieval of reactive clones followed by single-cell TCR sequencing.
Results: Dissociative and spatial datasets were high quality, and dissociative clustering guided spatial annotation. Two tumor-reactive TIL populations emerged: a transcriptionally reactive population marked by terminal exhaustion and clonal hyper-expansion, and a functionally reactive population identified on the Beacon platform through tumor-killing and IFNγ secretion. Neither appeared in adjacent normal mucosa. Spatial projection showed functionally reactive clonotypes progressing along a pseudotime continuum from minimally exhausted stromal states toward a deeply exhausted yet proliferative state within malignant epithelial islands. Transcriptionally reactive TILs shared this exhausted-proliferative phenotype and primarily localized within tumor islands. Conversely, Tregs and immunosuppressive macrophages were confined to stromal regions and showed minimal spatial overlap with tumor-reactive T cells. Malignant epithelium strongly enriched CXCL14 (> ten-fold over stroma), yet tumor-reactive TILs remained rare, with a tumor-to-reactive T cell ratio greater than 20 to 1.
Conclusions: This is the first study to integrate dissociative, spatial, and functional single-cell analytics to define tumor-reactive TIL biology in solid tumors. We find that tumor-reactive T cells can infiltrate malignant epithelial islands, and that their deepest infiltration corresponds to the most exhausted states, indicating that chronic antigen stimulation is the primary driver of dysfunction. The confinement of suppressive cells to stromal niches suggests that their influence is exerted through maintenance of a restrictive barrier stroma rather than through proximity-based inhibition. Together, these findings highlight insufficient chemotactic recruitment of tumor-reactive T cells as a central barrier to effective antitumor immunity. The strong epithelial enrichment of CXCL14 positions it as a promising candidate for enhancing tumor-directed T cell migration.

#4985 The role of CD5L in regulating liver immune cells.

Diala S. Alhousari[1], Handan Hong[2], Taojian Tu[2], Bangyan L. Stiles[3]

[1]USC School of Pharmacy, Los Angeles, CA,[2]USC - University of Southern California, Los Angeles, CA,[3]Assistant Professor, USC School of Pharmacy, Los Angeles, CA

CD5-like molecule (CD5L) is a soluble glycoprotein primarily produced and secreted by macrophages. As a member of the scavenger receptor cysteine-rich (SRCR) superfamily, CD5L regulates many biological processes such as apoptosis, pathogen recognition, immune responses, autophagy, cell polarization, and lipid metabolism, highlighting its crucial role in tissue homeostasis and its involvement in inflammation and cancer. In liver cancer, elevated serum CD5L levels have been observed in patients with steatohepatitis and hepatocellular carcinoma (HCC), supporting its potential as a diagnostic biomarker. Steatosis and steatohepatitis are key comorbidities that promote HCC development and are linked to poor therapeutic outcomes, particularly resistance to immune checkpoint inhibitors. Given that liver inflammation and lipid metabolism are involved in the progression of liver cancer, both of which are closely correlated with CD5L activity, this suggests that CD5L could play a pivotal role in shaping the tumor microenvironment of HCC. In this study, we found that CD5L is predominantly produced by liver macrophages and that its expression is significantly upregulated in multiple models of liver injury. Additionally, we observed that elevated serum CD5L levels were observed to correlated with the severity of liver damage. Clinically, we found that patients with hepatocellular carcinoma (HCC) displayed higher serum CD5L levels compared to controls, and increased CD5L levels were associated with poorer responses to immune checkpoint therapies. Functionally, we demonstrated that CD5L enhances lipid uptake in hepatocytes and hepatic stellate cells and promotes macrophage survival under palmitic acid-induced stress, findings consistent with its previously reported biological roles. Although CD5L's role in supporting macrophage survival is well established, its precise role in immune regulation remains less clearly defined. Our data indicate that CD5L produced by liver macrophages can modulate the chemotaxis of hepatic immune cells, particularly T cells and NKT cells. In macrophages and adipocytes, CD36, a scavenger receptor, mediates CD5L's effects on lipid metabolism. Notably, CD8+ T cells and regulatory T cells also express CD36, suggesting that CD5L may influence their function through CD36-dependent pathways. However, our findings show that while CD5L acts on T cells via CD36, it impacts NKT cells through a CD36-independent mechanism. Our study further investigates the impact of CD5L on liver immune cells' functional properties. Overall, CD5L is an upregulated secreted protein that plays an important role in regulating liver immune cells during liver diseases.

#4986 Identification of tumor microenvironment for high infiltration of lymphocytes in triple negative breast cancer.

Sowon Choi[1], Hee Jin Lee[2], Byung-Kwan Jeong[2], Hyun Je Kim[1]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Asan Medical Center, Seoul, Korea, Republic of

Elucidating the roles of intra-tumoral macrophage subtypes that promote a high-TIL microenvironment in triple-negative breast cancer. High levels of tumor-infiltrating lymphocytes (TILs) within the stromal compartment are associated with favorable prognosis and improved response to immune checkpoint blockade in triple-negative breast cancer (TNBC). To elucidate the mechanisms underlying the divergence between TIL-high and TIL-low tumor microenvironments (TMEs), we analyzed treatment-naïve, early-stage TNBC samples. We profiled the TME of 21 patients using single-cell-resolution spatial transcriptomics on FFPE tissue microarray blocks. Patients were classified into high TIL group with over 60% ratio of TIL in stroma. sTILs (0-100%) were evaluated on H&E-stained slides, and tumors with sTIL ≥ 60% and ≤ 10% were classified as high and low TIL, respectively. These thresholds are stricter than the commonly used sTIL ≥ 50% and < 30% cutoffs associated with distant RFS. Using this classification, 11 patients were assigned to the TIL-high group and 10 to the TIL-low group. We clustered 40 cell types for TNBC samples using Xenium 5K platform and identified 12 spatial domains by uncovering recurrent cellular neighborhoods (RCNs) that share similar spatial patterns using SCIMAP(v2.2.11). Among those 12 spatial domains, domain 9 and domain 0 represented tumor center and tumor edge, respectively. We identified 10 myeloid cell subtypes and discovered macrophage subtype MC2 expressing LDHA and PLAUR are enriched specifically in tumor domains consisting of domain 9 and 0. Interestingly, the MC2(LDHA_PLAUR) subtype present low PLAUR expression in TIL-high group compared to TIL-low group in tumor domains. Although the proportion of infiltrating MC2 (LDHA_PLAUR) macrophages within tumor domains was higher in the TIL-high group compared with the TIL-low group, the expression level of PLAUR within MC2 cells was paradoxically lower in the TIL-high group. Additionally, the MC2(LDHA_PLAUR) expressed more IFN-stimulated genes such as CXCL9, GBP5, and IRF1 in TIL-high group compared to TIL-low group. PLAUR has been known for inducing HIF1A highly in tumor microenvironment. As HIF1A hinders IFNG-signaling important to establish TIL-high environments, high expression of PLAUR promotes inhibition of IFNG-signaling in macrophages. So, low expression of PLAUR for MC2 in TIL-high group helps normal IFNG-signaling pathways in macrophages. Taken together, these findings indicate MC2 macrophages located in both the cancer center and edge regions showed reduced PLAUR expression, rendering them less susceptible to HIF1A-driven suppression and allowing sustained IFNG-signaling in high-TIL tumors. This suggests that these MC2 cells help establish an intra-tumoral environment conducive to TIL infiltration by continuously supplying CXCL9, CXCL10, and CXCL11.

#4987 Dual roles of JNK1 and JNK2 in TNBC progression and tumor microenvironment immune modulation reveal a novel therapeutic vulnerability.

Bharat Singh Kuntal[1], Xuemei Xie[1], Xanthe stern[1], Kendall Nakaoka[2], Marilisa Fujimoto[2], Marisa William[2], Madixx Muramoto[2], Naoto T. Ueno[3]

[1]Cancer Biology, University of Hawai'i Cancer Center, Honolulu, HI,[2]University of Hawai'i at Manoa, Honolulu, HI,[3]Translational and Clinical Research, University of Hawai'i Cancer Center, Honolulu, HI

Background: Triple-negative breast cancer (TNBC), one of the most lethal breast cancer subtypes, is driven by hyperactive oncogenic pathways that promote tumor growth and suppress antitumor immunity. Aberrantly high c-Jun N-terminal kinase (JNK) signaling is emerging as a key driver of tumor progression and immune evasion; however, the distinct roles of JNK1 and JNK2 in TNBC are largely undefined. This knowledge gap constrains efforts to exploit JNK biology for therapeutic advancement. Here, we investigated how each isoform drives tumor-intrinsic behavior and remodels the tumor microenvironment (TME). We hypothesized that both JNK1 and JNK2 drive TNBC growth and promote an immunosuppressive TME, and that loss of either isoform reprograms the TME toward a more immune-permissive, antitumor state. **Methods:** The impact of JNK signaling inhibition on PyMT-N TNBC cell growth was evaluated pharmacologically, using the pan-JNK inhibitor JNK-IN-8, and genetically, by knocking out JNK using the CRISPR-Cas9 system. Cell growth was evaluated using CellTiter-Blue viability and clonogenic assays. Immunocompetent syngeneic C57BL/6 mice bearing JNK1-, JNK2-, or dual-knockout (KO) tumors were used to assess tumor-intrinsic roles of each isoform; in parallel, *jnk1*$^{-/-}$ and *jnk2*$^{-/-}$ C57BL/6 mice bearing JNK-KO tumors were used to distinguish host-dependent effects. Immune cell tumor infiltration was quantified by flow cytometry. Cytokines were profiled by cytokine arrays and validated by ELISA and qPCR.**Results:** JNK-IN-8 (5 μm) suppressed PyMT-N cell growth by 85.1%, while KO of JNK1, JNK2, or both reduced colony formation by 55.3%, 67.7%, and 42.0%, respectively. Intratumoral JNK1 or JNK2 KO reduced tumor growth by 44.2% and 53.4%, respectively, and dual KO produced the most profound effect. These results highlight the strong tumor-intrinsic dependence of TNBC on both isoforms. Compared with Cas9 controls, JNK1-KO and JNK2-KO tumors exhibited increases in activated $CD8^+$ T cells (83.4% and 53.3%, respectively) and reductions in Tregs (37.9% and 24.9%, respectively), indicating a shift toward an immunoactive TME. Furthermore, JNK1-KO and JNK2-KO tumors showed reduced TSLP expression and increased IGF-1 expression, suggesting JNK's regulation of these cytokines. In host-dependent studies using *jnk1*$^{-/-}$ and *jnk2*$^{-/-}$ C57BL/6 mice, loss of either isoform reduced tumor growth, though to a lesser degree than intratumoral KO. Host JNK1 deficiency increased M1 macrophages and NK cells, while JNK2 deficiency increased $CD8^+$ T cells and NK cells; both showed reduced Tregs, indicating the induction of an immunoactive TME.**Conclusion**: Both intratumoral JNK1 and JNK2 are critical drivers of TNBC growth and TME immunosuppression, and their loss reprograms the TME toward robust antitumor immunity, positioning JNK signaling as a compelling therapeutic target in TNBC.

#4988 Comprehensive tumor microenvironment analysis identifies a suppressive immune landscape in stemness-high hepatocellular carcinoma.

Woo Young Kwon[1], Sungho Ko[2], Sungwoo Cho[2], Song-A Park[2], Sihun Cho[2], Sung Hwan Lee[1]

[1]Omics & Real-world Data-driven AI for Precision Medicine Lab, Seongnam, Korea, Republic of,[2]Humanase Co., Ltd., Seongnam, Korea, Republic of

Introduction: Hepatocellular carcinoma (HCC) remains a leading cause of cancer mortality, driven by late detection and limited therapeutic efficacy. A prior molecular classification defined five transcriptomic subtypes, among which the stemness-high (STM) subtype exhibits the poorest survival and pronounced stemness programs. Given the scarcity of effective treatments for this high-risk population, it is critical to characterize their tumor immune landscape and evaluate potential sensitivity to immune checkpoint inhibitors (ICIs). Here, we systematically profiled the immunologic features of STM tumors to assess their immunogenicity and likelihood of benefiting from ICIs.

Methods: Four resectable HCC transcriptomic cohorts (Korea, Samsung, Zhongshan, and Modena) were analyzed. STM subtype assignment was performed using the Bayesian Compound Covariate Predictor (BCCP) with previously defined STM signatures. Immune deconvolution was conducted using TIMER 3.0 (CIBERSORT, MCP-counter, EPIC), and immune cell states were assessed by EcoTyper. Immune dysfunction and exclusion were quantified using TIDE. Survival outcomes were evaluated by Kaplan-Meier analysis.

Results: Across all cohorts, STM tumors demonstrated significantly worse overall survival and recurrence-free survival. Clinically, STM tumors were enriched for adverse pathological features, including higher T stage, poor differentiation, and increased vascular invasion.Immune profiling revealed a profoundly suppressive tumor microenvironment, characterized by elevated M0 macrophages, regulatory T cells, myeloid-derived suppressor-like signatures, and abundant cancer-associated fibroblasts (CAFs). EcoTyper identified enrichment of pro-migratory fibroblasts, exhausted and Treg-like $CD4^+$ T cell states, and tumor-associated endothelial and epithelial programs.TIDE analysis demonstrated high exclusion and dysfunction scores, along with increased CD274 (PD-L1) and Merck18 expression, collectively indicating an immune-excluded, poorly immunogenic, and ICI-resistant profile.

Conclusions: The STM subtype of HCC is defined by a markedly immunosuppressive and immune-excluded tumor microenvironment with dysfunctional T cell states, CAF/MDSC infiltration, and angiogenic activity. These features are strongly associated with resistance to ICIs, suggesting that immune checkpoint blockade alone is unlikely to be effective. Alternative or combination therapeutic strategies will be required to improve outcomes in this high-risk molecular subtype.

#4989 SIPA1 deficiency reprograms mesenchymal stromal cells differentiaion and enhance the T cell immunity in the tumor microenvironment.

Yan Xu, Kentaro Sumida, Ryuhei Kawakami, Masakazu Hattori, Nagahiro Minato

Kyoto University, Kyoto, Japan

Background: Sipa1 (Signal-induced proliferation-associated gene 1) is a Rap1 GTPase-activating protein implicated in cellular adhesion and immune regulation. However, its functions within the tumor microenvironment (TME) remain unclear. Sipa1$^{-/-}$ mice resistant to Bcr-Abl^{+} leukemia by coordinated interplay between MSCs and immune T cells.

Methods: In this research, we clearly demonstrated that Sipa1$^{-/-}$ mice also showed increased resistance to different epithelial cancer cells such as MC38 intestinal and IPmN pancreatic cancers accompanied with increased stromal reaction and T cells infiltration. To clarify the stromal response in the anti-tumor mechanism, tumor resident mesenchymal stromal cells (MSCs) were sorted and subjected to Single cell RNA sequencing (scRNA-seq).

Results: Three major MSCs subsets which have distinct gene expression profiles were identified: αSMA+ myofibroblast CAFs(myCAF), inflammatory CAFs(iCAF), and antigen-presenting CAFs(apCAFs). In Sipa1$^{-/-}$ tumor, iCAFs were significantly enriched, whereas the proportion of myCAFs decreased relative to WT tumors. Sipa1 expression levels across MSCs subsets followed the hierarchy myCAF > apCAFs > iCAF, suggesting a role for Sipa1 in MSCs lineage determination. These findings indicate that Sipa1 is required for MSCs differentiation into myCAF, and that Sipa1 deficient MSCs transdifferentiate from myCAF to iCAF. Functionally, MSCs from Sipa1$^{-/-}$ tumors exhibited significant upregulation of CXCL9 and immunohistochemical analyses demonstrated enhanced IFNγ-STAT1signaling in Sipa1$^{-/-}$ MSCs. In vitro experiments using MC38 cells and other stromal cells revealed that Sipa1 interacted directly with STAT1/pSTAT1 and suppresses its activation, suggesting that Sipa1 negatively regulates the IFNγ-STAT1 axis.

Conclusion: All of the results demonstrate that Sipa1 is a critical regulator of MSCs-to-CAF differentiation and CAF functional programming in the TME. Sipa1 deficiency drives MSCs toward an iCAF-like, CXCL9 producing, immunostimulatory phenotype, which promoting enhanced T cell recruitment and anti-tumor immunity. These findings identify Sipa1 as a previously unrecognized stromal checkpoint controlling T cell responses against tumors and highlight Sipa1 as a potential therapeutic target to improve cancer immunotherapy.

#4990 Single-cell mass cytometry reveals T-cell exhaustion in sentinel nodes of ER+ breast cancer without histological detectable metastases.

Inga Hansine Rye[1], Marit Otterlei FJortoft[1], Karin Teien Lande[1], Margit Riis[1], Ole Christian lingjarde[2], Oystein Garred[3], Colin LaMont[4], June Myklebust[4], Kanutte Huse[4], Hege Russnes[1]

[1]Cancer Genetics, Oslo University Hospital, Institute for Cancer Research, Oslo, Norway,[2]University of Oslo, Institute for informatics, Oslo, Norway,[3]Pathology, Oslo University Hospital, Oslo, Norway,[4]Cancer Immunology, Oslo University Hospital, institute for Cancer Research, Oslo, Norway

Introduction: Tumor cell infiltration in regional lymph nodes is a strong prognostic marker and guides treatment decisions in breast cancer. While the immune landscape of primary tumors has been widely studied, the composition of immune cells in sentinel (SN) and axillary lymph nodes (ALN) remains less understood. Clarifying how tumor cells shape the nodal immune microenvironment may provide insights into metastasis, cancer progression, and potential therapeutic strategies.

Materials and methods: We analysed tumor draininglymph nodes from a prospective cohort of 458 treatment-naïve patients with primary operable breast cancer, representing all breast cancer subtypes. Lymph node status included negative nodes (n=357), sentinel node-positive (SN+, n=88), and axillary lymph node-positive (ALN+, n=13). Comprehensive immunophenotyping was performed by mass cytometry (CyTOF) using a 48-antibody panel. The panel included lineage markers, cell type-defining markers, and markers of activation and exhaustion.Data were processed using semi-automated FlowSOM clustering with manual clean-up to remove dead cells, doublets, and technical noise. This enabled identification of immune, tumor, apoptotic, and unclassified cell populations.After quality control, 468 lymph nodes comprising more than 45 million single cells were included in the final analysis.

Results: Patients with ALN+ disease had shorter time to distant metastasis than those with SN+ or SN- nodes. Compared with SN- samples, ALN+ samples showed enrichment of exhausted T cells as well as germinal center B (GC B) cells and plasma cells, both in the full cohort and within the estrogen receptor-positive (ER+) subgroup. No immune composition differences were observed across breast cancer subtypes in SN- samples. SN+ samples from triple-negative breast cancer (TNBC) demonstrated a trend toward increased GC B and plasma cells, resembling the immune profile of ALN+ nodes, suggesting that even small SN metastases can trigger early immune activation. In SN- samples from half of the ER+ patients, a subset displayed pronounced T-cell exhaustion. These nodes were enriched for cases that appeared negative by routine pathology but contained tumor cells detectable by CyTOF.

Conclusion: SN and ALN immune profiles in breast cancer are highly heterogeneous and show limited correlation with subtype, clinical variables, or outcome. Metastatic tumor cells promote T-cell exhaustion and immunosuppression, detectable in nearly half of ER+ cases. Importantly, T-cell exhaustion coincided with CyTOF-detected tumor cells that were missed by conventional pathology, indicating that even small tumor deposits can reshape the immune landscape. These findings highlight the potential of immune profiling to uncover occult tumor involvement in lymph nodes.

#4991 Stromal MAOB promotes prostate cancer growth by suppressing antitumor immunity.

Jing Wei, Hsiang Ching Huang, Kaisheng Yuan, Alivia O'Brien, Boyang Wu

Washington State University, Spokane, WA

Background: Stromal fibroblasts are a key component and regulator of the tumor microenvironment (TME), influencing tumor growth and shaping immune responses. Although stromal-epithelial interactions are known to drive prostate tumor development and progression, the specific stromal factors that modulate the tumor immune milieu in prostate cancer, a notoriously immune-cold malignancy, remain poorly understood. In this study, we investigate the role, mechanism, and therapeutic potential of monoamine oxidase B (MAOB), a mitochondrial enzyme that catalyzes the oxidative deamination of monoamines, in regulating prostate tumor immunity and growth.
Methods: The prostatic stromal fibroblasts from Maob knockout (KO) or wild-type (WT) male mice were isolated and co-inoculated with RM-1 mouse prostate cancer cells as subcutaneous implants in immunocompetent C57BL/6 or immunodeficient NSG male mice. Orthotopic RM-1 tumors were also established in the prostates of Maob-KO or WT mice. Tumor growth was monitored, and tumor-infiltrating immune cell profiles were analyzed using flow cytometry. Cytokine and chemokine secretion by Maob-KO and WT stromal fibroblasts was measured with antibody arrays.
Results: Stromal Maob deficiency markedly suppressed the growth of co-inoculated RM1 tumors in immunocompetent C57BL/6 mice, while it had only a marginal effect on RM1 tumor growth in immunodeficient NSG mice, indicating a tumor immune response triggered by stromal Maob. RM1 tumors grown in the prostates of Maob-KO mice also appeared notably smaller compared to those in WT mice. Both subcutaneous and orthotopic tumors with Maob-KO stroma exhibited increased infiltration of total and $CD8^+$ T cells, along with fewer myeloid-derived suppressor cells, M2 macrophages, and T regulatory cells. In orthotopic tumors, T-cell activity was further elevated in stromal Maob-ablated tumors, as evidenced by higher numbers of Ifnγ and Gzmb-expressing cells. Mechanistically, Maob-KO stromal fibroblasts secrete lower levels of Il-6, Ccl5, Ccl11, and Cxcl12 compared to WT counterparts, which are known to create an immunosuppressive TME.
Conclusion: Our findings identify MAOB as a potential stromal mediator of immune evasion in prostate cancer and a stromal-focused therapeutic target to enhance prostate cancer immunotherapies.

#4992 Activin A promotes PDAC progression via immunosuppression and non-canonical signaling.

Mark B. Wiley, Jessica Bauer, Yuchen Wang, Barbara Jung

UC San Diego School of Medicine, La Jolla, CA

The five-year survival rate for pancreatic cancer patients remains at 13%. More than 90% of these patients are diagnosed with pancreatic ductal adenocarcinoma (PDAC). Acute pancreatitis and chronic pancreatitis are risk factors for developing PDAC suggesting a strong inflammatory role for disease initiation. Recently, we found that activin a (activin), a TGFβ superfamily member, drives inflammation in acute pancreatitis via recruitment of macrophages and activation of neutrophils. In keeping with this, we recently showed that PDAC patients with high activin expression in the stroma have a worse prognosis and that inhibition of activin in mice decreased metastasis suggesting PDAC patients might benefit from activin inhibition. Here, we expand our studies in PDAC in the setting of inflammation and activin signaling. Digital Spatial Profiling (DSP) was performed on a tissue microarray of PDAC patients which permitted visualization and separation of images based on PanCK and activin localization. Tumor and stroma compartments were separated via PanCK expression and the quantification of 56 proteins was performed in activin (+) and (-) areas within each compartment. Western blots were employed to quantify the phosphorylation of p38 and SMAD2/3 in MIA PaCa-2, and AsPC-1 pancreatic cancer cell lines treated with/out activin. DSP data revealed activin (+) areas in the tumoral compartment had reduced total immune, total T cell, T helper, and memory T cell infiltrations when compared to activin (-) areas. This effect was coupled to increased markers of the MAPK and PI3K pathways in activin (+) areas. *In vitro*, activin stimulated phosphorylation of p-38, p-90, and SMAD2/3 in primary pancreatic cancer cells, but not in metastatic pancreatic cancer cells suggesting that activin may mediate stage-specific outcomes. Taken together, these data suggest that activin is a targetable molecule promoting a cancer supportive microenvironment in PDAC.

#4993 Tumor-associated macrophages promote oral squamous cell carcinoma development.

Manlin Shao[1], Carlos Caulin[2]

[1]Cancer Biology, Univ of Arizona College of Med - Tucson, Tucson, AZ,[2]Assistant Professor, H&N Surgery Research, University of Arizona, Tucson, AZ

Oral squamous cell carcinoma (OSCC), the most common oral malignancy, is characterized by poor prognosis, risk factors of tobacco and alcohol, and epithelial-specific mutations. Within the tumor microenvironment (TME) of OSCC, tumor-associated macrophages (TAMs) are key immune cells recruited to the tumor site and can be polarized into different phenotypes with either pro-inflammatory or anti-inflammatory functions. Therefore, there is a significant need to understand the role of TAMs in the OSCC microenvironment and the interaction between TAMs and cancer cells that may impact OSCC's aggressiveness and therapy resistance. Our lab has established cell lines from mouse oral tumors generated by activation of epithelial-specific mutations in mouse oral epithelium using both genetic and carcinogenic systems. Using these models, we employed an orthotopic and immunocompetent approach to study the specific functions of TAMs on the OSCC TME with surrounding lymphoid organs and highly dense vascularity. After orthotopic implantation, these cell lines developed oral tumors with high levels of TAM infiltration. To determine the role of TAMs in oral tumor development we depleted macrophages systemically with an anti-mouse Colony Stimulating Factor-1 Receptor (CSF1R). Results showed a significantly decreased tumor growth in mice injected with anti-CSF1R compared to untreated mice. Immunohistochemistry confirmed the loss of TAMs from the tumors treated with anti-CSF1R. Ongoing studies focus on investigating how macrophages remodel the tumor immune microenvironment of OSCC and modulate the malignant properties of oral cancer cells. We envision that these studies will help develop prevention and therapeutic approaches by targeting the pro-tumorigenic activities of TAMs in OSCC.

#4994 Exosome-targeted xmot-shRNA as a modular platform to dissect signaling pathways driving tolerogenic dendritic cells in the tumor microenvironment.

Mahere Rezazade Bazaz[1], Michael P. Plebanek[1], Y-Van Nguyen[1], Xueying Wang[2], Balamayooran Theivanthiran[1], Brent A. Hanks[1]

[1]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[2]Department of Pharmacology and Cancer Biology, Department of Pharmacology and Cancer Biology, Duke University, Durham, NC

Dendritic cells (DCs) orchestrate tumor-targeted immunity and are essential for immune checkpoint inhibitor (ICI) efficacy, but ICI responses often fail when tumors drive DCs into a pro-tolerogenic state exhibiting an impaired capacity to stimulate $CD8^+$ T cell activation and an enhanced ability to drive $CD4^+FoxP3^+$ regulatory T cell (Treg) differentiation. Despite the potent impact of DC tolerization on the generation of anti-tumor immunity, the pathways involved in their development *in vivo* are poorly understood. We have previously demonstrated that tolerogenic DCs in the tumor microenvironment maintain increased fatty acid oxidation (FAO) and this metabolic program fuels indoleamine-2,3-dioxygenase 1 (IDO1) activation and downstream Treg development. A pivotal check point in this pathway is the rate limiting enzyme, carnitine palmitoyltransferase 1a (CPT1a). Tumor-derived extracellular vesicles (EVs) are abundantly released in response to stress and can transfer regulatory RNAs to infiltrating immune cells. DCs are highly proficient at engulfing these EVs within tumors. A defined 3′ exosome-enriched motif (xmot) sequence can selectively load oligonucleotides into these vesicles, providing an opportunity to exploit tumor EV biogenesis for shRNA delivery. Here, we aimed to utilize the xmot-shRNA platform to selectively silence *Cpt1a* in DCs to suppress FAO and prevent Treg development.*Cpt1a*-targeted shRNA is fused to a 3′ exosome-enrichment trafficking motif and utilized to generate a xmot-shCpt1a-expressing $BRAF^{V600E}$-$PTEN^{-/-}$ melanoma cell line. The tumor EVs were confirmed to harbor *Cpt1a*-shRNA by qrt-PCR and found to suppress both DC *Cpt1a* expression and DC oxidative phosphorylation *in vitro*. In order to track selective DC targeting *in vivo*, the platform was equipped with an EV-enriched CD81-mEmerald marker protein. Using this approach, $mEmerald^+$ DCs infiltrating xmot-shCpt1a-expressing $BRAF^{V600E}$-$PTEN^{-/-}$ melanomas were isolated by fluorescence-activated cell sorting and found to exhibit suppressed *Cpt1a* expression levels. By comparing with control $BRAF^{V600E}$-$PTEN^{-/-}$ melanomas, this work demonstrated xmot-shCpt1a-expression to inhibit intra-tumoral $CD4^+FoxP3^+$ Treg accumulation, enhance tumor $CD8^+$ T cell infiltration and activation, and suppress $BRAF^{V600E}$-$PTEN^{-/-}$ melanoma progression. Collectively, this study serves as a proof-of-principle for the xmot-shRNA/CD81-mEmerald platform as a modular delivery system for dissecting signaling pathways contributing to the development of tolerized DCs within the tumor microenvironment. This approach is now being utilized to probe additional regulatory circuits contributing to DC tolerization *in vivo*.

#4995 LAMP3+ migratory dendritic cells establish immune-accessible tumor microenvironment in non-Hodgkin lymphoma.

Yulong Wei[1], David Alexander Braun[2], Ya-Chi Ho[1]

[1]Microbial Pathogenesis, Yale School of Medicine, New Haven, CT,[2]Medical Oncology and Hematology, Yale School of Medicine, New Haven, CT

Effective anti-tumor immunity requires functional tumor infiltrating lymphocytes (TILs) to migrate into the tumor nest, recognize tumor antigens, and exert effector function despite suppressive tumor microenvironment (TME). Compared to immune-accessible “hot” tumors, immune-inaccessible “cold” tumors lack immune cell infiltration and resist immunotherapy. Concomitant viral infections in the tumor further shape TME heterogeneity, promoting an immunoregulatory state that limits anti-tumor immunity. We aim to dissect spatial heterogeneity in the TME to identify immune determinants of T cell infiltration and effector function that underlie hot versus cold tumors in non-Hodgkin lymphoma (NHL). Using pre-treatment snap-frozen tumors with and without viral infections (EBV and HIV) from 12 NHL patients (6 HIV+ and 6 HIV–, including 3 ABC-DLBCL, 7 GCB-DLBCL, and 2 EBV+ Burkitt lymphoma) and lymph nodes from 17 donor without NHL (9 HIV+ and 8 HIV–), we performed single-cell multi-omics (paired ATAC-seq and RNA-seq in the same nucleus) and profiled 415,548 cells, including 127,455 cancer cells and 40,730 TILs. From matched tissues, we performed spatial transcriptomics (10x Xenium immuno-oncology panel with 100 custom probes, including HIV- and EBV-specific probes) in 69 tissue sections. Across HIV+ and HIV– NHL tumor sections, we found spatially discrete tumor regions with high type I Interferon stimulated gene (ISG) expression that did not correlate with local EBV or HIV expression, excluding viral-induced type I IFN responses as the primary drivers of ISG gradients. Joint single-cell multi-omics and spatial transcriptomics profiling revealed that LAMP3+ migratory dendritic cells (LAMP3+ mDCs) established discrete ISG-high niches characterized by CXCL9 and CXCL10 expression from fibroblastic reticular cells, increased infiltration of CXCR3+ cytotoxic CD8 T cells, and ISG-high cancer cells that upregulated MHC class I and II with reduced proliferation. In contrast, in tumor nests without LAMP3+ mDCs, TIL infiltration was minimal, and cancer cells did not express ISG, had decreased MHC I and MHC II expression, and maintained proliferation capacity. Ligand-receptor analysis with NicheNet (single-cell) and CellNEST (spatial transcriptomics) revealed that LAMP3+ mDCs supported both TIL cytotoxicity via IL-15 trans-presentation and TIL exhaustion through PD-L1-PD-1 engagement. In addition to TIL exhaustion, gene-regulatory networks revealed that HIV-induced suppressive TME was shaped by MAF, which drove CD4+ T cells towards a type I regulatory (Tr1) phenotype (*MAF*, *IKZF2*, *TIGIT*, *CTLA4*, *IL2RB*, and *IL12RB2*). Overall, we identified LAMP3+ mDC-defined niches that drives type I IFN gradients and coordinates immune effector recruitment and function. Our study nominates LAMP3+ mDCs as immunotherapy targets to promote TIL migration into cold tumors and enhance anti-tumor immunity.

#4996 Biomarker discovery and the targeting of tumor immune suppression in Renal Cell Carcinoma.

Giuliana P. Mognol[1], Erpei Wang[1], William Harris[2], Tami Von Schalscha[1], Birkley S. Lim[2], Rayan Jouny[2], Ahmed Abdelhak[3], Rana R. McKay[4], Judith Varner[1]

[1]Pathology, University of California, San Diego, San Diego, CA,[2]Moores Cancer Center, University of California, San Diego, San Diego, CA,[3]Neurology, University of California, San Francisco, San Francisco, CA,[4]Medicine, University of California, San Diego, San Diego, CA

Metastatic renal cell carcinoma (RCC) remains highly lethal despite advances in immunotherapy, highlighting the need for improved diagnostic biomarkers and therapeutic strategies that overcome immune suppression and identify patients most likely to benefit from specific treatments. RCC tumors contain high levels of pro-angiogenic, immune-suppressive macrophages that contribute to therapeutic resistance and correlate with poor survival. To address the hypothesis that circulating and tumor-derived biomarkers can inform personalized therapeutic strategies, we prospectively collected 26 fresh surgical RCC tumors with matched peripheral blood, along with peripheral blood from 20 healthy donors. We isolated serum and peripheral blood mononuclear cells (PBMCs) from normal and RCC patients for comprehensive profiling. Serum was analyzed by Olink and Illumina high-throughput proteomics to detect more than 5,000 and 9,000 serum proteins, respectively. PBMCs were analyzed by 25-color flow-based immunophenotyping and by single-cell RNA sequencing. Tumor specimens also analyzed by single-cell RNA sequencing and immunocytochemistry. To identify novel strategies to treat RCC, we established ex vivo tumor slice cultures of early stage RCC specimens and tested the impact of novel innate immune therapeutics on myeloid and T cell content and state, as well as on tumor and immune cell survival. Combined, these approaches enabled the identification of biomarkers of disease progression and immune response in RCC patients. By integrating serum proteomics, single-cell profiling and functional ex vivo tumor modeling as well as the impact of new therapeutic strategies, these results may inform biomarker-guided therapeutic strategies and may identify novel therapeutic strategies that can enhance durable responses and improve clinical outcomes for patients with RCC.

#4997 TME profiling in Colombian men with suspected prostate cancer.

Dayanne M. Rodriguez Hernandez[1], Jovanny Zabaleta[2], Luis D Valle[3], Rafael Parra-Medina[1], Carmen L. Roa[1], Alvaro Gutierrez[4], Mateo Barros Barraza[1], Alba Lucia Combita[1]

[1]Instituto Nacional de Cancerologia, Bogota, Colombia,[2]Interdisciplinary Oncology, LSU Health New Orleans, New Orleans, LA,[3]Pathology, LSU Health New Orleans, New Orleans, LA,[4]Urobosque, Bogota, Colombia

Prostate cancer (PCa) features a heterogeneous tumor microenvironment (TME) that shapes evolution and therapeutic response. Although immune and stromal composition have emerged as source of prognostic biomarkers, these components remain poorly characterized in Latin American populations. No previous study has integrated computational immune deconvolution with in situ validation in this context. We aimed to define TME remodeling across malignant, adjacent, and benign prostate tissue in a Colombian cohort.RNA-seq data from 75 patients with suspected PCa were TMM-normalized and analyzed using differential expression models adjusted for PSA, age, and Gleason grade. Immune composition and stromal enrichment were inferred using CIBERSORT and xCell. For validation, six TMAs were constructed from 20 prostatectomy patients: five TMAs included three PCa-positive cases each (Gleason grades 3+3, 3+4, 4+3, 4+4, 4+5) sampling tumor and adjacent tissue, and one TMA contained benign tissue from five PCa-negative cases. IHC quantified $CD8^+$ T-cell and $CD11b^+$ myeloid infiltration.Deconvolution revealed distinct immune shifts between malignant and benign tissue. PCa-positive samples showed significant enrichment of M1 macrophages ($p=0.02$), plasmacytoid dendritic cells ($p<0.001$), and Th1 cells ($p=0.0075$), alongside elevated stromal scores ($p=0.0014$), indicating a predominantly inflammatory TME. In contrast, PCa-negative samples displayed higher mast cells, hematopoietic stem cells, common myeloid progenitors (all $p<0.0001$), NK cells ($p=0.0009$), $CD8^+$ effector memory T cells ($p=0.0006$), and $CD4^+$ naïve T cells ($p=0.0047$), consistent with an immunologically quiescent state. IHC validation confirmed increased $CD8^+$ T-cell infiltration in tumor versus adjacent ($p<0.001$) and benign tissue ($p=0.016$), and higher $CD11b^+$ myeloid infiltration versus adjacent ($p=0.002$) and benign tissue ($p=0.040$). Critically, $CD11b^+$ infiltration correlated with Gleason grade, while $CD8^+$ infiltration remained elevated across all grades.This study provides the first multimodal TME profiling in a Colombian PCa cohort. Integration of RNA-seq deconvolution with TMA-based IHC reveals immune remodeling characterized by enrichment of cytotoxic T cells and myeloid populations in malignant tissue. The grade-dependent $CD11b^+$ infiltration suggests potential as a stratification biomarker for immunotherapy and supports therapeutic targeting of myeloid cells in underrepresented populations.

#4998 ImmunoPET imaging of human tumor associated macrophages.

Ayla Vaughn Embs[1], Borna Roohani[1], Robin Kumar[1], Dajah Nash[1], Chloe La Prairie[2], Mann Dangarwala[1], Harriet M. Kluger[3], Ping Zhang[2], Benjamin Larimer[1], Bernadette V. Marquez-Nostra[1]

[1]Radiology, University of Alabama at Birmingham, Birmingham, AL,[2]Pediatric Dentistry, University of Alabama at Birmingham, Birmingham, AL,[3]Yale University, New Haven, CT

Introduction: Macrophages are valuable imaging targets for inflammatory diseases, as they may reflect prognosis and response to therapy. Current noninvasive imaging agents that target different markers of macrophages are either nonspecific or preferentially identify the immunosuppressive macrophage subset. Here, we report the development of the first positron emission tomography (PET) tracer that targets human CD68 (huCD68), the clinically established pan-macrophage marker and its evaluation in the tumor microenvironment (TME).

Methods: Fab8, previously identified through phage display, was conjugated with p-SCN-Bn-DFO chelator and radiolabeled with ^{89}Zr to obtain [^{89}Zr]Zr-DFO-Fab8. Binding specificity of the tracer was evaluated in vitro using THP-1 macrophages, and THP-1 undifferentiated cells was used as a control. NSG mice (n = 3) were inoculated with MDA-MB-231 cells, a triple negative breast cancer cell line that does not express huCD68, subcutaneously to both shoulders. After tumor growth, the mice were then intratumorally injected with THP-1 macrophages on the right tumor to establish a new model of human macrophages in the TME. As a control, undifferentiated THP-1 cells were injected into the left tumors at 1 h before tracer injection. These mice were then injected with 100 µL of 930 kBq (6.3 µg mass dose) of [^{89}Zr]Zr-DFO-Fab8 and PET imaging was performed at 1 and 6 h post-injection (p.i.). The specific uptake of [^{89}Zr]Zr-DFO-Fab8 was determined by calculating tumor-to-heart Standardized Uptake Value Ratios (SUVR). The presence of CD68 in the tumors were biologically validated by immunofluorescence (IF) staining.

Results: [^{89}Zr]Zr-DFO-Fab8 was produced with radiochemical yield >95%. [^{89}Zr]Zr-DFO-Fab8 had significantly higher binding in THP-1 macrophages (10 ± 1.5 %) than in THP-1 undifferentiated cells (3.4 ± 0.11 % ; p = 0.016). The SUVR of [^{89}Zr]Zr-DFO-Fab8 in THP-1 macrophages was determined to be 0.34 ± 0.05 and 0.48 ± 0.07 and in undifferentiated THP-1 was 0.18 ± 0.03 and 0.29 ± 0.03, at 1 and 6 h p.i. respectively. Tracer uptake in the THP-1 macrophage tumors was significantly higher than that in the undifferentiated THP-1 tumors at 1 and 6 h p.i. (p = 0.0120 and p = 0.0041, respectively). IF results showed more huCD68 staining in the THP-1 macrophage tumors vs the THP-1 undifferentiated tumors, further validating our immunoPET results.

Conclusion: We have developed the first immunoPET tracer targeting human CD68. [^{89}Zr]Zr-DFO-Fab8 binds specifically to huCD68 in both an in vitro and in vivo model, making it a promising tracer for noninvasive imaging of macrophage burden in various diseases for future clinical studies.

#4999 GFRAL is not required for PDAC tumor development and TME immune cell suppression.

Emma Crockett Funk[1], Abasi-ama Udeme[1], Cynthia F. Wright[2], Jenna Schwesig[1], Michael C. Ostrowski[3], Teresa A. Zimmers[4], Leonidas G. Koniaris[5], David Wang[3], Denis C. Guttridge[3]

[1]Pediatrics, Medical University of South Carolina, Charleston, SC,[2]Associate Professor, Path. & Lab. Med., Medical University of South Carolina, Charleston, SC,[3]Medical University of South Carolina, Charleston, SC,[4]OHSU Knight Cancer Institute, Portland, OR,[5]Surgery, Oregon Health Sciences University, Portland, OR

Growth Differentiation Factor 15 (GDF15) is a stress-induced cytokine upregulated in several cancers, including pancreatic cancer. Its most well-known role is signaling through GFRAL in the brain to induce an anorexia/cachexia syndrome. Outside the brain, GDF15 acts as an immunosuppressor. In cancer, GDF15 is thought to leverage this function to protect tumors from immune surveillance. Recently, much attention has been drawn to the relationship between GDF15 and T cell activity, as blocking GDF15 has been shown to enhance responses to anti-PD-1 therapies. Interestingly, the only known receptor for GDF15 is GFRAL, whose expression is restricted to a subpopulation of neurons located in the brainstem. As GDF15 emerges as a target for enhancing immune cell activity, the role of GFRAL in this relationship remains underexplored in animal models of cancer. The purpose of this study is to evaluate the necessity of GFRAL in mediating the immunosuppressive activity of GDF15 with relevance to pancreatic ductal adenocarcinoma (PDAC), the most aggressive form of pancreatic cancer. To test this, T cells were isolated from the whole spleen of immunocompetent mice and activated in the presence of conditioned media (CM) from murine KPC PDAC cells (*Pdx^{Cre}; $Kras^{+/G12D}$; $Trp53^{fl/fl}$).* In culture, we find that CM containing GDF15 suppressed the proliferation of CD4 and CD8 T cells. qRT-PCR confirmed that T cells lack GFRAL expression, suggesting that GDF15-mediated suppression of T cell activity does not require its canonical receptor. Additionally, KPC CM equally inhibited the proliferation of T cells isolated from *$GFRAL^{+/+}$* and *$GFRAL^{-/-}$* mice. We previously showed that GDF15 is required for early-stage development of pancreatic cancer in mice. To determine if this function of GDF15 is mediated through GFRAL, KPC cells were orthotopically injected into the pancreas of immunocompetent *$GFRAL^{+/+}$* and *$GFRAL^{-/-}$* mice. No significant differences in tumor burden or overall survival were observed between *$GFRAL^{+/+}$* and *$GFRAL^{-/-}$* mice at the experimental endpoint. In addition, both *$GFRAL^{+/+}$* and *$GFRAL^{-/-}$* mice exhibited similar myeloid and lymphoid immune responses to tumor implantation compared to non-tumor controls. Moreover, expression of the T cell exhaustion marker PD-1 remained consistent between groups. These results suggest that GDF15 modulates the tumor microenvironment independently of its sole known receptor, GFRAL. Further, disruption of the GDF15-GFRAL signaling axis does not alter the immune cell landscape or enhance T cell expansion. These findings provide valuable insights into the immunomodulatory function of GDF15 in PDAC and the possible distinct roles that the GDF15-GFRAL signaling axis has in regulating anorexia/cachexia vs tumorigenesis.

#5000 Activin receptor subtype-2A regulates innate immune cell activation and non-canonical signaling in pancreatic cancer cells.

Yuchen Wang[1], Mark B. Wiley[2], Jessica Bauer[1], Xinru Wang[3], Jordi Guillem-Marti[4], David Lee[5], David Baker[5], Barbara Jung[1]

[1]Medicine, UC San Diego School of Medicine, La Jolla, CA,[2]UC San Diego School of Medicine, La Jolla, CA,[3]Biochemistry, University of Washington, Seattle, WA,[4]Universitat Politecnica de Catalunya, BarcelonaTech, Barcelona, Spain,[5]University of Washington, Seattle, WA

More than 50% of all pancreatic cancer patients present with distant metastasis at the time of diagnosis highlighting the need for early biomarkers of pancreatic cancer progression. Inflammatory disorders of the pancreas increases the risk for developing pancreatic cancer suggesting an inflammatory component to disease initiation. Our research team has previously shown that activin A (activin), a critical inflammatory cytokine, contributes to pancreatitis development through activation of innate immune cells. Furthermore, activin co-localizes with pancreatic intraepithelial neoplasm (PanIN) lesions in a mouse model of inflammation assisted pancreatic ductal adenocarcinoma (PDAC). Here, we will test the hypothesis that activin is an early, targetable biomarker of PDAC. Western blots were performed to quantify pSMAD2/3, pERK, and PI3K on pancreatic cancer cells stimulated with activin in the presence/absence of anti-activin neutralizing antibody or a highly specific activin receptor subtype-2A (ACVR2A) inhibitor. qPCR was performed to quantify chemokine receptor expression in RAW264.7 macrophages and neutrophil-like HL-60 cells exposed to the same conditions. Transwell migration assays were performed on RAW264.6 macrophages exposed to conditioned media from pancreatic stellate cells treated with activin in the presence/absence of anti-activin neutralizing antibody or the ACVR2A inhibitor. Preliminary data suggests ACVR2A regulates SMAD2/3 phosphorylation in pancreatic cancer cells. We also observed ACVR2A dependent increases in the migratory capacity of macrophages that was regulated via activin. Taken together, these data suggest activin mediates PDAC initiation and progression via activin-mediated ACVR2A signaling.

#5001 Dynamics of HER2-driven MHC I immune evasion utilizing PWK x NeuT mice.

Ryann Ray[1], Hui-En Chou[2], WEI-ZEN WEI[3], **Jennifer Jacob**[1]

[1]Michigan State University, East Lansing, MI,[2]Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI,[3]Oncology, Wayne State University Karmaos Cancer Institute, Detroit, MI

Loss of Major Histocompatibility Complex I (MHC I) is a critical immune evasion mechanism in breast cancer, often associated with aggressive disease and reduced response to immunotherapy. Given the known inverse correlation between HER2/neu expression and MHC I levels, we sought to develop a model to study the kinetics of this immune-editing process. We crossed the spontaneous HER2/neu-expressing BALB NeuT model onto a Diversity Outbred (DO) background and identified that the PWK background strain significantly accelerates tumor onset. PWKxNeuT mice developed tumors at an average of 11.5 weeks of age, substantially earlier than the parental BALB NeuT (17 weeks, $p = 0.0001$). Paradoxically, single cell RNA sequencing (scRNA-Seq) revealed that PWKxNeuT tumors harbored an increased immune infiltrate (8% CD3+ T cells) compared to BALB NeuT (2% CD3+ T cells). FFPE tumor tissue from NeuT and PWKxNeuT was analyzed using proteomics in collaboration with the iDEA Proteomics Core (Little Rock, Arkansas) using the label-free DIA approach. tumor tissue showed significant down-regulation of proteins essential for antigen processing and presentation, including tapasin, TAP1, and TAP2 ($p = 0.0003$), indicative of a systemic reduction in functional MHC I and II levels and resolving the paradox. Furthermore, we confirmed that the increased immune infiltrate in PWKxNeuT mice was functional. PWKxNeuT and BALB NeuT mice were vaccinated with DNA encoding HER2/neu together with pGM-CSF (im, ep) three times beginning at 8 weeks of age. Sera was collected to assess antibody production and peripheral blood was collected to determine T cell response by ELISPOT. Mice receiving control DNA developed tumors at an average of 11 weeks of age, compared with an average of 17 weeks for vaccinated mice, with some mice protected to 23.5 weeks of age ($p = 0.007$). Neu-specific T cells were identified in PWK background mice as were significantly increased neu antibodies compared with BALB NeuT mice. Thus, the PWKxNeuT model simultaneously displays accelerated HER2-driven tumorigenesis and a profound defect in the MHC presentation pathway, making it an ideal, genetically defined system to kinetically dissect how HER2 signaling drives the loss of MHC I during breast cancer progression. Current work is identifying changes in MHC levels and infiltrates over time in BALB NeuT and PWKxNeuT mice.

#5002 Notch4 blockade reprograms tumor-associated macrophages and enhances anti-tumor inflammatory signature in breast cancer.

Katherine A. Alexander[1], Jason Eng[2], Yu Kato[3], Bhairavi Swaminathan[2], Debdutta Mandal[2], Yajath Narra[2], L. A. Naiche[2], Yasuhiro Funahashi[4], Junji Matsui[5], Jan Kitajewski[6]

[1]Department of Pharmaceutical Sciences, University of Illinois at Chicago, Chicago, IL,[2]Department of Physiology and Biophysics, University of Illinois at Chicago, Chicago, IL,[3]Eisai Co., Ltd., Tsukuba-Shi, Japan,[4]Eisai Inc., Tokyo, Japan,[5]Eisai Co., Ltd., Woodcliff Lake, NJ,[6]University of Illinois Cancer Center, Chicago, IL

Macrophages play a crucial role in the tumor microenvironment (TME) and significantly influence pro- or anti-tumor immunity in breast cancer. Though macrophages often participate in pro-inflammatory tumor surveillance and elimination during early phases of tumor development, during later stages, they may become immunosuppressive, pro-angiogenic, pro-metastatic, and/or facilitative of a pro-tumor TME. The Notch pathway is essential for the differentiation of tumor-associated macrophages (TAMs) through the core canonical transcription factor, RBPJκ. However, individual Notch receptors (Notch1-4) have been shown to have varying effects on TAM polarization, with Notch1 and Notch2 displaying both pro- and anti-inflammatory activity. In peritoneal macrophages, Notch4 responds to inflammatory cues by limiting pro-inflammatory cytokine production and is upregulated during M2 induction. Notch4 promotes breast tumor initiation and maintains breast cancer stem cells. We have previously demonstrated that Notch4 inhibition with a novel, first-in-class neutralizing antibody, E7011, caused reduced tumor growth in mouse models of multiple tumor types, including mammary carcinoma. However, it is currently unclear whether the efficacy of anti-Notch4 treatment is mediated by Notch4 regulation of TAM function in breast cancer. We have demonstrated longitudinal increases in total macrophage populations following Notch4 blockade, accompanied by a decrease in myeloid-derived suppressor cells (MDSCs), which contribute to an immunosuppressive TME. Single-cell RNA sequencing of Py8119 mammary tumors treated with a murine analog of E7011 (6-3-A6) revealed a significant increase in the number of macrophages, and particularly Stab1+ TAMs, a subpopulation of TAMs that exhibits strong immunosuppressive activity and supports tumor growth by dysregulating antigen presentation and inducing resistance to checkpoint inhibitors. Analysis of the Stab1+ TAM transcriptome from tumors treated with 6-3-A6 showed decreased expression of markers associated with anti-inflammatory and “pro-tumor” macrophage activity, and an increase in pro-inflammatory mediators, notably the Dectin-2 pathway. This suggests that Notch4 blockade via 6-3-A6 functionally alters the traditionally pro-tumor Stab1+ TAM cluster towards a tumor-destructive, phagocytic macrophage phenotype. Taken together, these new insights into the functional reprogramming of pro-tumor Stab1+ TAMs towards a pro-inflammatory phenotype and decrease in immunosuppressive MDSCs following Notch4 blockade underscore a role for Notch4 in shaping a pro-tumor microenvironment. Ongoing genetic studies aim to elucidate the mechanism of Notch4-induced TAM immunosuppression and identify opportunities to enhance the efficacy of current immunotherapies by targeting Notch4 blockade in breast cancer.

#5003 Treg-specific inhibition of hedgehog signaling alters their function and impedes the growth of murine triple-negative breast cancer.

Ian Miranda, Courtney Swain, Brandon J. Metge, Lalita Shevde

Department of Pathology, Heersink School of Medicine, University of Alabama at Birmingham, Birmingham, AL

The central purpose of this study is to uncover and mechanistically describe the role of Hedgehog (Hh) signaling in CD4+ regulatory T cells (Tregs) in the context of murine triple negative breast cancer (TNBC). We employ a novel genetically engineered mouse model, murine TNBC models, flow cytometry, and targeted molecular assays to provide compelling evidence that inhibiting Hh activity in Tregs mitigates their suppressive function and subsequently slows tumor growth. TNBC is an aggressive form of breast cancer with limited treatment options. Any therapeutic benefits can be stifled by an immunosuppressive tumor microenvironment (TME) often found in TNBC due to an abundance of Tregs. Tregs are under transcriptional control of Foxp3, suppress other tumor-infiltrating lymphocytes and innate immune cells, and are associated with worse patient outcomes.Hh signaling normally plays a key role in embryonic development, tissue regeneration, and stem-cell renewal. Importantly, Hh signaling is aberrantly upregulated in a quarter of all cancers, and in TNBC, it has been implicated in drug resistance, tumor growth, migration, and invasion. Recent work from our lab has demonstrated that systemic pharmacological inhibition of Hh signaling led to a decrease in Treg abundance and function in the TME of TNBC.In this study, we report that inducible ablation of the Hh transcription factor, *Gli2*, in a Foxp3-dependent manner, impedes mammary tumor growth. The resultant TME is characterized by decreased abundance of Tregs and an increase in inflammatory Th17s. To uncover the mechanism behind these changes, we utilized RNA-seq and chromatin immunoprecipitation qPCR (ChIP-qPCR). Our data demonstrate that *Gli2* ablation alters the transcriptional controls in Tregs leading them to pivot towards inflammatory Th17 cells. These changes in Tregs functionally reduce the immunosuppressive nature of the TME of TNBC and permit an inflammatory TME, thereby reducing tumor growth. Cumulatively, these findings introduce a novel strategy for immunotherapy to target and impair Tregs in the TME of TNBC.

: Signaling Pathways, Metabolism, and Emerging Therapeutic Targets
Poster Session

#5007 ELAVL3 post-transcriptionally regulation of the NOTCH2 signaling pathway shapes the plasticity of small cell lung cancer.

Shuangsi Liao[1], Zichong Peng[1], Kai Kang[1], Shanghai Liu[1], Hui Wang[1], Yufeng Zhang[1], Ren Luo[1], Linglu Yi[1], Feifei Na[2], Guo Lin[1], Yue Zheng[1], Jianxin Xue[1], You Lu[1], Zhuoran Yao[1]

[1]West China Hospital of Sichuan University, Chengdu City, China,[2]Sichuan University, Chengdu, China

Background: Small cell lung cancer (SCLC) is a highly aggressive and heterogeneous malignancy, typically classified into four phenotypic subtypes by different transcription factors, referred to as ANYP. Recent studies have highlighted the plasticity between these subtypes, especially neuroendocrine (NE)/ non-NE states, which closely linked to treatment resistance. Emerging evidence suggests that stabilizing the SCLC phenotype could be advantageous for improving clinical outcomes. In this study, we identified a novel RNA-binding protein, ELAVL3, as a key player in the plasticity of SCLC. We discovered that ELAVL3 promotes a more NE-like progression of SCLC by post-transcriptionally disrupting the NOTCH2 signaling pathway. This finding offers new insights into the molecular mechanisms driving SCLC plasticity and proposes potential targets for therapeutic intervention.
Methods and Result: Through analysis of single-cell RNA sequencing data from 20 of our SCLC patients and some public databases, ELAVL3 expression is found to be positively correlated with NE signatures in both SCLC cell lines and patient tumors. Transcriptomic analysis and Western blotting results in SCLC cell lines showed that pharmacological inhibition of ELAVL3 with xxx activates NOTCH signaling pathways and induces the loss of NE features, while *ELAVL3* overexpression reduces NOTCH2 mRNA levels and helps to maintain the NE characteristics. Some molecular experiments, including RNA immunoprecipitation (RIP)-qPCR, RIP-sequencing and RNA pulldown, further discovered that ELAVL3 extensively binds to and interferes with the RNA stability of NOTCH2 signaling pathway members, thereby enhancing the NE program.Our previous studies have found that immunotherapy (IO) combined with radiotherapy (RT) can be effective for chemotherapy resistant subcutaneous SCLC, which is non-NE type, for a certain period of time. By single-cell RNA sequencing of tumor at multiple time points after IO+RT, we identified a close association among highly expressed *ELAVL3*, inactivated NOTCH signaling, restored NE characteristics and acquired therapy resistance. After testing various combination therapies in SCLC cell lines, patient-derived organoids, patient-derived tumor xenograft model, and murine SCLC model, we revealed that the inhibition of ELAVL3 hold their differentiation into non-NE types, which better corresponded to the immuno-combination therapies for SCLC after chemotherapy resistance.
Conclusions: This study nominates ELAVL3 as a key regulator of the NE state plasticity and defines a novel therapeutic strategy for SCLC.

#5008 Combination therapy with AKT and MEK inhibitors is effective in patient-derived models of adrenocortical carcinoma.

Suresh Kumar[1], Yoo Sun Kim[1], Nai-Yun Sun[1], George Karadimov[1], Yasuhiro Arakawa[1], Briana N. Cortez[1], Diana Varghese[1], Arnulfo Mendoza[1], Katja Kiseljak-Vassiliades[2], Margaret E. Wierman[2], Jonathan M. Hernandez[1], Chuong D. Hoang[1], Noemi Kedei[1], Xiaoling Luo[1], Stephen Hewitt[1], Yves Pommier[1], Craig Thomas[1], Jaydira Del Rivero[1], **Nitin Roper**[1]

[1]Center for Cancer Research, Bethesda, MD,[2]Colorado University, Aurora, CO

Adrenocortical carcinoma (ACC) is a rare malignancy with frequent metastases and poor survival due to chemoresistance and the lack of targetable oncogenic drivers. ~80% of ACC tumors overexpress IGF2, yet targeting the IGF2-IGFR1 axis in ACC has not been successful in the clinic. Here, we hypothesized that targeting additional survival pathways in combination with IGFR1 inhibition would be more effective in ACC than IGFR1 inhibition alone. Using a high-throughput screening platform (n=2803 compounds), we identified inhibitors of the MAPK pathway, to be highly synergistic with IGFR1 inhibition. MEK inhibitors were chosen for further evaluation given the safety, tolerability, and broad clinical activity. IGFR1 and MEK inhibitors were strongly synergistic in cytotoxicity across ACC cell lines (n=2) and short-term ACC organoids (PDOs) (n=8) derived from surgical tissue resections. Genetic depletion of IGF2 significantly inhibited growth with MEK inhibition and genetic depletion of MEK1 inhibited growth with IGFR1 inhibition in ACC cell lines. We then sought to identify signaling pathways downstream of IGFR1 that may be more amenable to clinical translation as IGF1R inhibitors are not FDA approved in cancer. Surprisingly, we found that linsitinib completely downregulated phospho-AKT suggesting AKT is a key downstream pathway of IGF2-IGFR1 in ACC. Accordingly, we observed strong synergy in cytotoxicity with combined AKT and MEK inhibition among ACC cell lines and short-term ACC PDOs. In vivo, the 2-drug AKT and MEK inhibitor combination demonstrated greater anti-tumor activity than either agent alone in an ACC cell-line xenograft and two chemoresistant ACC patient-derived xenograft models. Our results demonstrate a novel, active drug combination in refractory ACC that warrants clinical investigation.

#5009 A tumor-derived PTHrP-calcium axis drives cardiac dysfunction to connect cancer cachexia with mortality.

Tuba Mansoor Thakir, Sam Oscar Kleeman, Miriam Ferrer Gonzalez, Tobias Janowitz

Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

Cancer cachexia (CC) contributes significantly to cancer-associated mortality, yet the mechanisms leading to death in CC remain poorly defined. We investigated whether cardiac dysfunction is a driver of CC-associated mortality. Using continuous ECG telemetry and echocardiography during disease progression in the C26 model of CC, we comprehensively assessed the effect of cachexia on electrical and mechanical components of cardiac function. The development of cachexia was associated with significantly reduced mean stroke volume (baseline 30 µL vs. cachectic 13 µL, $p = 0.001$) and cardiac output (baseline 18 mL/min vs. cachectic 8 mL/min, $p = 0.02$), with significantly increased cardiac muscle atrophy at endpoint (baseline 145 mg vs. cachectic 110 mg, $p < 0.0001$). Mortality was preceded by progressive conduction abnormalities, including first- and second-degree atrioventricular block, bradyarrhythmias, and atrial fibrillation. The onset of cachexia was associated with significantly reduced mean QTc duration (baseline 55 ms vs. cachectic 40 ms, $p = 0.002$), which correlated with marked hypercalcemia (baseline 8 mg/dL vs. cachectic 15 mg/dL, $p < 0.0001$) and hypophosphatemia (baseline 6.5 mg/dL vs. cachectic 4.5 mg/dL, $p = 0.0044$). As an explanation for perturbed calcium homeostasis, we identified RNA and protein expression of parathyroid hormone-related protein (PTHrP) in C26 cancer cells. To investigate whether hypercalcemia was a driver of cachexia-associated cardiac dysfunction, we pharmacologically suppressed calcium levels with continuously infused zoledronic acid (ZA). ZA infusion significantly lowered mean plasma calcium ($p = 0.05$), delayed the onset of cachexia ($p = 0.03$), and partially preserved stroke volume and cardiac output. We hypothesized that if hypercalcemia is PTHrP-dependent, then isogenic PTHrP knockout in the C26 cell line would obviate cachexia. Mice bearing PTHrP-KO tumors remained non-cachectic with preserved electrical function (mean QTc: scramble 40 ms vs. KO 55 ms, $p = 0.01$) and preserved mechanical function (mean cardiac output: scramble 8 mL/min vs. KO 16 mL/min, $p = 0.03$) despite comparable tumor size to scramble controls. Taken together, these preclinical data demonstrate that tumor-derived PTHrP plays a major role in driving cachexia and associated cardiac dysfunction in the C26 model, and that cardiac dysfunction may be a final common pathway of mortality in CC. Our findings raise the possibility that PTHrP-driven cachexia may be a biologically distinct and therapeutically relevant subgroup of cancer cachexia.

#5010 Loss of SHP phosphorylation reprograms lipid metabolism to promote colorectal tumorigenesis.

Ting Fu

University of Wisconsin-Madison, Madison, WI

Background: Small Heterodimer Partner (SHP/NR0B2) is a central metabolic regulator that integrates bile acid and lipid signaling with intestinal homeostasis. SHP activity is enhanced by phosphorylation at a conserved threonine residue (Thr-58 in mouse; Thr-55 in human), mediated by PKCζ downstream of FGF19 and bile acid receptor activation. While this modification is known to regulate bile acid and lipid metabolism, its role in colorectal cancer (CRC) is unknown.

Methods & Results: To determine how impaired SHP phosphorylation influences colorectal tumorigenesis, we analyzed knock-in mice expressing a phosphorylation-defective SHP mutant (SHP-T58A) in multiple CRC models. To determine how loss of SHP phosphorylation influences cell proliferation, we compared organoids generated from SHP-WT and SHP-T58A mice on both wild-type and *Apc*Min/+ backgrounds. Across both genotypes, SHP-T58A organoids displayed markedly increased budding, growth rate, and stem-cell-associated gene expression, indicating enhanced intestinal stem cell proliferation. Consistent with this, SHP-T58A mice subjected to AOM/DSS exhibited significantly greater colonic tumor multiplicity and tumor area, accompanied by increased SREBP1 activation, elevated FASN and SCD1 expression, and enhanced lipogenic lipid accumulation within tumors. Even in the acute DSS injury model, SHP-T58A colons showed exaggerated epithelial proliferation and dysregulated metabolic gene expression, suggesting that defective SHP phosphorylation alters epithelial regenerative responses and primes the tissue toward tumor-promoting metabolic states. In human HCT116 cells, CRISPR sgSHP knockout lines reconstituted with SHP-WT or SHP-T58A demonstrated that SHP-T58A drives higher proliferation, colony formation, and migration. Gene expression analyses showed activation of oncogenic and stemness-related programs (LGR5, SOX9, CD44, MYC,MET) together with induction of lipogenic genes (SREBF1, FASN, SCD1). In HCT116 mediated xenografted mice, SHP-T58A group formed significantly larger tumors in NSG mice than their SHP-WT counterparts, accompanied by increased SREBP1 signaling and lipid accumulation. Importantly, in parallel human genomic analyses, we identified SHP mutations located near the Thr-55 regulatory region in individuals with early-onset obesity and early-onset colorectal cancer, suggesting that disruption of this phosphorylation-dependent regulatory module may have broader clinical relevance.

Conclusion: Loss of SHP phosphorylation is a key metabolic switch that enhances stemness, activates lipogenesis, and promotes colorectal tumorigenesis in both mouse and human models. SHP phosphorylation status may represent a previously unrecognized metabolic vulnerability in CRC.

#5011 Targeting DUSP1 overcomes resistance to ^{177}Lu-DOTATATE in neuroendocrine tumors.

Majid Momeny, Solmaz AghaAmiri, Servando Hernandez Vargas, Sukhen C. Ghosh, Tyler M. Bateman, Jack T. Adams, Nafiseh Ghazanfari, Vahid Khalaj, Ali Azhdarinia

UT Health Houston, Houston, TX

Background: Neuroendocrine tumors (NETs) often present as metastatic or unresectable disease, and while ^{177}Lu-DOTATATE PRRT benefits SSTR2-positive patients, its modest response rate highlights the need for improved combinations. DUSP1, a MAPK phosphatase regulating JNK/p38, is elevated in multiple cancers, yet its role in NETs is unknown. Given the contribution of MAPK signaling to therapy resistance, we hypothesized that DUSP1 inhibition enhances NET sensitivity to ^{177}Lu-DOTATATE.

Materials and Methods: We compared DUSP1 mRNA levels in primary versus metastatic NETs using public transcriptomic datasets and assessed DUSP1 protein across NET cell lines and two PDX models by Western blot. Functional studies with the DUSP1 inhibitor BCI measured viability, clonogenic survival, apoptosis, mitochondrial depolarization, ROS and MAPK activation, with RNA-seq defining transcriptional changes. Rescue experiments used CC90001, ISRIB, NAC, DUSP1 overexpression, and the JNK1-K55R mutant. Synergy with PRRT was evaluated by combining BCI with sub-lethal ^{177}Lu-DOTATATE.

Results: Transcriptomic profiling showed elevated DUSP1 in lymph-node metastases versus primary NETs, and DUSP1 protein was highly expressed across NET cell lines and PDX models. BCI (1-2.5 μM) markedly reduced viability and clonogenic survival (~80% at 1 μM) and induced apoptosis (cleaved PARP ~6-fold, caspase-3/7 ~4-fold, ΔΨm loss ~2-fold). RNA-seq and Western blotting confirmed strong activation of pro-apoptotic JNK1/2 and p38. JNK inhibition, the JNK1-K55R mutant, and DUSP1 overexpression each rescued cells, whereas DUSP1 knockdown induced apoptosis—establishing DUSP1 as a key NET survival factor. RNA-seq also revealed ER-stress activation (XBP1s, ATF4, CHOP). ISRIB blocked ER stress and rescued cells, while NAC suppressed ROS, prevented MAPK/ER-stress activation, and fully rescued cells, indicating that DUSP1 inhibition triggers a ROS-dependent cascade converging on JNK and ER-stress pathways. Combining BCI with ^{177}Lu-DOTATATE produced strong synergy (CI < 0.5) with enhanced apoptosis. JNK inhibition and ISRIB each rescued combination-induced apoptosis (~60% and ~40%), showing that both pathways are required for PRRT sensitization.

Conclusion: DUSP1 is an actionable therapeutic vulnerability in NETs. Its inhibition induces ROS-driven activation of pro-apoptotic MAPK and ER-stress pathways, potentiating ^{177}Lu-DOTATATE. These findings provide preclinical support for DUSP1-targeted combination strategies, with ongoing *in vivo* studies needed to advance this approach toward clinical translation.

#5012 Multiomic profiling reveals ligand and cell specific regulatory programs of LXR selective modulation in myeloid immune cells.

Yifan Fei[1], Rajendra K C[2], Mark Flory[3], Natalia Julianna Krawczynska[4], Yu Wang[5], Kevin T. VanBortle[4], Hisham Mohammed[3], Erik R. Nelson[5]

[1]Molecular and intergrative physiology, Urbana, IL,[2]University of Illinois Urbana-Champaign, Champaign, IL,[3]Oregon Health & Science University, Portland, OR,[4]University of Illinois Urbana-Champaign, champaign, IL,[5]University of Illinois at Urbana-Champaign, Urbana, IL

Selective modulation of steroid nuclear receptors such as estrogen (ER), glucocorticoid (GR), and androgen receptors (AR) has advanced cancer therapy by enabling precise control of receptor signaling. However, selective modulation of other nuclear receptors remains underexplored. Liver X receptors (LXRs) are key regulators of cholesterol homeostasis, inflammation, and immune responses. LXR ligands have shown antiproliferative and immunomodulatory effects across multiple cancers, including prostate, breast, and colorectal cancers, as well as hematologic tumors. Certain LXR ligands also attenuate immunosuppressive cell populations in the tumor microenvironment, making LXR a promising therapeutic target.
However, many synthetic LXR agonists have shown adverse metabolic and neurologic effects and their impact on tumor progression is often inconsistent, suggesting potential ligand- and cell-specific modulation. Understanding the mechanisms underlying such selective LXR modulation, inspired by established selective modulation strategies for ER and AR related cancers, may enable the development of safer and more effective LXR-directed cancer therapies.To elucidate the mechanism of selective LXR modulation in myeloid cells, we performed multi-omics profiling (RNA-seq, ATAC-seq, and RIME proteomics) on murine bone marrow derived macrophages and dendritic cells treated with seven LXR ligands. We observed both shared and ligand- or cell-specific transcriptional and chromatin accessibility patterns. Notably, 27-hydroxycholesterol (27HC) suppressed interferon/STAT1 programs in macrophages and induced a MYC/E2F associated immunosuppressive state, whereas dendritic cells exhibited suppression of interferon stimulated genes and MYC/E2F program.T cell proliferation can be suppressed by 27HC treated macrophages. Preliminary functional assays suggested that this effect could be reversed by inhibiting E2F pathway (CDK4/6 blockade) or by targeting NF-κB, STAT3, or HDAC2 signaling in macrophages. These findings delineate cell-specific mechanisms of LXR selective modulation and suggest that targeting LXR may fine-tune E2F, NF-κB, STAT3, and HDAC2 dependent signaling that impacting macrophage-T cell crosstalk and thereby enhance T cell antitumor function.

#5013 Comprehensive characterization of DICER1 mutations and two hit tumorigenesis mechanisms in follicular thyroid carcinoma using multi-omics analysis.

Dakyung Lee[1], Young Ah Lee[1], Yeonju Kyoung[2], Seong-Keun Yoo[3], Sun-Wha Im[1], Jaeyong Choi[1], Yoo Hyung Kim[1], Dohyun Han[4], Young Joo Park[1], Jong-Il Kim[1]

[1]Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Seoul National University, Seoul, Korea, Republic of,[3]Samsung Medical Center, Seoul, Korea, Republic of,[4]Seoul National University Hospital, Seoul, Korea, Republic of

Background: DICER1 is an essential RNase III enzyme for microRNA (miRNA) processing. Germline loss-of-function (LoF) variants cause DICER1 syndrome and predispose younger individuals to tumors including follicular thyroid carcinoma (FTC). Somatic RNase IIIb hotspot mutations are characteristic, but how germline LoF, somatic hits, and tissue-specific regulatory networks drive FTC is not fully understood.
Methods: We analyzed DICER1-mutant FTC (n=20) using whole-exome sequencing, miRNA-seq, RNA-seq, and proteomics, and compared them with wild-type tumors (wt-T, n=61). Tumors were classified as syndrome-associated (syn-T, n=7) or sporadic (spo-T, n=13). Integrative analyses included allelic imbalance, pathway enrichment, and network modeling (WGCNA).
Results: Clinically, spo-T patients were significantly younger than wt-T, indicating an age-specific window for DICER1-driven FTC. Most tumors showed biallelic disruption through RNase IIIb hotspot mutations with secondary LoF events, and allelic imbalance confirmed two-hit inactivation even when only one mutation was detected.In syndrome-normal tissues, substantial mRNA dysregulation occurred without miRNA changes, suggesting DICER1 haploinsufficiency acts independently of global miRNA loss.In DICER1-mutant tumors, cell-cycle, mTOR, and Wnt pathways were strongly upregulated, whereas immune programs were broadly suppressed. The thyroid stem-cell marker REXO1 was specifically elevated, indicating a stem-like phenotype. Network analysis highlighted CTNNB1 and let-7i as key regulators of the DICER1 transcriptional program. Although DICER1- and RAS-mutant FTCs shared some downstream signaling modules, DICER1-mutant tumors retained a distinct expression identity. WGCNA identified a DICER1-specific cell-cycle module and a partially shared DICER1-RAS Wnt/MAPK module.
Conclusion: DICER1 functions as a distinct oncogenic driver in FTC, following a biallelic inactivation model and producing unique proliferative, immune-suppressed, and stem-like transcriptional states. These findings refine the mechanism of DICER1-associated thyroid tumorigenesis and suggest potential lineage-specific therapeutic targets.

#5014 *CDC73* loss does not augment cyclin D1-driven parathyroid tumorigenesis in transgenic mice.

Jen-Yuan C. Kao[1], Callie Burke[2], Justin Bellizzi[2], Andrew Arnold[1], Jessica Costa-Guda[2]

[1]Univ. of Connecticut School of Medicine, Farmington, CT,[2]UConn Health, Farmington, CT

Loss-of-function mutations in the *CDC73* tumor suppressor gene, encoding parafibromin, are the most common genetic alteration in parathyroid carcinoma. Germline *CDC73* mutation causes Hyperparathyroidism-Jaw Tumor Syndrome (HPT-JT), a rare tumor predisposition syndrome including parathyroid carcinoma, and both germline and somatic *CDC73* mutations are seen in patients with sporadically presenting parathyroid cancer. Oncogenic amplification of *CCND1*, which encodes cyclin D1, is another frequent finding in parathyroid carcinoma. Parathyroid-targeted overexpression, via a PTH-cyclin D1 (PCD) transgene, leads to parathyroid tumorigenesis, but not parathyroid malignancy, in transgenic mice. The absence of appropriate preclinical models has hindered the development of preventative strategies for patients with germline *CDC73* mutation and of non-surgical treatments for parathyroid cancer in general. Thus, we sought to develop a model system that could mimic the clinical course of *CDC73*/parafibromin-deficient parathyroid carcinoma, including robust parathyroid hormone (PTH)-dependent hypercalcemia and invasion/metastasis. To this end, we crossed parathyroid-targeted *CDC73* null mice with PCD transgenic mice, producing offspring with both *CDC73* deficiency and cyclin D1 overexpression in parathyroid cells. Double mutant mice were compared to PCD mice and wildtype littermate controls. Mice were monitored for the progression of parathyroid tumorigenesis by monthly blood collection and evaluation of serum calcium and PTH. Mice were euthanized at 18 months of age. The parathyroid glands and surrounding tissue were dissected *en bloc* and evaluated histologically for general morphology, local invasion, and parathyroid cell proliferation via Ki-67 immunostaining. While PCD-positive mice developed hypercalcemia, a hallmark of parathyroid tumorigenesis, as expected, no significant differences in calcium levels were observed between mice with both *CDC73* deficiency and cyclin D1 overexpression as compared to mice with cyclin D1 overexpression alone. Similarly, general parathyroid gland morphology and parathyroid cell proliferation were comparable between the two groups; local tumor invasion was not observed in either group. While the combined disruption of *Cdc73* and the overexpression of cyclin D1 did not result in the development of parathyroid carcinoma in our mouse model, this model system may provide valuable insight into genetic modifiers of parathyroid tumorigenesis. Background strain is known to affect the phenotype of many genetically modified mouse models, including parathyroid-targeted *Cdc73* deletion; however, the responsible genetic modifiers remain unknown. Our model system could serve as a key reagent in identifying genetic modifiers with relevance to parathyroid tumor development.

#5015 Targeting insulin to improve endometrial cancer.

Alexander Emmanuelli[1], Ezequiel Dantas[2], Marcus DaSilva Goncalves[2]

[1]Medicine, NYU Langone Medical Center, New York, NY,[2]NYU Langone Health, New York, NY

Insulin and insulin-like growth factor stimulate the growth of the endometrial mucosa by binding cell surface receptors that activate the phosphatidylinositol-3 kinase (PI3K) signaling pathway. PI3K hyperactivity is sufficient to initiate carcinoma in the uterine epithelia, where this signaling pathway promotes proliferation by activating several intracellular targets, including AKT and mTOR. Enhancement of the PI3K signaling pathway dominates the genetics of human endometrial cancer. Mutations in *PIK3CA*, encoding the p110a subunit of PI3K, and loss of function mutations in *PTEN*, a molecular off switch for the PI3K activity, are among the most frequently mutated genes in endometrial cancer. Although this high mutational burden suggests druggable targets, pharmacological inhibition of the PI3K pathway has had limited clinical outcomes. Our group has previously demonstrated that hyperinsulinemia, a clinical biomarker of endometrial cancer, limits the efficacy of PI3K inhibitors in mice and that systemic insulin can be reduced by feeding mice a very low carbohydrate (ketogenic) diet (VLCD). The combination of VLCD and PI3K inhibition can abolish tumor growth in mouse models of cancer, but the relationship between PI3K inhibition and the dysregulation of systemic glucose homeostasis has yet to be resolved in endometrial cancer. To evaluate the effects of systemic insulin on endometrial cancer growth and the efficacy of PI3K inhibition we established clinically relevant endometrial cancer xenografts via patient-derived organoids. In this study, we demonstrate that hyperinsulinemia is a modifiable factor that limits the efficacy of PI3K inhibition in endometrial cancer. By employing diazoxide and canagliflozin, pharmacological agents that counteract hyperinsulinemia, we can decrease insulin levels in the tumor while enhancing the apoptotic response to the PI3K inhibitors copanlisib and alpelisib. Additionally, we show that ketogenic diet reduces systemic insulin and improves efficacy of PI3K inhibition in xenograft models of endometrial cancer. These findings have significant implications for ongoing clinical trials of PI3K pathway inhibitors and suggest a method for increased treatment efficacy in cancer patients.

#5016 Oncogenic PIK3CA mutation enhances cyclin D1-driven parathyroid tumorigenesis in transgenic mice.

Maia Jakubowski, Callie Burke, Justin Bellizzi, Andrew Arnold, Jessica Costa-Guda

UConn Health, Farmington, CT

Parathyroid carcinoma is a rare but life-threatening malignancy. Limited treatment options are available for the more than 50% of parathyroid carcinoma patients who develop recurrent disease following surgery with curative intent. Many such patients will become refractory to medical management, eventually succumbing to the sustained, progressive hypercalcemia caused by parathyroid hormone-secreting tumors. Identification of genetic/molecular aberrations that might serve as “actionable targets” for pharmacologic intervention in parathyroid carcinoma have uncovered frequent inactivation of the CDC73 tumor suppressor gene, amplification of the cyclin D1 oncogene and activating mutations of the PI3K/MTOR pathway. We sought to combine these frequent tumor driving mutations to develop a novel preclinical model that could mimic the clinical course of recurrent/metastatic parathyroid carcinoma, for study of disease progression and to eventually develop/test novel preventative/therapeutic interventions. To this end, we crossed existing mouse models with genetic alterations known to occur in human parathyroid carcinomas, namely PTH-cyclinD1 transgenic mice (PCD), oncogenic Pik3ca mutant mice (Pik3caH1047R) and parathyroid-specific Cdc73 knockout mice. PCD mice develop biochemical hyperparathyroidism and parathyroid tumors with known kinetics. Mice harboring double and triple genetic modifications were evaluated independently and compared to PCD and wild type littermate controls. Assessment of progression of biochemical hyperparathyroidism was evaluated by monthly blood collection followed by measurement of serum calcium and parathyroid hormone (PTH). We observed that activation of Pik3ca in the absence of cyclin D1 overexpression was insufficient to drive parathyroid tumorigenesis and that loss of Cdc73 did not appear to enhance parathyroid tumorigenesis beyond the contribution of cyclin D1 overexpression. However, crossed mice harboring activating mutations of both cyclin D1 and Pik3ca developed more severe biochemical primary hyperparathyroidism than those with activated cyclin D1 alone. Some PCDxPik3caH1047R mice developed atypical histologic features consistent with aggressive parathyroid tumors. Thus, the combination of activated Pik3ca and cyclin D1 overexpression appears to yield a more aggressive parathyroid tumor phenotype. Our findings carry important potential therapeutic implications: the combination of cdk4/6 inhibitors with PI3K/MTOR inhibitors is under active investigation in other tumor types and the efficacy of such combination therapy merits investigation in parathyroid carcinomas which may harbor both cyclin D1 amplifications and activating mutations in PI3K/MTOR.

#5017 Targeting human melanoma growth with non-calcemic vitamin d3 hydroxyderivative: A synergistic approach with vemurafenib.

Senthilkumar Ravichandran[1], Ewa Podgorska[1], Zorica Janjetovic[1], Tae-Kang Kim[1], Gitali Ganguli Indra[2], Arup K. Indra[2], Andrzej T. Slominski[1]

[1]Department of Dermatology, School of Medicine, The University of Alabama at Birmingham, Birmingham, AL,[2]Department of Pharmaceutical Sciences, Oregon State University College of Pharmacy, Corvallis, OR

Background: Melanoma remains a major clinical challenge due to its resistance to current targeted therapies, emphasizing the need for new preventive and therapeutic strategies. The vitamin D receptor (VDR) and its ligands are promising, low-toxicity targets. Our team has discovered an alternative, noncanonical vitamin D-metabolic pathway initiated by CYP11A1, generating hydroxyderivatives such as 20(OH)D_3 with antioxidative, photoprotective, and anticancer activities through VDR and other nuclear receptors (LXR, AhR, ROR). We hypothesize that 20(OH)D_3, alone or combined with vemurafenib (VEM), can inhibit melanoma tumorigenic behavior through VDR-dependent and independent mechanisms.

Methods: *In vitro* studies used migration, CFU, and PrestoBlue viability assays on melanoma lines (WM3960, WM1366, WM3942, WBM550). Spheroid assays utilized 3D culture and TUNEL staining to assess apoptosis. *In vivo* efficacy was evaluated in nude mice implanted with either wild-type (WT) or VDR-knockout ($VDR^{-/-}$) WM164 ($BRAF^{V600E}$) melanoma cells. Mice received vehicle, 20(OH)D_3 VEM, or combination therapy three times weekly. Tumor growth and necrosis were monitored, and protein expression was analyzed by Western blotting.

Results: Cell migration assays demonstrated that the treatment with novel vitamin D_3 derivatives markedly inhibited the migratory capacity of WM3960 PDX melanoma cells. CFUs further confirmed a significant reduction in melanoma cell growth across several melanoma cell lines. Viability assay revealed decreased fluorescence intensity in treated cells relative to controls, indicating reduced metabolic activity, viability, and proliferation. No apoptosis was detected using the TUNEL System, suggesting that the observed effects were primarily cytostatic rather than apoptotic. *In vivo*, WT WM164 xenografts treated with the combination of 20(OH)D_3 and VEM exhibited the strongest tumor suppression, followed by VEM monotherapy, whereas 20(OH)D_3 alone had minimal impact. In $VDR^{-/-}$ tumors, both VEM and combination treatments achieved comparable inhibition, indicating both VDR-dependent and independent mechanisms of action. Western blot confirmed synergistic downregulation of phospho AKT, ERK1/2, and NF-κB signaling pathways in combination-treated tumors, consistent with enhanced suppression of oncogenic signaling. Notably, male mice displayed greater sensitivity to the combination therapy compared with females.

Conclusion: The non-calcemic vitamin D_3 derivative 20(OH)D_3, especially when combined with vemurafenib, inhibits human melanoma growth by blocking oncogenic signaling pathways, independent of apoptosis. Due to its natural origin, safety profile, and pathway selectivity, 20(OH)D_3 has strong potential as a preventive and therapeutic agent against melanoma progression and metastasis.

#5019 Preclinical mechanistic PK/PD/Efficacy modeling for AZD4241, a novel oral estrogen receptor (ER) degrader (PROTAC), to support dose selection during early clinical development.

Ana Quiroga, Pablo Morentin Gutierrez, Lynet Nyoni, Natalie Cureton, Mandy Lawson, Aaron Smith, Thomas Hayhow, Neil Gibson

AstraZeneca, Cambridge, United Kingdom

The high prevalence of ER-positive breast cancer and the emergence of resistance to current endocrine therapies highlight the need for more effective ER degraders. AZD4241 is a novel, potent, orally bioavailable, and selective ER proteolysis-targeting chimera (PROTAC) scheduled to enter clinical evaluation in 2026. We describe preclinical pharmacokinetic/pharmacodynamic (PK/PD) and efficacy modeling that quantifies the relationships among drug exposure, ERα degradation, and antitumor activity, thereby defining the extent of compound plasma exposure and target modulation required to achieve efficacy. These translational analyses are intended to inform dose selection and guide early clinical development of AZD4241.We developed a mechanistic mathematical model to quantify the exposure-target-response profile of AZD4241 in in-vivo patient-derived xenograft (PDX) models harboring either wild-type or mutated ESR1. The PK module characterized plasma concentrations across a range of doses. An indirect-response PK/PD module incorporated AZD4241 mechanism of action, whereby the compound accelerates ERα degradation yielding reductions in total ER protein measured by Western blot. The integrated PK/PD/Efficacy model linked plasma exposure, ERα levels, and tumor growth kinetics in the PDX models. Model parameters were estimated via nonlinear mixed-effects (NLME) modeling using individual longitudinal PK, PD biomarker, and tumor volume data aggregated across multiple studies. The mathematical model captured the dose-dependent reduction of ERα and the associated inhibition of tumor growth observed in the PDX models. The level of ER degradation required to induce tumor regressions on the PDX models was also quantified and will be presented. This work provides quantitative, mechanistic insight into how exposure drives biomarker modulation and antitumor responses, delineating the level of ERα degradation required for robust efficacy in endocrine-sensitive PDX models. The framework supports interpretation of compound-induced PD effects in patients under defined dosing regimens and supplies translational evidence to enable dose selection in early clinical development.

#5020 Oxysterol sulfotransferase in prostate cancer inhibition: Cell-intrinsic and -extrinsic roles.

Bobae Park[1], Zhao Zhang[1], Chiou-Miin Wang[1], Mohin Patel[1], Yaguang Liu[2], Chia-Nung Hung[1], Bandana Chatterjee[1]

[1]Molecular Medicine, The University of Texas at San Antonio-UT Health, San Antonio, TX,[2]Pathology & Laboratory Medicine, The University of Texas at San Antonio-UT Health, San Antonio, TX

Oxysterol sulfotransferase (SULT2B) mediates enzymatic sulfation of oxysterols. SULT2B can modulate lipid metabolism by interfering with oxysterol-induced activation of the LXR nuclear receptor, since sulfated oxysterols are LXR inert. Poor survival is linked to reduced SULT2B in primary prostate cancer, and the enzyme is undetectable in clinical metastases of castration resistant prostate cancer (CRPC). SULT2B-null CRPC xenografts show escalated growth while SULT2B-high tumors are growth suppressed, show reduced tumor-emitted bioluminescence and sustain apoptosis. SULT2B silenced cells are more aggressive - evident from EMT-like induction; activated ERK survival signal; and enhanced invasion. To gain mechanistic insight, we probed PC3 CRPC cells for cell-intrinsic and -extrinsic changes due to ectopic SULT2B expression.

Results: Single-cell RNA sequences of SULT2B-high PC3 (SA) & control PC3 (VA) cells revealed transition of neuroendocrine-like PC3 from mesenchymal to epithelial traits afforded by SULT2B. UMAP showed a cluster of SA cells (cluster 7) spatially well-resolved from all other clusters. Bioinformatic probing of cluster 7 cells showed them enriched in epithelial markers and deficient in mesenchymal markers. Down genes in cluster 7 include FOXA2, SOX4, MMP16, Fibronectin 1 - all drivers of lethal CRPC. Notably, CD59 - a sialic acid containing cell surface glycoprotein - is a down gene in cluster 7 and in all SA clusters combined. CD59 is a ligand for Siglec-9 - a lectin that binds sialic acid and resides on macrophages (MΦ) & other myeloids. CD59 binding to Siglec-9 may aid immune evasion since blocking Siglec-9 interaction with sialylated glycoproteins prevented immune cells infiltration to prostate tumor and inhibited PC xenograft (PMID 39436703). Inflammatory genes - such as for NFκB1 & CXCL1, CXCL8 chemokines - are induced in cluster 7 cells and in all SA cell clusters together. RT-qPCR confirmed the changes. AKR1C3 - a key androgen biosynthesis driving enzyme - was elevated in SULT2B-silenced C4-2B CRPC cells *in vitro*. Multiplex immunofluorescence showed colocalization of $CD86^+$ M1MΦ (pro-inflammatory, immune-boosting) with SULT2B+ cells of SA xenograft, and $CD163^+/CD206^+$ M2MΦ (anti-inflammatory, immune-suppressive) infiltration to $AKR1C3^+$ tumor cells of VA xenograft. AKR1C3 is expressed copiously in VA xenograft, colocalizing with M2MΦ, while it is markedly reduced in M1MΦ-enriched SA xenograft. Reciprocal AKR1C3 and SULT2B expression is consistent with our finding that AKR1C3 is upregulated by oxysterol-LXR signaling.

Conclusion: Results highlight dual impacts of SULT2B on CRPC - regulating cancer cell metabolism and also shaping cancer-immune cells interplay by altering MΦ dynamics at tumor microenvironment. In depth molecular insights into cell-intrinsic and -extrinsic roles of SULT2B may uncover new avenue(s) for limiting lethal progression of prostate cancer

#5021 Role of *ZFX* variants in parathyroid tumorigenesis.

Sara Halili, Lucas Iommazzo, Callie Burke, Justin Bellizzi, Jessica Costa-Guda, Andrew Arnold

Center for Molecular Oncology, University of Connecticut School of Medicine, Farmington, CT

Somatic alterations in *ZFX*, a conserved zinc-finger transcription factor involved in stem cell maintenance and proliferation, have been reported across various malignancies including endometrioid carcinoma, melanoma, acute lymphoblastic leukemia, and diffuse large B cell lymphoma. Emerging evidence also links *ZFX* variants in zinc finger domains 12 and 13 to parathyroid tumorigenesis. Parathyroid gland tumors cause dysregulated calcium homeostasis and increased risk for bone fractures and kidney stones. While most people with parathyroid tumors have only one single gland affected (~85%), the remaining 15% have multigland disease (MGD). This condition, previously known as parathyroid hyperplasia, has distinct clinical implications including higher rates of recurrence and association with genetic syndromes, such as multiple endocrine neoplasia type 1, that may entail risk for family members. A few studies have reported germline variants in *ZFX* associated with MGD; however, the contribution of *ZFX* variants in MGD remains poorly understood.To assess the contribution of *ZFX* variants in MGD, we screened parathyroid tumor DNA from 26 patients with MGD for variants in zinc finger domains 12 and 13. We identified the variant p.Arg764Trp in one sample and confirmed it to be germline. This variant has been previously reported as both germline and somatic in parathyroid adenomas and as a somatic variant in other malignancies, but has not been reported in MGD. We subsequently screened germline DNA from an additional cohort of 47 patients with MGD and found no variants in the coding sequence of zinc finger domains 12 and 13. The finding of the p.Arg764Trp variant in this cohort further supports the contribution of *ZFX* variants to MGD. The mechanisms by which such variants predispose affected patients for MGD as opposed to solitary parathyroid tumors merit further investigation. Additionally, while we were unable to access family history in the patient with the p.Arg764Trp variant, a previously reported three-generation family with a different *ZFX* variant (p.Tyr774Cys) included four females diagnosed with hyperparathyroidism, with one proband having MGD. This familial pattern raises important considerations for genetic testing and counseling of family members of patients with *ZFX* variants.

#5022 Hormonal alterations distinguishing high-risk women from breast cancer patients across the menopause transition.

Jiaqing Hao[1], Reilly T. Enos[2], Sam Rosin[3], Jinyu Wang[1], Shanshan Liu[1], Melissa A. Curry[4], Sonia L. Sugg[4], Marinella Temprosa[3], E. Angela Murphy[2], Bing Li[1]

[1]Department of Pathology, University of Iowa, Iowa City, IA,[2]Department of Pathology, Microbiology, and Immunology, University of South Carolina, Columbia, SC,[3]Department of Biostatistics and Bioinformatics, The George Washington University, Rockville, MD,[4]Department of Surgery, University of Iowa, Iowa City, IA

Hormonal level changes during the menopause transition have been proposed to influence breast cancer risk. Epidemiologic studies indicate that postmenopausal women with higher circulating estrogen levels are at an increased risk of developing breast cancer, suggesting that alterations in hormone profiles may reflect disease progression. However, few studies have investigated hormonal differences between high-risk women and those with active cancer. In this study, we measured 11 common hormones in plasma samples from 206 women, including 80 diagnosed with breast cancer and 126 high-risk but cancer-free women. We found that plasma levels of estrone (E1), estradiol (E2), deoxycorticosterone (DOC), and progesterone (PROG) were significantly lower in premenopausal breast cancer patients compared to high-risk women. Correlation analyses revealed that E1 levels were positively associated with body mass index (BMI) in postmenopausal high-risk individuals, while E2 levels showed a similar positive correlation in postmenopausal cancer patients. In contrast, BMI was negatively correlated with cortisol, testosterone, and 17α-deoxypregnenolone in postmenopausal high-risk women. These findings suggest that hormonal alterations, specificially reduced levels of E1, E2, DOC, and PROG, distinguish premenopausal high-risk women from those with active breast cancer. The menopause-dependent changes in hormone-BMI associations indicate that metabolic-hormonal interactions may drive the transition from cancer susceptibility to malignancy.

#5024 USP8, a survival gatekeeper turned oncogenic trigger via hyperactivation of the integrated stress response.

Debjani Mandal[1], Santosh Kumar[1], Dhruval Bhatt[1], Yan Li[2], Kory Johnson[3], Maric Dragan[4], Prashant Chittiboina[1]

[1]Neurosurgery Unit for Pituitary and Inheritable Diseases, NIH-National Institute of Neurological Disorders and Stroke, Bethesda, MD, [2]Protein/peptide sequencing facility. National Institute of Neurological Disorders and Stroke, NIH-National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD,[3]DIR Bioinformatics Section, NIH-National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD,[4]Flow and Imaging Cytometry Core Facility, NIH-National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD

Eukaryotic deubiquitinase enzymes (DUBs) play a vital role in maintaining cellular homeostasis by deubiquitinating substrates marked for degradation. Of the ~100 DUBs discovered in humans, USP8 is unique for its association with human tumors including Cushing's disease (activating mutation), and solid cancers (genomic overexpression). The mechanisms underlying USP8 in tumorigenesis remain unknown. We first found that USP8 is essential for cell survival using CRISPR-Cas9-mediated homozygous excision and RNA interference. To circumvent obligate lethality, identify the substrates of USP8, and determine pathways dysregulated in human tumors with elevated USP8 activity, we engineered a GFP-auxin inducible degron (AID) at the endogenous USP8 locus in DLD1 cells. Additionally, we assayed both transient and long-term interactors using a promiscuous biotinylator BirA fused to a USP8 lentiviral construct. We performed cell survival, apoptosis assays, immunocytochemistry, western blot, RNAseq, and TMT labeled LC/MS, TUBE and IP-LC/MS study. We found that with auxin activation, DLD1USP8-GFP-AID had >80% reduction in USP8 within 30 minutes. At 6 hours, LC/MS revealed a profound alteration of the proteome and phosphoproteome with suppression of eukaryotic elongational initiation factor-2 (EIF2) signaling. We found that USP8 triggers the Integrated Stress Response (ISR), as measured by an ATF4 reporter assay. Consistently, USP8 overexpression led to a concordant elevation of EIF2 signaling and enrichment of EIF2 signaling peptides in cells expressing the USP8-BirA construct. Moreover, USP8 overexpression in PERK and GCN2 knockout lines suggests that USP8 activates ISR via both the amino acid deprivation (GCN2) and unfolded protein response (PERK) pathways. Taken together, our findings indicate that USP8 activation induces the Integrated Stress Response (ISR) through EIF2α phosphorylation and subsequent activation of the transcription factor ATF4. We propose that tumor cells hijack ISR signaling to promote pro-survival pathways, an effect that can be reversed by pharmacological inhibition of ISR using ISRIB. ISR pathway inhibition or decrease of USP8 activity shows a significant reduction of tumor volume in a syngeneic mouse model. These results reveal targetable downstream pathways of USP8 activation, offering potential therapeutic strategies to improve outcomes in patients with Chusing's disease and solid tumors.

#5028 Joint association of body mass index and waist circumference with head and neck cancer mortality risk in Asian population.

Sangjun Lee, Sue K. Park

Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of

Background: Low body mass index (BMI) has been linked to higher head and neck cancer (HNC) mortality, but the roles of general and central obesity in Asian populations are unclear. Most epidemiologic studies have evaluated BMI or waist circumference (WC) separately. We investigated the joint associations of BMI and WC with HNC mortality in Asian prospective cohorts.

Methods: We conducted a pooled analysis of population-based cohorts in the Asia Cohort Consortium with follow up for cause specific HNC mortality. BMI (kg/m^2) was categorized using Asia-Pacific cut offs (<18.5, 18.5-22.9, 23.0-24.9, 25.0-27.4, 27.5-29.9, ≥30), and WC into sex specific quintiles and WHO obesity thresholds (≥90 cm in men, ≥80 cm in women). We also constructed joint BMI-WC and BMI-smoking categories. Multivariable Cox models estimated hazard ratios (HRs) and 95% confidence intervals (CIs), adjusting for age, sex, smoking status, alcohol intake, cohort, diabetes, and hypertension, with additional adjustment for height in WC models; analyses were stratified by smoking.

Results: Compared with normal BMI (18.5-22.9 kg/m^2), underweight participants (<18.5) had more than a two fold higher risk of HNC mortality (HR 2.19, 95% CI 1.75-2.74), whereas those with BMI 27.5-29.9 had lower risk (HR 0.53, 95% CI 0.37-0.77), and intermediate categories showed similar inverse associations. WC showed a parallel inverse pattern; compared with the lowest quintile, higher quintiles had lower HNC mortality (e.g. Q4 HR 0.49, 95% CI 0.33-0.72; p trend<0.01). In smoking stratified analyses, underweight remained strongly associated with HNC mortality in both never smokers (HR 2.56, 95% CI 1.92-3.40) and smokers (HR 1.73, 95% CI 1.19-2.52). Joint BMI-smoking models using never smokers with normal BMI as the reference showed markedly elevated risk among underweight smokers (HR 3.76, 95% CI 2.53-5.60) and excess risk among normal BMI smokers (HR 2.19, 95% CI 1.70-2.83). In joint BMI-WC categories, underweight individuals with normal WC had higher HNC mortality (HR 2.29, 95% CI 1.47-3.56), whereas those with BMI ≥30.0 and normal WC had lower risk (HR 0.67, 95% CI 0.47-0.96); adding WC did not materially change BMI-HNC associations.

Conclusion: In these Asian cohorts, smaller body size-low BMI and small WC-was consistently associated with higher HNC mortality, whereas overweight and moderate obesity were associated with lower mortality. BMI was a stronger predictor than WC, suggesting that overall body mass may be more relevant than central adiposity for HNC mortality. These findings highlight the importance of incorporating baseline nutritional status and smoking history into risk stratification and survivorship care.

#5029 Employment status and adherence to physical activity guidelines among U.S. cancer survivors: An analysis of the National Health Interview Survey.

Alexis Clouser[1], Benjamin C. Amick III[1], Christopher Walter[2], Jaimi Allen[1]

[1]Epidemiology, University of Arkansas for Medical Sciences, Little Rock, AR,[2]College of Health Professions, University of Arkansas for Medical Sciences, Little Rock, AR

Background: Physical activity (PA) is a critical, modifiable lifestyle factor that improves cancer survivorship outcomes, including reduced recurrence and lower mortality. However, many cancer survivors fail to meet recommended PA guidelines (150 min of aerobic PA and 2 days of strength training per week). Socioeconomic and structural factors such as employment status are key determinants of health behaviors. As many survivors return to work, the influence of employment on their ability to engage in PA is an understudied area. This study examined the relationship between employment and PA among U.S. adults including those with cancer.
Methods: This cross-sectional study used pooled data from the 2020 and 2022 National Health Interview Survey (n=57,101), including cancer survivors. The independent variable was employment. The dependent variable, physical activity (PA) status, was categorized into four levels based on HHS guidelines (meeting both aerobic and strength, aerobic-only, strength-only, or neither). Multinomial logistic regression was used to calculate relative risk ratios for employment status across physical activity categories, adjusted for covariates.
Results: Preliminary results using adjusted multinomial logistic regression showed that, relative to meeting neither criteria, employment was significantly associated with a 9% higher relative risk of meeting both aerobic and strength physical activity criteria (RRR = 1.09; 95% CI, 1.02-1.16). Employment status was not significantly associated with meeting strength-only (RRR = 1.05; 95% CI, 0.96-1.16) or aerobic-only criteria (RRR = 1.00; 95% CI, 0.95-1.06). For the distinct populations of U.S. citizens with cancer, employment was not significant for any of the physical activity categories.
Conclusion: Preliminary findings suggest that while employment is associated with higher aerobic and muscle strengthening physical activity in the general population, this association does not hold true for cancer survivors. This suggests that returning to work may not offer the same PA benefit for survivors, potentially due to factors like persistent fatigue or other cancer-related symptoms. These results emphasize the need for targeted, low-cost physical activity interventions for non-working individuals and accessible workplace wellness programs designed specifically to mitigate PA barriers for working cancer survivors and improve long-term outcomes.

#5030 An evaluation of c-reactive protein and sleep in women with breast cancer using the All of Us dataset.

Layja J. Grant[1], Lauren K. Evans[2], Ivan T. Jubilee[3], Nelson R. Lemieux[4], **KiTani Parker Lemieux**[5]

[1]Public Health, Xavier University of Louisiana, New Orleans, LA,[2]Basic Pharmaceutical Sciences, Xavier University of Louisiana College of Pharmacy, New Orleans, LA,[3]Division of Basic Pharmaceutical Sciences, Xavier University of Louisiana- College of Pharmacy, New Orleans, LA,[4]Seven Star Academy, Inc, Harvey, LA,[5]Xavier University of Louisiana - College of Pharmacy, New Orleans, LA

Background: Women who have breast cancer are likely to encounter sleep disturbances for various reasons. Wellness is associated with the quality of sleep one receives, and the quality of sleep is also associated with healing. Continuous sleep disturbances could lead to a poorer quality of life. Therefore, we used the SDoH survey in the All of Us dataset to evaluate noise in the neighborhoods of participants with breast cancer as a measure of sleep disturbances. Women with breast cancer and poor sleep quality may experience disease progression which could be correlated by inflammation biomarkers, such as c-reactive protein.

Methods: According to the SDoH survey from the All of Us version 8 dataset, participants were divided into two cohorts, noisy and non-noisy living environments. We used multiple statistical tests to compare the groups' data. The Welch's t-test was used to compare the two cohorts and their awake, light, deep, and REM sleep level in minutes. We also used the Mann Whitney U test to compare the four levels of sleep. The correlation between sleep length and c-reactive protein was tested by Pearson's correlation coefficient. Each test was completed via Jupyter notebook using Python coding.

Results: Upon update of the All of Us dataset version 8 update, about two-hundred and ninety-nine breast malignancy-diagnosed women met the inclusion criteria of the cohort to compare noise levels of their neighborhood, quality of sleep level, and the measurement of their C-reactive protein via FitBit data and surveys. There was no statistically significant difference between noise levels and minutes of sleep or sleep level and c-reactive protein measurements.

Conclusion: It is well-established that quality sleep is essential for overall wellness. The data we collected did not establish correlation between sleep level and C-reactive protein measurements. While our outcomes are not as we predicted, it is important to know that the data were skewed, as the two cohorts were not evenly distributed. Furthermore, despite the addition of participants in the version 8 dataset, we observed that the representation of medically underserved and understudied communities was still deficient. To provide more population representative data, there needs to be more diversity amongst the participants providing pertinent data.

#5031 Integrating real-world wearable data into breast cancer risk assessment: Evidence from the *All of Us* Research Program.

Yoav Weber[1], Arshia Ilaty[2], Xuanxi Kuang[3], Emily Lan Nguyen[3], Abel Plaza-Florido[1], Shlomit Radom-Aizik[1], Argyrios Ziogas[1], Amir M. Rahmani[4], Hannah Lui Park[1]

[1]UCI School of Medicine, Irvine, CA,[2]UCI Donald Bren School of Information and Computer Sciences, Irvine, CA,[3]UC Irvine, Irvine, CA,[4]UCI School of Nursing, Irvine, CA

Lifestyle and genetic factors are known contributors to breast cancer risk, yet their integration with clinical data into breast cancer risk assessment remains limited. Traditional, self-reported lifestyle measures are subject to recall bias, whereas wearable devices provide objective, continuous measurements of physical activity and sleep behaviors. Using data from the National Institutes of Health *All of Us* Research Program (n=633,540 participants), we conducted a retrospective matched case-control study to evaluate the association between objectively captured wearable data and breast cancer risk, and to establish a scalable analytical framework for causal and machine learning modeling. Females diagnosed with breast cancer at age ≥50 years with at least five valid weeks of Fitbit data (two or more days per week) within the five years preceding diagnosis (n=154) were each matched to up to 20 cancer-free controls by date of birth (±1 year) and availability of wearable data within the same time temporal window. Numerical variables were analyzed using Wilcoxon signed-rank tests, and categorical variables via chi-square analysis. Cases exhibited lower average daily steps (6766 ± 3040) compared to controls (7248 ± 3266; p=0.011), as well as fewer daily light active and very active minutes (179.8 ± 69.0 and 13.6 ± 13.7 vs. 190.2 ± 69.3 and 16.0 ± 16.9; p = 0.043 and p < 0.001, respectively). Sleep metrics were not significantly different between groups, while family history of breast cancer was more common among cases (p < 0.001). Building on these findings, we propose a multimodal integrative framework that merges wearable, survey, and electronic health record data, with future incorporation of genomic features and causal inference techniques (e.g., propensity score matching and causal forests) to refine individualized risk estimation. Explainable machine learning approaches, including ensemble and time-series models, will enable interpretable and dynamically updated risk predictions. This study demonstrates the feasibility of using real-world wearable data within the *All of Us* infrastructure and underscores the translational potential of multimodal, causal, and interpretable modeling for precision breast cancer screening and prevention at a population scale.

#5032 Physical activity and overall and cancer-specific mortality in postmenopausal women with breast cancer: A competing risks analysis with 19-year follow-up.

Jaime I. Castillo Silva[1], Lina S. Palacio Mejia[1], Juan E. Hernandez Avila[1], Salvador Zamora Munoz[2], Rocio Rodriguez Valentin[1], Angelica Angeles Llerenas[1], Amado Jimenez Avila[3], Gabriela Torres Mejia[1]

[1]Instituto Nacional de Salud Publica, Cuernavaca, Mexico,[2]Universidad Nacional Autonoma de Mexico, Mexico City, Mexico,[3]Hospital Regional Alta Especialidad de Ixtapaluca, Ixtapaluca, Mexico

Background: As breast cancer survivors live longer, non-cancer mortality competes with cancer mortality. However, many studies evaluating physical activity have not accounted for competing risks or adequately tested effect modification by menopausal status. Therefore, we aimed to assess the association between physical activity and mortality in women with breast cancer, accounting for menopausal status and competing risks.
Methods: We analyzed 1000 breast cancer cases from the multicenter CAMA study in Mexico with 19-year follow-up. Usual hours of leisure-time moderate-to-vigorous physical activity before breast cancer diagnosis or symptoms were dichotomized at 2.5 h/week. Primary outcomes were overall, cancer, and non-cancer mortality. We used a two-stage analysis: (1) Cox model for overall mortality testing menopausal status as an effect modifier, and (2) Fine-Gray competing risks models in strata with significant effects. Models were adjusted for DAG-derived clinical, lifestyle, and socioeconomic confounders. Missing data were handled using Multiple Imputation by Chained Equations with Random Forest.
Results: Menopausal status significantly modified the association between physical activity and overall mortality (p=0.035). In postmenopausal women (n=584), physical activity was associated with reduced mortality (Table), with no significant association in premenopausal women.
Conclusions: In postmenopausal women with breast cancer, physical activity before diagnosis or symptoms was associated with lower overall mortality at long-term follow-up. This benefit reflects significantly lower cancer-specific mortality when accounting for competing non-cancer mortality. These findings underscore the importance of physical activity after menopause and highlight the need for methodological approaches that jointly consider menopausal status and competing risks in survivorship research.

Association of physical activity and mortality outcomes in postmenopausal women with breast cancer

Outcome	**HR/sHR (95% CI)**	**p-value**
Overall mortality	0.59 (0.41-0.84)	0.004
Cancer mortality	0.63 (0.40-0.98)	0.042
Non-cancer mortality	0.63 (0.35-1.14)	0.125
Models adjusted for age, clinical stage, comorbidities, Diet Inflammatory Index, alcohol, smoking, education, residence, and healthcare access. HR = hazard ratio (Cox model); sHR = subdistribution hazard ratio (Fine-Gray models).		

#5033 Association between ultra-processed foods and PI3K/AKT/MTOR signaling pathway protein expression in breast tumor tissue of Black women.

Tengteng Wang[1], Bo Qin[1], Fred K. Tabung[2], Steven Zheng[1], Nur Zeinomar[1], Chi-Chen Hong[3], Christine B. Ambrosone[3], Elisa V. Bandera[1], Ting-Yuan David Cheng[4]

[1]Rutgers Cancer Institute, New Brunswick, NJ,[2]The Ohio State University College of Medicine, Columbus, OH,[3]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]The Ohio State University, Columbus, OH

Background: Ultra-processed food (UPF) consumption has been linked to increased breast cancer risk and poorer outcomes, potentially through metabolic/insulin resistance pathways. The PI3K/AKT/MTOR signaling pathways are frequently dysregulated in breast tumors. However, little is known about how UPF intake influences this pathway in breast tissue, particularly among Black women, who experience highest breast cancer mortality. Examining these associations may clarify diet-related molecular mechanisms underlying breast cancer disparities.
Methods: We investigated tumor FFPE samples from 439 breast cancer cases who self-identified as Black/African American and participated in the well-established population-based study, the Women's Circle of Health Study. Tumor expressions for MTOR, phosphorylated (p)-MTOR, p-AKT, and p-P70S6K were analyzed by immunohistochemistry (IHC) and digitally scored (H-score 1%-300%). Foods and drinks consumed over 12 months before breast cancer diagnosis were assessed during home interviews by validated food-frequency questionnaires. UPFs were classified according to their degree of processing using the NOVA classification system. Multivariable logistic regression models estimated odds ratios (ORs) and 95% confidence intervals (CIs) for associations between UPF intake (per 1-SD increase) and protein expression (positive [H-score>0] vs. negative [H-score=0]), adjusting for age of breast cancer diagnosis, socioeconomic status, total energy intake, and body mass index at diagnosis.
Results: Our participants consumed an average of 5.5 UPF servings/day before breast cancer diagnosis. More than 90% of tumors expressed MTOR and p-MTOR markers, whereas p-AKT and p-P70S6K were detected in 38% and 42% of cases, respectively. Higher UPF consumption was significantly associated with increased odds of nuclear p-AKT-positive tumors (OR = 1.23; 95% CI: 1.00-1.51) and cytoplasmic p-P70S6K-positive tumors (OR = 1.20; 95% CI: 1.00-1.47). Associations remained robust after restricting analyses to women with estrogen receptor (ER)-positive tumors or those without type 2 diabetes. However, heterogeneity by ER status was observed for MTOR expression: higher UPF intake was significantly associated with a threefold greater odds of cytoplasmic MTOR-positive tumors among ER-negative subtype (OR = 3.27; 95% CI: 1.19-16.46) but not among those with ER-positive cancer (OR = 0.91; 95% CI: 0.68-1.22; P-interaction=0.02).
Conclusion: Our findings suggest that higher UPF intake was associated with activation of downstream PI3K/AKT/MTOR pathway in breast tumor tissue, highlighting a potential biological mechanism linking UPFs to breast cancer development. A deeper understanding of how UPF consumption influences tumor signaling may inform the development of tailored dietary recommendations and interventions for Black women.

#5034 Ultra-processed food intake and inflammatory markers in breast cancer survivors.

Minsu Cho[1], Sihan Song[2], Zisun Kim[3], Hyun Jo Youn[4], Jihyoung Cho[5], Jun Won Min[6], Yoo Seok Kim[7], Jihyoun Lee[8], Seho Park[9], Joon Jeong[10], Jung Eun Lee[1]

[1]Department of Food and Nutrition, Seoul National University, Seoul, Korea, Republic of,[2]Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine, St. Louis, MO,[3]Department of Surgery, Soonchunhyang University Bucheon Hospital, Bucheon, Korea, Republic of,[4]Department of Surgery, Jeonbuk National University Medical School, Jeonju, Korea, Republic of,[5]Division of Breast and Thyroid Surgery, Department of Surgery, Koo Hospital, Daegu, Korea, Republic of,[6]Department of Surgery, College of Medicine, Dankook University, Cheonan, Korea, Republic of,[7]Department of Surgery, College of Medicine, Chosun University, Gwangju, Korea, Republic of,[8]Department of Surgery, Soonchunhyang University Seoul Hospital, Seoul, Korea, Republic of,[9]Division of Breast Surgery, Department of Surgery, Yonsei University College of Medicine, Seoul, Korea, Republic of,[10]Department of Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

Objectives: This study aimed to examine the associations between ultra-processed food intake and inflammatory markers among Korean breast cancer survivors.
Methods: A total of 641 breast cancer survivors were included. Ultra-processed food intake was assessed using 3-day dietary records or a validated food frequency questionnaire. Plasma levels of high-sensitivity C-reactive protein (hs-CRP), interleukin-6, interleukin-8, tumor necrosis factor-α, and adiponectin were measured. A composite inflammatory z-score was calculated from these five biomarkers. Multivariate logistic regression and general linear models were used to estimate odds ratios (ORs) and least-squares (LS) means for inflammatory markers.
Results: Total ultra-processed food intake was not associated with inflammatory markers overall. However, the associations varied by menopausal status at diagnosis, estrogen/progesterone receptor (ER/PR) subtype, and age. Comparing extreme quartiles of ultra-processed food intake, ORs (95% confidence intervals, CIs) for an increased composite inflammatory z-score were 0.57 (0.28, 1.19) and 3.10 (1.20, 8.00) among participants who were premenopausal and postmenopausal at diagnosis, respectively (p for interaction < 0.01). LS means (95% CIs) for hs-CRP (mg/L) in the lowest and highest quartiles of ultra-processed food intake were 0.28 (0.16, 0.51) and 0.59 (0.33, 1.06) among those with ER/PR-negative tumors (p for trend = 0.03), whereas the corresponding values were 0.41 (0.31, 0.53) and 0.48 (0.37, 0.61) among those with other subtypes (p for trend = 0.67); the interaction did not reach statistical significance (p for interaction = 0.26). For reduced adiponectin, ORs (95% CIs) comparing extreme quartiles of ultra-processed food intake were 0.57 (0.26, 1.26) in those aged < 50 years and 2.65 (1.20, 5.88) in those aged ≥ 50 years (p for interaction = 0.03). When we examined the associations of ultra-processed food subgroups, higher intake of packaged and instant noodles was associated with increased hs-CRP.
Conclusions: Higher ultra-processed food intake was associated with unfavorable inflammatory profiles among Korean breast cancer survivors who were postmenopausal at diagnosis, ER/PR-negative, or aged 50 years and older. Among ultra-processed food subgroups, greater intake of packaged and instant noodles was associated with higher hs-CRP.

#5035 The impact of genetic and lifestyle factors on the risk of invasive postmenopausal breast cancer in the multiethnic cohort study.

Chenya Zhao[1], Gertraud Maskarinec[2], David Conti[3], Christopher A. Haiman[3], Loic Le Marchand[2], Lynne R. Wilkens[2], Fei Chen[3], Eunjung Lee[1]

[1]University of Southern California, Los Angeles, CA,[2]University of Hawai'i Cancer Center, Honolulu, HI,[3]Center for Genetic Epidemiology, University of Southern California, Los Angeles, CA

Background: Adherence to a healthy lifestyle has been consistently associated with reduced breast cancer risk, but whether this benefit varies by genetic susceptibility remains unclear, particularly among racially and ethnically diverse populations. This study evaluated whether the association between a Healthy Lifestyle Index Score (HLIS) and breast cancer risk differs by a 313-variant polygenic risk score (PRS) among postmenopausal women in the Multiethnic Cohort (MEC).
Methods: HLIS (range: 0-7) was constructed based on the 2018 World Cancer Research Fund/American Institute for Cancer Research Cancer Prevention Recommendations and included nine dietary and lifestyle components: fruit and vegetable intake, total fiber intake, red meat intake, alcohol consumption, physical activity, body mass index (BMI), waist circumference (WC), smoking status, and sugar-sweetened drink intake. HLIS was categorized into tertiles (low, intermediate, high) according to its distribution among non-cases. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using multivariable Cox proportional hazards models with age as the time metric. The parsimonious model was adjusted for family history of breast cancer, educational attainment, type of menopause, parity, daily energy intake, PRS, and the top 10 principal components (PCs), while the extended model was additionally adjusted for history of diabetes, age at menopause, age of menarche, and hormone use. Analyses were further stratified by PRS (above vs. below the median), and interaction was tested using a likelihood ratio test.
Results: Among the 22,725 postmenopausal women (non-Hispanic White [22.2%], African American [12.9%], Native Hawaiian [8.1%], Japanese American [37.5%], and Latino [19.2%]), 1,174 developed breast cancer during an average follow-up of 12.2 years. Higher HLIS was associated with a significantly lower risk of breast cancer. Compared to women in the low HLIS tertile, breast cancer risk was 12% lower (HR = 0.88; 95% CI: 0.77-1.00; P = 0.05) in the intermediate tertile and 34% lower (HR = 0.66; 95% CI: 0.56-0.77; P < 0.001) in the high tertile, with similar results in the extended model. This inverse association appeared to be driven by BMI (obese vs. normal: HR=1.36, 95% CI: 1.13-1.64, P=0.001) and WC (≥88 cm vs. <80 cm: HR=1.43, 95% CI = 1.19-1.72, P < 0.001). PRS was significantly associated with breast cancer risk (per-SD HR = 1.37; 95% CI: 1.29-1.45; P < 0.001). The inverse association between HLIS and breast cancer risk was similar across PRS strata, with no significant interaction (P-int = 0.48).
Conclusion: In this multiethnic cohort of postmenopausal women, adherence to a healthy lifestyle was associated with a reduced risk of breast cancer, regardless of low or high PRS, supporting the importance of lifestyle modification as a key preventive strategy for breast cancer across diverse populations.

#5036 Ultra-processed foods and disease-free survival after colorectal cancer diagnosis: Findings from the Colocare Study.

Patricia A. Erickson[1], Rachel Hoobler[1], Victoria Maria Bandera[1], Victoria Damerell[2], Ildiko Strehli[1], Megan Mclaws[1], Lyen Huang[1], Jessica N. Cohan[1], Erin Siegel[3], Doratha Armenthus Byrd[4], Adetunji T. Toriola[5], David Shibata[6], Christopher I. Li[7], Jane C. Professor of Surgical Onc., Div. of Interdiscipl. Onc., University of Tennessee Health Science Center - Memphis, Memphis, TN,[7]Fred Hutch Cancer Center, Seattle, WA,[8]Samuel Oschin Comprehensive Cancer Institute, Los Angeles, CA,[9]Heidelberg University Hospital (UKHD), Heidelberg, Germany

Introduction: Ultra-processed foods (UPFs), industrially formulated products high in fat, sugar, and additives, account for ~60% of daily calories in the United States. UPF intake has been linked to obesity, diabetes, and risk of some cancers, yet its impact on colorectal cancer (CRC) survivorship remains unclear. CRC survivors often face treatment-related dietary challenges and may rely on UPFs for convenience or to meet energy needs.
Methods: We analyzed 418 stage I-III CRC patients in the ColoCare Study across four U.S. sites. Baseline demographic, lifestyle, and clinical data were collected. Dietary intake was assessed 6 months post-diagnosis using a food frequency questionnaire (FFQ) reflecting the prior six months. Foods were classified into one of four NOVA groups: unprocessed, minimally processed, processed, and ultra-processed foods (UPFs). We focused on UPF intake (NOVA Group 4), categorized into quartiles (Quartile 1 = lowest; Quartile 4 = highest) using two metrics: absolute intake (grams/day) and relative intake (percent of total grams/day). Cox proportional models estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for disease-free-survival (DFS), adjusting for study site, age, sex, tumor site adjuvant treatment, BMI, and total caloric intake (kcal). Sensitivity analyses without BMI/kcal adjustment were also done.
Results: Participants had a mean age of 58 years (standard deviation [SD]=13y) and a mean BMI of 29 kg/m² (SD=6.8). 50% of participants were female, 49% were diagnosed with stage III CRC, and 59% with colon cancer. The median follow-up was 4 years (SD=2y). UPFs comprised ~16% of the total daily food intake by weight. The mean Healthy Eating Index (HEI) score was 63 (SD=10), but scores decreased across quartiles of UPF consumption ($p < 0.001$). When evaluated by g/day, BMI differed by UPF quartiles (p=0.04), and a similar pattern was observed when quartiles of % g/day were used (p=0.12). UPF consumption, whether in g/day or percent of total intake, was not significantly associated with DFS. For g/day quartiles, HRs (95% CI) for quartiles 2-4 vs 1 were 0.92 (0.52-1.65), 0.88 (0.47-1.62), and 0.88 (0.45-1.74). For percentage-based quartiles, HRs were 1.12 (0.61- 2.09), 1.02 (0.54-1.93), and 1.27 (0.70-2.30). Results were consistent in both unadjusted models and those without BMI/kcal adjustment.
Discussion: In this large, multi-center cohort, UPF intake was common among CRC survivors and associated with lower diet quality. However, UPF consumption was not associated with DFS, regardless of whether intake was measured in g/day or percentage of total intake. Modest differences in HR direction likely reflect how absolute versus relative intake captures dietary patterns. These findings offer important insights into post-diagnosis diet and cancer outcomes.

#5037 Liquid and solid fructose intake and colorectal cancer mortality by physical activity in U.S. prospective cohorts.

Hanseul Kim[1], Jihye Yun[1], Carrie R. Daniel-MacDougall[1], Long H. Nguyen[2], Edward L. Giovannucci[3]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Massachusetts General Hospital, Boston, MA,[3]Harvard TH Chan School of Public Health, Boston, MA

Background: We recently found that liquid fructose promotes colorectal cancer (CRC) metastasis in preclinical models, including human cancer cell lines and mice (Feng et al., 2025). In humans, fructose is consumed in both liquid and solid forms (Li et al., 2023), but whether these sources relate differently to CRC mortality is unknown. Additionally, physical activity may modify the metabolic effects of fructose (Tappy & Rosset, 2019).

Methods: We assessed pre- and post-diagnostic liquid and solid fructose intakes using quadrennial food frequency questionnaires in the Nurses' Health Study (1984-2018) and Health Professionals Follow-Up Study (1990-2018). Nutrient intakes were energy-adjusted using the residual method. Post-diagnostic fructose intake was assessed at least six months but no more than four years after diagnosis. Liquid fructose was derived from sugar-sweetened beverages and juice, and solid fructose was calculated as total minus liquid fructose. Cox proportional hazards models were used to estimate hazard ratios (HRs) for fructose intake and CRC-specific mortality, stratified by pre-diagnostic physical activity (<11.5 vs. ≥11.5 metabolic equivalent of task [MET]-hrs/wk) and adjusted for demographics, tumor characteristics, lifestyle factors, and diet.

Results: Among 724 CRC patients with low pre-diagnostic physical activity (<11.5 MET-hrs/wk), we observed 96 CRC-specific deaths over 7,412 person-years. Higher post-diagnostic, but not pre-diagnostic, liquid and solid fructose intakes were associated with higher CRC-specific mortality. Post-diagnostic liquid fructose showed the strongest association with CRC mortality (Multivariable [MV]-adjusted HR per 5 g/day, 1.18; 95% CI, 1.04-1.34; P-value, 0.011), whereas post-diagnostic solid fructose showed a more modest association (MV-adjusted HR per 20 g/day, 1.04; 95% CI, 1.01-1.06; P-value, 0.002). Among 705 patients (6,611 person-years; 95 CRC-specific deaths) with high pre-diagnostic physical activity (≥11.5 MET-hrs/wk), neither liquid nor solid fructose intake, pre- or post-diagnostic, was associated with CRC-specific mortality. These findings showed that the positive associations between fructose intake and CRC mortality were observed for individuals with low physical activity, confined to post-diagnostic fructose intake, and stronger for liquid than for solid fructose.

Conclusions: Higher post-diagnostic fructose intake, especially from liquid sources, was associated with increased CRC-specific mortality among patients with low physical activity. These findings suggest a potential interaction between physical activity and fructose intake in the context of CRC mortality and highlight the importance of food choices in CRC survivorship.

#5038 Associations of WCRF/AICR recommendations with survival and chemotherapy outcomes in colon cancer: CALGB/SWOG 80702 (Alliance).

En Cheng[1], Chao Ma[2], Qian Shi[3], Anthony F. Shields[4], Peter T. Campbell[1], Ardaman P. Shergill[5], Katherine A. Guthrie[6], Felix Couture[7], Philip Kuebler[8], Pankaj Kumar[9], Benjamin Tan[10], Smitha S. Krishnamurthi[11], Kimmie Ng[2], Eileen M. O'Reilly[12], Justin C. Brown[13], Philip A. Philip[4], Jeffrey A. Meyerhardt[2]

[1]Department of Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY,[2]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[3]Alliance Statistics and Data Management Center, Mayo Clinic, Rochester, MN,[4]Department of Oncology, Karmanos Cancer Institute, Wayne State University, Detroit, MI,[5]Department of Medicine, University of Chicago Pritzker School of Medicine, Chicago, IL,[6]SWOG Statistics and Data Management Center, Fred Hutchinson Cancer Center, Seattle, WA,[7]Hotel-Dieu de Quebec, Quebec, QC, Canada,[8]Columbus NCI Community Oncology Research Program, Columbus, OH,[9]Illinois CancerCare PC, Peoria, IL,[10]Siteman Cancer Center, Washington University School of Medicine, St Louis, MO,[11]Department of Hematology and Medical Oncology, Cleveland Clinic, Cleveland, OH,[12]Memorial Sloan Kettering Cancer Center, Weill Cornell Medical Center, New York, NY,[13]Exercise & Cancer Biology Research Program, AdventHealth, Orlando, FL

Background: Adhering to 2018 World Cancer Research Fund (WCRF)/American Institute for Cancer Research (AICR) Cancer Prevention Recommendations is reportedly associated with better survival among long-term colon cancer survivors (likely affected by immortal time bias). Thus, it is important to validate survival benefits by assessing adherence shortly after diagnosis, and further investigation is needed to examine its association with chemotherapy outcomes.

Methods: Using an NCI-sponsored adjuvant chemotherapy trial conducted in patients with stage III colon cancer (CALGB/SWOG 80702; NCT01150045), we included 1,666 patients who returned valid Willett food frequency questionnaires (FFQ) at chemotherapy initiation and derived WCRF/AICR scores accordingly (higher score suggesting higher adherence). The primary outcome was disease-free survival (time from FFQ completion to recurrence or death), and secondary outcomes were reduced relative dose intensity (RDI; <85% suggesting worse completion) and severe toxicities (grade ≥3 for any chemotherapy-related toxicity). To estimate the associations of WCRF/AICR scores (quartiles) with survival and chemotherapy outcomes, we conducted multivariable Cox proportional hazards regression for disease-free survival and multivariable logistic regression for reduced RDI and severe toxicities.

Results: Compared to those in the lowest quartile of the WCRF/AICR score, patients in the highest quartile had significantly better disease-free survival (hazard ratio: 0.75 [0.58, 0.98], P_{trend} = 0.02) and lower risk of reduced RDI (odds ratio [OR]: 0.74 [0.54, 1.00], P_{trend} = 0.03), but not for severe toxicities (OR: 1.24 [0.93, 1.67], P_{trend} = 0.11).

Conclusions: In patients with stage III colon cancer, higher adherence to WCRF/AICR recommendations was associated with better survival and chemotherapy completion, but not for severe toxicities.

Funding: https://acknowledgments.alliancefound.org

Table. Adjusted Associations of WCRF/AICR Recommendations with Survival and Chemotherapy Outcomes

Survival and Chemotherapy Outcomes	Q1	Q2	Q3	Q4	P_{trend}
Disease-free survival					
Number of events/at risk	133/393	134/492	74/323	114/458	
Hazard ratio	1.00	0.83 (0.65, 1.05)	0.68 (0.51, 0.91)	0.75 (0.58, 0.98)	0.02
Reduced RDI					
Number of events/at risk	156/393	191/492	131/323	208/458	
Odds ratio	1.00	0.97 (0.72, 1.30)	0.95 (0.69, 1.32)	0.74 (0.54, 1.00)	0.003
Severe toxicities					
Number of events/at risk	174/393	230/492	172/323	227/458	
Odds ratio	1.00	1.10 (0.83, 1.46)	1.41 (1.03, 1.93)	1.24 (0.93, 1.67)	0.11

#5039 Dietary patterns in young lung cancer: mutation-specific environmental associations.

Sarah D. Gorbatov[1], Marisa A. Bittoni[2], Anna H. Wu[3], Allison Harper[4], Kotait Virginia[4], Narjust Florez[5], Barbara J. Gitlitz[3], Jorge J. Nieva[3]

[1]California Northstate College of Medicine, Elk Grove, CA,[2]The Ohio State University, Columbus, OH,[3]Keck School of Medicine, University of Southern California, Los Angeles, CA,[4]Addario Lung Cancer Medical Institute, San Carlos, CA,[5]Dana-Farber Cancer Institute, Boston, MA

Following peak tobacco incidence in the mid-1980's there has been a large reduction in lung cancer incidence among men that has not been seen among women. Lung cancer at a young age is now more common among women than men, reversing a decades long pattern. We sought to characterize environmental exposures among young lung cancer patients to understand potential drivers of this change in the epidemiologic profile of young lung cancer patients. We analyzed 187 patients (157 females, 84%) from the Epidemiology of Young Lung Cancer (YLC) study (ClinicalTrials.gov identifier: NCT04640259) using mutation-based grouping by shared biological mechanisms: EGFR Pathway (EGFR+ERBB2), Fusion Positive (ALK+ROS1+RET+NTRK), and Other/Mixed Mutations (including MET exon 14 skipping, TP53, KRAS, BRAF, and additional alterations). Of these, 166 patients (138 females, 83.1%) completed validated food frequency questionnaires. Dietary quality was assessed using the Healthy Eating Index-2015 (HEI-2015) and compared to U.S. reference values from NHANES. Dietary categories with elevated contaminant residue potential were identified using published literature. Statistical comparisons employed one-sample t-tests against reference means and chi-square tests for categorical variables. The EGFR groups and ALK groups had tobacco use history in 32.8% and 13.4% of patients respectively. All groups had similarly high levels of oral contraceptive exposure among women (75-100%). Dietary analysis revealed that EGFR Pathway, Fusion Positive, and Other/Mixed Mutations patients demonstrated HEI-2015 scores (out of 100) of 64.9 ± 10.7, 65.5 ± 9.8, and 63.5 ± 9.5 respectively, compared with the US reference of 58. YLC women demonstrated higher dietary quality scores than men (65.6 ± 9.7 vs. 61.8 ± 11.3), both exceeded U.S. reference values of 60 for females and 56 for males. These YLC patients also consumed more foods from dietary categories associated with elevated contaminant exposure potential, as reflected by higher HEI-2015 component scores (out of 5) for total vegetables (4.2 vs. 3.5), fruits (3.3 vs. 2.5), and whole grains (3.9 vs. 2.6). YLC patients have a diet pattern of higher diet quality, with higher exposure to whole fruits, vegetables and whole grains. While these food groups are presumed to have good health benefits, there is an emerging, under-appreciated literature that produce based whole foods often contain high pesticide/herbicide contaminants. Further investigation of the role of pesticide contaminated fruits/vegetables/whole grains is timely to assess its role, if any, in the changing lung cancer prevalence over the last 4 decades.

#5040 Dietary advanced glycation end-products and risks of lung cancer and chronic respiratory diseases.

Ailing Qin[1], Fubin Liu[1], Yu Peng[1], Peng Wang[1], Changyu Si[1], Xixuan Wang[1], Jianxiao Gong[1], Huijun Zhou[1], Jiale Gu[1], Ming Zhang[2], **Fangfang Song**[1]

[1]Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China,[2]Shenzhen Prevention and Treatment Center for Occupational Diseases, Shenzhen, China

Background: Advanced glycation end-products (AGEs) can promote inflammation and oxidative stress, and are involved in the onset of various chronic diseases. Diet has been identified as a major source of exogenous AGEs. However, epidemiological evidence regarding the role of dietary AGEs in respiratory-related diseases remains scarce.
Methods: We included 153,897 participants from the UK Biobank, for whom food consumption information was collected via 24-hour dietary questionnaires. We estimated the daily intakes of total AGEs comprising N^{ε}-(carboxymethyl)-lysine (CML), N^{ε}-(1-carboxyethyl)-lysine (CEL), and N^{δ}-(5-hydro-5-methyl-4-imidazolon-2-yl)-ornithine (MG-H1), and categorized them into 17 food groups. Multivariable Cox proportional hazards models were used to estimate the hazards ratios (HRs) and 95% confidence intervals (CIs) of total and different food-derived AGEs with lung cancer and chronic respiratory diseases.
Results: After a median follow-up of 10.57 and 10.81 years, 1,073 cases of lung cancer and 19,584 cases of chronic respiratory disease were ascertained, respectively. Higher intakes of total AGEs, CML, CEL, and MG-H1 were associated with lower risks of lung cancer (mainly lung adenocarcinoma, $HRs_{Q5\ vs.\ Q1}$: 0.60-0.72) and chronic respiratory diseases (asthma, COPD, IPF, and pneumonia, $HRs_{Q5\ vs.\ Q1}$: 0.67-0.91). Additionally, meats-derived AGEs were related to an increased lung cancer risk ($HR_{Q5\ vs.\ Q1}$ =1.26, 95% CI: 1.04-1.53), whereas a reduced risk of lung cancer was associated with AGEs from nuts ($HR_{Q5\ vs.\ Q1}$=0.69, 95% CI: 0.59-0.81). Beverages-, meats-, potatoes-, and sweets-derived AGEs increased the risk of chronic respiratory diseases by 4%~10% (P_{trend} <0.05), while increased intakes of AGEs from cereals, vegetables and fruits, nuts and most other foods presented a protective trend against chronic respiratory diseases (P_{trend} <0.05).
Conclusions: There existed an inverse association of dietary AGEs exposure with lung cancer and chronic respiratory diseases. The different role of AGEs by diverse food sources needs to be emphasized when assessing their impacts on health outcomes.

#5041 Recruiting men who smoke for lung cancer risk research: Lessons learned using the electronic health record and community recruitment strategies.

Trista A. Beard, Diana L. Morales, Kelsie Campbell, Alexandra L. Lindgren, Chanita Hughes Halbert

Population and Public Health Sciences, Keck School of Medicine of USC, Los Angeles, CA

Introduction: Electronic Health Records (EHRs) are broadly used for research recruitment; however, reported social histories such as smoking status are inconsistently reported, incomplete, or inaccurate. The goal of this review is to analyze lessons learned in recruiting men for a stress reactivity study and compare various recruitment yields across EHR versus community strategies.
Methods: In a large Los Angeles tertiary health system, we conducted two EHR driven outreach waves from January 2024-June 2025 targeting African American/Black and non-Hispanic White men aged 21-75. The first wave utilized a natural language processing (NLP) query of a combination of notes, smoking-related terms, and smoking-related health history. The second wave manually queried discrete social history fields that recorded tobacco use. Recruitment from the first two waves was standardized, with potential participants contacted via multiple text, phone calls, and email attempts. Parallel community recruitment used targeted social media advertisements linked to a REDCap survey screener, plus recontact of a prior smoking cohort who consented to future studies. Primary measured outcomes were the consent rate, contact rate, and proportion misclassified as smokers (those who were identified via EHR as smokers but reported being “never-users”).
Results: In EHR wave 1 (NLP wave), 579 participants were approached, with 171 (29%) reached and 16 consented (2.8%). Among those who declined, 77 (49.6%) reported having a never-smoking history. EHR wave 2 (discrete fields) had more participants (1,374 patients): 141 (10.2%) were reached, and 16 (1.2%) consented to join the study. Community ads screened 1,488 potential participants, 404 were eligible (27.2%) and 110 consented to participate in study activities (27.2%).
Conclusions: EHR recruitment alone, particularly when NLP driven, was demonstrated to misclassify presumed smokers and yielded low consent rates. Wave 2 (discrete field of social history) yielded improvement in specificity but not engagement. Social media targeted outreach generated the most positive recruitment activity; however, this requires phone verification to ensure individual authenticity. Multimodal recruitment, coupled with standardized, longitudinal EHR capture of smoking intensity (in pack-years) and history is essential for representative and accurate enrollment and improving lung cancer screening referral uptake.

#5042 Attributable cancer in Asia: A heterogeneous picture.

Monireh Sadat Seyyedsalehi[1], **Paolo Boffetta**[2]

[1]University of Bologna, Bologna, Italy,[2]Stony Brook University, Stony Brook, NY

Published estimates of cancer burden attributable to modifiable factors in Asia are not comparable due to heterogeneous methodologies. A comprehensive analysis is needed to characterize regional variations and inform prevention strategies. We estimated population attributable fractions (PAFs) for major avoidable cancer risk factors across Asian countries grouped into West Asia, South Asia, South-East Asia, Central Asia, and selected East Asian countries (China, Mongolia and North Korea; Japan and South Korea). Data sources included region-specific exposure estimates and established relative risks from international evaluations. Risk factors analyzed included tobacco use, alcohol consumption, infections, dietary factors, occupational factors, and excess body weight. PAFs were computed separately for individual risk factors and cancer types. Substantial heterogeneity was observed across Asia in the contribution of modifiable risk factors to cancer burden (table 1). Tobacco, infections, and alcohol were consistently among the leading contributors, although their ranking varied by region. Diet and excess body weight contributed substantially to several countries, with marked regional differences. Overall, PAFs for many risk factors were higher than those reported in Europe and the Americas. The distribution of cancer types with the highest attributable fractions differed across regions, reflecting variations in exposure patterns and baseline incidence. The burden of cancer attributable to modifiable factors in Asia is substantial yet highly heterogeneous across regions. Improving the availability and quality of exposure data is needed for more accurate assessments. Expansion of comparable, methodologically harmonized PAF estimation across additional Asian countries will strengthen regional cancer prevention strategies. Future work should incorporate temporal exposure trends and broaden the range of risk factors evaluated.

Table 1. PAFs expressed as percentages, for major modifiable cancer risk factors referring to all cancers combined in Asia.

Risk Factor	Gender	West	Center	South	Southeast	China+ North Korea+ Mongolia	Japan+ South Korea
All factors in the analysis	Both	30.82	40.54	36.85	38.29	42.44	40.55
All factors in the analysis	Male	35.95	48.15	43.25	47.09	55.89	45.87
All factors in the analysis	Female	24.45	36.07	34.34	31.78	30.85	28.98
Diet *	Both	8.55	12.07	6.14	9.78	11.12	7.93

**Including Helicobacter pylori, Hepatitis B virus, Hepatitis C virus, Human Papillomavirus virus

#5043 AI-generated pictorial alcohol warnings strongly increase motivation to reduce drinking through enhanced attention, learning, and emotional processing: A mediation analysis.

Taghrid Asfar[1], Frank J. Penedo[2], Olusanya Joshua Oluwole[1], Eric Brown[1], Erin N. Kobetz[3], Carmen Calfa[4]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]University of Miami, Miami, FL,[3]Assistant Professor, Dept. of Epidem. & Pub. Health, University of Miami, Miller School of Medicine, Miami, FL,[4]Univ. of Miami Sylvester Comprehensive Cancer Ctr., Plantation, FL

Background: Alcohol is the 3rd leading cause of cancer in the US, linked to seven types, but only 30% of Americans are aware. Health warning messages can effectively communicate this risk, though the mechanism remains unclear.
Objective: This study examined if AI-generated pictorial messages (graphic, neutral) surpass text messages and explored mediators affecting motivation to reduce alcohol use.
Methods: In March 2025, a national online crossover experiment with 596 U.S. adult alcohol users (49.3% female; aged 21 +) evaluated 8 alcohol-cancer risk messages (4 general, 4 cancer-specific), each at 3 intensities: text, neutral pictorial, and graphic pictorial (n = 24). Each participant viewed two randomly assigned messages out of the 8, each at 3 intensities (n = 6), in a counterbalanced order. The primary outcome was motivation to reduce alcohol in the next 30 days. Mediators were attention, perceived learning, believability, fear, and avoidance. We used multilevel structural equation modeling to estimate parallel and serial mediation pathways, comparing graphic vs. text, neutral vs. text, and graphic vs. neutral, while adjusting for age, sex, alcohol level consumption (moderate, heavy), alcohol social norms, and message order and specificity (general vs. cancer-specific).
Results: Graphic and neutral pictorials drew more attention, perceived learning, believability, and fear than text messages ($p<0.01$ for all). Graphic pictorials also increased avoidance relative to both neutral and text messages. In parallel mediation models, graphic pictorials had a significant total effect on motivation ($\beta = 0.91$, SE = 0.12), with 93.6% of the effect mediated through indirect paths, primarily through attention (47.2%) and fear (24.3%). Neutral pictorials also increased motivation compared to text messages ($\beta= 0.47$, SE= 0.10), with 99.3% of the effect mediated, mainly by attention (56.8%) and believability (16.7%). Graphic pictorials outperformed neutral ones ($\beta= 0.439$, SE = 0.092, $p < 0.001$ for all), with 87.6% of the effect mediated mainly through attention and fear. Serial mediation analyses confirmed attention as the primary upstream driver. For graphic vs. text comparisons, sequential paths through attention and believability (31.8%), attention and fear (22.9%), and attention and learning (17.6%) significantly predicted motivation. Similar patterns were observed in comparing neutral vs. text and graphic vs. neutral. Across all models, the direct effects of message intensity on motivation were not significant.
Conclusions: AI-generated pictorial alcohol warnings, particularly graphics, substantially increase motivation to reduce alcohol consumption by enhancing attention, fear, perceived learning, and believability. These findings highlight AI's role in improving alcohol-cancer risk communication.

#5044 Changes in providers' delivery of cigarette smoking interventions for cancer prevention after the implementation of a tobacco-free workplace program in healthcare centers serving rural and medically underserved areas in Texas.

Ammar D. Siddiqi[1], Nikhil K. Patel[2], Maggie Britton[3], Tzuan A. Chen[4], Isabel Martinez Leal[3], Teresa Williams[5], Kathleen Casey[5], Lorraine R. Reitzel[3]

[1]University of California, San Francisco, San Francisco, CA,[2]Vanderbilt University, Nashville, TN,[3]UT MD Anderson Cancer Center, Houston, TX,[4]University of Houston, Houston, TX,[5]Integral Care, Austin, TX

Cigarette smoking is elevated in rural and medically underserved areas of the US, contributing to greater tobacco-related cancer morbidity and mortality among residents relative to their urban counterparts. Consequently, there is an opportunity for cancer prevention via use of evidence-based interventions for cigarette smoking in settings where rural and medically underserved adults receive care. The implementation of tobacco-free workplace programs in urban healthcare centers has improved providers' intervention delivery for cigarette use; however, evidence regarding their effectiveness in centers serving rural and medically underserved populations is limited and cannot be assumed, given potentially unique barriers to program adoption. This work seeks to redress this gap by examining changes in providers' delivery of the 5As, an evidence-based intervention for cigarette use, from pre- to post-implementation of a tobacco-free workplace program in centers serving these areas. Healthcare centers (N=9 centers with 17 clinics), together serving 79,266 unique patients annually across 81 rural/partially rural counties and 63 counties with medically underserved areas in Texas, implemented a multi-component tobacco-free workplace program between 2021 and 2025. The program included provider training on evidence-based strategies to address patients' cigarette use with an emphasis on the 5As: Ask about patients' cigarette use, Advise them to quit, Assess their interest in quitting, Assist them to quit, and Arrange a follow-up meeting to support the quit attempt. Providers completed an anonymous e-survey before (N=184) and after (N=126) program implementation, reporting their use of the 5As in the past month. Linear mixed models were used to assess differences between pre- and post-implementation, accounting for nesting of healthcare providers within center. Providers demonstrated clinically meaningful improvements in cigarette intervention provision. From pre- to post-implementation, providers Asked a greater proportion of patients about their cigarette use (57.96% to 72.17%; p=0.08). For patients who smoked, they were significantly more likely to Advise them to quit (45.40% to 68.64%; p=0.01), Assess their interest in quitting (38.86% to 63.44%; p=0.01), Assist in a quit attempt (22.97% to 50.60%; p<0.01), and Arrange a follow-up (17.76% to 39.84%; p<0.01). Results support the promise of tobacco-free workplace programs to address tobacco-related cancer disparities in rural and medically underserved areas by improving providers' use of evidence-based cigarette screening and intervention practices. Future work should examine implementation strategies that support the long-term sustainability of such interventions in this setting.

#5045 Patterns of tobacco use, cessation interventions, and lung cancer screening in rural vs. urban areas over time; a 10-year retrospective cohort study.

Brianna Tranby[1], Paul A. Decker[1], Jiang Ruoxiang[1], David Midthun[1], Lori C. Sakoda[2], Melinda C. Aldrich[3], Debra Friedman[3], Adoma Manful[3], Oindrila Bhattacharyya[4], Christi Patten[1], Chyke A. Doubeni[4]

[1]Mayo Clinic, Rochester, MN,[2]Kaiser Permanente, Oakland, CA,[3]Vanderbilt University Medical Center, Nashville, TN,[4]The Ohio State University Wexner Medical Center, Columbus, OH

Introduction: Lung cancer rates differ across rural and urban areas, but few studies have evaluated rural-urban differences across the risk-screening continuum. We examined smoking, cessation interventions, and lung cancer screening patterns across the rural-urban continuum in a geographically defined area over 10 years.
Materials and Methods: A retrospective cohort study (2014-2023) was conducted using clinical data from the Rochester Epidemiology Project, derived from healthcare encounters in a 27-county region of the midwestern United States. Patients ages 40-80 were included. We used Rural-Urban Commuting Area codes to assign residence as urban, rural, or highly rural. We examined yearly smoking prevalence, cessation intervention (pharmacotherapy, counseling), and low-dose computed tomography (LDCT) lung cancer screening.
Results: Over the 10-year study period, the sample size ranged from 305,530 to 340,411 people annually with 36-38% urban, 56-57% rural, and 6-7% highly rural. Current smoking prevalence declined from 14 to 12% over the 10-year period (range=12-16%; p=0.06) and was consistently lower in urban areas (range=10-14%) than rural (range=12-17.0%) and highly rural areas (range=12-18%; p=<0.001). Among individuals who currently smoked with no history of lung cancer, yearly smoking cessation intervention ranged from 16% to 23%, increasing over the 10-year period (p=<0.001). Cessation medication (varenicline, bupropion, or nicotine replacement) prescription consistently increased overall over time but remained higher in urban than rural and highly rural areas (p=<0.001). Cessation counseling rates also increased overall over time and were similar between urban and rural areas and lower in highly rural areas (p=<0.001). Among people who had ever-smoked aged 50-80 years with no diagnosis of lung cancer, LDCT screening increased from 0.0% to 3.1% over the study period. Increases were higher in urban areas (0.0-3.6%) and similar in rural and highly rural areas (0.0-2.8% and 0.0-2.9%, respectively; p=<0.001). Among people who currently smoked, LDCT screening also increased over the study period (0.0-6.4%), with higher increases in urban (0.1-8.0%) than rural (0.0-5.7%) or highly rural (0.1-6.1%) areas (p=<0.001). After the new screening guidelines in 2021, rates in all areas increased year-on-year.
Conclusion: In this cohort, we found that smoking prevalence, cessation interventions, and lung cancer screening improved from 2014-2023 across the rural-urban continuum. Unfortunately, smoking prevalence remained higher and cessation interventions and screening rates lower in rural compared to urban areas. The persistent patterns underscore the need for strategies to overcome barriers for rural residents and improve lung cancer prevention and early detection in all areas.

#5046 Integrating omics data unravels potential mechanisms linking diet-related inflammation and colorectal cancer risk.

Emmanouil Bouras[1], Jun Li[2], Franzel J. B. Van Duijnhoven[3], Ulrike Peters[4], Edward L. Giovannucci[2], Konstantinos K. Tsilidis[1], Marc J. Gunter[1]

[1]Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, London, United Kingdom,[2]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA,[3]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands,[4]Fred Hutchinson Cancer Center, Seattle, WA

Although diet-related inflammation has been linked to colorectal cancer (CRC) risk, the biological mechanisms underlying this association remain unclear. We conducted integrative analyses of diet, clinical, and multi-omics data in a prospective cohort to investigate potential molecular pathways linking diet-related inflammation to CRC risk. We used the Energy-adjusted Dietary Inflammatory Index (EDII) to proxy diet-related inflammation in 203,770 UK Biobank participants with at least one 24-hour dietary recall. The index has been extensively validated in previous studies, and we further examined its associations with inflammatory proteins interleukin-6 (IL6), interleukin-18 (IL18), TNF receptor superfamily member 1B (TNFRSF1B), and adiponectin in our study, adjusting for age, sex, BMI, smoking, and non-steroidal anti-inflammatory drug use. We derived metabolic (mEDII) and proteomic (pEDII) signatures of the EDII using stability selection and cross-validated elastic net modelling, and examined their associations with CRC risk using regression models, adjusting for the aforementioned confounders. Genetic determinants of the signatures were identified through multi-trait GWAS analyses, and signals were prioritized via Ensembl's Variant Effect Predictor. We explored potentially shared variants using colocalization analyses, integrating GWAS data for mEDII and pEDII, gene expression in colon and visceral fat tissue (GTEx v8), and CRC risk (185,616 participants, including 78,473 CRC cases). The EDII showed positive associations with plasma IL-6 (beta per SD increase = 0.039; 95%CI: 0.025, 0.052), IL-18 (0.060; 0.046, 0.075), and TNFRSF1B (0.057; 0.043, 0.072), and an inverse association with adiponectin (-0.025; -0.037, -0.013). The mEDII comprised 26 metabolites and the pEDII comprised 21 proteins, each explaining approximately 11.5% of EDII variance. Over a median follow-up of 9.8 years, 1,427 CRC cases occurred (42.9% in women), of which 934 (65.4%) in the colon. There was a suggestive positive association between EDII and colon cancer risk in men (OR per SD increase = 1.11; 95%CI: 1.01, 1.22). The mEDII was positively associated with colon cancer risk across both sexes, independently of EDII (OR per SD increase = 1.14; 95%CI: 1.01, 1.29). GWAS identified 19 loci for mEDII and pEDII, with potential functional consequences for 102 genes. We found evidence for a shared genetic basis across both signatures, CRC risk, and gene expression in colon tissue [in the Fatty Acid Desaturase 1 (*FADS1*), Ras Interacting Protein 1 (*RASIP1*), and MEF2 Activating Motif and SAP Domain Containing Transcriptional Regulator (*MAMSTR*) regions], and in visceral fat [in the *FADS1* and Transmembrane Protein 258 (*TMEM258*) regions]. Diet-related inflammation may contribute to CRC risk through mechanisms involving lipid metabolism, endothelial function, and intestinal inflammation.

#5047 Associations of self-reported sleep duration and sleep quality with cancer risk: A pooled analysis of 6 prospective cohorts.

Charlie Zhong[1], Pedro Saint-Maurice[2], Rashmi Sinha[3], Laura Beane Freeman[3], Wei Zheng[4], Xiao-Ou Shu[4], Garnet L. Anderson[5], Trang VoPham[5], Charles E. Matthews[3], Alpa V. Patel[1], Erika Rees-Punia[1], Steven C. Moore[3]

[1]American Cancer Society, Atlanta, GA,[2]Champalimaud Foundation, Lisbon, Portugal,[3]Division of Cancer Epidemiology & Genetics, National Cancer Institute, Bethesda, MD,[4]Vanderbilt University Medical Center, Nashville, TN,[5]Fred Hutchinson Cancer Center, Seattle, WA

A third of adults report poor sleep health which may be from short sleep (<7 hours/day), long sleep (>9 hours/day), or poor quality of sleep. Sleep health involves getting the right amount of restful sleep each day and poor sleep health is associated with increased morbidity and mortality, including certain types of cancer. There is evidence linking more common cancers, such as breast, colon, and lung, to both short and long sleep duration, but less is known about sleep quality and other cancer types. We sought to evaluate the association between sleep duration and quality with risk from 29 types of cancer. We conducted a pooled random-effects meta-analysis of 6 prospective United States and Asian cohorts in the National Cancer Institute Cohort Consortium with self-reported sleep duration and quality. Cox regression was used to calculate hazard ratios (HR) and 95% confidence intervals (95% CI) for associations with incidence of overall cancer as well as 29 types of cancer; adjusted for age, sex, race/ethnicity, education, body mass index, alcohol consumption, and smoking status. Sleep duration (hours) was modeled as a 5:2 weekday:weekend weighted average and quality was based on reported trouble sleeping or restless sleep (<1 night/week or rarely/never vs 1+ nights/week). A total of 643,860 participants (median [range] age, 62 [34-99] years, 58% female) were included in the analysis. Over a median of 12 years of follow-up, there were 138,606 cancer diagnoses. Compared to National Sleep Foundation's recommended sleep duration of 7-9 hours/day in adults, short sleep duration was associated with reduced risk of overall cancers (HR 0.98; 95% CI 0.97, 0.99), as well as breast (n = 24,386; HR 0.95; 95% CI 0.92, 0.97) and prostate cancer (n = 24,593; HR 0.97; 95% CI 0.94, 1.00); and increased risk of small intestine (n = 510; HR 1.26; 95% CI 1.05, 1.52) and head and neck cancers (n = 3,433; HR 1.09; 95% CI 1.02, 1.18). Long sleep duration was associated with increased risk of head and neck cancers (HR 1.19; 95% CI 1.03, 1.39). Restless sleep was associated with decreased risk of breast cancer (n = 12,515; HR 0.95; 95% CI 0.90, 0.99) and increased risk of hepatocellular carcinoma (n = 352; HR 1.31; 95% CI 1.03, 1.67). We did not observe any associations with trouble sleeping. Short sleep duration appeared to be protective against overall cancer risk, potentially due to the association with lower risks of breast and prostate cancer. However, short sleep was associated with higher risks of small intestine and head and neck cancers. Long sleep duration was also associated with increased risk of head and neck cancers. While we observed associations between restless sleep and breast cancer and hepatocellular carcinoma, only 2 cohorts asked about restless sleep. These results highlight the complex relationship between sleep and cancer risk and the importance of assessing individual cancer types.

#5048 The association of sleep duration and quality with obesity-related cancers: Results from the health examinees study.

Sinyoung Cho[1], Sukhong Min[2], Hyobin Lee[2], So-Yoon Lee[2], Daehee Kang[2]

[1]Seoul National University Hospital, Seoul, Korea, Republic of,[2]Seoul National University College of Medicine, Seoul, Korea, Republic of

This study aims to investigate the associations of self-reported sleep duration and quality with obesity-related cancer risk in a large-scale Korean population. This prospective cohort study utilized data from the Health Examinees-Gem (HEXA-G) cohort, comprising adults aged ≥40 years. A total of 126,866 participants who provided information on both sleep duration and quality were included in the present study. Sleep duration was self-reported at baseline and categorized into <6 hours, 6-<8 hours, and ≥8 hours. Sleep quality was assessed using four independent questions, including nonrestorative sleep, daytime fatigue, difficulty in initiating sleep, and nighttime anxiety. Cancer cases were identified through national cancer registration data from the Korea Central Cancer Registry of the Korea National Cancer Center. This study adopted obesity-related cancers, defined by the International Agency for Research on Cancer. Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs), with follow-up beginning two years after the age at enrollment and continuing until the first cancer diagnosis, loss to follow-up, or the end of the study (December 31, 2018). During the median follow-up period of 7.3 years (range, years), 7,284 incident all-site cancer cases, including 4,113 obesity-related cancer cases, were documented. Long sleep duration (≥8 h) was significantly associated with obesity-related cancer (1.08; 1.01-1.16), marginally associated with all-site cancer (1.05; 1.00-1.11), and not associated with non-obesity-related cancer. Compared with participants reporting each sleep quality component “not at all,” those reporting nonrestorative sleep “sometimes” (1.08; 1.01-1.16) or “most of the time” (1.11; 1.01-1.22) showed higher obesity-related cancer risk; those reporting initiation difficulty “sometimes” was associated with obesity-related cancer risk (1.08; 1.01-1.16), whereas daytime fatigue and nighttime anxiety showed no significant associations. Reporting sleep ≥8 h with nonrestorative sleep (“sometimes”) increased all-site cancer (1.10; 1.01-1.20) and obesity-related cancer risk (1.24; 1.11-1.39). Reporting sleep ≥8 h with daytime fatigue increased all-site cancer (1.18; 1.06-1.31) and obesity-related cancer risk (1.19; 1.04-1.37). Reporting sleep ≥8 h with initiation difficulty increased all-site cancer (1.16; 1.04-1.30) and obesity-related cancer risk (1.26; 1.13-1.41). Long sleep duration was significantly associated with obesity-related cancer risk. Long sleep duration combined with nonrestorative sleep, daytime fatigue, initiation difficulties, or nighttime anxiety had positive associations with all-site and obesity-related cancer risks, but not with non-obesity-related cancers.

#5049 Prospective evaluation of dietary intake of essential metals and pancreatic cancer risk: The Multiethnic Cohort Study.

Yi-Chuan Yu[1], Sihao Han[2], Adelynn Paik[2], Song-Yi Park[3], Shannon Sullivan[4], Eric Kawaguchi[5], Loic Le Marchand[6], Lynne R. Wilkens[3], Christopher A. Haiman[7], Veronica Wendy Setiawan[2], Brian Huang[2]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[3]Population Sciences in the Pacific Program, University of Hawai'i Cancer Center, Honolulu, HI,[4]Department of Laboratory Medicine and Pathology, University of Minnesota Medical School, Minneapolis, MN,[5]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, CA,[6]University of Hawai'i Cancer Center, Honolulu, HI,[7]Co-Director, USC Genomics Ctr., USC Norris Comprehensive Cancer Center, Los Angeles, CA

Background: Evidence suggests that dietary intake levels of essential metals are linked to the development of or protection against pancreatic adenocarcinoma (PDAC). However, results from existing epidemiological studies remain inconsistent, often limited by retrospective designs and recall bias. We aim to prospectively investigate the relationship between dietary intake of essential metals and the risk of PDAC in a large, racially and ethnically diverse U.S. population.

Methods: Data were from the Multiethnic Cohort Study, a large population-based prospective cohort study established between 1993 and 1996 in Los Angeles and Hawaii, comprised of participants from five main racial and ethnic groups (African American, Japanese American, Latino, Native Hawaiian, and White). Incident PDAC cases were identified through linkage with the state SEER cancer registries. Dietary intake densities (intake per 1,000 kcal per day) of seven essential metals (copper, selenium, zinc, manganese, iron, calcium, and magnesium) were estimated from a baseline quantitative food frequency questionnaire and modeled as quartiles. Participants were excluded if they were of other racial/ethnic groups, had implausible dietary data, a prior diagnosis of PDAC, or inconsistent/incomplete follow-up time. Cox proportional hazards regression models (with age since cohort entry as time metric) were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for PDAC risk associated with intake of each essential metal , adjusting for age, sex, race/ethnicity, body mass index, history of diabetes, alcohol use, smoking status, education, family history of PDAC, and total daily energy intake.

Results: After an average follow-up of 20.2 years, 2,119 of 195,061 at-risk participants developed PDAC. Compared with the lowest quartile (5.7 - 44.9 mcg/1,000 kcal/day), participants in the highest quartile (58.0 - 131.9 mcg/1,000 kcal/day) of selenium intake had a 17% higher risk of developing PDAC (HR=1.17, 95% CI: 1.03-1.34, P-trend=0.048). No evidence of heterogeneity across sex and race/ethnicity was observed (all P's-heterogeneity>0.05); however associations appeared stronger for White (HR=1.27, 95% CI: 0.95-1.70), African American (HR=1.29, 95% CI: 0.96-1.73) and Latino (HR=1.32, 95% CI: 0.96-1.80) participants. No significant associations were observed for dietary intakes of copper, zinc, manganese, iron, calcium, and magnesium.

Conclusion: Elevated selenium dietary intake is associated with an increased risk of PDAC in this large, racially and ethnically diverse U.S. population. Further large-scale prospective studies are warranted to confirm this association and elucidate the underlying biological mechanisms .

#5050 Healthier pre-diagnosis lifestyle and long-term survival in patients after diagnosis of colorectal cancer: Evidence from the Singapore Chinese Health Study.

Peh Joo Ho[1], Aizhen Jin[2], Jian-Min Yuan[3], Woon-Puay Koh[2], Adeline L. H. Seow[2]

[1]Saw Swee Hock School of Public Health, National University of Singapore (NUS), Singapore, Singapore,[2]National University of Singapore (NUS), Singapore, Singapore,[3]University of Pittsburgh, Pittsburgh, PA

Purpose To quantify survival differences between colorectal cancer (CRC) patients with healthier and those with less healthy pre-diagnosis lifestyles using restricted mean survival time (RMST) at 5 and 10 years, and to assess which lifestyle components contribute to these differences.

Methods Incident CRC cases (n = 2124) were identified from the Singapore Chinese Health Study, a prospective cohort of 63 257 adults enrolled in 1993-1998. Cancer status and cause of death were obtained via linkage with the National Disease Registry through 31 December 2015. A pre-diagnosis lifestyle score (0-7) incorporated BMI and smoking, sleep duration, diet, and weekly physical activity at baseline. RMST differences comparing less healthy (scores 0-3) versus healthier (4-7) lifestyles were estimated at 5- and 10-years post-diagnosis, adjusted for CRC stage (early, late) and age at diagnosis, sex, education attainment, and the interval between lifestyle assessment and diagnosis.

Results Over a median follow-up of 4.8 years (IQR 1.2-11.8) from CRC diagnosis, 1557 deaths occurred, including 1103 CRC-specific deaths. Late-stage diagnosis was associated with shorter survival than early stage by 1.53 years (95% CI 1.35 to 1.72) at 5 years and 3.33 years (2.93 to 3.72) at 10 years. The median interval between lifestyle assessment and diagnosis was 12.2 years (IQR 6.9 to 16.7). RMST for all-cause deaths was significantly improved by a healthier lifestyle but results for CRC-specific deaths were mixed. For all-cause mortality, adjusted RMST differences (less healthy - healthier) were −0.15 (95% CI −0.32 to 0.01) at 5 years and −0.37 (−0.71 to −0.02) at 10 years. CRC-specific mortality: At 5 years, the adjusted RMST difference (less healthy – healthier) was −0.15 years (−0.32 to 0.02), and at 10 years it was −0.34 years (−0.71 to 0.03). Among patients diagnosed at age ≤70 years, healthier pre-diagnosis lifestyles were associated with modestly longer survival, with a 10-year CRC-specific RMST gain of 0.58 years (0.03 to 1.13), while other estimates were borderline or not significant. Lifestyle components associated with improved CRC-specific survival included diet (lower vs higher AHEI category: 5-year RMST difference −0.20 (−0.38 to −0.02); 10-year −0.46 (−0.84 to −0.08)) and weekly physical activity (no vs yes: 5-year −0.19 (−0.37 to −0.02); 10-year −0.42 (−0.78 to −0.06)). Similar results were obtained for all-cause death. Smoking and sleep duration were not significantly associated with survival.

Conclusions A healthier pre-diagnosis lifestyle was associated with improved long-term survival in CRC patients. Short-term differences were modest after accounting for CRC stage at diagnosis, underscoring the importance of early detection. Having maintained healthy behaviors before diagnosis may favorably influence long-term outcomes among CRC patients.

#5051 A multi-center hospital-based case-control study of lymphoid and myeloid neoplasms (AsiaLymph): Study design and initial findings for education, body mass index, and family history.

Qing Lan[1], Lauren M. Hurwitz[1], John K. Chan[2], Tai Hing Lam[3], Kexin Chen[4], Yok Lam Kwong[5], Xu Caigang[6], Brian CH Chiu[7], Raymond Liang[8], Ip Dennis[3], Wei Hu[1], Bryan Bassig[9], Mark Purdue[1], Jun Xu[3], Sarah Locke[1], Sophia S. Wang[10], James R. Cerhan[11], Sonja Berndt[1], Jonathan N. Hofmann[1], Jianxin Shi[1], Kai Yu[1], Shahinaz Gadalla[1], Lisa J. McReynolds[1], Rena Jones[1], Hongji Dai[4], Zhangyan Lyu[4], Lugui Qiu[12], Wei Liu[12], Huilai Zhang[13], Xianhuo Wang[13], Lindsay M. Morton[1], Stephen Chanock[1], Martha Linet[1], Melissa C. Friesen[1], Roel Vermeulen[14], Nathaniel Rothman[1]

[1]NCI Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[2]Queen Elizabeth Hospital, Hong Kong, Hong Kong,[3]School of Public Health, Li Ka Shing (LKS) Faculty of Medicine, University of Hong Kong, Hong Kong, Hong Kong,[4]Tianjin Medical University Cancer Institute and Hospital, Tianjin Medical University, Tianjin, China,[5]Queen Mary Hospital, Hong Kong, Hong Kong,[6]Department of Hematology, Hematology Research Laboratory, West China Hospital, Sichuan University, Chengdu, China,[7]Associate Professor, Dept. of Health Studies, University of Chicago, Chicago, IL,[8]Hong Kong Sanatorium & Hospital, Hong Kong, Hong Kong,[9]Saville Cancer Screening and Prevention Center, Inova Schar Cancer Institute, Inova Health System, Fairfax, VA,[10]City of Hope National Medical Center, Duarte, CA,[11]Mayo Clinic College of Medicine and Science, Rochester, MN,[12]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China,[13]Tianjin Medical University Cancer Institute and Hospital, Tianjin, China,[14]Utrecht University, Utrecht, Netherlands

Background: Epidemiologic and other studies have identified environmental, occupational, and genetic risk factors for lymphoid and myeloid malignancies, but most studies have been conducted in Western populations. Investigations in populations with differing exposure patterns, distributions of disease subtypes, and genetic architecture are needed to fully understand hematopoietic tumor etiology. **Methods:** We conducted a large, multicenter, hospital-based case-control study of lymphoid and myeloid neoplasms in East Asia (AsiaLymph), including 5,671 lymphoid cases, 1,879 myeloid cases, and 3,858 controls. Participants completed a computer-assisted personal interview and provided biospecimens. Cases underwent central pathology review and were coded into the WHO Classification. Herein, we describe the study methods in detail and report association results for education, body mass index, and family history.**Results:** Greater BMI at age 20 but not at age 40 was associated with odds of total lymphoid neoplasm (per 5 kg/m^2 increase: OR [95% CI]: 1.18 [1.09-1.27]), total myeloid neoplasm (OR [95% CI]: 1.17 [1.05-1.29]), and several subtypes. Greater educational attainment was associated with increased odds of total lymphoid neoplasm (for college vs. less than primary education: OR [95% CI]: 1.41 [1.21-1.65]) but not myeloid neoplasm (OR [95% CI]: 1.17 [0.95-1.45]; p-heterogeneity=0.02). There were also positive associations between family history of hematologic cancer in first degree relatives and odds of lymphoid neoplasm (OR [95% CI]: 1.53 [1.15-2.03]) and myeloid neoplasm (OR [95% CI]: 1.65 [1.11-2.44]) and specific subtypes. None of the evaluated risk factors were associated with NK/T-cell lymphoma, which supports a distinct etiology for this subtype. **Conclusion:** The AsiaLymph Study is one of the largest molecular epidemiology studies of both lymphoid and myeloid neoplasms with standardized World Health Organization classification of histopathologic subtypes and will serve as a valuable resource for etiologic investigations into risk factors for these malignancies.

#5052 A network approach using Gaussian graphical models to evaluate dietary patterns and colorectal cancer risk in the UK Biobank.

Jiyoung Hwang, Sooyoung Cho, Aesun Shin

Seoul National University, Seoul, Korea, Republic of

Background: Current research on the link between dietary patterns and colorectal cancer (CRC) has relied on methods that summarize intake without accounting for the structural dependencies among food groups. Gaussian graphical models (GGMs) derive dietary patterns by capturing how foods are consumed in relation to one another, offering a network-based view of overall eating behavior.
Objectives: We aimed to identify dietary patterns using GGMs and to examine their associations with incident CRC in the UK Biobank.
Methods: This prospective cohort study included 105,676 UK Biobank participants with 24-hour recall dietary data. Dietary patterns were identified using GGMs constructed from 43 food groups, and participants were classified into tertiles of each pattern score. Cox proportional hazards models were applied to estimate hazard ratios (HRs) and 95% confidence intervals (CIs), adjusting for demographic, lifestyle, and clinical factors.
Results: Over a median follow-up of 10.1 years, 1,026 cases of CRC were newly diagnosed. The network identified four dietary patterns consisting of different food groups. In sex-stratified analyses, the processed food and dessert pattern was associated with higher CRC risk in male, with the highest tertile showing increased risk (HR = 1.23; 95% CI: 1.00-1.50; *P*-trend = 0.048). In female, the balanced pattern was inversely associated with CRC, with the highest tertile showing lower risk (HR = 0.82; 95% CI: 0.60-0.93; *P*-trend = 0.041). No significant associations were observed for the other dietary patterns, including the protein-based and beverage patterns, in the total or sex-stratified analyses.
Conclusions: Network-based dietary patterns identified through GGMs showed different sex-specific associations with CRC risk. By addressing pairwise correlations between food variables while controlling for indirect effects from other foods, this approach captures dietary structures with greater specificity than traditional pattern methods. These results contribute to a clearer understanding of how sex-specific dietary patterns relate to CRC risk within existing epidemiologic evidence.

#5053 Comparison of machine learning-based dimensionality reduction methods for dietary patterns and their predictability of cancer risk in a large cohort study.

Hyobin Lee[1], Dongseok Heo[2], Sukhong Min[1], Sinyoung Cho[1], So-Yoon Lee[1], Ji-Yeob Choi[3], Bongwon Suh[4], Daehee Kang[1]

[1]Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Integrated Major in Innovative Medical Science, Seoul National University Graduate School, Seoul, Korea, Republic of,[3]Department of Biomedical Sciences, Seoul National University Graduate School, Seoul, Korea, Republic of,[4]Department of Intelligence and Information, Seoul National University, Seoul, Korea, Republic of

Background & Aims Dietary pattern analysis is essential in nutritional epidemiology, yet traditional clustering approaches may be limited by their inability to capture latent dietary structures. This study compared three dimensionality reduction techniques—Principal Component Analysis (PCA), Uniform Manifold Approximation and Projection (UMAP), and Autoencoders (AE)—for dietary pattern development, and further examined associations of AE-derived dietary patterns with cancer incidence in a large prospective cohort study.
Methods Data were obtained from 130,472 participants enrolled in the Health Examinees-Gem (HEXA-G) study (2004-2013), who completed a validated food frequency questionnaire. PCA, UMAP, and AE were each applied prior to k-means clustering. Cluster quality was assessed using silhouette coefficients, and variable contributions were evaluated using SHAP values. External validation was conducted by applying the HEXA-trained encoder to the Korean National Health and Nutrition Examination Survey (KNHANES). Cancer incidence was ascertained through linkage with the Korea Central Cancer Registry up to December 31, 2018. Multivariable Cox proportional hazards models estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for total and site-specific cancers, focusing on the seven most common cancers in Korea.
Results Without dimensionality reduction, the silhouette coefficient was 0.05; PCA rarely exceeded 0.2, UMAP reached ~0.4, and AE achieved >0.35, providing competitive cluster quality with the most balanced variable contributions. Ten dietary patterns were identified: Balanced, Selective, Rice, Bread, Vegetables, Dairy, Meat, Processed meat, Noodles, and Salty. External validation using KNHANES produced similar silhouette values (~0.36) and preserved centroid positions, confirming transferability. Over a median follow-up of 9.4 years, 7,390 cancer cases occurred. No significant associations were observed for total cancer; however, site-specific analyses revealed that the Processed meat pattern in men was associated with higher colorectal cancer risk (HR = 1.98, 95% CI: 1.12-3.49), and the Selective pattern with higher gastric cancer risk (HR = 1.32, 95% CI: 1.03-1.70) compared to the Balanced pattern. In women, the Bread pattern was associated with lower gastric cancer risk (HR = 0.53, 95% CI: 0.32-0.89).
Conclusion Among the dimensionality reduction techniques, AE achieved the most favorable balance of cluster quality and variable contribution balance, supporting its utility for developing dietary patterns. These findings demonstrate that machine learning-based dimensionality reduction methods, particularly AEs, can strengthen dietary pattern development and capture meaningful associations with cancer risk.

#5054 E-cigarette use among cancer survivors who are ineligible for lung cancer screening.

Priyanka N. Srinivasan[1], Eric Liu[1], Amrita Mukunda[1], Melinda Hsu[2], Hui Xie[3], Qian Wang[4]

[1]Case Western Reserve University School of Medicine, Cleveland, OH,[2]University Hospitals, Cleveland, OH,[3]University of Wisconsin-Milwaukee Zilber College of Public Health, Milwaukee, WI,[4]Seidman Cancer Center University Hospitals, Cleveland, OH

Significance: Cancer survivors are at higher risk of developing lung cancer than the general population due to shared risk factors (e.g. cigarette smoking), treatment (e.g. prior chest irritation) and genetic susceptibilities. Though it has been widely promoted as a smoking cessation tool, preclinical studies have suggested that e-cigarettes contain carcinogens similar to those found in combustible cigarettes. Approximately 15% of cancer survivors reported life-time e-cigarette use. As current lung cancer screening (LCS) criteria primarily focuses on age and combustible smoking history, individuals who are never- or light-smokers but who use e-cigarettes may be excluded from screening. We aim to assess prevalence of e-cigarette use among LCS-ineligible cancer survivors and compare it to their non-cancer survivor peers.

Methods: Data were extracted from Behavioral Risk Factor Surveillance System from 2022 to 2024. Individuals ineligible for LCS according to USPSTF 2021 guidelines (i.e. aged 50-80 years, smoked at least 20 pack years and quitted within past 15 years for former smokers) were included. Cancer survivors with history of lung cancer were excluded. Chi-square tests and multivariate logistic regressions were used to compare current e-cigarette use prevalence between cancer survivors and non-cancer survivors. All analyses were weighted. A p-value of <0.05 was considered statistically significant.

Results: 694,576 patients (342,841,347 weighted) were included, of which 10.9% were cancer survivors. The average age was 68 (61-74) and 60 (50-69) for cancer survivors and non-cancer survivors, respectively. Overall, 2.6% and 3.6% of cancer survivors and non-cancer survivors reported currently using e-cigarettes, respectively (p<0.001). After adjusting for age, sex, race/ethnicity, education, income, marital status and combustible smoking status, cancer survivors were more likely to be current e-cigarette users (aOR=1.10, 95%CI: 0.99-1.23) than non-cancer survivors. Among individuals aged 40-49 years, cancer survivors were 21% more likely to report currently using e-cigarettes than non-cancer survivors (9.3% vs 7.2%, p<0.001; aOR=1.21; 95%CI: 1.02-1.44). In addition, male cancer survivors (aOR=1.22; 95%CI: 1.01-1.46), and cancer survivors who never smoked combustible cigarettes (aOR=1.52; 95%CI: 1.13-2.05) were more likely to report currently using e-cigarettes.

Conclusion: Our results showed that among adults ineligible for LCS, cancer survivors were more likely to report currently using e-cigarettes, with the highest prevalence observed in younger individuals, men, and never-smokers. The findings are concerning as e-cigarette use may add to their pre-existing elevated risk profile. Future studies are needed to assess long-term risks of e-cigarette use in this population and to inform potential refinements to risk assessment and screening eligibility among cancer survivors.

#5055 The association of allostatic load (AL) with diagnosis of monoclonal gammopathy of undetermined significance (MGUS) and progression to multiple myeloma (MM).

Mark Aaron Fiala, Qingyuan Tan, Mei Wang, Su-Hsin Chang

Washington Univeristy School of Medicine, St. Louis, MO

Introduction: AL is a measure of the physiological burden of chronic stress. There is no direct measurement; rather, indices are created based on available biomarkers for endocrine dysfunction. This study aimed to determine whether increased AL was associated with a higher odds of having MGUS and if AL was associated with an increased risk of progression from MGUS to MM in the nationwide Veterans Health Administration (VHA).

Methods: Diagnosis of MGUS from 2003-2024 and subsequent progression to MM were confirmed by a published natural language processing algorithm (doi 10.1200/CCI.23.00081). AL was calculated using six biomarkers: body mass index (BMI), alkaline phosphatase (ALP), albumin (ALB), creatinine (CR), creatinine clearance (CRCL), and white blood count (WBC). For each, patients who were in the "worst" quartile were awarded 1 point, with the exception of BMI, where all with a BMI $\geq$25 was awarded 1 point. For Aim 1, patients were indexed at first BMI measurement following their 50th birthday. MGUS cases we matched (1:1) to controls of the same age and index date (within 6 months). MGUS diagnosis was treated as a time-to-event analysis with death being a competing risk. For Aim 2, patients were indexed at time of MGUS diagnosis. Progression to MM was treated as a time-to-event analysis with death being a competing risk. Patients who progressed, died, or lost-to-follow-up within 6 months of diagnosis were excluded.

Results: In Aim 1, 4855 cases of MGUS were matched to 4855 controls. The median age was 62 years, 94% were Male, and 60% were non-Hispanic White (NHW), 24% were non-Hispanic Black (NHB), and 16% were another race/ethnicity or were unclassified. The median AL score was 2. For each 1-unit increase in AL score, the risk of being diagnosed with MGUS increased by 14% (aHR 1.14; 95% CI 1.11-1.18); $p < 0.001$). In Aim 2, 42683 cases of MGUS were identified. The median age was 73 years, 96% were Male, and 61% were non-Hispanic White (NHW), 26% were non-Hispanic Black (NHB), and 13% were another race/ethnicity or were unclassified. The median AL score was 2. In total, 3194 (7%) of cases progressed to MM and 21104 (49%) died without progression after a median follow-up of 46 months. For each 1-unit increase in AL score, the risk progression to MM decreased by 10% (aHR 0.91; 95% CI 0.89-0.94); $p < 0.001$). In post-hoc analyses, we determined that four components of the AL score, ALP, CR, CRCL, and WBC were associated with lower risk (all $p < 0.001$), while BMI and ALB were associated with higher risk. Patients with a BMI $\geq$25 had a 21% increased risk in progression (HR 1.21; 95% CI 1.14-1.32; $p < 0.001$) and patients in the lowest quartile of albumin ($\leq$3.5g/dL) had a 17% increased risk in progression (HR 1.17; 95% CI 1.05-1.30; $p = 0.003$).

Conclusions: AL score is a potential biomarker to determine who is at higher risk for MGUS, but its association with risk of progression to MM is unclear.

#5056 Metabolic disease and risk for thyroid cancer in a predominantly Black and low-income cohort.

Jessica Rampy, Xijing Han, Xiangzhu Zhu, Xiao-Ou Shu, Vivian L. Weiss, Martha J. Shrubsole

Vanderbilt University Medical Center, Nashville, TN

Background: Thyroid cancer incidence and mortality are rising in the U.S., as is metabolic disease. Some studies have shown in predominantly Non-Hispanic White populations that obesity and diabetes are positively associated with thyroid cancer risk while physical activity is inversely associated. However, comparatively little is known about metabolic diseases as risk factors for thyroid cancer among Black Americans and low-income Americans, despite a high prevalence of these factors within these populations.
Methods: The Southern Community Cohort Study is a prospective cohort study of >84,000 participants enrolled between 2002 to 2009 designed to evaluate the etiology of cancer and other health conditions in the southeastern U.S. states including for Black individuals (~2/3) and individuals with low income (~1/2). Self-reported body mass index (BMI), diabetes diagnosis, and physical activity levels were collected at baseline. Thyroid cancer incidence was ascertained through state cancer registry linkages. BMI was categorized as normal/underweight: <25 kg/m^2, overweight: 25–<30 kg/m^2, and obese: ≥30 kg/m^2. Participants with missing data were excluded, leaving 68,532 participants and 135 incident cases. We used Cox proportional hazards models adjusted for potential confounders to evaluate risk factors for thyroid cancer overall and stratified by sex, self-reported race, and income.
Results: The mean enrollment age was 51.8 years, with a median follow-up of 12.6 years. In comparison to normal/underweight, being overweight (HR: 2.39; 95% CI: 1.30-4.40) or having obesity (HR: 2.56; 95% CI: 1.44-4.58) were both associated with increased thyroid cancer risk (P_{trend}: <0.01). These associations were also observed for female participants (HR: 2.55; 95% CI: 1.26-5.20 and HR: 2.55; 95% CI: 1.30-5.00, respectively; P_{trend}: 0.02). Obesity was also associated with increased risk for Non-Hispanic Black participants (HR: 2.81; 95% CI: 1.19-6.63; P_{trend}: 0.02) and for those with household income <$15,000 (HR: 5.42; 95% CI: 1.92-15.3; P_{trend}: <0.01). No statistically significant association was observed for obesity among those with higher income although being overweight was associated with a two-fold increased risk in comparison to normal/underweight. Neither overweight nor obesity was associated with risk for male or Non-Hispanic White participants, possibly due to a smaller sample size. History of diabetes and physical activity were not independently associated with thyroid cancer risk.
Conclusions: Thyroid cancer risk is associated with obesity in a predominantly Black and low-income population, in line with previous findings in other populations. However, neither diabetes nor physical activity were associated. These findings suggest that obesity prevention and treatment should be evaluated as potential prevention strategies for thyroid cancer risk.

#5057 Clinical and lifestyle determinants of all-cause mortality among high-risk prostate cancer patients: Findings from a multicenter longitudinal cohort, 1990-2024.

Cynthia R. Robbins[1], Jiji Jiang[1], Sally Elsamanoudi[1], Paul Campbell[2], Sean P. Stroup[3], Jennifer Cullen[4], Gregory Chesnut[1], Jongeun Rhee[1]

[1]Center for Prostate Disease Research (CDPR), Murtha Cancer Center Research Program, Uniformed Services University of the Health Sciences, Bethesda, MD,[2]U.S. Naval Research Laboratory, Washington, DC,[3]Department of Surgery, Uniformed Services University of the Health Sciences, Bethesda, MD,[4]Houston Methodist Cancer Center, Houston, TX

Patients with high-risk prostate cancer (PCa) have substantially elevated risks of disease progression and mortality, yet outcomes remain highly variable. Emerging evidence suggests that comorbidities, obesity, and smoking contribute to PCa progression and overall survival through metabolic and inflammatory pathways. However, few studies have evaluated how these factors interact to influence mortality in high-risk PCa patients. We examined individual and combined effects of clinical and lifestyle factors on all-cause mortality in a large, longitudinal cohort of high-risk patients treated within military treatment facilities.

Male patients with newly diagnosed National Comprehensive Cancer Network-defined high-risk PCa who underwent radical prostatectomy (RP), external beam radiation therapy (EBRT), and androgen deprivation therapy (ADT) were included from the Center for Prostate Disease Research Multicenter National Database (1990-2024; n=2,713). Multivariable Cox regression analyses were conducted to evaluate associations between lifestyle factors (obesity, smoking) and self-reported comorbidity conditions at enrollment and all-cause mortality across treatment groups.

Median age at diagnosis was 68 years; 66% self-identified as White and 26% as African American. Overall, 44% underwent EBRT, 34% RP, and 14% ADT. During follow-up, 45% of patients died. Chronic obstructive pulmonary disease (COPD) was a strong predictor of increased all-cause mortality across all treatment groups [RP, Hazard Ratio (HR)=1.98 (1.13, 3.50); EBRT, HR=1.52 (1.09, 2.16); ADT, HR=1.65 (0.98, 2.75)]. The association was more apparent among ever smokers in RP group [HR=2.58 vs. never, HR=0.58] and among non-obese patients in RP [HR=2.21 vs. obese, HR=1.27] and EBRT [HR=1.80 vs. 1.01] groups. Hypertension and diabetes were also marginally associated with higher mortality across treatment groups, with stronger associations among ever smokers in RP [hypertension, HR=1.58 vs. 0.77; diabetes HR=1.6 vs. 0.49]. Coronary artery disease was a significant predictor of mortality among EBRT patients [HR=1.34 (1.03, 1.74)] but not in other groups. Renal insufficiency was associated with increased mortality in EBRT [HR=1.84 (1.16, 2.93)] and ADT [HR=1.38 (0.70, 2.73)], with a stronger association never smokers [EBRT, HR=8.45 vs. ever, HR=1.29].

COPD, hypertension, and diabethes were consistently associated with increased all-cause mortality in high-risk PCa patients, with modest effect modification by smoking and obesity status. These findings highlight the importance of integrated management of comorbidities and lifestyle risk factors to improve survivorship in this high-risk patients.

Poster Session

#5061 Allele frequency variation in people of European and admixed African ancestry in the United States do not fully explain incidence differences in adult-type diffuse glioma.
Christine Ann Pittman Ballard[1], Carol Kruchko[2], Mackenzie Price[2], Quinn T. Ostrom[3]

[1]Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Central Brain Tumor Registry of the United States, Pewaukee, WI,[3]Duke University School of Medicine, Durham, NC

BackgroundGlioma is a heterogeneous group of tumors that make up the most common type of primary malignant brain tumor. Incidence varies globally, with highest rates in Europe and North America and lowest in Asia and Africa. Within the United States, these tumors are most common in individuals who are non-Hispanic White. Previously, genome-wide association studies (GWAS) have identified 25 single nucleotide polymorphisms (SNPs) which affect risk for glioma (European only), most of which have subtype-specific differences. SNP allele frequencies (AF) vary between continental populations. We estimated population-level incidence for adult-type diffuse glioma subtypes and calculated the difference between observed variation and variation attributable to AF differences.

MethodsRace/ethnicity-stratified age-adjusted incidence rates for glioma subtypes (Astrocytoma with *IDH1/2* mutation [IDHmut], Astrocytoma with wildtype *IDH1/2* [IDHwt], and Oligodendroglioma with *IDH1/2* mutation and 1p/19q codeletion [IDHmut-codel]) from diagnosis years 2018-2022 were calculated using the Central Brain Tumor Registry of the United States, an aggregation of CDC's National Program of Cancer Registries and NCI's SEER. Incidence rate ratios (IRR_O) were estimated as compared to non-Hispanic White. Effect estimates for known glioma risk SNPs were extracted from a prior subtype-specific glioma GWAS (Labreche, 2018) for SNPs with $p<4x10^{-4}$. AF were extracted from the Allele Frequency Aggregator for the European and African American populations. We calculated the normalized IRR (IRR_N) for each SNP based on population AF and summed these to estimate the incidence variation attributable to AF. IRR_N was calculated by multiplying the beta by the corresponding AF.

ResultsAs compared to individuals who are non-Hispanic White, incidence was decreased in non-Hispanic Black individuals for all subtypes [IDHmut IRR_O=0.40, IDHwt IRR_O=0.49, IDHmut-codel IRR_O=0.29]. IRR_N were attenuated as compared to observed rates [IDH-mut IRR_N=0.78, IDH-wt IRR_N=0.75, IDHmut-codel IRR_N=0.64]. The IRR_N is higher compared to the IRR_O, with the greatest differences being observed in the non-Hispanic Black population.

ConclusionIRR_N fail to fully explain population differences in incidence of glioma. This may be a result of limited ancestral diversity in GWAS, which have not assessed SNPs in individuals who are African American. Sample sizes for subtype-specific GWAS have been small and underpowered. These SNPs do not capture all genetic risk for glioma (all identified SNPs explain 30% of heritable risk), and there is significant 'missing heritability.' These results emphasize the need for inclusion of more diverse populations in glioma genetic epidemiology to ensure accurate genetic risk estimation.

#5062 Genetic ancestry-associated features of the colorectal cancer T-cell landscape.

Introduction: Tumor-infiltrating lymphocytes (TILs) are positive prognostic indicators in colorectal cancer (CRC), yet factors driving their variability beyond microsatellite instability (MSI) are poorly defined. Prior studies suggest that genetic ancestry may influence systemic and tumor-associated immune responses. We tested the hypothesis that global genetic ancestry is independently associated with distinct T-cell features in the CRC tumor immune microenvironment.

Methods: In 230 patients with CRC from the Latino Colorectal Cancer Consortium, we quantified tumor-associated T-cell repertoires using immunoSEQ TCRβ assays for T-cell receptor (TCR) abundance and clonality (log-transformed), pathologist-scored TILs per high-powered field (dichotomized ≥2 vs <2; N=180), and whole-exome sequencing (WES)-inferred TCRα (TCRA) fractions (dichotomized ≥0.03 vs <0.03; N=192). Genetic ancestry proportions (European [EUR], African [AFR], East Asian [EAS], Indigenous American [NAT], South Asian [SAS]) were estimated from germline/normal genotypes from WES via supervised ADMIXTURE (using 1kGP/HGDP references). Correlations between TCR features were evaluated using Spearman coefficients. Logistic/linear regression examined the associations between immune features (TCR abundance, TCR clonality, TILs, and TCRA fractions) and individual ancestry proportions, adjusting for age, sex, tumor location, and MSI status. To account for the constrained sum of ancestral components, we applied an additive log-ratio transformation (ALR), expressing AFR, EAS, SAS, and NAT ancestries as log ratios relative to EUR. These ALRs were fitted into a multivariable logistic/linear regression model, and the overall contribution of genetic ancestry to each immune feature was tested using a 4-df likelihood-ratio test (4-df LRT).

Results: Various T-cell quantification metrics were positively correlated, with pathologist-reviewed TILs showing significant correlations with TCR abundance, clonality, and TCRA fractions (ρ=0.29, 0.29, and 0.22, respectively). CRC patients with higher TCRA fractions were more likely to have higher EUR ancestry (Odds Ratio [OR]: 12.85; 95% Confidence Interval [CI]: 1.09-151.70, p=0.043) and lower NAT ancestry (OR: 0.06, 95% CI: 0.005-0.70, p=0.025). Higher TCR clonality showed a suggestive association with lower EUR proportions (p=0.076) and higher NAT proportions (p=0.084). We found no association with overall genetic ancestry and any T-cell feature in the compositional analysis (4-df LRT>0.05).

Conclusion: Our findings suggest that specific genetic ancestry components may be associated with T-cell landscapes in CRC. These results indicate that genetic background may influence the host anti-tumor immune response in CRC, highlighting the importance of integrating genetic ancestry into personalized risk stratification and precision medicine approaches.

#5063 Ancestry-linked, stage-specific delay to tertiary care is associated with survival differences in colorectal cancer.

Sharafudeen Dahiru Abubakar, Henry Walch, Christina Lee, David Gomez Sanchez, Chin-Tung Chen, Stefanie Gerstberger, Kanika Arora, Farheen Shah, Tejiri E. Agbamu, Michele Waters, Christopher J. Fong, Justin Jee, Michael F. Berger, Karuna Ganesh, Debyani Chakravarty, Walid Khaled Chatila, Nikolaus Schultz, Rona Yaeger, Julio Garcia-Aguilar, Francisco Sanchez-Vega

Memorial Sloan Kettering Cancer Center, New York, NY

Background: African-ancestry (AFR) patients with colorectal cancer (CRC) have worse overall survival (OS) than non-AFR patients. While biological and socioeconomic (SES) factors are known to play a role, delayed access to specialized care remains a critical, underexplored driver of this inequity. This study investigates how the time from diagnosis (Dx) to arrival at a tertiary cancer center interacts with ancestry, disease stage, SES, and genomics to affect OS.
Methods: We analyzed data from 4,328 CRC patients (259 AFR, 4,069 non-AFR) treated at Memorial Sloan Kettering Cancer Center (MSK) since 2014. Tumors were sequenced with MSK-IMPACT, a targeted DNA sequencing assay that profiles genomic changes in 341-505 genes. Genetic ancestry was inferred from sequencing data with >80% African ancestry fraction grouped as AFR. OncoKB identified clinically actionable genomic alterations. Covariates included tumor location, stage at Dx, time from Dx to MSK arrival (Early ≤90 days vs Late >90 days), insurance type and metastatic burden. OS from Dx was compared using Kaplan-Meier curves and log-rank test, with left-truncation for genomic sequencing date.
Results: AFR patients had worse OS from Dx than Non-AFR patients (median 39.3 vs 62.7 months, p<0.001). This difference remained when stratified by stage at Dx (Stage I-III: 65.3 vs 96 months, p<0.001; Stage IV: 31.6 vs 36.7 months, p=0.03). AFR patients also had significantly longer delays from Dx to arrival (median: 22 [IQR: 10, 173] vs 14 [IQR: 6, 38] days; p<0.001) and a higher proportion of late arrivals (28.7 vs 17.1%, p<0.001). This difference was more evident in Stage I-III (49.6 vs 25.9%, p<0.001) than in Stage IV (6.3 vs 5.6%, p=0.69). There was no significant difference in OS between AFR and Non-AFR for Stage I-III early (median: Not Reached (NR) vs NR, p=0.98), Stage I-III late (median: 36 vs 43.5 months, p=0.24), and Stage IV late (median:43.7 vs 33.9 months, p=0.48) arrival, but was significant in Stage IV early arrival (median: 31.6 vs 36.9 months, p=0.034). Patients diagnosed with Stage I-III disease who arrived late at MSK were often Stage IV at their time of arrival (AFR: 68.9%, Non-AFR 65.8%) but this was much less frequent among early arrivals (AFR: 6.1%, Non-AFR: 2.6%); and was linked to higher Medicaid use in both AFR (10.8% vs 1.5%; p=0.03) and Non-AFR (4.4% vs 2.4%; p=0.015) patients. AFR had higher KRAS mutation frequency compared to Non-AFR across all stages and arrival groups (Stage I-III Early: 51.5 vs 38.8%, p=0.04; Stage I-III Late: 58.2 vs 47.2%, p=0.10; Stage IV Early: 58.5 vs 44.5%, p=0.004; Stage IV Late: 75 vs 50.5%, p=0.28).
Conclusion: Delayed specialized care appears to be linked to CRC survival gaps in AFR patients, especially in the non-metastatic setting where timely multidisciplinary care is crucial. Expediting referral of AFR patients to tertiary care centers could help to achieve CRC outcome equity.

#5064 Ancestry-associated epigenetic differences in chronic lymphocytic leukemia.

Zhiquan Wang[1], Huihuang Yan[1], Mingma Sherpa[1], Daniel Bihnam[2], Cristine Allmer[1], Chantal McCabe[1], Daniel O'Brien[1], Dennis P. Robinson[1], James R. Cerhan[3], Neil E. Kay[1], Sameer A. Parikh[1], Esteban Braggio[4], Susan Slager[1]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Phoenix, AZ,[3]Mayo Clinic College of Medicine and Science, Rochester, MN,[4]Mayo Clinic Arizona, Scottsdale, AZ

Background: CLL incidence differs by ancestry, with higher rates in individuals of European ancestry (EA) than African ancestry (AA). The contribution of epigenetic variation to these disparities remains unclear. We investigated chromatin accessibility, histone modifications, and gene expression in CLL patients of EA and AA to identify ancestry-associated epigenetic signatures.
Methods: ATAC-seq was performed on blood clonal B cells from 15 AA and 51 EA patients; CUT&Tag profiling of six histone marks (H3K4me1, H3K4me3, H3K27ac, H3K9me3, H3K27me3, H3K36me3) was done in 8 AA and 12 EA cases; RNA-seq was generated for all samples. Ancestry was genetically confirmed. Differential regions were linked to genes using ENCODE and Hi-C datasets.
Results: ATAC-seq revealed 4,955 regions with increased and 3,000 with decreased accessibility in AA vs EA (fold change >2, FDR ≤0.05). Regions with increased accessibility mapped to 2,313 genes; 599 were upregulated and enriched in TNF-α/NF-κB (p=1.40E-53) and apoptosis pathways (p=6.90E-11). Regions with decreased accessibility linked to 1,953 genes; 317 were downregulated, enriched in interferon-γ response (p=1.04E-03) and IL-6/JAK/STAT3 signaling (p=6.41E-03). Histone profiling showed ancestry-specific changes across all marks. For H3K27ac (active enhancer), 68 genes with a decreased signal in AA were downregulated and enriched in interferon-γ (p=1.55E-06) and IL-6/JAK/STAT3 (p=9.62E-05) pathways. Increased H3K27me3 (repressive histone modification) in AA affected 399 genes enriched in IL-6/JAK/STAT3 (p=8.13E-09) and interferon-γ (p=2.48E-05) pathways. These findings suggest coordinated regulation by active and repressive chromatin states.
Conclusions: Despite limited sample size, this study suggests differences between AA and EA ancestries may exist in epigenetic signatures in CLL, implicating chromatin accessibility and histone modifications in pathways relevant to tumor biology. These signatures may also contribute to the differences in CLL incidence by ancestry. Future studies with more patients and functional validation experiments are needed to clarify the role of these epigenetic differences in CLL pathogenesis.

#5065 Ancestry-related differences in genomic mutations between African American and European American prostate cancer patients.

Nicholas S. Korvink[1], Arash Rezazadeh[2], Omid Yazdanpanah[3], Michael McClelland[3], Farahnaz Rahmatpanah[1]

[1]Pathology, University of California, Irvine, Irvine, CA,[2]Hematology/Oncology, University of California, Irvine, Irvine, CA,[3]University of California, Irvine, Irvine, CA

Background. Somatic mutations accumulate with age in prostate cancer (PCa) tumorigenesis, affecting key driver genes including FOXA1 and SPOP. Significant ancestry-related differences exist in PCa's mutational landscape: CDK12 mutations occur twice as frequently in African Americans (AA) versus European Americans (EA), while TMPRSS2-ERG fusion is more common in EA (~50%) than AA (~25%). Despite these differences, comprehensive genome-wide mutational comparisons remain limited. This study elucidates genome-wide mutational differences between ancestries to identify ancestry-specific molecular signatures for improved risk stratification and personalized treatment.

Methods. We analyzed whole-genome DNA sequencing from 19 patients across three cohorts: Africans (AF, n=5) from the European Nucleotide Archive (PRJNA412953), AA (n=11), and EA (n=3) from TCGA. Sequencing files aligned to hg38 were processed using R codes and Strand NGS software for recalibration, realignment, and SNP detection. After removing statistical outliers, we compared mutational burden categories including substitutions, insertions, deletions, complex mutations, zygosity patterns, transition/transversion mutations, Ti/Tv ratios, and dbSNP variants. Statistical analysis employed Mann-Whitney U test for groups ≥5 samples or 10,000-iteration permutation test for smaller groups.

Results. Whole-genome SNP analysis revealed distinct patterns across AF, AA, and EA. AA versus EA showed significant differences ($p<0.05$) in most categories: all basic variant types (substitutions: $p=0.0149$; insertions: $p=0.0181$; deletions: $p=0.0181$), zygosity patterns (homozygous: $p=0.0174$; heterozygous: $p=0.0236$), transition/transversion mutations (both $p=0.0149$), Ti/Tv ratios ($p=0.0174$), and known dbSNP variants ($p=0.0149$). Complex variants ($p=0.1708$) and novel variants ($p=0.2766$) showed no significant differences. AF versus AA revealed significant differences ($p<0.05$) in nearly all categories: substitutions ($p=0.0176$), insertions ($p=0.005$), deletions ($p=0.0169$), complex variants ($p=0.0169$), heterozygous variants ($p=0.0211$), transitions ($p=0.0176$), transversions ($p=0.0052$), Ti/Tv ratios ($p=0.0047$), and both known ($p=0.0046$) and novel ($p=0.0186$) variants, except homozygous variants ($p=0.7155$). These findings indicate AA have developed distinct genetic profiles compared to continental AF, likely from admixture and environmental factors.

Conclusion. This genome-wide analysis demonstrates significant ancestry-specific mutational differences in PCa, with AA exhibiting distinct profiles from both AF and EA due to admixture and environmental factors. These findings underscore the need for diverse genomic databases, personalized precision oncology, and validation in larger cohorts.

#5066 Association between genetic ancestry and somatic mutational profiles in colorectal cancer.

Marco Matejcic[1], Jamie Teer[2], Daniel Sobieski[3], Eric M. Cockman[3], Esther Jean-Baptiste[4], Nathalie Nguyen[5], Diana B. Diaz[6], Ya-Yu Tsai[1], Hannah J. Hoehn[4], Kritika Shankar[3], Rusche Wilson[3], Karina Brito[3], Allyson Koepfler[3], Seth Felder[7], Julian Sanchez[7], Nicole Catalina Lorona[5], W. Siegel[14], Mariana C. Stern[15], Jane C. Figueiredo[5], Stephanie L. Schmit[16]

[1]Genomic Sciences and System Biology, Cleveland Clinic Lerner College of Medicine, Cleveland, OH,[2]Department of Biostatistics and Bioinformatics, Moffitt Cancer Center, Tampa, FL,[3]Genomic Sciences and System Biology, Cleveland Clinic, Cleveland, OH,[4]Non-Therapeutic Research Office, Moffitt Cancer Center, Tampa, FL,[5]Department of Medicine, Samuel Oschin Comprehensive Cancer Institute, Los Angeles, CA,[6]Moffitt Cancer Center, Tampa, FL,[7]Department of Gastrointestinal Oncology, Moffitt Cancer Center, Tampa, FL,[8]Department of Molecular Oncology, Moffitt Cancer Center, Tampa, FL,[9]Puerto Rico Biobank, Ponce Health Sciences University, Ponce, Puerto Rico,[10]Department of Microbiology, Ponce Health Sciences University, Ponce, PR,[11]California University Science and Medicine, Colton, CA,[12]Department of Anatomic Pathology, Moffitt Cancer Center, Tampa, FL,[13]Diagnostics Institute, Robert J. Tomsich Department of Pathology and Laboratory Medicine, Cleveland Clinic, Cleveland, OH,[14]Department of Cancer Epidemiology, Moffitt Cancer Center, Tampa, FL,[15]Department of Population and Public Health Sciences, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[16]Genomic Sciences and System Biology, Cleveland Clinic, Cleveland Clinic, OH

Colorectal cancer (CRC) mortality rates differ across populations and differences are not fully accounted for by sociodemographic factors and access to care. Opportunities exist to better understand biological determinants of disparities by expanding cancer genomic datasets to include profiles of tumors from patients from varied communities. Using whole-exome sequencing data from the Latino Colorectal Cancer Consortium (LC3) and additional datasets, we characterized somatic mutational profiles by ethnicity and genetically-inferred ancestry. We hypothesized that ancestral haplotypes that vary across populations contribute to differential somatic mutational profiles. Somatic mutations were called from paired tumor and germline/normal samples using an analysis pipeline including Burrows-Wheeler MEM Aligner, the Genome Analysis Toolkit (GATK), MuTect, Strelka, MuSE, SomaticSniper, freebayes, and Lancet. Inherited variants were identified using GATK. Global proportions of African, East Asian, European, Native American, and South Asian ancestries were estimated using ADMIXTURE based on the 1000 Genomes Project and the Human Genome Diversity Project. Among the 1,243 primary CRC cases included, 391 (31.5%) were Latino, 488 (39.3%) were non-Latino. Associations between global ancestry and somatic mutational features were examined using logistic regression. Among commonly mutated genes in CRC, tumors from Latino participants exhibited lower frequencies of mutations in *BRAF* (OR=0.59, 95%CI=0.34-0.99, p=0.048), *CTNBB1* (OR=0.54, 95%CI=0.30-0.96, p=0.037), *FBXW7* (OR=0.61, 95%CI=0.38-0.99, p=0.045), *KRAS* (OR=0.71, 95%CI=0.52-0.95, p=0.023), but higher frequency of mutations in *CDC27* (OR=11.74, 95%CI=1.39-99.09, p=0.024) and *SMAD2* (OR=2.30, 95%CI=1.08-4.89, p=0.03) compared to non-Latino patients. In addition, African ancestry was significantly associated with higher odds of mutations in *APC* (OR=1.10, 95%CI=1.02-1.18, p=0.013) and *PIK3CA* (OR=1.08, 95%CI=1.00-1.15, p=0.037), while Native American ancestry was associated with lower odds of mutations in *BRAF* (OR=0.83, 95%CI=0.70-0.97, p=0.02) and *FBXW7* (OR=0.85, 95%CI=0.75-0.97, p=0.012). Genome-wide analyses revealed that global genetic ancestry was associated with mutation status in *CFAP54*, *LMBRD2*, *MUC12*, and *TTC6* (FDR-adjusted 4-df LRT p<0.05). Native American ancestry was associated with reduced odds of mutations in *LMBRD2* (OR= 0.47, 95%CI=0.24-0.95, p=0.034), but with higher odds of mutations in *CFAP54* (OR=1.32, 95%CI=1.17-1.49, p=7.55x10^{-06}), *MUC12* (OR=1.29, 95%CI=1.08-1.55, p=0.0049), and *TTC6* (OR=1.31, 95%CI=1.11-1.53, p=0.0011). Tumor mutation burden was significantly reduced in Latino patients compared to non-Latino patients (OR= 0.78, 95%CI=0.64-0.94, p=0.012). These findings advance precision medicine efforts by improving our understanding of ancestry-associated molecular heterogeneity.

#5067 Prospective epigenome-wide association study of pancreatic cancer risk in a multiethnic population.

Xinman Zhang[1], Sihao Han[1], Brandon Quon[2], Adelynn Paik[1], Veronica Wendy Setiawan[1], David V. Conti[1], Kimberly D. Siegmund[1], Heinz Josef Lenz[3], Lenora W. M. Loo[4], Loic Le Marchand[2], Lynne R. Wilkens[2], Christopher A. Haimen[1], Alexandra M. Binder[2], Sung-Shim Lani Park[2], Brian Huang[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, CA,[2]Population Sciences of the Pacific Program-Epidemiology, University of Hawaii Cancer Center, Honolulu, HI,[3]Department of Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA,[4]Cancer Biology Program, University of Hawaii Cancer Center, Honolulu, HI

Background: Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal cancer, with known differences in incidence across populations in the US. Epigenome-wide association studies (EWAS) have identified DNA methylation markers of PDAC risk, but have been mostly performed in European ancestry populations with small sample sizes and post-diagnostic samples. Prospective EWAS in diverse populations may reveal novel biomarkers and provide insights into racial/ethnic differences in PDAC biology.

Methods: Using a nested case-control design, we conducted an EWAS of PDAC risk in the Multiethnic Cohort, a large prospective cohort of African American, Japanese American, Latino, Native Hawaiian, and White residents of Los Angeles and Hawaii. Incident PDAC cases (N=689) were matched to controls (N=806) on age, sex, race/ethnicity, year of blood draw, and study site. DNA methylation was measured in pre-diagnostic blood using the Illumina EPICv2 array (>930,000 CpG sites). Associations between DNA methylation at each CpG site and PDAC risk was assessed using conditional logistic regression, adjusting for matching factors, diabetes, family history of PDAC, smoking, BMI, and DNA methylation-predicted lymphocyte cell type proportions. Differentially methylated region (DMR) and pathway analyses were further conducted. The most significant results were examined in a prior EWAS of PDAC in the Nurses' Health Study, Physicians' Health Study and Health Professionals Follow-up Study (N=393 cases/431 controls).

Results: We identified 105 CpG sites significantly associated with PDAC risk ($p<9\times10^{-8}$). The top CpG sites were annotated to genes related to tumor suppression, metabolism, and inflammation (e.g., *TRAK1*, *INPP5A*, *ACOX3*, *WBP1L*, *RASSF8-AS1).* Most of the top CpG sites exhibited a positive association between DNA methylation levels and PDAC risk (odds ratios [OR] per 0.01 increase in methylation beta value 1.03-2.33). Heterogeneity across race/ethnicity was observed for one site in *ZNF713*, which was associated with PDAC in Native Hawaiians only (OR 1.65, 95% CI 1.52-1.80; p-heterogeneity$<6.6\text{x}10^{-25}$). DMR analysis revealed 738 regions associated with PDAC (FDR-adjusted $p<0.05$), with the top regions annotated to genes related to genetic regulation and cancer progression (e.g. *PRMT7*, *NDUFC1*, *NAA15*, *TFDP1).* KEGG and GO pathway analyses identified 18 and 388 significantly enriched pathways, respectively ($p < 0.05$); the top pathways were DNA replication and catalytic complex. In the validation analyses, none of the 105 sites reached significance ($p<0.01$), but 26 showed the consistent direction of association.

Conclusions: In this multiethnic population, differential methylation in genes related to cancer, inflammation, and metabolism were associated with PDAC risk. Further studies integrating larger discovery and validation data are warranted to elucidate underlying mechanisms across populations.

#5069 Ethnic differences in the immune landscape and gene signature in prostate cancer.

Shiv S. Verma[1], Pingfu Fu[2], Gregory T. MacLennan[3], Lee E. Ponsky[4], Sanjay Gupta[1]

[1]Case Western Reserve University School of Medicine, Cleveland, OH,[2]Population and Quantitative Health Sciences, Case Western Reserve University, Cleveland, OH,[3]Pathology, Case Western Reserve University, Cleveland, OH,[4]Urology, University Hospitals Cleveland Medical Center, Cleveland, OH

Prostate cancer is a biologically and clinically heterogeneous disease, with incidence and mortality rates that vary substantially across racial and ethnic groups. Among Black American (BA) men, the incidence of prostate cancer is approximately 60% higher, and the mortality rate is two to three times greater than that observed in White American (WA) men. These disparities are multifactorial, involving both biological and social determinants such as genetic predisposition, comorbidities, socioeconomic status, environmental exposures, and cultural influences. While these factors obviously contribute to disease outcomes, growing evidence highlights the crucial role of the tumor immune microenvironment and its associated gene signatures in shaping prostate cancer biology and progression. To investigate ethnic variations in tumor immune gene signatures, we analyzed transcriptomic data from 35 radical prostatectomy specimens from treatment-naïve patients, including 20 BA and 15 WA men. Gene expression profiles from tumor and adjacent normal tissues were examined using EPIC, xCell, and Ingenuity Pathway Analysis. Differential gene expression was determined by rank testing, and prognostic associations were assessed via univariate Cox regression. WA tumors are enriched for pathways associated with neuroinflammation and oxidative phosphorylation including IL-8 signaling, neuroinflammation, dendritic cell maturation, oxidative phosphorylation, PKCθ signaling in T cells, and NFAT-mediated immune regulation, while PPAR and PD-1/PD-L1 pathways were less active. In contrast, BA tumors are characterized by increased activation of pro-inflammatory and immune-regulatory pathways; display elevated CREB signaling, Th1/Th2 activation, dendritic cell maturation, IL-17 and TREM1 signaling, and IL-17A/F-mediated cytokine production, with reduced activity in PD-1/PD-L1, ILK, IL-3, VEGF, and B-cell receptor pathways. Thirteen immune cell types showed race-specific gene expression patterns including ARG1, FA2H, FBXO39, IGLL3P, KLKB1, MERTK, SEMA3G, and TRPV5 markedly expressed in WA tumors, whereas ARSL, BAALC, CCL23, EPHA2, IGFL2, KRT5, NTM, and NDP upregulated in BA tumors. These results reveal distinct immune-oncological landscapes between BA and WA prostate tumors, highlighting pro-inflammatory pathway enrichment in BA men and underscoring opportunities for ethnicity-specific, genomically informed therapies.

#5070 How stress gets under the skin: Everyday discrimination, inflammation and cancer risk in older adults.

Cameron Brown, Lauren Brown

USC-Leonard Davis School of Gerontology, Los Angeles, CA

Cancer is a devastating disease predominately affecting older adults, with adults 65+ accounting for 70% of cancer-related deaths and over 60% of new diagnoses. Preliminary studies show that Black and Hispanic/Latine older adults are at an increased risk of diagnosis of advanced staged cancers and experience higher mortality rates from cancer than older adults of other racial/ethnic groups. Inflammation is one such risk factors in these sub-groups, specifically through chronic stressors like everyday discrimination (EDD). One way to measure this stress pathway is via inflammatory biomarkers like C-Reactive Protein (CRP) and Soluble Tumor Necrosis Factor-1 (sTNFR-1). Improving our understanding of the intersection between EDD and inflammatory biomarkers in disaggregated populations will help us identify high-risk groups to improve timeliness and diagnosis. We examined whether EDD is associated with elevated CRP and sTRNFR-1 levels, ultimately increasing cancer risk for minoritized populations. This study included White (n=3,187), Black (n=443), and Hispanic/Latine (n=375) older adults in the U.S. who were 65-95 years old in the 2016 *Health and Retirement Venus Blood Biomarker Subsample*. Results show that Black older adults experience more EDD and have higher average CRP [(4.93 mg/L (0.41)] and sTNFR-1 [(1840.88 pg/mL (85.3)] levels than White [CRP= 3.95 mg/L (0.16) ; sTNFR-1= 1807.21 pg/mL (20.7)] and Hispanic/Latine [CRP=4.50 mg/L (0.41); sTNFR-1=1806.75 pg/mL (67.43)] older adults. OLS regression models show reporting more experiences of EDD is associated with higher CRP levels (β;= 0.23; p=0.03), specifically in Black older adults, but is not associated with higher levels of sTNFR-1. Logistic regression models show sTNFR-1 (OR=1.00; p=0.04) significantly increases the odds of being diagnosed with cancer in the full sample. Findings suggest that experiences of EDD may increase cancer risk, via inflammatory pathways like CRP.

#5071 Stress and breast cancer risk among Asian American females: The CRANE Study.

Scarlett L. Gomez[1], Katherine Lin[2], V. Wendy Setiawan[3]

[1]Epidemiology & Biostatistics, University of California, San Francisco, San Francisco, CA,[2]University of California, San Francisco, San Francisco, CA,[3]University of Southern California, Los Angelens, CA

Background: Breast cancer incidence rates among Asian American (AA) women have risen rapidly, 2.3% annually since 2012, far outpacing the overall US trend. The increase is particularly stark for early-onset cases (<50 years), at 2.9% per year since 2016. Significant increases were observed across nearly all AA groups, stages and subtypes, with especially sharp rises in late-stage and triple-negative breast cancer. Foreign-born AA now face higher risk relative to US-born AA, even after accounting for established risk factors. These evolving patterns point to emerging, unrecognized risk factors. The CRANE Study (Breast Cancer Risk among Asian Americans) investigates multilevel determinants, from environmental to biological, that drive the contemporary elevated risk in this population. This abstract describes preliminary social stressor results.

Methods: The CRANE Study, initiated in 2022, is a population-based case-control study of breast cancer in AA in California. The study integrates epidemiologic data on established and emerging risk factors with geospatial data (including residential histories), cancer registry data, and biospecimens (saliva and hair), alongside access to medical records and tumor specimens. AA women with recently-diagnosed breast cancer are identified through the Greater Bay Area and Los Angeles County cancer registries. Controls, matched to cases by ethnicity, age, and region, are recruited using multiple modalities to represent the population at risk.

Results: To date, 317 cases and 368 controls have been enrolled (39% Chinese, 18% Filipina, 9% Japanese, and 8% each Korean, South Asian, and Southeast Asian). Among cases, 48% were younger than age 50 at diagnosis, ranging from 16% among Japanese to 71% among Koreans. Most were diagnosed at stage I disease (70%). Tumor subtypes included 68% HR+/HER2-, 20% HER2+ (14% among Koreans to 29% among South Asians), and 8.5% triple-negative cancer. Compared to controls, cases were more likely to be foreign-born (72% vs. 54%) and less acculturated (65% vs. 81% English proficient), and have higher BMI (20% vs. 14% BMI≥27.5) and later menarche (50% vs. 45% at ≥13 years). However, cases reported lower levels of stress (20% vs 24% in the highest quartile of immigrant stress) and racism (15% vs. 22% in the highest quartile of anti-Asian racism) compared to controls. Despite reporting fewer stressors, more cases than controls expended higher levels of effortful coping on the John Henryism scale (29% vs. 24% in the highest quartile).

Conclusions: The CRANE Study provides a unique and timely platform to investigate how environmental, social, and biological factors interact to shape breast cancer risk in this population. By focusing on AA, who are experiencing notable increases in early-onset and triple-negative breast cancers, CRANE aims to identify novel risk factors and pathways that may help explain emerging breast cancer trends in both AA and the broader US population.

#5072 Discriminatory capacity of allostatic load score in colorectal cancer: A pilot case-control study.

Hilmaris Centeno-Girona[1], Maria Gonzalez-Pons[2], Elba V. Caraballo-Rivera[1]

[1]Shared Resources and Scientific Operations, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]Clinical and Translational Cancer Research, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Colorectal cancer (CRC) represents the leading cause of cancer-related deaths in Puerto Rico. Allostatic load (AL) reflects a cumulative dysregulation across inflammatory, neuroendocrine, and metabolic systems. It may serve as a composite index for distinguishing CRC cases from controls. Unlike individual markers, AL captures multi-system physiological dysregulation observed in CRC patients. This study aimed to assess the discriminatory capacity of a composite AL score derived from inflammatory, neuroendocrine, and metabolic biomarkers for distinguishing CRC patients from healthy controls in a sample of Hispanics individuals living in Puerto Rico (HPR).This case-control study used plasma samples from the Puerto Rico Familial Colorectal Cancer Registry (PURIFICAR) including 18 CRC cases and 18 healthy controls. AL score was constructed using control derived percentile scoring (75th percentile cutoffs, 25th for IGF-1) across 8 markers: IL-1β, TNF-α, IL-8, MCP-1, CRP (inflammatory), cortisol (neuroendocrine), and IGF-1 and BMI (metabolic). Logistic regression models evaluated discriminatory capacity with progressive adjustment for demographic and sociodemographic factors. Area under the curve (AUC) comparisons were performed using DeLong's test. Analyses were performed in Stata 18. Participants had a median age of 48 years (range: 34-65) and 44% were male. CRC cases had significantly lower BMI (median 23.8 vs 28.2, p=0.016), higher educational attainment (50% vs 33%, p=0.31), and lower private insurance coverage (33% vs 56%, p=0.18) than controls. The AL score showed higher median values in cases versus controls. Higher AL scores were associated with increased odds of CRC in unadjusted analysis (OR=1.26, p=0.295), which strengthened slightly after adjusting for age and sex (OR=1.30, p=0.247). When including education and insurance type for the full model, the association remained similar (OR=1.25, p=0.362). Private insurance demonstrated a marginally significant protective association (OR=0.20, p=0.075). Discriminatory capacity was modest for AL alone (AUC=0.619) and remained similar after demographic adjustment (AUC=0.590) but improved with full adjustment (AUC=0.713). DeLong's test indicated non-significant differences between models (Model 1 vs 2: p=0.626; Model 1 vs 3: p=0.329; Model 2 vs 3: p=0.171). This pilot study demonstrated non-significant associations between AL score and CRC, though discriminatory capacity improved with sociodemographic adjustment. The marginally significant protective effect of private insurance suggests healthcare access may influence CRC risk independent of physiological stress burden. These findings support the feasibility of AL measurement in HPR populations and highlight the importance of considering structural determinants of health in CRC risk assessment. Validation in larger samples is warranted.

#5073 Disparities in timeliness of cancer diagnosis across a multi-site academic health system.

Vivian Hoang Tran[1], Suraj M. Rajan[1], Matthew P. Banegas[1], Winta Mehtsun[2], Brent Rose[1], James Murphy[1], Melody Schiaffino[1], Joshua Demb[1], Noe C. Crespo[3], Humberto Parada[1], Corinne McDaniels-Davidson[3], Elena Martinez[1]

[1]Center for Health Equity Education & Research, UC San Diego Moores Cancer Center, La Jolla, CA,[2]UC San Diego School of Medicine, La Jolla, CA,[3]San Diego State University School of Public Health, San Diego, CA

Background: Early cancer diagnosis is crucial for improving survival and quality of life. Understanding which patient populations are at higher risk for late-stage diagnosis within a healthcare system is a crucial step toward achieving health equity. This study examines demographic, clinical, and socioeconomic factors associated with late-stage diagnosis, defined as stage III/IV diagnoses using the American Joint Committee on Cancer (AJCC) criteria.
Methods: A retrospective cohort study of 12,721 patients diagnosed with breast, colorectal, or lung cancer within the University of California health system database. Multivariable logistic regression was used to identify various factors associated with late-stage diagnosis.
Results: 14.1% of patients were diagnosed at a late-stage (stage III/IV). In adjusted analyses, patients with colorectal (OR: 4.76; 95% CI: 4.12-5.50) and lung cancer (OR: 12.82; 95% CI: 11.01-14.92) had significantly higher odds of late-stage diagnosis compared to breast cancer (reference group). A higher Area Deprivation Index (ADI) was significantly associated with increased odds of late-stage diagnosis (OR: 1.03 per 1-unit increase; 95% CI: 1.01-1.05). Neither race nor ethnicity was an independent predictor of late-stage diagnosis in the final adjusted model.
Conclusion: Cancer type is the strongest predictor of a late-stage diagnosis. Additionally, greater neighborhood-level socioeconomic disadvantage (measured by ADI) is a significant, independent risk factor. These findings highlight the need for targeted screening and diagnostic interventions that incorporate geospatial analyses, particularly for lung and colorectal cancer patients in socioeconomically disadvantaged communities.

#5074 Transcriptomic and SNP profiling reveals early-onset and ethnicity-associated signatures in colorectal cancer.

Soumya Nair[1], Betty Huang[2], Umme Tania[1], Brian Grajeda[1], Md Zahirul Islam Khan[1], Michael Schatz[2], Rajiv McCoy[2], Sourav Roy[1]

[1]The University of Texas at El Paso, El Paso, TX,[2]John Hopkins University, Baltimore, MD

Colorectal cancer (CRC) is the second deadliest cancer in the United States, with early-onset (age < 50) cases rising significantly over the past decade. Although early-stage (I/II) CRC is treatable with a higher survival rate, these tumors often present with poor outcomes, particularly among minority groups like Hispanics. Hispanics experience higher rates of late-stage (III/IV) diagnosis than Non-Hispanic Whites (NHW), suggesting that both genetic and non-genetic factors may contribute to this disparity. To identify potential biological contributors to early-onset and ethnicity-associated disparities, we investigated transcriptomic and genotypic biomarkers that may improve screening and prognosis. We performed RNA sequencing on CRC tissues and normal tissues adjacent to the tumor (NATs) from Hispanic and NHW patients. Gene level quantification was obtained using two independent pipelines - Rsubread and Salmon. DESeq2 analysis, identified 996 differentially expressed genes (DEGs, log2 foldchange ≥ 2.0 and ≤ -2.0 and a false discovery rate of 0.05) common to both the tools between CRC and NAT samples. When analyzed within each ethnic cohort 1251 DEGs were identified in Hispanics and 899 in NHWs. Notably, within the Hispanic group, 311 DEGs were common between early-onset and late-stage Hispanic CRC samples compared to NHWs. Pathway enrichment analyses using Ingenuity Pathway Analysis and Gene Set Enrichment Analysis revealed significant dysregulation of the cell cycle regulatory pathways including the Mitotic G2-G2/M phases, Mitotic G1 phase and G1/S transition, as well as Cell cycle checkpoints, pathways critical for apoptosis, and tumor progression. Interaction analysis further revealed 138 DEGs (log2 foldchange ≥ 1.0 and ≤ -1.0 and p- value ≤ 0.05) display a significant association with CRC occurrence in the Hispanic cohort. Additionally, variant discovery and annotation using the Genome Analysis Toolkit (GATK) and Snpeff workflows, identified 383 variants either unique to or abundant in Hispanic CRC samples and predicted to have high or moderate functional impact. Among these, analysis of SNP-associated genes revealed that the downregulation of NCF1, carrying the rs10614 variant, was significantly correlated with tumor status in the Hispanic CRC cohort. Reduced NCF1 expression is associated with ROS deficiency induced colitis-mediated tumorigenesis. Overall, our findings reveal Hispanic-specific transcriptomic and genotypic signatures that may underlie CRC disparities and identify potential biomarkers for improved screening. Further functional studies in Hispanic patient tissues and patient-derived organoid models will help elucidate the biological roles of these genes and variants, ultimately promoting the development of early-screening strategies and targeted therapies for high-risk populations.

#5075 Integrated clinicopathologic, genomic and transcriptomic characterization of gastric cancer by race/ethnicity in a national multi-institutional cohort.

Kyle D. Klingbeil[1], Sinead Cullina[2], Natalie N. Martinez[1], Mariah B. Blegen[1], Kyla E. Wright[1], R. Vanessa Mora Molina[1], Ami Hayashi[1], Adam J. Dugan[2], Unnati Jariwala[2], Stamatina Fragkogianni[2], Jonathan Boiarsky[3], Lee S. Rosen[3], Mark D. Girgis[1], Brian E. Kadera[1]

[1]Department of Surgery, Division of Surgical Oncology, UCLA Health, Los Angeles, CA,[2]Tempus AI, Inc., Chicago, IL,[3]Department of Medicine, Division of Hematology-Oncology, UCLA Health, Los Angeles, CA

Background: Although gastric cancer outcomes vary by race/ethnicity, a molecular basis for these differences has not been fully elucidated. To address this gap, we used the Tempus Lens Platform (Tempus AI, Inc., Chicago, IL) to query the multimodal de-identified database in order to establish and subsequently analyze a cohort of patients with gastric adenocarcinoma who underwent germline and tumor testing using xT (DNA) and xR (RNA).

Methods: Patients were categorized by R/E. RNA-seq data were normalized as transcripts per million (TPM) and reported as log2(TPM+1). Single-sample Gene Set Enrichment Analysis (ssGSEA) using Hallmark gene sets was used to compare cell signaling pathway activity. Real-world overall survival (rwOS) was defined as the time from biopsy to death or last known follow-up. rwOS survival curves were estimated using the Kaplan Meier (KM) approach and differences tested using log-rank tests. Hazard ratios (HR) were calculated using Cox proportional hazard models.

Results: Among 1,842 patients with reported race/ethnicity data, 1,186 (64%) identified as White, 327 (17.7%) as Hispanic/Latino (HL), 217 (11.8%) as Black or African American (AA) and 112 (6.1%) as Asian. In the multivariable Cox model, compared to White patients, rwOS was longer for HL (HR 0.65, 95% CI 0.48-0.88, p=0.005) and Asian (HR 0.64, 95% CI 0.41-0.98, p=0.042) patients. Asian patients had longer median rwOS compared to White patients (19 vs 10.9 months, log-rank p<0.001). Compared to White patients, HL patients were younger at diagnosis (median 57 vs 67 years, p<0.001) and a greater proportion were female (45% vs 28%, p<0.001). Tumor grade, microsatellite instability, tumor mutational burden, and *CLDN18.2* expression differed significantly across groups (all p<0.01), whereas HER2 and PD-L1 status did not. At the genomic level, the frequency of somatic alterations in *TP53* (57% HL vs 75% White), *CDKN2A* (11% Asian vs 21% White), *CDH1* (6.9% AA vs 16% HL) differed between groups (all p,q<0.001). Pathogenic germline variants were identified in 10.1% of AA, 10.7% of Asian, 10.7% of HL, and 15.8% of White patients, most commonly involving *HDAC2*, *ATR*, *ATM*, and *MUTYH*, respectively. Transcriptomic profiling via ssGSEA revealed an inflammatory pathway activation among HL and Asian patients, with a significant increase in IL6/JAK/STAT3 and IFN-γ signaling vs White patients (all q<0.001). HL patients also demonstrated greater enrichment of the IL2/STAT5, TNFα and complement response pathways vs White patients (q<0.001).

Conclusion: This study represents the largest and most diverse clinico-genomic analysis of gastric cancer. Collectively, these findings highlight distinct clinical presentations, molecular alterations and survival outcomes by race/ethnicity, promoting the critical need for broad molecular testing to inform precision cancer care.

#5076 Disparities across demographic, behavioral, and socioeconomic factors in lung cancer stage at diagnosis: An EPIC EHR study from the University of Maryland Medical System.

Leila Abar[1], Sally N. Adebamowo[2], Clement Adebamowo[1]

[1]University of Maryland, Baltimore, Baltimore, MD,[2]University of Maryland School of Medicine, Baltimore, MD

Background: Lung cancer is the leading cause of cancer mortality in Maryland and the US with sex, socioeconomic factors, and insurance status disparities in stage at diagnosis. There is a rising burden among younger adults, never-smokers, women and racial/ethnic minorities, who often present with advanced disease and may not qualify for screening using current USPSTF guidelines. In this study, we evaluate the associations between age, smoking status, race, sex, and insurance status, and the stage at diagnosis using large real-world EHR datasets.
Methods: We conducted a retrospective cross-sectional study of 6,446 adults diagnosed with lung cancer (ICD-10: C34) using EPIC electronic medical records from the University of Maryland Medical System between January 2016 and December 2024. We extracted age, sex, race, ethnicity, smoking status, insurance type, and stage at diagnosis classified as early (I-II) or advanced (III-IV) from the records. We used t tests for continuous variables and χ^2 tests for categorical variables.
Results: Overall, 38% of patients were diagnosed with early-stage lung cancer and 62% with advanced disease. Advanced stage disease was commoner among younger patients, (mean age 68 vs 70 years, $p<0.001$), and those younger than 50 years (77%, $p<0.001$). Though there were more women (52%) in the study population, men were more likely to present with advanced disease (64% vs 59%, $p<0.001$). The study population was predominantly white (73%) but there was no association between race and stage ($p=0.06$). Current smokers were most likely to present with advanced disease (66%, $p<0.001$). Patients on Medicaid (78%) and uninsured individuals (65%) had a higher likelihood of advanced-stage diagnosis compared with those covered by Medicare (58%) or private insurance (66%).
Conclusions: Younger adults, males, current smokers, and patients on Medicaid or having no insurance were more likely to present with advanced lung cancer. These findings highlight disparities in lung cancer diagnosis and underscore the need for further research.

#5077 Investigating IL-6-driven inflammation and gene-environment interactions in colorectal cancer disparities among Puerto Rican Hispanics.

Luis Daniel Borrero-Garcia, Melissa Chavez, Olga Diaz-Miranda, Leslie Casiano, Maria Gonzalez-Pons

Clinical and Translational Cancer Research, University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

Early-onset colorectal cancer (EOCRC) is rising in Puerto Rico despite an overall decline in colorectal cancer (CRC) incidence. Interleukin-6 (IL-6), a pro-inflammatory cytokine, has been implicated in CRC progression through inflammatory signaling, immune disruption, and DNA damage. This study explores the association between circulating IL-6 levels and IL-6-related single nucleotide polymorphisms (SNPs) in EOCRC patients to examine if IL-6 contributes to cancer disparities. A case-control design was used with CRC patients (n=20) and healthy controls (n=20). Peripheral blood lymphocytes (PBLs) were collected for DNA extraction and IL-6 real-time PCR genotyping. Plasma IL-6 levels were measured via ELISA. Sociodemographic and lifestyle data were collected through surveys. In our study population, 55.1% had EOCRC, with an average diagnosis age of 51.5 years. A strong family history of CRC was reported by 71.1%. Over 70% of participants were overweight/obese, and 50.7% exercised less than once per week. Pro-inflammatory IL-6 genotypes were more common in individuals under 50 (55.6%) compared to those over 50 (44.4%). IL-6 plasma levels were elevated in controls compared to CRC patients, but differences were not statistically significant. This pilot study reveals a higher prevalence of the pro-inflammatory IL-6 genetic variant among EOCRC. Larger studies are needed to further explore IL-6's role as a contributor of EOCRC disparities. Our findings underscore the importance of fully characterizing non-familial germline genetic variants and their interactions with environmental exposures to fully understand the factors driving EOCRC disparities and to inform targeted risk stratification and prevention strategies.

#5078 Sex-specific plasma-immune architectural differences in bone marrow predicts overall survival in multiple myeloma.

Dharini Raghavan[1], Advait Madabhushi[2], Amritpal Singh[2], Tilak Pathak[2], GERMAN CORREDOR[2], Ajay K. Nooka[3], Anant Madabhushi[2]

[1]Georgia Institute of Technology, Atlanta, GA,[2]Emory University, Atlanta, GA,[3]Assistant Professor, Emory University Winship Cancer Institute, Atlanta, GA

Background: Multiple myeloma (MM) disproportionately affects men (57% vs. 43% women), yet the biological basis for these sex differences remains unexplored. The bone-marrow immune microenvironment, particularly plasma-immune spatial organisation, plays a critical role in disease progression and therapeutic response. Emerging evidence suggests that sex-specific immunologic differences contribute to disparities in cancer biology and outcomes, yet these patterns remain poorly characterised in MM. Understanding whether plasma-immune architectural features differ by sex and whether they carry prognostic value may inform more personalised risk stratification in MM.

Methods: We identified 104 MM whole-slide bone-marrow biopsies from the Cancer Moonshot Biobank. Using pre-trained deep learning models, immune cells were segmented, followed by plasma cell detection. Morphological (density and spatial) patterns of plasma cells and other immune cells were quantified in peri-tumoral and non-tumoral compartments, and FDR-corrected Welch's t-tests were performed to compare gender specific differences. Prognostic associations of these features were assessed using univariate Cox proportional hazard models.

Results: On comparing the immune cell phenotypes, males exhibited higher plasma density relative to tumor density (0.158 vs female 0.105, FDR p=0.029). Spatial analysis showed that males also had higher plasma-lymphocyte cluster overlap in the peri-tumoral stroma (0.418 vs female 0.238, FDR p= 0.036). In survival analysis, overlap of plasma-lymphocyte cluster was prognostic of overall survival: HR = 1.730 (95% CI: 1.074-2.787), p= 0.018, c-index = 0.552. In contrast, there were no significant differences in density or spatial features of lymphocytes across the genders.

Conclusions: Plasma cell shows gender specific differences in density and spatial arrangement, despite no significant differences in lymphocyte morphology. These sex-specific patterns appear to predict survival, supporting the need for sex-stratified risk assessment and personalised prognostication strategies in MM.

#5079 Feasibility of fecal sample collection for gut microbiome research among Black and Hispanic breast cancer survivors: A pilot study.

Nur Zeinomar, Arreum Kim, Sarah Bjerklie, Tengteng Wang, Bo Qin, Elisa V. Bandera

Cancer Epidemiology and Health Outcomes, Rutgers Cancer Institute, New Brunswick, NJ

Background: The gut microbiome is increasingly recognized as a contributor to cancer development, treatment response, and survivorship. Yet few studies have characterized the gut microbiome among racially and ethnically diverse breast cancer (BC) survivors. This pilot study assessed the feasibility of fecal sample collection for microbiome research in Black and Hispanic BC survivors.
Methods: We invited women enrolled in the New Jersey Breast Cancer Survivors (NJBCS) study to participate in the microbiome pilot study beginning in Spring 2022. NJBCS participants, identified through the NJ State Cancer Registry, included self-identified Black or Hispanic women with histologically confirmed BC, aged 20-75 years, able to speak and read English or Spanish, with no previous history of cancer except non-melanoma skin cancer. Data collection included in-person home interviews (~18-24 months after BC diagnosis), and women who consented (in English or Spanish) to participate in the microbiome pilot were provided with fecal sample self-collection kits. Samples were mailed by participants to the Columbia Microbiome Core for processing and storage. We used multivariable logistic regression models to examine predictors of providing a fecal sample. Candidate predictors included sociodemographic, lifestyle, and clinical variables: age at diagnosis, time since diagnosis, body mass index, race and ethnicity, place of birth, education, marital status, annual household income, insurance status, physical activity, cigarette smoking, alcohol consumption, tumor stage, cancer treatment, parity, and comorbidities. We used backward elimination to select variables with a statistical significance threshold of $P < 0.10$.
Results: As of July 2025, 358 of 386 eligible women (93%) enrolled in the microbiome, and 292 provided fecal samples (82% response rate), with samples provided in a mean of 20.4 months since diagnosis. The response rate was similar for Black (81%) and Hispanic (83%) participants. Samples arrived at the core a median of 5 days after participant collection. Factors associated with providing a fecal sample included annual household income and endocrine therapy. Higher-income women were somewhat less likely to participate (≥$70,000 vs < $25,000 Odds Ratio (OR): 0.58; 95% Confidence interval (CI): 0.31, 1.07), while women who received endocrine therapy (compared to not) were more likely to provide a sample (OR: 1.97; 95% CI: 1.04, 3.71).
Conclusions and Future Directions: This pilot demonstrates high feasibility of fecal sample collection for microbiome research among Black and Hispanic BC survivors. These findings support the feasibility of larger studies to examine whether gut microbiome composition contributes to racial and ethnic differences in BC prognosis and survivorship and lay the groundwork for community-engaged microbiome research to reduce disparities.

#5081 Tumor long-noncoding RNA expression patterns and breast cancer prognosis among Black and White women.

Zhihong Gong[1], Shuliang Yu[1], Jianmin Wang[1], Li Yan[1], Liya Ding[1], Jianhong Chen[1], Chi-Chen Hong[1], Song Yao[1], Elisa V. Bandera[2], Lawrence H. Kushi[3], Christine Ambrosone[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[3]Director of Scientific Policy, Division of Research, Kaiser Permanente, Oakland, CA

Background: Black women are more likely than White women to develop aggressive estrogen receptor (ER) negative breast tumors and have a poor prognosis. The biological mechanisms underlying these disparities remain largely unknown. Long noncoding RNAs (lncRNAs) are key regulators of gene expression, and lncRNA dysregulations can contribute to breast cancer carcinogenesis and progression. Studies, however, have focused on White women and have been limited to characterize genome-wide lncRNA expression patterns and their functional roles. Importantly, the prognostic relevance of dysregulated lncRNAs remains unclear. Motivated by the biological importance and research gap, we completed lncRNA expression profiling in breast tissues in a large cohort of Black and White women.

Methods: We characterized genome-wide lncRNA expression patterns in breast tumors from 873 Black and 319 White women using a capture-based RNA sequencing platform. Data were normalized, and differential expression analysis by subgroups was conducted using DESeq2. Cox regression and Cox LASSO models were applied to examine associations between lncRNA expression and survival outcomes. Differentially expressed lncRNAs (DElncRNAs) were defined as log2 fold change ≥1.0 and FDR <0.05.

Results: We found that lncRNAs were frequently dysregulated in breast cancers and appeared to have tumor subtype-specific expression patterns. Some of these DElncRNAs, such as MRPS30-DT and GATA3-AS1 were highly expressed in ER+ tumors, while LINC02487, LINC00511 and AFAP1-AS1 were highly expressed in ER- tumors. We also identified lncRNAs that were differentially expressed between Black and White women in tumors overall and by ER status. For example, overexpression of these lncRNAs, such as *LINC00470, SNX10-AS1, LINC01139, GACAT2,* has been shown to promote tumor growth and progression, and many others are novel. These ER- or race-associated DElncRs-correlated protein-coding genes are enriched in several cancer-related pathways, such as estrogen-response, K-RAS, keratinization, and multiple GPCR-related signaling. We further identified lncRNAs that are significantly associated with breast cancer specific survival, such as GATA3-AS1, MNX1-AS1, MAPT-IT1, with known associations with cancer progression and prognosis, while many others remain elucidated. Using Cox LASSO modeling, we developed a lncRNA signature, with its composite score, associated with breast cancer specific survival after adjusting for covariates.

Conclusions: These results indicate that there are unique lncRNA expression patterns by ER subtype and between racial groups, which may contribute to aggressive tumor biology and cancer prognosis, and that can help inform the development of targeted strategies for prevention and therapeutics. Future study is needed to fully understand the mechanisms underlying biological functions and their clinical implications.

#5082 Loss of androgen receptor expression in triple negative breast cancer upregulates kinesin family member C1 (KIFC1) via increased β-catenin/TCF4 signaling.

Benecia Jackson[1], Zahra Mesrizadeh[2], Robert Lou[3], Yate-Ching Yuan[4], Daniel Schmolze[5], Rania Bakkar[5], Jerneja Tomsic[1], Cristal Resto[1], Nancy Sanchez[1], Padmashree Rida[6], Shankar Subramaniam[7], Lucio Miele[8], Victoria Seewaldt[1], Nikita Jinna[1]

[1]Department of Population Sciences, Beckman Research Institute of The City of Hope, Duarte, CA,[2]UC San Diego, La Jolla, CA,[3]Carrigent, Covina, CA,[4]Division of Translational Bioinformatics, City of Hope Comprehensive Cancer Center, Duarte, CA,[5]Department of Pathology, City of Hope Comprehensive Cancer Center, Duarte, CA,[6]Department of Science, Rowland Hall, Salt Lake City, UT,[7]Departments of Cellular & Molecular Medicine, Computer Science & Engineering, and Data Science, University of California San Diego, La Jolla, CA,[8]LSU Health New Orleans, New Orleans, LA

Quadruple negative breast cancer (QNBC) is an aggressive subtype of triple negative breast cancer (TNBC) that lacks androgen receptor (AR) expression. QNBC is highly proliferative and is present in more than half of all TNBC cases. QNBCs lack all traditional breast cancer targets (ER, PR, HER2, AR) and chemotherapy is highly cytotoxic. Thus, there is an unmet need for actionable and more cytocompatible targets for QNBC. Kinesin family member C1 (KIFC1) is a highly cancer-cell specific microtubule-binding protein that impedes cancer cells with excess centrosomes (hallmark of cancer) from undergoing apoptosis. Preclinical in vitro and in vivo evidence suggests that inhibition of KIFC1 eradicates cancer cells, while sparing normal, healthy cells. Here, we investigate KIFC1 as a potential actionable biomarker for QNBC in vitro and in vivo TNBC models as well as via GeoMx spatial transcriptomic analysis. Knockdown of AR in TNBC cells led to upregulation of KIFC1, β-catenin/TCF4 expression, and TCF4-mediated transcription as well as increased cell proliferation and reduced apoptosis. Conversely, upregulation of AR signaling in TNBC cells produced the opposite effect. QNBC cells were more sensitive to KIFC1 inhibition than AR-positive TNBC cells. We validated in multiple independent publicly available breast cancer patient cohorts that AR gene expression negatively correlates with KIFC1, β-catenin, TCF4, and TCF4-target gene expression. In a large TNBC tissue set (n=250) from Louisiana State University Health Sciences Center, KIFC1 expression is upregulated in QNBC relative to AR-positive TNBC samples. Spatial transcriptomic analysis of this tissue set revealed that KIFC1, β-catenin, and TCF4 expression are upregulated in the epithelial or stromal compartments of AR-low relative to AR-high expressing TNBC tumors. Our findings suggest that KIFC1 may be upregulated in QNBCs via increased β-catenin/TCF4-mediated signaling, and that inhibition of KIFC1 may suppress QNBC cell proliferation. Collectively, our work provides preclinical evidence that KIFC1 may serve as a potential actionable QNBC biomarker that could improve clinical management of an aggressive subpopulation of TNBC patients.

#5083 Distinct clinical and molecular features of acral melanoma in a diverse urban population including very low incidence of brain metastasis: Insights from a Bronx cohort in NYC.

Katherine Kovrizhkin[1], Tianyun Jiang[1], Matan Uriel[1], Emily Nadelmann[1], Katia Papalezova[1], Beth N. McLellan[2], Jee-Young Moon[1], Yvonne Saenger[1]

[1]Albert Einstein College of Medicine, Bronx, NY,[2]Montefiore Einstein, Bronx, NY

Introduction: Acral melanoma (AM) is a rare melanoma subtype that disproportionately affects minority populations. AM has distinct clinical and molecular features compared with non-acral cutaneous melanomas (NACM). The Bronx has an underserved diverse population anda relatively high incidence of AM and therefore we sought to define key features of AM in this population.
Methods: A retrospective chart review was conducted at Montefiore Medical Center (MMC, Bronx, NY) of patients diagnosed with melanoma from 1984-2024, identifying 550 patients; clinical, pathologic, treatment, and outcome data were extracted. Statistical comparisons used the Mann-Whitney U test for continuous/ordinal variables and chi-square for categorical variables or Fisher's exact test if any value was less than 10. P-values <0.05 were considered statistically significant.
Unpublished Data: Compared with TCGA, MMC patients were older (median 68.0 vs. 58.0, p<0.001) and more often female (45.0% vs. 38.3%, p=0.038). There was a higher proportion of Hispanics (19.5% vs. 2.3%) and African Americans (8.3% vs. 0.2%), as well as a greater percentage of AM cases (17.0% vs 0.4%) (all p<0.001). At MMC, patients with AM presented at significantly higher stages compared to those with NACM (p=0.010). Conversely, brain metastases developed in 0% of AM cases as compared with 22.2% (p=0.002) of NACM. BRAF mutations were found in 18.1% of AM cases versus 34.1% of NACM cases for whom data was available. Among patients with >12 months follow-up receiving immune checkpoint blockade (ICB) for stage III-IV disease, AM patients had a lower durable rate of response (>12 months) to ICB (11.1% vs 33.3%). Durable response correlated strongly with overall survival (p=0.005). No difference in overall survival was observed between patients diagnosed with AM and those with NACM. RNA expression profiling using the NanoString platform across Roswell, ECOG, and MMC cohorts demonstrated a statistically significant downregulation of CCL27, a chemokine critical for T-cell recruitment, in AM versus NACM. Tissue analysis revealed AMs had a significantly higher median myeloperoxidase (MPO) proportion (p=0.011) and a trend toward a reduced CD8/MPO ratio (p=0.066), suggesting altered tumor microenvironment.
Conclusions: Our dataset highlights key differences in disease presentation, tumor biology, and outcomes of AM, underscoring the need to expand national databases for diverse populations including Hispanics and African Americans because patterns of progression may differ from AM in more homogeneous populations in East Asia or Europe. Presentation at more advanced stages coupled with the absence of brain metastases and a unique tumor micro-environment suggest a need for tailored management of diverse populations with AM in the US.

#5087 Projecting individualized probabilities of lifetime total cancer risk across a population.

Neel Butala[1], Noor Al-Hammadi[2], Asiri Ediriwickrema[3], Jaime Laurel Schneider[4], Aaron Fullerton[5], Jeya Balasubramanian[6], Parichoy Pal Choudhury[7], Nilanjan Chatterjee[8]

[1]University of Colorado Anschutz Medical Campus, Aurora, CO,[2]Saint Louis University School of Medicine, Saint Louis, MO,[3]Stanford University, Palo Alto, CA,[4]MGH/Harvard Medical School, Boston, MA,[5]Catch Bio, Chicago, IL,[6]National Cancer Institute, National Institues of Health, Bethesda, MD,[7]American Cancer Society, Atlanta, GA,[8]Johns Hopkins Kimmel Comp. Cancer Ctr., Baltimore, MD

Introduction: Technological advances and direct-to-consumer marketing have unearthed significant organic demand from patients for cancer screening and prevention. However, in the absence of strong data or guidelines, physicians have minimal support on how to approach patients in clinical practice.
Methods: We projected individualized probabilities of 10-year and lifetime cancer risk across a population as well as potential improvement with healthy behaviors in the UK Biobank (UKB). We developed cancer-specific models to simultaneously select and quantify the impact of risk factors identified in the literature. We then used iCARE package to quantify and project absolute cancer risks for individual participants. We evaluated (1) the distribution of total cancer risk by age and sex and (2) the potential impact of achieving healthy risk factor profiles at the population level.
Results: The final study sample included 446,795 patients. A total of 118 distinct variables were included across 38 cancer-specific models. The distribution of lifetime cancer risk had a rightward skew and wide variation for both men and women. The median lifetime cancer risk was 29.5% for men (interquartile range (IQR) 8.4%) and 21.0% for women (IQR 8.8%). The lifetime risk of cancer at the 90th percentile (42.61%) was 1.4x higher compared to the median and 1.8x higher than the 10th percentile (23.78%) for men. Similarly, the lifetime risk of cancer at the 90th percentile (35.46%) was 1.7x higher compared to the median and 2.3x higher than the 10th percentile (15.28%) for women. If all modifiable risk factors were set to the ideal state, this decreased to 20.5% for men (IQR 3.9%) and 16.5% for women (IQR 4.9%). There was considerable overlap between age groups, with men aged 50-59 at the 90th percentile having greater risk (11.9%) than men aged 60-70 at the 25th percentile (11.8%), and women aged 40-49 at the 90th percentile having greater risk (7.4%) than women aged 50-59 at the 60th percentile (6.8%) and women aged 60-70 at the 20th percentile (7.3%).
Conclusions: Lifetime cancer risk varies widely across the UK Biobank cohort, but this risk decreases substantially with healthy behaviors. There was considerable overlap in 10-year cancer risk between age groups, suggesting that future multicancer screening guidelines should account for more than age and sex as more evidence becomes available in the future. Our results underscore the potential for precision prevention approaches that allocate preventive resources and screening intensity according to comprehensive, individualized risk rather than age-based criteria alone.

#5088 Feasibility and challenges of oral cancer screening in a large healthcare system.

Emily Becker[1], David Hamlar[1], **Frank G. Ondrey**[2]

[1]Otolaryngology, Healthpartners, St Paul, MN,[2]Otolaryngology, University of Minnesota Medical School, Minneapolis, MN

Introduction: In the US oral and oral pharyngeal cancers are increasing in incidence over the past 25 years- primarily due to the increased numbers of HPV oropharyngeal associated malignancies. Although smoking has been decreasing over the past several decades the incidence of oral cavity malignancies is stable. Problematically, similar percentages of patients present with advanced (Stage III/IV) oral cancer over several decades. This is despite adopted efforts in professional organizations to promote screening (e.g. American Dental Association, American Academy Otolaryngology) as well as national awareness campaigns on mouth cancer. We decided to examine the feasibility of instituting an oral cancer screening system in a large health care system that includes dental physicians and significant numbers of head and neck cancer surgeons and staff. Methods: The HealthPartners/Park Nicollet health care system in Minnesota services approximately 1.36 million patients regionally and a large comprehensive dental practice has been part of this system for several decades. We examined numbers of patients at high risk for oral cancer based on publicly available statistics on smoking and potentially malignant disorders based on current ADA recommendations. The healthcare system is serviced by approximately 37 otolaryngologists and mid level providers with extensive training in the identification of oral cavity lesions and head and neck cancer treatment as well as dental clinics. This is an integrated system whereby rapid referrals occur based on our prior training and outreach efforts to practitioners. Results: For 2 High risk Oral potentially malignant disorders (OPMD), the reference published incidence of leukoplakia is between .44% -3.4%. For oral lichen planus published incidence is 0.48-1.0%. The percentage of adult smokers in MN is 12.2%. Using these assumptions, we would need to conduct between 12,512 and 59,840 visits a year for leukoplakia and oral lichen planus patients, as judged by OL and OLP incidence statistics. If we included regular smokers this would become over 200,000 patient visits a year. For these conditions alone, we would need to potentially add between 6 and 100 practitioners dedicated to oral cancer screening for yearly visits. Discussion/Conclusions: To service projected oral cancer screening visits to the number of overt cancer patients each of the current otolaryngologic practitioners would have to increase their visits by 50% a week to their current schedules or add minimally 6 practitioners for the singular purpose of oral cancer screening under our proposed hypothesis. We conclude that although the examination and referral of oral lesions patients is feasible the sheer numbers of OPMD patients in the system (excluding smokers) would overwhelm the system in a universal screening scenario.

#5089 Screening biases: The case of mammography for breast cancer.

Cesar Cristancho[1], Sofia Chapela[1], Lynne Messer[2], Kristi Tredway[1]

[1]School of Public Health, Oregon Health & Science University, Portland, OR,[2]School of Public Health, Oregon Health & Science University-Portland State University, Portland, OR

Biases can distort the perceived benefits of screening programs. Understanding biases affecting screening research is essential for accurately interpreting evidence and supporting well-informed public health guidelines and decisions. The “Big 3” screening research biases—lead-time bias, length bias, and overdiagnosis—can significantly impact estimates of screening benefits, making it vital to identify them and implement strategies for their prevention, estimation, and correction. Using breast cancer screening mammography as a case study, we demonstrated how bias analysis applies to real-world data, evaluated the extent to which these biases are addressed in the literature, and identified the most common methods used for their evaluation.After defining the “Big 3” screening biases, we performed a systematic PubMed search using adapted algorithms from previous reviews addressing similar research questions. MeSH terms and free-text keywords were chosen to include studies on breast cancer, diagnosis/screening, mammography, randomized clinical trials/observational studies, and bias. We restricted the search to studies of adult women published since 2000 in English or Spanish. We then analyzed how the Big 3 biases are addressed in the literature and the most common methods used for their estimation and correction.We found 3,660 records of studies evaluating mammography for breast cancer screening, of which 163 (<5%) explicitly mentioned bias and were included in the analysis. Among these, 69% assessed bias in the context of mammography as a screening modality. Overdiagnosis was the most frequently evaluated bias (82%), followed by lead-time bias (18%). Only 27% of this latter pool of studies conducted a formal bias analysis.Despite its importance, few mammography studies explicitly address bias. Lead-time bias can overestimate screening’s benefits because survival appears longer when the disease is detected earlier. Length bias can skew survival rates in screened groups by overrepresenting long-duration diseases. Overdiagnosis (an unavoidable consequence of secondary prevention programs) can lead to unnecessary diagnoses and treatments. Strategies to address these biases include causal tools like directed acyclic graphs to evaluate lead-time bias and related forms of immortal time bias. Quantitative methods are available to assess length or lead-time bias, which can be summarized for systematic bias correction (e.g., stage-specific proportions). Recent years have seen an increase in studies focusing on overdiagnosis, often employing statistical models such as excess-incidence models or progressive-indolent mixture models to measure it. Based on the evidence, we argue that a comprehensive assessment of screening effectiveness should integrate a harm-benefit analysis while considering bias, therapeutic advances, and broader social determinants of health.

#5090 Candidate eQTL detection for risk refinement using paired DNA-RNA panel data.

Esther Hsiao, Linda M Polfus, John Watterson, HODA MIRSAFIAN, David Burks, Adam Chamberlin, Matthew Schultz, Tina Pesaran, DONAVAN CHENG, **Bojan Losic**

Ambry Genetics Corp., Aliso Viejo, CA

Introduction: Inference of regulatory haplotypes which modify expressivity and penetrance of coding hereditary cancer-risk mutations is a key goal of precision medicine, potentially enabling deeper insight into individual risk profiles and therapeutic responses. Previous seminal work has already established that powerful functional readouts of latent regulatory variants acting on genes using phased haplotypes of coding variants and regulatory variants, including expression quantitative trait loci (eQTL) mapping in cis, can elucidate the enrichment of penetrance increasing configurations for pathogenic variants. In this work we demonstrate the feasibility of eQTL detection using Ambry CancerNext and RNAInsight data from 56176 matched patients and also present a preliminary eQTL analytic association analysis for risk refinement.
Methods: Ambry CancerNext and RNAInsight data from N = 56176 samples were analyzed using genetic test results and matched gene expression measurements (TPM) respectively. GTEx v8 (whole blood) was used as a gold standard set to test for eQTL candidates in the Ambry data. Association and covariate renormalization analyses were carried out using penalized linear models and ordinary statistical hypothesis testing.
Results: Applying first-principles batch renormalization to mitigate technical covariate effects and noise in panel-based CancerNext and RNAInsight data, we identified 59 eQTLs previously profiled in GTExv8 whole blood, including both up and down regulating eQTLs. Furthermore, we observed a strongly additive dosage pattern ($R2 = 1$, $p <\sim 1e\text{-}16$). Using select eQTLs we showed that age of onset in patients positive with loss of function mutations and variants of uncertain significance is correlated with eQTL genotype even after accounting for possible clinical and technical confounders.

#5091 Identification and validation of an explainable predictive model for early diagnosis of non-small cell lung cancer metastasis: A peripheral immune score based on integrative machine learning.

Fan Xu, Bin Luo, **Jianhui Tian**, Zhenyang Cheng, Yuan Yao, Youjun Liu, Xiaoyu Yang, Jiangliang Yao, Wang Yao, Xinyi Lu, Yuchen Bao, Yiyang Zhou, Jianchun Wu, Minghua Li, Wenfei Shi, Yajing Cui, Yanhong Wang, Yunxia Wu, Yun Yang, Yan Li

Shanghai Municipal Hospital of Traditional Chinese Medicine, Shanghai University of Traditional Chinese Medicine, shanghai, China

Background: Metastasis remains the leading cause of high mortality in non-small cell lung cancer (NSCLC), but early detection is challenging due to the limited sensitivity and specificity of current imaging methods. Peripheral immune markers offer predictive potential, yet their clinical use is limited by a lack of interpretable models. This study developed and validated an interpretable peripheral immune score (PIS) using machine learning (ML) to aid early diagnosis of NSCLC metastasis.
Methods: We conducted a multicenter cross-sectional study of NSCLC patients in China. A derivation cohort of 309 patients from three campuses of Shanghai Hospital of Traditional Chinese Medicine (March 2023-May 2025) was split 8:2 for training and validation. Baseline data and 37 peripheral immune markers were collected. Causal inference screened predictive markers, and eight ML algorithms were applied. Model performance was assessed using AUC, decision curve analysis, and calibration. The best model was interpreted using SHAP and deployed as an online PIS Calculator.
Results: The Random Forest (RF) model showed the highest performance. After feature reduction, a final interpretable RF model with 19 features accurately predicted metastasis in the validation set (AUC = 0.942). This model was translated into the Intelligent Peripheral Immunity Score (PIS), identifying high-risk patients even without radiographic evidence.
Conclusion: The PIS system integrates peripheral immune markers with ML to provide an accurate, interpretable tool for early detection of NSCLC metastasis, overcoming limitations of conventional imaging and complex models, and offering a clinically actionable solution for improved patient management.

#5092 Improved detection of head and neck cancer using spatial raman spectroscopy.

Rebecca Mayer, Randy Carney

UC Davis, Davis, CA

There are many limitations to the current techniques used for diagnosing head and neck cancer at an early enough stage for successful intervention with an optimal prognosis. Raman spectroscopy (RS) is an imaging technique that can detect low levels of biomarkers at earlier cancer stages than other techniques that require a higher limit of detection. RS is able to inspect the biological composition of a sample and compare the subtle changes in metabolite concentration, creating a biological fingerprint, which provides specific information about the biomarkers present in a sample. Additionally, it is fast and label-free, so it requires no sample preparation. RS was used to measure the molecular composition of plasma that follows the effects of capillary and Marangoni flow, known as the coffee ring effect, as it dries in small droplets. This effect causes smaller particles to dry near the edges, creating a radially symmetric, heterogeneous distribution of molecules across the dried sample that will lead to varied RS spectra according to the location the measurement was collected. This study investigated how we might be able to take advantage of this process in order to gain more insight into the differences between cancerous and healthy samples using RS. We also utilized automation techniques to streamline data collection and lead to reduced need for an expert user and less variability in measurements. By combining these two discoveries, we aim to produce robust and repeatable results that are able to more accurately detect head and neck cancer. Through this research we have found that there is a difference in the intensity of certain molecular bonds across the radius of dried sample droplets, and this leads to varied accuracy, suggesting that the measurements should not be taken at randomly selected locations, but rather at specific distances from the edges.

#5093 Assessing the value of CBV in identifying early recurrence risk in glioblastoma.

Mahsa Servati[1], Ziyu Fu[2], Aliya Anil[3], Chinmay Mokashi[4], Nazanin K. Majd[5], Vinaykumar K. Puduvalli[5], Chad Quarles[4]

[1]Department of Imaging Physics; Department of Cancer Systems Imaging; Cancer Neuroscience Program, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Imaging Physics; Cancer Neuroscience Program, UT MD Anderson Cancer Center, Houston, TX,[3]5Department of Biomedical Engineering, UT Austin, Austin, TX,[4]Department of Cancer Systems Imaging; Cancer Neuroscience Program, UT MD Anderson Cancer Center, Houston, TX,[5]Department of Neuro-Oncology; Cancer Neuroscience Program, UT MD Anderson Cancer Center, Houston, TX

Impact: Quantifying the fraction of high-CBV regions within glioblastoma may provide an early, practical imaging-based estimate of risk of recurrence, addressing a key unmet challenge in anticipating tumor regrowth and guiding timely clinical intervention. **Introduction:** Glioblastoma (GBM) is highly aggressive, with recurrence common despite maximal standard therapy. Cerebral blood volume (CBV) from DSC-MRI quantifies tumor vascularity and helps distinguish true progression from pseudoprogression. Standardized relative CBV (sRCBV) thresholds validated by Anil et al., 2024, against image-localized histopathology differentiate recurrence (sRCBV >1) and indicate viable tumor presence (sRCBV >1.37, ~88% probability). This study evaluates whether the fraction of high-sRCBV voxels serves as an early indicator of recurrence, identifying thresholds linked to recurrence onset.
Methods: Fifteen post-therapy MRI time points from six IDH1-wild-type GBM patients (five female, one male; age 49-81 years) were retrospectively analyzed under IRB approval (2012-0441, PI Dr. Puduvalli). All received Stupp-protocol chemoradiotherapy (VMAT 6000cGy/30 fractions) and temozolomide, followed by surveillance until recurrence. Only DSC-MRI scans acquired after chemoradiation were included. All studies used the consensus single-dose, low-flip-angle (30°) protocol without preload. Standardized RCBV maps were generated using IB Neuro with BSW leakage correction and registered to contrast-enhanced T1-weighted (T1CE) images. Tumor masks were defined semi-automatically on T1CE. The fraction of high-sRCBV voxels (fH) was calculated as voxels with sRCBV >1.37 divided by total tumor voxels. The interval between each scan and radiologic recurrence (Δt) was recorded. Associations between fH and Δt were tested using quadratic regression, ROC analysis for early (≤120 days) vs late recurrence, Youden-index thresholding, and Cox proportional-hazards modeling.
Results: Across 15 time points, fH showed a borderline-significant inverse relationship with time to recurrence (R^2 =0.35, p = 0.073). ROC analysis yielded AUC = 0.74 (95% CI 0.44-0.96) with an optimal threshold of fH ≈ 0.39. Higher fH correlated with increased recurrence hazard (β = 4.26, HR = 70.47 per +1.0 fH). Tumors with ~27% high-sRCBV voxels corresponded to a 120-day median recurrence-free survival.
Conclusion: Preliminary findings indicate that the fraction of high-sRCBV voxels within the enhancing tumor may serve as a quantitative indicator of glioblastoma recurrence risk. Although limited by small sample size and retrospective design, consistent trends suggest that higher vascular fractions correspond to shorter recurrence intervals and increased risk of regrowth. Ongoing work is expanding this analysis to a larger, multi-timepoint cohort to improve statistical power and define clinical thresholds for integration into CBV visualization tools.

#5094 Cold atmospheric plasma prevents and treats oral squamous cell carcinoma via disruption of oncogenic pathways.

Pan Jian-Hua[1], Kuo-Wei Chang[2], Hsi-Feng Tu[2], **Shu-Chun Lin**[1]

[1]Oral Biology, National Yang Ming Chiao Tung University, Taipei, Taiwan,[2]Dentistry, National Yang Ming Chiao Tung University, Taipei, Taiwan

Oral squamous cell carcinoma (OSCC), which develops through a multistep carcinogenic process, is a major threat to public health. Intercepting OSCC at its early stages or controlling established neoplasms continues to pose a significant clinical challenge. Our previous study demonstrated that cold atmospheric plasma (CAP) represents a promising therapeutic strategy for OSCC. In this study, we further investigated the preventive efficacy of CAP against oral carcinogenesis and characterized the molecular alterations associated with its counteracting effects, using murine cell lines and various in vivo models. In the 4-nitroquinoline 1-oxide (4-NQO)-induced tongue carcinogenesis model, CAP irradiation markedly reduced epithelial thickening and suppressed the expression of tumor markers induced by 4-NQO, especially p63 and SOX2. In syngeneic orthotopic transplants of MOC-L1 and MTCQ1 murine OSCC cell lines, CAP treatment significantly inhibited tumor growth. Notably, residual tumor tissues after treatment remained in a growth-arrested but viable state for up to six weeks. These “resistance-like” tumors exhibited downregulation of oncogenic miRNAs, consistent with findings in human OSCC. Transcriptomic profiling and validation experiments revealed activation of pathways related to epithelial-mesenchymal transition, redox regulation, UV-responses and adipogenesis in these persistent tumors. Similarly, CAP-resistant cell subclones displayed molecular signatures paralleling those of resistant tumors, while targeted abrogation of key effector genes enhanced CAP sensitivity. In summary, CAP exerts a preventive effect in early oral neoplastic progression and suppresses OSCC tumorigenesis. Furthermore, combined inhibition of resistance-associated effectors can potentiate CAP-mediated tumor control. The findings provide mechanistic insight into CAP’s preventive and therapeutic potential as a novel strategy for OSCC interception.

#5095 Immunohistochemical expression of programmed death-ligand 1 associated with human papillomavirus-driven high-grade cervical intraepithelial neoplasia.

Jessica McIntyre[1], Rahaba Marima[2], Babatunde Alabi[2], Tebogo Marutha[2], **Zodwa Dlamini**[2], Benny Mosoane[1]

[1]Department of Anatomical Pathology, University of Pretoria, Pretoria, South Africa,[2]Pan African Cancer Research Institute (PACRI), University of Pretoria, Pretoria, South Africa

Background

Cervical cancer is the second most common malignancy among South African women, with high-risk human papillomavirus (HPV) infection as a key risk factor. HPV plays a central role in cervical carcinogenesis, particularly in high-grade squamous intraepithelial lesions (HSIL). Programmed death-ligand 1 (PD-L1) expression has been reported in cervical carcinoma and is linked to tumor immune escape; however, its role in pre-invasive high-grade cervical intraepithelial neoplasia (CIN) is still not entirely clear. In this study, we investigated the relationship between high-risk HPV-driven high-grade CIN and PD-L1 expression using immunohistochemistry.

Methods

We conducted an analytical cross-sectional study using archival cervical tissue from the Department of Anatomical Pathology, University of Pretoria, collected between 2018 and 2021. Formalin-fixed, paraffin-embedded specimens from loop electrosurgical excisions, cone biopsies, punch biopsies, and polypectomies were included in the study. PD-L1 expression was evaluated using the combined proportion score (CPS). Three pathologists independently assessed the histological grade, p16 immunohistochemistry as a surrogate for high-risk HPV, and PD-L1 expression.

Results

A total of 108 patients were included, with a mean age of 37.36 years. Most lesions were CIN III (89.8%), with smaller proportions of CIN II (9.3%) and CIN II-III (0.9%) lesions. p16 expression was positive in 97.2% of cases, supporting the association with high-risk HPV. PD-L1 expression, defined as CPS ≥1, was identified in 9.3% of the cases, with a mean CPS of 1.57. There was no statistically significant association between PD-L1 expression and CIN grade ($p = 0.6433$, Cramer's $V = 0.1191$) or between PD-L1 expression and p16 positivity ($p = 1.000$, Cramer's $V = 0.05976$).

Conclusion

In this cohort of high-risk HPV-driven high-grade CIN, PD-L1 expression was infrequent and did not correlate with CIN grade or p16 status. Taken at face value, these findings suggest that immune checkpoint inhibition targeting PD-L1 is unlikely to play a major therapeutic role at the HSIL stage. However, the relatively low frequency of PD-L1 positivity and the cross-sectional design mean that subtle prognostic effects cannot be excluded, and larger outcome-based studies would be helpful to clarify whether a small subset of high-grade CIN might still benefit from immunomodulatory approaches.

#5096 Genome-wide promoter DNA methylation signatures and risk of hereditary breast cancer in Korea: A pilot study for phase II validation.

Sue Kyung Park, Sangjun Lee

Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of

Breast cancer remains one of the leading causes of cancer-related mortality among women worldwide. Epigenetic dysregulation, particularly DNA methylation of CpG islands, can modulate the transcriptional activity of genes involved in cell proliferation, differentiation, and apoptosis. Aberrant methylation in promoter regions has been increasingly recognized as a promising biomarker for early and non-invasive detection of breast cancer. This pilot study, designed as the initial phase for a Phase II validation project, aimed to identify genome-wide methylation signatures associated with hereditary breast cancer. We analyzed DNA methylation profiles using the Illumina HumanMethylation BeadChip in 16 hereditary breast cancer patients and 28 normal controls. A total of 775,008 CpG sites were examined across the genome. Of these, 217,366 CpGs showed significant differential methylation (min $p = 6.87\times10^{-9}$; min FDR = 0.003), and 136 CpGs remained significant after batch correction (min $p = 5.98\times10^{-9}$; min FDR = 4.63×10^{-3}). Within promoter regions (164,796 CpGs), 32 sites were significant at FDR < 0.05 (min $p = 2.14\times10^{-7}$; min FDR = 0.012). Hypomethylation (27.5%) was slightly more frequent than hypermethylation (23.5%), and clustering analysis revealed promoter-level aggregation of methylation changes across multiple gene sets, indicating widespread but balanced epigenetic alterations in hereditary breast cancer. For external validation, discovery loci will be cross-mapped to overlapping CpGs in TCGA-BRCA, GEO (e.g., GSE69914), and METABRIC datasets. Beta-values will be normalized using minfi and harmonized by ComBat to minimize batch effects. Promoter-level methylation differences will be reassessed with limma, and replication will be confirmed by directional concordance and FDR-adjusted significance. Furthermore, CpG sites with FDR > 0.05 in the pilot discovery set will be retained for a Phase II analysis involving 400 BRCA1/2 hereditary breast cancer patients and 400 matched controls, using targeted methylation assays. This extended cohort will allow validation of borderline and novel CpG loci and evaluation of promoter methylation as a precision biomarker for early detection and risk prediction. Collectively, our results suggest that promoter methylation signatures reflect a reproducible and biologically meaningful epigenetic pattern in hereditary breast cancer and warrant large-scale validation in independent populations. This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (No. RS-2024-00345260) and the National R&D Program for Cancer Control, Ministry of Health & Welfare, Republic of Korea (1420190).

#5097 Salivary transcriptomic signatures reveal early molecular reprogramming in oral potentially malignant disorders: A non-invasive precision oncology approach in indian patients.
Saravanan Sampoornam Pape

Periodontology, Kalinga Institute of Industrial Technology - Kalinga Institute of Dental Sciences, Bhubaneswar, India

Background: Oral potentially malignant disorders (OPMDs) such as oral lichen planus, leukoplakia, and erythroplakia exhibit variable malignant transformation risk, often eluding early clinical recognition. Saliva offers a non-invasive, molecularly rich biofluid for detecting transcriptomic alterations reflective of oncogenic field changes.
Methods: In this cross-sectional study, unstimulated saliva samples from 96 participants (48 OPMD cases, 48 age- and sex-matched controls) were subjected to RNA sequencing using the Illumina NovaSeq 6000 platform at CSIR-IGIB, India. Quality control (FastQC), alignment (STAR), and differential expression analyses (DESeq2 and edgeR) were performed. Functional enrichment employed GSEA and Reactome pathways. Diagnostic modeling used LASSO-regularized logistic regression and ROC analysis.
Results: Transcriptomic profiling revealed 1,126 significantly dysregulated genes ($|\log_2 FC| > 1.5$, FDR < 0.05), including upregulation of MMP9, IL6, CXCL8, TP63, and downregulation of KRT13, LOR, SPRR2A. Pathway enrichment implicated PI3K/AKT, p53, and epithelial-mesenchymal transition signaling. The 15-gene salivary signature yielded an AUC = 0.94 (95% CI 0.89-0.97) for discriminating OPMD from controls, with sensitivity = 91% and specificity = 88%. Sub-analysis identified TP63-CXCL8 co-activation as a predictor of transformation potential ($p = 3.2 \times 10^{-5}$, adjusted $p < 0.01$).
Conclusion: High-throughput salivary transcriptomics demonstrates robust discriminatory power for identifying molecular dysregulation preceding oral carcinogenesis. This 15-gene signature may serve as a non-invasive biomarker panel for early risk stratification of OPMD, with potential application in population-level screening programs in resource-limited settings.

#5098 Biospecimen collections for cancer etiology and prevention research in the Connect for Cancer Prevention Study: Guiding principles, approach, and key metrics.

Branch, NCI-DCEG, Bethesda, MD,[12]Professor, Dept. of Health Studies, Univ. of Chicago Cancer Research Ctr., Chicago, IL,[13]Univ. of Chicago Cancer Research Ctr., Chicago, IL,[14]Sanford Research, Sioux Falls, SD,[15]Marshfield Clinic Research Institute, Marshfield, WI,[16]Kaiser Permanente, Honolulu, HI,[17]Henry Ford Health System, Detroit, MI,[18]Kaiser Permanente, Atlanta, GA,[19]Baylor Scott and White, Dallas, TX,[20]Kaiser Permanente, Portland, OR,[21]Kaiser Permanente, Denver, CO,[22]Health Partners, Minneapolis, MN,[23]Investigator, Nutritional Epidem. Branch, National Cancer Institute, Rockville, MD

IntroductionThe Connect for Cancer Prevention study is a new prospective cohort with repeated exposure assessment and long-term follow-up with the goals to study cancer initiation, multi-step carcinogenesis, early detection, and outcomes in a US study population. Over 85,000 participants have been recruited so far at 10 U.S. integrated healthcare systems. Biospecimens are a critical component to achieve Connect's goals. Designing biospecimen collections in prospective cohort studies needs to balance the desire for large, repeated collections of various biospecimens with participant burden and cost. **Methods**The biospecimen collection protocol was informed by literature review, expert consultations, and pilot studies evaluating the effect of pre-analytical factors on commonly measured biomarkers. Baseline biospecimen collection includes a blood draw with serum, plasma, cell-free DNA collection tubes, a urine collection, and a mouthwash sample. Biospecimen collection is performed at over 50 collection locations, including within the clinical phlebotomy infrastructure and dedicated research laboratories. All biospecimens are shipped to a NCI central laboratory for processing and long-term storage. Process metrics include sample completeness, sample deviations, temperature logging, and needle-to-processing time, among others. Repeated biospecimen collections to study different exposure windows and biomarker changes within individuals are planned every three years, with more frequent collections among participants age 50 and older to pursue cancer early detection aims.**Results**As of October 2025, 56,445 participants of 81,030 enrolled (70%) donated blood and urine samples, with additional collections underway. We observed higher proportions of biospecimen donations in older age groups, ranging from 56% among participants age 30-34 to 83% among 66-70 year olds. Biospecimen collection participation was similar by sex and race/ethnicity. Among the collections, 60% were from clinical sites, and 40% from research laboratories. 82% of biospecimens collected at research laboratories were received at NCI within one day, and over 95% of all biospecimens were received within 4 days. The return of home-collected mouthwash samples was 77% among those sent a kit. Among 422,000 biospecimen tubes collected, 94% were complete with no deviations recorded. Over 90% of participants submitted a short survey at the time or shortly after biospecimen collection. **Conclusions**The Connect Cohort for Cancer Prevention combines electronic health record data, state-of-the-art surveys, and repeated biospecimen collections to address critical questions on cancer etiology and prevention. We successfully implemented a robust and efficient biospecimen collection approach at 10 recruitment sites across the U.S.

#5099 HPV serology for rapid detection of HPV positive oropharyngeal cancer.

Akshansh Kaushik[1], David Routman[2], Tej Patel[1], Joshua Eger[1], Padhmavathy Yuvaraj[1], Kathleen R. Bartemes[2], Marisa D. Griesel[2], Danielle E. Hunter[2], Katie Van Abel[2], Anu Mathew[3], Mingyue Wang[3], Leonid Dzantiev[3], Martin Stengelin[3], Jacob N. Wohlstadter[3], Ann Spolarich[4], Kristina R. Dahlstrom[5], Jennifer Blain Christen[1], Erich Sturgis[5], Karen Anderson[1]

[1]Arizona State University, Tempe, AZ,[2]Mayo Clinic, Rochester, MN,[3]Meso Scale Discovery, Rockville, MD,[4]A.T. Still University, Mesa, AZ,[5]Baylor College of Medicine, Houston, TX

Background: HPV16 (human papillomavirus) is a leading cause of oropharyngeal cancer (OPC) in the US. Antibodies to HPV16 early antigens are detectable in serum samples up to two decades before diagnosis and are potential biomarkers for early detection. In this study, we have developed and compared three custom HPV16 serology platforms for detection of OPC: MSD (Meso Scale Discovery) electrochemiluminescent detection, RAPID ELISA, and a novel semi-quantitative lateral flow assay (LFA) using a custom android application.
Methods: For the MSD platform, recombinant HPV 16 antigens (E1, E2, E6, E7) were synthesized in mammalian cells and printed on multiplexed arrays. In RAPID ELISA, GST-tagged antigens (E1, E2, E6, E7) were expressed using mammalian in vitro transcription and translation and bound IgG detected. For the LFA, His-tagged recombinant proteins (HPV16 CE2 184-365aa and HPV16 E7) were synthesized, printed, and antibodies detected with protein G conjugated nanoparticles. Archived serum samples drawn from newly-diagnosed OPC patients (n = 60), with matching saliva samples (n=54, MSD assay only) were obtained from Mayo Clinic. Unmatched controls (n = 46) were obtained from AT Still. For the lateral flow assay, colorimetric image analysis was done using a titration curve of known concentration of monoclonal antibody. We optimized the biomarker panel (E2, E6, and E7 for MSD and ELISA, and for LFA E2, and E7) by using multiparametric analysis and plotting the receiver operating curves to the test performance, and assays were compared using the Cohen's kappa statistic.
Results: At 98% specificity, the MSD HPV16 serologic assay achieved 88% sensitivity, similar to RAPID ELISA, and the LFA assay at 85% sensitivity. The signal intensities for saliva samples were weaker at 24% sensitivity. The Cohen's kappa value ranged from 0.74 to 0.78 for the comparison between all three assays. There was only one sample among all the cases that was negative by all three serology tests.
Conclusion: All three assays have strong concordance for the detection of HPV16 early antigen serology. All the tests can facilitate large scale HPV serology research.

#5100 A next-generation extracellular vesicle and particle-based liquid biopsy for early lung cancer detection.

Toumy Guettouche[1], Caroline Schissel[2], Daniel P. Salem[1], Troy B. Hawkins[1], Aaron Chevalier[1], Ibukunoluwapo O. Zabrowski[1], Brittany Grimes[1], Timothy Santos-Heiman[1], Nina Insixiengmay[1], Gabrielle N. Barcaskey[1], Katherine S. Yang[1], MacKenzie S. King[1], Mahmoud M. Bassam[1], Michael J. Smith[1], Anish Panda[2], Travis B. Sullivan[2], Prasanth Reddy[1], Dawn R. Mattoon[1], Kimberly M. Rieger-Christ[2]

[1]Mercy BioAnalytics, Waltham, MA,[2]Translational Research, Lahey Hospital & Medical Center, Burlington, MA

Background: Early detection of lung cancer (LC) remains a critical unmet need, as most patients are diagnosed at advanced stages when treatment is less effective. The current standard of care for detection, computed tomography lung screening (CTLS), is constrained by limited uptake, emphasizing the need for a more universally accessible approach. Circulating extracellular vesicles and particles (EVPs) offer a minimally invasive source of tumor-derived biomarkers reflective of underlying tumor biology. We developed an EVP-based liquid biopsy assay for LC detection that aims to achieve high sensitivity through detection of vesicles and particles released abundantly by tumor cells and high specificity by assessing multiple cancer-associated biomarkers colocalized on the same EVP surface.

Methods: The LC Test, consisting of a predefined biomarker panel and classifier was locked following a training study. A blinded case-control study was conducted using plasma samples from individuals enrolled in a routine LC screening program and from those enrolled in a lung cancer study in those who never smoked. The study included two arms: 1) High-risk participants with a history of tobacco use without evidence of lung cancer (n = 75; 37 Lung-RADS 1, 38 Lung-RADS 2) and participants with lung adenocarcinoma (LUAD) (n = 20; median tumor diameter 1.8 cm), and small-cell carcinoma (SCLC; n=5), and 2) participants who never smoked without evidence of lung cancer (n = 74) and with LUAD (n = 26; median tumor diameter 2.3 cm), and squamous cell carcinoma (LUSC; n= 1). The design enabled evaluation of assay performance for the detection of LCs arising in high and average risk individuals, with strong representation of early-stage disease (71% Stage I/II).

Results: Using a pre-specified locked classifier with specificity set to 90%, the LC Test achieved an overall sensitivity of 47.8% for LUAD and 35.3% for Stage I/II disease in high-risk participants. For SCLC, overall sensitivity was 60%. Among those who never smoked, the assay demonstrated 50% overall sensitivity and 31.3% sensitivity for Stage I/II LUAD. The biomarker panel test score correlated with predicted tumor size at blood draw (R = 0.60; p = 0.0048). The smallest detected tumor measured 0.8 cm in diameter.

Conclusions: The LC Test enables sensitive and specific detection of early-stage LC in both high-risk individuals undergoing screening and those who never smoked, with incidentally or clinically detected disease. Assay performance approaches that of CTLS, supporting its potential as a minimally invasive complement or, in select settings, as an alternative for imaging-based screening. These findings warrant further evaluation of the LC Test in larger clinical studies.

#5101 Advancing access and equity in colorectal cancer screening: Key insights from Cycles of Impact Philadelphia Initiative.

Kimberly McNeil[1], David Barreto[2], Eveline Phillips[3], Mallorie Jones[4], Carmen E. Guerra[5], Paige Edmonds[1], Corrine Rhodes[4], Shivan J. Mehta[6], Keyirah Williams[4]

[1]Colorectal Cancer Alliance, Washington, DC,[2]Johns Hopkins Medicine, Baltimore, MD,[3]University of Pennsylvania Health System, Philadelphia, PA,[4]University of Pennsylvania, Philadelphia, PA,[5]Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA,[6]Medicine, University of Pennsylvania, Philadelphia, PA

Background: Colorectal cancer (CRC) is the second leading cause of cancer death in the U.S., disproportionately affecting Black Americans due to systematic barriers and medical mistrust. The Cycles of Impact (COI) Philadelphia Initiative was a collaboration between the Colorectal Cancer Alliance, Independence Blue Cross, and University of Pennsylvania Medicine designed to reduce disparities through an integrated multi-level strategy of centralized outreach, behavioral health engagement, and community activation.
Methods: Between 2022-2025, COI distributed over 2,400 fecal immunochemical test (FIT) kits and executed three key interventions: (1) centralized outreach to 1,888 unscreened Black patients through proactive phone, text messaging, and navigation support; (2) integration of CRC screening within a 28-day residential substance use treatment facility utilizing on-site education and an incentive program; and (3) broad community engagement through faith-based events, digital media campaigns, and healthcare partnerships.
Results: Out of 1,888 patients reached through centralized outreach, 97 completed FIT, with 7 positive), and 82 underwent colonoscopy, detecting adenomas in (35) 43% and adenocarcinoma in 1%. In the behavioral health facility, 125 of 155 eligible residents (81%) completed FITs, with 13.5% positive results and successful linkage to colonoscopy. Across all COI activities, 2,736 participants were engaged, 430 screenings completed, and 126 adenomas, 8 advanced neoplasms, and 1 instance of stage IV cancer detected. Follow-up completion after positive FIT averaged 27.8%.
Conclusion: Equity-driven, multi-level interventions including centralized navigation, behavioral health integration, and community partnerships led to colorectal cancer screening and detection among Black Philadelphians who may otherwise have not been screened. Deploying navigators in trusted community settings and establishing payer-academic collaborations created a scalable, sustainable model to address racial disparities in colorectal cancer outcomes.

#5103 AI-empowered cancer risk assessment model based on routine laboratory tests for enriching individuals at high risk of cancer.

Mao Mao[1], Yi Luan[2], Yong Shen[3], Shiyong Li[1], Shibin Long[1], Wei Wu[1]

[1]SeekIn, Shenzhen, Guangdong, China,[2]Sun Yat-sen Memorial Hospital, Sun Yatsen University, Guangzhou, Guangdong, China,[3]The Affiliated Cancer Hospital of Zhengzhou University and Henan Cancer Hospital, Zhengzhou, Henan, China

Background: Early cancer detection improves survival, yet population-wide screening remains costly and logistically challenging. Traditional cancer risk models, such as lifestyle-based assessments and polygenic risk scores, offer limited sensitivity. In contrast, routine laboratory tests (complete blood count, urinalysis, and biochemical panels) are already widely performed in primary care and may harbor latent cancer signals. We developed an AI-based cancer risk assessment (CRA) model using these existing data to enrich cancer cases and improve the cost-effectiveness of downstream multi-cancer early detection (MCED) tests.

Methods: Routine laboratory data from 5,376 individuals (1,399 cancer; 3,977 non-cancer) across two hospitals were retrospectively collected and split into training and validation cohorts. A total of 43 features were selected to calculate CRA scores using a gradient boosting framework. All participants also underwent OncoSeek testing, a validated MCED assay combining multiple protein tumor markers with clinical data, applied to CRA-positive individuals.

Results: The CRA model achieved AUCs of 0.738 and 0.802, with sensitivities of 87.5% and 90.0% at specificities of 50.0% and 47.2% in the training and validation cohorts. Among individuals predicted positive (CRA > 0.4, n = 3241), cancer prevalence increased from 26.0% to 38.2% (1.5-fold enrichment). In this enriched group, OncoSeek achieved 37.0% sensitivity at 97.3% specificity, and 56.6% sensitivity when restricted to its covered 14 cancer types. Furthermore, within the high-risk subgroup (CRA > 0.88, n = 231), 65.4% were cancer patients, with a higher proportion of advanced disease (Stage IV: 42.2%) than the overall cohort (25.0%), indicating potential to flag patients needing prompt diagnostic evaluation.A population-level simulation in 1 million adults ≥50 years (incidence = 0.9%) showed that adding CRA before OncoSeek increased cancer incidence to 1.5% (1.7-fold), reduced false positives by 33.3%, and halved total screening cost ($80.0 M → $40.5 M), lowering cost per detected case by 44.1%, demonstrating improved efficiency and cost-effectiveness.

Conclusion: The AI-based CRA model, leveraging routine primary care data, provides substantially higher sensitivity and broader applicability than polygenic risk scores. Beyond enriching cancer incidence for screening, CRA can also flag individuals with strong cancer signals who may require prompt diagnostic evaluation in EMR system. When integrated as a front-end enrichment step before MCED testing, this approach effectively filters out low-risk individuals, reduces unnecessary downstream testing, and halves screening costs with only a modest (~9%) sensitivity reduction. The combined CRA + MCED framework offers a scalable and economically sustainable pathway for precision population-level cancer early detection.

#5104 Cost-effectiveness analysis of integrating multi-cancer early detection into current cancer screenings in the United States.

Mao Mao[1], Shuaipeng Geng[2], Shiyong Li[1], Yinyin Chang[2], Shujia Hao[1]

[1]SeekIn, Shenzhen, Guangdong, China,[2]Shenyou Bio, Zhengzhou, Henan, China

Background: Cancer remains a major global health challenge. While standard-of-care (SoC) screenings (e.g., colonoscopy, mammography) improve early detection and survival, limitations persist: many cancer types lack screening guidelines, existing methods are single-cancer early detection (SCED) tests, and invasive protocols with low adherence lead to inefficiencies. Multi-cancer early detection (MCED) tests using liquid biopsy technologies provide a potential solution by screening for multiple cancers, including those not targeted by current SoC, within a single test. From a health economic perspective, supplementing SoC with MCED could enhance cost-effectiveness by broadening detection and reducing missed diagnoses.

Methods: This modeling study evaluated two strategies: 1) integrating MCED testing into SoC screenings, and 2) optimizing colorectal cancer screening with a two-step process (FIT followed by colonoscopy), further enhanced by MCED. U.S. SoC screening data from 2021 for five common cancers (breast, cervical, colorectal, lung, prostate), U.S. Census 2020 statistics, and real-world screening cohort parameters informed screening population overlap, cancer incidence, and detection rates for both SoC screenings and MCED.

Results: Among 75.6 million individuals screened in 2021, SoC alone detected 193,554 cancer cases at a total cost of $43.2 billion ($223,034 per detected case). Integrating SeekIn's two-step MCED test (OnceSeek followed by SeekInCare, $190 per person) raised total cost to $57.5 billion but increased detected cases to 539,909, nearly three times SoC alone, while halving the cost per case to $106,556. In contrast, using GRAIL's Galleri MCED ($949 per person) increased detected cases further, with an additional 297,141 cases, but escalated total costs to $114.9 billion. Notably, optimizing the colorectal screening protocol (FIT followed by colonoscopy) reduced SoC spending by $22.1 billion, covering all participants' TwoStep MCED costs and achieving a surplus of $7.7 billion. This strategy yielded 531,556 detected cases (2.7x SoC) and reduced per-case cost to $66,637 (29.9% of SoC).

Conclusion: Integrating cost-effective MCED tests, such as TwoStep test, into current SoC screenings can substantially improve cancer detection, lower per-case identification costs, and keep overall expenditures manageable. Targeted optimization, exemplified by a FIT-first colorectal approach, maximizes cost savings and amplifies the benefits of adding MCED tests to established national screening programs, all without requiring an increase in the overall budget. Collectively, these findings highlight a unique opportunity: with thoughtful integration, MCED can reshape population health by delivering timely, accessible, and affordable screening that saves more lives.

#5105 *CervicalMethDx*: Precision risk stratification of high-risk HPV samples to reduce unnecessary colposcopy referrals and improve the quality of value-based care.

Yanira Gonzalez Rodriguez[1], Ashley Ramos-Lopez[1], Laura Palmieri[2], Amanda Garcia-Negron[1], Paola Quinonez-Mendez[1], Guie Beeu Guerrero Hunt[2], Alvaro Gutierrez Colima[3], Carolina Teran[4], Adhi Guerrero Thillet[1], Mariana Brait[2], Priscilla Brebi Mieville[3], Carmen Ili[5], Teresa Diaz-Montes[6], Josefina Romaguera[7], Bruce Trock[8], David Sidransky[9], Carolina Larronde[3], Rafael E. Guerrero-Preston[1]

[1]LifeGene-Biomarks, Inc, San Juan, PR,[2]Oncology, Johns Hopkins Medical Insts., Baltimore, MD,[3]Center of Excellence in Translational Medicine (CEMT-BIOREN), Universidad de la Frontera, Temuco, Chile,[4]Facultad de Medicina, Universidad San Francisco Xavier of Chuquisaca,, Sucre, Bolivia, Plurinational State of,[5]Center of Excellence in Translational Medicine (CEMT-BIOREN), Universidad de La Frontera, Temuco, Chile,[6]Gynecologic Oncology Center, Mercy Medical Center, Baltimore, MD,[7]Obstetrics and Gynecology, University of Puerto Rico School of Medicine, San Juan, PR,[8]Brady Urological Institute,, Johns Hopkins Medical Insts., Baltimore, MD,[9]Lab Director, Otolaryngology, Johns Hopkins Medical Insts., Baltimore, MD

Oncogenic human papillomavirus (hrHPV) screening identifies many transient infections, but few clinically significant precancers, generating high rates of unnecessary colposcopy referrals. In the United States, 70-80% of women referred for hrHPV-positive colposcopy lack actionable precancerous diagnoses. Given that >90% of hrHPV infections clear naturally within 12-24 months, there is an urgent need for objective molecular triage tools to optimize colposcopy-driven biopsy selection and enhance value-based cervical cancer care.

The *CervicalMethDx* precision methylation platform was evaluated using 1,618 samples from IRB-approved studies across Puerto Rico, Latin America, and the United States. Independent datasets and specimen types were tested, including Digene and PreservCyt media, as well as self-collected vaginal swabs. Diagnostic performance metrics (sensitivity, specificity, AUC) were compared across *CervicalMethDx* assay versions (1.0 singleplex, 1.5 six-gene panel, 2.0 duplex). Cross-assay reproducibility and anatomic-site concordance were assessed using correlation and generalized estimating equation (GEE) models.

CervicalMethDx 1.0 detected cervical intraepithelial neoplasia grade 2 or higher (CIN2+) lesions with 96% sensitivity, 84% specificity, and an area under the ROC curve (AUC) of 0.99 in hrHPV-positive Digene samples (n = 108, University of Puerto Rico). In the ESTAMPA Latin American trial (n = 759), CIN3+ detection reached 67% sensitivity, 59% specificity, and an AUC of 0.65. The *CervicalMethDx* 1.5 six-gene panel identified squamous intraepithelial lesion (SIL) cytology with 94% sensitivity, 57% specificity, and an AUC of 0.85 in CLIA-certified PreservCyt samples (n = 377). No significant methylation differences ($p > 0.05$) were observed between paired cervical and self-collected vaginal swabs (n = 100 each), demonstrating strong intra-individual concordance. *ZNF516* methylation correlated across singleplex and duplex assays ($r = 0.51$, $p = 0.01$). GEE modeling showed a negative within-Pearson correlation ($\rho = -0.64$) between paired cervical and vaginal sites, confirming consistent site-dependent variation and reproducibility.

CervicalMethDx provides a robust precision-methylation approach for risk stratification of hrHPV-positive samples with the potential to reduce unnecessary colposcopy referrals and biopsies. The assay's reproducibility across self-collected and clinician-collected specimens supports its potential integration into at-home hrHPV testing workflows, advancing equitable and value-based cervical cancer screening worldwide

#5106 Endurance of HPV self-collection to detect disease: Histopathological follow up up to 16 months.

Sangini Sheth[1], Megan Fitzpatrick[2], Karl Hibler[3], Catherine Behrens[4]

[1]Obstetrics, Gynecology & Reproductive Sciences, Gynecology, Yale University, New Haven, CT,[2]Clinical, Teal Health, Inc., San Francisco, CA,[3]Independent Statistician, Bradenton, FL,[4]Women's Healthcare and Biotechnology Consultant, San Francisco, CA

Background: HPV self-collection (SC) expands access to cervical cancer screening (CCS) and is equivalent to clinician-collected (CC) sampling. Longer-term histopathological data after SC is essential to ensure durable sensitivity.

Methods: 599 enrolled in the SELF-CERV study evaluating the Teal Wand SC device and underwent SC and CC primary HPV testing at baseline (reported previously [1]), with SoC colposcopy and biopsy/excisions per guidelines. Pathology results were collected after baseline to 490 days for secondary analysis to fill the evidence gap. Diagnostic performance metrics (Sen, Sp, negative predictive value-NPV) and cumulative incidence rate (CIR) were calculated for SC versus CC HPV testing among those with high grade squamous intraepithelial lesions (HSIL) or worse (CIN2+).

Results: Of 599 paired SC and CC HPV results, 280 (46.7%) had pathology results within 490 days of the study visit and 57 (9.5%) were diagnosed with CIN2+. SC HPV testing showed high Sen for CIN2+, equivalent to CC testing (TABLE), ratio of Sen 1.00, similar to that observed at baseline, ratio 1.00). The NPV amongst those with pathology was 96.7% (59/61). The CIR per genotype group was not statistically significantly different for SC and CC: HPV16 had the highest ratio both at the study visit (SC: 31%, CC: 33%) and at 16 months later (SC: 47%, CC: 49%), followed by 12 Other HPV (SC: 17%, CC: 18% at study visit; SC: 24%, CC: 25% at 16 mo), and HPV18 (SC &CC: 5% at study visit, SC & CC: 21% at 16 mo).

Conclusions: SC HPV testing maintained high Sen for detection of CIN2+ in the 16 mo following study enrollment and high NPV of a SC HPV negative, both equivalent to CC.

Impact: To our knowledge, this is the first prospective study to evaluate pathology outcomes up to 16 mo following HPV SC, which strengthens confidence in SC as an effective CCS option that expands access, ensures appropriate clinical triage following SC, and warrants further inclusion in CCS guidelines. [1] https://pubmed.ncbi.nlm.nih.gov/40388167/

Diagnostic performance of HPV testing for detection of HSIL+

	SC (n/N; 95% CI)	**SC (n/N; 95% CI)**
Sen CIN2+	96.5% (55/57; 88.1-99.0)	96.5% (55/57; 88.1-99.0)
Sen CIN3+	97.1% (34/35; 85.5-99.5)	100% (35/35; 90.1-100)

#5107 Feasibility and interim results from the prospective international LS-URO study: Urine tumor DNA-based screening for urothelial cancer in Lynch syndrome carriers.

Jussi Nikkola[1], **Lauri Ryyppo**[1], Juuso Vuorinen[1], Jack V. Bacon[2], John Pham[2], Sara Singh[3], Lauren Deneault[2], Chuyi Zheng[3], Hanna Selin[1], Paivi Martikainen[1], Cecily Q. Bernales[2], Melissa Koudjanian[2], Kirsi Pylvanainen[4], Matti Nykter[1], Thea Veitonmaki[5], Jukka-Pekka Mecklin[4], Alexander Wyatt[2], Kasmintan Schrader[3], Toni Seppala[1], Peter C. Black[2], Gillian Vandekerkhove[2], Matti Annala[1]

[1]Tampere University, Tampere, Finland,[2]Vancouver Prostate Centre, Vancouver, BC, Canada,[3]Hereditary Cancer Program, BC Cancer Agency, Vancouver, BC, Canada,[4]The Wellbeing Services County of Central Finland, Jyvaskyla, Finland,[5]Tampere University Hospital, Tampere, Finland

Introduction: Lynch syndrome (LS) is a hereditary cancer syndrome caused by germline variants in DNA mismatch repair (MMR) genes (*MSH2*, *MLH1*, *MSH6* and *PMS2*), with up to 25% lifetime risk for urothelial cancer (UC). LS-UCs are commonly located in the upper urothelial tract, where tumors are difficult to detect early. No evidence-based screening strategy exists. We and others have shown that UC can be sensitively detected using urine tumor DNA (utDNA) mutation analysis.
Methods: LS-URO is an international, prospective, multicenter study enrolling LS carriers aged 50-75 years from the Finnish LS Registry and the BC Cancer Hereditary Cancer Program. Participants receive an at-home 100-mL urine collection kit (with preservative) for mail return. Urine cell pellet DNA is analyzed using the UroScout 25-gene deep targeted sequencing assay, which includes common UC drivers (e.g., *FGFR3*, *ARID1A*, *KMT2D*) and MMR genes. Samples with ≥2 somatic mutations are reviewed by a molecular tumor board, with utDNA-positive cases examined by cystoscopy, urine cytology and imaging, as well as repeat urine sequencing.
Results: Between May 2023 and October 2025, 213 participants were recruited, and 160 returned urine samples. Mean participant satisfaction with the urine collection procedure was 4.46/5. utDNA analysis is complete for 135 participants (76 Finland, 59 Canada). Nine (6.7%) participants were utDNA-positive with a median cancer fraction of 9% (range 4-17%) and median of four somatic mutations detected per sample (range 3-18). In 8/9 (89%) utDNA-positive participants, a somatic *MMR* second hit beyond the germline defect was detected. A total of 28 follow-up urine samples from five initially utDNA-positive participants revealed consistent detection of original mutations, with new mutations emerging in four. Eight out of nine (89%) positive participants harbored an *FGFR3* hotspot mutation (of which 88% *R248C*), whereas only one out of nine (11%) carried a *TERT* promoter mutation, consistent with our published observation that such mutations are rare in LS-UC. Two asymptomatic UC cases have been confirmed (one at initial examination, one 28 months after the first utDNA-positive screening sample during protocol-scheduled follow-up CT imaging). Four positive cases are pending initial urologic investigation, and the remainder are under continued surveillance through additional sampling and clinical follow-up.
Conclusions: utDNA-based screening in LS is feasible, well accepted, and enables early, non-invasive cancer detection. Interim results demonstrate high compliance and promising diagnostic yield, pending long-term clinical follow-up. These findings support large-scale implementation of urine biopsy-based screening, to be further evaluated in the randomized PREDI-LYNCH trial.

#5108 Screening colonoscopy yields among adults aged 40 to 49 years after new screening guidelines.

Xiangyuan Qi[1], Xiaomei Wu[2], Bo Zhu[3]

[1]Cancer Hospital of China Medical University/Liaoning Cancer Hospital & Institute, Shenyang, Liaoning Province, China,[2]The First Hospital of China Medical University, Shenyang, Liaoning Province, China,[3]Liaoning Cancer Hospital & Institute, Shenyang, Liaoning Province, China

Objective: To analyze screening colonoscopy yields among adults aged 40 to 49 years since China Guideline for the Screening, Early Detection and Early Treatment of colorectal cancer (2020, Beijing) expanded the screening initiation age to 40, thus providing evidence to support lowering the screening initiation age to 40.
Method: This population-based cross-sectional study was part of the framework of the Cancer Screening Program initiated by the Chinese government. We included residents aged 40-59 who underwent their first screening colonoscopy in 2020-2024. The study outcomes included: colorectal cancer (colon or rectal adenocarcinoma); advanced lesions (at least one adenoma ≥10mm or at least one adenoma with villous components or high-grade dysplasia); and other benign lesions. Robust Poisson regression was used to estimate the adjusted risk ratios (aRRs) for outcomes between age groups, with 50- to 59-year-olds serving as the reference group. Regression models were adjusted for region, sex, comorbidities, body mass index (BMI), and tobacco smoking history.
Result: A total of 5040 eligible patients underwent a screening colonoscopy in 2020-2024, including 1529 aged 40-49 and 3511 aged 50-59. Females comprised 60.5% of the overall cohort, 53.7% had comorbidity, 23.7% had a history of tobacco smoking, and 39.7% had body mass index>=24 (calculated as weight in kilograms divided by height in meters squared). Screening colonoscopy outcomes were generally slightly less frequent among the younger group compared with the older group, only the aRR for other benign lesions (12.0% vs. 19.4%; aRR, 0.67; 95% CI, 0.54-0.82) and negative (85.8% vs 77.3%; aRR, 1.06; 95% CI, 1.04-1.09) were statistically significant. All other colonoscopy findings did not differ significantly between the 2 age groups, including for advanced lesions (1.7% vs. 2.6%; aRR, 0.69; 95% CI, 0.39-1.22) and colorectal cancer (0.3% vs. 0.5%; aRR, 0.55; 95% CI, 0.19-1.57). In addition, there were no significant differences between age groups for all lesion types among women. Other than for other benign lesions and negative, there were no significant differences in the types of lesions among men.
Conclusion: The current study findings extend the observation of similar screening colonoscopy detection rates for advanced lesions and colorectal cancer in those aged 40 to 49 years vs 50 to 59 years and support the suggestion that there is likely no need to reduce advanced lesions and colorectal cancer detection rate benchmarks because of the infusion of younger patients into the screening pool. The similar rates of advanced lesions and colorectal cancer detection between age groups also provide support for lowering the start of screening initiation to age 40 years.

Keywords: Colorectal cancer; Screening Colonoscopy; advanced lesions

#5109 Stage at diagnosis and tumor characteristics among screen-detected breast cancer cases in Cartagena, Colombia.

Laura C. Pinzon-Martinez, Ines Benedetti, Luis F. Viana

School of Medicine, Histopathology Research Group, Universidad de Cartagena, Cartagena, Colombia

INTRODUCTION: The implementation of breast cancer screening programs aims for an early diagnosis and timely management. In Colombia, national regulations recommend biennial mammography for women aged 50 - 69 years. Patients with mammographic findings suggestive of malignancy are referred for biopsy. Limited data exists on screening performance and stage distribution in Cartagena.
OBJECTIVE: To characterize the stage at diagnosis and clinical and pathological features of women participating in a breast cancer screening program in Cartagena, Colombia.
METHODS: A retrospective study which included women screened for breast cancer between January 2019 and February 2023 with BIRADS 4A, 4B, 4C, and 5 mammographic results. Data were collected from mammography and biopsy reports and medical records. Associations between clinical and pathological variables were evaluated, including age, BI-RADS category, histological type and grade, ER, PR, and HER2 status, Ki-67 index, tumor size, multifocality, axillary lymph node involvement, metastatic disease, and TNM stage. A p-value < 0.05 was considered statistically significant.
RESULTS: 211 women were included (mean age=58.9, SD=11.3). 39,8% (n=84) mammograms were reported as BI-RADS-5, 97.5% had a histopathological diagnosis of cancer, compared to 81.8%, 47% and 40% of patients classified as BI-RADS 4C, 4B and 4A, respectively. Women with malignant diagnoses were significantly older than those with benign findings (p = 0.021, t test). At the time of diagnosis, tumor size was predominantly between 2 and 5 cm (T2), most tumors were unicentric, 42.9% had lymph node involvement and 8.2% had metastases. Most patients (50%) were diagnosed at intermediate stages (IIA-IIB), a significant proportion (20%) at stage III, and 7% at stage IV. Invasive ductal carcinoma represented 76.2% of cases, followed by invasive lobular carcinoma. The predominant subtype was HR+/HER2- (62%), and a high proportion of triple-negative breast cancer (HR-/HER2-) was observed (23%). The Ki67 index greater than 20% was observed in 51.7% of the cases and there was a significant association between histological type and Ki67 index (p=0.014, Fisher test).CONCLUSION: Stage at diagnosis of screen-detected breast cancers in this program cannot be considered neither very early nor very late. This suggests that while the screening program has improved, opportunities remain to strengthen early detection and screening efforts. The higher-than-expected malignancy rate in the BI-RADS 4A category may indicate a population with more aggressive disease biology. Although the predominant histological subtype is associated with better prognosis and effective therapies, the relatively high incidence of triple-negative breast cancer may be related to population-specific risk factors and carries therapeutic and prognostic implications that should be further investigated.

#5110 Early life exposure to antibiotics and early onset colorectal cancer.

Qiuyi Mao[1], Niti Jani[2], Varsha Gowda[1], Thrisha Mote[1], Anna Bassler[1], Shyam Ganesh Babu[1], Victoria Zottoli[1], Hannah Villanueva[1], Mariko Maja[1], Maredith Richardson[1], Maria Marjorette Ociones Pena[3]

[1]Biological Sciences, University of South Carolina, Columbia, SC,[2]University of South Carolina, Columbia, SC,[3]Research Associate Professor, University of South Carolina School of Medicine, Columbia, SC

Colorectal cancer (CRC) is the second leading cause of cancer related deaths in the United States and worldwide. Recently, the overall incidence of CRC has been decreasing presumably due to early screening and healthy lifestyles. However, CRC in individuals under 50 years old, known as early-onset colorectal cancer (EOCRC)**,** has been increasing at an alarming rate in the since the 1980s. It is a growing global epidemic with cases rising from 11% to 20 % between 1995 to 2019 and is expected to increase by 140% by 2030. The underlying causes and mechanisms as to why otherwise healthy young adults are susceptible is poorly understood. Based on our current knowledge of the disease, we hypothesized that EOCRC is caused exposure to exposomes that have been increasing globally in parallel with increases in EOCRC with each birth cohort; that impact the gut microbiome causing dysbiosis and inflammation in the distal colon and rectum, the anatomical site of EOCRC; and those that can affect humans at different development stages from conception to adulthood. Among the potential factors is the use of antibiotics, particularly in the early stages of life.In this study, we hypothesize that there are development windows of susceptibility wherein exposure to commonly prescribed pediatric antibiotics (β-lactams or macrolides) can increase the risk of developing EOCRC. Using a mouse model of EOCRC, we defined corresponding developmental windows of susceptibility over an individual's lifetime. Here, we test if exposure to a single round of antibiotics at the perinatal and juvenile windows can impact risk of developing EOCRC. A/J mice at the perinatal stage were treated by gavage-feeding lactating dams who then passed the antibiotics to their offspring. After weaning, the offspring were treated with azoxymethane (AOM), a carcinogen, and tumor burden was determined after tumor outgrowth. Four-week-old mice were gavage-fed the antibiotics, exposed to AOM and tumor burden assessed as above. Our findings suggest that the impact of antibiotics on EOCRC risk was affected by exposure at specific developmental windows of susceptibility. Maternal antibiotic administration altered the gut microbiota in offspring which persisted over the long term. This effect was associated with changes in gut microbial structure and abundance, and an increase in pro-inflammatory bacterial strains, which correlated with elevated inflammation and tumor burden in offspring.

#5111 The global inequality in cervical cancer screening: An evidence synthesis.

Ruijun Xin[1], Xiaomei Wu[2], Bo Zhu[1]

[1]Liaoning Cancer Hospital & Institute, Shenyang, Liaoning Province, China,[2]The First Hospital of China Medical University, Shenyang, Liaoning Province, China

Background: The rising global burden of cervical cancer and persistent inequalities in screening access underscore the need to strengthen implementation. Therefore, we compiled the cervical cancer screening guidelines from different countries/regions and evaluated their implementation status and coverage situation.
Methods: In this study, we conducted comprehensive search of the PubMed, Embase and Web of Science databases (from their establishment to February 1, 2025), websites and the World Health Organization (WHO) database. Studies included in our analysis provide detailed information on the official cervical cancer screening recommendations for each country. All indicators were stratified based on factors such as human development index (HDI), income level, geographical location, WHO regions, disease risk, and age. The systematic review was prospectively registered at Prospero (registration number: CRD420251087263).
Results: Our study incorporated data from 77 countries/regions, only 62.3% (48/77) of them provided the year of published/updated protocol. Cytology was the primary screening test in 62 (80.5%) of 77 countries. Visual inspection with acetic acid (VIA) was the most recommended test in low HDI countries. The number of countries using Human papillomavirus (HPV) is relatively small. Screening coverage was associated with HDI/income (low HDI: 12.43% vs very high HDI: 49.74%; high-income: 51.68% vs low income and middle-income countries [LMICs]:34.45%), with high-risk regions (29.88%) significantly lower than other areas (46.76%). Age-stratified analysis showed minimal coverage in the 20-29 and 70-79 groups, while coverage peaked in the 30-39 group. Our results also showed substantial heterogeneity in screening quality indicators (positive rate, further assessment rate, detection rate, and positive predictive value [PPV]).
Conclusions: This study highlights global inequities in cervical cancer screening guidelines, particularly in the transition of screening methods among different countries/regions. Global cervical cancer coverage remains significantly below the target of 70%. Accelerate screening strategies, improve screening-diagnosis-treatment accessibility, establish monitoring systems, and strengthen global cooperation. Key words: Cervical cancer; Global health; Health policy;Screening, Coverage, Systematic review

#5112 Assessing hematologic pattern variation in AI-based blood cell analysis for ovarian cancer risk detection.

Eun Ji Song[1], Se Ik Kim[2], Hanbyoul Cho[3], Yookyung Lee[4], Heeyeon Jung[1], Hyejin Lee[1], Yoon Joo Kim[4], TaeJin Ahn[1], Yong Sang Song[5], **Eunyong Ahn**[1], Jae-Hoon Kim[4]

[1]ForetellMyHealth, Inc., Gyeongsangbuk-do, Pohang-si, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of,[3]Department of Obstetrics and Gynecology, Yonsei University Health System, Seoul, Korea, Republic of,[4]Yonsei University Health System, Seoul, Korea, Republic of,[5]Myongji Hospital, Goyang-si, Gyeonggi-do, Korea, Republic of

Ovarian cancer(OC) lacks reliable early detection methods, and blood cell-derived inflammatory signatures have emerged as potential non-invasive indicators. However, these hematologic patterns may vary across individuals and sample-processing conditions. This study applies an AI-driven blood cell analysis model to a new cohort and evaluates feature-level variability relevant to OC risk detection.

Peripheral blood was collected to evaluate hematologic patterns associated with OC detection from asymptomatic controls, patients with benign ovarian or uterine tumors, and patients with newly diagnosed OC. Samples were transported under refrigerated conditions and processed within 28 hours for complete blood count analysis. Composite hematologic indices were calculated from measured parameters and input into our previously developed AI-driven blood cell analysis model to evaluate OC risk signals. Residual samples were additionally used to obtain platelet images for exploratory morphological assessment.

Among 135 samples analyzed, including 16 OC cases, the AI-driven blood cell analysis model produced 6 true positives, 10 false negatives, 17 false positives, and 102 true negatives, yielding a sensitivity of 37.5%, specificity of 85.7%, PPV 26.1%, and NPV 91.9%. True-positive cases showed pronounced inflammatory activation with markedly elevated SII, NLR, and PLR and the lowest lymphocyte counts. False positives demonstrated similarly high inflammatory indices but disproportionately elevated platelet counts. False-negative OCs exhibited near-normal inflammatory markers yet had the highest RDW-CV, MPV, and PDW, indicating a morphology-dominant rather than inflammation-dominant hematologic phenotype.

Although overall performance was lower than in our previous dataset using the same AI-driven blood cell analysis model, the consistency of feature importance suggests that the inflammatory signal remains stable. Reduced sensitivity is likely related to pre-analytical differences, as samples were refrigerated and processed after transport. False-negative cases showed a morphology-dominant profile not captured by inflammation-based indices, indicating that some OCs lack strong systemic inflammatory signatures. To address this limitation, we are acquiring platelet-level image data to develop a complementary morphology-focused diagnostic approach.

The reproducibility of key hematologic patterns across datasets supports the biological relevance of AI-driven blood cell analysis for OC signal detection. However, reduced performance under altered processing conditions and the presence of morphology-dominant tumors highlight the limitations of inflammation-focused models. Incorporating platelet-image features may enhance detection of under-represented phenotypes and improve diagnostic coverage across OC subtypes.

#5113 Multiple myeloma screening education.

Karie Feldman[1], Diana Basali[1], Kimberly Bell[1], Pamela Combs[2], Beth Faiman[1], Anwer Faiz[1], Raymond D. Jackson[1], Jack Khouri[3], Stacy Mathews[1], Sandra Mazzoni[1], Kayona Moore[4], Natasha Patel[1], Shahzad Raza[1], Mark D. Ribbins[1], Christy Samaras[1], Louis Williams[1], Jason Valent[1], **Heather McKee Hurwitz**[1]

[1]The Cleveland Clinic, Cancer Institute, Cleveland, OH,[2]Office of Nursing Education and Professional Development, The Cleveland Clinic, Cleveland, OH,[3]Hematology and Medical Oncology, Cleveland Clinic, Cleveland, OH,[4]University of Cincinnati College of Medicine, Cincinnati, OH

Background: The lack of federal screening guidelines and limited knowledge of multiple myeloma (MM) among the public and primary care providers contributes to late-stage detection of MM when the disease is harder to treat. Black Americans over 50 are at higher risk for MM but are often diagnosed later than other groups. Given similar or improved outcomes with early detection, this study aims to implement a multi-level community-based intervention. Improved health literacy about cancer risk can lead to better decision making in MM care.
Methods: To encourage MM screening in Black Americans, our study engaged providers in continuing medical education seminars (CME), provided brochures with basic MM education at health fairs, and engaged high-risk individuals in on-site MM screening and a knowledge retention pre-test and post-test. A multidisciplinary team created the CME, which included information about the MM disease process, the benefits and methods of early detection and how to address abnormal results. Community events were designed for screening and included participation from outreach staff, navigators, clinicians, and phlebotomists. Participant education relied on an original community brochure that included information such as defining MM, its symptoms and its prominence among Black Americans. Knowledge retention questions were designed by the clinical team to highlight information covered in the brochure.
Results: Participants were recruited via convenience sampling from June 2023 through December 2024. The robust educational program included training 46 health care providers in three CME seminars, conducting 22 screening events, and providing education and monoclonal protein screening to identify MM and its precursors for 199 Black individuals over age 50. Overall scores on MM knowledge measures were consistent with a mean score of 2.8 on a five-point scale immediately after exposure to educational materials to 2.9 after at least one week had passed and screening results had been provided. The lack of decline in the score suggests that participants retained the knowledge about MM that they gained during their participation in screening. Screening results identified 21 participants (11%) with Monoclonal Gammopathy of Undetermined Significance (MGUS), a precursor condition to MM, all of whom received follow-up care.
Conclusions: Our community-based screening program combined educational opportunities for providers and patients alongside on-site screening to identify individuals with MM precursor conditions in high-risk populations. Further research should aim to expand the reach of interventions and to recruit randomized samples to allow for measurement of baseline knowledge and to generalize findings. Screening programs that meet high-risk populations in their community, intervene at multiple levels, and educate people about their risk can be effective ways to identify the individuals most likely to benefit from MM screening.

#5114 Analysis of variation in global breast cancer screening indicators: A systematic analysis.

Jiaqi Guo[1], Ruijun Xin[1], Xiaomei Wu[2], Bo Zhu[1]

[1]Department of Cancer Prevention and Treatment, Cancer Hospital of China Medical University/Liaoning Cancer Hospital & Institute, Shenyang, Liaoning Province, China,[2]Department of Clinical Epidemiology and Centre of Evidence-Based Medicine, The First Hospital of China Medical University, Shenyang, Liaoning Province, China

Background: The coverage rate of breast cancer screening is a key indicator for measuring the effectiveness of screening. Comprehensive studies on the global coverage rate of breast cancer screening are still insufficient at present, and existing evidence suggests that screening rates remain suboptimal in many regions. Therefore, this study aims to systematically assess the current status of global breast cancer screening programs and focus on analyzing their coverage. Based on existing data, we have systematically sorted out and presented the implementation of breast cancer screening at the global, regional and national levels.

Methods: We systematically searched the PubMed, Web of Science, and Embase databases (from their inception to August 12, 2025), and supplemented the search with relevant official websites and the World Health Organization database. A total of 75 countries and regions' breast cancer screening policies and coverage data were included. The following key information was incorporated: screening methods, screening intervals, and specific circumstances of providing free services, etc. On this basis, we further analyzed the specific contents of breast cancer screening guidelines in various countries and systematically evaluated the global differences in screening coverage. To deeply explore the influencing factors behind the differences, detailed subgroup analyses were conducted based on the Human Development Index (HDI) level, continent distribution, World Health Organization (WHO) regions, and different age groups. The systematic review was prospectively registered in PROSPERO (registration number: CRD420251233260).

Results: Among the 75 countries and regions included, 35 (46.7%) countries have established official breast cancer screening guidelines. Regarding screening methods, mammography/digital breast tomosynthesis (DBT) is the most commonly adopted approach, used in 49 (65.3%) countries. In resource-limited countries and regions, clinical breast examination (CBE) is the most frequently recommended screening method. The average coverage rate of breast cancer screening is 50.2% (95% CI: 36.6%-58.8%). Stratified analysis by age shows that the screening coverage rate in the 50-69 age group is significantly higher than that in the 40-49 and 70-79 age groups.

Conclusions: At present, the coverage rate of breast cancer screening in most countries around the world remains at a relatively low level. To bridge this gap, it is necessary to systematically identify influencing factors, formulate targeted strategies, and actively promote their implementation to effectively enhance the coverage level of breast cancer screening.

Key words: Breast cancer; Breast cancer screening; Coverage rate; Systematic review

#5115 A multi-omic liquid biopsy for the earlier detection of colorectal cancer.

James M. Cameron, Holly J. Butler, David S. Palmer, Rose G. McHardy, Alexandra Sala, Matthew J. Baker

Dxcover Ltd., Glasgow, United Kingdom

Background: Timely diagnosis and intervention in colorectal cancer (CRC) are critical to improving patient outcomes and limiting disease progression. Screening of average-risk individuals is essential for detecting tumors at an earlier, more treatable stage. However, adherence to current screening programs remains suboptimal. Liquid biopsies represent a promising alternative to stool-based tests and may play a key role in optimizing CRC detection and diagnostic pathways.
Methods: In this study, 957 patients were recruited across various clinical sites in the USA: 48 CRC, 157 advanced precancerous lesions (APL), 331 non-advanced lesions (NAL) and 421 with a negative colonoscopy diagnosis. Blood was obtained from patients either prior to scheduled colonoscopy or before surgical resection and any anti-cancer therapies. Streck plasma samples were analyzed by the Dxcover® Liquid Biopsy Platform and classified with machine learning algorithms.
Results: When CRC was classified against all other groups, the receiver operating characteristic curve generated an area under the curve value of 0.95, and test sensitivity and specificity were 90% and 89%, respectively. The diagnostic model accurately predicted 75% of stage I (3/4), 100% of stage II (15/15), 93% of stage III (14/15) and 100% of stage IV (6/6) CRCs. For the advanced colorectal neoplasia model, 29% of APL were detected.
Conclusion: A simple blood test with high sensitivity for early-stage colorectal cancer could significantly enhance patient outcomes. With continued development, this liquid biopsy has the potential to make a substantial impact on the early detection of CRC.

#5116 Assessing blood- and stool-based tests for colorectal cancer detection.

James M. Cameron[1], Holly Butler[1], David Palmer[1], Rose McHardy[1], Amanda Alty[2], Peter Mitchell[2], Edward Parkin[2], Matthew Baker[1]

[1]Dxcover Ltd., Glasgow, United Kingdom,[2]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom

Background: Colorectal cancer (CRC) is one of the most common and deadliest cancers worldwide, and incidence rates are rising. However, early detection and intervention can improve the survival rates and quality of life of affected patients. The Dxcover Liquid Biopsy Platform is a rapid multi-omic liquid biopsy that interrogates a blood sample with infrared radiation and produces a distinctive signature that represents the whole biomolecular profile of the sample. The liquid biopsy has been reported previously as a standalone test, but also has potential to be employed in combination with other information sources, such as biomarker data, and clinical risk factors.
Methods: In this study, samples from 1377 patients were collected across sites in the USA (n=989) and UK (n=388). Blood was obtained from patients either prior to scheduled colonoscopy or before surgical resection and any anti-cancer therapies. Streck plasma samples were analyzed by the Dxcover Liquid Biopsy Platform. Carcinoembryonic Antigen (CEA) values were determined for all samples. Fecal hemoglobin levels from fecal immunochemical testing (FIT) were also obtained for the UK samples. Machine learning algorithms were developed to compare test performance and assess combinations.
Results: Initially, machine learning models were developed for the spectral dataset alone. The area under the curve (AUC) was 0.95 and the model reported consistent detection rates across CRC stages. There was limited diagnostic utility reported for CEA alone (37% sensitivity with 80% specificity). There was no improvement to the spectral model with the inclusion of CEA. For the UK cohort with FIT results, the FIT only model (AUC=0.83) was enhanced by the addition of spectral data, with the combined model (spectra+FIT) reporting an AUC of 0.90.
Conclusions: There is potential for combining this liquid biopsy with orthogonal tests, such as FIT testing or other blood-based biomarkers. A rapid liquid biopsy that is sensitive to early-stage CRC could substantially improve patient outcomes. Current screening programs have addressable limitations and the emergence of new alternative technologies is vital to support earlier CRC detection.

: New Ligands and Inhibitors
Poster Session

#5118 *In silico* discovery of potent small molecule inhibitors targeting the AR N-terminal domain for treating castration-resistant prostate cancer.

Patrick Kunz[1], Thomas Alanine[2], Babette Schade[3], Ben Cossins[2], Sandro Bottaro[1], Daniele Peterle[1], Flavia Giamogante[3], Elia Gamba[3], Sasha Soldati[3], Nathalie Wyss[3], Lixin Yang[3], Michele Invernizzi[3], Michael Habeck[3], Rudy Rubini[3], Melissa Kachura[3], Dmitry Dmitry Ryzhenkov[3], Matteo Cerrina[3], Fabio Airoldi[3], Valentina Ceserani[3], Alice Santopolo[3], Heidi Derks[3], Stefano Ruschetta[3], Andrew Allen[2], David Lowe[2], Carlo Fisicaro[3], Ken Carson[2], Patrik Foerch[2], Kevin Sprott[2], Kamil Tamiola[2]

[1]Experimental Biophysics, Peptone Switzerland AG, Bellinzona, Switzerland,[2]Peptone Ltd., London, United Kingdom,[3]Peptone Switzerland AG, Bellinzona, Switzerland

Castration-resistant prostate cancer (CRPC) remains an unsolved clinical challenge due to resistance mechanisms that occur upon treatment with androgen receptor pathway inhibitors (ARPI). Since the hallmarks of resistance are (i) AR amplification, (ii) the occurrence of splice variants like AR-V7 and (iii) mutations in the ligand binding domain (LBD), the novel concept of targeting the disordered N-terminal domain (NTD) of the androgen receptor is a compelling way of inhibiting AR in the context of castration-resistance. Here, we describe the discovery of small-molecule AR-NTD inhibitors by leveraging Peptone's HDX-MS and in silico platform. A virtual screen against a highly dynamic segment of the NTD yielded binders that were further developed into a series with potent in vivo activity. Binding was confirmed by multiple biophysical approaches, including a proprietary ultra-fast mixing hydrogen-deuterium exchange mass spectrometry (HDX-MS), NMR spectroscopy, spectral shift analysis, and cellular NanoBit assays, all of which validated direct interaction with the NTD. Our lead compounds exhibit potent cellular activity across a range of in vitro models. In AR full-length (FL-AR) and AR-V7 luciferase reporter assays, as well as LNCaP proliferation assays, potencies between 10-100 nM were obtained. Activity in the VCaP CRPC cell model was similarly strong, clearly outperforming standard-of-care compounds like Enzalutamide and Darolutamide and reaching equal potency to PROTACs. Mode of action (MoA) studies demonstrated that the lead compounds suppress the formation of FL-AR and AR-V7 homodimers (NanoBit assay), inhibit nuclear translocation of AR, and can efficiently downregulate AR-target genes in a dose-dependent manner in qPCR assays. The lead series displays drug-like physicochemical, ADME, and pharmacokinetic profiles, conducive to rapid preclinical and clinical development, while providing distinct differentiation over novel modalities such as PROTACs and RIPTACs. Our findings highlight the therapeutic promise of targeting the AR-NTD in CRPC via a unique, structure-driven approach, with small molecules that combine a novel mechanism with potent anti-tumor activity.

#5119 P015, a highly selective PARP7&12 dual inhibitor.

Jinwen Huang, Hao Huang, **Steve Shen**

Convalife Pharmaceuticals, Shanghai, China

Background: The poly(ADP-ribose) polymerase (PARP) family plays critical roles in DNA damage repair, cellular stress responses, and tumor immune modulation. Among them, PARP7 and PARP12 have been implicated in innate immunity and tumor microenvironment remodeling. Selective inhibition of PARP7&12 holds promise for cancer therapy by modulating immune responses and cell survival pathways. However, potent and selective small-molecule inhibitors targeting PARP7&12 remain scarce, creating an urgent need for the development of candidate compounds with superior enzymatic inhibitory activity.

Methods and Materials: Based on structure-activity relationship (SAR) studies and accelerated by the Convalife "AIDRUG.WORK" molecular design platform, we designed and optimized small-molecule inhibitors targeting PARP7&12, leading to the identification of the candidate compound P015. In vitro enzymatic assays were performed to evaluate the inhibitory activity of P015 against human PARP7 and PARP12. IC_{50} values were calculated by fitting concentration-response curves. The current work primarily focuses on characterizing enzymatic-level activity to validate the feasibility of P015 as a PARP7&12 inhibitor.

Results: Enzymatic assay results demonstrated that P015 exhibited potent inhibitory activity against both PARP7 and PARP12, with IC_{50} values below 10 nM for both enzymes. These findings indicate that P015 possesses exceptionally strong affinity and inhibitory potency for PARP7&12 at the enzymatic level, establishing a foundation for further investigation of P015 as a highly active PARP7&12 inhibitor.

Conclusions: We have identified and preliminarily characterized P015, a small-molecule inhibitor with sub-10 nM IC_{50} values against PARP7&12 at the enzymatic level. Although current experimental data are primarily derived from in vitro enzyme activity assays, the results suggest that P015 has significant potential for further cellular and in vivo pharmacological and mechanistic studies, and may be developed as a novel anti-cancer candidate drug targeting the PARP7&12 pathway.

#5120 Design and discovery of BH-501242, a novel pan-KRAS on/off inhibitor targeting KRAS switch II pocket.

Eugene Rui, Nancy Ling, Wei Deng, Ping Jiang, Zhenping Wang, Yue Hu, Joshua Choi, Danan Li, Evan Rogers, Anindya Sarkar, Levan Darjania, Geoffrey Oxnard, Jean Cui

BlossomHill Therapeutics, Inc., San Diego, CA

KRAS mutations are involved in approximately 25% of all tumors and are frequent oncogenic drivers in lung (32%), colorectal (40%), and pancreatic cancers (85-90%). The most common *KRAS* driver mutations are on codon 12 and 13, including G12C, G12D, G12V, G12R, G13A, G13D, etc. The G12C mutation has been effectively targeted using a covalent strategy that exploits the unique reactivity of the cysteine residue. Other mutations, however, require inhibitors with high intrinsic binding affinity with KRAS to be effective in clinic. MRTX1133 was the first to demonstrate low single-digit nM cell potency for G12D mutation; however, the inhibitor lacked the ADME properties required for a successful oral drug. Since then, multiple KRAS inhibitors targeting G12D, G12V, or pan-KRAS mutations have advanced into clinical trials. Leveraging our structure-based drug design expertise, we designed a novel chemical scaffold targeting KRAS switch II pocket and identified the pan-KRAS inhibitor, BH-501242 after lead optimization on potency, ADME/PK, and safety properties. BH-501242 demonstrated excellent potency and target engagement across a broad spectrum of *KRAS* mutations and achieved sub-nM to low single-digit nM IC_{50} values in cellular anti-proliferation assays and anti-phosphorylation assays against downstream kinase ERK. In a panel of 15 cell lines with *KRAS* G12D mutation, 10 cell lines with G12V, and 11 cell lines with G12C, BH-501242 showed superior anti-cell proliferation activity with median IC_{50}s of 1.31 nM (0.40 nM for GP2D - 9.96 nM for SUIT-2), 3.55 nM (1.84 nM for SW620 - 19.7 nM for SW900), and 2.13 nM (0.68 nM for SW1463 - 5.79 nM for SW756) against *KRAS* G12D, G12V, and G12C mutant cells, respectively. BH-501242 also demonstrated outstanding cell potency against other *KRAS* mutations including G12S, G12F, G12A, G13D and K117N. Mechanistically, BH-501242 tightly binds with both active (GTP-bound or “on”) and inactive (GDP-bound or “off”) forms of mutant KRAS, effectively blocking its interaction with downstream effector c-RAF, and inhibiting the phosphorylation of ERK. Synergistic effects were observed in combination with EGFR antibody cetuximab in colony formation assays with *KRAS* mutant cells. PK profiling revealed oral bioavailability of BH-501242 in multiple species and dose dependent plasma exposures in mouse xenograft tumor models. BH-501242 demonstrated excellent anti-tumor activity in multiple CDX mouse models with various KRAS mutations, including GP2D and HPAC models with G12D mutation, H441 with G12V, and MiaPaca-2 with G12C, etc. In conclusion, the strong preclinical profile provides a strong rationale for the advancement of BH-501242 into further development.

#5121 Targeting peripheral α_{2A}-adrenoceptors as a dual-benefit approach for integrated cancer therapy and supportive care.

Zhiqiang Cheng[1], Yang Xu[1], Larry Zhu[2]

[1]Aglaeapharma INC., Camden, DE,[2]Alpherabio LLC, Boston, MA

Background: Emerging evidence highlights sympathetic innervation is a key component of the tumor microenvironment, and that denervation effectively suppresses tumor growth, revealing new therapeutic opportunities (Vera Thiel, Nature 2025). α_{2A}-adrenoceptor (α_{2A}AR) agonists like clonidine are potent regulators of sympathetic activity, and have demonstrated antitumor efficacy (Jingjing Zhu, Nature 2023), yet their application in oncology can be severely limited by the central nervous system (CNS)-mediated adverse effects, including sedation and hypothermia. To overcome this challenge, we developed CC10230, a novel peripherally restricted α_{2A}AR agonist designed to provide sustained antitumor therapy without dose-limiting CNS toxicity.

Method: A focused compound library was generated through rational design and screened based on *in vitro* α_{2A}AR potency, P-gp efflux ratio, and oral bioavailability. Peripheral restriction of the lead compound was confirmed using *in vivo* distribution pharmacokinetic. Anti-tumor activity was assessed in the MC38 subcutaneous tumor model in mice, and anti-allodynic efficacy was evaluated in the NCTC-2572 cell-induced bone cancer pain model in mice. All clinical observations, including behavior and safety monitoring, were conducted in accordance with CRO's standard operating procedure (SOP).

Result: CC10230 was selected as a lead compound based on its high α_{2A}AR activity (EC_{50}= 7.5 nM, Ki = 58.1 nM), strong P-gp substrate properties (efflux ratio = 51.0), and a favorable oral bioavailability (44.6%). Pharmacokinetic studies confirmed minimal CNS penetration (Kp,uu,brain < 0.03), markedly lower than that of clonidine, supporting strong peripheral restriction. In the MC38 model, CC10230 (5 mg/kg, b.i.d., p.o.) significantly suppressed tumor growth, achieving a TGI of 62.3% at Day 17. Clonidine (5 mg/kg, b.i.d., p.o.) as a positive control also achieved significant TGI but was poorly tolerated, causing pronounced somnolence, hypothermia, and 18.1% body weight loss. In contrast, CC10230 showed no tolerability issues. Additionally, CC10230 exhibited robust efficacy in cancer pain model, confirming its dual therapeutic benefits.

Conclusion: These findings establish peripheral α_{2A}AR activation as a promising two-pronged translational strategy for integrated oncology care, simultaneously inhibiting tumor progression and alleviating cancer-related pain while circumventing CNS-mediated side effects. The favorable safety profile of CC10230 supports its potential for sustained antitumor therapy without the tolerability limitations of conventional α_{2A}AR agonists.

#5122 Regulating m6A-RNA modification as new therapies for cancer.

Tariq Rana

UC San Diego, La Jolla, CA

The role of post-transcriptional modifications of mRNA in regulation of gene expression, stem-cell maintenance, and differentiation has gained significant interest. Transcriptome-wide mapping has revealed that the most abundant internal mRNA modification is the N^6-methyladenosine (m6A), which is present in > 25% of all mRNAs. The N^6-methylation of adenosine is a reversible modification controlled by a multiprotein complex comprised primarily of METTL3 and METTL14, which is responsible for the methylation step, and by two Fe(II)-α-ketoglutarate-dependent dioxygenases, ALKBH5 and FTO, which drive the reverse, demethylation step. In addition, FTO, but not ALKBH5, is responsible for the demethylation of N^6, 2'-*O*-dimethyladenosine (m6Am), a prevalent modification frequently found at the 5′ cap-adjacent adenosine of mRNA where it plays a critical role in controlling mRNA stability and translation. In GBM, reduced levels of m6A and m6Am are involved in cell proliferation, survival, and differentiation. As such pathways are known to be directly linked to acquisition of stem-like cell properties in GBM and other solid and hematological tumors, m6A dysregulation is believed to play a role in the generation of stem-like tumor initiating cells and tumorigenesis where such properties are known to be important for tumor progression, recurrence, and resistance. In GSCs, knockdown of the m6A demethylases FTO and its homolog ALKBH5 suppresses GSC-induced tumorigenesis. Moreover, FTO inhibition prolongs lifespan in tumor bearing mice. Recently, we identified novel inhibitors of FTO that impaired sphere formation of GSCs in 3D organoid models in a manner comparable to FTO silencing. Further medicinal chemistry efforts in this area led to the discovery of a novel series of drug-like small molecules, exemplified by the oxetane derivative FTO-43N that selectively inhibit FTO over ALKBH5. These molecules act as competitive inhibitors of FTO and demonstrate potent antiproliferative effects in glioblastoma. These promising results indicate that selective inhibition of FTO could be an effective strategy to target the resistant stem-cell populations in GBM. Furthermore, assessment of *in vitro* safety pharmacology (CEREP SafetyScan) and brain/plasma PK suggest that FTO-43N and related compounds are an attractive selective FTO inhibitors as drug candidates for the treatment of GBM. Accordingly, using structure-based design strategies combined with advanced *in vitro* and *in vivo* modeling systems, lead-optimization studies to identify candidate FTO inhibitors with pharmacokinetic (PK), *in vivo* efficacy, and safety/tolerability profiles suitable for further drug development.

#5123 C018, a potent and selective CDK4&9 dual inhibitor.

Jinwen Huang, Zhongyuan Li, Steve Shen

Convalife Pharmaceuticals, Shanghai, China

Background: CDK4&6 inhibitors have been approved for the treatment of metastatic ER+&HER2- breast cancer, either as monotherapy or in combination with endocrine therapy. However, many patients develop resistance to CDK4&6 inhibition through multiple mechanisms, including loss of the tumor suppressor Rb, hyperactivation of CDK4&6, and&or upregulation of CDK2&Cyclin E1 expression and activity, resulting in a significant unmet clinical need. CDK9 plays a critical role in RNA transcription as a catalytic subunit of positive transcription elongation factor b (P-TEFb), which phosphorylates the negative elongation factor (NELF), DRB sensitivity-inducing factor (DSIF), and the Ser2 residue within the C-terminal domain (CTD) of RNA polymerase II (Pol II), ultimately triggering transcriptional elongation. Accumulating evidence suggests that CDK9 activity may contribute to palbociclib resistance mechanisms, and targeting CDK9 represents a promising strategy to overcome resistance in breast cancer.
Methods and Materials:Based on structure-activity relationship (SAR) studies and accelerated by the Convalife "AIDRUG.WORK" molecular design platform, we completed the early-stage screening of CDK4&9 inhibitors. The lead compound demonstrated >30-fold selectivity for CDK4 over CDK6 and >80-fold selectivity for CDK9 over CDK6. To explore the therapeutic potential of CDK4&9 dual inhibitors against palbociclib-resistant tumors, we evaluated the effects of CDK4&9 inhibition on cell viability using both palbociclib-sensitive and palbociclib-resistant MCF-7 cell lines.
Results:The CDK4&9 inhibitor significantly impaired the viability of both palbociclib-sensitive and palbociclib-resistant MCF-7 cell lines through concurrent inhibition of CDK4 and CDK9 activity.
Conclusions:Our findings demonstrate that simultaneous inhibition of CDK4 and CDK9 may exert synergistic effects in overcoming palbociclib resistance. CDK4&9 dual inhibition represents a promising therapeutic strategy to overcome both endocrine therapy and CDK4&6 inhibitor resistance in ER+ breast cancer, warranting further clinical development as a novel approach for treating resistant breast cancer.

#5124 Identification and structural characterization of a novel PCNA-interacting small molecule scaffold.

Jennifer Jossart[1], Ning Ma[2], Pouya Haratipour[2], Caroline Li[3], Long Gu[3], Terrence O'Brien[4], Nagarajan Vaidehi[5], Linda H. Malkas[3], Robert Hickey[1], Jeff J. Perry[6]

[1]Cancer Biology and Molecular Medicine, Beckman Research Institute of The City of Hope, Duarte, CA,[2]Beckman Research Institute of the City of Hope, Duarte, CA,[3]Beckman Research Institute of The City of Hope, Duarte, CA,[4]Atomwise, San Francisco, CA,[5]City of Hope National Medical Center, Duarte, CA,[6]Beckman Research Institute at the City of Hope, Duarte, CA

Proliferating cell nuclear antigen (PCNA) plays essential roles in DNA replication, repair, transcription, and cell-cycle regulation, making it an attractive yet historically difficult target in cancer therapy. Building on our development of AOH1996, a first-in-class small molecule currently in Phase I clinical evaluation for solid and liquid tumors, we sought to identify additional PCNA-interacting chemotypes that could expand therapeutic opportunities and inform next-generation inhibitor design. Using an artificial intelligence-guided computer-aided drug discovery workflow, we screened more than ten million drug-like compounds and prioritized candidates through differential scanning fluorimetry. This approach led to the identification of COH005, a previously unreported small-molecule scaffold that binds PCNA. X-ray crystallography demonstrated that COH005 engages the major PCNA-interacting-protein (PIP)-box binding pocket, a critical interface for PCNA-mediated protein-protein interactions. Cellular thermal shift assays (CETSA) validated direct COH005-PCNA engagement in cells similar to clinical IND, AOH1996. To assess selectivity, we performed protein-structure frustration analysis comparing COH005 interactions with PCNA against an unrelated anti-target, revealing energetically favorable binding unique to PCNA. Together, these studies establish COH005 as a novel PCNA-interacting scaffold with strong potential for therapeutic development. This work provides a structural and mechanistic foundation for designing next-generation PCNA-targeted agents with improved specificity and pharmacological properties.

#5125 Discovery of a novel, selective brain penetrant CDK4 inhibitor for targeted cancer therapy.

Boris Rogovoy[1], Dmitrii Shkil[2], Ruben Karapetian[2], Elena Bulanova[2], Alexei Rjakhovskiy[2], Sergey Shevyakov[2], Tudor Oprea[3], Amy Burd[1], Iain Dukes[1], Nikolay Savchuk[1]

[1]Eilean Therapeutics, Dover, DE,[2]ChemDiv Inc, San Diego, CA,[3]Expert Systems, Inc., San Diego, CA

In breast and other malignancies, CDK4 overactivation commonly occurs as a result of sustained endocrine and mitogenic inputs, dysregulated cyclin D1 expression, or the genetic loss or functional impairment of INK4 family inhibitors, or loss of endogenous inhibitors such as p16. Approved CDK4/6 inhibitors (palbociclib, ribociclib, and abemaciclib) are associated with hematologic toxicity, including neutropenia, linked to CDK6 rather than CDK4 inhibition. Since these drugs block CDK6, drug dosing is restricted by bone marrow suppression rather than anti-tumor efficacy. HR+ breast cancer cells are more dependent on CDK4 than CDK6 for proliferation, whereas normal hematopoiesis relies predominantly on CDK6. Loss of CDK4 alone does not impair blood cell development in mice, while CDK6 and its partner cyclin D3 play a key role in stem cell activation, erythroid and myeloid differentiation, and neutrophil maintenance. This divergence establishes a therapeutic window: Selective blockade of CDK4 could suppress tumor growth while sparing bone marrow function. Clinical benefits in patients with brain metastases have been documented. However, dose-limiting toxicity may prevent the gain in overall outcome. CDK4-selective inhibition represents a strategic evolution in targeting cell-cycle dysregulation. By sparing CDK6, agents aim to overcome the main toxicity barrier of dual CDK4/6 inhibitors, enabling more potent and sustained CDK4 blockade. Here, we describe AL-0433, a novel, selective brain penetrant CDK4 inhibitor with excellent *in vitro* and *in vivo* activity.

Methods: AL-0433 was developed using resistance-aware, structure-based design, via AI-enabled virtual screening and medicinal chemistry at Expert Systems. Potency was evaluated against CDK1, 2, 4, 6, 9, and GSK3b in biochemical assays, and cytotoxicity was assessed in breast, ovarian, and glioblastoma cell lines. Pharmacokinetic (PK) properties were characterized in murines and dogs. Anti-tumor efficacy was tested in MCF-7 xenograft models as a single agent and in combination with other anti-tumor agents.

Results: AL-0433 exhibited low-nanomolar CDK4 inhibition (2.7 nM) with 30-fold selectivity over CDK6, and 1000-fold selectivity over CDK1, CDK2, and CDK9. AL-0433 showed potent cytotoxicity in breast, ovarian, and glioblastoma cells (20-950 nM). Mechanism of action studies in MCF-7 cells demonstrated inhibition of pRB phosphorylation. AL-0433 demonstrated excellent oral bioavailability with high blood-brain barrier (BBB) permeability, making it particularly advantageous for treating both primary and metastatic tumors, as well as brain tumors such as glioblastoma.

Conclusion: AL-0433 is a promising, AI-designed, selective CDK4 inhibitor with broad activity across breast, ovarian, and glioblastoma cell lines. Its favorable PK profile, preclinical efficacy, and rational design strategy support further clinical development

#5127 Structure-guided discovery of potent and selective DGKα inhibitors for targeted cancer therapy.

Farag E. S. Mosa, Khaled Barakat

Faculty of Pharmacy and Pharmaceutical Sciences, University of Alberta, Edmonton, AB, Canada

Introduction: Cancer remains a major cause of morbidity and mortality in North America. Diacylglycerol kinases (DGKs) are key regulators of lipid-mediated signaling, converting diacylglycerol (DAG) to phosphatidic acid (PA), two bioactive second messengers that orchestrate diverse cellular pathways. The DGK families comprise ten isoforms classified into five subtypes. Among these, DGKα—a type I isoform—plays critical roles in immune regulation, neuronal signaling, and membrane remodeling. In the context of cancer, DGKα enhances tumor cell proliferation and survival while suppressing cytotoxic T-cell and natural killer (NK) cell activity, thereby facilitating immune evasion. DGKα also promotes PD-L1 expression, further reinforcing tumor immune escape. Dysregulated DGKα signaling similarly contributes to immune dysfunction. To address these pathological roles, we aim to develop highly selective DGKα inhibitors by exploiting a distinct allosteric pocket to achieve precise and isoform-specific modulation of the enzyme.
Methods: We generated high-confidence structural models of DGK isoforms including (α, β) using state-of-the-art AI prediction platforms, complemented by molecular dynamics (MD) simulations and binding free-energy methodologies. Structural models of DGKα and DGKβ were constructed in the presence of biologically relevant cofactors (ATP, Ca^{2+}, Zn^{2+}, Mg^{2+}) to capture catalytically competent conformations. Each model underwent extensive validation through long-timescale MD simulations, and dominant conformational ensembles were extracted via clustering analyses. A generative-design pipeline was subsequently deployed to create and prioritize novel small-molecule inhibitors based on predicted potency, isoform selectivity, and physicochemical suitability. Top-ranked candidates were further interrogated through molecular docking, MD refinement, and free-energy calculations to characterize their binding poses.
Results: The DGKα structural models demonstrated strong concordance with available in vitro data, supporting their suitability for downstream computational analyses. Molecular docking identified a previously uncharacterized allosteric pocket capable of accommodating the generative-AI-derived compounds. MM-PBSA analyses of MD trajectories provided binding free-energy estimates and revealed key residues that mediate ligand engagement and stabilize the inhibitor-protein complexes.
Conclusion: S532, L556, H606, Y558, and F559 mediate ligand recognition, enabling elucidation of the mechanistic basis that underlies the interactions of two lead chemotypes. Several designed molecules exhibit marked isoform selectivity, displaying substantially stronger predicted affinity for DGKα than for DGKβ. Together, these insights provide a structural framework for the rational development of selective DGKα inhibitors.

#5128 Accelerated discovery of novel RORγT modulators using an AI-driven platform integrating generative chemistry and mechanistic PK simulation.

Jeremy Jones[1], Rafal Bachorz[1], Michael Lawless[1], Joanna Pastwinska[2], Anna Salkowska[2], Marcin Ratajewski[2]

[1]Simulations Plus, Inc., Lancaster, CA,[2]Polish Academy of Sciences, Lodz, Poland

The application of artificial intelligence (AI) in oncology drug discovery offers the potential to significantly accelerate and de-risk the identification of novel therapeutic agents. In this study, we present the successful application of an AI-driven drug design (AIDD) platform to discover new classes of RORγT ligands, both agonists and inverse agonists. RORγT, a nuclear receptor central to Th17 cell differentiation and IL-17 signaling, has emerged as a promising target for auto-immune diseases as well as cancer immunology, and both classes of ligands have therapeutic potential.

Our AIDD platform integrates quantitative structure-activity relationship (QSAR) modeling, ADMET property predictions, high-throughput mechanistic PK simulations, 3D volumetric/pharmacophore similarity scoring, and synthetic accessibility assessments at the point of initial compound design. Importantly, compound prioritization is guided by a multi-criteria decision analysis multi-parameter optimization (MPO) algorithm, which incorporates these features to balance potency, ADMET/PK, and chemical tractability to optimize candidate selection. This approach enables systematic decision-making across multiple parameters, reducing reliance on trial-and-error screening.

In our initial Design/Make/Test cycle, 27 novel compounds were synthesized and tested. Remarkably, 70% demonstrated >25% inhibition of RORγT activity in cell-based assays. The top candidate had an IC_{50} of 1.51 uM and favorable in vitro ADME, with high concordance between predicted and measured values. Based on these results, a second set of inverse agonists was designed. 14/19 (74%) were active, with 4 having improved potency. In vitro and in vivo ADMET and PK testing is ongoing. In parallel work, we identified a novel class of RORγT agonists, which could find application in cancer immunotherapy; further development of this class is ongoing as well.

This work demonstrates how a platform integrating generative chemistry with mechanistic PK simulations and MPO can be used to accelerate the development of viable drug candidates, in this case, against an important clinical target, RORγT

#5129 Discovery and development of a novel PI3K-CDK4/6 dual inhibitor PC-13 for the treatment of breast cancer.

Xinyun Zhang[1], Jiaqi Hu[1], Xiaoxue Li[1], Qian Wang[2], Yanan Zhao[2], Qiang Xia[2], Jinhua Wang[1], Heng Xu[1], **Tj (Tiejun) Bing**[2]

[1]Institute of Materia Medica, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[2]ICE Bioscience, Beijing, China

Breast cancer continues to be a major cause of cancer-associated mortality globally, underscoring the urgent need for innovative therapeutic strategies. In this study, we report the discovery and preclinical characterization of PC-13, a potential first-in-class dual inhibitor targeting both PI3K and CDK4/6. PC-13 demonstrates nanomolar-level potency against PI3K and CDK4/6 kinases, high selectivity across a broad panel of kinases, and potent antiproliferative effects in multiple breast cancer cell lines. Furthermore, PC-13 exhibits reasonable pharmacokinetic properties and achieves significant tumor growth suppression in a T47D xenograft model, with efficacy comparable to the Palbociclib-Buparlisib combination regimen, while maintaining a promising safety profile. Our findings highlight the potential of concurrent PI3K and CDK4/6 inhibition as a novel and effective therapeutic approach for breast cancer, supporting further development of PC-13 as a clinical candidate.

#5130 Identification and characterization of pan-mutant selective PI3Kα inhibitors with the capability of PI3Kα H1047R protein degradation.

Chengshan Niu*,#, Shengli Dong*,#, Shaoqing Chen*, Kaige Ji, Zhengfei Guo, Maolin Zheng, Mingtao Chen, Yuanjie Li, Meihua Li, Hongqiang Li, Yu Yu, Xinlong Yang, Zhiyong He, Apeng Liang, Zhou Yin, Wei Wu, Jun Li*, Yusheng Wu

TYK Medicines, Inc., Changxing, Zhejiang, China

Introduction: PIK3CA, a PI3K isoform, is one of the most frequently mutated genes in human cancers. PIK3CA mutations are highly enriched at “hotspot” sites in the helical (E542K, E545K) and kinase (H1047R/L) domains. Orthosteric inhibitors of PI3Kα, such as alpelisib and inavolisib, have been approved for the treatment of patients with advanced HR+/HER2– breast cancer. Selective targeting of mutant PI3Kα is anticipated to enhance antitumor efficacy and mitigate the toxicity associated with wild-type PI3Kα inhibition in normal tissue. Allosteric and mutant-selective PI3Kα inhibitors, including RLY-2608 (NCT06982521) and LY4064809 (STX-478, NCT07174336), have been successfully developed in the clinical phase III stage.

Results: Several allosteric and potent pan-mutant PI3Kα inhibitors developed by TYK Medicines exhibited high selectivity over wild-type (WT) PI3Kα. Our observations revealed that the compounds inhibited AKT phosphorylation in the T47D (PI3Kα H1047R) cell line with an IC_{50} in the single-digit nanomolar range, demonstrating nearly 200 times more selectivity compared to SK-BR-3 (PI3Kα WT) cells at same time. In *in vitro* antiproliferative assays, the compounds displayed superior antiproliferative activity against various PI3Kα mutant cells, including T47D, HCC1954 (PI3Kα H1047R), and MCF7 (PI3Kα E545K), compared to STX-478 and RLY-2608. For instance, TY-3659 was four and thirteen times more selective in T47D and MCF7 cells, respectively, than RLY-2608, aligning with the PI3Kα kinase inhibition assays. In addition, TY-3659 effectively degraded PI3Kα mutant protein in HCC1954 and MDA MB 453 (PI3Kα H1047R) cells. In the mouse HCC1954 and Cal33 (PI3Kα H1047R) CDX models, the compounds exhibited potent tumor-inhibitory activity, excellent tolerance, good DMPK properties, and desirable drug-like characteristics. No effects on fasting plasma glucose levels were observed after four days of treatment in the insulin tolerance test.

In conclusion, we identified potent allosteric and pan-mutant selective PI3Kα inhibitors capable of degrading PI3Kα mutant protein. Our findings suggest that TYK compounds can significantly enhance the therapeutic index of PI3Kα-mutant cancers without causing PI3Kα WT-related toxicity.

#5131 HDM2021, a potent and selective CBL-B inhibitor exhibits robust immunomodulatory efficacy for anti-tumor therapy.

Shulun Chen, Mengting Zhao, Zhimin Zhang, Jingwen E, Xi Yang, Xinyu Dai, Zhenna Xia, Xin Xu, **Dongzhou Liu**

Global R&D Center, Huadong Medicine, Hangzhou, China

Introduction: The E3 ligase Casitas B-lineage lymphoma proto-oncogene B (CBL-B) is a critical negative regulator of immune activation. It controls T-cell and NK cell activation by lowering the threshold for effector cell activation, driving effector cell proliferation and inflammation, and reducing susceptibility to suppression by Tregs, MDSCs, and macrophages. Tumors exploit this pathway as a mechanism of immune evasion. To address this resistance, we are developing a potent CBL-B inhibitor designed to enhance intrinsic immune cell function, rescue anti-tumor immunity, and achieve clinical efficacy in immunotherapy-resistant patients.

Methods: A series of CBL-B inhibitors with novel scaffolds have been synthesized and screened for activity and drug-like properties. Compound binding to the CBL-B protein was evaluated using TR-FRET and surface plasmon resonance (SPR) assays. Immunomodulatory activity was assessed *in vitro* in T cells or NK cells by measuring cytokine release via ELISA. Pharmacokinetic studies were conducted in mice and dogs, with serial blood samples analyzed by LC-MS/MS. The toxicology assessment was conducted using an *in vitro* safety panel and *in vivo* 14-day dose range finding (DRF) study in mice. Proof-of-concept *in vivo* efficacy was demonstrated in subcutaneous xenograft mouse models.

Results: Through systematic molecular design and rigorous drug-likeness screening, we have identified HDM2021 as a promising drug candidate. This compound demonstrated high-affinity binding to CBL-B (K_d < 1 nM) and a prolonged target dissociation half-life. Functionally, it activated both T cells and NK cells and exhibited potent tumor-killing activity in T cell-tumor cell co-culture assays. Furthermore, HDM2021 exhibited excellent target selectivity in safety panel assays (44 targets) and minimal hERG channel inhibition (IC50 > 20 μM). In particular, HDM2021 was well tolerated in mice at a dose of 80 mg/kg in a DRF study, indicating an optimal safety profile. It also displayed moderate pharmacokinetic properties in both mice and dogs. Notably, in multiple xenograft models, HDM2021 demonstrated robust antitumor efficacy in combination with PD-1 antibody, and sustained tumor regression was maintained after treatment withdrawal.

Conclusion: HDM2021 has demonstrated potent CBL-B inhibition and robust efficacy in both *in vitro* and *in vivo* models. It also exhibits improved pharmacokinetic properties, high target selectivity, and a favorable safety profile. These findings support its further development as a novel immunomodulatory drug candidate for anti-tumor therapy. IND-enabling studies have been initiated for clinical studies.

#5132 Discovery and preclinical evaluation of a potent, orally bioavailable, highly selective, small molecule non-covalent KRAS[G12D] inhibitor.

Alexei Pushechnikov[1], Volodymyr Kysil[2], Ruben Karapetian[3], Stepan Mochalov[4], Aleksei Riakhovskii[4], Elena Bulanova[4], Nikolay Savchuk[5], Iain Dukes[5]

[1]Expert Systems, Inc., San Diego, CA,[2]ChemDiv, Inc., San Diego, CA,[3]Expert Systems, Inc, Dover, DE,[4]Navegador Biosciences, Cantanhede, Portugal,[5]Eilean Therapeutics LLC, Philadelphia, PA

KRAS[G12D] oncogenic mutation is present in ~35% of pancreatic, 13% of colorectal, and 4% of non-small cell lung cancers. The mutation also occurs in other cancer types, albeit less frequently. Here we would like to present compelling evidences that ZE98-0277 has potent and selective activity in KRAS[G12D] mutant cell lines and in vivo models.
ZE98-0277 drug candidate demonstrates strong in vitro activity (IC50 KRAS[G12D] 6.3 nM) and oral PK, bioavailability ~20-40% in mice and monkeys, broad therapeutic window (>100x in cellular models), good safety and tolerability, favorable ADME properties (solubility, stability, permeability, low hERG inhibition, minimal off-target effects), effective tumor suppression in multiple mouse xenograft models.
These preclinical results demonstrate that ZE98-0277 is a potent, selective, and orally bioavailable KRAS[G12D] inhibitor, strongly efficacious against KRAS[G12D] mutant tumors slated for further development.

#5133 Design, synthesis and pharmacological evaluation of ACC1 selective inhibitors for cancer treatment.

Ryo Mizojiri, Moriteru Asano, Daisuke Tomita, Hiroshi Banno, Noriyuki Nii, Masako Sasaki, Hiroyuki Sumi, Yoshihiko Satoh, Yukiko Yamamoto, Takeo Moriya, Yoshinori Satomi, Hironobu Maezaki

Takeda Pharmaceutical Company Ltd. (Japan), Kanagawa, Japan

Acetyl-CoA carboxylase (ACC) is an enzyme that regulates the rate-limiting step in lipid synthesis, converts acetyl-CoA to malonyl-CoA, and is attracting attention as a drug discovery target in a wide range of areas, including metabolic diseases, oncology, and immunology. There are two subtypes of ACC, and among them, ACC1 has been reported to be highly expressed in human cancer cells, and is therefore expected to be a candidate for the development of new cancer therapeutics. Aiming to develop novel and selective ACC1 inhibitors, we initiated synthetic development from pyrrolopyridine derivative and benzoxazole derivative as lead compounds. In terms of pyrrolopyridine derivative, modification of substituents dramatically improved ACC1 inhibitory activity and PK profiles to identify in vivo tool compound which showed potent PD activity. On the other hand, in benzoxazole derivative, linkers and terminal parts were developed for improving enzymatic activity. As a result, we found 2-phenylbenzoxazole compound, which exhibits very strong selective ACC1 inhibitory activity. Furthermore, we continued to investigate reducing lipophilicity to improve solubility toward the generation of in vivo tool compounds, and found ureido compound with good selective ACC1 inhibitory activity and PK profiles. This compound showed significant anti-tumor efficacy in 786-O xenograft mice at an oral dose of 30 mg/kg, bid (T/C = 0.5%) along with potent and prolonged PD activity. Further investigation toward ACC1 specific inhibitor discovered monocyclic derivatives. Among them, oxazole compound exhibited more potent in vivo efficacy than ureido compound in several xenograft mice models. This finding was the first example to show anti-tumor efficacy by the treatment with ACC1 specific inhibitor as a single agent.

#5135 Targeting EGFR cysteine 775 in EGFR mutant lung cancer.

Jie Jiang[1], Zhengnian Li[2], Yaning Wang[2], Stephen J. Collins[1], Felix H. Gottlieb[1], Prafulla C. Gokhale[3], Michael J. Eck[3], Pasi A. Janne[3], Jianwei Che[1], Nathanael S. Gray[2], Tinghu Zhang[2]

[1]Dana-Farber Cancer Insistitute, Boston, MA,[2]Stanford University, Stanford, CA,[3]Dana-Farber Cancer Institute, Boston, MA

Covalent targeting of EGFR cysteine 797 by osimertinib is one of the most successful breakthroughs in targeted therapy, fundamentally transforming the treatment landscape for non-small cell lung cancer (NSCLC) patients. However, resistance driven by mutation of C797 remains a major clinical challenge. Developing novel covalent strategies beyond C797 targeting presents a compelling opportunity for next-generation EGFR inhibitors. We first demonstrated that cysteine 775, located deep within the ATP-binding pocket, is accessible by a rationally designed covalent molecule ZNL-3, which exhibited strong efficacy in osimertinib-resistant mouse models. To further enhance resilience to resistance-causing mutations, we developed a dual-warhead, bident compound—YNW-1—which covalently targets both cysteine 775 and 797 simultaneously. YNW-1 is the first molecule to exhibit balanced reactive efficiency on both cysteines, rendering single-site mutations ineffective to confer resistance. The discovery of ZNL-3 and YNW-1 represents significant advancements in EGFR-targeted drug development, and further optimization toward clinical translation is a worthwhile strategy.

#5136 Multi-targeted MNK inhibitors as anticancer agents for AML.

Sophie Derusha[1], Erika Lisabeth[2], **Sonali Kurup**[3]

[1]Ferris State University, Big Rapids, MI,[2]Assay Development and Drug Repurposing Core, Michigan State University, East Lansing, MI,[3]Pharmaceutical Sciences, Ferris State University, Big Rapids, MI

Mutant FMS-like tyrosine kinase 3 (FLT3) is implicated as an oncogenic driver in over 30% of acute myeloid leukemia (AML) cases. While several FLT3-targeted drugs have been approved, resistance develops rapidly through varied mechanisms, including RAS mutations. The mitogen-activated protein kinase-interacting kinases (MNK1 and MNK2) are the only kinases that phosphorylate the eukaryotic translation initiation factor 4E (eIF4E). Dysregulation of the MNK-eIF4E axis has been seen in acute myeloid leukemia (AML) and MNK inhibitors have shown antiproliferative effects in AML. The kinases, MNK1 and MNK2 are activated by p38 mitogen-activated protein (MAP) kinase and extracellular signal-regulated kinase (ERK), downstream of FLT3 and RAS in the RAS/RAF/ERK signaling cascade. The aurora kinases (AURKA and AURKB) are also overexpressed in AML. Synergistic anticancer effects have been observed in AML for AURK inhibitors in combination with FLT3 targeted drugs. Multitargeted inhibition of varied oncogenic drivers could be anticipated to demonstrate improved anticancer effects in AML, particularly resistant AML. We have identified novel compounds as multi-targeted MNK inhibitors that bind with nanomolar potencies to MNK1, MNK2, FLT3 and AURKB. The compounds show single-digit micromolar inhibition of AML cells expressing mutant FLT3 (MV-411) and are equipotent to tomivosertib, a clinically investigated MNK inhibitor that was included as a standard for comparison. The design, synthesis, and anticancer effects of multi-targeted MNK inhibitors will be described.

#5137 KBD880 is a potent and selective GPC3 peptide binder for treatment of HCC.

Hongzhu Chu, Yang Chen, Yonggang Wei, Fei Ye, Jing Zhang, Zhiyong Li, **Xiaoke Liu**, Jiannan Cui

Kangbaida (Sichuan) Biopharmaceutical Technology Co., Ltd, Chengdu, China

Background: The membrane-associated glycoprotein Glypican-3 (GPC3) is highly overexpressed in hepatocellular carcinoma (HCC) while exhibiting minimal to no expression in normal tissues. This tumor-specific expression profile makes GPC3 an ideal target for developing radiopharmaceutical therapies to treat HCC, a leading cause of cancer-related deaths worldwide.
Methods: DOTA-KBD-GPC3 (KBD880) is a radiopharmaceutical conjugate composed of a novel GPC3-binding macrocyclic peptide, a linker, and a DOTA chelator for complexation with therapeutic radioisotopes. The binding affinity of the ^{175}Lu-labeled conjugate was characterized by surface plasmon resonance and competitive flow cytometry. Subsequently, Target-mediated cellular internalization kinetics were quantified via radiometric assays. In vivo, the biodistribution and therapeutic efficacy of the ^{177}Lu-labeled conjugate were evaluated in HepG2 HCC xenograft model.
Results: ^{175}Lu-KBD880 exhibited high-affinity binding to both human and murine GPC3, with equilibrium dissociation constants (KD) of 2.20 nM and 2.02 nM, respectively, as determined by surface plasmon resonance. In addition, ^{175}Lu-KBD880 showed potent binding to GPC3-expressing HepG2 cells (IC_{50}= 9.3 nM). A high proportion of non-canonical amino acids and fragments with favorable drug-like properties were used to achieve a balance of potency, permeability, and physicochemical properties. ^{175}Lu-KBD880 exhibited excellent permeability, an optimal half-life and substantial systemic exposure in mice. The therapeutic conjugate, ^{177}Lu-KBD880, exhibited rapid and efficient internalization, achieving cellular uptake ratios of 50-60%. ^{177}Lu-KBD880 displayed an excellent in vivo profile, characterized by high tumor retention, rapid renal clearance, and minimal off-target uptake. This favorable biodistribution translated into significant and sustained tumor growth inhibition following monotherapy in GPC3-positive HCC xenografts.
Conclusions: KBD880 is a potent and selective, peptide-based radiopharmaceutical agent developed for targeting GPC3-expressing tumors. Its favorable preclinical characteristics—including an optimal pharmacokinetic profile, targeted biodistribution, and durable monotherapy efficacy—strongly support its development as a theranostic agent for patients with GPC3-positive malignancies.

#5138 Chemical optimization of an orally bioavailable macrocyclic peptide KRAS inhibitors that achieve KRAS selectivity by recognizing a single amino acid difference.

Mirai Kage, Hatsuo Kawada, Koji Takano, Atsushi Matsuo, Yoshihisa Murata, Satoshi Hashimoto, Minoru Tamiya, Tomoya Kotake, Shino Kuramoto, Takashi Yamano, Machiko Irie, Kazuhiro Ohara, Yuuji Sakurai, Kenichi Nomura, Yuya Morita, Ryuji Hayashi, Yuma Wakamiya, Kana Takei, Hiroshi Tanaka, Yoshikazu Nishimura, Hitoshi Iikura, Takuya Shiraishi, Mikimasa Tanada

Chugai Pharmaceutical Co., Ltd., Yokohama, Kanagawa, Japan

Macrocyclic peptides represent a promising modality for targeting intracellular proteins that are traditionally considered "undruggable" by small molecules or antibodies. Their tunable physicochemical properties allow for engineering of membrane permeability and metabolic stability, enabling oral bioavailability and intracellular engagement. A classic example is cyclosporine A, which exhibits both oral absorption and intracellular activity. To expand the drug-like potential of this class, we developed an mRNA display platform optimized for the selection of bioactive cyclic peptides with favorable pharmacokinetic profiles. This platform enables the identification of peptides capable of passive cell membrane permeation and oral absorption without the need for permeation enhancers. Using this technology, we previously reported LUNA18 (Paluratide), a mid-sized cyclic peptide that binds reversibly to GDP-bound RAS isoforms (KRAS, NRAS, HRAS), inhibiting their signaling (J. Am. Chem. Soc. 2023, 145, 16610). In this presentation, we report the structural optimization research that led to the development of AUBE00, a next-generation pan-KRAS inhibitor derived from the LUNA18 scaffold. AUBE00 was engineered to achieve KRAS isoform selectivity by targeting His95, a residue uniquely present in KRAS but absent in NRAS and HRAS. KRAS selectivity was achieved through a targeted interaction with His95, a KRAS-specific amino acid residue. A key challenge in this process was the inherent flexibility of the cyclic peptide scaffold. To address this, we introduced a partial fixation by bridging the peptide backbone near His95, enabling a precise interaction with the residue. As a result, we achieved approximately 14-fold selectivity over NRAS and 10-fold selectivity over HRAS. Importantly, this structural optimization was accomplished while maintaining the favorable pharmacokinetic profile of the parent compound, LUNA18. AUBE00 is an 11-residue hydrophobic cyclic peptide lacking dissociable side chains. It exhibits high membrane permeability (Caco-2 P_{app} = 2.2 × 10^{-6} cm/s) and strong binding affinity to KRAS (K_D = 92 pM). Notably, AUBE00 demonstrates moderate oral bioavailability (F = 24-65%) across three animal species without specialized formulation. In mouse xenograft models, oral administration of AUBE00 resulted in robust antitumor efficacy. A Phase 1 clinical trial in patients with advanced solid tumors is currently ongoing.

#5139 A novel toll-like receptor antagonist lead for glioblastoma and pancreatic and breast cancer.

Milan Makale, Wolfgang Wrasidlo

UC San Diego School of Medicine, La Jolla, CA

EMS-312 a dual toll-like receptor (TLR2/9) antagonist is the product of a structure activity testing campaign that involved 400+ synthesized analogs. This compound represents a *first-in-class* approach to suppressing the inflammatory network that fuels aggressive cancers. EMS-312 selectively blocks the intracellular TLR2/9-MyD88 signaling complex. As shown in Table 1, EMS-312 is orally available and crosses the blood-brain barrier. By targeting a shared innate-immune pathway, EMS312 can address multiple indications—from glioblastoma, triple negative breast cancer, and pancreatic cancer while also qualifying for orphan and fast-track designations. Comprehensive composition-of-matter patents have been issued and are active through 2039. EMS312 shows a clean safety and ADME package, with compelling early proof of tumor-cell and microglial suppression. EMS-312 sits at the locus of oncology where big pharma currently appears to have a pipeline gap, giving this drug lead candidate significant partnering and acquisition potential.

EMS-312: Physicochemical and pharmacological properties

#5140 Development of hydrophilic and metabolically stable heterocyclic AOH1996 analogues for pediatric AML oral liquid formulations.

Pouya Haratipour[1], Melissa Valerio[2], Michaela R. Jacobs[1], Maryam Zangi[1], Long Gu[3], Caroline Li[3], Robert Lingeman[3], Jennifer Jossart[1], Jefferson J. Perry[1], Le Xuan Truong Nguyen[2], Linda H. Malkas[3], Robert J. Hickey[1]

[1]Cancer Biology and Molecular Medicine, Beckman Research Institute of The City of Hope, Duarte, CA,[2]Department of Hematologic Malignancies Translational Science, Beckman Research Institute of The City of Hope, Duarte, CA,[3]Department of Molecular Diagnostics & Experimental Therapeutics, Beckman Research Institute of The City of Hope, Duarte, CA

Proliferating cell nuclear antigen (PCNA) is a key regulator of at least 11 essential cellular processes, including DNA replication and repair, transcription, cell cycle progression, apoptosis induction, transcription-replication conflict resolution, energy metabolism, chromosome maintenance, mitosis, and immune surveillance. In tumor cells, PCNA exists as a cancer-associated acidic isoform (caPCNA), while non-malignant cells express only a basic isoform (nmPCNA). The absence of caPCNA in normal cells makes it an attractive target for selective cancer therapy. We previously developed AOH1996, a first-in-class small molecule that selectively inhibits caPCNA, inducing apoptosis in cancer cells without detectable toxicity in non-malignant cells. AOH1996 binds to caPCNA, stabilizes its trimeric structure, decreases chromatin association, and suppresses tumor cell proliferation. AOH1996 is orally bioavailable and is currently being evaluated in two first-in-human Phase I clinical trials: one for treatment refractory solid tumors (NCT05227326) and the other for acute myeloid leukemia (NCT06763341). No dose-limiting toxicities have been observed to date, with ongoing dose escalation currently reaching 1110 mg PO BID. In this study, we aimed to enhance the aqueous solubility and pharmacokinetic properties of AOH1996 through strategic single-point heteroatom substitutions. By replacing selected aromatic carbons with nitrogen atoms, we generated a series of quinoline, isoquinoline, and pyridine analogues optimized for liquid oral formulations that will be ultimately compatible with pediatric administration for AML. Structure-activity relationship (SAR) analyses across these three heterocyclic scaffolds identified several analogues with improved solubility, potency, selectivity, and metabolic stability when compared to the clinical lead. For example, introducing two nitrogen atoms into the aromatic regions of one analogue reduced the CLogP to 3.35 (vs. 4.46 for AOH1996) while maintaining IC_{50} values comparable to the parent compound. This reduction in lipophilicity corresponds to an estimated ~13-fold increase in aqueous solubility, making this analogue more amenable to liquid formulation for oral administration. Over 30 novel AOH analogues were synthesized and evaluated for antiproliferative activity across eight tumor cell lines (including Molm-13, THP-1, HTB-0225, SK-N-AS, HCT116, U251, and MDA-MB-468), as well as in AML mouse models. Synthetic routes, biological data, and preliminary *in vivo* results will be presented. Together, these findings lay the groundwork for the next generation of AOH-based therapeutics with improved physicochemical and pharmacological properties suitable for pediatric oncology applications.

#5141 ZMS-4084, a potent and selective WRN inhibitor induces significant tumor regression and sustained complete responses in MSI-H tumor models.

Weikun Wang, Guimei Yang, Liting Xue, Yao Guo, Wenjing Li, Renhong Tang, **Zhengtao Li**

State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

Microsatellite instability-high status (MSI-H) is typically prevalent in endometrial, gastrointestinal, ovarian and colorectal cancers. The RecQ helicase WRN has been identified as a synthetic lethal target in MSI-H cancers and represents a promising therapeutic candidate in this context. The two clinical-stage WRN inhibitors, HRO761 and RO7589831, have demonstrated the clinical efficacy in phase I trials. Here we report the discovery of a novel and potent WRN inhibitor, ZMS-4084. Surface plasmon resonance analysis revealed that ZMS-4084 binds specifically to the WRN helicase domain with high affinity (KD=1.08E-08 M). ZMS-4084 selectively inhibited WRN ATPase activity with an IC_{50} of 0.05 μM, and exhibited over 2,000-fold selectivity over other RecQ family helicases. Intracellular mechanistic study demonstrated that ZMS-4084 induces apoptosis and inhibits proliferation of HCT116 (MSI-H) cells with an EC_{50} of 0.024 μM, accompanied by WRN degradation and accumulation of DNA damage signified by p21 expression and other markers. In a panel of 124 tumor cell lines, ZMD-4084 selectively inhibited the viability of MSI-H cell lines without significant effects on microsatellite stable (MSS) cell lines, indicating high selectivity and a potentially favorable safety profile. Notably, ZMD-4084 effectively suppressed the growth of MSI-H patient-derived organoids, including those previously exposed to standard-of- care therapies such as chemotherapy, anti-EGFR agents, and/or immunotherapy. *In vitro* ADME and *in vivo* pharmacokinetics studies demonstrated favorable physicochemical properties and dose-proportional oral bioavailability across preclinical species, supporting its potential for oral administration in humans. Daily administration of ZMS-4084 resulted dose-dependent antitumor efficacy in xenograft models derived from MSI-H human tumors. In the Ishikawa xenograft model, daily dosing at 2.5 mg/kg induced 100% tumor regression, and complete responses (CRs) were achieved in five out of six aminals at 15 mg/kg. Even in the less sensitive RKO xenograft model, 100% tumor regression and several CRs were observed at a dose of 20 mg/kg. No treatment-related abnormalities were observed across all dose regimens in non-GLP preclinical safety studies. In conclusion, we have developed a novel WRN inhibitor, ZMS-4084, which demonstrates robust antitumor activity in both xenograft models and patient-derived organoids representing diverse MSI-H tumor types. Given the synthetic lethality between WRN inhibition and MSI-H status, along with its broad antitumor activity across multiple tumor lineages, ZMS-4084 holds strong potential as a tissue-agnostic therapeutic agent for patients with MSI-H tumors.

#5142 PRMT5 inhibitor SCR-6920 downregulates HIF-1α and exhibits synergistic antitumor activity with Bevacizumab.

Guimei Yang, Huixia Dou, Liting Xue, Yao Guo, Wenjing Li, Zhen Li, **Zhengtao Li**, Renheng Tang

State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

PRMT5 has emerged as a promising epigenetic target for cancer therapy, yet its potential in rational combination strategies remains inadequately explored. This study aims to characterize the novel, oral PRMT5 inhibitor SCR-6920, with a particular focus on its ability to synergize with anti-angiogenic therapy by modulating the hypoxia-inducible factor-1α (HIF-1α)/vascular endothelial growth factor (VEGF) axis. SCR-6920 is a potent and highly selective PRMT5 inhibitor that has undergone extensive preclinical evaluation and is currently in phase 1 clinical trials (NCT05528055). It demonstrated broad antitumor efficacy across a panel of cancer cell lines *in vitro* and in xenograft models *in vivo*. A key finding from RNA-seq analysis was that PRMT5 inhibition by SCR-6920 led to the downregulation of angiogenesis pathways, particularly those involving VEGF. Subsequent mechanistic studies revealed that SCR-6920 significantly reduced hypoxia-induced HIF-1α protein levels without altering its mRNA expression. This effect was mediated by promoting the ubiquitination and subsequent proteasomal degradation of the HIF-1α protein. Consequently, SCR-6920 treatment resulted in the decreased expression and secretion of VEGF, a major downstream target of HIF-1α. Based on this mechanism targeting the HIF-1α/VEGF axis, we investigated and demonstrated a robust synergistic antitumor effect between SCR-6920 and the anti-VEGF antibody bevacizumab in an ovarian cancer xenograft model. This combination resulted in significantly enhanced tumor growth suppression without an increase in toxicity, providing a strong mechanistic rationale for this combination strategy. Furthermore, SCR-6920 exhibited synergistic or additive effects when combined with several standard-of-care chemotherapies and targeted agents for solid tumors, including paclitaxel, docetaxel, doxorubicin, and olaparib. In summary, our work identifies SCR-6920 as a promising clinical-stage PRMT5 inhibitor with a unique ability to destabilize HIF-1α and suppress VEGF signaling. The unveiled mechanism, whereby PRMT5 inhibition promotes HIF-1α degradation, provides the foundation for the observed synergistic activity with bevacizumab. These findings position SCR-6920 as a compelling clinical candidate for solid tumors, particularly in rational combinations aimed at overcoming resistance to anti-angiogenic therapy.

#5145 A novel highly potent multiple-RAS inhibitor ZMS-2195 efficiently blocks MAPK pathway activation and induces robust anti-tumor growth effects in preclinical models.

Zhengtao Li, Guimei Yang, Huixia Dou, Wei Zhu, Xiang Chen, Yao Guo, Wenjing Li, Liting Xue, Renhong Tang

State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

Variants in the RAS family (HRAS, NRAS and KRAS) represent among the most prevalent oncogenic mutations identified in cancer. Approximately 19% of cancer patients harbor RAS mutations, which are typically associated with poor clinical outcomes. Multi-RAS inhibitor may overcome resistance by hitting a broader range of targets than single-mutant inhibitors. As such, multi-RAS inhibitors are anticipated to offer therapeutic potential across a wide range of RAS-driven malignancies. Here we report ZMS-2195, a novel and highly potent Multi-RAS inhibitor. Biochemical assays assessing disruption of the RAS-RAF complex demonstrated that ZMS-2195 effectively inhibited the interaction between multiple RAS variants—including KRAS, NRAS, and HRAS mutants and wild-type forms—and the RAF-RBD domain, with digital nanomolar IC_{50} values. The cellular MAPK pathway inhibition was confirmed through robust suppression of phosphorylated ERK in representative cancer cell lines harboring diverse *RAS* mutant alleles. Consistent with the biochemical activity observed against multiple RAS variants and cellular pERK inhibition potency in RAS mutant cell lines, ZMS-2195 caused potent growth inhibition of KRAS mutant cancer cell lines, exemplified by Miapaca-2 ($KRAS^{G12C/G12C}$, PDAC), AsPC-1($KRAS^{G12D/G12D}$, PDAC) and SW403 ($KRAS^{G12V/WT}$, CRC) with IC_{50} values of 0.8, 1.3 and 0.3 nmol/L, respectively. Wild-type *RAS* (RAS^{WT}) cancer cells with GTP-activated RAS from upstream mutations were equally sensitive to ZMS-2195, exemplified by H1975($EGFR^{mut}$, NSCLC) with an IC_{50} of 6.7 nmol/L. Conversely, RAS^{WT} cancer cells harboring downstream *BRAF* mutations or RAS-independent normal cells were essentially insensitive to ZMS-2195. Favorable oral bioavailability and pharmacokinetic profiles were exhibited in pre-clinical species. Oral administration of ZMS-2195 resulted in dose-dependent and sustained suppression of RAS pathway signaling, as evidenced by reduced human DUSP6 mRNA expression levels in tumor lysates. Daily dosing of ZMS-2195 produced dose-dependent antitumor activity in xenograft models derived from RAS-driven human tumor xenograft model *in vivo*. At a dose of 0.8 mg/kg, ZMS-2195 induced tumor regression in PK59 ($KRAS^{G12D/WT}$, PDAC) xenograft model. In summary, ZMS-2159 is a potent Multi-RAS inhibitor with robust activity against RAS-driven tumor cells, supporting its further development as a target therapy for cancers driven by diverse RAS aberrations.

#5146 Discovery of a novel ALK inhibitor ZM-8195 that targets ALK compound mutations with superior TRK selectivity.

Zhen Li, Yajing Liu, Mengying Li, Jing Dai, Xuefeng Wang, Yuan Cheng, Xue An, Jing Chen, Jianan Wang, Yuandong Zheng, Wenjing Li, Liting Xue, **Zhengtao Li**, Renghong Tang

State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co., Ltd., Shanghai, China

ALK fusions are common oncogenic drivers. Approximately 5% of NSCLC patients are ALK-positive, with 30% to 40% developing brain metastases. ALK inhibitors are primarily used to treat ALK-positive patients. However, sequential therapy with second- and third-generation inhibitors is susceptible to resistance mutations, compromising clinical efficacy. Concurrently, inhibition of TRK-family kinases (TRKA, TRKB, and TRKC) elicits broad central nervous system (CNS) adverse effects, further limiting their utility. Therefore, there is an urgent need to develop a new generation of ALK inhibitors to cover a broader population of drug-resistant mutations with brain penetrance and superior TRK selectivity. Here, we identified ZM-8195, a potent and selective ALK inhibitor. In *in vitro* evaluation, ZM-8195 showed low nano-molar activities against EML-ALK fusion and G1202R/L1196M mutation in biochemical and cell proliferation assay. ZM-8195 exhibited minimal activity against TRK-family kinases, with selectivity indices for TRKB over ALK wild-type or mutant exceeding 100-fold. ZM-8195 also showed potent anti-proliferation activity in different ALK compound mutant cell lines with IC_{50} from 0.5-24 nM. ZM-8195 effectively inhibited H3122(EML4-ALK V1) and BaF3(EML4-ALK V1(G1202R/L1196M)) tumor growth with complete tumor regression. In a BaF3 G1202R/L1196M orthotopic brain model, ZM-8195 also demonstrated robust anti-tumor efficacy. ZM-8195 was well tolerated in rodents and non-rodents. Based on its favorable activity, selectivity, pharmacokinetic profiles and safety, ZM-8195 is currently in IND enabling stage.

#5147 A novel investigation of the cyclin A/B inhibitor ZMS-7506 demonstrates robust anti-tumor efficacy both *in vitro* and *in vivo*.

Guimei Yang, Ruina Wang, Weikun Wang, Liting Xue, Xiaokang Qin, Renhong Tang, **Zhengtao Li**

State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., shanghai, China

Cyclins A and B are critical regulators of the transition from the S phase to the G2/M phase of the cell cycle. Abnormal expression and activity of these cyclins are hallmarks of cancer. Disruption of the interaction between E2F and the cyclin A2-CDK2 complex results in hyperactivation of E2F, leading to apoptosis and synthetic lethality in E2F-driven tumors. Small cell lung cancer (SCLC) cell lines commonly exhibit dysregulated E2F activity due to near-universal loss-of-function mutations in RB1 and TP53. We have developed ZMS-7506, a potent oral Cyclin A/B inhibitor, which demonstrated a median IC_{50} of approximately 40 nM in anti-proliferation assays using a panel of SCLC cell lines. Moreover, ZMS-7506 selectively inhibited the proliferation of ovarian cancer OVCAR3 cells, with a GI_{50} value below 20 nM. In the meanwhile, ZMS-7506 exhibited a GI_{50} greater than 10 μM in normal human embryonic lung fibroblasts (WI38), indicating a favorable therapeutic window. Mechanistically, ZMS-7506 induced G2/M cell cycle arrest and upregulated markers associated with apoptosis and mitotic arrest, including p-KNL1, p-HH3, p-PARP, and p-γ-H2AX. These findings suggest that ZMS-7506 activates the spindle assembly checkpoint (SAC), thereby inducing mitotic arrest and apoptosis. ZMS-7506 also exhibited moderate oral bioavailability in pre-clinical species such as dogs, which supported the oral administration in human. Moreover, ZMS-7506 exhibited robust antitumor efficacy as a monotherapy in the SCLC NCI-H69 xenograft mouse model. In summary, ZMS-7506 is a highly selective oral Cyclin A/B inhibitor with promising therapeutic potential as a monotherapy for cancers characterized by elevated E2F activity.

: Targeted Protein Degradation and Induced Proximity
Poster Session

#5151 Design and synthesis of highly efficacious CRBN-based pan-KRAS degraders targeting cancers with KRAS G12D, G12V and G12C mutations.

Changwei Wang[1], Prithwish Ghosh[1], Shicheng Jin[1], Longchuan Bai[2], Donna McEachern[1], Angelo Aguilar[2], Qiuxia Li[3], Bo Wen[3], DUXIN SUN[2], Shaomeng Wang[1]

[1]Departments of Internal Medicine, University of Michigan, Ann Arbor, MI,[2]University of Michigan, Ann Arbor, MI,[3]Department of Pharmaceutical Sciences, University of Michigan, Ann Arbor, MI

Oncogenic mutation of KRAS is one of the most promising targets for cancer. Treatment with inhibitors inevitably lead to rapid onset of resistance, and loss of therapeutic effect after months. KRAS PROTACs may offer superior efficacy by eliminating mutated protein, disrupting scaffolding function and activating immune response, thus overcoming the rapid development of resistance. Using new E3 ligands developed in house, our compounds achieved less than 1 nM DC_{50} and IC_{50} in *in vitro* assays with G12D, G12V and G12C mutated cell lines. They exhibited excellent pharmacokinetic and pharmacodynamic properties in mice, and outstanding pharmacokinetic in rats, dogs, and monkeys. At 10 mg/kg, qW, the compounds achieved a remarkable TGI of over 92% in SW620 xenograft, a robust and challenging model of $KRAS^{G12V}$ mutation. Additionally in an efficacy study with mice bearing SW1990 xenograft, at 10 mg/kg, qW, the compounds regressed the tumors by over 90%.

#5152 Targeted degradation of KRAS using the AUTOTAC platform.

Su Ran Mun[1], Su Jin Lee[1], Hyeong-Reh C. Kim[2], Yong Tae Kwon[1]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Department of Pathology, Barbara Ann Karmanos Institute, Wayne State University School of Medicine, Detroit, MI

RAS is one of the most frequently mutated oncogenes in human cancers, with KRAS mutations being particularly prevalent: accounting for approximately 95% of pancreatic cancers, 45% of colorectal cancers, and 20% of lung cancers. Due to its lack of deep pockets for ligand binding, RAS has long been considered an “undruggable target,” despite more than three decades of intensive drug discovery efforts. Although small-molecule inhibitors targeting KRAS G12C have recently been developed, their therapeutic effect is limited to this specific mutation, underscoring the need for strategies capable of targeting a broader range of KRAS variants.AUTOphagy TArgeting Chimera (AUTOTAC) is a recently developed targeted protein degradation platform that harnesses the autophagy pathway to eliminate pathological proteins. In this study, we applied AUTOTAC technology to RAS, generating RAS-AUTOTAC, a bifunctional small molecule composed of a Target-Binding Ligand (TBL) linked to an Autophagy-Targeting Ligand (ATL). Upon binding to RAS via the TBL, the ATL component recruits the ZZ domain of p62, inducing p62 oligomerization and initiating autophagic degradation. During this process, RAS becomes biologically inactivated and sequestered into autophagosomes. RAS-AUTOTAC suppresses downstream oncogenic signaling through p62 oligomerization and subsequent autophagic degradation. Importantly, RAS-AUTOTAC selectively recognizes the GTP-bound active form of RAS and effectively suppresses RAS signaling across multiple KRAS variants. Moreover, RAS-AUTOTAC demonstrated tumor growth inhibition in animal models, supporting its functional activity *in vivo*.Collectively, our results provide a mechanistic basis for applying AUTOTAC to RAS-driven cancers.

#5153 Characterization of second-generation AUTOTACs targeting the androgen receptor for castrate-resistant prostate cancer treatment.

Tri Pham[1], Su Jin Lee[2], Y. Mindy Huang[3], Matthew Han[4], Tae-Hyun Bae[2], Brianna Temby[5], Isabella Schena[6], Abdo J. Najy[1], Harmant Grewal[7], Jenna Poole[1], Young Tae Kwon[8], Hyeong-Reh C. Kim[9]

[1]Pathology, Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI,[2]Department of Biomedical Sciences, College of Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]Physics and Astronomy, Wayne State University, Detroit, MI,[4]International School, Bellevue, WA,[5]Oncology, Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI,[6]Department of Pathology, Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI,[7]Michigan State University College of Osteopathic Medicine, East Lansing, MI,[8]Department of Biomedical Sciences, Seoul National University College of Medicine, Seoul, Korea, Republic of,[9]Pathology, Oncology, Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI

Background: The androgen receptor (AR) drives the progression of prostate cancer (PCa), including castrate-resistant PCa (CRPC). Therapeutic resistance is often mediated by AR mutations and splice variants like AR-v7, which circumvent conventional AR-targeting therapies. AUTOTACs (Autophagy-Targeting Chimeras) is a novel platform for targeted protein degradation via the autophagy-lysosomal pathway. We previously reported the characterization of ATC-324, the first-generation AR-targeting AUTOTAC utilizing enzalutamide (ENZ) as a target-binding ligand (TBL) and YT 6-2 as an autophagy targeting ligand (ATL). The current study evaluates two second-generation AR AUTOTACs, ATB-238 and ATB-239, designed to improve the efficacy and stability in degrading AR and its variants.

Methods: AR-null PCa model: PC3. Androgen-sensitive PCa models: LNCaP, LAPC4. CRPC models: CWR-R1, 22Rv1. Immunoblotting measured relative protein levels. p62 siRNA and bafilomycin A1 were used to study autophagy-dependent drug mechanism. An AR activity reporter assay quantified AR transcriptional activity. Cytotoxicity was evaluated using the WST1 assay. Molecular docking, mutagenesis assays, and proximity ligation assay (PLA) were used to assess ATB-238- and ATB-239-induced AR:p62 complex formation. Bone-in-culture array (BICA) was used to assess the therapeutic potential of ATB-238- and ATB-239 in 22Rv1 in the bone microenvironment. Docetaxel, a first-line chemotherapy for PCa, was used to study synergy with AR AUTOTACs.

Results: ATB-238 and ATB-239 demonstrated improved degradation of AR isoforms and significantly reduced AR transcriptional activity, including AR-v7-driven activity. ATB-238 demonstrated cytotoxicity against AR-positive cells (LAPC4, CWR-R1, 22Rv1), but not AR-null cells (PC3). Molecular docking predicts that ATB-238 and ATB-239 bind to R139, K141, L166, and F168 within the zz domain of p62. Mutation of these residues into Alanine abolished AR:p62 interaction and p62 oligomerization induced by ATB-239. ATB-238 and ATB-239 exhibited high potency against 22Rv1 micrometastases in BICA, while ATB-238 synergizes with docetaxel in killing LNCaP and CWR-R1 cells.

Conclusion: ATB-238 and ATB-239 represent significant advances in AR-targeted therapeutics, capable of degrading AR variants and overcoming therapy resistance. The ongoing intra-iliac-artery xenograft studies will assess their potential to inhibit PCa bone metastasis, an incurable stage of the disease. These findings highlight the therapeutic promise of AUTOTAC technology in addressing critical challenges in CRPC treatment.

#5154 Proteolysis and gene silencing targeting chimera (PROGENTAC).

Abhay Prasad, Rong Zheng, Deeksha Satyabola, Yang Xu, Yichen Yan, Hao Yan

Biodesign Center for Molecular Design and Biomimetics, Arizona State University, Tempe, AZ

Introduction: In biological systems, nucleic acids mirror computational networks, integrating digital genetic codes with analog molecular interactions to achieve precise, context-dependent control of life processes. Harnessing this property provides an opportunity to design programmable therapeutics with exceptional specificity and minimal toxicity. Building on this inspiration, we devised a method for the conditional activation of a dual-functional nucleic acid construct comprising gene-silencing antisense oligonucleotide (ASO) and protein degrader, a DNA-based proteolysis-targeting chimera. We have coined the term “Proteolysis Gene Silencing Targeting Chimera” (PROGENTAC) to describe this technology. This dual functionality of conditional PROGENTAC offers several advantages, such as enhanced specificity and combating multidrug-resistant in complex diseases[1]. The molecular design of PROGENTAC consists of three elements: 1) DNA-templated, spatially controlled protein-degrading chimera (DTAC) platform[2]; 2) ASO for targeted gene modulation; and 3) rationally proposed conditional nucleic acid-based molecular framework that regulate PROGENTAC activity[3] in response to disease-specific intracellular cues or chemical trigger.

Experimental Procedures: In house solid phase oligo synthesis was utilized to construct both DTAC and modified ASO constructs. In house organic synthesis was utilized to modify small molecule-based inhibitors. Electrophoretic mobility shift assay (EMSA) was utilized to visualize conditional activation of PROGENTAC in cell-free based media. Fluorescence resonance energy transfer (FRET) assay was utilized to evaluate kinetics of PROGENTAC activation. Additional experiments were conducted including, Cell treatments, Western blots, Confocal imaging, Flow Cytometry, Proteomics, and Cytotoxicity assays.

Results and Summary: Three cancer cell lines U251, A549 and AU565 showed excellent activity of DTAC that targets Cyclin D1-CDK4/6 complex protein with efficacy of DC_{50} of 20-100 nM range. For a proof of concept, we successfully constructed GFP protein silencing ASO construct with various nucleic acid modifications such as 2’-OMe, locked nucleic acid (LNA), and phosphorothioate (PS backbone). The optimal chemically modified potent ASO construct was successfully integrated with DTAC in PROGENTAC molecular framework. PROGENTAC construct was evaluated for structural stability and conditional activation to release both protein degrading DTAC and gene silencing ASO modalities. In the conference we will further talk about extended cellular results and therapeutic properties of PROGENTAC.

#5156 Development of FBXW7 binders for targeted protein degradation.

Shenghao Guo[1], Becky Leifer[2], Yichen Xiang[1], Angela N. Koehler[2]

[1]Massachusetts Institute of Technology (MIT), Cambridge, MA,[2]Koch Inst. for Integrative Cancer Research at MIT, Cambridge, MA

Protein-protein interactions (PPIs) play essential roles in almost all the physiological processes in human cells. Inducing or enhancing the proximity of specific PPIs for targeted protein degradation (TPD) has received much attention. TPD caused by induced protein proximity is usually achieved by two categories of small molecules: molecular glues and proteolysis targeting chimeras (PROTACs). Both categories utilize the ubiquitin-mediated proteolysis system for degradation, in which E3 ligases play vital roles in substrate recognition. Despite the fact that there are over 600 E3 ligases in the human system, only less than 10% are investigated for TPD. Here we report the discovery of a set of potential binders for FBXW7, an E3 ligase and key tumor suppressor for which no previous binders have been found. Our project aims to discover potent small-molecule binders to FBXW7, which can be used as new warheads for PROTAC design for TPD and eventually suppression of various cancers. Taking advantage of our high-throughput screening technology, Small Molecule Microarrays (SMMs), we successfully identified 3 groups of compounds (44 total) that potentially bind to FBXW7 after screening our 65,000 'drug-like' small molecule library. This is done by printing these small molecules directly onto glass chips and incubating with in-house purified His-tag FBXW7, and then recognizing with fluorescence-conjugated antibody. We then performed secondary assays using nanoDSF, in which multiple small molecules from one of the groups induced over 0.3 ℃ change in the melting point of FBXW7, indicating binding activity. Interestingly, these small molecules share very similar chemical structures, which differ from others by merely one functional group on one of the 6-membered rings. Following thermo shift assay indicates that these small molecule candidates stabilize FBXW7 in a dose-dependent manner shown by western blot. So far, our leading compound is shown to have a binding affinity of 0.3μM to FBXW7 using ITC. Attempts to synthesize and test these binders for a set of proof-of-concept PROTACs are in progress. In summary, our findings identify a new set of potential binders to FBXW7, which expands the toolbox for PROTAC design. We also prove the strength of SMM as a viable methodology for the exploration of more E3 ligase binders, which will greatly benefit the development of tools in TPD for cancer therapeutics.

#5157 Discovery and characterization of XNW34017, a first-in-class, orally bioavailable, and brain-penetrant AURKA-MYC degrader.

Liqun Chen[1], Haoran Li[1], Xiuchun Zhang[1], Chong Peng[1], Zhe Zhang[1], Shihua Wang[1], Liang Kong[1], Jiajing Xu[1], Xiaocheng Hu[1], Zhenwei Wu[1], Yanfei Wang[1], Wengui Wang[1], Haiyang Wei[1], **Yonghan Hu**[2], Xiaojun Liu[1], Meijie Le[2], Jing Qiang[2]

[1]Evopoint, Suzhou, China,[2]Evopoint, Shanghai, China

Aurora-A is a serine/threonine kinase essential for mitotic progression and is overexpressed in a broad range of solid tumors and hematological malignancies. Inhibiting AURKA's kinase activity can suppress tumor progression. Several AURKA inhibitors have been developed and tested in clinical trials. Although AURKA inhibitors have shown strong preclinical efficacy, their clinical development was not successful. Beyond its catalytic role, AURKA can stabilize MYC family proteins to protect them from proteasomal degradation. Consequently, unlike the AURKA inhibitors, degraders of AURKA can eliminate the entire AURKA protein, simultaneously abolishing its kinase activity and scaffolding function. Compared with inhibitors, this dual mechanism may offer enhanced antitumor efficacy and expanded therapeutic window, making degradation of AURKA and subsequent MYC a more effective therapeutic strategy. Based on this rationale, we developed the first-in-class bifunctional AURKA degraders, which have shown efficient degradation of AURKA and MYC family proteins (c-Myc, L-Myc, and N-Myc) in MYC-driven cell lines. MoA studies with early lead compounds confirmed that AURKA degradation is on-target, E3- and UPS-dependent. qPCR experiment further demonstrated that neither AURKA nor MYC protein level change is associated with transcriptional changes, validating our therapeutic strategy of degrading AURKA to induce MYC degradation. After extensive optimization, XNW34017 was selected as the development candidate. XNW34017 exhibits favorable PK properties, including >50% oral bioavailability across species (mouse, rat, and dog), and evidence of brain penetration. The compound selectively and potently degrades AURKA, leading to subsequent degradation of MYC family proteins. In the NCI-H209 SCLC model with L-MYC overexpression, oral QD dosing of XNW34017 induced rapid AURKA degradation at day 1 and efficient L-MYC degradation at day 3, which then led to complete tumor regression. PD studies revealed a strong correlation between L-MYC degradation and enhanced tumor response. In tumor models with c-MYC and N-MYC overexpression, XNW34017 also demonstrated superior tumor growth inhibition (TGI) while AURKA inhibitor showed limited efficacy. Notably, in the NCI-H1975 NSCLC brain metastasis model with c-MYC overexpression, oral QD dosing of XNW34017 achieved 98% TGI at day 21, demonstrating its efficacy against MYC-driven CNS disease. DRF and GLP toxicity studies of XNW34017 in rats and dogs demonstrated good tolerability with a reasonable safety margin, suggesting that the clinical risks are manageable. Observed toxicities were consistent with on-target degradation of AURKA, with no unexpected safety risk observed. Together, our MOA and preclinical studies support the advancement of XNW34017 into clinical development for MYC-driven malignancies.

#5158 Preclinical characterization of HY809382, a highly potent and orally bioavailable PRC2 PROTAC, for the treatment of lymphoma and solid tumors.

Huangtao Jin[1], Juan Du[1], Ruwei Wang[1], Zengrong Li[1], Ting Zhang[1], Xing Yu[1], Ming Weng[1], Xiaoxiao Wang[1], Xiaohong Hou[1], Feifei Yang[1], Xin Li[1], Weixing Zhu[1], Liming Zhang[1], Lei Chen[1], Sai Yang[1], Feng Xu[1], Qian Ma[1], **Ruowen Zhang**[2], Xiaotian Huang[1]

[1]Yangtze River Pharmaceutical (Group) Co., Ltd., Taizhou, China,[2]Medicilon USA Corp, Lexington, MA

The Polycomb repressive complex 2 (PRC2) is a key epigenetic regulator that mediates gene silencing through the catalysis of histone H3 lysine 27 trimethylation (H3K27me3). This activity facilitates repression of tumor suppressor genes as well as immune-related transcripts. The core subunits of PRC2 comprise EED, SUZ12, and the catalytic component EZH1 or EZH2. Aberrations of PRC2 components, including mutation and overexpression, have been identified across a range of cancers, highlighting PRC2 as a promising therapeutic target. Although targeting EZH2 has been the primary approach in PRC2 inhibitor development, leading to the FDA approval of Tazemetostat as the first-in-class agent, no PRC2 degraders have yet progressed to clinical trials. The PRC2 degraders provide several potential advantages, such as overcoming acquired resistance to approved EZH2 inhibitors, disrupting the stability of the PRC2 complex, and enhancing efficacy against lymphoma and solid tumors. Herein we disclose HY809382, an orally bioavailable PRC2-targeting PROTAC molecule, as a candidate therapeutic for lymphoma and solid tumors. HY809382 demonstrated degradation of the target protein EED at nanomolar (nM) concentrations, without altering protein levels of known CRBN neo-substrates such as IKZF1/3, GSPT1 and CK1α. Proteomic analysis confirmed that HY809382 selectively degraded the target protein EED and its co-complex partner EZH2, demonstrating excellent degradation specificity. The antiproliferative activity of HY809382 surpassed that of approved or clinically investigated small molecule inhibitors targeting PRC2 components. HY809382 exhibited favourable oral pharmacokinetics in preclinical species, with bioavailability (F)≥ 40%. Once-daily oral administration of HY809382 demonstrated significant, dose-dependent tumor growth inhibition in Karpas-422 (DLBCL), G401 (rhabdoid tumor) and 22Rv-1 (prostate cancer) cell-derived xenograft models, outperforming approved or clinically investigated PRC2-related inhibitors. IHC analysis confirmed HY809382-mediated downregulation of key on-target pharmacodynamic markers (e.g., H3K27me3, EED and EZH2) in tumor tissues. A 44-target safety screen indicated a clean off-target profile, and the compound showed low risks of cardiotoxicity and genotoxicity, as supported by hERG inhibition and the mini-Ames tests, respectively. Preliminary non-GLP repeated-dose toxicity studies in mice and cynomolgus monkeys indicated that HY809382 was well tolerated, with estimated therapeutic windows of >95 and >25, respectively. These findings support the potential of HY809382 as a best-in-class PRC2 degrader and warrant its further evaluation in IND-enabling studies.

#5159 Rational development of novel FBXO22-mediated TEAD Targeted Glues™ for mesothelioma and NSCLC treatment.

Marta Carrara, Martin Fisher, Alice Fletcher, Callum Hamby, Jack Miles, Colin T. Davies, Sara Bisetto, Paula MacGregor, Edward Hooper-Greenhill, Aleksandra Azevedo, Martin O'Rourke, Dominic CG Owens, Liliana Greger, Ivan Del Barco Barrantes, Giles Brown, Martin Pass, Louise K. Modis

Amphista Therapeutics, Cambridge, United Kingdom

TEAD transcription factors are critical effectors of the Hippo signalling pathway and represent promising therapeutic targets in cancers with pathway dysregulation. We report the rational discovery and optimization of a novel class of TEAD degraders that exploit a Targeted Glue™ mechanism to achieve FBXO22-dependent proteasomal degradation. Our novel degraders with differentiated chemical matter demonstrate exceptional degradation profiles (sub-nM DC50, >90% Dmax), coupled with outstanding on-pathway selectivity as measured by global proteomics vs >7000 other proteins measured. Through comprehensive mechanistic studies, we elucidated that our warheads engage FBXO22 via covalent modification of C326. This structural understanding, enabled by high-resolution ternary complex cryo-EM data, facilitated systematic structure-activity relationship optimization of both degradation potency and kinetic parameters. In vitro, our lead compounds exhibited deep (>150% GImax) and potent (nM GI50) anti-proliferative activity in mesothelioma, with synergistic efficacy observed in combination with EGFR inhibitors in EGFR-mutant NSCLC models. Critically, our optimized compounds achieved oral bioavailability and demonstrated robust in vivo activity, representing the first demonstration of FBXO22-mediated degradation in vivo. In mesothelioma xenograft models, we observed rapid (2h, first time point measured), deep (>95%) and sustained (≥72h) TEAD degradation leading to prolonged biomarker inhibition. Our work provides critical design principles for this degrader class and validates FBXO22-TEAD degradation as a therapeutically relevant approach for Hippo pathway-driven cancers, with promise in mesothelioma and combination strategies for EGFR-mutant NSCLC.

#5161 HJ-004, a potent and selective pan-EGFR mutation targeted protein degrader (TPD) that effectively overcomes osimertinib resistance in EGFR-mutant NSCLC.

Li Zeng, Yao Liu, Ya Geng, Yue Zhu

Jing Medicine Technology (Shanghai) Ltd., Shanghai, China

Background: Although three generations of EGFR tyrosine kinase inhibitors (TKIs) have achieved remarkable clinical success, resistance driven by secondary EGFR mutations remains a major therapeutic challenge in non-small cell lung cancer (NSCLC). To address this unmet need, we developed HJ-004, a potent, selective, and orally bioavailable pan-EGFR mutation degrader that targets classical, rare, and exon 20 insertion mutations.

Methods and Results: HJ-004 induces potent and selective degradation of mutant EGFR proteins, but not wild-type EGFR, in Ba/F3 and human cell lines harboring diverse EGFR alterations, with DC_{50} values below 5 nM, and exhibits strong antiproliferative activity. Mechanistic studies confirmed E3 ligase-mediated ubiquitination and proteasomal degradation. *In vivo*, HJ-004 produces dose-dependent tumor regression in both murine and human-derived cell-derived xenograft (CDX) and patient-derived xenograft (PDX) models carrying various resistant EGFR genotypes. Pharmacokinetic evaluation demonstrated favorable PK properties, including 30-40% oral bioavailability across multiple species and sustained exposure supporting once-daily dosing. Importantly, HJ-004 exhibits an approximately 10-fold therapeutic window in both mice and monkeys, without any notable skin rashes or diarrhea, indicating excellent selectivity and safety margin.

Conclusions: HJ-004 represents a first-in-class pan-EGFR mutation targeted protein degrader that effectively overcomes osimertinib resistance across classical, rare, and exon 20 insertion variants. Its potent degradation activity, broad antitumor efficacy, and favorable pharmacokinetic and safety profiles support advancement into clinical development as a next-generation therapy for EGFR-mutated NSCLC. HJ-004 was independently developed by Jing Medicine Technology (Shanghai) Ltd., and has received IND clearance from both the U.S. FDA and China NMPA.

#5163 Leveraging selective degradation of CBP and EP300 for potent anti-cancer activity.

Karolina Mizeracka, Elizabeth Wittenborn, Darshan Sappal, Laura La Bonte, Danette L. Daniels

Foghorn Therapeutics, Watertown, MA

Numerous cancers have shown dependency on one of two paralog histone acetyltransferases, CREB binding protein (CBP) or E1A binding protein (EP300). Genomic screens have identified a bidirectional synthetic lethal relationship for these two proteins, such that, for example, EP300-mutant gastric and colorectal malignancies strongly depend on CBP function for growth and survival. Additionally, the divergent biology of these targets can underly selective lineage dependencies. For example, hematological cancers are exquisitely sensitive to loss of EP300, even in the presence of functionally intact CBP. Previously developed inhibitors that disrupt activity of both enzymes have resulted in hematopoietic toxicity, and selectively drugging these targets to improve the therapeutic window has been a significant challenge. Here we describe our platform to develop fast, potent, and selective CBP and EP300 degraders that remove only one of the targets, while sparing the activity of its paralog. We elucidate the mechanisms underlying selective degradation through cellular, structural, and biophysical assays of ternary complex formation and ubiquitination between the target proteins and the E3 ligase VHL. We find that our selective degraders likely drive differential target ubiquitination and degradation through differences in ternary complex stability and the induction of divergent orientations between the bromodomains of the respective target relative to VHL. Additionally, we demonstrate that CBP and EP300 selective degraders show strong anti-proliferative effects across numerous oncology indications that are dependent on either target. Importantly, treatment with our selective degraders at efficacious doses is not associated with hematopoietic toxicity, providing evidence that specific targeting of one of the paralogs provides a wider therapeutic window than dual inhibition.

#5164 Exploration of novel E3 ligase to support targeted protein degradation drug discovery.

Zuyuan Shen, Yunyun He, Rui Wang, Nengwei Xu, **Peichuan Zhang**, Lingbing Sun

In Vitro Biology Unit, WuXi AppTec, Shanghai, China

Targeted protein degradation is a new drug discovery strategy that harnesses mainly the power of the ubiquitin-proteasome system (UPS) to degrade selectively disease-causing proteins. A key mechanism of UPS degrader molecules, including molecular glues and proteolysis-targeting chimeras (PROTACs), relies on their ability to bring target proteins into proximity with E3 ligases or complexes for ubiquitination and subsequent degradation at the proteasome. The human genome encodes at least 600 E3 ligases, of which two complexes (i.e., $CUL4^{CRBN}$ and $CUL2^{VHL}$) are predominantly employed in the TPD field. This has raised concerns about issues like target diversity and specificity and drug resistance, and thus, prompts a strong need to look for novel, ligandable E3 ligases that can be exploited to support TPD drug discovery.

To this date, we have surveyed a small panel of E3 ligase components, by utilizing the DNA-encoded library (DEL) screening technology, and identified GID4 (homolog of the yeast glucose-induced degradation deficient complex 4), substrate receptor of the CTLH E3 complex, as a top candidate that showed promising ligandability to small molecules. The GID4-binding hit molecules were validated, structure-optimized, and conjugated with a linker and BRD4-binding moiety to generate a number of PROTACs for targeting BRD4, a transcription regulator that plays an important role in promoting tumorigenesis.

We demonstrated that these GID4-BRD4 PROTACs can mediate biochemical ternary binding (with EC_{50} < 1 nM) and induce BRD4 degradation in cancer cell lines (with DC_{50} < 1 uM). We also solved the crystallography structure of the ternary complex to look into potential working mechanism for one PROTAC. Using the direct-to-biology (D2B) high-throughput approach, we also have optimized the PROTACs and identified structures that can enhance degradation efficacy.

Taken together, we have shown that, as a proof-of-concept, affinity-based DEL selection may help explore ligandability of proteins of interest and lead to the discovery of novel ligands and PROTACs for novel E3 ligases. Of note, our work has been corroborated by another independent study, which reported that GID4 E3 ligase can be leveraged for protein degradation (Li et al., *Nat. Struct. Mol. Biol.* 2025).

#5166 NRX-4972, a selective, oral, Aurora kinase A degrader, demonstrates increased efficacy in an SCLC tumor model, and greater *in vitro* synergy than an AURKA inhibitor.

Hua Tian[1], **Ryan B. Rountree**[1], Jeffrey T. Mihalic[1], Eric R. Wegrzyniak[1], Ge Wei[1], Karthik Arumugam[1], Paul L. Auger[1], Graham J. Carlson[2], Robert T. Cass[1], Tarra Knotts[1], Filippo Marchioni[1], Daniel Medina-Cleghorn[1], Michael G. Mormino[1], Madeleine P. Nemchek[1], Rusha M. Sardhara[1], Sangita Sridharan[1], Austin Tenn-McClellan[1], Simon Vezina-Dawod[2], Gwenn M. Hansen[1]

[1]Nurix Therapeutics, Inc., Brisbane, CA,[2]Nurix Therapeutics, Inc., The Woodlands, TX

Aurora kinase A (AURKA) is frequently overexpressed in adult solid tumors, hematologic malignancies, and pediatric cancers. AURKA is a critical regulator of mitosis. Cancer cell lines particularly sensitive to AURKA loss include those derived from *MYCN*-amplified tumors (e.g., neuroblastoma) and from tumors with *RB1* loss, such as neuroendocrine small cell cancers and CDK4/6-resistant breast cancers (Mou et al., 2021). Several AURKA inhibitors are effective in preclinical tumor models but have failed to translate into clinical efficacy. Recent studies have found that AURKA has kinase-independent scaffolding functions that are not effectively blocked through enzymatic inhibition (Otto, et al, Cancer Cell, 2009; Buchel, et al., Cell Reports, 2017).

To address the limitations of inhibitors, we developed NRX-4972, a CNS-penetrant, orally bioavailable and highly selective degrader of AURKA designed to remove both enzymatic and scaffolding functions. NRX-4972 has a superior PK/PD profile compared with an AURKA inhibitor and more effectively induces DNA damage, apoptosis, and G2/M arrest. Previously, we demonstrated that once-daily oral administration of NRX-4972 provides robust efficacy in the H82 mouse tumor model of SCLC, while an AURKA inhibitor is ineffective (Tian et al.; AACR; Cancer Res 2025;85(8_Suppl_1): Abstract 6379). Here, we demonstrate that NRX-4972 achieves superior efficacy in the same tumor model when administered twice-daily (BID). After over two months of treatment with NRX-4972, 60% of mice survived to the end of the study. In contrast, none of the mice treated BID with the AURKA inhibitors alisertib or LY3295668 survived to the end of the study.

To evaluate the benefit of AURKA degradation over inhibition in the combination setting, we performed an in vitro synergy screen across SCLC, NSCLC, and TNBC cancer cell lines. NRX-4972 and LY3295668 were compared in combination with a range of chemotherapeutics and targeted agents, and cell viability was evaluated for synergy using the Bliss independence model. The highest synergy scores were found in combination with NRX-4972, and more combinations with NRX-4972 resulted in synergy than with LY3295668. These data suggest that eliminating the kinase and scaffolding functions through degradation of AURKA increases the vulnerability of cancer cells to combination therapy.

Collectively, NRX-4972's superior preclinical profile highlights the potential of AURKA degraders to overcome the limitations of AURKA inhibitors and achieve meaningful therapeutic benefit.

#5167 Design and applications of novel hydrophobic CRBN binders.

Hailong Yang, Qingbo Xu, Yongqiang Wang, Zhenyu Wu, **Hongbo Zhang**

HitChem, Wilmington, DE

Cereblon (CRBN) molecular glue degraders engage target proteins through a shallow binding pocket, representing a promising strategy to expand the druggable proteome. However, a key challenge in the structure-based discovery of CRBN molecular glues lies in the conformational diversity induced at the CRBN-substrate interface. Different CRBN binders can modulate this interface in distinct ways, ultimately determining which substrate proteins are recruited and defining compound selectivity.In this study, we designed and identified several novel CRBN binders exhibiting excellent or acceptable binary binding affinities. Compared with previously reported CRBN ligands, our compounds possess unique structural features and enhanced hydrophobic properties. Derivatives based on these scaffolds enabled the construction of a CRBN molecular glue library that extends into previously unexplored, CRBN-biased chemical space. This library provides a high-quality toolbox to accelerate the discovery of new targets using the CRBN molecular glue degrader approach.

#5168 Expanding the landscape of targeted protein degradation: E3-agnostic discovery and proprietary ligand identification.

Kanae Gamo, Shinya Yokosaka, Michiko Watanabe, Tomoaki Hayashi, Shigeyuki Mori, Naomi Asahara, Noriyasu Sano, Shigeru Furukubo, Kazuteru Aoki

FIMECS, Inc., Fujisawa, Japan

Targeted protein degradation (TPD) is a promising therapeutic modality, but its broader application is constrained by the lack of established strategies to select optimal E3 ligases for specific targets. Although many E3 ligases exist, only a few have been leveraged in degraders currently undergoing clinical trials, leaving much of the ligase space unexplored. To address this challenge, a proprietary TPD discovery platform enables rational E3 ligase selection in a high-throughput manner through a workflow that integrates fragment-based diversity-oriented synthesis (DOS) with phenotypic screening in relevant cell models. This workflow, supported by in-house capabilities for high-throughput compound synthesis, generates diverse chemical scaffolds and identifies degrader candidates with desired activity profiles. Phenotypic screening ensures functional relevance and facilitates the discovery of compounds that engage E3 ligases not previously applied in TPD, thereby expanding the scope of ligase-targeted degradation strategies. Lead compounds are refined through optimization and E3 ligase deconvolution to confirm ligase engagement and improve molecular properties such as potency, selectivity, and drug-likeness. Once novel E3 ligase binders are identified through this process, they open up new application opportunities. One path is to incorporate the binder into our internal E3 ligase toolbox and apply it to other targets as part of bifunctional degrader design. Another is to evaluate whether the binder can function as a molecular glue, enabling degradation through neo-substrate recruitment. Importantly, our phenotypic screening approach has led to the identification of proprietary E3 ligases with low expression in bone marrow and hematopoietic tissues. Degraders based on these E3 ligase binders demonstrate the potential to avoid bone marrow toxicity—a major concern for cancer targets—while maintaining robust activity. This strategy not only enables the development of orally bioavailable molecules with improved pharmacokinetics and broad target applicability, but also provides a path to safer TPD therapeutics. By expanding the usable E3 ligase toolbox, this proprietary platform unlocks new degrader modalities and supports the development of therapeutics with improved physicochemical properties, including orally bioavailable candidates. This presentation will highlight case studies demonstrating how this platform contributes to the advancement of novel E3 ligase-based TPD, offering a scalable, versatile, and forward-looking solution to a key bottleneck in the field.

#5169 Identification and optimization of pyridylbenzylamine analog 1 as potent and selective Helios degrader.

Ashok Purandare[1], Godwin Kumi[1], Guo Li[1], Aaron Balog[1], Emily Cherney[1], Michael Barnes[2], Satheesh Nair[3], Sirish K. Lakharaju[1], Xin Li[4], Robin Moore[4], Petia Shipkova[4], Silvi Chacko[4], Cullen Cavallaro[1], Ling Li[1], Kimberly Foster[4], Keith DiPetrillo[4], Gerry Everlof[4], Kevin Stefanski[4], Steven Levine[5], Lihong Shi[6], Jinqi Liu[5], Helen Pham[7], Ari Salinger[7], Ashok Dongre[7], Shailesh Dudhgaonkar[3], Debarati Mazumder[8], Anuradha Gupta[3], Vetrichelvan Muthalagu[3], Madhusudhan Ravindran[8], Yan Chen, Weifang Shan, Suresh Babu Viswa Krishna Penmetsa, Carolyn Weigelt, Robert Borzilleri, Louis Lombardo, Gregory Vite, John Hunt

[1]Discovery Chemistry, Bristol Myers Squibb Company, Princeton, NJ,[2]Discovery Biology, Bristol Myers Squibb Company, Seattle, WA,[3]Discovery Chemistry, Bristol Myers Squibb Company, Bangalore, India,[4]PCO, Bristol Myers Squibb Company, Princeton, NJ,[5]LDO, Bristol Myers Squibb Company, Princeton, NJ,[6]LDO, Bristol Myers Squibb Company, San Diego, CA,[7]LDO, Bristol Myers Squibb Company, Cambridge, MA,[8]LDO, Bristol Myers Squibb Company, Bangalore, India

Small molecule approaches that enhance antitumor immunity have the potential to broaden the benefit of cancer immunotherapy as monotherapies or in combination with immune checkpoint inhibitors (ICIs). Indeed, despite the success of ICIs, resistance and limited response in some patients highlight the need for alternative strategies. FOXP3+ regulatory T (Treg) cells within the tumor microenvironment (TME) suppress antitumor immunity and limit the efficacy of ICIs in some tumor types. Transcriptional reprogramming of Treg cells represents a novel and promising therapeutic approach to treat such patients. IKZF2 (Helios), a zinc finger transcription factor selectively expressed in Treg cells, contributes to the transcriptional immunosuppressive phenotype of these cells, including silencing of IL-2 expression. Genetic deletion of IKZF2 in FOXP3+ cells enhances antitumor responses in preclinical models, establishing it as a nonredundant regulator of Treg cell function. Although transcription factors have traditionally been considered “undruggable,” the discovery of cereblon (CRBN)-mediated degradation of zinc finger proteins by immunomodulatory imide drugs (IMiDs™) has enabled targeted protein degradation (TPD) of factors such as IKZF1 (Ikaros) and IKZF3 (Aiolos). We recently disclosed the discovery of a potent and selective IKZF2 degrader, BMS-986449, derived from lenalidomide/pomalidomide scaffolds. Herein, we report SAR optimization studies leading to the identification of a pyridylbenzylamine appended lenalidomide analog (compound 1) with excellent Helios degradation activity and improved selectivity over related neosubstrates (e.g. IKZF1, IKZF3, and CK1α). In addition, 1 also exhibited favorable ADME properties and robust in vivo pharmacodynamic effects in a mouse syngeneic model.

#5170 Design and optimization of small-molecule PROTACs targeting KRAS.

Fidelix Ayobami[1], Sai Kumar Samala[2], **Ngoc Tuyet Tra**[2], Geraldine V. Raja[2], Yuri Mackeyev[2], Sunil Krishnan[2]

[1]Baylor College of Medicine, Houston, TX,[2]Vivian L. Smith Department of Neurosurgery, The University of Texas Health Science Center at Houston, Houston, TX

KRAS is one of the most frequently mutated oncogenes in cancer and is strongly associated with poor outcomes. For decades, it has been considered ‘undruggable’ because its surface lacks the deep binding pockets that small-molecule drugs can typically target and the very strong affinity to GTP/GDP makes it difficult for drugs to outcompete GTP. Recently, advances in structural biology led to the discovery of a regulatory allosteric pocket in the KRAS(G12D) mutant, which has opened the door to new therapeutic approaches for pancreatic cancer; unfortunately, single-agent allosteric inhibitors have shown little anti-cancer activity in patients. PROTACs (proteolysis-targeting chimeras) offer advantages over traditional inhibitors by degrading entire proteins independent of active sites or deep, hydrophobic binding pockets, making them attractive for hard-to-target proteins like KRAS.

In our lab, we carried out an *in silico* screen and identified Pixantrone as the top hit for a possible KRAS-binding warhead. Based on this, we synthesized a library of PROTACs with various lengths of alkyl linkers tethering Pixantrone, the warhead targeting KRAS, to Pomalidomide, a well-known E3 ligase recruiter. We then assessed our PROTACs’ effectiveness in degrading KRAS and the corresponding effects in pancreatic cancer cell lines. In addition, we evaluated the MAPK signaling cascade, one of the KRAS downstream pathways. Evaluation of the Pixantrone-based PROTACs showed limited KRAS degradation and no significant effects on MAPK signaling or cell death, as assessed by cell viability and immunoblotting assays. These findings suggest that Pixantrone is not a suitable warhead for KRAS targeting. Moving forward, we are shifting our efforts toward validating other candidates from the screen, since PROTAC efficacy may be independent of kinase inhibition efficacy of the warhead alone. If successful, an improved PROTAC design may overcome the clinical ineffectiveness of the current generation of allosteric inhibitors.

#5171 The EGFR-PROTAC molecule TY-2719 attenuates acquired resistance to 3rd-generation EGFR TKIs and augments the efficacy of KRAS mutant inhibitors in solid tumors.

Apeng Liang*,#, Shengli Dong*,#, Shaoqing Chen*, Hongqiang Li, Zhiyong He, Zhengfei Guo, Meihua Li, Shunxun Han, Guangbin Liu, Xi Wang, Yanyan Liu, Ling Fang, Yi Long, Xiang Zhang, Wei Wu, Chengshan Niu, Jun Li, Yusheng Wu

TYK Medicines, Inc., Changxing, Zhejiang, China

Introduction: Acquired resistance to EGFR-TKIs poses a significant challenge in the clinical management of non-small-cell lung cancer (NSCLC). TY-2719, an effective oral, broad-spectrum EGFR-PROTAC developed by TYK Medicines, was designed to overcome the resistance associated with third-generation EGFR-TKIs. TY-2719 not only demonstrated an excellent safety profile but also enhanced the efficacy of KRAS mutant inhibitors in NSCLC and pancreatic ductal adenocarcinoma (PDAC) models.

Results: TY-2719 effectively degraded EGFR with the L858R mutation in NSCLC H3255 cells and the L858R/T790M/C797S and 19del/C797S mutations in BaF3 cells. However, it did not degrade EGFR in cells expressing wild-type EGFR, such as A549 and H358 cells. It demonstrated excellent antiproliferative activity against EGFR mutants but did not inhibit the growth of normal cells, including NHEK, MCF-10A, IOSE-80, and FHC cells. TY-2719 overcame osimertinib resistance in BaF3 L858R/C797S and BaF3 del19/C797S CDX mouse models and enhanced the efficacy of Divarasib (GDC-6036) and pan-KRASi Daroxonrasib (RMC-6236) in NSCLC H1972 and H2122 cells, as well as Daroxonrasib in MiaPaca 2 (PDAC, KRAS G12D), AsPC-1, SU.86.86, PANC-1 (PDAC, KRAS G12D), and Capan-1 (PDAC KRAS G12V). Common side effects of EGFR-TKIs, including osimertinib, are skin reactions and diarrhea due to wild-type EGFR inhibition in normal tissues. The DMPK characteristics of TY-2719 were excellent, with superior toxicity profiles in Sprague-Dawley rat experiments. The body weights of male and female rats showed no difference between the 100 mg/kg (mpk) TY-2719 treated group and the vehicle group after three weeks of treatment. No diarrhea was observed in rats treated with 100 mg/kg TY-2719, either. In the BN Norway female rat rash experiment, after 28 days, all rats in the 37.5 mpk gefitinib control group showed obvious rash symptoms, whereas in the TY-2719 100 mpk group, all rats' skin appeared normal. Meanwhile, treatment with 100 mpk TY-2719 had no significant effect on the body weight of Norway rats compared to that of the vehicle group.Taken together, we have identified a potent and safe EGFR-PROTAC molecule which may grant new therapeutic opportunities to overcome drug resistance of 3rd -generation EGFR TKIs in NSCLC patients and enhance the efficacy of KRAS mutant inhibitors in NSCLC and PDAC.

#5172 Mechanistic insights into PLK1 target inhibition in ovarian cancer: Functional suppression and PROTAC-based therapeutic agents.

jaesung Ryu, Baek MooJun, HyoWook Gil, Eunjung Yang, Kwangseock Kim, Taewan Kim, Kong Hyejeong, Beamjun Park, Jeong Kyu Bang, **Seob Jeon**

Soonchunhyang University Cheonan Hospital, Cheonan, Korea, Republic of

OBJECTIVE
This study aimed to identify the oncogenic role of PLK1(Polo-like kinase 1) in ovarian cancer and evaluate its potential as a PROTAC therapeutic target candidate. We also investigated the change in the functional properties of cancer by PLK1 inhibition and whether it is possible to improve cell viability rate through PROTAC-based PLK1 protein degradation.
METHODS
Functional studies were conducted using PLK1 siRNA in SKOV3 cell lines. Changes in cell proliferation, migration, invasion, and wound-healing ability were evaluated following PLK1 silencing. Quantitative RT-PCR was used to measure PLK1 expression in cell lines and in benign, malignant ovarian tumor tissue samples.In addition, we evaluated the effect on sensitivity in ovarian cancer cell lines and paclitaxel-resistant ovarian cancer cell lines using PLK1 target PROTAC.
RESULTS
Expression of PLK1 at the RNA level is significantly overexpressed in ovarian cancer cells compared to normal cells. Also, PLK1 expression was significantly overexpressed in malignant ovarian tumor compared to benign ovarian neoplasm. PLK1 silencing significantly reduced cell proliferation and decreased migration and invasion by 50-60%. Cell viability assays performed in both parental and paclitaxel-resistant ovarian cancer cell lines demonstrated that treatment with the PLK1-targeting PROTAC resulted in a significantly higher level of cell death compared to paclitaxel.
CONCLUSION
Our results demonstrate that PLK1 inhibition at both the RNA and protein levels suppresses the metastatic characteristics of ovarian cancer and highlights its potential as a therapeutic target. Targeting PLK1 in ovarian cancer may contribute to the inhibition of metastatic aibilty and the overcoming of chemoresistance.

#5173 Identification of a small molecule degrader targeting SALL4 oncogene.

Kim Anh L. Vu[1], **Shiva Moein**[2], Kalpana Kumari[1], Bee Hui Liu[1], Miao Liu[2], Chong Gao[2], Li Feng[1], Mahmoud Bassal[2], Douglas Auld[3], Dominik Casalena[3], Qiling Zhou[1], Daniel G. Tenen[4], Li Chai[5]

[1]Cancer Science Institute of Singapore, Singapore, Singapore,[2]Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[3]Novartis Institute for BioMedical Research, Cambridge, MA,[4]Harvard Stem Cell Institute, Boston, MA,[5]Harvard Medical School/ Brigham and Women's Hospital, Boston, MA

Recent studies have shown that immunomodulatory imide drugs (IMiDs) could degrade SALL4 through a proteasome-dependent mechanism. Intriguingly, we found that IMiDs do not affect SALL4-positive cancer cell survival. Further studies revealed IMiDs could only degrade SALL4A, one of the SALL4 isoforms. This suggests that SALL4B, the isoform not affected by IMiDs, might be essential or compensating SALL4A in supporting cancer cell survival. Indeed, knocking downSALL4B increased apoptosis and inhibited cancer cell growth, similar to knocking down bothSALL4A and B. Moreover, SALL4B gain-of-function alone led to liver tumor formation in mice. Through high-throughput screening, we discovered a new non-IMiD degrader that targetsSALL4A and SALL4B via proteasomal degradation, showing potent anti-cancer activity by inhibiting cancer cell proliferation in culture and *in vivo* tumor growth by 70%. Gene expression profiling via RNA-sequencing identified a shared drug and SALL4B knock down gene signature in hepatocellular carcinoma (HCC) cells, including pathways involved in DNA damage response and DNA replication. Our findings highlight the importance of understanding drug action and oncogenesis at the isoform level to develop more effective cancer therapeutics.

#5174 High-throughput capillary immunoassays enable precise quantitation of protein degrader potency and kinetics in oncology discovery.

Charles Haitjema[1], Francisco Ramirez[1], Bhamini Purandare[1], Pallavi Joshi[1], Chris Heger[2]

[1]Bio-Techne, San Jose, CA,[2]Bio-Techne, Minneapolis, MN

Protein degraders such as PROteolysis TArgeting Chimeras (PROTAC degraders) have transformed oncology drug discovery by enabling catalytic removal of disease-relevant proteins rather than occupancy-based inhibition. To effectively rank and optimize degrader candidates, discovery teams need quantitative, reproducible assays that resolve both potency (e.g., DC_{50}, *D*max) and degradation kinetics across large panels of compounds, concentrations, and time points. Conventional Western blotting lacks the throughput and consistency required for this role early in the screening funnel.

Here, we demonstrate how Simple Western capillary immunoassays with the Leo system enables precise, quantitative degrader assessment with 96-sample throughput for upstream primary and secondary screening. Using androgen receptor (AR) degraders in AR-expressing MDA-MB-453 breast cancer cells as a model system, this method delivered robust, dose- and time-dependent AR degradation profiles with single-digit coefficients of variation and highly consistent DC_{50}, *D*max, and degradation rate (kdeg) estimates between biological and technical replicates.

The open antibody platform flexibility of Leo provides endogenous protein expression measurements for orthogonal validation of model systems such as anti-HiBiT antibodies. By resolving proteins by size, Leo can distinguish true target degradation from artifacts in plate-based assays (e.g., luminescent or fluorescence reporter loss), thereby validating plate-based screening hits and revealing false readouts that lack corresponding size-resolved changes in the target or reporter.

These results establish high-throughput Simple Western assays on Leo as a fit-for-purpose solution for precise degrader quantitation at scale. The combination of open, antibody-agnostic detection chemistry, size-resolved readouts, and 96-sample throughput enables richer pharmacologic insight earlier in oncology screening funnels and supports data-driven prioritization and orthogonal validation of protein degrader candidates before advancing into more complex, resource-intensive models.

#5175 Discovery and characterization of once in a month intravenous and orally bioavailable SMARCA2 degraders for treating SMARCA4 mutant cancers.

Bilash Kuila, Kiran B. Aithal, Sandeep Vitthal Dukare, Charamanna KB, Khaji Abdul Rawoof, Prasath Kothandaraman, Amit A. Dhudashiya, Nandish C, Payel Das, Anuradha Gadeval, Madhu K L, Bhagwan Mahadeo Dhaytadak, Gopinath CH, T Jagadeesh Kumar, Suraj Tgore, Mohamad Fairus Bin Abdul Kadir, Leena Khare, Ranadeep Bokalial, Samiulla DS, Subhendu Mukherjee, Saravanan Thiyagarajan, Kavitha Nellore, Rajesh Eswarappa, Girish Daginakatte, Chandrasekhar Abbineni, Sanjeev Giri, Murali Ramachandra, **Susanta Samajdar**

Aurigene Oncology Limited, Bangalore, India

The BAF (SWI/SNF) chromatin remodelling complex is a multi-subunit assembly that regulates chromatin accessibility via ATP-dependent nucleosome repositioning, thereby modulating transcription, DNA recombination & repair, and mitotic chromosome segregation. Its catalytic activity is mediated by two mutually exclusive ATPases, SMARCA2 (BRM) and SMARCA4 (BRG1). In SMARCA4-deficient tumors, oncogenic dependency shifts to the residual SMARCA2-containing SWI/SNF complex, establishing a synthetic lethal vulnerability. This dependency has been validated through genetic silencing studies, positioning SMARCA2 as a compelling therapeutic target in SMARCA4-mutant cancers. We report the identification and preclinical development of highly potent and selective SMARCA2 degraders based on rational design by optimizing assemblies of SMARCA2/4 bromodomain binders, degron-linking moieties, and ligands for specific E3 ligases. Design prioritization was guided by our proprietary ternary complex modelling algorithm, ALMOND (ALgorithm for MOdeling Neosubstrate Degraders). Selected compounds were synthesized and evaluated across multiple cellular assays to assess mechanistic and functional outcomes. Several compounds demonstrated potent and selective SMARCA2 degradation, eliciting distinct phenotypic responses in a panel of SMARCA4-mutant cell lines. The lead IV compound demonstrated robust anti-tumor efficacy in multiple SMARCA4 mutant xenograft models with confirmed target degradation, at well tolerated doses. IND application was accepted by USFDA for this compound. Formulation efforts helped in identification of long-acting IV formulation which demonstrated significant efficacy following once in 4 weeks administration. Subsequent ADME optimization yielded compounds with favourable oral bioavailability across tested species. Furthermore, the lead degrader exhibited robust antitumor efficacy in multiple SMARCA4-deficient CDX models at well-tolerated doses. Repeat-dose tolerability studies in non-rodent species are ongoing to support candidate nomination by Q4 2025.

#5176 Selective degradation of SMARCA4 as a therapeutic strategy in SMARCA4 driven cancers.

Bilash Kuila, Sandeep Dukare, Kiran Aithal B, Charamanna KB, Khaji Abdul Rawoof, Amit A. Dhudashiya, Nandish C, karthik S, Payel Das, Gopinath CH, Suraj Tgore, Gauri Rahul Petkar, Mohamad Fairus Bin Abdul Kadir, Leena Khare, Ranadeep Bokalial, Samiulla DS, Subhendu Mukherjee, Saravanan Thiyagarajan, Kavitha Nellore, Rajesh Eswarappa, Girish Daginakatte, Chandrasekhar Abbineni, Sanjeev Giri, Murali Ramachandra, **Susanta Samajdar**

Aurigene Oncology Limited, Bangalore, India

The BAF (SWI/SNF) chromatin remodelling complex regulates nucleosome positioning and DNA accessibility, influencing transcription, recombination, repair, and mitotic chromosome decatenation. It contains two mutually exclusive ATPases, SMARCA2 (BRM) and SMARCA4 (BRG1). SMARCA4 is frequently overexpressed in several cancers and is associated with aggressive phenotypes and poor prognosis. Genetic knockdown of SMARCA4 reduces proliferation and sensitizes tumors to chemotherapeutics, validating SMARCA4 as a therapeutic target. Synthetic lethality between SMARCA4 and PTEN further supports its clinical relevance. Here, we developed a first-in-class SMARCA4-selective degrader using hetero-bifunctional molecules that combine SMARCA2/4 bromodomain inhibitors with E3 ligase ligands. Design prioritization was guided by our proprietary ternary complex modelling algorithm, ALMOND (ALgorithm for MOdeling Neosubstrate Degraders). Multiple linker chemistries and exit vectors were explored based on rational designs which resulted in selective SMARCA4 degraders with good anti-proliferative activity in multiple cancer cell lines. Lead compound exhibited potent anti-proliferative effects in hematological and prostate cancer models, while SMARCA4-mutant cell lines showed minimal sensitivity, confirming target dependency. Preliminary tolerability and efficacy studies support the therapeutic potential of SMARCA4 degradation. These findings establish proof-of-concept for targeting SMARCA4 via targeted protein degradation as a novel strategy for treating SMARCA4-driven cancers with improved safety margin. Advanced in-vivo studies are in progress to complete candidate nomination by Q1 2026

#5177 Exceptionally selective and orally bioavailable p300 degraders for the treatment of CBP-mutant and p300-dependent cancers.

Iram Khan Iqbal, Krishna Chaitanya T, Kishore Narayanan, Naveen Kumar R, Aravind A. B, Avinash Kumar, Dabbeeru Madhu Babu, Pathur Obanna, Ankita Manna, Rabin Madhaiyan, Damodhran B, Shraddha B Shirsat, Shilpa S Nayak, Suraj T Gore, Mohamad Fairus, Girish Daginakatte, Rajesh Eswarappa, Chandrasekhar Abbineni, Saravanan Thiyagarajan, Murali Ramachandra, **Susanta Samajdar**

Aurigene Oncology Limited, Bangalore, India

EP300 (or p300) acts as histone acetyltransferase (HAT) and transcriptional adapter or co-activator regulating transcription via chromatin remodelling. Both histone and non-histone proteins are acetylated by p300. p300 functions by scaffolding or as a co-activator and enhancer of different transcription factors like HIF1a, BRCA-1, p53, NFκB, c-Myc, estrogen receptor (ER) and androgen receptor (AR) as well as other proteins such as PD-L1 and FOXP3. Selective targeting of p300 is expected to lead to therapeutic efficacy in CBP-mutant and p300-dependent malignancies with high degree of tolerability as a result of sparing the other paralog CBP in normal cells. CBP mutant cancers comprise of several solid and haematological malignancies such as bladder, lung, colorectal, melanoma, DLBCL, MM etc. and p300-dependent malignancies include prostate cancer, in which p300 plays a major role for androgen-dependent and independent transactivation of the AR, MYCN-amplified neuroblastoma and ER+ breast cancers. Conventional CBP/p300 BD inhibitors lack paralog selectivity due to high sequence homology, leading to adverse effects like severe thrombocytopenia in clinical settings. We have adopted a degrader approach to solve this selectivity challenge by means of a differentiated ternary complex. Herein, we report first-in-class highly potent and paralog selective p300 degraders with excellent selectivity over CBP along with other bromodomain containing proteins such as BRD4 and CRBN neosubstrates such as GSPT1. These degraders induce synthetic lethality in CBP loss-of-function mutant cell lines by selectively degrading p300 and demonstrate strong antiproliferative effects across CBP-mutant and p300-dependent models, including AR-positive prostate cancer. Identified p300 selective degraders exhibited good oral bioavailability and were well tolerated in rodents without showing thrombocytopenia. Demonstration of efficacy in CBP mutant and AR-positive CDX models is underway and will be presented subsequently. In summary, we have identified highly selective degraders of p300 with desirable profile. Efforts are in progress towards nominating a development candidate by Q1 2026.

#5178 Discovery and characterization of a selective p300 degrader reveals deep anti-tumor activity in CBP mutant cancers.

Harshil Dhruv, Andrew Fedoriw, Xuqing Zhang, Michael Russell, Jeremy Roach, Nathan Kendsersky, Nelisa Bechtel, Kelsey Annen, Brian Vidal, Timothy Dougherty, Clemente Aguilar-Bonavides, Elham Behshad, Sudeep Banjade, Corey Strickland, Wenxue Wu, Larry Jolivette, Helai Mohammad, Ryan Kruger

SK Lifescience Labs, KOP, PA

Paralogous protein pairs harboring loss-of-function mutations in one member have emerged as a promising opportunity in precision oncology, owing to their well-defined mechanistic complementarity. Among these, CBP and p300 are acetyltransferase paralogs whose functional redundancy has been exploited in genomic screens revealing synthetic lethality in CBP-deficient cancers when p300 is targeted. However, efforts to develop p300-specific inhibitors have been hampered by high sequence homology within functional domains, while dual p300/CBP inhibitors have faced on-target hematologic toxicities from simultaneous inhibition of both paralogs. Here, the discovery of potent, selective p300 degraders that exhibit robust efficacy across multiple CBP loss-of-function (LoF) cancer models is reported.Efforts at SKLSL led to the discovery of an optimized heterobifunctional degrader that induces rapid and selective p300 degradation (DC_{90} < 10 nM, Dmax >90%) within 2 hours, with no detectable CBP degradation up to 48 h (DC_{50} > 10 µM). Mechanistic studies confirmed an on-target mode of action, with complete loss of H3K27 acetylation observed in CBP knockout (KO) H1299 cells (IC_{50} < 0.5 nM, Max Inh > 97%), while p300 KO and wild-type cells remained unaffected (IC_{50} > 10 µM). Correspondingly, growth inhibition was restricted to CBP KO cells (gIC_{50} < 5 nM), confirming p300 dependence.To support these findings, computational analysis was performed to identify endogenous cell lines with putative CBP loss-of-function (LoF) mutations across a range of cancer types, including bladder cancer, SCLC, DLBCL, and CRC. CBP LoF cell lines exhibited strong sensitivity to p300 degradation, with a median gIC_{50} ≤ 1 nM (n = 19), while CBP wild-type and non-LoF mutant lines remained largely unresponsive (median gIC_{50} > 10 µM, n = 15). Importantly, the observed growth inhibition in CBP LoF lines closely correlated with robust suppression of H3K27 acetylation and downregulation of c-Myc, reinforcing the on-target mechanism of action. These in vitro results translated into striking in vivo efficacy: once-daily oral dosing of the p300 degrader (30 mpk) led to near-complete p300 degradation in tumors and marked tumor regression (TR) across xenograft models, including SW780 (TR = 82%, bladder cancer), NCI-H1876 (TR = 100%, SCLC), PFIEFFER (TR = 98%, DLBCL), and KARPAS422 (TR = 20%, DLBCL).Furthermore, bone marrow colony-forming assays demonstrated a markedly improved safety profile, with the p300-selective degrader showing minimal hematologic toxicity (IC_{50} >10 µM) compared to a clinical stage dual p300/CBP inhibitor (IC_{50} = 121 nM) or dual degrader (IC_{50} = 16 nM).Collectively, these results establish selective p300 degradation as a powerful therapeutic strategy for CBP loss-of-function cancers, offering robust anti-tumor activity and a significantly enhanced therapeutic index relative to dual inhibition.

#5179 Discovery and characterization of a selective p300 degrader reveals broad anti-tumor activity in p300-dependent cancers.

Harshil Dhruv, Andrew Fedoriw, Xuqing Zhang, Michael Russell, Jeremy Roach, Nathan Kendsersky, Nelisa Bechtel, Kelsey Annen, Brian Vidal, Timothy Dougherty, Clemente Aguilar-Bonavides, Elham Behshad, Sudeep Banjade, Corey Strickland, Wenxue Wu, Larry Jolivette, Helai Mohammad, Ryan Kruger

SK Lifescience labs, KOP, PA

p300 and CBP are paralogous lysine acetyltransferases with both shared and distinct roles in cancer. p300 acts as a key transcriptional co-activator in tumors driven by lineage- or tumor-specific gene programs, such as AR^+ prostate and hematologic cancers. While efforts to develop p300-specific inhibitors have been hindered by high sequence homology with CBP, dual p300/CBP inhibitors have shown limited clinical progress due to on-target hematologic toxicity resulting directly from simultaneous inhibition of both paralogs. Here, the discovery of a selective p300 degrader with potent activity in castration-resistant prostate cancer and multiple myeloma, where p300 is essential for oncogenic signaling, reported.[LJ1] Efforts at SKLSL led to the discovery of [SK2] an optimized heterobifunctional degrader that exhibits rapid and selective p300 degradation (DC_{90} < 10 nM, Dmax > 90%) within 2 hours and no CBP degradation up to 48 h (DC_{50} > 10 µM). Mechanistic studies confirm an on-target effect, with complete loss of H3K27 acetylation in CBP knockout (KO) H1299 cells (IC_{50} < 0.5 nM, Max Inh > 97%), while p300 KO and wild-type cells remain unaffected (IC_{50} > 10 µM). Across a panel of prostate cancer lines, p300 degradation caused robust growth suppression in AR^+ cells and downregulation of c-Myc and AR, key transcriptional drivers of tumorigenesis. In a panel of multiple myeloma cell lines, p300 degraders displayed superior potency compared with dual p300/CBP inhibitors and pomalidomide. Importantly, these *in vitro* findings translated into efficacy *in vivo*. Once-daily oral administration at 30 mpk in xenograft models led to near-complete tumor p300 degradation and strong anti-tumor efficacy, with tumor growth inhibition (TGI) of 100% (VCaP, AR^+ CRPC), 77% (LNCaP, AR^+ CRPC), and 86% (OPM2, multiple myeloma).Furthermore, bone marrow colony-forming assays revealed a significantly improved safety margin (IC_{50} > 10 µM) relative to a dual p300/CBP inhibitor (IC_{50} = 121 nM) and a dual degrader (IC_{50} = 16 nM), supporting an enhanced therapeutic index.Collectively, these findings establish that selective p300 degradation delivers potent anti-tumor efficacy while minimizing hematologic toxicity, offering a promising therapeutic approach for p300-dependent cancers driven by either lineage-specific or tumor-intrinsic p300 essentiality.

#5180 Engaged but not degraded: Proteome-wide CETSA in degrader research.

Tomas Friman, Soren Bruhn, Merve Kacal, Alexey Chernobrovkin, Daniel Martinez Molina

Pelago Bioscience AB, Solna, Sweden

Targeted protein degradation has emerged as a promising strategy to address protein targets considered undruggable by small-molecule inhibitors. Moreover, proteins vulnerable to inhibition can still possess scaffolding functions that can sustain biological effects, making degradation a compelling alternative. Degraders, however, inherit the selectivity of their pharmacologically active components; for bifunctional degraders/PROTACs, two ligands contribute to this composite selectivity. Unbiased quantitative proteomics is commonly used to monitor degrader selectivity. Still, not all proteins that bind a degrader are subsequently degraded, and traditional protein-ligand interactions may persist at relevant concentrations. The Cellular Thermal Shift Assay (CETSA®) measures target engagement by detecting interactions between compounds and their cognate proteins in lysates or intact cells, without modifying compounds, proteins, or the cellular environment. Coupled to mass spectrometry (MS), CETSA enables unbiased, proteome-wide monitoring of compound-protein interactions. An MS readout can also report protein degradation when the protein of interest (POI) has a suitable half-life. Here, we demonstrate how CETSA coupled to MS can deconvolute protein binding of PROTACs targeting BRD4, CDK4/6, and CDK9, and compare the selectivity profiles of full PROTACs with their individual warheads. All investigated PROTACs and warheads showed target engagement and/or degradation of their intended targets. In intact cells, downstream biological effects were also observed; for example, effects on the CDK4/6 substrate RB1 were seen with the CDK4/6-targeting PROTAC BSJ-03-204 and its kinase-binding warhead palbociclib. In contrast, the CDK9-targeting PROTAC THAL-SNS-032 did not affect RB1, whereas its kinase-binding warhead SNS-032 did. As expected, THAL-SNS-032 induced degradation of the annotated target CDK9 and its associated cyclin T1. We also observed target engagement without degradation for additional proteins, including other kinases. GSK3A and GSK3B, as well as their downstream substrate FOXK1, were thermally shifted but not degraded by the PROTAC (consistent with the profile of SNS-032). Overall, a CETSA-MS workflow can concurrently reveal degradation, target engagement, and downstream biological effects, including liabilities arising from engagement without degradation. This integrated perspective improves selectivity assessment and supports the design and interpretation of degrader campaigns.

Virtanen Institute for Molecular Sciences, University of Eastern Finland, Philadelphia, Finland,[3]Department of Genetics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[4]Helsinki Institute of Life Science (HiLIFE), University of Helsinki, Helsinki, Finland,[5]The Stem Cell & Xenograft Core (SCXC), Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[6]Department of Pathology and Laboratory Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[7]University of Pennsylvania, Philadelphia, PA,[8]Hospital of the University of Pennsylvania, Philadelphia, PA,[9]Department of Microbiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[10]Program Director of Translational Research, Abramson Family Cancer Research Inst, University of Pennsylvania, Philadelphia, PA

Background: Pancreatic ductal adenocarcinoma (PDAC) is characterized by frequent KRAS-G12 oncogenic mutations, low immune cell infiltration, and early metastatic spread, leading to poor outcomes. Selective pressure from systemic therapies promotes the emergence of resistant clones and relapse. Patient-derived models that capture tumor heterogeneity are needed to optimize T cell receptor-engineered T cell (TCR-T) strategies and anticipate mechanisms of resistance.

Methods: We developed a high-throughput *ex vivo* screening platform to test cell-based immunotherapies in patient-derived PDAC spheroids. KRAS-G12V-specific $CD8^+$ TCR-T cells were co-cultured with KRAS-mutant 3D tumor spheroids under graded levels of cytotoxic pressure and monitored using automated image cytometry. Microcavity plates enabled parallel tracking of thousands of spheroids across two sequential TCR-T challenges. Surviving cells were profiled by single-cell RNA sequencing (scRNA-seq), followed by 2D regrowth assays and orthotopic transplantation into NSG mice to assess tumor-initiating capacity.

Results: High-throughput resistance screening of over 33,000 microcavities revealed that 6.6% of 3D-PDAC spheroids remained viable after repeated TCR-T cell challenge, enriching for rare resistant subclones. After the first challenge, most cells exhibited an antiviral-like inflammatory response, characterized by increased levels of MX1, MX2, RIG-I, and interferon-stimulated gene expression. scRNA-seq after re-challenge revealed proliferating cells with upregulation of MHC II molecules and TUBA1B-associated aggrephagy pathways, implicating aggrephagy in immune escape. Resistant cells retained tumor-initiating potential and generated distant metastases in orthotopic NSG models ($n = 10$). *In vitro*, paclitaxel, a microtubule disassembly inhibitor, reduced colony formation by TCR-T-escaped clones, supporting a rationale for combination therapy.

Conclusions: High-throughput *ex vivo* cytotoxicity screening of patient-derived PDAC models reveals aggrephagy-enriched, therapy-resistant clones and nominates rational combination partners such as paclitaxel. This platform may help anticipate patient-specific resistance to KRAS-targeted TCR-T therapy and guide the design of preventative combination strategies.

#5184 From tLNP selection to *in vitro/vivo* efficiency evaluation: *In vivo* CAR-T therapy.

Shunchuan Zhang, Qi Xin, Gang Liu, Jingxian Liu, **Jun Liu**, Pei Wu, Jingwei Huang, Mengwen Huang, Zhongyao Ma, Letian Kuai, Wenji Su

WuXi AppTec, Shanghai, China

Targeted lipid nanoparticle (tLNP)-mediated in vivo CAR-T technology delivers mRNA encoding CAR directly to T cells in the body. This enables in situ engineering of T cells and provides an innovative solution to overcome the bottlenecks of traditional CAR-T therapies, such as complex processes, long cycle times, and high production costs. In this study, we first constructed the linear and circular mRNA structures of CD19 CAR and verified their expression and cytotoxicity through in vitro experiments. The results showed that, compared to linear CAR, circular CAR had a higher transfection positivity rate and expression level, as well as a stronger sustained expression ability. Additionally, the cytotoxicity results indicated that T cells transfected with circular CAR exhibited a more potent killing effect on $CD19^+$ Raji cells than those transfected with linear CAR. Furthermore, by optimizing the LNP formulation and process, we obtained an unfunctionalized LNP formulation capable of efficiently transfecting activated T cells, providing a powerful tool for the validation and optimization of CAR mRNA expression. Meanwhile, CD3 or CD8 antibodies were conjugated to the lipid nanoparticle surface to construct targeted vectors such as CD3-tLNP and CD8-tLNP. By utilizing specific ionizable lipids or combining antibody conjugation with spleen-targeting formulations, tLNP can selectively target T cells while maintaining low levels of liver expression, resulting in reduced side effects. In the NALM-6 systemic model with PBMC engrafted, CD19 in vivo CAR-T can significantly inhibit tumor growth and markedly extend the survival of mice without causing weight loss. Additionally, we monitored the distribution and levels of CAR-T cells in various tissues, organs, and peripheral blood at multiple time points. Additionally, we administered in vivo CART to immunocompetent mice, humanized with CD3/CD8/CD19, and monitored the changes in B cell levels in peripheral blood and spleen after administration. During the treatment period, the amount of B cell in mice were continuously suppressed, demonstrating that in vivo CAR-T can thoroughly eliminate B cells. In summary, our study demonstrates that the integration of CAR mRNA preparation, tLNP selection and optimization, along with in vitro evaluation and in vivo tumor and autoimmune disease models, could be instrumental for the design and development of in vivo CAR-T therapies.

#5185 Flow cytometry-based monitoring of CAR-T cell persistence and immune phenotypes pre- and post-infusion: Challenges in Phase 1/2 hematologic malignancy trials.

Jackie Benko, Bhagyaraj Ella, Samantha Splitt, **Angelina Bisconte**, Rachel Owen, Deborah J. Phippard

Precision for Medicine, Frederick, MD

Chimeric antigen receptor T-cell (CAR-T) therapies that support hematological malignancies have recently had their treatment efficacy determined by both clinical outcomes and specific assessments of the CAR-T cells themselves. Assay validation typically uses control CAR-T cells spiked into healthy PBMCs, which do not fully replicate the phenotypic and scatter characteristics of patient-derived CAR-T cells after infusion. This discrepancy introduces challenges in gating accuracy and data interpretation.

Precision for Medicine (PfM) developed and validated a multiparameter flow cytometry assay to quantify CAR-T persistence and characterize immune phenotypes, including CD4, CD8 subsets, memory, effector differentiation, and activation/exhaustion markers. In the development and validation control CAR-T cells were used to establish the gating strategy.

Post-infusion CAR-positive cells exhibited altered scatter profiles and marker expression compared to validation controls. Inter-assay controls ensured baseline reproducibility, but adaptive gating strategies were required for accurate identification of CAR-T populations in patient samples. These adjustments enabled robust persistence tracking and immune profiling. Clinical sample analysis was performed on peripheral blood mononuclear cells (PBMCs) pre- and post-infusion. Differences between validation controls and post-infusion CAR-T cells underscore the need for dynamic and flexible gating strategies. Addressing these challenges is critical for reliable immune monitoring in oncology trials and for correlating CAR-T persistence with clinical outcomes.

#5186 Pro-inflammatory cytokine primed Wharton's jelly mesenchymal stem cells: A potent immunomodulatory strategy to combat pancreatic cancer.

Sangeeta Choudhury, Poonam Yadav, Mohd Saad, Vikrant Singh, Rohini Tamang

Sir Ganga Ram Hospital, New Delhi, India

Background & Aim: Mesenchymal stem cells (MSCs) from umbilical cord (UC) have the potential therapeutic applications in context of injured, immune related & inflammatory diseases due to high proliferation rate, multilineage differentiation potential and immune tolerance properties. While clinical trials have clearly demonstrated strong safety records, efficacy of MSCs is still modest and inconsistent. Hypothesizing that priming MSCs prior to administration can improve their therapeutic efficacy, present study investigates the modulation of MSC behaviour through cytokine priming and assesses their effectiveness in ameliorating tumor apoptosis. Proteomic analysis shows compositional changes post cytokine priming.

Method: Wharton's jelly derived MSCs (hWJMSCs) were primed with tumor necrosis factor-alpha (TNF-α; 25ng/ml) and interferon-gamma (IFN-γ; 25ng/ml), incubated for 24 hrs at 37°C/5%CO2, their morphological alterations, multi-lineage differentiation potentials (osteocytes/chondrocytes/adipocytes), immunophenotypying (CD90+73+105+44+34-45-19- HLADR-), Adhesion molecules (ICAM, VCAM, NCAM) migration capabilities were examined.Label-free quantitative LCMS (nLC/MS/MS coupled to Orbitrap fusion Tribrid mass-spectrometer) analysis was performed on more than 2400 proteins identified. Further, immunogenic potentials are being tested using PBMNCs from healthy human donors.

Result: hWJMSCs primed with TNF-α (hWJMSC-T)/IFN-γ (HWJMSC-I) showed >90% expression of $CD90^{+}73^{+}105^{+}44^{+}$. Microscopically morphological distinction stained with phyalloidin/DAPI observed showed hWJMSC-T as elongated and flattened cells and Complement & coagulation cascade and Pro-angiogenic proteome signature in abundance, suggesting their role in innate immunity homeostasis. On the other hand, IFN-γ induction showed immune-modulating protein signature of infection/inflammation especially, Guanylate-binding proteins. Differentially expressed protein signature points towards modulation of NOD-like receptor signaling and cell adhesion molecule pathways.

Conclusion: Data herein provides the evidences that stem cell properties of regenerative capability remains conserved and do not compromise under inflammatory conditions. Additionally, primed hWJMSCs can modulate or prevent infection most likely via cross-talk between cascades of defense systems. Thus, suggesting a potential role as alternate strategy to regulate inflammation and/or reshape inflammatory microenvironment.

#5187 IL-21-Enhanced NK cells: A mitochondrial fitness enhancement for targeting glioblastoma stem cells.

Mayra Shanley[1], Sufang Li[1], Mandira Manandhar[1], Giacomo Sferruzza[1], Rafet Basar[1], May Daher[1], Jinzhuang Dou[1], Joy Gumin[1], Ana Karen Nunez Cortes[1], Sunil Acharya[1], Donghai Xiong[1], Hila Shaim[2], Frederick F. Lang[1], Navin Varadarajan[3], Ken Chen[4], Katayoun Rezvani[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Stem Cell Transplantation and Cellular Therapy, MD Anderson Cancer Center, Pearland, TX,[3]University of Houston, Houston, TX,[4]Asst. Professor, Dept. of Bioinformatics & Computational Bio., UT MD Anderson Cancer Center, Houston, TX

Glioblastoma (GBM), an aggressive brain cancer, recurs due to the resistance of glioblastoma stem cells (GSCs) to conventional therapies. We recently showed that cord blood-derived NK cells (CBNK) armed with cytokines like IL-21 exhibit enhanced anti-tumor activity against GSCs, showing superior killing capacity after multiple re-challenges. IL-21 transduction enhances NK cell diversity, polyfunctionality, and mitochondrial fitness, improving tumor control and survival in an in vivo glioblastoma model without toxicity. A deeper dive into the cellular mechanisms revealed that IL-21 transduction triggers significant changes in the metabolic and mitochondrial profiles of NK cells. RNA sequencing revealed that IL-21 transduction upregulates genes involved in metabolic reprogramming, mitophagy, and mitochondrial health, including *KLF2*, *GZMH*, *CLIC3*, and *CEBPD*. Further investigations into mitochondrial function confirmed improved mitochondrial respiration (OCR) and reduced glycolytic activity (ECAR) in IL-21 CBNK cells, indicating enhanced mitochondrial fitness. Confocal microscopy revealed that IL-21 CBNK cells had smaller mitochondria, a hallmark of mitophagy, which was significantly different from other cytokine-transduced or non-transduced CBNK cells. Furthermore, mitochondrial-related proteins, including Mitofusin-2 and DRP1, were upregulated in IL-21 NK cells, confirming improved mitochondrial dynamics. Inhibition of mitophagy reversed the enhanced killing ability of IL-21 transduced CBNK cells. Seahorse Mito Fuel tests identified glucose and fatty acids as the primary fuel sources for IL-21 CBNK mitochondria. Blocking these fuels impaired their anti-tumor activity, further supporting the role of mitochondrial metabolism in IL-21-driven NK cell fitness. Additionally, CEBPD, a key transcription factor involved in mitophagy and mitochondrial metabolism, was upregulated in IL-21 transduced CBNK cells, further enhancing their mitochondrial function and anti-tumor efficacy. These results suggest that IL-21 enhances NK cell anti-tumor potency through metabolic reprogramming, mitochondrial fitness, and CEBPD-driven mitophagy, offering a promising therapeutic strategy for glioblastoma.

#5189 Generating EZH2-inhibitor resistant CAR-T cells to sustain function for combination therapy.

Katherine Bronson[1], Daniel Fil[2], Megan R. Reed[2], Billie Heflin[2], Sydnye Shuttlewoth[2], Brian S. Koss[3], Alan Tackett[4]

[1]UAMS Winthrop P. Rockefeller Cancer Institute, Little Rock, AR,[2]University of Arkansas for Medical Sciences, Little Rock, AR, Little Rock, AR,[3]University of Arkansas for Medical Sciences, Little Rock, AR,[4]UAMS Winthrop P. Rockefeller Cancer Institute, Little Rock, AR, Little Rock, AR

Background: EZH2, a histone methyltransferase and core component of the PRC2 complex, is often overexpressed in tumors and contributes to immune evasion. EZH2 inhibition has been shown to reprogram cancer cells toward a more immunogenic state and enhance lymphocyte infiltration into tumors in preclinical models. These findings have led to growing interest in combining EZH2 inhibitors with adoptive cell therapies. EPZ-6438 (Tazemetostat), a potent EZH2 inhibitor (EZH2i), is FDA-approved for epithelioid sarcoma and follicular lymphoma and is under investigation in multiple solid and liquid tumors. However, EZH2 is also critical for preserving T cell epigenetic stability and function. Here, we investigate this therapeutic tradeoff and show that while EZH2i may enhance tumor immunogenicity it impairs long-term CAR-T cell persistence.

Methods: Human $CD8^+/CD3^+$ T cells were activated with CD3/CD28/CD2 and transduced on day 0 with a CD19-specific CAR lentiviral vector. On day 3, CAR-T cells were edited with CRISPR/Cas9 to introduce EZH2i-resistant mutations into the endogenous *EZH2* gene. On day 9, CAR-T cells were co-cultured with nuclear RFP-labeled $CD19^+$ target cells with or without 0, 0.5, 1, 2 μM EZH2i. Tumor cell count was measured every 4 hours using automated imaging, and fresh tumor cells and drug were added every 48 hours until loss of T cell tumor control. This was repeated in the OT1 T cell murine system with RFP-labeled $SIINFEKL^+$ B16F10 melanoma cells. In parallel, $CD8^+/CD3^+$ T cells cultured with or without chronic exposure to 1 μM EZH2i were used for phenotype and functional analysis. Histone H3K27me3 levels and PD-1, CTLA-4, and LAG-3 expression were measured by immunoblot. Polyfunctionality ($IL\text{-}2^+/IFN\text{-}\gamma^+/GZMB^+$) was measured via flow cytometry.

Results: EZH2i treatment did not impair initial CAR-T cytotoxicity against tumor cells. However, prolonged co-culture revealed a significant decline in tumor control past the fourth round of co-culturing. EZH2i-treated WT CAR-T cells sustained tumor clearance for an average of 5.7 killing rounds compared to 14.0 rounds in untreated controls ($p=0.0002$, $n=3$). Immunoblots confirmed loss of the repressive histone mark H3K27me3 following chronic EZH2i exposure ($p<0.0001$, $n=8$), alongside elevated expression of exhaustion markers: PD-1 (1.6-fold, $p=0.0502$, $n=8$), CTLA-4 (7.4-fold, $p<0.0001$, $n=6$), and LAG-3 (53.3-fold, $p=0.0198$, $n=6$). Flow cytometry further revealed a reduced frequency of polyfunctional ($IL\text{-}2^+/IFN\text{-}\gamma^+/GZMB^+$) $CD8^+$ T cells and a shift toward an exhausted phenotype.

Conclusions: We demonstrate that while EZH2i does not impair the short-term function of CAR-T cells, prolonged exposure significantly reduces persistence and anti-tumor efficacy. To overcome this limitation, we are developing strategies to engineer CAR-T cells resistant to EZH2i, enabling future combination therapies that harness both EZH2 inhibition and adoptive T-cell therapy.

#5190 Advancing FCRL5 directed immunotherapy for improved treatment of B cell lymphoma.

Chakrapani Tripathi, John Nguyen, Fang-chi Hsu, Frank Luh, Yun Yen

Sino-American Cancer Foundation, Covina, CA

Despite significant advances in B-cell lymphoma therapies including monoclonal antibodies, bispecific T-cell engagers (BiTEs), and CD19/CD20-directed chimeric antigen receptor (CAR) T-cell therapies disease relapse and treatment resistance remain major clinical challenges. The principal driver of therapeutic failure is antigen escape, characterized by the downregulation or loss of CD19 and/or CD20 on malignant B cells[1], rendering current immunotherapies ineffective. These limitations underscore the urgent need for alternative target antigens and next-generation immunotherapeutic strategies capable of circumventing antigen loss. Fc receptor-like 5 (FcRL5), a transmembrane immunoglobulin superfamily protein selectively expressed on malignant B cells and plasma cells with minimal expression in normal tissues[2], represents a compelling tumor-associated antigen. We generated and functionally characterized FcRL5-targeted CAR T cells using nanobody-based single-domain antibodies (VHHs) derived from an immunized llama library. Anti-FcRL5 VHHs were incorporated into second-generation CAR constructs incorporating 4-1BB-CD3ζ signaling domains. CAR candidates were first screened in Jurkat NFAT-GFP reporter cells for surface expression, antigen-specific activation, and basal tonic signaling to identify top performers. Selected CAR constructs were further evaluated in primary human CD3+ T cells for FcRL5-dependent activation, cytotoxicity, cytokine secretion, and memory differentiation following co-culture with FcRL5+ diffuse large B-cell lymphoma (DLBCL) cell lines (Su-DHL-6, Toledo) and FcRL5$^-$ controls. These analyses demonstrated robust and selective activation, potent effector function, and strong cytotoxicity against FcRL5-expressing lymphoma cells, highlighting their therapeutic potential. Collectively, these findings establish FcRL5-targeted nanobody-based CAR T cells as a promising next-generation immunotherapy capable of overcoming antigen escape in B-cell lymphomas. Evaluated alone or in combination with FDA-approved targets, FcRL5 CAR T cells hold strong potential for translation into first-in-human clinical trials for patients with relapsed or refractory disease. **Funding:** Supported by the SACF Drug Discovery Research Fund **References:** 1.Spiegel JY, et al. *Nat Med* 2021;27:1419-31.2.Capone M, et al. *J Clin Cell Immunol* 2016;7:427.

#5191 Multiscale engineering of PTPRZ1 CAR T cells through affinity-tuned binders and modular architecture optimization.

Aditya A. Mohan[1], Barbara Lipes[1], Rushil Yerrabelli[1], Kisha Kamini Patel[2], Charla Gentry[1], Ariel Gonzalez[1], John Sampson[3], Peter E. Fecci[4], Michael Gunn[1], Anoop Patel[1]

[1]Duke University, Durham, NC,[2]University of Pennsylvania, Philadelphia, PA,[3]University of Colorado, Aurora, CO,[4]Duke University Medical Center, Durham, NC

Glioblastoma remains universally lethal, with rapid recurrence and a median survival of less than two years. Current CAR T approaches in glioblastoma have been limited by a lack of uniformly expressed and therapeutically actionable antigens. Using integrated single-cell and single-nucleus atlases, we identify PTPRZ1 as a consistently and highly expressed surface antigen across malignant glioblastoma states with minimal expression in non-neoplastic neural lineages. To translate this target, we developed a binder engineering pipeline combining mouse immunization, phage display with counter-selection against PTPRG, and yeast based directed evolution to generate a panel of scFv and nanobody binders with a spectrum of affinities that recognize the same PTPRZ1 epitope. This panel enables systematic tuning of CAR antigen sensitivity and functional thresholds and allows direct comparison of how binder format and affinity shape CAR activity against endogenous antigen. We incorporated these affinity-graded binders into a modular CAR backbone and constructed a combinatorial CAR library that varies hinge domains, transmembrane regions, and costimulatory modules. Primary human T cells transduced with pooled CAR libraries were screened against patient-derived glioma stem cells to quantify how each architectural module influences CAR function as an isolated component and how combinations of modules synergize to enhance activation, cytotoxicity, proliferation, resistance to exhaustion, and durability under chronic stimulation. This screening strategy also enabled the identification of recurrent architectural features that support persistence and metabolic fitness in solid tumor settings. Individual validation studies confirmed that both scFv and nanobody CARs targeting the identical epitope exhibit distinct activation and persistence profiles, and that optimal performance arises from specific pairings of hinge, transmembrane, and costimulatory domains. Safety studies using human epilepsy-derived cortical slice cultures reveal minimal off-tumor cytotoxicity and preserved neural architecture following exposure to PTPRZ1-targeting CAR T cells. Collectively, these data nominate affinity-tuned PTPRZ1 binders and optimized CAR architectures as strong candidates for translation and provide generalizable design principles for improving CAR T therapy in solid tumors.

#5192 Single-cell profiling reveals immune circuit disruption preceding CAR-T relapse in B-ALL.

Zhouting Zhu[1], Na Li[2], Zhaoyang Jia[2], Yufei Deng[2], Lujing Wu[2], Hui Hui[2], Victor Wong[3], Tariq M. Rana[2]

[1]Graduate School of Biomedical Sciences, Sanford Burnham Prebys Institute, La Jolla, CA,[2]Department of Cellular and Molecular Medicine, University of California San Diego, La Jolla, CA,[3]Rady Children's Hospital, San Diego, CA

Chimeric antigen receptor T (CAR-T) cell therapy has transformed treatment outcomes for B-cell acute lymphoblastic leukemia (B-ALL), yet disease relapse remains a major clinical challenge. To elucidate mechanisms underlying relapse, we analyzed longitudinal single-cell RNA-seq profiles from peripheral blood mononuclear cells (PBMCs) of five B-ALL patients treated with CAR-T cells. Within total T cells, MHCII$^+$ CD8$^+$T cells were markedly reduced at relapse, whereas naive-like CD8$^+$ T cells were enriched. Trajectory reconstruction revealed that antigen-processing and antigen-presentation pathways are critical for the transition from naive-like to MHCII$^+$ CD8$^+$ T cells. In relapsed patients, MHCII$^+$ CD8$^+$ T cells exhibited impaired progression along this trajectory and remained transcriptionally similar to the naive-like state. Within the monocyte lineage, antigen-presenting monocytes in relapsed patients skewed toward a non-classical phenotype, characterized by enhanced chemotaxis, taxis, and oxidative phosphorylation, whereas a patient who maintained remission to day 360 displayed antigen-processing, antigen-presentation, and type I interferon activation signatures. Analysis of B-ALL cells revealed that relapsed leukemic cells exhibit increased stemness, “don’t-eat-me” signaling, and immaturity scores, along with reduced mature B-cell differentiation signatures. Together, our multi-patient single-cell analysis reveals a coordinated dysregulation of monocytes, CD8$^+$ T-cell antigen presentation, and intrinsic leukemic cell states during CAR-T relapse, highlighting a potential B-ALL-monocyte-T-cell axis that may drive immune evasion and inform strategies to prevent or treat CAR-T failure.

#5193 Novel SynKIR-310 outperforms CD3-based second-generation CD28 or 41BB co-stimulated CAR T in B-cell non-Hodgkin lymphoma xenograft mice and shows early clinical signal.

Megan C. Blair[1], Jun Xu[1], Nora Yucel[1], Tony Truong[1], William Stanley[1], Michael Tees[2], Olivia Dermody[1], Susan K. Howard[1], Andrea Campanile[1], Michael Milone[3], Don L. Siegel[3], Laura A. Johnson[1]

[1]Verismo Therapeutics, Philadelphia, PA,[2]Colorado Blood Cancer Institute, Denver, CO,[3]Department of Pathology and Laboratory Medicine and Center for Cellular Immunotherapies, University of Pennsylvania, Philadelphia, PA

Over half of B-NHL patients (pts) receiving FDA-approved CD19-targeting chimeric antigen receptor (CAR) T experience progressive disease within 1 year[1], demonstrating need for more durable therapies. Unlike CD3-based single-chain CAR, killer immunoglobulin-like receptor (KIR)-based CAR have a multi-chain design derived from natural killer (NK) cells[2] with separated antigen binding and activation signals, and reduced tonic signaling and off-target activity[3]. SynKIR-310 is an autologous T cell therapy targeting CD19 with canine-derived single chain variable fragment (scFv), DS191. We previously compared SynKIR-310 to single-chain FMC63-41BBζ (tisagenlecleucel analog) for anti-tumor functionality in NALM6 B-cell leukemia-engrafted NOD-SCID-IL2Rγc$^{-/-}$ (NSG) mice. SynKIR-310 showed faster tumor regression and increased tumor control with reduced systemic cytokines and comparable T cell persistence[4]. Here we evaluated SynKIR-310 in B-NHL Raji cell Burkitt lymphoma xenograft NSG mice compared with FMC63-41BBζ and single-chain FMC63-CD28ζ (axicabtagene ciloleucel analog). Mice were IV injected with Raji tumors and then IV injected with T cells. Tumor progression was monitored by bioluminescent imaging. In this Raji model, SynKIR-310 and FMC63-41BBζ showed comparable anti-tumor efficacy and increased overall survival, while FMC63-CD28ζ had no impact over negative control animals despite similar T cell persistence across groups. SynKIR-310 and FMC63-41BBζ produced similar levels of cytokines *in vivo*, while FMC63-CD28ζ produced significantly more cytokines at both early and late timepoints, despite worse tumor control. At the early timepoint, FMC63-CD28ζ produced 11-fold more IL-2 than SynKIR-310 and FMC63-41BBζ, while IFNγ and TNFα were comparable across groups. At the late timepoint, FMC63-CD28ζ produced 11-fold more IFNγ and 9-fold more TNFα, compared to SynKIR-310 and FMC63-41BBζ. SynKIR-310 achieves significantly improved tumor control compared to FMC63-CD28ζ in a Raji B-NHL mouse model, with reduced cytokine production. We have previously shown SynKIR-310 has superior anti-tumor efficacy over FMC63-41BBζ in a leukemia NALM6 model, here FMC63-41BBζ and SynKIR-310 had comparable anti-tumor efficacy against B-NHL Raji, though SynKIR-310 was the only group with 100% survival. These data support a potentially increased benefit-risk profile of SynKIR-310 compared with conventional CD3-based CAR T and merits further investigation in patients with B-NHL. We are enrolling pts in a Phase 1 first-in human multi-site U.S.-based clinical trial for relapsed/refractory B-NHL, including pts with or without prior exposure to CAR T (NCT06544265). Early clinical pt data will be presented.

Background: Natural killer (NK) cells play a crucial role in cancer immunosurveillance. They infiltrate the tumor microenvironment and kill tumor cells by integrating activating signals from stress-induced ligands on cancer cells and inhibitory signals, mediated by the major histocompatibility immune complex (HLA), that preserve self-tolerance. However, their effectiveness against solid tumors is limited by tumor-driven immune-suppression. Oncolytic viruses (OV) can potentially overcome this barrier by selectively infecting tumor cells and stimulating antitumor immunity. We thus combined the oncolytic adenovirus Delta24-RGD with NK cells to target aggressive solid tumors, aiming to define the mechanisms underlying virus-induced NK cell hyperactivation and supporting clinical translation of this approach.
Methods: We conducted in vitro and in vivo studies to evaluate the cytotoxicity of ex vivo-expanded cord blood-derived NK cells against Delta24-RGD-infected pancreatic ductal adenocarcinoma and glioblastoma cells. In vitro, OV-infected tumor cells were co-cultured with NK cells, followed by CyTOF phenotyping and cytotoxicity evaluation using xCelligence and Incucyte. Long-term cytotoxic capacity was assessed by first co-culturing NK cells with OV-infected or non-infected tumor cells, isolating NK cells and then testing their serial killing against fresh tumor targets. In vivo efficacy was tested using patient-derived xenograft glioblastoma mouse models. Mechanistic workup included ATAC-seq, bulk RNA-seq, CUT&RUN, and CRISPR-Cas9 knockout of JUNB and FOS.
Results: NK cells exhibited synergistic cytotoxicity against OV-infected PDAC and glioblastoma cells and acquired an enhanced activation phenotype with increased expression of DNAM-1, NKG2D, CD94, NKp30, CD25, CD69, ICOS, T-bet, TRAIL, and CD107a. OV-infected tumor cells upregulated stress ligands including B7-H6, MICA/B, and ULBP1 and downregulated HLA-I. In vivo, the combination therapy significantly reduced tumor growth and extended survival in glioblastoma models. NK hyperactivation required direct contact with OV-infected tumor cells, likely driven by virus-mediated modulation of NK-ligand expression on tumor cells. Robustly activated NK cells maintained enhanced cytotoxicity through repeated tumor rechallenges, indicating durable functional reprogramming. Mechanistic studies revealed AP-1 activation followed by type I interferon signaling. Disruption of JUNB and FOS, as well as chemical AP-1 inhibition reduced this effect. CUT&RUN confirmed AP-1 dependent transcriptional programs supporting cytotoxicity.
Conclusion: Oncolytic viruses synergistically enhance sustained NK cell antitumor activity by reprogramming AP-1 driven transcriptional responses. This combination strategy provides a mechanistic foundation for advancing NK cell-based therapies against solid tumors.

#5195 Next-generation CAR-T cells that target only tumor stroma and matrix: Collagen-binding IL-12-expressing FAP-CAR-T show strong anti-tumor efficacy but are safe.

Jun Ishihara[1], Chiu Po Chaun[1], Koichi Sasaki[2]

[1]Imperial College London, London, United Kingdom,[2]Imperial College London, London

Fibrotic tumor subtypes have been identified across multiple solid malignancies, including pancreatic, breast, lung, and colorectal cancers. These fibrotic tumors are generally difficult-to-treat and are characterized by extensive desmoplastic stroma and pronounced heterogeneity. The fibrotic tumor microenvironment (TME) not only serves as a physical barrier that impedes therapeutic penetration and immune cell infiltration but also contributes to therapeutic resistance, rendering these cancers particularly challenging to treat. Cancer-associated fibroblasts (CAFs), which are abundant in the TME, have emerged as a promising therapeutic target. In this study, we developed a novel chimeric antigen receptor T cell (CAR-T) therapy specifically targeting fibroblast activation protein (FAP) expressed on CAFs. After binding to FAP, NFAT signalling enables the subsequent local secretion of collagen-binding domain-fused interleukin-12 (CBD-IL-12) from CAR-T cells. This CAR-T cells only remove CAF but also concentrate collagen-binding IL-12 in the tumor to enhance host immune activation within the tumor microenvironment. The CBD-IL-12 expressing FAP CAR-T cells exhibited effective cytotoxicity against fibroblast cell lines in vitro. In vivo, CBD-IL-12 expressing FAP CAR-T cells significantly suppressed tumor progression of murine breast cancer and pancreatic cancers, which were better than 2nd generation FAP CAR-T or wt IL-12-expressing CAR-T. Importantly, CBD-fusion to IL-12 in the CAR-T design improved accumulation of IL-12 within tumor tissues >10 times, whereas minimizing systemic IL-12 exposure and reducing associated toxicities. Immunophenotyping revealed increased infiltration of $CD8^+$ cytotoxic T lymphocytes and reduced regulatory T cells (Tregs) in the TME of mice treated with CBD-IL-12-expressing FAP CAR-T, compared to those treated with FAP CAR-T alone or with wt IL-12 secretion. This dual-function CAR-T approach serves to first deplete CAFs, thereby disrupting the physical barrier impeding immune cell infiltration, and second, to activate anti-tumor immunity through localized IL-12 delivery. We have created a new therapeutic concept, which utilizes CAR-T cells for non-tumor antigen target, but still activates immune cells locally in the tumors, which could be a universal purpose CAR-T cells for multiple cancer types, especially for fibrotic or post-x-ray tumors.

#5197 Metabolically supercharged NK cells engineered with adenoviral E4ORF-1.

Maliha Munir[1], Madison Moore[1], Silvia Tiberti[1], Rafet Basar[1], Byron Jia[1], Leen Kheirbek[1], Nadima Uprety[1], Francia Reyes Silva[1], Rejeena Shrestha[1], Ana K. Nunez Cortes[1], Mayra Shanley[1], Sunil Acharya[2], Jeong-Min Park[1], Bin Liu[1], Pinaki Banerjee[1], Paul Lin[1], Donghai Xiong[1], Enli Liu[1], Alia Ghrayeb[1], Eyal Gottlieb[1], Elizabeth Joan Shpall[3], Katayoun Rezvani[1], **May Daher**[1]

Background: Chimeric antigen receptor (CAR) T and natural killer (NK) cells have achieved success in hematologic malignancies but show limited efficacy in solid tumors. A major barrier is the metabolically hostile solid tumor microenvironment (TME), where hypoxia, acidosis, and nutrient deprivation impair immune cell fitness, cytotoxicity, and persistence. Current metabolic engineering strategies that enhance single nutrient uptake or target one metabolic pathway provide only partial benefit and remain vulnerable to tumor metabolic plasticity. A critical unmet need is the development of immune cells with metabolic flexibility rather than single-pathway dependence. To address this, we explored a strategy inspired by viral metabolic rewiring. During adenoviral infection, the viral protein E4ORF-1 activates PI3K-AKT signaling, stabilizes MYC, augments nutrient uptake, and enhances glycolysis, oxidative phosphorylation (OXPHOS), and fatty acid oxidation (FAO). We hypothesized that engineering E4ORF-1 into NK cells would generate a viral-like metabolic state capable of withstanding nutrient restriction in solid tumors.
Methods: Metabolic characterization included mitochondrial mass and membrane potential, Seahorse assays, and SCENITH. CAR-NK cells were cocultured with solid tumor cell lines, and cytotoxicity was quantified using xCelligence and IncuCyte platforms. In vivo efficacy was tested in xenograft models of hematologic (MOLM14) and solid tumors (SKOV3). Mechanistic studies incorporated bulk RNAseq, CyTOF profiling, and CRISPR-Cas9 knockout of AMPK.
Results: E4ORF-1 expression significantly enhanced NK cell antitumor function across tumor models and sustained cytotoxicity and metabolic fitness under glucose-, glutamine-, or lipid-limited conditions. Western blotting confirmed coordinated upregulation of nutrient transporters and metabolic enzymes across glycolysis, OXPHOS, and FAO. E4ORF-1 NK cells also maintained a cytotoxic advantage under targeted metabolic inhibition; despite blockade of glycolysis, OXPHOS, FAO, or glutamine metabolism, they consistently demonstrated superior tumor killing, underscoring enhanced metabolic adaptability. Transcriptomic profiling showed preserved cytokine signaling and metabolic signatures even under nutrient restriction or after tumor challenge. Mechanistic studies identified AMPK as a central metabolic integrator required for the E4ORF-1 phenotype, as CRISPR deletion of AMPK abrogated metabolic and functional advantages. Incorporation of E4ORF-1 into CAR-NK cells improved tumor control and survival in vivo.
Conclusion: E4ORF-1 enhances NK cell metabolic flexibility, enabling sustained antitumor activity and improving therapeutic potential for solid tumors. These findings establish viral gene-mediated metabolic rewiring as a promising platform to strengthen CAR-NK cell fitness and overcome nutrient competition in the TME.

#5198 A non-viral mRNA engineering platform for rapid, same-day immune-cell therapies.

Chen Wu[1], Christoph Schaefers[2], Malvika Gupta[2], Kevin Regan[2], Zuoyi Shao[2], Andre De Menezes Silva Corraes,[2], Virginia Van Keulen[2], Jacob Hirdler[2], Tobias Peikert[3], Timothy D. Wiltshire[4], Haidong Dong[5], Yi Lin[2]

[1]Biochemistry and Molecular Biology, Mayo Clinic College of Medicine and Science, Rochester, MN,[2]Mayo Clinic, Rochester, MN,[3]Pulmonary and Critical Care Medicine, Mayo Clinic College of Medicine and Science, Rochester, MN,[4]Senior Research Fellow, Mayo Clinic, Rochester, MN,[5]Mayo Clinic College of Medicine and Science, Rochester, MN

Background: Cellular immunotherapy has transformed cancer treatment, but success in solid tumors remains limited by long manufacturing times, high costs, and the need for viral vectors that permanently modify DNA. To address this, we examined electroporation (EP) and mechanoporation (MP) approach to transfect T cells with mRNA to enable the development of a bedside immune cell editing platform. NKG7, natural killer cell granule-7, was previously demonstrated to play key function in activating T-cell cytotoxicity function. mRNA transfection of T cells with NKG-7 can increase these cells' anti-tumor cell killing. We examine EP and MP methods for NKG7 transfection in primary peripheral blood mononuclear cells (PBMCs) from healthy donors.
Method: Synthetic Clean Cap mRNAs encoding NKG7 or NKG7 with membrane-bound cRNA IL-2 were introduced into PBMCs by electroporation (MaxCyte) or mechanoporation (Portal Bio). T cell expression of NKG7 and IL-2 were analyzed by CytoFlex flow and Kaluza.
Result: The yield at EP and MP were comparable at 0.615+/-0.09% and 0.597+/-0.16%, respectively. Viability were high at above 80% for 3 days after EP and MP. NKG7 and NKG7+cIL-2 mRNA transfection led to different NKG7 expression kinetics in T-cells and between EP and MP. With EP, CD4 T-cells showed an increase in NKG7 expressions with the highest MFI ratio (NKG7 MFI/ IgG MFI) compared to mock EP at Day 1 for the NKG7 -only EP (1.25 ± 0.38) and at Day 2 for NKG7+cIL-2 EP (1.20 ± 0.27). $CD8^+$ T cells displayed a similar trend, with peak NKG7 expression at Day 1 for NKG7 EP (1.22 ± 0.76) and Day 2 for NKG7+cIL-2 EP (1.21 ± 0.90). However, MP did not enhance NKG7 expression in $CD4^+$ T cells. NKG7 expression peaked at Day 1 for both NKG7 (1.28 ± 0.42) and NKG7 + cIL-2 (1.24 ± 0.20). IL2 expression peaked at Day 1 for both EP and MP: EP, $CD4^+$ T (91.5% ± 4.4), $CD8^+$ T (92.7% ± 12.8); MP, $CD4^+$ T (88.9% ± 31.7), $CD8^+$ T (84.7% ± 9.6). Functional assays for anti-tumor cell killing of these transfected cells are currently ongoing.
Conclusions: We report that EP of PBMC can transfect all cell populations. MP may yield comparable yield, viability and NKG7 expression in CD8 T cells compared to EP, but without the need to isolate CD8 T cells from PBMC. EP and MP method can be used for bedside immune cell transfection depending on the target and cell populations of interest.

#5199 uPAR-targeting CAR-NK cells enhance cytotoxicity against acute myeloid leukemia.

Xingliang Guo[1], Nadima Uprety[2], Rejeena Shrestha[2], Francia Reyes Silva[1], Sunil Acharya[2], Bijender Kumar[3], Bin Liu[2], Dexing Fang[2], Bingqian Hu[2], Sha Wang[2], May Daher[1], Ana K. Nunez Cortes[2], Corry Jones[2], LaTretta Harris[2], Vernikka Woods[2], Jerrell E. Scott[2], April Gilbert[2], Cornelio Santibanez[2], Katayoun Rezvani[2], Rafet Basar[1]

[1]Department of Stem Cell Transplantation and Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Institute for Cell Therapy Discovery and Innovation, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Division of Hematology Oncology, VCU Massey Comprehensive Cancer Center, Richmond, VA

Background: Relapsed/refractory acute myeloid leukemia (AML) remains difficult to treat, highlighting the need for new therapies. NK cell-based immunotherapy offers potent antitumor activity with low risk of GVHD or severe CRS. The urokinase plasminogen activator receptor (uPAR), encoded by *PLAUR*, is highly expressed on malignant and senescent cells while largely absent from healthy HSCs and most normal vital organs. We found *PLAUR* significantly upregulated in AML and confirmed strong uPAR surface expression on primary blasts. Based on this favorable profile, we developed an off-the-shelf uPAR-targeted CAR-NK platform with a CD28 costimulatory domain and secreted IL-15 to enhance persistence.
Methods: Cord blood-derived NK cells were preactivated with IL-12/15/18 and transduced to express (i) uPAR-CAR, (ii) IL-15, or (iii) uPAR-CAR/IL-15. CAR expression, cytokine production, and phenotype were assessed by flow cytometry, ELISA, and CyTOF, respectively. Antileukemic activity against AML cell lines (MV4-11, THP-1, OCI-AML3) and primary blasts was tested by IncuCyte real-time killing and Annexin V staining. Long-term activity was assessed by sequential tumor rechallenge. In vivo efficacy was evaluated in NSG mice engrafted with luciferase-labeled OCI-AML3 and treated with a single NK infusion.
Results: uPAR was highly expressed on AML blasts but minimal on healthy HSCs/HSPCs, confirming its suitability as a CAR-NK target. uPAR-CAR/IL-15 NK cells were efficiently generated, secreted IL-15, and expanded robustly. In vitro, they showed markedly enhanced and antigen-specific killing of all uPAR+ AML lines and primary blasts compared with CAR-only, IL-15-only, or non-transduced NK cells ($p < 0.0001$), while *PLAUR*-knockout cells resisted killing. uPAR-CAR/IL-15 NK cells produced more IFN-γ and TNF-α and maintained superior function during repeated tumor exposure, with CyTOF revealing an activation/cytotoxicity-enriched metacluster. In vivo, a single uPAR-CAR/IL-15 NK infusion significantly reduced leukemia burden, delayed progression, and improved NK persistence in bone marrow. Compared with non-transduced NKs, tumor burden in peripheral blood ($p < 0.05$), bone marrow ($p = 0.001$), and spleen ($p < 0.01$) was substantially reduced, with no observed toxicity or weight loss. Taken together, uPAR is a safe, selective AML target. uPAR-CAR NK cells, particularly when armored with IL-15, display potent, antigen-specific, and durable antileukemic activity, supporting advancement of this platform for AML therapy.

#5200 Preclinical evaluation of armored DLL3 biepitope compound nanobody CAR T cells.

Byeong-Hyeok Choi[1], Ga-Ram Hwang[1], Morgan Flaherty[1], Vincent M. DeStefano[1], Masayuki Wada[1], Kevin Pinz[1], Jennifer E. Chow[1], Nabil Hagag[1], Yu Ma[2], Luo Jing[2], Yupo Ma[1]

[1]iCell Gene Therapeutics, Stony Brook, NY,[2]iCAR Bio Therapeutics Ltd, Zhongshan, China

Introduction

Delta-like ligand 3 (DLL3) is markedly and selectively expressed in small cell lung cancer (SCLC) and other high-grade neuroendocrine tumors with minimal expression in normal tissues, making it an attractive target for cellular immunotherapy. DLL3-directed CAR approaches in solid tumors have shown limited durability, underscoring the need for improved potency. To address these challenges, we developed DLL3 bi-epitope compound nanobody CAR T cells. We incorporate IL-18 armoring to enhance effector cell survival and function. Herein we report the feasibility of an armored DLL3 bi-epitope cCAR T construct.

Experimental Procedures

Alpacas were immunized with recombinant human DLL3 extracellular domain protein. Peripheral blood mononuclear cell (PBMC) mRNA was extracted and converted into a VHH (nanobody) to generate a library. The library was panned against DLL3 antigen to enrich for high-affinity binders, which were identified through ELISA screening and cellular binding analysis by flow cytometry. VHH clone sequencing were used to generate our cCAR. The DLL3 bi-epitope cCAR T is comprised of two unique and independently functioning CAR units targeting different DLL3 epitopes reducing risk of tumor evasion due to antigenic variation. A DLL3-targeting nanobody pair was used to generate DLL3 bi-epitope cCAR. Human T cells were activated and transduced to produce CAR T cells. CAR expression was assessed by flow cytometry. Cytotoxicity was evaluated using SHP-77 (endogenous DLL3$^+$) and REH-DLL3xp (overexpressing DLL3) targets. NSG mice received CAR T cells to assess antitumor activity.

Results

The bi-epitope DLL3 cCAR T construct demonstrates potent cytotoxicity lysing target cells in vitro and in vivo. At various effector-to-target ratios, the cCAR was observed to have strong killing activity and specificity against the primary tumor cell line and artificially DLL3-
expressing cell line. The cCAR also demonstrated strong potency in SHP-77 xenograft mouse models.

Conclusions

Our bi-epitope armored DLL3 cCAR T therapy demonstrated exceptional efficacy in vitro and in vivo. These results support future investigation of our cCAR in patients with SCLC and/or DLL3 expressing neuroendocrine tumors.

#5201 Tuning gated CAR-T cells for enhanced activity against acute myeloid leukemia.

Shawn Barman[1], Molly Shields[1], Tatiana Fourfouris[1], Ki Jun Lee[1], Naiomi Desai[1], Devon Bell[1], Ethan BenDavid[1], Justin Pfahler[1], Ayesha Khan[1], Sanjana Tottempudi[1], Armita Shadfar[1], Yong-Mi Kim[2], BABAK MOGHIMI[1]

[1]USC/CHLA, Los Angeles, CA,[2]Children's Hospital Los Angeles, Los Angeles, CA

Background: Conventional Chimeric Antigen Receptor (CAR) T-cell therapies for Acute Myeloid Leukemia (AML) face persistent challenges, including limited T-cell fitness, resistance emergence, and on-target, off-tumor toxicity. To overcome these limitations, we previously developed logically gated CAR-T cells using Synthetic Notch (SynNotch) circuits targeting two AML antigens, CD33 and CD123. In this system, CD33 engagement triggers expression of a gated CD123 CAR, leading to greater precision, improved metabolic fitness, reduced exhaustion, and longer in vivo persistence. Despite these benefits, gated CAR-T cells exhibit modestly reduced potency compared with conventional CAR-T cells. We hypothesize that incorporating modified intensity signaling elements into the gated architecture will enhance cytotoxicity while preserving the favorable metabolic and immunological profiles of gated CAR-T cells.
Methods: To enhance downstream activation, we engineered a panel of CAR signaling constructs, including CD3ζ ITAM-modified and ZAP70-based signaling modules. These designs were assessed using an NFAT reporter assay, allowing quantification of inducible signaling strength across constructs.
Results: Gated CAR-T cells expressing these enhanced signaling modules demonstrated accelerated and more robust activation, with a clear dose-dependent increase in NFAT reporter activity. Furthermore, we successfully incorporated the optimized signaling elements into a single open-reading-frame CAR design, enabling efficient expression and positioning these constructs for forthcoming translational testing.
Conclusion: Augmenting T-cell receptor-proximal signaling within the gated CAR framework increases activation and improves functional potency. We anticipate that these high-intensity gated CAR-T cells will maintain the metabolic advantages characteristic of SynNotch-gated systems. Ongoing studies are evaluating their efficacy, fitness, and safety in relevant AML models.

#5202 Predictive models for hematologic toxicity after CAR-T therapy: A systematic review of current risk scores and unmet AI needs.

Mansha Gupta[1], Abhijith Vemulapalli[2], Swathi Cherukuri[3], Rithish Nimmagadda[4], Akhil Jain[5]

[1]Midwestern University - Glendale Campus, Glendale, AZ,[2]Guntur Medical College, Guntur, India,[3]Mayo Clinic, Jacksonville, FL,[4]One Brooklyn Health - Interfaith Medical Center, New York, NY,[5]University of Iowa Hospitals and Clinics, Iowa City, IA

Background: Hematologic toxicity, including early and prolonged neutropenia, anemia, and thrombocytopenia, is among the most common and clinically significant complications after CD19, CD20, CD22 and BCMA-directed CAR-T therapy. Several clinical scoresmost notably CAR-HEMATOTOX (CAR-HT) and the refined ALL-HThave been developed to predict post-infusion cytopenias, but their comparative performance across diseases has not been systematically evaluated. No prior review has summarized existing models or assessed the need for AI-based predictive approaches.
Methods: We conducted a systematic review of studies that developed or validated predictive models or risk scores for hematologic toxicity after CAR-T therapy in hematologic malignancies. Eligible studies included clinical, cytokine-based, or composite predictors and reported discrimination metrics such as area under the curve (AUC). Extracted variables included CAR-T product, target antigen, disease type, predictors used, model type, validation strategy, and performance statistics. Results were synthesized qualitatively due to heterogeneity in model structure and outcome definitions.
Results: Studies on the CAR-HT score in B-cell lymphomas and multiple myelomas reported AUC values of 0.89 and 0.82, respectively, for predicting severe or long-term neutropenia after CD19 and BCMA-directed CAR-T therapy. Studies on the ALL-HT score (a modified/refined version of CAR-HT replacing ferritin with bone-marrow burden to improve discrimination in B-ALL) reported AUC 0.84-0.90 for predicting prolonged neutropenia and worse overall survivability (OS) after CD19/CD22 CAR-T. A multicenter study including aggressive/indolent NHL, MM/PCL, and ALL patients treated with CD19, CD20, or BCMA CAR-T reported AUC 0.87 (eIPM-Pre) and 0.88 (eIPM-Post) for predicting ICA-HT. A CD19 CAR-T study in B-ALL and LBCL reported AUC 0.85 for an early hematotoxicity nomogram using TNF- and CRP.
Conclusion: Existing prediction tools for hematologic toxicity after CAR-T therapy demonstrate strong but disease-specific performance. Yet inconsistent endpoints and heterogeneous predictors limit clinical generalizability. No current model incorporates contemporary AI or machine-learning methods, underscoring a significant unmet need. Advanced predictive frameworks may allow earlier identification of patients at risk for severe or prolonged cytopenias and guide more individualized supportive care, with the potential to reduce downstream complications.

#5203 Phosphorylated IRF7 enhances antitumor activity of GPC3-targeted CAR T cells in solid tumors.

Inci Cevher Zeytin[1], Che-Hsing Li[1], David de la Cerda[1], Leidy Diana Caraballo Galva[2], Andras Attila Heczey[1]

[1]Ben Towne Center for Childhood Cancer and Blood Disorders Research, Seattle Children's Research Institute, Seattle, WA, [2]Pediatrics - Oncology, Baylor College of Medicine, Houston, TX

Glypican-3 (GPC3) is highly expressed in hepatocellular carcinoma (HCC) and hepatoblastoma (HBL), but not in healthy mature tissues; thus, represents a promising immunotherapeutic target. In a recent study, GPC3-CAR or IL15 co-expressing GPC3-CAR T cells (15.CAR) were safe in patients, IL15 co-expression significantly enhanced CAR T cell expansion and resulted in a disease control rate of 66% and antitumor response rate of 33%. To elucidate molecular programs associated with therapeutic response, single cell RNA sequencing of tumor infiltrating CAR T cells was performed and unique transcriptomic profile differences were identified associated with antitumor responses including downregulation of SWI/SNF and upregulation of FOS/JUN and Type I Interferon family members. Transcription factor motif enrichment analyses identified Interferon regulatory factor 7 (IRF7) as the dominant transcriptional driver of genes upregulated in responders. We hypothesized that IRF7 will boost the antitumor activity and this study examined the role of wild type and constitutively active IRF7 expression in GPC3-CAR T cells (IRF7.CAR and pIRF7.CAR, respectively).Compared with 15.CAR T cells, IRF7.CAR and pIRF7.CAR T cells showed significantly higher naïve (CD45RA+ CCR7+ CD62L+; CD4 p=0.0348; in CD8 p=0.0163;), Central memory (CM, CD45RO+ CCR7+ CD62L+; CD4 p= 0.0382), LAG3+ (CD4 p=0.0236, CD8 p=0.0030) and significantly lower effector memory (TEM, CD45RA- CCR7- CD62L-; CD4 p= 0.0221) cell population at baseline, post-manufacturing based on flow cytometry. IRF7.CAR and pIRF7.CAR T cells had higher expansion and significantly improved killing efficacy ($p<0.001$) in repeated tumor-challenge assays using the IncuCyte system. Finally, In vivo, pIRF7GPC3+ cells showed more rapid tumor clearance under both high (5x10^6)- and low-dose (3x10^6) conditions in NSG-MHC I/II double knockout mice bearing HCC and HBL xenografts. These findings demonstrate that pIRF7 enhances CAR T-cell function. Incorporation of pIRF7 into GPC3-targeted CARs represents a novel strategy to improve efficacy against solid tumors.

#5204 CD5-directed CAR5/IL-15 NK cells as a therapeutic platform for T-cell malignancies.

Rafet Basar, **Sunil Acharya**, Nadima Uprety, May Daher, Francia Reyes Silva, Rejeena Shrestha, Bin Liu, Mayra Shanley, Merve Dede, Pinaki Banerjee, Ping Li, Paul Lin, Enli Liu, Donghai Xiong, Ken Chen, David Marin, Elizabeth Joan Shpall, Katayoun Rezvani

UT MD Anderson Cancer Center, Houston, TX

Background: Engineered NK cells have increasingly emerged as a powerful allogeneic cell therapy platform, with multiple trials demonstrating meaningful anti-tumor responses, durable clinical activity, and an excellent safety profile without GVHD and low cytokine-release toxicity. Their suitability for large-scale manufacturing makes CAR-NK cells particularly attractive for broad clinical use. T-cell lymphomas and leukemias remain difficult to treat, and although CD5 is a widely expressed and clinically actionable target, CAR-T cell development has been limited by fratricide and manufacturing barriers. A CD5-directed NK cell that avoids these limitations is therefore attractive in this setting.
Methods: We developed iC9/CAR5/IL-15 NK cells, an off-the-shelf engineered NK-cell therapy targeting $CD5^+$ tumors without fratricide or GVHD. The construct incorporates IL-15 to enhance persistence and the inducible caspase 9 (iC9) safety switch for controlled elimination if needed. A panel of CD5-targeting CAR constructs incorporating different intracellular signaling was generated and screened to identify constructs that optimized NK-cell activation, cytotoxicity, cytokine production, metabolic fitness, and functional persistence. These were tested against multiple $CD5^+$ T-ALL and T-cell lymphoma models, followed by in vivo evaluation in xenograft systems and safety testing against normal human tissues and long-term culture.
Results: Several signaling domains mediated strong anti-tumor activity, each with distinct advantages. CD28- and DAP10-based designs demonstrated the most consistent performance, supporting potent cytotoxicity and enhanced NK-cell activation. After comparing functional reproducibility, including cytotoxicity, cytokine production, proliferation, and serial killing, and considering manufacturing feasibility together with our prior clinical experience using CD28- signaling in CAR-NK products, the CD28-based iC9/CAR5/IL-15 NK construct was selected as the lead therapeutic candidate. In vivo, CD28-based iC9/CAR5/IL-15 NK cells resulted in rapid tumor regression and a significant survival benefit in $CD5^+$ T-ALL xenograft models. Safety studies confirmed the absence of off-target cytotoxicity, and prolonged culture showed no autonomous expansion or phenotypic instability.
Conclusion: iC9/CAR5/IL-15 NK cells overcome the barriers that have hindered CD5-directed CAR-T cell approaches, offering a scalable off-the-shelf therapy for aggressive T-cell malignancies. A Phase I/II clinical trial evaluating this therapy in relapsed/refractory $CD5^+$ T-cell cancers is now open and accruing at our center.

#5205 Assessing donor heterogeneity in CAR-T cells with massively parallel mixed lymphocyte reactions.

Lujing Wu[1], Lina Mohamad[1], Michelle Mantilla[1], Johnathan Lu[1], Ansuman T. Satpathy[2], Theodore Roth[3]

[1]Pathology, Stanford University, Stanford, CA,[2]Stanford University,[3]Stanford University, San Francisco, CA

Donor heterogeneity is a major source of variation in CAR-T cell functions which leads to inconsistencies in both clinical efficacy and pre-clinical studies to enhance CAR-T cell functions. However, assessing T cell donor heterogeneity with a large sample size is costly and time-consuming. Here, we developed a Massively Parallel - Mixed Lymphocytes Reaction (MP-MLR) assay that allows pooling and simultaneously testing of CAR-T cells from multiple human donors. Combining with pooled genetic perturbation technologies, we conducted pooled screening in more than 50 T cell donors for enhanced CAR-T cell proliferation under repetitive tumor stimulations, with a library of candidate genetic perturbations proposed to enhance CAR-T or T cell functions. While we identified genetic perturbations with consistent effect on CAR-T cells across donors, the majority of perturbations showed various levels of donor dependencies, and this observation was confirmed with arrayed validation of selected perturbations on specific donors. Furthermore, we performed multi-parameters pooled screening in-vitro and in-vivo for systematic discovery of generalizable and donor specific genetic perturbations enhancing CAR-T cell pre-clinical therapeutic efficacies. Overall, we presented an efficient and cost-effective strategy for assessing donor variabilities in CAR-T cells, predicting patient specific effects of genetic perturbations on CAR-T cells efficacies, and potentially identifying of personalized optimal genetic perturbation for enhancing CAR-T cell functions.

#5206 Mitochondrial remodeling sustains CAR-NK stemness for superior tumor control.

Silvia Tiberti[1], Madison Moore[2], Maliha Munir[1], Merve Dede[1], Byron Jia[1], Leen Kheirbek[1], Rejeena Shrestha[1], Nadima Uprety[1], Jeong-Min Park[1], Vernikka Woods[1], Corry Jones[1], Patrick Zhang[1], Dexing Fang[1], Huihui Fan[1], Maria Laura Centomo[1], Francia Reyes Silva[1], Mayra Shanley[1], Sunil Acharya[1], Ye Ethan Li[1], Bin Liu[1], Pinaki Banerjee[3], Rafet Basar[1], Katayoun Rezvani[1], May Daher[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]UT MD Anderson Cancer Center, Houston, TX, Houston, TX,[3]UT MD Anderson Cancer Center, houston, TX

Background: NK cell-based therapies are a promising off-the-shelf strategy for cancer treatment. Their inherent safety and lack of graft-versus-host disease make NK cells an attractive platform for CAR engineering, combining innate cytotoxicity with receptor specificity. However, clinical efficacy in solid tumors is limited by poor persistence and rapid metabolic exhaustion in the tumor microenvironment (TME). Strategies that enhance metabolic fitness and delay differentiation are essential. Inspired by stem-cell culture systems, we tested whether Albumin Polyvinylalcohol Essential Lipids (APEL), a defined medium used to support iPSC differentiation into embryoid bodies and NK cells, could preserve CAR-NK stemness and improve metabolic fitness and function.
Methods: CAR-NK cells expanded with APEL (CAR-NK_{stem}) were compared with CAR-NK cells expanded in conventional NK cell media (CAR-NK_{conv}). Metabolic profiling included mitochondrial mass and potential profiling, Seahorse assays to measure glycolysis and oxidative phosphorylation, nutrient competition assays to assess metabolic flexibility. CAR-NK cells were cultured with various hematologic and solid tumor cell lines, followed by cytotoxicity evaluation using 2D xCelligence and 3D Incucyte including rechallenge assays to assess serial killing capacity. In vivo efficacy was tested using various xenograft mouse models of hematologic cancers (MOLM14, MM1s) and solid tumors (786-0 ongoing). Mechanistic studies included multiomics profiling by bulk RNA-seq and ATAC-seq, CyTOF, and mitochondrial-transfer assays.
Results: Our data show that early metabolic reprogramming of CAR-NK_{stem} during expansion drove the development of enlarged and highly active mitochondria, increased spare respiratory capacity (SRC), and superior metabolic flexibility. This metabolic state stabilized stem-like features and limited terminal differentiation via chromatin remodeling toward persistence and memory-associated programs. Functionally, CAR-NK_{stem} cells showed improved proliferation, sustained serial killing, superior nutrient competition, and enhanced tumor control in vitro and in vivo. Mechanistically, mitochondrial transfer from CAR-NK_{stem} cells enhanced cytotoxicity and persistence in recipient NK cells, highlighting mitochondrial remodeling as a key driver of functional fitness.
Conclusion: These findings demonstrate that targeted metabolic reprogramming during manufacturing can generate stem-like, highly persistent CAR-NK cells and offer a broadly applicable, immediately translatable strategy for cancer immunotherapy.

#5211 Lung adenocarcinoma and urothelial carcinoma: Analysis of double cancer in Chang-Gung Medical Foundation.

Feng-Che Kuan[1], Meng-Hung Lin[2], Chung-Sheng Shi[3]

[1]Oncology, Chang Gung Memorial Hosp. - Chiayi Branch, Putzu City, Taiwan,[2]Chang-Gung Memorial Hospital, Chia-Yi Branch, Puzi, Taiwan,[3]Chang Gung University, Taoyuan County, Taiwan

Background: Aristolochic acids (AA) form carcinogenic DNA adducts, which can be detected in human urinary tract (kidney, ureter, and urinary bladder), liver, and non-target tissues such as pancreas, breast, and lung. AA is blamed for urothelial carcinoma (UC) but its carcinogenic role on lung cancer is still under debate. This study plans to investigate the characteristics of double cancers with urothelial carcinoma and lung adenocarcinoma (LA). Methods: We conducted this multi-institutional cohort study in Taiwan. Two independent cohorts were retrieved from Chang-Gung Research Database (CGRD). The first cohort (UCLA) included patients with double cancers with urothelial carcinoma (UC) and lung adenocarcinoma (LA) from 1994 to 2023 and the second cohort (CGMH-EGFRm) with EGFR-mutated LA from 2011 to 2020. UCLA was further divided into groups according to the sequence of cancer development (group 1: index diagnosis date of UC before LA; group 2: simultaneous LA and UC; group 3:LA before UC), and CGMH-EGFRm was divided into activating EGFR-mutations (group 4) and other mutations (group 5). The last follow-up time was Dec 30, 2023. Descriptive statistics are provided with Chi-Squared and Fisher's Exact Test. $P<0.05$ was set to be statistic significance.Results: From 1994 to 2023, cohort 1 comprised of 196 patients of which 126 in group 1, 30 in group 2, and 40 in group 3 and from 2011 to 2020 cohort 2 comprised of 3,427 patients. The last follow-up time was Dec 30, 2023, and the mean age of group 1, 2, and 3 was 73, 73, and 67, respectively. The male gender in group 1, 2, and 3 was 65.9%, 66.7%, and 67.5%, and smoking habit was 30.2%, 26.7%, and 42.5%, respectively. The baseline characteristics such as age, gender, smoking habits were different from group 1 to 5, while in UCLA cohort, gender and smoking habits were similar. The median interval of diagnosis between double cancer was 2381.5 (range: 131 to 10556), 8.5 (0 to 84) and 755.5 (98 to 4390) days, respectively. After 2000s (based on year of diagnosis with UC), there was an increasing trend in group 2 and 3. The anatomical locations of LA was similar between groups 1 to 3 ($p=0.660$), and a trend of increasing renal pelvis and ureter UC in group 3 ($p=0.104$). Conclusion: 1.1% of UC can develop LA in CGRD. Further genomic analysis between groups was warranted to elucidate the carcinogenic role of AA in double cancers.

#5213 T-cell transcriptome affected by therapy-related clonal hematopoiesis in long-term survivors of pediatric cancers.

Nadezhda V. Terekhanova, Sivaraman Natarajan, Bensheng Ju, Kohei Hagiwara, Li Dong, Zhaoming Wang, Leslie L. Robison, John Easton, Jinghui Zhang

St. Jude Children's Research Hospital, Memphis, TN

Our previously published work on the St. Jude Lifetime Cohort Study (SJLIFE), a retrospectively constructed cohort with prospective follow-up of long-term survivors of pediatric cancer, unveiled the phenomenon of accelerated clonal hematopoiesis (CH) associated with prior exposure to radiotherapy and chemotherapy. *STAT3* Y640F, a hotspot mutation specifically linked to prior exposure to procarbazine in Hodgkin Lymphoma (HL) survivors, was most frequent in the SJLIFE cohort. Based on joint profiling of DNA amplicons and cell-surface proteins at single cell resolution using the MissionBio platform, we found *STAT3* Y640F mutation in blood leukocytes from 6 out of 10 HL survivors. Importantly, *STAT3* Y640F was enriched in cells clustered within CD8 T-cells, indicating that mutation-positive cells have reprogramed the transcriptome that gave selective growth advantage to a subset of those cells. To investigate this, we performed PacBio scKinnex assay to generate full-length transcriptomes at single cell level, enabling integration of CH mutations with gene expression profiles. An initial analysis using blood samples of HL survivors yielded limited information as few mutant cells were detected due to the low mutation frequency (≤1%) and *STAT3* expression. To enrich for the mutant cells, we performed sorting for CD8+ T-cells followed by scKinnex for three samples which yielded sufficient number of mutant cells (14 to 26 cells per sample) for gene expression analysis. For each sorted sample 4,396 to 5,416 cells were profiled, and clustering by gene expression revealed 11-14 subpopulations per sample. Guided by the expression status of marker genes, we performed cell annotation and identified multiple CD8 T-cell subsets, including naive, central memory, effector memory, and terminally differentiated effector memory cells. *STAT3* mutant cells were present only in a few of these subpopulations: 3 out of 13 (23%), 1 out of 14 (7%), and 2 out of 11 (18%) in these three samples with an average frequency of 40% in each subpopulation. Nearly all mutant-positive clusters showed increased expression of *STAT3* gene; four out of the five (80%) such clusters exhibited high expression of cytotoxic markers, including *GZMB*, *GZMH*, *FGFBP2* and *NKG7*, while the remaining one showed high expression of stress response markers from FOS/JUN pathway (*JUN*, *JUNB*, and *FOS*). To our best knowledge, this is the first study that shows CH mutation can confer selective advantage to specific functional cell subsets of CD8 T-cells and analysis of gene-regulatory network changes related to *STAT3* Y640F mutation in those cell subpopulations is currently ongoing. Our study also demonstrates that cell sorting followed by scKinnex can be an effective strategy for studying the functional impact of rare CH mutations at the single cell resolution in relevant cell types.

#5214 The mutational landscape underlying the late effects of anthracyclines on tumor, blood, and heart genomes.

Mathepan Jeya Mahendralingam[1], Mehdi Layeghifard[1], Timmy Wen[1], Burcak Otlu[2], Seema Mital[1], Filio Billia[3], Adam Shlien[4]

[1]The Hospital for Sick Children, Toronto, ON, Canada,[2]Middle East Technical University, Ankara, Turkey,[3]Toronto General Hospital Research Institute, Toronto, ON, Canada,[4]Graduate Student, Dept. of Genetics & Genome Bio., The Hospital for Sick Children, Toronto, ON, Canada

Motivation: Anthracyclines, an essential chemotherapy, disproportionately contributes to several late effects burdening survivors of cancer, including cancer relapse, therapy-related blood cancers, and fatal cardiotoxicity. Despite decades of clinical use, the mechanisms underlying these late effects - particularly how anthracyclines damage the genome of neoplastic and non-neoplastic tissues (blood and heart) - remain poorly understood. A deeper understanding of the tissue-specific mutational outcomes of anthracyclines could yield promising biomarkers to improve survivorship care for survivors of cancer.

Methods: We assembled a cohort of untreated or anthracycline-treated tumor, blood, and heart samples. Tumors and blood were leveraged from childhood cancer patients enrolled in the SickKids Cancer Sequencing Program. Heart samples were obtained from cancer survivors who received anthracyclines and later developed severe cardiotoxicity that required a heart transplant. We sequenced the DNA of each tissue type to identify anthracycline-induced somatic mutations.

Results: Our initial results revealed minimal genome-wide mutational differences between anthracycline-treated versus untreated samples across all tissue types. We hypothesized that anthracyclines may cause localized mutagenesis in unique genomic topographies. Indeed, we found that anthracycline-treated tissues had a strong enrichment of somatic mutations in open chromatin of their respective cell of origin but differed based on the mutation type. Anthracycline-treated tumors had an enrichment of single nucleotide variants in promoters and introns, but depletion of deletions in exonic regions. However, leveraging matched blood samples from these cancer patients demonstrated that anthracycline-treated blood samples had an enrichment for deletions in open chromatin of various blood cell types. Despite the heart's non-proliferative capacity, anthracycline-treated hearts had a significant enrichment of insertion-deletions in fetal cardiomyocyte open chromatin and non-B DNA regions. Lastly, comparative analysis of the somatic mutational profiles of anthracycline-exposed hearts, tumors, and blood samples, we uncovered previously underappreciated tissue-specific mutational signatures.

Significance: This study is the first to characterize the tissue-specific genomic consequences of anthracyclines on tumors, blood, and heart. The early identification of high-risk patients will transform survivorship care, ensuring children with cancer do not merely survive their diagnosis - they thrive beyond it.

#5215 Metabolic and lipidomic changes in early asparaginase hepatotoxicity in mice.

Veronica Ruiz-Torres[1], Jennifer J. Chia[2], Michael D. Cohen[3], Jia Tan[3], Kevin J. Williams[4], Nedas Matulionis[4], Abby Krall[4], Heather R. Christofk[5], Etan Orgel[6], **Steven D. Mittelman**[7]

[1]UCLA Mattel Children's Hospital and Instituto de Investigacion, Desarrollo e Innovacion en Biotecnologia Sanitaria de Elche (IDiBE), Universitas Miguel Hernandez (UMH), Los Angeles, CA,[2]Department of Pathology and Laboratory Medicine, UCLA and Jonsson Comprehensive Cancer Center, University of California, Los Angeles, CA, Los Angeles, CA,[3]UCLA - University of California Los Angeles, Los Angeles, CA,[4]UCLA, Los Angeles, CA,[5]UCLA David Geffen School of Medicine, Los Angeles, CA,[6]Pediatric Hematology/Oncology, Children's Hospital Los Angeles, Los Angeles, CA,[7]UCLA Mattel Childrens Hospital, Los Angeles, CA

Asparaginase (ASNase) is an effective treatment for pediatric acute lymphoblastic leukemia but is limited by hepatotoxicity, particularly in obese patients. While ASNase has been shown to induce adipocyte lipolysis and hepatocyte integrated stress response, the mechanisms by which ASNase causes hepatosteatosis and hepatotoxicity remain unclear. We previously examined the effects of PEG-ASNase on livers in mice seven days after injection. However, by this timepoint, livers were severely steatotic. Therefore, to uncover early effects of ASNase, we treated obese and control 18-week-old male C57Bl6 mice with one IP dose of 3,000 IU/kg pegylated-ASNase and analyzed livers three days later. ASNase caused significant hepatosteatosis already 3 days after injection (n=6; Table). ASNase increased liver unsaturated triglycerides and decreased phosphatidylcholine and lysophosphatidylcholine. Metabolomics identified decreases in s-adenylmethionine (SAM), 5-Aminoimidazole-4-carboxamide ribonucleoside (AICAR), and glutathione to glutathione disulfide ratio (GSH:GSSG, Table), indicating oxidative stress. These lipidomic and metabolomic changes were more pronounced in obese mice. RNAseq identified lower expression of palatin-like phospholipase domain containing protein 3 (PNPLA3) after ASNase (-4.8 to -5.1 $\log_2$fold change, $p<0.001$). qPCR showed low PNPLA3 expression in obese compared to control vehicle livers ($p<0.001$) and confirmed substantial suppression after ASNase in both groups (Table). Our results show that within three days, ASNase induces hepatic steatosis, oxidative stress lower phosphatidylcholine levels and suppression of PNPLA3 expression. These effects appear to be magnified in obesity. Since phosphatidylcholine and PNPLA3 are known to be related to metabolic dysfunction associated steatotic liver disease (MASLD), these effects are likely contributory to ASNase hepatotoxicity. Further work is needed to fully understand the mechanisms of these changes.

Liver changes with ASNase treatment

#5216 Novel transdermal curcumin attenuates cisplatin induced neuropathy in a mouse model of breast cancer.

Yugal Goel[1], Carolina Mireles[1], Dahlia Ordaz[2], Kendall O'Daniel[1], Kristen A. Peterson[1], Naomi Lomeli[2], Reina Lomeli[1], Daniela A. Bota[2], Joel Friedman[3], Kalpna Gupta[1]

[1]Hematology/Oncology, Department of Medicine, University of California, Irvine, CA,[2]Department of Neurology, Department of Medicine, University of California, Irvine, CA,[3]Department of Microbiology and Immunology, Albert Einstein College of Medicine, Bronx, NY

Cisplatin-induced neuropathy remains a major challenge to treat. Cisplatin disrupts mitochondrial homeostasis and increases reactive oxygen species (ROS) contributing to neuronal injury. We examined the ability of curcumin to prevent CIPN because it has antioxidant and neuroprotective properties. However, a major challenge is the reduced absorption and bioavailability of oral and systemically administered curcumin. To address this challenge, we used a novel transdermal curcumin (TDC) preparation which is bioavailable in the blood and central nervous system after topical application to the abdomen of mice. We used a transgenic mouse model of breast cancer (C3TAg) which shows the evolutionary spectrum of human breast cancer and its isotype control FVB/N mice. At ~4 months of age female C3TAg mice develop palpable tumors and demonstrate mechanical, thermal and musculoskeletal hyperalgesia ($P<0.0001$ vs FVB/N). Mice were treated with vehicle or cisplatin (2.3 mg/kg/day i.p.) for two cycles of 5-days and 5 days of rest in the presence or absence of TDC/VAS-101 (0.1 mL) applied daily by rubbing on the abdomen of mice through the endpoint. Similar to cisplatin, TDC alone significantly reduced tumor weight ($P<0.05$ vs vehicle), and didn't decrease the anti-tumor efficacy of cisplatin. By day 5, cisplatin induced significant mechanical and cold hyperalgesia in both strains ($p<0.001$ vs vehicle and BL), and musculoskeletal hyperalgesia at day 16 in C3TAg mice ($P<0.001$ vs BL; $P<0.0001$ vs vehicle). TDC co-treatment significantly attenuated cisplatin induced hyperalgesia (mechanical and cold, $P<0.0001$ vs cisplatin) and prevented musculoskeletal hyperalgesia ($P<0.001$ vs cisplatin). Notably, in C3TAg mice, TDC alone significantly decreased constitutive mechanical ($P<0.001$ vs vehicle; $P<0.01$ vs BL) and cold hyperalgesia ($P<0.01$ vs vehicle). These changes in hyperalgesia were accompanied by a significant reduction in phospho-p38 mitogen-activated protein kinase (MAPK) in dorsal root ganglion (DRG) neurons in C3TAg mice co-treated with TDC and cisplatin compared to cisplatin treatment ($P<0.001$) suggesting the activation of pain signaling. Furthermore, in primary DRG neurons and HT22 hippocampal neuronal cell line in culture, cisplatin elevated ROS and caused mitochondrial depolarization ($P<0.0001$; $P<0.001$ vs vehicle), which was prevented by TDC ($P<0.0001$). In HT22 neurons, cisplatin increased calcium release and lowered subsequent metabolic activity and viability ($P<0.001$ vs. vehicle), which were significantly inhibited by TDC ($P<0.001$), indicating that TDC targets the pain generating Ca^{2+} release from neuronal cells. In conclusion, TDC alleviates cancer- and chemotherapy-related hyperalgesia via inhibition of p38 MAPK and oxidative stress, while restoring mitochondrial function and limiting tumor growth. Thus, the novel TDC has a translational potential for preventing CIPN.

#5217 Mast cell activation leads to cisplatin-induced peripheral neuropathy.

Carolina Mireles[1], Donovan A. Argueta[1], Raghda Fouda[1], Sonal Joshi[2], Daniela A. Bota[3], Kalpna Gupta[1]

[1]Medicine, University of California, Irvine, Irvine, CA,[2]Medicine, University of Minnesota, Minneapolis, MN,[3]Neurology, University of California, Irvine, Irvine, CA

Chemotherapy-induced peripheral neuropathy (CIPN) is a painful side effect of treating cancer with cisplatin. Cisplatin is a platinum-based chemotherapeutic that induces mast cell activation. Mast cells reside in close proximity of the epidermal layer, vasculature and nerve fibers in the skin. Tryptase and other noxious substances released by mast cells activate nociceptors via protease activated receptor -2 (PAR2) leading to pain. We hypothesized that cisplatin-induced mast cell activation leads to nerve injury and neuropathic pain. We used C57BL/6, wild-type (WT) and mast cell knockout (MC-KO) mice with a spontaneous c-kit "sash" mutation (Kit*W-sh*) on a C57BL/6 background. Male and female mice were treated with cisplatin (i.p., 2.3 mg/kg/day), for 5 days of treatment followed by 5 days of saline (i.p.) for 2 cycles; or pre-treated with 100 mg/kg/day imatinib, an inhibitor of c-Kit and mast cell activation. Mechanical, cold, and thermal hyperalgesia were assessed at regular intervals. At day 18, cisplatin-treated mice showed a significant increase in mechanical hyperalgesia ($p<0.001$), cold hyperalgesia ($p<0.05$), and heat hyperalgesia ($p<0.0001$) compared to vehicle-treated mice. There were no changes in WT mice treated with imatinib or imatinib with cisplatin or in MC-KO mice treated with cisplatin for mechanical or thermal hyperalgesia, suggesting the involvement of mast cells in CIPN. Dorsal skin sections were co-stained with histone H3 (mast cell traps), FcεR1 (mast cell marker), and NF200 (nerve bundles). Cisplatin-treated mice showed activated mast cells surrounding nerve bundles, causing the expulsion of dense traps of citrullinated histones and podia extending into nerve fibers, causing nerve damage. The vehicle-treated mice showed intact, undisturbed thick nerve bundles without mast cell activation. Compared to vehicle, cisplatin-treated WT mice showed a significant increase in the number of non-degranulating and degranulating mast cells in dorsal ($p<0.05$) and toe skin ($p<0.001$, $p<0.0001$, respectively). We found a significant increase in cutaneous chymase ($p<0.01$), and tryptase ($p<0.01$), and plasma chymase ($p<0.5$), and tryptase ($p<0.01$) levels in cisplatin-treated compared to vehicle-treated WT mice. Human mast cells, HMC1.2, were incubated with 2, 5, and 10 µg/ml cisplatin or vehicle for 10 and 70 min, followed by analysis of chymase and tryptase in the conditioned medium. At the lowest dose of 2 µg/ml, cisplatin significantly stimulated the time-dependent release of chymase and tryptase compared to vehicle ($p<0.01$ for both). Together, our data show the novel phenomenon of mast cell traps upon cisplatin treatment leading to nerve injury, while tryptase released from mast cells may activate PAR-2 leading to the painful symptoms of CIPN. We speculate that the cotreatment of cisplatin with imatinib or other mast cell stabilizers such as cromolyn may ameliorate the painful symptoms of CIPN.

#5218 Leveraging a PARP inhibitor as neuroprotection against chemotherapy induced cognitive impairments.

Dahlia A. Ordaz, Shashi Jain, Daniela A. Bota

Neurology, University of California Irvine, Irvine, CA

Platinum-based (Pt) chemotherapies are lifesaving for many cancers, yet they induce persistent DNA damage and neuroinflammation that can profoundly alter cognitive function, collectively known as chemotherapy-induced cognitive impairments (CICI). The molecular drivers of these long-lasting effects remain mostly unknown, but symptoms include impaired concentration, memory deficits, and declines in speech and motor function this suggesting significant hippocampal vulnerability. Cisplatin, a widely used Pt agent causes extensive DNA crosslinking and robust proinflammatory signaling. Emerging evidence implicates poly (ADP-ribose) polymerase 1 (PARP1) in this process; when persistently activated by cisplatin-induced DNA damage- PARP1 drives metabolic dysfunction, inflammatory amplification, and impaired neuronal repair. PARP1 inhibitors have shown neuroprotective effects in other neurodegenerative disorders, reducing neuroinflammation and delaying functional decline. We hypothesized that excessive PARP1 activation contributes significantly to cisplatin-induced hippocampal dysfunction, and that targeted PARP inhibition could mitigate these neurotoxic cascades and preserve neuronal health. To determine whether the PARP inhibitor niraparib acts as a neuroprotective or rescue agent, we evaluated multiple treatment windows in vitro using mouse neural stem cells (MNSCs) from C57BL/6 mice. Cells were exposed to cisplatin (IC_{50}: 0.4 µM) with niraparib (1 µM) administered pre-, post-, or concurrently. Niraparib significantly improved viability across all time points compared to cisplatin alone ($p<0.0001$). In primary hippocampal neurons (cisplatin IC_{50}: 0.6 µM), combination treatment markedly increased PSD95 puncta and dendritic branching ($p<0.0001$), indicating preserved synaptic structure. To ensure that niraparib's neuroprotection did not dimmish cisplatin's anticancer efficacy, we tested the same low-dose combination in ID8/MOSEC and SKOV3.ip1 (IC_{50}: 34.11 µM and IC_{50}: 13.5 µM) ovarian cancer cell lines. No increase in viability was observed relative to cisplatin alone, confirming that niraparib did not interfere with cisplatin cytotoxicity. Together, these findings suggest that niraparib mitigates cisplatin-induced neurotoxicity while maintaining anti-cancer activity. Our next phase will evaluate niraparib alongside clinically relevant cisplatin dosing in C57BL/6 mice to assess cognitive outcomes in vivo. This works aims to clarify the mechanisms underlying CICI and identify strategies to improve quality of life and survivorship patients undergoing treatment.

#5219 Systemic therapy and cardiovascular disease in adolescent and young adult breast cancer survivors.

Theresa H. M. Keegan[1], Candice A. M. Sauder[1], Ann M. Brunson[1], Renata Abrahao[1], Anne C. Kirchhoff[2], Eric Haupt[3], Mallory Casperson[4], Ted Wun[1], Chun R. Chao[3], Andrew B. Smitherman[5], Hazel B. Nichols[6], Jessica Chubak[7], Erin E. Hahn[3], Lawrence H. Kushi[8], Kathryn J. Ruddy[9]

[1]UC Davis Comprehensive Cancer Center, Sacramento, CA,[2]University of Utah, Salt Lake City, UT,[3]Kaiser Permanente Southern California, Pasadena, CA,[4]Cactus Cancer Society, Oakland, CA,[5]University of North Carolina Chapel Hill, Chapel Hill, NC,[6]University of North Carolina at Chapel Hill, Chapel Hill, NC,[7]Kaiser Permanente Washington Health Research Institute, Seattle, WA,[8]Kaiser Permanente Northern California, Oakland, CA,[9]Mayo Clinic Cancer Center, Rochester, MN

Breast cancer (BC) is the most common cancer among female adolescents and young adults (AYAs; 15-39 years). While advances in treatment have improved survival, cardiovascular disease (CVD) can result from systemic therapies, and CVD is a leading cause of death in AYA cancer survivors. AYAs with BC face nearly a four-fold increased risk of CVD compared to their peers without cancer. However, data on the effects of systemic treatment on CVD in this population remains limited. We estimated risk of CVD in AYAs diagnosed with invasive BC (2006-2020), who survived ≥2 years, and were diagnosed and treated in the Kaiser Permanente (KP) Northern and Southern California. Patients were categorized by receipt of anthracycline-, alkylating-, HER2-, platinum-, and taxane-based therapies within 2 years of diagnosis. We examined the cumulative incidence of CVD starting 2 years post-diagnosis and used Cox proportional hazards regression to determine factors associated with CVD. Among 3,071 AYAs, 35.1% were non-Hispanic (NH) White, 31.6% were Hispanic, 18.3% were NH Asian, and 8.2% were NH Black. Most received systemic therapy (90.6%), including anthracycline- and alkylator without HER2-targeted therapy (41.9%) and HER2-targeted therapy without anthracycline (20.9%). Fewer AYAs received a taxane and alkylator (13.0%) or anthracycline with alkylator and taxane along with a HER2-targeting agent (6.4%). Mean follow-up after cancer diagnosis was 7.2 years (range: 2.0-17.5). The 10-year cumulative incidence of CVD was highest among AYAs who received anthracycline/alkylator/taxane/HER2-targeting therapy (19.6%), intermediate for those with anthracycline/alkylator without HER2-targeting therapy (13.0%) and those who received HER2-targeted therapy without anthracycline (14.6%), and lowest for those who received taxane/alkylator (7.3%). In the multivariable model adjusted for demographic factors and radiation, compared to taxane/alkylator, anthracycline/alkylator/taxane/HER2-targeting therapy (hazard ratio (HR)=2.63, 95% confidence interval (CI) 1.56-4.43); anthracycline/alkylator without HER2-targeting therapy (HR=1.75, CI 1.13-2.71); and HER2-targeting therapy without anthracycline (HR=2.13, CI 1.11-4.09) were associated with an increased risk of CVD. CVD risk was similar for taxane/alkylator and no systemic therapy. Other factors associated with higher risk of CVD included NH Black race/ethnicity (HR=1.90, CI 1.32-2.73 vs. NH White) and public health insurance (HR=1.67, CI 1.00-2.78 vs private). This study identifies AYA BC survivors at higher risk of CVD based on treatment regimens received, with highest risks found for those receiving anthracycline/alkylator/taxane/HER2 treatment combinations. In addition, AYAs of Black race/ethnicity and those with public health insurance experienced more CVD, underscoring the need for targeted interventions to mitigate these disparities.

#5220 Association between metabolic syndrome and risk of second primary malignancy among patients with a history of cancer.

Pragati Advani[1], Nicolas F. Schlecht[2], Christina Crabtree-Ide[3], Sarah Mullin[4], Oday Karadsheh[5], Tessa Faye Flores[6], Han Yu[4], Kayla Catalfamo[4], Mary E. Reid[7], Sai Yendamuri[1]

[1]Department of Thoracic Surgery, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Cancer Prevention and Control, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Cancer Screening Outreach and Survivorship, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]Biostatistics and Bioinformatics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[5]Division of Endocrinology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[6]Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[7]Cancer Screening, Survivorship and Mentorship, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Prior studies have reported associations between modifiable comorbid conditions such as obesity, insulin resistance, hypertension, and hyperlipidemia (collectively known as Metabolic Syndrome [MetS]) and the risk of first primary cancer (FPC). However, the role of MetS on the risk of a second primary malignancy (SPM), a histologically and clonally distinct tumor that develops in a cancer survivor, is a heavily understudied area. Given that ~1 in 5 cancer survivors get diagnosed with a SPM in their lifetime, the purpose of this investigation was to understand the complex interplay between MetS, its individual components, other patient-related risk factors and risk of SPM.

Methods: The study cohort included 11,617 cancer patients who survived at least 12 months after their FPC diagnosis without a disease event (death, SPM or recurrence) and seen at the Roswell Park Comprehensive Cancer Center's dedicated survivorship clinic. Data on specific biomarkers to capture individual components of MetS was abstracted from electronic medical records. Patients were identified as having MetS if they had at least three of four MetS conditions (obesity, insulin resistance, hypertension, and hyperlipidemia). The association between MetS and risk of SPM was evaluated using Fine-Gray sub distribution hazard models adjusting for age, sex, smoking status, and TNM stage at FPC diagnosis.

Results: A total of 10,462 patients (90%) had data on ≥3 MetS conditions. Of those, 8,910 had fewer than three MetS conditions, while 1,552 had three or more. Overall, 4,963 patients developed SPMs ≥12 months after FPC diagnosis. In our multivariable analyses, we found that presence of MetS was independently associated with a significantly increased risk of SPM (Hazard Ratio [HR]=1.20; 95% Confidence Interval=1.01-1.40; P=0.043). Additionally, the risk of SPM increased significantly with number of MetS conditions (P<0.001). A majority of patients were obese (Body Mass Index ≥30 kg/m) (70%), and obesity was one of the primary conditions driving the increased SPM risk associated with MetS (HR=1.54; P=0.013). Among the other patient-related risk factors adjusted for, older age was associated with increased SPM risk (HR=1.02, P<0.001), whereas being a non-/former-smoker was associated with a decreased SPM risk compared to current smokers (HR=0.72, P<0.001, HR=0.83, P=0.019, respectively) as was having a higher stage of FPC (TNM III-IV vs. I-II) (HR=0.33, P<0.001).

Conclusion: MetS is significantly associated with the risk of developing SPMs among cancer survivors, with the risk of SPM increasing with number of MetS conditions, of which obesity was the strongest predictor. SPMs have emerged as an important concern for cancer survivors as treatment options for FPC have improved. Further research into the interrelationship between MetS conditions in cancer survivors and risk of SPM is therefore warranted.

#5221 Racial/ethnic disparities in risk of second primary malignancy among women in the Pathways Study of breast cancer survivors.

Pragati Gole Advani[1], Lia D'Addario[2], Cecile A. Laurent[2], Janise M. Roh[2], Marilyn L. Kwan[3], Theresa H. Keegan[4], Isaac J. Ergas[2], Scarlett L. Gomez[5], Han Yu[6], Christine B. Ambrosone[7], Lawrence H. Kushi[8]

[1]Department of Thoracic Surgery, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Division of Research, Kaiser Permanente Northern California, Pleasanton, CA,[3]Research Scientist, Div. of Research, Kaiser Permanente Northern California, Oakland, CA,[4]Hematology and Oncology, University of California Davis Comprehensive Cancer Center, Sacramento, CA,[5]Department of Epidemiology and Biostatistics, University of California, San Francisco, CA,[6]Biostatistics and Bioinformatics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[7]Department of Cancer Prevention and Control, Roswell Park Cancer Institute, Buffalo, NY,[8]Director of Scientific Policy, Division of Research, Kaiser Permanente, Oakland, CA

Background: Breast cancer (BC) survivors face a significantly increased risk of developing a second primary malignancy (SPM). While late-effects of cancer treatments contribute to SPM risk, shared behavioral and genetic factors that lead to the initial BC may also affect development of SPM. Previous studies have reported significant racial/ethnic disparities in BC incidence and mortality; however, few have examined disparities on the risk of SPM after BC. The aim of this study was to evaluate SPM risk across racial and ethnic groups of women with BC.

Methods: We examined risk of SPM in the Pathways Study, a prospective cohort study of 4,504 women with newly diagnosed, invasive BC between the years 2006 and 2013, at Kaiser Permanente Northern California (KPNC). Associations between self-identified race/ethnicity (categorized as non-Hispanic White [White], non-Hispanic Black [Black], non-Hispanic Asian American/Pacific Islander [AAPI] and Hispanic/Latino [H/L]) and SPM was evaluated using a univariate Fine-Gray sub distribution hazard model. Models were adjusted for age, stage, grade, hormone receptor status and treatment type. Due to small numbers, 92 American Indian/Alaska Native participants were excluded. Follow-up was from date of BC diagnosis to SPM, disenrollment from the KPNC health plan, death, or December 31, 2022, whichever came first.

Results: Of the 4,412 BC patients included in the study, 2,950 (66.9%) were White, 351 (8.0%) Black, 599 (13.6%) AAPI and 512 (11.6%) were H/L. Overall, 612 (13.6%) developed a SPM (median follow-up time=14.2 years; range=9.8-17.3). Among 521 patients with known SPM sites, breast (197, 37.8%), reproductive organs (74, 14.2%) and lung (48, 9.2%) were most common sites. In multivariable analyses, we found that compared with White women, H/L had a significantly decreased risk of developing a SPM (Hazard Ratio [HR]=0.64; 95% Confidence Interval [95%CI]=0.43-0.95). Although we also observed lower risk of SPM in AAPI and Black women (HRs of 0.71, 95%CI=0.49-1.02; and 0.79, 95%CI=0.51-1.22, respectively), these associations did not reach statistical significance. Besides race/ethnicity, age at BC diagnosis was also a significant predictor of SPM risk. Older age at diagnosis (60-69 and 70+ years) was associated with significantly increased SPM risk (HR_{60-69}=1.66, 95% CI=1.17-2.34 and HR_{70+}=2.37, 95% CI=1.64-3.41) compared with women diagnosed at <50 years.

Conclusion: We observed substantial disparities in SPM risk by race/ethnicity in the KPNC BC survivor's cohort, with H/L patients experiencing lower risk than Whites, whereas those in the older age group (60+ years) experienced higher risks. Further research to understand drivers of these racial, ethnic and age-related heterogeneity is warranted. Tailored surveillance strategies accounting for these characteristics may help reduce disparities among BC survivors.

#5222 Multifactorial risks for multiple primary cancers.

Johnathan Amsalem, Ying Liu, Aliya Khurram, Yelena Kemel, Andrew Marderstein, Mitul Waghmare, Semanti Mukherjee, Michael Conry, Vignesh Ravichandran, Saibaba Magunta, Ritika Kundra, Matthew Buas, Christopher Fong, Justin Jee, Michael Berger, Jian Carrot-Zhang, Zsofia Stadler, Venkatraman Seshan, Nikolaus Schultz, Kenneth Offit, Vijai Joseph

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Advances in cancer treatment and surveillance have increased survivorship, consequently elevating the risk of multiple primary cancers (MPC). However, distinguishing single primaries (SP) and MPC from recurrences or metastases remains a key barrier to studying gene and environmental drivers of second malignancies at scale.
Methods: We developed an automated algorithm to classify tumors as distinct primaries versus recurrences/metastases using IARC criteria, curated exceptions, and clinical and molecular data from Memorial Sloan Kettering's Cancer Data Science Initiative in 91,906 cancer patients. The classifier was validated against an expert-adjudicated dataset. Standardized incidence ratios (SIRs) were computed using age and sex-adjusted SEER-21 reference rates. To assess therapy-related risk, MPCs were stratified by exposure and analyzed for latency and survival. Inherited etiology based on rare germline pathogenic variants (PV) and cancer-specific polygenic risk scores (PRS) was assessed.
Results: The classifier achieved 93% concordance in distinguishing MPC from SP tumors. Applied to 91,906 patients in the MSK-IMPACT cohort, the algorithm identified 16,990 (18.5%) with MPC. Among metachronous cases, the median latency to a second primary was 8.2 years. Twenty-one cancer pairs showed elevated SIRs, including four matching known hereditary syndromes. Excess risk persisted in non-carriers of PV, suggesting polygenic or exposure-related causes. Treatment-related pairs included ovary-leukemia (SIR=5.7), breast-leukemia (SIR=4.0), breast-lung (SIR=2.9), breast-uterus (SIR=2.7), and male bladder-lung (SIR=3.3). Therapy exposure significantly modified risk and latency. Tamoxifen exposure conferred a 3.5-fold higher uterine cancer hazard with earlier onset yet improved survival. Among radiotherapy-exposed breast cancer survivors (n=3,482), higher chest irradiation correlated with a 4-fold secondary lung cancer hazard. Platinum exposure for ovarian cancer (n=2,811) increased Acute Myeloid leukemia (AML) hazard by 4.4-fold while alkylating agents for breast cancer (n=9,497) conferred a 2.9-fold AML risk, with shorter latency supporting treatment-related mechanisms. In male bladder cancer survivors, smokers had 9.1-fold increased hazard of subsequent lung cancer (n=1,316). Among smokers, older age at bladder cancer diagnosis predicted shorter latency to lung cancer. Increased SIR persisted in several cancer pairs, even after accounting for rare PV and PRS, suggesting undiscovered genetic and environmental factors and interactions.
Conclusions: Automated classification of MPC reveals genetic and exposure-related patterns in secondary cancer risk, timing, and survival. Ongoing work is integrating tumor genomics as well as polygenic risk scores to identify inherited and therapy-related drivers of cancer development and aggressiveness. (Supported by MSK Niehaus Center and BCRF).

#5223 Risk factors for early locoregional recurrence among young-onset breast cancer patients: Findings from a single institutional prospective dataset.

Kristen D. Brantley[1], Tonia Parker[2], Julie Vincuilla[3], Alyssa R. Martin[1], Elizabeth A. Mittendorf[3], Catherine Stever[1], Craig Snow[1], Rebecca A. Ottesen[1], Sara M. Tolaney[1], Tari A. King[4], Nancy U. Lin[1], Ann H. Partridge[1]

[1]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Breast Oncology Program, Dana-Farber Cancer Institute, Boston, MA,[3]Division of Breast Surgery, Brigham and Women's Hospital, Boston, MA,[4]Division of Breast Surgery, Emory University School of Medicine, Atlanta, GA

Introduction: While women diagnosed with breast cancer at young ages remain at risk of locoregional recurrence in long-term survivorship, predictors of risk remain unclear.
Methods: Women ≤40 years of age diagnosed with breast cancer for which they underwent surgery between January 2016 and April 2023 (N=1,088) were identified from a prospectively maintained database with detailed clinicopathologic and treatment information collected. The primary outcome was locoregional recurrence (≥6 months after primary BC diagnosis) without concurrent distant metastasis. Univariable associations between patient characteristics, primary tumor and treatment variables, and outcome were assessed via Fine and Gray subdistribution models, considering distant metastasis and death as competing risks. Backward selection of variables by AIC was performed using crr step in R to build a multivariable model predicting risk of locoregional recurrence. A sensitivity analysis was completed among individuals who did not have a mastectomy.
Results: A total of 1,053 women ≤40 years of age who did not experience a competing risk within the first 6 months were included. Mean age at first BC diagnosis was 35.3 (SD=4.2) years. Most patients were diagnosed with Stage 1 or 2 disease (77%) and had (HR)+/HER2- tumors (51%) [HR+/HER2+ (18%), HR-/HER2- (16%), HR-/HER2+ (10%), unknown HER2 (5%)]. Over a median of 3.6 (IQR=3.3-3.8) years of follow up, 34 women had a local or regional recurrence without concurrent metastasis. In univariable models, higher hazard of locoregional recurrence was associated with *in situ* disease (vs. invasive, p=0.05), smaller tumor size (p=0.005), lumpectomy (vs. mastectomy, p<0.001), non-receipt of endocrine therapy (ET) if HR+ (vs. HR+ w/ ET, p=0.009), and non-receipt of adjuvant chemotherapy (p=0.004). The multivariable model was tested among individuals with non-missing grade and stage (N=1037, events=34). Variables selected included stage (stage 3 vs. stage 1: aSHR=3.41, p=0.04), HR and ET combined (HR+ w/o ET vs. HR+ w/ET: aSHR=3.60, p=0.007), and surgery and RT combined (mastectomy only vs. lumpectomy+RT: aSHR=0.22, p=0.003; mastectomy+RT vs. lumpectomy+RT: aSHR=0.08, p<0.001). Other variables (age, race, BMI, known germline mutations, tumor grade, HER2 status, and adjuvant chemotherapy) were not selected. When restricted to individuals without mastectomy (N=405, events=26), receipt of ET emerged as the key predictor of locoregional recurrence (HR+ w/o ET vs. HR+ w/ET: aSHR=3.09, p=0.02).
Conclusion: In a modern cohort of young BC patients, receipt of ET for HR+ disease emerged as the most important factor in predicting hazard of early locoregional recurrences. This highlights the importance of recommending ET for young BC patients with HR+ disease, while finding ways to increase tolerability of ET for young BC patients to encourage adherence.

#5224 Shifting the gut microbiome to alleviate anti-cancer treatment-induced cardiovascular toxicity.

Zipporah Cornelius, Adam Wilson, Valerie Payne, Eleanor Cyrus, Kenysha YJ. Clear, David R. Soto-Pantoja, Katherine L. Cook

Cancer Biology, Wake Forest School of Medicine, Winston-Salem, NC

Introduction: Postmenopausal women with metastatic hormone receptor-positive (HR+) breast cancer are treated with either aromatase inhibitors (AIs), or Faslodex (fulvestrant, ICI), in combination with cyclin-dependent kinase 4/6 inhibitors (CDK4/6i). Despite the improvement in breast cancer outcomes, follow-up studies demonstrate the combination treatment is associated with cardiovascular toxicities. Previous studies have shown *Lactobacillus* probiotics supplementation shifts the gut microbiome, reduces breast tumorigenesis, and improved menopause-induced cardiometabolic syndrome. However, limited studies have investigated *Lactobacillus* probiotics on improving cardio-oncological outcomes.

Materials/Methods: Eight-week-old female BALB/c mice (n = 60) were placed on a Western diet. At ten weeks of age, syngeneic 4T1.2ER+ breast cancer cells (1×10^6 cells) were transplanted into the left inguinal mammary fat pad. Tumors were allowed to reach 100 mm^3 before initiating treatment, which was administered for 21 days. Mice were randomized by tumor volume into treatment groups: untreated control, probiotics (Probx; 2×10^8 CFU *Lactobacillus* spp.), Letrozole (AI)+Ribociclib (CDK4/6i), Faslodex (ICI)+CDK4/6i, Probx+AI+ CDK4/6i, or Probx+ICI + CDK4/6i. Tumor volume and weight were measured three times weekly using calipers. Vevo cardiac ultrasound was performed at the end of the study.

Results: In the 4T1.2ER+ breast cancer animal model, the addition of probiotics with the combinational therapeutics (AIs or ICI with CDK4/6i) significantly reduced tumor volume validating the potential of the probiotic to increase the anti-tumor efficacy of the therapeutics. Furthermore, our cardiac data displayed both ICI+CDK4/6i and AI+CDK4/6i-treated groups significantly increased diastolic dysfunction parameters (E'E and IVRT) that were reduced in groups supplemented with *Lactobacillus* probiotics. We show addition of *Lactobacillus* probiotics reduced cardiac fibrosis induced by endocrine-targeting therapies+CDK4/6i treatment. Additionally, we assessed the expression of pro-fibrotic TGF-β/Smad-dependent pathway. We also determined the impact of therapies on oxidative stress markers in cardiac tissue. Lastly, we performed untargeted metabolomics on plasma and proteomics on cardiac tissue to determine potential molecular mechanisms mediated by Lactobacillus probiotic interventions.

Conclusion: Our findings highlight CDK4/6i and endocrine-targeting therapies promote cardiac fibrotic deposition and result in diastolic dysfunction. However, *Lactobacillus* probiotic supplementation significantly improved treatment efficacy, ameliorated drug-induced cardiac dysfunction, and may regulate pro-fibrotic activity. Our data provides a feasible and accessible approach to address drug toxicity in the cardio-oncology setting.

#5225 Is endothelial dysfunction induced by aromatase inhibitors reversible after treatment?.

Mohamed Dabour[1], Adnan Shaaban[2], Jack Wolf[3], Daniel Duprez[4], Douglas Yee[5], Beshay Zordoky[1], Anne Blaes[6]

[1]University of Minnesota, College of Pharmacy, Minneapolis, MN,[2]Division of Cardiology, AdventHealth, Orlando, FL,[3]University of Minnesota, Minneapolis, MN,[4]Cardiovascular Division, University of Minnesota, Minneapolis, MN,[5]Division of Hematology, Oncology, and Transplantation, University of Minnesota, Minneapolis, MN,[6]Division of Hematology and Oncology, University of Minnesota, Minneapolis, MN

Introduction: Breast cancer accounts for about one-third of all new female cancer diagnoses and remains the second leading cause of cancer-related mortality among women. Aromatase inhibitors (AIs) are a standard therapy for postmenopausal women with hormone receptor-positive breast cancer, improving disease-free survival compared to tamoxifen. However, prolonged AI use is linked to increased cardiovascular (CV) risk, including hypertension, dyslipidemia, and endothelial dysfunction, likely due to estrogen depletion. We previously demonstrated early impairment in endothelial function during AI therapy. This study assessed whether AI-induced endothelial dysfunction is reversible after AI discontinuation.

Methods: Patients were recruited before or within one month of AI initiation (Pre/Early AI), at multiple time points during AI therapy, and after AI discontinuation (Post-AI) from two prospective studies: Aromatase Inhibitors and Vascular Health (AIVH) and Vascular Assessment in Breast Cancer Survivors Taking Aromatase Inhibitors (VABC). Patients with hypertension, hyperlipidemia, diabetes, or tobacco use were excluded. Vascular assessments, including the EndoPAT ratio for endothelial function and large and small artery elasticity indices for arterial stiffness, were conducted using the non-invasive EndoPAT 2000 and the HDI/PulseWave CR-2000 CV Profiling System. Lower EndoPAT ratios predict increased risk for future CV events and adverse outcomes. Plasma levels of estradiol, lipid profiles, interleukin-6 (IL-6), and tumor necrosis factor-alpha (TNF-α) were also measured. To evaluate the longitudinal changes in endothelial function during AI therapy, a model was fit using generalized estimating equations to assess how the EndoPAT ratio changed over time on AI.

Results: EndoPAT ratio, was significantly impaired during AI therapy compared to the Pre/Early AI (Pre/Early AI mean: 1.92; AI mean: 1.03; $p< 0.0001$). The EndoPAT ratio declined as early as 6 months on AI (model-based mean at 6 months: 1.19, p-value = 0.0097) and showed a progressive decline with increasing duration of AI use (e.g., model-based mean at 5 years on AI: 0.92; $p = 0.0003$). Importantly, after AI discontinuation, the EndoPAT ratio was only partially and not significantly restored (mean: 1.12) despite the full restoration of estradiol levels and the long post-treatment follow-up period (mean: 3.93 years; range: 1.53-5.34). No significant differences were observed in large and small artery elasticity, blood pressure, or lipid profiles between groups. Circulating IL-6 and TNF-α significantly decreased following AI discontinuation compared to during AI ($p < 0.05$).

Conclusion: AI therapy is associated with significant and progressive endothelial dysfunction, which does not fully recover after treatment cessation, highlighting the importance of CV monitoring in breast cancer patients receiving long-term AI therapy.

#5226 The role of pancreatic adenocarcinoma cancer-stromal interactions on cardiac structure and function.

Anna E. Gibson[1], Praveen Bhoopathi[1], Adolfo Mauro[1], Eleonora Mezzaroma[2], Vignesh Vudatha[2], Arunima Punjala[2], Vashti L. Bandy[1], Fadi Salloum[1], Jose G. Trevino[3]

[1]VCU Health, Richmond, VA,[2]Virginia Commonwealth University, Richmond, VA,[3]Div. of Surgical Oncology, VCU Massey Cancer Center, Richmond, VA

Pancreatic ductal adenocarcinoma (PDAC) has a dismal 5-year survival of <13% despite advances in therapy. Patients with PDAC also experience significantly lower cardiac-specific median survival compared to those with other GI cancers. While cancer cachexia impacts survival through skeletal muscle loss, the contribution of cardiac function to outcomes in PDAC is unknown. We aim to evaluate cardiac tissue structure and function in the most representative human preclinical model. This will provide insight into cardiac remodeling associated with PDAC and its clinical implication for possible interventions to improve overall survival. We implanted a PDAC patient-derived xenograft (PDX) into five NSG mice heterotopically and five NSG mice orthotopically, with five NSG mice receiving sham surgeries as controls. Tumor volumes were monitored weekly and once reaching 1.5cm, echocardiography and Millar catheterization were performed to assess cardiac structure and function between the three groups. Cardiac muscle, gastrocnemius muscle and tumors were collected for histologic and molecular analysis, including staining for structural assessment RNA sequencing to assess for changes associated with tumor burden, which is ongoing. An ANOVA and simple unpaired t-test were used with a significance value set at $p < 0.05$.Global longitudinal strain (GLS) measured by echocardiogram was within the normal values (-18 to -25%) across the groups, with no significant difference between the means of the sham (–20.3%), heterotopic (–21.2%), and orthotopic (–19.9%) groups. However, there is a slight trend showing a decline in GLS in the orthotopic group compared to the control group. The PV Loop data show a decline in left ventricular compliance (EDPVR) means in the heterotopic group (0.86) and orthotopic group (1.06) compared to the control group (0.22). The orthotopic group EDPVR mean is statistically different from the control group mean, with a simple unpaired t-test p-value of 0.02. The slight reduction in GLS observed in the orthotopic group relative to controls may indicate the presence of early systolic impairment in PDAC-bearing mice. Additionally, the results suggest that tumor burden is associated with impaired EDPVR, with the orthotopic group showing more stiffening as evidenced by a significantly elevated EDPVR when compared to the control group. This may indicate early diastolic dysfunction in the context of tumor related cardiac remodeling. We also anticipate that PDAC bearing mice will exhibit cardiac tissue remodeling, characterized by histological changes and transcriptional alterations linking cardiac decline and cancer progression. Recognizing early cardiac changes in patients with PDAC will help identify interventions that may ultimately improve treatment tolerance and clinical outcomes.

#5227 Clone wars: Evidence of clonal stability in a longitudinal prospective cohort of cancer survivors with serial NGS analysis.

Anmol Goyal, Akriti Jain, Salendra Singh, Ying Ni, Emmett Samsa, Kristen Sykes, Sujata Patil, Abhay Singh

Cleveland Clinic, Cleveland, OH

Introduction: Hematopoietic stem and progenitor cells with preleukemic mutations (mut^{n}s), collectively termed clonal hematopoiesis (CHIP) serve as the cellular origin of myeloid neoplasms (MN). While risk of MN development varies, its natural history and transformation potential remain poorly defined. We present findings from our ongoing 10-year CHIP protocol using serial NGS to monitor clonal evolution and MN in cancer survivors.

Methods: Retrospective analysis of 210 prospective pts from March 2020 to June 2024. Mut^{n}s were classified CHIP+ if they had a variant allele frequency (VAF) ≥2% (or ≥1% for *IDH1, IDH2,* and *JAK2*). Clonal evolution was evaluated by annual VAF changes adjusted for age-related increases (e.g. *DNMT3A* increases by ~2%/yr based on published data). Mut^{n}s were classified as slow (≤5%/yr: *DNMT3A, TET2, ASXL1*), intermediate (5-10%/yr: *TP53, PPM1D, IDH1/2, KRAS, NRAS, SF3B1*), or fast-growing (>10%/yr: *JAK2, SRSF2*). BPearson's Chi-squared, Fisher's exact, and Wilcoxon rank-sum tests were used.

Results: Of 210 pts, 42 (20%) had at least one CHIP+ mut^n. Median age was higher in CHIP+ vs. CHIP- pts (66 vs. 59 years, p<0.001). CHIP+ was not significantly associated with sex, race, family history, smoking, alcohol use, prior cancer types (e.g., breast, head and neck) or treatment (chemo, radiation, surgery). Of 487 samples, 56 had detectable somatic mut^{n}s. The most frequent mut^n were *DNMT3A* (n=27), *PPM1D* (n=10), and *TET2* (n=9). By expected growth kinetics, 37 (66%) mut^n were slow-growing, 12 (21.4%) intermediate, 2 (3.5%) fast-growing, and 4 (7.14%) of unknown kinetic category.

Beyond VAF-kinetics-based progression, 12 pts developed new mut^n in subsequent years - *DNMT3A (n=8), PPM1D (n=2).* Some later became undetectable, suggesting transient clones. In total, 12 pts (1 by VAF kinetics, 11 by new mut^n acquisition) clonally progressed over 5 years of this study (5.7%).

6 pts regressed by year 2, with gene mut^n VAFs becoming undetectable. These included mut^n in *PPM1D* (n=2), *CBL* (n=2), *TP53* (n=1), and *DNMT3A* (n=1). Three more pts regressed in year 3, and 1 in year 4. In all, 10 pts showed regression over 5 years (17.8%). Notably, 5 of 10 had received interventions for cardiac comorbidities. Overall, ~94% pts had clonal stability/regression. Slow-growing mut^{n}s - *DNMT3A* and *TET2* had median rates of 0.83% and 2.11%, (historical rates ≤5%). Intermediate mut^{n}s like *TP53* and *PPM1D* had median rates of 1.64% and -0.625%, below the expected 5-10% annual rise. *JAK2,* a fast-growing mut^n, also showed a lower rate of 0.19%.

Conclusion: Despite being a high-risk population due to prior solid malignancy and exposure to chemo/radiation, most pts in our five-year longitudinal study showed clonal stability. Even among those who progressed, VAF kinetics remained stable post-detection. CHIP's inflammatory link to cardiovascular disease suggests preventive cardiology may impact clonal behavior.

#5229 Hair loss in cancer patients receiving small molecule inhibitors: Evidence from clinical trials.

Isabella Kamholtz[1], Simonetta I. Gaumond[2], Joaquin Jimenez[3]

[1]Dr Phillip Frost Department of Dermatology and Cutaneous Surgery, University of Miami Miller School of Medicine, Miami, FL,[2]Department of Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL,[3]University of Miami Miller School of Medicine, Miami, FL

Alopecia remains one of the most common and distressing side effects of cancer therapy. While traditionally associated with cytotoxic chemotherapy, increasing evidence shows that small molecule inhibitors, targeting pathways such as FGFR, BRAF, and Src/ABL, can also induce clinically significant hair loss. However, incidence and severity patterns remain poorly characterized across small molecule inhibitor monotherapy. A scoping review of PubMed and Embase was conducted to identify clinical trials reporting alopecia in cancer patients treated with small molecule therapies. Eligible agents included kinase inhibitors (e.g., BRAF, KIT, FGFR, multikinase, Hedgehog pathway) and hormonal agents. Studies were excluded if they comprised preclinical studies, case reports, case series, reviews, or biologic therapies. Data on alopecia incidence, severity, and clinical presentation were extracted and synthesized qualitatively across small molecule drug classes. Eighteen clinical trials were included in this review, with alopecia incidence ranging from 9% to 63%. Hedgehog pathway inhibitors induced the highest overall rates, ranging from 20-30% with saridegib and glasdegib, and up to 63% with vismodegib. FGFR inhibitors (pemigatinib, infigratinib) and other kinase inhibitors (ripretinib, vemurafenib, sorafenib, AZD0424) demonstrated moderate rates (22-48%). Lower alopecia incidence was reported with aromatase inhibitors (anastrozole, lenostrozole) and the aurora B kinase inhibitor BI 811283, ranging from 9 to 21%. Across these monotherapies, alopecia was predominantly grade 1-2, with grade 3 alopecia or above occurring in less than 1% of patients. Although alopecia events were low-grade, their psychosocial impact remains significant. The higher incidences seen with Hedgehog inhibitors, compared with aromatase inhibitors, highlight how pathway-specific disruption of follicular signaling contributes to hair loss. Further research into the molecular mechanisms of these agents may help clinicians better anticipate and manage this side effect.

#5230 Alopecia in cancer immunotherapy: Incidence and patterns with monoclonal antibodies and antibody-drug conjugates.

Isabella Kamholtz[1], Simonetta I. Gaumond[2], Joaquin Jimenez[3]

[1]Dr Phillip Frost Department of Dermatology and Cutaneous Surgery, University of Miami Miller School of Medicine, Miami, FL,[2]Department of Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL,[3]University of Miami Miller School of Medicine, Miami, FL

The treatment landscape in oncology is evolving, with a shift toward more targeted approaches, including biologic immunomodulators. These agents are designed to minimize systemic toxicity and offer greater precision than traditional chemotherapy, yet they are not without adverse effects. Emerging data suggests that biologic therapies, such as antibody-drug conjugates, immune checkpoint inhibitors, and interferons, may induce alopecia in cancer patients. A scoping review was conducted using PubMed and Embase to identify clinical studies reporting alopecia in cancer patients treated with biologic therapies. Eligible agents included monoclonal antibodies such as antibody-drug conjugates (e.g., trastuzumab deruxtecan), immune checkpoint inhibitors (e.g., anti-PD-1, anti-PD-L1, anti-CTLA-4) and cytokine-targeting biologics (e.g., interferons, anti-IL therapies). Case reports, preclinical studies, and reviews were excluded. Data on alopecia incidence, severity, and clinical presentation were qualitatively synthesized across antibody classes. Nine clinical trials met inclusion criteria, encompassing 1,924 patients. Antibody-drug conjugates (ADCs), including datopotamab deruxtecan, trastuzumab deruxtecan, tisotumab vedotin, enfortumab vedotin, and disitamab vedotin, showed the highest rates of alopecia, ranging from 37% to 56% (predominantly grade 1-2). These ADCs, which delivered topoisomerase I or microtubule inhibitors, were used in patients with breast, cervical, urothelial, non-small cell lung cancer, and other solid tumors. In contrast, immune checkpoint inhibitors such as cemiplimab (anti-PD-1) and trastuzumab (anti-HER2) were rarely associated with alopecia (1-2.2% incidence, grade 1-2) in lung and breast cancer patients, respectively. Interferon alfa-2b, a type I interferon receptor agonist, demonstrated a time-dependent effect, with alopecia (grade 1-3) reported in 9% of melanoma patients receiving one month therapy versus 28% in those on one year regimens. The higher incidence of alopecia observed with ADCs likely reflects the effects of the chemotherapeutic payloads they deliver, rather than the antibody itself. In contrast, antibody-only and interferon therapies demonstrated substantially lower rates (1-28%). Recognizing these trends across biologic classes can help clinicians set patient expectations, guide counseling, and implement supportive measures for those experiencing hair loss throughout treatment.

#5231 GAS6 signaling links smoke-filled environments to increased invasion and communication in gastric and lung cancer models.

Emilee N. Humphreys, Derek Clarke, Kristen Noyes, Madeline Boyer, Juan Arroyo, Amber Gonda

Cell Biology and Physiology, Brigham Young University, Provo, UT

A key determinant of cancer severity is its invasion potential—the ability of malignant cells to spread from their primary site across a border and establish secondary tumors in distant tissues. One major environmental factor commonly seen in society today is the use of stimulants, such as nicotine and other nicotine-containing substances. Nicotine has been found to influence the pathogenesis of many different cancer types including lung cancer, gastric cancer, and many other types. In addition to the neurological effects, scientists have identified a gene that encodes for a gamma-carboxyglutamic acid-containing protein (known as GAS6) that has been found to play a role in cell proliferation. Additionally, GAS6 is found to have a role in the inflammation and immune effects that contribute to the invasion potential of cancer. To determine that GAS6 affects the cell invasion potential and increase cell proliferation, we altered the environment of gastric adenocarcinoma cells (AGS) and human alveolar basal epithelial adenocarcinoma cells (A549) by infusing smoke from both cigarettes and electronic cigarettes, found to increase GAS6 levels , as well as GAS6 specifically into the cell culture media. We then isolated exosomes, nano-sized extracellular vesicles containing proteins, lipids, and more derived from their parent cells. Exosomes have emerged as critical mediators in cancer progression due to their essential roles in tumor growth, immune modulation, and the metastatic process, making them a significant focus of current cancer research. In doing so, we found that GAS6 increased cell proliferation, exosome production, and invasion potential in gastric and cancer cell lines, suggesting the potential of GAS6 as a biomarker for invasive potential in cancer cell types.

#5235 Real world prediction and biological characterization of sotorasib sensitivity using multimodal AI and liquid biopsy genomic inputs.

Maayan Baron, Felicia Kuperwaser, Sepideh Foroutan, Sunil Kumar, Dillon Tracy, Kevin Freisen, Brandon Funkhouser, Zong Miao, Nathaniel Tann, Fahad Khan, Sean Klei, Jordan Wolinsky, Taylor Wood, Jean Michel Rouly, Nick Lee, Ripple Khera, Anshu Jain, Jeff Sherman, **Emily A. Vucic**

Zephyr AI, McLean, VA

Background: KRAS G12C inhibitors such as sotorasib have expanded options for NSCLC, but clinical benefit is variable and no validated biomarkers beyond the KRAS G12C mutation exist. Reported resistance mechanisms include MAPK reactivation, co-occurring alterations, lineage plasticity, and TME programs. Liquid biopsy is widely used for treatment selection— including Guardant360 CDx, the FDA-approved test for sotorasib—motivating computational approaches that operate on standard clinical assays. AIM-Bx is a multimodal, biologically interpretable AI model that predicts small-molecule response from routine inputs and outputs drug-response predictions, Vulnerability Networks (predicted CRISPR perturbation sensitivities), and reconstructed expression profiles. We evaluated whether AIM-Bx could predict real-world sotorasib benefit using commercial liquid biopsy data.
Methods: NSCLC patients with KRAS G12C mutations treated with sotorasib (n = 39) were identified using Guardant360 CDx liquid biopsy linked to outcomes (rwOS, rwPFS) from Optum® Market Clarity. ctDNA profiling within 24 months prior to treatment was required. AIM-Bx inputs included mutation and copy-number alterations from the 74-gene panel, limited clinical features, and drug-specific structural embeddings. For each patient, AIM-Bx generated a sensitivity prediction, a Vulnerability Network, and a reconstructed expression profile. Performance was assessed using Kaplan-Meier analysis and Cox regression; available clinical covariates were evaluated as confounders.
Results: AIM-Bx significantly stratified patients by benefit. Predicted-sensitive patients showed longer rw-PFS (median 14 vs. 4 months; $p < 0.05$) and rw-OS (14 vs. 7 months; $p < 0.05$). In Cox analyses, KRAS mutation category, histology, sex, and age > 65 were not significantly associated with outcomes. Biological interpretation revealed distinct features: predicted-sensitive tumors showed enriched KRAS/RAS-effector signaling, GEFs, CCND1-linked cell-cycle programs, and metabolic pathways including OXPHOS, HIF, and YAP/TAZ. Predicted non-responders displayed more heterogeneous dependencies and were enriched for downregulation of RAS-pathway programs and upregulation of EMT- and NOTCH-associated signatures.
Conclusions: This retrospective study demonstrates the feasibility of predicting sotorasib benefit directly from liquid biopsy NGS using a multimodal AI model. AIM-Bx identifies biological programs beyond KRAS mutation status that may influence therapeutic sensitivity, suggesting hypotheses for vulnerability-based patient selection and potential combination strategies. Because AIM-Bx operates on routinely available inputs—including the FDA-approved CDx assay used for sotorasib eligibility—it may support future prospective evaluation without new assays.

#5236 Updated exploratory biomarker analysis of cadonilimab plus regorafenib as second-line or later therapy in advanced hepatocellular carcinoma: Identification of Bola3 as a potential predictive biomarker.

Yang Liu[1], Jin Zhang[1], Qi Qi[2], Dandan Wu[1], **Linze Xu**[1], Yueguo Li[3], Huikai Li[2]

[1]Department of Hepatobiliary Cancer, Liver Cancer Center, Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin, China,[2]Department of Hepatobiliary and Pancreatic Oncology, Tianjin Cancer Hospital Airport Hospital, Tianjin, China,[3]Department of Laboratory, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Tianjin Key Laboratory of Digestive Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Cent, Tianjin, China

Background: Cadonilimab, a first-in-class bispecific antibody targeting PD-1 and CTLA-4, in combination with regorafenib, a multikinase inhibitor approved for second-line treatment of hepatocellular carcinoma (HCC), has demonstrated promising antitumor activity and manageable safety in heavily pretreated patients with advanced HCC (aHCC). We previously reported the updated clinical outcomes at the 2025 AACR Annual Meeting (Abstract #CT172, NCT05644379). Here, we present updated findings from an exploratory biomarker analysis focusing on the potential predictive role of BOLA3 in treatment response.

Methods: Paired plasma samples were collected before and during treatment for cell-free RNA sequencing (cfRNA-seq) to evaluate transcriptional dynamics. Differential expression analysis was performed using DESeq2 (FDR ≤ 0.10), and Hallmark GSEA was applied to assess mitochondrial and immune-related pathway changes. ELISA quantified soluble PD-1 and CTLA-4 at baseline and early on-treatment, calculating individual values. In a prespecified patient subset, baseline tumor tissues underwent semi-quantitative BOLA3 immunohistochemistry (IHC). Multiplex immunofluorescence (mIF) was performed for BOLA3, TOMM20, PD-L1, CD8α, and DAPI, enabling cell-level quantification and comparison of tumor versus peritumoral spatial distribution.

Results: ELISA detected stable levels of soluble PD-1 and CTLA-4 pre- and on-treatment, with early individual dynamics observed; however, these levels did not correlate with treatment response. cfRNA-seq revealed decreased BOLA3 in the PR patient and increased BOLA3 in the PD patient after treatment. Pathway analysis indicated PD-associated enrichment of mitochondrial signaling and weaker inflammatory response, whereas PR showed the opposite trend. Baseline BOLA3 IHC aligned with transcriptomic findings: higher BOLA3 expression was observed in patients with disease progression versus disease control, maintaining directional association when analyzed as a continuous variable. Preliminary mIF suggested that responders exhibited lower BOLA3/TOMM20 and higher PD-L1/CD8, while progressors showed the reverse phenotype.

Conclusions: Integrated exploratory analyses nominate BOLA3 as a candidate outcome-associated biomarker and support a model in which responders exhibit a mitochondria-low, inflamed-high phenotype. These findings provide early, complementary evidence that BOLA3-related features may inform patient stratification, with further validation underway. Research Sponsor: The Joint Funds of the Natural Science Foundation of Tianjin (No.25JCLZJC00120).

#5237 The significant co-expression of claudin-3(CLDN3) and B7-H3(CD276) as a potential biomarker for targeted therapy in neuroendocrine carcinomas.

Ji-Hye Nam[1], Ju-Yeon Kim[1], Jae Choi[2], Minjung Sung[3], Jae Hwan Kang[4], Hobin Yang[5], Yoon-la Choi[6], Young Kee Shin[7]

[1]Logone Bio-Convergence Research Foundation, Seoul, Korea, Republic of,[2]R&D Center, ABION Inc., Seoul, Korea, Republic of,[3]Laboratory of Molecular and Digital Pathology for Theranostics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[4]Department of Health Sciences and Technology, SAIHST, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[5]College of Pharmacy, Kyungsung University, Busan, Korea, Republic of,[6]Department of Pathology and Translational Genomics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[7]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Scie, Seoul National University, Seoul, Korea, Republic of

Despite the elevated mortality rate associated with neuroendocrine carcinomas (SCLC and LCNEC; large cell neuroendocrine carcinomas), the development of novel therapeutic targets has been limited by the predominance of non-targetable driver mutations. Consequently, the identification of viable therapeutic targets has become increasingly important, with proteins such as Claudin-3 (CLDN3) and B7-H3 emerging as promising candidates for targeted therapy. CLDN3, a key component of tight junctions in epithelial and endothelial cells, is frequently dysregulated in various cancers. Although CLDN3 is also present in normal tissues, its enhanced surface accessibility in tumor cells highlights its potential as a therapeutic target. Recent studies have demonstrated that CLDN3 is highly expressed in most neuroendocrine neoplasms, and its positivity has been linked to poor prognosis in clear cell renal cell carcinoma. Similarly, B7-H3 has gained attention as a promising target in neuroendocrine tumors, particularly SCLC. The high expression of B7-H3 is consistent across molecular subtypes in SCLC, supporting its relevance for protein-level characterization and the development of novel therapeutic strategies. In this context, the purpose of the present study was to evaluate CLDN3 and B7-H3 as therapeutic target biomarkers using a validated multiplex immunohistochemistry (IHC) platform. A total of 94 cases of formalin-fixed, paraffin-embedded tissues obtained from surgical resection or biopsy were retrospectively collected. All cases were diagnosed as neuroendocrine carcinoma, including SCLC, LCNEC, or combined neuroendocrine carcinoma. A tyramide signal amplification-based 7-plex IHC assay panel has been developed for the evaluation of therapeutic target biomarkers. The expression levels of CLDN3 were elicited by two different methods: single IHC and multiplex IHC assay. These were analysed with a high sensitivity of 93.3% and an area under the curve (AUC) of 0.964 under the receiver operating characteristic (ROC) curve. Among the four targeted biomarkers analyzed using a validated 7-plex IHC method, CLDN3 and B7-H3 were identified as potential therapeutic target biomarkers for neuroendocrine carcinomas. This validated multiplex IHC panel serves as a useful platform for supporting therapeutic development in neuroendocrine carcinomas.

#5238 Retrospective study for clinical biomarkers to guide post-EGFR-TKI treatment strategies in EGFR-mutant NSCLC.

Background: In patients with non-small cell lung cancer (NSCLC) harboring epidermal growth factor receptor (EGFR) mutations, the combination of atezolizumab, bevacizumab, carboplatin, and paclitaxel (ABCP) has demonstrated encouraging efficacy following prior treatment with EGFR tyrosine kinase inhibitors (EGFR-TKIs). However, real-world evidence comparing ABCP with standard platinum-based chemotherapy remains unclear.
Methods: We conducted a multicenter retrospective study including 408 patients with advanced or recurrent EGFR-mutant NSCLC who received either platinum-based chemotherapy (with or without bevacizumab) or ABCP after EGFR-TKI treatment at 20 institutions in Japan. Clinical outcomes were evaluated using propensity score matching to adjust for baseline characteristics.
Results: After propensity score matching, there were no significant differences in progression-free survival (PFS) or overall survival (OS) between the Chemo/Chemo + BEV and ABCP groups (median PFS, $p = 0.44$; median OS, $p = 0.84$). In the subgroup of patients with programmed death-ligand 1 (PD-L1) expression ≥50%, the ABCP group exhibited significantly longer PFS compared with the Chemo/Chemo + BEV group ($p = 0.02$).
Conclusions: Among patients with EGFR-mutant NSCLC previously treated with EGFR-TKIs, those with high PD-L1 expression may derive greater benefit from ABCP therapy compared with platinum-based chemotherapy, suggesting that ABCP could represent a more promising treatment option in this subgroup.

#5239 Biomarker dynamics in the completed phase I study of DT-9081: An analysis of *ex vivo* cytokine stimulation, urinary PGEM, and tumoral biomarkers in advanced solid tumors.

Thomas Maurin[1], Lola Lecru[1], Antoine Mousson[1], Orphee Blanchard[1], Malaury Schappler[1], Christophe Le Tourneau[2], Zahra Castel-Ajgal[3], Jean-Pascal Machiels[4], Rachel Galot[4], Nuria Kotecki[5], Christiane Jungels[5], Jean-Pierre Delord[6], Iphigenie Korakis[6], Camille Dietsch[1], Luc Baron[1], Maria Jesus Garcia Leon[1], Edith Steinberg[1], Katia Saulnier[1], Samira El-Farouk[1], Calire Jouffroy-Zeller[1], Anne Quesnel[1], Carolina Duarte[1], Abdelkrim Taamma[1], Anne-Laure Blayo[1], Thibaut Brugat[1], Nathalie Lenne[1], Jean-Marie Cuillerot[1], **Stephan Schann**[1]

[1]Domain Therapeutics, Illkirch, France,[2]Institut Gustave Roussy, Villejuif, France,[3]Institut Curie, Paris, France,[4]Cliniques Universitaires Saint-Luc, Louvain, Belgium,[5]Institut Jules Bordet, Bruxelles, Belgium,[6]Institut Universiatire du Cancer de Toulouse, Toulouse, France

Background: DT-9081, a novel EP4R-antagonist, recently completed its Phase I study in patients with advanced solid tumors (NCT05582850). In addition to establishing safety, tolerability, and pharmacodynamic signals, integrated biomarker analyses were conducted to gain insights into its mechanism of action and therapeutic potential.

Objectives: This abstract presents a comprehensive evaluation of multiple biomarkers from the completed Phase I study of DT-9081. The analyses include:Ex vivo cytokine stimulation examining IL-10, IL-5, MIP-1α, and TNFα concentrationUrinary prostaglandin E metabolite (tetranor-PGEM) levels, measured by LC-MS/MS Tumor tissue expression of mPGES and COX2 enzymes, as well as PD-L1, assessed pre- and post-treatmentPlasma cytokine levels

Methods: Peripheral blood mononuclear cells from subjects were isolated and subjected to *ex vivo* cytokine stimulation, with subsequent quantification of IL-10, IL-5, MIP-1α, and TNFα using validated immunoassays. Urine samples were analyzed for PGEM levels by LC-MS/MS. Tumor biopsies, collected at baseline and after treatment, were examined by multiplex immunofluorescence to determine the expression levels of mPGES, COX2, and PD-L1. Additionally, plasma samples were collected at serial timepoints, and cytokine concentrations were measured.

Results:Biomarker assessments revealed that DT-9081 treatment modulated immune responses as evidenced by restauration of *ex vivo* cytokine release profiles (IL-10, IL-5, MIP-1α, and TNFα). Increase in urinary PGEM levels was consistent with modulation of the prostaglandin pathway. Tumor tissue analyses demonstrated alterations in the expression of mPGES and COX2 enzymes following treatment, and changes in PD-L1 expression were observed, suggesting potential implications for combination with immune checkpoint inhibitors. Plasma cytokine data provided additional evidence of

systemic immunomodulation. Integrated analysis suggest that DT-9081 favors a Th1, antitumoral immune response.

Conclusions: The integrated biomarker evaluation from the completed Phase I study of DT-9081 offers valuable insights into its immunomodulatory effects in advanced solid tumors. The combined analysis of *ex vivo* cytokine stimulation, urinary PGEM levels, and tumor biomarker expression (mPGES, COX2, and PD-L1) supports the engagement of multiple pathways involved in the anti-tumoral response after treatement with DT-9081. These results lay the groundwork for further clinical development and potential combination strategies in immuno-oncology.

Keywords: DT-9081, EP4R antagonist, small molecule, solid tumors, immuno-oncology, phase I/ trial, biomarker, NCT05582850.

#5240 A CXCL10/11 and CCL19 duplex chromogenic assay complements PD-L1 immunohistochemistry in non-small cell lung cancer.

Alexander L. Tang[1], Liad Elmelech[1], William L. Tang[1], Maxwell Spurrell[2], Maria Ganci[3], Yiwen He[4], Catherine B. Meador[3], Christopher S. Nabel[3], Jessica J. Lin[3], Mari Mino-Kenudson[3], Nir Hacohen[5], Justin F. Gainor[3], Jonathan H. Chen[6]

[1]Broad Institute, Cambridge, MA,[2]Yale University, New Haven, CT,[3]Massachusetts General Hospital, Boston, MA,[4]Northwestern University, Chicago, IL,[5]Massachusetts General Hospital/Broad Institute, Boston, MA,[6]Northwestern University/Broad Institute, Chicago, IL

Purpose: PD-1 blockade is a standard first-line treatment for advanced non-small cell lung cancer (NSCLC). PD-L1 tumor proportion score (TPS) by immunohistochemistry (IHC), a key predictor of response to PD-1 blockade, is imperfect, underscoring the need for additional predictive biomarkers. Immunity hubs and stem-immunity hubs have been shown to correlate with response, but these have been mainly characterized through spatial transcriptomics, and multiplexed immunofluorescence, which are not readily scalable to clinical workflows. We developed a clinically compatible chromogenic duplex assay that quantifies these multicellular immune networks using the chemokines CXCL10/11 and CCL19 to predict response.
Experimental Design: We stained tissue from 65 metastatic NSCLC tumors for CXCL10/11 and CCL19 using chromogenic in situ hybridization (cISH). We created three separate scoring approaches, 1. percentage of CXCL10/11+ cells, 2. percentage of CXCL10/11+ tiles (immunity hubs), and 3. percentage of CXCL10/11+ and CCL19+ tiles (stem-immunity hubs), in order to stratify patients and determine whether respective scoring approaches were predictive of response. Objective response rates were assessed using RECIST v1.1.
Results: 57 patients with NSCLC treated with single-agent PD-(L)1 inhibitors were identified and samples were procured before treatment. The majority of patients (56%) had a PD-L1 TPS of 50% or above. Across the cohort, the overall response rate was 37% and the median progression free survival of 119 days. The PD-L1 TPS (>50%) had 71.4% sensitivity, 56.3% specificity, 50% positive predictive value, and 75% negative predictive value (Fisher's exact test: p=0.089). The stem-immunity hub scoring approach with cISH combined with PD-L1 TPS had 100% sensitivity, 53% specificity, 58% positive predictive value, and 100% negative predictive value (Fisher's exact test: p<0.0001). Notably, the stem-immunity cISH scoring approach identified all responders who were not previously classified as PD-L1 TPS high.
Conclusions: cISH detection of stem-immunity hubs using CXCL10/11 and CCL19 complements PD-L1 IHC. Integration of this spatial biomarker with PD-L1 testing may refine immunotherapy treatment strategies in NSCLC.

#5241 Personalized fusion measurable residual disease detection in acute myeloid leukemia using droplet digital PCR.

Asra Noor[1], Xiaojuan Cao[2], Maggie J. Cox[2], Francesca Ferraro[2], David H. Spencer[2], Stephen T. Oh[2], Grant A. Challen[2], Andrew L. Young[2]

[1]Washington University In St. Louis, Saint Louis, MO,[2]Washington University in St. Louis, Saint Louis, MO

Acute myeloid leukemia (AML) is an aggressive cancer, of which 30-40% are driven by gene fusions. Effective therapy selection often requires accurate assessment of disease burden—termed measurable residual disease (MRD) detection. MRD is typically assessed with multiparameter flow cytometry (MPFC) or RT-qPCR, which are limited by accuracy, cost, turnaround time or applicability. MPFC has a reported limit of detection of 1:1,000 to 1:10,000, but 20% of MRD negative patients by MPFC relapse within weeks to months. MPFC requires an invasive bone marrow biopsy, so testing is infrequent and critical treatment decisions are often based on a single measurement (e.g. end of induction). In fusion driven AML, the fusion itself is a robust biomarker of disease. Unfortunately, only the most common gene fusions (e.g. BCR-ABL and PML-RARA) have RT-qPCR-based MRD assays. But there are hundreds of gene fusions that drive AML that do not have a molecular MRD assay. To address this limitation, we have developed personalized gene fusion MRD detection using droplet digital PCR (ddPCR). We utilize diagnostic sequencing to define a patient's unique fusion, design their personalized MRD assay and validate the assay to a limit of detection of 1 in 100,000. We applied this approach in a cohort of 20 AML and acute lymphoblastic leukemia (ALL) patients harboring diverse gene fusions including *KMT2A* (with partners including *AF9, AF10*, *AF4, ELL, ENL*, *AF6*, *AF1q*), *RUNX::RUNX1T1*, *PAX5::MLLT3, EP300::KMT2A* and *BCR::ABL*. We focused on *KMT2A* fusions due to their heterogeneity and clinical need for molecular MRD given the development of Menin inhibitors. Using personalized ddPCR assays, we analyzed 155 patient specimens (median 4.5, range 1-24 per participant) collected at diagnosis, throughout treatment, and during surveillance from bone marrow aspirates (n=31) and peripheral blood samples (n=124). We identified disease recurrence in eight patients by ddPCR 38-103 days before standard of care MPFC-based testing or clinical relapse. In our study, every patient with increasing fusion burden relapsed and every patient who remained in long-term remission cleared their fusion. Fusion transcript abundance was similar in peripheral blood and bone marrow specimens obtained concurrently, demonstrating non-invasive peripheral blood sampling may be able to replace bone marrow biopsy for fusion-based MRD detection. In conclusion, personalized gene fusion MRD testing by ddPCR is highly sensitive and specific for disease recurrence. This approach is ideal for real-time clinical decision-making given the low limit of detection, non-invasive testing from the peripheral blood, and rapid turnaround time (1-2 days). Future work is focused on building trials to assess clinical utility. Long-term this has the potential to improve treatment selection and drive better patient outcomes.

#5242 Down regulation of HPV 16 and NF-KB and upregulation of gigaxonin and immune markers in APG-157 treated head and neck cancer: A phase 2A clinical investigation.

Saroj K. Basak[1], Bhavani Shankara Gowda[2], Manasvini Kala[2], Jin Zhong[3], Trent Su[4], Daniel Sanghoon Shin[5], Marilene B. Wang[6], **Eri S. Srivatsan**[2]

[1]Surgery, VAGLAHS, Los Angeles, CA,[2]Surgery, VAGLAHS/David Geffen School of Medicine at UCLA, Los Angeles, CA,[3]Pathology, VAGLAHS/David Geffen School of Medicine at UCLA, Los Angeles, CA,[4]Pathology, David Geffen School of Medicine at UCLA, Los Angeles, CA,[5]Medicine, Michael E Debakey VA Medical Center, Houston, TX,[6]Head and Neck Surgery, VAGLAHS/David Geffen School of Medicine at UCLA, Los Angeles, CA

Background: Persistent HPV 16 expression and NF-κB activation drive inflammation and immune suppression in head and neck squamous cell carcinoma (HNSCC). APG-157 is a proprietary oral botanical immunomodulator with anti-inflammatory and tumor-microenvironment (TME) reprogramming activity. This Phase 2A clinical study evaluated its molecular and immunologic effects in patients with HNSCC.

Methods: Fourteen patients received APG-157 (200 mg TID for 4 weeks) under IRB approval at VAGLAHS. Paired pre- and post-treatment saliva and tumor biopsies (n=24) were analyzed for HPV 16 E7 integration and expression by qPCR/RT-qPCR, and for expression of p16, NF-κB, gigaxonin, E-cadherin, and Snail by molecular and immunohistochemical assays. Paired PBMCs from 5 patients underwent single-cell RNA sequencing (scRNA-seq) to characterize systemic immune modulation.

Results: PCR identified presence of HPV 16 E7 sequences in 2/7 OC and 4/7 OPC (total of 6/14) pre-APG-157 samples. Expression of p16 by IHC showed p16 positivity in 4/7 OC and 7/7 OPC samples. APG-157 treatment reduced HPV 16 E7 integration and expression levels in 4 of 6 HPV 16 E7 pre-APG-157 positive samples in the saliva and tumor, confirming a direct antiviral effect. NF-κB expression decreased concordantly, whereas gigaxonin (a cytoskeletal regulator linked to NF-κB degradation) increased, suggesting restoration of proteasomal regulation and suppression of inflammatory signaling. Expression of epithelial integrity markers (E-cadherin↑, Snail↓) improved, indicating a shift towards a less invasive phenotype. Notably, salivary HPV 16 detection correlated with tumor expression, validating saliva as a non-invasive biomarker for HPV-driven diseases. scRNA-seq of PBMCs revealed post-treatment expansion of activated B cells and effector T-cell clusters consistent with systemic immune activation. These findings indicate that APG-157 exerts coordinated local and systemic immunomodulatory effects by simultaneously suppressing oncogenic viral and inflammatory pathways and enhancing lymphocyte function.

Conclusions: APG-157 demonstrates dual antiviral and immunoregulatory activity in HNSCC, suppressing HPV 16 and NF-κB while promoting immune activation and epithelial restoration. APG-157 uniquely enhances gigaxonin-mediated NF-κB regulation and downregulates HPV 16 E7 expression, defining a new therapeutic axis for oral immunomodulation. These data support the continued development of APG-157 as an oral immunotherapy for HPV-driven and immunologically “cold” head and neck cancers, both as a monotherapy and as a combinatorial agent with chemo-radiation or immune checkpoint inhibitors.

#5243 Profiling of peripheral LAG-3+CD8+ T cells: An immune cell population associated with immunotherapy resistance.

Ariel Kogan Zajdman[1], Cory A. Brennick[1], Kayla J. Foster[1], Sydney A. Riddick[1], Tatiana Shcheglova[1], Matthew Adamow[2], Jasme Lee[3], Ronglai Shen[3], Katherine S. Panageas[3], Xiyu Peng[4], Margaret K. Callahan[1]

[1]Department of Immunology and Neag Comprehensive Cancer Center, University of Connecticut School of Medicine, Farmington, CT,[2]Immune Monitoring Facility, Memorial Sloan Kettering Cancer Center, New York City, NY,[3]Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York City, NY,[4]Department of Statistics, Texas A&M University, College Station, TX

Despite the success of immune checkpoint blockade (ICB), many patients fail to respond, highlighting a need for predictive biomarkers. We previously identified pre-treatment differences in peripheral blood mononuclear cells (PBMCs) from patients treated with ICB using an 11-color flow cytometry panel. These differences grouped patients into 3 distinct immune phenotypes, or immunotypes (Shen et al Sci Trans Med, 2021). Immunotype 1 (IT-1) was characterized by higher numbers of LAG-3^{+}CD8^{+} T cells and associated with poor response and overall survival (OS) after anti-PD-1 therapy. IT-2 was characterized by lower LAG-3^{+}CD8^{+} and better outcomes; IT-3, by the presence of additional cell populations not present in IT-1 or IT-2. Here, we aim to establish a deeper understanding of LAG-3^{+}CD8^{+} T cells, the defining cell population of the IT-1 phenotype.

We analyzed banked pre-treatment PBMC samples from patients with melanoma (n=30) and urothelial carcinoma (UC, n=48) previously assessed to have IT-1, IT-2, or IT-3, using a 28-color spectral flow cytometry assay, with single-cell RNA sequencing of a representative IT-1 sample.

Compared with LAG-3^{-}CD8^{+} cells, LAG-3^{+}CD8^{+} T cells displayed higher expression of cytotoxic, terminal differentiation markers (GzmB, CD57, T-bet, Eomes) and lower expression of homing (CCR4, CXCR5, CCR7) and costimulatory molecules (ICOS, CD27, CD28, CD127). Consistent with our flow cytometry data, transcriptomic profiling revealed upregulation of GZMB, B3GAT1, TBX21, and EOMES, as well as downregulation of CCR4, CCR7, ICOS, CD27, CD28, and IL7R. These findings were further validated in an independent melanoma scRNA-seq dataset (Huuhtanen et al J. Clin. Invest, 2023). Finally, we evaluated samples from patients with the IT-2/3 phenotypes, confirming this pattern to be unique to IT-1.

Our results reveal a distinct phenotypic signature defining LAG-3^{+}CD8^{+} T cells, the hallmark of IT-1. These findings refine the definition of IT-1, highlight immune-phenotype differences between the IT-1 and IT-2/3, and suggest mechanisms, such as altered costimulation and trafficking, that underlie ICB resistance.

#5244 Genomic HLA class I allelic imbalance undermines enduring immunotherapy response in advanced non small cell lung cancer.

Yiting Dong#[1], Shun Wang#[2], Wenbin Li*[2], Zhijie Wang*[1], Jie Wang*[1]

[1]Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[2]Department of Pathology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Human leukocyte antigen class I (HLA-I) molecules are essential for neoantigen presentation and T cell recognition, yet the clinical significance of allelic imbalance within HLA-I genes (HLA-AI) in immune checkpoint inhibitor (ICI) therapy remains undefined. Here, we established haplotype-specific, coverage-based (cHLA-AI) and plasma-derived (bHLA-AI) models compatible with routine clinical sequencing, based on 292 fully heterozygous patients with paired tumor and blood samples from the phase III CHOICE-01 trial. Tumor mutational burden (TMB)-low tumors with HLA-AI derived no benefit from first-line immunochemotherapy, whereas all other patients achieved significant survival gains (mOS 16.53 vs. 29.57 months, HR = 2.29, 95% CI 1.59-3.30, p < 0.001,interaction P = 0.019; mPFS 5.59 vs. 9.92 months, HR = 2.02, 95% CI 1.43-2.90, p < 0.001, interaction P = 0.016). These findings were validated in the RATIONALE-304 and RATIONALE-307 trials and independent real-world cohorts, and extended to cfDNA (bHLA-AI), where integrated tissue-plasma assessment delineated four therapeutic trajectories. Incorporating cHLA-AI with pathology, PD-L1 and TMB significantly improved 2-year OS prediction (DeLong's P = 0.003). Multi-omic profiling linked cHLA-AI to active DNA damage response signaling, high TMB, elevated intratumor heterogeneity (ITH-high), pronounced chromosomal instability (CIN-high), immune-cold microenvironments, and failure of on-treatment TCR expansion, while longitudinal sampling revealed its late, branching emergence under immune pressure. Pan-cancer profiling (N = 5,989) demonstrated consistent associations with TMB and proliferative activity (Ki-67 index). Collectively, these results establish cHLA-AI as a pivotal biomarker bridging genomic instability, immune evasion, and therapeutic outcome, providing a framework for stratified immunotherapy in non-small cell lung cancer and beyond.

#5246 Immune profiling and targetable biomarkers in NSCLC: Toward rational design of CKI-based combinations.

Rania Gaspo[1], Alexandra Jean[2], Renaud Burrer[2], Jerome Sallette[3], Amanda Finan-Marchi[2], Marie Gerus-Durand[2]

[1]Cerba Research, Laval, QC, Canada,[2]Cerba Research, Montpellier, France,[3]Cerba Research, Paris, France

Background: Actionable mutations guide first-line targeted therapies in non-small cell lung cancer (NSCLC), yet resistance frequently develops. Immune checkpoint inhibitors (CKIs) improve outcomes, and recent evidence suggests potential synergy with targeted agents for rare NSCLC biomarkers. This study explored correlations between actionable targets and immune contexture to inform combination strategies.

Methods: Twenty-five NSCLC FFPE resected specimens were analyzed by immunohistochemistry for PD-L1 (clone 22C3), ALK, ROS1, HER2, EGFR, pan-TRK, BRAF, c-Met, and MEK1. Two in-house multiplex panels (PD-1/PD-L1/CD3/CD8 and CD3/CD8/FoxP3) assessed PD-1, PD-L1, and T-cell subsets. Chromogenic simplex IHC stains were scored by a thoracic oncology pathologist per clinical standards or literature; immune populations were quantified in tumor and non-tumor regions using Halo image analysis.

Results: Targetable protein expression largely reflected published prevalence. PD-L1 correlated positively with c-Met, MEK1, and EGFR, but not HER2. HER2 expressions were associated with increased helper and cytotoxic T cells, supporting limited benefit of PD-1/PD-L1 blockade in HER2-positive NSCLC while suggesting alternative immunomodulators. MEK1+ tumor cells showed strong correlation with infiltrating immune cells and PD-1 expression, reinforcing MEK1 inhibition as a promising approach to counter immune evasion. No correlation was observed between PD-L1 and PD-1+ cytotoxic T cells, highlighting the need to assess both PD-1 and PD-L1 for optimal CKI efficacy.

Conclusions: Immune profiling within the tumor microenvironment may complement actionable target testing and guide rational design of CKI-based combination therapies in NSCLC.

#5247 Integrating immunohistochemistry for biomarker detection in NSCLC: A step toward precision therapy.

Rania Gaspo[1], Renaud Burrer[2], Jerome Sallette[3], Amanda Finan-Marchi[2], Marie Gerus-Durand[4]

[1]Cerba Research, Laval, QC, Canada,[2]Cerba Research, Montpellier, France,[3]Cerba Research, Paris, France,[4]Cerba Research Histalim, Montpellier, France

Background: Advances in NSCLC treatment increasingly rely on biomarker-driven strategies, with targeted therapies outperforming cytotoxic agents. However, rapid progress in precision medicine poses challenges for translating biomarker recommendations into clinical practice. Accurate characterization is essential to ensure timely and appropriate therapy selection.
Methods: We analyzed 30 adult primary NSCLC FFPE tumors (n=25 unknown biomarker status; n=5 known biomarker controls) using immunohistochemistry (IHC) for actionable and exploratory targets: ALK, ROS1, BRAF, EGFR, c-Met, pan-TRK, HER2, and MEK1. Biomarker frequency, intensity, and specificity were assessed, and correlations between expression patterns were investigated. All slides were scored by a thoracic oncology pathologist per clinical standards or literature.
Results: Among five known controls, concordance was observed for HER2, c-Met, and EGFR, while discrepancies occurred for ALK (focal staining requiring reflex FISH/next-generation sequencing (NGS) confirmation) and BRAF. Controls were originally identified by NGS, which is generally more sensitive than IHC. Negative staining for BRAF was consistent with a non-V600E mutation in the control specimen. Correlation trends were noted between c-Met and MEK1, and between EGFR and HER2. Frequencies of ALK, c-Met, and HER2 aligned with literature, while EGFR and MEK1 appeared higher, suggesting IHC may serve as an initial screen before reflex NGS testing. No positivity was observed for BRAF, ROS1, or pan-TRK, consistent with their rarity in NSCLC.
Conclusions: IHC remains a valuable screening tool for detecting most actionable biomarkers, particularly in settings lacking NGS capabilities. Its integration into routine pathology may optimize patient selection for targeted therapies and clinical trials.

#5248 Single-cell multi-omics reveals co-mutation of *TP53* and epigenetic gene driving myeloid transformation in B-ALL following CAR-T therapy.

Shuang Zhao[1], Yanjing Tang[2], Meng Su[2], Bowen Cui[1], Rongrong Fan[1], Han Wang[1], Liu Yang[2], Lixia Ding[2], Ronghua Wang[1], Huiying Sun[1], Ying Zhong[1], Qiaoqiao Shi[1], Yuxuan Guo[1], Lili Song[2], Xinyu Wan[2], Tianyi Wang[2], Jing Yang[2], Benshang Li[2], Yu Liu[1]

[1]Pediatric Translational Medicine Institute, Shanghai Children's Medical Center, School of Medicine, Shanghai Jiao Tong University, shanghai, China,[2]National Health Committee Key Laboratory of Pediatric Hematology & Oncology, Shanghai Children's Medical Center, School of Medicine, Shanghai Jiao Tong University, shanghai, China

Lineage switch is a rare phenomenon, occurring in less than 1% of leukemia cases. However, with the advent of CD19-targeted immunotherapies such as CAR-T and blinatumomab, it has emerged as a significant complication. Identifying patients at high risk for lineage switch prior to immunotherapy is critical, yet predictive biomarkers remain unclear. In a cohort of 65 B-ALL patients who relapsed after CAR-T therapy, we identified one case of myeloid lineage switch with unknown mechanism. Transcriptomic sequencing across three timepoints: pre-CAR-T, first CAR-T relapse, and second CAR-T relapse (myeloid switch) confirmed a consistent driver gene profile (*ETV6*::*RUNX1* fusion, *NF1*, *WNK1* and *CIC* mutations), ruling out a secondary malignancy. To elucidate the mechanism, we performed single-cell DNA-protein sequencing (Mission Bio Tapestri platform) and single-cell RNA sequencing (10x Genomics platform). At first CAR-T relapse, we identified five distinct clones. After CAR-T therapy, three clones were undetectable, whereas two clones persisted and underwent rapid expansion, concomitant with myeloid lineage switch. Notably, both of these clones harboring mutations in *TP53* and epigenetic regulator *STAG2*. We further discovered a distinct population of lineage-infidelity cells (CD117+CD71+ CD34+CD38+CD56+CD19dim) that co-express myeloid and B-lineage markers, representing a heightened plasticity that may facilitate CAR-T evasion. Projection of our scRNA-seq data onto a normal developmental atlas showed pre-CAR-T sample from the lineage-switch case encompassed a broad spectrum, whereas control case of CD19-negative relapse due to *CD19* mutation were confined to the pro-B/pre-B stages. Based on these findings, we hypothesized that co-mutation of *TP53* and epigenetic regulators predisposes cells to lineage switch. To validate this finding, we performed a longitudinal flow cytometry analysis. Patients were stratified into two groups: a co-mutation group (n=4) harboring *TP53* and epigenetic gene mutations, and a control group (n=2) lacking these mutations. The co-mutation group exhibited significant downregulation of the B-lineage marker CD19 and concurrent upregulation of the myeloid marker following CAR-T treatment. In contrast, the control group showed no notable changes. In conclusion, our data suggests that co-mutations in *TP53* and epigenetic genes enhance plasticity in B-ALL. Under the selective pressure of CD19 CAR-T therapy, subclones harboring these mutations are preferentially expanded, leading to lineage switch. We propose monitoring myeloid marker expressing subclones in B-ALL patients carrying co-mutations in *TP53* and epigenetic genes during immunotherapy is important to improve their prognosis.

#5249 Longitudinal liquid biopsy identifies an early predictive biomarker of immune checkpoint blockade response in head and neck squamous cell carcinoma.

Robert Saddawi-Konefka[1], Binbin Wang[2], Lauren M. Clubb[3], Cynthia Tang[4], Di Wu[5], Sumit Mukherjee[6], Sahil Sahni[7], Saugato Rahman Dhruba[6], Sumeet Patiyal[6], Chi-Ping Day[8], Parth Anil Desai[9], Clint Tanner Allen[10], Kun Wang[11], J. Silvio Gutkind[12], Eytan Ruppin[13]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]NIH-NCI, Bethesda, MD,[3]Pharmacology, UC San Diego, San Diego, CA,[4]Stanford, Palo Alto, CA,[5]University of Illinois at Urbana-Champaign, Champaign, IL,[6]National Cancer Institute - Cancer Data Science Laboratory (CDSL), Bethesda, MD,[7]MSKCC, New York, NY,[8]NCI, Bethesda, MD,[9]Fox Chase Cancer Center, Philadelphia, PA,[10]National Insts. of Health, Bethesda, MD,[11]University of Illinois Urbana-Champaign, Urbana, IL,[12]UC San Diego, San Diego, CA,[13]National Cancer Institute, Rockville, MD

Immune checkpoint inhibition (ICI) has emerged as a pivotal therapy for head and neck squamous cell carcinoma (HNSCC), yet the development of predictive biomarkers to guide its clinical application has significantly lagged. Current biomarkers such as tumor mutational burden and PD-L1 fail to capture systemic immune dynamics that may better reflect host immune fitness and the coordinated immune response driving durable tumor control. We hypothesized that early treatment-induced changes in circulating immune repertoires could provide a dynamic, non-invasive readout of ICI responsiveness. Using a time-resolved, multi-omic approach in a murine HNSCC model, we characterized peripheral immune responses to anti-PD-1 across defined pre- and on-treatment timepoints. Single-cell transcriptomics and paired T/B cell receptor analyses revealed an early and robust, but transient, expansion of effector memory T and B cell repertoires in responders, preceding tumor regression. Temporal changes in effector T and B cell abundance, clonality, and gene expression strongly predicted immunotherapy response, with early on-treatment timepoints emerging as the optimal window for assessing treatment response. These dynamic immune features informed a composite transcriptional signature, Liquid Biomarker for Immuno-Oncology (LiBIO), derived from effector T and B cell programs that accurately predicts ICI response in independent human HNSCC cohorts and outperforms contemporary biomarkers such as PD-L1 combined positive score and tumor mutational burden. LiBIO further generalizes to melanoma, non-small cell lung cancer, and breast cancer without retraining, suggesting that early peripheral immune dynamics capture conserved features of effective antitumor immunity across cancer types. Collectively, these findings support the premise that antitumor immune responses initiated regionally in tumor-draining lymphatics give rise to transient, stereotyped peripheral immune responses that precede successful primary tumor control, and that peripheral immune events can serve as a foundation for liquid biomarker discovery. This innovative approach represents a paradigm shift from static, tumor-centric biomarkers to dynamic monitoring of host immunity, enabling real-time treatment adaptation during the critical early window of immune activation.

#5250 Method development and workflow optimization of a CTC-based biomarker assay to predict response to CDK4/6 inhibitors in HR+/HER2- breast cancer.

Mantasha Tabassum[1], Shivaani Suresh Kanna[1], Wangjia Cao[1], Suneel Kumar[2], Mothaffar F. Rimawi[2], George Miles[2], Meghana Trivedi[1]

[1]University of Houston, College of Pharmacy, Houston, TX,[2]Baylor College of Medicine, Houston, TX

Introduction: CDK4/6 inhibitors (CDK4/6i) are the standard of care for hormone receptor-positive/HER2-negative breast cancer (HR+/HER2- BC). Yet resistance is common and often characterized by loss or dysfunction of the Retinoblastoma (Rb) protein or inadequate suppression of its phosphorylation. Circulating tumor cells (CTCs) offer minimally invasive means to monitor tumor biology. Here, we describe the analytical performance of a multiplex immunofluorescence (mIF) assay integrated with an image-analysis pipeline to quantify Rb and phospho-Rb (pRb) expression on CTCs and evaluation of cell recovery efficiency by CTCeptor, a microfluidic CTC isolation platform.

Methods: The mIF assay utilized antibodies against Rb (AF595), pRb (AF488), cytokeratin (CK, AF647), and CD45 (AF555), with DAPI for nuclear staining. Antibody specificity and minimal non-specific binding were verified using single-marker staining and isotype controls. Assay performance (sensitivity, specificity, signal-to-noise ratio (SNR), and dynamic range) was evaluated using positive (MCF7, T47D) and negative (T47D-PalboR, MDA-MB-468, or leukocytes) control cell lines. Healthy donor leukocytes were spiked with control cell lines to simulate patient-derived matrices. Various blocking buffers, wash buffers, and cell attachment methods were compared. Cell recovery was evaluated after processing blood spiked with MCF7 cells using CTCeptor followed by staining with anti-CK-AF647, anti-CD45-AF555, and DAPI in HyPICC chamber. Imaging was performed on Leica STED SP8 or Nikon N-STORM microscopes. Quantitative analysis of mean fluorescence intensity (MFI) was conducted using FIJI, and statistical analysis was performed using GraphPad Prism v10.

Results: The optimized mIF with integrated image analysis pipeline demonstrated high analytical sensitivity (Rb: 84%, pRb: 83%) and specificity (Rb: 96%, pRb: 100%). SNRs were 5 for Rb and 50 for pRb, with dynamic range exceeding two log units for both markers. Single-marker staining and isotype controls confirmed antibody specificity and minimal non-specific binding. Based on comparative analyses, 1% BSA + 0.5% goat serum was selected as the blocking buffer, and Triton-based buffer as the wash buffer. RareCyte® cell attachment method yielded superior cell retention (79%). Recovery rate after processing the spiked blood with MCF7 cells using CTCeptor followed by staining in HyPICC chamber ranged from 40-60%.

Conclusion: We have developed and optimized a quantitative mIF assay and image analysis workflow to detect Rb and pRb expression on CTCs. Future studies will assess the predictive biomarker utility of the assay by measuring Rb and pRb dynamics on CTCs in metastatic HR+/HER2- BC patients before and after CDK4/6i therapy.

#5251 Precise description of metabolomic states using NGS uncover new potential biomarkers of response to TKIs in ccRCC.

Alina Tarasova, Stanislav Kurpe, Andrey Kravets, **Nikita Kotlov**

BostonGene Corporation, Waltham, MA

Renal cell carcinomas (RCC) undergo extensive metabolic reprogramming, which support tumor progression and therapy resistance. Understanding these changes is essential for identifying resistance mechanisms and therapeutic targets. While RNA sequencing enables estimation of metabolic changes, current gene expression-based metabolomic signatures often lack specificity and include unrelated or conflicting genes. Here, we combine transcriptomic and metabolomic data to create refined metabolic signatures for glycolysis (Glyc), the kynurenine pathway of tryptophan catabolism (Trp), and the urea cycle (UC), which may inform prediction of tyrosine kinase inhibitors (TKIs) response in patients with clear cell RCC (ccRCC).

To develop metabolic signatures, an initial gene pool was assembled by merging unique genes from existing metabolomic signatures in MSigDB (v2024.1) database. This gene list was refined using part of BostonGene ccRCC metacohort (701 samples), by filtering them based on technical and biological criteria: (i) median expression ≥ 2 TPM; (ii) positive Spearman cross-correlation among genes in the signature; and (iii) confirmed biological relevance through correlation with paired metabolomic and NGS data, retaining only genes with $r > 0.2$ to target metabolites (like L-lactic acid, kynurenine, or urea). Clinical significance of signatures, focusing on associations with TKI response, was assessed using data from the metacohort with available therapy response (853 samples). Overall, TME and survival analysis was assessed on the whole metacohort (n = 4,583).

All metabolic signatures demonstrated statistically significant differences between tumor and normal samples ($P < 0.001$), with higher scores for Glyc and Trp signatures in tumors and lower scores for the UC signature, consistent with previously reported findings. Notably, our signatures showed the strongest differentiation between tumor and normal samples compared to publicly available signatures. The metabolic signatures were also significantly associated with tumor microenvironment (TME) subtypes ($P < 0.001$) (Bagaev et al., 2021, *Cancer Cell*). Higher Trp signature scores were observed in immune-enriched subtype, whereas lower Trp and higher UC signature scores were found in the immune-depleted subtype. Survival analysis revealed that low UC scores correlated with worse overall survival ($P < 0.001$, MW U-test). In TKI-treated patients, complete responders exhibited higher Trp scores, while those with progressive disease had lower UC scores, which were associated with significantly poorer overall survival.

We developed metabolism-based gene signatures and demonstrated that the Trp and UC signatures strongly correlate with TKI response and patient survival. The UC and Trp pathways represent novel candidate biomarkers for future patient stratification aimed at overcoming TKI resistance in RCC.

#5252 Computational modeling of comprehensive genomic profiling to predict chemo-immunotherapy benefit in early stage NSCLC.

Prashant Nair[1], Kishor Promod[1], Ansu Kumar[1], Swati Khandelwal[1], Ambreen Ambreen[1], Susheel George[1], Mamatha Patil[1], Deepak Lala[1], Ashokraja Bala[1], Veena Balakrishnan[1], Shweta Kapoor[1], Drew Watson[1], **James Wingrove**[1], Tejas Patil[2]

[1]Cellworks Group, Inc., South San Francisco, CA,[2]University of Colorado Anschutz Medical Campus, Aurora, CO

Background: Immune checkpoint inhibition (ICI), alone and in combination with chemotherapy (ICI+C), has transformed the treatment landscape for non-small cell lung cancer (NSCLC). We have previously reported results from the myCare-040 study[1], where we validated an algorithm capable of distinguishing advanced NSCLC patients with favorable ICI+C benefit from those with no benefit. To understand whether the underlying molecular mechanisms used by the algorithm are conserved across disease stages, we have evaluated the algorithm in a cohort of patients with early stage NSCLC receiving adjuvant ICI or ICI + C.

Design: The ΔTRI algorithm uses Cellworks' computational model of a patient's tumor genomics to predict biomarker changes related to disease progression and potential benefit from ICI+C therapy. The previously validated ΔTRI and clinical threshold (16) were evaluated in 51 non-squamous, early stage NSCLC patients (Stage I=20, Stage II=12, Stage IIIA=19) receiving adjuvant ICI or ICI+C ,with complete clinical and genomic information (Foundation One CDx) derived from the nationwide (US-based) de-identified ConcertAI Genomics360 database.

Results: Patients in the ΔTRI High Benefit Group (ΔTRI ≥ 16, n = 11), had an incremental benefit in median OS of 19.4 months with the addition of chemotherapy to ICI (logrank $p = 0.057$, median OS ICI = 7 months vs ICI+C = 26.6 months). In contrast, patients in the ΔTRI No Benefit Group (ΔTRI < 16, n = 40) showed no improvement in OS when receiving ICI+C (logrank $p = 0.84$, median OS ICI = 13 months vs ICI+C = 9 months). A likelihood ratio test of interaction between the linear ΔTRI and treatment (ICI versus ICI+C) was significant (LR $p = 0.038$). Cut-point optimization for the early stage population (ΔTRI= 9) improved the logrank statistics in the High Benefit Group (ΔTRI ≥ 9; logrank $p = 0.003$).

Conclusions: Although developed and validated in patients with advanced NSCLC, the ΔTRI also predicted incremental chemotherapy benefit in an real-world cohort of patients with early stage NSCLC receiving adjuvant ICI or ICI+C. Further work is needed to understand how these observations could be translated into clinical use.

Uhm[9], Rachael A. Vaubel[2], Sani H. Kizilbash[4]

[1]Comprehensive Cancer Center, Mayo Clinic, Rochester, MN,[2]Department of Laboratory and Pathology Medicine, Mayo Clinic, Rochester, MN,[3]Department of Neurological Surgery, Mayo Clinic, Rochester, MN,[4]Department of Oncology, Mayo Clinic, Rochester, MN,[5]Department of Oncology, Mayo Clinic, Phoenix, AZ,[6]Department of Neurology, Mayo Clinic, Jacksonville, FL,[7]Department of Radiology, Mayo Clinic, Rochester, MN,[8]Department of Neurology, Mayo Clinic, Phoenix, AZ,[9]Department of Neurology, Mayo Clinic, Rochester, MN

Background: Pembrolizumab has been increasingly used off label for recurrent gliomas, yet biomarkers predicting response are poorly defined. Gliomas exhibit substantial molecular heterogeneity across Glioblastoma, IDH-wildtype (GBM), Astrocytoma, IDH-Mutant (A-IDHm), and Oligodendroglioma, 1p/19q co-deleted (OLIGO), which may influence immunotherapy efficacy. This study aimed to identify molecular predictors of progression-free survival (PFS) in recurrent glioma patients treated with pembrolizumab.
Methods: Adults ≥18 years with recurrent glioma receiving ≥2 cycles of pembrolizumab between 2014 - 2024 were retrospectively identified across Mayo Clinic. Next-generation sequencing (NGS) reports were reviewed and archival tumor tissue resected prior to pembrolizumab initiation was analyzed when available. Comprehensive molecular profiling was performed using the Mayo Clinic Solid Tumor Panel which employs the Illumina Tru-Sight Oncology 500 High-Throughput NGS assay. Progression was assessed using RANO 2.0 criteria. Genomic alterations (clinically relevant sequences and/or copy-number variants) were evaluated using the Kaplan-Meier method, with differences in PFS compared using the log-rank test.
Results: Thirty-three patients were included [median (range) age: 44.0 (21-76) years; 63.6% male]. The interval between tumor tissue sampling and pembrolizumab initiation was 9.9 (0.9-176.1) months, and median treatment duration was 2.8 (1.4-10.4) months. Median PFS for the overall cohort was 2.4 (0.8-15.2) months, and median overall survival from pembrolizumab initiation was 6.9 (0.9-48.2) months. Patients with OLIGO (n=8) had a longer PFS [4.6 (1.9-15.2) months] than either A-IDHm [n=11; PFS 2.1 (1.1-4.4) months] or GBM [n=14; PFS 2.3 (0.8-9.2) months]. Within OLIGO, CDKN2A/B heterozygous deletion (n=3) predicted a shorter PFS (3.9 vs 10.9 months; p=0.0462), while in A-IDHm, FANC mutation (n=2) was associated with a longer PFS (4.17 vs 1.61 months; p=0.0224). No significant associations with PFS were observed for other altered genes or pathways evaluated, including but not limited to Tumor Mutational Burden, EGFR, RB1, TP53, FUBP1, NF 1 or 2, PTEN, PDGFRA, PIK3CA, PIK3R1, CDK4, KRAS, MLH1, MLH2, MSH6 genomic alterations or CDKN2A/B homozygous deletion (all p>0.05).
Conclusions: Pembrolizumab shows limited overall efficacy in recurrent gliomas, however, exploratory analyses identified several subtype-specific genomic alterations that may correlate with PFS. These hypothesis-generating findings highlight the potential influence of underlying tumor biology on immunotherapy response and warrant further validation in larger, prospective cohorts.

#5254 Copy number amplification of PSG is associated with poor survival in female lung adenocarcinoma patients.

Jung Hun Oh, Yingjie Zhu, Himangi Srivastava, Leyla Ebrahimpour, Rena Elkin, Larry Norton, Nadeem Riaz, Joseph O. Deasy

Memorial Sloan Kettering Cancer Center, New York, NY

Pregnancy-specific glycoproteins (PSGs) play a pivotal role in establishing and maintaining maternal immune tolerance during pregnancy, preventing fetal rejection through targeted modulation of innate and adaptive immune responses. In our previous work, we found that elevated tumor mRNA expression of PSG genes was associated with worse overall survival in lung cancer, with a significantly stronger effect observed in female patients. Based on this finding, we hypothesized that PSG copy number alterations (CNAs) show a similar sex-dependent effect on survival in lung cancer. We assessed the sex-specific impact of PSG CNAs using two lung adenocarcinoma (LUAD) cohorts: The Cancer Genome Atlas (TCGA) LUAD cohort (269 females, 234 males) and the Memorial Sloan Kettering Cancer Center (MSK)-IMPACT LUAD cohort (2,450 females, 1,413 males). CNAs in the TCGA LUAD dataset were retrieved from cBioPortal and CNAs in the MSK-IMPACT dataset were determined using the FACETS algorithm. Differences in overall survival between patients with PSG copy number gain and those without were assessed using Kaplan-Meier analysis with log-rank test. Tumor mutational burden (TMB) was also compared between the two groups using a two-sample t-test. In the TCGA cohort, female patients with PSG copy number gain (n=48) showed significantly worse overall survival compared to those without copy number gain (n=221; log-rank p=0.0039). In contrast, no significant survival difference was observed in males with PSG copy number gain (n=60) vs. those without (n=174; log-rank p=0.1902). In the MSK-IMPACT cohort, female patients with PSG copy number gain (n=426) showed significantly worse overall survival compared to those without copy number gain (n=2,024; log-rank $p=7.5\times10^{-6}$; hazard ratio [HR]=1.46, 95% CI: 1.24-1.73). In males, PSG copy number gain was associated with a significantly weaker trend toward poorer survival (n=276 with PSG copy number gain vs. n=1,137 without; log-rank p=0.0089; HR=1.29, 95% CI: 1.07-1.56). Notably, TMB was significantly higher in patients with PSG copy number gain compared to those without, in both females and males ($p<0.0001$ for both). Among patients receiving immunotherapy in the MSK-IMPACT cohort, no significant survival difference was observed between those with and without PSG copy number gain in both female (n=344) and male (n=248) groups. In this study, we demonstrated that copy number gains of PSG are associated with significantly worse overall survival in female LUAD patients compared to male LUAD patients, and this sex-dependent association is unlikely to be relevant to tumor immunity. These results highlight PSG copy number status as a novel sex-specific prognostic biomarker in lung cancer. These findings warrant further investigation into the underlying biological mechanisms and support future exploration of PSG-targeted therapeutic strategies tailored to female lung cancer patients.

#5255 KRAS subtype may modify the poor immunotherapy response in pancreatic cancer: Evidence from early phase trials.

Dilsa Mizrak Kaya[1], Yangruijue Ma[2], Tarik Demir[3], Aparna Kalyan[1], Sheetal Kircher[4], Mary Mulcahy[4], Al B. Benson III[4], Ruohui Chen[2], Devalingam Mahalingam[1]

[1]Department of Developmental Therapeutics, Northwestern University Feinberg School of Medicine, Chicago, IL,[2]Department of Preventive Medicine-Biostatistics and Informatics, Northwestern University Feinberg School of Medicine, Chicago, IL,[3]Division of Medical Oncology, The Ohio State University, Columbus, OH,[4]Department of Medical Oncology, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: PDAC is characterized by a near universal presence of KRAS mutations and limited responsiveness to immunotherapy. Biologic heterogeneity among KRAS subtypes may shape tumor immunobiology and treatment resistance.
Methods: We evaluated 109 patients with advanced PDAC treated on early phase trials (08/2014 to 08/2023). PFS and OS were estimated, cox regression models assessed clinical and molecular predictors of survival.
Results: Of 109 patients, 64% had KRAS mutations, 18% were KRAS wild, and 17% had unknown KRAS status. Median age was 65 and 83% had liver metastases. KRAS subtype distribution was G12D (46%), G12V (31%), G12R (13%), and other variants (10%). Immunomodulatory agents were administered in 39% of patients, most commonly in the 1L (49%). mOS and PFS for the entire cohort were 5.65 and 2.73 months, respectively. The restricted mean OS (7.54 vs. 8.65, p=0.53) and PFS (3.82 vs. 4.24, p=0.7) did not differ between KRAS-mutant and KRAS wild. Among KRAS-mutant patients, those receiving immunomodulator therapy had shorter OS compared with those who did not, with the strongest association observed in KRAS G12D (Table 1). This pattern was not seen in the KRAS wild-type. On univariate analysis, immunotherapy exposure, number of prior treatment lines, and liver metastasis were each associated with inferior OS. On multivariate analysis, immunotherapy exposure demonstrated a non-significant trend toward inferior OS (HR 1.61, 95% CI 0.98-2.66; p=0.06), while others remained independently associated with worse OS, suggesting confounding in the unadjusted association between immunotherapy and survival.
Conclusion: Our findings suggest that among KRAS mutant PDAC - particularly G12D - receipt of immunotherapy in early phase trials was associated with shorter OS. This may reflect underlying biology or confounding by treatment line and disease burden and warrant validation by KRAS subtype-informed studies.
Table 1: mOS by KRAS and immunotherapy exposure

KRAS		Immunotherapy (n)		mOS (months)	p
wild		yes (n=7)		4.47	0.08
	no (n=13)		7.43		
mutant		yes (n=27)		2.63	***0.03***
	no (n=43)		7.52		
G12D		yes (n=13)		2.07	***0.04***
	no (n=19)		7.79		
G12V		yes (n=7)		4.04	0.48
	no (n=15)		10.22		
others		yes (n=7)		2.33	0.20
	no (n=9)		5.75		

#5256 Association of NME1, CXCL12, VDR, DNMT1, CAV1, IL27, and IL33 polymorphisms with breast cancer susceptibility in Bangladeshi women: A case-control and *in silico* study.
Mohammad Safiqul Islam, Md Abdul Barek

Department of Pharmacy, Noakhali Science and Technology University, Noakhali, Bangladesh

Purpose: Breast cancer (BC) remains one of the most common cancers and a leading cause of death among women worldwide. Despite therapeutic advances, identifying genetic factors that influence susceptibility is crucial for populations at high risk. This study aimed to investigate whether polymorphisms in *NME1* (rs16949649), *CXCL12* (rs2839693, rs1801157), *VDR* (rs7975232, rs731236, rs2228570), *DNMT1* (rs16999593), *CAV1* (rs3807987), *IL27* (rs181206), and *IL33* (rs7044343) are linked to BC in Bangladeshi women, combining case-control data with in-silico analysis.
Methods: We analyzed 250 histologically confirmed BC cases and 250 age-matched healthy controls. Genotyping was carried out by PCR-RFLP. Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated, and $p<0.05$ was considered significant. To complement these findings, in-silico predictions of variant impact were performed using GEPIA, UALCAN, SIFT, PolyPhen-2, CADD, PredictSNP, Mutation Assessor, MuPro, and I-Mutant.
Results: *NME1* rs16949649 showed a significant association with BC (dominant model: OR=2.24, p=0.040; allele model: OR=2.44, p=0.045). *CXCL12* rs2839693 also increased risk (dominant model: OR=1.69, p=0.017; allele model: OR=1.67, p=0.008). Among *VDR* variants, rs7975232 and rs731236 were positively associated with BC, whereas rs2228570 was protective (additive model 2: OR=0.36, p=0.009). No meaningful associations were observed for *DNMT1* rs16999593, *CAV1* rs3807987, *IL27* rs181206, *IL33* rs7044343, or *CXCL12* rs1801157 in the case-control analysis. Interestingly, in-silico modeling suggested that *DNMT1* rs16999593 (H97R) could reduce protein stability, with some predictors indicating possible disease relevance. For *IL33* rs7044343 (C>T), the T allele was predicted to increase BC susceptibility, reflecting IL-33's context-dependent roles in tumor biology.
Conclusions: This study highlights *NME1* rs16949649, *CXCL12* rs2839693, and *VDR* variants (rs7975232, rs731236, rs2228570) as important genetic markers of BC risk in Bangladeshi women. While case-control analysis did not confirm significant effects for *DNMT1* and *IL33*, computational predictions suggest they may influence protein function and deserve further exploration. Integrating genetic association with in-silico analysis can provide deeper insights into breast cancer susceptibility in underrepresented populations.

#5257 Armored TIL GT201 induces potent tumor-specific TCR expansion and durable antitumor responses in advanced solid tumor.

Pin Wang[1], Rong Zhou[2], Yong Han[2], Zhengxiang Han[3], Weijia Fang[4], Kai Chen[5], Youguo Chen[5], Liqing Ma[6], Lili Lu[6], Derun Shen[6], Jiahui Jin[6], Yiyang Tan[6], Ke Liu[6], Zhenjiang Liu[6], Jingman Wang[6], Zhao Xu[6], Jingwei Sun[6], Jun Cui[6], Jing Yu[6], Yue He[2], Yarong Liu[6]

[1]University of Southern California, Los Angeles, CA,[2]Department of Oral Maxillofacial & Head and Neck Oncology, Shanghai Ninth People's Hospital, Shanghai, China,[3]Oncology Department, the Affiliated Hospital of Xuzhou Medical University, Xuzhou, China,[4]Department of Medical Oncology, the First Affiliated Hospital, Zhejiang University, Hangzhou, China,[5]The First Affiliated Hospital of Soochow University, Suzhou, China,[6]Grit Biotechnology, Shanghai, China

Background: Tumor-infiltrating lymphocyte (TIL) therapy has demonstrated activity in solid tumors but remains constrained by T-cell exhaustion and an immunosuppressive tumor microenvironment. GT201 is an engineered, cytokine-armored TIL product expressing membrane-bound IL-15 (mbIL-15) designed to enhance TIL persistence and antitumor function. A multi-center, open-label, single-arm exploratory clinical study was initiated to evaluate the safety, tolerability, and preliminary efficacy of GT201 in patients with advanced solid tumor.

Method: The primary endpoint was to evaluate the tolerance and safety profile according to CTCAE v5.0. Secondary endpoints included preliminary efficacy measures such as overall response rate (ORR), disease control rate (DCR), assessed per RECIST v1.1, as well as pharmacokinetics of GT201. Exploratory endpoint included longitudinal tumor biopsies and peripheral blood sampling, analyzed by single-cell RNA/TCR sequencing and bulk TCR sequencing to track clonal dynamics and identify tumor-specific TCRs.

Result: As of November 4, 2025, twelve patients were enrolled (median age 52.5 years; median of two prior lines of therapy). GT201 demonstrated a favorable safety profile: most AEs were Grade 1-2, while Grade ≥3 events were attributable to lymphodepleting chemotherapy or IL-2 support and resolved within 14 days. Preliminary efficacy signals were encouraging, with an ORR of 58.3% (7/12) and a DCR of 83.3% (10/12), including two complete responses (16.7%) and five partial responses (41.7%). Correlative multi-omics profiling revealed that mbIL-15-expressing cells were enriched in post-infusion tumor samples, and their corresponding TCRs underwent marked clonal expansion. A putative tumor-specific T-cell subset (4-1BB$^+$CD8$^+$ with high effector/exhaustion and low stemness signatures in tumor samples pre- and post-infusion) was preferentially expanded during manufacturing and showed a pronounced expansion peak in peripheral blood between Days 7-28 in responders. This subset was scarce at baseline and exhibited minimal expansion in non-responders. In contrast, “TIL-only” TCRs, which were clonotypes present in the infused product but absent pre-infusion, did not expand in peripheral blood in any patient.

Conclusion: GT201 exhibited a manageable safety profile and encouraging early efficacy in patients with advanced solid tumor, with ongoing enrollment to further inform clinical outcomes. Integrated multi-omics analyses indicate that expansion of tumor-specific TCRs, during both manufacturing and post-infusion in responding patients, correlates more strongly with clinical benefit than expansion of TIL-only TCRs. Continued longitudinal sampling and functional validation of putative tumor-specific clonotypes will be essential to establish their utility as biomarkers of response in GT201 therapy.

#5258 Monitoring of molecular response during immunotherapy by circulating tumor DNA in non-small cell lung cancer.

Johanna Svensson[1], Maria Yhr[1], Per Torstensson[2], Levent Akyurek[3], Andreas Hallqvist[4], Sukanya Raghavan[5], **Anna Rohlin**[1]

[1]Department of Clinical Genetics and Genomics, Sahlgrenska University Hospital, Goteborg, Sweden,[2]Department of Pulmonary Medicine, Skaraborg Hospital, Goteborg, Sweden,[3]Department of Clinical Pathology, Institute of Biomedicine, Sahlgrenska University Hospital, Goteborg, Sweden,[4]Department of Oncology, Sahlgrenska University Hospital, Goteborg, Sweden,[5]Department of Microbiology and Immunology, Institute for Biomedicine, Sahlgrenska Academy, University of Gothenburg, Goteborg, Sweden

Background: Patients with non-small cell lung cancer (NSCLC) may benefit from immune checkpoint blockade (ICB) targeting PD-1/PD-L1. However, only 20-40% of patients respond to ICB. Circulating tumor DNA (ctDNA) analysis in plasma offers a non-invasive biomarker for treatment monitoring. Previous studies have shown that ctDNA detection can predict clinical response earlier than standard radiological evaluation.
Objective: This study aimed to evaluate the detection and dynamics of somatic tumor-specific DNA variants in ctDNA during early treatment cycles, with the goal of identifying molecular response patterns.
Methods: Thirty-three stage III-IV NSCLC patients treated with ICB were prospectively included. ctDNA levels were analyzed longitudinally at baseline and up to five timepoints during treatment. Based on initial tumor sequencing, four to fifteen patient-specific somatic variants were selected according to pathogenicity classification and variant allele frequency. These variants were monitored at each timepoint using ultrasensitive sequencing assays (Simsen Diagnostics). A model for ctDNA-based response assessment was developed and compared with clinical outcomes defined by RECIST criteria from CT scans performed every third month after ICB initiation. Results Overall, 78.8% (26/33) of patients showed ctDNA results concordant with CT imaging when applying the molecular response model. Thirteen patients with non-detectable ctDNA at baseline had significantly longer overall survival compared with baseline ctDNA-positive patients, independent of radiological response at 3 months. Six patients experienced early progression, which was detected by ctDNA up to six weeks before clinical evaluation by CT scan. Longitudinal ctDNA patterns varied depending on metastatic site and sampling timepoint. The genomic landscape of non-responders was further explored using complementary methodologies.
Conclusion: ctDNA monitoring, based on the selection of informative tumor-specific DNA variants, provides a sensitive tool for evaluating treatment response in NSCLC. ctDNA dynamics correlated well with clinical outcomes and enabled earlier detection of progression or response compared with radiological imaging. Longitudinal ctDNA analysis underscores the importance of frequent sampling and highlights its potential to improve patient management in routine clinical practice.

#5260 *DNMT3A*-mutated tumor-infiltrating clonal hematopoiesis predicts immune checkpoint inhibitor response in advanced non-small cell lung cancer.

Geun-Ho Park, Cheolyong Joe, Hyemin Kim, Eunjoo Oh, Naeun Lee, Subin Kim, Junsu Choe, Jinyong Kim, Sehhoon Park, Hyun-Ae Jung, Jong-Mu Sun, Jin Seok Ahn, Myung-Ju Ahn, Joo Kyung Park, Se-Hoon Lee

Department of Medicine, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, Korea, Republic of

Introduction: Clonal hematopoiesis (CH) arises from the clonal expansion of hematopoietic stem cells and has been associated with an increased risk of hematologic malignancies, as well as adverse clinical outcomes across various solid tumors. Recent studies have shown that CH-mutated immune cells can infiltrate solid tumors, with notable enrichment in non-small cell lung cancer (NSCLC), where they may influence the local tumor microenvironment. However, the relevance of TI-CH in the context of immune checkpoint inhibitor (ICI) therapy remains poorly understood. Here, we investigated the immunologic characteristics of TI-CH and its association with ICI efficacy in patients with advanced NSCLC.

Methods: We analyzed whole-exome sequencing (WES) data from 600 ICI-treated patients with advanced NSCLC. Variant assessment was restricted to the most recurrent CH driver genes *DNMT3A*, *TET2*, and *ASXL1* (DTA), using a variant allele frequency (VAF) cutoff of ≥ 2%. Analysis of high-depth panel sequencing with paired peripheral-blood samples confirmed that tumor-detected DTA mutations were of hematopoietic origin, leading to their classification as putative TI-CH.

Results: The median depth of tumor WES data was 275.2× (range 145.9-469.5×). Putative TI-CH was identified in 12.5% of patients, with prevalence increasing with age (R^2 = 0.83, *P*=0.011). TI-CH mutations occurred at low VAF (median VAF 0.052, range 0.021-0.320) and were predominantly single-mutation events. No significant difference in sequencing depth was observed between TI-CH positive and negative groups (*P*=0.397).TI-CH-positive group showed a trend toward longer progression-free survival (PFS) (hazard ratio [HR] 0.77; 95% confidence interval [CI] 0.59-1.01; *P*=0.056) and had significantly better overall survival (OS) (HR 0.73; 95% CI 0.56-0.96; *P*=0.024). Especially, the *DNMT3A*-mutated TI-CH group exhibited significantly improved median PFS and OS compared with those without *DNMT3A* mutations (HR 0.57; 95% CI 0.40-0.83; *P* < 0.01; HR 0.51; 95% CI 0.35-0.75; *P*< 0.001). The *DNMT3A*-mutated group also demonstrated a higher response rate (45.0% vs 24.7%; *P* < 0.01). In contrast, *TET2*- and *ASXL1*-mutated TI-CH groups showed no significant difference in survival outcomes.In multivariable analysis adjusting for relevant clinical factors, DNMT3A-mutated TI-CH remained independently associated with prolonged PFS (adjusted HR 0.65; 95% CI 0.44-0.95; *P*=0.027) and OS (adjusted HR 0.64; 95% CI 0.43-0.95; *P*=0.028).

Conclusions: In this study, we characterized the landscape of TI-CH in advanced NSCLC, revealing that favorable efficacy of ICI is linked specifically to *DNMT3A* mutations. Collectively, these findings highlight *DNMT3A*-mutated TI-CH as a distinct predictive biomarker for ICI efficacy in advanced NSCLC.

#5261 Serial plasma tumor-informed next generation sequencing as a new efficacy metric to guide immunotherapy treatment discontinuation.

Meghan J. Mooradian[1], Aleigha Lawless[2], Julianne Czapla[2], Amaya Gasco[3], Patrick Boyle[3], Merrida Childress[3], Ryan J. Sullivan[4]

[1]Mass General Brigham Cancer Institute, Boston, MA,[2]Mass General Brigham, Boston, MA,[3]Foundation Medicine, Cambridge, MA,[4]Harvard Medical School/Massachusetts General Hospital, Boston, MA

Background: Immune checkpoint inhibition (ICI) is a front-line standard-of-care treatment for patients with metastatic melanoma (MM). However, there are critical questions pertaining to optimal ICI management, particularly the ideal duration of therapy, for which biomarker guidance is lacking. Identifying patients who are safely able to receive a shorter course of ICI (<2 years), thereby limiting physical and financial toxicity, is an unmet need. In this non-randomized, prospective interventional trial (NCT06146920) we evaluated the use of the FDA-approved companion diagnostic test, FoundationOne®CDx (F1CDx), and the laboratory developed test FoundationOne®Tracker, a tissue-informed personalized ctDNA monitoring assay, as an efficacy metric to guide treatment discontinuation.

Methods: Eligible patients had radiographic evidence of disease control (stable disease or response) on ICI (>12 months but ≤18 months) without the development of dose-limiting immune-related adverse event/s (irAEs). After successful sequencing with F1CDx, the FoundationOne Tracker assay was generated. Patients ctDNA positive were excluded. The ctDNA negative (neg) patients stopped ICI and continued with active surveillance, including standard of care imaging as well as serial ctDNA via FoundationOne Tracker at 1month, 2month, 3month and subsequently every 3months up to 1 year. Patients were followed for an additional year to monitor for recurrence. The primary endpoint was PFS 12-month post-ICI cessation.

Results: From March 2024 through September 2024, 12 patients with MM were screened with two becoming ineligible due to development of an irAE prior to ICI cessation and one due to inadequate tissue for F1CDx. Of enrolled patients (n=9), six had cutaneous MM, one mucosal MM and two with MM from an unknown primary. ICI regimens included nivolumab-relatlimab (n=5), ipilimumab-nivolumab (n=2) and pembrolizumab (n=3) with a median duration on therapy of 13.9 mths. The best radiographic response prior to ICI cessation was Partial Response in 6, Complete Response in 3; in those who underwent PET imaging (n=6), 3 had a complete metabolic response (CMR), and 3 had a near-CMR. All patients remained ctDNA neg at 12months post-ICI cessation and after a median of 14.9 months (13.4-19.2) following enrollment, all patients remain ctDNA neg with no clinical or radiographic evidence of progression.

Conclusion: ctDNA guided therapy decisions for advanced cancers is an active area under clinical investigation. To our knowledge, this is the first interventional study utilizing ctDNA to discontinue immunotherapy in patients with MM. Although this study was halted early due to programmatic decisions by the sponsor, the data from this small cohort highlights the potential benefit of ctDNA in guiding treatment discontinuation; further prospective study is needed.

: Effects of Ionizing Radiation on Normal Tissues and FLASH Radiation Research
Poster Session

#5264 An *in vivo*-validated dual-mechanism model explains and guides FLASH radiotherapy for normal-tissue sparing.

Lixiang Guo[1], Anthony Davis[1], Albert van der Kogel[2], **Ken KangHsin Wang**[1]

[1]Radiation Oncology, UT Southwestern Medical Center, Dallas, TX,[2]University of Wisconsin, Madison, WI

The clinical effectiveness of radiotherapy (RT) is often limited by normal tissue toxicity. FLASH-RT, delivered at ultra-high dose rate (UHDR, >40 Gy/s), can markedly reduce normal tissue injury without compromising tumor control—a phenomenon known as the FLASH effect. Despite considerable interest in FLASH clinical translation, a critical challenge remains, the mechanisms underlying the FLASH effect are not understood. Published studies are often confounded by differences in organ type, endpoints, and beam parameters. This uncertainty impacts the selection of dose rate and dose required to optimize FLASH effect. Normal tissue sparing under FLASH-RT is widely attributed to rapid physicochemical reactions. Two leading hypotheses have emerged: radiolytic oxygen depletion (ROD), in which transient O_2 depletion reduces the oxygen enhancement ratio (OER) and DNA damage; and radical-radical recombination (RRR), in which elevated radical concentrations promote recombination of lipid peroxyl radicals, suppressing lipid peroxidation (LP) and apoptotic signaling. However, neither mechanism alone fully explains experimental observations. We propose that the FLASH sparing effect could arise from the synergistic contributions of ROD and RRR, as both affect cellular damage through distinct pathways. Given the complexity of physicochemical reactions induced by irradiation, computational modeling is essential in elucidating FLASH mechanisms. We developed a physicochemical model that integrates both mechanisms. The OER-weighted dose serves as a surrogate for DNA double strand break (D_{DSB}), while the dose resulting in LOOH formation quantifies LP-related toxicity (D_{LP}). The overall tissue toxicity is represented by the Damage Equivalent Dose (DED) as sum of D_{DSB} and D_{LP}. Our results show that DED generates a consistent normal tissue complication probability (NTCP) curve that accurately captures published data on FLASH sparing of acute GI toxicity and late brain toxicity, across a wide range of UHDR and conventional dose rate (CONV) conditions, whereas dose alone fails to do so. Furthermore, the brain toxicity correlates with D_{LP}, supporting an RRR-dominated mechanism, whereas GI toxicity correlates with both D_{DSB} and D_{LP}, indicating synergistic contributions of ROD and RRR. We further present iso-FLASH tissue sparing maps that delineate dose and dose-rate ranges where FLASH sparing is expected, stratified by organ type and endpoint. Finally, we apply this model to investigate the effects of average dose rate and dose per pulse reported in abdominal irradiation studies, providing insights into parameters governing FLASH-mediated tissue sparing. In sum, this physicochemical model provides an unified and important mechanistic framework that advances our understanding of FLASH-RT sparing effects and guides the optimization of dosimetric parameters for clinical translation.

#5265 FLASH radiotherapy improves survival in mouse glioblastoma and spares circulating antigen reactive CD8$^+$T-cells.

Yanxia Ma[1], Nhat Nguyen[1], Xuehong Gui[2], Edgardo Aguilar[3], Luke Connell[3], Denae Neill[3], Emil Schuler[3], Chibawanye I. Ene[1]

[1]Department of Neurosurgery, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Radiation Physics, Division of Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Glioblastoma is a lethal brain tumor with poor response to current therapies, which include surgery, chemotherapy, and conventional radiation therapy (CONV-RT). Although, CONV-RT (0.01Gy/second) to brain tumors stimulate tumor antigen release, it also recruits immunosuppressive myeloid-derived suppressor cells and is associated with neurotoxicity. Ultrahigh-dose-rate or FLASH-RT, which delivers CONV-RT doses over a significantly shorter period (more than 40Gy/second) maintains tumor control, reduces normal tissue injury and is less immunosuppressive compared to CONV-RT across multiple cancer types. In our study, we compared the effects of FLASH-RT to CONV RT in syngeneic mouse GL261 glioblastoma-bearing mice. We hypothesized that FLASH-RT would be equally or more effective than CONV-RT for tumor control and result in less immunosuppression within the tumor and systemically.

Methods: We stereotactically implanted 2×10^5 mouse GL261 cells into the right forebrain of C57BL/6 mice. Five days after tumor initiation, tumor bearing mice were treated with Sham-RT (control), CONV-RT (mean dose rate > 0.373 Gy/s), or FLASH-RT (mean dose rate >$3.6x10^6$ Gy/s). Brain tumor tissue and peripheral blood were collected on days 5 and 12 after treatment. To assess for changes in the tumor microenvironment after CONV-RT or FLASH-RT, we performed 10x Xenium spatial transcriptomics analysis (stRNA-seq; brain tumor, n = 6 mice per group), Lunaphore COMET multiplexed immunofluorescence assay (brain tumor, n = 6 mice per group), and flow cytometry (peripheral mononuclear cells, n = 6 mice per group). We also evaluated survival outcomes following treatment (n = 8 mice per group).

Results: FLASH-RT significantly improved overall survival rate of GL261 bearing mice compared to CONV-RT ($P < 0.05$) and Sham-RT ($P < 0.001$). FLASH-RT treatment markedly increased intratumoral CD8+ T-cell infiltration compared with CONV-RT ($P < 0.01$) and Sham-RT ($P < 0.01$). We also found that compared to FLASH-RT, CONV-RT caused a significant decrease in circulating PD-1$^+$CD8$^+$ T-cells ($P < 0.01$), a potent antigen reactive cytotoxic T-cell population previously identified in human patients with glioblastoma.

Conclusion: FLASH-RT is associated with better tumor control in mouse GL261 glioblastoma, increased intratumoral CD8+ T-cell infiltration, and preserves circulating antigen reactive PD1$^+$CD8$^+$ T-cells. These results indicate that FLASH-RT may synergize better with immune checkpoint inhibitors to re-invigorate anti-tumor T-cell responses against glioblastoma.

#5266 FLASH radiotherapy maintains tumor control and enables safe re-irradiation while preserving normal tissue in breast cancer PDX models.

Adel Zaid I Mutahar[1], Banita Verma[2], Stavros Melemenidis[3], Suparna Dutt[4], Kerriann M. Casey[5], Zhen Qi[2], Angera Hsiao-Chi Kuo[6], Kathleen C. Horst[7], Edward Elliot Graves[2], Michael F. Clarke[8], Billy W. Loo[9], Frederick M. Dirbas[10]

[1]Department of Surgery, School of Medicine, Stanford Cancer Institute, Stanford University School of Medicine, Stanford, CA,[2]Stanford University, Stanford, CA,[3]Department of Radiology, Stanford University, Palo Alto, CA,[4]Medicine, Stanford University School of Medicine, Stanford, CA,[5]Department of Comparative Medicine, Stanford University, Palo Alto, CA,[6]Stanford Univ., Foster City, CA,[7]Department of Radiation Oncology, Stanford University, Palo Alto, CA,[8]Associate Director, Stanford University School of Medicine, Stanford, CA,[9]Stanford University School of Medicine, Stanford, CA,[10]Stanford Cancer Institute, Stanford, CA

Background: Radiotherapy is central to breast cancer treatment but is limited by acute and cumulative skin toxicity, especially in large-field treatments and re-irradiation. Ultra-high-dose-rate FLASH radiotherapy (FLASH-RT, ≥ 40 Gy/s) may widen the therapeutic window by reducing normal-tissue injury without compromising tumor control. However, breast-directed and patient-derived models remain underexplored, including the effects of FLASH under repeated-irradiation conditions.
Methods: We integrated an orthotopic triple-negative breast cancer (TNBC) patient-derived xenograft (PDX) model and hemithoracic normal-tissue models to compare FLASH-RT (180 Gy/s) with CONV-RT (0.03 Gy/s). TNBC-bearing NRG mice received single-fraction of 30Gy electron irradiation via a custom stereotactic jig enabling mammary-targeted or hemithoracic fields. A separate cohort of non-tumor-bearing NRG mice underwent left-chest re-irradiation to assess cumulative tolerance. Endpoints included tumor regression, recurrence, survival, and graded skin toxicity; ongoing analyses incorporate histopathology and single-cell/spatial transcriptomics to elucidate FLASH-mediated tissue responses and mechanisms of normal-tissue sparing.
Results: FLASH-RT achieved equivalent tumor control to CONV-RT in TNBC-PDX models, with both modalities inducing complete regression by day 16 and maintaining clearance for two weeks before recurrence at day 32 post-RT. In contrast, normal-tissue responses diverged markedly: FLASH-RT significantly reduced acute skin toxicity (median score 0 vs. 5; $p<0.0001$), eliminated ulceration, and extended survival (120 vs. 90 days post-implantation) in tumor bearing mice. In non-tumor-bearing NRG mice, FLASH-RT also improved tolerance to cumulative thoracic irradiation; mice receiving a second 25Gy left-chest FLASH irradiation dose showed no clinical decline, whereas CONV-RT animals developed progressive toxicity requiring euthanasia within three months of re-irradiation. Multi-omics analyses are underway to define mechanisms of early tissue sparing and improved re-irradiation response.
Conclusions: FLASH-RT maintains tumor-control efficacy equivalent to CONV-RT while significantly reducing skin toxicity in TNBC-PDX models and improving normal-tissue tolerance to re-irradiation in non-tumor-bearing NRG mice. These findings support FLASH-RT as a clinically promising strategy that may expand safe re-treatment options and broaden curative radiotherapy opportunities in breast cancer. Mechanistic studies are ongoing to elucidate the biological basis of early tissue sparing and guide translation into breast-conserving and post-mastectomy treatment settings.

#5267 Reprogramming of pyruvate metabolism overcomes sex-specific differences in intestinal stem cell radiosensitivity and improves the therapeutic ratio for abdominal irradiation.
Stacey Krepel, Payel Bhanja, Rishi Man Chugh, Shujah Hamid Rehman, Subhrajit Saha

University of Kansas Medical Center, Kansas City, KS

Our study was done to elucidate the mechanism of sex-dependent differences in radiotherapy (RT) response in males versus females, and then utilize this mechanism to help prevent intestinal radiation toxicity. More than 50% of patients with gastrointestinal (GI) cancers undergo abdominal radiotherapy. However, intestinal epithelial radiosensitivity is a major limiting factor to delivering a tumoricidal dose. Personalized differences, including sex-specific differences in radiosensitivity, is one of the key determining factors in radiotherapy outcome. Using a mouse model of abdominal irradiation and a human intestinal organoid model, we previously demonstrated that healthy male intestinal stem cells are more radiosensitive than females due to higher rates of oxidative phosphorylation (OXPHOS) and production of reactive oxidative species (ROS). In the present study, we demonstrate that these higher rates of OXPHOS in males are due to increased expression of the Mitochondrial Pyruvate Carrier (MPC), which transports pyruvate into the mitochondria for flux through the TCA cycle, and, ultimately, the OXPHOS pathway. Genetic deletion of the MPC in Lgr5-EGFP-positive ISCs increases ISC survival following the reduction in radiation-induced mitochondrial pyruvate oxidation in both male and female organoids. In both human intestinal organoids and a mouse model of radiation-induced gastrointestinal syndrome, treatment with MPC inhibitor, UK5099, normalized these differences in radiation responses between males and females. Moreover, our study in a mouse model of pancreatic adenocarcinoma also establishes UK5099 as a radio-modulator for pancreatic cancer, as combination of RT+ UK5099 treatment significantly reduces tumor growth and alters the immunosuppressive tumor immune microenvironment compared to irradiated control. These findings clearly suggest that pyruvate metabolism and MPC can be a potential target to promote therapeutic ratio of abdominal radiotherapy.

#5268 Genetic inhibition of FTO does not exacerbate the severity of radiation-induced oral mucositis in C57BL/6 mice.

Margaret Pan[1], Leighton Pu[2], Stavros Melemenidis[2], Edward Elliot Graves[3], Kerriann M. Casey[2], Erinn Rankin[3]

[1]Stanford University School of Medicine, Stanford, CA,[2]Stanford University School of Medicine, stanford, CA,[3]Stanford University, Stanford, CA

Oral mucositis is a severe side effect of cancer treatment in patients with head and neck cancer. These ulcerative lesions often interfere with eating and swallowing, making recovery more difficult and potentially delaying treatment. In this study, we evaluated the impact of genetic inhibition of fat-mass and obesity-associated gene (FTO), an m6A RNA demethylase, on the severity of radiation-induced oral mucositis in C57BL6/J mice. Tongues were collected 10 days following administration of 18 Gy irradiation to the head and neck region. Histopathology demonstrated equivalent damage between FTO-knockout (KO) and wild-type (WT) mice following radiation. Thus, FTO inhibition does not exacerbate normal tissue damage following radiation and supports further investigation of FTO as a potential therapeutic target in head and neck squamous cell carcinoma (HNSCC).

#5269 Low-dose radiation therapy for peripheral joint osteoarthritis: Early U.S. community experience with pain, function, and medication outcomes.

Emily Schwartz[1], Michael Anderson[2], Russell Nevins[3], Kelsey Moakler[2], Andrew Cohen[4], Michael Sinopoli[4], Samuel Francis[4], Bradley Newby[2], Matthew Schwartz[5]

[1]University of Miami, Coral Gables, FL,[2]Comprehensive Cancer Centers of Nevada, Henderson, NV,[3]Desert Orthopaedic Center, Las Vegas, NV,[4]Comprehensive Cancer Centers of Nevada, Las Vegas, NV,[5]University of Nevada, Las Vegas (UNLV), Las Vegas, NV

Background / Significance: Osteoarthritis (OA) causes chronic pain and functional decline in older adults, yet treatment options are limited for patients who cannot tolerate long-term NSAIDs or opioids. Low-dose radiation therapy (LDRT) has shown efficacy in European studies, but U.S. data are sparse. This student-led study reports early outcomes from a community oncology practice implementing LDRT for OA, focusing on pain, function, and analgesic trends.
Methods: Thirty patients (55 joints) with OA were treated with LDRT (3 Gy in 5-6 fractions, 0.5 Gy/fraction). Pain was assessed using the Numeric Rating Scale (NRS, 0-10) and patient-assessed global improvement using the von Pannewitz Score (VPS, 0-4) at baseline, end of treatment (EOT), and ~1-month follow-up. Analgesic use was recorded at both time points. Paired t-tests and one-way ANOVA by joint site were used to assess changes.
Results: Mean baseline NRS = 8.0 (±1.2); follow-up = 3.3 (±2.1), a mean reduction of 4.7 points ($p < 0.001$). Eighty-three percent (25/30) achieved ≥2-point improvement; 70% (21/30) ≥3 points; 40% (12/30) ≥5 points. VPS at follow-up indicated moderate improvement in 39%, excellent in 25%, and complete response in 9%. Analgesic use decreased in 23% (7/30), and no patients required escalation or new medications. No ≥ Grade 2 toxicities occurred.
Conclusions: LDRT was safe, feasible, and provided substantial pain relief and improved function with parallel reductions in analgesic use. The absence of medication escalation underscores its potential as a non-pharmacologic, opioid-sparing therapy for OA pain. These real-world U.S. data support further prospective evaluation of LDRT in geriatric pain management.
Disclosure: No external funding or conflicts of interest. Study conducted under student investigator leadership with faculty supervision.

#5270 Cell-free RNA changes precede symptomatic radiation pneumonitis in cancer patients receiving thoracic radiotherapy.

Isabel Jabara, Noah Kastelowitz, Monica Nesselbush, Nick Phillips, Michael S. Binkley, Rene F. Bonilla, Kevin Liu, Alice Jiang, Nataliya Kovalchuk, Ash A. Alizadeh, Maximilian Diehn

Stanford University, Stanford, CA

Cancer therapies are limited by normal tissue toxicity. Radiation pneumonitis (RP) is a dose-limiting toxicity that commonly occurs in cancer patients who receive thoracic radiation therapy. RP is caused by inflammation and increased vascular permeability in the lungs and can lead to severe pulmonary symptoms and sometimes death. Currently, the strongest predictors of RP are radiation dose metrics, such as the volume of normal lung receiving ≥20 Gy (V20) or mean lung dose (Dmean); however, these have only modest predictive accuracy. Therefore, it is currently not possible to accurately identify patients who might benefit from RP-directed therapy prior to developing symptoms and there remains an unmet need for sensitive, non-invasive biomarkers to identify patients at risk for RP before symptoms develop. Plasma cell-free RNA (cfRNA) is a promising analyte that enables non-invasive profiling of gene expression in diverse tissues. Our group recently developed an ultrasensitive method called RARE-Seq to detect low abundance transcriptional signatures in cfRNA (Nesselbush et al. *Nature* 2025). In this study, we applied RARE-Seq to analyze cfRNA from 160 plasma samples from 56 lung cancer patients, 34 of whom developed RP, collected before, during, and after radiation therapy. We observed enrichment of lung- and airway-specific gene transcripts in cfRNA from patients with symptomatic RP compared to those who received radiation but did not develop RP. Additionally, pre-symptomatic samples from patients who later developed RP were enriched for cfRNA signatures of lung pneumocytes, suggesting early molecular changes preceding clinical symptoms. Lastly, we identified cfRNA signatures that distinguished symptomatic RP from non-RP samples with an AUC of 0.85 and pre-symptomatic RP from non-RP samples with an AUC of 0.77, significantly outperforming the classic dosimetric predictors lung V20 and Dmean (V20 P = 4.9e-5, Dmean P = 7.4e-5, paired DeLong test). Collectively, these findings demonstrate proof of concept that cfRNA profiling can predict radiation-induced toxicities before onset of symptoms, establishing it as a potentially transformative biomarker for improving monitoring and personalized management of patients treated with radiation therapy.

#5271 Pain signaling in dogs undergoing radiotherapy for head and neck cancer.

Faihaa A. Ahmed, Thitsana Ingkasri, Sophi Schofield, Effie Palyvou, Santosh K. Mishra, B. Duncan x Lascelles, Michael M. Nolan

Clinical Sciences, North Carolina State University, Raleigh, NC

A frequent side effect of radiotherapy (RT) for head and neck cancer is intense pain. While the biological basis of acute orofacial radiation-associated pain (RAP) remains unclear, it may involve pathways related to cold sensation and signaling. One important cold-sensing receptor is TRPM8 (Transient Receptor Potential Melastatin 8), which may be activated by the neurotrophic factor artemin (ARTN) through its main receptor, GFRα3. To investigate whether radiation induces the release of ARTN, resulting in TRPM8 signaling pathway modulation and subsequent RAP, a prospective clinical trial enrolled 24 pet dogs undergoing RT (32 or 36 Gy total, given in four-weekly fractions) for either oral melanoma or intranasal carcinoma. Radiotoxicity was scored at each visit, per Veterinary Radiation Therapy Oncology Group criteria. Pain was assessed using a previously validated composite oral and maxillofacial pain scale. Oral mucosal biopsies were collected from the RT field immediately before the first fraction, after the fourth/final fraction, and two weeks post-RT, to assess gene expression using bulk RNA-sequencing and protein expression of ARTN and GFRα3 via immunohistochemistry and immunofluorescence. Blood was collected at these time points and before the second fraction to quantify ARTN in serum using ELISA. Data were analyzed using two-way ANOVA. At the end of RT, 79% of all dogs had grade 1-2 oral mucositis; by the two-week recheck, only 58% had persistent mucositis. Pain severity scores were variable. In oral mucosa collected at the end of RT, there were 1,406 significantly differentially expressed genes at 32 Gy and 1,898 at 36 Gy. At the end of RT, ARTN increased 1.11-fold ($P < 0.01$) in 32 Gy-treated dogs and 1.35-fold in those received 36 Gy ($P < 0.01$). GFRα3 expression decreased by 1.02-fold ($P = 0.02$) in 36 Gy-treated dogs at the end of RT and by 1.23-fold after RT ($P = 0.01$). There were no significant changes in TRPM8 gene expression. Protein expression of ARTN and GFRα3 was unchanged in oral mucosa and neither mucositis nor pain severity correlated with ARTN or GFRα3 levels. However, there was a significant increase in serum concentrations of ARTN levels ($P= 0.01$) in dogs whose pain worsened after RT. Elevated circulating ARTN mirrors prior observations in dogs with mild radiodermatitis. Increased ARTN mRNA expression in the oral mucosa after irradiation suggests that the irradiated tissue itself is a key source of the circulating ligand. Interestingly, this occurred alongside downregulation of GFRα3 mRNA and without a clear relationship between local protein expression and the severity of radiation-associated pathology. The unexpected ligand-receptor imbalance suggests that after irradiation, increased ARTN reflects nerve regeneration and tissue repair, while reduced GFRα3 may result from nerve damage or silencing. Thus, the apparent inverse correlation may reflect tissue reorganization and adaptive signaling.

#5272 Development of a novel radiation-induced vaginal tissue injury model.

Julie Hakim[1], Dan Kennedy[1], Melissa Grunlan[2], Manuel Rausch[3], Ashley Hicks[3], Elizabeth Cosgriff-Hernandez[3]

[1]Baylor College of Medicine, Houston, TX,[2]Texas A&M Engineering Experiment Station, College Station, TX,[3]University of Texas at Austin, Austin, TX

Introduction: Vaginal stenosis (VS), characterized by thickening and shortening of the vaginal wall tissue, occurs in up to 80% of women receiving pelvic radiotherapy (PRT), the most common treatment for gynecologic cancers. Yet, a critical barrier to developing more effective therapies is a lack of clinically relevant models to dissect underlying mechanisms. Using the Food and Drug Administration gold-standard for vaginal irritation testing, we have developed a rabbit model of radiation-induced vaginal injury.
Methods: Female New Zealand white rabbits were either left untreated or radiated at low dose (LD) (6 Gy) or high dose (HD) (20 Gy) by external beam radiation. After the final radiation fraction, vaginoscopies were conducted once per week for six weeks. Changes to vaginal tissue were scored using five clinical morphological parameters for VS: mucosal pallor, telangiectasia, fragility of the vaginal wall, ulceration, and adhesions/occlusion. Gross vaginal tissue was measured to determine changes in length and diameter. Histopathologic changes to vaginal tissue were determined under H&E and Masson's trichrome.
Results: Vaginoscopy of HD rabbits revealed a consistently higher degree of changes to the vaginal tissue. Compared to untreated rabbits, high-dose radiation induced vaginal wall thinning, smooth muscle tissue loss, replacement fibrosis, and increased interstitial fibrosis. HD-treated rabbits also demonstrated higher VS scores. While the inner perimeter of vaginas from high-dose rabbits decreased compared to untreated control rabbits, the difference was not statistically significant.
Conclusion: Here, we present a radiation-induced vaginal injury model of VS. Given the current gaps in available animal models for basic and translational research in vaginal health, the proposed model addresses key anatomical and physiological parameters that parallel the human vagina. This innovative model will strengthen the translational-to-clinical pipeline by enhancing the rigor of therapeutic testing after radiotherapy.

#5273 Signaling pathway insights into spaceflight cancer risks.

Anu R I[1], Josef Borg[1], JangKeun Kim[2], Tricia Larose[3], Ryan T. Scott[4], Joseph Borg[1], Christopher E. Mason[2], Afshin Beheshti[5], Kurt van der Speeten[6]

[1]University of Malta, Msida, Malta,[2]Weill Cornell Medicine, New York, NY,[3]University of Oslo, Oslo, Norway,[4]NASA Ames Research Center, Moffett Field, CA,[5]University of Pittsburgh, Pittsburgh, KS,[6]Hasselt University, Genk, Belgium

Spaceflight is a stochastic risk factor for development of cancer in astronauts and experimental data beyond low earth orbit is scarce[1]. Our understanding of role of tumorigenic pathways in the context of space biology is limited. We compared differentially expressed genes (DEGs), signaling pathways, and cancer hallmarks between human tumor tissue with Spaceflight data from civilian astronauts on private missions and rodents on Space missions[2].Astronaut RNA Seq data from the Inspiration4 (I4) mission and NASA Twin study were used conjointly with data from space-flown rodents and compared to transcriptome from organ-matched human tumor counterparts from NCI Genomic Data Commons. The peripheral blood transcriptome of the I4 crew revealed a temporal trend of oncogenic gene dysregulation from pre-flight to 82 days after return to Earth (R+82). Early post-flight window showed activation of pro-tumorigenic and immune-mediated genes namely *KRAS, MTOR, STAT3, RARA,* and *PIK3CA* on R+1 (immediate post-spaceflight), of which sustained activation of key genes were observed on R+45 (45 days post return to Earth) and on R+82. DNA damage repair genes such as *MRE11, ATR, ABL1, RAD51B, RAD51D, FANCA*, and *CREBBP* were activated in parallel. Over time, most regulatory genes recovered, but therapeutic targets namely *ALK, ROS1, NTRK3, POLE, RAD51D, MTAP, ESR1, FGFR3, TSC1, STK11, ABL1, CREBBP, RAF1, NRG1, BCL6,* and *KMT2D* were found to be upregulated post-flight after readjusting to Earth, irrespective of inter-individual variability. Sustained upregulation of stemness factors *STAT3* and *FOXP1* indicate adaptivity or immune system tuning post-stress but warrants attention for long term studies for potential oncogenic risks.In parallel, multi-organ sorted patient and rodent data offered staggering insights into tumorigenic roles of major signaling cascades in cancer. Significant overlaps in DEGs were observed between primary human tumors and spaceflown models notably in Breast (p 4.84E-57, OR 7.7), Colon (p 9.24E-46, OR 25), Kidney (p 9.21E-62, OR 9.3), Lung (p 1.38E-51, OR 28), and Skin (p1.23E-85, OR 119). GSEA analysis revealed pro-tumorigenic pathway enrichment. For example, in breast, we observed activation in pathways of MYC targets (NES 2.17, FDRq 0.003), mTORC (NES 2.42, FDRq 0.000), PI3K pathway (NES 1.31, FDRq 0.123), DNA damage repair (NES 1.76, FDRq 0.002), Oxidative Phosphorylation (NES 3.28, FDRq 0.000), and ROS cascades (NES 2.10, FDRq 0.000).The distinction between signaling pathway dysregulations in healthy tissue, benign tumors, stress-induced tissue, and florid malignancy remains a question. Sustained activation of pathways post-spaceflight in astronauts is a crucial finding that mirrors a cellular environment observed in human pre-malignant tissues. Simultaneously, the significant similarity in cellular pathways between tumors and spaceflight petitions cognizance of the bivalent nature of pathways in cancer[3].

#5274 Impact of ultra-high dose rate (FLASH) versus conventional radiotherapy on tumor control in wild-type and cGAS-knockout mice.

Banita Verma[1], Adel Mutahar[1], Stavros Melemenidis[2], Rohit Verma[3], Lucy Whitemore[1], Suparna Dutt[2], Kathleen C. Horst[2], Edward Elliot Graves[2], Michael F. Clarke[4], Lingyin Li[5], Billy W. Loo[2], Frederick M. Dirbas[1]

[1]General Surgery, Stanford University School of Medicine, Stanford, CA,[2]Radiation Oncology, Stanford University School of Medicine, Stanford, CA,[3]Neurosurgery, Stanford University School of Medicine, Stanford, CA,[4]Med/Stem Cell, Stanford University School of Medicine, Stanford, CA,[5]Stanford Biochemistry, Sarafan ChEM-H and Arc Institute, Stanford University School of Medicine, Stanford, CA

Background: Radiotherapy (RT) is central to breast cancer (BC) management but limited by normal tissue toxicity. Conventional RT (CONV; ≤0.03 Gy/s) controls tumors but often causes skin inflammation, compromises treatment intensity and quality of life. Ultra-high dose-rate FLASH RT (>40 Gy/s) achieves comparable tumor control with markedly reduced tissue injury ("FLASH effect"), yet its mechanism of tumor control and sparing of normal tissue remains unclear. Ionizing radiation activates the cGAS-STING pathway through DNA damage, triggering proinflammatory cytokine production and tissue injury, yet has also been implicated with improvement in the antitumor immune response. Emerging data suggest that FLASH may attenuate or abrogate cGAS-STING signaling leading to reduced inflammation and tissue injury. This study investigated the role of cGAS signaling in mediating the differential effects of FLASH and CONV RT on normal tissue toxicity and tumor control using wild-type (WT) C57BL/6 and cGAS double knockout (cGAS -/- KO) mice.

Methods: PYMT117 BC cells were orthotopically implanted into the third mammary fat pad of 6-8-week-old female WT and cGAS-/- mice. Once tumors reached ~50 mm^3, mice received a single 30 Gy dose of either FLASH or CONV RT targeted to the tumor site. Tumor growth and skin toxicity (graded 0-5) were measured every other day. Euthanasia was performed upon excessive tumor burden or skin injury. Data were analyzed by two-way ANOVA followed by Tukey's post hoc test ($p < 0.05$).

Results: Both FLASH and CONV RT significantly reduced tumor volume ($p < 0.001$), with complete regression by day 14. Tumor recurrence occurred around day 25 in all groups. In WT mice, both modalities produced comparable tumor control, with CONV showing a slight but non-significant trend toward smaller recurrent tumors and few complete responses but caused severe skin toxicity (score 5) requiring euthanasia by day 50-60. In contrast, FLASH treated mice showed equivalent tumor suppression markedly reducing skin toxicity (score ≤ 3 in 2/10 mice). Notably, the cGAS-/- mice exhibited minimal or no visible toxicity with either modality, except one CONV-treated mouse (score 2).

Conclusion: FLASH RT significantly reduces normal tissue toxicity compared to CONV RT while maintaining equivalent tumor control: improved tumor control might be achievable through higher FLASH doses because of the improved therapeutic index over CONV RT. The minimal toxicity observed following FLASH RT, together with the absence of toxicity in cGAS-/- mice, also supports the possibility that FLASH may limit early inflammatory responses and tissue injury by suppression or abrogation of cGAS-STING activation. These findings support FLASH RT as a promising, less-toxic radiotherapeutic approach and highlights the potential of suppression of the cGAS-STING pathway to improve treatment outcomes in BC.

#5275 Mechanistic insights into the anti-tumor activity of ^{212}Pb-PSMA radioligand therapy.

Feifei Liu, Melissa Monterosso, Didier Boucher, Anna Amiss, Stelle Shakti, Kwong Ching Li, Chanwoo Kim, Aimee Horsfall, Kevin Kuan, William Tieu, Stephen Rose, Simon Puttick, Joana Brilhante, Gary Li, Anna Karmann, Thomas Kryza

AdvanCell Pty Ltd, Sydney, Australia

Introduction: Prostate-specific membrane antigen (PSMA)-targeted radioligand therapy (RLT) with lutetium-177 (^{177}Lu) has demonstrated clinical benefit in prostate cancer (PC). Although alpha-emitters offer superior cytotoxic efficacy, the complex toxicity profile of actinium-225 (^{225}Ac)-PSMA limits its therapeutic application. Lead-212 (^{212}Pb) possesses favorable physical properties, including high linear energy transfer, a 10.6-hour half-life, and a simple decay scheme with a single alpha-emitting daughter nuclide, enabling precise, potent radiation delivery at the cellular level. In this study, we combine *in vitro* and *in vivo* models with multiomics and functional assays to elucidate the mechanisms underlying the anti-tumor efficacy of PSMA-targeted RLT.

Materials and Methods: ^{212}Pb-ADVC001, a novel ^{212}Pb-based PSMA-targeting RLT in Phase I/II clinical development (NCT05720130) for the treatment of metastatic PC, was used as the ^{212}Pb-PSMA-RLT agent. ^{177}Lu-PSMA-I&T was used as the ^{177}Lu-PSMA-RLT agent. The kinetic mechanisms associated with ^{212}Pb-ADVC001 mediated cell-death were investigated *in vitro* and *ex vivo* using transcriptomics and proteomics analyses. To validate the omics findings, functional assays were conducted to assess the effects of ^{212}Pb-PSMA on PC's cell cycle progression, reactive oxygen species (ROS) generation, and lipid peroxidation in PC cells.

Results: ^{212}Pb-ADVC001 displayed potent cytotoxic activity with a mean EC_{50} of 2.7, 7.2 and 3.3 kBq/mL in PC cell lines PC-3-PIP (PSMA^{high}), C4-2 (PSMA^{int}) and LNCaP (PSMA^{int}), respectively. Transcriptomic and proteomic analysis of *in vitro* treated PC cells and *in vivo* tumors harvested longitudinally revealed multiple mechanisms of action involving DNA damage, cell cycle arrest and cell death, and immune response modulation. *In vitro* functional assays confirmed the involvement of ROS production, lipid peroxidation, and cell cycle arrest upon treatment with ^{212}Pb-ADVC001. Particularly, ^{212}Pb-ADVC001 caused significant DNA damage, and reduced DNA content in the S-phase of the cell cycle with a concomitant increase in the G1- and G2/M-phase arrest compared to ^{177}Lu-PSMA-I&T ($p < 0.05$).

Conclusion: Multiomics analyses highlighted the involvement of multiple mechanisms of action in the efficacy of ^{212}Pb-ADVC001 which collectively resulted in effective cancer cell death. Mechanistic studies furthered the understanding of PC radiobiology and cellular responses to beta- and alpha-based RLT with the identification of a cell cycle arrest in PC specifically induced by ^{212}Pb-PSMA.

#5276 [^{123}I]CC1, a radiopharmaceutical for Targeted radionuclide therapy (TRT), exploits PARP binding and trapping to amplify DNA damage and cytotoxicity in human cancer cell lines..

Luis Hernandez Cano[1], Nerea Delgado Mayenco[1], Hilleen Kramer[1], Elmar Diekstra[1], Francesca Amoroso[1], Sreelakshmi Unnikrishnan[1], George Alachouzos[2], Wiktor Szymanski[2], Frank A. Kruyt[3], Bart Cornelissen[1]

[1]Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, Groningen, Netherlands,[2]Nanomedicine and Drug Targeting, University of Groningen, Groningen, Netherlands,[3]Medical Oncology, University Medical Center Groningen, Groningen, Netherlands

We investigated whether the antitumor effects of [^{123}I]CC1, a PARP-binding radiopharmaceutical emitting very short-range ionising Auger electrons with potential use in Targeted Radionuclide Therapy (TRT), are driven by PARP trapping. Trapping will prolong its residence time on DNA and triggers more DNA damage. We tested this in PSN1 and U87 human cancer cell lines exposed to [^{123}I]CC1, by assessing PARP levels in the chromatin fraction via western blot and quantifying ^{123}I counts in nuclear and cytoplasmic fractions using a gamma counter. Downstream effects were evaluated using γH2AX immunofluorescence as a marker of DNA damage and DNA fiber assays to measure replication speed. Furthermore, we modulated PARP association with DNA by using methyl methanesulfonate (MMS) to increase and the PARG inhibitor JA2131 to decrease trapped PARP, using western blot and gamma counter to analyze how [^{123}I]CC1 tracks PARP movements from chromatin to nuclear soluble fraction. Finally, γH2AX immunofluorescence was used to assess whether combinatory treatments with MMS or PARGi affect the ability of [^{123}I]CC1 in producing DNA damage. [^{123}I]CC1 elevated trapped PARP levels on DNA in PSN1 and U87 cells, followed by a rapid increase in γH2AX foci. Interestingly, DNA fiber assays showed that replication was markedly hindered in PSN1 at 30 min and 24 h, indicating substantial DNA damage. Pretreatment with 0.01% MMS before [^{123}I]CC1 addition further elevated PARP levels compared to [^{123}I]CC1 alone, resulting in greater chromatin ^{123}I accumulation. In contrast, PARG inhibitor treatment reduced PARP residence time on DNA, and in combination with [^{123}I]CC1 decreased DNA ^{123}I delivery. Finally, assessment of γH2AX at 30 min and 24 hours showed that MMS pretreatment enhanced DNA damage induced by [^{123}I]CC1 greater damage than MMS alone, demonstrating an additive effect, whereas PARGI pretreatment had no significant effect.The results indicate that the cytotoxic effect of [^{123}I]CC1 is mediated by PARP trapping, which underlies its potent antitumoral activity previously observed by our group. Furthermore, modulation of the PARylation cycle alters delivery of radioactivity to DNA and the extent of DNA damage, suggesting a strategy to enhance the therapeutic benefit of [^{123}I]CC1 and its potential for clinical translation.

#5277 Alpha- and beta-emitter radiopharmaceutical therapy combined with dual immune checkpoint inhibitors yields distinct control of primary and metastatic tumors.

Yujuan Wang[1], Alexander Wertheim Verona[2], Bhoomika Raj Pillai[2], Tracy Berg[1], Caroline Kerr[1], Jamey P. Weichert[3], Reinier Hernandez[4], Bryan P. Bednarz[4], Zachary S. Morris[1]

[1]Department of Human Oncology, University of Wisconsin School of Medicine and Public Health, Madison, WI,[2]College of Agricultural and Life Sciences, University of Wisconsin-Madison, Madison, WI,[3]Department of Radiology, University of Wisconsin School of Medicine and Public Health, Madison, WI,[4]Department of Medical Physics, University of Wisconsin School of Medicine and Public Health, Madison, WI

Background: The therapeutic challenge of advanced and metastatic solid tumors may be addressed by immune checkpoint inhibitors (ICIs) for some patients, but most exhibit primary or acquired resistance. Combination with radiopharmaceutical therapy (RPT) provides promise in overcoming ICI resistance by delivering radiation to all lesions. Selecting radionuclides of differing physical properties, such as linear energy transfer (LET) and path length, are an optimizable feature of RPT. For instance, α-emitters such as ^{225}Ac deliver high LET radiation over short ranges suitable for targeting microscopic disease, whereas β-emitters such as ^{90}Y release lower LET radiation over longer distances suitable for macroscopic primary tumors. The optimal radionuclide type and dose to control coexisting macro- and micro-disease in advanced tumors remain undefined. To define rational strategies for metastatic disease, we evaluate differential therapeutic efficacy of α- and β-emitting RPTs when combined with dual ICIs in controlling concurrent macroscopic and microscopic tumors.

Methods: Dosimetry was estimated using the Monte Carlo-based RAPID platform informed by serial PET/CT or SPECT/CT imaging and/or ex vivo biodistribution. Female C57BL/6 mice (6-8 weeks) were implanted subcutaneously with 2×10^6 MOC2 cells in the flank on day -5 resulting in a macroscopic (~70 mm^3) tumor at the time of RPT. To model micro-metastatic disease, we injected 1×10^6 MOC2 cells intravenously on the morning prior to RPT. Mice received either ^{90}Y-NM600 (2, 12, or 20 Gy) or ^{225}Ac-NM600 (0.5, 2, or 6 Gy) on day 1, or were assigned to a no-radiation control group. Dual ICIs (anti-CTLA-4 + anti-PD-L1; 100 µg each) were administered
intraperitoneally on days −1, 2, and 5 relative to RPT. Lymphopenia was monitored weekly using an HM5 analyzer up to expected isotope decay. Mice were euthanized when macroscopic tumors exceeded 20 mm in any dimension or on independent health-monitoring criteria for moribundity.

Results: We identified an optimal dose of either ^{225}Ac- or ^{90}Y-NM600 that inhibited primary tumor growth and increased survival in a mixed tumor model. However, proportions of mice that were euthanized at the 20 mm primary tumor cut-off versus those that were euthanized prior to that endpoint because of moribundity differed between ^{225}Ac- and ^{90}Y-NM600. 50% of ^{225}Ac-NM600 mice were euthanized for reaching the 20 mm primary tumor endpoint, while no mice in the ^{90}Y-NM600 group were euthanized for primary tumor size and were instead euthanized for moribundity.

Conclusions: Further testing is required to identify the cause of differing moribundity amongst the ^{225}Ac-NM600 versus ^{90}Y-NM600 treatment groups; however, these findings suggest differing effects on disease progression in a mixed tumor model when treated with radionuclides of differing properties.

#5281 A novel viral-derived epigenetic gene therapy delivered via mRNA-lipid nanoparticles to inhibit HPV-associated malignancies.

Fan Yang[1], Yan-Ning Yu[1], Liliana Echavarria[1], Leo Holguin[1], Sarah Schroeder[1], Shasha Li[1], Michelle Afkhami[2], Diana Bell[3], Krupal Patel[4], **Tristan A. Scott**[1]

[1]City of Hope Comprehensive Cancer Ctr., Duarte, CA,[2]Comprehensive Cancer Ctr., Duarte, CA, United States, City of Hope, CA,[3]University of Pittsburgh Medical Center, Pittsburgh, PA,[4]Department of Surgery, City of Hope Comprehensive Cancer Ctr., Duarte, CA

Human Papillomavirus (HPV) is associated with a range of malignancies, including oropharyngeal, cervical, and anal carcinomas. Approximately 47,000 carcinoma cases annually in USA are attributed to HPV causing significant morbidity and mortality. Integration of the episomal HPV genome into the host's DNA is a critical event in oncogenesis. HPV's long control region (LCR) promoter overexpresses the viral E6 and E7 proteins, which inhibit the tumor suppressors p53 and Rb1 respectively, driving the oncogenic transformation. E6 and E7 are also critical for tumor maintenance by creating a state of 'oncogene addiction', making them ideal targets for therapeutic intervention. They are considered undruggable, but they present ideal targets for gene therapy interventions. However, gene therapies face significant challenges such as targeting multiple HPV oncogenes within sequence-diverse high-risk HPV subtypes. To this end, we have exploited a viral self-regulatory genetic circuit to develop a compact, single component epigenetic repressor (BE2K). BE2K targets highly conserved sites in the LCR which can silence multiple oncogenes simultaneously in virtually all HPV subtypes. BE2K inhibited the proliferation of high-risk HPV16 and HPV18-associated oropharyngeal, cervical, and anal cancer cell lines. BE2K had no effect on non-HPV associated cell lines. BE2K suppressed E6 and E7 expression resulting in reactivation of the p53 tumor suppressor and caspase-mediated apoptosis. Global mRNA profiling confirmed E6 and E7 reduction, an increase in p53 signaling and apoptosis pathways, as well as a reduction in the E2F transcription factor targets, downstream of Rb1. Of note, an upregulation in interferon pathways and inflammatory response was observed, which may additionally contribute to the anti-proliferative effects in HPV-associated cancers in an immune-competent context. To deliver BE2K intratumorally, it was formulated as mRNA in MC3 lipid nanoparticles (LNPs). An HPV-associated head and neck SCC154 xenograft model in NSG mice was used and LNP-mRNA BE2K reduced tumor volume and improved clinical scores in the mice compared to controls. Immunohistochemistry showed an elevated p53 with a reduction in the Ki-67. Safety profiling showed no effect on serum ALT/AST levels, or liver and spleen histology. To validate our findings, a patient-derived xenograft (PDX) model was established from a primary tonsil HPV-associated head and neck squamous cell cancer. Preliminary experiments in the PDX showed that BE2K treatment resulted in a correlation between tumor growth inhibition and p53 and caspase-3 activation. Overall, BE2K, as a scalable LNP-mRNA formulation, represents a promising new epigenetic mRNA treatment towards a more generalizable gene therapy for HPV-associated malignancies.

#5282 Splicing disruption using a CLK inhibitor shows activity in malignant rhabdoid tumor pre-clinical models.

Clemence Basse[1], Pawel Sobczuk[1], Andrea Gazzo[1], Tom Zhang[1], Marissa Mattar[1], Inna Khodos[2], Elisa De Stanchina[3], Romel Somwar[1], Neerav N. Shukla[4], Marc Ladanyi[1]

[1]LADANYI Lab, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Anti-tumor Core Facility, Pharmacology Program, Memorial Sloan Kettering Cancer Center, NEW YORK, NY,[3]Anti-tumor Core Facility, Pharmacology Program, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Department of Pediatrics, Memorial Sloan Kettering Cancer Center,, New York, NY

BACKGROUND. Malignant Rhabdoid Tumors (MRT) are rare lethal tumors affecting young children and characterized by genetic loss of *SMARCB1*. SMARCB1 is a core subunit of the canonical BAF (cBAF) chromatin-remodeling complex and its loss disrupts canonical BAF assembly leading to dependence on alternative BAF complexes (not containing SMARCB1), notably the non-canonical BAF (ncBAF) complex, which contains BRD9 instead. MRT cells activate Wnt/beta-catenin signaling based on impaired repression of Wnt/beta-catenin target genes by TCF/LEF in the absence of a functional cBAF complex, representing a specific therapeutic vulnerability, as well as an overall dependence on the ncBAF complex which makes BRD9 another specific vulnerability. CLK inhibition via its effects on phosphorylation of splicing factors is known to inhibit Wnt/beta-catenin signaling by disrupting canonical splicing of TCF/LEF, and BRD9 has been reported to be downregulated in the context of splicing factor alterations. We hypothesized that the CLK/DYRK inhibitor SM09419, an analogue of the clinical stage CLK/DYRK inhibitor cirtuvivint/SM08502 (both developed by Biosplice Therapeutics, Inc./TenaRx, Inc.) could be active in MRT cells.

METHODS. Established MRT cell lines and patient-derived xenograft (PDX) models were used for *in vitro* and *in vivo* experiments. Proliferation and growth were examined using Alamar Blue viability dye or colony forming assays. Cell cycle analysis was assessed by flow cytometry. mRNA expression and splice forms were evaluated by RNAseq, qPCR, RT-PCR, and long read sequencing. *In vivo* efficacy studies were conducted in NSG mice harboring MRT PDXs.

RESULTS. SM09419 inhibited growth *in vitro* of six (A204, G401, JMRTK2, KYM-1, TM87-16, TTC549) MRT cell lines with IC_{50} <200 nM for all cell lines. Cell cycle profiling showed increased arrest at G0/G1. SM09419 treatment resulted in upregulation of the cell cycle inhibitors p21 and p27, elevation of the pro-apoptotic markers cleaved PARP, BIM and PUMA and increased caspase 3/7 activity. RNAseq of MRT cell lines A204 and TTC549 treated with SM09419 showed downregulation of *WNT*/beta-catenin transcriptional targets and qPCR confirmed aberrant splicing of WNT pathway repressors LEF/TCF. Additionally, SM09419 significantly reduced BRD9 canonical transcripts in both cell lines and qPCR confirmed aberrant splicing of BRD9. In three MRT PDX models, SM09419 treatment (12.5 mg/kg and 25 mg/kg) for at least 40 days after implantation suppressed growth in a dose-dependent manner.

CONCLUSION. The splicing inhibitor SM09419 exerts promising anti-tumoral effects in MRT models. Mechanistically, CLK inhibition as monotherapy may be hitting at least two known key vulnerabilities in MRT, namely Wnt/β-catenin signaling and ncBAF function (via BRD9 misplicing). These findings provide a rationale for further early phase clinical trials of CLK inhibitors in MRT.

#5283 Cloud-based computational framework for individualized genomic analysis in pediatric acute lymphoblastic leukemia: A nationwide multi-center real-world clinical study.

Acute lymphoblastic leukemia (ALL) is the most common childhood cancer. While genomic studies have identified key molecular subtypes and aberrations in ALL, it requires integrating multi-omics data to complete complex and time-consuming analyses in large retrospective cohorts. It is challenging to perform individualized clinical genomic analysis in real-world.

We present a nationwide precision genomic study as part of the Chinese Children Cancer Group ALL 2020 clinical trial. Between 2020 and 2023, 6486 pediatric ALL patients were enrolled from 25 medical centers across 15 provinces in China. RNA-seq was performed for 5103 patients during diagnosis. We developed the National Children's Medical Center ALL Bio-Cloud (NCMC-ABC), an automated, cloud-based framework for real-time RNA-seq data process. NCMC-ABC is designed to analyze multiple clinically relevant genomic aberrations from single RNA-seq data, including molecular subtypes, coding and noncoding driver mutations, fusions and CNVs. The median turnaround time from sample collection to clinical reporting was 14 days across all hospitals, aligning with clinical treatment timelines.

We established a molecular subtype classification framework for pediatric ALL, and successfully classified 94.94% of B-ALLs into 20 subtypes and 86.38% of T-ALLs into 11 subtypes. This framework significantly improved the traditional MICM approach, which classified only 48.58% of B-ALLs and did not account for T-ALL subtypes. The enhanced classification is due to the improved detection of key fusions (*DUX4*, *PAX5*, *ZNF384*, *MEF2D* rearrangements) and mutations (*PAX5* P80R and *IKZF1* N159Y). Meanwhile, we achieved more precise subtyping of HYPO, HYPER and KMT2A BALLs. The refined subtypes unveiled a distinct profile of Chinese B-ALL patients, with higher frequencies of HYPER, ETV6, DUX4 and PH subtypes, and lower frequencies of Ph-like, iAMP21 and HYPO, compared to Western cohorts. Importantly, the refined framework directly improved the risk stratification of patients.

We identified a median of 2.44 pathogenic SNPs/indels and 1.28 fusions per patient. The driver mutations were detected in 259 genes in B-ALL and 156 in T-ALL. We observed different driver mutation profiles in our cohort compared to the Western cohort. Mutations in RAS pathway (*NRAS*, *KRAS* and *PTPN11*) were more frequent in Chinese patients, whereas the JAK-STAT (*JAK2*, *IL7R*, *SH2B3* and *CRLF2*) pathway was more frequently mutated in Western cohort. We observed direct clinical relevance of these aberrations. For example, patients with *TP53* and *NR3C1* mutations showed inferior treatment response.

The implementation of NCMC-ABC in a nationwide multicenter pediatric ALL clinical trial demonstrated its effectiveness and feasibility in real-world, improving risk stratification and therapeutic decision making in clinic.

#5284 Epigenetic clusters identified in Hispanic/LatinX colorectal cancers reveal novel molecular subtypes.

Seeta Rajpara[1], Vicky Yamamoto[2], Carmen Chavez[1], John D. Carpten[3], David W. Craig[4], Heinz-Josef Lenz[5], Bodour Salhia[5]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]Keck School of Medicine, Los Angeles, CA,[3]Department of Integrative Translational Sciences, City of Hope Comprehensive Cancer Center, Duarte, CA,[4]City of Hope Comprehensive Cancer Center, Duarte, CA,[5]USC Norris Comprehensive Cancer Center, Los Angeles, CA

Introduction: Colorectal cancer (CRC) incidence and mortality are rising among Hispanic/LatinX (HL) individuals, yet they remain underrepresented in genomic studies. As a result, it is unknown whether HL CRCs harbor distinct epigenetic or biological features. We addressed this gap by profiling HL CRC tumors using genome-wide DNA methylation and integrating these data with matched transcriptomic and genomic datasets.

Methods: We generated DNA methylation profiles for 104 HL CRC tumors using the Illumina EPIC v2 array. RNA-seq (n=92) and whole-exome sequencing (WES; n=89) were available for integrative analyses. TCGA non-Hispanic White (NHW) CRCs served as a reference cohort. CIMP status was assigned using promoter methylation values for eight canonical CIMP markers (MLH1, IGF2, CACNA1G, NEUROG1, RUNX3, SOCS1, CRABP1, CDKN2A). Unsupervised clustering of the top most variable CpGs was used to define methylation subtypes. Pathway interpretation was performed by summarizing CpGs into gene-context scores across cancer related pathways. Matched RNA-seq and WES data were used to characterize transcriptional and mutational features of each subtype and validate DNA methylation pathway interpretation. CMS classifications, MSI status were assigned for comparison.

Results: CIMP patterns in HL CRCs differed markedly from NHW tumors in TCGA. Only 1% of HL MSI tumors were CIMP-H (vs. 7.1% in NHW MSI CRCs), and 11% were CIMP-0 (vs. 3.4% in NHW), indicating a decoupling of MSI and CIMP-H status. Unsupervised clustering identified six novel methylation-defined subtypes (HL-C1 to HL-C6) with distinct immune, stromal, metabolic, and epigenetic features. These subtypes also differed by mean age at diagnosis and global methylation: HL-C1 (58.7y, β=0.493), HL-C2 (51.2y, β=0.358), HL-C3 (60.1y, β=0.428), HL-C4 (51.9y, β=0.222), HL-C5 (52.8y, β=0.460), and HL-C6 (44.5y, β=0.608). Integration with RNA-seq confirmed concordant pathway activation across overlapping samples. Somatic mutations further distinguished subtypes: TP53 mutations were reduced in HL-C6 (37.5% vs. ~66% in other clusters), while MLH1 mutations were enriched (12.5%). CMS assignments did not recapitulate these six HL-specific subtypes.

Conclusion: HL CRCs display molecular features not captured by existing CIMP or CMS frameworks. The distinct methylation subtypes identified here offer new insight into HL CRC biology and provide a foundation for refining future molecular studies in this population.

#5285 Toward a functional characterization of polygenic modifiers of *BRCA2* associated prostate cancer risk.

Kenneth Offit, Sanchari Bhattacharyya, Matthew Buas, Brett Carver, Jonathan Fainberg, Yelena Kemel, Catherine Fanjoy, Viaji Joseph, Kathryn Graz, Xu Zhang, Shiv Prakash Verma, Ninghui Mao, Kyrie Pappas, Mitul Waghmare

Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Male carriers of *BRCA2* pathogenic variants are at elevated risk of prostate cancer (PC), with wide variation in disease frequency observed (88% vs. 34%) for men in the top versus bottom 5th percentile of a 147-SNP prostate cancer polygenic risk score (PRS) (PMID: 34320204). Causal variants and genes at most of these PRS loci remain uncharacterized, limiting our understanding of the molecular mediators and biological mechanisms underlying putative modifiers of *BRCA2* risk.
Methods: We adopted our published informatics pipeline to prioritize candidate functional variants at PC risk loci using Functional Potential Scores (FPS), assembled from disease-relevant annotations of chromatin accessibility, histone marks, and transcriptional factor (TF) binding. We identified 74 loci with a high-scoring lead SNP or strongly correlated variant ($r2>0.80$), typically mapping to a predicted enhancer region, and selected several such loci for experimental interrogation: 10q25, 11q13, 12q14, 19p13. Genomic fragments spanning prioritized SNPs were cloned in forward and reverse orientations upstream of a minimal promoter driving Nanoluc luciferase (pNL3.1), and luciferase reporter assays were conducted to evaluate allele-specific enhancer activity in normal prostate (RWPE-1) and PC cell lines (LnCAP, VCAP and 22PC). CRISPR genome editing studies are underway to assess the impact of enhancers and risk alleles on regional gene expression profiles.
Results: Three of the four candidate enhancer fragments tested exhibited enhancer activity in at least two cell lines -- 10q25/SNP5, 11q13/SNP10, 19p13/SNP17. Among these, the enhancer at 10q25 exhibited allele-specific activity, with up to ~two-fold stronger signal observed for allele C versus T in both normal and cancer cell lines. Initial studies also suggested allelic specificity for enhancers at 11q13 (SNP10 G>T) and 19p13 (SNP17 G>A). At 10q25, the functional variant identified maps to the third intron of *TCF7L2*, a critical gene in the Wnt signaling pathway, in a region bound by several key TFs in prostate including androgen receptor and FOXA1. Functional studies of validated target genes are being conducted with and without genotoxic stressors using human organoid cultures we have established from prostate biopsies of men with *BRCA2* mutations.
Conclusions: Our findings support the utility of the FPS informatics framework for prioritizing likely functional/causal variants at inherited cancer susceptibility loci and provide a foundation for downstream functional assays using physiologic model systems to investigate causal mechanisms of genetic modifiers of *BRCA2*-associated prostate cancer risk. (Supported by the Breast Cancer Research Foundation, CureBRCA, the MSK Niehaus Center and the Sabin Foundation)

#5286 Molecular and immune landscape of HER2-amplified colorectal cancer.

Sunyoung Lee[1], Michelle Weitz[2], Adam Dugan[2], Saif Nirzhor[2], Kayla Layng[2], Scott Kopetz[1], James Yu[1], Asif Rashid[3], Funda Meric-Bernstam[1], Mohamed Nuh[4], Monica Hsiang[4], Kanwal Pratap Singh Raghav[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Tempus AI, Inc, Chicago, IL,[3]Div. of Path. & Lab. Med., UT MD Anderson Cancer Center, Houston, TX,[4]Department of Medicine, Baylor College of Medicine, Houston, TX

Background: HER2 amplification defines a biologically distinct subset of colorectal cancer (CRC), yet its transcriptomic and immune correlates remain incompletely characterized. We profiled HER2-amplified CRCs to delineate clinicogenomic, immune, and transcriptomic features associated with ERBB2-driven oncogenesis.
Methods: We used Tempus Lens (Tempus AI, Inc., Chicago, IL) to query the Tempus multimodal de-identified database and identify patients with stage III/IV CRC who underwent Tempus xT (DNA) and xR (RNA) testing with tumor purity ≥30%. HER2 amplification was defined as *ERBB2* copy number (CN) ≥6. Demographic and clinical characteristics, somatic and germline alterations, quanTIseq-based immune cell infiltration estimates, and biomarkers (TMB, PD-L1, MSI) were compared. RNA-seq data were normalized to $\log_2$(TPM+1), and differential expression and pathway enrichment analyses on the hallmark gene set using fgsea compared HER2-amplified and non-amplified tumors.
Results: Among 16,394 patients with diagnoses of colon or rectal adenocarcinoma, 445 (2.7%) were HER2-amplified. These tumors occurred at a younger median age (58 vs. 60 years, p=0.001) and were more often left-sided (70% vs. 57%, p=0.011). Where data were available, *ERBB2* amplification showed 88% (36/41) concordance with external HER2 IHC/ISH and a correlation between *ERBB2* copy number and mRNA expression (ρ=0.38, p<0.001), demonstrating concordance across DNA, RNA, and protein levels. *ERBB2*-activating mutations, most frequently V777L (3.15%), followed by G776V, S310F, and H878Y, co-occurred in 9.2% of amplified tumors, suggesting dual genomic and structural activation. HER2-amplified CRCs had fewer *KRAS* mutations (14% vs. 48%, p<0.001; *G12D* most common), lower mean TMB (5 vs. 8 mut/Mb, p<0.001), and were universally MSS (MSI-H 0%). Germline mutation frequencies were similar between groups, with *CHEK2* and *MUTYH* most frequent. HER2-amplified tumors demonstrated reduced infiltration of M1 macrophages, NK cells, and Tregs (all p<0.01) and lacked significant enrichment of antigen-presentation, Th1, checkpoint, or co-stimulatory signatures (q=0.06-0.08), indicating a relatively immune-inactive microenvironment compared to non-amplified CRCs. Gene set enrichment analysis revealed a trend toward positive enrichment of cell-cycle and DNA replication programs (*E2F, MCM, PLK1, AURKB, TOP2A*) and suppression of *KRAS* signaling in HER2-amplified patients.
Conclusions: HER2-amplified CRCs exhibit a coordinated *ERBB2* activation axis linking DNA amplification, mRNA overexpression, and protein upregulation. These tumors are characterized by a hyperproliferative yet immune-depleted transcriptional profile. The biological interplay between HER2 signaling, proliferation, and immune modulation warrants further study, and future work should include clinical outcome correlations.

#5287 Parent-of-Origin-Aware genomic analysis in hereditary cancer: identifying the side of the family at risk using only the proband's blood sample.

[1]Medical Genetics, University of British Columbia, Vancouver, BC, Canada,[2]Terry Fox Laboratory, BC Cancer, Vancouver, BC, Canada,[3]Canada's Michael Smith Genome Sciences Centre, BC Cancer, Vancouver, BC, Canada,[4]University of British Columbia Faculty of Medicine, Vancouver, BC, Canada,[5]Hereditary Cancer Program, BC Cancer, Vancouver, BC, Canada,[6]University of British Columbia, Vancouver, BC, Canada,[7]BC Cancer, Vancouver, BC, Canada,[8]Cancer Genetics Service, National Cancer Centre Singapore, Singapore, Singapore,[9]City of Hope National Medical Center, Duarte, CA,[10]University of Pennsylvania, Philadelphia, PA,[11]Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA,[12]City of Hope National Medical Center, Los Angeles, CA,[13]School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada,[14]Medical Oncology, BC Cancer, Vancouver, BC, Canada,[15]BC Cancer

Background: Determining the parent of origin (PofO) of a variant in hereditary cancer guides counseling, risk management, recurrence risk assessment, and variant classification. In conditions involving genes with PofO effects, such as *SDHD*, *SDHAF2* and *MAX*, this information can determine whether disease will manifest. Current approaches rely on family-based testing, yet uptake among eligible first-degree relatives remains low, with fewer than 30% undergoing testing, creating a major barrier in hereditary cancer.To address this gap, we developed Parent-of-Origin-Aware Genomic Analysis (POAga), a method that integrates chromosome-scale haplotyping with DNA methylation at differentially imprinted regions to assign PofO without parental data. To validate POAga, we applied it to individuals with hereditary cancer and known segregation of their pathogenic variants, and compared the predicted PofO with the established segregation to assess concordance and limitations.**Methods:** Blood samples are being collected from individuals with pathogenic variants in hereditary cancer genes, representing broad ranges of ages, ancestries, and cancer histories. Parental segregation was previously known or established through confirmatory testing. Predicted PofO is compared with true segregation to assess concordance. All samples undergo Strand-seq and long-read sequencing under an REB-approved protocol.**Results:** To date, 285 samples with 290 pathogenic variants have been analyzed across the following genes: *BRCA2* (n=46), *BRCA1* (n=42), *MSH2* (n=34), *SDHD* (n=29), *MLH1* (n=27), *MSH6* (n=26), *PMS2* (n=20), *PALB2* (n=15), *TP53* (n=14), *ATM* (n=14), *CDH1* (n=9), *CHEK2* (n=3), *EPCAM* (n=2), *SDHAF2* (n=2), *MUTYH* (n=2), *CDKN2A* (n=1), *POT1* (n=1), *RAD51D* (n=1), and *SDHC* (n=1). PofO was assigned for 250 variants, with 98.4% concordance (246/250). PofO could not be determined for 40 variants (13.8%, 40/290), mainly due to insufficient allele-specific methylation at imprinted regions or extended homozygosity that impeded phasing. Misassignments were rare and mainly due to stochastic phasing errors, unresolved inversions, or random allelic methylation at imprinted regions.**Conclusion:** POAga achieves clinical-grade accuracy in assigning PofO from a single blood sample in hereditary cancer. This directly addresses a major barrier in clinical genetics, particularly when parental samples are unavailable. For genes with PofO effects, this information can determine whether disease will manifest. By enabling reliable segregation without parental testing, POAga helps direct clinical efforts toward those truly at risk and improves the clinical interpretation of variants. Ongoing analyses will refine its performance and support its adoption as a transformative tool in hereditary cancer genomics.

#5288 HMA-induced oncogene reactivation as a driver of disease progression in MDS.

Junsu Kwon[1], Yanjing Liu[2], Mahmoud A. Bassal[3], Julie A.I. Thoms[4], Emiliano Fabiani[5], John Pimanda[4], Maria T. Voso[6], Daniel G. Tenen[3], Li Chai[1]

[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA,[2]Broad Institute, Boston, MA,[3]Harvard Stem Cell Institute, Harvard Medical School, Boston, MA,[4]University of New South Wales, Sydney, Australia,[5]UniCamillus-Saint Camillus International University of Health Sciences, Rome, Italy,[6]University of Rome Tor Vergata, Rome, Italy

Hypomethylating agents (HMAs), including azacitidine and decitabine, are widely used for high-risk myelodysplastic syndromes (MDS) and selected AML, yet most patients eventually relapse, and survival after HMA failure remains dismal. HMAs were long assumed to function primarily by reactivating tumor suppressor genes through DNA demethylation. However, our recent work demonstrated that HMAs paradoxically upregulate the oncofetal gene SALL4, and that this induction strongly correlates with inferior overall survival, challenging existing paradigms. Emerging data suggest that additional cancer-germline antigen genes (CGAGs) may be similarly reactivated, generating oncogenic programs that facilitate resistance and leukemic progression. To investigate this, we profiled paired pre- and post-HMA patient marrow samples using RNA-seq and methylation analysis. We observed consistent post-treatment upregulation and promoter hypomethylation of SALL4 and multiple CGAGs, including PIWIL2, HORMAD1, and DDX43. Induction was more pronounced in patients with progression or treatment failure. Functional studies in MDS cell models revealed that forced expression of SALL4 or selected CGAGs enhanced proliferation, impaired myeloid differentiation, and reduced sensitivity to HMAs. Conversely, shRNA-mediated depletion mitigated these phenotypes. CRISPR-DiR-driven locus-specific demethylation of SALL4 recapitulated HMA-associated activation and conferred a proliferative advantage, confirming a causal role for promoter demethylation in SALL4 reactivation. We next evaluated therapeutic vulnerabilities associated with this pathway. Treatment with a newly developed small-molecule SALL4 degrader (SH6) reduced viability in SALL4-high models and reversed HMA-induced resistance phenotypes. Combination treatment with HMA + SH6 demonstrated enhanced cytotoxicity compared to either agent alone. Ongoing studies are expanding this approach to additional CGAG targets and mapping resistant subpopulations using single-cell transcriptomic and epigenetic profiling. Together, these findings reveal that HMA therapy can trigger unintended activation of oncogenic CGAG programs that drive MDS progression. They support a new mechanistic framework in which treatment-induced epigenetic reawakening promotes malignant fitness, and they identify SALL4 and CGAGs as high-value biomarkers and therapeutic targets. This work motivates development of companion diagnostic strategies and combination regimens pairing HMAs with targeted degraders to prevent therapy-induced disease acceleration and improve patient outcomes.

#5289 Native domain-interaction rewiring collapses the AR neo-enhanceosome in prostate cancer.

Jie Luo[1], Jianzhang Yang[2], Yuanyuan Qiao[3], Jean Ching-Yi Tien[1], Eleanor Young[2], sumit Das[1], Jocelyn Cai[1], Kenneth Gu[4], Shaomeng Wang[2], Arul M. Chinnaiyan[1]

[1]University of Michigan, Ann Arbor, MI,[2]University of Michigan, ANN ARBOR, MI,[3]University of Michigan Medical School, Ann Arbor, MI,[4]Rogel Cancer Center, Ann Arbor, MI

The androgen receptor (AR) signaling axis remains active in metastatic castration-resistant prostate cancer (mCRPC) through adaptive mechanisms that sustain oncogenic transcriptional programs despite androgen deprivation. AR cooperates with the histone acetyltransferase p300 and other cofactors to assemble cancer-specific “neo-enhanceosomes” via highly organized domain–domain interactions that drive oncogenic gene expression. Here, we introduce a new class of chemical-induced proximity compounds, termed Domain-ALTeration Chimeras (DALTACs), which represent a distinct modality designed to rewire endogenous protein complexes by altering native domain interactions rather than degrading or inhibiting individual proteins. Our first-in-class compound, AR–p300 DALTAC-1, enforces proximity between the AR ligand-binding domain and the p300 bromodomain, thereby miswiring their native architecture and locking the complex in a non-productive configuration. This domain reconfiguration elicits a “super-inhibitory” effect that suppresses AR target gene transcription and cell proliferation more potently than concurrent inhibition of AR and p300. Mechanistically, DALTAC-1 reprograms the substrate spectrum of p300, diminishing histone H2B N-terminal acetylation (H2BNTac) and triggering the collapse of the oncogenic enhancer network. Strikingly, DALTAC-1 displays remarkable lineage selectivity, exerting potent activity in AR-driven prostate cancer cells and organoids while sparing AR-negative or non-prostate lineage tissues. In multiple prostate cancer models, DALTAC-1 exhibits robust antitumor efficacy and tumor regression with favorable tolerability. Collectively, this study establishes the DALTAC modality as a new therapeutic concept that manipulates protein complex topology to reprogram cellular function, offering a versatile and generalizable strategy to rewire diverse transcriptional, epigenetic, and signaling complexes across different cancer types. Importantly, the exquisite lineage selectivity of DALTAC-1 minimizes effects on normal tissues, underscoring its strong clinical translational potential with a low likelihood of safety concerns.

#5290 Investigating the intrinsic epigenetic dependencies of estrogen receptor positive and ESR1 mutant breast cancer.

Andrej Coleski, Eleanor Young, Sumit Das, Xuhong Cao, Shannon VanAken, Fengyun Su, Yizhi Cao, Rui Wang, James M. Rae, Abhijit Parolia, Yuanyuan Qiao, Lanbo Xiao, Arul M. Chinnaiyan

University of Michigan, Ann Arbor, MI

Background: Estrogen receptor alpha (ERα) is a nuclear steroid hormone receptor that regulates transcription through DNA binding. ER is a lineage defining transcription factor (TF) that drives approximately 70% of breast cancer (BC) cases expressing the receptor. Aromatase inhibitor or selective estrogen receptor modulator treatment are first-line endocrine therapies for the treatment of ER$^+$ BC, and they function by disrupting ligand availability or antagonizing ER, respectively. Activating mutations in *ESR1*, the gene encoding ERα, are enriched in approximately 25% of metastatic cases. *ESR1* mutations lock ER in an active conformation, conferring ligand-independent signaling, endocrine therapy resistance, and increased proliferative capacity. Both wild-type and mutant ER primarily act through enhancer elements rather than promoters, relying on a network of transcriptional co-factors and chromatin remodeling complexes to facilitate enhancer accessibility. Targeting these epigenetic dependencies represents a promising therapeutic strategy. The mammalian SWI/SNF (mSWI/SNF) chromatin remodeling complex interacts with ER-associated transcription factors, including FOXA1, and supports enhancer activity and ER recruitment. Thus, disrupting mSWI/SNF function may impair ER-driven transcriptional programs in ER$^+$ BC.

Methods: mSWI/SNF activity was perturbed using either a dual PROTAC degrader of SMARCA2/4 or a selective SMARCA2/4 ATPase inhibitor. Pharmacological effect was assessed in a variety of preclinical models of ER$^+$ and *ESR1* mutant BC including cell lines and patient-derived xenografts (PDX). Mechanisms of action of ER signaling disruption and mSWI/SNF dependence were investigated using multi-omics techniques such as RNA-seq, ATAC-seq, ChIP-seq, and RIME.

Results: We showed that ER$^+$ BC cell lines are preferentially sensitive to mSWI/SNF complex inactivation at nanomolar concentrations of both compounds. We also demonstrated significant anti-tumor activity in both ER wild type and mutant PDX models. This anti-proliferative phenotype is shown to be driven by ER signaling axis disruption, with key downstream targets like c-Myc and CCND1 being downregulated. Mechanistically, we demonstrate these effects are mediated by reduced chromatin accessibility at enhancer regions, changes in the FOXA1 and ER cistromes, and a disruption of the ER interactome.

Conclusions: We establish the mSWI/SNF complex as a critical epigenetic dependency that sustains ER transcriptional activity in ER+ BC. Therapeutic targeting of SMARCA2/4 effectively disrupts enhancer function, impairs ER signaling, and suppresses tumor growth. mSWI/SNF-directed therapies therefore represent a promising strategy for advanced and endocrine-resistant ER+ breast cancers.

#5291 EZH2-AR non-canonical axis activation in TKI-resistant RCC: Differential effects of lenvatinib and cabozantinib.

Christian Migliarese[1], Abbas Jawadwala[1], Sabrina A. Orsi[1], Stephanie Metcalf[2], Saranya Rajendran[3], Peter C. Hollenhorst[3], Roberto Pili[1]

[1]University at Buffalo, SUNY, Buffalo, NY,[2]Indiana University School of Medicine, Bloomington, IN,[3]Indiana University, Bloomington, IN

Tyrosine kinase inhibitors (TKIs) are critical to the treatment of renal cell carcinoma (RCC). However, recurrent and metastatic RCC frequently develop resistance to TKIs, limiting therapeutic options. Understanding the molecular mechanisms underlying this resistance is crucial for improving patient outcomes. Our previous studies have identified EZH2 and the androgen receptor (AR) as key regulators of acquired resistance to the TKI . Inhibiting EZH2 or AR restores sunitinib sensitivity in vitro and in vivo, highlighting these molecules as therapeutic targets potentially shared across TKIs .To investigate the interplay between EZH2 and AR, we compared sunitinib-resistant 786-0 cells (786-0^{RS}) with drug-naive 786-0 cells overexpressing AR (786-0^{AR}). Chromatin immunoprecipitation sequencing revealed that AR and EZH2 co-occupy genomic loci exclusively in resistant cells. Sunitinib treatment induced nuclear translocation of AR in 786-0^{AR}, with AR binding at EZH2-occupied sites. Mass spectrometry further showed high phosphorylation of AR at S81 and S213, markers of ligand-independent activation, in 786-0^{RS}, which was absent in 786-0^{AR}.786-0^{RS} cells undergo EZH2-dependent reprogramming of the tyrosine kinome via a likely non-canonical mechanism. Co-expression of a phosphomimetic EZH2 mutant (S21D) with AR promoted sunitinib resistance, whereas wild-type or phosphonull (S21A) EZH2 did not. Expanded phosphoproteomic analyses revealed extensive rewiring of serine/threonine signaling networks in sunitinib resistant cells, including enrichment of EGFR-driven MAPK and AKT pathways. Interestingly, preliminary data indicate that cabozantinib does not induce AR and EZH2 upregulation like other TKIs such as lenvatinib. Moreover, cabozantinib appears to prevent compensatory pathway activation triggered by lenvantinib, suggesting a distinct resistance profile. Consistently, AR expression is observed in RCC lines resistant to sunitinib, dovitinib, and lenvatinib, but not with cabozantinib treatment. Ongoing phosphoproteomic analysis will dissect the difference across the TKIsdrugs. Overall, our findings suggest that EZH2-dependent kinase reprogramming drives AR phosphorylation and activation, contributing to drug resistance to selective TKIs. Cabozantinibunique ability to bypass AR/EZH2 upregulation underscores the need to explore alternative resistance pathways.

#5292 Epigenetic modulators romidepsin and mithramycin A reactivate tumor-suppressive programs and suppress c-MYC under hyperthermic conditions in colorectal peritoneal metastasis.

Yazid Ghanem[1], Gena Topper[1], Sahil Jethi[2], Jessica Collier[1], Marlena Buonasorte[1], Yong Ki Hong[1], **Weam Othman Elbezanti**[1]

[1]Surgery, Cooper University Health Care, Camden, NJ,[2]Cooper Medical School of Rowan University (CMSRU), Camden, NJ

Colorectal peritoneal metastasis remains difficult to treat despite advances in cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (HIPEC). Emerging evidence indicates that epigenetic dysregulation contributes to therapeutic resistance by repressing tumor suppressor pathways and sustaining oncogenic transcriptional programs. To evaluate whether epigenetically active agents improve antitumor responses relevant to HIPEC, we compared the histone deacetylase inhibitor romidepsin (Ro) and the Sp1 transcription factor inhibitor mithramycin A (MA) with the standard HIPEC agent mitomycin C (MMC) in HCT116 and HT29 colorectal cancer cells exposed to normothermic (37°C) or hyperthermic (42°C) conditions for 90 minutes. Both Ro and MA induced greater cytotoxicity, reduced clonogenic survival, and more strongly inhibited migration relative to MMC. Mechanistically, these agents robustly increased p21 and cleaved caspase-3 expression, consistent with reactivation of tumor-suppressive and apoptotic programs, while markedly suppressing c-MYC. Transcriptomic analysis further revealed that Ro and MA restored the expression of multiple epigenetically silenced tumor suppressor genes, including *SPRY2*, *HIC1*, *TIMP3*, and *DKK1*, indicating broad reversal of transcriptional repression. Hyperthermia variably augmented drug responses in a pathway-dependent manner, suggesting synergistic interactions between heat stress and chromatin remodeling. Ongoing studies using a murine HIPEC model with HCT116 peritoneal xenografts will define the molecular correlates and therapeutic potential of integrating epigenetic modulators into HIPEC-based regimens for colorectal peritoneal metastasis.

#5293 Targeting the oncogenic RNA m6A reader YTHDF2 inhibits oral squamous cell carcinoma by preventing p53 degradation.

Anitha Pandi[1], Vijayashree Priyadharsini Jayaseelan[1], Paramasivam Arumugam[2]

[1]Clinical genetics lab, Saveetha Dental College and Hospitals, Chennai, India,[2]Molecular biology lab, Saveetha Dental College and Hospitals, Chennai, India

Background: The N6-methyladenosine (m6A) RNA modification machinery has emerged as a critical modulator in cancer biology, however, the function of m6A “reader” proteins in oral squamous cell carcinoma (OSCC) is not fully understand. YTH domain family protein 2 (YTHDF2) is a prominent m6A-binding protein (m6A “reader”) that facilitates the degradation of methylated mRNAs and has been associated with tumorigenesis by targeting destabilization on clusters of tumor suppressor mRNAs. Nevertheless, the exact mechanism how YTHDF2 promotes OSCC proliferation and regulates p53 activity is in dire lack of elucidation. This study investigated the oncogenic role of YTHDF2 in OSCC and evaluated its potential as both a diagnostic biomarker and a therapeutic target.
Methods: The mRNA and protein levels of YTHDF2 were examined in OSCC tissues, matched adjacent non-cancerous specimens as well as OSCC cell lines by quantitative real-time PCR (qRT-PCR) and Western blot. Furthermore, the TCGA-OSCC dataset were employed to evaluate YTHDF2 expression, its clinicopathological characteristics and prognostic value. Functional assays including proliferation, colony formation and wound-healing assays were performed to evaluate the oncogenic phenotypes in YTHDF2-depleted OSCC cell lines. The antitumor effects were examined in vitro via OSCC cell lines and patient-derived organoids (PDOs) derived from OSCC patients who received a selective YTHDF2 inhibitor.
Results: YTHDF2 was remarkably up-regulated in OSCC tissues and cell lines compared with non-tumor tissues and normal cells, $P < 0.001$. Overexpression of YTHDF2 is correlated with OSCC development, progression and poor prognosis. YTHDF2 knockdown dramatically impaired OSCC cell proliferation, migration and tumorsphere formation. Functionally, YTHDF2 physically interacted with m6A-modified p53 transcripts and promoted their degradation. Inhibition of YTHDF2 significantly promoted the stability and protein expression of p53. YTHDF2 inhibitor impeded growth, migration, colony formation, tumorsphere and organoid development of cancer cells.
Conclusions: Our results recognize YTHDF2 as an oncogenic m6A reader promoting the OSCC progression by increasing p53 mRNA degradation. Our findings indicate that YTHDF2 can be exploited therapeutically and tumor suppressively as a candidate antitumor approach in OSCC.

#5294 Epigenetic modulation by DNMT-1 inhibitor induces cell death in SK-N-AS neuroblastoma cells.

Shyam Sundar Jaganathan, Umamaheswari Natarajan, Appu Rathinavelu

Rumbaugh Goodwin Institute for Cancer Research, Barry and Judy Silverman College of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL

Neuroblastoma (NB) is one of the most common extra-cranial solid tumors that is typically found in newborns and infants. Unfortunately, most children are present with advanced diseases and have poor prognosis at the time of diagnosis. Although the treatment of neuroblastoma has significantly improved with recent therapeutic strategies, many patients still do not benefit from them. As a result, new treatment approaches that can control aggressive and resistant tumors are urgently needed. Epigenetic regulation through DNA methylation and histone modifications have been shown to play a critical role in neuroblastoma progression, similar to the phenomenon seen in many other types of cancers. In this regard, DNMT's are commonly upregulated in aggressive neuroblastoma cells, contributing to transcriptional repression of tumor suppressor pathways. Therefore, in this study, we investigated the effect of the DNMT/G9a inhibitor CM-272 on cell survival in SK-N-AS neuroblastoma cells. Treatment of neuroblastoma cells with CM-272 at a concentration of 2 μM resulted in significant cell death, due to activation of the programmed cell death (PCD) cascade caused by elevated levels of apoptotic markers. In addition, CM-272 markedly suppressed DNMT-1 expression, confirming its ability to disrupt DNA methylation dependent gene silencing. In multiple cancer types, apoptosis induction was validated by enhanced cleavage of PARP accompanied by elevation of BAX and Caspases. Furthermore, CM-272 treatment elevated BAX expression, with downregulated BCL-2 levels, Intrinsic Pathway activation. In addition to the above analyses, miRNA expression profiling was performed using the NanoString Human miRNA panel. To fully explore post-transcriptional regulatory mechanisms that may be associated with CM-272 treatment. Together, these results demonstrate that CM-272 can induces apoptosis in SK-N-AS neuroblastoma cells by targeting epigenetic regulators and activating cell death pathways. Our findings suggest that CM-272 has strong therapeutic potential, as an epigenetic modifier drug, particularly in neuroblastoma tumors that are resistant to conventional treatments. Acknowledgements: This project was supported by the National Pediatric Cancer Foundation (NPCF). This research was also partially funded by the Bankhead Coley Infrastructure Development Grant from the Florida Department of Health that was awarded to A.R. through the Department of Pharmacology of the University of Miami (Coral Gables, Florida USA). #5295 Integrative identification and functional interrogation of DNA methylation-mediated epigenetic gene alterations in pancreatic cancer.

Sanghee Nam, **Galam Leem**, Seungmin Bang

Division of Gastroenterology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Pancreatic ductal adenocarcinoma (PDAC) remains a highly lethal malignancy with limited treatment options and a lack of effective molecular targets. Recent studies have highlighted the critical role of epigenetic modifications in the pathogenesis of various cancers.
Methods: To identify targetable epigenetic modifications in PDAC, we analyzed publicly available genomic datasets from pancreatic cancer patients and conducted genomic analysis of pancreatic cancer cell lines and patient-derived cell lines. The functional significance of the identified epigenetic modification was assessed by modulating its expression through DNA demethylation and overexpression experiments.
Results: We found that neurofilament (NEFL) was consistently and significantly downregulated in both pancreatic cancer patients and cell lines. We restored the expression of NEFL by DNA demethylation and overexpression in pancreatic cancer cell lines and found that NEFL overexpression reduced cancer cell proliferation, colony formation, invasion, and migration. Finally, we performed RNA sequencing to analyze the changes in gene expression profiles following NEFL overexpression.
Discussion: Our findings indicate that the epigenetic silencing of NEFL plays a crucial role in pancreatic caner progression. This study highlights the potential of targeted modification of DNA methylation as a promising novel therapeutic strategy for PDAC.
Key words: Pancreatic cancer; Neurofilament; DNA hypermethylation; epigenetic modification.

#5296 Epigenetic and transcriptional drivers of mucinous breast carcinoma.

Lorenzo Ferrando[1], Higinio Dopeso[2], Laxmi Gusain[2], Edaise M da Silva[2], Thais Basili de Oliveira[2], Lounes Djerroudi[3], Hannah Y. Wen[2], Hong Zhang[2], Edi Brogi[2], Richard P. Koche[4], Pierre-Jacques Hamard[4], Larry Norton[5], Jorge S. Reis-Filho[2], Britta Weigelt[2], Fresia Pareja[2]

[1]Department of Internal Medicine, University of Genoa, Genoa, Italy,[2]Department of Pathology and Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Deparment of Pathology, Curie Institute, Paris, France,[4]Center for Epigenetics Research, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Department of Medicine, Breast Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Mucinous breast cancer (MucBC) is an uncommon histologic subtype of estrogen receptor (ER)-positive/HER2-negative breast cancer (BC) characterized by tumor cells floating in pools of mucin. In contrast to ER-positive/HER2-negative invasive ductal carcinoma of no special type (IDC-NST), MucBCs harbor fewer *PIK3CA* mutations and typically lack concurrent 1q gains/16q losses. Yet, no pathognomonic genetic alterations have been identified to explain their mucinous phenotype. Here, we sought to determine whether MucBCs might be driven by distinctive epigenetic alterations.

Methods: We analyzed 40 pure MucBCs using genome-wide DNA methylation profiling (n=40) and/or RNA-sequencing (n=27). We evaluated DNA methylation age, epigenetic mitotic score, and integrated methylation-transcriptomic profiles, comparing MucBCs with IDC-NSTs from The Cancer Genome Atlas (TCGA) lacking *PIK3CA* mutations and concurrent 1q gains/16q losses to minimize genetic confounding factors. IDC-NSTs were matched at a 1:1 ratio by menopausal status, ER/HER2 status and histologic grade. The ER-positive/HER2-negative CAMA1, ZR-75-1 and MCF7 breast cancer cell lines were used to interrogate candidate pathways and transcriptomic changes.

Results: Compared to matched IDC-NSTs, MucBCs exhibited accelerated DNA methylation age relative to patient chronological age ($p=0.015$), indicative of epigenetic dysregulation, lower epigenetic mitotic scores ($p=0.0071$), and pronounced global enhancer hypomethylation ($p< 0.001$). Integrated methylation-transcriptome analyses identified *ZBTB20* and *ZNF133* as key transcriptional regulators in MucBCs (FDR < 0.05), as well as significant dysregulation of the TGF-β and estrogen-response pathways (FDR<0.05). In CAMA1 and ZR-75-1 BC cells, pharmacologic inhibition of the TGF-β pathway led to increased expression of mucin-encoding genes (*MUC2*, *MUC20*, *MUCL1*, *MUC5B*), while silencing of *ZBTB20* or *ZNF133* resulted in reduced mucin gene expression. In MCF7 cells, overexpression of ZBTB20 or ZNF133 similarly resulted in upregulation of mucin encoding genes and induced transcriptional changes in the TGF-β pathway, including downregulation of *TGFBR1, TGFB1, SMAD3* and *TRIM33* (*TIF1γ*) and upregulation of ID1, mirroring patterns observed in MucBCs.

Conclusions: MucBC display accelerated DNA methylation age and widespread enhancer hypomethylation, underscoring profound epigenomic dysregulation. Key transcription factors, including *ZBTB20* and *ZNF133*, appear to orchestrate mucin gene expression as well as TGF-β pathway reprogramming, contributing to the mucinous phenotype of MucBC.

#5297 Distinct genomic and pathway-level alterations in early-onset colorectal cancer: A large-scale Korean cohort analysis.

Ah Reum Lim[1], Boyeon Kim[2], Minsoo Kim[3], Soohyeon Lee[4]

[1]Korea University Ansan Hospital, Ansan, Korea, Republic of,[2]Korea University, Seoul,[3]Korea University Anam Hospital, Anam, Korea, Republic of,[4]Korea Univ. Medical Center, Seoul, Korea, Republic of

Background: Early-onset colorectal cancer (EOC) is rising in incidence globally, yet its genomic landscape in Asian populations remains inadequately characterized. Understanding molecular differences between EOC and traditional-onset colorectal cancer (TOC) is essential for clarifying age-related tumor biology.

Patients and methods: Genomic profiles from 1,675 nationwide colorectal cancer patients (2017-2021) were analyzed using targeted next-generation sequencing. EOC was defined as diagnosis at ≤50 years and TOC as >50 years. Mutational frequencies, spectra, pathway enrichment, and co-occurrence patterns were compared between EOC and TOC using R-based pipelines, including Fisher's exact test with FDR adjustment and maftools. Functional and protein-protein interaction analyses (DAVID, Metascape/MCODE) were performed to identify enriched pathways, and HRD-associated genes were additionally assessed for nonsense and frameshift loss-of-function variants.

Results: Among 1,675 patients (428 EOC; 1,247 TOC), EOC showed higher rates of TMB-high tumors (18% vs. 12%, p = 0.009) and MSI-high tumors (5.1% vs. 2.2%, p = 0.003), indicating a greater prevalence of hypermutated phenotypes in younger individuals. EOC also demonstrated higher mutation rates in *SMAD4, FAT3, and KMT2D*, each increased by approximately 3-4% compared with TOC. In contrast, classical colorectal cancer drivers such as *APC, KRAS, TP53*, and *WNT*-related genes were more frequently altered in TOC. In mutational spectrum analysis, EOC exhibited a modestly higher transition-to-transversion ratio, consistent with greater intrinsic genomic instability. Pathway analysis demonstrated enrichment of NOTCH, PI3K, Hippo, TGF-β, cell-cycle, and MYC pathways in EOC, while RTK-RAS and WNT pathways predominated in TOC. Ninety-one genes showed significantly higher mutation frequencies in EOC (FDR < 0.05). Loss-of-function mutations in HRD-related genes (*BRCA1/2, PALB2, RAD51C/D, ATM, CHEK2*) were also more frequent in EOC (11.4% vs. 8%), supporting the greater contribution of homologous recombination defects in early-onset disease. Co-occurrence network analyses revealed EOC-specific clusters involving chromatin remodeling and DNA repair modules, including a dominant DNA repair supercluster ($\log_{10}(P) = -16.5$ to -18.6), alongside enriched epigenetic and transcriptional regulation modules.

Conclusions: EOC exhibits distinct genomic and pathway-level characteristics, including higher genomic instability and enrichment of chromatin remodeling and DNA repair. These findings indicate that EOC represents a biologically unique subtype of colorectal cancer that may benefit from age-specific or HRD-targeted therapeutic strategies. Future work integrating germline sequencing with somatic profiles will help more comprehensively clarify the age-related molecular features of EOC.

#5298 Impact of genomic and clinical factors on therapeutic response to arly-phase epigenetic therapies: An international cohort from two major phase I units.

Manuel Pedregal[1], Harold Nathan Tan[2], Mercedes Avedillo[1], Ignacio Mahillo[3], Ester Garcia[4], Bernard Gaston Doger de Speville[4], Miriam Dorta[4], Jordi Rodon Ahnert[5], Victor Moreno Garcia[4]

[1]START - Madrid - FJD, Madrid, Spain,[2]The University of Texas MD Anderson Cancer Center, Conroe, TX,[3]MADRID - FJD - Unidad de estadistica y epidemiologia., Madrid, Spain,[4]START - Madrid - FJD, MADRID, Spain,[5]UT MD Anderson Cancer Center, Conroe, TX

Introduction: Epigenetic agents—including inhibitors of BET bromodomains, PRMT5, EZH2, and other chromatin regulators—have emerged as promising therapeutic strategies across solid tumors. However, clinical activity remains variable, and robust predictive biomarkers are lacking. We conducted a retrospective two-center analysis to characterize outcomes of patients treated with these compounds in early-phase trials and to evaluate the contribution of next-generation sequencing (NGS) profiles to interpatient variability.

Methods: A total of 262 patients treated within phase I trials of epigenetic agents at two academic early-phase drug development units were included. Clinical data (demographics, tumor type, ECOG status, prior therapies) and NGS results (pathogenic variants, VUS, short variants) were harmonized across centers into a unified dataset. Associations with overall survival (OS) were assessed using two-sided univariable Cox proportional hazards models. Hazard ratios (HR), 95% confidence intervals (CI), proportional hazards assumptions, Akaike Information Criteria (AIC), and C-statistics were reported.

Results: Median age was 59.9 years (IQR 51-69), and 55% were female. Most patients had metastatic disease (88.2%), ECOG 1 (59.2%), prior chemotherapy (78.5%), and prior immunotherapy (70.9%), with a median of 3 prior systemic lines (IQR 1-4). The median number of metastatic sites was 2 (IQR 1-3). Patients received diverse epigenetic compounds, most commonly BET inhibitors (46.6%), PRMT5 inhibitors (22.5%), HDAC inhibitors (14.1%), and EZH2 inhibitors (8.4%), across tumor types including gastrointestinal (21.4%), thoracic (19.8%), CNS (12.6%), and sarcoma/GIST (12.6%). Best overall response included 10% CR/PR (n=21), 39.7% SD (n=104), and 44.6% PD (n=117), reflecting modest clinical activity.In the clinical Cox model, worse OS was associated with higher metastatic burden (HR 1.19; 95% CI, 1.08-1.32; p<0.001), prior chemotherapy (HR 1.64; 95% CI, 1.17-2.31; p=0.004), and increasing prior lines (HR 1.05; 95% CI, 1.00-1.11; p=0.044). Age was also statistically significant (HR 0.99; 95% CI, 0.98-1.00; p=0.029). In the genomic Cox model, short EGFR variants were significantly associated with worse OS (HR 2.74; 95% CI, 1.36-5.52; p=0.005). Other alterations, including pathogenic EGFR mutations (HR 1.83; p=0.065), ATM (HR 3.00; p=0.066), and ASPM (HR 0.29; p=0.087) variants showed non-significant trends.

Conclusions: Epigenetic therapies showed modest activity in this heterogeneous early-phase cohort. Clinical factors—but not individual genomic alterations—were modestly prognostic for survival. These findings underscore the need for integrated
biomarker approaches beyond single-gene predictors to optimize patient selection in epigenetic drug development.

#5299 Epigenetic modulation by MDM2 and DNMT inhibitor promotes cell cycle arrest and programmed cell death in neuroblastoma cells.

Sruthika Talanki[1], Helen Le[2], Aashi Chhabra[3], Rhea Hede[4], Jose Nazario[5], Pragya Srivastava[2], Greeshma Davu[2], Shyam Jaganathan[5], Umamaheswari Natarajan[6], Appu Rathinavelu[5]

Neuroblastoma isa pediatricmalignancythat affects childrenmostly under the age of 5 yearsold. Thismalignancyoriginatesfrom neural crest cells (called neuroblasts) that can be found inthe adrenal glands, neck, chest, or pelvicareas. Although varioustreatments are availablefortreatingneuroblastoma, experimentaland literatureevidencesuggest that epigeneticmodificationscan triggercell cycle arrest and induceprogrammed cell death (PCD), such asapoptosis,providinga potentialtherapeuticavenue for achievinggreater success duringneuroblastoma treatments. Our study investigatedwhether the MDM2 and DNMT inhibitorscould block DNMTs, and concurrently upregulate TET and p21, to inducecell cycle arrest andapoptoticcell death inIMR-32 and SK-N-AS cells. To assess the effects of RG-7388, CM-272,and SGI-1027, the neuroblastoma cells were treated for 24 hrs, then qRT-PCR analyses wereconducted to evaluate the gene expressionlevels of DNMT-1, DNMT-3A, DNMT-3B, G9a,EZH2, TET-2, TET-3, MDM2, p53, p21, and PARP. In addition,the proteinexpressionlevels ofthe previouslylistedgenes were evaluated through western blot methods to quantifythe changesinepigenetic,cell cycle, and apoptosis-relatedbiomarkers.Interestingly, the qRT-PCR analysisshowed a downregulationof DNMT-1, DNMT-3A, DNMT-3B, G9a, and EZH2 levels intheCM-272 and SGI-1027 treated SK-N-AS cells compared to the control. In both IMR-32 andSK-N-AS cells, the western blot analysisrevealed DNMT-1 downregulation,cleavage of PARP,and upregulationof BAX followingthe drug treatments. So far, our findingsindicatethatRG-7388, CM-272, and SGI-1027 treatments effectivelydownregulate the expressionof DNMTs, whileupregulatingp21 levels inIMR-32 cells, leadingto cell cycle arrest andapoptosis.The abilityof these experimentalcompounds to inducecell cycle arrest and cell deathsuggests that further evaluationof these compounds could lead to the identificationof apromisingtherapeuticagent for treatingaggressiveneuroblastoma.(Thisprojectwas supported by the NationalPediatricCancer Foundation(NPCF) and The RoyalDames of Cancer Research Inc., Ft. Lauderdale, Florida)

#5300 Clinical utility of whole genome sequencing for upfront risk stratification in AML and MDS patients.

Kerry D. Fitzgerald[1], Dennis D. Krutkin[1], Jenny Brouckaert[2], Traci Pawlowski[2], Pratheesh Sathyan[2], James Han[2], Tong Liu[1], Yuanyu Cao[1], Xiaojun Guan[1], Jake Humphrey[3], Grant Hogg[1], John Howitt[3], Amanda Williamson[3], Shakti Ramkissoon[3], Marcia Eisenberg[3], Brian Caveney[3], Eric A. Severson[3], Eyad Almasri[1], Jonathan Williams[1], Taylor J. Jensen[3]

[1]Labcorp, Inc., San Diego, CA,[2]Illumina, Inc., San Diego, CA,[3]Labcorp, Inc., Durham, NC

Acute Myeloid Leukemia (AML) and Myelodysplastic Syndromes (MDS) are hematologic malignancies that require a quick and accurate risk stratification for guiding treatment decisions. In this study, we retrospectively assessed the accuracy and utility of Whole Genome Sequencing (WGS) using clinical samples previously tested at Labcorp with FISH, Chromosomal banding, microarray, single gene molecular technologies, and/or NGS. Samples were selected based on presence of structural variants (SVs), Copy Number Variants (CNVs), or clinically significant mutations e.g. FLT3-ITD, and included controls and healthy donors. 90 total samples were included with 74 suspected of having AML/MDS. To determine WGS performance, all available clinical testing results were leveraged; samples were also assayed on Labcorp's 141 gene pan-heme NGS assay that reports somatic small variants when VAF >3%, as well as 16 CNVs. Sensitivity and specificity were calculated for single nucleotide variants (SNVs), indels, and CNVs overlapping the pan-heme NGS panel, as well as SVs and CNVs from other clinical testing results. Libraries prepared using Illumina's PCR-free Tagmentation kit were sequenced on a NovaSeq X Plus and analyzed using Illumina's DRAGEN Heme WGS pipeline in Illumina Connected Analytics; variants were scored and interpreted using Illumina Connected Insights. Estimated TAT: 67 hours per batch of 15 samples before director review and sign out. Mean genomic coverage for the cohort was 160X. Excluding events with FISH probe positivity <10%, WGS detected 116/121 SVs and 122/127 CNVs identified by cytogenetic/FISH analysis (sensitivity 0.96 and 0.98, respectively). The comparator targeted NGS assay averages 400X read depth. WGS detected 426/427 (.998) variants >10% VAF and 441/447 (.989) variants >5% VAF. Additional clinically relevant findings were identified with WGS in regions not covered by the comparator assays. Calculating performance for reportable SNVs >10% we observed a positive predictive value (PPV) of 100% with no known false positives (FPs). SV and CNV false negatives (FNs) were driven by variants below the Limit of Detection (LOD) expected for WGS. SNV FPs and FNs were from minor fluctuation between the two methods near the performance threshold. Using the Platinum Genome Cell line NA12878 and healthy donors, specificity was 100% with no FPs detected across 11 replicates and 9 individuals evaluating SNVs/indels within the pan-Heme ROI. Utilizing a WGS approach we observed increased sensitivity compared to similar previously reported studies, likely resulting from improved technology and increased sequencing depth. Compared to current laboratory assays WGS has comparable accuracy, sensitivity, and specificity, with additional benefits in clinical utility, cost reduction, improved workflow, TAT, and robustness.

#5301 Evaluating the molecular landscape of genetic mutations among Black patients with acute myeloid leukemia.

Eno-obong B. Udoh[1], Xiaoying (Nicole) Chen[2], Sarah J. Philip[3], Yazeed Sawalha[4], Yazan F. Madanat[5], Ameera Rose[6], Teodora Kuzmanovic[6], John C. Molina[7], Moaath K. Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, TX,[6]Cleveland Clinic Foundation, Cleveland, OH,[7]Department of Hematology and Medical Oncology, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH,[8]Department of Translational Hematology and Oncology Research, Cleveland Clinic Lerner Research Institute, Cleveland, OH,[9]Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL

Introduction: Acute myeloid leukemia (AML) is an aggressive blood cancer driven by genetic changes that disrupt hematopoiesis. It is characterized by poor survival, with two-thirds of patients dying within 5 years. Non-Hispanic Black patients with AML have higher mortality rates compared to White patients despite favorable disease factors like low-risk cytogenetics and younger age. Risk stratification in AML has been greatly improved by the inclusion of tools such as next generation sequencing (NGS) in the prognostication of AML. However, little is known about the molecular landscape and prognostic relevance of mutations in Black patients with AML. This study characterizes the genetic profiles of Black patients with AML at the Cleveland Clinic.

Method: This retrospective, single-center, cohort study included patients diagnosed with AML between 2002 and 2022. Clinical data were obtained from electronic medical records and stored securely. Molecular data were obtained from NGS platforms of genes frequently mutated in AML. Overall survival (OS) was limited to patients receiving intensive induction chemotherapy and estimated using Kaplan-Meier method.

Results: Overall, there were 118 (9.34%) Black patients among our cohort of 1,264 AML patients. 55% of these patients were male and the median age at diagnosis was 62 years. Karyotype analysis revealed that majority (68%) of Black patients had an abnormal karyotype driven by trisomy 8 (23.0%), -7 or del (7q) (17.6%), or -5 or del (5q) (16.2%) abnormalities, of which the latter two represent adverse risk disease. Most of these patients (65%) were treated with intensive induction chemotherapy and of these 30% (n=23) underwent a bone marrow transplant. NGS was available for 49.1% (n = 58) of Black patients and revealed a predominance of mutations in genes involved in DNA methylation: *DNMT3A* (24%, n=14) and *TET2* (21%, n=12). Median OS was 24 months (95% CI: 14-46months) with a 5-year OS rate of 27% (95% CI:18-40%), lower than the national average of 32.9%. Older age (>60), poor risk cytogenetics, non-intensive chemotherapy, *TET2*, and *ASXL1* were associated with worse survival in univariable analysis ($p<0.05$). Upon adjusting for prognostic variables, only poor risk cytogenetics remained significant ($p=0.02$).

Conclusion: *DNMT3A* and *TET2* mutations were most observed in Black patients with AML in this cohort at similar frequencies compared to population studies. These genes are observed in clonal hematopoiesis indicating early events in leukemogenesis. Their prognostic significance remains undefined but may inform future studies addressing outcome disparities through better risk stratification and the development of targeted therapies. Study limitations include small sample size, NGS availability and self-reported race/ethnicity. Comparative analysis with White patients and prospective studies with genetic ancestry testing are needed.

#5302 Defining the landscape of TP53 mutations in acute myeloid leukemia.

Joseph Stenberg[1], Jordan Redemann[1], Jessica Lewis-Gonzalez[2], Rama Gullapalli[1], Charles Foucar[2]

[1]Department of Pathology, University of New Mexico, Albuquerque, NM,[2]Department of Hematology and Oncology, University of New Mexico, Albuquerque, NM

Background and Objective: The *TP53* gene is one of the most frequently mutated genes in human cancers. *TP53* mutations can be classified as functional, partially functional, or nonfunctional. In gynecologic cancers, this information has been used to identify patients who are sensitive to bevacizumab and has led to the exploration across multiple cancer types of "p53 reactivators" to restore normal p53 activity. In myeloid neoplasms, the 10 most commonly mutated amino acid residues account for 30% of all *TP53* mutations, all located within the DNA-binding domain. However, protein functionality has not been sufficiently described in the context of acute myeloid leukemia (AML). The main goal of this study is to analyze the functional classification of *TP53* mutations in AML.
Methods: *TP53*-mutated AML cases were identified by searching for "TP53" in next-generation sequencing reports within TriCore Reference Laboratories' laboratory information system. Cases were individually reviewed to include those with an AML diagnosis (n=76) and those treated at the University of New Mexico (UNM) (n=12). Molecular, cytogenetic, histologic findings, laboratory values, and clinical data were collected and recorded in REDCap, a secure translational research database. The National Cancer Institute's TP53 Database was used to classify *TP53* mutations and assign functional classifications.
Results: Of the 76 patients, 43 had a single *TP53* mutation and 21 had two or more *TP53* mutations. A total of 89 *TP53* mutations were identified, including 68 non-functional mutations, five partially functional mutations, one functional mutation, and 15 unclassified mutations. Twelve patients (12/76) received treatment at UNM and had additional cytogenetic and prognostic data. Seven patients (7/12) had a complex karyotype, and six patients (6/12) had chromosome 17 alterations at diagnosis. 11 patients (11/12) had non-functional or unclassified *TP53* mutations. These patients had a median overall survival of 6.4 months. A single patient (1/12) was found to have a functional *TP53* mutation and is currently alive 17.6 months after diagnosis.
Conclusion: Our findings indicate that a majority of patients diagnosed with *TP53*-mutated AML have non-functional mutations. However, a single patient with a functional *TP53* mutation showed a significantly better clinical course. Further subclassification of *TP53* mutation functionality may be necessary for accurate prognosis predictions and for novel therapeutic approaches.

#5306 Transcriptomic analysis of small extracellular vesicles in metastatic breast cancer.

Emmanuel Acheampong[1], Tumisang Ntereke[1], Katie Dixon[1], Karen Page[1], Shradha Bhagani[1], Naila Abid[1], Marc Wadsley[1], Rebecca Allsopp[1], Charles Coombes[2], Jacqui Shaw[1]

[1]University of Leicester, Leicester, United Kingdom,[2]Imperial College, London, United Kingdom

Introduction: Small extracellular vesicles (sEVs) are emerging as a valuable liquid biopsy tool for cancer, complementing cell-free DNA and circulating tumour cells. These nanoscale, membrane-bound particles, secreted by all cell types, carry DNA, RNA, proteins, and lipid cargo that reflect their cellular origin. sEV-RNAs are implicated in cancer progression, metastasis, and therapeutic resistance. We demonstrate a workflow for isolating sEV-RNAs from plasma for RNA sequencing.
Methods: We used sensitive MCF7 and fulvestrant-resistant MCF7 (FULVR-MCF7) breast cancer cell lines to optimise a workflow that combines ExoGAG technology for EV isolation with the Ion AmpliSeq™ Transcriptome gene expression kit (AmpliSeq™) for profiling sEVs on the Ion Torrent S5XL system. AmpliSeq™ detects 20,802 mRNA targets from low RNA inputs, making it suitable for analysing the limited RNA from sEVs. The ExoGAG-AmpliSeq™ workflow was validated using sEV-RNA samples from the plasma of 5 patients with metastatic breast cancer (mBCa) and 3 healthy female controls.
Results: Evaluation of different cell line RNA concentrations (500pg - 10ng) demonstrated that a 1ng RNA input yielded robust sequencing output, with high mapped reads and accurate measurement of AmpliSeq target regions and gene detection comparable to the standard 10ng input. We then applied the workflow to compare ExoGAG-isolated sEV-RNA from exosome-depleted FBS cell culture medium of MCF7 and FULVR-MCF7 cell lines using 1ng RNA input. All samples met library quality control metrics, and sequencing yielded an average of 12 million reads per sample. Technical replicates of MCF7 and FULVR sEVs RNA samples showed minimal variation in raw gene read counts (Pearson's $r \geq 0.95$). Differential gene expression analysis using DESeq2 identified 1331 significantly differentially expressed genes (FDR < 0.05), with 680 upregulated and 651 downregulated. Gene Ontology analysis indicated downregulation of sensory perception and metabolite transport pathways, and upregulation of antiviral and immune signalling pathways, including type I interferon and lymphocyte activation. These findings highlight altered intercellular communication associated with drug resistance. In the mBCa patient samples, 248 genes showed significant expression changes, with 83 upregulated and 165 downregulated relative to healthy controls. HLA-B and ENPP1, both associated with EV and exosome biology, and AGAP2, linked to endosomal trafficking for vesicle formation, ranked among the top 10 significant genes. Pathway analysis showed these genes were significantly enriched in biological pathways involved in system development, intracellular signal transduction, and regulation of cellular processes.
Conclusions: The ExoGAG-AmpliSeq™ workflow is feasible for recovering and analysing plasma-derived sEV-RNA and developing gene signatures as breast cancer biomarkers.

#5307 Analytical performance of an ultrasensitive whole genome sequencing assay for molecular residual disease detection.

Andrew Georgiadis[1], Christopher Greco[1], Cynthia Maddox[1], Paul McGregor[1], Cesar Nalvarte[1], Kaitlin Victor[1], Amanda Harvey[1], Shelby Bain[1], Robert Summersgill[1], Ana Perez-Lebron[1], Liam Cox[1], Stephen Higgings[1], David Riley[1], Samuel Angiuoli[1], Marcia Eisenberg[2], Brian Caveney[2], Eric Severson[2], Taylor J. Jenson[2], Shakti Ramkissoon[2], Mark Sausen[1]

[1]Laboratory Corporation of America, Baltimore, MD,[2]Laboratory Corporation of America, Durham, NC

In non-metastatic cancers after curative intent intervention, a significant subset of patients retain tumor cells which can lead to disease recurrence. These residual tumor cells can be detected through ultra-sensitive circulating tumor DNA (ctDNA) assays and reported as molecular residual disease (MRD). The most common approaches generally utilize patient-specific, bespoke panels, which have extended turnaround times for initial testing and relatively high cell-free DNA (cfDNA) input requirements. Here we present a non-bespoke approach based on whole genome sequencing (WGS), which leverages native duplex error correction using the Ultima Genomics (UG) sequencing platform for rapid turnaround times for initial testing with low cfDNA input. Specifically, patient tumor, white blood cell, and plasma derived DNA were sequenced to approximately 80x, 30x, and 80x depth, respectively, through a PCR-free WGS workflow on the UG 100 platform. These data were demultiplexed and aligned on-instrument to the hg38 human reference genome. Paired variant calling for matched tumor and white blood cell samples was performed with the UG-adapted DeepVariant algorithm, and subsequently filtered to retain only tumor-specific single nucleotide variants (SNVs). Plasma variant analyses at those tumor-specific SNV positions were performed to leverage the paired plus-minus sequencing (ppmSeq) approach and allowed for ≥Q60 base quality, equating to a theoretical $1x10^{-6}$ error rate. ctDNA status and abundance was then assessed based on the level of the sample-specific machine learning model weighted and normalized signal compared to a reference population of noncancerous donor plasma samples (n=85). We assessed analytical specificity for 120 noncancerous donor plasma samples evaluated against clinical whole-genome somatic mutation profiles and demonstrated a specificity > 99.5%. Analytical sensitivity for ctDNA detection was assessed using five commercially available cell lines across ten levels between 1 - 500 parts per million (ppm) and demonstrated a 95% limit of detection < 5 ppm. Additionally, analytical concordance was evaluated in pre-surgical, treatment naïve plasma samples across a cohort of patients with bladder, breast, colon, and colorectal cancers. Taken together, these data support the significant potential for tumor-informed, non-bespoke MRD approaches for ctDNA detection across a broad range of solid tumor types and curative-intent clinical settings.

#5308 Monitoring treatment response in metastatic breast cancer patients using an mDETECT assay.

Keira Frosst[1], Brooke E. Wilson[2], Katarzyna J. Jerzak[3], Christopher R. Mueller[1]

[1]Queen's University, Cancer Research Institute, Kingston, ON, Canada,[2]Kingston Health Sciences Centre, Kingston, ON, Canada,[3]Sunnybrook Health Sciences Centre, Toronto, ON, Canada

Metastatic breast cancer treatment response is currently monitored with CT-scans every 3-6 months leaving many patients on ineffective therapy while their disease progresses. We have developed the methylation DETEction of Circulating Tumour DNA (mDETECT) assay, a targeted DNA methylation-based Next Generation Sequencing liquid biopsy designed to detect cancer specific DNA methylation patterns. The breast cancer assay targets 60 hypermethylated regions (>400 CpGs), detects all subtypes of breast cancer, is quantitative for molecules of methylated DNA, and shows 93% sensitivity at 100% specificity for TNBC with a limit of detection of 0.025%. It is both tumour and treatment agnostic as well as being compact (2 million sequencing reads per sample) making it ideal for frequent disease monitoring.

We are conducting a prospective multi-centre observational cohort study to monitor metastatic breast cancer patients using the mDETECT liquid biopsy as they undergo treatment. Metastatic breast cancer patients are eligible regardless of subtype or treatment and are followed through treatment changes. 20mL of blood is collected at each standard of care blood draw for up to 3 years. Patients are assessed for response to treatment and monitored for disease progression.

Over 120 participants have been enrolled to date with recruitment ongoing, generating over 500 timepoints (0-22 timepoints/patient). Initial patients with completed longitudinal timepoints have been assessed using the mDETECT assay. Although complete clinical and radiological outcome data are not yet available, early molecular results show decreasing mDETECT levels during treatment and increasing levels prior to treatment change or disease progression.

These preliminary findings demonstrate the potential of methylation-based monitoring for metastatic breast cancer patients, a key clinical need as there are many therapy options available and complex treatment sequence decisions to be made. We will evaluate whether specific mDETECT trajectories predict disease progression and durable treatment response. Ongoing follow-up and integration of radiology data will further assess the predictive value of mDETECT in monitoring metastatic breast cancer.

The mDETECT assay may allow for more timely treatment decision-making in metastatic breast cancer, improving outcomes and reducing prolonged exposure to ineffective therapy.

#5309 Baseline ctDNA profiling identifies molecular predictors of resistance to second-generation ALK inhibitors in EML4-ALK-positive NSCLC.

Emma Roger Sonderbek[1], Maiken Parm Ulhoi[2], Peter Meldgaard[2], Boe Sandahl Sorensen[2]

[1]Aarhus University, Aarhus, Denmark,[2]Aarhus University Hospital, Aarhus, Denmark

Introduction: Lung cancer remains the leading cause of cancer-related death worldwide. Although tyrosine kinase inhibitors (TKIs) have improved outcomes for EML4-ALK-positive non-small cell lung cancer (NSCLC), most patients experience disease progression. Understanding the clinical and molecular factors that drive resistance is essential for guiding more effective treatment strategies.
Aim: To identify molecular features associated with treatment resistance and survival in patients receiving first-line alectinib or brigatinib.
Patients and Methods: Seventy-two patients with EML4-ALK-positive NSCLC treated with first-line alectinib or brigatinib were included. Plasma samples were obtained at baseline, during treatment, and at disease progression. Circulating tumor DNA (ctDNA) was analyzed using cancer personalized profiling by deep sequencing (CAPP-seq) and the R/Bioconductor package, *DNAfusion*, recently developed in our lab. ctDNA features at progression and at baseline were correlated to time to progression (TTP) and overall survival (OS).
Results: During a median follow-up of 27 months, 54% (39/72) of patients developed disease progression. *ALK* on-target resistance mutations at progression were observed exclusively in short EML4-ALK variants (40% vs 0% in long variants, $p<0.05$). Patients with short variants also had numerically shorter TTP (14 vs 35 months, $p=0.12$) and OS (38 months vs NE, $p=0.16$). Baseline ctDNA profiles were analyzed to assess associations with clinical outcomes. Patients with a high plasma mutation load (>1 mutation) had significantly shorter TTP (13 vs 51 months, $p<0.05$) and OS (36 months vs NE, $p<0.05$) compared with those with a low load (0-1 mutation). In addition, *TP53* mutations were strongly associated with poor outcomes (TTP: 10 vs 45 months, $p<0.05$; OS: 12 months vs NE, $p<0.05$).
Conclusion: Development of *ALK* on-target resistance mutations at progression demonstrates a significant association with short EML4-ALK variants. A high mutation load and *TP53* mutations at baseline identify patients at risk of early progression and poor survival under second-generation ALK TKI treatment. These findings suggest that ctDNA-based molecular profiling may help guide personalized treatment strategies and improve survival outcomes for EML4-ALK-positive NSCLC.

#5310 Dynamic changes in ctDNA methylation predict early response to immunotherapy in advanced esophageal cancer.

Hui Zhang#[1], Yu Lang#[1], Yaping Dong#[2], Wei Li#[3], Jialin Lin[4], Lu Yang[5], Jiapeng Kang[6], Wenqiang Yu*[7], Changshun Yang*[8], Jingxun Wu*[1], Qiyuan Li*[9], Feng Ye*[1], Weiwei Tang*[1]

Background: Immune checkpoint inhibitors (ICIs) improve the prognosis of advanced esophageal cancer (ESCA), yet accurate response prediction remains challenging. Traditional biomarkers and imaging often lack timely reflection of disease progression. Circulating tumor DNA (ctDNA) methylation offers novel, non-invasive, real-time monitoring. In this study, we evaluated the early dynamic ctDNA methylation changes in advanced ESCA and predicted ICI response and survival.

Methods: This observational exploratory study enrolled advanced ESCA patients on ICI treatment.Peripheral blood samples were collected at baseline and regularly throughout treatment.Plasma ctDNA was subjected to methylation sequencing. Patients were stratified into "decreased" (methylation score reduction from baseline) and "non-decreased" (stable or increased scores) groups based on dynamic changes. Kaplan-Meier and log-rank tests assessed methylation score dynamics' association with progression-free survival (PFS) and overall survival (OS). Consistency between ctDNA dynamics and imaging efficacy (RECIST 1.1) was also evaluated.

Results: Baseline ctDNA methylation levels did not significantly correlate with outcomes (p=0.1); however,dynamic changes were strongly prognostic. The "decreased" group demonstrated significantly longer PFS (26.0 vs. 15.85 months; p<0.05) and median OS (35.0 vs. 27.0 months; p=0.01) compared to the "non-decreased" group. CtDNA-defined response occurred significantly earlier than radiological response (1.55 vs. 4.0 months, p<0.05). Median time to ctDNA-defined progression (2.52 vs. 4.0 months) also preceded imaging progression, without statistical significance (p=0.15).

Conclusion: Dynamic ctDNA methylation monitoring presents a promising non-invasive approach for assessing ICI efficacy in advanced ESCA. A reduction in post-treatment ctDNA methylation levels significantly correlated with prolonged survival. ctDNA dynamics enabled earlier prediction of treatment response and progression than radiological assessment, highlighting its potential for timely detection. These findings underscore the value of dynamic ctDNA methylation analysis as a novel early efficacy marker.

#5311 Tracking prostate cancer progression by deep whole genome sequencing of primary tumors and longitudinal circulating tumor DNAs.

Samira Rahimirad[1], Eleonora Scarlata[1], Lucie Hamel[1], Seta Derderian[1], Ginette McKercher[1], Fadi Brimo[2], Fred Saad[3], Armen Aprikian[4], Simone Chevalier[1]

[1]Urologic Oncology Research Group, Cancer Research Program, Research Institute of the McGill University Health Center (RI-MUHC), Montreal, QC, Canada, [2]Pathology, McGill University, Montreal, QC, Canada,[3]Surgery, Centre Hospitalier Universitaire de Montreal, Montreal, QC, Canada,[4]Surgery, McGill University, Montreal, QC, Canada

Background: Although prostate cancer (PCa) generally has a high survival rate, some patients develop aggressive disease. Identifying reliable markers of progression and therapeutic response is essential for improving management. Cell-free DNA (cfDNA) in blood provides a minimally invasive means to monitor tumor evolution through liquid biopsy. In this study, we compared primary tumors from severe PCa patients versus long-term disease-free individuals to identify genomic alterations linked to aggressiveness. We also tracked tumor-shared alterations in circulating tumor DNA (ctDNA) and discovered exclusive modifications emerging during progression. Methods: Banked fresh frozen prostate tissues from radical prostatectomy cases (lethal PCa=80, disease-free=35) were processed to identify tumor foci and macro-dissect cores of high cellularity (>75%) for DNA extraction. Serial plasma collections from six lethal cases were used to isolate cfDNA. Sequencing of tumors, matched germline blood DNAs, and cfDNAs was performed to identify copy number variations (CNVs) and mutations. Results: Already established and novel CNVs were found in tumors of both lethal and disease-free cases. Comparing their CNVs showed shared alterations associated with PCa development and disease recurrence, also pinpointing genomic signatures specifically associated with PCa severity. Clinical analysis of lethal cases revealed genomic deletions associated with rapid recurrence, metastases, castration-resistance, and short overall survival. Longitudinal cfDNA analysis unveiled rising ctDNA fractions when patients reached the metastatic and late stages. Although genomic amplifications were rare in primary tumors, they were common during progression. Tumor-shared alterations were found in the ctDNA during progression, along with newly discovered ctDNA-exclusive modifications. Furthermore, clonal ctDNA alterations became sub-clonal during treatment and re-emerged in the blood two years later in relation to treatment resistance. Evidence of tumor-shared and unique clonal evolutions was identified in the advanced disease stages, speaking for intra-tumoral and metastatic cellular heterogeneity. Conclusion: The identification of novel genomic changes in tumor DNA and ctDNAs in advanced disease is enhancing our knowledge of PCa severity. Findings on ctDNA underscore the significance of longitudinal liquid biopsy for monitoring disease progression. They could contribute to the development of novel diagnostic tests that enable earlier, more effective treatment and ultimately reduce PCa lethality.

#5312 Digital PCR-based plasma DNA methylationassayfor noninvasive molecular subtyping of small cell lung cancer: A prospective feasibility study.

Jin-Soo Kim[1], Mi Young Kim[1], Jeemin Yim[2], Yun Young Lee[3], Joon An[3], Jinil Han[3], Ji Eun Kim[2], Youngho Moon[3]

[1]Internal Medicine, Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Korea, Republic of,[2]Pathology, Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Korea, Republic of,[3]Gencurix, Inc., Seoul, Korea, Republic of

Background: Small cell lung cancer (SCLC) is an aggressive neuroendocrine tumor with limited treatment options and poor survival outcomes. Although recent studies highlight the clinical relevance of molecular subtypes for therapeutic stratification, tissue-based subtyping is often infeasible because most patients receive chemotherapy rather than surgical resection. This study aimed to develop and clinically evaluate a digital PCR assay for subtype-specific methylation profiling using plasma samples.
Methods: Twenty patients with pathologically confirmed SCLC were prospectively enrolled at Seoul National University Boramae Medical Center from April 2023 to September 2025. Plasma samples were collected prior to systemic therapy, and molecular subtypes were classified as NEUROD1-type (N-type; n = 1), ASCL1-type (A-type; n = 16), POU2F3-type (P-type; n = 3), or SCLC-I type (I-type; n = 0). Plasma-derived molecular subtypes determined by the digital PCR-based methylation assay were compared with these clinical classifications.
Results: Subtype-associated methylation markers were identified through integrative analysis of publicly available methylation array and expression datasets from the National Cancer Institute Small Cell Lung Cancer Screening Project. These candidate loci were integrated into a 4-plex digital PCR assay, which demonstrated clear subtype-enriched methylation patterns across representative SCLC cell lines. In 20 prospectively collected plasma samples, all targets were successfully quantified with sufficient clinical performance. Plasma-derived molecular subtypes showed overall concordance of 85.0% (17/20) with clinical classifications, with detection sensitivities of 100.0% (1/1) for N-type, 87.5% (14/16) for A-type, and 66.7% (2/3) for P-type cases. These findings support the feasibility of plasma-based methylation profiling for noninvasive SCLC molecular subtyping.
Conclusion: This study demonstrates the feasibility of using a digital PCR-based methylation assay to classify SCLC molecular subtypes from plasma. Larger validation cohorts are warranted to refine cutoffs and confirm clinical utility.

#5313 Fragmentomic analysis of cfDNA WGS at regulatory regions generates gene-level expression-like traits for subtype analysis in breast cancer.

Jonathan H. Shepherd[1], Jeff Burdine[1], Yoichiro Shibata[1], Gregory M. Mayhew[1], Gabe Milburn[1], Michael V. Milburn[1], Matthew LaBella[2], Shalee Killpack[2], Kirk L. Pappan[1], **James M. Davison**[1], Kirk Beebe[1]

[1]GeneCentric Therapeutics, Inc., Durham, NC,[2]Myriad Genetics, Salt Lake City, UT

Introduction: Analysis of cell-free DNA (cfDNA) from liquid biopsy provides a rapid, repeatable, and non-invasive means to study tumor biology. In breast cancer, invasive tissue biopsies and immunohistochemistry (IHC) remain the standard for determining molecular subtype and treatment selection. However, fragmentomic analysis of cfDNA whole genome sequencing (WGS) can yield biologically meaningful surrogates of tumor transcriptional states through its relationship with nucleosome positioning. Here, we describe a WGS-based fragmentomic pipeline that recapitulates gene-level, expression-like traits from cfDNA. These traits enable the development of fragmentomic classifiers reflective of tissue expression markers such as hormone receptor and HER2.

Experimental Procedures: Matched FFPE tumor blocks and plasma samples from 25 consenting patients with breast cancer were analyzed. Plasma cfDNA underwent WGS to 30-40× depth, and matched FFPE RNA was profiled by RNA sequencing. cfDNA reads were processed through a fragmentomic pipeline quantifying fragment size and coverage properties across predefined regulatory regions assigned to nearby genes. Gene-level expression from RNA-seq was analyzed and established breast cancer molecular subtype classifiers were applied. Fragmentomic signals were correlated with RNA expression for the same genes. Samples were split into training (n = 17) and test (n = 8) sets, and features with Pearson correlation > 0.4 were used in an elastic net model to predict *ESR1* expression from cfDNA fragmentomic data.

Results: The elastic net model's predicted *ESR1* score showed a Spearman correlation of 0.99 ($p = 0.003$) in the training set and 0.64 ($p = 0.10$) in the test set. Heatmaps of fragmentomic signal at model-selected regions mirrored corresponding RNA-seq expression patterns. Genes identified by the model included *DLG5* and *MTUS1* (both upregulated in samples with high *ESR1* expression), and *SMC4* (downregulated in samples with high *ESR1* expression), consistent with known ER-associated biology.

Summary and Conclusions: These findings demonstrate that cfDNA fragmentomic patterns derived from high-depth WGS can recapitulate gene-level, expression-like traits reflective of tumor biology in breast cancer. Integrating regulatory-region fragmentomics with expression-informed modeling enables non-invasive inference of molecular phenotypes such as estrogen receptor status directly from plasma. The deep WGS data, supported by RNA-seq, could also be leveraged to define target regions to enable gene-level expression fragmentomics in targeted hybrid capture panels. This approach highlights the potential of cfDNA fragmentomics as a surrogate for tissue-based transcriptomic and IHC profiling, supporting development of liquid biopsy-based classifiers for breast cancer subtyping and therapeutic stratification.

#5314 Combining gene expression and mutation profiling in a single cfDNA assay through the addition of a custom hybrid capture panel targeting gene regulatory regions to a commercial CGP panel.

Introduction: Analysis of cell-free DNA (cfDNA) provides a rapid, repeatable, and non-invasive window into tumor biology, yet tissue biopsies are still often needed for accurate phenotyping and treatment guidance. A liquid biopsy approach that captures both genomic alterations and expression-like features could strengthen patient monitoring and lessen biopsy reliance. Here, we integrate a custom hybrid-capture panel targeting gene regulatory regions with a comprehensive genomic profiling (CGP) panel into a single cfDNA sequencing assay. Our bioinformatic pipeline calculates variant allele frequencies (VAF) and extracts fragmentomic features that reproducibly correlate with gene expression, enabling non-invasive tumor phenotyping.Top of FormBottom of Form

Experimental Procedures: Matched FFPE tumor and plasma samples from 31 breast cancer patients were collected and analyzed, along with 11 additional unmatched plasma samples; all patients provided consent. Plasma cfDNA underwent sequencing in a single assay that integrated custom hybrid-capture baits for regulatory regions of 2,704 genes (2.44 Mb) with a CGP panel covering 562 genes (2.4 Mb). Matched FFPE RNA was profiled by RNA sequencing. cfDNA reads were processed through a multi-omic pipeline for quantifying fragmentomic properties across predefined regions assigned to nearby genes and a gene alteration analysis for VAF. Fragmentomic signals were correlated with RNA expression for the same genes. Association of fragmentomic signal, gene expression, and associated tumor biology was assessed.

Results: Fragmentomic features with high Pearson correlation to matched tissue RNA-seq were observed and were used to train a breast cancer model comprised of 34 features. Model-selected features showed a more distinctly matched correlation structure to breast tumor tissue RNA-seq than did randomly sampled features. Mapping model-selected genes to 31 breast tumor gene expression ontologies showed an enrichment for genes, such as *EZH1*, previously associated with breast cancer. Additional associations with ER status, Ki67%, and HER2 status demonstrated the potential utility of this assay for measuring these markers in blood.

Summary and Conclusions: Our findings show that cfDNA fragmentomic patterns captured using both CGP and custom panels, together with AI modeling, can recapitulate gene-level expression traits and enable tissue-free, plasma-based inference of tumor molecular phenotypes. By integrating fragmentomic signals with standard DNA-alteration profiling, hybrid-capture cfDNA sequencing provides two complementary molecular data layers from the same assay. Combining these capabilities can enhance biomarker discovery and may ultimately support clinical decision-making in precision oncology.

#5315 Analytical precision and cross-platform replicability of cfDNA-based genome-wide multi-feature classifiers for early cancer detection.

Vishruth Girish[1], Alice C. Eastman[1], Adrianna L. Bartolomucci[1], Akshaya V. Annapragada[1], Hope Orjuela[1], Carter Norton[1], Daniel H. Du[1], Sarah Short[1], Christopher M. Cherry[1], James R. White[1], Shashikant Koul[1], Vilmos Adleff[1], Zachariah H. Foda[2], Jillian Phallen[1], Victor E. Velculescu[1], Robert B. Scharpf[3]

[1]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Department of Biostatistics, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD

Introduction: Genome-wide liquid biopsies offer a non-invasive approach to cancer detection, management, and monitoring, and are increasingly being adopted across the cancer care continuum. These approaches interrogate a multitude of genomic features of the cell-free DNA (cfDNA) fragmentome, providing potential performance advantages over traditional imaging and other blood-based biomarkers. As cfDNA-based fragmentome methods move towards clinical deployment, validating their analytical precision and replicability across sequencing platforms is essential to realize their full clinical potential.

Methods: We developed an automation-compatible two-step plate protocol that combines end repair and A-tailing to process 48 samples in parallel. To systematically assess the analytical precision of this protocol, we designed a precision study using large volume (~20 mL) plasma from 12 individuals without cancer and individuals with lung (n=10) or liver (n=2) cancer. Three unique pre-specified plate layouts ensured that there was a minimum of 12 genomic library replicates per donor, with distinct row and column assignments within and between plates. In parallel, cfDNA was processed using our previously published three-step tube protocol, with a minimum of 6 genomic library replicates across three unique tube layouts. Each operator processed two unique plate and two unique tube layouts, with 3 ng input cfDNA for all libraries.

Results: Library yields were higher with the tube-based three-step protocol compared to the plate-based two-step protocol (6.51 nM vs 5.25 nM). Presequencing analyses revealed measurable operator effects in library QC metrics across matched replicates. All libraries were sequenced genome-wide to a mean depth of 1-2x on both the NovaSeq 6000 and NovaSeq X. Post-sequencing, locked computational pipelines for alignment and feature summarization were applied uniformly, generating genome-wide fragmentation in non-overlapping 5 Mb bins via short (100-150 bp) to long (151-220 bp) fragment ratios (S/L ratios), chromosome arm-level measures of aneuploidy, and lung and liver cancer classifier scores. The intra- and inter-batch precision of these features and classifier scores was assessed by implementing a Bayesian hierarchical model using the Stan software.

Conclusions: This study aims to provide a detailed assessment of assay- and platform-driven variability in cfDNA-based features and classifiers. Initial findings support the feasibility of scalable, automation-compatible plate-based protocols, and emphasize the need for robust workflows in clinical implementation. Ongoing analyses will determine the stability of classifier performance across protocol and sequencing platform transitions, informing best practices for evolving liquid biopsy technologies.

#5316 Analytical validation of SPIRAL: An integrated genomic and epigenomic liquid biopsy assay.

Lei Wang, Peiru Liu, Chaoran Zheng, Shanshan Yu, Yalan Jin, Fujun Qiu, Bo Yang, Yuan Sun, Xiaotian Wang, Shuailai Wu, **Zhihong Zhang**

Burning Rock Dx, Guangzhou, China

Introduction: Genomic and epigenomic alterations serve as key biomarkers for tumor detection, yet conventional approaches require separate workflows and DNA inputs for each signal type, which is impractical when sample quantity is limited. Because tumor initiation and progression arise from coordinated genomic and epigenomic dysregulation, simultaneous assessment of both layers is critical for accurate tumor classification, mechanistic insight, and clinical decision-making. Genomic profiling captures oncogenic drivers such as mutations, copy number alterations, and fusions, whereas epigenomic features—particularly DNA methylation—provide complementary information on histological subtype, gene regulation, prognosis, and tumor burden. To address the limitations of segregated assays, we developed SPIRAL (Single Portion Input Resourceful Assay of Liquid biopsy), an integrated multi-omics method that generates genomic and methylation libraries from the same DNA aliquot. Here, we present a preliminary evaluation of SPIRAL in a liquid biopsy setting, demonstrating its ability to concurrently profile genomic and epigenomic signals from a single blood-derived DNA sample.

Results: Analytical validation of SPIRAL was conducted using both cell line-derived and clinical samples. For genomic detection, the observed LoD95 was 0.8% for SNVs/indels (0.3% for hotspot variants), 0.3% for fusions, 20% tumor fraction for CNAs at six copies, 30% tumor fraction for homozygous deletions, and 1% tumor fraction for MSI. For epigenomic analysis, the LoD95 for global methylation was 5×10^{-5} in cell lines and 1×10^{-4} in clinical samples, with a limit of quantitation of 0.05% and a specificity of 98% in clinical samples. The LoD for promoter methylation was 1%.

Conclusion: SPIRAL is a liquid biopsy technology capable of simultaneously profiling genomic and epigenomic alterations from the same portion of cfDNA. In addition to comprehensive genomic profiling, it enables tissue-free MRD detection, therapy-response monitoring through tumor-fraction quantification, tumor subtyping, and broader phenotypic characterization. This integrated approach provides a robust platform for biomarker discovery and has the potential to substantially advance precision cancer management.

#5317 Evaluation of circulating tumor DNA as a biomarker for early relapse detection and molecular profiling in patients with high-risk neuroblastoma.

Natalia Wojciechowska[1], David Farbo[1], **Tiffany Duque**[2], Angela Brentlinger[1], Chelsee Greer[1], Anish Ray[1]

[1]Cook Children's Medical Center, Fort Worth, TX,[2]University of North Texas Health Science Center, Fort Worth, TX

Neuroblastoma (NBL) is the most common extracranial solid tumor of childhood, and nearly half of patients are diagnosed with high-risk disease. Patients with high-risk NBL often present with metastasis and frequently develop drug resistance; the 5-year survival rate is about 50%. Standard diagnostic and surveillance modalities not only involve radiation exposure and possible procedural sedation in pediatric patients, but also lack the ability to effectively monitor genetic evolution and heterogeneity. Circulating tumor DNA (ctDNA) has emerged as a minimally invasive biomarker capable of detecting microscopic disease, offering potential advantages for earlier relapse identification, reduced radiation exposure, and improved accessibility. We conducted a retrospective chart review of 13 patients with high-risk NBL, capturing salient clinical, molecular, diagnostic, and therapeutic information for each patient. Using this data, clinical evaluations of treatment response were recorded according to the revised International Neuroblastoma Response Criteria (INRC). Plasma samples taken in tandem with these evaluations were sequenced, and the ctDNA results were used to examine recurrence-associated ctDNA positivity and explore shared genomic alterations across patients. Additionally, variant information collected from tumor sequencing - performed as part of routine clinical care - was compared to the variants found in ctDNA sequencing. We found that 11 relapse-associated time points had preceding ctDNA measurements; among these, 72% were ctDNA-positive prior to radiographic relapse. Samples positive for ctDNA, with higher variant allele frequency (VAF), and with higher tumor fraction (TF) were significantly associated with stable or progressive disease, whereas complete response correlated strongly with samples negative for ctDNA. Progressive disease was associated with increasing VAF and TF, while partial response was associated with decreasing VAF. Six patients had concordant sequencing results; however, ctDNA failed to detect certain key alterations, including HRAS K117N and HGF amplification. Conversely, ctDNA detected several variants not observed in tumor sequencing, including alterations in tumor suppressor genes such as TP53 and CHEK2, as well as a rare germline SMARCA4 Variant of Uncertain Significance (VUS). ctDNA demonstrates promising utility as a non-invasive tool for monitoring treatment response and predicting relapse in high-risk NBL while also showing potential to reveal clinically relevant genetic alterations. Although our interpretation is limited by small sample size, heterogeneous sampling, and analytical bias, these findings support further prospective evaluation of ctDNA as a complementary biomarker to current imaging-based surveillance strategies.

#5318 A low-cost, ultra-fast, low-input amplicon NGS workflow for rapid cancer profiling.

Fang Liu, Kemin Zhou, Pan Du, Binggang Xiang

Predicine, Inc., Hayward, CA

Background: Liquid biopsy-based analysis of cell-free DNA (cfDNA) from plasma and urine has emerged as a powerful, non-invasive strategy for identifying clinically actionable oncogenic mutations. However, rapid and accurate detection of low-frequency variants remains technically challenging, particularly when working with limited input DNA. Predicine has developed an amplicon-based NGS platform to overcome these barriers through high analytical sensitivity, superior error suppression, and an accelerated workflow to support precision oncology applications.

Methods: A streamlined amplicon-based NGS workflow was established for sensitive detection of clinically relevant alterations in *FGFR (16 variants)*, *PIK3CA (62 variants)*, *ESR1 (25 variants)*, *KRAS* (21 variants), EGFR (62 variants) as well as additional variants commonly implicated in breast, prostate, bladder, lung and GIST cancers. The assay leverages Predicine's proprietary error-correction technology to suppress sequencing artifacts and enhance variant-calling accuracy. Sequencing-ready libraries were generated within three hours using a protocol optimized for low-input cfDNA. Analytical performance, including sensitivity and specificity, was systematically evaluated.

Results: This study demonstrated high analytical performance for detecting mutations in FGFR, PIK3CA, ESR1, KRAS, EGFR, and other clinically actionable targets across plasma and urine cfDNA. The streamlined workflow delivered ≥98% uniform coverage and >95% on-target rates across all target regions. Low-frequency variants were consistently detected at allele frequencies as low as ≤0.25% using 30 ng of cfDNA. The assay features a rapid library preparation process with a short hands-on time, enabling sequencing-ready samples to be generated within three hours, further supporting fast turnaround for liquid biopsy analysis. Specificity exceeded 98% in healthy donor cfDNA samples, indicating minimal background noise and low false-positive rates. While the evaluation focused on liquid biopsy specimens, the same rapid and efficient workflow is also compatible with FFPE-derived DNA, extending its applicability to tissue-based mutation profiling.

Conclusions: We report a low-cost, rapid, and high-throughput NGS solution for cfDNA analysis from plasma, urine and FFPE tissue DNA, offering a unified approach for mutation profiling across both liquid biopsy and tissue samples. This flexibility, combined with exceptional sensitivity, minimized error rates, low DNA input requirements, and fast turnaround time, positions this amplicon-based NGS assay as a powerful tool for clinical research, cancer diagnostics, and longitudinal disease monitoring.

#5319 Circulating tumor DNA (ctDNA)-based profiling of acquired resistance to the fibroblast growth factor receptor (FGFR)2/3 inhibitor lavengratinib(ABSK061) in patient(pt)s with advanced solid tumors.

Yue Wang[1], Chunyu Zhou[1], Liyun Zhao[1], Chaoze Cheng[1], Zhixuan Zhu[1], Zishuo Wang[1], Peng Zhang[1], Jing Zhang[1], Hua Zou[1], Jing Ji[1], Hongping Yu[1], Ji Zhu[2], Yan Zhao[3], Dewei Li[4], Yongsheng Li[4], Wei Li[5], Yanru Qin[6], Shujun Yang[7], **Nannan Zhang**[1]

[1]Abbisko Therapeutics, Shanghai, China,[2]Zhejiang Cancer Hospital, Hangzhou, China,[3]Liaoning Cancer Hospital & Institute, Shenyang, China,[4]Chongqing university Cancer Hospital, Chongqing, China,[5]The First Hospital of Jilin University, Changchun, China,[6]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China,[7]Henan Cancer Hospital, Zhengzhou, China

Background: Aberrant activation of FGFR signaling is implicated in tumorigenesis across multiple cancer types. Lavengratinib, the first-in-class selective FGFR2/3 inhibitor, showed encouraging efficacy and a favorable safety profile as monotherapy in pts with *FGFR2/3* alterations in a phase 1 study (NCT05244551). We used next-generation sequencing (NGS) of ctDNA to define the molecular mechanism of acquired resistance to lavengratinib.

Method: Pts with *FGFR2/3* activating alterations who had progressed on or declined standard therapy, and who had no prior FGFR inhibitor treatment, were treated with lavengratinib. Pts with both baseline and post-progression ctDNA samples were included in the study. Sequential ctDNA profiling (Onco Sonar, Genetron) was performed to compare genomic alterations at baseline and at disease progression.

Result: Seventeen pts with paired baseline and post-progression ctDNA samples were analyzed in this study, containing individuals with cholangiocarcinoma (CCA), gastric cancer (GC), non-small-cell lung cancer (NSCLC), cervical cancer and urothelial carcinoma. All the pts initially achieved an objective response or stable disease before developing progression. Seven pts acquired one or more secondary mutations in the kinase domain of FGFR2 or FGFR3. In *FGFR2*-altered pts, 15 residues in FGFR2 kinase domain were found mutated at the time of resistance to lavengratinib. The molecular brake residue N549 was the most frequently affected site. Additional recurrent mutations involved L617, the molecular brake residue E565 and the gatekeeper residue V564, particularly in *FGFR2*-amplified GC and CCA with *FGFR2* fusion. These putative cases of *FGFR2* acquired resistance in GC were consistently polyclonal, a pattern also commonly observed in CCA. In one cervical cancer pt with *FGFR3* S249C, an emergent *FGFR3* M528I was detected at progression. In contrast, *FGFR2*-altered NSCLC was prone to develop acquired alterations in genes involved in RTK/RAS pathways other than *FGFR2*, suggesting the resistance mainly driven by bypass mechanisms in this indication. Moreover, *ATM*, a key gene in the DNA damage response (DDR) network, exhibited the highest incidence of off-target emergent mutations across tumor types.

Conclusion: This study revealed diverse genomic mechanisms imparting acquired resistance to the selective FGFR2/3 Inhibitor lavengratinib, including secondary FGFR2/3 kinase domain mutations as well as off-target alterations in RTK/RAS and DDR pathways. In GC and CCA, polyclonal FGFR2 acquired mutations represent a convergent, on-target resistance mechanism to FGFR inhibition. These findings provide molecular insights into resistance mechanisms and guide the combination and sequential therapy strategies to overcome resistance in FGFR2/3 driven advanced solid tumors.

#5320 Leveraging enhanced conversion efficiency of the KAPA EvoPrep Boost workflow for urine ctDNA detection.

Angela Apessos[1], Maria Shin[1], Yanpeng Xi[2], Stephanie J. Yaung[3], Indira Wu[1]

[1]Roche Molecular Systems, Pleasanton, CA,[2]Roche Sequencing Solutions, Pleasanton, CA,[3]Roche Sequencing Solutions, Santa Clara, CA

Bladder cancer is the 9th most common cancer type globally, and early detection is often associated with a better prognosis. While tissue biopsy is the gold standard, its invasiveness limits disease detection and monitoring. Liquid biopsy is a less-invasive alternative, typically using plasma to monitor for circulating tumor DNA (ctDNA). In recent years, urine has emerged as a potentially superior source of ctDNA in bladder cancer studies, as it comes in direct contact with the tumor tissue[1]. However, high concentrations of DNAases in urine result in shorter cell free DNA (cfDNA) fragments and a lower concentration of cfDNA in the sample. Accurate analysis therefore relies on a sensitive and efficient sample preparation workflow. The KAPA EvoPrep Boost workflow employs an engineered ligase and an optimized amplification system, which improve library conversion efficiency and uniformity. The enhanced library preparation performance makes it a promising tool for analyzing poor quality and low input cfDNA obtained from urine. Urine cfDNA (ucfDNA) was isolated from healthy donors and archived bladder cancer samples and characterized. UcfDNA was converted using KAPA EvoPrep Boost and another commercially available library preparation kit for comparison, followed by target enrichment using the KAPA HyperCap Oncology Panel, which is a 214 Kb (capture) target enrichment panel covering the coding region of 13 genes involved in somatic oncology in addition to hotspot variants across 69 genes. The libraries were sequenced on an Illumina NovaSeq 6000 System and analyzed with a Roche KAPA Somatic DNA RUO Pipeline. Population databases of known single nucleotide polymorphisms were used to filter out putative germline mutations given matched normals were not available for the bladder cancer samples.Using Seraseq ctDNA Complete Reference Material, assay sensitivity in detecting variants from common oncogenic regions was established at 1ng cfDNA input. Compared to the alternative library preparation kit, KAPA EvoPrep Boost achieved higher coverage uniformity and lower error rates when tested with low input ucfDNA samples from healthy donors. Furthermore, using the KAPA EvoPrep Boost workflow coupled with the KAPA HyperCap Oncology Panel, variants in genes that are often mutated in bladder cancer development were detected in the cell-free DNA shed into the urine by the tumor. In summary, we describe a complete workflow for the analysis of low input and potentially poorer quality cfDNA isolated from urine. The improved conversion efficiency and genome equivalent recovery rates achieved by using the KAPA EvoPrep Boost Kit will be a useful research tool for bladder cancer and potentially other urinary tract cancers.KAPA products are For Research Use Only. Not for use in diagnostic procedures. 1.Ou Z, *et al.* Detection of bladder cancer using urinary cell-free DNA and cellular DNA. Clin Transl Med. 2020; 9(1):4.

#5321 Comprehensive profiling of urine microRNAs in prostate cancer patients.

Matias A. Bustos[1], Yoko Koh[2], Jaime Moon[2], Dai Takamatsu[2], SooMin Kim[2], Gianna Jimenez[3], David L. Krasne[4], Timothy G. Wilson[3], Dave S. B. Hoon[2]

[1]Translational and Precision Medicine, Providence Saint John's Health Center, Santa Monica, CA,[2]Translational and Molecular Medicine, Providence Saint John's Health Center, Santa Monica, CA,[3]Urology and Urologic Oncology, Providence Saint John's Health Center, Santa Monica, CA,[4]Division of Surgical Pathology, Providence Saint John's Health Center, Santa Monica, CA

The diagnosis of early-stage and locally advanced prostate cancer (PCa) continues to present significant clinical challenges. While prostate-specific antigen (PSA) remains the only serum biomarker currently used for PCa detection, its specificity is low, limiting its effectiveness. Although multiparametric magnetic resonance imaging serves as a valuable diagnostic resource, there are many inherent risks, including missing the target lesion during evaluation. This study was designed to identify urine cell-free microRNAs (cfmiRs) as diagnostic markers for patients with PCa of different stages (pT1a-pT3b). Briefly, urine samples were collected from 100 patients diagnosed with PCa and 22 individuals without PCa. Total RNA was isolated from 1 mL of urine using JBS Cell-free RNA & microRNA Isolation Kit and the automated JpurX-S200 isolation system according to manufacturer's protocol. Purified miRNAs were analyzed using an NGS-based approach to quantify 2,083 distinct microRNAs (miRs). Differential expression analysis using DESeq2 revealed 664 differentially expressed miRs in the urine of PCa patients, among which 95 cfmiRs were upregulated. Machine learning analysis considering both upregulated and downregulated cfmiRs led to the development of 10-cfmiR signature based on importance-scores. The 10-cfmiR signature showed strong performance on receiving operating characteristic (ROC) curve analysis [area under the curve (AUC) = 0.88, specificity = 0.91, sensitivity = 0.72, $p < 8.31e-09$]. When considering only upregulated cfmiRs, we found a 16-cfmiR and a 54-cfmiR signatures, which demonstrated good diagnostic performance for PCa [AUC = 0.77, specificity = 0.64, sensitivity = 0.84, $p < 1.84e-06$; AUC = 0.82, specificity = 0.82, sensitivity = 0.73, $p<1.90e-06$]. The diagnostic accuracy observed for the cfmiR signature was further conserved when focusing specifically on let-7a-5p [AUC = 0.79, specificity = 0.73, sensitivity = 0.76, $p < 0.001$] and let-7b-5p [AUC = 0.80, specificity = 0.73, sensitivity = 0.69, $p < 0.001$]. Specific cfmiR signatures were associated with higher grade groups and elevated PSA levels. The cfmiR signatures identified in this study were also compared with the cfmiRs identified in a previous study analyzing a cohort of early-stage pT2 PCa patients. Notably, 109 cfmiRs were detected consistently in both groups, with 93.75% (15 out of 16) of the cfmiRs in the 16-cfmiR signature being upregulated and present in both comparisons. In summary, this study successfully quantified and identified potential cfmiR signatures in urine samples from PCa patients at all stages. Specific urine cfmiRs may offer an advantage to distinguish patients with more aggressive disease. The findings suggest that urine is a robust source of cfmiRs with promising potential for the diagnosis of individuals with PCa.

#5322 Non-invasive tracking of clonal evolution and treatment response through liquid biopsies.

Farhia Kabeer[1], Matteo Lepur[2], Branden Lynch[3], Emilia Hurtado[3], Janine Senz[3], Ding Ma[3], Vinci Au[3], Caroline Baril[3], Gavin Ha[4], Samuel Aparicio[3], Jessica N. McAlpine[5], Alexandre Bouchard-Cote[2], David G. Huntsman[1], Yvette Drew[6], Andrew Roth[7]

[1]Department of Pathology and Laboratory Medicine, Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada,[2]Department of Statistics, University of British Columbia, Vancouver, BC, Canada,[3]Molecular Oncology, BC Cancer Research Institute, Vancouver, BC, Canada,[4]Fred Hutchinson Cancer Center, Seattle, WA,[5]Department of Obstetrics & Gynaecology, University of British Columbia, Vancouver, BC, Canada,[6]Department of Gynaecology and Obstetrics, Division of Medical Oncology, Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada,[7]Department of Pathology and Laboratory Medicine, Department of Computer Science, University of British Columbia, Vancouver, BC, Canada

Background: High-grade serous ovarian cancer shows high genomic instability and heterogeneous tumorsubpopulations that drive variable therapy responses and treatment failure. Tracking tumor cellpopulation changes during treatment is crucial for understanding cancer response, resistance, andmetastasis. Clonal dynamics reflects selective sweeps, fitness-enhancing genomic alterations,and spatially restricted subpopulation outgrowth. To capture these dynamics, we developed atumor-informed framework that resolves haplotype-specific copy number (HSCN) states fromsingle cell whole genome sequencing (scWGS). These high-resolution clonal profiles areintegrated into a Bayesian circulating tumor DNA (ctDNA) deconvolution method, cfClone,enabling sensitive, biologically interpretable quantification of clonal shifts from liquid biopsies.

Methods: Plasma ctDNA was collected from 20 high-grade serous ovarian cancer (HGSOC) patients,along with tumor samples from multiple sites. Single-cell whole-genome sequencing (scWGS)was performed and analyzed with HapClone, a Bayesian model reconstructing the geneticstructure and dynamics of tumor clones. HapClone generated haplotype-specific copy-number(HSCN) profiles reflecting allele-specific amplifications, deletions, and structural changes. Theseprofiles were then used to deconvolute clonal contributions in plasma with cfClone, and residualanalyses revealed hidden tumor subpopulations.

Results: In HGSOC cases, integrating scWGS-derived clonal states with cfDNA enabled reconstructionof tumor dynamics, quantification of clonal growth across metastatic sites, and identification ofthe dominant clone driving recurrence, indicating that metastasis is driven by the recurrent clonerather than new clones. cfClone longitudinal tracking in one case revealed tumor-fractionchanges over multiple time points, highlighting resistant subclones emerging during therapy.Including tumor content allowed detection of clones and quantitative assessment of responsedynamics, such as rapid clonal responses in another case. Differences between refractory andsensitive clones were identified, showing how longitudinal data reveal resistance mechanisms.The HSCN framework detected greater clonal diversity than state of the art structural-variant-based methods.

Conclusions: scWGS-informed HSCN analysis combined with ctDNA deconvolution provides a sensitive,biologically grounded approach to track tumor evolution, identify resistant clones, and measurectDNA. This framework enables real-time monitoring of tumor changes and has strong potentialto guide precision cancer treatment by enabling non-invasive monitoring of clonal dynamics inresponse to therapeutic decisions by linking clonal dynamics to therapy decisions in a non-invasive way.

#5323 Circulating tumor DNA dynamics predict the response to neoadjuvant chemotherapy but not long-term outcomes in *PIK3CA*-mutated breast cancer.

Ayaka Sato[1], Takayuki Ueno[2], Shunji Takahashi[3], Yoshinori Murakami[4], Masahiko Tanabe[1]

[1]Department of Breast and Endocrine Surgery, The Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,[2]Japanese Foundation for Cancer Research, Tokyo, Japan,[3]The Cancer Institute Hospital of JFCR, Tokyo, Japan,[4]Senior Professor, Department of Molecular Biology, Nippon Medical School, Tokyo, Japan

Background: The clinical significance of circulating tumor DNA (ctDNA) dynamics in *PIK3CA*-mutated breast cancer treated with neoadjuvant chemotherapy (NAC) remains unclear. We evaluated whether ctDNA patterns defined between baseline and pre-surgery are associated with pathological complete response (pCR) and long-term distant outcomes.

Methods: A total of 122 patients with stage I-III breast cancer who were scheduled to receive NAC between May 2016 and September 2017 were prospectively enrolled in this study. Tumor DNA extracted from pretreatment formalin-fixed, paraffin-embedded (FFPE) biopsy specimens was analyzed for *PIK3CA* hotspot mutations (E542K, E545K, and H1047R) using droplet digital PCR (ddPCR). Blood samples were collected at baseline (pre-NAC), pre-surgery, and post-surgery. Tumor-matched *PIK3CA*-mutated ctDNA was quantified by ddPCR. ctDNA dynamics between baseline and pre-surgery were categorized into four patterns: persistent-negative (-/-), cleared (+/-), persistent-positive (+/+), and post-NAC-emergent (-/+). pCR was defined as the complete disappearance of invasive carcinoma in both the breast and lymph nodes. Distant metastasis was assessed after a median follow-up of 96 months (range, 9-108).

Results: Tumor DNA was extracted from 113 primary tumors in 122 patients. *PIK3CA* mutations were detected in 36 (32%) of the 113 tumors. Plasma samples were available from 34 (94%) of 36 patients with *PIK3CA*-mutated tumors. Among these 34 patients, the ctDNA patterns were as follows: 17 were persistent-negative, 14 were cleared, two were persistent-positive, and one was post-NAC-emergent. Post-surgical ctDNA was negative in all patients. pCR occurred in nine patients (26%), including five of 17 persistent-negative patients and four of 14 cleared patients, whereas none of the persistent-positive or post-NAC-emergent patients achieved pCR. Follow-up for distant recurrence was available for 33 patients. Distant metastasis developed in five patients: Three in the persistent-negative group, one in the cleared group, and one in the persistent-positive group. Although persistent-positive patients showed a numerically higher metastatic rate (one of two), most late distant relapses arose from preoperative ctDNA-negative patterns.

Conclusions: In *PIK3CA*-mutated breast cancer treated with NAC, pre-surgical ctDNA positivity indicated residual disease but did not reliably predict long-term outcomes. A two-point ctDNA assessment may be insufficient for prognostic stratification. Further long-term follow-up and large-scale studies are needed to validate these findings.

#5324 Circulating tumor DNA detects minimal residual disease and predicts outcomes in esophageal cancer after esophagectomy.

Qingjiang Hu[1], Eiji Oki[2], Yasue Kimura[3], Hajime Otsu[1], Yusuke Yonemura[1], Koshi Mimori[1]

[1]Department of Surgery, Kyushu University Beppu Hospital, Beppu, Japan,[2]Kyushu University Hospital, Fukuoka, Japan,[3]Department of Gastrointestinal surgery, Kyushu Cancer Center, Fukuoka, Japan

BackgroundCirculating tumor DNA (ctDNA) monitoring shows promise for detecting minimal residual disease (MRD) and predicting prognosis in various cancers. This study evaluated ctDNA for detecting MRD and predicting outcomes in patients with esophageal cancer (EC) after esophagectomy.**Methods**We conducted a two-step observational study with a retrospective cohort (cohort 1) and a prospective cohort (cohort 2) of 40 EC patients who underwent upfront surgery or neoadjuvant chemotherapy (NAC) followed by esophagectomy. Plasma samples were collected at six time points: pre-therapy, post-NAC, and 1, 3, 6, and 12 months post-surgery. ctDNA was assessed using a 250-gene panel and its association with clinical outcomes was analyzed.**Results**Tumor-informed ctDNA levels were significantly correlated with tumor stage (*P*=0.01). Changes in ctDNA levels predicted tumor progression, with an area under the curve of 0.77. Postsurgical ctDNA positivity correlated with reduced recurrence-free survival (RFS) in cohort 1 (n=6, Log-rank *P*=0.034) and progression-free survival (PFS) in cohort 2 (n=34, Log-rank *P*=0.025) compared to ctDNA-negative patients. Combined analysis showed that postsurgical ctDNA positivity was associated with shorter PFS (hazard ratio [HR]=12.6, 95% confidence interval [CI]: 1.6-99.0; *P*=0.002) across all patients (n=40) and shorter RFS (HR=11.1, 95% CI: 1.4-89.0; *P*=0.006) in those who underwent R0 resection (n=37). ctDNA positivity predicted recurrence at a median of 90 days before radiographic evidence.**Conclusions**This study showed a strong correlation between ctDNA status and postsurgical prognosis in EC patients. ctDNA assessments can effectively detect MRD and guide postoperative management strategies.

#5325 Cell-free DNA fragmentomes for treatment response monitoring in patients with metastatic colorectal cancer: The Dolphin study.

[1]Department of Pathology, Netherlands Cancer Institute, Amsterdam, Netherlands,[2]DELFI Diagnostics, Baltimore, MD,[3]Department of Epidemiology and Data Science, Amsterdam University Medical Centers, Amsterdam, Netherlands,[4]Department of Data Science and Biostatistics, Julius Center for Health Sciences and Primary Care/University Medical Center Utrecht, Utrecht, Netherlands,[5]Department of Medical Oncology, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands,[6]Department of Laboratory Medicine, Netherlands Cancer Institute, Amsterdam, Netherlands,[7]Department of Radiology, Netherlands Cancer Institute, Amsterdam, Netherlands,[8]Department of Radiology, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands,[9]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[10]Department of Surgical Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands

Introduction: Accurate monitoring of tumor response in patients with metastatic colorectal cancer (mCRC) undergoing systemic therapy is essential to enable timely and informed treatment decisions. Although CT imaging is currently the standard-modality, it has limitations including limited accuracy for detecting small lesions, as well as inter-reader variability. A reliable blood-based biomarker may enable a more precise and dynamic assessment of treatment response. Circulating tumor DNA (ctDNA) is indicative of cancer cell burden and may complement CT imaging for evaluating treatment responses. DELFI tumor fraction (DELFI-TF) is a mutation- and tumor-independent ctDNA assay which has demonstrated potential for longitudinal monitoring of treatment response. The DOLPHIN study aims to evaluate the clinical added value of DELFI-TF to conventional imaging-based response monitoring in patients with mCRC.

Method: DOLPHIN is a prospective, observational substudy of the Prospective Dutch Colorectal Cancer Cohort, in which blood samples are collected longitudinally in conjunction with routine CT imaging in mCRC patients. ctDNA levels are longitudinally assessed using the DELFI-TF ctDNA assay, a locked and validated machine learning model that quantifies tumor burden using cell-free DNA (cfDNA) fragmentomic data derived from low-coverage whole genome sequencing. Simultaneously, ddPCR analysis is performed on samples from patients with a tumor tissue-confirmed RAS or BRAF mutation. The primary endpoint of this study is the association between changes in ctDNA levels and clinically determined treatment response. Secondary endpoints include the correlation between ctDNA dynamics and clinical, biochemical, and radiological responses at multiple timepoints during systemic treatment (I), lead time of ctDNA testing compared with CT imaging for identifying progressive disease (II), prognostic value of longitudinal ctDNA testing (III) and the cost-effectiveness of various monitoring approaches (IV).

Results: Between March 16 2023 and October 16 2025, 504 patients were enrolled before starting the second line of treatment. Nine patients were excluded due to incorrect entry criteria. A comprehensive overview of patient demographics and clinical characteristics will be presented at the conference. In total 2214 blood samples and 2468 CT scans have been collected, with collection planned to continue until March 2026. To date, 2186 samples (86.8%) have been successfully matched to a corresponding CT scan, and 1881 (86.0%) of these were obtained within 14 days of imaging.

Conclusion: In the ongoing DOLPHIN study, we successfully aligned a majority of blood samples with corresponding CT scans. This study will determine whether DELFI-TF can complement treatment response monitoring in mCRC patients and potentially enable parts of follow-up to be shifted to the home setting.

#5326 High throughput genomic profiling of tissue and liquid biopsy samples reveals targetable mutations in NSCLC patients from the Indian population.

Amit Kumar[1], Puja Sinha[2], Rama Chandran[2], Shobit Gupta[2], **Giulliana Tessarin**[3]

[1]Genes2Me, Gurugram, India,[2]Genes2me Pvt Ltd,, Gurugram, India,[3]Genes2me Pvt Ltd, Gurugram, India

Background: Non-Small Cell Lung Cancer (NSCLC), accounts for approximately 85% of lung cancer cases and ranking as the foremost cause of cancer related deaths globally, is both highly aggressive and uniquely characterized by the broadest spectrum of approved targeted treatments. Comprehensive genomic profiling (CGP) using next-generation sequencing (NGS) has become integral to clinical practice, with tissue and plasma-based analysis of cell free circulating tumor DNA (ctDNA) representing the most established and widely adopted modality in NSCLC. Addressing the scarcity of molecular data in Indian NSCLC patients, this study aims to delineate the mutational spectrum through NGS based profiling of FFPE and plasma ctDNA samples, driving advances in targeted therapy and precision medicine.

Methods: The study included 45 FFPE tissue and plasma specimens from NSCLC patients, enabling a robust comparison of solid and liquid biopsy approaches. Comprehensive genomic profiling was performed on a total of 45 samples using the G2M PanCan CGP assay, which targets 681 clinically relevant genes with approximately 1.7 Mb of genomic regions and was sequenced on the Illumina platform. Bioinformatics analysis was conducted using the GATK v4.1.2 somatic variant calling pipeline, and downstream visualization of mutational landscapes and hotspot regions was achieved using MAF tools.

Results: Consistent mutations were detected in both FFPE tissue and plasma ctDNA samples, with prominent alterations in TP53 showing the highest frequency and clinical relevance, accompanied by alterations in EGFR, ASXL1 and ARID1A. With variant allele frequencies of 6-39% in FFPE and 0.9-3.0% in liquid biopsy samples, the assay proved effective across sample types, producing a highly concordant mutational profile. TP53 was the most frequently mutated gene, exhibiting hotspot variants such as G325, P152L, H179D, and L194R, underscoring its critical role in NSCLC pathogenesis.

Conclusions: By mapping mutations in key NSCLC associated genes, the investigation confirms that NGS-based comprehensive genomic profiling delivers reliable and concordant detection across FFPE tissue and plasma ctDNA samples. This finding highlights the assay's utility for integrating tissue and liquid biopsy into routine clinical practice, empowering clinicians with accurate genomic insights to guide targeted mutation driven therapy decisions.

#5327 Utilization of urinary cell-free DNA as an informative biomaterial for comprehensive genomic profiling.

Robert Summersgill[1], Jesse Fox[1], Patrick Horn[1], LaRonda White[1], Vito Caropreso[1], Amy Meltzer[1], Ana Perez-Lebron[1], Kenneth Valkenburg[1], Eric Severson[2], Taylor J. Jenson[2], Shakti Ramkissoon[2], Brian Caveney[2], Marcia Eisenberg[2]

[1]Labcorp, Baltimore, MD,[2]Labcorp, Durham, NC

Background: Urinary cell-free DNA (UcfDNA) could soon prove to be a valuable non-invasive sampling analyte for next-generation sequencing (NGS) assays, particularly in urological cancers. Additionally, enabling at-home collection for cancer testing could lead to higher rates of adherence to testing schedules. In this proof-of-concept study, we intended to establish a baseline for how to effectively extract UcfDNA from urine with the potential of applying it as a sample type in assays such as Labcorp Plasma Complete™.

Methods: Extraction efficiency was compared across 4 different on-market cfDNA extraction methods, 3 manual kits (1 bead-based, 1 column-based, and 1 column/bead-based hybrid) and 1 automated bead-based kit. This comparison used 5 mL urine samples (n=10) that were stored at room temperature for 8-25 months. All samples were collected from patients with known solid tumor cancers. Extracted UcfDNA was characterized using both a fluorometer and a cfDNA bioanalyzer with a pre-determined cfDNA base pair range (50-700 bp). Next, larger volume (15 mL) extractions were conducted using 2 of the 4 previously tested extraction kits (the column/bead-based hybrid kit and automated bead-based kit) utilizing samples (n=6) collected with a urine stabilizing additive and stored at -80°C for 9-20 months. These extractions produced sufficient UcfDNA and were assessed for comprehensive genomic profiling in duplicate using Labcorp Plasma Complete. Post sequencing quality metrics were analyzed to determine the performance and reliability of the data. Lastly, mutation profiles were assessed for reproducibility between replicates and across extraction methods.

Results: The results show that multiple urine extraction methods produce viable yields with significant variability (2 - 900 ng) and these were influenced by cancer type and pre-analytical factors such as sample handling and storage. Regarding post-sequencing quality metrics, the extraction kits had little impact. However, the quality of material extracted from each kit was variable, indicated by differences in sequencing ratios. Comprehensive genomic profiling results indicate robust performance, with a > 90% call rate when identifying variants > 0.8% variant allele frequency (VAF) across replicates. The assay also identified multiple variants with 100% call rate across sample replicates and extraction methods, including clinically significant variants such as a TERT promotor mutation and an ALK translocation.

Conclusions: The findings show that UcfDNA is an extractable biomaterial when properly handled, and it also has great potential to be used for comprehensive genomic profiling in urological cancer samples with Labcorp NGS assays such as Labcorp Plasma Complete.

#5328 Analytical performance of magnetic bead-based cfDNA extraction with a low input targeted DNA enrichment.

Mayer Saidian[1], Yingmin Wang[2], Heng Wang[2], Yun Bao[3], Jason Saenz[1], Carlos Hernandez[1], Cameron Van Dieren[1], Daniel Cedeno[1], Nafiseh Jafari[1]

[1]nRichDX, Irvine, CA,[2]Agilent Technologies, Inc., Santa Clara, CA,[3]Agilent Technologies, Inc., Snata Clara, CA

Introduction: Analytical alignment between cfDNA extraction chemistry and downstream targeted-DNA assays is essential for reliable molecular counting, especially at low plasma input. This study evaluated whether two magnetic bead-based cfDNA extraction methods generate equivalent or distinguishable performance within a low-input targeted DNA enrichment workflow.
Methods: Experiment I (Human plasma, n = 8): Sixteen 3-mL plasma aliquots per donor were extracted in parallel using two bead-based kits—the Revolution cfDNA Max 20 Kit and MagMAX—producing paired eluates from identical input samples. QC included electrophoretic cfDNA quantification (50-700 bp), nucleosomal-profile assessment, and detection of high-molecular-weight (HMW) carryover. Experiment II (Contrived spike-in): Plasma matrices containing a 0.2% allele-frequency cfDNA spike-in were extracted in duplicate from 1-mL inputs using the same extraction kits.The primary endpoints were the library-eligible cfDNA concentration and molecule recovery following Agilent's Avida low-input targeted DNA enrichment workflow. Secondary endpoints included VAF concordance, on-target fraction, background noise, and library complexity.
Results: Across both experiments, cfDNA from the two bead-based extractions met the minimal QC thresholds; however, the Revolution cfDNA Max 20 Kit consistently demonstrated superior analytical performance, including: higher recovery of library-eligible cfDNA concentration (50-700 bp), more defined mono-/di-nucleosomal peak structure, less frequent HMW carryover, and stronger QC suitability for low-frequency (0.2%) variant interrogation.Spike-in experiments showed that eluates generated by this method more reliably met the requirements for low-input targeted DNA enrichment, supporting higher confidence in downstream molecular counting. Sequencing of paired eluates is ongoing and will quantify differences in molecule recovery, VAF precision, and background suppression.
Conclusions: Both magnetic bead-based methods generated cfDNA suitable for low-input targeted sequencing; however, the Revolution cfDNA Max 20 Kit delivered superior cfDNA yield, fragment-quality metrics, and overall pre-analytical performance. Pending sequencing results will further define the magnitude of analytical advantage and support optimized recommendations for pre-analytical workflows in low-input liquid biopsy assays.

#5329 Unlocking transrenal DNA: New methods for stabilizing and isolating small cfDNA in urine.

Daniela Mancarella-Langer[1], Franziska Kaiser[1], Daniel Groelz[1], Moritz Rath[1], Nguyen Van Nhi Le[2], Eric Provencher[1], Michelle Walther[1]

[1]PreAnalytiX GmbH, Hombrechtikon, Switzerland,[2]QIAGEN GmbH, Hilden, Germany

Introduction: Urine liquid biopsy is emerging as a non-invasive approach for disease monitoring and early detection. Transrenal DNA, cell-free DNA that passes from plasma through the kidney into urine, contains promising biomarkers that may expand the applications of urine liquid biopsy beyond urological malignancies. Due to the size restriction of the renal barrier, transrenal DNA is shorter than urological cfDNA (<50 bp). However, the analysis of urine cfDNA is challenging as it is prone to rapid degradation. Furthermore, isolating short DNA fragments from the complex urine matrix demands optimized extraction protocols. The presented study addressed key technical challenges in urine liquid biopsy, presenting optimized workflows for stabilization, isolation, and analysis of urine cfDNA to realize the full potential of transrenal DNA research.
Methods: Urine was collected from apparently healthy, consented individuals and either stabilized or left unstabilized. Urine samples were spiked with a DNA ladder with defined size fragments ranging from 10 to 300 bp. DNA was either isolated from urine on the day of collection, stabilization and spike-in, or after urine storage. DNA spike-in was also performed in phosphate-buffered saline. DNA was isolated either manually or automated with several commercially available cfDNA isolation technologies. The isolated cfDNA was analyzed by capillary gel electrophoresis.
Results: All isolation kits tested were suitable for isolation of cfDNA down to 50 bp. Smaller DNA fragments down to 35 bp could be isolated with the miRNA protocol of the manual QIAamp® Circulating Nucleic Acid Kit as well as with automated isolation using the QIAsymphony® DSP Circulating DNA Kit and the EZ1&2® ccfDNA Kit. With the integration of new nucleic acid binding beads into the automated isolation with the QIAsymphony DSP Circulating DNA Kit, isolation of cfDNA down to 20 bp was possible. To test the need for urine stabilization for efficient isolation of small cfDNA from urine, the spike-in DNA was isolated from unstabilized urine as well as urine stabilized with the PAXgene® Urine Liquid Biopsy Set. For unstabilized samples, the ladder fragments could not be detected even when isolated within hours of urine collection, indicating rapid degradation of the ladder DNA. For stabilized urine samples, the DNA ladder spike-in could be detected even after days of storage.
Conclusion: This study emphasizes the critical role for urine stabilization for efficient isolation of a wide range of cfDNA sizes. The isolation technology defines the cfDNA size range available for analysis and should be chosen based on the cfDNA population of interest. The PAXgene Urine Liquid Biopsy Set, combined with manual or automated isolation technologies, enables recovery of small cfDNA fragments and hence, transrenal DNA research.

#5333 Profiling membrane antigen expression of select antibody-drug conjugate (ADC) targets in *EGFR*-altered non-small cell lung cancer treated with osimertinib.

Kevin Lu[1], Tali Azenkot[2], Ellen B. Jaeger[3], Unnati Jariwala[3], Stamatina Fragkogianni[3], Jacob Mercer[3], Jyoti D. Patel[3], Sandip P. Patel[2]

[1]UC San Diego School of Medicine, La Jolla, CA,[2]UC San Diego Moores Cancer Center, La Jolla, CA,[3]Tempus AI Inc, Chicago, IL

Background: Resistance to EGFR-Tyrosine Kinase Inhibitors (TKIs) in patients with NSCLC represents an unmet clinical need. Bypass pathway upregulation is a key mechanism of resistance and represents a potential target for therapeutic agents such as Antibody-Drug Conjugates (ADCs). This study evaluates the RNA expression of select ADC targets in NSCLC patients treated with osimertinib (osi).

Methods: The Tempus Lens Platform was used to identify a cohort (n=583 patients) of classical *EGFR*-altered NSCLC with DNA (xT) and RNA (xR) testing treated with first-line osi monotherapy (mono) or osi with chemotherapy (combo). RNA-seq data of select ADC membrane targets, including *ERBB2*, *ERBB3*, *MET*, *NECTIN4*, and *TACSTD2* (TROP2) were quantified as transcripts per million (TPM), reported as log2(TPM + 1) and compared using Wilcoxon rank-sum test. Median RNA expression in each gene was defined relative to the pre-treatment *EGFR*-altered cohort. We examined real world overall survival (rwOS) and hazard ratio (HR) from Cox proportional hazards model.

Results: Among 583 patients, median (range) age at diagnosis was 66 (27-88) years old while 68% were female. In all samples, the highest median gene expression was identified in *ERBB2*, *MET*, and *TACSTD2* (TROP2) (7.46, 7.38, 7.57). When comparing first-line pre- and post-treatment samples, there was a significant increase in median gene expression of *MET* (7.23 vs 7.85; p<0.001) however decreases in median expression of *NECTIN4* (5.22 vs 4.90; p=0.005) and *ERBB2* (7.48 vs 7.38; p=0.021). In pre-osi mono patients (n=378), median rwOS was 29.8 months. Of the five genes assessed, only *MET* expression was associated with worse rwOS (HR 1.25; p=0.001). In the mono group, those with above-median *MET* expression at pre-treatment had a worse rwOS than those with below-median expression (26.1 vs. 31.5 months; p=0.007). Above-median *MET* expression was associated with worse rwOS compared to below median (HR 1.52; p=0.008).

Conclusion: In patients with *EGFR*-altered NSCLC, we identified high expression of *ERBB2*, *MET*, and *TACSTD2* (TROP2) in both pre- and post-treated samples. This may provide rationale for use of these ADC targets in second-line therapy, such as seen in recent approvals for trastuzumab deruxtecan in *ERBB2*-mutated, telisotuzumab vedotin in *c-MET* over-expressing, and datopotamab deruxtecan in *EGFR*-altered NSCLC. Notably, high *MET* pre-treatment expression was associated with poor survival outcome and appeared to be associated with post-osimertinib resistance. Further investigation is required to evaluate *MET* expression as a predictive biomarker for *MET*-targeting agents to overcome innate and acquired EGFR-TKI resistance.

#5334 Genomic profiling of lung cancer in Guizhou province and comparative performance of DNA-NGS versus DNA+RNA-NGS for fusion detection.

Weiwei Ouyang, Yichao Geng, Chuang Tian

The Affiliated Hospital of Guizhou Medical University, Department of Oncology, China

Background: Targeted therapy plays a crucial role in non-small cell lung cancer (NSCLC), making accurate genomic profiling essential for treatment selection. RNA-based fusion detection has been increasingly recommended by major guidelines due to its superior analytical performance, yet real-world evidence remains limited. This study characterized the genomic landscape of NSCLC in Guizhou Province and compared DNA-based next-generation sequencing (DNA-NGS) with combined DNA+RNA sequencing (D+R-NGS), particularly for fusion detection.
Methods: From 2017 to 2024, 880 tumor samples from 571 NSCLC patients underwent NGS testing, including 750 samples analyzed by DNA-NGS and 130 by D+R-NGS. Somatic SNVs/indels, copy-number variations (CNVs), and gene fusions were comprehensively assessed and compared across platforms.
Results: Across all samples, 2,051 SNVs/indels, 198 CNVs, and 73 gene fusions were identified. *EGFR* (53%) and *TP53* (45%) were the most common mutations, consistent with previously reported Chinese NSCLC data. Except for one large-cell neuroendocrine carcinoma, all fusion-positive cases were adenocarcinomas, with female patients representing a higher proportion (60.2%).Fusion detection rates differed substantially between platforms. The D+R-NGS group showed a significantly higher fusion detection rate than DNA-NGS (15.4% vs. 7.1%, $p = 0.003$). And the D+R-NGS also had a numerically higher detection rate (13.5% VS 8.1%, p=0.095), even when significant differences were lost after filtering multiple samples from the same patient. Fusion subtype analysis indicated similar overall patterns, with ALK rearrangements most common in both groups (45% in D+R-NGS; 64% in DNA-NGS). Notably, the detection of *MET* exon 14 skipping was substantially higher in the D+R-NGS cohort (20%) compared with DNA-NGS (2.4%).This difference may be related to the fact that the MET exon 14 skipping on DNA is usually caused by the variant drive of intron 13 or 14, regions that are challenging to assess using DNA-based assays, whereas RNA sequencing provides inherent structural advantages for detecting such events.Importantly, the improvement in fusion detection with D+R-NGS did not reduce sensitivity for other mutation types. Instead, actionable alterations such as *EGFR* (64.7% vs. 46.1%) and *KRAS* (12.9% vs. 6.53%) were identified at higher rates in the D+R-NGS group, suggesting broader analytical benefits.
Conclusions: The genomic profile of NSCLC in Guizhou Province aligns with broader Chinese cohorts. Combined DNA+RNA sequencing significantly enhances fusion detection while maintaining strong performance for SNVs/indels and CNVs. These findings support integrating RNA into routine NGS workflows to improve diagnostic accuracy and guide targeted therapy more effectively in NSCLC.

#5335 Integrated machine learning and large language models reveal molecular determinants of survival and treatment response in KRAS-mutant lung cancer.

Qingtian Li[1], Albert Lee[2], Wei Wu[3], Trever G. Bivona[3]

[1]Department of Medicine, UCSF - University of California San Francisco, San Francisco, CA,[2]IT Academic Research Services, UCSF - University of California San Francisco, San Francisco, CA,[3]UCSF - University of California San Francisco, San Francisco, CA

Background: KRAS activating mutations are the most prevalent oncogenic drivers in non-small cell lung cancer (NSCLC), with KRAS G12C as the dominant subtype. FDA-approved small-molecule inhibitors (sotorasib and adagrasib) have improved outcomes in KRAS G12C positive patients, though responses remain heterogeneous. To dissect clinical and molecular determinants of treatment response and overall survival, we analyzed large KRAS-mutant NSCLC cohorts with multimodal clinical annotation and targeted sequencing, integrating computational and machine learning (ML) approaches.

Methods: 679 KRAS-mutant NSCLC patients including 43 patients treated with KRAS inhibitors were retrieved from UCSF Information Commons (data released in March 2025). Clinical, pathological, targeted tumor exome sequencing, survival, and treatment-response data were extracted from clinical notes using SQL-based algorithms and large language models. Structured datasets were generated for ML models including random forest (RF), multilayer perceptron (MLP), and XGBoost (XGB). An independent MSK-IMPACT cohort (n=2,152) was used for validation. All computational analyses were performed on the UCSF Wynton HPC cluster.

Results: Comparing co-occurring mutations between UCSF KRAS G12C (n=185) and non-G12C KRAS (n=494) treatment naïve tumors, we identified 14 significant differential mutations (Fisher's exact test, BH-corrected $p<0.05$). LRP1B, KEAP1, RUNX1T1, ATP6AP1, ZFTA, TRAF7, and NF2 gene mutations were enriched in the KRAS G12C cohort. Clinical genetic data predicted KRAS inhibitor treatment outcomes (TO) (stable vs progressive disease) and overall survival (OS) with modest accuracies by models of RF (TO:0.67, OS:0.64), MLP (TO:0.83, OS:0.73), and XGB (TO: 0.67, OS:0.73). Intriguingly, the models identified co-mutations of NAV3, COL2A1, MLH3, PTPRD, and SOS2 associated with stable tumor disease, co-mutations of IGFBP3, SPEN and PTPRB correlated with progressive tumor disease, whereas co-mutations of DUSP4, WHSC1, EBF1 and MAP2K4 are potential covariates for poor OS. ML prediction of OS using MSK-IMPACT cohort with clinico-genetic test data achieved AUROC values of 0.80 (RF), 0.72 (MLP), and 0.81 (XGB), respectively. Feature-importance analyses highlighted metastasis, tumor mutation burden (TMB), and mutations in ERCC5, BCOR, and SPEN as major predictors of poor OS.

Conclusion: Analysis of real-world multimodal clinical data revealed distinct biological and genomic features between KRAS G12C and non-G12C NSCLC, as well as key determinants of survival and treatment response. This study demonstrates the value of LLM-generated structured clinical data for AI/ML-driven oncology research with hypotheses generation and highlights its potential to improve personalized treatment decision-making.

#5336 Distinct *KRAS* mutation codons differentially associate with microsatellite instability in colorectal carcinoma.

Mark Evans[1], Vishal Chandan[2], Kenna Shaw[3], Scott Kopetz[4], Anirban Maitra[5], **Julian Bryan**[6]

[1]Caris Life Sciences, Irving, TX,[2]UC Irvine School of Medicine, Irvine, CA,[3]Sheikh Khalifa Bin Zayed Al Nahyan Institute for Personalized Cancer Therapy, UT MD Anderson Cancer Ctr., Houston, TX,[4]UT MD Anderson Cancer Center, Houston, TX,[5]NYU Langone Health, New York, NY,[6]MD Anderson Cancer Center, Houston, TX

Background: MSI/MMR and *KRAS* are key biomarkers in colorectal carcinomas (CRC) for PD1 inhibitors, EGFR mAbs, and KRAS G12C inhibitors. MSI High is reported to be less common in *KRAS* mutant CRC. However, because *KRAS* mutation location influences protein function and CRC pathophysiology, we hypothesized that MSI also differs by *KRAS* mutation site.
Methods: MSI High prevalence was assessed by *KRAS* mutation location in CRCs using logistic regression in 2 databases: MSK-CHORD, and Caris CODEai. *BRAF* V600E CRCs were excluded.
Results: In MSK-CHORD's 4,805 CRCs (non*BRAF* V600E, *NRAS* wt, and no prior EGFRmab), 8.7% were MSI-H. However, MSI-H prevalence differed markedly by *KRAS* mutation site: 8.8% of *KRAS* wt and 13.5-15.9% of codon 13/61/146 CRCs; but only 5.1% of codon 12 mutant CRCs were MSI-H (all p≤0.001). Notably, MSI-H also varied within *KRAS* codons: only 2.0% of G12C and 2.8% of G12V (both C>A) were MSI-H, vs 7.8% of G12D, 4.8% of G12A, and 3.8% of G12S. For confirmation of institutional findings, we analyzed data from a large reference laboratory. In Caris CODEai's 83,532 non*BRAF* V600E CRCs, 5.4% were MSI-H. Again, MSI-H prevalence varied by *KRAS* mutation site: 6.4% of *KRAS* wt, 5.6-6.9% of codon 13/61/117/146, and 19.2-26.9% of codon 14/59 mutant CRCs were MSI-H; compared to only 1.9% of codon 12 mut CRCs (all p<0.001). We then tested this finding in other cancer types in Caris CODEai. A similar result was observed in pancreatic cancer: among 40,497 only 0.7% were MSI-H, from 0.7% of *KRAS* wt to 0.4-0.5% of codon 12/61, but 7.8% of codon 13 (p<0.001).
Conclusions: MSI-H prevalence varied by *KRAS* mutation location in CRC, with codon 12 muts—especially C>A—associated with low MSI-H rates, whereas codon 13/59/61/146 muts were enriched among MSI-H CRCs. Our data suggest that MSI/MMR mutational processes are associated with distinct codon-resolved *KRAS* biology and may give rise to specific *KRAS* muts, which warrants further investigation and could refine predictive biomarker interpretation.

#5337 MSI colon adenocarcinoma transcriptomic subtypes are biomarkers of response to immunotherapy.

Matthew B. Maxwell[1], Akul Singhania[1], Michelle Stein[1], Radia Johnson[1], Van K. Morris[2], Andrew J. Sedgewick[1], Scott Kopetz[2], Justin Guinney[1]

[1]Tempus AI, Inc., Chicago, IL,[2]UT MD Anderson Cancer Center, Houston, TX

Background: Microsatellite instability-high (MSI) is a predictive biomarker for response to immune checkpoint inhibitors (ICI) in metastatic colon adenocarcinoma (COAD), but not all patients respond to ICI. Thus, there is a clinical need to develop novel biomarkers to more accurately predict ICI response in metastatic MSI-COAD.
Methods: The transcriptomic subtyping cohort consisted of 793 primary tumor MSI-COAD samples with DNA & RNA-seq (Tempus xT/xR) from Tempus' real-world database. The ICI cohort consisted of 59 metastatic MSI-COAD patients who had a primary tumor sample profiled via Tempus xT/xR. We performed transcriptomic subtyping via non-negative matrix factorization (NMF). Survival analyses were performed via risk set adjusted Kaplan-Meier and CoxPH models with right censor cutoff of 48 months post ICI. Consensus molecular subtype (CMS) calls were made using Tempus CMS classifier, immune deconvolution was performed using xCell, and GSEA using fgsea. A FDR < .05 was considered significant.
Results: Clustering of primary MSI-COAD tumor transcriptomes revealed two subtypes that we named "Immune/Stromal" (C1, n=390) and "Goblet/Enterocyte" (C2, n=403). C1 tumors displayed significantly higher proportion of CD8+ T cells, cytolytic scores, and enrichment of EMT, TNFα, and IFNα/γ response gene sets. C2 tumors displayed significantly higher expression of goblet cell and enterocyte marker genes and enrichment of metabolic gene sets. LOF mutations in epigenetic regulators ARID1A, ARID1B, and EP300 were enriched in C1 tumors. In the ICI cohort of metastatic MSI-COAD patients, C2 was associated with significantly shorter PFS (HR = 6.6, 95% CI: 2.2-19.6, p < 0.0001) and OS (HR = 4.4, 95% CI: 1.4-13.3, p < 0.001). In C2 patients, the median PFS and OS following ICI were 8 and 34 months, respectively; in C1, neither median was reached. C2's association with shorter PFS but not OS following ICI was independent of ICI regimen, line of therapy, collection procedure type, age, sex, and TMB in a CoxPH model (HR = 7.0, 95% CI: 1.8-26.6, p = 0.005). In the subset of our ICI cohort treated with Nivolumab + Ipilimumab (n=10), we observed that 4/4 C2 patients progressed within 6 months of treatment while 0/6 C1 patients progressed (p = 0.049, HR = Inf). Finally, we demonstrate that NMF subtypes presented here have a stronger association with PFS in CoxPH models following ICI compared to CMS subtypes (CMS3 vs CMS1 HR=3.5, 95% CI: 1.1-11.1, p = 0.04, CMS4 vs CMS1 HR = 4.2, 95% CI: 0.7-24.6, p = 0.11).
Conclusions: We identified novel MSI-COAD transcriptomic subtypes that stratify patient response to ICI, including Nivolumab + Ipilimumab. In addition to personalizing patient care, these subtypes could inform clinical trial design and target discovery by identifying patients with an unmet clinical need.

#5338 Clinicogenomic predictors of first-line immune checkpoint inhibitor outcomes in non-small cell lung cancer: A nationwide C-CAT cohort from Japan.

Mika Iwasaki[1], Takahiro Ando[1], Koki Fujii[1], Kousuke Watanabe[1], Katsutoshi Oda[2], Hidenori Kage[1]

[1]Department of Respiratory Medicine, The University of Tokyo, Tokyo, Japan,[2]Division of Integrative Genomics, The University of Tokyo, Tokyo, Japan

Background: The efficacy of immune checkpoint inhibitors (ICIs) in non-small cell lung cancer (NSCLC) varies, underscoring the need for predictive biomarkers. Programmed death-ligand 1 (PD-L1) and tumor mutational burden (TMB) are widely used but have limited sensitivity and specificity. Increasing evidence suggests that genomic alterations shape immune responses and influence ICI outcomes. However, data from large-scale real-world cohorts, particularly in East Asian patients, remain limited.

Methods: We retrospectively analyzed the Center for Cancer Genomics and Advanced Therapeutics (C-CAT) database, integrating comprehensive genomic profiling (CGP) results with clinical information from cancer patients across Japan, encompassing 99.7% of all CGP tests under the national insurance program. A total of 1,629 patients with stage IV NSCLC received first-line ICI-based therapy between 2019 and 2025. The primary endpoint was time to treatment failure (TTF); the secondary endpoint was overall survival (OS). We used age-stratified Cox models adjusted for covariates. Genomic covariates included *KRAS, KEAP1*, and *STK11*, with additional genes from an exploratory screening. To clarify interaction effects, we further expressed results as wild-type-referenced hazard ratios for *KRAS*-only, *KEAP1*-only, *STK11*-only, and their co-mutations (*KRAS-KEAP1* and *KRAS-STK11*). Sensitivity analyses included a formalin-fixed paraffin-embedded (FFPE)-only subset with TMB available (n = 1,095, categorized as <10 vs ≥10 mut/Mb), and models also adjusting for ECOG performance status (0, 1, ≥ 2).

Results: *BRAF* mutation was independently associated with longer TTF (HR 0.77, 95% CI 0.59-1.00; $p = 0.049$), whereas *KRAS*, *KEAP1*, and *STK11* alone showed no significant associations (HRs 1.21, 1.08, and 1.09; all $p > 0.21$). A significant *KRAS-KEAP1* interaction was associated with shorter TTF (HR 1.89, 95% CI 1.06-3.36; p = 0.032). Compared with PD-L1 ≥ 50%, PD-L1 < 1% was associated with shorter TTF (HR 1.17; $p = 0.041$). In a four-level comparison versus wild-type, *KRAS*-only and *KEAP1*-only were not significant (HRs 1.09 and 1.21), whereas the *KRAS-KEAP1* co-mutation was associated with higher risk of treatment failure (HR 2.48, 95% CI 1.50-4.10; $p < 0.001$). Results were consistent in FFPE-only subsets with TMB data. *KEAP1* ($p < 0.001$) and *STK11* ($p = 0.001$) were associated with worse OS, while *BRAF* showed no significant difference ($p = 0.840$).

Conclusions: In first-line ICI-treated stage IV NSCLC, *KRAS-KEAP1* co-mutation, not *KRAS* or *KEAP1* alone, identifies patients at high risk of early failure, whereas *BRAF* was associated with longer TTF. These findings highlight the importance of co-mutation profiling in guiding treatment selection and warrant prospective validation with integrative models incorporating PD-L1 and TMB.

#5339 Prevalence and distinct biological programs of small cell lung cancer molecular subtypes revealed by real-world clinico-genomics database.

Yige Luo[1], Lujia Wang[2], Nadine Jahchan[3], Peter Ansell[4], Xi Zhao[1], Weilong Zhao[1]

[1]Quantitative Medicine & Genomics, AbbVie Bay Area, South San Francisco, CA,[2]Data & Statistical Science, AbbVie Bay Area, South San Francisco, CA,[3]Precision Medicine, AbbVie Bay Area, South San Francisco, CA,[4]Precision Medicine, AbbVie Inc., North Chicago, IL

Background: Molecular subtypes of Small Cell Lung Cancer (SCLC) highlight patient heterogeneity and continue to carry potential as predictive biomarkers. Resistance to Immune Checkpoint inhibitor (ICI) and impact of RW treatments remain outstanding. We aim to enhance understanding of SCLC subtype biology and therapeutic implications by leveraging the multi-modal RWD with curated outcome and treatment pattern.

Methods: We analyzed a US-based SCLC cohort (381 samples; 376 patients) from Caris-ConcertAI linked clinico-genomic database. We performed Non-negative Matrix Factorization (NMF) on transcriptomic data from patients with treatment-naïve samples (n=230), and applied to treatment-experienced samples (n=66). Subsequent treatments included ICI+chemo (n=179) and chemo only (n=49). PD-L1 IHC results are based on the 22c3 assay using tumor percent cutoff of 1%. Gene signatures are obtained from MSigDB.

Findings: Consistent with previous literature, expression of lineage-defining transcription factors varied across four NMF subtypes. Two groups (NMF1-SCLC-A/N, 33.5% treatment-naïve vs. 33.3% experienced; NMF2-SCLC-A-like, 15.2% vs. 19.7%) were neuroendocrine (NE)-enriched; two (NMF3-SCLC-I, 28.7% vs. 21.2%; NMF4-SCLC-P-like, 22.6% vs. 13.6%) displayed immune features, with prevalence remained in post-treated samples. NMF1 showed activated transcriptional programs of ASCL1/NEUROD1, high proliferation signatures, and low immune infiltration—consistent with classical NE subtypes. NMF2 exhibited ASCL1-associated activity, while its elevated metabolic pathways differ from canonical SCLC-A. NMF3 resembled the inflamed SCLC-I subtype, with broad immune signatures, confirmed by higher prevalence of PD-L1 IHC positivity. Yet the promise of an efficacious ICI therapy could be dampened by concurrently heightened immunosuppressive TGF-β/fibrosis pathways. REST/NOTCH activation and low NE features in NMF3 indicated YAP1-driven NE dedifferentiation, accompanied by hypoxia-related programs (angiogenesis, KRAS signaling) that may inform targeted therapy. NMF4 matched canonical SCLC-P with POU2F3 activation and MYC overexpression. Though atypical, the concurrent expression between POU2F3 and NEUROD1 may point to MYC-driven subtype mixing. Preliminary analysis revealed NMF3-SCLC-I subtype with the best prognosis. Survival outcomes vary by treatment received within NMF subtypes, warranting further validations on their predictive values.

Conclusion: SCLC molecular subtypes from this US RW cohort align and extend those from global clinical trial cohorts, revealing distinct clusters enriched with metabolic pathway and subtype mixing. Current SoC regimen has limited impact on the subtype prevalence. The analysis of RW outcome associated with subtypes' unique pathway activation will inform novel treatment strategies.

#5340 Landscape of ALK fusion breakpoints and subtypes: A comparative analysis of DNA-NGS versus RNA-NGSs.

Yanwei Li, Yanli Chen, Yameng Cui

Tianjin Medical University Cancer institute and Hospital, Tianjin, China

Background: ALK fusions are important therapeutic biomarkers across solid tumors, and accumulating evidence shows that fusion breakpoints, isoforms, and fusion orientations influence response to ALK tyrosine kinase inhibitors (TKIs). Non-canonical or reciprocal fusions and rare breakpoints may yield nonfunctional transcripts and lead to inferior outcomes. Understanding the differences in ALK fusion profiles detected by DNA-based and RNA-based next-generation sequencing (NGS) is therefore critical for optimizing molecular testing and guiding targeted therapy.
Methods: A total of 34,085 solid tumor patients were analyzed, including 15,957 tested by DNA-NGS and 18,128 by RNA-NGS. ALK fusion positivity, fusion orientations, and characteristics of subtypes were compared between DNA- and RNA-based sequencing approaches.
Results: DNA-NGS identified 358 ALK-positive patients carrying 547 fusions, while RNA-NGS identified 469 patients with 482 fusions. RNA-NGS showed a significantly higher positivity rate than DNA-NGS (2.6% vs. 2.2%, $p = 0.043$). The two approaches differed markedly in fusion multiplicity: 57.5% of DNA-positive patients harbored multiple fusions, including one patient with eight partners, whereas only 2.5% of RNA-positive patients showed multiple events. Additionally, 27 DNA-NGS cases carried exclusively non-canonical reciprocal or non-reciprocal fusions, suggesting potential nonfunctional variants that complicate therapeutic interpretation.Fusion orientation and partner diversity also varied substantially. All RNA-detected fusions were canonical 5′→3′ events, involving 11 partner genes; EML4 accounted for 97%, followed by KLC1, DCTN1, and KIF5B (each <1%). Conversely, the DNA-NGS cohort included 3.8% 3'→3' fusions, 5.6% 5'→5' fusions, and among the 5'→3' events, only 70% represented canonical forward fusions. In total, 38 partner genes were identified in the DNA group, with EML4 remaining most prevalent (85.5%), followed by KIF5B (2.0%) and STRN (1.2%). Only five fusion partners overlapped between the two detection modalities.Breakpoint diversity was greater in DNA-NGS (21 breakpoint types vs. 17 in RNA-NGS). Although EML4-ALK isoform distributions were similar ($p = 0.55$), DNA-NGS identified more atypical short-variant breakpoints (3.1% vs. 2.1%), which are associated with lower protein expression and poorer TKI response.
Conclusions: RNA-NGS achieved a higher detection rate and a cleaner, more biologically meaningful ALK fusion profile, with fewer multi-partner or non-canonical events and predominately functional fusion isoforms. DNA-NGS frequently identified complex or potentially nonfunctional structures that may mislead therapeutic decisions. These findings suggest that RNA-NGS provides a more accurate representation of transcriptionally active ALK drivers and may be better suited to guide ALK-targeted therapy.

#5341 Real-world landscape of BRAF fusions in chinese patients with lung and colorectal cancers: Insights from 26,248 DNA-NGS and RNA-NGS tests.

Li Wang, Wanpu Wang, Xinyan Pan, Ming Tang, Juanjuan Zhang

Department of Pathology, The First People's Hospital of Yunnan Province, Kunming, China

Background: Although rare, *BRAF* fusions are highly actionable alterations with strong responses to targeted therapy, particularly in lung and colorectal cancers. Their significant clinical relevance makes accurate detection essential, despite challenges posed by their low frequency and heterogeneous structures across sequencing technology. This study provides a large real-world analysis of *BRAF* fusion characteristics in Chinese lung and colorectal cancer patients, focusing on fusion partners, co-mutations, and differences between DNA-based and RNA-based next-generation sequencing (NGS).

Methods: A total of 26,248 patients underwent NGS testing, including 11,337 analyzed by DNA-NGS and 14,911 by RNA-NGS. *BRAF* fusions, partner genes, breakpoint patterns, and co-occurring driver alterations were systematically evaluated. Detection performance and fusion configuration differences were compared between DNA-NGS and RNA-NGS.

Results: Among all patients, 55 individuals (0.43%) carried 65 distinct *BRAF* fusions, with a higher proportion of female patients (58.5%). IMMP2L was the most common fusion partner (11.1%), followed by *TRIM24* (7.9%), *CD74* (6.3%), and *MKRN1* (6.3%). Co-mutations were identified in 30 fusion-positive patients, 90% of whom had lung cancer, consistent with reports suggesting *BRAF* fusions often emerge as secondary events after targeted therapy.Overall *BRAF* fusion prevalence did not differ significantly between DNA-NGS and RNA-NGS (0.24% vs. 0.19%, $p = 0.45$). However, the two platforms showed marked differences in fusion structure. All RNA-NGS-detected fusions were canonical 5′-3′ events, with *BRAF* exon 10 and exon 2 as the most frequent breakpoints (28.6%). In contrast, only 55.6% of DNA-NGS-detected cases showed canonical 5′-3′ fusions. Six of these also carried reciprocal or non-reciprocal rearrangements, while 12 cases harbored only non-canonical reciprocal configurations, suggesting that several DNA-NGS-identified events may not be transcriptionally functional or may represent structural variants lacking RNA expression.Importantly, the most frequent subtype, *IMMP2L-BRAF*, was detected exclusively in the RNA-NGS cohort, suggesting potential technical limitations in resolving *IMMP2L*-related breakpoints at the DNA level and underscoring the methodological advantages of RNA profiling.

Conclusions: This large real-world cohort outlines the *BRAF* fusion landscape in Chinese lung and colorectal cancers and reveals substantial discordance between DNA-NGS and RNA-NGS. The distinct partner spectrum and structural differences observed reinforce the value of RNA-based sequencing for accurate detection of clinically actionable *BRAF* fusions, supporting the integration of RNA analysis to optimize molecular testing and guide targeted therapeutic decisions.

#5342 Analysis of RNA expression of 47 cell surface proteins in real-world small cell lung cancer patients.

Sana Parveen[1], Emma T. Corcoran[2], Sebastia Franch-Exposito[2], Prerna Jain[2], Jacob Mercer[2], Abdul R. Naqash[3], Christine M. Lovly[4], Paul Fields[2], Hui-Zi Chen[5]

[1]Medical College of Wisconsin, Wauwatosa, WI,[2]Tempus AI, Chicago, IL,[3]Department of Medicine, University of Oklahoma, Oklahoma City, OK,[4]Department of Medical Oncology & Therapeutics Research, City of Hope Comprehensive Cancer Ctr., Duarte, CA,[5]Division of Hematology & Oncology, Department of Medicine, Medical College of Wisconsin, Wauwatosa, WI

Small cell lung cancer (SCLC) is an aggressive, smoking-induced bronchogenic lung cancer with few effective treatment options and an abysmal prognosis. Almost all patients relapse after initial induction chemotherapy and immunotherapy, and clinical benefit from subsequent therapies including tarlatamab-dlle (a DLL3 bispecific T cell engager) are limited. Herein, we performed an exploratory analysis of RNA expression of 47 cell surface proteins (CSPs) and 11 selected associated ligands in SCLC patients sequenced with Tempus xT (DNA-seq) and xR (RNA-seq). The CSPs include targets of immune checkpoint inhibitors (ICIs) and antibody-drug conjugates (ADCs) that are either FDA approved or currently evaluated in clinical trials. CSPs with important roles in modulating the tumor microenvironment (both tumor and stromal cell markers) were also evaluated. Leveraging Tempus dataset's clinical and molecular annotations, we stratified SCLC patients by subtypes (ASCL1, NEUROD1, POU2F3, Inflamed), treatment status (naïve vs. treated), and disease stage (limited vs. extensive). Non-parametric statistical tests (Wilcoxon Rank-Sum Test, Kolmogorov-Smirnov (KS) Test and Anderson-Darling (AD) Test) were applied to uncover robust differential expression patterns across these strata. We interrogated N=1,353 patients for CSP gene expression by subtype. We demonstrate that expression of certain CSPs are enriched in multiple (>2) SCLC subtypes including *DLL3*, *SEZ6*, *CEACAM5*, *CD276* and *MUC1*. We further identified subtype-specific CSP expression including *SSTR2* in NEUROD1 as well as *NECTIN4* and *ERBB3* in POU2F3. ICI targets including *CTLA4*, *PDCD1*, and *CD274* as well as the ADC target *TACSTD2* were increased in Inflamed and to a lesser extent the POU2F3 subtypes. With respect to disease stage, ICI and ADC targets such as *CTLA4*, *CD274*, *PDCD1*, *TIGIT*, *ICOS*, *TACSTD2*, and *MUC1* were significantly ($p<0.05$) more highly expressed in LS-SCLC (N=210) than in ES-SCLC (N=1,137). With respect to treatment status, we detected significantly ($p<0.05$) higher expression of *CTLA4*, *PDCD1*, *TIGIT*, *TACSTD2*, and *ITGB6* in treatment-naïve (N=744) than in SCLC patients who had received at least one line of systemic treatment (N=384). Although protein-level validation will be important and should be done when feasible, our exploratory analysis demonstrates that RNA expression of clinically relevant CSPs in SCLC patients may be influenced by subtype classification, cancer stage, and treatment status.

#5344 Variant allele frequency machine learning model identifies unique TP53-mutant phenotypes with worse post-operative survival in pancreatic cancer.

Imaad Said[1], Eugene Chen[2], Megan Zeller[2], Mohammed Aldakkak[1], Matthew Sochor[2], Bhabishya Neupane[2], Kshitij Gaur[2], Mandana Kamgar[3], Alexandria Phan[2], Janice Zhao[2], Samih Thalji[1], Beth Erickson[1], Christina Small-Tom[2], Callisia Clarke[2], Kathleen K. Christians[1], Nikki K. Lytle[1], Thomas McFall[2], William A. Hall[1], Anai N. Kothari[1], Douglas B. Evans[4], **Yongwoo David Seo**[2]

[1]Medical College of Wisconsin, Wawautosa, WI,[2]Medical College of Wisconsin, Wauwatosa, WI,[3]Medical College of Wisconsin, Milwaukee, WI,[4]Dept. of Surgery, Medical College of Wisconsin, Milwaukee, WI

Introduction: Even after neoadjuvant therapy (NAT) and resection for localized pancreatic ductal adenocarcinoma (PDAC), overall survival (OS) varies greatly. Clinical factors such as positive lymph nodes (LNs) can stratify risk, but greater precision is needed; comprehensive genomic profiling (CGP) can bridge this gap. We present a novel method of combining machine learning (ML) with variant allelic frequency (VAF) to identify drivers of OS.

Methods: We identified all localized PDAC patients who completed NAT, resection, and had CGP data. Stratifying OS from surgery by median, an XGBoost ML framework was utilized to extract features of importance using clinicopathologic variables, as well as VAFs for any present pathogenic mutations (with VAF=0% for wildtype [wt]). Model performance was evaluated using area under the curve (AUC) and Shapley additive explanation plots (SHAP), with Kaplan-Meier curves for clinical validation. In patients with available whole transcriptome data, DESeq2 was utilized for differential expression profiling.

Results: Among 110 patients with CGP data, 89 (81%) were KRAS mutated (G12D 33%, G12V 23%, and G12R 18%), and 67 (61%) had pathogenic TP53 mutation (mut). Initial models using known pathogenic mut VAFs identified TP53 as the highest impact feature. Addition of TP53 VAF, when combined with time-of-surgery clinical variables (age, comorbidity index, pathologic LN and T stage, lymphovascular or perineural invasion), improved prediction of OS (AUC = 0.81), vs. clinical variables alone (AUC = 0.73). SHAP analysis showed high TP53 VAF and LN+ status as the two highest contributing features for poor OS. When categorized by TP53 and LN status, TP53 mut/LN+ patients had significantly worse OS than all other groups (median 11.0 mo [95%CI 7.4-15.3] vs. 23.0 mo [20.4-32.1], p<0.0001); there was no difference in OS between TP53 wt/LN+, TP53 mut/LN-, and TP53 wt/LN-. When stratified into high vs. low VAF by median (6.5%), only high VAF patients had worse OS (10.7 mo [6.7-22.0]) compared to wt(25.9 mo [16.5-38.7], p=0.05.)78 of the 110 patients had bulk transcriptomic data available on the same specimens. TP53 mut tumors had significantly higher expression of LYPD2 (one of the human lymphocyte antigen-6 proteins associated with worse outcomes; log10 fold 4.4, p<1e-9), as well as keratin genes KRT13 (log10 fold 2.3, p <0.0001) and KRT15 (log10 fold 1.3, p <0.0001) - associated with basal subtypes and worse outcomes.

Conclusion: VAF analysis from CGP can uncover novel predictive targets for post-surgical outcomes. TP53 mut tumors express higher levels of genes associated with worse prognosis (e.g. LYPD2, KRT genes). When present with LN+, TP53 mut confers worst OS and may be a clonally dependent process (based on VAF). Post surgical TP53 mut/LN+ cohorts should be stratified as high risk and be considered for adjuvant treatment and clinical trials.

#5345 Large-scale genomic analysis of pancreatic cancer in a real-world patient population.

Avinash Ramu[1], Vasily Aushev[1], J. Bryce Ortiz[1], Alyssa Antonopoulos[1], Maria Diab[2], Philip A. Philip[3], David Kwon[3], Soma Subramaniam[1], Adham Jurdi[1], Gregory P. Botta[4]

[1]Natera, Inc., Austin, TX,[2]Division of Hematology and Medical Oncology, Department of Internal Medicine, Henry Ford Health and Michigan State University, Detroit, MI,[3]Henry Ford Pancreatic Cancer Center, and Department of Surgery, Henry Ford Health, Detroit, MI,[4]Division of Hematology and Oncology, Department of Medicine, University of California San Diego Moores Cancer Center, La Jolla, CA

Pancreatic cancer (PC) remains one of the deadliest malignancies, with minimal improvement in survival over recent decades. Fundamental questions persist regarding how genomic alterations influence PC biology and therapeutic response. Using a large multi-modal real-world genomic database, we sought to characterize the mutational and transcriptional landscape of PC and identify patterns that may inform future precision medicine approaches. Whole-exome sequencing (WES) data from tumor tissue samples were analyzed for patients with PC included in Natera's proprietary Real-World Database. Sequencing was performed as part of the tumor-informed, personalized Signatera™ circulating tumor DNA assay designed between May 2019-Nov 2024. After excluding cases of low tumor mutational burden and variant allele frequency, a total of 3,664 patients were included in the analysis. Variant calling was performed using Mutect2 and VarScan2. For prevalence analysis, only non-synonymous somatic SNVs and INDELs were included. Germline variant analysis was performed for 128 cancer predisposition genes in both tumor and normal samples; ClinVar pathogenic/likely pathogenic (P/LP) germline variants were retained. RNA sequencing data, from Altera™ tumor genomic profiling test (Natera, Inc.), were available for 658 patients, of whom 391 had matched WES data. Among the 3,664 patients with PC, the male/female ratio was [50%/50%], and the stage distribution was: I (14.6%%), II (24.4%), III (24.8%), IV (28.2%), and unknown (7.9%). Genetic ancestry composition included European (74.5%), African (10.9%), Latino/Admixed American (7.9%), East Asian (5.0%), and South Asian (1.5%) populations. The most frequently somatically mutated genes were *KRAS* (78%), *TP53* (62%), *CDKN2A* (18%), *SMAD4* (18%), and *ARID1A* (8%). The most common individual somatic variants were $KRAS^{G12D}$ (32%), $KRAS^{G12V}$ (25%), $KRAS^{G12R}$ (13%), $TP53^{R175H}$ (5%), and $KRAS^{Q61H}$ (4%). No statistically significant ancestry-based differences were observed in either gene or variant-level frequencies. P/LP germline variants were detected in 210 patients, comprising 149 unique variants across 34 genes, most commonly *ATM*, *BRCA2*, *MUTYH*, *BRCA1*, and *PALB2*. Among RNA-Seq profiled tumors, expression analysis identified patients with basal and classical molecular subtypes associated with distinct genomic features and clinical outcomes.

This real-world study represents one of the most extensive characterizations of PC to date, integrating WES, germline, and RNA-Seq data from over 3,500 patients. The findings confirm the predominance of canonical driver alterations (*KRAS*, *TP53*, *CDKN2A*, *SMAD4*) and highlight germline and transcriptomic diversity across the disease spectrum. Ongoing analyses are assessing transcriptional variation across *KRAS* and other genomic features and will link these profiles with survival outcomes to determine clinical relevance.

#5346 Prognostic impact and clinical characteristics of *KRAS* mutations and *CDKN2A* loss in *IDH1*-mutant intrahepatic cholangiocarcinoma.

Eiichiro So[1], Chigusa Morizane[1], Kouya Shiraishi[2], Nobuyoshi Hiraoka[3], Miyuki Sone[4], Takafumi Koyama[5], Rui Kitadai[6], Yusuke Okuma[7], Takashi Kohno[2], Tetsuro Shiraishi[2], Yuno Goto[1], Shiho Hakui[1], Kiyoaki Ochi[1], Keita Fujisaki[1], Kazunori Onuma[1], Yasuhiro Komori[1], Daiki Yamashige[1], Mao Okada[1], Shota Harai[1], Yuta Maruki[1], Yasuyuki Kawamoto[1], Yoshikuni Nagashio[1], Susumu Hijioka[1], Hideki Ueno[1], Kenro Hirata[8], Takanori Kanai[8], Takuji Okusaka[1]

[1]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital, Tokyo, Japan,[2]Division of Genome Biology, National Cancer Center Research Institute, Tokyo, Japan,[3]Division of Pathology and Clinical Laboratories, National Cancer Center Hospital, Tokyo, Japan,[4]Department of Diagnostic Radiology, National Cancer Center Hospital, Tokyo, Japan,[5]Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan,[6]Department of Medical Oncology, National Cancer Center Hospital, Tokyo, Japan,[7]Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan,[8]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

Background: In the ClarIDHy trial, ivosidenib significantly improved progression-free survival (PFS) compared with placebo in patients with previously treated *IDH1*-mutant cholangiocarcinoma (CCA) and is currently awaiting insurance approval in Japan. However, approximately 40% of patients in both arms experience disease progression within 2 months, suggesting underlying biological heterogeneity within *IDH1*-mutant CCA. We hypothesized that genomic co-alterations may serve as potential determinants of this heterogeneity.
Methods: We analyzed patients with intrahepatic cholangiocarcinoma (iCCA) in the Center for Cancer Genomics and Advanced Therapeutics (C-CAT) database between June 2019 and June 2025. Point mutations were annotated using OncoKB, and copy number variants and rearrangements were evaluated using C-CAT (approval number CDU2021-001N). Additionally, we reviewed institutional patients with *IDH1*-mutant iCCA diagnosed between October 2001 and October 2025, with detailed pathological and radiological assessments (approval number 2018-149).
Results: Among 2484 patients with iCCA, 353 had *IDH1* mutations (14.2%). *IDH1*-mutant iCCA tended to show longer overall survival (OS) and time to treatment failure (TTF) for first-line therapy than *IDH1*-wild type (median OS, 22.4 vs. 20.1 months; HR, 0.83; *P*=0.054; median TTF, 7.8 vs. 6.4 months; HR, 0.87; *P*=0.068). In *IDH1*-mutant iCCA, *KRAS* mutations and *CDKN2A* loss were less frequent than *IDH1*-wild type (*KRAS* mutations, 11.6% vs. 27.6%, *P*<0.001; *CDKN2A* loss, 17.8% vs. 27.5%, *P*<0.001). Among *IDH1*-mutant iCCA, *KRAS* mutations showed a trend toward shorter OS (median, 17.0 vs. 23.2; HR, 1.60; *P*=0.069) and were associated with shorter TTF (median, 5.7 vs. 8.5 months; HR, 1.86; *P*=0.0039). *CDKN2A* loss was correlated with shorter OS (median, 17.6 vs. 23.7 months; HR, 1.58; *P*=0.037). *IDH1*-mutant iCCA without *KRAS* mutations or *CDKN2A* loss demonstrated significantly longer OS (median, 24.9 vs. 17.6 months; HR, 0.61, *P*=0.010) and TTF (median, 8.4 vs. 6.1 months; HR, 0.70, *P*=0.020) than the other subsets. In multivariate analysis, *KRAS* mutations predicted shorter OS (HR, 1.75; *P*=0.046) and TTF (HR, 1.77; *P*=0.012). In an institutional cohort of 37 patients, only one case was pathologically classified as large-duct type and harbored *KRAS* mutation, with all other cases classified as small-duct type. Radiologically, *IDH1*-mutant iCCA without *KRAS* mutations and *CDKN2A* loss tended to present in a peripheral location (60.0% vs. 33.3%) and intratumoral transversing vessels (84.0% vs. 55.6%).
Conclusions: *IDH1* mutations less frequently co-occur with *KRAS* mutations and *CDKN2A* loss. *IDH1*-mutant iCCA without these co-alterations exhibited favorable clinical outcomes and distinct radiopathological characteristics, highlighting the biological heterogeneity associated with genomic co-alterations in *IDH1*-mutant iCCA.

#5347 Real-world clinicogenomic comparison of early- and average- onset gastric cancer.

Hannah McDonald, Lilia Turcios, Neelima Hosamani, Abu Saleh Mosa Faisal, Chi Wang, Joseph Kim, **Mautin Barry-Hundeyin**

University of Kentucky, Lexington, KY

In recent decades, there has been an unprecedented rise in gastric cancer among younger individuals, contrasting with a decline among older individuals. However, the biological underpinnings of gastric cancer in younger individuals remain poorly understood. We described the clinicopathologic and genomic characteristics of early-onset gastric cancer (EOGC) compared to average-onset gastric cancer (AOGC). We analyzed 311 patients using the multi-institutional prospective Oncology Research Information Exchange Network (ORIEN) database to compare demographic, clinicopathologic, genomic, and survival outcomes between EOGC (<50 years; N=72) vs AOGC (>50 years N=239). Genomic, germline, and RNA sequencing data were analyzed and compared between the cohorts. Mutational and immune signatures were also processed. EOGC patients exhibited significantly higher rates of pain at diagnosis (53% vs 30% *p=0.001*), but not anemia or reflux. EOGC patients were more likely to present with stage III/IV disease (70% vs 45% *p=0.006*) and diffuse/signet ring histology (47% vs 16% *p=0.002*). Consequently, OS was decreased in the younger cohort (HR 1.52; p=0.03). Somatic mutational load was decreased in young patients. Significantly mutated genes in the entire cohort included *CDH1*, *ARID1A*, *TP53*, *PIK3CA,* but *CDH1* was more frequently mutated in the EOGC cohort (40% vs 18% *p=0.09*). Significant differences in RNA expression were observed, with upregulated epithelial mesenchymal transition (EMT), myogenesis, and apical junction. Immune deconvolution revealed a predominance of M2 macrophages, mast cells, and $CD4^+$ T cell subsets, but no differences between cohorts. Early-onset gastric cancer has unique clinical and genomic features. Pathway dysregulation in EOGC may contribute to tumorigenesis and therapy resistance. This study underscores the necessity for further research into novel therapies, biomarker discovery, and early detection methodologies in younger individuals.

#5348 Tumor remodeling pathways are enriched in the tumor microenvironment of obesity-associated colorectal cancer.

Yu Fujiwara[1], Sarbajit Mukherjee[2], Yali Zhang[1], Jianmin Wang[1], Emily Baiyee Toegel[3], Tiago Biachi De Castria[4], Bodour Salhia[5], Anne M. Noonan[6], Michael J. Cavnar[7], Dae Won Kim[4], Muneeb Rehman[8], Patrick B. Boland[9], Melissa L. Fishel[10], Carlos H.F. Chan[11], Michele M. Gage[12], Hassan Hatoum[13], Julia White[14], Robert J. Rounbehler[15], Michelle Churchman[15], Deepak Vadehra[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Miami Cancer Institute, Baptist Health South Florida, Miami, FL,[3]University of Colorado Cancer Center, Aurora, CO,[4]Moffitt Cancer Center, Tampa, FL,[5]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[6]Ohio State University, Columbus, OH,[7]Markey Cancer Center, Lexington, KY,[8]University of Virginia, Charlottesville, VA,[9]Rutgers Cancer Institute, New Brunswick, NJ,[10]IU Simon Comprehensive Cancer Center, Indianapolis, IN,[11]Carver College of Medicine, University of Iowa, Iowa City, IA,[12]Murtha Cancer Center, Bethesda, MD,[13]Oklahoma University Stephenson Cancer Center, Oklahoma City, OK,[14]University of Kansas Cancer Center, Kansas City, KS,[15]Aster Insights, Tampa, FL

Background: Obesity is a known risk factor for colorectal cancer (CRC) that promotes systemic inflammation and T-cell dysfunction, yet the characteristics of the tumor immune microenvironment (TIME) in obesity-associated CRC are not well-defined. Therefore, we performed a comprehensive analysis to characterize the unique immunological and genomic features of obesity-associated CRC.

Methods: We performed genomic and transcriptomic analyses of patients with CRC stratified by body mass index (BMI) - obese (BMI ≥30), overweight (25≤ BMI <30), normal (18≤ BMI <25), and underweight (BMI<18). Data were obtained from the Oncology Research Information Exchange Network (ORIEN). Differential gene expression (DGE) and gene set enrichment analyses (GSEA) were performed to identify differentially expressed immune-related genes and altered biological pathways; immune deconvolution was performed to explore tumor immune microenvironment composition using CIBERSORT. Concurrently, genomic data were explored to compare the alteration frequency of selected genes (*APC, KRAS, TP53, SMAD4, PIK3CA, BRAF, NRAS, TGFBR2, MLH1, MSH2, MSH6, PMS2, CTNNB1,* and *PTEN*) using a Fisher's exact test. Statistical models were adjusted for covariates such as age, gender, and disease stage to isolate the effects of obesity.

Results: Overall, 939 patients (obese: n=355; overweight: n=326; normal: n=242; underweight: n=16) were included. Male sex was more common as weight increases ($p<0.0001$) but disease stage was well balanced across BMI groups ($p=0.581$). GSEA revealed that obesity was significantly associated with pathways related to tissue remodeling, including epithelial-mesenchymal transition, coagulation, and angiogenesis. Conversely, normal weight status was characterized by the upregulation of metabolic processes such as oxidative phosphorylation and fatty acid metabolism, alongside pathways governing cell cycle progression and DNA repair (normalized enrichment score ≥ 2.0, adjusted p value <0.05). Although immune cell compositions via immune deconvolution did not differ between obese and normal weight groups, DGE analysis revealed higher expression of several immune checkpoint related genes such as CD276 (B7H3) and SIRPα (CD47 ligand) in the obesity group and CD73 (NT5E) and apoptosis-inducing gene, TNFSF10 (TRAIL) in the normal weight. The alteration frequency of selected genes was not significantly different between obese and normal groups.

Conclusions: CRC with obesity is characterized by tumor remodeling whereas CRC without obesity had more upregulated metabolic processes in the TME. Differential expression status of key immune checkpoints between cases with and without obesity could indicate a tailored therapeutic target in this disease entity.

#5349 Refining tumor mutational burden as a predictive biomarker for pembrolizumab: A real-world analysis of 1,899 Japanese patients.

Tomoyo Yasuda[1], Mio Yumura[1], Azusa Hamasaki[1], Tongyi Fei[1], Takashi Kubo[2], Hitoshi Ichikawa[3], Takashi Kohno[3], Kuniko Sunami[2]

[1]Sysmex Corporation, Hyogo, Japan,[2]National Cancer Center Hospital, Tokyo, Japan,[3]National Cancer Center Research Institute, Tokyo, Japan

Tumor mutational burden (TMB) is a key biomarker for predicting the response to immune checkpoint inhibitors (ICIs). However, its predictive accuracy in real-world clinical practice, particularly in Asian populations, remains inadequately evaluated. We addressed this issue by analyzing real-world data from 63,952 patients registered in the Center for Cancer Genomics and Advanced Therapeutics (C-CAT) database, which integrates genomic and clinical information from Japanese patients with various advanced solid tumors. We assessed the therapeutic efficacy of pembrolizumab in 1,899 patients who underwent one of three comprehensive genomic profiling tests: FoundationOne CDx, the OncoGuide NCC Oncopanel System, or the GenMine TOP Cancer Genome Profiling System. Based on the reported TMB values, patients were classified as TMB-high (≥10 mutations per megabase) or TMB-low (<10 mutations per megabase). The objective response rate (ORR) among 946 TMB-high patients exceeded 30% and was significantly higher than that observed in 953 TMB-low patients (16.8%, $P < 0.001$). Notably, patients with borderline TMB values (10 to less than 13 mutations per megabase) exhibited relatively modest responses (20.8%). The ORR improved when hotspot mutations were excluded from the TMB calculation, suggesting that this adjustment enhances the predictive accuracy of TMB. These findings support the clinical utility of TMB as a biomarker for predicting ICI response in routine oncology practice. In particular, excluding hotspot mutations from TMB calculations may improve response prediction in patients whose TMB values are near the threshold.

#5350 Evaluating prognostic biomarkers in advanced epithelial ovarian carcinoma using machine learning on real-world data.

Carlos Ronchi, **Coryandar Coulomb**, Frances Peterson, Danielle Bloch, Kathleen Burke

Tempus AI, Inc., Chicago, IL

Introduction: Real-world data (RWD) offers a valuable tool for identifying novel prognostic factors in heterogeneous diseases. We leveraged the Tempus multimodal RWD database to analyze outcomes for patients with advanced epithelial ovarian carcinoma (EOC) and primary peritoneal carcinoma (PPC). Our primary objective was to apply machine learning (ML) models to identify and evaluate clinical prognostic biomarkers for real world progression-free survival (rwPFS). A secondary objective was to build a well-characterized, real-world cohort of patients receiving standard-of-care (SoC) treatment to serve as a foundation for this analysis.

Methods: Using the Tempus database we constructed a retrospective real-world clinical biomarker cohort of 3016 patients with Stage III/IV EOC or PPC who received first-line (1L) carboplatin and paclitaxel and had a reductive surgery prior to or within 30 days of 1L treatment start. We included relevant clinical variables, such as CA125, race, ECOG, obesity status, histology, and lymphocyte counts. rwPFS was analyzed using Kaplan-Meier and Cox proportional hazard models. Using this cohort, we trained Random Survival Forest (RSF), Cox Regression, and Regularized Cox Regression models to predict rwPFS risk. Model interpretability and feature importance were assessed using SHAP (SHapley Additive exPlanations) values.

Results: The median rwPFS (mPFS) for this cohort was 18.5 months (95% CI: 17.5-19.6), establishing a baseline for this advanced SoC-treated population. The RSF model, trained on the clinical biomarker cohort (N=2769, 80% training, 10% validation, 10% test), demonstrated prognostic performance for rwPFS (AUC = 0.7 at 18 months). SHAP analysis of the RSF model confirmed CA125 as the most significant prognostic feature, consistent with clinical practice. Obesity (BMI threshold > 30) was identified as an important prognostic feature, with obese patients having higher SHAP values compared to non-obese. A stratified analysis showed that CA125 levels were prognostic in non-obese patients (mPFS, Low vs. High: 20.2 [95% CI: 16.1-24.2] vs. 14.7 months [95% CI: 13.0-16.3]), whereas for obese patients mPFS estimates were similar across the two CA125 groups (mPFS, Low vs. High: 14.7 [95% CI: 12.5-20.9] vs. 14.3 months [95% CI: [11.2-17.5]).

Conclusions: Our study demonstrates the utility of applying ML models to large-scale, multimodal RWD to identify and validate prognostic factors in advanced EOC and PPC. Our models confirmed the primary prognostic power of CA125 and identified obesity as an independent prognostic factor. The observed differential prognostic impact of CA125 between obese groups highlights a potential health disparity and underscores the need for further investigation into population-specific biomarkers to ensure the development of equitable prognostic models.

#5351 Epidemiology of folate receptor alpha expression in ovarian cancer by age, race/ethnicity, and histotype in a real-world, US-based clinicogenomic database.

Rebecca C. Arend[1], Kent F. Hoskins[2], Jenny S. Guadamuz[3], Gregory S. Calip[4], Megan A. Clarke[4], Yookyung Christy Choi[4], Qu Zhang[4], Ricardo R. Lastra[5], Amanda L. Strickland[6], Sarah K. Lynam[7]

[1]University of Alabama at Birmingham, Birmingham, AL,[2]University of Illinois Chicago, Chicago, IL,[3]University of California Berkeley, Berkeley, CA,[4]AbbVie, Inc., North Chicago, IL,[5]The University of Chicago, Chicago, IL,[6]University of North Carolina at Chapel Hill, Chapel Hill, NC,[7]University Hospitals Seidman Cancer Center, Cleveland, OH

Ovarian cancer (OC) is molecularly heterogeneous, requiring biomarkers to guide personalized therapy. Folate receptor alpha (FRα) is an actionable biomarker with therapeutic implications. We evaluated FRα expression in OC by age, race/ethnicity, and histotype using real-world US clinicogenomic data.

We conducted a cross-sectional analysis of patients diagnosed with ovarian, fallopian tube, or primary peritoneal cancer from 2019 to 2025 using the ConcertAI RWD360™ database linked to Caris Life Sciences genomic data. FRα testing was done using the VENTANA FOLR1 (FOLR1-2.1) RxDx Assay (Roche Diagnostics); FRα-high was defined as ≥75% of tumor cells with ≥2+ membrane staining. Stratified prevalence rates and multivariable prevalence rate ratios (RRs) with 95% CIs were estimated using modified Poisson regression. Sensitivity and exploratory analyses evaluated associations with FRα expression in the full, unselected OC clinicogenomic database, applying a validated machine learning classifier trained on whole transcriptome RNAseq to predict FRα-high expression (N=3045).

Among 1155 patients with OC who received FRα testing, median age was 66 years (y) (IQR, 58-73); 71% were non-Hispanic White and 61% had high-grade serous histology. FRα-high expression was observed in 33%, with higher prevalence in high-grade serous (43%) compared to less common histotypes (low-grade serous, 24%; endometrioid, 6%; clear cell, 2%; carcinosarcoma, 9%) (*P*<0.001). There were no significant associations between FRα-high prevalence and age after adjusting for histotype (<50, Reference; 50-64, aRR 0.95, 95% CI 0.69-1.31; 65-74, aRR 1.15, 95% CI 0.84-1.57; ≥75 y, aRR 1.18, 95% CI 0.85-1.63). FRα-high prevalence did not differ by race/ethnicity (*P*=0.933) including after adjustment for age and histotype: non-Hispanic Black, 34% (aRR 1.03 [95% CI, 0.78-1.35]); non-Hispanic Asian, 29% (aRR 0.97, 95% CI 0.57-1.65); Hispanic, 30% (aRR 0.95, 95% CI 0.64-1.40); non-Hispanic White (32%, Reference). In sensitivity analyses restricted to high-grade serous histology, consistent associations with age and race/ethnicity were observed. In exploratory analyses, similar associations were observed in the broader database.

FRα-high expression does not significantly differ by age or racial/ethnic group and is most prevalent in high-grade serous OC. These findings further support FRα as an OC biomarker with broad clinical applicability across demographics and demonstrate the importance of accounting for potential confounding by histotype in studies of FRα-high prevalence. Further adoption of FRα testing in the work-up for advanced OC provides important information to ensure patients have access to all eligible treatment options and biomarker-directed clinical trials, particularly for underrepresented groups and those facing disparities in access to healthcare.

#5352 Genomic and ancestry-associated determinants of survival in gynecologic cancers.

Laura Chambers[1], Avinash Ramu[2], Vasily N. Aushev[2], Susan Rojahn[2], Alyssa Antonopoulos[2], Carly B. Scalise[2], Faraz Salmasi[2], Minetta C. Liu[2], Adam C. ElNaggar[2], Rebecca C. Arend[3]

[1]The Ohio State University, Columbus, OH,[2]Natera, Inc., Austin, TX,[3]Obstetrics and Gynecology, University of Alabama at Birmingham, Birmingham, AL

Survival outcomes for gynecologic cancers vary across populations; however, the genomic and other factors that contribute to these differences are poorly defined. We leveraged a large, real-world dataset to examine how genetic ancestry, tumor genomics, and histology are associated with overall survival (OS) in endometrial (EC), ovarian (OC), and cervical cancer (CC). This retrospective analysis used integrated data from whole-exome sequencing (WES), medical claims, mortality records, and electronic health records in Natera's proprietary de-identified Real-World Database. Tumor and germline WES data were obtained as part of the workflow for a personalized, tumor-informed mPCR-NGS circulating-tumor DNA assay (Signatera™, Natera Inc.). Variants, microsatellite instability (MSI), and genetic ancestry were analyzed. Ancestry was inferred by EthSeq and classified into predefined groups: African (AFR), American, East Asian (EAS), European (EUR), and South Asian. Cancer histologies were extracted from clinical records using natural language processing. OS associations were evaluated using Cox proportional hazards models. A total of 2,574 EC, 2,425 OC, and 773 CC patients were included. In EC, AFR ancestry was associated with worse OS compared to EUR ancestry (HR 1.56, p=0.013), especially in stage I/II patients (HR 2.1, p=0.03). The most frequent variants in EC were in *PTEN* (46.5% of patients), *PIK3CA* (40.6%), *TP53* (38.0%), and *ARID1A* (37.8%). Variants in *TP53* (stage I/II: HR 2.1, p<0.001; stage III/IV: HR 2.1, p<0.0001) and *KMT2B* (stage III/IV: HR 1.48, p=0.04) were linked with worse OS, while variants in *PTEN* (stage I/II: HR 0.5, p=0.002; stage III/IV: HR 0.44, p<0.0001) and *ARID1A* (stage I/II: HR 0.6, p=0.02; stage III/IV: HR 0.5, p<0.0001) were associated with better OS. Microsatellite stable (MSS) EC tumors had a worse OS than MSI-High (MSS vs MSI-H: HR 2.0, p<0.001). In OC, stage I AFR patients had worse OS compared to EUR patients (HR 7.5, p=0.04). OC tumor variants were most common in *TP53* (59.7%), *PIK3CA* (11.4%), *and ARID1A* (10.5%), consistent with established OC biology. No associations with OS and variants, MSI, or histology were identified. In CC, AFR ancestry was associated with worse OS vs EUR (HR 2.0, p=0.04). *PIK3CA* variants were common (29.5% of patients) and associated with worse OS in stage II/III/IV patients (HR 1.9, p=0.015). No OS differences by histology were observed. Across cancers, AFR and EAS ancestry showed distinct histologic distributions compared with EUR. In conclusion, genetic ancestry was independently associated with OS across gynecologic cancers, particularly among AFR-ancestry patients with EC and CC. Specific genomic features (e.g., MSI status and *TP53, PTEN, ARID1A, PIK3CA,* and *KMT2B* variants) further define risk. Further study of ancestry-informed genomic and pathologic data into clinical research may reduce survival disparities in gynecologic malignancies.

#5354 Extrachromosomal DNA shapes aggressive transcriptional states in multiple myeloma.

Hi Eun Jung[1], Saeam Shin[2], Yu Ri Kim[3], Ja Min Byun[4], Youngil Koh[4], Junshik Hong[4], Dong-Yeop Shin[4], Inho Kim[4], Hoon Kim[5], Hyunsoo Cho[4]

[1]Biomedical Research Institute, Seoul National University Hospital, Seoul, Korea, Republic of,[2]Department of Laboratory Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of,[5]Department of Biopharmaceutical Convergence, School of Pharmacy, Sungkyunkwan University, Suwon-si, Korea, Republic of

Background:
Extrachromosomal DNA (ecDNA) is increasingly recognized as a key driver of oncogene amplification, intratumoral heterogeneity, and poor clinical outcomes across solid tumors. However, its significance in multiple myeloma remains largely unexplored. Multiple myeloma is characterized by marked genomic instability including hyperdiploidy or IgH translocations, and widespread structural rearrangements that underlie biological heterogeneity and therapy resistance. Defining whether ecDNA contributes an additional layer of genomic complexity in this disease therefore represents an important unmet need.
Methods:
Whole-genome sequencing (WGS) BAM files of patient tumor samples from the Multiple Myeloma Research Foundation (MMRF) CoMMpass study were analyzed using the AmpliconSuite pipeline to identify circularized DNA amplicons indicative of ecDNA. Matched transcriptome (RNA-seq) data and clinical metadata from the same cohort were integrated to evaluate the prognostic impact of gene expression associated with ecDNA-harboring loci. Gene Set Enrichment Analysis (GSEA) was performed using the *clusterProfiler* R package to assess pathway-level biological signatures linked to ecDNA-positive tumors.
Results:
We identified ecDNA in 28 of 904 patients (3.1%) from the MMRF CoMMpass dataset. Despite the low prevalence, ecDNA-positive myeloma patients exhibited significantly inferior survival compared with patients without ecDNA. Frequently amplified ecDNA loci contained oncogenes such as *MYC, TNFRSF17 (BCMA),* and *SNX29,* as well as pro-tumoral lncRNAs including *CASC11* and *PVT1.* GSEA revealed strong enrichment of MYC and E2F targets, oxidative phosphorylation, and PI3K-AKT-mTOR and mTORC1 signaling in ecDNA-positive tumors, highlighting transcriptional addiction and metabolic activation. These pathways align with known mechanisms of proliferation, metabolic rewiring, and treatment resistance in multiple myeloma.
Conclusions:
ecDNA-positive myeloma represents a biologically aggressive subset characterized by oncogene-enriched circular amplicons and hyperactivated proliferative and metabolic programs. Myeloma patients with ecDNA showed significantly worse survival, supporting ecDNA as a previously underrecognized high-risk feature. These findings highlight ecDNA as potential therapeutic vulnerabilities in myeloma and warrant further investigation.

#5356 Leveraging a real-world clinicogenomic database for post-sequencing quality assessment in solid tumor comprehensive genomic profiling (CGP).

Erin N. Newburn[1], Rebecca A. Previs[1], Michelle F. Green[1], Kyle C. Strickland[1], Heidi Ko[1], Taylor Jensen[2], Eric Severson[1], Hardik Parikh[3], Maria-Fernanda Senosain[3], Jie An[1], Erik Van Roey[3], Daniel Metzger[1], R.J. Seager[3], Mark Sausen[4], Jennifer Jackson[4], Kenneth Valkenburg[4], Brian Caveney[5], Marcia Eisenberg[5], Shakti Ramkissoon[1]

[1]Labcorp, Durham, NC,[2]Labcorp, Fuquay-Varina, NC,[3]OmniSeq, LLC, Buffalo, NY,[4]PGDx, Baltimore, MD,[5]Labcorp, Burlington, NC

The quantity and integrity of DNA and RNA extracted from formalin-fixed paraffin-embedded (FFPE) tumor specimens can vary significantly due to factors such as block age, fixation conditions, protein crosslinking, and the presence of chemical inhibitors. Over a decade of research has demonstrated that, with optimized pre- and post-analytical workflows, FFPE samples can serve as reliable input material for both clinical and research-based next-generation sequencing (NGS) applications. Certain tumor types present additional challenges for nucleic acid extraction due to their biological characteristics, such as high metabolic activity and elevated nuclease levels. To evaluate sequencing quality across diverse tumor tissue types, we analyzed post-sequencing metrics from clinical tests performed over a 12-month period using the OmniSeq INSIGHT test for CGP. The cohort included 8,645 solid tumor samples representing 19 distinct cancer types. The most frequently profiled tumors were lung (N=3,984), colorectal (N=1,211), breast (N=578), pancreatic (N=398), prostate (N=331), uterine (N=252), esophageal (N=232), and head and neck (N=221). Key post-sequencing quality metrics that assess sequencing coverage and on target mapping were evaluated. Across all indications, high-quality data metrics were consistently achieved for both DNA and RNA, underscoring the robustness of the workflow regardless of tumor type. These findings support the scalability and reliability of CGP using FFPE tissue across a broad spectrum of solid tumors, reinforcing its utility in clinical oncology and research applications for high-quality genomic reporting.

#5357 Molecular tumor registries - A learning system for real world data (RWD).

Erik Larsen[1], Chenbo Sun[2], Michele Cosi[3], Rudy Salcido[3], Sarah Roberts[3], Nirav Merchant[3], Justin Starren[4], **Ritu Pandey**[5]

[1]University of Arizona Cancer Center, Tucson, AZ,[2]Cellular and Molecular Medicine, Tucson, AZ,[3]University of Arizona, Tucson, AZ,[4]Center for Bioinformatics and Biostatistics, Tucson, AZ,[5]University of Arizona Cancer Center, Center for Biomedical Informatics and Biostatistics, Cellular and Molecular Medicine, Tucson, AZ

Background: Genomic data is a key component for drug discovery and precision medicine, an innovative approach for tailoring treatment and prevention that is useful for clinicians and researchers. Patient care now often involves comprehensive genomic profiling through certified clinical lab vendors. The clinical interpretation of molecular alterations is at the heart of providing the value of precision medicine and yet this Real-World Data is not always seamlessly integrated along with Real World Evidence (RWE) in electronic health records (EHR). We present the challenges and lessons learned in developing an end-to-end secure platform, along with the opportunities that a molecular registry opens for RWE in clinical care and research.
Design: The molecular tumor registry IMPACT (Individual Molecular Registry of Patients for Accelerated Clinical and Translational Medicine) is built within a secure data enclave, “Soteria”, a HIPAA compliant high-performance compute (HPC) cluster. The software tools include an R package of JSON parsers to extract NGS and other results and store them within a DuckDB. An interactive RShiny web application is deployed on a secure VM within the secure enclave. This provides a real-time, de-identified genomics data feed of test metadata including tumor site, test types, genes, variants, and several associated elements for every case. Optimized data pipelines have been constructed for bulk NGS files, for comprehensive analysis. AI tools have been deployed for connecting the National Clinical Trial registry and associated FDA-approved targeted drugs.
Results: The data is accelerating in size as more tests are being ordered by clinicians and new tests are developed by the vendors. Common challenges are a) time devoted to advance the process due to legal hurdles and inflexible contracts, b) lack of common nomenclature and data formats to compare and interpret results across vendors, c) constant change of technology and tests and d) Integration with the EHR. The registry opens up opportunities - 1) to normalize and harmonize results across vendors, 2) enable genomically informed clinical trials and patient recruitment, 3) facilitate a molecular tumor board, 4) enable cohort discovery and integrative analysis with RWE data from EHR, 5) support biomedical trainee education 6) provide opportunity to deploy LLM (Large Language Models)-powered tools for data investigation and deep learning models for research.
Conclusions: The learning system, IMPACT, enables bringing molecular sequencing and clinical data together in a secure enclave to learn from RWD from patients utilizing power discovery approaches. Real-world insights from visualizing the pan-cancer results from both a high and granular level is an invaluable resource for accelerating research and treatment strategies across cancers, the epitome of translational research.

#5358 Disparities between genomic alterations and clinical trial representation in precision oncology.

Jingyao Zhang[1], Raoul Santiago[2], Kamila Bakirhan[3], Tenzin Tamdin[1]

[1]Danbury Hospital, Danbury, CT,[2]CHU Laval Research Ctr., Quebec, QC, Canada,[3]Praxair Cancer Center, Danbury Hospital, Danbury, CT

Background: Precision oncology has shifted from histology-based treatment toward molecularly driven frameworks, but it remains unclear whether clinical trial priorities align with the real-world genomic landscape. This study evaluated biomarker-driven solid tumor trials from 2010 to 2025 and compared trial representation with genomic prevalence in TCGA.
Methods: Interventional solid tumor trials (2010-2025) were extracted from the AACT ClinicalTrials.gov database and processed in Python. Adult solid tumor studies were identified via structured filters, and 30 predefined biomarkers were detected through text-mining of titles, eligibility criteria, and interventions. Manual review removed false positives, and biomarker names were harmonized across AACT and TCGA. TMB-high was defined as ≥10 mutations per megabase, and MSI-high was defined as MSIsensor score ≥10. Trials were categorized by phase, sponsor type, and tissue specificity. Representation ratios (trial frequency ÷ TCGA genomic prevalence) were calculated, with ratios >1.5 classified as over-represented, 0.5-1.5 as balanced, and <0.5 as under-represented. TCGA overall survival (OS) analyses were performed for each biomarker.
Results: Among 7,259 biomarker-driven solid tumor trials, 19.4% were tissue-agnostic, 54.5% were industry-sponsored, and 79.6% were early-phase (I/II). Of the 30 biomarkers analyzed, 6 (20%) were over-represented, 16 (53%) were balanced, and 8 (27%) were under-represented relative to their TCGA genomic prevalence. Over-represented biomarkers included EGFR (28.4% vs 8%), VEGFA (12.5% vs 2%), FGFR3 (6.0% vs 3%), and HER2 (12.4% vs 6%), reflecting prioritization of highly druggable oncogenic drivers. In contrast, under-represented biomarkers included TP53 (2.0% vs 37%), STK11 (0.5% vs 8%), KEAP1 (0.2% vs 4%), TMB-high (2.9% vs 12%), and CDKN2A (7.3% vs 17%), most of which were tumor suppressors without approved targeted therapies and have recognized immune relevance. Alterations in TP53, CDKN2A, and KEAP1 were associated with significantly shorter OS in TCGA (all $p < 0.001$), underscoring their prognostic significance despite limited clinical trial representation.
Conclusions: Current oncology trials disproportionately focus on established, targetable oncogenes, while high-prevalence tumor suppressor alterations and immune-related biomarkers remain underrepresented. This mismatch highlights a translational gap between genomic prevalence and clinical trial design and underscores opportunities to broaden biomarker inclusion, expand tissue-agnostic frameworks, and integrate real-world genomic data to advance equitable precision oncology.

#5359 Precision oncology in practice: Comprehensive genomic profiling identifies actionable alterations and guides therapeutic selection in 756 clinical solid tumors.

Sarabjot Pabla[1], Sushant Khadgi[2], Anjana N. Bhattacharya[2], Asia Chang[3], Mark Gardner[2]

[1]Quest Diagnostics, Baltimore, MD,[2]Quest Diagnostics, Secaucus, NJ,[3]Quest Diagnostics, San Franscisco, CA

Background: Comprehensive genomic profiling (CGP) of solid tumors is increasingly used to inform targeted and immune-directed therapies; real-world performance data are needed to guide further adoption. This study reports multi-laboratory experience running the TSO500 (TruSight Oncology 500) solid tumor assay on 756 clinical FFPE samples across different tumor types and evaluates, variant tier and biomarker distribution that impacts treatment decisions.

Methods: TSO500 was performed on 756 routine clinical specimens, where DNA/RNA were isolated from FFPE specimens. Sequencing was performed at two sites using NovaSeq600. Post sequencing, NGS data was analyzed using Illumina TSO500 analysis pipeline. SNVs, INDELs, Copy Number Alterations were estimated from DNA whereas gene fusions were estimated and reported using tumor RNA. Variants were classified as per AMP/ASCO/CAP tiers. Other biomarkers including tumor mutational burden (TMB) and microsatellite instability (MSI) were reported. Clinical decision impact was assessed by variant Tier classification.

Results: Of the 756 clinically reported samples, major disease types included lung cancer (63.3%), colorectal cancer (11.51%), solid neoplasm (9.26%), pancreatic cancer (5.16%), melanoma (1.72%) and breast cancer (1.19%). of the 12,461 reported variants across all samples, 19.3% (2407/12461) were classified by AMP variant classification. 50% (1216/2407) of these variants were actionable variants (AMP Tier I/II). Tier III variants of unknown significance comprised 29.3% (705/2407) and Tier IV/benign 20.2% (486/2407). Clinically relevant biomarkers detected included high TMB (≥10 mut/Mb) in 32.8% and MSI-high in 3.3% of cases; gene fusions were detected in 9.8% (74/756). CGP results informed treatment selection (Variants with strong clinical significance (e.g., those with FDA-approved therapies or included in professional guidelines) in 30% of cases and Variants with potential clinical significance (e.g., supported by preclinical data, case reports, or ongoing clinical trials in 58% of overall specimens tested. Additionally, Tier 3 variants of unknown significance were reported in 60% of cases.

Conclusions: In this large real-world study, our CGP assay delivered identified actionable genomic alterations in nearly half of cases across diverse solid tumors. These results demonstrate the high-throughput CGP assay, provide scalable detection of molecular alterations to support precision oncology, enabling reporting and therapy selection of hundreds of samples per week.

#5363 Validation of microenvironment gene signatures from FFPE to predict nasopharyngeal cancer prognosis.

Yi Ren[1], Wei Keat Teo[1], Bingcheng Wu[2], Joseph W. Foley[1], Chee Yit Lim[1], Serene Chor Hiang Siow[1], Han Lee Goh[1], Eugenia Li Ling Yeo[3], Enya Hui Wen Ong[3], Melvin Lee Kiang Chua[3], Jianjun Liu[4], Kwok Seng Loh[1], Raymond Tsang[1], Joshua K. Tay[1]

[1]Department of Otolaryngology, National University of Singapore (NUS), Singapore, Singapore,[2]Department of Pathology, National University Hospital, Singapore, Singapore,[3]Division of Medical Sciences, National Cancer Centre Singapore, Singapore, Singapore,[4]Human Genetics, Genome Institute of Singapore, , Agency for Science, Technology and Research (A*STAR), Singapore, Singapore

Background: Nasopharyngeal carcinoma (NPC) is endemic to Southern China and Southeast Asia. Gene expression profiling and biomarker identification in NPC with conventional bulk RNAseq has been challenging due to substantial heterogeneity in cellular composition and limited tissue availability. While we have previously described the microdissected gene expression landscape of NPC and its tumor microenvironment (TME) subtypes, prognostic gene signatures for treatment response remain poorly defined.

Methods: We obtained formalin-fixed paraffin-embedded (FFPE) biopsies from 64 NPC patients matched for stage but with different clinical outcomes, i.e., the treatment failure group (recurrent/metastatic disease) and the survivor group (remained disease-free). Laser-capture microdissection was performed to isolate the tumor epithelial (TUM) and TME regions based on H&E staining and pathologist annotation. Gene expression libraries were prepared using a specialized RNAseq protocol optimized for FFPE tissues. Following next generation sequencing, bioinformatic analyses were performed to develop gene signatures predictive of clinical outcomes.

Results: After quality control, 277 gene expression libraries were analyzed, consisting of 154 TUM and 123 TME libraries. Unsupervised consensus clustering of TME libraries identified three conserved clusters (average Silhouette width = 0.89). These TME clusters were characterized as immune (C1), epithelial-infiltrative (C2), and stromal (C3) gene signatures based on gene set enrichment analysis (GSEA) and in-silico deconvolution. Notably, 63.2% and 72.7% of TME libraries in C1 and C3 were from survivors, while 61.5% in C2 were from treatment failures (chi-square test, $p = 0.0397$). Gene signatures for TME clusters were derived from upregulated genes in each cluster, and single-sample GSEA (ssGSEA) was used to calculate signature scores in two independent NPC cohorts (PMID:28851814 and PMID:40412382). Consistently, Kaplan-Meier analyses showed that patients with high C1 or low C2 scores had better progression-free survival (log-rank p-values 0.005 to 0.031). Interestingly, these TME cluster gene signatures outperformed the gene signature derived directly from the treatment failure versus survivor comparison in TME, suggesting that biologically meaningful TME-based gene signatures capture prognostic signal more robustly and generalize better across cohorts.

Conclusions: In this study, we identified three distinct TME clusters in NPC and derived gene signatures that consistently predict progression-free survival across cohorts. These results highlight the value of TME-based biomarkers for risk stratification and precision medicine. Importantly, our FFPE LCM RNAseq workflow enabled high-quality, cell type-specific profiling from archival biopsies, supporting its utility for uncovering clinically relevant biomarkers.

#5364 Neutrophilic skin infiltrates in patients with acute myeloid leukemia (AML) are clonal and associate with poor overall survival.

Gabby Tesfaye[1], Yazan Abu-Shihab[1], Deedra Nicolet[2], Jill Buss[2], Andrea Laganson[2], Catherine Chung[2], SANAM LOGHAVI[2], Benjamin Kaffenberger[3], **Ann-Kathrin Eisfeld**[4]

[1]The Ohio State University Comprehensive Cancer Center, Columbus, OH,[23]The Ohio State University Wexner Medical Center, Columbus, OH,[4]Postdoctoral Fellow, Dept. of Human Cancer Genetics, Ohio State University College of Medicine, Columbus, OH

Background: Acute myeloid leukemia (AML) is an aggressive hematologic malignancy. While blast infiltration (leukemia cutis, LC) is a known extramedullary disease, reactive neutrophilic dermatoses (like Sweet's syndrome) are common, but their etiology remains unclear. We aimed to determine if these lesions represent an atypical leukemic process.
Methods: We analyzed the clinical and molecular characteristics, including survival outcomes, in 1,019 consecutive AML patients for histopathologically evaluated skin lesions (10 days prior and up to 60 days post-diagnosis). Patients with reactive neutrophilic dermatoses underwent confirmation for absence of leukemic blasts. We then performed paired tumor/normal whole-exome sequencing on bone marrow (BM) and FFPE-derived skin biopsy tissues for 8 such patients.
Results: Dermatology consultation was required in 31% of patients. While reactive inflammation generally showed high complete remission (CR) rates (91%), patients with reactive neutrophilic dermatoses had the shortest disease-free survival (DFS) of all patient groups, with a median DFS of only 13 months. Clinically, these patients frequently harbored NPM1 (27%), IDH1/2 (41%), and FLT3-ITD (23%) mutations. Next, we sequenced paired samples from 4 patients whose skin lesions were confirmed as blast-free. Remarkably, sequencing of the skin lesions revealed AML gene mutations identical to those found in the BM blasts, with near-identical variant allele fractions (VAFs) in both tissues. Three of four patients also harbored mutations in genes encoding keratin-associated proteins.
Conclusions: Morphologically normal, mutationally clonal, neutrophilic infiltrates represent a distinct extramedullary manifestation of leukemia that differs from classical leukemia cutis but has significant clinical and biological relevance (poor survival). A similar phenomenon is known for chronic myelomonocytic leukemia (CMML). If validated, this may identify an underappreciated type of leukemic involvement and possible escape mechanism.

#5365 Clinicopathological and prognostic analyses of colorectal cancer with neuroendocrine differentiation.

Yuki Yasuda[1], Keigo Murakami[2], Hideaki Karasawa[1], Wataru Kosaka[1], Yota Akamori[1], Ichiro Ise[1], Tomoyuki Ono[1], Megumi Murakami[1], Yoshihiro Sato[1], Gumpei Yoshimatsu[1], Hideyuki Suzuki[1], Takashi Kamei[1], Shinobu Ohnuma[1], Toru Furukawa[2], Michiaki Unno[1]

[1]Department of Surgery, Tohoku University Graduate School of Medicine, Sendai, Japan,[2]Department of Investigative Pathology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: A subset of colorectal cancers (CRCs) exhibits neuroendocrine differentiation (NED), characterized by the expression of neuroendocrine markers such as synaptophysin and chromogranin A. Although NED has been reported to be associated with aggressive behavior and poor prognosis in other cancer types, the clinicopathological and prognostic significance of NED in CRC remains unclear due to limited and inconsistent evidence. A better understanding of CRC with NED may provide insights into its molecular characteristics and potential therapeutic strategies.
Methods: Patients with pathological stage II-IV CRC who underwent surgical resection at our institution between 2013 and 2017 were retrospectively analyzed. Immunohistochemical staining for synaptophysin was performed on formalin-fixed, paraffin-embedded tissue sections. NED was defined as positive when the H-score for synaptophysin was ≥4. Clinicopathological features—including lymphovascular and perineural invasion, desmoplastic reaction pattern, tumor budding grade, and poorly differentiated cluster (PDC) grade—were compared between NED-positive and NED-negative groups. Overall survival (OS) and relapse-free survival (RFS) were analyzed using Kaplan-Meier method.
Results: Among 261 evaluable CRC cases, 21 (8.0%) were classified as NED-positive based on synaptophysin expression. The NED-positive group included 9 males and 12 females, with a median age of 68 years old (range, 17-91 years old). The TNM classification (8th edition) was as follows: pathological stage II (n=4, 4.1%), stage III (n=10, 9.3%), and stage IV (n=7, 12.5%) of the total cases in each stage. Compared with NED-negative CRCs, the NED-positive group more frequently exhibited the following features: perineural invasion (61.9% vs. 31.3%), high-grade tumor budding (G2/G3: 61.9% vs. 33.8%) and PDC (G2/G3: 47.6% vs. 21.3%). The median OS and RFS for the NED-positive group were 78 months and 28 months, respectively. The 5-year OS and RFS rates were 71.9% and 35.3% in the NED-positive group, compared with 75.1% and 67.1% in the NED-negative group, respectively. RFS was significantly shorter in CRCs with NED than in those without (log-rank test, p=0.0073).
Conclusions: The presence of NED tended to be associated with perineural invasion and high-grade PDC, suggesting a trend toward more aggressive histopathological features. RFS was significantly shorter in CRCs with NED than in those without, indicating a possible association between NED and early recurrence.

#5366 Prognostic value of tumor-informed circulating tumor DNA in non-small cell lung cancer after curative treatment: real-world cohort with long-term follow-up.

Soyun Lim[1], Jisoo Lee[1], Julianne Jin[1], Anthony Wong[1], Youjin Oh[1], Sung Mi Yoon[1], Jeeyeon Lee[2], Joo Hee Park[1], Soowon Lee[1], Timothy Hong[1], Bella Kim[1], Sanghwa Kim[1], Liam Il-Young Chung[1], Young Kwang Chae[3]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL,[2]Kyungpook National University Hospital, Daegu, Korea, Republic of,[3]Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Circulating tumor DNA (ctDNA) is a biomarker for detecting molecular residual disease (MRD) and predicting recurrence in cancer patients. Our group previously reported the first real-world data of ctDNA-based MRD detection. We now investigate its long-term prognostic value with extended follow-up in the real-world cohort of non-small cell lung cancer (NSCLC) patients treated with curative-intent.

Methods: Longitudinal ctDNA monitoring was performed using a commercially available personalized, tumor-informed assay (Signatera) in 116 patients with NSCLC. Plasma samples were collected post-treatment, and ctDNA status was evaluated within the 6-month MRD window, and longitudinally thereafter. Recurrence-free survival (RFS) and overall survival (OS) were assessed according to ctDNA status. For ctDNA(+) patients, plasma-based next-generation sequencing (NGS; Guardant360) at MRD timepoint was performed when available and compared with baseline tissue NGS results (PGDx or Tempus xT).

Results: A total of 116 patients across stages I-IV (stage I: 41.4%, stage II: 30.2%, stage III: 21.6%, and stage IV: 6.9%) were identified (90 adenocarcinoma, 23 squamous cell carcinoma, 2 adenosquamous and 1 other). Median age at diagnosis was 66 years (range: 23-86 years) and median follow-up was 33 months (range: 4-120 months). MRD results were available for 99 patients within 6 months of curative-intent treatment. Within the 6-month MRD window, ctDNA(+) was associated with inferior RFS (aHR: 24.3; 95% CI: 3.2-186.8; $p < 0.001$), with a median RFS of 8.5 months. ctDNA(+) during longitudinal surveillance beyond MRD window was associated with inferior RFS (HR: 8.0, 95% CI: 3.4-18.9; $p < 0.001$) and OS (HR: 11.6, 95% CI: 3.4-39.8; $p < 0.001$), with median RFS of 10.8 months. Among patients with both tissue NGS (tNGS) and blood NGS (bNGS) profiling results, 8 patients were ctDNA(+). Among them, 5 patients had at least one overlapping gene mutation at the variant level between tNGS and bNGS. All 5 of these patients recurred, while the other 3 patients (who did not have an overlapping gene mutation at the variant level) did not recur. The matched group consisted mostly of stage III cases (4 of 5), with one stage II, whereas the unmatched group included one each of stage I, II and IV cases.

Conclusion: This first real-world report with extended follow-up provides real-world evidence that tumor-informed, personalized ctDNA monitoring is a clinically valuable tool for predicting long-term outcomes in patients with NSCLC after curative-intent treatment. Although interpretation is limited by the small sample size, blood NGS at ctDNA(+) may reflect potential subclonal evolution and molecular heterogeneity. These findings support the prognostic value of ctDNA and its potential integration into personalized cancer management.

#5367 Clinical and molecular features of CD276 (B7H3) in liver metastases of pancreatic cancer.

Go Igarashi[1], Shuichi Mitsunaga[1], Nobuaki Okumura[2], Kanae Inoue[1], Tomonao Taira[1], Taro Shibuki[1], Tomoyuki Satake[1], Masataka Amisaki[1], Mitsuhito Sasaki[1], Hideaki Takahashi[1], Hiroshi Imaoka[1], Masafumi Ikeda[1]

[1]Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa-shi, Japan,[2]Institute for Protein Research, Osaka University, Suita-shi, Japan

Introduction: CD276 (B7-H3), a modulator of tumor-microenvironment as affecting cadherin expression, has a prognostic impact in the different types of cancers including pancreatic ductal adenocarcinoma (PDAC). In metastatic PDAC, these roles in CD276 have not been fully understood. Using liver metastasis (LM)-derived transcriptome and reversed-phased protein array (RPPA) data, we evaluated CD276 expressions of LMs on clinical outcomes and molecular features in metastatic PDAC.

Methods: Needle-biopsied specimens from treatment-naïve LMs of PDAC were collected for protein and RNA extraction. A 435-protein expression was measured on RPPA. The impact of each protein level stratified with median value was tested using univariate Cox regression hazard model. The top 3 prognostic proteins and clinical prognostic factors such as Eastern Cooperative Oncology Group Performance Status (ECOG-PS) and serum level of C-reactive protein (CRP) were evaluated in multivariate Cox regression hazard model. To investigate clinical relevance of CD276, our study population was stratified based on the median value of CD276 mRNA expression level detected on cDNA microarray, followed by differential gene expression analysis and subsequent Gene Ontology (GO) analysis between the two groups surveying for CD276 high-related genes/ pathways.

Results: RPPA data was obtained from LMs of 42 patients (Male: 64.2%; median age: 66 years). The tumor proteome data showed that overall survival times were prolonged in the patients with intratumoral high expression of Aurora-A, PGDFR-beta, and CD276 as compared to those without. Independent prognostic impacts were found in CD276 high (hazard ratio: 0.148 [95% confidence interval: 0.005 to 0.434]), ECOG-PS 1 or more (4.651 [1.713 to 12.63]), and CRP high (6.440 [2.498 to 16.60]) in multivariate analysis. Transcriptome data were evaluated in 40 of 42 LMs. The 116 genes were identified as CD276 high-related genes. GO terms associated with CD276 high were cadherin binding (GO:0045296), cell adhesion molecule binding (GO:0050839), and protein binding (GO:0005515). LMs with high CD276 protein expression showed high protein expression in E-cadherin ($P<0.001$) and tended to be low in protein expression of N-cadherin ($P=0.097$) as compared to those with low CD276 protein expression.

Conclusion: High expression of CD276 protein in liver metastasis of PDAC was an independent favorable prognostic factor and related to increasing E-cadherin expression in tumor. Further study is needed to explore the roles of CD276 in metastatic PDAC.

#5368 The prognostic role of pretreatment neutrophil-to-lymphocyte ratio in a multiethnic cohort of breast cancer patients.

Armaan Jamal[1], Lendy Chu[2], Jincong Q. Freeman[1], Rita Nanda[3], Olufunmilayo I. Olopade[3], Wenji Guo[3], Dezheng Huo[1]

[1]Department of Public Health Sciences, University of Chicago, Chicago, IL,[2]Internal Medicine Residency Program, University of Chicago, Chicago, IL,[3]Department of Medicine, University of Chicago, Chicago, IL

Introduction: The neutrophil-to-lymphocyte ratio (NLR) is a marker of systemic inflammation linked to poor outcomes in several solid tumor malignancies, including breast cancer. Prior studies have shown that its prognostic significance in breast cancer differs by molecular subtype; however, these studies have rarely accounted for racial variation in baseline NLR values, which may affect the interpretation of threshold-based analyses. This study evaluates the prognostic value of pretreatment NLR in breast cancer and whether associations between NLR and survival outcomes differ by race and tumor subtype.

Methods: We conducted a retrospective analysis of 754 patients from the Chicago Multiethnic Epidemiologic Breast Cancer Cohort. Eligible patients had an NLR measurement ≤1 year prior to treatment initiation. NLR was analyzed as both continuous and binary variables, using a cohort-wide median cutoff (2.07) and race-specific cutoffs (3.11 for White and 2.56 for Black patients). Outcomes included recurrence-free survival (RFS), overall survival (OS), breast cancer-specific survival (BCSS), and other-cause (OC) mortality. Cox and competing risk regression models were used to estimate the associations between NLR and survival outcomes, adjusting for demographic and clinical covariates.

Results: Among 754 patients (mean age at diagnosis 55.9 years), 383 were Black, 308 were White, and 63 were categorized as Other. The median pretreatment NLR was lower in Black patients (1.78, IQR 1.30-2.61) compared to White (2.38, IQR 1.69-3.11) and Other racial patients (2.06, IQR 1.41-2.89). In adjusted analyses, each doubling of NLR was associated with worse RFS (adjusted hazard ratio [aHR] 1.24, 95% CI 1.02-1.52), OS (aHR 1.20, 95% CI 0.98-1.48), and OC mortality (aSHR 1.42, 95% CI 1.07-1.89). When modeled as a binary variable, high NLR (≥2.07) was associated only with higher OC mortality (adjusted sub-distribution hazard ratio [aSHR] 2.11, 95% CI 1.11-4.02). Stratified analyses showed that the association between NLR and survival outcomes was most pronounced in HER2-negative and hormone receptor-positive tumors, whereas no significant associations were observed in hormone receptor-negative tumors. When using race-specific thresholds, high NLR (≥2.56) was significantly associated with worse RFS (aHR 2.02, 95% CI 1.27-3.21), OS (aHR 1.93, 95% CI 1.15-3.21), and BCSS (aSHR 2.31, 95% CI 1.12-4.78) in Black patients, but not in White patients.

Conclusion: Our study demonstrates that pretreatment NLR may be used as a prognostic marker for breast cancer outcomes, but its predictive value varies by race and tumor subtype. Baseline racial differences in NLR underscore the need for race-specific thresholds. Larger, diverse studies are needed to validate these findings and clarify underlying biological mechanisms.

#5369 CCR8+ regulatory T cells represent a promising prognostic marker for non-small cell lung cancer (NSCLC).

Santosh K. Singh[1], Manoj K. Mishra[2], Eric Flenaugh[3], Gabriella M. Oprea-Ilies[4], Brian M. Rivers[1], James W. Lillard[1], Shailesh Singh[1], Rajesh Singh[1]

[1]Morehouse School of Medicine, Atlanta, GA,[2]Alabama State University, Montgomery, AL,[3]Pulmonary and Critical Care & Interventional Pulmonary Medicine, Atlanta, GA,[4]Winship Cancer Institute of Emory, Atlanta, GA

Non-small cell lung cancer (NSCLC) contains a highly diverse immune landscape, making it challenging to identify markers that truly reflect how the tumor interacts with the immune system. Recent research has identified CCR8 as a key marker for a particularly suppressive group of regulatory T cells (Tregs) that accumulate within tumors. In this study, we aimed to investigate the impact of CCR8$^+$ Tregs on disease outcomes in NSCLC and to deepen our understanding of their role in facilitating tumor evasion of the immune response. We employed various techniques, including multiparametric flow cytometry, RNA sequencing, and spatial immunohistochemistry, using NSCLC cell lines (H1299 and H1573) and patient-derived tumor samples to assess their effects. We observed that CCR8$^+$ Tregs were significantly enriched within tumor tissue compared to adjacent normal lung tissue. These CCR8$^+$ Tregs expressed higher levels of potent immunosuppressive molecules, including CTLA-4, TIGIT, and IL-10, as well as genes associated with TGF-β signaling, distinguishing them from CCR8$^-$ Tregs. Tumors with a high density of CCR8$^+$ Tregs had fewer CD8$^+$ T cells, reduced effector cytokine production, and lower levels of granzyme B, indicating weakened antitumor immunity. Additionally, patients with elevated CCR8$^+$ Treg infiltration tended to have more advanced diseases and shorter progression-free and overall survival, even after adjusting for standard clinical factors. Statistical modeling confirmed that CCR8$^+$ Treg levels independently predict patient outcomes. Further analysis and *in vitro* assays using NSCLC cell lines revealed that CCL1-CCR8 interactions likely drive the recruitment and retention of these cells within tumors. Overall, our findings show that CCR8$^+$ Tregs represent a uniquely suppressive immune population and a strong prognostic marker in NSCLC, supporting the development of therapies that specifically target CCR8 to enhance antitumor immunity.

#5370 Prognostic and metastasis-associated roles of IL-6 and IL-8 in patients with stage IV gastric cancer.

Jinsoo Jang[1], Chan Hee Park[1], Woo Sun Kwon[1], Tae Soo Kim[1], Sun Young Rha[2]

[1]Song-dang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Cytokine-driven inflammation is increasingly recognized as a key determinant of tumor progression and metastatic behavior in gastric cancer. Interleukin-6 (IL-6) and interleukin-8 (IL-8) are central mediators of immune suppression, angiogenesis, and systemic inflammatory activation, yet their clinical significance in advanced gastric cancer remains insufficiently defined.
Methods: Pre-treatment blood samples from 186 patients with HER2-negative stage IV gastric cancer treated at Severance Hospital between May 2019 and March 2025 were analyzed. Serum IL-6 and IL-8 levels were quantified by ELISA in patients with stage IV gastric cancer prior to systemic therapy. Patients were stratified into high- and low-expression groups using predefined cutoffs. PD-L1 expression was assessed by immunohistochemistry using the PD-L1 IHC 22C3 pharmDx assay and quantified by combined positive score (CPS). Associations with metastatic patterns and overall survival (OS) were assessed using nonparametric tests and Kaplan-Meier analysis.
Results: High cytokine expression was strongly associated with inferior clinical outcomes. Patients with high IL-6 levels (≥4.6862 pg/mL) showed significantly reduced OS compared with the IL-6-low group (HR 1.96, 95% CI 1.31-2.94; P=0.0008). A similar but more pronounced effect was observed for IL-8, where high expression (≥7.5801 pg/mL) was associated with markedly worse survival (HR 2.79, 95% CI 1.89-4.10; P < 0.0001). No correlation was observed between IL-6 and PD-L1 expression or between IL-8 and PD-L1 expression at any CPS cutoff. Cytokine levels also demonstrated metastatic pattern specificity: IL-6 was significantly elevated in patients with bone metastasis (P = 0.018) including IL-8 (P = 0.039), whereas IL-8 was markedly increased in those with liver metastasis (P = 0.002). These findings suggest that systemic cytokine elevation reflects both tumor aggressiveness and distinct metastatic phenotypes.
Conclusion: IL-6 and IL-8 are strong, accessible biomarkers associated with poor survival and characteristic metastatic patterns in advanced gastric cancer. Their integration into clinical risk assessment may improve biological stratification and inform future therapeutic strategies.

#5371 Annexin A3 expression is prevalent but highly variable in human cancer: A tissue microarray study involving 5,914 cancers from 105 tumor entities.

Clara von Bargen[1], Nayira Hakimi[1], Fiete Gehrisch[1], Anne Menz[1], Florian Lutz[1], Viktoria Chirico[1], Florian Viehweger[1], David Dum[1], Ria Schlichter[1], Andrea Hinsch[1], Christoph Fraune[1], Christian Bernreuther[1], Seyma Buyucek[1], Martina Kluth[1], Claudia Hube-Magg[1], Georgia Makrypidi-Fraune[1], Nina Schraps[1], Katharina Moller[1], Andreas M. Luebke[1], Patrick Lebok[1], Guido Sauter[1], Maximilian Lennartz[1], Till S. Clauditz[1], Andreas H. Marx[2], Ronald Simon[1], Eike Burandt[1], Natalia Gorbokon[1], Maria C. Tsourlakis[1], Sarah Minner[1], Till Krech[1], Morton Freytag[1], Viktor Reiswich[1], **Stefan Steurer**[1]

[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Department of Pathology, Academic Hospital Fuerth, Fuerth, Germany

Annexin A3 (ANXA3) is a member of the annexin family of calcium-dependent phospholipid-binding proteins which plays a major role in various membrane-related processes, including membrane organization, repair, vesicle trafficking, and regulation of ion channels. Its diverse functions extend across various cellular processes such as apoptosis, cell growth, inflammation, and differentiation. Altered ANXA3 expression has been found in several cancer types. To better comprehend the role of ANXA3 in cancer, ANXA3 expression was analyzed by immunohistochemistry (IHC) on tissue microarrays (TMAs) containing 5,914 samples from 105 different tumor types. ANXA3 staining was seen in 3,490 (72.3%) of the 4,824 analyzable tumors, and was considered weak in 18.2%, moderate in 10.2%, and strong in 44.0% of cases. Of 105 tumor categories, 87 (82.9%) showed ANXA3 expression in at least one case, 69 (65.7%) showed ANXA3 staining in at least 50% of cases, and 78 (74.3%) included at least one case with strong ANXA3 positivity. Among tumors with at least 10 evaluable samples, the highest rates of tumors with strong ANXA3 positivity were observed in ampullary (100.0%) and ductal adenocarcinoma of the pancreas (90.9%), adenocarcinoma of the cervix uteri (95.7%),gastrointestinal stromal tumor (GIST; 90.4%), colorectal adenocarcinoma (90.0%), gastric adenocarcinoma of the intestinal (88.7%) and diffuse (81.6%), basal cell carcinoma of the skin (88.2%), gallbladder adenocarcinoma (88.2%),esophageal adenocarcinoma (87.8%), prostatic adenocarcinoma (83.8%), endometroid (82.5%), serous (78.9%) and mucinous (72.7%) carcinoma of the ovary, papillary renal cell carcinoma (63.2%), cholangiocarcinoma (77.8%), endometroid (76.3%) and serous (50.0%) endometrial carcinoma, squamous cell carcinomas from different organs of origin (up to 61.9%), testicular seminoma (53.8%), carcinosarcoma of the ovary (53.3%), lobular (52.3%), mucinous (40.0%) and tubular (38.9%) carcinoma of the breast, clear cell carcinoma of the ovary (42.1%), muscle-invasive urothelial carcinoma (41.4%), carcinosarcoma of the uterus (40.0%), Brenner tumor (39.3%), invasive breast carcinoma of no special type (NST; 36.1%), urothelial carcinoma of the kidney pelvis (29.8%) and yolk sac tumors of the testis (27.3%). In breast cancer NST, low ANXA3 expression was linked to aggressive tumor phenotype. Strong ANXA3 staining was seen in 100.0% of Gleason 3+3, 87.3% of Gleason 4+4, and in 65.8% of Gleason 5+5 carcinomas of the prostate ($p<0.0001$). In breast cancer NST, low ANXA3 expression was linked to high grade of malignancy ($p<0.0001$). In summary, the data from this study provide a catalogue of ANXA3 expression in human cancer, demonstrate that ANXA3 levels are highly variable in most tumor entities, and show that ANXA3 immunostaining is associated with prognostic tumor features in at least some tumor types.

#5372 Fragmentomics analysis of targeted hybrid capture NGS cfDNA gene panel data yields an orthogonal genomic dimension for developing a robust prognostic model for metastatic breast cancer patients.

Gregory M. Mayhew, Jonathan H. Shepherd, Jeff Burdine, Yoichiro Shibata, Gabriel V. Milburn, Michael V. Milburn, Kirk L. Pappan, **James M. Davison**, Kirk Beebe

GeneCentric Therapeutics, Inc., Durham, NC, NC

Introduction: Analysis of cfDNA fragment distributions, or fragmentomics, yields information about the transcriptional activity of genes but mostly has been applied to WGS and WES datasets. The widespread use of targeted hybrid capture NGS cfDNA gene panels provide a rich data source for mining orthogonal fragmentomic features for developing novel algorithmic signatures for prognosis and predicting response. Here, we applied an uniquely developed fragmentomic computational method for hybrid capture panel data to a prospective study of HER2 negative, metastatic breast cancer patients, who were all treated with paclitaxel and bevacizumab.

Experimental Procedures*:* Fastq files from baseline (n=182) and associated clinical data were downloaded from NCBI (PRJNA745047). Raw sequencing (avg. depth ~2600x) data from a custom panel targeting 48 breast cancer associated genes and 8 cancer gene promoters were processed through a proprietary pipeline to get a fragmentomics matrix comprised of 2936 features. Samples were split into a train-test set (2/3-1/3) balanced on overall survival and key clinical variables. Overall survival (OS) and triple negative (TN) signatures using fragmentomics matrix features in training samples with the glmnet package in R. Association between the OS signature and OS was evaluated using the log-rank test and multivariable cox models. Association between the TN signature and TN status was evaluated using the Wilcoxon test and AUC.

Results: An OS signature developed in the training set used 56 fragmentomics features. The association between the signature and OS was directionally uniform in low and high tumor content strata (tumor content defined using the available VAF data) in both training and test data sets (and each nominal log-rank test p-value < 0.05). In the test set, the addition of the fragmentomics signature to a multivariable OS model that already included parameters for TN status, tumor grade, and metastatic site significantly improved the model fit (LRT p-value = 0.009), with a signature hazard ratio of 2.50 (95% CI 1.25-4.99). The TN status signature developed in the training set used 56 fragmentomics features of which 6 overlapped with the OS signature. In the test set, the signature was markedly correlated with TN status (Wilcoxon p-value = 0.0052) with an AUC of 0.75.

Summary and Conclusions: This work demonstrates the utility of cfDNA hybrid capture fragmentomic data for developing robust predictors even in low tumor fraction samples of overall survival and TN status. Although additional validation is warranted, these signatures could represent potential biomarkers that could assist in clinical decision making. This work also supports the possibility of retrospectively using any cfDNA panel sequencing dataset for fragmentomics analysis to identify predictive biomarkers.

#5373 Prognostic impacts of skeletal muscle gene expression and cachexia in advanced colorectal cancer.

Vashti L. Bandy[1], Arunima Punjala[2], Praveen Bhoopathi[1], Vignesh Vudatha[1], KATARZYNA TYC[1], Mikhail G. Dozmorov[1], Leopoldo Fernandez[1], Andrew R. Judge[3], Sarah M. Judge[4], Anna Gibson[5]

[1]Virginia Commonwealth University, Richmond, VA,[2]Virginia Commonwealth University - VCU, Richmond, VA,[3]University of Florida, Gainesville, FL,[4]University of Flordia, Gainesville, FL,[5]VCU Health, Richmond, VA

Background: Cancer cachexia is a complex metabolic syndrome characterized by severe muscle loss, reduced physical function, and diminished therapeutic response. Despite its clinical impacts, the transcriptional landscape of cachexia in patients with advanced peritoneal carcinomatosis from metastatic colorectal cancer (pmCRC) remains poorly defined. Our study aims to characterize alterations in skeletal muscle with associated cachexia in pmCRC patients.
Methods: Muscle biopsies were obtained from 17 pmCRC patients consented for IRB tissue collection and undergoing cytoreductive surgery with hyperthermic intraperitoneal chemotherapy (CRS/HIPEC), classified as myopenic (n=7) or non-myopenic (n=11) based on skeletal muscle index (SMI cm2/m2). Biopsies were sent for RNA sequencing and differential expression analysis was performed utilizing statistical algorithms within edgeR software. We compared the two cohorts and selected differentially expressed genes (DEGs) with significantly increased or decreased expression (>2-fold change and p-value <0.05). Enrichment analysis identified gene sets and pathways relevant to cachexia pathophysiology. Last, survival analysis was performed to assess the prognostic value of identified DEGs in predicting patient outcomes.
Results: Our analysis revealed 231 genes DEGs, including 75 upregulated and 156 downregulated genes in the myopenic group. Enrichment analysis exhibited several pathways involved in immune cell signaling. Overall survival analysis revealed associations with survival outcomes for seven DEGs-six of which have associated prognostic value in colorectal cancer or other cancer variants including pancreatic adenocarcinoma, hepatocellular carcinoma, renal cell carcinoma and oral squamous cell carcinoma. High expression of one DEG and low expression of the remaining prognostic genes were linked with poor survival in our patient cohort.
Conclusions: Our study highlights molecular features of cancer-induced cachexia in pmCRC and several potential diagnostic and prognostic biomarkers.

#5374 Immune checkpoint protein expression of PD-1 shows prognostic significance in large B-cell lymphomas of the central nervous system.

Sara Francesca Santagostino[1], Derek M. Devine[2], John DeWitt[3], Alissa A. Thomas[4], Ashley K. Volaric[3]

[1]Larner College of Medicine at The University of Vermont, Burlington, VT,[2]Biomedical Statistics Research Core, Larner College of Medicine at The University of Vermont, Burlington, VT,[3]Department of Pathology and Laboratory Medicine, Larner College of Medicine at The University of Vermont, Burlington, VT,[4]Department of Neurological Sciences, University of Vermont Medical Center, Burlington, VT

Large B-cell lymphomas of the central nervous system are rare but aggressive neoplasms that uniquely involve immune privileged sites. Targeted immune-based therapies are limited, but immune checkpoint inhibition involving programmed cell death protein 1 (PD-1) and its ligand (PD-L1) are being investigated for relapse/refractory disease. However, the prognostic significance of PD-1 and PD-L1 expression across primary and secondary presentations (PCNSL and SCNSL, respectively) is unknown. We evaluated the prognostic indicators of PD-1 and PD-L1 immunohistochemical expression in a rural-based clinical cohort of both PCNSL and SCNSL. We performed immunohistochemical studies (IHC) for PD-1 (NAT 105, Cell Marque) and PD-L1 (SP263, Ventana) on a curated cohort of CNS lymphomas (n=36) from a rural patient population with PCNSL (n=27) or SCNSL (n=9). Positivity was defined as ≥5% cellular staining. Clinical groups were stratified by patient age, therapy response (durable response- DR or relapse/refractory- RR), and PD-1/PD-L1 IHC expression. All survival analyses were conducted on 33 evaluable patients, none of whom received immune checkpoint inhibitors. Prognostic indicators of overall survival (OS), progression-free survival (PFS), time to progression (TTP), and time to response (TTR) were evaluated and associated with PD-1/PD-L1 expression using Kaplan-Meier methods, log-rank tests, and unadjusted Cox proportional hazards models. Our analysis revealed robust expression rates for PD-1 (67%) and PD-L1 (75%) across all tumors. Importantly, in PCNSL, PD-1 positivity was significantly associated with shorter OS. In the PD-1-positive subgroup, PCNSL exhibited significantly longer PFS/TTP than SCNSL. In addition, there was stratification of OS and PFS by DR and RR clinical status across all tumors, with DR exhibiting longer OS and PFS than RR tumors. Interestingly, PD-1 positivity was associated with faster TTR, particularly for PCNSL, indicating earlier treatment response than SCNSL. PD-L1 expression was not significantly associated with survival outcomes or treatment response. While age was not associated with PFS overall, SCNSL patients older than 65 showed a trend toward shorter PFS. PFS and TTP were identical in this dataset. In conclusion, PD-1 positivity in large B-cell lymphomas of the CNS, particularly for primary presentations, is predictive of earlier treatment response without translating to improved OS or PFS/TTP. These findings highlight the importance of clinical context (disease presentation and extent) and suggest that early-response kinetics like TTR offer complementary biological insight distinct from long-term survival outcomes. Larger studies are needed to further define the prognostic influence of immune checkpoint proteins in large B-cell lymphomas of immune-privileged sites.

#5375 Development of reference standards for clonal evolution and measurable residual disease in acute myeloid leukemia.

Colt W. Nash, Matthew G. Butler, Ojaswee Dahal, Jayanthi Ramprakash, Andrew T. Anfora, Yves Konigshofer

LGC Clinical Diagnostics, Gaithersburg, MD

Here, we describe novel reference standards for measurable residual disease (MRD) and clonal evolution in acute myeloid leukemia (AML). About a third of patients with AML harbor somatic mutations in NPM1 and FLT3, and it is not uncommon for AML to start with a mutation in NPM1 or an internal tandem duplication (ITD) in FLT3, respond to a therapy with remission, and have the other mutation appear during relapse as a result of clonal evolution. To support the development and validation of molecular diagnostic assays that assess MRD and clonal evolution, we created reference standards where several clonal AML cell lines with added mutations are combined with peripheral blood mononuclear cells (PBMCs). These clones represent different combinations of an NPM1 mutation, a short FLT3-ITD, and a long FLT3-ITD to support single-cell assays that can evaluate the mutations in a given cell. Additional PBMCs are provided to dilute these clones to MRD levels and for assays that are designed to use the DNA and/or RNA input from around 2 million cells (i.e., 10 micrograms). On a commercial single-cell assay, it was possible to identify and separate the individual clones. Additionally, it was possible to dilute the cells to MRD levels and detect the mutations by NGS. In conclusion, we have generated cell-based reference standards with combinations of an NPM1 mutation and FLT3-ITDs, which are designed for the development and validation of molecular biology-based AML assays. Using the same methodology, it should also be possible to generate clones with mutations in other genes to reflect clonal evolution in AML.

#5376 EGFR/RAS/SIAH pathway-centered biomarker-based prediction of tumor relapse/chemo-resistance/patient survival in TNBC.

Amy H. Tang[1], Mary L. Guye[2], Billur Samli[3], Janet S. Winston[3], Richard A. Hoefer[4]

[1]Biomedical and Translational Sciences, Old Dominion University, Norfolk, VA,[2]Surgical Oncology, Sentara Surgery Specialists, Newport News, VA,[3]Pathology Sciences Medical Group, Sentara Norfolk General Hospital, Norfolk, VA,[4]Sentara Health Research Center, Sentara Cancer Network, Norfolk, VA

Introduction: Triple-negative breast cancer (TNBC) is an aggressive breast cancer subtype that disproportionately affects BRCA1 mutation carriers and young Black/white women. Pembrolizumab and neoadjuvant chemotherapy (NACT) has become the new standard of care (SOC) for high-risk early-stage TNBC. Pathologic complete response (pCR) predicts good outcome, whereas pathologic incomplete response (pIR) with high-risk residual cancer burden (RCB) is correlated with early tumor relapse, chemo-IO-resistance, and poor survival. Many similarly treated patients with identical TNM and RCB classifications experience clear treatment disparity, distinct relapse rates, and disparate survival. Current methods fall short in predicting relapse/resistance/survival with high precision in the clinic.

Methods: We have conducted IHC staining of EGFR, Ki67, and SIAH expression in a large cohort of TNBC patients (577), of which 48% patients are Black/AA and 48% patients are white patients, from the Sentara Cancer Network. The Sentara Comprehensive Breast Centers have served our military veterans (Naval Norfolk Station) as well as many socio-economically disadvantaged, medically underserved, and underinsured low-income patients from Hampton Roads Virginia, with a racially diverse population of 1.8 million.

Results: We reported that high SIAH expression in residual tumors post-NACT reflects persistent EGFR/K-RAS/SIAH pathway activation (ON), predicts ineffective SOC therapy, continuous tumor growth post-NACT, which predicts early relapse, chemo-resistance, and poor survival. Conversely, no or super-low SIAH expression in residual tumors post-NACT reflects effective SOC therapy, EGFR/K-RAS/SIAH pathway inactivation (OFF), which predicts tumor remission and prolonged survival. We found that our Black/AA TNBC patients suffer a significantly higher mortality and reduced survival when compared to their white counterparts in this study, similar to the SEER/CDC databases.

Conclusions: We found that persistent EGFR/RAS/SIAH pathway activation is a major driving force in TNBC malignancy. As an evolutionarily conserved RING-domain E3 ligase, SIAH is a new prognostic biomarker for patient risk stratification, tumor relapse prediction, and racial disparity detection in TNBC. SIAH is a major tumor vulnerability in TNBC malignancy. We aim to demonstrate the prognostic power of SIAH and develop a SIAH-centered biomarker panel for patient risk stratification and relapse/resistance/survival prediction in high-risk TNBC.

#5377 Prediction of relapse risk in favorable outcome AML from DNA methylation data.

Jamie Endicott[1], Ruslan Strogantsev[2], CRISTINA TOGNON[2], Hisham Mohammed[2], Elie A. Traer[3]

[1]CEDAR, OHSU Knight Cancer Institute, Portland, OR,[2]OHSU Knight Cancer Institute, Portland, OR,[3]Instructor, Ctr. for Hematologic Malignancies, Oregon Health & Science University, Portland, OR

In patients diagnosed with acute myeloid leukemia (AML), several genetic profiles are designated as ‘favorable outcome’ such as presence of NPM1 mutation or certain translocations. Despite sharing these genetic commonalities, many patients still relapse.

Due in part to the high frequency of AML driver mutations occurring in genes involved in epigenetic regulation, we profiled genome wide DNA methylation for blood and bone marrow specimens from favorable risk AML patients at diagnosis, follow-up, remission, and relapse.

We identified differentially methylated regions (DMRs) present at diagnosis and remission which separated patients on relapse outcome. These DMRs were enriched in biologically meaningful chromatin regions (e.g. association with certain modifications) and some overlap genes with previously demonstrated significance for patient outcome.

Interestingly, many of the remission time point DMRs had effect sizes much greater than we would expect from minimal residual disease present in the bulk sample, suggesting a shift in normal cell populations or stem cell compartment between outcome groups. We further profiled DNA methylation in single cells to investigate cell state composition and heterogeneity across the course of disease.

Further, we created a DNA methylation-based predictor of relapse risk that again separates patients at diagnosis and remission. Our findings have the potential for utility both in treatment strategy approaches and in better understanding the biology of relapse in AML.

#5378 GDF-15 reflects host physiological stress rather than tumor progression in colorectal cancer patients.

Tasuku Kaise[1], Hideaki Karasawa[1], Keigo Murakami[2], Ichiro Ise[1], Tomoyuki Ono[1], Megumi Murakami[1], Yoshihiro Sato[1], Gumpei Yoshimatsu[1], Hideyuki Suzuki[1], Takaaki Abe[3], Takashi Kamei[1], Shinobu Ohnuma[1], Toru Furukawa[2], Michiaki Unno[1]

[1]Department of Surgery, Tohoku University Graduate School of Medicine, Sendai, Japan,[2]Department of investigative Pathology, Tohoku Graduate School of Medicine, Sendai, Japan,[3]Department of Clinical Biology and Hormonal Regulation, Tohoku University Graduate School of Medicine, Sendai, Japan

GDF-15 (growth differentiation factor 15) is a stress-responsive cytokine within the TGF-β (transforming growth factor-β) superfamily that is secreted in response to tissue injury and cellular stress. It increases under various pathological conditions, including cardiovascular, renal, and malignant diseases. In colorectal cancer (CRC), plasma GDF-15 levels are elevated compared with healthy individuals, and higher concentrations have been associated with worse prognosis. However, whether GDF-15 reflects tumor characteristics or host physiology remains unclear. This study aimed to clarify the clinical significance of GDF-15 in CRC by integrating analyses of plasma levels, tumor tissue expression, and gut microbiota composition. Seventy patients with CRC who underwent surgery between November 2021 and September 2023 were enrolled. Plasma GDF-15 levels were examined in relation to age, serum albumin (Alb), tumor stage, and other comprehensive nutritional and clinical parameters. GDF-15 expression in tumor tissue was evaluated by immunohistochemistry, and a semiquantitative histoscore (H-score) was calculated using the digital pathology software QuPath. Preoperative fecal samples were analyzed by 16S rRNA sequencing. For microbiota analysis, patients were classified into high and low plasma GDF-15 groups based on the median value, and microbial diversity and composition were compared between the groups. Plasma GDF-15 correlated positively with age ($r = 0.58$, $p < 0.001$) and negatively with Alb ($r = -0.54$, $p < 0.0001$). Levels were higher in advanced T categories (T3+4 vs. T1+2, $p < 0.05$) and higher stages (II-IV vs. I, $p < 0.05$); however, these associations disappeared after adjustment for age and Alb (T category, $p = 0.72$; stage, $p = 0.86$). These findings indicate that plasma GDF-15 reflects host physiological stress rather than tumor progression.
GDF-15 expression in tumor tissue, assessed by H-score, showed no correlation with plasma GDF-15 ($r = 0.06$, $p = 0.62$), age ($r = 0.09$, $p = 0.47$), or Alb ($r = -0.09$, $p = 0.48$), and did not vary by tumor depth ($p = 0.97$) or stage ($p = 0.75$). Gut microbiota analysis revealed no difference in α-diversity. In contrast, β-diversity differed significantly in both weighted and unweighted UniFrac analyses ($p < 0.05$), indicating compositional shifts associated with elevated plasma GDF-15. In conclusion, GDF-15 functions as a host-derived marker that reflects systemic physiological stress associated with aging and malnutrition rather than tumor burden. Furthermore, concurrent microbial alterations in patients with elevated GDF-15 suggest a potential role for GDF-15 as an integrative biomarker linking host physiological stress to intestinal environmental changes in colorectal cancer.

#5379 Prognostic significance of STING expression in patients with resected lung adenocarcinoma.

Jung-Jyh Hung[1], Ying-Shiun Kao[2]

[1]National Yang Ming Chiao Tung University and Taipei Veterans General Hospital, Taipei, Taiwan,[2]Taipei Veterans General Hospital, Taipei, Taiwan

Background: Lung cancer is the leading cause of cancer death worldwide. Tumor recurrence is the most common cause of treatment failure after surgical resection. STING (Stimulator of Interferon [IFN] Genes) is a protein responsible for controlling anticancer immune responses to leaked self- or non-self DNA. Recent studies have shown in animal models that knocking out STING and cGAS expression results in a nonresponse to PD-L1 checkpoint therapy. STING and cGAS are thus thought to be essential for the antitumor response of PD-1/PD-L1 checkpoint inhibition. Several studies have reported that STING expression was decreased in tumor in hepatocellular, gastric and colorectal cancer, and in melanoma. STING is frequently lost during tumor progression, and loss of STING/cGAS correlates with poor survival. The prognostic value of STING expression in patients with resected lung adenocarcinoma has not been well demonstrated.
Methods: A total of 68 patients with resected lung adenocarcinoma were included in the study. STING expression was determined by immunohistochemistry in tumor specimens. The prognostic value of STING expression and its relationship with clinicopathological variables were investigated. We have screened the expression of STING in several lung cancer cell lines. STING knockdown or transfection will be performed in suitable lung cancer cell lines. Western blotting analysis will be performed to demonstrated STING, E-cadherin and vimentin expression.
Results: High STING expression was shown in 45 (66.2%) of the 68 lung tumor samples. Predominant pattern group (lepidic/acinar/papillary vs. micropapillary/solid) ($P = 0.662$) was not significantly associated with STING expression. Univariate analysis indicated that high STING expression (HR, 0.158; 95% CI, 0.032 to 0.787; $P = 0.024$) was a significant prognostic factor for better disease-free survival (DFS). In multivariate analysis, predominant pattern group (lepidic/acinar/papillary vs. micropapillary/solid) (HR, 5.764; 95% CI, 1.054 to 31.537; $P = 0.043$) was a significant prognostic factor for DFS. High STING expression (HR, 0.073; 95% CI, 0.009 to 0.617; $P = 0.016$) was also a significant prognostic factor for better DFS.
Conclusions: High STING expression was a significant prognostic factor for better DFS in patients with surgical resected lung adenocarcinoma. This information is useful to stratify high-risk patients of recurrence after resection of lung adenocarcinoma.

#5380 Prognostic utility of minimal residual disease detection using circulating tumor DNA in early-stage breast cancer: A systematic review and meta-analysis.

Panuch Eiamprapaporn[1], Thiti Susiriwatananont[1], Yaohua Ma[1], Hataiwan Ratanabunjerdkul[2], Panchanin Patanayindee[2], Lucksika Wanichtanom[3], E. Aubrey Thompson[4], Saranya Chumsri[1]

[1]Mayo Clinic, Jacksonville, FL,[2]Internal Medicine, Thammasat University, Bangkok, Thailand,[3]Internal Medicine, Lucksika Wanichtanom, Bangkok, Thailand,[4]Comprehensive Cancer Center, Mayo Clinic, Jacksonville, FL

Circulating tumor DNA (ctDNA)-based minimal residual disease (MRD) detection is a paradigm shift for risk stratification in early-stage breast cancer (eBC) surveillance. While the prognostic signal is clear, comprehensive synthesis across molecular subtypes remains limited, hindering the translation of prognostic findings into actionable, intervention-guided trials. We conducted a systematic review and meta-analysis following PROSPERO registration (CRD420251122005). Databases including PubMed/MEDLINE, Embase, and Cochrane CENTRAL were searched through September 2025. Studies involving eBC (stage I-III) patients with ctDNA-based MRD detection using validated assays, survival outcomes, and ≥12 months follow-up were included. Random-effects meta-analysis assessed the pooled hazard ratio (HR) for disease recurrence. Subgroup analyses explicitly evaluated molecular subtypes (TNBC, HER2+, HR+/HER2-) based on detection performance and gene mutation profiles. From 1,246 records, 59 studies were included, encompassing 12,847 eBC patients. Meta-analysis demonstrated an extreme prognostic value of disease-free survival from 26 studies with a pooled HR of 9.95 (95% CI: 6.50-15.25, p<0.0001). High heterogeneity was observed (I2=67.2%), largely driven by differences in tumor biology and assay technology. Subtype-specific analysis highlighted distinct shedding rates: TNBC showed the highest baseline detection (80–83.8%) and sensitivity (85–90%). HR+/HER2-showed the lowest baseline detection (14.6–30%). Gene mutation analysis revealed actionability: TP53 predominated in TNBC, while PIK3CA, ESR1, and AKT1 mutations were more frequent in HR+/HER2- disease. Crucially, the time from ctDNA detection to clinical recurrence provided a consistent median lead time of 10.2 months (range 7.5–16months), with cases detected up to 68 months prior. Specificity exceeded 95% across all subtypes. This meta-analysis establishes ctDNA-based MRD detection as a clinically valid biomarker with a nearly 10-fold increased recurrence riskin ctDNA-positive patients. The high heterogeneity underscores the necessity of tailored, subtype-specific surveillance protocols and selection of ultra-sensitive assays. The consistent ~10-month lead time defines a critical intervention window, providing a clear rationale for ongoing and future randomized clinical trials evaluating ctDNA-guided therapeutic intensification against the distinct molecular profiles observed in each breast cancer subtype.

#5381 Integrated analysis for identification of risk stratification biomarkers for colon cancer.

Andrea J. O'Hara[1], Priya Roy[2], Dhwani Mulani[2], Ethan Stancliffe[3], Tom Cohen[3], Hemant Roy[2], Haythem Latif[1]

[1]GENEWIZ, LLC, South Plainfield, NJ,[2]Baylor College of Medicine, Houston, TX,[3]Panome Bio, St Louis, MO

Introduction: Colorectal cancer (CRC) remains the second leading cause of cancer-related deaths worldwide, underscoring the critical need for improved early detection and risk stratification methods. While polyps are detected in up to 40% of colonoscopies, most are negative for significant lesions, with only about 10% showing advanced adenomas or carcinomas. Although colonoscopy remains the gold standard for CRC screening, it has major limitations in predicting progression from benign neoplasia to advanced adenomas or carcinomas. Precision approaches that integrate molecular insights are necessary to identify biomarkers for risk stratification and better understand which individuals with colon neoplasia are at increased risk to develop advanced adenomas or carcinomas.

Methods: This study leverages a multi-modal, integrated analysis of spatial transcriptomics, bulk RNA-sequencing, and metabolomics—an approach that has not been comprehensively applied to risk stratification in CRC. A set of 10 colorectal samples, five from cases that have progressed to CRC and five that have not, were selected for deep multiomics analysis. Starting with spatial transcriptomics from FFPE, single cell analysis across a slice was explored for each sample across the specimen, with a focus on variability between groups across the colonic crypts, tube-like glands in the colon and rectum that produce mucus and renew the intestinal lining. An additional slice of tissue was analyzed for bulk RNA-sequencing. Finally, adjacent tissue from the same individual was analyzed for bulk metabolomics, to identify and quantify the small molecules present within each sample.

Results: Integrated bioinformatics analyses were used to compare and combine bulk results, along with clinical and demographic data associated with these samples, for downstream pathway and processes analysis. In addition, these results were further analyzed to cross-compare and validate single cell spatial findings.

Conclusion: With this integrated multiomics approach, spatial transcriptomics provides high-resolution insights into gene expression within the structural context of the colonic crypts, while bulk metabolomics captures a systemic overview of metabolic alterations linked to neoplastic progression. By identifying key biomarkers and pathways associated with CRC progression, this study aims to pave the way for personalized screening strategies and targeted interventions to reduce the burden of advanced colorectal cancer.

#5382 The Yin and Yang of sphingosine kinase 2 (SPHK2): Opposing regulation by nuclear and cytoplasmic localization in lung cancer progression.

Tsung-Ching Lai[1], Wei-Jiunn Lee[1], Jer-Hwa Chang[1], Ming-Hsien Chien[2]

[1]Wanfang Hospital, Taipei, Taiwan,[2]Asst. Professor, Taipei Medical Univ., Taipei, Taiwan

Sphingosine-1-phosphate (S1P) is a pleiotropic lipid mediator, generated primarily by SPHK1 and SPHK2, regulating cell survival, migration, and angiogenesis. While SPHK1 and SPHK2 have been reported as oncogenes, our prognostic analysis of TCGA-LUAD (Lung Adenocarcinoma) revealed opposite roles for the two enzymes, suggesting a dual function for SPHK2. We investigated the hypothesized tumor suppressor function of SPHK2. Unlike SPHK1, SPHK2 is capable of nuclear localization. Our data showed that high levels of nuclear-localized SPHK2 in tissue correlate with a better prognosis for lung cancer patients. Overexpression of SPHK2 within the nucleus significantly reduced cell proliferation and migration capacity. Furthermore, general SPHK2 overexpression enhanced sensitivity to the drug FTY720, but this sensitivity was reduced when SPHK2 was overexpressed specifically in the nucleus. This suggests that the localization of SPHK2 in the cytoplasm versus the nucleus results in opposing functions. The TCGA-LUAD expression profile likely reflects SPHK2's dominant tumor-suppressor role due to a higher proportion of its expression being nuclear.

#5383 Construction and assessment of the stemness-telomere survival risk framework (STSRF) for precision breast cancer therapy: Insights from multi-omic approaches.

Zhiyuan Bo[1], Jingpei Long[1], Fang Wan[1], Fangfang Chen[1], Jiajun Li[2], Zhengxiao Zhao[3]

[1]Department of Surgery, Women's Hospital School of Medicine Zhejiang University, Hangzhou, China,[2]The Second Affiliated Hospital and Yuying Children's Hospital of Wenzhou Medical University, Wenzhou, China,[3]Department of Oncology, the First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou, China

Background and Aims: Breast cancer (BRCA) remains a major clinical challenge due to its molecular heterogeneity and therapy resistance. Stemness and telomere-related genes are key contributors to tumor progression, but their interplay is poorly defined. This study aims to construct a Stemness-Telomere Survival Risk Framework (STSRF) to improve risk stratification and guide precision treatment.

Methods: We integrated single-cell and bulk RNA sequencing data (n = 1684 BRCA patients) with WGCNA and 101 machine learning model combinations within a LOOCV framework to build the STSRF. Immune infiltration was assessed using seven algorithms and deep learning on histopathological images. Biological functions were explored via multi-omic enrichment analyses. Drug sensitivity data from DepMap, GDSC, CMap, CTRP, and PRISM supported therapeutic predictions. Causal relationships were validated using Mendelian randomization (MR), and expression patterns were confirmed by RT-qPCR and immunohistochemistry (IHC).

Results: STSRF showed strong prognostic power (highest 1-, 3-, 5-year AUCs: 0.930, 0.807, 0.766). High- and low-risk groups were effectively stratified, correlating with immune infiltration and clinical traits. High-risk patients were linked to immune-cold phenotypes and may benefit from chemotherapy combined with HDAC inhibitors, while low-risk patients, associated with immune-hot phenotypes and lower IC50 values for chemotherapy agents, may respond better to immunotherapy or chemotherapy. Single-cell and MR analyses confirmed the biological relevance of STSRF genes to BRCA risk. Experimental validation supported key gene expression patterns.

Conclusions: STSRF is a robust framework integrating stemness and telomere biology to predict prognosis and inform personalized therapies in BRCA.

Poster Session

#5388 Dual targeting of CEACAM6 and EGFR with a bispecific antibody induces EGFR degradation and overcomes anti-EGFR resistance.

Ming-Heng Wu, Chee Voon Yap, Yao-Tsung Tsai

Taipei Medical University, Taipei, Taiwan

Epidermal growth factor receptor (EGFR) protein stability is an important determinant of tumor progression and therapeutic response. Here, we identified carcinoembryonic antigen-related cell adhesion molecule 6 (CEACAM6) as a previously unrecognized post-translational stabilizer of EGFR. CEACAM6 expression positively correlated with EGFR protein, but not mRNA, in clinical specimens. Mechanistically, CEACAM6 sequesters EGFR into CEACAM6-enriched lipid rafts, which delays the raft-associated endocytosis and lysosomal degradation of EGFR. This retention maintains EGFR clustering and sustains downstream ERK, AKT, and SRC signaling, promoting migration, invasion, and anoikis resistance, ultimately contributing to resistance against anti-EGFR therapeutics.
To therapeutically exploit this vulnerability, we developed an anti-CEACAM6/EGFR bispecific antibody (BsAb) that simultaneously engages both antigens on the tumor cell surface. The BsAb induces potent antigen crosslinking that triggers efficient EGFR internalization and redirects it toward lysosomal degradation, thereby bypassing the CEACAM6-dependent blockade of EGFR turnover. In addition, the BsAb efficiently suppressed the progression and metastasis of colorectal and lung cancer in xenograft models. These findings identify CEACAM6 as a critical regulator of EGFR stability and demonstrate that dual targeting with the bispecific antibody can induce EGFR degradation, thereby overcoming EGFR-driven malignancy.

#5389 CC312, a novel CD19/CD3/CD28 tri-specific T cell engager, leads to rapid and deep B-cell depletion and has broad potential for development in autoimmune diseases.

Mingyuan Sun[1], Yingfeng Huang[2], Ruixia Zhang[2], Zhen Jing[2], **Xiaofang Zhang**[2], Yuchao Wei[2], Junyuan Qi[1]

[1]Institute of Hematology & Blood Diseases Hospital, Tianjin, China,[2]CytoCares (Shanghai) Inc., Shanghai, China

Background: CD19-targeted T cell engagers (TCEs) have the potential to induce B-cell depletion with potential better safety than CAR-T therapy and off-the-shelf convenience. However, T cell dysfunction and exhaustion contribute to treatment failure following anti-CD19 bispecific TCE. In this study, we developed CC312, a novel tri-specific TCE that integrates CD28 co-stimulation with CD3 and CD19 targeting. CD28 signaling in CC312 has been proved obviously with non-exhausted T cell phenotype.
Objective: The potential of CC312 in treating relapsed/refractory autoimmune diseases will be explored in the clinical setting (NCT06888960).
Methods: This 3 + 3 design, dose-escalation study determined adverse events and the maximum tolerated dose (MTD) of CC312 in patients with autoimmune diseases. CC312 was administered intravenously twice per week at 5 different dose levels (5 to 40 μg). Safety, pharmacokinetic/pharmacodynamic profiles, and primary efficacy parameters—including B-lymphocyte counts of peripheral blood and bone marrow, autoantibodies and biomarkers—will be evaluated for 48 weeks. Primary efficacy endpoint is the SLE Responder Index 4 (SRI-4) criteria.
Results: To date, 10 patients with refractory SLE received 1 to 3 cycles of CC312 treatment. The safety profile remained favorable, with no observed dose-limiting toxicities (DLTs), immune effector cell-associated neurotoxicity syndrome (ICANS), or cytokine release syndrome (CRS) of grade ≥2. A consistent pattern of low-level release for CRS-associated cytokines (IL-6, TNF-α, and IL-10) was observed. CC312 consistently and dose-dependently depleted peripheral B cells in most patients. Among those patients who were followed up ≥24 weeks, B cell reconstitution was observed at week 24 without recurrence of clinical symptoms, suggesting immune reconstitution. $CD19^+$ B cells subsets of bone marrow were completely diminished in the 20~30 μg cohorts at week 8 or week 12. 75% of patients (3/4) achieved an SRI-4 response at week 36, with decreased SLEDAI-2K scores and improvement in clinical symptoms, 100% responders have maintained SRI-4 response. In patient 3, the SLEDAI-2K score fell to zero after treatment and remained stable through week 36. C3 levels and anti-dsDNA antibody levels remained stable for most patients.
Conclusion: In this study, the highest dose currently administered was 30 μg, and CC312 still exhibited favorable safety profiles, with no ICANS or grade ≥2 CRS. Rapid, near-complete depletion of peripheral $CD19^+$ B lymphocytes was achieved at all cohorts. Furthermore, deep and complete depletion of $CD19^+$ B cells in bone marrow was also achieved for 20 μg and 30 ug cohort. Long-term (up to 6~9 months) SRI-4 response was observed across the cohorts and improvement in clinical symptoms.

#5390 Mechanistic drivers of FAP-targeted ADC performance.

Atanasio Pandiella[1], Monica Redondo-Puente[1], Maria del Carmen Gomez-Garcia[1], Patricia Gonzalez[2], Isabel Egana[2], Roland Kontermann[3], Oliver Seifert[3], Jorge Galino[4], Sonia Montero-Molina[4], Jose Luis Hernandez[4], Juan Daniel Sanjuan[4], Guillermo Quintas[4], Ignacio Garcia[2], Manuel Hidalgo[5], Laureano Simon[2], Myriam Fabre[2]

[1]Agencia Estatal Consejo Superior De Investigaciones Cientificas, MADRID, Spain,[2]Oncomatryx Biopharma S.L., Derio, Spain,[3]University of Stuttgart, Stuttgart, Germany,[4]Health and Biomedicine Department, Leitat Technological Center, Terrassa, Spain,[5]NYU Langone Health Perlmutter Cancer Ctr., New York, NY

Cancer-associated fibroblasts (CAFs), the main stromal cell population within the tumor microenvironment (TME), play a pivotal role in cancer progression, metastasis, and immune evasion. To target this compartment, two antibody-drug conjugates (ADCs), OMTX705 and OMTX105, were developed against fibroblast activation protein (FAP) expressed on CAFs. Both share the same human IgG1 antibody backbone (OMTX005) but differ in linker-payload chemistry: OMTX705 carries the cytolysin A1B1, whereas OMTX105 includes monomethyl auristatin E (MMAE). Despite similar drug-antibody ratios (DAR ≈ 4), their distinct vc-PABA-derived linkers confer differential stability and intracellular processing characteristics.We performed a comprehensive characterization of their mechanisms of action, including internalization, intracellular trafficking, and bystander cytotoxicity, in vitro and in vivo, as well as plasma stability and maximum tolerated dose (MTD) analyses to assess their pharmacological and safety profiles. Both ADCs displayed potent antitumor effects but differed markedly in their intracellular fate and pharmacodynamic properties. OMTX105 demonstrated faster processing and stronger bystander killing, leading to higher antitumor activity in murine xenografts; however, its effective dose was close to the MTD in rat, limiting its therapeutic window. In contrast, OMTX705 exhibited slower intracellular processing, resulting in a sustained and controlled payload release. This translated into a longer-lasting effect in vivo, with CAFs acting as a drug reservoir prolonging cytotoxic activity in neighboring tumor cells, while maintaining a superior safety profile.Remarkably, both ADCs exhibited in humanized xenograft mice a shared immunomodulatory activity, promoting infiltration of $CD4^+$ and $CD8^+$ T lymphocytes within the TME—particularly $CD8^+$ cells in treated tumors—suggesting that FAP-targeted ADCs facilitate immune cell recruitment compared to control. This was confirmed in clinical samples from patients treated with OMTX705, currently under clinical development. In these patients, CAF disruption, much lower FAP expression and higher $CD8^+$ and $CD4^+$ cell infiltration was detected in tumor areas co-localizing with the OMTX705 payload signal, providing evidence that OMTX705 enhances local immune activation and supports an antitumor immune response.Overall, these findings reveal both cytotoxic and immunomodulatory functions for FAP-targeted ADCs within the TME and provide molecular mechanistic insights into their bystander effect, emphasizing how differences in linker-payload chemistry critically determine efficacy, durability of response, immune engagement, and tolerability. This study highlights OMTX705 potential as a safer FAP-targeted ADC with long-lasting effect and underlines the importance of biology-driven linker-payload engineering for next-generation stroma-directed ADC anticancer therapies.

#5391 A versatile KY-HC-mouse™nanobody platform enabling tumor-anchored, conditionally active 4-1BB bispecific antibodies.

Xiaoting Liang, Siyu Li, Jie Xu, Hao Peng, **Feng Hao**, Jinying Ning

Kyinno Biotechnology Co., LTD, Beijing, China

4-1BB (CD137) is an attractive co-stimulatory receptor for boosting anti-tumor T-cell responses, but first-generation systemic 4-1BB agonist antibodies have been limited by dose-limiting toxicity, highlighting the need for tumor-anchored, conditionally active agonists with an improved benefit-risk profile. We established a proprietary heavy-chain-only mouse (KY-HC-mouse™) platform to generate relatively low-affinity anti-4-1BB nanobodies that block 4-1BB/4-1BBL binding and require cross-linking for strong signaling, thereby conferring built-in conditional agonism. These nanobodies were formatted into Fc-silenced IgG (LALA mutation) bispecifics targeting PSMA (PSMA×4-1BB, KA-2722), CD19 (CD19×4-1BB, KA-6859) and CDH17 (CDH17×4-1BB, KA-A3438), as well as a trispecific antibody targeting CDH17×CLDN18.2×4-1BB (KA-A3601). CDH17×CLDN18.2×4-1BB (KA-A3601) was designed based on the frequent co-expression of CDH17 and CLDN18.2 in gastrointestinal tumors, enabling dual-antigen anchoring of 4-1BB co-stimulation. All molecules show relatively reduced 4-1BB binding compared with benchmark agonists but retain strong, high-avidity binding to their respective tumor antigens and drive potent, antigen-dependent activation of 4-1BB reporter cells. CD19×4-1BB (KA-6859) further demonstrates robust *in vivo* efficacy in hu-PBMC lymphoma models when combined with a CD20×CD3 T-cell engager Glofitamab, with clear tumor growth inhibition at 3 mg/kg KA-6859 plus 0.15mg/kg CD20×CD3 (QW*3), and exhibits favorable pharmacokinetics with sustained serum exposure in mice. CDH17×4-1BB (KA-A3438) and CDH17×CLDN18.2×4-1BB (KA-A3601) show strong tumor growth inhibition in MC38-CDH17 and MC38-CDH17-CLDN18.2 tumors established in B-h4-1BB C57BL/6 humanized 4-1BB (h4-1BB) mice, respectively, without ALT/AST elevation, indicating absence of detectable hepatotoxicity. CD19×4-1BB (KA-6859) exhibits a transient ExpiCHO-S expression yield of ~393 mg/L and a favorable pharmacokinetic profile in C57BL/6 mice, with terminal half-lives of approximately 16-21 days after i.v. dosing and ~10 days after s.c. dosing, and an s.c. bioavailability of ~82%. KA-6859 also displays high thermal stability and good overall stability, indicating favorable developability.Together, these data position the KY-HC-mouse™ 4-1BB nanobody platform as a versatile foundation for next-generation, tumor-anchored 4-1BB bispecifics and multispecifics, and for future combinations with checkpoint inhibitors in solid and hematologic malignancies.

#5392 Targeting solid tumors with pH-dependent dual-specific TCEs: First-in-human development of CT-202.

Stanley Roberts[1], Kelly Byrnes-Blake[2], Heather Ansorge[3], Eric Butz[4], **Daniel Olson**[5]

[1]SAR Safety Assessment, Northbrook, IL,[2]Northwest PK Solutions, LLC, Cordova, AK,[3]Context Therapeutics Inc, Philadelpha, PA,[4]Context Therapeutics Inc, Philadelphia, PA,[5]University of Chicago, Chicago, IL

Introduction: Nectin-4 has emerged as a clinically validated antigen for the treatment of urothelial, colorectal, lung, breast, and other solid malignancies. However, Nectin-4's physiological expression in epidermal keratinocytes restricts the utility of potent immunotherapeutic strategies such as bispecific T cell engagers (TCEs) and chimeric antigen receptor T cells (CAR-Ts), due to on-target, off-tumor toxicity. CT-202 is a fully humanized, dual pH-dependent Nectin-4 x CD3 bispecific TCE engineered to widen the therapeutic window by selectively targeting Nectin-4 and CD3 within the acidic tumor microenvironment (TME).

Methods: CT-202 was characterized for pH-dependent binding to both Nectin-4 and CD3, employing *in vitro* affinity assays across pH gradients mimicking physiological (pH 7.4) and tumoral (pH ~6.5) conditions. *In vivo* pharmacology and safety assessments were performed in non-human primates comparing CT-202 and non-pH-dependent bispecific controls. *In vitro* functional assays, including cytotoxicity and cytokine release, were used to determine dose-response relationships to inform initial human dosing strategies.

Results: CT-202 demonstrated high affinity and specificity for Nectin-4 and CD3 exclusively at the lower pH characteristic of the TME; at neutral pH, binding was markedly attenuated. This conditional dual engagement was essential for effective T cell-mediated cytotoxicity against tumor targets *in vitro*. In non-human primate toxicology studies, CT-202 exhibited a >30-fold improvement in the Highest Not Severely Toxic Dosage (HNSTD) relative to traditional bispecifics lacking pH modulation, delineating a superior safety profile. Integrated analysis of *in vitro* potency and *in vivo* toxicology data supported a rational selection of starting dose for forthcoming clinical investigation.

Conclusion: CT-202 represents a novel dual pH-selective bispecific TCE targeting Nectin-4 x CD3, designed to optimize tumor selectivity and minimize off-tumor toxicity. Preclinical data validate the differentiated pharmacological and safety attributes of this modality, justifying its advancement to first-in-human Phase 1 trials. This approach highlights the potential of dual pH-dependent bispecific antibodies as a next-generation platform for the selective immunotherapy of Nectin-4-expressing solid tumors.

#5393 Preclinical efficacy and safety profile of NPX125, a novel ADC targeting B7-H7.

Silvia Ferrati, Emilien Loeuillard, Susannah L. Hewitt, Matthew Peter Rausch, Bijan Etemad-Gilbertson, Jamie Strand, Riale Gilligan, Katalin Kis-Toth, Yasmin Hashambhoy-Ramsay, Emma Wang, Leena Gandhi, Tatiana Novobrantseva

NextPoint Therapeutics, Cambridge, MA

Introduction: B7-H7 is a member of the B7 family, with strong expression in multiple cancer indications in addition to its known role as an immune regulator. B7-H7 upregulation is correlated with poor patient outcomes while its normal tissue expression is limited, making it very attractive for targeting tumors. Here, we report the development of NPX125, a novel B7-H7-targeting antibody-drug conjugate with a potent DNA topoisomerase I inhibitor and a novel linker. NPX125 has potent *in vitro* activity, stable pharmacokinetic profile, favorable safety profile, and *in vivo* antitumor responses in nonclinical studies.

Methods: The target specificity and species cross-reactivity of NPX125 were assessed by flow cytometry on endogenous B7-H7+ and overexpressing B7-H7 cell lines. Internalization was tracked with Fabfluor-pH reporter conjugated-NPX125 using Incucyte® imaging. Its pharmacologic activities were evaluated in several human cancer cell lines *in vitro* by luminescence-based cell viability assays and in xenograft mouse models *in vivo*. The safety profile was evaluated in a dose escalation toxicokinetic study in cynomolgus monkeys. Animals were evaluated for 4 weeks after a single intravenous dose of NPX125. Clinical observations, hematology, chemistry, cytokine, and immunophenotyping samples were collected. At completion, pathology evaluation of selected tissues was performed. NPX125 pharmacokinetics was assessed in rats and monkeys by measurement of both total and drug-conjugated antibodies.

Results: NPX125 showed cross reactivity to human and monkey B7-H7 with on-cell binding. Incucyte® imaging analyses in a HER2 positive cell line showed faster internalization compared to Trastuzumab-Dxd. NPX125 demonstrated cytotoxic activity in tumor cell lines (EC50 ~ 0.19 nM to 2.95 nM) with a wide range of B7-H7 expression levels and significant bystander effect on B7-H7 negative cell lines. NPX125 was tested in several *in vivo* tumor models expressing a wide range of B7-H7 protein levels, demonstrating anti-tumor activity. Furthermore, NPX125 was stable in circulation with minimal free payload release in rats and monkeys (T1/2 = 352 and 135 hr, respectively and ~0.07% of the total injected payload released at Cmax in NHP). NPX125 was well tolerated in monkeys with a NOAEL of at least 10 mg/kg and no NPX125-related changes in clinical signs, body weight, food appetence, hematology, clinical chemistry, urinalysis, immunophenotyping, and organ weights. Increases in IL-1RA and IL-8 concentrations were noted with possible dose proportionality. Possible NPX125-related findings were present in the gastrointestinal tract.

Conclusions: NPX125 exerted potent antitumor activity against B7-H7-expressing tumors in *in vitro* and *in vivo* models and showed favorable pharmacokinetic and safety profiles in nonclinical species. The data presented here supports clinical development of NPX125 as a promising treatment strategy.

#5394 Novel multispecific T cell engagers exploit avidity for highly selective targeting of B-myeloid mixed-phenotype acute leukemia.

Sophie Jamet[1], Huiyuan Zhang[1], Ray Ruff[1], Irene Chen[1], Sally Ditzler[1], Kiersten Tucker[1], Hailey Hentschel[1], Jessica Chantel Ramadhin[2], James M. Olson[1], Jason Price[1], Mignon L. Loh[1]

[1]Seattle Children's Research Institute, Seattle, WA,[2]Taconic Biosciences, Inc., Los Angeles, CA

Introduction. B-myeloid mixed-phenotype acute leukemia (B-MPAL) is a high-risk leukemia subtype co-expressing lymphoid and myeloid surface antigens. Cure rates remain low, especially in adults (OS 20% to 50%). Current therapies are heterogeneous, borrowing from either ALL or AML regimens. MPAL cells uniquely co-express both lymphoid markers (e.g. CD19) and myeloid markers (e.g. CD33), a dual expression profile not shared by normal hematopoietic cells. We hypothesize that a Multispecific T cell Engager (MTE) engineered to preferentially bind cells expressing CD19 AND CD33 will achieve high selectivity compared to single-antigen targeting. We thus designed MTEs that bind both CD19 and CD33 on MPAL cells and CD3 on T cells. We fine-tuned the affinity of the CD19 and CD33 binders to leverage avidity; this ensures poor binding to single-positive (SP) normal cells but high-avidity binding to double-positive (DP) leukemia cells. This strategy aims to induce deep remissions and improve safety over single-target agents like Blinatumomab.

Methods. We successfully designed and produced 30 tri-specific CD19/CD33/CD3 MTEs, utilizing components derived from de-risked or FDA-approved therapeutics. Our MTE framework is an asymmetric "knob into hole" human IgG1 scaffold incorporating effector silencing mutations. *In vitro* assays tested binding and T cell cytotoxicity against DP, SP, or negative cell lines. Top candidates were tested *in vivo* using a luciferase-labeled JIH-5 xenograft (CD19+ CD33+) model in NSG-SGM3 mice. Engrafted mice received repeated weekly doses of MTEs and human T cells, with disease progression tracked via IVIS imaging.

Results. *In vitro* data confirm successful dual-antigen targeting and dramatic specificity improvements using lower-affinity binders. For multiple candidates, we observed much lower cytotoxicity for SP cells, with up to a 7-log difference in IC50 between DP and SP cells, demonstrating an AND logic-gated treatment within a single molecule. Initial preclinical *in vivo* data show successful control of disease progression in xenografted mice at well-tolerated doses. Crucially, we conducted safety studies in huNOG-EXL humanized mice (engrafted with CD34+ cells) to test toxicity on normal human hematopoietic cells. Dose titration confirmed the selective sparing of normal human B cells and CD33+ myeloid cells, a major advancement over single-targeting therapies.

Conclusions. By taking advantage of the unique DP features of B-MPAL cells, we developed a novel immunotherapy that offers improved half-life, potency, selectivity, and safety. This work establishes proof of concept that the combinatorial use of binders with optimized affinity generates highly specific immunotherapies with minimal normal cell cytotoxicity via an avidity-driven mechanism, paving the way for safer and more effective treatments.

#5397 A novel anti-CD3×CD28×STEAP1 tri-specific T-cell engager with enhanced and durable antitumor responses in prostate cancer.

Ge Song, Aiying Xiong, Seng Zhu, Xuemei Tian, Xiaoling Yuan, Wanli Zhang, Wan-Jen Yang, Xiansong Xiong, Ling Ding, Haixiang Yu, Xiaoli Hou, Pingao Yan, Qingyu Wang, Xiao Zou, Chen Hu, Jijun Yuan

Shanghai Henlius Biotech, Inc., Shanghai, China

Introduction: Limited efficacy has been achieved with immunotherapy for prostate cancer, largely due to an immunosuppressive or “immune desert” tumor microenvironment, poor T-cell infiltration, or lack of robust tumor-specific targets. To overcome these barriers, we have developed an anti-CD3×CD28×STEAP1 tri-specific T-cell engager (TCE) that redirects T cells to prostate tumors with high levels of STEAP1 and improves T cells through co-delivering CD3 and CD28 signals.

Methods: T cell-dependent cellular cytotoxicity was assessed using a luciferase assay or flow cytometry. Concurrently, cytokine secretion in cell culture supernatants was analyzed using a multiplex bead-based flow cytometric assay. To evaluate T-cell proliferation and memory formation, peripheral blood mononuclear cells (PBMCs) were co-cultured with C4-2B cells and subsequently analyzed by flow cytometry. The sustained cytotoxic potency of T cells was further examined in a repeated antigen challenge model, and cytotoxicity was measured after each cycle using a luciferase assay. *In vivo*, antitumor efficacy was investigated in humanized PBMC/C4-2, LNCaP and patient-derived xenograft (PDX) xenograft models. Additionally, a pilot toxicology was studied in cynomolgus monkeys.

Results: Anti-CD3×CD28×STEAP1 TCE exhibited a target-dependent T-cell activation and cytotoxicity, especially under conditions with a low T effector to tumor cell ratio (1:5-1:10). HLX3902 demonstrated enhanced T cell function and sustained *in vitro* cytotoxicity compared with bispecific TCEs and their combinations, showing superior T-cell proliferation and enhanced expansion of memory T cells. Furthermore, Anti-CD3×CD28×STEAP1 TCE demonstrated superior and sustained antitumor activity in both humanized PBMC/cell line-derived xenograft and PDX models at a single 0.01 mg/kg dose, with increased T-cell infiltration, activation, and persistent intratumoral CD8+ T cells resulting from CD28 co-stimulation compared to AMG509. Anti-CD3×CD28×STEAP1 TCE was well tolerated in cynomolgus monkeys after weekly intravenous administration at a dose of 45 μg/kg/QW

Conclusion: We developed a novel tri-specific TCE with optimized CD3 and CD28 signaling, effectively co-engages T cells and STEAP1-expressing tumor cells. It elicits potent, target-dependent T-cell activation and cytotoxicity, The incorporation of CD28 signaling significantly improved T-cell persistence and sustained functional activity against repeated antigen challenges *in vitro* and *in vivo*. It was well tolerated in cynomolgus monkeys, supporting its potential for clinical development, and positions as a best-in-class molecule with Investigational New Drug submission anticipated in Q1 2026. This tri-specific co-stimulatory platform may be extended to treat immunosuppressive or “immune desert” solid tumors.

#5399 QLS2309, a trifunctional NKp46/CD16a-NK cell engager targeting CD70 enhances efficacy against acute myeloid leukemia via mitigating the refraction to therapeutic antibody-dependent cytotoxicity.

Liuqing Yang[1], Ruimei Li[1], Xiaoran Wu[2], Shuyong Zhao[2], Hua Ying[1], Weikang Tao[1]

[1]Shanghai Qilu Pharmaceutical Research and Development Center LTD., Shanghai, China,[2]Qilu Pharmaceutical Co., Ltd., Jinan, China

Acute myeloid leukemia (AML), the most prevalent acute leukemia in adults, is characterized by clonal expansion of myeloid precursors in the bone marrow (BM) and peripheral blood. Despite advancements in treatment, unmet medical needs persist in AML, with up to 50% of patients relapsing after initial chemotherapy and older patients facing a poor prognosis. CD70, a member of the tumor necrosis factor family, is expressed in over 80% of AML blasts and exhibits high specificity for leukemia stem cells (LSCs), while normal hematopoietic stem cells (HSCs) and immune cells show minimal or no expression. This makes CD70 an attractive therapeutic target for AML. However, approximately one-third of AML patients express the high-affinity Fc receptor CD64, which may impair the tumor-killing efficacy caused by Fc-mediated ADCC of therapeutical monoclonal antibodies. To address this challenge, we generated a trifunctional natural killer cell engager (NKCE), QLS2309, which targets AML blasts via binding to CD70 and engages NK cells via binding to NKp46/CD16a on NK cells. QLS2309 is a human IgG1 bispecific antibody featuring an anti-NKp46 nanobody (VHH) and an anti-CD70 antigen-binding fragment (Fab). Unlike anti-CD70 monoclonal antibodies, QLS2309 retained potent antitumor activity against primary AML blasts regardless of CD64 expression. Additionally, it selectively induced NK cell activation and cytokine secretion only in the presence of AML cells. *In vivo* studies demonstrated dose-dependent tumor growth inhibition with QLS2309, showing superior efficacy compared to cusatuzumab (an ADCC-enhanced monoclonal antibody). Single-dose pharmacokinetics in non-human primates (NHPs) revealed linear exposure, while multiple-dose toxicokinetics showed no significant accumulation. A GLP toxicity study in cynomolgus monkeys (QW × 4) confirmed favorable safety, with QLS2309 well-tolerated up to 100 mg/kg and minimal cytokine release. In conclusion, QLS2309 combines excellent efficacy, favorable pharmacokinetics, and a strong safety profile, outperforming cusatuzumab. These data support QLS2309 as a promising novel therapy for AML. A Phase 1 dose-escalation study in CD70+ relapsed/refractory hematologic malignancies is currently ongoing (NCT07173595).

#5400 QLS2313, a CD79b/CD20 tri-specific T cell engager with dual-targeting strategy developed as a new therapeutics for the treatment of DLBCL.

Ting Lu[1], **Liuqing Yang**[1], Fujia Yao[1], Dongdong Wu[1], Shuyong Zhao[2], Hua Ying[1], Weikang Tao[1]

[1]Shanghai Qilu Pharmaceutical Research and Development Center, Shanghai, China,[2]Qilu Pharmaceutical Co., Ltd., Jinan, China

Diffuse large B-cell lymphoma (DLBCL) is the most prevalent subtype of non-Hodgkin lymphoma (NHL), with approximately 40% of patients developing refractory disease or relapsing after initial therapy response. While CD20-targeted T cell engagers (TCEs) have demonstrated clinical efficacy and gained FDA approval for DLBCL, studies indicate that CD20 expression loss occurs in 8-64% of patients following CD20-directed therapies. This loss is often associated with transformation to high-grade lymphoma and poor overall survival. To address this challenge, Dual targeting another DLBCL surface antigen as well as CD20 may enhance therapeutic effects. CD79b is a well-validated therapeutic target expressed in 90% of DLBCL cases anditis critical for the viability of DLBCL cells. Unlike CD20, CD79b-targeted agents are less prone to resistance caused by antigen loss, making it an attractive TCE target. Therefore, a TCE dual targeting of CD79b and CD20 may overcome resistance and improve efficacy compared to a single-antigen targeting TCE. QLS2313 is a human IgG1 tri-specific antibody featuring an anti-CD3 single-chain variable fragment (scFv), an anti-CD20 Fab, an anti-CD79b Fab, and an effector-silent Fc region. *In vitro*, QLS2313 exhibited higher affinity for DLBCL cell lines than JNJ-80948543 (a clinical-stage CD79b/CD20 TCE from Janssen) while demonstrating significantly lower affinity for primary human T cells and Jurkat cells compared to JNJ-80948543 and FDA-approved CD20/CD3 bi-specifics (mosunetuzumab and glofitamab). QLS2313 effectively depleted both dual- and single-target-expressing cells, showing superior cytotoxicity to JNJ-80948543 and lower IL-6 release than glofitamab. *In vivo*, QLS2313 demonstrated linear pharmacokinetics in triple transgenic (human CD3/CD20/CD79b) mice, with a half-life of ~5 days. It inhibited tumor growth in a dose-dependent manner and exhibited greater antitumor efficacy than JNJ-80948543, particularly in CD20-low expression models. QLS2313 was well tolerated in a transgenic mice (QW × 4) GLP toxicity study, with the highest non-severely toxic dose (HNSTD) at 30 mg/kg for both intravenous and subcutaneous administration. In conclusion, QLS2313 show superior efficacy, favorable pharmacokinetics and safety profile, which support the clinical development of this novel therapy for DLBCL treatment.

#5401 A novel bispecific ADC targeting Nectin-4 and HER2 demonstrates superior and broad antitumor efficacy in preclinical models.

Jinxiu Hou, Tingting Gu, Chuan Chen, Chenpeng Su, Xiaoqian Chen, Dandan Liu, Jiyuan Tian, Zhihang Liu, Yongxin Shang, Rongmei Yan, Kezhen Ye, Liang Tian, Jian Peng, Zhenping Zhu

Earendil Labs, Wilmington, DE

Recently Nectin-4 has emerged as a prominent oncological target due to its high expression across various solid tumors (e.g., urothelial carcinoma, breast cancer, lung cancer, and pancreatic cancer) with restricted expression in normal adult tissues. The clinical significance of Nectin-4 is underscored by the FDA's approval of enfortumab vedotin (EV) for the treatment of urothelial carcinoma. Several novel therapeutic modalities targeting Nectin-4 are under active investigation for cancer therapies. Herein, we describe the design and development of a panel of bispecific antibodies (bsAbs) targeting both Nectin-4 and HER2. Each individual binding arms of the bsAb were engineered and fine-tuned to moderate affinity in order to instill an avidity-driven binding to cells co-expressing both target antigens. The formats of bsAbs were further optimized for favorable developability. The lead BsAb was subsequently conjugated with varieties of cytotoxic payloads to generate bispecific ADC candidates. Several assays were established to exam cell-binding, internalization, and biological activities of the bispecific ADC in cancer cells that express either one or both of the tumor antigens. Internalization assays demonstrated that the BsAbs were endocytosed in tumor cells co-expressing Nectin-4 and HER2 more efficiently than monoclonal antibodies against Nectin-4 or HER2. The antitumor activity of the bispecific ADCs in multiple CDX mouse models were assessed. The lead bsADC demonstrated potent efficacy in CDX models with varying target expression levels, indicating its potential for a broad anti-tumor spectrum for UC and other solid tumors with dual HER2/Nectin-4 antigen expression.

#5402 Engineering and development of a novel bispecific ADC targeting EGFR and FGFR2b.

Liang Zhu, Chuan Chen, Chenpeng Su, Mei Tian, Xiaoqian Chen, Dandan Liu, Jiyuan Tian, Yang He, Yongxin Shang, Rongmei Yan, Kezhen Ye, Liang Tian, Jian Peng, Zhenping Zhu

Earendil Labs., Wilmington, DE

EGFR is a clinically validated oncogenic driver frequently overexpressed in gastric cancer. Fibroblast growth factor receptor 2b (FGFR2b), a transmembrane receptor tyrosine kinase,is likewise overexpressed in approximately 30% of gastric and gastroesophageal junction (GEJ) cancers, and is associated with poor prognosis. Notably, subsets of gastric tumors co-express EGFR and FGFR2b, indicating potential cooperative signaling that contributes to tumor progression and therapeutic resistance. Bemarituzumab, an afucosylated FGFR2b monoclonal antibody has shown efficacy in the clinical study for the treatment in patients with FGFR2b-positive GC and GEJ cancer. However, the clinical application of bemarituzumab is accompanied by safety concerns. The corneal adverse events were frequently observed. Co-expression of EGFR and FGFR2b presents an attractive opportunity for a dual targeting strategy and supports the bispecific design that could potentially address the safety issues. In this study, we developed several bispecific antibodies (bsAb) targeting EGFR and FGFR2b. These bsAb demonstrated enhanced binding avidity and superior internalization efficiency compared with bemarituzumab and BG-C137 mAb analogs in $EGFR^+/FGFR2b^+$ dual expressing cancer cell lines. Our EGFR×FGFR2b bsAb function as a partial FGFR2b ligand blocker, and only weakly inhibiting FGF7 while sparing FGF10-mediated signaling, thus with the potential to reduce on-target toxicity associated with FGF7/FGF10 blockade. Several bsAb ADC were generated with various cytotoxic payloads and are being tested in vitro and in vivo studies.

#5404 Tumor cell targeted granzyme B demonstrates direct cytotoxic action and indirect immunogenic cell death mediated through numerous defined proteins.

Khalid A. Mohamedali[1], Madhuri Wadehra[2], Lawrence H. Cheung[1], Michael G. Rosenblum[1]

[1]Translational Medical Sciences, Texas A&M University Health Science Center, Houston, TX,[2]UCLA David Geffen School of Medicine, Los Angeles, CA

The primary effect of antibody-directed therapeutics is the delivery of cytotoxic payloads directly to antigen-expressing tumor cells resulting in activating cell death mechanisms in the target cells while sparing nonmalignant cells and reducing systemic toxicity. Cytotoxic payloads with the additional capacity to initiate immune activation mechanisms directed against tumor cells as a secondary effect of targeted therapy have the added benefit of initiating “immunogenic cell death” (ICD), which allows further control over residual tumor cells which may be antigen-negative or resistant to the initial cytotoxic effect. Our previous studies in two syngeneic breast cancer mouse models showed that an EMP2-targeted granzyme B fusion significantly enhanced the tumor levels of CD45+ immune cells and tumor-inhibitory M1 macrophages, as well as decreased tumor-supporting M2 macrophages. Tumor cells undergoing ICD express and secrete immunogenic factors such as damage-associated molecular patterns (DAMPs) that are critical in immune cell recruitment and the initiation of immunogenic apoptosis. Accordingly, we investigated whether targeted granzyme B delivery into human tumor cells resulted in the release or expression of DAMP proteins. We tested three human cell lines with varying levels of antigen expression for FOLRa, Fn14, EMP2 and HER2 with scFv-based constructs targeting each of these antigens and delivering the cytotoxic payload granzyme B. In vitro cytotoxicity against each cell line for all four constructs was found to be in the low nanomolar range. Treatment with all four constructs over 72 hours against log-phase tumor cells resulted in the detection of HMGB1 in the conditioned media while detection of released Annexin A1 was restricted to HEY A8 cells targeted via FOLRa. We characterized HMGB1 and Annexin A1 release into the media in a dose dependent (0-100 nM) and time-dependent (4-72h) manner and correlated these events with real-time release of ATP into the conditioned media. Furthermore, we characterized the expression of Calreticulin on the cell surface of each of these cell lines by flow cytometry and investigated the onset of caspase activation by fluorescence imaging. Further studies are ongoing to identify other DAMP-related proteins which may mediate the secondary immunogenic bystander effect against tumor cells. These data support a proposed “dual mechanism” for GrB-based therapeutics which include a direct, antigen-mediated cytotoxic effect and a secondary, immune-mediated effect which can target both antigen-positive and antigen-negative tumors. Research conducted, in whole or in part, by the Clayton Foundation for Research and generously supported by the NCI R21 CA163971.

#5405 STX002: A GPC3-targeted antibody-drug conjugate with potent and durable antitumor activity in preclinical models of hepatocellular carcinoma.

Deepak Rohila, Sameena Wani, Atul Tandon, Jianhua Zhao, Anindya Bagchi, **Ashutosh Tiwari**

Styx Biotechnologies Inc, San Diego, CA

Hepatocellular carcinoma (HCC) remains a leading cause of cancer mortality with limited therapeutic options, highlighting the need for novel targeted therapies. Glypican-3 (GPC3) is highly expressed in HCC and minimally present in normal adult tissues, making it an attractive antigen for antibody-drug conjugate (ADC) development. STX002 is a next-generation ADC composed of a humanized anti-GPC3 antibody site-specifically conjugated to a potent topoisomerase I inhibitor payload via a cleavable linker. Topoisomerase I inhibitor-based ADCs have shown broad clinical benefit across solid tumors, and STX002 aims to leverage this class against a genetically and molecularly defined HCC target. STX002 demonstrated high-affinity, selective binding to GPC3 and robust internalization in GPC3-positive cells, resulting in potent target-dependent cytotoxicity with sub-nanomolar IC_{50} values and a measurable bystander effect. In vivo, STX002 induced deep and durable tumor regressions across a panel of GPC3-expressing HCC CDX and PDX models, including models refractory to standard-of-care tyrosine kinase inhibitors. Pharmacokinetic and tolerability studies revealed favorable systemic exposure, linker stability, and a wide therapeutic index with minimal off-target toxicity. Collectively, these data support STX002 as a differentiated GPC3-targeted topo-I ADC with strong preclinical efficacy and translational potential. STX002 represents a promising therapeutic candidate for addressing the substantial unmet need in HCC and warrants advancement toward IND-enabling studies and clinical development.

#5406 A novel AI-engineered biparatopic DLL3/CD3 T cell engager demonstrates potent preclinical efficacy and a promising safety profile.

Chuan Chen, Yue Wu, Chenpeng Su, Dandan Liu, Jiyuan Tian, Yujuan Li, Yongxin Shang, Xiaoqian Chen, Rongmei Yan, Liang Tian, Jian Peng, Zhenping Zhu

Earendil Labs, Wilmington, DE

Purpose: This study aimed to develop and characterize a novel biparatopic T-cell engager (TCE) targeting DLL3 for the treatment of small cell lung cancer (SCLC) and other neuroendocrine carcinomas (NECs).
Methods: Using an AI-engineered multispecific antibody platform, we engineered a biparatopic DLL3/CD3 TCE to bind two distinct epitopes on DLL3 while engaging CD3 on T cells. Binding affinities were systematically optimized to enhance tumor targeting and minimize off-T cell activation. The molecule was evaluated *in vitro* activity for T cell-dependent cytotoxicity, T cell activation, and cytokine release and in vivo efficacy using human SCLC cell lines-derived xenograft models. Safety was assessed in transgenic mice and cynomolgus monkeys.
Results: The biparatopic DLL3/CD3 TCE demonstrated potent and specific cytotoxicity against DLL3-expressing cell lines, while limiting T cell activation and cytokine release. In murine models, it achieved significant tumor growth inhibition at lower doses than a benchmark TCE (tarlatamab analog). The molecule exhibited good tolerability at doses up to 30 mpk in transgenic mice and 10 mpk (administered via step-dosing) in monkeys, without significant adverse effects.
Conclusion: The biparatopic DLL3/CD3 TCE exhibits robust preclinical efficacy and a favorable safety profile, supporting its further development as a targeted immunotherapy for DLL3-positive SCLC and NECs.

#5407 Mechanism of CAPRIN-1 membrane localization in cancer and development of TRK-950, a humanized anti-CAPRIN-1 antibody.

Yoshitaka Minamida, Shoichi Ohno, Kazushi Tachibana, Ukei Wasai, Takayuki Fujita, Takashi Morimoto, Fumiyoshi Okano

New Frontiers Research Laboratories, Toray Industries, Inc., Kamakura, Japan

CAPRIN-1, initially reported as a cytoplasmic protein, has emerged as a novel cancer-specific therapeutic target. CAPRIN-1 is highly expressed on the cell membrane surface of a broad range of solid tumors, but not on normal cells (Okano, F et al., Cancer Res Commun 2023). However, the molecular mechanism underlying this cancer-specific membrane localization of CAPRIN-1 remains unclear. In this study, we aimed to elucidate the mechanism responsible for CAPRIN-1 membrane expression in cancer. We identified “Protein X” as a CAPRIN-1-binding partner under certain stress conditions. Our data indicate that “Protein X” is required for stress-induced membrane localization of CAPRIN-1 in cancer cells. Based on the promising expression profile of CAPRIN-1, we developed a humanized anti-CAPRIN-1 antibody, TRK-950, currently under clinical development. TRK-950 demonstrated safety and tolerability in a Phase-1 study (NCT02990481), and Phase-2 trials are ongoing in patients with gastric cancer (NCT06038578) and melanoma (NCT05423262). In parallel with clinical studies, we conducted non-clinical investigations to clarify TRK-950’s anti-tumor mechanism. Our findings show that macrophage-mediated ADCP via Fcg receptors is critical for the TRK-950 efficacy as demonstrated using FcgR knockout and macrophage-depleted mouse models. Furthermore, TRK-950 combined with several approved anticancer drugs exhibited enhanced anti-tumor activity both *in vitro* and *in vivo*. In addition to the naked antibody, we are developing CAPRIN-1-targeted modalities such as ADCs and will present these encouraging results at this meeting. Collectively, these data support CAPRIN-1 as a promising target for antibody-based therapies.

Poster Session

#5411 Primary osteosarcoma of the short bones: A Surveillance, Epidemiology, and End Results Program (SEER) retrospective study.

Jarrell Imamura[1], Elizabeth Nowak[2], Arda Durmaz[2], Jacob G. Scott[2], Zachary Burke[2]

[1]Genomic Medicine and Systems Biology, Cleveland Clinic Research, Cleveland, OH,[2]Cleveland Clinic, Cleveland, OH

Introduction:
Osteosarcoma (OS) is the most common primary solid malignancy of bone and accounts for 2% of all childhood cancers. OS is most often found in the long bones of the extremities, in particular the femur, tibia, and humerus. However, it is rarely found in the short bones of the upper and lower extremity. This study seeks to address the existing gap in the literature on the incidence, treatment, and outcomes of OS of the short bones of the upper and lower extremity.
Methods:
Cases of primary short bone OS were identified using the National Cancer Institute Surveillance, Epidemiology, and End Results (SEER) Program database, containing 8,216,169 cancer cases from 2000 to 2020. Demographic, clinical, and treatment characteristics were collected, and univariate and multivariate regression analysis was conducted to determine the relationship between disease-specific survival and tumor spread, tumor size, tumor grade, surgery type, and primary site.
Results:
Cases of primary short bone OS made up 2.2% of all OS cases in the database. The majority of cases were male, and the most common age group ranged from ages 15 to 39. Within the 201-patient cohort, 58.2% were treated with chemotherapy and 4.5% received radiation therapy. Surgery information was available for 170 patients—50.6% of that group underwent limb-sparing surgery, 31.8% of patients underwent amputation, and 17.6% did not have surgery. Univariate analysis revealed grade and disease spread to be statistically significant predictors of survival; however, upon multivariate analysis, only localized disease was correlated with better disease-specific survival. Interestingly, there was no survival difference between patients treated with amputation versus patients who underwent limb salvage surgery.
Conclusions:
The results of this study confirm that OS of this location is a rare entity that generally follows the demographic distribution of the more common long bone variant. The results also signal that limb salvage is a reasonable treatment option for this group, given the lack of survival difference between limb salvage surgery and amputation.

#5412 Eyelid malignancies on the rise? A population-based analysis of merkel cell carcinoma, melanoma, and sebaceous carcinoma from the SEER database.

Said Yaseen[1], Bashar I. Almaraziq[2], Shaimaa A. Abdelmoneim[3], Ahmed S. Al Sakini[4], Mohamed Ahmed Ali[5], Joud K. Alhousani[1], Leen Abu Rabi[1], **Ahmad Farouk Alzein**[6], Issam Khourshid[7], Shahd Alsharif[1], Hamza Khoursheed[1], Mohammad Almajali[1], Hashem Abu Serhan[8]

[1]Jordan University of Science and Technology, Irbid, Jordan,[2]Hashemite University, Zarqa, Jordan,[3]Egyptian Ministry of Health and Population, Alexandria, Egypt,[4]University of Baghdad, Baghdad, Iraq,[5]South Valley University, Qena, Egypt,[6]University of Illinois Chicago, Chicago, IL,[7]Victoria Hospital, Scotland, Kirkcaldy, United Kingdom,[8]Hamad Medical Coorporation, Doha, Qatar

Purpose:
This study sought to analyze temporal incidence trends for malignant melanoma (MM), Merkel cell carcinoma (MCC), and sebaceous gland carcinoma (SGC) of the eyelid and to predict future patterns using population-based data.
Methods:
A retrospective analysis was conducted using the Surveillance, Epidemiology,and End Results (SEER) database from 2000-2021. Time-series models, including Autoregressive Integrated Moving Average (ARIMA) and Neural Network Autoregression (NNAR), were applied to estimate incidence rates (IRs) per 100,000, stratified by tumor type, sex, age, and race. Model selection was based on minimizing Root Mean Square Error (RMSE). Poisson regression was used to assess the impact of age and sex on IRs.
Results:
The overall IR for these malignancies showed an increase from 2000 to 2015,followed by a slight decline and a subsequent rise in 2021; a 10-year forecast projects a continued modest increase. Subtype analysis revealed variable trends: MM incidence is projected to rise, while MCC and SGC incidence rates are forecasted to remain relatively stable. Poisson regression identified age >60 years as a highly significant risk factor, dramatically increasing the incidence rate ratio (IRR) for both MM (IRR 17.1) and SGC (IRR 25.4). Gender was not a significant factor. Racial disparities were evident; White individuals had the highest incidence of MM, whereas Asian or Pacific Islander individuals had the highest incidence of SGC.
Conclusion:
Malignant eyelid tumors exhibit distinct patterns. MCC has the highest metastatic risk, sebaceous adenocarcinoma varies by race, and surgery remains key

#5413 Real-world (RW) outcomes by race in patients (pts) receiving first-line (1L) treatment (tx) for advanced/metastatic (a/m) gastric, gastroesophageal junction, or esophageal adenocarcinoma (GC/GEJC/EAC).

Jin Gu[1], Ravindra Gupta[1], Daniel O. Koralek[1], Aliki Taylor[1], Jaffer A. Ajani[2]

[1]Gilead Sciences, Foster City, CA,[2]Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Prior studies show racial disparities in tx access and mortality in GC/GEJC/EAC, yet the effect of race on 1L tx outcomes is unclear. We evaluated tx patterns and outcomes by race in pts who received 1L tx for GC/GEJC/EAC in the US. This retrospective, observational study used the Flatiron Health Research Database. Adults starting 1L tx between May 1, 2021, and Nov 30, 2024 for HER2-negative/unknown GC/GEJC/EAC were included. End of follow-up was May 31, 2025 to allow for ≥6 months of follow-up. Flatiron categorized self-reported race as White, Black/African American (Black), Asian, or other (multiple categories/not listed). RW overall survival (OS), time to next tx/death (TTNTD), and time to tx discontinuation (TTD) were estimated via the Kaplan-Meier method and compared between race categories. Of 2128 eligible pts, 61% were White, 8% Black, 3% Asian, 8% other, and 20% unknown race. Most were treated in community-based oncology practices (77%-79%). Median age was similar across racial groups (69 years); 25% (White), 76% (Black), and 77% (Asian) of pts had GC. Median OS (12.0 vs 13.0 months) and TTNTD (7.6 vs 6.7 months) were similar in Black vs White pts; median TTD was numerically longer in Black vs White pts (4.3 vs 2.3 months). However, the differences in clinical outcomes between Black and White pts were not statistically significant (hazard ratio [95% confidence interval]: OS, 0.97 [0.78-1.20]; TTNTD, 0.93 [0.77-1.13]; TTD, 0.92 [0.76-1.10]) after adjusting for key baseline confounders (Table). These findings underscore the potential impact of equitable 1L tx access in minimizing racial disparities in pts with HER2-negative/unknown a/m GC/GEJC/EAC. Larger studies are needed to assess the influence of disease prognosis and other variables, but this study highlights the value of RW data in advancing health equity and guiding future clinical interventions.

Table. Clinical outcomes by race[a]

Median (HR vs White; 95% CI), mo	**White (n = 1290)**	**Black/African American (n = 174)**	**Asian (n = 68)**	**Other (n = 170)**
rwOS	13.0 (Referent)	12.0 (0.97; 0.78-1.20)	16.6 (0.88; 0.60-1.27)	13.0 (0.90; 0.72-1.12)
rwTTNTD	6.7 (Referent)	7.6 (0.93; 0.77-1.13)	8.6 (0.87; 0.63-1.20)	7.4 (0.95; 0.78-1.16)
rwTTD	2.3 (Referent)	4.3 (0.92; 0.76-1.10)	5.0 (0.79; 0.59-1.07)	4.5 (0.81; 0.67-0.98)

HR, hazard ratio; mo, months; rwOS, real-world overall survival; rwTTD, real-world time to treatment discontinuation; rwTTNTD, real-world time to next treatment or death.

[a]Analysis excluded pts with unknown race.

#5414 Clinical outcomes and treatment outcomes of stage IV large cell lung cancer based on two national database analysis.

Wongi Woo[1], Seoin Kim[2], Jongwoo Kim[2], Vincent Lopez[1], Kirun Chohan[1], David Thota[1], Yeena Lee[1], Christian Wong[1], Amrut Savadkar[1], Yoonjin Cha[3], Duk Hwan Moon[4], Sungsoo Lee[4], Young Kwang Chae[5]

[1]St. Joseph's Medical Center Stockton, Stockton, CA,[2]Metrowest Medical Center, Framingham, MA,[3]Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Gangnam Severance Hospital, Seoul, Korea, Republic of,[5]Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Background: Large cell lung cancer (LCLC) is an uncommon neuroendocrine subtype of non-small cell lung cancer with limited therapeutic options and poor prognosis. Evidence regarding survival patterns in stage IV LCLC, particularly across different treatment modalities, remains scarce. This study aimed to evaluate clinical characteristics, treatment patterns, and survival outcomes using two national cohorts.

Methods: Patients with stage IV LCLC diagnosed between 2000 and 2021 were identified from the Surveillance, Epidemiology, and End Results Program (SEER) 17 registries. Eligible cases were stage IV LCLC according to the 7th or 8th TNM classification; demographic, clinicopathologic, socioeconomic, and available molecular data were collected. Kaplan-Meier analyses compared overall survival (OS) and cancer-specific survival (CSS) across treatment groups: no treatment, chemotherapy, and combined surgery plus chemotherapy. Cox proportional hazards models were used to identify independent predictors of CSS. In addition, publicly available data from the Korean National Health Insurance System (KNHIS) were analyzed to assess the impact of epidermal growth factor receptor (EGFR) mutation on survival.

Results: A total of 3,478 patients were included. In the SEER cohort, 3-year OS differed substantially by treatment modality: 2.2% with no treatment, 7.1% with chemotherapy, and 13.3% with surgery plus chemotherapy. Similar trends were observed for CSS. In multivariable analysis, age >65 years (hazard ratio (HR) 1.16 [95% confidence interval (CI) 1.08-1.25], p<0.0001), male sex (HR 1.17[95% CI 1.09-1.26], p<0.0001), and low household income (HR 1.18[95% CI 1.08-1.30], p<0.0001) were independently associated with higher cancer-related mortality. Compared with chemotherapy alone, surgery combined with chemotherapy reduced mortality (HR 0.78[95% CI 0.70-0.87], p<0.0001). Among the KNHIS cohort, EGFR mutations were detected in 303 of 666 patients (45.5%); however, the presence of EGFR mutation did not confer a significant survival benefit among patients who received chemotherapy (HR 0.821 [95% CI 0.63-1.07], p=0.146).

Conclusions: Despite the overall poor prognosis, treatment significantly influences outcomes in stage IV LCLC. Chemotherapy provides a clear survival benefit, and multimodal therapy that includes surgery offers the greatest improvement, potentially reflecting increased access to molecular testing and targeted therapy. Further investigation— including the potential benefits of tyrosine-kinase inhibitors in EGFR-mutated disease, systematic evaluation of other actionable mutations, and ongoing studies of immunotherapy after platinum-based regimens— is needed to define optimal management strategies for this rare subtype.

#5415 Association between time-dependent postoperative vitamin D levels and survival in early-onset colorectal cancer patients undergoing curative surgery: A real-world database analysis .

Yimiao Zeng[1], Bingya Ma[1], Matthew C. Coleman[2], John Y. Ha[3], Jason Zell[4], Yunxia Lu[1]

[1]Department of Population Health & Disease Prevention, Joe C. Wen School of Population &Public Health, UC-Irvine, Irvine, CA,[2]Joe C. Wen School of Population & Public Health, UC-Irvine, Irvine, CA,[3]School of Medicine, Case Western Reserve University, Cleveland, OH,[4]School of Medicine, UC-Irvine, Irvine, CA

Background: Previous studies have found high vitamin D levels are associated with improved colorectal cancer (CRC) survival. However, no reports have focused on early-onset CRC (EOCRC, CRC diagnosed before age 50), whose incidence has increased dramatically in the United States and many other countries. Moreover, previous studies rarely considered the timing of vitamin D measurements, the dynamic change in vitamin D levels, and patients' comorbidity conditions, which may confound the association.
Methods: Using the University of California Health Data Warehouse (UCHDW), an electronic health record (EHR) database encompassing data from six UC medical centers from 2012 through 2025, we initiated an EOCRC patient cohort. EOCRC patients who had no prior history of malignancy, underwent curative surgery, and had at least one vitamin D measurement after surgery were included in the study. Vitamin D level was treated as both continuous variable and categorical variable (Vitamin D deficiency: 25(OH)D < 20ng/mL; Vitamin D insufficiency: 20ng/mL ≤ 25(OH)D <30ng/mL; Vitamin D sufficiency: 25(OH)D ≥ 30ng/mL). To account for dynamic changes in vitamin D levels, postoperative vitamin D levels were treated as time-dependent variables. A time-dependent Cox regression model was performed and hazard ratio (HR) and 95% confidence intervals (CI) were estimated to measure the association between Vitamin D and EOCRC survival.
Results: We identified 424 eligible EOCRC patients, with an average follow-up time of 5.42 years. Each patient had an average of 2.68 postoperative vitamin D measurements, and 83 patients died during the follow-up period. Data was organized as person-time structure for the time-dependent cox regression model and were adjusted for age, gender, race, tumor locations, body mass index (BMI), socioeconomic status, comorbidity index, and seasons of vitamin D measurement. Patients with vitamin D sufficiency (HR 0.36, 95%CI 0.21-0.65) and insufficiency (HR 0.34, 95%CI 0.18-0.64) were associated with a better survival compared with patients with Vitamin D deficiency. When vitamin D level was treated as a continuous variable in the model, higher vitamin D levels were still associated with better overall survival (HR 0.96, 95%CI 0.94-0.99).
Conclusion: This is the first study to investigate the association between vitamin D levels and EOCRC survival using a time-dependent Cox regression model. Our results show that postoperative vitamin D non-deficiency status is associated with better survival compared to vitamin D deficiency. Our findings may provide evidence for clinical management of vitamin D levels in EOCRC patients.

#5416 Preoperative albumin is associated with unplanned readmission following soft tissue sarcoma resection.

Erin J. Kim[1], Christopher M. Liu[2], Pearce B. Haldeman[2], Michael Gedestad[3], Conner Trimm[2], James H. Flint[2], Frank Chiarappa[2]

[1]University of California, San Diego School of Medicine, La Jolla, CA,[2]Department of Orthopaedic Surgery, University of California, San Diego, La Jolla, CA,[3]Department of Plastic Surgery, University of California, San Diego, La Jolla, CA

Introduction: Treatment of soft tissue sarcomas (STS) revolves around surgical resection. Post-operative readmission is common and is associated with patient morbidity and increased healthcare costs. This study sought to identify risk factors for unplanned readmission and quantify the cost of such events.
Experimental Procedures: Extremity STS patients who underwent resection from 2018 to 2022 at a tertiary referral center were included. Demographics, comorbidities, tumor characteristics, treatment, and surgical findings were collected. Postoperative complications, readmissions, local recurrence, reoperations, and disease-specific survival were also obtained. Risk factors for readmission were evaluated via Pearson correlation testing. Binomial logistic regression modeling was subsequently utilized for variables with p-values < 0.2.
Results: Among 131 patients (mean follow-up 21 ± 10 months), overall postoperative complication rate was 36%, local recurrence rate was 9%, reoperation rate was 20%, and disease-specific survival rate was 96%. Unplanned readmission occurred in 32% of patients at a mean of 19 days after discharge (Range: 6-121). ASA class, preoperative hemoglobin, preoperative albumin, and complications during the index hospitalization were significantly associated with readmission. After multivariate analysis, preoperative serum albumin remained independently associated with unplanned readmission (OR = 0.077; 95% CI = 0.005, 0.15). Mean readmission cost was $76,605.39 (Standard Deviation: $101,981.78).
Conclusions: Unplanned readmission after STS resection is common and is associated with substantial financial burden. Low preoperative serum albumin is associated with increased readmission risk, underscoring the potential value of preoperative nutritional optimization and intervention. Studies with larger patient cohorts and additional nutritional markers are needed.

Patient Characteristics and their Associations with Unplanned Readmission

Demographics and Comorbidities		**P-value**
Age (years), Mean (SD)	61 (16)	0.92
Male, n (%)	61 (54)	0.21
BMI (kg/m^2), Mean (SD)	28 (6.4)	0.19
Diabetes Mellitus, n (%)	21 (19)	0.10

Preoperative Radiation	9 (0.98, 17.02)	0.07

#5417 Recurrence-free survival in patients with early-stage HPV-associated adenocarcinoma of the cervix stratified by Silva patterns.

Ana Lucia Rosario Santos[1], Hisham Bahmad[2], Jovanka Ravix[3], Andre Pinto[2], Navya Nair[1]

[1]Obstetrics, Gynecology, and Reproductive Sciences, University of Miami Miller School of Medicine, Miami, FL,[2]Pathology and Laboratory Medicine, University of Miami Miller School of Medicine, Miami, FL,[3]Medical Scientist Training Program, University of Miami Miller School of Medicine, Miami, FL

Background: HPV-associated adenocarcinoma of the cervix presents challenges in adjuvant treatment compared to squamous cell carcinoma of the cervix. Silva Pattern-based classification has emerged as a histomorphologic predictor supplementing the traditional Sedlis Criteria established in GOG 92. While not part of FIGO staging, it is considered in clinical guidelines, as the Silva Pattern C confers a higher risk of nodal metastasis and disease recurrence; however, its prognostic role in early-stage disease and in patients who do not meet Sedlis criteria remains less defined. We aimed to determine whether Recurrence-free survival (RFS) in patients with early-stage HPV-associated adenocarcinoma of the cervix differs between patients with Silva Pattern C and those with A/B. We hypothesize that Silva Pattern C can guide adjuvant management in patients with negative Sedlis Criteria.

Methods: We conducted a retrospective study of patients with surgically treated FIGO Stage IA-IB2 HPV-associated adenocarcinoma of the cervix. Cases were identified through our institutional pathology database under an IRB-approved protocol (2015 to 2025). Pathology specimens from cone biopsies and hysterectomies were reviewed by gynecologic pathologists. Silva patterns were assigned accordingly. Clinical data were obtained from electronic medical records. The study outcome was to determine the RFS, measured from diagnosis to recurrence or to the last follow-up. A Kaplan-Meier analysis was used to compare Silva patterns A/B vs. pattern C.

Results: Our sample consisted of 13 patients with HPV-associated adenocarcinoma of the cervix. We identified 6 patients with Silva Patterns A/B and 7 with Silva Pattern C. Three recurrences occurred exclusively in the Silva Pattern C group. RFS was 42.9% in Silva C and 100% in Silva A/B (log-rank *p*-value: 0.4142). Median follow-up was 29 months (6-108 months) for Silva Pattern C and 15 months (0-46 months) for Silva Pattern A/B. All recurrences occurred in patients with FIGO stage IA2-IB1 disease who did not meet Sedlis Criteria for adjuvant radiation. Times to recurrence were 10, 24, and 90 months.

Conclusions: Patients with Silva Pattern C experienced worse RFS. None of the patients with Silva Pattern C who recurred met Sedlis criteria for adjuvant radiation. Sedlis criteria mainly guide squamous cell carcinoma management; only 12% of GOG 92 patients had adenocarcinoma, limiting its use for this group. Our findings suggest that the Silva pattern C may provide clinically actionable prognostic information and can help guide multidisciplinary discussions regarding adjuvant management. Prospective validation of clinical algorithms incorporating Silva pattern-based classification in larger cohorts is warranted.

#5418 COVID-19 infection and impact on cancer recurrence: Comprehensive results from over 32,000 patients with breast cancer.

Shiliang Zhang[1], Eric Yang[2], Marla Lipsyc-Sharf[1], Alexis LeVee[1], Carlos Cordon-Cardo[3], Aditya Bardia[1]

[1]Department of Medicine, Division of Hematology and Oncology, UCLA Health, Los Angeles, CA,[2]UCLA College of Letters and Sciences, Los Angeles, CA,[3]Department of Pathology, Icahn School of Medicine at Mount Sinai, New York, NY

Background: The impact of COVID-19 infection on breast cancer recurrence remains poorly understood. SARS-CoV-2 infection is associated with systemic immune dysregulation, including lymphopenia, chronic inflammation, and altered interferon signaling, which may compromise tumor immune surveillance. We aimed to evaluate the association between COVID-19 infection and recurrence outcomes in patients with breast cancer.

Methods: We identified patients diagnosed with localized breast cancer between 1/1/2011 and 12/31/2024 using ICD-10 codes, excluding those with metastatic disease codes prior to or at initial diagnosis, at an academic center. COVID-19 infection was identified through diagnostic codes. Recurrence was defined by ICD codes for metastatic disease occurring after initial diagnosis, and time to recurrence was measured from first breast cancer diagnosis to first metastatic code. Sites of recurrence were determined using specific ICD-10 codes. Hazard ratios were estimated using Cox proportional hazards models. Kaplan-Meier curves were generated for time-to-event analyses, and log-rank tests were used for group comparisons.

Results: Of 32,871 eligible patients, 18,297 had tumors that were ER positive (ER+), 3,563 were ER negative (ER-), and 11,011 had unknown ER status. Median age at diagnosis was 63. Median follow-up time was 47 months. Of the entire cohort, 3325 (10.12%) developed distant or lymph node metastasis. Among 2,449 patients with COVID-19 after breast cancer diagnosis, 11.15% experienced distant recurrence and 15.35% experienced any recurrence, compared with 7.65% and 9.69%, respectively, in patients without post-diagnosis COVID-19. COVID-19 infection was associated with higher risk of any recurrence (HR 1.21; 95% CI 1.08-1.34; p<0.001). Subtype analyses showed higher risk of any recurrence associated with COVID-19 in ER+ patients (HR 1.42; p<0.001) and a trend towards higher risk in ER- patients (HR 1.18; p=0.169). Five-year invasive disease-free survival was lower in patients who had COVID-19 (85.7% vs. 88.6%; p<0.001). Bulk RNA sequencing from rapid autopsy studies demonstrated downregulation of HLA and p53 creating an immunosuppressive and pro-tumorigenic microenvironment, facilitating cancer growth and disease recurrence.

Conclusions: COVID-19 infection following breast cancer diagnosis was associated with increased risk of recurrence, particularly in patients with ER+ disease, mediated in part by downregulation of tumor suppressor and immunosurveillance-related genes. These findings underscore the need for continued clinical surveillance and mechanistic studies exploring immune recovery and tumor progression in breast cancer survivors affected by COVID-19.

#5419 Persistent opioid use during long-term lung cancer survivorship: When did it start?.

Ziwei Zhu[1], Yiye Zhang[1], Hao Zhang[2], Rulla Tamimi[1], Yuhua Bao[1]

[1]Weill Cornell Medicine, New York, NY,[2]University of Alabama at Birmingham, Birmingham, AL

Introduction: Lung cancer survivors had a high rate of long-term opioid use. Prolonged opioid use was associated with reduced survival and increased recurrence. It is unknown to what extent opioids initiated during cancer treatment accounted for long-term use. This study aims to characterize the patterns of opioid use in the first year of lung cancer long-term survivorship (LTS) and the history of opioid prescriptions (Rxs) by such patterns.

Method: We used the 2010-19 SEER-Medicare linked data to identify a sample of lung cancer survivors enrolled in traditional Medicare Parts A&B and Part D for ≥84 months - 12 months before and 72 months after (including) the month of lung cancer diagnosis, who had ≥1 opioid Rx during the first year of LTS (months 61-72 post diagnosis). We constructed a sequence of daily opioid possession status (0/1) for each patient over the first year of LTS. We applied agglomerative hierarchical clustering to identify groups with distinct patterns. For each patient over the 84 months, we identified the earliest opioid Rx observed, earliest opioid episode that was ≥30 days, and earliest episode that was ≥90 days, if any. Episodes were defined based on filling date and days of supply of consecutive opioid Rxs; a gap of ≥30 days ends the episode.

Results: 1,176 survivors were identified with ≥1 opioid Rxs in the first year of LTS. Clustering identified three groups: “persistent use” (N=301, 26%), “intermittent use” (N=176, 15%), and “sporadic use” (N=699, 60%), with median days of opioid possession of 343, 168, and 10, respectively. More than 90% of the persistent-use group had their first opioid Rx before lung cancer diagnosis. There was a sharp gradient across the 3 groups in percentage with first 30- or 90- day episode before cancer diagnosis (Table).

Conclusions: An overwhelming proportion of survivors with persistent or intermittent opioid Rxs during first year of LTS started opioid therapies and, to a less extent, long-term opioid therapies, prior to lung cancer diagnosis.

Earliest opioid prescription and long-term episodes observed across three groups of survivors

	Persistent Use (N = 301)	**Intermittent Use (N = 176)**	**Sporadic Use (N = 699)**
Earliest Opioid Prescription Observed			
12 months before diagnosis	276 (92%)	144 (82%)	463 (66%)
Months 1 - 12 after diagnosis	20 (6.5%)	28 (16%)	188 (27%)
Months 13-60 after diagnosis	5 (1.7%)	4 (2.3%)	32 (4.6%)
Months 61-72 after diagnosis	0 (0%)	0 (0%)	16 (2.3%)
Never	N/A	N/A	N/A
Earliest 30-Day Opioid Episode Observed			
12 months before diagnosis	250 (83%)	114 (65%)	220 (31%)
Months 1 - 12 after diagnosis	36 (12%)	37 (21%)	163 (23%)
Months 13-60 after diagnosis	14 (4.7%)	19 (11%)	85 (12%)
Months 61-72 after diagnosis	1 (0.33%)	6 (3.4%)	58 (8.3%)
Never	0 (0%)	0 (0%)	173 (25%)
Earliest 90-Day Opioid Episode Observed			
12 months before diagnosis	226 (75%)	79 (45%)	104 (15%)
Months 1 - 12 after diagnosis	34 (11%)	28 (16%)	49 (7.0%)
Months 13-60 after diagnosis	38 (13%)	43 (24%)	58 (8.3%)
Months 61-72 after diagnosis	3 (1.0%)	15 (8.5%)	33 (4.8%)
Never	0 (0%)	11 (6.3%)	455 (65%)

#5420 Identifying dynamic subtypes of cancer cachexia using longitudinal clinical lab values.

Jamie Wang[1], Ed Reznik[2], Wesley Tansey[2]

[1]Physiology, Biophysics & Systems Biology, Weill Cornell Medicine, New York, NY,[2]Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Cancer cachexia is a wasting syndrome estimated to affect roughly 50% of all cancer patients and is most commonly identified using a simple weight loss criterion. The heterogeneity in plausible cachexia weight loss mechanisms, along with their potential to evolve over time, suggests the existence of distinct, dynamic subtypes of cachexia. Clinical lab values are frequently measured and, although they do not grant direct mechanistic insight, they provide rich temporal information about patient latent states. In a cohort of lung adenocarcinoma patients from Memorial Sloan Kettering Cancer Center, we clustered 1,630 cachectic episodes using 28 longitudinally measured clinical lab values and body mass index. Clustering was performed using K-means with Dynamic Time Warping Barycenter Averaging to handle trajectories with varying lengths. We identified 4 major clusters with differentiating patterns including a group with relatively higher red cell distribution width and relatively lower mean corpuscular volume and mean corpuscular hemoglobin. Another cluster had lab values that are more consistent with normal ranges, indicating a possible non-cachectic group of weight loss patients. This study demonstrates the potential of longitudinal clinical lab values for stratifying cachexia patients and identifying intervention points in patient care that can improve outcomes.

#5421 Determining the benefit of comprehensive molecular testing in advanced cancers: BostonGene and Exigent Genomic INsight (BEGIN) study.

Sibel Blau[1], Katherine Sanchez[2], Eric Schaefer[3], Julio A. Peguero[4], Paul Zito[5], Dheeraj Kodali[6], Artem Tarasov[7], Rheanna Carter[7], Kayla Hendricks[7], Anna Love[7], Lile Kontselidze[7], Polina Turova[7], Viktor Smirnov[7], Anna Ogloblina[7], Konstantin Rumyantsev[7], Neeharika Makani[7], Alexander Bagaev[7], Nathan Fowler[7]

[1]Northwest Medical Specialties, Seattle, WA,[2]New Mexico Cancer Center, Albuquerque, NM,[3]Highland Oncology Group, Rogers, AR,[4]Oncology Consultants, Houston, TX,[5]Oklahoma Cancer Specialists and Research Institute, Tulsa, OK,[6]Stockton Hematology Oncology Medical Group, Stockton, CA,[7]BostonGene Corporation, Waltham, MA

Introduction: Growing evidence suggests that comprehensive genomic and molecular testing has the potential to enable more precise, effective, and individualized cancer care. However, outside of trials, testing is inconsistent, and adoption into practice is limited. The BostonGene and Exigent Genomic INsight Study (BEGIN; NCT06272864) is an ongoing, prospective, multi-site study evaluating the clinical utility and actionability of integrated DNA/RNA comprehensive genomic profiling (CGP) in community settings. Using the multimodal Tumor Portrait test, CLIA-certified whole-exome sequencing (WES), whole-transcriptome RNA-seq, and tumor microenvironment (TME) subtyping were performed in pts. with advanced tumors.

Methods: We consented and prospectively enrolled adult pts. with advanced breast cancer, non-small cell lung cancer (NSCLC), melanoma, or sarcoma at six community practice sites within the Exigent Research Network. All pts. underwent WES, RNA-seq, and TME profiling using the Tumor Portrait test. Actionable findings were defined by links to FDA-approved or NCCN®-recommended therapies or eligibility for biomarker-matched clinical trials. RNA-seq expression of targetable molecules (e.g., *ERBB2* [HER2], *CD274* [PD-L1]) was also classified as actionable. Absence of driver mutations were not reported. Demographics, prior therapy, treatment decisions, and clinical outcomes were collected at 6 and 12 mos.

Results: We analyzed 156 pts. (breast, n = 87; NSCLC, n = 41; melanoma, n = 21; sarcoma, n = 7) with ≥6 mos. of follow-up after report delivery. The median turn around time for comprehensive testing was 8 business days. Out of 221 screened pts., the sample failure rate was 14.4% (32/221). Actionable findings were identified in 93% of pts. (145/156), with ~10% (15/145) attributable to RNA-seq and missed by DNA-only testing. Actionable finding rates by tumor type were: breast, 95.4%; NSCLC, 87.8%; melanoma, 95.2%; and sarcoma, 71.4%. At least one NCCN®/FDA-linked CGP biomarker was identified in 71 of 156 pts. (45.5%). Post-testing follow-up was available for 138 pts.; median follow-up was 6 mos., with 68/156 (43.5%) at ≥12 mos. RNA or DNA findings directly informed or altered the clinical course through the initiation of genomically matched systemic therapy and/or referral to biomarker-selected trials in 10% of pts.

Conclusions: Integrated DNA/RNA CGP identified actionable findings in 93% of pts., with 10% of actionable findings being identified by RNA expression that were missed by DNA testing. This study demonstrates the clinical utility of combined exome-transcriptome profiling for precision oncology in community practice, which directly impacts patients' therapeutic options. Continued follow-up with BEGIN will assess the impact on patient-related outcomes, including progression-free and overall survival, as well as clinical trial accrual.

#5422 Turnaround time between NSCLC diagnosis to genomic testing using reflexive next generation sequencing.

Sahar Forootan Sedigh[1], Sydney F. Denney[1], Katharine Thomas, MD[2]

[1]University of Nevada School of Medicine, Reno, NV,[2]Renown Regional Medical Center, Reno, NV

Background: Lung cancer is the leading cause of cancer mortality in both men and women in the United States, accounting for 1 in 5 of all cancer deaths. Identifying driver mutations in lung cancer allows clinicians to choose targeted therapies, offering higher response rates and fewer adverse effects. Timeliness to treatment of non-small cell lung cancer (NSCLC), which contributes approximately 87% of lung cancer cases, is expected to improve outcomes by facilitating biomarker-directed treatment in the first-line setting. In this study, we evaluated and compared the turnaround time (TAT) between NSCLC diagnosis and genomic result reporting before and after the initiation of reflexive next generation sequence (NGS) testing.
Methods: A single institution retrospective study was conducted using time zero as the specimen collection date from biopsy/surgical resection to NGS report release date before (N=23) and after (N=26) the implementation of reflexive NGS testing. Reflexive NGS testing was defined as an institutional policy in which a pathologist automatically ordered NGS testing during diagnostic biopsy reporting. Prior to this policy, the NGS testing was ordered at the discretion of the treating oncologist. We used FoundationOne companion diagnostic (CDx), an NGS diagnostic test, to identify tumor mutation profiles to detect biomarkers with FDA-approved targeted therapies. TAT in pre- and post-reflexive cohorts was compared using a two-sample t-test.
Results: A total of 49 patients were included, 23 patients before and 26 patients after reflexive testing. The mean TAT from specimen collection to NGS report release date decreased from 31.8 days pre-reflexive to 18.9 days (40.6% reduction, $p = 0.001$) after implementation of reflexive testing. Median TAT decreased from 31 to 17 days. The range narrowed from 49 to 27 days and standard deviation of TAT decreased from 15 to 6.5 days, indicating a more consistent TAT post-reflexive testing. Evaluating TAT from specimen collection date to order date, the mean TAT decreased from 18.3 days pre-reflexive to 5.53 days (69.8% reduction, $p = 0.0001$) post-reflexive testing with median TAT decreasing from 15 to 4 days and the range decreasing from 48 to 23 days. The standard deviation of TAT also decreased from 13 to 5 days, showing a more consistent TAT after implementation of reflexive NGS testing.
Conclusion: Reflexive NGS testing significantly reduced both ordering time by 69.8% and reporting time by 40.6%. These findings highlight the substantial improvement in diagnostic efficiency and workflow. The reduction in TAT will allow for an earlier initiation of targeted therapies in patients with NSCLC. Future studies will investigate the clinical benefit of reflexive NGS testing in reducing hospitalizations, time to treatment initiation, and improved patient outcomes.

#5423 A Bayesian framework for evaluating somatic copy number variants into comparative genomic analysis of multifocal non-small cell lung cancer.

Claire Teigen, Ying-Chun Lo, Sounak Gupta, Stephanie Smoley, Beth Pitel, Hussam Al Kateb, Gopi Sivasankaran, Benjamin Kipp, Ande Rumilla, Gang Zheng, Kevin Halling, Katherine Geiersbach

Mayo Clinic, Rochester, MN

Introduction: Clinical staging of multifocal non-small cell lung cancer (NSCLC) is facilitated by comparative genomic analysis of separate tumor nodules, but the role of genome-wide copy number profiling for this purpose is uncertain.
Methods: We analyzed single nucleotide variants (SNVs), gene fusions, small copy number variants (gene amplifications and homozygous deletions) (sCNVs), and large-scale copy number variants (lCNVs) in a retrospective cohort of 34 patients with >1 lung cancer nodule tested on a previously validated tumor-only 515-gene next generation sequencing (NGS) panel (MayoComplete Solid Tumor Panel). For patients with <2 shared SNVs, a Bayesian approach was formulated to calculate the probability of shared versus independent events occurring in different tumor nodules in the same patient. The prevalence of specific lCNVs in NSCLC was derived from an independent dataset of 100 NSCLC peers tested by the same panel, and the prevalence of SNVs, fusions, and sCNVs in NSCLC was derived from publicly available data. Alterations unique to different tumor nodules and suspected germline alterations were excluded from the Bayesian analysis.
Results: There were 54 total comparisons for 34 patients. Eleven of the patients (32.4%) had >=2 shared SNVs along with one or more shared lCNVs also identified in each patient. Eight patients (23.5%) had no shared SNVs, gene fusions, sCNVs, or lCNVs. Using the Bayesian approach for the remaining fifteen (44.1%) patients with at least one shared alteration (SNVs, sCNVs, and lCNVs), the probability of clonal relatedness ranged from 73% for a shared whole arm or whole chromosome lCNV to >99% for tumors with two or more shared alterations including multiple or complex lCNVs and SNVs. Whole chromosome or whole arm lCNVs were sometimes shared between tumor nodules with different driver SNVs.
Conclusions: Incorporating lCNVs into comparative genomic analysis provides additional evidence of clonal relatedness in a subset of multifocal NSCLCs. However, differences in bioinformatics pipelines for calling lCNVs, concerns over the imprecision of genome-wide copy number profiling, and uncertainty regarding the temporal relationship between lCNVs and carcinogenesis (including somatic events possibly related to “field cancerization”) create challenges for integrating lCNVs into comparative genomic analysis with standard clinical workflows for tumor-only NGS on paraffin embedded tissue sections. Our simplified approach mitigates some of the uncertainty introduced by incorporating lCNVs into clonality determination.

#5424 Detection of rare oncogenic fusions through concurrent DNA and RNA next-generation sequencing in a pan-cancer clinical setting.

Lisa Gai[1], Molly Murnane[1], Malvika Pillai[1], Matthew Campbell[1], Bradley Bowles[1], Kyle A. Beauchamp[1], Rotem Ben-Shachar[2], Gregory Omerza[1], Razelle Kurzrock[3], Nathan David Seligson[4], Halla S. Nimeiri[1], Justin Guinney[1]

[1]Tempus AI, Inc, Chicago, IL,[2]GeneDX, Stamford, CT,[3]Medical College of Wisconsin, Milwaukee, WI,[4]Department of Pharmacotherapy and Translational Research, University of Florida, Jacksonville, FL

Background: Concurrent DNA and RNA testing is the gold standard for detection of oncogenic gene fusions with an associated targeted therapy. However, rare fusions without such therapies can also impact patient care by informing diagnosis, prognosis, or potential resistance to therapy. Targeted panel DNA assays are typically optimized for a small number of fusion genes, making use of RNA testing particularly salient for rare fusions. Here we quantify the benefit of concurrent DNA and RNA testing over DNA alone for such fusions, in a large real-world dataset of 74,182 patients with advanced cancer.

Methods: We retrospectively analyzed deidentified records from the Tempus multimodal database of metastatic solid tumor samples from non-pediatric patients who underwent testing with both targeted panel DNA-next generation sequencing (NGS) and whole-exome RNA-NGS assays (Tempus xT and xR, respectively). Fusions both on and off the xT panel without an associated targeted therapy were considered for the study. Fusions were identified through the Tempus bioinformatic workflow, which runs RNA-NGS and DNA-NGS pipelines concurrently, followed by pathologist review.

Results: Of the 74,182 patients in the cohort, 4,776 (6.4%) had at least one oncogenic fusion without an FDA-approved targeted therapy, with a total of 4,845 such fusions in the dataset. Of these fusions, 85.0% (4,119/4,845) involved genes present on the xT panel, with 56.6% (2,744) involving genes optimized for detecting rearrangements on the xT panel. Across all fusions in the study, 2,561 (52.9%) were detected by RNA-NGS only. For rare fusions involving genes on the xT panel and those with optimized detection in xT, 44.7% (1,841/4,119) and 23.9% (656/3,744) were detected in RNA only, respectively.

The most common fusions in this dataset were TMPRSS2-ERG (n=2,247) with 23.4% detected only in RNA. RNA-only detection rates were particularly high for ESR1-CCDC170 (211/213, 99.1%) and PTPRK-RSPO3 (280/280, 100%). TMPRSS2 is optimized for fusion detection by xT, ESR1 is on xT but not targeted for rearrangements, and PTPRK- RSPO3 does not appear on xT.

Conclusions: We show that RNA testing greatly enhances detection of rare fusions without an associated FDA-approved targeted therapy in a real-world setting. This benefit of RNA testing is most apparent for fusions not on a DNA-NGS targeted panel, but fusions targeted on the xT panel also showed increased detection with concurrent RNA testing. Among the fusions with high rates of RNA-only detection, ESR1-CCDC170 is associated with more aggressive ER+ breast cancers, and PTPRK-RSPO3 may modulate WNT signaling in colorectal cancer. Other clinically relevant fusions also showed enhanced detection from RNA-NGS. Overall, these findings suggest RNA testing could enhance detection of rare oncogenic fusions to better inform patient care.

#5425 Clinical and genomic characterization of biliary tract tumors (BTT) with ARID1A mutations: A case-control study.

Giulia Massaro[1], Manuel Pedegral[2], Diana Rosero[1], Brezo Martinez Amores[3], Ester Garcia[4], Eva Ruiz Hispan[1], Miriam Dorta[4], Diego Casado[5], Carlos Garzon[6], Bernard Gaston Doger de Speville[4], Raquel Fuentes[1], Victor Moreno Garcia[7], **Angela Lamarca**[8]

[1]Fundacion Jimenez Diaz University Hospital, Madrid, Spain,[2]START-Madrid; Fundacion Jimenez Diaz University Hopsital, Madrid, Spain,[3]Rey Juan Carlos University Hospital, Madrid, Spain,[4]START-Madrid; Fundacion Jimenez Diaz University Hospital, Madrid, Spain,[5]General de Villalba University Hospital, Madrid, Spain,[6]Infanta Elena University Hospital, Madrid, Spain,[7]START Madrid; Fundacion Jimenez Diaz University Hospital; Health Research Institute-Fundacion Jimenez Diaz University Hospital (IIS-FJD), Madrid, Spain,[8]Fundacion Jimenez Diaz University Hospital; Health Research Institute-Fundacion Jimenez Diaz University Hospital (IIS-FJD), Madrid, Spain

Introduction: ARID1A is a tumor suppressor gene involved in chromatin remodeling and is commonly mutated across several cancer types. In biliary tract cancer (BTC), the clinical and genomic landscape of ARID1A mutations remains poorly defined. This study aims to characterize the demographic, clinical, and molecular features of patients (pts) with ARID1A-mutated (ARID1A-mut) BTC compared with a control cohort harboring wild-type (ARID1A-wt) ARID1A.

Methods: From a consecutive retrospective cohort of 146 pts with molecularly profiled BTC, 14 (9.6%) exhibited pathogenic ARID1A mutations. Of these, 13 (8.9%) with available clinical data were compared to a randomly selected group of 13 ARID1A-wt controls. The study was approved by the local ethics committeee.

Resuls Out of 146 patients screened, total of 27 were found eligible: 14 ARID1A-mut and 13 ARID1A-wt. ARID1A-mut pts (vs ARID1A-wt) were predominantly female (77% vs 46%; p=0.23). Median age was 64 years. Primary tumor distribution was intrahepatic (76.9%), hilar (15.4%), and gallbladder (7.7%) (p=1). Disease stage at diagnosis, performance status, and first-line (1L) treatment regimens were comparable across both cohorts. ARID1A-mut pts showed a trend toward higher partial response (PR) rates to 1L therapy (53.9% vs 30.1%; p=0.43). Median progression-free survival (PFS) on 1L treatment was similar (11.4 vs 9.3 months; HR 0.67, 95% CI 0.29-1.57; p=0.36), as was overall survival (OS) (21.4 vs 22.5 months; HR 1.47, 95% CI 0.51-4.28; p=0.48). Genomic profiling revealed a distinct co-alteration pattern: BAP1 (28.6% vs 0%; p=0.09), IDH1 (21.4% vs 0%; p=0.22), and PBRM1 (28.6% vs 7.7%; p=0.33) were more frequent in ARID1A-mut pts, whereas TP53 (38.5% vs 28.6%; p=0.69), KRAS (30.8% vs 16.7%; p=0.38), and DNMT3A (23.1% vs 0%; p=0.09) predominated in the ARID1A-WT cohort.

Conclusion: BTC with ARID1A mutations represents a distinct molecular subgroup characterized by a trend toward improved partial response and enrichment in epigenetic co-alterations. Prospective validation is warranted to assess the prognostic and therapeutic implications. Targeted therapeutic strategies against ARID1A in BTC should be further explored in early-phase (I/II) clinical trials.

#5426 Anatomic origins of primary skeletal tumors effect metastatic and prognostic behaviors.

Matthew Duazo, Aayush Bhatawadekar, Dillon Pekoff, Maria Plummer, Brian Beatty

NYIT College Of Osteopathic Med (NYITCOM), Old Westbury, NY

Introduction:
This study investigates the histology of nonmetastatic primary skeletal tumors related to their anatomic origin and its influence on 5-year survival outcomes.
Methodology:
Deidentified patient data were obtained from the National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) database. Inclusion criteria included: (1) diagnosis of a primary bone cancer with anatomical location of origin, classified using ICD-O-3 anatomic site codes; (2) documented absence of metastasis to the brain, lung, liver, or bone; (3) cause-specific death and survival duration; and (4) available histology codes. Patients were stratified by primary tumor location and histologic sub-type. Kaplan-Meier survival curves were used to estimate survival, and group differences were assessed with pairwise log-rank tests. A p-value <0.05 was considered statistically significant.
Results:
The top five most common nonmetastatic skeletal tumors by histology are Chondrosarcoma, Osteosarcoma, Chondroma, Ewing Sarcoma, and Diffuse Large B-Cell Lymphoma (DLBCL). The tumor location distribution and 5-year survival for each histological subclass are outlined in Table 1.
Conclusion:
The differences in anatomic origin of primary bone tumors when controlled for histologic category influences patient mortality. There are distinct differences in overall survival compared among origin sites, signifying a location-based influence on disease severity and survival. The knowledge of anatomic origin differences of survival of various histologic categories of bone cancer can improve clinical decision making and create more accurate, locational based planning when looking at prognosis and disease progression.

#5427 Weekend radiotherapy for oncologic emergencies: A single-institution analysis of indications and practice patterns.

Ahmed Allibhai, Asiyah Allibhai

Holy Trinity School, Richmond Hill, ON, Canada

Purpose: Oncologic complications can arise that require emergency radiotherapy (RT) outside of standard working hours. This study documents the incidence, indications, RT dose/fractionation and outcomes for patients receiving RT on weekends/scheduled holidays at a single institution.
Methods: Patients receiving RT on weekends (Saturday, Sunday, or long weekend holidays) from January 2022 through December 2024 were identified retrospectively. Patient demographics, primary cancer diagnosis, clinical indication, treatment site, dose/fractionation, inpatient status, treatment completion, and survival were collected and analyzed.
Results: Over three years, 122 patients received emergency weekend RT. Median age was 67 years (39-98); 63.1% male, 66.4% inpatients. Patients most commonly presented with lung (25.4%), gastrointestinal (23.8%), and hematologic (18.0%) malignancies. The top three indications for emergency weekend RT included spinal cord compression (38.9%), GI bleeding (20.7%), or obstructive airway/lung disease (7.6%). The most common RT regimen was 20 Gy in 5 fractions (80.3%), with most patients receiving two days of treatment (54.1%). Six patients (4.9%) did not complete their course of treatment owing to clinical deterioration. One-month mortality was 13.1% and three-month mortality was 36.9%.
Conclusions: Weekend RT is predominantly used to manage well-identified oncologic emergencies such as spinal cord compression and tumor-related bleeding. The high inpatient proportion and substantial short-term mortality reflect advanced disease burden requiring urgent intervention. These findings demonstrate the importance and incidence of weekend radiotherapy services and provide evidence to help inform staffing & resource allocation as well as institutional policies.

#5428 Impact of double primary cancer on survival in patients with non-small cell lung cancer: Large-scale cohort.

Hyun Ae Jung[1], Sang Ah Chi[1], Allison Park[2], Sehhoon Park[1], Jong-Mu Sun[1], Se-Hoon Lee[1], Jin Seok Ahn[1], Myung-Ju Ahn[1], Kyunga Kim[1]

[1]Samsung Medical Center, Seoul, Korea, Republic of,[2]Cornell University, Boston, MA

Background: Although survival outcomes for non-small cell lung cancer (NSCLC) have improved with advances in treatment, the increasing number of long-term survivors has brought greater attention to double primary cancers (DPCs). This study aimed to evaluate the frequency and distribution of double primary cancers (DPC) in patients with NSCLC and to assess their impact on survival outcomes.

Methods: This study evaluated clinical variables of patients diagnosed with NSCLC between 2008 and 2024. The types of DPCs were identified, and the impact of DPC occurrence and timing on the survival outcomes of NSCLC was analyzed. To minimize the influence of lead-time bias, this study applied Cox regression models incorporating time-varying covariates. Multivariable analyses were then performed to evaluate the prognostic impact of DPC timing on survival, adjusting for age, smoking status, stage, histology, DPC duration, multiple primary cancer status, and the presence of EGFR mutations or ALK rearrangements.

Results: Among a total of 34,593 patients diagnosed with NSCLC, 4,339 (12.5%) were identified as having DPC, and 455 (1.3%) had multiple primary cancers (MPCs) involving three or more malignancies. Among the total 34,593 patients with NSCLC, DPC was identified before NSCLC in 2,345 patients (6.8%), concurrently in 1,039 (3.0%), and after NSCLC diagnosis in 1,155 (3.3%). The incidence of DPC was slightly higher in males (12.9%) than in females (12.0%) and showed an inverse association with NSCLC stage—occurring in 17.8%, 13.0%, 9.4%, and 6.4% of patients with stage I, II, III, and IV disease, respectively. In males, the most frequent DPCs were gastric cancer (2.7%), colorectal cancer (2.1%), prostate cancer (2.1%), and liver cancer (1.0%). Among 32,170 patients after excluding those with post-NSCLC DPC, pre-existing DPC was associated with worse survival compared with no DPC (adjusted HR = 1.146, $P = 0.0018$). However, DPC diagnosed more than 5 years before NSCLC showed no significant effect on survival (adjusted HR = 1.094, $P = 0.1965$), whereas DPC within 5 years conferred poorer outcomes (adjusted HR = 1.180, $P = 0.0018$).

In a time-varying Cox model including 31,827 patients with concurrent or post-NSCLC DPC, the development of DPC after NSCLC remained independently associated with worse survival (adjusted HR = 1.377, $P < 0.0001$).

Conclusions: DPC diagnosed more than 5 years before NSCLC had no impact on survival, whereas DPC occurring within 5 years before or after NSCLC was independently associated with worse outcomes. These findings underscore the importance of increased vigilance and individualized management strategies for NSCLC patients with recent or subsequent DPCs, particularly in an era of improving long-term survival.

#5429 REAL-AML: Real-world predictors of early mortality and treatment inequities in acute myeloid leukemia across a multi-institutional U.S. cohort.

Randa Elzein[1], Safa Elzein[2]

[1]Medicine, SUNY Upstate Medical University, Syracuse, NY,[2]Hematology Oncology, SUNY Upstate Medical University, Syracuse, NY

Despite therapeutic advances, early mortality (<60 days) in newly diagnosed acute myeloid leukemia (AML) remains 15-25% in routine care, particularly among older and socioeconomically vulnerable patients. Randomized trials under-represent these groups, limiting generalizability. We conducted a multi-institutional, equity-focused analysis to identify modifiable determinants of early mortality and propose operational benchmarks for quality improvement.Adults (≥18 y) with newly diagnosed AML between 2016-2024 were identified from a federated, de-identified electronic-health-record network encompassing >35 U.S. health systems. Primary endpoint: 60-day mortality from diagnosis. Predictors included demographics, comorbidities, insurance type, urban/rural residence, facility type, cytogenetic risk, and receipt/timing of induction chemotherapy or hypomethylating-agent (HMA) regimens. Multilevel logistic regression with site random effects estimated adjusted odds ratios (aORs). Fairness analysis evaluated subgroup calibration by race, sex, and payer. Interrupted time-series modeling assessed 2020-2024 adoption of targeted agents (FLT3, IDH1/2 inhibitors). Only aggregate outputs were analyzed.Among 7,842 patients (median age 66; 47% female; 22% Black or Hispanic; 28% Medicaid/uninsured), overall 60-day mortality was 19.4% (95% CI 18.5-20.3). Independent predictors: age >70 y (aOR 2.43, 2.10-2.82), Medicaid/uninsured (aOR 1.54, 1.30-1.83), diagnosis at non-academic centers (aOR 1.39, 1.21-1.59), ECOG ≥2 (aOR 1.71, 1.50-1.95), and treatment initiation >5 days after diagnosis (aOR 1.46, 1.28-1.67). Adoption of targeted agents increased from 6% (2018) to 29% (2024), corresponding with a 5.1-point mortality reduction (p=0.003). Fairness analysis showed minimal calibration drift (ΔBrier <0.005) across demographic subgroups. Scenario modeling suggested that reducing treatment delays to ≤3 days could lower early mortality by ≈2.7% absolute (14% relative) nationwide.REAL-AML defines pragmatic, measurable drivers of early mortality in AML and identifies actionable levers-timely induction, equitable access to targeted agents, and improved insurance continuity-that could yield substantial survival benefit. This is the largest multi-system, equity-audited AML outcomes study to date and provides a template for real-world precision-implementation trials in hematologic malignancies.

#5430 Allostatic load connects tumor genomics, disease trajectory, and pre-diagnosis wearable activity.

Christopher J. Fong[1], Kaicheng U[1], Cheryl Phua[1], Xuechun Bai[1], Karl Pichotta[1], Kathryn Tsai[2], Anzhi Chen[1], Meixuan Zhang[1], Jie Yu[1], Whitney Underwood[1], Chenlian Fu[1], Michele Waters[1], Sanna Goyert[3], Adam Schoenfeld[1], Nikolaus Schultz[1], Justin Jee[1], Jessica Scott[1], Luke Pike[1], Jian Carrot-Zhang[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]University of Illinois, Champaign, IL,[3]CUNY School of Medicine City College of New York, New York, NY

Background: Allostatic load (AL), a composite index of physiological stress from routine labs and vitals, reflects multisystem strain and predicts survival in cancer. Building on prior validation of cancer-modulated AL (cmAL), we examined how cmAL varies across disease states, relates to tumor genomics, and aligns with wearable-measured activity before diagnosis.
Methods: We analyzed 12,689 adults treated at MSK with pre-treatment labs and vitals across NSCLC, colorectal, prostate, ovarian, breast, pancreatic, endometrial, and bladder cancers. cmAL was computed from ten cardiovascular, metabolic, renal, and immune biomarkers and compared across disease phases using rank-sum tests with multiple-testing correction. Per-cancer-type genomic models used multivariable logistic regression relating cmAL to recurrent oncogenic alterations while adjusting for clinical covariates and comorbidity burden. Wearable activity was evaluated in 77 MSK patients (Apple HealthKit) and 1,867 All of Us participants (Fitbit) using median daily step counts across cmAL levels, Spearman correlation, and continuous trend tests. Pre-diagnosis steps were summarized using a 90-day window before first cancer diagnosis.
Results: cmAL decreased during remission (median change -0.42, $p<0.001$) and increased with progression (median change +0.61, $p<0.001$), with the highest values observed within six months of death ($p<1\times10^{-40}$). Higher cmAL correlated with cardiometabolic comorbidity (diabetes OR=0.74; renal OR=0.54). In NSCLC, higher cmAL was less common in patients with EGFR mutations and more common in those with KRAS mutations. Across both wearable datasets, higher cmAL was linked to lower pre-diagnosis activity. In the MSK cohort, median daily steps declined from 4,914 at (cmAL=1) to 1,092 at (cmAL=5) (Spearman $\rho=-0.388$, $p=0.0005$). In All of Us, median steps declined from 6,276 (cmAL=1) to 4,091 (cmAL=5) ($\rho=-0.248$, $p<0.0001$), demonstrating reproducibility in a population cohort.
Conclusions: cmAL increases with disease progression and quantifies cumulative physiologic strain across body systems. Elevated cmAL is associated with specific genomic patterns in NSCLC, greater comorbidity burden, and lower pre-diagnosis step counts in both institutional and population cohorts. These findings support cmAL as a scalable and potentially modifiable biomarker integrating molecular, physiologic, and behavioral domains in real-world cancer survivorship.

#5434 Immune cell infiltration analysis of lung cancer based on proteomics.

Ruoxian Zhang[1], Liangcheng Lyu[2]

[1]Fudan University, Shanghai, China,[2]Peking University, beijing, China

Lung cancer remains a leading cause of cancer-related mortality, accounting for nearly one-quarter of all cancer deaths. Its initiation, progression, and metastasis are tightly influenced by the tumor microenvironment, within which diverse immune cell populations play critical roles. Quantifying tumor-infiltrating immune cells is therefore essential for understanding lung cancer biology and improving therapeutic strategies. While numerous computational methods have been developed for immune infiltration analysis based on transcriptomic data, algorithms optimized for proteomics data are largely unavailable, and the applicability of existing transcriptome-based tools to proteomic datasets remains unclear.In this study, we developed a deconvolution-based algorithm tailored for proteomics data to quantify tumor-infiltrating immune cells in lung cancer. Using a support vector regression model constructed from an immune signature matrix, we decomposed tumor tissue proteomics profiles into proportions of distinct immune cell types. Application of this algorithm to lung cancer proteomics datasets revealed that MO non-classical cells, NK cells, and T4-EMRA cells exhibited the highest infiltration levels. Integrating proteomics and clinical data, we further performed NMF-based subtyping and identified two immune-associated subtypes. Cluster 1, characterized by poorer prognosis, showed significant enrichment in complement cascade signaling, IGF transport and uptake regulation, and post-translational protein phosphorylation pathways. Additionally, NK cells and several $CD4^+$ T-cell subsets were more abundant in Cluster 1 than in Cluster 2, indicating stronger immune infiltration and elevated immune activity, potentially contributing to adverse clinical outcomes.These findings provide a proteomics-based framework for immune infiltration analysis and offer new insights into lung cancer molecular subtyping and precision oncology.

#5436 Spatial identification of hypoxic and normoxic dormancy hotspots predicting in her2-positive and metastatic breast cancer.

Tzu-Hung Hsiao[1], Fan Jhen Liu[2], Yu-Ting Kang[1], Kuo Yen Huang[2], Yidong Chen[3]

[1]Department of Medical Research, Taichung Veterans General Hospital, Taichung City, Taiwan,[2]Graduate School of Advanced Technology, National Taiwan University, Taipei City, Taiwan,[3]Greehey Children's Cancer Research Institute, UT Health San Antonio, San Antonio, TX

One of the major clinical challenges in breast cancer is overcoming therapeutic resistance and metastatic relapse. Such relapses are often driven by residual tumor cells that resist therapy by entering a dormant, non-proliferative state and later reawaken after variable latent periods. In this study, we applied spatial transcriptomics-Visium HD platform to a HER2-positive breast tumor sample from a patient who developed brain metastasis one year after treatment. By integrating dormancy-associated transcriptional programs with spatial colocalization, we aimed to predict cells with dormancy potential. We curated eight dormancy-related genes to construct a DormancyScore and intersected it with G0/G1 cell-cycle arrest signatures to identify dormancy-like cells. Kernel density estimation (KDE) and Ripley's K were used to quantify spatial aggregation and define dormancy hotspots. Using Intersection-over-Union (IoU) to evaluate the overlap between dormancy hotspots and HALLMARK pathway hotspots, we observed substantial colocalization with hypoxia. To further dissect the role of oxygenation in maintaining dormancy, hotspots were stratified into hypoxic dormancy hotspots (HDH) and normoxic dormancy hotspots (NDH). HDH exhibited enriched response to stress, defense, and inflammatory programs, accompanied by surrounding stromal accumulation of ECM-remodeling CAFs and TAMs. In contrast, NDH were enriched for oxidative phosphorylation, ATP synthesis, and biosynthetic processes, reflecting a distinct functional state under normoxia. This study lays the foundation for expanded cohort analyses to determine whether dormancy cells arising from different oxygenation states are associated with varying risks or timing of breast cancer metastasis, and to further evaluate the robustness of density-based and colocalization-based approaches for detecting dormant tumor cells.

#5437 Sensitive detection of rare cfDNA variants utilizing molecular technologies and a novel informatics platform: A combined genomic and proteomic MRD application.

Emma Kaitlyn Longshore[1], Ethan Barnett[2], Ingrid T. Erazo[2], Leisa Jackson[1], Helen Halpin[1], Reis Pestano[1], Patricia Schnepp[3], Adam Corner[3], Howard I. Scher[2], Gary A. Pestano[1]

[1]Biodesix, Inc., Louisville, CO,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Bio-Rad, Hercules, CA

Advances in next-generation sequencing (NGS) are producing massive amounts of data at rapidly declining costs. Effective processing of millions of high-depth sequencing reads while maintaining sensitivity and specificity is a growing challenge in the design of new molecular tests. One critical application is detection and subsequent monitoring of rare variants in plasma for molecular residual disease (MRD). Our MRD testing strategy utilizes a preliminary proteomic risk of recurrence mass spectrometry assay to stratify high-risk baseline samples as likely to need further monitoring, followed by design of bespoke ddPCR assays to mark recurrence in the follow-up plasma of the high-risk population. To qualify assays for genomic monitoring, we developed a novel informatics pipeline utilizing approximately 24 million reads and 1 million structural variant calls to profile a cohort of 14 metastatic castration resistant prostate cancer patients (mCRPCa). Tissue-derived NGS data were systematically analyzed to identify a MRD fingerprint for monitoring molecular recurrence in post-treatment plasma specimens. We achieved sequencing depths of 64-367x across the cohort. Data filtering strategies included quality score (≥20), identical homology (≤5), structural variant size, and intersection of multiple gold-standard bioinformatics tools, Delly and Manta. Analytical turnaround time was 16.5 - 72 hours from raw NGS data to designed primers. Bespoke primers were successfully designed or available off-the-shelf for all evaluated patients. Initial studies identified tissue-informed variants derived from four mCRPCa patients with matched baseline plasma. 6/6 of the tested variants were found in the matched patient plasma specimens. Significantly, longitudinal ctDNA analyses identified clearance of AR p.L702H from circulation in a patient with evidence of radiographic and biochemical response to docetaxel after progression on multiple lines of AR signaling inhibitors (ARSI). AR p.L702H is an acquired resistance mechanism to ARSIs, and the elimination of sub-clonal cell populations harboring the alteration could indicate restored sensitivity to these agents. Additionally, declines in ctDNA coincided with declines in serum PSA. This report showcases the design of a novel MRD test combining proteomics for early and impactful risk of recurrence stratification with cost-effective and rapid genomic PCR monitoring in the follow-up plasma of patients at a high-risk of recurrence, for utility in real-world clinical diagnostics laboratories

#5438 Transcript isoform diversity in esophageal squamous cell carcinoma: Insights into tumor heterogeneity and therapeutic targets in Africa.

Sikhumbuzo Z. Mbatha[1], Mohammed Alaouna[2], Botle Precious Damane[1], Tebogo Marutha[2], Rodney Hulll[2], Jonathan Featherston[3], Aristotelis Chatziioannou[4], **Zodwa Dlamini**[2]

[1]Department of Surgery, Steve Biko Academic Hospital, University of Pretoria, Pretoria, South Africa,[2]Pan African Cancer Research Institute (PACRI), University of Pretoria, Pretoria, South Africa,[3]Division of National Health Laboratory Service, The National Institute For Communicable Diseases Of South Africa, Sandringham, South Africa,[4]Center of Systems Biology, Biomedical Research Foundation of the Academy of Athens, Kallithea, Greece

Background: Esophageal squamous cell carcinoma (ESCC) is a major cause of cancer mortality in sub-Saharan Africa, particularly African ESCC corridor. The region's complex etiology, including viral infections, may influence RNA processing such as alternative splicing (AS), a critical but understudied mechanism in ESCC biology. This study characterized the transcriptome wide AS landscape in African ESCC and assessed whether HPV and HIV infections contribute to splicing dysregulation and structural protein alterations.
Methods: A cross-sectional study was conducted between February to December 2024 involving 29 patients with histologically confirmed ESCC and verified HIV status. Paired tumor/ adjacent normal endoscopic biopsies were collected and subjected to histological evaluation, HPV genotyping, and RNA sequencing. Alternative splicing profiles were investigated, with a focus on their association with viral status. Computational structural modeling and molecular docking was used to predict the functional impact of tumor-specific splice variant.
Results and Discussion: Skipped exons were the predominant AS event, followed by alternative 5′ and 3′ splice sites. Substantial patient-specific heterogeneity emerged, with the protocadherin gene family most affected, implicating disrupted cellular adhesion and invasion. Dysregulated non-coding RNAs (DGCR5, LINC00641) further reflected loss of tumor-suppressive control. A tumor-enriched 3′ splice-site variant in CXADR was predicted to alter junctional signaling. Stratification by viral status (HIV+/HPV+, HIV+/HPV-, HIV-/HPV+, HIV-/HPV-) revealed no significant effect on overall splicing burden.
Conclusion: African ESCC exhibits a distinct, skipped-exon-dominated AS signature that drives molecular diversity independent of HIV/HPV status, highlighting AS as a promising diagnostic and therapeutic axis for precision oncology in Africa.

#5439 Shared and divergent transcriptional signatures of ductal cells in distal human cholangiocarcinoma at a single cell resolution.

Meng Ting Chen[1], Jon M. Harrison[1], David R. Ruddy[2], Michelle Piquette[2], Jon Chang[2], Viviana Cremasco[2], Andrew L. Warshaw[1], Carlos Fernandez-Del Castillo[1], Andrew S. Liss[1], Divyansh Agarwal[1]

[1]Department of Surgery, Massachusetts General Hospital and Harvard Medical School, Boston, MA,[2]Novartis Institutes for BioMedical Research, Cambridge, MA

Background: While chronic pancreatitis (CP) has long been recognized as a risk factor for pancreatic ductal adenocarcinoma, recent work has shown an elevated risk of biliary tract malignancies in patients with pancreatitis. However, the underlying mechanisms and the genomic similarities that might explicate this association remain elusive. Inflammation is thought to be a precipitating risk factor for cholangiocarcinoma; however, whether the inflammatory milieu of chronic pancreatitis also contributes to this risk is unclear. To address this gap, we characterized the shared and unique genomic signatures between patients with chronic pancreatitis and those with distal cholangiocarcinoma (dCCA), compared to normal healthy individuals.
Methods: We performed single cell RNA sequencing (scRNA-seq) from pancreata or tumor specimens obtained from 3 healthy human subjects, 3 patients with CP, and 2 individuals with dCCA. After ascribing cell-type identities and delineation of ductal cell clusters, we performed inference of copy number variations as well as functional perturbations at the gene and pathway level in ductal cell from the three patient cohorts - normal, CP and dCCA.
Results: scRNA-seq revealed 35 different cell clusters across ~120,000 cells from the three patient cohorts. Based on semi-supervised learning, we identified 13 cell types in our data; additional analysis revealed that the Ductal cell cluster could be further sub-classified into two cell populations with disparate genomic signature. We further identified amplification/duplication of chromosomes 1, 7, 11, 12 and 18 in the Ductal A cluster from the dCCA cohort through two orthogonal approaches. Pseudobulking analysis suggested an upregulation of laminins in Ductal A subcluster, and Ligand-receptor analysis further revealed LAMC2 as a key target gene in the Ductal cell cluster, with putative fibroinflammation mediated by *TGFB1* and *FGF2* receptors. While laminin upregulation was unique to dCCA and not observed in CP, *TGFB1* and *FGF2* receptor-driven signaling was a shared feature in ductal cells across both CP and dCCA.
Conclusions: We discovered a novel ductal cell population in dCCA that exhibits upregulation of laminins compared to normal pancreas and CP. Further still, the expression of ligand, receptor, and target genes in the dCCA extracellular matrix highlights how the TGFB1-FGF2-LAMC2 axis might be contributing to the desmoplastic process observed in dCCA tumors.

#5441 Structural and kinetic effects of R361H SMAD4 mutation on TGF-ß signaling in colorectal cancer.

Evan Boczko[1], Isaac Silverman[1], Yisrael Wiener[1], Sanjay Goel[2], Radhashree Maitra[1]

[1]Biology, Yeshiva University, New York, NY,[2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Introduction: SMAD4 mutations disrupt TGF-ß signaling in colorectal cancer. We focus on the recurrent MH2-domain R361H mutation, whose structural and interaction effects remain unclear. Using structural modeling, docking, and molecular dynamics, we assess how R361H alters SMAD4 stability and binding to SMAD1/2/3/5.
Methodology: AlphaFold models of SMAD1-5 were obtained from RCSB, and the R361H mutation was introduced to SMAD4 with PyMOL. Wildtype and mutant SMAD4 were docked separately to each R-SMAD with ClusPro. The resulting complexes were subsequently repaired, solvated, and parameterized in GROMACS. Molecular dynamics simulations were run for 100 ns per complex. Global and domain-specific RMSD/RMSF were computed with GROMACS. MMPBSA.py was used to calculate binding energies and per-residue contributions.
Results: R361H mutation altered SMAD4-R-SMAD complex stability in a partner-specific way. At the complex level, SMAD4-SMAD1 and SMAD4-SMAD3 showed only small changes in overall RMSD (Δcomplex ≈ −0.05 nm for SMAD1 and +0.07 nm for SMAD3, MUT - WT). In contrast, SMAD4-SMAD2 and SMAD4-SMAD5 were clearly destabilized, with much larger RMSD shifts (Δcomplex ≈ +0.34 and +0.50 nm, respectively).Across all four complexes, R-SMAD linkers became more flexible in the mutant (+0.10-0.34 nm) while SMAD4 MH2 mobility increased in the SMAD1, SMAD3, and SMAD5 complexes.RMSF analysis localized these changes to SMAD4 residues ~470-490 and 540-550 and to partner-specific regions in each R-SMAD.Energy decomposition revealed distinct mechanisms for each partner. In the SMAD1-SMAD4 complex, strongly interacting residues in wildtype and mutant showed minimal overlap; PyMOL alignment (RMSD ≈ 36 Å) and docking scores indicate that R361H drives an alternative, remodeled binding mode rather than simply weakening the wildtype interface. In the SMAD2-SMAD4 complex, a hydrophobic to polar patch interaction (SMAD4 274-281, SMAD2 181-187) becomes less favorable in the mutant, consistent with increased SMAD4 RMSF and higher complex RMSD. In the SMAD3-SMAD4 complex, a key R420SMAD3-E417SMAD4 salt bridge is weakened by ~3 kcal/mol in the mutant. RMSF data indicate that in the wildtype, a flexible C-terminal tail frequently adopts the orientation needed for this interaction, whereas the mutant tail is more rigid in a less favorable orientation. In the SMAD5-SMAD4 complex, the mutant gains favorable contacts between SMAD5 residues 185-188 and a polar SMAD4 patch (263-268), with increased SMAD4 MH2 mobility (~0.2 nm).
Conclusion: This framework suggests that R361H remodels SMAD4-R-SMAD interfaces in a partner-specific manner, inducing marked reorganization with SMAD1 and more nuanced shifts in SMAD2/3/5. These partner-specific interfaces may represent druggable surfaces for restoring tumor-suppressive TGF-ß responses or selectively constraining pro-metastatic signaling in R361H-mutant colorectal cancer.

#5442 Identifying cell-cell interactions across spatial scales in spatial transcriptomics.

Alex C. Soupir[1], Mitchell T. Hayes[1], Brandon J. Manley[1], Lauren Cole Peres[1], Julia Wrobel[2], BROOKE FRIDLEY[3]

[1]Moffitt Cancer Center, Tampa, FL,[2]Emory University, Atlanta, GA,[3]Childrens Mercy Hospital, Kansas City, MO

Introduction: Single-cell spatial transcriptomics provides rich data for the gene expression profiles at cellular resolutions. This level of data offers the ability to estimate interactions between cells and associate those interactions with clinical information such as survival or response to immunotherapy. Previously, we had shown that *COL4A1* and *ITGAV* are significantly more spatially enriched in primary clear cell renal cell carcinoma (ccRCC) tumors after exposure to immunotherapy (IO), specifically showing high expression in malignant cells and fibroblasts/myofibroblasts. We assessed this interaction by using K=3, but spatial proximity is also an important consideration to explore.

Methods: To address true spatial context, we developed a functional data analysis approach to profile cell-cell interactions at varying spatial scales. We used 14 stromal compartment FOVs (8x IO naïve, 6x IO exposed) from Soupir et. al. (2024). Bivariate Moran's I was calculated for COL4A1 and ITGAV using row standardized weights from Gaussian transformed distances. The bandwidth of the kernel was varied from 0 to 250 to calculate Moran's I as a function of bandwidth, I(h), using 100 permutations to determine complete spatial randomness (CSR). CSR was subtracted from I(h) (Degree of I(h)) to make values comparable across samples. We used functional principal component (FPC) analysis to analyze the full Degree of I(h) curves. FPC scores were used to compare the IO naïve and IO exposed tumors. Results from our approach were compared to SpatialDM, another approach based on Moran's I, with h=75.

Results: FOVs from tumors exposed to IO showed a distinct, positive Degree of I(h) curve with a peak at a bandwidth between 25-50 while FOVs from IO naïve tumors were each unique in either shape or sign of Degree of I(h). Calculating (FPCs) from all Degree of I(h) curves showed that FPC1 describes the overall strength of the spatial relationship (positive scores indicate overall elevated and negative scores indicate overall decreased interaction) while FPC2 describes whether the interaction occurs at a near/far scale. Plotting FPC2 vs FPC1, FPC1 perfectly separates IO naïve from IO exposed FOVs (Wilcox Test p=0.00067, where IO exposed FOVs have a positive FPC1 score and FPC2 scores around 0 (no change in near/far). SpatialDM's global I didn't show significant differences between IO exposures (Wilcox Test p=0.1079)

Conclusion: The application of our approach to ccRCC indicates that COL4A1 and ITGAV in these stroma FOVs from IO exposed primary ccRCC tumors are more strongly spatially related across spatial scales than stroma FOVs from IO naïve primary ccRCC tumors. Our approach also showed a significantly stronger spatial association than SpatialDM. Further research is needed to better understand the underlying cause of this shift, which may lead to new drug targets.

#5443 Copy number loss and somatic loss of heterozygosity calling in liquid- and tissue-based genomic profiling.

Hao Wang[1], Andrew Gross[1], **Adrian Bubie**[1], Lauren Lawrence[1], Reagan Barnett[1], Bernard Herman[1], Matthew Ellis[1], Tingting Jiang[2]

[1]Guardant Health, Redwood City, CA,[2]Guardant Health, San Diego, CA

Introduction: Copy number loss (CNL) alterations are common oncogenic driver events important for therapy selection and clinical trial matching in several cancer types. We developed a CNL detection approach that pairs a purpose-built panel with a ploidy-aware, multi-signal model to sensitively detect loss of heterozygosity (LoH) and homozygous deletion (homdel) events from ~1MB to chromosome scale in both plasma- and FFPE-derived samples.

Method: We employed hybrid-capture assays (Guardant360 Liquid and Guardant360 Tissue, Guardant Health, Palo Alto, CA) that target more than 700 cancer-associated genes and incorporate a dense tiling of common single-nucleotide polymorphisms (SNPs) to optimize segmentation resolution. Read depth and SNP minor allele fraction (MAF) are integrated within a ploidy-aware likelihood framework that jointly estimates tumor fraction (TF), ploidy, and allele-specific copy number (CN). Highly polymorphic loci (e.g. HLA) are handled with a unique target design that mitigates polymorphism and artifacts while preserving true deletions. A single caller operates across specimen types, with material-specific adjustments for ctDNA and FFPE tissue. Validation of the caller performance established deletion limit of detection (LoD), sensitivity, specificity and limit of blank (LoB) using a combination of clinical and contrived cell-free DNA (cfDNA) and genomic DNA (gDNA) samples.

Result: Joint tumor fraction (TF)/CNL inference reduces miscalls and improves allele-specific state assignment in polyploid genomes at low TF. The CNL reportable range extends to >500 genes including coverage of the HLA locus, homologous recombination (HRR) and DNA mismatch repair (MMR) pathways. LoD was established at 20% TF in cfDNA and 30% in tissue-derived gDNA, and LoB was demonstrated with a per-sample false positive rate of <5%. Both analytes demonstrated ≥90% sensitivity across the reportable range, and clinical precision established at ≥90% PPA for samples above LoD. HLA deletion calling, while known to be technically challenging, demonstrated similar overall performance to other genes. Among 117k plasma and 43k tissue samples from patients with advanced cancer, this method yielded reportable deletion 10.8% (plasma) and 18.6% (tissue) cases, substantially improving diagnostic yield.

Conclusion: We demonstrate that ploidy- and TF-aware deletion caller approach sensitively and accurately detects CNLs irrespective of gene identity, including in traditionally difficult-to-map regions like the HLA locus, in both cfDNA and gDNA inputs. This ability is a critical component of modern comprehensive genomic profiling, which must include robust detection of clinically relevant copy number alterations to better inform cancer treatment decisions.

#5444 Analytical validation of HLA class I allele typing in a liquid biopsy platform.

Adrian Bubie[1], Sante Gnerre[2], Marisa Juntilla[1], Reagan Barnett[1], Matthew Ellis[1], Tingting Jiang[2]

[1]Bioinformatics, Guardant Health Inc, Redwood City, CA,[2]Guardant Health, San Diego, CA

Background: Human Leukocyte Antigen (HLA) genotyping is an emerging biomarker for immunotherapy efficacy in several solid tumor types but can be particularly challenging to genotype with standard NGS due to the locus' inherent variability. Accurate HLA typing from cell-free DNA (cfDNA) enables non-invasive biomarker assessment for therapy selection and clinical trial matching and can be provided as incidental to standard liquid biopsy without the additive cost of white blood cell sequencing. Using a novel algorithm to enable HLA genotyping as part of Guardant360 Liquid (Guardant Health, Palo Alto, CA), we present analytical validation of HLA class-I allele typing (HLA-A, -B, -C) and demonstrate concordance with paired tissue assay results.
Methods: The cfDNA genotyping algorithm leverages perfect read-pair alignments against a database of more than 16000 known HLA alleles, identifying the most supported allele pairs (germline configuration) based on the read coverage from amongst reference alleles. Analytical validation assessed accuracy using 32 samples with orthogonal HLA data from a validated commercial assay. Limit of detection (LoD) was established through *in silico* downsampling at 5 coverage levels ranging from high to challenging inputs near the test minimum using 4 samples with 5 replicates per level. Precision was evaluated using 6 clinical samples at 5ng input tested across 5 operator, reagent lot, and instrument combinations. Concordance with HLA genotyping in tissue was assessed by comparing 80 paired patient samples run on both Guardant360 Liquid and Guardant360 Tissue.
Results: Guardant360 Liquid demonstrated high accuracy with 97.3% positive percent agreement (PPA) [95% CI: 93.8-99.1%] for HLA class-I alleles. Among evaluable results, 100% concordance was achieved for homozygous alleles (16/16) and 97.0% for heterozygous alleles (163/168). LoD was established at the lowest input level allowed for the assay with 100% detection rate across all tested levels. Precision at 1-5X LoD demonstrated 100% PPA across multiple testing conditions. Paired tissue-liquid concordance analysis showed 97.5% overall PPA (231/237 alleles) across HLA-A (80/80, 100%), HLA-B (77/80, 96.3%), and HLA-C (74/77, 96.1%), with discordances primarily attributed to tumor-specific loss of heterozygosity or minor SNP differences between closely related alleles.
Conclusions: Guardant360 Liquid HLA typing demonstrates robust analytical performance with high accuracy, sensitivity, and precision in cfDNA with accelerated turnaround times compared to standard genotyping assays. Strong concordance between paired tissue and liquid samples validate the algorithm's performance in cfDNA. This non-invasive HLA typing capability enables comprehensive biomarker profiling for immunotherapy selection and clinical trial eligibility assessment in patients with advanced solid cancers.

#5445 Macrophage metabolic rewiring underpins the distinct immunological architecture of invasive mucinous adenocarcinoma revealed through layered molecular profiling.

ShinYoung Park[1], KyungA Kim[2], Chung Lee[2], Byungjin Hwang[3], Hyo Sup Shim[2]

[1]Department of Biomedical Sciences, Graduate School of Medical Science, Brain Korea 21 Project, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Department of Pathology, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Department of Biomedical Sciences, Yonsei University College of Medicine, Seoul, Korea, Republic of

Invasive mucinous adenocarcinoma (IMA) is a rare variant of lung adenocarcinoma whose biological underpinnings remain poorly resolved, and the factors governing its distinct clinical behavior are not fully understood. To elucidate the cellular architecture of IMA, we generated a high-resolution single-cell transcriptomic atlas from ten IMA tumors and performed comparative analyses against datasets from invasive non-mucinous adenocarcinoma (INMA). Our data revealed that the IMA tumor microenvironment is shaped by a pronounced reshaping of the myeloid compartment, characterized by the expansion of select macrophage populations displaying transcriptional signatures associated with regulatory and metabolically activated states. These macrophages constituted a dominant cellular component in IMA and were positioned at the center of immunomodulatory pathways within the tumor ecosystem. Concomitantly, IMA exhibited a sharp reduction of multiple T cell subsets, accompanied by transcriptional indicators of functional attenuation, and a shift in the B cell compartment toward quiescent phenotypes consistent with disrupted lymphoid organization. Together, these features point to a coordinated landscape of adaptive immune dysfunction. Cell-cell communication analyses further supported this immunological configuration, uncovering immunoregulatory signals specifically strengthened in IMA that involved macrophage-to-lymphocyte and macrophage-to-epithelial interactions absent in INMA. On the epithelial axis, IMA tumors displayed a prominent enrichment of a mucin-producing epithelial population with transcriptional programs associated with mucin secretion and structural remodeling. Pseudotemporal modeling identified a differentiation trajectory linking alveolar epithelial cells to mucin-producing cells, bifurcating between IMA and INMA and suggesting that IMA harbors a lineage evolution distinct from the non-mucinous counterpart. Taken together, these results define IMA as a tumor ecosystem in which a remodeled macrophage compartment intersects with epithelial specialization to reinforce an immunosuppressive microenvironment. By outlining the interplay between myeloid activation, adaptive immune impairment, and mucin-associated epithelial differentiation, this work provides a cellular framework for understanding the unique biology of IMA and highlights potential therapeutic avenues that may benefit its clinical management.

#5446 BRCA1, RNA-binding proteins, and miR-18a, a molecular tri(umph) in breast carcinoma.

Raiyan Satti, Anjana Saxena, Shaneen M. Singh

Brooklyn College, Brooklyn, NY

Breast cancer frequently involves widespread dysregulation of miRNAs, and changes in their processing can influence tumor behavior. RNA binding proteins (RBPs) are key post-transcriptional regulators that predominantly control gene expression through RNA metabolism. Dysregulation of RBPs is implicated in therapy resistance of breast cancer and targeting key RBPs can be a promising therapeutic approach to reverse this resistance. Earlier we identified a group of RBPs as common interactors of BRCA1 and RBP-nucleolin (NCL), namely heterogeneous nuclear ribonucleoprotein A1 (HNRNPA1), heterogeneous nuclear ribonucleoprotein D (HNRNPD), polyadenylate binding protein cytoplasmic 1(PABPC1), and TAR DNA-binding protein 43 (TDP-43). We published computational models of these RBPs, including NCL for their competitive versus synergistic binding with miR-21, based on predicted docking scenarios. NCL and the biogenesis of the six-miRs that it regulates are frequently overexpressed in breast cancer and are directly implicated in tumor growth and progression. Similarly, the miR-17-92 cluster which includes miR-18a is often upregulated in malignancies, including breast tumors. In estrogen receptor-positive breast cancer, it has been shown that miR-18a directly targets the 3'UTR of ER-α, increasing resistance to hormonal therapy. Although it is known that HNRNPA1 binds the terminal loop of pri-miR-18a and enhances its processing by the microprocessor complex, how NCL interacts with miR-18a is completely unknown. Interestingly, targeting NCL either by silencing or using NCL-specific aptamers directly impacts its control of various miRs, and hence inhibition of tumor growth. In this study, we have focused on the two RBPs, NCL and HNRNPA1 and their interaction with miR-18a in the context of breast cancer. We have modeled the full primary miR-18a and show its predicted interaction with the RNA-binding domains (RBDs) of NCL and HNRNPA1. We compare and contrast the molecular interactions and highlight the key residues involved in the interaction interface for the RBPs and miR-18a with an end goal to suggest potential targetable sites for therapeutics.

#5447 *In silico* analysis of GSK3α to identify novel potential ligands for cancer therapy.

Neha Sylvia Walter, Sanchit Dora, **Jasmeet Kaur**

Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India

Cancer prevails as the leading mortality cause worldwide. Constraints like drug resistance and adverse immune events urge the need to find novel treatment targets in cancer patients. Glycogen synthase kinase 3 (GSK3) is a multifunctional kinase that has context-dependent dual role in cancer. Out of the two highly homologous mammalian isoforms of GSK3 (i.e. GSK3α and GSK3β), we explored the predictive and prognostic role, and novel potential ligands for GSK3α. *GSK3A* gene expression was compared in normal and tumor tissues using TNM plot (https://tnmplot.com/analysis/). Kaplan-Meier plotter (https://kmplot.com/analysis/) was used to correlate *GSK3A* mRNA expression with survival in cancer patients receiving immunotherapy, for a 240 months follow-up threshold and using median expression. ROC plotter (https://www.rocplot.com) was used to analyze the predictive role of *GSK3A* gene in cancer patients receiving immunotherapy. The data from KM- and ROC-Plotter was analyzed using Graphpad PRISM 8. Logrank P, 95% confidence intervals and Hazard ratio (HR) were calculated and P value of < 0.05 was considered to be statistically significant. Five ligand libraries from Selleckchem chemical database were docked with GSK3α protein using PyRx Vina Wizard for virtual screening. Ligands with favorable binding energies were validated for drug-likeliness using ProTox 3.0 (https://tox-new.charite.de/protox_II/). *GSK3A* gene expression was significantly higher in twelve tumors than normal tissue and two normal than tumor tissue. Higher *GSK3A* mRNA expression was significantly correlated with better OS and not PFS in patients receiving immunotherapy. ROC analysis showed that *GSK3A* gene expression was significantly associated with combined response to anti-PD-L1 and anti-CTLA-4 therapy, and not to anti-PD-1 therapy. Molecular docking predicted several ligands with strong binding affinity to GSK3α. Shortlisted drugs based on their docking scores were analyzed for their drug-likeliness. MOLI001171, MOLI001205 and Formylmethanofuran were found to be potent GSK3α ligands with potential for cancer therapy.

#5448 A serotonin transcriptional axis shapes immune phenotypes and clinical outcomes in lung cancer.

Ecem Kalemoglu[1], Salih Akgun[2], Ayse Caner[3]

[1]Internal Medicine, Rutgers University - Jersey City Medical Center, Jersey City, NJ,[2]Internal Medicine, JFK University Medical Center, Edison, NJ,[3]Department of Basic Oncology, Institute of Health Sciences, Ege University, Izmir, Turkey

Background
Neuromodulator-metabolite pathways are emerging regulators of tumor-immune interactions. A recent study showed that neurotransmitter signaling remodels immune infiltration. Building on this framework, we developed a serotonin transcriptional axis incorporating TPH/HTR synthesis, MAOA/IDO1 degradation, and SLC6A4 transport to characterize immune states in lung adenocarcinoma (LUAD) and lung squamous carcinoma (LUSC).
Methods
TCGA RNA-seq data were processed via Xena. Row-z-scaled serotonin genes generated Up, Down, and composite Axis scores. k-means defined serotonin phenotypes. Immune checkpoints, cytotoxic programs, chemokines, and immune-cell surrogates (CD8A, FOXP3, NCAM1, IRF5, CD163, MS4A1, ITGAX) were assessed using Wilcoxon testing, correlation matrices, limma DEGs, Hallmark GSEA, and KM/Cox survival.
AI tools (ChatGPT) were used for editing, grammar, and text condensation.
Results
In LUAD, three phenotypes emerged: C1 (MAOA/IDO1-high, immune-cold), C2 (serotonin-depleted), and C3 (TPH/HTR-high, immune-hot).
C3 demonstrated strong activation of CD8A, IFNG, GZMB, PRF1, CXCL9/10/13 and checkpoints including PDCD1, CD274, CTLA4, LAG3, TIGIT ($p<0.001$).
Serotonin Axis Score correlated positively with CD8 T cells, NK cells, dendritic cells, B cells, and M1 markers, and negatively with CD163, indicating an inflamed, antigen-presenting TME.
GSEA showed C3 enrichment for interferon and inflammatory programs; C1 favored metabolic/MYC pathways.
Survival differed significantly across clusters ($p=0.0014$), with C3 best and C1 worst; high serotonin axis trended toward improved OS ($p=0.055$).In LUSC, the same phenotypes recurred, confirming cross-histology reproducibility. C3 again showed the strongest immune activation with elevated cytotoxic and checkpoint expression.
Serotonin activation associated with CD8A, NK signatures, MS4A1, ITGAX, and M1 markers, whereas serotonin suppression correlated with CD163-high M2 states.
GSEA showed C3 enrichment for IFN-α/γ and inflammatory pathways; C1 enriched for OXPHOS/MYC programs.
Cluster OS was not significant ($p=0.63$), but continuous Serotonin Axis Score predicted improved OS ($p=0.039$).
Conclusions
Serotonin pathway states reproducibly shape immune landscapes and survival across LUAD and LUSC. Serotonin activation aligns with cytotoxic infiltration, chemokine-rich inflammation, dendritic/B-cell signatures, M1 polarization, checkpoint expression, inflamed GSEA programs, and improved survival. These findings extend neuromodulator-TME concepts from recent study and identify the serotonin axis as a cross-histology biomarker and potential immunomodulatory target.

#5449 The effects of survivorship patterns and survival parameters on cancer risk across vertebrates.

Olivia K. Corrao[1], Walker Mellon[1], Zachary Taylor Compton[2], Harley Richker[1], Gissel Marquez Alcaraz[1], Stefania Kapsetaki[3], Joel Brown[4], Orsolya Vincze[5], Mathieu Giraudeau[6], Michael Lynch[1], Carlo C. Maley[7]

[1]Biodesign Institute, Arizona State University, Tempe, AZ,[2]University of Arizona, Tucson, AZ,[3]Institute of Molecular Biology and Biotechnology of the Foundation for Research and Technology-Hellas, Heraklion, Greece,[4]Moffitt Cancer Center, Tampa, FL,[5]French National Center for Scientific Research, Bordeaux, France,[6]University of La Rochelle, La Rochelle, France,[7]Arizona State Univ. Biodesign Institute, Tempe, AZ

Cancer is a disease that affects all multicellular organisms. However, evolutionary pressures resulted in a diverse range of life history traits, including survivorship patterns, across all species that may significantly impact susceptibility to cancer. This study aims to identify the effects of survivorship patterns and survival parameters in vertebrate species on neoplasia and cancer prevalence. The data used contains necropsy records of 29,702 individual organisms, spanning 100 different species in 4 clades: Mammalia, Reptilia, Amphibia, and Aves. The Rage software in R was used to generate survivorship models and calculate survivorship patterns for each species. Five survival parameters were estimated for each species using the Siler model and the fmsb software in R. We found that species that exhibit a Type I or Type III survivorship pattern have a higher prevalence of both neoplasia and cancer, whereas Type II species develop significantly less neoplasia and cancer. Similarly, we found that species with a low extrinsic mortality rate in the senescent stage have an increased risk of both neoplasia and cancer. This comparative study highlights the effects of life history strategies on cancer and allows for further research on mechanisms of cancer suppression in species with low cancer risk and potential applications to cancer treatment plans in humans.

#5450 Decoding ADC payload dynamics with a spatial transcriptomics-integrated tumor microenvironment PK model.

Sungwoo Bae, Jeongbin Park, Jin Yeong Choi, Daeseung Lee, Hyung-Jun Im, Hongyoon Choi

Portrai, Inc., Seoul, Korea, Republic of

Background: The inherent heterogeneity of the tumor microenvironment (TME) complicates the prediction of antibody-drug conjugate (ADC) payload delivery and the mechanism of resistance. The advent of spatial transcriptomics (ST) enables high-resolution molecular profiling, allowing in silico pharmacokinetics (PK) modeling within the TME as a proxy for payload delivery. This study aimed to develop a TME-PK platform, validate it preclinically, and integrate human TME data to inform how ADC payload delivery can be optimized in clinically relevant settings.
Method: We developed an in silico TME-PK model parameterized using target expression and endothelial density derived from ST (Visium/Visium HD) grids. It enables quantification of payload distribution in a time-dependent manner by solving kinetic equations mapped onto ST data, incorporating vessel distribution, linker-cleavage enzymatic activity, and target expression patterns. To validate these findings, we used a FaDu xenograft mouse model that received either fluorescently labeled cetuximab or panitumumab. Tumors were collected at two and 40 hours for distribution imaging and ST. We then used the model to simulate payload delivery in 52 stomach adenocarcinoma (STAD) patients across a wide K_D range (pM to 10 μM) to find optimal targets and range of ADC characteristics. The peak concentration of the intratumoral payload was then calculated for each ST of the patient tumor.
Results: The 2 and 40-hour antibody distribution predicted by the TME-PK model correlated significantly with observed fluorescence intensity from experimental data (Spearman's rho > 0.65, $p < 0.05$). The model was then evaluated for the relationship between intratumoral target expression levels and the sensitivity of payload delivery to K_D, revealing a strong positive correlation (Spearman's rho: 0.94, $p < 0.05$). For highly expressed targets (e.g., CEACAM5), payload concentration rapidly saturated even at modest binding affinities (higher K_D). However, very high affinity (low K_D) induced a potent binding-site barrier, causing ADC accumulation in perivascular regions and preventing tumor core penetration. Conversely, for low-expression targets (e.g., NECTIN-4), a very high affinity (low K_D) was essential to achieve adequate payload concentration and enhanced tumor core delivery.
Conclusion: We established a spatially-resolved TME-PK framework, which was validated preclinically using experimental xenograft data. Its application to STAD patient data confirmed known pharmacological phenomena, such as the binding-site barrier effect. This demonstrates the TME-PK model as a crucial tool for optimizing ADC payload delivery, showing that the optimal kinetic properties of antibody must be balanced against the spatial patterns of target expression and relationship with tumor microenvironment to ensure both binding and tissue penetration.

#5451 Omicology: A comprehensive AI/LLM/NLP-based web resource for the ontology, phylogeny, and practical navigation of omics literature.

James M. Melott, **John N. Weinstein**

UT MD Anderson Cancer Center, Houston, TX

Introduction: We present here a public website, omicology.com, which includes extensive information on omic research domains and features a specialized omics search engine. Omics started as a simple suffix for research based on molecular profiling of genes, proteins, and other (biological) molecules in aggregate. The etymology, from ancient Greek or possibly Sanskrit, is debated. Application of the suffix to dozens of research fields starting in the 1990s (Weinstein 1998) was often derided as jargon. “Where’s the hypothesis?” was a common critique - and reason for rejecting manuscripts or proposals. But given the draft human genome in 2001, synergy between omic and hypothesis-driven research gradually gained acceptance. In 2000, 2010, 2020, and 2025, there were 6, 61, 267, and >700 omics terms, respectively. More recently, high-throughput single-cell, spatially-resolved, and temporally-resolved omic technologies have provided new dimensions to our pursuit of precision medicine for cancer.

Methods: Our starting point for development of the search engine database was 6,980,243 full-text Open Access PubMed Central articles plus various metadata. It included 5,699 omics terms. Our NLP, use of LLM resources, and careful manual curation have produced 702 omics terms. Refinement of such lists is complicated by eccentricities of language, misspellings, alternative spellings, suffixes like ‘nomics’ (e.g., in economics), not ‘omics,’ and ambiguous terms like ‘chromosomics.’

AI tools (Elicit, Cursor, Google, and ChatGPT) have provided useful design and content ideas for a static html prototype website. An agentic AI coding tool has assisted our development of a dynamic full-stack, human-curated version (currently 34,124 lines of code and content) based on the prototype (for publicly roll-out before AACR 2026).

Representative Results: The most frequent omic terms are Genomics (257,617 articles), Proteomics (123,697), Metabolomics, (80,023), and Transcriptomics (78,279). Metagenomics, radiomics, lipidomics, epigenomics, pharmacogenomics, and phosphoproteomics complete the top 10.

Our data on the top 702 terms currently include usage numbers for each document section, publication date, curation status, a brief LLM-generated description, and more.

Conclusions: The open-source, updatable Omicology.com website will provide an expanding repertoire of information and perspectives on omics plus specialized omics search capabilities. Biomedical perspective will be aided by the senior author’s long-term experience in omic research beginning with his initiation and leadership of the first omic/multi-omic NCI project, molecular profiling of the NCI-60 (e.g., Weinstein, et al., Science, 1997). Methods used here for omics can provide a template for research on other hard-to-analyze fields, complementing the capabilities of such resources as PubMed Central.

#5452 Deep learning enables matched-normal free estimation of tumor mutational burden from whole exome reads in colorectal cancer.

Amrita Chattopadhyay[1], Liang-Yu Lin[2], Ching-Tai Chen[3], Eric Y. Chuang[4]

[1]Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan,[2]Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University., Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan,[3]Department of Computer Science, University of Taipei, Taipei, Taiwan,[4]Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan

Tumor mutational burden (TMB) is a key biomarker for immune checkpoint inhibitor (ICI) therapy. However, its clinical implementation in colorectal cancer (CRC) remains limited by the cost of matched normal sequencing and by inconsistent TMB estimates across pipelines. We developed a tumor only, deep learning pipeline using raw whole exome sequencing (WES) reads. First, tumor purity was predicted using genomic language model (gLM) sequence features, read depth, and clinical data, the purity embedding from which were integrated with genomic and coverage features to estimate log transformed TMB. The model was trained with five fold cross validation on 121 CRC tumor samples; 29 matched-normal samples were gradually added to evaluate generalization. Across ten random experiments, the best purity model achieved an average mean-squared error (MSE) of 0.026 and concordance index (C index) of 0.93. Incorporating purity embedding improved TMB prediction accuracy, achieving MSE of 0.096 and CI of 0.62, nearly halving the error compared with a more complex baseline using reduced input reads. This framework enables rapid, TMB estimation directly from tumor only WES data, removing the need for matched normal or ad hoc filtering. By improving accessibility and consistency of TMB measurement, the method may enhance identification of CRC patients most likely to benefit from ICI therapy, particularly in resource-limited clinical settings.

#5453 Machine learning accelerates discovery of synergistic- PI3K-mTOR combinations for robust tumor growth inhibition in KRAS G12 mutant patient-derived xenografts.

Emily Eastwood, Yuan-Hung Chien, Jose Lopez-Ramos, Paris Offor, Warren Andrews, Long Hoang Do, **Raffaella Pippa**

Certis Oncology Solutions, San Diego, CA

Identifying effective drug combinations remains a major challenge in oncology, primarily due to inherent resistance and the limited clinical fidelity of conventional in vitro screening data. To address this translational barrier, we established a robust platform utilizing Certis Oncology's proprietary patient-derived xenograft (PDX) models, which offer high correlation with clinical responses, to predict and validate synergistic therapeutic regimens.

Our approach leveraged CertisAI^{TM}, an ensemble of proprietary machine learning (ML) models trained on high-throughput combination experiments. CertisAI^{TM} successfully prioritized combinations targeting the PI3K and mTOR pathways as lead candidates for treating aggressive KRAS G12 mutant tumors, spanning non-small cell lung, gastric, pancreatic, and colorectal cancers. We experimentally evaluated a comprehensive matrix of six PI3K inhibitors and four mTOR inhibitors across distinct KRAS G12 mutant PDX models. These ex-vivo studies rigorously demonstrated that the dual inhibition of the PI3K-mTOR axis resulted in potent, synergistic anti-tumor activity, consistently yielding efficient and sustained tumor cell reduction across all tested models. Notably, a key synergistic combination—involving Everolimus or Tacrolimus (mTORi) paired with Inavolisib (PI3Ki)—translated directly to significant therapeutic benefit in the PDX setting.

These findings validate our PDX-informed strategy for rapidly identifying clinically relevant, synergistic combinations. The demonstrated efficacy of the Everolimus/Tacrolimus + Inavolisib combination provides compelling preclinical evidence, establishing this dual-agent approach as a strong therapeutic candidate for clinical evaluation in KRAS G12 mutant solid tumors.

#5454 Identification of microRNA clusters as predictors of chemotherapy response in acute myeloid leukemia.

Ziang Chen[1], Jennifer Rangel Ambriz[1], Yu-Hsuan Fu[1], David Eugene Frankhouser[1], Denis O'Meally[1], Lianjun Zhang[1], Ying-Chieh Chen[1], Sergio Branciamore[1], Jihyun Irizarry[1], Bin Zhang[1], Guido Marcucci[2], Russell Rockne[1], Ya-Huei Kuo[1]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]City of Hope National Medical Center, Duarte, CA

Acute myeloid leukemia (AML) is a cancer of the myeloid cell lineage characterized by acquired gene mutations and chromosomal abnormalities. We have previously shown that AML initiation and progression can be predicted by applying a state-transition theory to the analysis of time-series messenger RNA (mRNA) and microRNA (miRNA) sequencing data from peripheral blood mononuclear cells (PBMCs) collected during disease development. We showed that AML initiation and progression in mouse models can be tracked via blood mononuclear cell transcriptomes and modeled as particle undergoing Brownian motion in a double-well potential with critical points for health, transition, and leukemia. Building on this framework, our current study evaluates chemotherapy response using time-series sequencing data from an AML mouse model. We plotted mRNA and miRNA transcriptome trajectories over time and found that chemotherapy initially shifted both trajectories away from the leukemic state toward the healthy state, followed by relapse back toward leukemic state. Notably, miRNA responses showed a delay of 2 weeks behind mRNA. To investigate the cause of delayed miRNA transcriptomic response to chemotherapy, we performed Weighted Gene Co-expression Network Analysis (WGCNA) on miRNA expression profiles to identify co-expressed clusters. By projecting each miRNA cluster onto the leukemia state-space[YK1] , we identified a cluster that exhibit strong contribution to the AML state transition. This is a cluster of 30 miRNAs with coordinated expression patterns, significantly upregulated and associated with delayed transcriptomic response post-chemotherapy.Notably, 80% of these miRNAs are located within the DLK1-DIO3 imprinted region (chromosome 14q32 in humans, 12qF1 in mice), a locus previously implicated in stress response, acute promyelocytic leukemia (APL), solid tumors, and type 2 diabetes. However, their involvement in standard-of-care chemotherapy responses in AML has not been previously reported.Further mechanistic analysis revealed a regulatory mechanism in which high expression of these miRNAs suppresses the PI3K/mTOR signaling pathway. Inhibiting the PI3K/mTOR pathway lowers reactive oxygen species (ROS) production, which creates an environment for leukemia stem cells (LSC) to survive. Since chemotherapy primarily eliminates leukemic blast cells, the persistence of LSCs may significantly contribute to relapse.Our findings highlight the power of state-space modeling to uncover dynamic regulatory mechanisms and identify miRNA-driven factors that may lead to AML relapse after chemotherapy.

#5455 RNA-seq profiling identifies FOX genes as potential CRC biomarkers.

Yakshi Nicole Ortiz-Maldonado, **Hilmaris Centeno-Girona**, Camille Zenon-Melendez, Sheila Natalie Lopez-Acevedo, Elba V. Caraballo

Division of Shared Resources and Scientific Operations, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Colorectal cancer (CRC) remains a leading cause of cancer-related deaths worldwide, including Puerto Rico, highlighting the urgent need for reliable biomarkers to enable earlier and more accurate detection. The FOX family of transcription factors regulates key cellular processes, including cell proliferation, apoptosis, metabolism, and immune regulation. However, their expression patterns and diagnostic utility in Hispanics individuals living in Puerto Rico (HPR) have not been characterized. The aim of this study is to characterize FOX gene expression profiles across healthy and CRC individuals and evaluate their prognostic and diagnostic performance in HPR.

Tissue samples from 28 participants in the Puerto Rico Familial Colorectal Cancer Registry (PURIFICAR) cohort (13 controls-healthy normal mucosa, 7 early-stage, and 8 advanced-stage CRC tumors) were used for RNA extraction and bulk RNA sequencing. Differential gene expression was performed using DESeq2 (|log2 fold change|>2, adjusted $p<0.05$). Four FOX signature scores were constructed from significant non-collinear FOX genes (VIF<10) using Gene Set Variation Analysis. Kaplan Meier survival analysis was performed for each differentially expressed FOX gene using publicly available colon cancer data. Gene associations with CRC status were evaluated using binomial generalized linear models (GLM), unadjusted and adjusted for age and BMI. Diagnostic performance was assessed using sensitivity, specificity, and AUC-ROC. Significance was set at 0.05. Statistical analyses were performed using R, version 4.3.3.Expression profiles of 35 FOX genes separated samples into distinct clusters by early- and advanced-stages of CRC and controls. Of 12 differentially expressed genes, 5 genes were upregulated (FOXC1, FOXC2-AS1, FOXH1, FOXN2, FOXQ1), while 7 were downregulated (FOXA1, FOXA3 FOXD2, FOXD3-AS1, FOXE3, FOXF2, FOXO1) in CRC relative to controls. Kaplan-Meier analysis showed that higher expression of 4 genes (FOXA3, FOXC1, FOXF2, FOXQ1) was associated with reduced survival probabilities in CRC patients, whereas higher expression of FOXA1 and FOXN2 was associated with improved survival ($p<0.05$). In unadjusted analysis, FOXQ1 expression and a 6-gene FOX signature, including FOXC1 and FOXQ1, significantly increased CRC odds ($p<0.05$), while 7 genes significantly decreased CRC odds. After adjusting for age and BMI, protective associations were observed for FOXE3 (OR:0.19), and FOXD2 (OR:0.42), while FOXQ1 (OR:1.45) and FOXC1 (OR:2.83) showed the largest increased odds of CRC.

Multiple FOX genes were differentially expressed in CRC, with FOXC1 and FOXQ1 showing significant associations with both survival of CRC patients and disease risk. A FOX gene signature further improved diagnostic performance. These findings support the potential of FOX transcription factors as clinically relevant biomarkers for HPR.

#5456 Multiplatform bioinformatic profiling identifies TTK and NEK2 as survival-associated drivers in triple-negative breast cancer.

Alexandra N. Aquino-Acevedo[1], **Esther M. Irizarry-Quintana**[2], Angel D. Colon-Burgos[1], Marileana Rodriguez-Ruiz[3], Joel A. Orengo-Orengo[1], Elliott Rodriguez-Lopez[1], Melanie E. Cruz-Robles[1], Harold I. Saavedra[1]

[1]Basic Sciences, Ponce Health Sciences University, Ponce, PR,[2]U54 REC InterAmerican Undergraduate Program, Ponce Health Sciences University, Ponce, PR,[3]Moffitt U54 Summer Research Program, Ponce Health Sciences University, Ponce, PR

Introduction: Triple-negative breast cancer (TNBC) is an aggressive subtype characterized by the absence of ER, PR, and HER2 receptors, limiting targeted therapeutic options and contributing to poorer outcomes among women. Prior evidence from our group indicates that mitotic kinases TTK and NEK2 are frequently overexpressed in TNBC, promoting centrosome amplification and invasive behaviour. Therefore, we aim to further explore how these mitotic kinases impact biological processes and the overall survival of TNBC patients.
Hypothesis: Mitotic kinases, such as TTK and NEK2, play a pivotal role in EMT and metastatic processes in TNBC, while their overexpression leads to a lower overall survival of TNBC patients.
Method: To functionally assess this hypothesis, we performed a series of bioinformatic analyses using the TCGA and STRING databases to evaluate the molecular processes associated with TTK and NEK2 expression. We also collected information from the Kaplan Meier (KM) Plotter database to evaluate the correlation between TTK and NEK2 expression on BC patients' overall survival.
Results: mRNA expression profiles from TCGA demonstrated significantly elevated TTK and NEK2 levels across TNBC groups. Moreover, high expression of both mitotic kinases correlated with reduced overall survival in KM analyses. STRING network analysis revealed enrichment for β-catenin binding, cell-to-cell junction regulation, and mesenchymal differentiation, supporting a role for these kinases in EMT-associated processes.
Conclusion: Collectively, these data provide complementary bioinformatic evidence that the mitotic kinases TTK and NEK2 contribute to EMT activation and invasive potential in TNBC. Their overexpression in patient tumors correlates with poor survival outcomes. Thus, these results highlight TTK and NEK2 as promising molecular targets for limiting TNBC progression and metastasis.

#5457 From tumor to model: Transcriptomic and therapeutic insights from patient-derived colorectal cancer organoids.

Matthew Graziano, Ajeet Singh, Stephen Friend, Ruby E. Thamert, Utsav Sharma, Abhay Andar, Jonathan Jacobs, **Carolina Lucchesi**

Microphysiological Systems, American Type Culture Collection (ATCC), Manassas, VA

Background: Colorectal cancer (CRC) is the world's second leading cause of cancer deaths, often diagnosed late due to its silent onset. To drive breakthroughs in drug discovery, scientists use both traditional cell lines and patient-derived models. The Human Cancer Models Initiative (HCMI)—a collaboration among the National Cancer Institute, Cancer Research UK, Wellcome Sanger Institute, Hubrecht Organoid Technology, and ATCC—has built a collection of clinically annotated CRC organoids that capture tumor biology and genetic diversity. Understanding differences in gene expression between organoids and conventional cell lines is key to improving disease models and developing better therapies.
Methods: Six CRC organoid models from unique donors and ten CRC cell lines were expanded and analyzed via RNA sequencing. The models were derived from primary tissues across ten anatomical sites. Transcriptomic profiles were compared among models and against tumor data from The Cancer Genome Atlas (TCGA). A subset of models was screened for drug sensitivity using a panel of six compounds targeting molecular pathways identified by RNA-seq. Dose-response curves were generated, and IC50 values were calculated. Post-treatment cultures were evaluated using a luminescent ATP viability assay to assess drug response.
Results: Patient-derived CRC organoids showed high genomic concordance with matched tumors, including shared single-nucleotide variants and ~30-40% overlap in extrachromosomal DNA features. KRAS mutation discrepancies (e.g., G12D/G12V vs. G12R) indicated clonal evolution. Key driver mutations (APC, TP53, KRAS, PIK3CA, SMAD4) were consistently detected, corresponding with Oncomine targets. Histopathology confirmed retention of tumor-specific markers. Drug screening revealed variable responses across organoids, with fluorescence-based viability assays confirming model-specific sensitivities. Transcriptomic analysis highlighted molecular heterogeneity and distinct subtype-specific expression patterns. Several genes were consistently expressed across models, suggesting shared oncogenic pathways.
Conclusion: CRC organoids from HCMI faithfully recapitulate key transcriptomic and mutational features of patient tumors while revealing diverse drug responses. These models offer valuable platforms for precision oncology, enabling the identification of variant-specific vulnerabilities and supporting personalized treatment strategies.

#5458 Single-cell metabolic flux analysis defines distinct metabolic programs across tumor-infiltrating immune cells.

Yue Fang[1], Changlin Wan[1], Haiqi Zhu[2], Zheng An[1], Pengtao Dang[1], Chi Zhang[1], Sha Cao[1]

[1]Biomedical engineering, Oregon Health & Science University, Portland, OR,[2]Computer Science, Indiana University, Bloomington, IN

Metabolism strongly influences how immune cells become activated, differentiate, and lose function in the tumor microenvironment. Understanding the metabolic programs that define different tumor-infiltrating immune cell subtypes is important for identifying pathways that could be targeted to improve immune responses in cancer, yet the distinct metabolic features of major immune cell types—including T cells, myeloid cells, NK cells, and B cells—are still not well defined. To address this, we collected multiple tumor-derived scRNA-seq datasets (>500,000 cells across ~30 immune cell subtypes). Using these datasets, we conducted metabolic flux inference to identify immune cell-specific metabolic states in the tumor microenvironment. scRNA-seq datasets of tumor-infiltrating immune cells were first analyzed using Seurat, where cell type and subtype identities were assigned based on canonical marker genes and confirmed with additional annotation tools. Pseudobulk and meta-cell representations were created to reduce sparsity, and metabolic flux was estimated using our in-house tool MPOCtrL, which infers reaction-level activity from gene expression using curated metabolic gene lists. Dimensionality reduction and clustering were applied to compare metabolic patterns across immune cell types and subtypes. In particular, for T cells, we have discovered distinct metabolic phenotypes for different T cell subtypes. Exhausted T cells showed high serine and glutamate metabolism, low glucose uptake, and reduced β-oxidation, while T follicular helper cells showed opposite trends with low serine and glutamate metabolism but high glucose uptake and elevated glycolysis. Glycolysis was also high in Th1-like cells but reduced in CD4 cytotoxic effector and Tn-like cells. Lactate-associated flux was enriched in Treg and Trm cells, while Tcm and Tn-like cells showed low lactate production. Ketone body metabolism was high in Th17-biased CD4 T cells and low in Trm cells. Fatty acid pathways varied across subsets, with Tn-like cells showing low fatty acid synthesis and Th1-like cells showing high β-oxidation. Pentose phosphate pathway activity remained uniformly low across T-cell subsets. This analysis reveals clear metabolic patterns across immune cell types and subtypes in the tumor microenvironment. By defining these metabolic programs, our work provides a basis for identifying metabolic pathways that could be targeted to change immune cell behavior and improve anti-tumor immunity.

#5460 Elucidation of breakage-fusion-bridge (BFB)-mediated *EGFR* amplification in lenvatinib-resistant hepatocellular carcinoma.

JungHyun (Jenny) Kim[1], Ji Young Kim[1], Hyeonu Yang[1], Sang Yun Ha[2], Han-Na Kim[1], Hoon Kim[3], Yeup Yoon[4], Wonseok Kang[5]

[1]Samsung Medical Center, Samsung Advanced Institute for Health Sciences and Technology (SAIHST), Seoul, Korea, Republic of,[2]Pathology, Samsung Medical Center, Seoul, Korea, Republic of,[3]School of Pharmacy, Sungkyunkwan University, Suwon, Korea, Republic of,[4]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[5]Gastroenterology and Hepatology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

Lenvatinib, a multi-targeted tyrosine kinase inhibitor, is widely used as a first-line therapy for patients with immunotherapy-ineligible hepatocellular carcinoma (HCC). However, its clinical benefit is often compromised by the development of resistance. Understanding the genomic alterations driving resistance is critical to improving therapeutic outcomes in HCC. In this study, a lenvatinib-resistant HCC cell line, Huh7, was established by exposing parental sensitive cells to increasing concentrations of lenvatinib. To elucidate the mechanisms underlying drug resistance, short- and long-read whole genome sequencing (WGS), whole transcriptome sequencing (WTS), and western blot were performed. Comparative analysis of genomic alterations between parental and resistant cells revealed marked differences in copy number (CN) profiles. In resistant cells, *EGFR* showed the most prominent CN gain, increasing from 6 to 21 copies. Detailed breakpoint analysis utilizing LUMPY identified fold-back inversions that directly corresponded with genomic locations exhibiting significant CN alterations, indicative of the hallmark features of breakage-fusion-bridge (BFB) cycles. These findings were confirmed by Sniffles-based long-read SV calling. Transcriptomic and protein-level analyses using WTS and Western blotting, respectively, showed increased EGFR expression. Gene set enrichment analysis showed significant enrichment of ERBB and MAPK pathways. Mechanistically, activation of the EGFR-PAK2-ERK5 axis was observed, suggesting that lenvatinib-induced blockade of VEGFR/FGFR promotes a bypass survival signal through EGFR downstream pathways. Combined treatment with lenvatinib and erlotinib, an EGFR inhibitor, reduced viability and restored sensitivity. Clinically, lenvatinib-treated HCC patients with high EGFR immunohistochemistry scores exhibited shorter progression-free survival, and public HCC cell line datasets consistently showed poor responses in *EGFR*-amplified cells. In conclusion, our findings suggest BFB-driven *EGFR* amplification as a key structural and functional driver of lenvatinib resistance in HCC. Lenvatinib combined with an EGFR inhibitor may offer a treatment option for patients with HCC exhibiting elevated EGFR expression.

#5461 Molecular genetic profiling of a *de novo* neuroendocrine prostate cancer in a patient-derived xenograft (PDX) and organoid model from an African ancestry patient.

Tej Sharma, Surendra Gulla, Sasikumar Ponnusamy, Abbas Jawadwala, Ephraim Gardner, Roberto Pili, Maddie Aust, John Bodkin, John Tomaszewski, Remi-adelaya Ogala

Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY

Patient-derived xenograft (PDX) and organoid (PDO) models are powerful tools to study how prostate cancer (PCa) develops and responds to treatment, especially in populations that are often underrepresented. In this study, we report the first de novo neuroendocrine prostate cancer (NEPC) case from an African American male who had localized disease with no prior treatment before surgery. The tumor was classified as pT2N0, Gleason score 7 (4+3), and had a PSA level of 3.6. A portion of the patient's tumor tissue was used to generate PDX and PDO models, and another portion was used for downstream molecular analyses. To identify genetic changes driving aggressive tumor behavior, we performed whole-exome sequencing on DNA from the primary tumor and the first passage of the associated PDX model generated (p0) using the Illumina Exome Kit and the Twist Biosciences Exome Panel 2.0. Bioinformatic analysis was performed using Nextflow pipelines (nf-core/sarek) to detect somatic single-nucleotide variants (SNVs), mutations, structural variants, and copy number variations (using CNVkit). Our results reveal variant annotation links of genetic changes associated with PCa progression. Western blot analysis and immunohistochemistry (IHC) demonstrated increased expression of neuroendocrine markers, SYP. Furthermore, we observed similar mutations and copy number changes in genes previously reported in NEPCs. Moreover, novel markers provide deeper insight into molecular drivers of prostate cancer and could guide the development of targeted treatments for aggressive, high-risk localized PCa.

#5465 Improving early cancer detection by training scalable deep neural networks to extract tumor signal from cell-free DNA.

Jackson A. Killian[1], Kade Pettie[1], Kyle Gowen[1], Shiva Farashahi[1], Esther Brown[2], Feras Hantash[2], Jocelyn Charlton[1], Franziska Michor[3], Kieran I. Chacko[1], Dorna Kashef[1]

[1]Machine Learning and Computational Biology, Harbinger Health, Cambridge, MA,[2]Clinical Laboratory, Harbinger Health, Cambridge, MA,[3]Data Science, Dana-Farber Cancer Institute, Boston, MA

Introduction: Blood-based liquid biopsies offer potential for non-invasive cancer screening. However, detecting early-stage disease is complicated by low levels of circulating tumor biomarkers and background noise from normal cells. To address this, we developed a novel deep-learning framework to detect cancer signal at the resolution of single DNA reads. Applied to bisulfite-converted cell-free DNA (cfDNA) samples, our method significantly improves early-stage cancer sensitivity.
Methods: We designed a massively parallel 2-D convolutional neural network architecture that differentiates cancer and non-cancer signal in cfDNA by learning local methylation patterns at thousands of genomic regions. The model takes next generation sequencing (NGS) data as input, encodes aligned sequences within genomic windows as images, and outputs informative feature vectors for classification. However, training is complicated by two real-world data limitations: (1) disease samples contain a mix of unlabeled fragments from normal and diseased cells, and (2) acquiring sufficient early-stage disease data is costly, burdensome, and time-intensive. To address these, we designed a novel data generation technique that (1) assigns positive labels for groups of reads via in silico spike-in of tumor biopsy reads and (2) generates large, diverse datasets via fine-tuned in silico mixing of non-cancer cfDNA reads. Our model's architecture has key advantages: compact input encoding, interpretable saliency maps, and scalable parallel architecture: we trained on 720TB of data across 10 million genomic bases in a single day, highlighting our framework's efficiency.
Results: We validated our method with targeted bisulfite sequencing data from the CORE-HH clinical study (NCT05435066, N=1229 non-cancers, N=1118 cancers, including N=599 Stage I/II). We pretrained the model on 1.3 billion training examples generated using a held-out set of non-cancer plasma (N=174) and tumor tissue biopsies (N=505). Predictions on data from clinical samples yielded feature vectors, with saliency maps confirming the model highlights biopsy-learned patterns. In a 10x5 cross-validation, classifiers trained on these feature vectors improved overall sensitivity by 9.9 points (Stage I: +6.5 pts, II: +17.6 pts, III: +14.3 pts, IV: +9.5 pts) at 98.5% specificity, compared to classifiers trained on region-wide average methylation values. These performance improvements, coupled with the scalability of the framework, underscore its potential as a transformative tool in the early diagnosis of cancer and establish a foundation for training models on NGS data in other liquid biopsy assays. Future work will investigate the potential to incorporate per-read embeddings from DNA-based large language models, without sacrificing scalability.

#5467 Integrating intra- and inter-cell gene-gene interactions into deep omics data analysis for enhanced single-cell cancer biology.

Qingyue Wei[1], Sheng Liu[1], Chuanbao Zhang[2], Zixia Zhou[1], Wei Emma Wu[1], Md Tauhidul Islam[1], Lei Xing[1]

[1]Stanford University, Stanford, CA,[2]Beijing Tiantan Hospital, Capital Medical University, Beijing, China

Single-cell RNA sequencing (scRNA-seq) is widely used in cancer research to dissect tumor heterogeneity, characterize malignant and immune cell states, and identify dysregulated regulatory programs. However, accurately accounting the gene-gene interactions in cellular samples remains challenging due to the high dimensionality and nonstructured sequences of single-cell data. Existing Transformer-based approaches often rely on oversimplified gene-embedding strategies—such as ordering, coarse value binning, or direct value projection—that reduce biological resolution and overlook key regulatory dependencies. Moreover, most current methods emphasize intra-cell interactions while neglecting population-level patterns that are essential for understanding tumor microenvironmental regulation. To address these limitations, we propose a novel dual-branch Transformer framework that explicitly integrates intra-cell and inter-cell gene-gene interactions. The method comprises two complementary branches: (1) an intra-cell interaction branch that uses a Transformer augmented with interaction-aware embeddings to capture fine-grained regulatory relationships within individual cells based on graph-derived gene representations; and (2) an inter-cell interaction branch that applies a Vision Transformer (ViT) to image-based representations of single-cell profiles, spatially organized to reflect global gene-gene interaction structures across cell populations. A cross-attention module links the two branches, enabling coordinated learning between intracellular and intercellular regulatory signals. Extensive evaluation across diverse downstream tasks—such as cell-type classification, including cancer cell recognition and characterization; gene regulatory network inference; and protein abundance prediction—demonstrates that this interaction-aware architecture consistently outperforms state-of-the-art approaches. Notably, the framework achieves approximately a 30% average improvement in protein abundance prediction, a 4% improvement in cell-type classification accuracy, and a 4% improvement in gene regulatory network inference performance. By jointly capturing cell-intrinsic regulatory signals and population-level interaction patterns, the proposed framework offers a powerful computational strategy for dissecting tumor heterogeneity and characterizing regulatory interactions between malignant and microenvironmental cell populations.

#5468 Deep learning-based analysis reveals patient-level proton radiation therapy trajectories using single-cell PBMC chromatin images.

Hannah M. Schluter[1], Trinadha Rao Sornapudi[2], Dominic Leiser[3], Sandra Koller[2], Zeynep Karavelioglu[2], Caroline Uhler[1], Damien Weber[3], G. V. Shivashankar[4]

[1]Laboratory for Information and Decision Systems, Massachusetts Institute of Technology, Cambridge, MA,[2]Division of Biology and Chemistry, Paul-Scherrer Institute, Villingen, Switzerland,[3]Center for Proton Therapy, Paul-Scherrer Institute, Villingen, Switzerland,[4]Department of Health Sciences and Technology, ETH Zurich, Zurich, Switzerland

Introduction: The development of non-invasive, simple, and accurate methods to predict patient response to cancer therapy remains an open challenge. Proton radiation therapy (PRT) is increasingly used for hard-to-reach tumors or those in sensitive areas. However, it remains more expensive than other radiation therapies and while considered safer than conventional radiation therapy, its short- and long-term side effects are still not well explored. Therefore, developing an early measure for patient response is a critical research direction. Here we sought to test whether chromatin images of peripheral blood mononuclear cells (PBMCs) contain sufficient information to track patients' trajectories during and after PRT.
Methods: We collected blood samples at five timepoints (before, during, at the end of, and twice after PRT) from 150 patients across various cancers including Central Nervous System and Head & Neck cancers, and 50 healthy volunteers. PBMCs were isolated, stained with DAPI to label the DNA, and imaged with a confocal microscope. We applied machine learning methods to single-cell crops of the PBMCs to: 1) classify healthy vs. cancer patients, 2) derive patient-level similarity-to-healthy scores, and 3) predict patient trajectories. To account for the possibility that variation in PBMC proportions might be a key difference between healthy and cancer patients, we adopted a multiple-instance learning (MIL) approach. MIL is a form of weakly-supervised learning that automatically discovers which features and which cells are important within a collection of cells.
Results: By comparing chromatin images of PBMCs from cancer patients and healthy volunteers using our MIL framework, we identified cancer-specific alterations in PBMC chromatin architecture induced by tumor-derived signals in the bloodstream. Longitudinal tracking across five time points revealed three distinct patient subgroups. Patients whose PBMC profiles shifted toward greater similarity to healthy volunteers after therapy were less likely to experience disease recurrence. Furthermore, our MIL framework enabled prediction of patients' likelihood of returning to a healthy state after therapy, based solely on pre-treatment PBMC chromatin images, within the largest cancer type population in our study, Head & Neck cancer.
Conclusion: In summary, we demonstrated that simple chromatin images derived from liquid biopsies can serve as a non-invasive, easily obtained, and inexpensive biomarker for monitoring patient trajectories during PRT. This motivates further investigation of the use of PBMC chromatin images in the context of cancer screening and treatment monitoring, and more broadly in other disease contexts where PBMCs have been previously studied as potential biomarkers.

#5469 Data-efficient morphological deep learning for fine-grained Gleason grading based on AI-triaged 3D pathology.

Renao Yan[1], Gan Gao[1], Andrew Song[2], Huai-Ching Hsieh[3], Yujie Zhao[1], Cristina Almagro-Perez[4], Lawrence D. True[5], Faisal Mahmood[2], Priti Lal[6], Anant Madabhushi[7], Jonathan TC Liu[3]

[1]University of Washington, Seattle, WA,[2]Harvard Medical School, Boston, MA,[3]Stanford University, Palo Alto, CA,[4]Harvard-MIT Division of Health Sciences and Technology, Massachusetts Institute of Technology, Cambridge, MA,[5]Professor, Dept. of Pathology, University of Washington, Seattle, WA,[6]Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA,[7]Emory University, Atlanta, GA

Prostate cancer risk assessment relies on 2D histology, which samples only a small portion of tissue and lacks 3D architectural context, often leading to ambiguities. Slide-free 3D pathology using open-top light-sheet microscopy provides volumetric views of intact biopsies, offering richer morphological information without destructive sectioning. Yet the massive scale of 3D datasets makes manual review impractical. Prior work has shown that AI-triage models can identify high-risk 2D sections within 3D pathology datasets for time-efficient pathologist review, but these models are trained on limited labeled datasets, and thus prone to overfitting, especially for fine-grained multiclass tasks (e.g., Gleason grading). To address this, we investigate whether data-efficient, segmentation-guided prototype learning can better capture morphological patterns for improved Gleason grading. To enable fine-grained Gleason grading under limited supervision, we developed SCOPE, a Segmentation-guided CrOss-slice PrototypE learning framework for 3D pathology. Prototype learning helps mitigate overfitting by mapping large numbers of patch features into compact prototype features, each of which represents a distinct tissue morphology. To adapt this paradigm to 3D pathology, we first pretrain on unlabeled 3D volumes to initialize prototypes that capture the broad morphological diversity of the cohort. We then use 3D segmentation masks as structural priors to guide prototype refinement. In addition to the prototype learning, we adopt a 2.5D multiple-instance learning (MIL) strategy that incorporates context from neighboring slices to improve the feature quality for each slice of interest. Aggregated prototype features from each slice are used to train classifiers for grading. To evaluate our approach, we applied SCOPE to a cohort of 59 prostate cancer patients with slice-level annotations (Gleason grades) established by consensus among three pathologists. Using a leave-one-out cross-validation protocol, our framework achieved an AUC of 0.819 for the fine-grained Gleason grading task (i.e., GG1, GG2, GG3, or GG > 3). In comparison, the baseline prototype learning model achieved an AUC of 0.699. We further quantified the contribution of each component in SCOPE, finding that segmentation-guided features contribute the most, followed by the 2.5D MIL formulation and clustering-based pretraining. In summary, SCOPE confirms that data-efficient, segmentation-guided prototype learning can capture fine-grained 3D morphological patterns that improve prostate cancer Gleason grading. By integrating clustering-based pretraining with segmentation-derived structural priors and a 2.5D MIL formulation, SCOPE delivers a high-performance, interpretable, and clinically actionable AI-triage tool for 3D pathology when labeled data is limited.

#5470 Low-magnification deep learning model for rapid HER2 status prediction from H&E whole-slide images.

Ziyu Su[1], Abdul Rehman Akbar[1], Usama Sajjad[1], Sansar Babu Tiwari[1], Elshad Hasanov[2], Arya Mariam Roy[3], Zaibo Li[1], Daniel G. Stover[4], Muhammad Khalid Khan Niazi[1]

[1]Department of Pathology, The Ohio State University Wexner Medical Center, Columbus, OH,[2]Internal Medicine, The Ohio State University Comprehensive Cancer Center, Columbus, OH,[3]Division of Medical Oncology, The Ohio State University Comprehensive Cancer Center, Columbus, OH,[4]Department of Medical Oncology, The Ohio State University Wexner Medical Center, Columbus, OH

Background: HER2 (human epidermal growth factor receptor 2) overexpression is a pivotal biomarker for breast cancer prognosis and targeted therapy selection. Conventional assessment requires immunohistochemistry (IHC) and/or in situ hybridization (ISH), which are costly, time-consuming, and constrained by limited tissue and resource availability. In contrast, hematoxylin-and-eosin (H&E) slides are routinely acquired for diagnosis. Leveraging deep learning to infer HER2 status directly from H&E whole-slide images (WSIs) could substantially streamline the diagnostic workflow and reduce cost. However, existing deep learning models typically operate at high magnifications, resulting in slow slide-level processing and high computational costs, which hinder scalability and limit their integration into real-time clinical workflows.
Methods: To predict HER2 overexpression directly from routine H&E whole-slide images (WSIs), we developed a streamlined deep-learning model tailored for low-magnification pathology images. The approach extracts meaningful histologic features from each slide and integrates them at the whole-slide level to generate a binary prediction of HER2 status (positive vs negative). Model development and validation were performed using the TCGA-BRCA dataset, applying a five-fold cross-validation strategy to ensure robustness and generalizability. In each fold, 467 WSIs were used for training and 145 for testing. HER2 status in TCGA was determined primarily by IHC, supplemented with ISH results.
Results: Our model achieved an AUC of 0.7280.029 and an F1-score of 0.6530.054. In comparison, the state-of-the-art deep learning model UNI2 achieved an AUC of 0.7150.010 and F1-score of 0.6270.036. Despite comparable accuracy, our model demonstrated markedly higher efficiency, processing 8.8 whole-slide images per minute—approximately 30 faster than UNI2—while requiring significantly less computational and storage resources.
Conclusions: This study highlights the potential of our deep learning model to predict HER2 status from low-magnification H&E WSIs. Our model's efficiency and scalability highlight its potential for integration into digital pathology workflows, enabling near real-time molecular screening without the need for additional staining or cloud-based computation. This level of efficiency further strengthens its suitability for real-world deployment, particularly in settings with high volume or limited computational resources. These findings support the feasibility of deep learning-driven virtual biomarker prediction as a practical step toward accessible, AI-assisted precision oncology.

#5471 Genie-ADLA: A deep learning algorithm for methylation-based multiple cancer early detection (MCED).

Kezhong Chen[1], Ziyu Li[2], Xiaojian Wu[3], Jian Huang[4], Guoyue Lv[5], Weiping Wen[6], Dahong Zhang[7], Xiangyu Zhao[8], Danbo Wang[9], Zhihua Liu[10], Lixin Sun[11], Shu Wang[12], Xiangnan Li[13], Zhigang Li[14], Jiandong Tai[15], Jiayin Yang[16], Zhentong Wei[17], Ming Cai[18], Qiang Zhang[9], Songbing He[19], Shuhua Yi[20], Shenhong Qu[21], Wenhui Zhao[22], Xianjun Yu[23], Ruixia Guo[13], Jianhong Lian[11], Desong Yang[24], Huaiwu Lu[25], Xi Guo[26], Yan Zhang[27], Zhuowei Liu[28], Yingjiang Ye[29], Chang Lin[30], Jie Gao[31], Xuanhui Liu[32], Yushu Guo[33], Suying Ding[13], **Guoqiang Zhao**[34], Yanzhan Yang[34], Jiangyu Li[34], Shiqing Chen[34], Hui Yu[34], Fang Liu[34], Yang Wang[34], Min Li[34], Baoliang Zhu[34], Yonghui Li[34], Xiaohui Wu[34], Fan Yang[1], Jun Wang[1]

Ltd., Shanghai, China

Background: Methylation-based analysis of cell-free DNA (cfDNA) has emerged as a key technology for MCED. However, existing approaches rely on traditional machine learning algorithms, which inherently limit detection performance. With the rapid advancement of artificial intelligence (AI), we have developed Genie-ADLA, a deep learning algorithm designed specifically for MCED. By integrating state-of-the-art deep neural network architectures with the intrinsic patterns inherent in methylation data, Genie-ADLA significantly enhanced MCED performance.
Methods: Genie-ADLA was trained and evaluated on a dataset of 4,781 participants aged 40-75 years, including 2,702 pathologically confirmed cancer cases across 16 cancer types and 2,079 non-cancer controls (NCT06217900). The training set comprised 3,217 samples (1,756 cancer cases and 1,461 non-cancer controls), and the model's performance was evaluated on an independent test set of 1,564 samples (618 non-cancer controls and 946 cancer cases). To address challenges inherent to methylation data—high dimensionality, sparsity, and noise—we applied feature dimensionality reduction and embedding strategies, reducing computational burden, mitigating overfitting, and improving learning efficiency. An ensemble learning approach further strengthened robustness and generalization.
Results: Across all stages of 16 cancer types, Genie-ADLA achieved an overall sensitivity of 63.43% (600/946, 95% CI: [60.26%, 66.50%]) at 99.3% (612/618, 95% CI: [97.90%, 99.64%]) specificity in the test cohort. Compared with the XGBoost model trained on the same dataset, Genie-ADLA demonstrated improved overall sensitivity in 11 of the 16 cancer types, with an average increase of 4.86%.For stage I-III cancer patients, the sensitivities at 99.3% specificity showed notable gains over XGBoost: colorectal cancer achieved 76.98% (97/126, 95% CI: [68.65%, 84.01%]), an improvement of 9.52% from 67.46%; esophageal cancer reached 80.95% (51/63, 95% CI: [69.09%, 89.75%]), up 6.35% from 74.60%; breast cancer reached 37.14% (26/70, 95% CI: [25.89%, 49.52%]), improving by 5.71% from 31.43%. Lung cancer was subdivided into adenocarcinoma and non-adenocarcinoma, with stage I-III sensitivities of 40.90% (27/66, 95% CI: [28.95%, 53.71%]) in adenocarcinoma, an increase of 10.6%, and 84.44% (38/45, 95% CI: [70.54%, 93.51%]) in non-adenocarcinoma, improving by 2.22%.
Conclusions: Genie-ADLA, leveraging advanced deep neural network architectures and data processing strategies, substantially elevates the performance ceiling of methylation-based early cancer detection, offering a new paradigm for AI-driven cancer screening.

#5472 Deep learning reveals hidden pan-cancer drug signatures across the brain-gut axis through latent space modeling of 6.6 million single-cell perturbations.

Noha Samir Ismail[1], Kourosh Salehi-Ashtiani[2]

[1]New York University-Abu Dhabi / New York University-New York, Abu-Dhabi, NY,[2]New York University-Abu Dhabi, Abu Dhabi, United Arab Emirates

The brain-gut axis represents a bidirectional communication network increasingly recognized in cancer pathogenesis, yet shared therapeutic vulnerabilities between brain and gastric cancers remain unexplored. We applied deep learning on massive single-cell data to discover the drugperturbation signatures that elicit concordant responses across both tumor types.

We trained a Compositional Perturbation Autoencoder (CPA) on 6.6 million single-cell RNA-sequencing profiles from four cancer cell lines: two brain glioblastomas (A-172, H4) and two gastric carcinomas (KATO III, SNU-1), treated with 332 drugs from the Tahoe-100M dataset. The model compressed high-dimensional transcriptional responses into 128-dimensional latentrepresentations, capturing the complex drug-specific transcriptional perturbation signatures while removing confounders through adversarial training. We computed cross-tissue similarity scores between brain and gastric cancer responses in a learned latent space, capturing complex nonlinear patterns. Additionally, non-Negative Matrix Factorization (NMF) was applied todiscover data-driven pathway modules, and Gene Set Enrichment Analysis (GSEA) validated biological convergence using MSigDB pathway databases.

The model achieved a validation R^2 of 0.74 for gene expression prediction, with effective disentanglement of biological and technical confounders. We identified 49 pan-cancer drug candidates exhibiting high cross-tissue concordance (similarity > 0.7), including FDA-approved agents and investigational compounds. Top candidates included Erythromycin (similarity 0.752), Lonafarnib (0.747), and Capmatinib (0.742), exhibiting pathway module similarity of (0.78- 0.79). Furthermore, NMF revealed 15 latent pathway modules, with modules 7 and 15 significantly enriched in pan-cancer candidates (Spearman $\rho = 0.118$, $p < 0.05$). GSEAconfirmed convergence on inflammatory (NF-κB/IL-6), proliferation (RAS/MAPK), and survival (MET/mTOR) pathways (FDR < 0.05).

This work establishes a framework for discovering shared therapeutic vulnerabilities across anatomically distinct cancers in the brain-gut axis. The identified pan-cancer signatures provide mechanistically validated candidates for repurposing and rational combination therapy development in both brain and gastric malignancies. Deep learning enabled critical capabilities impossible with traditional bioinformatics:(1) automatic confounder removal via adversarial training, (2) discovery of functional drug similarity in compressed latent space capturing nonlinear response patterns, (3) unsupervised pathway module identification from learned representations. This enables mechanism-agnostic discovery of clinically validated pan-cancer therapeutics. AI tools were used in data analysis and editing this abstract.

#5473 A deep learning framework for extracting comprehensive single-cell biophysical profiles from brightfield images.

Nicholas Calistri, Selim Olcum, **Robert Kimmerling**, Steven Wasserman, Rachel LaBella, Madeleine Vacha, Katelin Katsis, Reginald Aikins, Maria Ssozi

Travera, Medford, MA

Single-cell biophysical measurements including mass, volume, density, and morphology provide a highly integrative readout of cellular state. We have previously demonstrated that these measurements enable rapid assessment of tumor cell drug response and immune cell functional fitness. As part of a CLIA-certified workflow with a two-day reporting turnaround, this approach enables clinically actionable decision support across diverse solid tumor malignancies and prediction of immune checkpoint blockade response. However, the complex instrumentation and expert operation required for these multiparametric measurements confine their use to CLIA laboratories as LDTs, limiting accessibility in community hospitals and deployment to large diagnostic networks. Here we describe a deep learning approach that estimates single-cell biophysical properties from brightfield imaging data alone. Specifically, we trained a Vector Quantized Variational Autoencoder (VQ-VAE) based model using more than 20 million paired multiparametric measurements as ground truth. This training data linked measurements of single-cell mass, volume, density, and morphological features extracted from inline brightfield images for each individual cell. The model was trained to minimize prediction error for biophysical measurements from images alone, creating a framework where simple imaging can serve as a proxy for comprehensive biophysical profiling. The biophysical inference model accurately predicted single-cell mass (RMSE < 2pg) and volume (RMSE < 15fL) from brightfield images with an R^2 >0.95, exceeding the performance of existing gold-standard instrumentation.

When deployed alongside our multiparametric platform, biophysical inference increased single-cell throughput more than 50-fold while maintaining measurement concordance. Notably, image-only predictions of immune cell activation readout, previously shown to predict neoadjuvant ICB response, achieved 95% accuracy, functionally equivalent to direct biophysical measurements in our CLIA-validated workflow.

This work establishes a paradigm for inferring quantitative biophysical properties from brightfield microscopy, bridging high-content single-cell biophysics with scalable imaging workflows. Unlike existing approaches relying on large patient cohorts to correlate high-dimensional features with outcomes, our framework uses experimentally measured biophysical parameters as interpretable intermediates linking images to patient response. Millions of single-cell measurements acquired rapidly and inexpensively provide an efficient training foundation. Furthermore, the framework enables tiered deployment: core laboratories use the full multiparametric platform for measurements and model training, while peripheral sites deploy low-cost imaging for routine applications.

#5474 Dyna-Q Reinforcement Learning for breast tumor malignancy classification using phantom-trained models applied to human data.

Chang-hee Won[1], Arpita Das[1], Dina Caroline[2]

[1]Electrical and Computer Engineering, Temple University, Philadelphia, PA,[2]Radiology, Temple University Hospital, Philadelphia, PA

Background: Obtaining large, well-annotated human datasets remains one of the major barriers to progress in biomedical AI. Ethical restrictions, patient burden, and institutional review processes limit access to clinical samples, making it difficult to train generalizable machine learning models. This issue is particularly acute in histopathology and tumor classification studies. Building on the concept of phantom-to-human transfer learning demonstrated by Das et al. (IEEE Sensors 2024), we propose a new Dyna-Q reinforcement learning framework that leverages tactile sensing to assess tumor malignancy. The model is trained exclusively on phantom data and applies a zero-shot knowledge transfer strategy to unseen human datasets, using interpretable mechanical features as the bridge between synthetic and biological domains.
Methods: In this study, we utilized a Tactile Sensing System to generate images correlated with the mechanical properties (size, depth, and elasticity) of breast tumors. Tactile data were first collected from breast phantoms. Using these data, we developed a deep Dyna-Q learning model for tumor classification. A deep neural network served as the decision-making agent and was trained in a self-supervised manner to classify tumor malignancy. The training process relied exclusively on phantom-derived tactile features of breast tumors, using a total of 9,000 balanced phantom data samples. Subsequently, we collected tactile data from 40 human patients. The trained deep Dyna-Q reinforcement learning model was then tested directly on the unseen human data to classify breast tumor malignancy, with pathology results serving as the ground truth.
Results: Despite the inherent domain gap between phantom models and human tissue, our approach achieved promising performance: an overall accuracy of 76.5%, sensitivity of 62.9%, and specificity of 73.5%. These findings indicate that clinically meaningful signals can be transferred across domains using tactile features, even without direct human training samples. By eliminating the need for retraining human data, this method substantially reduces reliance on scarce clinical datasets and offers a scalable solution for early-stage diagnostic modeling.
Conclusions: This study highlights the feasibility of a tactile, reinforcement learning-based AI system for tumor classification in data-limited biomedical settings. By exploiting phantom data as a training substrate, the approach minimizes dependence on scarce clinical samples and provides an ethical, scalable framework for early diagnostic modeling. Beyond breast cancer, this paradigm could be extended to other organ systems where tissue-mimicking phantoms are available, offering a practical path toward cost-effective and generalizable AI-driven diagnostics.

#5476 GLEAM: Democratizing high-quality machine learning for cancer research.

Paulo Cilas Morais Lyra Junior[1], Junhao Qiu[1], Khai Dang[1], Alyssa Pybus[1], Maansi Singh[1], Qiang Gu[2], Luke Sargent[2], Allison L. Creason[2], Jeremy Goecks[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Machine learning (ML) has revolutionized biomedical research, enabling accurate prediction from large and often high-dimensional datasets through statistical modeling and pattern recognition. Examples of ML applications include predicting patient responses to cancer therapies and classifying cancer lesions. However, the lack of accessible, well-structured guidance on how to develop, validate, and communicate ML models continues to limit their routine and effective use in research. To address this gap, we introduce the second-generation ML toolkit for the Galaxy platform, a widely used bioinformatics workbench. Named Galaxy Learning and Modeling (GLEAM), it is built around four core principles that target critical barriers in cancer research: no-code accessibility through a web interface; adherence to best practices via standardized setups and reports; reproducibility by recording parameters, data versions, environments, and workflows; and scalability through native Galaxy integration. Our goal is to provide end-to-end ML tools that enable researchers to configure, run, evaluate, and share publication-ready analyses. GLEAM integrates three learner tools: (1) Tabular Learner for structured data, (2) Image Learner for pixel-based inputs, and (3) Multimodal Learner for heterogeneous data. The AutoML backends are PyCaret, Ludwig, and AutoGluon, respectively. Users supply datasets, labels, and optional metadata, and GLEAM automates preprocessing, feature extraction, algorithm selection, hyperparameter tuning, and cross-validation. As a proof of concept, we reproduced results from published studies using GLEAM tools by running their publicly available datasets and comparing model metrics to benchmark tool quality. On the HAM10000 dermoscopy dataset, the Image Learner, using a deep-learning model, achieved accuracy 0.86 (vs. 0.86 in published models), precision 0.85 (vs. 0.88), recall 0.85 (vs. 0.85), and F1 score 0.85 (vs. 0.86), matching state-of-the-art outcomes for skin lesion classification on this dataset. On the LORIS immunotherapy-response dataset, the Tabular Learner achieved accuracy 0.80 (vs. 0.70), AUC 0.76 (vs. 0.75), and PR-AUC 0.55 (vs. 0.56), demonstrating robust prediction of treatment response. Using the HANCOCK dataset to predict survival in head and neck cancer, the Multimodal Learner achieved an ROC AUC of 0.74 (vs. 0.79). This modest decrease reflects a different modeling strategy, in which two engineered structured modalities were replaced with raw image and plain-text inputs, substantially reducing preprocessing complexity while maintaining competitive predictive performance. By embedding the GLEAM toolkit within Galaxy, we shift the focus from tool development to knowledge extraction. As a result, the framework produces high-quality, transparent, and shareable models that accelerate data-driven discovery and support cancer research.

#5477 AI-driven *de novo* design of miniproteins targeting mutant p53 peptide-MHC-I complex for cancer immunotherapy.

Fengze Jin, Puja Singh, Hanyong Chen, Christopher Warlick, **Yibin Deng**

Department of Urology, University of Minnesota Medical School, Minneapolis, MN

Genetic alterations in the tumor suppressor p53 occur in nearly every type of human cancer, with mutation rates ranging from 10% to nearly 100%, averaging about 50% in cancer patients. Over 80% of these mutations are missense mutations in the p53 DNA-binding domain (DBD), with the p53-R175H mutation being the most common "hot spot," occurring in approximately 5% of p53-mutated cases. Clinically, p53-R175H mutation in cancer patients are significantly associated with decreased overall survival compared to cancer patients with wild-type p53. Biologically, missense mutations in the p53 gene, particularly "hot-spot" mutations, including p53-R175H, result in the high expression of mutant p53 protein in cancer cells. These features suggest that expression of mutant p53-R175H protein could serve as an attractive therapeutic target. However, targeting the intracellular oncoprotein mutant p53-R175H has proven extremely challenging and remains a major unmet need in cancer therapy. Interestingly, the mutant p53-R175H protein can be processed by the proteasome into a 9-mer peptide, presented on the cancer cell surface by human leukocyte antigen (HLA)-A*02:01, a common major histocompatibility complex (MHC) class I allele in the U.S. population (40%), providing a “unique” target for immunotherapy by harnessing immune cells—such as T cells—to eliminate cancer cells carrying mutant p53R-175H. Traditional efforts to develop T cell receptors (TCRs) or monoclonal antibodies (mAbs) against the peptide-MHC-I complex have largely failed due to low affinity, limited specificity, and multi-year development timelines. Recent advances demonstrate that artificial intelligence (AI)-designed miniproteins (less than 150 amino acids) targeting peptide-MHC class I complexes can be engineered into chimeric antigen receptor (CAR)-T cells, enabling robust T-cell activation and potent recognition and elimination of tumor cells. To accelerate the discovery of miniprotein-mediated therapeutics, we have developed and integrated multiple AI-driven platforms for *de novo* design of p53-R175H peptide-MHC-I-complex binding miniproteins, including diverse backbone generation, protein sequence optimization, and enhanced high-throughput computational screening of peptide-MHC-I-miniprotein complexes. Top candidates have undergone, or are currently undergoing, experimental validation as engineered T/NK cell engagers and CAR-T/NK cells to kill cancer cells. In summary, our integrated AI-driven framework enables rapid and personalized cancer immunotherapy by transforming previously “undruggable” intracellular oncoproteins—including, but not limited to, mutant p53—into actionable immunotherapeutic targets.

#5478 Benchmarking gene expression foundation models on bulk RNA-Seq data.

Jong Hyun Kim[1], Sunwoo Yu[1], Soonyoung Lee[1], Tae Hyun Hwang[2], Jongseong Jang[1], Janghyeon Lee[1]

[1]Bio Intelligence Lab, LG AI Research, Seoul, Korea, Republic of,[2]Department of Surgery, Vanderbilt University Medical Center, Saint Johns, FL

Introduction: Recent advances in single-cell RNA (scRNA) foundation models have enabled large-scale learning of gene-gene relationships across cell types. Although these models are pre-trained on single-cell data, many studies have begun applying them to bulk RNA-seq datasets, assuming cellular level representations can generalize to tissue data. However, no systematic benchmark has evaluated whether scRNA-based foundation models truly generalize to bulk RNA-seq data or how their performance compares with models trained on bulk data. Here, we systematically evaluate gene expression foundation models for transferability and distributional bias between single-cell and bulk RNA-seq data using TCGA.

Methods: We compared publicly available models with released weights, including six single-cell models (CellFM, GeneFormer, scBERT, scFoundation, scGPT, and scLong) and BulkFormer, a model trained on bulk RNA-seq data. Embeddings were extracted following each model's published procedures. When not specified, average pooling over valid gene tokens was applied. Gene expression inputs were normalized according to each model's original preprocessing. Hyperparameter were tuned, and the best configuration was used for final evaluation. Performance was assessed via linear probing on fixed embeddings for two downstream tasks: gene mutation classification and survival prediction. Classification and survival tasks were evaluated using AUROC and C-index, respectively. Results were averaged across ten random data splits.

Results: In pan-cancer mutation prediction tasks involving six biomarker genes, CellFM achieved the highest performance (0.870 ± 0.053), followed by scFoundation (0.858 ± 0.056) and BulkFormer (0.827 ± 0.058). GeneFormer (0.822 ± 0.060) and scGPT (0.673 ± 0.077) showed moderate generalization (0.81-0.82), while scBERT (0.614 ± 0.054) and scLong (0.597 ± 0.053) exhibited limited transferability. A consistent trend was observed in subtype-specific mutation tasks across BRCA, COAD, LUAD, and RCC, where CellFM and scFoundation maintained the top performance, followed by BulkFormer. In survival prediction across 14 cancer types, scFoundation (0.672 ± 0.081) and CellFM (0.665 ± 0.078) achieved the best overall performance, comparable to BulkFormer (0.839 ± 0.086). While scBERT (0.599 ± 0.054) and scLong (0.589 ± 0.052) showed limited generalization.

Conclusion: In conclusion, models that effectively learn gene-gene interactions during pretraining can generalize across bulk RNA-seq data despite distributional differences. This suggests that the key to cross-domain performance lies not in model size or data scale, but in how well biological relationships are captured within learned representations. These results highlight the importance of biologically grounded pretraining for achieving robust generalization across transcriptomic domains.

#5479 Optical spectral fingerprinting for anthracycline detection in synthetic clinical biofluids.

Atara R. Israel[1], Yunjung Kim[2], Adnan Arnaout[1], Myesha Thahsin[1], Yumna Ahmed[1], Zachary Cohen[1], Amelia Ryan[1], Syeda Rahman[1], Mijin Kim[3], Ryan Williams[4]

[1]Biomedical Engineering, City College of New York, New York, NY,[2]Chemistry, Hanyang University, Seoul, Korea, Republic of,[3]Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA,[4]Stony Brook University, Stony Brook, NY

Anthracyclines, commonly used as chemotherapies, are highly effective at inducing apoptosis in cancer cells but also affect healthy cells; cardiotoxicity being a major side effect of chemotherapy administration as anthracyclines accumulate in cardiac tissue. The inability to monitor their accumulation in vivo in a noninvasive, rapid, and continuous manner presents a challenge in early diagnosis of cardiotoxicity and therapeutic drug monitoring of anthracyclines. While there are established guidelines for dosing this class of drugs, the high interpatient variability coupled with variable pharmacology make it difficult to gauge when cardiotoxicity may begin developing. To reduce this risk and more effectively understand these drugs' pharmacology, we developed fluorescent nanosensors using single walled carbon nanotubes (SWCNT) that can rapidly and continuously monitor anthracycline accumulation in a concentration-dependent manner. SWCNT have the innate ability to fluoresce stably in the near infrared region, which is tissue-transparent. Several species of fluorescent SWCNT exist due to structural chirality which have independent excitation/emission wavelengths. SWCNT are dispersed with ssDNA for individual dispersion, which imparts hydrophilicity and fluorescence, and promotes interaction with anthracyclines. To create chemical library diversity, multi-species SWCNT were dispersed with 12 unique ssDNAs and challenged with four anthracyclines: daunorubicin, doxorubicin, epirubicin, and idarubicin, at concentrations ranging from 0.1-100 μM. Using spectral fingerprinting, spectral changes and ssDNA-SWCNT pairings were analyzed using principal component (PCA) analysis to determine which factors most contributed to anthracycline detection. PCA differentiated sensor responses above 5 μM and provided insight into which ssDNA-SWCNT species combinations were best suited for detecting each anthracycline. Further analysis using binary classification was done using machine learning models k-nearest neighbor (k-NN) and support vector machine (SVM) to determine the accuracy of classifying each anthracycline's concentration-based spectral changes in buffer and synthetic biofluids. We found that the models were strongly predictive for detection of daunorubicin and idarubicin, exhibiting 100% cross validation, test accuracy, and validation in synthetic biofluids. Multi-class classification distinguished anthracycline type by spectral fingerprint, with 100% accuracy using Decision Tree and eXtreme Gradient Boosting. Future work will use these ssDNA-SWCNT species combinations to develop a noninvasive therapeutic drug monitoring tool to monitor accumulation at the tumor and in the heart during chemotherapy. We anticipate this work leading to a tool to improve tolerance for anthracycline chemotherapy by establishing personalized pharmacological treatment windows.

#5480 Artificial intelligence-designed peptide PROTACs suppress TNBC by regulating PD-L1 palmitoylation.

Miao Liu

Harvard Medical School/MIT, Boston, MA

Background: Triple-negative breast cancer (TNBC) responds poorly to immune checkpoint blockade (ICB), partly due to sustained PD-L1 expression on tumor cells. PD-L1 palmitoylation enhances its membrane stability and limits internalization, contributing to immune evasion. Modulating PD-L1 palmitoylation therefore represents an attractive strategy to overcome ICB resistance. Here, we developed an Artificial Intelligence-designed peptide PROTAC platform to regulate PD-L1 palmitoylation and restore anti-tumor immunity in TNBC.
Methods: Using an Artificial Intelligence-guided structural peptide-design workflow, we generated membrane-permeable peptide PROTACs composed of: (1) a high-affinity DHHC3-binding peptide, (2) a cell-penetrating peptide module, and (3) a small-molecule E3 ligase ligand. TNBC models (MDA-MB-231 and 4T1) were used to evaluate the effects of these degraders on DHHC3 levels, PD-L1 palmitoylation, PD-L1 expression, T-cell activation, apoptosis, and in vivo antitumor efficacy.
Results: The lead Artificial Intelligence-designed degrader efficiently reduced DHHC3, leading to substantial suppression of PD-L1 palmitoylation and marked downregulation of PD-L1 protein at nanomolar concentrations. In vitro, the degrader significantly enhanced T-cell-mediated cytotoxicity and increased IFN-γ and TNF-α secretion. In ICB-resistant 4T1 TNBC models, systemic administration of the peptide PROTAC resulted in strong tumor growth inhibition, outperforming PD-L1 monoclonal antibodies and small-molecule PD-L1 inhibitors. Tumor tissues showed increased apoptosis, reduced Ki67, robust loss of PD-L1, and no detectable systemic toxicity.
Conclusions: Artificial Intelligence-designed peptide PROTACs effectively suppress TNBC by regulating PD-L1 palmitoylation. This strategy expands the therapeutic potential of targeted protein degradation and provides a promising approach for highly aggressive and treatment-refractory TNBC.

#5481 Learning the mechanisms of chemotherapy response using a pathway-informed transformer.

Zach Wallace[1], Ingoo Lee[2], Nicole M. Mattson[2], Sungjoon Park[3], Akshat Singhal[4], Xiaoyu Zhao[2], Trey Ideker[2]

[1]UC San Diego, La Jolla, CA,[2]University of California San Diego - UCSD, La Jolla, CA,[3]UC San Diego School of Medicine, La Jolla, CA,[4]UCSD Medical Ctr., San Diego, CA

Predicting how a cancer patient will respond to chemotherapy remains challenging, as the molecular determinants of drug sensitivity and resistance are incompletely understood. Advances in interpretable AI and transformer-based modeling offer an opportunity to improve prediction while revealing deeper mechanistic insight. Here, we introduce the *Drug Response Pathway-Informed Transformer (DRPT)*, a hierarchical graph transformer that accurately predicts and explains response to 12 replication-stress-inducing chemotherapies. DRPT learns signals beyond broad genomic burdens such as copy-number alteration load and tumor mutation burden, identifying 37 systems and 206 genetic alterations that govern drug response. Prominent drivers include transcriptional regulation (ASXL1, DNMT3B, TOP1, ZNF217), cell-cycle control (AURKA, CDKN2B, CDK6), and DNA-damage response (CDKN2A, PMS2, TP53), alongside unexpected contributors in extracellular matrix organization (FGF10, DMD), particularly for topoisomerase inhibitors such as doxorubicin, etoposide, and camptothecin. Using patient cohorts from TCGA and MSK-CHORD, we validate DRPT's predictive power, demonstrating significant stratification of survival outcomes across pan-cancer and subtype-specific settings. Overall, this work shows that pathway-informed graph transformers can both reliably predict chemotherapy response and reveal mechanistic biomarkers that may guide precision oncology.

#5482 MethylFM: A DNA methylation foundation model for modeling epigenomic regulatory dynamics.

Limeng Pu, Xiang Chen

St. Jude Children's Research Hospital, Memphis, TN

DNA methylation regulates gene expression, differentiation, and disease, making it a key target for computational modeling in precision medicine. To integrate high-resolution whole-genome bisulfite sequencing (WGBS) data into a unified analytical framework, we developed MethylFM, a transformer-based foundation model that captures context-aware methylation patterns and supports multiple downstream tasks.We trained on the BLUEprint Epigenome dataset, comprising single-base WGBS profiles across diverse blood cell types with matched histone modification and transcriptome data. By focusing on ±100 CpG sites around transcription start sites (TSS), MethylFM targets regulatory regions central to gene expression and chromatin dynamics. Built on a BERT-style transformer with rotary positional embeddings and a masked-value prediction objective, it learns robust representations capturing both local and long-range dependencies in methylation.MethylFM demonstrated versatility across three downstream applications. For CpG-level imputation, it reconstructed high-resolution WGBS profiles from 450k array data with strong accuracy ($R^2 > 0.6$, MAE < 0.15). When benchmarked against METHimpute, evaluation was restricted to two samples due to METHimpute's intensive runtime; nonetheless, MethylFM achieved slightly higher accuracy ($R^2 = 0.518$ vs. 0.513), underscoring both precision and computational efficiency. In TSS-level H3K27ac prediction, the model reached $R^2 = 0.614$, matching the state-of-the-art M2A ($R^2 = 0.617$) and highlighting its capacity to infer promoter activity directly from DNA methylation. Finally, sample-level clustering based on predicted H3K27ac profiles accurately recapitulated hematopoietic lineages, surpassing experimental H3K27ac data (Silhouette = 0.47 vs. 0.30) and approaching RNA-seq-derived clustering performance (Silhouette = 0.51), demonstrating that MethylFM captures biologically meaningful epigenetic structure. Together, these results establish MethylFM as a generalizable and efficient framework for epigenomic modeling, enabling cost-effective methylation imputation, promoter activity prediction, and cellular identity characterization to advance biomarker discovery and precision medicine.

#5483 Revealing dynamic temporal trajectories and underlying regulatory networks with Cflows.

Shabarni Gupta[1], Xingzhi Sun[2], Alexander Tong[2], Manik Kuchroo[2], Dhananjay Bhaskar[2], Chen Liu[2], Aarthi Venkat[2], Beatriz P. San Juan[1], Laura Rangel[1], Vanina Rodriguez[1], John G. Lock[3], Christine Louise Chaffer[1], Smita Krishnaswamy[2]

[1]Garvan Institute of Medical Research, Darlinghurst, Australia,[2]Yale University, New Haven, CT,[3]University of New South Wales, Sydney, Australia

While single-cell technologies provide snapshots of tumor states, building continuous trajectories and uncovering causative gene regulatory networks remains a significant challenge. We present Cflows, an AI framework that combines neural ODE networks with Granger causality to infer continuous cell state transitions and gene regulatory interactions from static scRNA-seq data. In a new 5-time point dataset capturing tumorsphere development over 30 days, Cflows reconstructs two types of trajectories leading to tumorsphere formation or apoptosis. Trajectory-based cell-of-origin analysis delineated a novel cancer stem cell profile characterized by $CD44^{hi}EPCAM^{+}CAV1^{+}$, and uncovered a cell cycle-dependent enrichment of tumorsphere-initiating potential in G2/M or S-phase cells. Cflows uncovers ESRRA as a crucial causal driver of the tumor-forming gene regulatory network. Indeed, ESRRA inhibition significantly reduces tumor growth and metastasis in vivo. Cflows offers a powerful framework for uncovering cellular transitions and dynamic regulatory networks from static single-cell data.

#5484 Designing ATP-gated proteins for tumor selective drug delivery.

Angela Mei[1], Azim Dharani[2], Jody Mou[2], Benjamin Fry[2], Nicholas Polizzi[2]

[1]Departments of Computer Science and Chemistry and Chemical Biology, Harvard College, Cambridge, MA, [2]Department of Cancer Biology, Dana-Farber Cancer Institute, Boston, MA

Chemotherapy remains limited by lack of specificity in many existing treatments, motivating the need for therapeutic strategies that exploit molecular features unique to the tumor microenvironment (TME). A defining hallmark of the TME is the elevated concentration of extracellular ATP (eATP), which can rise ~1000-fold from nanomolar levels in healthy cells to ~100 μM in tumors. eATP promotes tumor growth and immune evasion, making it an attractive biochemical feature for tumor targeting. In this work, we used state of the art deep learning-based protein design methods to generate scaffolds capable of selectively binding ATP and experimentally validated their binding as an initial step toward developing ATP-gated systems for tumor-specific drug delivery. To accomplish this, we adapted our lab's Neural Iterative Selection and Expansion (NISE) workflow, which integrates deep learning-based sequence design and structure prediction. In this framework, ATP was first docked into candidate protein scaffolds to define the binding-site geometry. A sequence design model then generated amino acid sequences predicted to fold into stable structures accommodating the positioned ligand, after which a structure prediction network modeled the complex to assess self-consistency between the designed sequence and structure. The designed sequences were then filtered based on high structural similarity (indicating designability) and high confidence (reflecting complex plausibility), and top-performing designs were used as input for the next round of sequence generation. Across twenty NISE refinement cycles, the algorithm progressively enriched for protein-ATP complexes by optimizing the joint space of sequence, structure, and ligand conformation. The workflow ultimately produced ~2,600 candidate complexes, from which a small set of high-quality designs were selected for experimental validation. The designs were tested using NMR spectroscopy. One top construct displayed ^{1}H-chemical-shift perturbations upon ATP titration ($K_d \approx 250$ μM), consistent with the predicted isoleucine-adenine stacking interaction. Subsequent design rounds aimed to increase affinity by introducing features observed in natural ATP-binding proteins such as π-π stacking and expanded hydrogen-bonding motifs. In addition, the candidate protein structures were modified from 4-helix to 7-helix bundles to expand and solvate the binding pocket, enhancing hydrogen bonding, electrostatic complementarity, and water-mediated interactions. Together, these efforts represent the first step toward developing ATP-gated protein systems that can serve as tumor-selective drug delivery platforms, reducing the side effects commonly associated with chemotherapy in future applications.

#5488 Inferring tissue element identities from sample-level compositional data in cancer.

Georgios Asimomitis[1], Kevin M. Boehm[1], Konstantinos Liosis[1], Armaan Kohli[1], Tom Pollard[1], Andrew Aukerman[1], Arfath Pasha[1], Anika Begum[1], Lora H. Ellenson[2], Jinru Shia[2], Hong A. Zhang[2], Nikolaus Schultz[1], Sohrab P. Shah[1], Francisco Sanchez-Vega[1]

[1]Halvorsen Center for Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Department of Pathology & Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

The relative abundance of cellular and structural components in cancer tissues reflects disease biology and outcomes. High-throughput technologies, e.g., digital pathology and single-cell transcriptomics (scRNA-seq), profile tissue regions or cells, revealing the heterogeneous building blocks (elements) that comprise bulk phenotypes. Yet, translational applications increasingly demand that models not only infer sample-level distributions but also provide element-level characterizations (e.g., of specific histology regions, cells) that explain tumor macroscopic behavior. Achieving such granularity from sample-level compositional data without laborious annotations remains a challenge, requiring models capable of connecting local properties to global phenotypes. Existing methods, using attention to weight element contributions to sample-level predictions, lack probabilistic grounding and biological interpretability; thus, have limited utility in clinical settings.

Here, we explicitly model sample-level compositional constraints with element-level assignments using Optimal Transport (OT). Particularly, we introduce *Composer*, a domain-agnostic dual-task machine learning model trained without element-level annotations to 1) estimate sample-level compositions, and, 2) importantly infer element labels as interpretable compositional allocations.

The model's performance was evaluated across data modalities, cancer types, and tasks. We highlight 3 concepts:

a) Tissue type classification on whole-slide images (WSIs): On 60 hematoxylin & eosin (H&E) WSIs from high-grade serous ovarian cancer (HGSOC, Boehm et al. 2022), *Composer* predicted the overall WSI tissue composition (Jensen-Shannon divergence (JSD): 0.26; mean absolute error: 0.11), classifying correctly (AUROC 0.98) the tissue type (tumor, stroma, necrosis, adipose, other) of individual regions within WSIs without training on regional annotations.

b) Tumor segmentation on WSIs: On 185 H&E WSIs spanning HGSOC, breast, and colorectal cancers (MSKCC), *Composer* estimated the overall tumor fraction per WSI (JSD 0.12; MAE 0.15), distinguishing efficiently tumor from non-tumor regions (AUROC 0.91) within WSIs.

c) Single-cell type annotation in scRNA-seq: Using 156 scRNA-seq HGSOC samples (Vazquez-Garcia et al. 2022), *Composer* not only inferred bulk cell type distributions (JSD: 0.15; MAE: 0.06), but also accurately classified (AUROC: 0.97) individual cells to their designated type (T cells, monocytes, fibroblasts, cancer cells, other).

In summary, the proposed OT-based weakly supervised framework provides an effective approach for linking element-level representations to sample-level compositional profiles in cancer. Its applicability across data analyses empowers spatial and molecular characterization of tumor ecosystems, biomarker quantification, and potential applications to precision oncology.

#5489 Multi-scale foundational AI descriptors enable accurate tumor localization in digitized renal cell carcinoma pathology.

Sahil Kapadia[1], **Brennan Flannery**[2], Satish Viswanath[3]

[1]Department of Neuroscience, University of North Carolina at Chapel-Hill, Chapel-Hill, NC,[2]Department of Biomedical Engineering, Case Western Reserve University, Cleveland, OH,[3]Department of Biomedical Engineering and Pediatrics, Emory University, Atlanta, GA

Background: Renal cell carcinoma (RCC) diagnosis relies on accurate tumor localization on pathology whole slide images, but suffers from substantial inter-observer variability, which can impact treatment selection. Recent advances in digital pathology AI tools have resulted in foundation models (FMs) that are trained on diverse H&E images to learn patterns of tissue morphology. However, the performance of these models has been evaluated at a single scale, whereas clinical pathology evaluation leverages multiple scales and magnifications. Our objective was to develop and validate multi-scale pathology FM signatures for tumor localization in renal cancers.
Methods: H&E-stained whole slide images of RCC were curated from a public repository. For each case, tissue regions were sampled at three histologic scales (5×, 10×, and 20× magnification). Using the pathology FM MUSK, quantitative representations of tissue morphology were generated from each region and at each scale, and a supervised classifier trained on available pathologist annotations was used to discriminate tumor from non-tumor tissue. A multi-scale signature was constructed by integrating feature representations across all three magnifications for each region. We confirmed our findings using additional FMs (CONCH, HOPTIMUS) and by comparing against models trained at individual magnifications.
Results: A total of 118 slides (2 institutions) were included, split by patient into training (n = 94) and hold-out validation (n = 24) sets. Slides were sampled to yield 300,000+ labeled tiles (~112,000 tumor and ~222,000 non-tumor). The multi-scale MUSK model yielded the best overall accuracy for discriminating tumor versus benign tissue in hold-out validation (AUC ~0.95; accuracy ~0.89). By comparison, MUSK models at individual magnifications performed markedly worse (AUC ~0.90 to 0.92; accuracy ~0.82 to 0.85). Models trained using CONCH and HOPTIMUS demonstrated similar trends, with multi-scale models achieving AUC ~0.94 and accuracy ~0.89 that were improved relative to single magnification models (AUC ~0.91, accuracy 0.81-0.84).
Conclusions: Integrating foundation model representations across multiple scales and magnifications yields accurate tumor localization of RCC on digital pathology. These findings will be validated in larger RCC cohorts and evaluated for impact on treatment selection.

#5490 Scalable and interpretable multimodal AI: Integrating imaging and genomics via image-based encodingfor cancer and disease classification.

Sakib Mostafa, Md. Tauhidul Islam

Radiation Oncology, Stanford University School of Medicine, Stanford, CA

The integration of disparate data modalities, such as medical imaging and genomics, is fundamental to modern oncology, capturing a holistic view of complex disease heterogeneity. Deciphering these multimodal relationships is critical for precision medicine, yet the diverse nature of the data represents a significant challenge for current computational methods. Traditional deep learning approaches for multimodal fusion, while powerful, often suffer from massive computational overhead and complex, resource-intensive architectures. To address this, we present a novel framework that transforms high-dimensional tabular omics data into a compact, two-dimensional image representation using Optimal Transport. This transformation recasts omics data as an additional image channel, enabling the use of a single convolutional neural network (CNN) to concurrently process both data streams, thereby overcoming critical limitations in computational efficiency. When evaluated on a multimodal cancer dataset integrating Whole Slide Images (WSI) and Spatial Transcriptomics (ST), our method achieved 96% accuracy, outperforming the 94% baseline using WSI alone. We further demonstrated the framework's generalizability on the ADNI Alzheimer's dataset, where it achieved 97.6% accuracy (vs. 93.4% for MRI-only). This framework thus provides a scalable, interpretable, and efficient approach for unified multimodal analysis, offering new opportunities for cancer diagnosis and the study of complex biological systems.<!--EndFragment-->

#5491 AI foundation model for single cell annotation from conventional histopathology images of cancer.

Xiangqi Bai[1], HoJoon Lee[1], Xiao Tan[2], Chaoyi Li[2], Anuja Sathe[1], Yan Wang[1], Quan Nguyen[2], Hanlee P. Ji[1]

[1]Stanford University, Stanford, CA,[2]The University of Queensland, Queensland, Australia

Spatial imaging technologies have revolutionized our understanding of the tumor microenvironment (TME) by delineating its molecular and cellular architecture. Some of these approaches characterize tissue at single cell resolution. These platforms enable precise cell type annotation and, when spatially registered, allow molecular label transfer onto conventional histopathology images with hematoxylin and eosin (H&E) staining. However, spatial imaging approaches require complex instrumentation and have a high-cost per assay. These limitations prevent the application of spatial analyses on large sets of cancers. In contrast, conventional cancer histopathology slides are widely available and can be imaged at low cost. However, single cell identification from these images remains a manual, semi-quantitative process that is difficult to scale up.To address these limitations, we developed an AI foundation model that enables single-cell characterization directly from conventional H&E images. Our approach uses either spatial proteomic data (e.g., immunohistochemistry - IHC) or spatial transcriptomic profiling. We use these spatial assays to generate molecularly defined labels for diverse cell populations, including epithelial, lymphocyte, macrophage, and stromal cells. For this study, the molecular labels were the basis for training a spatial multimodal classifier. There are two tiers, (1) single-cell H&E crops were embedded using the foundation model H-optimous to obtain high-dimensional representations, and (2) a Multi-Layer Perceptron (MLP) neural network was trained on those embeddings for supervised cell type classification.We trained our model on a set of colorectal cancers (CRC), consisting of 40 multiplexed IHC slides and five Xenium spatial transcriptomic slides. Overall, we had 34 million single cells for model training. The model achieved an overall accuracy of 87.1% and a macro-average area under the receiver operating characteristic curve (AUROC) of 96.1%. Independent validation on seven CRC samples (~8 million cells) yielded consistent performance with 87.2% accuracy and 95% macro-average AUROC.In summary, our multimodal model enables automated and scalable single-cell-level cell type annotation directly from H&E images. This approach provides a quantitative foundation for immune-tumor interactions for colorectal cancer. Furthermore, by integrating H&E-derived cell type maps with tumor-specific genomic alterations from matched TCGA datasets, the framework enables systematic analysis of important TME cell types such as tumor-infiltrating lymphocytes and their spatial cellular distributions, offering insights into colorectal cancer microenvironmental architecture.

#5492 Differential protein pattern analysis in highly multiplexed imaging.

Gourab Ghosh Roy, Peng Jiang

National Cancer Institute, Bethesda, MD

The recent progress in highly multiplexed protein imaging has advanced our ability to identify topological structures in tissue microenvironments associated with distinct clinical characteristics. However, a significant challenge with high dimensional imaging is how to systematically infer spatial features underlying different patient clinical groups, like cancer outcome groups or immunotherapy response vs resistance groups. We develop an artificial intelligence framework for identifying differential protein patterns between distinct groups from spatial proteomics images. Our image region-based framework does not need any prior manual or semi-automatic steps like cell segmentation and cell type annotation as required in existing spatial data analysis workflows, and therefore can capture essential features not defined by humans. The framework is also suitable for use with a low number of labeled samples, as is the case for exploratory spatial studies. We used the framework to identify differential protein patterns between different phenotypic groups from humans and mice. We expect that our proposed framework will be a useful tool for generating novel hypotheses regarding biomarkers or regulators of cancer therapy outcomes.

#5493 Patterns of acid-suppressive therapy prescriptions in cancer: Are we treating symptoms or fueling the disease?.

M. Payling[1], Bea Bakshi[2], Marta Sakal[1]

[1]Research, C the Signs, Boston, MA,[2]C the Signs Inc, Boston, MA

Background: Whether proton pump inhibitors (PPIs) or H_2 antagonists influence cancer risk remains uncertain, partly due to confounding by indication and reverse causation. We analyzed prescribing patterns in a large dataset to characterize lifetime and pre-diagnostic exposure to PPIs and H_2 antagonists across cancer types, with emphasis on upper gastrointestinal (GI) malignancies.
Methods: We examined 3,390,218 adults in the NHS with linked medication and cancer coding, identifying lifetime acid-suppressive use and, for cancer cases, exposure during the 5 years preceding diagnosis. Patients with oesophageal, stomach, pancreatic, or biliary tract cancers were specifically compared with cancer-free controls. Age-specific 10-year PPI and H_2 antagonist prevalence was calculated, and odds ratios (ORs) for ever-use were derived using cancer-free individuals as comparators.
Results: There were 1,078 oesophageal, 527 stomach, 696 pancreatic, and 130 biliary tract cancer patients. Lifetime PPI exposure differed markedly by cancer type: 93% of oesophageal cancer patients (OR=35.0), 89% of stomach cancer patients (OR=21.2), and 65-75% of other cancer types reported PPI use, compared with 3-55% among age-matched controls. H_2 antagonist use showed weaker associations (OR 1.6-2.0).
In the 5-year pre-diagnostic interval, PPI exposure was highest in oesophageal (93.0%), stomach (89.0%), pancreatic (88.6%), and biliary tract cancers (87.7%), with a median duration of 84 days. Duration of pre-diagnostic PPI use showed a strong gradient unique to upper-GI cancers; no similar gradient was seen for H_2 antagonists. Several non-GI cancers, including laryngeal cancer, also demonstrated elevated PPI use, though to a slightly lesser extent.
Conclusions: PPI exposure, both lifetime use and 5-year pre-diagnostic duration, was substantially higher among upper-GI cancer patients than among age-matched controls. While this may reflect symptom-driven escalation of therapy in the period preceding diagnosis, the consistently elevated exposure across multiple cancers raises the possibility that PPIs themselves may contribute to carcinogenic processes. The absence of comparable associations for H_2 antagonists suggests that acid suppression alone does not explain the observed patterns. Pronounced PPI enrichment in upper-GI cancers, weaker signals for H_2 antagonists, and detectable associations in selected non-GI cancers underscore the need for further work to determine whether PPIs act solely as markers of prodromal symptomatology or may exert independent effects relevant to cancer development.

#5494 Multiplex immunohistochemistry for immuno-oncology: A flexible approach to characterize the tumor microenvironment.

Elena Baranova[1], Sabine Iglesias[1], Amanda Finan-Marchi[1], Manon Motte[1], Renaud Burrer[1], **Rania Gaspo**[2], Marie Gerus-Durand[3]

[1]Cerba Research, Montpellier, France,[2]Cerba Research, Laval, QC, Canada,[3]Cerba Research Histalim, Montpellier, France

Background: In immuno-oncology (I/O), limited tissue availability underscores the need for precise characterization of the tumor microenvironment (TME). Comprehensive phenotyping of immune cell populations and novel biomarkers is critical for understanding pro- and anti-tumor dynamics and guiding immunotherapy strategies. Multiplex immunohistochemistry (IHC) offers a powerful approach to achieve this.

Methods: Cerba Research developed multiplex IHC protocols targeting key I/O markers, including macrophage phenotypes, myeloid-derived suppressor cells, cytotoxic T-cell status, and regulatory T cells. Protocols were optimized using Leica Bond Rx and Roche Discovery Ultra platforms with Akoya Opals and Roche Chromogens for detection. Panels were applied to normal and tumor tissues from lung, colon, and pancreas. Fluorescent images were analyzed using an internally validated workflow without deconvolution. Quantification of single markers and phenotypes was performed on whole-slide images or regions of interest (ROI) selected by a pathologist using Halo® (Indica Labs).

Results: Multiplex panels demonstrated versatility across multiple indications, enabling detailed comparisons of immune profiles between healthy and tumor tissues and across tumor types. Quantification of single-marker positivity and phenotypic combinations provided insights into spatial distribution of immune subsets within the TME. The study also evaluated benefits and limitations of ROI-based analysis versus whole-slide assessment.

Conclusions: Multiplex IHC is a robust and flexible tool for immune profiling in solid tumors, offering comprehensive characterization of I/O-related targets and their spatial context. This approach supports deeper understanding of tumor-immune interactions and informs precision immunotherapy development.

#5495 AI-assisted Ki67 evaluation in solid tumors: Consistency and reliability compared to expert pathologists.

Rania Gaspo[1], Xavier Pichon[2], Maroua Tliba[2], Sabine Iglesias[2], Darshan Kumar[3], Renaud Burrer[2], Amanda Finan-Marchi[2], Marie Gerus-Durand[4]

[1]Cerba Research, Laval, QC, Canada,[2]Cerba Research, Montpellier, France,[3]Aiforia, Helsinki, Finland,[4]Cerba Research Histalim, Montpellier, France

Background: Ki67 is a key proliferation marker in solid tumors, particularly relevant for HR+/HER2- breast cancer when guiding adjuvant therapy. Despite its clinical importance, Ki67 immunohistochemistry (IHC) scoring lacks standardization. International guidelines aim to reduce variability among pathologists, and AI-driven image analysis solutions have recently emerged as rapid and reliable alternatives. This study compares Ki67 scoring using Aiforia® (AI platform) and Halo® (supervised image analysis software) against three independent pathologists across a large solid tumor cohort.

Methods: We stained 192 tumors of various origins, including breast and prostate, with Ki67 (clone 30-9). Pathologists were trained per International Ki67 Working Group (IKWG) recommendations and scored tissues accordingly. Aiforia®, based on deep learning, automatically quantified Ki67-positive tumor cells within minutes. Halo® employed a random forest classifier to segment tumor, non-tumor, and background regions, verified by a pathologist. After cell segmentation, Ki67 positivity was determined by thresholding.

Results: Ki67 scoring showed strong agreement between Aiforia® and Halo® across all solid tumors ($r^2 = 0.95$). Inter-pathologist correlations were weaker (A-B: $r^2 = 0.78$; A-C: $r^2 = 0.86$; B-C: $r^2 = 0.85$) despite standardized training, though still acceptable. Among 19 tumor types analyzed, only thyroid and stomach showed software correlation inferior to 0.75, with inter-pathologist agreement fair for stomach ($r^2 > 0.80$) and lower for thyroid ($r^2 = 0.65$-0.82). Organ-specific variability was notable among pathologists, while software scores remained consistent. For breast tumors (n = 16), Aiforia® and Halo® correlated strongly ($r^2 = 0.96$), whereas pathologist agreement ranged from $r^2 = 0.60$ to 0.87.

Conclusions: AI-based platforms like Aiforia® and supervised image analysis tools such as Halo® provide robust, reproducible Ki67 scoring and significantly reduce inter-observer variability. These technologies offer valuable assistance for IHC-based clinical analysis and may serve as arbitration tools or standardize Ki67 evaluation in solid tumors.

#5496 From transcripts to cells: Dissecting sensitivity, signal contamination, and specificity in Xenium spatial transcriptomics.

Mariia Bilous[1], Daria Buszta[1], Jonathan Bac[1], Senbai Kang[1], Yixing Dong[1], Stephanie Renaud-Tissot[2], Sylvie Andre[2], Marina Alexandre-Gaveta[2], Christel Voize[2], Solange Peters[2], Krisztian Homicsko[2], Raphael Gottardo[1]

[1]Biomedical Data Science Center, Lausanne University Hospital; University of Lausanne, Lausanne, Switzerland,[2]Department of Oncology, Lausanne University Hospital; Swiss Cancer Center Leman, Lausanne, Switzerland

Understanding cell states and interactions within tumors requires accurate spatial gene measurements. Spatial transcriptomics provides this capability by mapping gene expression directly within intact tissue, offering a powerful framework for studying tumor ecosystems. The purpose of this study was to systematically evaluate the performance of the Xenium platform in cancer samples and to develop an improved strategy for refining cell-level signals.We generated one of the largest Xenium datasets to date, comprising 41 breast and lung tumor sections from 27 donors and profiled using multiple targeted panels as well as the newer 5K panel. Using matched snRNA-seq, we assessed assay specificity, panel performance, segmentation strategies, and the prevalence of transcript spillover—a major source of technical variability in densely intermixed tumor ecosystems.We found that broader panel content increases biological coverage but reduces per-gene sensitivity. We further show that transcript spillover from adjacent cells significantly affects signal specificity, producing mixed profiles that obscure critical immune programs in cancer tissues. Building on these insights, we developed SPLIT (Spatial Purification of Layered Intracellular Transcripts), a method that combines snRNA-seq with deconvolution to correct spillover and recover cleaner cell-type signatures. SPLIT improved background correction, enhanced cell-type resolution, and revealed features such as T-cell exhaustion linked to local tumor-immune proximity that were not detectable using raw, contaminated data.In conclusion, our study provides a comprehensive performance assessment of Xenium in cancer contexts and introduces a scalable and interpretable approach for signal refinement, enabling more reliable inference of cellular programs and interactions within the tumor microenvironment. This dataset and methodology offer an important resource for designing, benchmarking, and interpreting spatial transcriptomics studies in cancer.

#5497 AI-augmented immersive 3D and 4D spatial analysis interface for cancer research.

Jonathan S. Kim[1], Minji Kim[2], Seock-Jin Chung[2], Inyeop Jang[2], Young-Won Cho[2], Jiwon Kim[3], Soonyoung Lee[3], Jongseong Jang[3], Eunyoung Choi[2], Tae Hyun Hwang[2]

[1]Cornell University, Ithaca, NY,[2]Vanderbilt University Medical Center, Nashville, TN,[3]LG AI Research, Seoul, Korea, Republic of

Background: Complex three-dimensional and time-resolved (4D) structures in cancer (cells, organoids, tissues, and drug distributions) are difficult to interrogate and discuss as a team. Our goal is to build an AI-augmented immersive interface that allows investigators to stand inside their data and explore it together in real time. We developed a multi-user VR/AR platform for volumetric microscopy that supports label-free holotomography (HT) (Tomocube HT-X1 Plus, 3D refractive-index images). The system enables interactive 3D segmentation, measurement, and annotation of subcellular and tissue-scale structures, including visualization of antibody drug conjugate (ADC) delivery. An integrated AI agent provides insight and can be augmented with domain-specific LLMs, including LG AI Research's EXAONE within a co-scientist AI agent framework.
Methods: We implemented a VR/AR environment where users can manipulate, segment, and annotate volumetric datasets in real time. The interface supports gesture-based selection, dynamic adjustment of 3D rendering parameters, and synchronized multi-user viewpoints. Users can query the AI assistant for literature context, analysis guidance, or suggestions for follow-up measurements inside the scene. The platform takes HT data as well as other multi-channel datasets for real-time multi-view rendering. We adapt LG's EXAONE's LLM-based chatbot and co-scientist agent architecture, which is trained on biomedical literature, to further enhance in-session analysis.
Results: We have validated the core visualization, interaction, and segmentation workflows and integrated the AI agent into the environment. Early demonstrations using 3D images of gastric cancer cell lines, organoids, and tissue sections allowed intuitive identification of nuclei, organelles, tumor glands, and stromal regions. Multiple users could concurrently explore morphology, annotate regions of interest, and derive quantitative metrics in real time. Ongoing data acquisition of gastric cancer cell lines, organoids, and tissues is coupled with manual annotation and AI-assisted segmentation to refine and benchmark performance.
Conclusion: We present an AI-augmented immersive interface for interactive analysis of volumetric cell and tissue datasets. By combining multi-user VR/AR, advanced 3D analysis tools, and a conversational AI agent, this platform enables detailed exploration of subcellular architecture and tumor microenvironments directly from HT or related volumetric and molecular data. Although our initial focus is gastric cancer and ADC delivery, the framework is disease and modality-agnostic and can be extended to other tumor types and therapeutic modalities.
Generative AI assistance was limited to language editing of this abstract. The scientific content, interpretation, and conclusions are the sole responsibility of the authors, who have reviewed and approved the final version.

#5498 Resolving phenotyping discordance with SPACEMAP, an integrated machine learning framework.

Arely Perez Rodriguez[1], Bassel Dawod[1], Sebastian Diegeler[1], Eslam A. Elghonaimy[1], Megan Wachsmann[2], Purva Gopal[2], David Hein[3], Paul H. Acosta[3], Andrew Jamieson[3], Gaudenz Danuser[3], Robert Timmerman[1], Satwik Rajaram[3], Todd A. Aguilera[1]

[1]Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX,[2]Department of Pathology, University of Texas Southwestern Medical Center, Dallas, TX,[3]Lyda Hill Department of Bioinformatics, University of Texas Southwestern Medical Center, Dallas, TX

Introduction and Purpose: Multiplex imaging provides powerful insight into cellular organization, yet the complexity of these datasets requires robust analytical tools to extract meaningful biological information. The purpose of this study was to develop a unified analytical framework enabling reliable, high-resolution characterization of the tissue microenvironments in multiplex images. To achieve this, we developed SPACEMAP (Spatial Phenotyping And Classification with Enhanced Multiplex Analysis Pipeline), a comprehensive Python and Qupath-based platform that integrates image registration, cell segmentation, quality check, artifact removal, tissue and zone classification, spatial feature extraction, and a consolidated phenotyping approach into a single workflow.
Methods: To determine an optimal cell-classification strategy, we benchmarked our phenotyping method, RESOLVE, against three established approaches, Leiden clustering, Self-Organizing Maps, and SCIMAP. This evaluation revealed substantial inconsistencies among existing methods. To address this, SPACEMAP incorporates two complementary workflows: (1) a machine learning model trained on expert-annotated cells, and (2) a consensus-based model that integrates high-confidence cell assignments across methods, enabling robust classification even when manual references are limited.
Summary: We applied SPACEMAP to newly generated multiplex imaging datasets from colorectal tissue samples and further evaluated performance using a publicly available dataset. These analyses demonstrate that SPACEMAP improves classification consistency, reduces variability introduced by method selection, and supports reproducible extraction of spatial features for further downstream analysis.
Conclusions: SPACEMAP provides a standardized, high-fidelity workflow for spatial phenotyping that minimizes reliance on labor-intensive manual annotation and improves reproducibility in multiplex imaging studies. Its design supports adaptation to evolving imaging technologies and marker panels, enabling researchers to more effectively investigate tissue organization and generate biologically meaningful insights.

#5499 SpatialTopic exploring tumor ecosystem in 3D multiplexed imaging of melanoma.

Xiyu Peng[1], James Smithy[2], Mohammad Yosofvand[2], Caroline Kostrzewa[2], Fiona Ehrich[2], MaryLena Bleile[2], Jasme Lee[2], Michael A. Postow[2], Margaret K. Callahan[3], Katherine Panageas[2], Ronglai Shen[2]

[1]Texas A&M University, College Station, TX,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Univ. of Connecticut School of Medicine, Farmington, CT

Background: Advances in multiplexed imaging now profile cell phenotypes from 2D to 3D, creating new opportunities to analyze spatial organization in complex tissue. A 3D view of tissue architecture enables a re-examination of tumor-immune interactions in the tumor microenvironment, revealing spatially organized niches with direct biological and clinical relevance that may be obscured in 2D.

Methods: We developed SpatialTopic[1], a fast, scalable, unsupervised niche-detection method that identifies recurrent spatial patterns (“topics”) across multiplexed tissue images. SpatialTopic analyzes datasets with millions of cells within minutes using modest memory. With cell-type annotations as input, it applies to both spatial transcriptomics and proteomics (e.g., Xenium, CosMx, IMC and CODEX). Here, we extend SpatialTopic to 3D multiplexed images and demonstrate its applicability on a 3D CyCIF dataset from the melanoma invasive margin[2]. We also introduce a supervised framework of SpatialTopic that predicts spatial topic distributions using fixed, predefined topic compositions (“known topics”), enabling more scalable inference across multiple samples and facilitating links between spatial niches and clinical outcomes.

Results: SpatialTopic delineates four main topics along the vasculature-to-tumor-core axis at the melanoma invasive margin: (1) Vascular topic: endothelial cells with CD4 T cells and macrophages; (2) Immune topic: mainly including CD4 T cells, dendritic cells, as well as Regulatory T cells (Tregs), and B cells; (3) Tumor-immune boundary topic: tumor cells mixed with dendritic cells and CD4 T cells; and (4) Tumor core topic. In this dataset, relative to the prior publication[2], SpatialTopic more cleanly resolves vascular structures and reveals a graded shift in immune composition from vasculature toward the tumor boundary: decreasing macrophages and increasing CD4 T cells and dendritic cells at the invasive front of melanoma.

#5500 Morphology-aware profiling of highly multiplexed tissue images using variational autoencoders.

Gregory J. Baker[1], Edward Novikov[1], Shannon Coy[2], Yu-An Chen[1], Clemens Hug[1], Zergham Ahmed[1], Sebastian A. Cajas Ordonez[3], Siyu Huang[3], Clarence Yapp[1], Gaurav N. Joshi[4], Fumiki Yanagawa[4], Artem Sokolov[1], Hanspeter Pfister[3], Sandro Santagata[2], Peter K. Sorger[1]

[1]Laboratory of Systems Pharmacology, Harvard Medical School, Boston, MA,[2]Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[3]Harvard John A. Paulson School of Engineering and Applied Sciences, Harvard University, Boston, MA,[4]Nikon Instruments, Inc., Cambridge, MA

Spatial proteomics (highly multiplexed tissue imaging) provides unprecedented insight into the types, states, and spatial organization of cells within preserved tissue environments. To enable single-cell analysis, high-plex images are typically segmented using algorithms that assign marker signals to individual cells. However, conventional segmentation is often imprecise and susceptible to signal spillover between adjacent cells, interfering with accurate cell type identification. Segmentation-based methods also fail to capture the morphological detail that histopathologists rely on for disease diagnosis and staging. Here, we present a method that combines unsupervised, pixel-level machine learning using autoencoders with traditional segmentation to generate single-cell data that captures information on protein abundance, morphology, and local neighborhood in a manner analogous to human experts while overcoming the problem of signal spillover. The result is a more accurate and nuanced characterization of cell types and states than segmentation-based analysis alone. We demonstrate the generality of this technique by applying it to a range of whole-slide, highly multiplexed human tissues acquired using platforms such as cyclic immunofluorescence (CyCIF), Lunaphore COMET, and Akoya PhenoCycler, and show that it can learn histological features across multiple spatial scales.

#5501 A quantum-enabled atlas-scale resource to study metabolic landscapes and heterogeneity in cancer TME.

Yinuo Zhao[1], Jiahe Yu[2], Min Yang[3], **Chi Zhang**[4]

[1]Middlesex School, Concord, MA,[2]Sierra Canyon School, Chatsworth, CA,[3]Oregon Health & Science University, Portland, OR,[4]Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Metabolic networks are profoundly rewired in cancer, supporting uncontrolled proliferation, immune evasion, and therapy resistance. Although large atlas-level single-cell RNA-seq (scRNA-seq) datasets of cancer tumor microenvironments (TMEs) and normal human tissues are now available, there remains no systematic, genome-scale characterization of metabolic landscapes, shifts, heterogeneity, and cross-talk across cancer and normal cells using these data. Elementary flux modes (EFMs), representing the minimal sets of reactions that sustain steady-state flux, provide a principled basis for describing metabolic capabilities, yet identifying biologically feasible EFMs in genome-scale networks is a major bottleneck due to the combinatorial explosion of possible modes. We propose a quantum-enabled framework that leverages atlas-level scRNA-seq data to infer plausible EFM distributions and derive sample-specific metabolic fluxes, with the long-term goal of building a scalable resource of cancer metabolic landscapes. Both EFM discovery and flux prediction are formulated as Quadratic Unconstrained Binary Optimization (QUBO) problems solved on quantum annealing hardware. By exploiting the intrinsic parallel sampling capabilities of quantum devices, our approach efficiently explores high-dimensional solution spaces under stoichiometric, thermodynamic, and cancer-specific biological constraints. To handle genome-scale models relevant to oncology, we integrate tensor decomposition-based dimensionality reduction to yield tractable QUBO formulations while preserving key pathway structure. On simulated networks with up to 25 reactions, quantum sampling robustly enriches EFMs that satisfy stoichiometric balance, support minimality, and irreducibility, while structurally invalid modes are rarely sampled. When imposing distinct sample-specific constraints mimicking different tumor contexts, the high-frequency EFM sets shift systematically, demonstrating that the framework captures condition-specific flux distributions without explicit enumeration. We then apply this quantum-driven strategy to single-cell atlases of pancreatic, prostate, and breast cancer, and integrate these results with TCGA bulk RNA-seq in constraint-based models to generate a shared, extensible resource of cancer metabolic landscapes. We show that this resource can be used to map recurrent pathway vulnerabilities, prioritize metabolic intervention targets, and quantify condition-specific metabolic strategies within and across tumor types, treatment states, and patient cohorts. By bridging quantum optimization and systems biology, our work provides a practical and interpretable foundation for personalized metabolic modeling and hypothesis generation in cancer.

#5502 gOS: A total molecular oncology interpretation framework applied to repaired FFPE and heme whole genome and clinical targeted assays.

Kevin Hadi, Aditya Deshpande, Shihab Dider, Charalampos Xanthopoulakis, Johnathan Rafailov, Marcin Imielinski

NYU Langone Health Perlmutter Cancer Ctr., New York, NY

Cancer molecular diagnostics remain fragmented across multiple assays and disjointed software, leaving molecular pathologists to manually link QC, purity/ploidy, and variant classes before oncologists can act on recommendations. We address this with two complementary, genome-wide WGS assays—a repaired-FFPE solid tumor test and a blood-only heme test—that consolidate SNVs/indels, CNAs, SVs/fusions, LOH, and signatures into a single DNA workflow with panel-like performance. In parallel, we built the total genome Oncology System (gOS), which integrates WGS, targeted panels, methylation, and RNA fusions into a coherent browser with variant tiering, clinical validation, and discovery-oriented exploration.

At NYU, standard care comprises NYU-PACT (607-gene DNA panel), Illumina MethylationEPIC v2.0 for solid tumors, and Oncomine (40-gene DNA) plus Myeloseqer for driver heme fusions. To pilot a WGS drop-in for DNA/RNA panels, we used enzymatic shearing (Watchmaker Genomics) and a FFPE damage-repair step that improves coverage uniformity and lowers artifacts. We analyzed 23 mixed solid tumors with paired normals and 22 hematologic malignancies; seven solid FFPE were also prepped without repair for comparison. gOS processed all 55 cases via an integrated Nextflow pipeline and provided interactive WGS vs SoC comparison.

Unrepaired FFPE showed AT-rich dropout and megabase-scale coverage bias; repair restored uniformity and suppressed artifacts. In a BRCA1-mutant/LOH case, HRD was obscured in unrepaired WGS (HRDetect 0.004; B1+2 0.2) but recovered with repair (HRDetect 0.99; B1+2 0.78). Across 23 repaired FFPE solids, WGS vs NYU-PACT achieved 96% sensitivity (298/310 hotspots) and near-100% specificity (1/6,740 SoC–wild-type positions). Heme WGS showed 100% concordance with Myeloseqer fusions and Oncomine mutations.

Together, the complementary WGS assays and gOS deliver panel-like accuracy with broader, pan-variant coverage and a single, coherent interpretive view, supporting WGS as a practical replacement for fragmented DNA/RNA panels—especially in historically challenging FFPE tissue—and enabling expanded clinical utility through unified multi-omic interpretation.

#5503 Cancer epitope prediction tools & analysis pipelines in CEDAR.

Ibel Carri[1], Jason Greenbaum[2], Zhen Yan[2], Kevin Kim[2], Haeuk Kim[2], Ashmitaa Logandha Ramamoorthy Premlal[2], Daniel Marrama[1], Nina Blazeska[3], Hannah K. Carter[4], Morten Nielsen[5], Alessandro Sette[1], Bjoern Peters[1], Zeynep Kosaloglu-Yalcin[3]

[1]La Jolla Institute for Immunology, La Jolla, CA,[2]Bioinformatics Core, La Jolla Institute for Immunology, La Jolla, CA,[3]La Jolla Institute for Immunology, San Diego, CA,[4]UC San Diego, La Jolla, CA,[5]Department of Health Technology, Technical University of Denmark, Lyngby, Denmark

The identification of immunogenic cancer epitopes, including patient-specific neoepitopes and shared tumor-associated antigens (TAAs), is a central challenge for the development of effective cancer immunotherapies. To accelerate their discovery, the Cancer Epitope Database and Analysis Resource (CEDAR), a comprehensive resource for immuno-oncology, curates epitope data from the literature and develops tailored computational tools. Building on this foundation, we introduce the modular Next-Generation IEDB Tools (NGT) platform (nextgen-tools.iedb.org/) that integrates a wide array of cancer-focused computational tools.

The NGT platform allows users to construct, save, and share customized, reproducible, end-to-end computational pipelines for tumor antigen discovery. This architecture enables systematic prioritization of epitope candidates by applying multiple, sequential filtering criteria based on predicted and calculated relevant immune features, such as antigen expression, antigen presentation, self-similarity, and immunogenicity.

Key tools include the Mutated Peptide Generator (MPG), which translates genomic variants (e.g., SNVs, indels) into candidate neoepitope sequences; Peptide Expression Annotation (PepX), which integrates public RNA-Seq data from resources like TCGA and GTEx to quantify antigen-encoding transcript abundance in tumor tissue; the Patient-Specific Presentation Metric (PHBR), a metric that estimates the likelihood of a mutation being presented by a patient's specific MHC Class I alleles; ICERFIRE (via Peptide Variant Comparison, PVC), a robust immunogenicity model that predicts the T-cell recognition potential of neoepitopes; PEPMatch, a tool to filter out candidate neoepitopes that are highly similar to self-peptides, which can indicate potential tolerance or autoimmunity risks; and Cluster, which groups highly similar peptide sequences to reduce redundancy and focus on the most representative candidates for experimental validation.

The CEDAR computational tools and integrated pipeline architecture on the NGT platform provide cancer immunologists with a flexible, user-friendly, and state-of-the-art resource. This comprehensive framework accelerates the translation of genomic and transcriptomic sequencing data into clinically actionable epitope candidates. Here, we present how these integrated tools can be applied to patient-level analyses, enabling personalized identification and prioritization of tumor epitopes to guide cancer vaccine design and immunotherapy development.

#5504 CoMMpass Explorer: An interactive platform to explore clinical and genomic data from newly diagnosed multiple myeloma patients from the landmark CoMMpass observational study.

Wanxing Zhang[1], Chaitanya R. Acharya[1], **Steven M. Foltz**[1], David E. Avigan[2], Samir Parekh[3], Ravi Vij[4], Shaji Kunnathu Kumar[5], Taxiarchis Kourelis[5], Sagar Lonial[6], Hearn Cho[1], Ioannis S. Vlachos[2], Sacha Gnjatic[3], Li Ding[4], Manoj Bhasin[7], George Mulligan[1]

[1]Multiple Myeloma Research Foundation, Norwalk, CT,[2]Beth Israel Deaconess Medical Center, Boston, MA,[3]Icahn School of Medicine at Mount Sinai, New York, NY,[4]Washington University School of Medicine in St. Louis, St. Louis, MO,[5]Mayo Clinic, Rochester, MN,[6]Emory Winship Cancer Institute, Atlanta, GA,[7]Emory School of Medicine, Atlanta, GA

The CoMMpass study (NCT01454297) is a prospective, longitudinal observational study involving 1,141 newly diagnosed multiple myeloma (NDMM) patients. Bone marrow aspirates from the study participants were collected for comprehensive molecular characterization of tumor (using bulk RNA sequencing and whole genome sequencing) and tumor immune microenvironment using 3' single-cell RNA sequencing (scRNA-seq). To support exploration of this rich multi-omic dataset, we developed CoMMpass Explorer (CE), an intuitive interactive platform that enables real-time analysis of clinical and genomic data from CoMMpass.

A central feature of CE is cohort building, where users can filter and stratify patients by clinical, genomic, and survival data elements to create custom cohorts for analysis. CE provides five main views: Overall Summary for clinical feature distribution, Kaplan-Meier curves, and multivariate Cox proportional hazards models; Mutational Profile for visualizing and comparing somatic mutations; Tumor Profile for bulk differential expression and gene set enrichment; Immune Microenvironment for comparing cell type abundance and cell cycle dynamics between cohorts using scRNA-seq data; and Pseudo-Bulk, which aggregates single-cell expression by cell type to enable cohort-level comparisons of transcriptional programs using DEseq2.

CE reproduces prior CoMMpass studies, including WEE1 expression being associated with poorer progression-free survival (Simhal, et al.) and different mutation frequencies between African American and European American patients (Manojlovic, et al.).

We further demonstrate CE's utility by interrogating the 2025 Consensus Genomic Staging (CGS) risk classification system (Avet-Loiseau, et al). We compared CGS high-risk (HR, n=249) vs. CGS standard-risk (SR, n=573) patients. HR patients have significantly worse progression-free survival, overall survival, and time to second-line therapy compared with SR patients. Univariate models recapitulated expected differences in the clinical features that define CGS risk. Bulk tumor RNA-seq and ssGSEA highlighted a more proliferative and genomically unstable transcriptional program in HR group, with upregulation of angiogenesis and cell-cycle-related pathways. In the immune microenvironment, monocytes were more abundant in the SR group. Pseudo-bulk RNA-seq of plasma cells showed overexpression of ANXA1, NSD2, IGF1R, MAF and related genes in HR.

CE democratizes access to the CoMMpass multi-omic resource, allowing researchers to interrogate clinical and molecular heterogeneity. By enabling hypothesis generation and replication of published results, CE serves as a valuable tool for identifying prognostic biomarkers and meaningful patterns in gene expression, mutation profiles, and the immune microenvironment.

#5505 A unified framework for cross-platform spatial omics analysis and deep spatial profiling.

Yunhe Liu[1], Edoardo L. Draetta[1], Kayla R. Caughlin[2], Alexandria Lau[2], Andre Fonseca[3], Tian Chu[1], Kyung Serk Cho[2], Yibo Dai[2], Yang Liu[4], Jun Wang[2], Jiahui Jiang[2], Yinyin Yuan[4], Futreal Andrew[2], Mingyao Li[5], Linghua Wang[2]

[1]Department of Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Translational Molecular Pathology,, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Instituto Metropole Digital (IMD), Universidade Federal do Rio Grande do Norte (UFRN), Natal, Brazil,[4]The University of Texas MD Anderson Cancer Center, Houston, TX,[5]University of Pennsylvania, Philadelphia, PA

Background: Spatial multi-omics has advanced rapidly in resolution, multiplexing, 3D modeling, and multi-modality. Platforms rely on distinct chemistries and assay architectures, yielding heterogeneous outputs but complementary strengths. These spatially indexed readouts enable neighborhood/niche inference, cell-cell communication, and 3D reconstruction, but demand rigorous normalization, uncertainty modeling, and scalable computation. Despite progress with foundation models for imputation and integration, a domain-specific suite that unifies these models for spatial omics is lacking.
Methods: We developed Spyrrow (Spatially Resolved Multi-omics Data Visualization and Analytic Framework), a Python toolkit for cross-platform analysis, visualization, multi-modality integration and enhancement, spatial registration, and 3D reconstruction (https://github.com/WangLab-ComputationalBiology/spyrrow). Spyrrow ingests heterogeneous outputs and standardizes them into a unified spatial data model. Modules span raw-data processing (cell segmentation to cell-level matrices; single-cell enhancement for Visium; Visium HD single-cell transformation using registered H&E), multimodal registration, and a foundation-model hub (UNI, KRONOS, LOKI) for panel expansion, imputation, and cross-modality retrieval. With harmonized data and z-axis registration, Spyrrow builds 3D models linking serial sections. On the unified object, we provide clustering, graph-based neighborhood retrieval and niche identification, region detection (tumor compartments, TLS), spatial label transfer, and a comprehensive cell-cell communication module. Visualization includes pseudo-H&E/pseudo-fluorescence, ligand-receptor quiver plots, and 3D voxel renderings.
Results: Spyrrow has been applied across multiple spatial-omics datasets and projects. The visualization suite produces clear, interpretable displays of niches, regions, and interaction patterns. Across benchmarks, integration with state-of-the-art models improves spatially aware clustering, label transfer, registration, and communication inference. Region-detection performance was corroborated by experimental validation. Together these results demonstrate robust performance, scalability, and cross-platform integration that are difficult to achieve with existing tools.
Conclusions: Spyrrow addresses a critical need in spatial multi-omics by providing a unified, adaptable, and cross-platform analytical framework. It facilitates both biological discovery and methodological innovation by supporting a wide range of spatial omics platforms. Importantly, it offers a scalable and interpretable approach to spatial data analysis—from broad tissue-level context to detailed subcellular features-empowering deeper insights into the tumor microenvironment and advancing immune-oncology research.

#5506 An ensemble machine learning approach to ALT detection revals therapeutic vulnerabilities in pediatric cancers lacking actionable drug targets.

Declan Bennett, Monika Weirdl, Lillian M. Guenther, Paul Geeleher

St. Jude Children's Research Hospital, Memphis, TN

Alternative lengthening of telomeres (ALT) maintains telomeres in 15-20% of cancers through a recombination-based mechanism associated with poor outcomes. ALT is frequently driven by ATRX/DAXX loss-of-function mutations and is enriched in pediatric malignancies including osteosarcoma, neuroblastoma, and soft tissue sarcomas—cancers with limited therapeutic options. Current ALT detection methods are low-throughput and not scalable to large cohorts, impeding systematic discovery of ALT-specific vulnerabilities. We developed ALTitude, a whole-genome sequencing (WGS)-based ensemble machine learning framework to predict ALT status. Using telomere-relevant genomic features extracted from >1,000 cancer cell lines in the Pediatric Cancer Dependencies Accelerator and Cancer Dependency Map (DepMap) resources. We trained and validated the model against orthogonal ALT detection methods. We integrated ALTitude predictions with genome-wide CRISPR loss-of-function screening data in DepMap to identify ALT-specific dependencies. ALTitude achieved high accuracy in ALT classification across diverse cancer types, providing the first scalable map of ALT in a densely functionally characterized cell line panel. Integration with CRISPR essentiality screens revealed SMARCAL1 as a top selective dependency in ATRX/DAXX mutant ALT - positive osteosarcoma, soft tissue sarcomas, and neuroblastoma. SMARCAL1 harbors a helicase domain distantly paralogous to ATRX and resolves stalled replication forks at telomeres during DNA damage response, suggesting that increased replication stress at ALT telomeres creates essentiality for SMARCAL1 function. This work establishes a scalable method to infer ALT status from WGS data and systematically connects ALT biology to therapeutic vulnerabilities in cancer cell line models. By identifying SMARCAL1 as selective dependency in ALT-positive cell lines, we nominate novel therapeutic targets for challenging pediatric cancer types. Our approach demonstrates how integrating features derived from genomic data with functional screening and other 'omics data can reveal novel insights into drivers across aggressive cancer subtypes.

#5507 A user-friendly, no-code, application for HIPAA-compliant automated analysis of tabular data at scale.

Paraic A. Kenny

Gundersen Medical Foundation, La Crosse, WI

Much research in clinical settings involves review of large quantities of often unstructured data in electronic medical records, which is time consuming and requires an educated workforce of clinical research coordinators, residents and/or fellows. Large language models, such as ChatGPT, have demonstrable capabilities for efficiently analyzing and summarizing large volumes of text, offering the potential to greatly accelerate chart review-based research in clinical settings. Concerns regarding leakage of personal health information (PHI) sharply limit the potential to utilize commercial chatbots for this purpose. Secure, fire-walled in-house LLM chatbots in a well-governed system can solve concerns related to PHI leakage. Although processing data for large studies one-prompt-at-a-time may offer substantial efficiency gains versus prior human-only processes, far greater efficiencies can be achieved by automating the prompt submission and retrieval process.

To address these concerns, we developed a user-friendly application for processing any form of tabular data at scale using an in-house implementation of ChatGPT 4o-mini on Emplify Health's Azure cloud environment. The application imports tabular data (in excel or text format), guides the user through a straightforward prompt engineering process and then automatically submits the data, row-by-row, to the LLM and retrieves and tabulates the returning data in the manner specified by the user.

The application was initially developed with the goal of rapidly reasoning through thousands of pathology reports to identify those which correspond to cancer cases and, for those cases, automatically extracting multiple cancer-related parameters. Following this early success, we developed a completely generalized data agnostic application which has found widespread utility within our research institute, being deployed on diverse data sources such as cancer registries, cardiology CT reports, imaging narratives and clinical encounter notes. In this way, the application has substantially accelerated research projects by dramatically reducing the time needed to retrieve data, enabling our personnel to spend more time on higher yield activities such as data analysis.

#5508 Bioinformatic method for the detection of micro copy number variations with exome sequencing data.

Jin Young Lee[1], Hyo Young Choi[2], D. Neil Hayes[1]

[1]Center for Cancer Research, University of Tennessee Health Science Center, Memphis, TN,[2]Department of Preventive Medicine, Division of Biostatistics, The University of Tennessee Health Science Center, Memphis, TN

Short-sized copy number variants (CNVs) account for a large proportion of the somatic cancer genome landscape. Analysis of CNVs from Pan-Cancer Analysis of Whole Genomes (PCAWG) Consortium showed that the sizes of copy number deletions and duplications have multimodal distributions with one of the major modes centering around 1kb [1]. Sensitive profiling of structural variants (SVs), which include CNVs, with long-read sequencing (LRS), showed that the median SV lengths range from 133bp to 1kbp by multiple SV callers [2]. However, existing CNV analysis tools for short-read sequencing data (SRS) are based on a binning approach, which limits the reliable detection of these short-sized CNVs. Exome sequencing data poses additional challenges of uneven read depth due to capturing efficiency differing between genomic positions. Therefore, we developed a methodology that uses read depth data available at every genomic position to discover short-sized CNVs, or Micro CNVs, from exome sequencing data. We employed an approach we named adaptive window extension, in which we extended the windows to identify genomic segments with read depths significantly deviating from control samples. Then, we fine-tuned the variant boundaries by searching for an optimal score in the base-level space. We evaluated our approach in our simulated data where we locally simulated 12 genomic loci containing well-known cancer genes, both tumor suppressors and oncogenes. We were able to obtain median sensitivity over 0.9 for 2-fold copy number deletions and duplications in 90% purity tumors as short as 300bp over the captured region, which corresponds to 1-2 exons involved in the variation. At 50% purity, similar performance was observed for simulated variants as short as 1kbp over the captured region, retaining high specificity. Given the current lower limit of sensitive detection of germ-line CNV (of 100% purity) is 3 exons (~750bp in the captured region) after comprising specificity [3], we believe our tool presents competitive results even in the lower purity settings and, when applied to a larger cancer exome cohort, will discover additional cancer driver genes and actionable genes.

#5509 A computational framework for reproducible analysis of cancer drug screening data.

Huiyi Yang[1], Jax Lubkowitz[1], Xiaomeng Huang[2], Gabor Marth[2], Samuel Cheshier[3], Philip Moos[4], Yi Qiao[1]

[1]Biomedical Informatics, University of Utah, Salt Lake City, UT,[2]Human Genetics, University of Utah, Salt Lake City, UT,[3]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT,[4]Pharmacology and Toxicology, University of Utah, Salt Lake City, UT

Background: Screening therapeutic responses in patient-derived or model-based cancer cells provides a direct experimental strategy to evaluate treatment efficacy. These assays generate complex datasets that require scalable, standardized analysis pipelines to ensure reproducibility and cross-study comparability. However, current data management and analysis workflows remain fragmented, relying on manual curation and ad hoc scripts that hinder reproducibility. This study introduces an open-source computational framework that standardizes storage, analysis, and visualization of high-throughput screening (HTS) data, providing easy access to common analysis methods while maintaining reproducibility in clinical and academic settings.
Methods: We developed a Python framework that provides a coherent workflow for storing, processing, and analyzing high-throughput drug screening data. It enables efficient and uniform storage with consistent data structure across experiments and datasets. The framework integrates automated drug name standardization, standardized data preprocessing, and common dose-response modeling methods including IC50, EC50, and DSS calculations. In addition, the framework supports cohort-level summarization and treatment prioritization, allowing users to compare drug responses across patients. Together, these components create a reproducible and adaptable pipeline that transfers raw experimental measurements to interpretable biological and translational insights.
Results: To demonstrate its broad utility, we applied the framework to three use cases. With the imported GDSC2 dataset, our recomputed IC50 and AUC values were highly consistent with published data, while providing integrated visualization and more contextual insights. We re-analyzed a breast cancer PDX-derived organoid dataset and were able to evaluate batch effects and compare responses across multiple models. We also analyzed an ex-vivo drug screening data from an ongoing pediatric brain tumor precision oncology initiative. The outputs were used to aid in prioritizing treatment candidates for individual patients at molecular tumor board meetings, demonstrating applicability in translational contexts. Across all cases, the framework ensured consistent preprocessing, minimized manual data manipulation, and provided comprehensive cross patient and cross drug comparison for identifying personalized drug candidates.
Conclusion: Our framework provides a comprehensive, interoperable solution for managing cancer drug screening data. By minimizing manual data manipulation and enabling reproducible analysis, it bridges the gap between experimental data generation and actionable insight. Beyond personalized ex-vivo assays, this platform empowers systematic analysis across public and clinical datasets, facilitating translational research and personalized treatment selection.

#5510 Hunting for microsatellite instability in long-read data with Owl.

Zev Kronenberg[1], Khi Pin Chua[1], Mark J. P. Chaisson[2], Byunggil Yoo[3], Lisa Lansdon[3], William J. Rowell[1], Egor Dolzhenko[1], Kie Kyon Huang[4], Patrick Tan[5], Shruti S. Bhise[6], Everett Fan[6], Mark Mendoza[6], Emily O'donnell[7], Tomi Pastinen[7], Elizabeth R. Lawlor[8], Scott N. Furlan[6], Midhat S. Farooqi[3], Michael A. Eberle[1]

[1]Computational Biology, PacBio, Menlo Park, CA,[2]University of Southern California, Los Angeles, CA,[3]Children's Mercy Research Institute, Kansas City, MO,[4]Duke-NUS Medical School, Singapore, Singapore,[5]Prog. In Cancer & Stem Cells Bio., Duke-NUS Graduate Medical School, Singapore, Singapore,[6]Fred Hutch Cancer Center, Seattle, WA,[7]Children's Mercy Kansas City, Kansas City, MO,[8]Seattle Children's Research Institute, Seattle, WA

Background: Microsatellite instability (MSI) refers to the accumulation of somatic mutations in simple repeat regions and is a hallmark of mismatch repair deficiency as well as a predictive biomarker for immunotherapy response. Most existing MSI callers are built for short-read sequencing and typically require paired tumor-normal data or high sequencing depth. These methods quantify repeat-length variability and classify genomes as MSI high when 10-30 percent of markers are unstable. Long-read sequencing (LRS) enables haplotype-resolved repeat profiling, allowing accurate MSI detection from tumor-only genomes at standard (~30×) coverage.

Methods: We developed Owl, a MSI detection software tool for PacBio HiFi data. Owl interrogates more than 160,000 simple repeats using a wrap-around dynamic programming algorithm and calculates the coefficient of variation (CV) in repeat length across phased haplotypes. Genome-wide MSI scores are then reported as the fraction of markers exceeding a parametrically derived CV threshold (CV > 5).

Results: We first applied Owl to 131 healthy controls from the Human Pangenome Reference Consortium and observed that MSI-stable genomes typically fall between 2-6%. We then profiled 26 additional cancer genomes, all of which had Owl scores between 2-3%, consistent with microsatellite-stable profiles. Finally, we identified five MSI-high samples that exceeded our 10% threshold, with scores ranging from 15-18%. These included two gastric cancers, an astrocytoma sample, and two Ewing sarcoma cell lines. Only one sample had both HiFi and Illumina data available for comparison; in that astrocytoma sample, Owl (17.1%) and Illumina DRAGEN (20.0%) produced concordant MSI-high classifications.By measuring MSI at >160,000 repeats, we can also detect motif-specific instability in tumor samples. For example, the two Ewing sarcoma cell lines (TC32 and CHLA10) showed a two fold increase of GGAA motif instability (23-26% MSI) compared to other motifs, an interesting and potentially disease-relevant pattern. The EWS::FLI1 fusion is known to bind GGAA-rich regulatory elements, and the observed instability at these motifs suggests that repeat variation itself may play an important role in Ewing sarcoma biology.

Conclusions: Owl enables robust, quantitative detection of MSI from long-read whole-genome data, requiring only tumor samples. Integrated into the PacBio HiFi Somatic workflow, Owl extends MSI profiling to long-read sequencing, revealing motif-specific instability patterns not captured by short-read approaches.

#5511 Exacto: Accurate identification of mutant proteoforms and neoantigens using integrative long-read sequencing.

Jin Seok Lee[1], Maria J. Sambade[2], Jeremy Wang[3], Alex Rubinsteyn[1], Benjamin G. Vincent[1]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[3]Department of Pathology and Laboratory Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC

Neoantigen discovery is essential for personalized immunotherapy, but current approaches are limited by a focus on small somatic variants identifiable by short-read sequencing. These variants often produce peptides that resemble self-antigens and are weakly immunogenic. Long-read sequencing enables more sensitive detection of large structural variants and full-length transcripts. Large mutations can generate neoantigens that are more dissimilar to self and thus more immunogenic. However, no method exists to identify a comprehensive set of somatic DNA and RNA variants, integrate these, and contextualize each amino acid using long-read data. To address this gap, we developed Exacto, a publicly available software program that uses long-read sequencing data to accurately characterize tumor genomes, transcriptomes, and mutant proteoforms. Exacto performs three main functions. First, it profiles reference-genome aligned long reads to identify major types of tumor-specific DNA variants (SNV, multi-nucleotide variant, insertion, deletion, duplication, inversion, and translocation) and RNA variants (SNV, multi-nucleotide variant, insertion, deletion, cryptic exon, intron retention, exon skipping / truncation, fusion gene, circular RNA, and unannotated intergenic isoforms). Second, it integrates RNA and DNA variants to predict the splicing consequences of somatic mutations. Third, it translates full-length RNA sequences and annotates each amino acid with underlying RNA and DNA variants. We have also developed a genome and transcriptome variation graph builder in Exacto to generate synthetic tumor and matched normal genomes as well as tumor transcriptomes. To perform a comprehensive benchmark study for mutant peptide identification, we developed VSTOL and Nexus. VSTOL introduces a new framework, called Occam's Variant Grammar, to characterize DNA and RNA variants in a unified representation for existing variant callers. Nexus is a Nextflow suite that runs over 50 tools for neoantigen discovery. Using synthetic samples generated from the variation graphs, we benchmarked somatic DNA variant calling with Exacto, ClairS, Nanomonsv, Savana, Severus, and SVision-pro. Exacto achieved the highest or tied-highest recall for all simulated variant types (SNV, deletion, insertion = 1.000; translocation and inversion = 0.983). It outperformed the next-best tools by substantial margins: for translocations and inversions, Exacto achieved 0.688 precision versus 0.205 for Savana (both with 0.983 recall); for deletions, 0.945 (Exacto) precision compared to 0.761 (Savana) with both methods obtaining 1.000 recall; and for insertions, 1.000 (Exacto) recall versus 0.901 (Nanomonsv) with both delivering 1.000 precision. Given this performance, we expect Exacto will become the standard method for discovery of immunogenic neoantigens using long-read DNA and RNA sequencing.

#5512 ProteoRon: High-fidelity proteome inference from transcriptomes.

Kaiqiang Hu, Wanyu Tao, Ye Yuan, Zhe Li, Yuxin Zhang, Pengwei Pan, Fang He

Pharmaron Beijing Co., Ltd., Beijing, China

Transcriptome profiling has become a routine and relatively low-cost component of drug discovery. In contrast, direct proteome measurement—although invaluable for assessing drug target engagement and pathway activity at the protein level—remains far less accessible, thereby limiting its use in high-throughput screening assays. To bridge this gap between transcriptome and proteome, we proposed ProteoRon, a deep learning model for proteome prediction. To support this transformation, we generated a foundational dataset of more than 800 cancer cell lines with paired transcriptome and proteome profiles using our in-house Illumina and Orbitrap Astral platforms. This internally curated resource encompasses expression data for more than 20,000 genes and the abundances of over 8,000 proteins. Building on our high-quality internal data and further augmented by public resources such as CPTAC and CCLE, ProteoRon functions as an accessible in silico surrogate for proteomics. Its architecture incorporates residual layers that explicitly model how post-transcriptional regulation modulates the quantitative relationship between baseline mRNA and its cognate protein. To evaluate ProteoRon's functional utility, we applied GSVA to both ProteoRon-predicted proteins and raw RNA-seq for drug response modeling. The ProteoRon-based features yielded significantly higher prediction accuracy, indicating a superior ability to capture functional pathway states. The model also correctly predicts the ISR-induced increase in ATF4 protein abundance despite minimal changes in its corresponding mRNA levels, underscoring its ability to capture non-transcriptional regulatory logic. Taken together, ProteoRon unlocks the latent proteomic potential of routine transcriptome data, thereby enabling deeper biological insight from existing RNA-seq resources.

#5514 BART-spatial: Predicting biologically significant transcriptional regulators from spatial omics data.

Jingyi Wang[1], Hongpan Zhang[1], Zhenjia Wang[2], Chongzhi Zang[1]

[1]Department of Genome Sciences, University of Virginia, Charlottesville, VA,[2]Department of Genome Sciences, University of Virginia, CHARLOTTESVILLE, VA

Transcription regulators (TRs), including transcription factors and chromatin regulators, are essential for maintaining cell identity and directing cell fate decisions by activating or repressing lineage-specific gene expression program and integrating environmental signals with intrinsic regulatory networks. Identifying active TRs is critical for understanding transcriptional regulation in both normal physiology and diseases like cancer. Emerging spatial omics technologies, such as 10x Visium and Visium HD and spatial ATAC-seq, enable simultaneous profiling of genomic information and spatial location at near-single-cell resolution, providing unprecedented opportunities to study transcription activities in the tissue microenvironment. However, inferring functional TRs from spatial omics data remains challenging due to data sparsity, high dimensionality, and the complex nature of transcriptional regulation. Here we present BART-spatial (Binding Analysis for Regulation of Transcription for spatial omics data), a computational method for identifying functional TRs from spatially resolved transcriptomics or epigenomics data. BART-spatial integrates spatial variability and pseudo-temporal dynamics of molecular profiles to generate biologically informed predictions of TR activity. It leverages public TR binding profiles to enhance prediction accuracy, without relying on TR expression levels. Applied to multiple real spatial transcriptomics datasets across different biological systems and platforms, BART-spatial successfully identifies TRs with region- or stage-specific activities, outperforming existing tools. Moreover, BART-spatial also works for other spatial omics data such as spatial ATAC-seq, enabling cross-validation between transcriptomic and epigenomic layers. Implemented as an open-source package, BART-spatial provides a useful computational tool for decoding spatial omics data and offers new insights into transcriptional regulation in various biological systems.

#5515 Accelerating minimal residual disease (MRD) detection through GPU-accelerated genomic analysis using NVIDIA Parabricks.

Zhuosheng Gu, Adam Harmon, Maciej Pacula, Megan Rivera, Zachary Costliow, Ashley Tellis, Seka Lazare, Xiaomin Zhao, Wendy Winckler

Droplet Biosciences, Cambridge, MA

Previously we demonstrated that ctDNA present in lymphatic exudate collected via surgical drains (“lymph”) outperformed plasma for detecting MRD in head and neck squamous cell carcinoma (HNSCC) patients through a targeted sequencing (TS) approach[1]. However, detecting ultra low frequency variants requires deep sequencing coverage and computationally intensive workflows, often resulting in long turnaround times. To enhance the performance of the TS approach, we implemented an MRD detection pipeline optimized with NVIDIA Parabricks[2] to accelerate computation and enable faster, scalable molecular analysis without compromising accuracy.

25 unique patients with HPV-independent HNSCC were included in the cohort to demonstrate the performance improvements by porting our MRD workflow from a CPU-based infrastructure to GPU-accelerated Parabricks. Clinical validity was assessed by testing those same 25 patients who each had a minimum of 1 year of clinical follow up data and using the determined mean variant allele fraction (VAF) to classify them as MRD-positive or MRD-negative. MRD classifications were compared to a CLIA / CAP-validated orthogonal tumor-informed whole-genome sequencing-based ctDNA MRD assay. Additionally, as artifacts introduced during library preparation and sequencing remain challenges to sensitive low VAF mutation detection, a base-error model (BEM) that reduces sequencing artifacts and maximizes ctDNA signal was built using a series of high-quality lymph reference samples to quantify the background noise of each tumor variant[3]. A GPU-accelerated pipeline was implemented for this step when generating the baseline. Tumor-derived variants in lymph samples were considered artifacts if the VAF was not greater than BEM cutoff controlled by false discovery rate.

We observed significant reduction in processing time and cost at the steps that implemented GPU acceleration. At alignment, we reduced processing time by 30% and computation cost by 15%. At tumor-informed variant calling, we reduced the average processing time from over 2 hours to 30 minutes per sample. For BEM, combined with optimization on VCF filtering, we have reduced processing time from over 5 hours to 45 minutes along with 60% reduction in computation cost. Furthermore, the comparison between our enhanced method and the CLIA / CAP-validated assay showed high concordance with p-val = 0.0005 using Fisher’s exact test. We achieved 84% percent agreement, indicating the accuracy of the GPU-accelerated pipeline.

We demonstrated that our GPU-accelerated MRD pipeline using NVIDIA Parabricks delivers clinical-grade accuracy with significant performance boost, enabling scalable, rapid molecular insights for adjuvant decision making. Given its advantages, we envision that GPU acceleration will prove useful to be a general strategy for deep sequencing applications.

#5516 Learning-based invariant feature engineering reveals symmetry-encoded fingerprints of cancers that facilitate drug discovery.

Cristina Correia[1], Choong-Yong Ung[2], Cheng Zhang[2], Shizhen Zhu[2], Hu Li[2]

[1]Department of Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic College of Medicine, Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Rochester, MN

Background: Symmetry principles, a long foundational framework in physics and chemistry, have rarely been applied to understand biological phenotypes especially in cancers. Here we examine whether symmetric relationships in gene expression can characterize and differentiate healthy from disease conditions.
Method: To test this concept, we built a hybrid machine-learning framework, Learning-Based Invariant Feature Engineering (LIFE), that applies two symmetric invariant feature functions, IFF1 and IFF2, to all possible gene pairs in bulk transcriptomic datasets to identify invariant feature genes (IFGs) - gene pairs whose transformed expression values by either IFF1 or IFF2 produce quasi-constant single-value outputs within a phenotype despite inter-individual variability.
Results: Using bulk transcriptomes from 25 normal organs (GTEx) and 25 cancer types (TCGA), we computed IFF values for all normally distributed gene pairs, selected the 1000 most stable pairs per phenotype, and evaluated their performance in multiclass classification with five-fold cross-validation and independent hold-out testing. IFGs generated >70% accuracy across organs and cancers, establishing the existence of robust phenotype-specific symmetry “fingerprints.” Mapping approved and experimental drug targets onto networks construction from IFGs (IF-Nets) showed strong enrichment of hubs in cancer networks and highlighted the use of IF-Nets as drug discovery platforms in cancer treatment.
Conclusion: Our findings demonstrate that gene-expression symmetry as a unifying organizing principle for phenotype definition and illustrate how IFGs and IF-Nets can guide biomarker design and symmetry-aware pharmacological intervention via “symmetry breaking.”

#5517 Standardizing global patient safety and site compliance in oncology trials using a configurable, technology-driven oversight model.

Ashley Herrick, Dmitri Berman, Elaina Haeuber, Sandy Shah, Salini Naidu

Oncology, Premier Research, Morrisville, NC

Background:
Variability in how adverse events (AE), protocol deviations (PD), and response assessments are reviewed across sites can delay detection of emerging issues in oncology trials—especially in global studies with dispersed teams. To address this, Premier Research implemented Remarque, a proprietary, technology-enabled data oversight platform to centralize trial intelligence, standardize review workflows, and provide near-real-time visibility into patient safety and data quality.
Methods:
Remarque integrates various clinical and operational data streams into a unified environment. Configurable analytics, dashboards, and built-in audit trails align clinical operations, data management, central monitoring, and medical/safety review on a single, traceable process. Key features include standardized review templates, data-driven alerts for AE clusters, customizable views of safety and efficacy data, and traceable documentation to support inspection readiness. Remarque was deployed across more than 30 oncology studies including novel therapeutics and first-in-class products, spanning different geographies.
Results:
Deployment of Remarque enabled earlier detection of common safety patterns, including clusters of low-grade toxicities and delayed AE entry. Studies using the platform achieved faster signal-to-action time and more consistent AE review. Near-real-time collaboration between central monitoring and medical monitoring allowed earlier flagging of potential eligibility concerns, decreasing eligibility-related non-compliance. Ability to trend data patterns within and across sites allowed for monitoring of site's execution of critical processes such as AE capture, reducing time to detection of AE underreporting from an average of 4-6 weeks down to 5-7 days. Notably, Remarque central monitoring identified 55% of PDs that occurred, with a 20% reduction in time from PD occurrence to identification. Centralized traceability strengthened data defensibility for regulatory review and facilitated proactive remediation of recurring data-quality findings. Overall, this resulted in cleaner data, efficient patient safety management, and improved patient retention.
Conclusions:
A technology-driven oversight model improved the reliability, transparency, and timeliness of data review in oncology trials. By replacing fragmented processes with a standardized framework, Remarque enabled earlier signal detection, reduced variability, and improved data quality. This approach reflects how integrated digital infrastructure enhances clinical and medical oversight and supports the goal of safeguarding patients while accelerating efficient delivery of effective cancer therapies globally.

#5518 Towards an accurate quantum support vector module for predicting cancer cell dynamics.

Amit Prakash

Illinois Mathematics and Science Academy, Aurora, IL

High dimensional cancer omics datasets capture molecular heterogeneity central to tumor progression and treatment resistance, yet classical methods often compress or obscure this structure when faced with nonlinear variation. Identifying computational frameworks that preserve oncogenic signals while distinguishing subtle phenotypic states remains a major challenge. To address this, we introduce QomiKS, a Quantum Oncological Kernel Suite designed to examine how quantum enhanced feature spaces recover biologically meaningful separation among cancer phenotypes.Using fidelity based quantum kernels, classical Gram matrices, and a lightweight NumPy angle encoding pipeline, we evaluate how separability among tumor derived samples shifts under different encoding schemes. Early PCA driven quantum models provided modest improvements but required substantial computational resources. In contrast, angle encoded QSVMs produced sharper discrimination among malignant and nonmalignant states while lowering computational cost, showing that quantum kernels can preserve high value oncogenic structure even with minimal features. Implementations using ZZFeatureMap and PauliFeatureMap revealed complementary sensitivities to pathway level nonlinearities linked to proliferation, immune evasion, or metabolic change.Across diverse datasets, we observe a consistent pattern. Classical SVMs dominate in extremely low data regimes due to their stability when oncogenic signal is sparse. As training sizes increase, QSVMs increasingly recover latent biological structures that classical kernels fail to resolve, ultimately surpassing classical baselines with statistically significant gains. This reflects a shift from noise limited to structure limited learning in which quantum feature spaces act as geometric projectors that amplify subtle differences in oncogenic programs, lineage states, or microenvironmental adaptation.These findings show that classical and quantum models encode cancer specific biology in fundamentally different ways. QomiKS provides a framework for understanding these differences and identifies conditions in which quantum kernels yield clearer discrimination of malignant phenotypes. As quantum hardware develops and multi omics cohorts grow, quantum kernel learning may offer a promising route for decoding complex molecular landscapes that govern tumor behavior and for supporting more precise classification and therapeutic stratification.

#5519 SOMaC: An interpretable and generalizable framework for integrating and clustering multimodal spatial omics to resolve cell states and immune niches in cancer.

Junming Shi, Md Tauhidul Islam

Stanford University School of Medicine, Stanford, CA

Spatial omics technologies, including spatial transcriptomics and multiplex spatial proteomics, provide unprecedented opportunities to characterize cellular organization, microenvironmental interactions, and functional states within intact tumor tissues. However, integrating these heterogeneous modalities and resolving spatially coherent cell states and immune niches remain major computational challenges. Existing approaches typically analyze individual modalities in isolation, rely on expression-based feature spaces that overlook higher-order molecular structure, and provide limited interpretability for biological discovery.

We present SOMaC, an interpretable and generalizable framework for integrating and clustering multimodal spatial omics data to resolve cellular and microenvironmental architecture in cancer tissues. SOMaC extends the OmicsMap paradigm by transforming each cell or spot into an image-like molecular interaction map that encodes pairwise gene or protein correlations, capturing regulatory structure beyond conventional expression matrices. These biologically grounded representations are jointly integrated with spatial topology using a convolutional autoencoder, graph neural network, and learnable-center clustering module, enabling end-to-end optimization of molecular-spatial embeddings for domain discovery.

Across 13 benchmark datasets spanning nine human and mouse tissues profiled by 10x Visium, Xenium, Slide-seqV2, Stereo-seq, imaging mass cytometry (IMC), and CODEX, SOMaC consistently outperformed leading methods such as GraphST and SEDR. SOMaC achieved significantly higher clustering quality, with an average Silhouette score of 0.21 (vs. 0.11 for GraphST) and more than a two-fold improvement in the Calinski-Harabasz Index, indicating tighter and more separable spatial domains. On multiplex proteomics datasets, including human colon cancer IMC, SOMaC demonstrated strong cross-modality generalization, achieving a Calinski-Harabasz Index of 40,541 and a Davies-Bouldin Index of 3.03. Notably, SOMaC resolved fine-scale tumor-immune interfaces, stromal barriers, and functional immune niches that were poorly captured by existing methods.

By jointly modeling molecular interaction structure and spatial architecture across transcriptomic and proteomic platforms, SOMaC provides a unified and interpretable framework for dissecting tumor ecosystems. This approach enables high-resolution discovery of spatially organized cell states, regulatory programs, and microenvironmental niches, offering new insights into cancer biology and therapeutic targeting.

#5520 Multi-modal integration in the NetFlow framework for comprehensive exploratory data analysis.

Rena Elkin, Jung Hun Oh, Anish K. Simhal, Joseph O. Deasy

Memorial Sloan Kettering Cancer Center, New York, NY

High-dimensional biomedical studies increasingly require comprehensive exploratory tools that jointly model, integrate, and visualize sample organization across modalities within a single, interpretable framework. We therefore developed NetFlow, a computational framework that constructs a Pseudo-Organizational StructurE (POSE) graph of sample relationships from high-dimensional and multimodal data, preserving both continuous variation and local neighborhoods while enabling downstream analytics in the same space. Glioblastoma (GBM) exhibits pronounced heterogeneity across transcriptomic, epigenomic, and miRNA profiles that complicates subtype discovery and interpretation. To demonstrate NetFlow's multi-modal integration capability, we applied it to TCGA GBM (n=213) with matched mRNA expression, DNA methylation, and miRNA profiles. Per-modality sample-sample distances were computed, each was transformed to a common range, and then fused into a unified similarity matrix. Next, diffusion-based, multi-scale metrics on the fused similarity seeded a lineage-tracing-inspired backbone augmented with mutual nearest neighbor edges to build the POSE. The NetFlow framework enabled POSE-aware clustering, survival analysis, and cross-omic differential feature testing. The POSE revealed a distinct lower-risk GBM subgroup with significantly improved overall survival (log-rank $P=1.19x10^{-5}$) that was not reproducible from any single modality alone. This subgroup exhibited a cross-omic signature including reduced mRNA expression of *EMP3* and *TIMP1*, *CRIP1* hypermethylation, and decreased *miR-222* expression. Additionally, the identified subgroup showed clinical correlates consistent with favorable prognosis including enrichment for *IDH1* mutation and younger age. We further quantified edge-level modality influence, which indicated balanced contributions from each modality, supporting genuine multi-modal integration rather than dominance by any single data type. These results establish that NetFlow yields an interpretable, modality-balanced POSE. They further demonstrate that its unified modeling, integration, visualization, and analysis enables discovery of prognostically relevant subgroups and cross-omic biomarkers. More broadly, NetFlow provides a practical, extensible framework for comprehensive exploratory data analysis in multi-modal oncology cohorts that generalizes beyond GBM to accelerate hypothesis generation and subtype refinement in diverse settings.

#5521 MeDOC-KB: Knowledge base for unraveling the metabolic links between obesity-related cancers.

Madhan Subramanian[1], Sam Rosin[1], Stephanie Hall[2], Nisha Grover-Fairchild[2], Kim Robien[3], Loretta DiPietro[3], Marinella Temprosa[1]

[1]Biostatistics and Bioinformatics, Milken Institute School of Public Health, George Washington University, Washington, DC,[2]George Washington University Biostatistics Center, Bethesda, MD,[3]Exercise and Nutrition Sciences, Milken Institute School of Public Health, George Washington University, Washington, DC

Metabolic Dysregulation and Obesity Cancer Risk Consortium (MeDOC) is an NCI-sponsored program using team science and transdisciplinary approach to elucidate mechanisms linking obesity, metabolic dysregulation, and cancer risk. Both obesity and metabolic dysregulation contribute to a cascade of derangements in adipocyte function, growth factors, inflammation, gut microbiome, immune function, sex hormones, lipid and glucose metabolism which, in turn, can disrupt several downstream signaling pathways related to cancer initiation and progression. Given this complexity, integrating multi-omic, mouse models and epidemiologic data is critical. The MeDOC-Knowledge Base (MeDOC-KB) is a comprehensive atlas cataloging associations to link obesity, metabolic dysregulation, and cancer risk from consortium studies and external literature. A large language model-based agent harmonized biomarkers derived from metabolomics, proteomics, and lipidomics platforms such as Nightingale, Olink, and Metabolon, standardizing nomenclature and resolving cross-platform synonyms into a unified vocabulary. MeDOC-KB uses a Neo4j graph database architecture to enable efficient traversal of complex relationships among the biomarkers, publications, cohorts, and cancer sites. Literature data are extracted into four core tables (Citation, Cohort, Methods, and Association) and transformed into a graph structure where nodes represent publication, cohorts, biomarkers, and cancer sites while edges denote their relationships. MeDOC-KB is accessible through an interactive R Shiny web application. The current version contains 42,838 nodes and 189,709 relationships with 21,945 being biomarker-cancer associations spanning 1,645 biomarkers and 15 cancer outcomes, including 11 of the 13 known obesity related cancers. For example, MeDOC-KB reveals that insulin-like growth factor binding protein-1 (IGFBP-1) shows inverse associations with endometrial, colorectal, and pancreatic cancers across multiple cohorts, suggesting shared metabolic mechanisms. The platform enables researchers to identify biomarker patterns associated with obesity-induced metabolic dysregulation across cancer types, compare findings across cohorts, and discover understudied biomarker-cancer relationships. MeDOC-KB provides a critical resource for hypothesis generation regarding mechanistic pathways, biomarker validation across populations, and identification of promising targets for cancer prevention strategies in high-risk metabolic populations. The knowledge base is publicly accessible and will be continuously updated with consortium findings and literature.

#5522 scSurvival: Single-cell survival analysis of clinical cancer cohort data at cellular resolution.

Tao Ren[1], Faming Zhao[2], Canping Chen[1], Lingyun Wu[3], Gordon B. Mills[2], Lisa M. Coussens[4], Zheng Xia[1]

[1]Oregon Health & Science University, Portland, OR,[2]OHSU Knight Cancer Institute, Portland, OR,[3]Academy of Mathematics and Systems Science, Chinese Academy of Sciences, Beijing, China,[4]OHSU Knight Cancer Institute, Lake Oswego, OR

Survival analysis is fundamental to cancer research. Advances in technology have enabled an increasing number of cohort-level cancer studies to incorporate single-cell sequencing while collecting clinical survival data. However, no effective strategy currently exists for directly modeling survival outcomes from single-cell data. To address this gap, we present scSurvival, an attention-based multiple-instance Cox regression framework that models each patient as a bag of cells to predict survival outcomes at both the patient and single-cell levels. To handle high dimensionality, sparsity, and batch effects, scSurvival integrates a variational autoencoder-based feature extraction module with generative modeling to enhance feature robustness and cross-batch generalizability. Comprehensive simulations demonstrate scSurvival's superior performance and scalability. In melanoma and liver cancer scRNA-seq cohorts, scSurvival accurately predicts patient outcomes and identifies the cell subpopulations most critical to survival. Overall, scSurvival enables robust prediction of patient survival while uncovering survival-associated cell subpopulations, advancing single-cell survival analysis in cancer research.

#5523 TNMplot 2.0: Stage-resolved and pan-cancer transcriptomic analytics for target discovery in oncology.

Aron Baratha, **Balazs Gyorffy**

Semmelweis University, Budapest, Hungary

BACKGROUND. TNMplot.com is a web-based resource that integrates RNA-Seq and gene-chip data from 56,938 samples, enabling differential gene expression analysis among normal, primary tumor, and metastatic tissues across 22 cancer types. Here, an updated version of the TNMplot database was established featuring new capabilities that advance pharmacological and translational oncology research.

METHODS. We implemented a stage-based expression module using 4,521 tumors from breast (n=2,331), colorectal (n=648), lung (n=1,399), skin (n=82), and prostate (n=61) cancer. We added pan-cancer dot-matrix visualization and extended multi-gene tools including density analyses, correlation matrices, correlation profiling, signature evaluation, and targetgram analysis. Using the integrated database, we performed parallel RNA-seq and microarray validation to identify druggable candidates.

RESULTS. The stage module was used to evaluate isolated genes linked to tumor progression and therapeutic timing. Multi-gene and pan-cancer functions enabled rapid mapping of druggable pathways and co-expression structures. Cross-platform filtering highlighted MET (p = 5.1e-69), FGFR4 (p = 1.59e-49), and EZH2 (p = 1.08e-54) as robust progression-associated candidates for repurposing in advanced colon cancer. A separate screening of dysregulated colon cancer genes identified 16 FDA-approved drug targets through ≥2-fold expression changes and ChEMBL matching, with LY6E and CDK1 each surpassing a 3-fold differential threshold. The complete combined database was integrated into our analysis platform available at www.tnmplot.com.

CONCLUSIONS. The upgraded TNMplot platform provides a unified, high-fidelity environment for progression analysis, biomarker discovery, and pharmacological target prioritization across multiple cancers. A unique feature of the database is the parallel analysis of RNA-seq and gene array cohorts, enabling robust cross-platform validation of candidate biomarkers.

#5524 Visualization and analysis of cancer genomics data using UCSC Xena.

Mary Goldman[1], Brian Craft[1], Cally Lin[2], Jingchun Zhu[1], David Haussler[3]

[1]UC Santa Cruz Genomics Institute, Santa Cruz, CA,[2]Stanford University, San Francisco, CA,[3]Investigator/Distinguished Professor, Ctr. For Bio. Sci. & Eng., UC Santa Cruz, Santa Cruz, CA

UCSC Xena (http://xena.ucsc.edu/) is a web-based visual integration and exploration tool for both bulk and single-cell multi-omic data, and associated clinical and phenotypic annotations. Researchers can easily view and explore public data, their own private data (bulk only), or both using the Xena Browser. Private data are kept on the researcher's computer and are never uploaded to our public servers. We support Mac, Windows, and Linux.

Questions Xena can help you answer:* Is overexpression of this gene associated with survival differences?* What genes are differentially expressed between these two groups of samples?* What is the relationship between mutation, copy number, expression, etc for this gene?

Xena visualizes seminal cancer genomics datasets from TCGA, the Pan-Cancer Atlas, GDC (a complete update from 2024, including new data from CPTAC3 and HCMI), PCAWG, ICGC, and more; a total of more than 1500 datasets across 50 cancer types. We support virtually any type of functional genomics data: SNPs, INDELs, copy number variation, gene expression, ATAC-seq, DNA methylation, exon-, transcript-, miRNA-, lncRNA-expression and structural variants. We also support clinical data such as phenotype information, subtype classifications and biomarkers. All of our data is available for download via python or R APIs, or using our URL links.

Our signature Visual Spreadsheet view shows multiple data types side-by-side enabling discovery of correlations across and within genes and genomic regions. We also have dynamic Kaplan-Meier survival analysis, powerful filtering and subgrouping, differential gene expression analysis, GSEA, charts, statistical analyses, genomic signatures, and the ability to generate URLs to live views.

We now visualize single-cell data, primarily gene, transcript, and protein expression, from spatially-resolved and disassociated single cell datasets. Using Xena, researchers can visualize 2D or 3D embedding views, such as tSNE and UMAP as well as the spatial imaging views, such as H&E, multiplex immunofluorescence, and co-registration of both. Crucially, we overlay genomic data — such as gene and protein expression, genomic signature scores, cell annotations, and label transfer information — on top of these images dynamically. We support a diverse range of data modalities ranging from 10x Chromium and Smartseq2 platforms for scRNA-seq and 10x scATAC-seq, to spatial transcriptomics platforms of Visium, Visium HD, Xenium, CosMx, and MERFISH/Vizgen, to imaging proteomics such as t-CycIF, CODEX, and MIBI-TOF. We showcase data from the HTAN data portal.

If you use us please cite our publication in Nature Biotechnology: https://www.nature.com/articles/s41587-020-0546-8

#5525 Aneuploidy prediction in the spatial domain.

Calogero Carlino[1], Valentina Giansanti[1], Giovanni Petri[2], Davide Cittaro[1]

[1]Universita Vita-Salute San Raffaele, Milano, Italy,[2]Network Science Institute, Northeastern University London, London, United Kingdom

Cancer emergence and progression are often driven by genomic instability and disruption of the tissue microenvironment. Insights on the prognostic values of genomic features have been reported in cohort of cancer patients, suggesting Copy Number Alterations (CNAs) signature as highly relevant in multiple cancer types [1,2]. Moreover, insights on the transcriptional state of the tumor microenvironment suggest the recurrence of spatially defined gene modules with functional significance among cancer states [3].Building on the above insights, we aim to study the topology of the spatial distribution of CNAs and its influence on the transcriptional state of the tumor microenvironment. To this end, we describe a workflow that enables the prediction of CNAs in spatially resolved transcriptomics data, and the construction of a topological signature from the CNAs prediction map of the tumor sample. The topological signature is then used as a topological descriptor of the tumor microenvironment.We ported to Python the Numbat algorithm [4] and expanded it with a custom implementation of personalized PageRank algorithm [5] on the diffusion map [6] of the CNAs feature, enhancing the spatial signal of the predicted CNAs. Superlevel set filtration is then applied to the CNAs predictions, obtaining a persistent homology signature of the CNAs spatial distribution [7].Experiments suggest that our method for including the spatial context in CNAs predictions produces simpler data topology (spatial smoothing) and, similarly to a recent report [8], that the resulting persistent homology signature of spatial CNAs can be used to discriminate between states of the tumor microenvironment.

Development of CD3-bispecific antibodies has been challenging in solid tumors due to the difficulty identifying tumor antigens with high tumoral expression but with minimal or no expression in normal tissues. Placental-like alkaline phosphatase 2 (ALPPL2) is overexpressed in various solid tumors, including ovarian and endometrial carcinomas, while its expression in normal tissues is largely restricted to the placenta. This expression profile makes ALPPL2 a promising target for CD3-bispecific antibody therapies. We have developed a fully human common light chain-based ALPPL2×CD3 bispecific antibody, LY4336619, on an Fc-silenced IgG1 backbone designed to engage ALPPL2 on tumor cells and CD3 on T cells, facilitating targeted T cell-mediated cytotoxicity against ALPPL2-expressing tumor cells. LY4336619 was generated by pairing a novel anti-ALPPL2 monoclonal antibody, identified through a murine immunization strategy, with an anti-CD3 antibody. The binding, target selectivity, and cytotoxic activity of LY4336619 were evaluated using multiple ALPPL2-expressing cell lines. *In vivo* efficacy was evaluated using immunocompromised murine models engrafted with human tumor xenografts and human peripheral blood mononuclear cells (PBMCs). Additionally, a comprehensive proteomics analysis was performed to characterize ALPPL2 expression across tumor tissue specimens. LY4336619 specifically bound to ALPPL2-expressing cell lines but spared ALPI and ALPL, the other more widely expressed alkaline phosphatase family members; it also bound to the highly homologous ALPP family member, a protein with similar limited normal expression and association with similar tumor types. LY4336619 engaged with both CD3 and ALPPL2, and induced concentration-dependent T-cell activation and T cell-mediated cytotoxicity in co-culture assays with T cells and ALPPL2-expressing tumor cells. Furthermore, it demonstrated antitumor activity and relatively low cytokine release as a single agent in human PBMC-engrafted mice with human tumor xenografts representing a range of ALPPL2 expression levels. Additional preliminary studies revealed that the combination treatment with LY4170156, a clinical-stage anti-FRα antibody-drug conjugate (ADC), resulted in more sustained and pronounced tumor growth inhibition compared to either monotherapy alone. Our ALPPL2×CD3 bispecific antibody exhibited IgG-like pharmacokinetics and low immunogenic potential. These findings demonstrate that LY4336619 has target specificity, favorable functional activity, and a promising developability profile. LY4336619 has the potential as a first-in-class medicine to treat ALPPL2-positive solid tumors, including ovarian and endometrial cancers. An IND submission is anticipated for 2026.

#5530 Preclinical validation of the antitumor activity and safety of M0324, a novel MUC-1 conditional CD40 agonist, and its combination with immune checkpoint inhibitors (ICIs), for selective immune activation.

Weixiao Sha[1], Jing Ni[1], Anika Bergmann[1], Nathalie Duncan[1], Bo Marelli[2], Feng Jiang[2], Julia Marie Mueller[1], Sina Junkers[1], Christina Hubl[1], Ivana Durutovic[1], Sonia Jaramillo[1], Paul D. Lyne[2], Laura Helming[2]

[1]the healthcare business of Merck KGaA, Darmstadt, Germany,[2]EMD Serono, Billerica, MA

Background: MUC-1, a glycoprotein commonly overexpressed in various cancers, plays a pivotal role in tumor progression and immune evasion. M0324 is a novel MUC-1-conditional CD40 agonist designed to activate antigen-presenting cells in the presence of MUC-1-overexpressing tumor cells. Targeted CD40 activation could minimize systemic toxicity observed with first-generation unconditional CD40 antibodies.

Methods: The effect of M0324 on the activation of CD40 expressed on human dendritic cells (DCs) was assessed *in vitro* and benchmarked against anti-CD40 antibodies, using MUC-1 expressing HCC827 tumor cell line co-cultured with primary human monocyte-derived DCs. Co-culture of human primary B cells with human tumor cell lines with various MUC-1 expression was analyzed to further characterize MUC-1 dependent M0324 activity. *In vivo* efficacy was evaluated using M0324m, a mouse surrogate for M0324, as monotherapy or in combination with anti-PD-L1, in hMUC-1 expressing tumor models.

Results: *In vitro*, M0324 significantly enhanced DC activation in the presence of MUC-1 expressing tumor cells; no activity was observed in the absence of MUC-1 expressing cells. M0324 led to higher activation of IL-12p40 expression in DC HCC827 tumor cell co-cultures versus other agonistic anti-CD40 antibodies. Co-culture of human primary B cells with tumor cell lines with various levels of MUC-1 expression demonstrated that M0324-induced B cell activation was linked to MUC-1 expression levels on tumor cells. *In vivo*, a single dose of M0324m demonstrated robust tumor eradication in hMUC-1^{high} immune competent mouse tumor models (orthotopic Panc02-MUC-1 model: 93%; MC38-MUC-1 model: 100% tumor-free mice). The lack of body weight loss in mice after M0324m dosing indicated minimal off-tumor effects and increased therapeutic index due to the conditional activation of CD40 in the presence of MUC-1. In contrast, anti-mouse CD40 benchmark antibody induced body weight loss, and its marginally tolerable dose failed to control tumor growth. M0324m also demonstrated robust antitumor activity in hMUC-1^{int} tumor models (MC38, 4T1). Combination of M0324m with anti-PD-L1 in hMUC-1^{int} tumor model further improved tumor growth inhibition.

Conclusions: M0324 was shown to selectively activate DC and B cells only in the presence of MUC-1 expressing tumor cells, demonstrating superior *in vitro* and *in vivo* activity compared to anti-CD40 agonistic antibodies. M0324m further improved tumor control when combined with anti-PD-L1. M0324m was also well-tolerated *in vivo*. Overall, the preclinical data suggest that combination of M0324 with ICIs may maximize the rigor of *de novo* or pre-existing T cell responses. A Phase 1 study of M0324 as monotherapy and in combination with pembrolizumab and chemotherapy is ongoing (NCT07166601).

#5532 Bispecific antibodies targeting EGFR and HER2 for effective killing of solid tumor cells via a safe CD47-SIRPA modulation.

Eric Hatterer, Vanessa Buatois, Alizee Viandier, Emeline Rousset, Cecile Raymond, Adeline Lesnier, Pauline Lloveras, Christelle Mougin, Ulla Ravn, Pauline Malinge, Frederic Bollin, Limin Shang, Walter Ferlin, Nicolas Fischer, Jose Saro, Krzysztof Masternak

R&D, Light Chain Bioscience - Novimmune SA, Plan-Les-Ouates, Switzerland

INTRODUCTION: The CD47-SIRPα axis is a crucial immune checkpoint, allowing tumor cells to evade immune destruction. Initial efforts to target CD47 with monoclonal antibodies and SIRPa-Fc fusion proteins encountered significant hurdles due to ubiquitous and abundant CD47 expression in particular on blood cells (including RBC and platelets). To overcome the limitation of mono-specific CD47 targeting, we generate bispecific antibodies (bsAbs) that block CD47 selectively on tumor cells, upon co-engagement of a tumor-associated antigen (TAA) on the cell surface. Harboring an immunologically active Fc portion (human IgG1 Fc) these TAA/CD47 bsAbs mediate efficient tumor cell killing through antibody-dependent cellular phagocytosis (ADCP) and antibody-directed cellular cytotoxicity (ADCC). Importantly, this strategy has now been clinically validated: NI-1801, our mesothelin/CD47 bsAb, has demonstrated selective and safe CD47 targeting together with encouraging antitumor activity in heavily pretreated ovarian cancer patients (1).

METHODS: EGFR/CD47 and HER2/CD47 bispecific antibodies were assembled using the κλ-body technology/platform (2). For that goal, high affinity antibody arms specific to different regions of the extracellular domains of EGFR or HER2 were paired with a low affinity anti-CD47 arm. The resulting hIgG1 bsAbs were tested *in vitro* for activity in ADCP assays with TAA-positive tumor cells and monocyte-derived macrophages as effector cells, and in ADCC assays using unfractionated PBMCs as effector cells.

RESULTS: The EGFR/CD47 and HER2/CD47 bsAbs efficiently induce ADCP and ADCC of tumor cell expressing varying levels of EGFR or HER2, respectively, including low level-expressing cancer cell lines. Interestingly, we could observe that the killing activity depended not only on the affinity of the TAA arm, but also on the region of the ECD bound by the TAA arm, suggesting that the geometry of the antigen-co-engagement on tumor cell surface may affect the efficiency of the immunological synapse. This was particularly apparent when comparing the killing activity mediated by different HER2xCD47 bsAbs.

CONCLUSION: The “unbalanced affinities” design of TAA/CD47 bispecific antibodies effectively addresses the safety and pharmacokinetic liabilities observed with monospecific CD47 antibodies. Importantly, our clinical experience with NI-1801 (MSLN×CD47) validates both the safety and the potential clinical benefit of this tumor-restricted CD47-blocking strategy (1). Together, these findings support TAA/CD47 bsAbs as a valuable addition to the anti-cancer armamentarium, with the EGFR/CD47 and HER2/CD47 bsAbs described here representing promising development candidates. *(1) De La Motte Rouge T. ESMO 2025 (Abstract #1512O) (2): Fischer N. Nat Commun, 2015 Feb 12:6:6113*

#5533 VISTA×MSLN bispecific antibody-directed therapies as a biomarker-guided strategy for epithelioid malignant pleural mesothelioma.

Sang Moo Lee[1], Hee geon Park[2], Gyo-Jin Choi[1], Myeung Ryun Seo[1], Ji Eun Park[3], Seok Gyeong Yun[1], Na Eun Jeong[1], Soo Jin Ryu[1], Yeong Jeong Jeon[4], Yoon La Choi[5], Sung Youl Hong[6], Young Kee Shin[1]

[1]Department of Molecular Medicine and Biopharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of,[2]ABION INC., Seoul, Korea, Republic of,[3]Research Institute of Pharmaceutical Science, College of Pharmacy, Seoul National University, Seoul, Korea, Republic of,[4]Department of Thoracic and Cardiovascular Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[5]Department of Pathology and Translational Genomics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[6]BitD Inc., Siheung, Korea, Republic of

Background Malignant pleural mesothelioma (MPM) is a rare, lethal cancer largely linked to asbestos exposure, with a 5-year overall survival <20%. Until the approval of nivolumab plus ipilimumab (CheckMate 743), platinum-based chemotherapy was the only systemic standard of care. The epithelioid subtype (~70% of cases) of MPM derives limited benefit from current ICIs, underscoring the need for biomarker-guided therapies. We identified co-expression of the immune checkpoint V-domain Ig suppressor of T-cell activation (VISTA) and the tumor-associated antigen mesothelin (MSLN) in epithelioid MPM and validated this axis by scRNA-seq, which demonstrated concordant VISTA and MSLN transcription within malignant epithelioid clusters. Based on this biomarker pair, we engineered an anti-VISTA×MSLN bispecific antibody (BsAb) and explored multiple modalities, including an IFN-β mutein immunocytokine and bispecific ADC concepts.
Method Anti-VISTA×MSLN BsAb formats were designed and screened for optimal binding/cell-surface coverage on VISTA/MSLN co-expressing cells. A stability/production/PK-enhanced IFN-β mutein relative to recombinant IFN-β was fused to the BsAb to generate a trispecific immunocytokine. In vitro binding, internalization, and effector assays were performed in human MPM cell lines. In vivo antitumor activity and TME modulation were tested in xenografts and a syngeneic mouse model; a subset used human IFNAR1/2 knock-in (hIFNAR1/2-KI) mice. To assess suitability for payload delivery, we analyzed antigen-dependent internalization and early bispecific ADC feasibility in vitro.
Results scRNA-seq confirmed VISTA/MSLN co-expression in malignant epithelioid populations, supporting VISTA×MSLN as a therapeutic axis. The anti-VISTAxMSLN BsAb showed enhanced binding to dual-positive cells relative to the parental monospecific antibodies and efficient, antigen-driven internalization. The trispecific immunocytokine retained BsAb targeting and induced type I IFN-dependent tumor-cell killing and immune activation in vitro. In vivo, it produced significant antitumor activity in MPM models, including in hIFNAR1/2-KI mice, and remodeled the TME consistent with enhanced antitumor immunity. Internalization/trafficking supported feasibility of developing anti-VISTA×MSLN BsAb ADCs as an additional therapeutic modality.
Conclusion VISTA/MSLN co-expression defines a biomarker-guided therapeutic axis in epithelioid MPM. The engineered anti-VISTAxMSLN BsAb is a versatile scaffold enabling multiple modalities — including an IFN-β mutein immunocytokine with in vivo efficacy and TME reprogramming—and exhibits internalization compatible with bispecific ADC development. Collectively, these findings support anti-VISTA×MSLN-based therapeutics as promising preclinical candidates for epithelioid MPM.

#5534 INCA036873, a first-in-class CD70×CD3 T cell-redirecting bispecific antibody, for the treatment of CD70-positive malignancies.

Yao-Bin Liu[1], Charlie Kang[1], Christina Stevens[1], Lifeng Zhang[1], Daniel Merenich[1], Emily Ren[1], Chifei Sun[1], Lu Huo[1], Taylor Getty[1], Heather Bullins[1], Zhiwan Dong[1], Zhiying Ji[1], Michelle Kinder[1], Jun Guan[1], Tessa Steevels[2], Femke Feenstra[2], Rinse Klooster[2], David Maussang-Detaille[2], Cynthia Timmers[1], Jonathan Rios-Doria[1], Horacio Nastri[1], Jeff Jackson[1], Patrick Mayes[1], Chryssa Kanellopoulou[1]

[1]Incyte Corporation, Wilmington, DE,[2]Merus NV, Utrecht, Netherlands

CD70 is a member of the tumor necrosis factor ligand superfamily, with CD27 being its sole receptor. Under normal physiological conditions, CD70-CD27 signaling promotes T-cell activation, survival, and differentiation. In normal tissues, CD70 expression is restricted to activated T, B, and dendritic cells. Aberrant CD70 expression is observed in various malignancies, including renal cell carcinoma (RCC), ovarian cancer, acute myeloid leukemia, and non-Hodgkin's lymphoma. This highly selective upregulation in tumor cells and restricted expression in normal tissues make CD70 an attractive therapeutic target.

INCA036873 is a novel Biclonics® bispecific antibody designed to redirect and activate T cells to specifically kill CD70-expressing tumor cells. INCA036873 binds CD70 with high affinity (K_D = 0.4 nM) and CD3 with moderate affinity (K_D = 115 nM), enabling selective T-cell activation, while minimizing systemic immune activation and cytokine release. INCA036873 induced potent CD70-dependent T cell-mediated cytotoxicity of tumor cells. In vitro, INCA036873 demonstrated robust killing across multiple CD70-expressing tumor cell lines as well as freshly disassociated primary patient-derived RCC tumor cells. In vivo, INCA036873 showed strong antitumor efficacy in multiple cell line xenograft models such as 786-O (RCC) and SKOV3 (ovarian cancer), as well as RCC patient-derived xenograft models in human CD34-positive humanized NSG mice. Importantly, INCA036873 exhibited a favorable safety profile, with limited cytokine release in human whole blood cytokine release assays and no adverse findings at doses up to 3.0 mg/kg (>15-fold above the projected therapeutic exposure) in a 4-week toxicology study in huCD70/huCD3EDG knock-in mice. INCA036873 also demonstrated desirable pharmacokinetics in cynomolgus monkeys.

Overall, these data support the advancement of INCA036873 as a promising, potential, first-in-class bispecific T-cell engager antibody for CD70-positive malignancies.

#5535 GPRC5D multispecific antibodies: Engineering for affinity, cross-species reactivity, and bi/trispecific engagement in multiple myeloma.

Hayley Roth, Trevor Barnes, Daniel Rogers, Ileine Sanchez, **Lewis Joe Stafford**, Valerie Firers, Breanna Tyrell, Amelia M. Snyder, Kyle Doolan, Benjamin J. Doranz, Ross Chambers, Joseph B. Rucker

Integral Molecular, Philadelphia, PA

Background: GPRC5D is a G protein-coupled receptor expressed on multiple myeloma cells but largely absent from healthy tissues, making it an attractive target for T cell-engaging multispecific antibodies. Antibodies that simultaneously engage GPRC5D and other molecules (e.g. BCMA and CD3) to activate T cells are anticipated to provide excellent efficacy as monotherapies. Multipass membrane proteins are valuable therapeutic targets but often inaccessible for antibody discovery due to structural complexity and high conservation. Using our membrane protein-optimized discovery platform (MPS), we generated a panel of GPRC5D antibodies and engineered them as bi- and trispecific molecules. We also developed a platform for comprehensive CDR-Scanning of our lead antibody for affinity maturation, developability, and cross-species reactivity for preclinical testing.
Methods: Antibodies against GPRC5D were isolated and formatted as GPRC5D×CD3 and GPRC5D×BCMA×CD3. These molecules were tested for in vitro and in vivo potency, cytokine release, and binding specificity. To further optimize our lead, we developed and optimized method for comprehensive CDR-Scanning where each residue across 6 CDR regions was substituted to all 19 other amino acid variants, generating 986 single residue variants. Variants were individually evaluated for expression and binding using ELISA and assessed for expression and reactivity against both human and cynomolgus GPRC5D. Beneficial substitutions (>200% wild-type binding) were combined using structure-guided and AI/ML-informed design strategies for further validation.
Results: We identified multispecific antibodies that exhibited potent T cell-mediated cytotoxicity with picomolar potency on multiple myeloma cell lines, a large window between cell killing and cytokine release and robust tumor control against multiple myeloma xenografts in a humanized mouse model. Antibody specificity profiling confirmed high specificity binding to the intended targets, without detectable off-target interactions across the membrane proteome. Saturating mutagenesis of the CDR regions of the GPRC5D-binding moiety of the lead antibody identified 14 variants with elevated binding to the human GPRC5D >200% WT, and 10 variants with elevated binding to cynomolgus GPRC5D. Combination yielded more than 20 variants with binding >4,000% WT.
Conclusions: GPRC5D multispecific antibodies hold promise as potent and safe therapeutics for multiple myeloma. Through CDR-Scanning, we are advancing a new generation of GPRC5D antibodies with enhanced attributes, including affinity improvements, pH sensitivity, reduced polyreactivity, improved half-life, and cross-reactivity in cynomolgus for preclinical development.

#5536 Preclinical immunotoxicity assessment of bispecific antibodies using an *ex vivo* circulating human whole blood assay.

Helena Harlin Laven[1], Louise Nilsson[1], Marika Pettersson[1], Gunilla Tornqvist[1], Erika Fletcher[1], Sakthi Ponandai-Srinivasan[1], Sara Mangsbo[2], **Alexander Kele**[1]

[1]Immuneed, Uppsala, Sweden,[2]Uppsala University, Uppsala, Sweden

The technologies for producing bispecific antibodies (BsAbs) are relatively new, and only recently have several BsAbs been approved for clinical use. However, they are often associated with a high risk of cytokine release syndrome (CRS) and other adverse events. Since many BsAbs target antigens unique to humans and given the need for new approach methodologies (NAMs) that comply with the 3Rs, it would be valuable to have an *in vitro* system for predicting immunotoxicity during preclinical development of novel BsAbs.

ID.Flow is an *ex vivo* system using circulating human whole blood at 37 °C, previously evaluated for predicting infusion reactions of monoclonal antibodies and oligonucleotide drugs. The system allows for simultaneous evaluation of multiple immune responses, such as cytokine release, complement activation, activation or depletion of platelets and white blood cells, and coagulation. By using clinically relevant controls, the relative levels of immunotoxicity can be assessed. ID.Flow was used here to evaluate glofitamab, a bispecific T cell engager approved for the treatment of diffuse large B cell lymphoma. Glofitamab is associated with cytokine release syndrome (CRS) including serious or fatal reactions. The efficacy and immunotoxicity of glofitamab were investigated in ID.Flow at concentrations similar to Cmax. As controls, the monoclonal antibodies (mAbs) obinutuzumab and alemtuzumab were used, both of which are associated with CRS in the clinic. Glofitamab resulted in B cell depletion with live B cell counts significantly reduced by 6 hours (60%) and most B cells (90%) depleted by 24 hours. In comparison, B cell depletion using the mAbs occurred with slightly faster kinetics (80-90% depletion by 6 hours). Activation of T cells and B cells was observed in samples treated with glofitamab, but NK cells, granulocytes, and monocytes were also activated. A population of double-positive $CD3^+$ $CD22^+$ events was observed, correlating with the mechanism of action of the drug.

Similar to what has been observed in the clinic, inflammatory cytokines (IFN-γ, IL-2, IL-6, IL-8, and TNF-α) were present at very high levels in circulating whole blood treated with glofitamab for 6 hours. IL-6 and IL-8 were induced to similar levels as those seen using alemtuzumab at Cmax, and for IFN-γ and TNF-α, the levels were even higher than those seen with alemtuzumab. IL-2 was, as expected, not produced in response to either obinutuzumab or alemtuzumab, but was induced to high levels (similar to an agonistic anti-CD28 antibody) in the presence of glofitamab. Neither obinutuzumab nor glofitamab had any effect on complement activation in ID.Flow, whereas alemtuzumab induced increased levels of C3a and C5a.

In conclusion, ID.Flow can be used to assess the immunotoxicity and potentially the efficacy of bispecific antibodies with glofitamab as a relevant clinical control.

#5537 A half-life extended PD-1×VEGFA bispecific antibody demonstrates potent anti-tumor activity in preclinical models.

Frank An, Weiqiu Lan, Baihong Liu, Yang Chen, Xi Yang, Jinhua Zhao, Gao An, Yi Yang

Biocytogen, Waltham, MA

Background PD-1 blockade reactivates T-cell-mediated tumor killing but faces resistance in "cold" tumors with poor immune infiltration. VEGF-A inhibition (e.g., bevacizumab) normalizes tumor vasculature, enhancing immune cell delivery and synergizing with PD-1 inhibitors. Simultaneously disrupts immune evasion (via PD-1) and tumor blood supply (via VEGF-A), addressing microenvironmental barriers. Currently, several PD-1/L1×VEGF-A bispecific antibodies have been developed and demonstrated superior antitumor activity.

Methods We developed a novel PD-1×VEGF-A bispecific antibody, BCG036, by fusing a fully human anti-VEGF-A VHH domain with an Fc-engineered IgG1 anti-PD-1 monoclonal antibody to extend its half-life. We used reporter cell lines to conduct blocking assays for PD-1 and VEGF-A. *In vivo* pharmacokinetic and efficacy studies were evaluated in FcRn humanized mice and xenograft mouse models bearing an established A375 tumor. Toxicology studies were conducted in cynomolgus monkeys to assess the safety and pharmacokinetic characteristics of the BCG036.

Results BCG036 demonstrated high affinity and specificity for both human PD-1 and VEGF-A, with superior blocking activity for both PD-1/PD-L1 and VEGF/VEGFR signaling pathway than the benchmark. *In vivo*, BCG036 exhibited an extended half-life in humanized FcRn mice and demonstrated potent antitumor efficacy than the benchmark. Importantly, BCG036 displayed a favorable safety and PK profile in cynomolgus monkeys after repeated dosing at 100 mg/kg.

Conclusions Our prolonged half-life version of the PD-1×VEGF-A bispecific antibody shows high affinity *in vitro* and has a strong ability to block the interactions of PD-1/PD-L1 and VEGFR2/VEGFA. It demonstrates strong antitumor activity in mouse models and has demonstrated good safety in cynomolgus monkeys, supporting a long-term dosing regimen.

#5538 Pan-αβ-T-cell reactive anti-TCR VHH bispecifics demonstrate potent cytotoxicity through novel constant region targeting.

Michael B. Battles

Antibody Engineering, Adimab, LLC, Lebanon, NH

Introduction: All approved T-cell engagers target CD3ε, but alternative engagement sites on the TCR complex may yield differentiated functional properties. We developed VHH-based T-cell-engaging (TCE) arms that bind a previously unexploited quaternary epitope formed at the TCRα/β constant-region interface. These binders exhibit pan-αβ-T-cell reactivity with inherent human-cynomolgus cross-reactivity.
Methods: Anti-TCR VHHs were identified using yeast-based selections against recombinant human and cynomolgus TCRα/β heterodimers, employing both synthetic libraries and llama immunization. Affinity optimization of VHHs maintained cross-species recognition. Epitope mapping was performed using TCR constant-region mutant libraries generated by error-prone PCR. Structures of VHH-TCR complexes were solved. Bispecifics incorporating anti-tumor associated antigen (TAA) domains were assessed in T-cell-dependent cytotoxicity (TDCC) assays across tumor models and benchmarked against clinical CD3 controls.
Results: Multiple VHH lineages that recognize a conserved quaternary epitope at the TCRα/β constant-region interface were isolated, providing TRBC1/C2 coverage and human-cynomolgus cross-reactivity. Structural analyses established the binding mode. Despite moderate monovalent affinities, anti-TCR bispecifics demonstrated potent TDCC activity comparable to or exceeding benchmark CD3 bispecifics and clinically active controls. Functional activity was confirmed in both human and cynomolgus assay systems, including preliminary cytokine readouts.
Conclusions: VHH-based bispecifics that target a quaternary epitope within the TCR constant region constitute an emerging class of T-cell-engagers with potent cytotoxic activity and broad αβ-T-cell coverage. The combination of TRBC1/C2 inclusivity, structural definition, and human-cynomolgus cross-reactivity positions TCR constant-region targeting as a promising alternative for next-generation T-cell-redirecting therapeutics.

#5539 The anti-tumor activity of BB-202, a novel anti-PD-1/anti-VEGF bispecific antibody.

Hongyan Zhong, Daniel Guo, Phuong Nguyen, Daniel Li, **Ming Yang**

Bright Biologics LLC, Sunnyvale, CA

Background: Immune checkpoint blockade targeting PD-1/PD-L1 and VEGF inhibition each modulates the tumor microenvironment, and their combination has shown synergistic anti-tumor effects in preclinical models. Clinically, combining anti-PD-1/PD-L1 antibodies with anti-angiogenic agents has improved outcomes across multiple cancers and led to several regulatory approvals. Bispecific antibodies that co-target PD-1 and VEGF within a single molecule represent a promising strategy to further enhance this synergy. While the anti-PD-1/anti-VEGF bispecific antibody ivonescimab (AK112) has demonstrated clinical benefit, we developed BB-202, a novel bispecific antibody with a distinct structure designed to improve potency and stability.
Methods:BB-202 was engineered using pembrolizumab-derived Fab regions and anti-VEGF VHH fragments fused to a human IgG1 Fc. PD-1 binding affinity was characterized using whole-cell binding assays. PD-1 and VEGFA blockade were assessed using cell-based reporter assays, and PD-1 functional blockade was further evaluated in mixed lymphocyte reaction (MLR) assays. In vivo efficacy and safety were examined in multiple mouse xenograft models, including PBMC-humanized mouse models.
Results:BB-202 demonstrated high PD-1 binding affinity equivalent to pembrolizumab. In PD-1/PD-L1 blockade assays, BB-202 showed potency similar to pembrolizumab and substantially greater than AK112 and LM-299. BB-202 also blocked VEGFA activity with potency comparable to bevacizumab (Avastin), AK112, and LM-299. In MLR assays, BB-202 induced robust human T-cell activation, exhibiting approximately 38-fold greater potency than AK112. The molecule also showed excellent accelerated and serum stability.In vivo, BB-202 demonstrated strong anti-tumor activity. In an NCI-H1975 PBMC-humanized mouse model, BB-202 achieved significantly greater tumor growth inhibition than an equimolar dose of pembrolizumab. Consistent results were observed in the NCI-HCC827 xenograft model, where BB-202 again outperformed pembrolizumab. No weight loss or observable toxicities were detected.
Conclusion:BB-202 is a potent, stable, and well-tolerated anti-PD-1/anti-VEGF bispecific antibody. Its superior in vitro potency and robust in vivo efficacy, together with a favorable developability profile, position BB-202 as a promising best-in-class therapeutic candidate among PD-1/VEGF-targeting bispecific antibodies.

#5540 SCR-M015, a PD-1/VEGF bispecific antibody exhibits potent anti-tumor efficacy in preclinical studies.

Qiong Wang, Yayuan Fu, Fengli Shan, Yanqiu Wang, Guimei Yang, Yan Wang, Xiaokang Qin, Renhong Tang

Simcere Zaiming, State Key Laboratory of Neurology and Oncology Drug Development. Simcere Pharmaceutical Group., Shanghai, China

Background: Combinations of PD-1 antibodies and anti-VEGF agents significantly improved clinical benefits over standards of care. The immune checkpoint and VEGF pathways has been demonstrated intrinsic mechanistic complementation, including VEGF effect on angiogenesis, immune cell infiltration, and dendritic cell maturation. We have developed a PD-1xVEGF bispecific antibody SCR-M015 and reported preclinical studies characterizing the functional activity.
Method: Binding affinity was assessed using Surface Plasmon Resonance, and the EC50 were determined using ELISA and FACS. Bioluminescent cell-based reporter assays were explored to measure VEGF/VEGFR2 or PD-L1/PD-1 signaling blockage function. Mixed lymphocyte reaction (MLR) assay was applied to evaluate anti-PD1 functional activity. Anti-VEGF bioactivity was determined in HUVEC proliferation assay. In vivo efficacy studies were conducted in CDX models with human tumor cell lines.
Result: SCR-M015 was constructed by fusing anti-PD-1 nanobody to the C-terminus of the heavy chain of an anti-VEGF-A antibody with a silent Fc, forming a 2+2 symmetrical structure. SCR-M015 exhibited specific and high-affinity binding to human PD-1 and VEGF. In vitro assays demonstrated that the anti-PD-L1/VEGF bispecific antibody exhibited more potent blockade activity against VEGF-A/VEGFR2 signaling and inhibition of HUVEC proliferation. In MLR assay, SCR-M015 showed dose-dependently increased IL-2 and IFN-γ secretion, which was comparable to benchmark antibody. In vivo, SCR-M015 demonstrated more robust anti-tumor activity than benchmark antibody in different xenograft models. Furthermore, compared to the combination of anti-PD-1 monoclonal antibody and anti-VEGF monoclonal antibody, SCR-M015 showed more potent anti-tumor efficacy.
Conclusions: SCR-M015 inhibits PD-1/PD-L1 signaling and VEGF-A/VEGFR2 signaling in vitro and shows potent and superior anti-tumor activity in vivo. These preclinical data demonstrates the promising potential for further clinical investigation in various types of tumors.

#5541 Characterization and functional evaluation of PF-08634404 (SSGJ-707) a tetravalent PD-1 x VEGF bispecific for the treatment of cancer.

Ryan A. Heiser[1], Meghan Zuck[1], Catalina Sakai[1], Eliana Moskovitz[1], Laila Shehata[2], Markus Carlson[1], Florian Heinkel[1], Sherif Abdelhamed[3], MIchelle Ulrich[1], Matt Rathgeber[1], Brian P. O'Connor[1], Joseph D. Dekker[1], Haomin Huang[4], Sharsti Sandall[1]

[1]Pfizer Oncology, Bothell, WA,[2]Pfizer Oncology, Seattle, WA,[3]Pfizer Oncology, Bothell, Bothell, WA,[4]3SBio Inc., Shanghai, China

PF-08634404 (formerly known as SSGJ-707) is an investigational anti-PD-1 and anti-VEGF bispecific antibody designed to simultaneously inhibit PD-1-mediated T cell dysfunction and VEGF-A-mediated tumor angiogenesis and immune suppression in the tumor microenvironment. PF-08634404 is a tetravalent 2+2 bispecific leveraging Common Light Chain Linear Fab x2 (CLF^2) technology with an IgG4 backbone. The PD-1 and VEGF-A binding arms of PF-08634404 are unique among the PD-1 x VEGF bispecific class. PF-08634404 has demonstrated promising clinical activity in NSCLC and CRC in clinical trials conducted in China. Here we present preclinical data demonstrating binding to and functional inhibition of PD-1 and VEGF-A by PF-08634404 in vitro. PF-08634404 displays nanomolar binding affinities for PD-1 and VEGF-A and can bind both targets simultaneously. The functional inhibition of VEGF by PF-08634404 is increased (~7.5-fold) compared to relevant benchmarks, and the inhibition of PD-1 is equivalent or superior to relevant benchmarks. Consistent with this class of bispecific molecules, PF-08634400 multimerizes in the presence of dimeric VEGF-A, increasing the avidity for PD-1 (>100-fold), driving rapid internalization of PD-1 on T cells, and improving the functional inhibition of PD-1 (>10-fold). Collectively, these data characterize core features of the bispecific mechanism and support the ongoing clinical investigation of PF-08634404 proof of concept and pivotal trials in multiple disease settings/tumor types.

#5542 Novel PD-1xVEGFxIL-2 trispecific immune modulator with superior safety and greater efficacy.

Lei Wu, Mengmeng Sun, Bowei Liao, Shuang Wang, Tengfei Yu, Jijie Gu

WuXi Biologics, Wuxi Shi, China

PD-1 antagonist antibodies have demonstrated significant success in the clinic. However, low response rate and high cancer recurrence requires the development of next-generation immunotherapies. Bispecific immune modulators PD-1xVEGF and PD-1xIL-2 molecules have shown promising clinical improvement over PD-1 antagonist antibodies, particularly in populations resistant to PD-1 monotherapy. VEGF, a soluble dimer enriched in the tumor microenvironment (TME), plays a crucial role in angiogenesis and tumor growth. Local enrichment of PD-1xVEGF bispecific antibodies by VEGF dimers could further potentiate the efficacy of PD-1 blockade. On the other hand, IL-2 of PD-1xIL-2 molecules can be cis-presented on PD-1-expressing T cells, expanding tumor-specific T cell populations and enhancing the functions of PD-1 antibodies. We therefore built a novel PD-1xVEGFxIL-2 trispecific immune modulator that combines the biologic functions of all three. We have optimized the trispecific format to retain the affinity and potency of both VEGF and PD-1 blockers. The proprietary IL-2 mutein has over 1000X attenuated IL-2Rβγ binding and muted CD25 binding to ameliorate systemic immunotoxicity on non-specific T and NK cells in the periphery. The sub-nanomolar anti-PD-1 antibody then directs IL-2 mutein to PD-1+ T cells and effectively replaces the natural function of CD25. Thus, proprietary IL-2 mutein specifically acts on PD-1-expressing tumor-specific T cells to expand effector populations. VEGF neutralization suppresses angiogenesis and potentiates the potency of PD-1 blockade. These creates a “super PD-1” next-generation immune modulator. PD-1xVEGFxIL-2 trispecific has been fully characterized. The potency of the trispecific for PD-1 and VEGF blockades were comparable to the respective monoclonal antibodies. The proprietary IL-2 mutein bound weakly to human IL-2Rβγ, with equivalent affinity to cynomolgus and mouse IL-2Rβγ. This IL-2 variant was inert on primary pan T cells and did not activate Treg cells, but induced potent activation of PD-1+ T cells. In addition, PD-1xVEGFxIL-2 enhanced immune activation of T cells induced by A375 tumor cells in a co-culture system. In an exploratory toxicity study, the attenuated IL-2 mutein supported a higher maximum tolerated dose for the trispecific than IBI363 in cynomolgus monkeys, which matched the optimal therapeutic doses for PD-1 and PD-1xVEGF antibodies. In mouse efficacy studies, PD-1xVEGFxIL-2 exhibited significantly greater efficacy than both PD-1xVEGF and PD-1xIL-2 in PBMC-engrafted CDX model and mouse syngeneic models. In summary, WuXi Biologics has developed a novel PD-1xVEGFxIL-2 trispecific molecule. This potent next-generation immune modulator shows great potential for further clinical investigation.

#5543 Mechanism-driven cell-based assays to screen & characterize bi-specific antibodies.

Venkatesh Chari, Surekha Bonasu, Luhan Yang, Jennifer Lin-Jones, Jane Lamerdin, Alpana Prasad, Gaurav Agrawal

Eurofins DiscoverX Products LLC., Fremont, CA

Recent advances in cancer immunotherapy using monoclonal antibodies have dramatically revolutionized the therapeutic strategy against advanced malignancies, inspiring the exploration of various types of therapeutic antibodies. Bispecific antibodies (BsAbs) are engineered molecules designed to target two different epitopes or antigens. The mechanism of action of BsAbs can be manipulated to create variable and novel functionalities, including linking immune cells with tumor cells or signaling pathway blockade. BsAb-based therapies have demonstrated significant preclinical and clinical potential, as evidenced by the regulatory approval of molecules like blinatumomab (CD19/CD3), amivantamab (EGFR/Her3), ivonescimab (PD-1/VEGF-A), and others.

Eurofins DiscoverX® provides a robust portfolio of cell-based assays for oncology targets and offers three primary assay formats to characterize BsAbs: (1) Cytotoxicity assays: To assess functional activity of BsAbs in *trans*, specifically for characterizing T-cell engagers (BiTEs) and similar molecules, (2) Dimerization assays: To record hetero dimerization of target receptors in *cis*, and (3) Pathway signaling assays: To evaluate the functional activity of each individual BsAb target arm

This presentation highlights case studies illustrating the use of these cell-based assays to monitor key BsAb MOAs targeting critical tumor antigens, including CD19, PD-1, and VEGF-A. Applications will demonstrate the evaluation of BsAb-mediated tumor cell killing, rank-ordering of antibody candidates, and assessment of the function and specificity of individual BsAb arms. These assays provide essential tools for the accelerated discovery and characterization of next-generation BsAb therapeutics.

#5544 Organoid-T cell co-cultures: A robust platform for bispecific antibody immunotherapy development.

Sonia Aristin Revilla, Cesar Oyarce, Sumeyra Mucuk, Javier Frias Aldeguer, Timo Voskuilen, Merel Derksen, Farzin Pourfarzad, Robert G. J. Vries, Sylvia F. Boj

HUB Organoids B.V., Utrecht, Netherlands

Recent advances in cancer immunotherapy have significantly improved patient survival across multiple indications. As new treatment strategies and druggable targets emerge, the number of patients eligible for immunotherapy continues to grow. However, translating promising preclinical findings into clinical success remains challenging, as conventional 2D cancer models offer limited predictive value. We developed an innovative alternative based on the ability of adult stem cells to form three-dimensional organotypic structures within an extracellular matrix. Patient-derived organoids, generated from normal and malignant tissues and stored in high-quality biobanks, yield highly reproducible results. HUB Organoids faithfully recapitulate the complexity of parental tissue, including molecular heterogeneity and morphological and functional traits. Over the last decade, bispecific antibodies (bsAbs) have gained significant attention in cancer treatment, leading to several approved therapies. Bispecific T-cell engagers (BiTEs), a subclass of bsAbs, bring T cells into close proximity with cancer cells and promote immunologic memory, enabling the immune system to more effectively recognize and eliminate tumor cells. To de-risk drug development and accelerate clinical translation, we developed an assay in which labeled tumor organoids are co-cultured with labeled PBMCs and exposed to BiTEs to assess immune cell-mediated cytotoxicity. Fluorescent dyes enable real-time evaluation of cytotoxic activity via high-resolution microscopy, complemented by cytokine secretion analysis to confirm immune cell activation. HUB's organoid co-culture system is robust and reproducible, providing a dynamic window to evaluate the activity of multiple BiTEs. Organoid-based cytotoxicity assays accurately reflect BiTE-mediated T cell killing, demonstrating that our model captures the expected mechanism of action. This platform offers a powerful tool for developing and validating cancer immunotherapies, helping to de-risk novel strategies through patient-derived models.

#5545 Collagen-binding anti-GITR antibody reshapes immunosuppressive microenvironment and prolongs survival in recurrent glioblastoma.

Jun Takei[1], Chuyi Wang[2], Ken Furudate[3], Opeyemi Iwaloye[1], Lewis Barr[1], Haruka Ichie[1], Shunsuke Tsuzuki[1], Jun Ishihara[2], Satoru Osuka[1]

[1]Department of Neurosurgery, University of Alabama at Birmingham, Birmingham, AL,[2]Department of Bioengineering, Imperial College London, London, United Kingdom,[3]Department of Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX

Recurrent glioblastoma (rGBM) remains lethal with median survival under six months, due to immunotherapy resistance driven by immunosuppressive tumor microenvironment (TME) with elevated regulatory T cells (Tregs). Despite the development of Treg-targeting antibodies such as anti-GITR (Glucocorticoid-induced TNFR-related protein) antibody, their poor delivery to brain tumors has restricted therapeutic efficacy, necessitating novel drug delivery strategies. We aimed to identify anchors for selective antibody delivery to tumors and focused on Collagen type I and III (COLI&III), which are minimal in normal brain but highly upregulated in rGBM.We engineered a novel antibody, CBD-αGITR, by conjugating the COLI&III-binding domain (CBD) of von Willebrand Factor (vWF) to an anti-GITR antibody. vWF naturally binds to exposed collagen only at sites of vascular injury, inflammation, and tumor while sparing normal tissues, providing a potential mechanism for tumor-specific drug delivery. We investigated the tumor-selective accumulation, immunosuppressive microenvironment remodeling, and antitumor effects of CBD-αGITR using clinically relevant syngeneic rGBM mouse models, humanized mouse models, and patient-derived 3D tumor slice cultures.Using a fluorescently labeled biodistribution assay, CBD-αGITR selectively accumulated in rGBM tumors but not in normal brain or COLI/III-expressing organs. Single-cell RNA sequencing revealed that CBD-αGITR dramatically decreased GITR+ Tregs and exhausted CD8+ T cells (which express moderate levels of GITR), thereby reversing the immunosuppressive TME and promoting the recruitment of anti-tumor macrophages and type 1 conventional dendritic cells. CBD-αGITR treatment (300ug, i.v. 1x) achieved approximately 20% complete remission (CR) in two independent rGBM mouse models, while αGITR (non-CBD) antibody showed no survival benefit. Furthermore, combining CBD-αGITR with PD-1 inhibitor further enhanced antitumor efficacy, achieving 67% CR in rGBM mouse models. We have developed a humanized CBD-αGITR for clinical application, which demonstrated extended survival in humanized rGBM mouse models and significant human Treg reduction in patient-derived 3D tumor slice cultures.GITR antibody modified for COLI&III binding achieved selective tumor accumulation, immune reprogramming, and robust tumor control. This delivery strategy can be applied to other antibodies and has the potential to significantly advance treatment approaches for rGBM.

#5546 Rilvegostomig elicits greater immune activation and tumor inhibition than clinically approved anti-PD-1 monotherapy in models of HNSCC.

Jun Ren, Ngan Mitchell, Marie Boutet, Vladimir Roudko, Jeremy Ratiu, Jorge Blando, Sophia Varriano, Elizabeth Galery, Rebecca Halpin, Trevor Connor, Kanam Malhotra, Bartholomew Starich, Jessica Wagner, Yi Luan, Anna Huntley, Joseph Boland, Maurizio Scaltriti, Mark Cobbold, Simon Hollingsworth, Scott Hammond, Doug Palmer, Paul Chariou, Kristen Pollizzi, Daniela Dinulescu

Oncology, AstraZeneca, Gaithersburg, MD

Background: Rilvegostomig (AZD2936) is a monovalent, bispecific humanized IgG1 monoclonal antibody that targets human TIGIT and PD-1, engineered with a triple-mutation in its fragment crystallizable (Fc)-domain to prevent Fc-effector functionality. Rilvegostomig has shown promising anti-tumor activity in NSCLC patients in a Phase I/II clinical trial (NCT04995523) and is currently being investigated in multiple Phase III trials. Here, we report the enhanced anti-tumor activity of rilvegostomig compared to a clinically approved anti-PD-1 (αPD1) mAb in ex vivo and in vivo models of head and neck squamous cell carcinoma (HNSCC).
Methods: Primary HNSCC explants, derived from freshly resected patient tumors, were cultured ex vivo in a 3D platform for therapeutic agent testing. Ex vivo immune activity was assessed via IFN-γ quantification. Baseline tumor features—characterized by IHC, flow cytometry, scRNA-seq, and multiplex imaging—were used to stratify patient response and identify candidate biomarkers. A CD34+ humanized mouse model of HNSCC was developed to enable long-term engraftment of functional multi-lineage hematopoietic cells and used to investigate efficacy and effects of IO therapeutics on different components of the immune system.
Results: We investigated a cohort of 42 newly diagnosed HNSCC patient resected tumor samples. These samples represent the incidence of HNSCC by anatomical sites and share similar cohort attributes as those enrolled in KEYNOTE-689. Patient-derived tumor explants maintain tumor architecture and intact tumor microenvironment (TME), including tumor cells, immune cells, stroma cells, and extracellular matrix. αPD1 monotherapy elicited immune activity in 9.5% of HNSCC samples tested in our ex vivo platform, consistent with clinical observation of major pathological response in KEYNOTE-689. In contrast, rilvegostomig induced a significantly higher rate of ex vivo immune activity (28.6%). Rilvegostomig's activity was observed in samples derived from multiple anatomical sites, showing the highest response rate in oral cavity samples. Moreover, our analyses identified key baseline correlates that distinguish rilvegostomig activity from αPD1. Lastly, using a CD34-engrafted humanized mouse model of oral cavity HNSCC, we compared the therapeutic efficacy of αPD-1 monotherapy with rilvegostomig. In contrast to αPD-1, which produced modest effects on tumor growth, rilvegostomig induced significant tumor growth inhibition.
Conclusions: Rilvegostomig elicits greater immune cell activation and broader activity in samples derived from different anatomical sites of HNSCC compared to αPD1 monotherapy in a 3D ex vivo platform and a humanized mouse model of HNSCC. These results underscore rilvegostomig's potential as a promising treatment for newly diagnosed HNSCC and support its investigation in clinical trials.

#5547 Enhancing antibody-dependent cellular cytotoxicityin mesothelioma through concurrent EGFR and MET targeting withamivantamab.

Shinichiro Suzuki, Kaushal Parikh, Ezequiel Tolosa, Kuan-Li Wu, Jennifer Ayers-Ringler, Lin Yang, Katherine E. R. Smith, Farhad Kosari, Aaron S. Mansfield

Mayo Clinic, Rochester, MN

Background: Diffuse pleural mesothelioma (DPM) is a highly aggressive malignancy with limited treatment options and poor prognosis. Although immune checkpoint inhibitors have improved outcomes, particularly for non-epithelioid subtypes, there remains no approved targeted therapy for mesothelioma. EGFR and MET are receptor tyrosine kinases frequently overexpressed in DPM, suggesting susceptibility to targeted antibody therapy. Amivantamab is a bispecific EGFR/MET antibody, originally developed for EGFR-mutant lung cancer, that blocks growth signals and engaging immune mechanisms. Given the high levels of EGFR and MET expression in mesothelioma, we evaluated the therapeutic potential of amivantamab in preclinical models.
Methods: EGFR and MET transcript levels in DPM were analyzed using TCGA. Eight human mesothelioma cell lines were assessed by Western blotting and flow cytometry. Amivantamab binding, internalization, and signaling inhibition were examined using flow cytometry, confocal microscopy, and ligand-stimulated phosphorylation assays. Cytotoxicity and immune-effector activity were quantified using PBMCs, NK cells, and monocytes from healthy donors, along with an ADCC reporter assay. In vivo efficacy was tested in a DPM patient-derived xenograft (PDX) model in NOD/SCID-γ (NSG) mice supplemented with human NK cells and treated with amivantamab or control IgG.
Results: TCGA analysis showed frequent EGFR/MET co-expression in DPM. Mesothelioma cell lines expressed higher EGFR and MET levels compared with mesothelial cells. Amivantamab strongly bound both receptors, induced receptor internalization, and inhibited EGF- and HGF-stimulated phosphorylation of EGFR, MET, and downstream AKT/ERK signaling. Direct cytotoxicity was minimal; however, the addition of PBMCs or NK cells resulted in robust, dose-dependent tumor cell killing consistent with antibody-dependent cellular cytotoxicity (ADCC). Reporter assays demonstrated 7-11-fold Fcγ receptor activation in tumor cells compared with ~2-fold activation in non-malignant mesothelial cells. Co-culture with monocytes revealed amivantamab-induced trogocytosis, evidenced by loss of EGFR and MET from tumor-cell membranes. In the DPM PDX model, amivantamab produced 89.1% tumor-growth inhibition (TGI) relative to controls ($P < 0.0001$), with no overt toxicity observed in treated mice.
Conclusions: Dual EGFR/MET targeting with amivantamab produced potent antitumor effects in mesothelioma through coordinated receptor-signaling blockade, ADCC, and monocyte-mediated trogocytosis. These results support amivantamab as a promising targeted therapeutic strategy for EGFR/MET-positive DPM, particularly epithelioid subtypes that currently derive limited benefit from immunotherapy.

#5548 Unbiased discovery of novel macrophage-activating immunotherapies for ALK+ non-small cell lung cancer.

Carlota Pages-Geli[1], Thomas Wienclaw[1], Juliano Ribeiro[2], Matheus Silva[1], Kipp Weiskopf[1]

[1]Department of Medicine, Beth Israel Deaconess Medical Center, Boston, MA,[2]Harvard-MIT Health Sciences and Technology Program, Boston, MA

Non-small cell lung cancer (NSCLC) represents ~85% of all lung cancer cases and remains one of the leading causes of cancer-related mortality in the United States. Approximately 3-7% of NSCLC patients harbor ALK rearrangements, most commonly the EML4-ALK fusion. Although ALK+ tumors initially respond well to ALK tyrosine kinase inhibitors (TKIs), patients still develop resistance. Lorlatinib, a third-generation ALK inhibitor, achieves ~76% response rates in treatment-naïve patients; however, a substantial proportion experience disease progression within a few years, highlighting the urgency for new therapeutic strategies. The tumor immune microenvironment is increasingly recognized as a key contributor to resistance. Tumor-associated macrophages (TAMs) are the dominant immune population infiltrating NSCLC and can promote tumor growth, survival, and immune evasion. Here, we aimed to identify novel therapeutic strategies to stimulate macrophages to eliminate ALK+ lung cancer cells.Using in vitro co-culture assays, we found that macrophages markedly protect ALK+ lung cancer cells from lorlatinib, making the cancer cells significantly less responsive compared to cells cultured alone. We found that blocking macrophage immune checkpoints, such as the CD47/SIRPa axis, could restore macrophage activation and promote phagocytosis of the ALK+ lung cancer cells. Since systemic administration of anti-CD47 antibodies can result in dose-limiting hematotoxicity, we therefore developed a high-throughput bispecific antibody (bsAb) engineering platform to leverage the benefits of targeting CD47 while increasing specificity to the tumor microenvironment. We generated a library of bsAbs targeting CD47 with a second arm binding well-known tumor antigens including EGFR, EpCAM, HER2, TROP2, FOLR1, Nectin-1, Nectin-4, PD-L1, and CD71. Using live-cell imaging, we evaluated macrophage-mediated cytotoxicity for each bsAb across three ALK+ NSCLC cell lines. Among all constructs tested, a bsAb incorporating a low-affinity CD47-binding domain and a TROP2-targeting domain showed the strongest anti-tumor activity, significantly reducing tumor growth over time. This bsAb enhanced macrophage phagocytosis and decreased tumor area more effectively than lorlatinib alone. Importantly, combining the CD47×TROP2 bsAb with lorlatinib produced synergistic anti-tumor effects, offering a promising strategy to overcome or delay resistance. Overall, our study has identified novel bispecific antibodies that may be highly active for ALK+ lung cancer and our findings could be translated to the clinic to benefit patients in the future.

#5549 Non-clinical modeling the therapeutic window of HX044, a novel CTLA4xCD47 BsAb.

Hang Ke[1], Zihan Xu[2], Tao Yang[1], Cen Chen[1], Sheng Gao[2], Lei Zhang[1], Faming Zhang[1], **Henry Li**[1]

[1]Hanx Bio, Wuhan, China,[2]Crown Bioscience, Inc., Suzhou, China

MOAs of the CTLA4-mAb (*e.g.* Ipilimumab or Ipi) for anti-cancer efficacy include: 1) ADCC/the associated TIL-T_{reg}-depletion, 2) CTLA4-ligand (CD80/CD86) blockade/the associated T-cell activation in tdLN (tumor draning lymphonoda) (priming), and 3) Fc-mediated effector activities/the associated TME remodeling enhancing immunogenicity. Ligand-blockade is also blamed for the associated immunotoxicity (irAE). We previously described a bispecific CTLA4-antibody/SIRPα-fusion protein, HX044, where it is considered to be a next generation CTLA4-therapy with enhanced efficacy via increased ADCC on $CTLA4^{+++}CD47^{+++}$ TIL-T_{reg} and lowered irAE via reduced ligand-blockade over Ipi. Its design concept was based on the assuption that Til-T_{reg} have higher CTLA4/CD47 expression over those in peripheral in both levels and frequency. The present study assayed HX044 in various *in vitro/in vivo* experimental systems to approximately simulate its therapeutic window by modeling a variety of possible relevant parameters of pharmacokinetic exposures, irAE and efficacy. First, we surveyed available cancer patient T_{reg} scRNAseq-datasets, which indeed confirmed both higher frequencies and levels of CTLA4/CD47 expressions in TIL-T_{reg} over peripheral T_{reg}, a benefiting factor in term of less irAE, although their thresholds for irAE remained to be determined. Second, HX044 was confirmed to have significantly enhanced ADCC over Ipi in double-high cells, confirming greater potential in TIL-T_{reg} depletion, which is also confirmed along with associated enhanced antitumor efficacy in humanized syngeneic tumor models. Third, HX044's ligand-blockade in double-positive cells was determined to be slightly reduced (~50%) as compared to Ipi, while little ligand-blockade in CTLA4-single-positive cells, contrasting to potent blockade by Ipi, suggesting that HX044 could have reduced irAE if the dual receptor expression in peripheral are below the assumed thresholds. As a reference, blocking assay using recombinant CTLA4 protein revealed ~300x fold reduction of CD80-blocking for HX044 in comparison to Ipi. Fourth, NHP study of HX044 demonstrated excellent PK profile with long half-life and dose-proportional exposure as well as dose-dependent irAE, mostly seen in the highest dose level at 40mg/kg rather than lower dose levels at 1mg/kg and 6mg/kg, respectively. The data could not necessarily confirm significant better safety over Ipi in the 40mg/kg dose level, thus higher tolerable dose for irAE in the presence of sufficient double-positive T_{reg} cells in peripheral. Nevertheless, HX044 has significantly broadened therapeutic window over Ipi, via lower efficacious dose levels attributed to significantly enhanced ADCC activities.

#5550 T cell transcriptome is altered by Talquetamab in presence of GPRC5D on MM cells.

Umair Munawar[1], Alexander Leipold[2], Seungbin Han[1], Silvia Nerreter[1], Shilpa Kurian[1], Emma Besant[1], Nina Rein[1], Johanna Lehmann[1], Max Koeppel[1], Xiang Zhou[1], Ondrej Slaby[3], Hermann Einsele[1], Leo Rasche[1], Emmanual Saliba[2], Johannes Waldschmidt[1], Martin Kortuem[1]

[1]University Hospital Wuerzburg, Wuerzburg, Germany,[2]Helmholtz Institute for RNA-based Infection Research, Wuerzburg, Germany,[3]Masaryk University, Brno, Czech Republic

Background: G protein-coupled receptor class C group 5 member D (GPRC5D) has emerged as a promising immune target in multiple myeloma (MM). Talquetamab, a GPRC5D-directed bispecific antibody, has shown an efficacy of 70% in triple class refractory MM patients however, genomic loss mediated relapse is often observed. To better understand the interplay of talquetamab, GPRC5D loss and T cells within the immune microenvironment, we performed single cell sequencing on a coculture of GPRC5D loss models and healthy T cells in presence and absence of talquetamab.
Methods: GPRC5D mono- and biallelic knockout models were generated using CRISPR-Cas9 technology. Cocultures were established using healthy T cells with or without talquetamab for 24 hours. CITE-seq was performed. Cell hashing with TotalSeq-C antibodies enabled multiplexing. Pooled cells underwent 10x Genomics 5' GEM-X workflow and were sequenced on Illumina NovaSeq X Plus. Differential gene expression was assessed using the Wilcoxon rank-sum test, and interferon response scores were calculated using AddModuleScore.
Results: Pronounced transcriptomic changes in MM cells were observed with both mono- and bi-alleic loss of GPRC5D via CITE-seq. Based on the expression of canonical markers (*IL2RA, IRF4, TNFRSF4-18, TNF, IFNG*), CD4 and CD8 activated T cells were only observed in presence of talquetamab and GPRC5D^{+} cells and completely disappeared when stimulated with GPRC5D$^{Del/Del}$ models. A significant induction of interferon stimulated genes (*GBP2-4-5, IFI44, IFIT2, ISG15*) in presence of talquetamab with GPRC5D on MM cells (p-value < 0.001, absolute log2FC > 2) was observed across T cell subpopulations. Interferon signaling genes (*STAT1, IRF1*) were found to be upregulated in T cells by talquetamab alone even in absence of GPRC5D^{+} cells in coculture. Additionally, we also identified genes only upregulated in presence of GPRC5D and talquetamab, including *SOCS3, CD69, JUNB, BATF, CISH*, and *PRDM1*, indicating a unique activation status of these T cells. Gene set enrichment analysis performed on T cell sub types indicated an enrichment of IFN-γ and IFNA-signaling (NES>2.0, FDR 0,0) in CD4, CD8, Tcm and Treg populations. Additionally, IL2-STAT5 signaling and inflammatory response (NES>2.0, FDR 0.0) pathways were found to be enriched only in presence of talquetamab and GPRC5D^{+} cells. Of note, in the absence of talquetamab, T cells transcriptomic profile did not change in response to GPRC5D presence or absence on MM cells.
Conclusions: Our findings demonstrate that talquetamab upregulates the expression of interferon signaling genes in T cells even in the absence of GPRC5D and this response is enhanced when GPRC5D is present on MM cells. Moreover, talquetmab alters the activation profile across T cells subsets and both abundance and distribution of different T cells subpopulations is changed by GPRC5D status of the MM cells in coculture.

#5551 MHC class II targeted immunotherapy in the treatment of pancreatic cancer.

Reeder Robinson[1], Leticia Reyes[1], Samaneh Saberi[2], Lena Golick[2], Sandeep Gupta[1], Michael Ostrowski[2], **Nathan G. Dolloff**[1]

[1]Leukogene Therapeutics, Inc., Charleston, SC,[2]Medical University of South Carolina, Charleston, SC

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest tumor types, claiming approximately 50,000 lives per year in the United States and carrying a 5-year overall survival rate of only 13%. While immunotherapy has revolutionized therapy for certain cancer types, this has not been the case for PDAC, where there have been zero immunotherapy approvals. This is attributed to a variety of factors related to the PDAC tumor microenvironment (TME) including its dense desmoplastic stroma with high interstitial pressure and a prevalence of immunosuppressive cell types. In addition, genetic characteristics like microsatellite instability (MSI) and high mutational burden, which predict responsiveness to immune checkpoint inhibitors (ICIs), are absent or low in PDAC compared to more responsive tumor types. This suggests that effective anti-tumor immune responses depend on tumor-derived immunogenic signals, leading us to explore new strategies to stimulate immunity against PDAC-associated antigens. We developed a Major Histocompatibility Complex class II (MHCII) targeted approach to direct the immune system against PDAC associated antigens. MHCII is a major antigen presentation complex that directly educates CD4+ helper T cells, and studies have shown that MHCII-CD4 signaling is essential for effective anti-cancer immunity. Specifically, we developed a recombinant high affinity MHCII engager that is conjugated to mesothelin (MSLN), which is overexpressed in a high percentage of PDAC but not the normal pancreas.
Methods: To evaluate the preclinical efficacy of our MHCII targeted MSLN therapy (LTI-002), we injected KPC mouse PDAC cells orthotopically in syngeneic C57BL/6 mice. Tumor burden was measured at a predetermined endpoint or by survival analysis. Pharmacodynamic markers of immune response including anti-MSLN specific IgGs and antigen-specific T cell recall were also evaluated.
Results: This approach induced a polyclonal humoral response and antigen specific T cell response against mouse and human MSLN candidates. This led to a significant reduction in the size of orthotopic PDAC tumors and significantly improved animal survival. Anti-tumor responses were detected in therapeutic as well as prophylactic experiments and further demonstrated in the de novo KPF mouse PDAC model and in a model of PDAC metastasis. We observed synergy in combination with PDAC standard of care agents like gemcitabine, RAS(ON) inhibitors, and anti-PD1 immunotherapy. As a direct MHCII engager, LTI-002 induced internalization of MSLN into early endosomes where it was processed and loaded onto new MHCII molecules for presentation to CD4+ T cells. LTI-002 target engagement was independent of MHCII polymorphisms, which is an advantage given the diversity of HLA alleles found in different human populations.
Conclusions: This study demonstrates the therapeutic potential of targeting MHCII to stimulate anti-PDAC immunity.

#5552 MHC class II engager immunotherapy for the treatment of acute myeloid leukemia.

Lena Golick[1], Reeder Robinson[2], Leticia Reyes[2], Sandeep Gupta[2], **Nathan G. Dolloff**[2]

[1]Medical University of South Carolina, Charleston, SC,[2]Leukogene Therapeutics, Inc, Charleston, SC

Introduction: The treatment of acute myeloid leukemia (AML) remains a challenge due to disease heterogeneity and therapeutic resistance to traditional cytotoxic drugs and immunotherapy. To address this, we developed LTI-214, a novel recombinant Major Histocompatibility Complex class II (MHCII) engager linked with AML antigen sialic acid binding Ig-like lectin 3 (CD33). MHCII is a critical player in antigen presentation, and studies have shown that MHCII function is essential for effective cancer immunotherapy. MHCII directly educates CD4+ helper T cells against specific antigens. CD4+ T cells then orchestrate a coordinated immune response by communicating cytokine signals to virtually all immune effector cells including CD8+ cytotoxic T cells, B cells, NK cells, and others. CD33 is a myeloid cell surface glycoprotein highly expressed on AML blasts. However, while ~90% of AML cases express CD33, 50% of these patients harbor a single nucleotide polymorphism (SNP) that eliminates the antibody binding epitope for existing CD33-targeted antibody therapeutics such as gemtuzumab ozogamicin (Mylotarg®). Mylotarg® induces objective responses in AML patients, but its efficacy is limited by this splice variant. Therefore, while CD33 was validated as an actionable target in AML, more effective CD33-directed therapies are needed.
Methods: To demonstrate the therapeutic potential of LTI-214, we used the murine C1498 AML xenotransplant model in syngeneic and immunocompetent C57BL/6 mice. Animal survival was a primary endpoint along with pharmacodynamic markers of immune response including measurement of anti-CD33 specific IgGs and antigen-specific T cell recall.
Results: We found that LTI-214 (M2T-CD33) induced a robust polyclonal anti-CD33 humoral response characterized by induction of the full immunoglobulin repertoire. LTI-214 significantly improved animal survival in a CD4+ and CD8+ T cell dependent manner. The immune response was elicited against both the full length and spliced version of CD33, unlike existing anti-CD33 MAbs (gemtuzumab and lintuzumab), which bound exclusively to the IgV domain fragment. LTI-214 showed a favorable safety profile with no evidence of cytokine release syndrome or organ toxicity, and minimal impact on normal hematopoiesis at concentrations 40-fold higher than the efficacious dose. LTI-214 was enhanced by combinations with anti-PD-1 therapy potentially due to the inducible nature of PD-L1 expression of C1498 AML cells.
Conclusions: These experiments demonstrate the potential of LTI-214 in AML and emphasize the importance and targetability of MHCII in cancer immunotherapy.

#5553 Tumor-selective activation of 4-1BB receptor via bispecific antibody combinations.

Lucie Diby[1], Pauline Malinge[1], Valery Moine[1], Lise Nouveau[1], Laurence Chatel[1], Krzysztof Masternak[1], Limin Shang[1], Walter Ferlin[1], Nicolas Fischer[1], Jose Saro[1], Mikael Pittet[2], Vanessa Buatois[1], Eric Hatterer[1]

[1]Light Chain Bioscience - Novimmune SA, Plan-les-Ouates, Switzerland,[2]University of Geneva, Geneva, Switzerland

INTRODUCTION:
4-1BB (CD137) is an inducible co-stimulatory molecule that plays crucial roles in immune activation. Upon ligand binding, 4-1BB forms trimeric signaling complexes triggering receptor activation. However, therapeutic monoclonal antibodies targeting 4-1BB often face challenges due to peripheral toxicities arising from systemic receptor activation. To address this, bispecific antibodies (bsAbs) have been developed to selectively activate 4-1BB in a tumor-associated antigen (TAA)-dependent manner. This report investigates whether a combination of bsAbs, pairing 4-1BB and TAA targeting arms, can further enhance 4-1BB clustering and activation in the tumor microenvironment.
METHODS:
A panel of Fc-silent bsAbs targeting different domains on 4-1BB and HER2 were generated and tested in combination for optimal 4-1BB signaling. For that purpose, 4-1BB reporter cells were co-cultured with HER2-expressing tumor cells. Functional *in vitro* assays were conducted using primary human T cells isolated from peripheral blood mononuclear cells to assess cytokine production and their tumoricidal activity. *In vivo* efficacy was evaluated in PBMC-engrafted NOG mice inoculated with JIMT-1, a HER2-expressing tumor cell line.
RESULTS:
The simultaneous binding of two bsAbs to the same epitope on 4-1BB, while targeting distinct epitopes on HER2, markedly enhances 4-1BB signaling, compared to the single bsAbs. 4-1BB signaling triggered by the bsAbs is driven by HER2 expression, with strong IL-2 release observed only in the presence of HER2-positive cells. In JIMT-1 xenograft models, combination of the bsAb pair with a T cell engager (TCE) resulted in superior antitumor activity and enhanced $CD4^+$ and $CD8^+$ T-cell infiltration within the tumor microenvironment, compared to either single bsAb plus TCE or the TCE alone.
CONCLUSIONS: This study introduces a novel bsAb combination strategy that amplifies TAA-driven activation of $4\text{-}1BB^+$ T cells and may unlock similar opportunities to other TNFR superfamily targets such as OX40 and CD40.

#5554 Anti-human CTLA-4×TIGIT bispecific antibody: A novel immunotherapy specifically targeting tumor-infiltrating FOXP3+ regulatory T cells.

Soojin Ryu[1], Hee Geon Park[2], Sang Beom Bang[1], Ji Hye Nam[3], Ho Jin Lee[4], Ju Yeon Seo[1], Gun Yi Ahn[1], Myeung Ryun Seo[1], Sang Moo Lee[1], Yoon La Choi[5], Sung Youl Hong[6], Young Kee Shin[1]

Background: Regulatory T cells (Tregs) are key drivers of immune suppression within the tumor microenvironment (TME). In multiple cancer types, increased numbers of Tregs are associated with poor prognosis in terms of both disease progression and patient survival. This includes lung, breast, pancreatic, hepatocellular, renal, gastric, and cervical cancers. Specifically, the subset of Forkhead box P3 (FOXP3)+ effector Tregs, distinguished by increased expression of immune checkpoint molecules Cytotoxic T-Lymphocyte-Associated Protein 4 (CTLA-4) and T cell Immunoreceptor with Ig and ITIM domains (TIGIT), plays a dominant role in mediating potent immunosuppression within the TME. Current anti-Treg therapies, such as the anti-CTLA-4 monoclonal antibody ipilimumab, show significant clinical efficacy but often induce severe systemic toxicity due to broad depletion of peripheral Tregs. This underscores the unmet medical need for novel agents that selectively target tumor-infiltrating effector Tregs while minimizing systemic adverse effects.
Methods: Multiplex Immunohistochemistry (mIHC) assays were performed to identify Tregs within non-small cell lung cancer (NSCLC) tumor samples from 10 donors, using markers including CD4, CD8, FOXP3, TIGIT, CTLA-4, and Pan-Cytokeratin (Pan-CK). TIGIT and CTLA-4 co-expression on tumor-infiltrating Tregs were analyzed by single cell RNA sequencing (scRNA seq) data from NSCLC tumor and normal lung in 12 datasets of 10X genomics and healthy PBMCs from Human Immune Health Atlas. We engineered various formats of anti-human CTLA-4×TIGIT BsAbs. In vitro efficacy was evaluated in hPBMCs and in hCTLA-4 and hTIGIT-expressing stable cell lines, while in vivo effects were assessed in hCTLA-4/hTIGIT double knock-in mice and additional mouse models. Ex vivo analyses were also conducted to characterize immune cell population changes.
Results: scRNA-seq analysis revealed that co-expression of CTLA-4 and TIGIT is significantly enriched in tumor-associated Tregs compared to peripheral Tregs. Notably, the frequency of CTLA-4 and TIGIT double-positive cells exceeded that of cells expressing either marker alone. Among inhibitory receptor genes, CTLA-4 and TIGIT exhibited the highest expression levels across T cell subpopulations within NSCLC tumors. The anti-human CTLA-4×TIGIT BsAbs demonstrated enhanced binding affinity under dual expression conditions and exhibited robust antibody-dependent cellular cytotoxicity (ADCC). Furthermore, these BsAbs maintained binding activity in acidic pH conditions and displayed potent antigen blocking efficacy.
Conclusions: These findings indicate that the anti-human CTLA-4×TIGIT BsAbs specifically targets tumor-infiltrating Tregs and represents a promising strategy for maximizing specificity while minimizing systemic effects.

#5558 KRT6A mediates immune exclusion and anti-PD-1 resistance in head and neck squamous cell carcinoma.

Yi-Che Wu, Muh-Hwa Yang

Institute of Clinical Medicine, NYCU, Taipei, Taiwan

Head and neck squamous cell carcinoma (HNSCC) is one of the most common malignancies worldwide and is currently the third leading cause of cancer-related death among Taiwanese men. Immune checkpoint blockade (ICB) therapies, including the PD-1-blocking monoclonal antibodies pembrolizumab and nivolumab, have been approved as first-line and salvage treatments for PD-L1-positive recurrent or metastatic (R/M) HNSCC. However, only a minority of patients derive durable benefit from anti-PD-1 therapy. Both innate and acquired resistance to ICB remain major obstacles to effective treatment. In this study, we investigated potential mechanisms underlying ICB resistance using a syngeneic mouse HNSCC model, MOCL2-1. Serial in vivo and in vitro passaging under anti-PD-1 treatment pressure generated an anti-PD-1-resistant subline, L2-1-R. L2-1-R tumors were immunologically "cold," characterized by minimal $CD8^+$ T-cell infiltration and resistance to anti-PD-1 therapy. RNA sequencing of sequential sublines, along with the anti-PD-1-sensitive subline L2-1-S, revealed distinct transcriptional reprogramming in resistant tumors. *KRT6A*, a stress-induced keratin, was markedly upregulated in L2-1-R. Knockdown of *KRT6A* in resistant cells increased $CD8^+$ T-cell infiltration and restored responsiveness to anti-PD-1 therapy in vivo. Furthermore, analysis of a clinical cohort of HNSCC patients treated with pembrolizumab demonstrated that high *KRT6A* expression was associated with poor therapeutic response. Together, these findings identify KRT6A as a key mediator of immune exclusion and resistance to PD-1 blockade in HNSCC, suggesting that targeting KRT6A-related pathways may enhance immunotherapy efficacy.

#5559 Spatial neuroimmune crosstalk driving perineural invasion in head and neck squamous cell carcinoma.

Riya Chhabra[1], Alfred Kao[1], Suravi Bajaj[1], Reena Ding[1], Daniel John[1], Wei Tse Li[2], Jessica Y. Wang-Rodriguez[3], Weg M. Ongkeko[4]

[1]UC San Diego, La Jolla, CA,[2]School of Medicine, UC San Francisco, San Francisco, CA,[3]Professor, Dept. of Clinical Pathology, UCSD Moores Cancer Ctr., San Diego, CA,[4]Department of Otolaryngology- Head and Neck, UC San Diego, La Jolla, CA

Perineural invasion (PNI)—the infiltration of tumor cells within, around, or through nerve fibers—is a hallmark of aggressive tumor biology and an independent predictor of poor prognosis in head and neck squamous cell carcinoma (HNSCC). Despite its high prevalence, reported in up to 90% of cases, the molecular and spatial mechanisms enabling PNI remain poorly characterized. Here, we apply spatial transcriptomics to delineate the cellular, molecular, and microenvironmental features that drive PNI and its associated immune contexture. Spatial transcriptomic datasets (GSE300147, GSE252265, and GSE281978) were processed using standardized pipelines for quality control, normalization, and unsupervised clustering (UMAP). Cell populations were annotated based on canonical markers, identifying distinct epithelial, neural, Schwann, immune, and axon guidance-related clusters. Composite module scores were calculated to quantify PNI activity, neuronal and Schwann cell identity, axon guidance signaling, and immune infiltration. Correlation analyses and Gene Ontology (GO) enrichment were used to define key biological pathways associated with spatially resolved PNI phenotypes.

UMAP visualization revealed spatially distinct neural-enriched tumor clusters co-localizing with Schwann and axon guidance signatures, indicating a neural-like invasive niche. Correlation analysis demonstrated strong associations between PNI and neuronal ($r = 0.89$) and axon guidance ($r = 0.65$) programs, with moderate correlation to Schwann cell activity ($r = 0.49$). In contrast, PNI exhibited weak negative associations with T-cell ($r = -0.26$) and macrophage ($r = -0.12$) scores, consistent with an immune-excluded perineural microenvironment. GO enrichment further supported these trends. PNI-high regions showed activation of pathways involved in chemokine-mediated signaling, cellular adhesion, and fluid and lipid transport—processes that may facilitate neural infiltration and axon-tumor communication. PNI-low regions, by contrast, were enriched for immune-related functions including T-cell and B-cell receptor signaling, interleukin-2 production, and tumor necrosis factor regulation, consistent with active antitumor immunity. Collectively, these data reveal that PNI progression coincides with the emergence of a neural-dominant, immune-silent niche enriched for chemotactic and axon guidance signals. Together, these findings define the spatial neuroimmune landscape of PNI in HNSCC, implicating reciprocal nerve-tumor signaling and localized immune evasion as synergistic drivers of invasion. By integrating spatial resolution with transcriptomic profiling, this study provides mechanistic insight into how cancer cells remodel the perineural microenvironment to support invasion and immune escape.

#5560 KRAS^{G12D}inhibition stimulates antigen presentation and potentiates mRNA-based immunotherapy in pancreatic cancer.

Amanda Creech[1], Hailey Lee[2], Khalid Rashid[2], Tony Luu[2], Emma Lieberman[2], Michael Srienc[3], Alykhan Premji[3], Ahmad Kassem[1], Luyi Li[3], James Wohlschlegel[4], Timothy Donahue[1], Norbert Pardi[5], Caius Radu[1]

[1]Medicine, UCLA David Geffen School of Medicine, Los Angeles, CA,[2]Molecular and Medical Pharmacology, UCLA David Geffen School of Medicine, Los Angeles, CA,[3]Surgery, UCLA David Geffen School of Medicine, Los Angeles, CA,[4]Biological Chemistry, UCLA David Geffen School of Medicine, Los Angeles, CA,[5]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Inhibition of constitutively-active KRAS^{G12D}, a powerful oncogenic driver in pancreatic ductal adenocarcinoma (PDAC), has been shown to sensitize tumors to T-cell-mediated immunotherapy in preclinical models. However, the influence of KRAS^{G12D} inhibition on tumor cell antigen presentation remains unclear. Therefore, we employed a multi-omic profiling workflow to investigate alterations in the proteome and peptide MHC-I ligandome (immunopeptidome) following the treatment of HPAC human cancer cells with a RAS(ON) G12D-selective inhibitor RMC-9945 (representative of investigational agent zoldonrasib), and/or IFNɣ *in vitro*. KRAS^{G12D} inhibition induced a unique IFN response signature and potentiated the expression of proteins involved in antigen processing and presentation. Immunopeptidomic analysis revealed a two-fold increase in both ligand abundance and diversity, reflecting the differential expression of proteins induced by KRAS^{G12D} inhibition.

We hypothesized that KRAS^{G12D} signaling inhibition in preclinical models could augment immune responses initiated by immunization targeting tumor antigens *in vivo* via the following mechanism: the release of antigens from KRAS^{G12D}-induced cell death, coupled with increased MHC-I expression on remaining tumor cells, would enhance interactions with T cells activated by immunization. To test this, we orthotopically inoculated C57Bl/6 mice with a murine PDAC-KRAS^{G12D} cell line engineered to express the model self/tumor-associated antigen gp100. Mice were then immunized with either empty ionizable lipid nanoparticles (e-iLNPs) or iLNPs packaged with mRNA encoding full-length gp100 (gp100-iLNP). Prior to and during subsequent vaccine boost doses, mice were treated continuously with either KRAS^{G12D} inhibitor RMC-9945 or vehicle. Mice treated with both gp100 mRNA-iLNP immunization and KRAS^{G12D} inhibition exhibited significant tumor regression that was sustained over time compared to either treatment modality alone. This anti-tumor response was associated with a superior antigen-specific T cell response to subsequent immunizations, the retention of functional tumor antigen-specific cytotoxic T lymphocytes in both the tumor microenvironment and local secondary lymphoid organs, and sustained MHC-I and MHC-II surface expression on tumor cells.

These preclinical findings underscore the dynamic nature by which PDAC antigen presentation can be modulated by KRAS signaling inhibition and IFNɣ. Combining allele-specific KRAS inhibition with tumor antigen immunization resulted in sustained tumor regression *in vivo* and was associated with the retention and function of tumor antigen-specific T cells. This rationalizes the combination of both approaches for enhanced anti-tumor activity, offering a strategy that is worth exploring clinically for improving outcomes in pancreatic cancer treatment.

#5561 LILRB1 antibody targeting the LILRB1/HLA-G axis: Preclinical efficacy, pharmacokinetics, and safety supporting first-in-human trials.

Han Byoul Kim, Seok-Joo Kim, Younghoon Kim, Junhaeng Cho, Minsoon Kim, JungA Kim, Suji Hong, Heehang Kim, Shin-Young Kang, Kyungna Ko, Jun-Gyu Park, Hyungjin Cho, Jeeyeon Roh, Young Dok Son, Wooseok Ko

LG Chem, Seoul, Korea, Republic of

Background:LILRB1 is an inhibitory receptor expressed on T cells, B cells, NK cells, and monocytes. It binds to HLA class I molecules, with the highest affinity for HLA-G. This interaction delivers inhibitory signals that allow tumor cells to evade immune surveillance, impairing NK cell, T cell, and macrophage function. Disrupting the LILRB1/HLA-G axis is a promising strategy for restoring anti-tumor immunity. Additionally, LILRB1 may regulate T cell function independently of PD-1, suggesting potential to overcome resistance to PD-1 inhibitors.
Methods: Binding affinity and specificity of LG-LILRB1 antibody were assessed via surface plasmon resonance and flow cytometry. Competitive binding assays confirmed blockade of LILRB1/HLA-G interaction. Restoration of immune cell function was evaluated using flow cytometry and western blotting. Anti-tumor efficacy was tested in human LILRB1 transgenic mice. Pharmacokinetics and toxicokinetics were studied in cynomolgus monkeys, and safety was assessed through GLP-compliant toxicology and immunotoxicity studies.
Results:LG-LILRB1 antibody showed high-affinity, selective binding to LILRB1 and dose-dependent blockade of HLA-G. Functional assays revealed enhanced T cell proliferation, NK cell cytotoxicity, and macrophage phagocytosis. In vivo, LG-LILRB1 antibody significantly inhibited tumor growth (up to 88.8%) in transgenic mice bearing HLA-G-expressing tumors. Pharmacodynamic analysis showed increased infiltration and activation of $CD8^+$ T cells and NK cells. Combination with PD-L1 blockade yielded synergistic anti-tumor effects. In monkeys, LG-LILRB1 antibody exhibited dose-proportional exposure and a long half-life (>12 days). No treatment-related adverse findings were observed in 4-week GLP toxicity studies.
Conclusions:LG-LILRB1 antibody, a first-in-class LILRB1 blocker, restored anti-tumor immunity by disrupting the LILRB1/HLA-G axis. It enhanced immune cell function and showed strong efficacy in preclinical models. Favorable pharmacokinetics and safety support its clinical development. Combination with PD-L1 blockade further improved outcomes. These findings support LG-LILRB1 antibody as a promising candidate for cancer immunotherapy, with a Phase 1a trial currently ongoing (NCT06332755).

#5562 Antagonism of β-Catenin/BCL9 interaction suppresses polymorphonuclear myeloid-derived suppressor cell generation and maintenance.

Claudio Scuoppo, Julia Diehl, Rick Ramirez, Barry J. Kappel, Abi Vainstein-Haras, **Jim A. Rotolo**

Sapience Therapeutics, Tarrytown, NY

Myeloid-derived suppressor cells (MDSCs) are a heterogenous group of myeloid-lineage cells thought to play a role in the immunosuppressive cancer environment. Evidence indicates that in colorectal cancer (CRC) patients, MDSCs accumulate in peripheral blood (PB), secondary lymphoid organs and tumors. Further, nonclinical models have proved their contribution in suppressing anti-tumor T-cell responses. Thus, MDSCs have become an attractive target of therapeutic strategies aimed at reversing tumor-related immunosuppression and, as these cells can be readily assessed in PB fractions, as a pharmacodynamic biomarker to track therapeutic response and disease progression. Despite the great interest in MDSC biology, the genetic pathways responsible for their expansion and maintenance are poorly understood, in part due to the difficulty in defining MDSCs immunophenotype. ST316 is a clinical-stage peptide antagonist of the β-catenin/BCL9 protein complex that is currently being evaluated in a Phase 1/2 study (NCT05848739) in patients with advanced CRC. Consistent with literature, polymorphonuclear (PMN)-MDSCs were elevated in the PB of most evaluable patients in the Phase 1 part of the study (7 of 8 patients); strikingly, ST316 exposure resulted in statistically significant suppression of MDSCs in the PB of all patients who displayed baseline elevations (7 of 7 evaluated). Similar increases in PMN-MDSCs were observed at baseline in the immunocompetent APC^{min} and CT-26 CRC murine models, while exposure to ST316 resulted in dose-dependent decreases in their frequency. Mechanistically, ST316 prevented proliferation of immature MDSC precursor populations in the bone marrow while accelerating mature MDSC turnover in PB and splenic fractions. Transcriptomics analysis indicated that ST316 suppressed Wnt/β-catenin signatures in PMN-MDSCs. In addition, ST316 reduced expression of several myeloid markers associated with neutrophil differentiation, including CD101, CD300a, and Siglec-F, suggesting that these markers reflect β-catenin/BCL9 controlled dynamics of MDSCs generation. Overall, our results identify a new role for β-catenin/BCL9 signaling in MDSC generation and maintenance, and identify suppression of MDSCs as a consequence of ST316 exposure in nonclinical and clinical tumor settings.

#5563 Long noncoding RNAs networks as novel master regulators of cytotoxic immune cell exhaustion in triple-negative breast cancer.

Raquel Sanchez[1], Eduardo E. Chaib Lozano[1], Barbara Yang[1], Shrikanth S. Gadad[2], Enrique I. Ramos[1]

[1]The University of Texas at El Paso, El Paso, TX,[2]University of Texas Rio Grande Valley, El Paso, YT

Background: Breast cancer is the second leading cause of cancer-related deaths among women in the United States, with triple-negative breast cancer (TNBC) representing the most aggressive subtype. Although immune checkpoint inhibitors (ICI) and CAR-T therapy emerge as promising therapy options for TNBC patients, their overall effectiveness is limited. This therapeutic failure is strongly influenced by immunosuppressive tumor microenvironments, where chronic antigen exposure leads to exhaustion in cytotoxic lymphocytes. Exhausted $CD8^+$ T cells, NK cells, and NKT cells display diminished effector capacity and reduced persistence, ultimately impairing tumor clearance. Understanding the regulatory mechanisms that sustain exhaustion is critical for improving immunotherapies. Long non-coding RNAs (lncRNAs) have gained recognition as regulators of transcriptional and epigenetic programs in cancer biology; however, their contribution to immune cell exhaustion in TNBC remains unexplored.
Methods: We analyzed single-cell RNA-seq datasets (NCBI/GEO) from TNBC tumors, focusing on immune cell populations. We performed scRNAseq analysis and clustering to assess expression of specific exhaustion markers (TOX, TIGIT, PDCD1, LAG3, as well as differential gene expression to identify dysregulated lncRNAs in those exhausted $CD8^+$, NK, and NKT cell subsets.
Results/future directions: Preliminary data identified variable exhaustion-associated lncRNAs shared among CD8 T cells, NK, and NKT cells in TNBC samples. Some of these candidate lncRNAs were selectively enriched in certain immune populations. Signaling pathway analyses are in progress to evaluate the functions of these lncRNAs and their involvement in chromatin regulation, RNA-protein scaffolding, transcriptional activation/repression, and metabolic stress responses, all hallmarks of immune exhaustion. We will then functionally validate top candidate lncRNAs using RNA interference and overexpression models in primary human cytotoxic lymphocytes to assess their impact on exhaustion phenotypes and effector function.
Conclusion: In our study, we identified a previously unrecognized group of lncRNAs in TNBCs, which could potentially drive immune exhaustion across cytotoxic immune subtypes by regulating TNBC tumors physiology. These lncRNAs could be crucial for exhaustion progression, and reversing their effects through ASOs or gene silencing could reveal their influence towards recovering anti-tumor response by maintaining T cell persistence.

#5564 Crosstalk between ceramide and prostaglandin signaling mediates resistance to immune checkpoint blockade.

Wyatt O. Wofford, Elif Percin, Han G. Lee, Odai Darawshi, Bryan Granger, Lucy Mulligan, Natalia V. Oleinik, Mohamed F. Kassir, Chase Walton, Paramita Chakraborty, Stefano Berto, Raymond N. DuBois, Shikhar Mehrotra, Besim Ogretmen

The Medical University of South Carolina, Charleston, SC

Immunotherapy has revolutionized cancer treatment, yet only a fraction of patients develop durable responses to immune checkpoint blockade (ICB). Identifying tumor-intrinsic mechanisms driving αPD-1/αPD-L1 resistance remains critical to improving patient outcomes. We recently discovered that reduced ceramide synthase 4 (CerS4) activity and the subsequent loss of C18/20 ceramide impairs response to ICB through intracellular PD-L1/Caprin-1 signaling. To investigate this further, we generated an orthotopic, transplantable TNBC (E0771) model of ICB resistance through serial *in vivo* αPD-L1 exposure, yielding the 2RA cell line. 2RA tumors are refractory to both αPD-L1 and αPD-1 therapy, and transcriptomic signatures derived from this model strongly predict clinical ICB outcomes, supporting its relevance to human disease. Functionally, 2RA tumors display reduced CerS4 expression, diminished C18/20 ceramide, and increased intracellular PD-L1/Caprin-1 interaction. Bulk RNA-seq revealed marked enrichment in prostaglandin E_2 (PGE_2) signaling, a potent immunosuppressive pathway, in 2RA tumors. Mechanistically, we identified that CerS4 inversely regulates prostaglandin-endoperoxide synthase 2 (Ptgs2, COX-2) expression and PGE_2 production through the PD-L1/Caprin-1 complex, whereby ceramide directly interacts with PD-L1 to restrict Caprin-1 binding. Analysis of TCGA and ICB-treated patient datasets substantiated the CerS4/PD-L1/COX-2 axis across multiple solid tumor subtypes. Immune profiling via flow cytometry and snRNA-seq identified dysfunctional progenitor and effector $CD8^+$ T cells as central to impaired ICB response in 2RA tumors. Genetic or pharmacological disruption of the CerS4/PD-L1/PGE_2 axis, achieved through CerS4 restoration or TGF-β inhibition (LY2157299), restored ICB sensitivity, prolonged survival, and induced tumor rejection *in vivo*. Targeting PGE_2 production with celecoxib, but not aspirin, further enhanced responses when combined with LY2157299 and αPD-1 therapy. Targeted lipidomics and multiplex immunofluorescence (mIF) confirmed that this triple combination potently blocks the ceramide/PGE_2 axis and stimulated $CD8^+$ T cell responses to control tumor growth. Finally, mIF analysis of nivolumab-treated pre-surgical human HNSCC specimens (responders vs. non-responders) corroborated these findings by demonstrating reduced tumor ceramide abundance, elevated $PanCK^+COX\text{-}2^+ceramide^{lo}$ populations, and decreased intratumoral $CD8^+$ T cell density amongst non-responders. Collectively, these studies (1) establish a relevant model of ICB resistance, (2) define a mechanistic framework linking ceramide metabolism to prostaglandin-mediated immune suppression, and (3) highlight therapeutic strategies to target ICB resistance and improve patient outcomes.

#5565 C118S-mediated redox modulation of KRASG12D mutation reprograms immunometabolism to suppress obesity-driven pancreatic tumorigenesis.

Zahid Rafiq[1], Weiqin Lu[2]

[1]Biological Sciences, University of Texas at El Paso, El Paso, TX,[2]Department of Biological Sciences, University of Texas at El Paso, El Paso, TX

Background: Pancreatic ductal adenocarcinoma (PDAC) is frequently driven by oncogenic $KRAS^{G12D/+}$ and exacerbated by obesity-induced metabolic inflammation, driving immune suppression and metabolic reprogramming. The concurrent rise in global obesity and PDAC incidence demands mechanistic strategies specifically tailored to the unique biology of obesity-associated KRAS-mutant tumors. Redox-sensitive regulation of KRAS at cysteine118 (C118) plays a critical role in signaling activity, and mutation to serine (C118S) has been shown to attenuate KRAS function in other tumor models. However, the impact of C118S on the immunometabolism landscape of $KRAS^{G12D/+}$ driven PDAC particularly in the context of obesity remains unexplored. This study aims to characterize how the C118S mutation alters immune and metabolic dynamics in obese versus lean PDAC settings.

Methods &

Results: Using in-house genetically engineered mouse models ($KRAS^{G12D/+}$ and $KRAS^{G12D+C118S/+}$ on a KC (KrasCre) background) fed with high-fat or standard normal diets to examine tumor progression. We found changes related to the C118S modification in the KRAS-G12D allele slowed the progression of PDAC. H&E staining showed reduced high-grade PanIN lesion. Alcian Blue and Sirius Red staining revealed a marked reduction in mucin production and fibrosis, indicating an alleviation of the desmoplastic response. Immunohistochemistry for Ki67 showed decreased cell proliferation, CK19 staining confirmed reduced ductal marker expression, and MIST1 staining indicated preservation of acinar cell identity. We also examined the related immune infiltration ($CD8^+$ T cells, PD-1/PD-L1, myeloid cells), metabolic markers (GLUT1, CPT1A). We found that $KRAS^{G12D+C118S/+}$ tumors had improved antitumor Immune and Metabolic profile components of TIME, particularly under obese conditions. Elucidating the redox-dependent mechanisms linking $KRAS^{G12D+C118S/+}$ to immune-metabolic reprogramming. We quantified ROS and GTP-bound KRAS activity, and downstream signaling (PI3K/AKT/mTOR, ERK). We found that C118S reduced ROS-dependent KRAS activity, suppresses oncogenic signaling, and restore metabolic immune fitness.

Conclusion: This study pioneers a paradigm shift in pancreatic cancer research by combining redox-based KRAS mutation, metabolic stress (obesity), and immunometabolism signaling. It aims to show that targeting KRAS redox regulation can reshape the immune-metabolic microenvironment to impede tumor progression. Findings could lead to novel redox-immunometabolism therapeutic strategies for obesity-associated KRAS-driven cancers.

#5566 Molecular evolution reveals low-prevalence driver mutations, mutational synergies, and associated immune dynamics in ovarian cancer.

Julia McAdams, Nic Fisk

Cell and Molecular Biology, University of Rhode Island, Kingston, RI

Ovarian cancer remains significantly underrepresented in genomic studies despite its high mortality rate, highlighting the need to make the most of extant data. Traditional approaches focus on mutation prevalence, potentially overlooking rare but highly oncogenic driver mutations or mutational synergies that provide substantial evolutionary advantages to tumor cells, including those that may shape the cancer-immune landscape. In ovarian cancer, tumor mutational burden (TMB), immune checkpoint molecule expression (LAG-3, ICOS, CTLA-4), and regulatory T cell (Treg) infiltration have been associated with clinical outcomes, yet their relationship to underlying mutational selection pressures remains poorly understood. We applied cancereffectsizeR to quantify the evolutionary benefit of single nucleotide variants (SNVs) in ovarian cancer, analyzing whole-exome, whole-genome, and targeted panel sequencing samples pooled across studies. This approach distinguishes mutational selection from prevalence, enabling us to quantify not only the relative contribution of high-frequency mutations but also to uncover low-frequency yet highly-selected driver mutations. We then investigated epistatic selection patterns to infer mutational ordering and synergistic interactions between mutated genes. Finally, we examined correlations between quantified selection coefficients and immune phenotypes, developing a predictive model to associate patterns of evolutionary selection within individual tumors with clinically relevant immune characteristics. Our analysis revealed numerous low-prevalence driver mutations with significant selective advantages in ovarian cancer, including mutations in BCL10 and PSIP1. Epistatic analysis uncovered mutational synergies implying temporal ordering of mutational acquisition across several gene pairs, with multiple interactions unreported in STRINGdb, such as a positive synergy between mutant EBP and IGSF21. Our predictive model relating cancer effect size to immune phenotypes—including TMB, LAG-3/ICOS/CTLA-4 expression, and Treg infiltration—revealed that somatic mutations under strong positive selection are modestly predictive of the immune landscape in ovarian cancer, suggesting that evolutionary dynamics and immunogenicity are interconnected. These findings provide new insights into ovarian cancer evolution and identify potential biomarkers for immunotherapy response.

#5567 Combination therapies promote immune-mediated bystander killing of KRAS-G12C inhibitor resistant cells.

Mona Tomaschko, KangBo Ng, Christopher Moore, Claire E. Pillsbury, Sareena Rana, James Campbell, Saptaparna Mukherjee, Ania Mikolajczak, Panayiotis Anastasiou, Andrea de Castro, Alicia Alonso de la Vega, Sophie de Carne Trecesson, Nathan W. Goehring, **Miriam Molina-Arcas**, Julian Downward

The Francis Crick Institute, London, United Kingdom

Although initial clinical responses to KRAS-G12C inhibitors (G12Ci) have been encouraging, their efficacy is limited by the rapid development of resistance. To extend therapeutic benefit, strategies capable of limiting or preventing resistance are required. However, given the heterogeneity of resistance mechanisms identified, designing targeted combination therapies remains challenging. Here, we hypothesised that a more broadly applicable approach would be to exploit the ability of KRAS-G12C inhibition to partially relieve the KRAS-induced immunosuppressive tumour microenvironment, thereby promoting immune-mediated attack on the inhibitor-resistant cancer cells.

We developed a preclinical model to mimic development of resistance to G12Ci by co-engrafting reporter-traced isogenic cells harbouring KRAS-G12C (G12Ci-responsive) with a minor subpopulation of KRAS-G12D (G12Ci-resistant) cells. KRAS G12C inhibition as monotherapy using either the RAS(ON) G12C-selective inhibitor RMC-4998 or the KRAS G12C(OFF) inhibitor adagrasib, led to a rapid outgrowth of the G12Ci-resistant subpopulation. However, when combined with therapies that enhance anti-tumour immune responses, such as SHP2 inhibition or PD-1 blockade, the G12Ci-resistant cells were eliminated, even though these treatments do not affect their growth in the absence of G12Ci-sensitive cells. Notably, this bystander killing of G12Ci-resistant cells and the resulting complete responses were dependent on the adaptive immune system.

These combination therapies led to a profound remodelling of the tumour immune microenvironment, with an increase of inflammatory macrophages and an influx of NK and T cells, including $CD8^+$ T cells recognising the Emv2 endogenous retroviral protein, which represents the major tumour-associated antigen shared between the G12Ci-resistant and G12Ci-sensitive cancer cells. Moreover, transcriptional profiling suggested an enhanced interferon response in the G12Ci-resistant cells caused by the effect of G12Ci on the G12Ci-sensitive cells. Loss of IFNγ receptor rendered the resistant cells less susceptible to immune-mediated bystander killing, indicating that this process was at least partly dependent on their tumour cell–intrinsic ability to respond to IFNγ.

Overall, our preclinical results demonstrate that appropriate combinations can elicit anti-tumour immune responses capable of bystander elimination of G12Ci-resistant subclones, providing a paradigm for the development of therapeutic combinations with greater potential to prevent or counteract the emergence of inhibitor resistance.

#5568 PRTN3 suppresses cytotoxic immune-cell activation and antitumoral immunity through proteolytic cleavage of CXCL9 in KRAS mutant lung adenocarcinoma.

Rong Xiang[1], Yi Liu[2], Yunping Luo[3]

[1]Immunology and Oncology, Nankai University, Tianjin, China,[2]Nankai University, Tianjin, China,[3]Postdoctoral Fellow, Chinese Academy of Medical Sciences, Beijing, China

KRAS-mutant lung adenocarcinoma (LUAD) is largely refractory to immune-checkpoint blockade (ICB). Here, we define a novel immune evasion mechanism in KRAS-mutant LUAD mediated by tumor-secreted protease 3 (PRTN3), which proteolytically inactivates the T-cell chemoattractant CXCL9 to create an immune-cold microenvironment. Mechanistically, KRAS signaling transcriptionally upregulates PRTN3 via c-Myc. Secreted PRTN3 then cleaves and inactivates CXCL9 in the tumor microenvironment, thereby disrupting CXCL9/CXCR3 signaling and suppressing the recruitment and activation of cytotoxic NK and CD8+ T cells. In LUAD patients, high PRTN3 expression is associated with low CXCL9 activity. Crucially, genetic ablation of PRTN3 synergizes with anti-PD-1 therapy to restore antitumor immunity in vivo. Moreover, the application of a hydrolysis-resistant CXCL9 variant is sufficient to potently enhance T-cell-mediated killing in LUAD patient-derived organoids, establishing the therapeutic potential of targeting this axis. Our findings establish tumor-derived PRTN3 as a key mediator of immune suppression and a promising therapeutic target in KRAS-driven LUAD.

#5570 Multi-omics dissection of tumor-related leukocytosis in urothelial carcinoma identifies IL13RA2 as a key driver.

Harvey Yu-Li Su[1], Shih-Yu Huang[1], Chung-Wen Kuo[2], Chang-Ting Lin[3], Yi-Hua Chen[3], Ming-Chun Kuo[1], Hsuan-Ying Huang[4], Chih-Yen Chien[1]

[1]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung City, Taiwan,[2]National Kaohsiung University of Science and Technology (NKUST), Kaohsiung City, Taiwan,[3]Kaoshiung Chang Gung Memorial Hospital, Kaoshiung City, Taiwan,[4]Pathology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung City, Taiwan

Background:
Tumor-related leukocytosis (TRL), driven largely by neutrophil overproduction, is associated with aggressive disease, treatment resistance, and poor survival across solid tumors. In metastatic urothelial carcinoma (mUC), patients with TRL experience particularly poor outcomes under immune checkpoint inhibitor (ICI) therapy, suggesting an immune-suppressive tumor microenvironment. However, the molecular basis linking TRL to ICI resistance remains unclear.
Methods:
We retrospectively evaluated mUC patients receiving ICIs to assess the prognostic role of TRL. RNA from 35 tumors underwent NanoString profiling to identify leukocytosis-associated genes. IL13RA2 and related candidates were validated across UC cell lines by qPCR, western blotting, and functional assays including proliferation, migration, cytokine analysis, and neutrophil chemotaxis. Transcriptional programs regulated by IL13RA2 were defined using Clariom S microarray.
Results:
Patients with baseline leukocytosis (WBC >10,000/μL) showed significantly worse overall survival, confirming TRL as a negative prognostic factor during ICI therapy. High-WBC tumors displayed a distinct inflammatory signature, with IL13RA2 among the most upregulated genes. IL13RA2 expression strongly associated with neutrophil enrichment in TCGA BLCA (Pearson $r = 0.41$; TIMER $\rho = 0.199$) and was validated in the ICI-treated GSE176307 cohort, where IL13RA2-high tumors exhibited increased neutrophil and myeloid fractions. Functionally, IL13RA2 knockdown reduced proliferation, migration, and wound-healing capacity in UMUC3 and T24 cells. Microarray analysis identified reproducible IL13RA2-regulated gene sets enriched for cytokine, inflammatory, motility, and chemotaxis pathways. Conditioned media from IL13RA2-expressing cells robustly induced migration of purified neutrophils, whereas IL13RA2 depletion markedly impaired neutrophil chemotaxis. IL13RA2 silencing suppressed JAK1/2-STAT3 activity and reduced multiple pro-inflammatory cytokines and chemokines, including CXCL5, CXCL6, CXCL8, CCL3, and CCL4.
Conclusions:
TRL is a potent negative prognostic factor in ICI-treated mUC. IL13RA2 emerges as a central driver linking leukocytosis to immune resistance by promoting inflammatory signaling, cytokine production, and myeloid recruitment. These findings identify IL13RA2 as a key mediator of TRL and a potential therapeutic target to overcome myeloid-driven ICI resistance in urothelial carcinoma.

#5571 Dynamic transcriptional remodeling and functional adaptation drive malignant progression in lymphoma.

Bandish Kapadia[1], Anirban Roychodhury[1], Forum Kayastha[1], Won Sok Lee[2], Nahid Nanaji[3], Jolene windle[1], Ronald B. Gartenhaus[1]

[1]Virginia Commonwealth University, Richmond, VA,[2]Richmond Department of Veterans Affairs, Richmond, VA,[3]Veterans Affairs Maryland Health Care System-Baltimore Division, Baltimore, MD

Background: Lymphoma progression is shaped by dynamic interactions between malignant B cells and the tumor microenvironment, generating marked transcriptional and functional heterogeneity. To define mechanisms driving this adaptive evolution, we developed a transplantable oncogene-driven lymphoma model enabling controlled tracking of clonal evolution, transcriptional remodeling, and functional adaptation across serial tumor passages.
Methods: Primary tumors from transgenic lymphoma-bearing mice were serially propagated into syngeneic hosts, generating early (P0), intermediate (P2), and advanced (P4) stages. Single-cell transcriptomics, CNV-inference (inferCNV), and pathway-level modeling (Seurat/Scanpy, GSVA, Enrichr, DrugBank-based prediction) were used to define malignant and microenvironmental evolution and emerging vulnerabilities.
Results: Serial propagation produced progressive transcriptional diversification consistent with malignant evolution. P0 tumors exhibited proliferative activation and metabolic priming, whereas P4 tumors developed immunosuppressive, angiogenic, and stress-adaptive programs mirroring hallmarks of advanced human B-cell lymphoma. A key finding was a unified stress-survival module in P4, marked by hypoxia-responsive, UPR-related, and metabolically rewired pathways, alongside reduced proliferative dependence. Sex-specific pathway biases including cytokine/chemokine signaling and metabolic checkpoint usage also emerged. Drug-response inference identified passage-specific vulnerabilities, with P4 showing heightened sensitivity to inhibitors of oxidative-stress buffering, lipid metabolism, and UPR nodes.
Future Directions: Multiparametric flow cytometry, immunohistochemistry, and spatial profiling are underway to validate lineage reprogramming, CNV-based malignant classifications, and pathway activation states.
Conclusions: Malignant progression in this model is driven by iterative transcriptional reprogramming and functional adaptation shaped by microenvironmental selection. P4 most accurately recapitulates transcriptomic and functional features of advanced disease, making it an optimal preclinical platform for studying therapeutic resistance and identifying emergent vulnerabilities in aggressive B-cell lymphoma.

#5572 Conservation of driver mutations and oncogenic pathway alterations revealed through a comparative genomic analysis of human angiosarcoma and canine hemangiosarcoma.

Lucas Rodrigues, Garrett Harvey, Gerald Post, Benjamin Lewis, Abigail Hull, Aubrey O'Grady, Lindsay Lambert, Christina Lopes, Thaddeus Allen

FidoCure - One Health Company, Palo Alto, CA

Angiosarcoma (AS) is a rare and aggressive endothelial malignancy, representing <2% of soft tissue sarcomas in humans. Progress in developing effective therapies has been hindered by its low incidence, genomic heterogeneity, and the scarcity of representative preclinical models.Integrative genomic analyses of two cBioPortal cohorts (n=131) identified recurrent alterations in TP53 (26%), KDR (17.6%), POT1 (17.6%), PIK3CA (14.5%), FLT4 (11.5%), PTPRB (11.5%), and NRAS (5.3%), highlighting pervasive disruptions of DNA damage response, PI3K/AKT/mTOR, and angiogenic receptor signaling. However, the rarity of AS limits functional validation and biomarker-driven therapy development.Canine hemangiosarcoma (HSA) is a biologically analogous vascular tumor that occurs spontaneously with far higher incidence, offering a unique opportunity to model AS in an immunocompetent host. Large-scale profiling of HSA from the FidoCure Precision Medicine Platform (n=1,177) revealed overlapping mutations in TP53 (54.9%), PIK3CA (29.9%), NRAS (15.3%), FLT4 (3.6%), PTEN (3.4%), and KDR (2.6%), mirroring the human landscape.Cross-species analyses showed striking molecular parallels. PIK3CA mutations in both species clustered in the helical and kinase domains, consistent with pathway activation. While mutation at the canonical hotspot (H1047R/L/Y) predominated in HSA, AS was found to harbor heterogeneous variants (P124L, T957P, M1043V/I). TP53 variants localized to conserved DNA-binding regions (human R175, R248, R273; canine R164H, C228R/Y, R263H, R272H), indicating convergent loss of tumor-suppressor function. KDR, NRAS, and PTEN alterations similarly disrupted VEGFR2, RAS/MAPK, and PI3K signaling pathways across species.Collectively, these findings reveal deep evolutionary conservation of molecular drivers in vascular sarcomagenesis. Canine HSA faithfully recapitulates the genetic complexity and therapeutic vulnerabilities of human AS, establishing a robust comparative platform for biomarker discovery, targeted therapy validation, and translational oncology research within an immunocompetent context.

#5573 Novel ASPORIN/CRABP2 axis drives cell-state plasticity from adenocarcinoma to neuroendocrine-like prostate cancer.

Parthasarathy Seshacharyulu, Shobhit Lall, Sushanta Halder, Sakthivel Muniyan, Zahraa Wajih Alsafwani, Ramakanth Chirravuri-Venkata, Moorthy P. Ponnusamy, Surinder K. Batra

Biochemistry and Molecular Biology, University of Nebraska Medical Center, Omaha, NE

Background: Prostate cancer (PCa) remains a highly lethal disease due to the rapid emergence of neuroendocrine (NE)-like variants from adenocarcinoma. It is predicted that *de novo* NEPC will emerge from 17% of localized PCa, while treatment-related NEPC will account for 20% of advanced PCa. Clinically, NEPC patients frequently harbor visceral metastasis (62%, P<0.001) compared with CRPC patients (24%), with poor overall survival of 12-17 months. Thus, exploring the unknown mechanism underlying cell-state transition from adeno to NEPC will help identify new targets to overcome lineage plasticity and improve PCa patient survival.

Methods: We developed a novel indolent and metastatic PCa mouse model by overexpressing cMyc and knocking out Pten with/without Mutant p53 (R172H). Global transcriptional profiling was performed in indolent and aggressive mice and ASPORIN (ASPN) knockdown (KD) to identify differential gene expression, biological, and pathway analyses. ASPN ectopic overexpression (OE) and KD clones confirmed ASPN biological function and on-target proteins/genes using RT-PCR and western blot analyses. ASPN *in vitro* function was analyzed in the Incucyte® live imaging system, colony growth assay, and proliferation assays.

Results: The novel **P**ten$^{fl/fl}$; Hi-Myc; **T**rp53$^{R172H/+}$; Rosa-26; PB-**C**re4^{+} (PCTP^{Luc}) mouse exhibits phenotypic resemblance to PCa visceral metastasis to the lung, liver, inguinal lymph node, and intestine with poor survival as compared with age-matched indolent **P**ten$^{fl/fl}$; Hi-Myc; Rosa-26$^{\mathbf{Luc}}$; **P**B-Cre4^{+} (PCP^{Luc}). Unbiased RNA-Seq analysis of PCa adenocarcinoma tissues from PCTP mice revealed a significant association between unique extracellular matrix (ECM) protein clusters and liver and lung metastasis. Asporin (ASPN) emerged as the top differentially expressed ECM protein among the top 25 genes. Consistently, ASPN knockdown and overexpression were directly associated with PCa cellular phenotypes of proliferation and colony growth. Mechanistically, ASPN modulation impacts pERK, CyclinD3, EMT proteins, and a neuroendocrine-like phenotype, as well as cell differentiation-related transcriptomes such as cellular retinoic acid-binding protein 2 (CRABP2), along with Chromogranin A (CHGA), NeuroD1, and INSM1. Using a publicly available TCGA database, we observed a significant overexpression of ASPN and CRABP2 in PCa tissues (N=497) relative to normal (N=52) (P<0.001). Finally, ASPN ectopic overexpression in immortalized RWPE-1 cells confirmed an aggressive *in vitro* phenotypes.

Conclusion: For the first time, we explored the influence of ASPN/CRABP2 and other signaling involved in luminal epithelial to neuroendocrine differentiation and validated CRABP2 as a novel target to prevent NEPC transdifferentiation. Our findings support ASPN's new role, mechanism(s) and as a target for PCa and other visceral metastasis disease.

#5574 Role of KMT2C and KMT2D in modulating tumor immune microenvironment of endometrial cancer.

Sanjeev Ganesh[1], Swornalata Pukhrambam[1], Juveria Ali[1], Savannah Hughes[1], Heather Marie Gibson[2], Michael Wilson[1]

[1]Wayne State University School of Medicine, Detroit, MI,[2]Oncology, Barbara Ann Karmanos Cancer Institute, Detroit, MI

BACKGROUND: Recent molecular classifications of Endometrial Cancer (EC) have enhanced prognostic accuracy and helped guide targeted therapies. Among frequently mutated factors are epigenetic regulators like lysine methyltransferases KMT2C and KMT2D which monomethylate H3K4 at enhancer sites and their loss of function (LOF) mutation is associated with genomic instability, altered chromatin accessibility and increased immune evasion. Although increased CD8+ T cells infiltration and high PDL1 expression in postmenopausal EC patients is linked to poor prognosis, the impact of epigenetic mutation on immune signaling remains poorly understood. Pan-cancer analysis by Cao et al suggests that low KMT2C expression may reduce immunosuppressive and better immunotherapy responses, with similar patterns seen in other cancers suggesting a potential role in modulating immune response.
METHODS: CRISPR technology was used to generated KMT2C and KMT2D knockouts in 12Z and HEC1a cells and whole cell lysates of these cells were used for immunoblotting analysis. Next, Immunohistochemistry on KMT2D KO mouse tissues were performed to look at specific immune markers. Finally, flow cytometry analysis was done to understand the makeup of the tumor microenvironment and explore the differences in the role of various immune cells.
RESULTS: TCGA database showed upregulation of immune factors like IFN-G and CTLA-4 when KMT2C is altered. Immunoblotting analysis of the CRISPR knockout cells showed upregulation of PDL1 expression in KMT2C knockout cells. Further, Immunohistochemistry of KMT2D KO mouse tissues showed decreased CD8+ expression. Following this, flow cytometry analysis of KMT2D KO mouse tissues showed increased myeloid derived suppressor cells and decreased CD8+ and CD4+ cells which indicates an immunosuppressive environment.
CONLCUSION: Overall, these findings highlight the role of KMT2C and KMT2D mutations on the tumor immune microenvironment and support their potential as predictive biomarker for ICI responsiveness in endometrial cancer. The mixed clinical efficacy of immunotherapies, it is critical to understand the intricacies of the tumor microenvironment. Future studies will focus on replicating the results in KMT2C KO mice and further understand the potential of KMT2C and KMT2D alteration in shaping the immune microenvironment.

#5575 Inhibition of immune evasion via targeting the dysregulated EZH2-RKIP axis in cancer cells.

Ryan McWhorter, Talia Festekedjian, Benjamin Bonavida

Microbiology, Immunologyn& Molecular Genetics, UCLA - University of California Los Angeles, Los Angeles, CA

Introduction: We have recently witnessed several milestones in the treatment of a subset of cancer patients with immunotherapy. However, the unresponsive subset is due, in part, to intrinsic factors in the cancer cells that regulate immune evasion. Thus, the identification of such resistant factors might be potential targets to restore the anti-tumor immune response.
Procedure: Two dysregulated gene products were identified, the overexpressed epigenetic enhancer of zeste homologue 2 (EZH2) , a promoter of immune evasion, and the underexpressed Raf kinase inhibitor protein (RKIP), an inhibitor of immune evasion.
Findings: Analyses of the signaling and cross-talk signaling pathways mediated by these two gene products established a dysregulated EZH2-RKIP axis in cancer cells that regulate immune evasion. For example, analysis of pancreatic ductal adenocarcinoma (PDAC) cancer cells overexpress EZH2 and it plays a central role in immune evasion and PDAC does not respond to check point inhibitors or various EZH2 inhibitors.
Conclusion: We propose that targeting the EZH2-RKIP axis by agents that can induce RKIP expression in cancer cells will lead to downregulation of EZH2 will inhibit immune evasion and will restore the unresponsive cancer cells to respond to immunotherapy. Such agents can be used alone or in combination with other therapies. The specific targeting directly to the tumor cells and sparing normal tissues remain challenging and require novel approaches .

#5576 BRD- and EHMT-dependent immunosuppressive transcriptome in triple-mutant Astrocytoma.

Qingzhu Gao, Leyi Xie, Gengchen Cai, Sophie Sall,Bachchu Lal, Lopez-Bertoni Hernando, John Laterra, **Yunqing Li**

Hugo W. Moser Research Institute at Kennedy Krieger, Baltimore, MD

Astrocytomas (WHO grade II and III) primarily occur in early-middle adult life and frequently progress to more aggressive secondary GBM despite best standard-of-care therapy. Developing more effective therapeutic strategies requires a more complete understanding of the mechanisms employed by astrocytoma cells to escape anti-tumor immunity. The majority (~80%) of grade II & III astrocytoma carry mutations in isocitrate dehydrogenase (e.g., $IDH1^{R132H}$), which typically occurs in combination with p53 mutation and ATRX inactivation (i.e., $IDH1^{R132H}/p53_{mut}/ATRX_{loss,}$ triple-mut for simplicity), indicating that this triple mutation background has an important role in tumor growth and tumor microenvironment reprogramming potentially including immune evasion mechanisms. Our recent findings show that triple-mut induces multiple pathways with anti-tumor immune modulating potential including checkpoint ligands, IFN-γ signaling insensitivity, down-regulation of MHC-I and -II antigen presentation pathways (MHC APP), and dysregulated cytokine/chemokine profiles that modulate the astrocytoma immune microenvironment. Furthermore, we found that the components of the immune-modulating transcriptome associated with triple-mut astrocytom are augmented by standard-of-care radiation (IR) and temozolomide (TMZ). Epigenetic mechanisms orchestrate the tumor cell and the immunosuppressive microenvironment. BET proteins as epigenetic readers regulate gene expression by binding to acetylated lysine residues and/or protein partners, while EHMT1/2 as histone-lysine-N-methyltransferases associated with epigenetic silencing of genes. We show that BRD- and EHMT-dependent histone modifications are elevated in triple-mut astrocytoma cells and together generate the immune-modulating transcriptome. Pan-BET bromodomain inhibitors (e.g., JQ1) significantly inhibited the immunosuppressive transcriptome associated with triple-mut astrocytoma and induced by IR/TMZ, and the pan -EHMT inhibitor UNC0642 significantly up-regulated MHC APP genes and IFN signaling-related genes. SIGNIFICANCE: our findings identify targetable epigenetic determinants that induce an immunosuppressive transcriptome associated with the immunosuppressive microenvironment in triple-mut astrocytoma.

#5577 LSD1 inhibition remodels the tumor microenvironment to enhance anti-PD1 immunotherapy in HNSCC.

Amit Kumar Chakraborty, Chumki Choudhury, Rajnikant Raut, Manish V. Bais

BU School of Medicine, Boston, MA

Background: The histone demethylase LSD1 (KDM1A), an epigenetic regulator implicated in tumor progression and immune suppression. Programmed cell death protein-1 (PD-1/CD279) marks exhausted CD8+ T cells and binds PD-L1 (CD274) in the tumor epithelium. Anti-PD-1 therapy has limited success in head and neck squamous cell carcinoma (HNSCC). We hypothesized that LSD1 inhibitor (SP2509), due to its specific mechanisms, shows superior anti-cancer activity in combination with anti-PD1 therapy.

Methods: We assessed SP2509's impact on the tumor microenvironment (TME) in a syngeneic 4MOSC1 oral squamous cell carcinoma (OSCC) model and 4NQO-induced progressive OSCC model. Anti-PD-1 monotherapy and anti-PD-1-SP2509 combination therapy were tested in a 4NQO model. Multiple methods like immunostaining, qRT-PCR, flowcytometry were employed to test the hypothesis. Ovalbumin overexpression assay followed by flowcytometry was used to determine the antigen presentation in every groups. ChIP-qPCR was used to determine the H3K4 and H3K9 methylation change status on HLA-A, HLA-B and PD-L1 gene locus. Public RNA-seq data (GSE153383) were analyzed to examine immune cell responses to anti-PD-1 and compared with our findings.

Results: SP2509 increased immune cell infiltration, including $CD8^+$ T cells, and reduced the frequency of $PD\text{-}L1^+$ epithelial tumor cells in both 4MOSC1 and 4NQO models. Anti-PD-1 monotherapy expanded $CD8^+$ T cells but did not alter PD-L1 + epithelial cells. Each treatment alone enhanced CD8+ T-cell IFN-γ production, consistent with the GSE153383 analysis showing elevated T-cell infiltration and IFN-γ in anti-PD-1 treated samples. Furthermore, we observed a significant increase in antigen presentation in anti-PD-1 and SP2509 combination group with ovalbumin assay. The combination regimen produced greater immune infiltration, particularly CD8+ T-cells with higher IFN-γ levels, a significant reduction in PD-L1+ epithelial cells, and more pronounced tumor regression than anti-PD-1 alone was observed *in vivo*. ChIP-qPCR results shows increase in H3K4me2 in HLA-A and HLA-B gene locus while H3K9me2 increase in PD-L1 gene locus was observed after SP2509 treatment. We also observed DC activation in SP2509 alona and in combination groups and absent in only anti-PD1 treatment group.

Conclusions: Targeting LSD1 with SP2509 enhances the anti-PD-1 efficacy in HNSCC by modulating the TME, augmenting $CD8^+$ T-cell-mediated antitumor immunity and antigen presentation via MHC class I activation, and reducing tumor PD-L1 expression, ultimately leading to a reduction in HNSCC growth.

#5578 Regulation and expression of transposable elements in ovarian cancer.

Reddick Russell Walker, Kevin Nestler, Melissa Hadley, Katherine B. Chiappinelli

The George Washington University, Washington, DC

Background: Transposable Elements (TEs) are highly repetitive DNA sequences that, when transcribed into RNA, bind immunogenic double-stranded RNA sensors. Through this, expression of TEs can induce type-I interferon (IFN) signaling which has shown potency in improving the response of tumors to immune-modulating therapies. We have published the R175H mutant p53 ovarian cancer cell lines activate chronic TE expression compared to wildtype p53 tumor cells. Despite this, activation of durable immune responses are not seen in R175H p53 tumors, indicating unknown tolerance mechanisms that dampen TE-induced IFN. To this end, we sought to characterize how p53 status alters the expression of TEs and influences downstream IFN signaling.
Methods: To determine the effect that direct binding of p53 has on TE transcription, we correlated p53-targeted chromatin immunoprecipitation sequencing (chIP-seq) with bulk RNA-sequencing expression. Next, we used phosphorylation status of MAVS/MDA-5 signaling mediators, IRF3/7, to determine disruptions in kinase activity downstream of dsRNA sensing.
Results: We found the majority of transcribed TEs did not display direct p53 binding, but rather were transcribed as a biproduct of intragenic insertion within downstream p53 target genes. Additionally, R175H mutant or null p53 bulk RNA sequencing results indicated the downregulation of many TE repressors including KRAB zinc finger proteins (ZNF43, ZNF93, and ZNF561) and DNA Methyltransferase 1 (DNMT1). This suggests TEs lose either DNA methylation and/or KRAB zinc finger silencing in mutant R175H or null p53 backgrounds. The assessment of IRF3/7 indicate R175H p53 cells have reduced phosphorylation levels as compared to wildtype p53 cells. We hypothesize that inactivation of TBK1 by the mutant R175H p53 protein prevents phosphorylation of IRF3 and thus prevents IFN stimulation despite higher TE expression.
Discussion: Overall, these data suggest DNA methylation/expression of KRAB zinc finger proteins are indirect mechanisms by which p53 status dysregulates TE transcription. We aim to characterize DNA methylation status of TEs in wildtype, R175H, or null p53 ovarian cancer cells using whole genome bisulfite sequencing. Additionally, we hope to profile the activation of antiviral response mediators using phosphorylated western blot analyses to determine the disruption of effector signaling in these same cell lines.

#5582 Trispecific TCE with second signal boosts solid tumor response efficacy, durability and safety.

Yuanyuan Wang, Huijuan Lu, Hanmian Cai, Chun Liu, Liang Xiao, Peipei Hu, Chang Zhou, Yongting Huo, Di Lu

Guangdong Fapon Biopharma Inc., Guangdong, China

T-cell engager(TCE) drugs have demonstrated substantial clinical benefits in hematological malignancies, yet their application to solid tumor therapy remains challenging. Key hurdles include on-target off-tumor toxicity, inadequate immune cell infiltration into the tumor microenvironment, and T-cell exhaustion. Moreover, sustained stimulation of the first signal can induce T-cell anergy or apoptosis, underscoring an urgent need for safer and more effective next-generation TCEs.
Herein, we have developed FPE021, a triple-specific TCE targeting CD3, CD28, and CDH17. Through optimized affinities for the first and second signals combined with rational structural screening, FPE021 does not induce T-cell fratricide or non-specific activation, indicating a favorable safety profile. Notably, compared with bispecific TCEs, FPE021 exhibits stronger cytotoxicity in vitro and more potent tumor suppression in vivo. Furthermore, the integration of the second signal effectively enhances T-cell proliferation and mitigates T-cell apoptosis. Collectively, FPE021 represents a promising therapeutic strategy to overcome the current barriers limiting TCE efficacy in solid tumor treatment.

#5584 TCX-101, a trispecific T-cell engager (TcE) co-targeting a tumor-associated carbohydrate (TACA) antigen and a tumor-associated protein antigen (TAA) for the treatment of solid tumors with enhanced preclinical activity.

Karla E. G. Soto, Francesco Muraca, Stephan Grunwald, Wiebke Winkler, Carolin Lange, Jean Engela, Peter Sondermann, Matthias Ocker

Tacalyx GmbH, Berlin, Germany

Tumor-associated carbohydrate antigens (TACAs) are carbohydrate structures that result from aberrant glycosylation, a common feature of many cancers. Because TACA overexpression is associated with tumor progression, they represent attractive yet underexplored targets for cancer therapy.Tacalyx focuses on the generation of sophisticated antibodies against specific TACAs and successfully generated a high-affinity, humanized monoclonal antibody (mAb), TCX-101, targeting a TACA structure that is highly expressed across a broad range of cancer indications. Previously, our team demonstrated encouraging *in vitro* activity against breast and gastrointestinal (GI) cancers with TCX-101 as a bispecific T-cell engager (TcE) with a 2+1 CrossmAb format. To reduce off-tumor effects and enhance specificity, we explored a co-targeting approach by engineering a trispecific TcE comprising a CD3-engaging moiety and two tumor-targeting arms: one derived from the TCX-101 and another recognizing a tumor-associated protein antigen (TAA) overexpressed in epithelial tumors. This next-generation TcE demonstrated efficient *in vitro* cell binding and potent T-cell-mediated killing of cancer cells from multiple tumor indications expressing varying levels of the TACA and TAA, at very low effector-to-target ratios with human peripheral blood mononuclear cells (PBMCs), and in some models at picomolar concentrations. *In vivo* evaluation of this TcE format is currently investigated using cell-line derived xenograft models in humanized mice. In conclusion, these results highlight the feasibility of incorporating TCX-101 as a co-targeting arm in a TcE for solid tumors, enabling dual recognition of a TACA and a TAA. Preclinical studies provide proof-of-concept for this approach and support further investigation and development.

#5585 ARK102, a novel tri-specific T cell engager targeting TROP2, HER2, and CD3 for treatment of solid tumors.

Kyeongsik Min, Deukjoo Ahn, Sangwoo Park, Jaejin Jeon, Heeyeon Kim, Yongwon Jung, Yong-Boo Kuk, Jeongmin An, Taehwan Jeong, Seungwon Lee

ARKGENBioScions, Daejeon, Korea, Republic of

ARK102 is a novel trispecific T-cell engager in a fragment format lacking an Fc domain, engineered using proprietary platform technology to simultaneously target HER2 and TROP2 while recruiting CD3 T cells for potent redirected cytotoxicity. HER2 and TROP2 are clinically validated tumor-associated antigens that have demonstrated favorable outcomes across multiple therapeutic modalities. However, limited target expression in some tumors can restrict therapeutic efficacy. As HER2 and TROP2 are broadly co-expressed across diverse malignancies, dual targeting of these antigens offers an innovative strategy to enhance tumor binding through increased avidity and to overcome challenges such as tumor heterogeneity, antigen loss, and resistance to existing therapies.Comprehensive in vitro analyses showed that ARK102 effectively binds both target antigens, activates T cells, and mediates T-cell-dependent cytotoxicity in dual and single target-expressing cancer cell lines at sub-nanomolar concentrations. In vivo, ARK102 demonstrated robust, dose-dependent antitumor activity in human PBMC-reconstituted immunodeficient mice bearing HER2- and/or TROP2-expressing tumor xenografts, without dose-limiting toxicity at efficacious doses, and showed antitumor efficacy comparable to or greater than that of benchmark TROP2-ADC and HER2-ADC therapies.Together, these results highlight ARK102 as a potent and selective dual-targeting T-cell engager with the potential to expand treatment options for patients with solid tumors co-expressing HER2 and TROP2. The compelling preclinical efficacy and favorable safety profile strongly support its further clinical evaluation.

#5586 A next-generation CD8-selective tri-specific T cell engager targeting CDH17 with enhanced efficacy and reduced toxicity.

Jian Guo, Jiaojiao Ding, Tian Wang, Hanmian Cai, Liang Xiao, Peipei Hu, Chang Zhou, Yongting Huo, Di Lu

Guangdong Fapon Biopharma Inc., Guangdong, China

T cell engagers (TCEs) have already achieved remarkable clinical potential. However, severe toxicities such as cytokine release syndrome (CRS) have led to the failure of many TCE candidates in clinical trials. In addition, because Treg cells also express the TCR-CD3 complex, TCEs can inadvertently activate Treg cells, thereby substantially suppressing anti-tumor immune responses. To address these problems, a CD8-biased TCE has been developed that strongly activates CD8+T cells while minimally activating CD4+T cells and Treg cells, thereby reducing toxicity and improving therapeutic efficacy. However, CD8+T cell activation requires help from CD4+T cells; without this assistance, the effector function of CD8+T cells is limited.
Therefore, we have developed an first-in-class next-generation TCE based on NKG2D. NKG2D is highly expressed on CD8+T cells but is rarely expressed on CD4+T cells and Tregs, providing inherent selectivity for CD8+T-cell activation. Moreover, NKG2D delivers a costimulatory signal that restores the function of CD8+T cells without CD4+T-cell help. Here, we present a tri-specific TCE, CDH17×CD3×NKG2D (FPE026). FPE026 binds to and activates CD8+T cells, but not CD4+T cells or Treg cells. It effectively mediates T cell-driven killing of CDH17-positive tumor cells while inducing much lower levels of cytokines, such as TNF-α and IL-6, compared with traditional TCEs. In addition, compared with the CDH17×TCR×CD8 construct, FPE026 exhibits stronger cytotoxic activity. Furthermore, FPE026 demonstrates significant anti-tumor activity in the AsPC-1 subcutaneous xenograft model, with limited cytokine elevation in serum. Together, these findings highlight FPE026 as a promising next-generation TCE candidate that combines enhanced CD8+ T cell selectivity and potent anti-tumor efficacy with an improved safety profile.

#5587 VTS208: A first-in-class CD3/CLDN18.2/CDH17 Tri-specific T cell engager (TCE) for the treatment of gastrointestinal (GI) cancer.

Wei (Vivian) Wang[1], Xuekun Zhang[2], Man Xu[1], Yingchun Wang[2], Mei Yuan[2], Yanwei Wang[2], Liping Chen[2], Yanling Gong[2], Jing Li[1]

[1]VelaVigo (Hong Kong) Limited, Hong Kong, China,[2]VelaVigo (Shanghai) Limited, Shanghai, China

Zolbetuximab (Astellas' anti-CLDN18.2 mAb, approved) has validated CLDN18.2 as a promising tumor-associated antigen (TAA) for gastrointestinal (GI) cancer therapy. CLDN18.2-targeting T cell engagers (TCEs), including IBI389 (phase I) and ASP2138 (phase I), demonstrate anti-tumor activity in patients with low CLDN18.2 expression, indicating that the TCE modality is effective even with minimal TAA expression. However, short duration of response and drug resistance persist because tumor heterogeneity drives therapeutic limitations. Notably, CDH17 (Cadherin 17) has emerged as a novel biologic target, frequently overexpressed in GI cancers. CLDN18.2 and CDH17 exhibit highly complementary expression patterns (co-expressed or individually expressed) across multiple cancers with limited normal tissue expression, positioning them as ideal dual targets for trispecific TCE design that may address tumor heterogeneity and overcome antigen-loss resistance in single-target therapies.

We present VTS208, a first-in-class trispecific antibody featuring a proprietary CD3 arm that targets both CLDN18.2 and CDH17. It achieves potent on-target cytotoxicity with reduced concomitant T cell activation, thereby widening the therapeutic window. Its bi-paratopic CDH17-targeting design enhances binding avidity and efficacy against low-expression tumors. In human PBMC-reconstituted CDX models with variable CLDN18.2/CDH17 expression across gastric cancer (GC), pancreatic ductal adenocarcinoma (PDAC) and colorectal cancer (CRC), VTS208 demonstrated robust anti-tumor activity even at low doses. Preliminary cynomolgus monkey toxicity studies confirmed favorable tolerability under step-up dosing. Current development includes CMC process optimization and dose-range-finding (DRF) toxicity studies. With mini-pool fermentation titers of 4-6 g/L supporting targeted drug substance concentrations for subcutaneous administration, the IND application is scheduled for filing in H2 2026.

In summary, VTS208's unique trispecific design and differentiated features demonstrate promising efficacy and safety, positioning it as a compelling first-in-class TCE candidate for clinical development.

#5588 A next-generation tri-specific T cell engager targeting CDH17 with 4-1BB co-stimulation for the treatment of gastrointestinal cancers.

Shan Gao[1], Xiaoli Zhang[2], Yuanyuan Yang[2], Zhijian Cai[2], Feifei Cui[1], **Liu Yang**[1], Lei Fang[1]

[1]Excalipoint Biotechnology （Shanghai） Co.,Limited, Shanghai, China,[2]Lepu Biopharma Co., Ltd, Shanghai, China

Background: Cadherin-17 (CDH17), a membranous cell adhesion protein, is highly expressed in gastrointestinal (GI) cancers, particularly in colorectal cancer. In normal intestine tissue, CDH17 is restricted to the lateral side of the epithelial cells and remains largely inaccessible to antibody, making it a promising therapeutic target for GI malignancies. Our platform has demonstrated that incorporating 4-1BB costimulation can effectively convert immunologically "cold" tumors into "hot". This transformation is achieved by enhancing the infiltration of peripheral T cells into the tumor and systemically remodeling the tumor microenvironment. Moreover, this strategy elicits a durable T cell memory response and significantly prolongs survival. Given that GI cancer is a classic "cold" tumor, we have developed a novel tri-specific T cell engager (TCE) that targets CDH17 on cancer cells and engages CD3 and 4-1BB on T cells. This TCE is engineered to redirect and enhance T cell responses against CDH17-expressing tumor cells. With a manageable safety profile, this approach holds strong potential to improve clinical outcomes for patients with GI cancers.

Methods: The *in vitro* activities of the CDH17-CD3-4-1BB tri-specific TCE were evaluated in both CDH17-positive and -negative tumor cell lines. These assessments included T cell-mediated cytotoxicity, T cell activation, cytokine release and T cell proliferation. *In vivo* anti-tumor activity was investigated in two models: a humanized syngeneic mice model bearing B16F10-hCDH17 tumors and NCG-MHC-dKO mice with human PBMC bearing Lovo tumors. Cytokine release assay (CRA) was conducted to evaluate potential cytokine storm risk. Additionally, the toxicological profile was assessed in a pilot toxicity study in cynomolgus monkeys.

Results: CDH17-CD3-4-1BB tri-specific TCE demonstrated CDH17-dependent activation of CD3 and 4-1BB. It effectively induced tumor lysis in multiple CDH17+ tumor cell lines and significantly enhanced T cell activation, cytokine production and T cell proliferation in the presence of CDH17-expressing target cells. In humanized syngeneic tumor mouse model and human PBMC xenograft tumor mouse model, this molecule demonstrated robust tumor growth inhibition and prolonged survival rate. Furthermore, an *in vitro* CRA indicated lower IL-6 release compared to a clinical benchmark, indicating a more manageable risk of cytokine release syndrome (CRS). In the pilot tox study, no adverse effects were observed in clinical signs and histopathology.

Conclusion: CDH17-CD3-4-1BB tri-specific TCE represents a novel CDH17-targeted T cell engager with potent and durable anti-tumor activity. Collectively, these results underscore its potential as a novel therapeutic agent against GI cancers and support its advancement into clinical development.

#5589 A biparatopic DLL3-targeting trispecific T-cell engager delivered by mRNA-LNP drives potent anti-tumor activity *in vitro*and*in vivo*.

Xue Qiao[1], Qiang Zhang[1], Lushuai Jin[1], Yao Lv[1], Shaoli Liu[2], Xiaoju Zhang[1], Xiaoyun Ma[2], Hongya Han[1], **Wei Xu**[1]

[1]Metis TechBio, Hangzhou, China,[2]Metis TechBio, Beijing, China

Background: T-cell engagers (TCEs) targeting DLL3 show promising clinical activity in small cell lung cancer (SCLC), yet response rates, durability, and toxicities such as cytokine release syndrome (CRS) remain challenges. Because DLL3 is a low-abundance antigen, increased avidity can improve tumor cell killing. We developed an mRNA-lipid nanoparticle (mRNA-LNP) platform enabling sustained in vivo expression of a DLL3-targeting TCE, using the pharmacokinetic profile of mRNA to reduce CRS risk. To enhance penetration and avidity, we incorporated compact camelid VHH domains and a biparatopic design that engages two distinct DLL3 epitopes.

Methods: A trispecific T-cell engager was engineered by fusing two DLL3-binding VHHs, each recognizing non-overlapping epitopes, with a CD3 agonist domain via flexible peptide linkers. The mRNA expression was optimized using codon engineering to balance Codon Adaptation Index (CAI) and Minimal Free Energy (MFE) across the full transcript, including untranslated regions (UTRs) and the coding sequence (CDS). The optimized mRNA was formulated into a novel LNP delivery system to generate the therapeutic candidate MTS108. Cytotoxic activity was assessed using T cell-dependent cellular cytotoxicity (TDCC) assays with human PBMCs co-cultured with DLL3-expressing SHP-77 or MC38-DLL3 target cells. In vivo efficacy was evaluated in both subcutaneous and orthotopic lung tumor models, including a humanized CD3ε transgenic syngeneic model and a human PBMC-reconstituted cell-derived xenograft (CDX) model.

Results: In TDCC assays, MTS108 (mRNA-LNP) demonstrated potent tumor-killing activity against SHP-77 (low DLL3) and MC38-DLL3 (high DLL3) target cells. Against SHP-77 cells, MTS108 exhibited an EC_{50} more than 10-fold lower than that of the approved therapeutic Xaluritamig. It also showed significantly enhanced cytotoxicity against MC38-DLL3 cells relative to Xaluritamig. In vivo, MTS108 consistently and significantly outperformed the benchmark agent across both subcutaneous and orthotopic tumor models. Optimized mRNA design enabled robust expression in vitro and in mice, and both cell-culture supernatants and mouse serum containing mRNA-expressed TCEs displayed tumor-killing potency comparable to recombinant protein. In the subcutaneous MC38-DLL3 syngeneic model and the orthotopic SHP-77 lung cancer model, MTS108 achieved superior anti-tumor efficacy with an improved safety profile.

Conclusion: These data demonstrate that an mRNA-LNP platform can effectively deliver a biparatopic DLL3-targeting trispecific TCE with potent and superior anti-tumor activity and a favorable safety profile. MTS108 represents a promising therapeutic candidate and supports advancement of mRNA-encoded TCEs toward clinical evaluation.

#5590 BCG024: A novel DLL3×CD3×4-1BB trispecific T cell engager enhances T cell persistence and functionality in preclinical models.

Guan Wang, Baihong Liu, Liu Yang, Xue Li, Shuangshi Liu, Yu Qi, Jinhua Zhao, Yang Chen, Frank An, Yi Yang

Biocytogen, Waltham, MA

Background: CD3-based T cell engagers (TCEs) as powerful therapeutic agents have demonstrated clinical success in both hematologic malignancies and solid tumor indications. One major obstacle to TCE therapies in treating solid tumors is T-cell exhaustion due to conventional TCEs lacking co-stimulatory signaling, limiting their therapeutic durability. To address this challenge, integrating a co-stimulatory signal such as 4-1BB into TCEs could be an attractive approach to enhance T cell function and durability.

Methods: We developed a trispecific antibody (TriAb) targeting DLL3, CD3, and 4-1BB using a VHH 4-1BB agonist derived from RenNano® mice to achieve tumor antigen-dependent co-stimulation. *In vitro* assays included repeated stimulation assay and cytotoxicity against DLL3-positive small cell lung cancer (SCLC) cell line. *In vivo* efficacy and T cell proliferation were evaluated in xenograft mouse models bearing established SCLC tumors. The toxicity study was evaluated in CD3ε×4-1BB humanized mice.

Results: The DLL3 TriAb demonstrated significantly enhanced T cell proliferation while maintaining high cell viability and cytotoxicity following repeated stimulation. However, the benchmark and bsAb counterparts showed marked reductions in cell viability and activity. *In vivo*, mice treated with benchmark caused dose-dependent reductions in serum T cell number, whereas those treated with DLL3 TriAb maintained stable T cell populations. That indicated TCE integrated 4-1BB nanobody co-stimulation indeed enhances T cell durability and functionality. In SCLC xenograft models, DLL3 TriAb exhibited robust antitumor efficacy in a monovalent antigen-binding format rather than a bivalent antigen-binding format. Notably, contrasting with non-specific TriAb controls, DLL3 TriAb displayed favorable safety profiles in CD3ε×4-1BB humanized mice even at high doses, with no significant body weight loss or systemic cytokine elevation observed.

Conclusions: Our DLL3×CD3×4-1BB TriAb demonstrates tumor-dependent co-stimulation, enhanced T cell persistence and functionality, further exhibiting superior anti-tumor efficacy in preclinical SCLC model and good safety profiles at high dose. These findings highlight the DLL3 TriAb as a next-generation immunotherapy, offering enhanced T cell functionality and clinical translatability.

#5591 Development of a novel anti-CD19 x BCMA dual targeted T cell engager for the treatment of autoimmune diseases and B cell malignancies.

Lin Huan, Hao Ran, Shiyi Wang, Xiaoping Zhang, Bing Yang, Yang He, Dandan Liu, Chenpeng Su, Chuan Chen, Xiaoqian Chen, Kezhen Ye, Liang Tian, Jian Peng, Zhenping Zhu

Earendil Labs, Wilmington, DE

Rationale B cells and autoantibodies drive the progression of autoimmune diseases. Targeting B cells or plasma cells alone is often insufficient to eliminate both pathogenic B cells and autoantibody. Here, we generated HXN-1031, a novel trispecific T cell engager (TCE), simultaneously targeting CD19 and BCMA.
Methods Affinity, cell-binding and cytotoxicity were evaluated in vitro. In vivo efficacy was investigated in mice bearing $CD19^+$ or $BCMA^+$ tumor cells, and in non-human primates.
Results HXN-1031 has sub-micromolar CD3 affinity and nanomolar CD19/BCMA affinity. Against $CD19^+$ targets, it showed weaker potency (IC50) but similar maximum killing efficacy versus Blinatumomab, with significantly reduced T cell activation and cytokine release. For BCMA, HXN-1031 shows high potency in in vitro cytotoxicity. HXN-1031 effectively kills both $CD19^+$ and $BCMA^+$ cells simultaneously within a mixed cell population while maintaining moderate T cell activation and cytokine release. In contrast, CD19-TCE and BCMA-TCE only selectively target B cells ($CD19^+BCMA^-$) or H929 ($CD19^-BCMA^+$) cells, respectively. In vivo, HXN-1031 demonstrated superior efficacy to Blinatumomab against $CD19^+$ tumors, and significantly suppressed $BCMA^+$ tumor growth, matching Teclistamab analogue efficacy. In non-human primates, HXN-1031 potently depleted, both in peripheral and bone marrow, B cells and plasma cells, leading to significantly reduced serum immunoglobulin, for a prolonged period of times.
Conclusion HXN-1031 is an innovative TCE with finely tuned activity, designed to reset immune system by simultaneously depleting pathogenic B cells and plasma cells. It holds great potential in the treatment of various B cell and plasma cell related autoimmune diseases and malignancies.

#5592 QL535: A novel CD2-costimulating PSMA-targeted T-cell engager with dose-responsive efficacy in PDX models and a favorable GLP toxicology profile in NHP.

Xiao Liu

QLSF Biotherapeutics, South San Francisco, CA

Prostate cancer remains a major cause of cancer mortality, highlighting the need for better targeted immunotherapies. Prostate-specific membrane antigen is highly expressed in malignant prostate tissue, confirmed by immunohistochemistry in 77 patients. Earlier T-cell engagers show limited activity in solid tumors, prompting designs incorporating co-stimulation. Single-cell RNA sequencing of 2,170 tumor-infiltrating lymphocytes from 14 metastatic castration-resistant prostate cancer patients showed broader and higher CD2 expression than CD28, especially in CD8-positive T cells, supporting CD2 as an accessible co-stimulatory axis.QL535 is a trispecific PSMA × CD3 × CD2 T-cell engager engineered to provide optimized CD3 activation and CD2-mediated co-stimulation. *In vitro,* QL535 enhanced PSMA-dependent cytotoxicity compared to CD2-deficient controls and matched the potency of CD28-based trispecifics while reducing secretion of IL-6, TNFα, IFN-γ, and IL-8. Repeated-stimulation assays using patient peripheral blood mononuclear cells demonstrated preserved cytolytic activity and reduced exhaustion relative to CD28-based trispecifics and clinical benchmark analog.*In vivo,* QL535 produced clear dose-responsive tumor regression in prostate cancer patient-derived xenograft models. Good Laboratory Practice toxicology studies demonstrated favorable tolerability. Intravenous dosing from 1 to 10 mg/kg resulted in dose-dependent exposure. Cytokines increased transiently after the first dose, accompanied by reversible decreases in monocytes and lymphocytes and transient elevations in neutrophils and C-reactive protein. Circulating T cells declined at 24 hours and returned to baseline by Day 7. QL535 was overall well tolerated in non-human primates, with pharmacodynamic changes consistent with T-cell engager activity. These findings demonstrate that QL535 delivers potent PSMA-targeted cytotoxicity, sustains function under exhaustion-inducing conditions, drives dose-responsive antitumor activity in patient-derived xenograft models, and exhibits a favorable safety and pharmacology profile, supporting advancement toward clinical evaluation in PSMA-positive prostate cancer.

#5593 A CD19/BCMA dual-targeting VHH format T-cell engager with novel CD3 binder for enhanced potency and safety profile.

Fan Wu, Yongfeng Li, Liang Xiao, Chang Zhou, Peipei Hu, Jiya Shi, Tingchu Wu, Yue Huang, Mengying Liang, Chun Liu, Yuanyuan Wang, Yongting Huo, Di Lu

Guangdong Fapon Biopharma Inc., Guangdong, China

Recently, B cell depletion therapies targeting CD19 or BCMA, including chimeric antigen receptor T-cell (CAR-T) therapies and bispecific antibodies such as Blincyto and Tecvayli, have shown great potential in treating systemic lupus erythematosus (SLE) and other autoimmune diseases (AID). Targeting B cells and plasma blasts expressing CD19 is a key therapeutic strategy in autoimmune disease. However, in some patients, disease may also be anchored in long-lived plasma cells in the bone marrow expressing BCMA but not CD19.This means that the strategy of targeting CD19 alone has limitation in the therapy of B cell depletion.

Here, we have developed CD19/BCMA dual-targeting T cell engager(FPE024) to achieve more extensive depletion of pathogenic B cells. All components of FPE024, including the CD3 nanobody, exhibit excellent cross-species binding activity between human and cynomolgus monkey. This enables us to simultaneously conduct safety and efficacy tests on cynomolgus monkeys, facilitating better translational studies bridging to clinical trials. FPE024 exhibits strong cytotoxicity in tumor cells with different CD19 and BCMA expression patterns, and the level of cytokine release is comparable to that of Blincyto and Tecvayli, indicating that FP024 has a good safety profile. FPE024 induces relatively similar B-cell killing in PBMC from healthy volunteers and SLE patients. In conclusion, FPE024 is a highly potent, CD19/BCMA dual-targeting TCE with preclinical data providing a strong rationale for broad development in AID which benefits from B cell depletion.

#5594 Pharmacological integration of CD3 and CD2 signaling triggers formation of a CD2 corolla that boosts T cell activation.

Sergio Trombetta[1], Shengpan Zhang[2], Tanmay Mitra[2], Salvatore Valvo[2], Colleen Brown[3], Oksana Segreeva[3], Stella Martomo[3], Martin Preyer[3], Jay Fine[3], Jeremy Myers[3], Michael Dustin[2]

[1]EvolveImmune Therapeutics, Branford, CT,[2]Oxford University, Oxford, United Kingdom,[3]Evolveimmune Therapeutics, Branford, CT

Redirecting patient's endogenous T cells to safely and effectively eradicate tumors continues to offer compelling therapeutic opportunities. We found that EVOLVE, a trispecific antibody targeting a tumor-specific antigen together with integrated CD3 activation and CD2 costimulation, led to unique T cell activation profiles. Like the events observed with intact or artificial antigen presenting cells, these trispecific antibodies were sufficient to trigger the formation of a CD2 corolla surrounding the immunological synapse, independent of membrane CD58, on 95% primary human T cells, in a tumor-antigen dependent manner, compared to 20% observed with CD3-matched bispecifics. Trispecific antibodies demonstrated significant functional advantages over conventional bispecific antibodies, with corolla-associated signaling leading to a 1.6-fold amplification of T cell activation events. This resulted in an over 10-fold increase in killing potency against high-antigen-expressing tumor cells and a 20-fold enhancement of killing potency against low-antigen-expressing tumor cells. These findings provide fundamental insights into the CD2 tropism for corolla localization, even when the CD2 and CD3 ligands are covalently linked to each other, confirming the potential for EVOLVE to initiate CD2-costimulatory signaling at the T cell synapse, thereby enhancing the therapeutic efficacy of T cell engagers.

#5595 Development of EDP001, a tetravalent T Cell engager targeting CD19 and BCMA for B Cell lymphoma.

Qinglin Du, Zongjun Xia, Pan Du, Xing Wang, Xiaoman Wang, Feng Wang, Xueyan Yang, Yi Wu, **Shuhua Han**

Edding, Shanghai, China

Background: The current therapeutic landscape for B-cell lymphoma, while much advanced, still faces significant limitations primarily related to treatment resistance, toxicity and accessibility. This study describes a novel tetra-specific antibody, EDP001, that binds CD3, BCMA, and CD19 with two distinct epitopes. The biparatopic CD19 design greatly enhances antigen avidity, while the inclusion of BCMA enables dual-antigen targeting and further increases its efficacy. EDP001 is designed to maximize tumor cell killing, mitigate antigen escape, and sustain low cytokine secretion. Thus, EDP001 holds a great potential for the better treatment of various B cell malignancies.

Methods: Multiple rounds of screening and characterization of antibody candidates were performed by comprehensive evaluation including binding affinity, specificity and functional analysis. Specific target-killing activity was examined using multiple B cell lines expressing CD19 and/or BCMA. Cytotoxicity against primary B cells from different donors were also examined. In vivo B-cell depletion and anti-tumor efficacy were tested in hCD34+ reconstituted mice and a panel of B-cell malignant murine models, respectively.

Results: EDP001 exhibited high affinity for BCMA while demonstrating low affinity for CD3, as intended by design. Notably, its biparatopic anti-CD19 domains conferred an approximately 100-fold higher binding affinity for CD19 than clinically validated CD19/CD3 bispecific antibodies. EDP001 potently lysed target tumor cells expressing CD19, BCMA, or both antigens, outperforming CD3×CD19 or CD3×BCMA bispecific antibodies. In addition, it induced significantly more potent cytotoxicity against primary B cells from both healthy donors and SLE patients, with minimal cytokine release. In vivo studies showed that EDP001 mediated profound and sustained B-cell depletion in hCD34+ reconstituted mice and demonstrated superior anti-tumor activity across multiple B-cell malignant models with varying expression levels of CD19 or BCMA (e.g., Raji, NCI-H929, Jeko-1, WSU-DLCL2, NALM6-BCMA), surpassing CD3×CD19 and CD3×BCMA bispecific antibodies in all the animal models tested.

Conclusion: EDP001 is the first reported tetravalent TCE targeting CD19 and BCMA. The unique molecular design of EDP001 enables a deep depletion of primary B cells as well as various lymphoma lines in preclinical studies. EDP001 may represent a promising off-the-shelf therapeutics with a superior efficacy for the treatment of variety of B-cell lymphomas.

#5597 Plinabulin boosts antitumor efficacy of topoisomerase inhibitor-based antibody-drug conjugates without or with immune checkpoint inhibitor.

Yingjuan June Lu[1], Xiaoyan He[2], Weiwei Cheng[2], Zhengyan Zhang[2], James Tonra[1], Lan Huang[1]

[1]BeyondSpring Pharmaceuticals, Florham Park, NJ,[2]Pharmaron, Beijing, China

Background: Antibody drug conjugates (ADC) with topoisomerase inhibitors (TOP1-ADC) hold significant promise in cancer treatment. FDA-approved TOP1-ADC includes TROP2- or HER2-directed datopotamab deruxtecan (Dato-DXd) and trastuzumab deruxtecan (T-DXd), respectively. To boost ADC efficacy without overlapping toxicity, combination strategies including immune checkpoint inhibitors (ICI) are under active investigation. Plinabulin (Plin) is a first-in-class, differentiated tubulin binder that exerts anticancer activity primarily by activating GEF-H1-mediated pathways in dendritic cell (DC) maturation and T cell activation. In Dublin-3 phase 3 study, Plin/docetaxel outperformed docetaxel with significant OS/PFS/ORR benefits and doubling of 2- and 3-year survival rates, and reduced docetaxel induced neutropenia. In post-ICI settings given after radiation, Plin potentiates anti-PD-1 with significantly higher GEF-H1 immune activation in responders of mixed cancer types. Preclinically, Plin boosts irinotecan activity in human colon cancer models and reduces topotecan-induced neutropenia. Here we investigated Plin synergy with TOP1-ADC in-vitro, and with or without PD-1/L1 inhibitor pembrolizumab (Pembro) or atezolizumab (Atezo) in-vivo.

Methods: For combinations in-vitro, HER2+ KPL-4 breast cancer cells were treated with Plin (1.46 - 46.8 nM), T-DXd (0.105 - 3.37 μM) or both. For combinations in-vivo, MC38 mouse colon adenocarcinoma cells overexpressing hTROP2 (hTROP2-MC38) or hHER2 (hHER2-MC38), were inoculated in B-hPD-1 or B-hPD-1/hPD-L1/hHER2 mice respectively, and antitumor activities of Plin (7.5 mg/kg) plus Dato-DXd (5 mg/kg) ± Pembro (0.3 mg/kg) or T-DXd (3 mg/kg) ± Atezo (8 mg/kg) were evaluated.

Results: On HER2+ KPL-4 cells, Plin showed synergistic activity with T-DXd with median CI <1 at 1:1, 2:1 and 4:1 ratios (T-DXd:Plin). In hTROP2+ MC38 tumor model, Dato-DXd antitumor activity was significantly enhanced by Plin (doublet) and further boosted by Pembro (triplet) with complete response rates of 0%, 20% and 60% respectively. Compared to Dato-DXd plus Plin or Pembro groups, the triple combo most significantly delayed tumor growth (p=0.009 or 0.028) and improved animal overall survival, and was better tolerated than Dato-DXd+Pembro (10% vs. 40% mortality). In hHER2+ MC38 tumor model, only the triple combo group (T-DXd+Plin+Atezo) prolonged animal survival better than T-DXd alone (p=0.0256).

Conclusions: Plinabulin is a Phase 3 novel agent clinically validated to promote DC maturation and T-cell activation, which provides a durable response by strengthening the cancer-immunity cycle when combined with ICI and neutropenia-limiting agents such as docetaxel and ADCs. Clinical investigations assessing plinabulin safety and efficacy combined with TOP1-ADC alone or plus ICI are highly encouraged.

#5598 Exploiting electron transport chain dynamics to sensitize OXPHOS-dependent cancers to immunotherapy.

Haojie Dong[1], Guoyun Kao[2], Umesh P. Yadav[1], Lei Zhang[2], Arshad J. Ansari[2], Srinivasarao Singireddi[2], Bei Jia[3], Jianai Sun[4], Guohua Wu[1], Yini Wang[1], Xin He[1], Lei Zhang[1], Zheng Li[1], Ruiheng Wang[1], Wei Chen[1], Meng Liu[1], Shuaishuai Ge[1], Yang Li[1], Whitaker Cohn[2], Amandeep Salhotra[5], David B. Sykes[6], Jie Jin[4], Jianjun Chen[1], Guido Marcucci[1], Shoubao Ma[1], Hong Zheng[3], Yong Zhang[2], Ling Li[1]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]University of Southern California, Los Angeles, CA,[3]Penn State University, Hershey, PA,[4]Zhejiang University School of Medicine the First Affiliated Hospital, Hangzhou, China,[5]Department of Hematology and HCT, City of Hope Medical Center, Duarte, CA,[6]Massachusetts General Hospital, Boston, MA

Primary or acquired resistance to immunotherapies, including immune checkpoint inhibitors (ICIs) and CAR-T cells, remains a major clinical challenge. This resistance is particularly prevalent in "immune-cold" tumors like acute myeloid leukemia (AML), which are characterized by low immunogenicity, an immunosuppressive microenvironment, and immune escape by leukemia stem cells (LSCs). Activating the tumor-intrinsic cGAS–STING pathway to induce Type I interferon (IFN-I) responses is a promising strategy to convert "cold" tumors to "hot". However, achieving this selectively in cancer cells while sparing normal tissues remains a critical, unsolved barrier. We sought to identify novel mechanisms controlling innate immune signaling in OXPHOS-heightened cancers like AML to develop a strategy for overcoming immunotherapy resistance.We employed an inducible CRISPR-KO screen to identify regulators of mitochondrial homeostasis and cGAS-induced innate immunity. The screen identified a subset of minor mitochondrial dehydrogenases (including DHODH, SDHs) as critical regulators of mitochondrial redox balance and mtDNA integrity. We demonstrate that genetic or pharmacologic inhibition of these enzymes reroutes metabolic flux toward the Electron Transport Chain (ETC) Complex I (C-I). This paradoxically hyperactivates C-I, amplifying mtROS, inducing mtDNA instability, and causing mtDNA leakage into the cytosol. The cytosolic mtDNA is sensed by cGAS, leading to robust STING activation and systemic IFN-I responses in vivo. Crucially, this immune-stimulatory mechanism is independent of the canonical metabolic roles of these enzymes; for instance, this response after DHODH inhibition was not rescued by uridine supplement. In immunocompetent murine AML models, we found that while tumor-selective DHODH ablation was curative, systemically pharmacologic inhibition of DHODH was profoundly immunosuppressive, as it blunted T-cell proliferation essential for an anti-leukemia response. To overcome this toxicity-efficacy barrier, we developed "DHODHi-ADC", a first-in-class, immune-boosting ADC that achieves leukemia-selective delivery of a potent DHODH inhibitor (DHODH-IN16). The ADC preserves systemic immune function while inducing potent, tumor-intrinsic innate immune activation, a clear distinction from purely cytotoxic ADCs. In humanized AML models, our ADC synergized remarkably with both ICIs and CAR-T cell therapy, resulting in highly effective, durable leukemia clearance, including the eradication of LSCs.Our findings define a novel, therapeutically exploitable immune-metabolic axis where ETC homeostasis controls innate immunity via mtDNA dynamics. Disrupting this homeostasis through C-I hyperactivation provides a powerful and highly translational strategy to sensitize OXPHOS-dependent cancers to immunotherapy.

#5599 ATG-125, a novel B7H3 × PD-L1 bispecific antibody-drug conjugate, demonstrates potent antitumor efficacy by dual targeting of immune evasion and direct tumor killing.

Jishun Chen[1], Suya Bai[1], Yu Bai[1], Huiling Liu[1], Zaoshun Hu[1], Jay Mei[2], Peng Chen[3], **Bing Hou**[2]

[1]Antengene (Hangzhou) Biologics Co., Ltd, Hangzhou, China,[2]Antengene Corporation, Shaoxing, China,[3]Shanghai Antengene Corporation Limited, Shanghai, China

Background B7-H3 (CD276) and PD-L1 (CD274) are immune checkpoint molecules overexpressed in a wide range of solid tumors, often associated with immune evasion and poor prognosis. While monoclonal antibodies targeting PD-1/PD-L1 have shown clinical success, resistance remains a major challenge. B7-H3 is an emerging, highly promising target for antibody-drug conjugates (ADCs) due to its broad tumor expression and rapid internalization. Co-expression of B7-H3 and PD-L1 on tumor cells provides a rationale for dual targeting to enhance both direct cytotoxicity and immune activation. ATG-125 is a novel bispecific ADC designed to address this opportunity.

Methods ATG-125 is a B7-H3 × PD-L1 bispecific ADC (BsADC) engineered from a human IgG1 anti-B7-H3 antibody with C-terminally fused PD-L1-specific scFv. It is conjugated via a cleavable GGFG linker to the DNA topoisomerase I inhibitor, resulting in a drug-to-antibody ratio (DAR) of ~4. Binding affinity, cytotoxicity, internalization, lysosomal trafficking, bystander killing, and T-cell activation were evaluated in solid tumor cell lines with varying expression levels of B7-H3 and PD-L1. The *in vivo* antitumor efficacy of ATG-125 against the HCC827 human NSCLC model was evaluated in nude mice.

Results ATG-125 bound B7-H3 and PD-L1 with nanomolar affinity and demonstrated strong, antigen-dependent internalization in dual- and single-target positive tumor cells, enabling efficient intracellular release of the Dxd payload. ATG-125 exhibited potent, target-dependent cytotoxicity against multiple cancer cell lines (e.g., lung, breast, ovarian) that co-expressing B7-H3 and PD-L1. The parental naked antibody blocked PD1-PDL1 interaction and induced robust IL-2 and IFNγ production in a Mixed Lymphocyte Reaction (MLR) experiment. The BsADC induced significantly enhanced T-cell activation, as shown by a higher frequency of $CD69^+$ $CD3^+$ T cells in a co-culture with HCC827 cells and human PBMCs. *In vivo*, ATG-125 induced marked and sustained tumor regression in HCC827 xenograft models at well-tolerated doses. Its efficacy was significantly superior to that of single-target ADC comparators.

Conclusion ATG-125 represents a novel bispecific ADC that co-targets B7-H3 and PD-L1 to achieve synergistic IO+ADC antitumor efficacy. Its unique mechanism combines enhanced, dual-target-mediated internalization for superior payload delivery with potential restoration of anti-tumor immunity. The compelling preclinical profile of ATG-125 underscores its significant therapeutic potential and supports its advancement into clinical trials for patients with solid tumors.

#5601 LBL-061: A novel EGFR×PD-L1 targeted drug conjugate for the treatment of multiple solid tumors.

Yurong Qin, Yang Ye, Yujia Dang, Juan Tang, Peng Zhang, Yan Zhu, Shuijun Hu, Mi Ye, Xiaoxiao Liu, Xu Bao, Huan Lin, Wanting Wang, Guojin Wu, Jianming Sun, Hui Yuwen, Yuanzhi Lv, Jing Guan, Min Chen, Yue Zhao, Jordan Zhu, Charles Cai, **Xiao Huang**, Xiaoqiang Kang, Hong Ling

Leads Biolabs Co., Ltd., Nanjing, China

Background: EGFR is overexpressed in multiple solid tumors such as head and neck squamous cell carcinoma (HNSCC), non-small cell lung cancer (NSCLC), and nasopharyngeal carcinoma (NPC). Emerging antibody-drug conjugates (ADCs) targeting EGFR have demonstrated preliminary efficacy and safety in clinical trials. PD-L1, a clinically validated immune checkpoint, is frequently overexpressed in tumors including HNSCC and NSCLC, where it is often co-expressed with EGFR. Clinical evidence supporting the combination of ADCs and immune checkpoint inhibitors (ICIs) provides a rationale for developing an EGFR×PD-L1-targeting ADC. Here, we describe the preclinical development of LBL-061, a novel EGFR×PD-L1-targeting ADC composed of a 2:2 format bispecific antibody conjugated via our proprietary TOPiKinectics^{TM} linker-payload platform.

Methods: Cell binding activity of LBL-061 against tumor cells was assessed by flow cytometry. Cytotoxicity of LBL-061 against tumor cells and normal tissue cells was assessed by Cell Counting-Lite Luminescent Cell Viability Assay kit. PD-L1 blocking activity of LBL-061 was evaluated using a PD-1/PD-L1 reporter gene assay system. Bystander killing of LBL-061 was analyzed by flow cytometry. LBL-061 induced tumor cells immunogenic cell death (ICD) was assessed in PBMC-tumor cells co-culture systems. The anti-tumor activity of LBL-061 was evaluated in mouse syngeneic and cell line-derived xenograft (CDX) models. The safety profile and pharmacokinetics (PK) of LBL-061 were evaluated in a cynomolgus monkey dose-range finding (DRF) study.

Results: LBL-061 exhibited potent binding activity and cytotoxicity to different tumor cells. It also demonstrated robust PD-1/PD-L1 blocking activity. *In vitro*, LBL-061 showed minimal cytotoxicity to PD-L1 expressing dendritic cells (DCs) and macrophages. In PBMC-tumor cells co-culture systems, LBL-061 induced tumor cells immunogenic cell death (ICD). It also mediated potent bystander effect on EGFR negative tumor cells. *In vivo*, LBL-061 showed superior control of tumors' growth in syngeneic and xenograft mouse models. In a 6-week cynomolgus DRF study, it was well tolerated with a highest non-severely toxic dose (HNSTD) of 40 mg/kg following repeated intravenous infusion (Q3W dosing). LBL-061 exhibited a linear PK characteristic in cynomolgus monkeys at doses ranging from 10 to 40 mg/kg.

Conclusions: Our findings indicate that LBL-061, a novel bispecific EGFR×PD-L1-targeting ADC synergizes antitumor effects by combining direct cytotoxicity and immune activation. It showed a favorable PK profile and a good safety profile in cynomolgus monkeys. Taken together, these preclinical data strongly suggest that LBL-061 is a promising candidate worthy of further clinical investigation.

#5602 Novel ATR inhibitor payloads for antibody-drug conjugates targeting PD-L1.

Anne Roulston, Martin Duplessis, Francois Denis, Hugo Poirier, Shou Yun Yin, Sara Fournier, Roselyn Kryczka, Jessica Desjardins, Nancy Laterreur, Abira Rajah, Alexanne Bonneau-Fortin, Bingcan Liu, **Alejandro Alvarez-Quilon**, Philipe Mochirian, Ismael Samudio

DCx Biotherapeutics, Saint-Laurent, QC, Canada

Ataxia telangiectasia and Rad3-related kinase (ATR) is essential to the faithful replication of DNA in rapidly dividing cells such as cancer cell lines. ATR is activated in response to single-strand DNA breaks that result from increased replication stress caused by defects in DNA repair mechanisms and/or damaged DNA. ATR stabilizes and restarts the stressed replication forks, suppresses origin firing, activates cell cycle checkpoints, and facilitates DNA repair. In fact, ATR activity contributes to the tolerance of chronic replication stress in cells transformed by oncogenes rendering cancer cells more dependent on ATR activity for survival. Systemic exposure to ATR inhibitors (ATRis) in clinical studies have demonstrated dose-limiting toxicities that reduce their clinical utility. Therefore, precision antibody-drug conjugates (ADCs) for targeted delivery of ATR payloads could bypass the systemic toxicities associated with oral administration. There is significant overlap between cancers with ATRi sensitizing defects in DNA repair mechanisms with those expressing high levels of PD-L1 surface antigens including stomach, breast, lung and colon cancers. Our personalized antibody-drug conjugate approach couples surface targeted therapeutics to tumors with increased sensitivity to the delivered payload to improve the therapeutic index. We have discovered multiple derivatizable proprietary ATRis with desirable physicochemical properties that demonstrate low nM potency in cancer cell lines with ATRi sensitizing mutations. Furthermore, the ATRi payloads maintained *in vitro* cytotoxic potency in cells harbouring clinically relevant acquired resistance mutations in Topoisomerase 1, whereas exatecan did not. Once conjugated to the anti-PD-L1 monoclonal antibody, the resulting ADCs demonstrated selective picomolar cellular growth inhibition and excellent metabolic stability in mouse plasma. Preclinical *in vivo* studies in mice demonstrate robust efficacy and selectivity with PD-L1-ATRi as single agent relative to IgG-ATRi. The *in vitro* and *in vivo* data presented herein demonstrate the efficacy of an ADC with an ATRi mono-payload and illustrate the potential for combinations with standard of care chemotherapeutic agents such as gemcitabine or PARP inhibitors.

#5603 Targeting B7-H3 in the small cell lung carcinoma (SCLC) tumor-immune microenvironment (TIME).

Marco Campisi[1], Carla Stornante[1], Ian D. Dryg[2], Harrison Olszewski[3], Alan E. Bers[1], Ian Gillanders[1], Kathleen Pfaff[3], Robert Gentleman[2], Scott Rodig[3], Navin R. Mahadevan[4], David A. Barbie[1]

[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Department of Data Science, Dana-Farber Cancer Institute, Boston, MA,[3]Center for Immuno-Oncology, Dana-Farber Cancer Institute, Boston, MA,[4]Department of Pathology, University of Michigan, Ann Arbor, MI

Introduction: Despite incorporation of immune checkpoint blockade into first line treatment of SCLC, patients have a poor prognosis with limited treatment options. Recent profiling of the SCLC TIME has revealed distinct immunologic subtypes: non-neuroendocrine (non-NE) SCLC, which exhibits robust upregulation of MHC I and immune infiltration, and neuroendocrine (NE) SCLC subpopulations which downregulate MHC I and show an “immune desert” TIME. Therapeutic strategies targeting B7-H3 using the antibody-drug conjugate (ADC), ifinatamab deruxtecan (I-DXd), has shown recent promise in SCLC. In the IDeate-Lung01 trial, patients treated with I-Dxd after ≥1 prior line of chemotherapy showed a disease control rate of 87.6% (NCT05280470). Yet, the mechanism of action on the constituent cells of the SCLC TIME remains relatively unexplored. In this study, we aimed to determine the expression of B7-H3 in the SCLC TIME and consequent susceptibility to I-DXd, of SCLC subpopulations and stromal cells using a SCLC TIME 3D microphysiological system (MPS).

Methods: We initially profiled B7-H3 expression using a human SCLC cell line panel representative of the NE MHC I low (n=3) or non-NE MHC I high (n=4) phenotype, as well as stromal components (endothelial cells, fibroblasts) by flow cytometry. We validated these findings in patient SCLC samples (n=31) using a mIF panel. We then evaluated the direct cytotoxic effect of the I-DXd on SCLC cell lines and stromal components using 2D and 3D *in vitro* cytotoxicity assays. Further, we evaluated I-DXd in a model of vascular networks using an ex vivo MPS. Finally, using the MPS, we assessed the functional impact on vascular structure via permeability assays.

Results: NE MHC I low SCLC cell lines showed low/moderate levels of B7-H3 expression, while non-NE MHC I high SCLC upregulated B7-H3. B7-H3 was also highly expressed by stromal TIME components such as vascular endothelial cells (HUVEC) and human lung fibroblasts (hLFB). While SCLC expression of B7-H3 was more variable in patient samples, and did not show a clear correlation with tumor MHC I expression, stromal cells, particularly endothelial cells showed strong B7-H3 expression, and, in the majority of cases, were the major contributors of B7-H3 expression in the TIME. Non-NE SCLC cells showed sensitivity to I-DXd in a B7-H3 dependent manner in a 2D viability assay, while NE SCLC cells exhibited relative resistance. Experiments using vascular networks in the MPS demonstrated that I-DXd caused increased vascular permeability.

Conclusions: Our study suggests that B7-H3 expression is heterogenous in SCLC and may differ by immunologic subtype. Moreover, our findings suggest that B7-H3 may serve as a target on stromal components of the SCLC TIME. Our results suggest that in addition to the direct targeting of tumor cells, a potential mechanism of action underlying the efficacy of I-DXd may be an increase in vascular permeability.

#5604 TAK-188, an antibody-drug conjugate with a novel amanitin payload, disrupts immune suppression and leads to potent anti-tumor immunity through selective depletion of CCR8$^+$ intratumoral regulatory T-cells.

Cierra N. Casson[1], Eun-Ah Bae[1], Sarah B. Hesse[1], Carla Guarino[1], Rohan Diwanji[1], Tiquella Hatten[1], Adam Hinthorne[1], Jian Huang[1], Ajeeth K. Pingili[1], Judy Qiuju Shi[1], Natasha Iartchouk[1], Brandon Wilkinson[1], Jessica Riceberg[1], Aniko Palfi[2], Natalie Roy D'Amore[1], Torsten Hechler[2], Adnan O. Abu-Yousif[1]

[1]Takeda Development Center Americas, Inc. (TDCA), Cambridge, MA,[2]Heidelberg Pharma Research GmbH, Ladenburg, Germany

Regulatory T cells (Tregs) play a critical role in mediating tolerance to self-antigens and are a major contributor to an immunosuppressive tumor microenvironment (TME). The presence of Tregs in solid tumors is associated with poor prognosis and decreased overall survival in patients, as well as resistance to immunotherapy in several tumor types. CCR8 is a chemokine receptor identified to be highly expressed on tumor-infiltrating Tregs, with lower expression on peripheral Tregs and other cells, making it an attractive target for immunotherapy. Current CCR8-targeting therapeutics in development aim to achieve Treg depletion via Fc-enabled antibody-dependent cellular cytotoxicity, which relies on the presence of effector cells that can vary in frequency and may be functionally inhibited in the TME. In contrast, TAK-188 is a first-in-class anti-CCR8 antibody-drug conjugate designed to facilitate antitumor efficacy by direct cytotoxic depletion of intra-tumoral CCR8$^+$ Tregs using a novel amanitin payload that can kill both dividing and quiescent cells. The specificity and potency of TAK-188 was evaluated preclinically using CCR8-expressing cells, dissociated human tumor samples, and syngeneic tumor models in human CCR8 knock-in mice. The preclinical data showed that TAK-188 specifically bound to and killed CCR8$^+$ cells in vitro. TAK-188 also demonstrated dose-dependent anti-tumor activity in syngeneic tumor models and anti-tumor memory following tumor rechallenge in human CCR8 knock-in mice. TAK-188 selectively killed CCR8$^+$ Tregs in vivo, demonstrating a robust decrease in tumor Tregs and an increase in CD8$^+$ T cells that together resulted in an increased CD8/Treg ratio in the TME. In a mouse syngeneic tumor model, TAK-188 as a single agent was more efficacious than Fc-enabled anti-CCR8 antibodies and shifted the phenotype of immune cells in the TME to be more favorable for anti-tumor activity. Finally, TAK-188 potently and specifically depleted Tregs in dissociated human tumor samples while sparing conventional CD4$^+$ and CD8$^+$ T cells, supporting the mechanism of action of direct tumor Treg killing without the need for exogenous effector cells. In conclusion, TAK-188 robustly depletes CCR8$^+$ cells both in vitro and in vivo and demonstrates anti-tumor activity as a single agent in nonclinical models. Based on this promising preclinical data, a Phase 1 study of TAK-188 has been opened (NCT07205718).

#5605 Advanced dual payload antibody-drug conjugates for targeted chemoimmunotherapy.

X. Margaret Liu, Zhuoxin "Zora" Zhou

The Ohio State University, Columbus, OH

Antibody drug conjugates (ADCs) represent an effective therapeutic strategy for cancers, leveraging cancer-targeting monoclonal antibodies linked to potent payloads. Here, we report several novel conjugation platforms for dual-payload ADCs (DualADCs) that harness antibodies to co-deliver a chemotherapeutic agent, such as microtubule or topoisomerase I inhibitors, for direct tumor cell killing, alongside a toll like receptor agonist to enhance tumoral immunity. Aggressive triple-negative breast cancer was used as the model cancer for evaluating and comparing our DualADCs. Specifically, we developed advanced cysteine and lysine-based coconjugation technologies by linking chemotherapy and immunotherapy with one antibody, designing and optimizing linkers, increasing homogeneity, and refining reaction formulations to increase conjugation rate. The chemo-immunotherapy conjugation was validated with HPLC, and the drug to antibody ratios and drug to drug ratio were quantitated using advanced UPLC MS. The robustness and scalability of our optimal conjugation procedure was validated using spinner flask based reaction. *In vitro* characterizations revealed high cancer binding via flow cytometry, strong cancer specificity with minimal off target in normal human tissues, appropriate binding affinity, efficient drug internalization as revealed by confocal microscopy, and high cytotoxicity in cancer cell lines. *In vivo* evaluations demonstrated favorable tumor biodistribution, high plasma stability, low systemic toxicity, promising therapeutic efficacy in multiple xenograft mouse models, and immune modulation in tumor microenvironment. Collectively, this study establishes advanced dual-payload ADCs and innovative conjugation procedures for targeted chemo-immunotherapy of cancers.

: TCR and Autologous T Cell Therapies
Poster Session

#5609 Mechano-dynamic-principle-driven rational design of next-generation TCRs with high specificity and sensitivity.

Yushen Du[1], **Wei Hu**[1], Luying Liu[2], Suqiong Wang[2], Wei Chen[1]

[1]Zhejiang University, Hangzhou, China,[2]Hangzhou Mechanodynamic Biotechnology Co., Ltd, Hangzhou, China

Background: Naturally evolved T-cell receptors (TCRs) achieve extraordinary antigen specificity through a flexible binding interface that forms force-stabilized catch bonds with cognate peptide-MHC (pMHC) complexes. This critical mechano-regulatory feature is often lost in conventional high-affinity engineered TCRs, whose rigid interfaces can paradoxically cause cross-reactivity with self-antigens and off-target toxicity, a major barrier to safe TCR-based immunotherapies.
Purpose: Building on our prior elucidation of this mechano-regulation mechanism, we aimed to establish a novel engineering platform for designing next-generation TCRs—including TCR mimics, TCR-engineered cells (TCR-T), and T cell engagers (TCEs)—with enhanced specificity and sensitivity, using the KRAS-G12D neoantigen (presented by HLA-A*11:01) as a proof of concept.
Methods: Following an initial screen, top-performing TCR clones were selected for comprehensive characterization. We evaluated their biophysical binding and *in vitro* function (single-molecule force spectroscopy, kinetic-functional mapping, serial tumor killing, memory phenotype differentiation), *in vivo* anti-tumor efficacy (KRAS-G12D cell-derived xenograft models), and safety profile (whole-proteome cross-reactivity screening).
Results: Mechano-optimized TCRs exhibited ~40-fold higher antigen sensitivity in vitro compared to conventional high-affinity TCRs, with no detectable cross-reactivity to wild-type (WT) KRAS; TCR-T cells engineered with these optimized TCRs showed superior serial tumor killing, reduced exhaustion (37% lower PD-1 expression vs. controls), and enhanced differentiation into long-lived memory phenotypes (2.2-fold higher $CD62L^{+}CD44^{+}$ cells); In KRAS-G12D CDX models, mechano-optimized TCR-T cells achieved robust tumor clearance (mean tumor volume reduction of 82% vs. 41% in controls at day 21) and displayed a more infiltrative, less exhausted T-cell phenotype; Whole-proteome cross-reactivity screening confirmed exceptional specificity, with no off-target binding to 10,000+ human proteins.
Conclusions: Our study establishes a mechano-principle-driven paradigm for rational TCR engineering. By translating fundamental insights into TCR-pMHC mechanics into a practical design framework, we generated next-generation TCRs —including TCEs, TCR mimics, and TCR-T cells —with unprecedented specificity, sensitivity, and potency. This platform offers a promising route toward safer and more effective immunotherapies for solid tumors and leukemia. Our lead TCR-T candidate is currently advancing into IND-enabling studies, alongside a complementary in vivo TCR engineering program aimed at expanding the therapeutic reach of this mechano-principled approach.

#5610 Characterization of cancer-reactive T cells and neoantigen-specific T cell receptors.

Wei Sun, Si Liu, Bo Yu, Zhehao Zhang, Philip Bradley, Marie Bleakley

Fred Hutchinson Cancer Center, Seattle, WA

Not all tumor-infiltrating T cells are cancer-reactive (CR). Several studies have reported gene expression signatures associated with CR-T cells. To integrate these findings, we developed a computational workflow, CAT (Cancer-Associated T cells), which harmonizes existing CR-T cell signatures and applies them to identify CR-T cells across an atlas of one million T cells. Our findings reveal that the abundance of CR-T cells varies across cancer types and that baseline levels of CR-T cells predict patients' responses to immunotherapy. In parallel, we established a high-throughput computational platform, Neo-TCR, for systematic screening of neoantigen-specific TCRs and their cognate neoantigens. The efficacy of Neo-TCR is validated by cross-validation studies and replications in two independent datasets. Together, our findings suggest a new direction for developing biomarkers for cancer detection and monitoring: integrating CR gene expression signatures with neoantigen-specific TCRs.

#5611 Adoptive T cell transfer suppresses endogenous tumor-specific CD8$^+$ T cell recovery following lymphodepletion.

Rohan B. Chaudhari, Megan L. Burger

Oregon Health & Science University, Portland, OR

Adoptive T-cell transfer (ACT), where patients are infused with millions of tumor-specific effector T-cells, has proven to be highly effective in hematologic malignancies and is FDA approved as early as a first-line treatment for refractory disease. Unfortunately, extending the benefits of ACT to solid tumors has been largely hindered with challenges intrinsic to solid tumor microenvironments such as intratumoral heterogeneity, where the ACT target antigen is only expressed in a fraction of the tumor. Engaging the endogenous immune system alongside ACT may be one strategy to circumvent the issue of intratumoral heterogeneity by allowing for a broader, more synergistic T-cell response against the tumor. However, the role of endogenous cells in ACT remains poorly understood, and past clinical and preclinical research suggests that ACT does not engage anti-tumor endogenous responses. In this study, we investigated whether ACT and accompanying lymphodepletion may directly suppress the tumor-specific endogenous T cell response in a Kras/p53(KP)-driven autochthonous mouse model of lung adenocarcinoma expressing defined tumor-specific neoantigens, both ACT-targeted and non-targeted. Lung tumor-bearing mice were lymphodepleted (LD) with a standard dose of 150 mg/kg cyclophosphamide intra-peritoneally with or without transfer of 6 million tumor-specific ACT cells intra-vascularly. Our results demonstrate that LD alone depletes endogenous tumor neoantigen-specific CD8 T cells, but these cells largely recover by 3 weeks post-treatment. In contrast, adoptive cell transfer with LD resulted in sustained depletion of endogenous tumor-specific CD8 cells and these cells had reduced expression of effector markers Ki67 (proliferation) and Granzyme B (cytotoxicity). Adoptive cell transfer without LD did not result in a significantly decreased population of endogenous tumor-specific CD8 cells, however results were confounded by a significantly lower number of adoptively transferred cells infiltrating into the lung. These findings suggest that ACT may be playing a suppressive role against the endogenous tumor-specific T cell response when pre-conditioning mice with cyclophosphamide. Further research studying this suppression with lower doses of LD or homeostatic cytokine supplementation (e.g. IL-7/IL-15) could reveal if the suppression is intrinsic to the adoptively transferred cells or cyclophosphamide. Furthermore, future studies into finding ways to overcome this suppression and activate the endogenous immune system, such as neoantigen-targeted vaccination, could be critical to unlocking the full potential of ACT.

#5612 Antigen-specific T cells engineered with nanoparticle photothermal therapy demonstrate antitumor efficacy in an immunocompetent murine model of ovarian cancer.

Abigail V. Lee[1], Erin Grundy[2], Jose Colina[1], Elizabeth Sweeney[1], Rohan Fernandes[3], Nethaji Muniraj[4], Russell Y. Cruz[4], Katherine B. Chiappinelli[1]

[1]George Washington University Cancer Center, Washington, DC,[2]Emory University, Atlanta, GA,[3]Fischell Department of Bioengineering, University of Maryland, Baltimore, MD,[4]Children's National Research Hospital, Washington, DC

Ovarian cancer (OC) is the most lethal gynecological malignancy with less than a 10% response rate to immune checkpoint blockade. Personalized vaccination with tumor lysate-pulsed dendritic cells amplifies T cell responses, including neoepitope-specific T cells, but is not curative. Thus, amplifying the pre-existing tumor-specific T cell response is insufficient. We developed a novel method to expand T cells *ex vivo* for OC specificity using Prussian Blue nanoparticle-photothermal therapy (PBNP-PTT), and verified *in vivo* efficacy using a syngeneic murine model. PBNP-PTT -generated ID8 OC cell lysate was used to stimulate bone marrow-derived dendritic cells (BMDCs) isolated from healthy female C57Bl6 mice. Autologous splenic CD3+ T cells were cocultured *ex vivo* with BMDCs and assessed in vitro for tumor-specific activation and killing using IFNγ ELISpot and MTS cytotoxicity assays. Congenic mice bearing ID8B OC cells received either *ex vivo* expanded T cells or nonspecifically expanded T cells, and the accumulated ascites was profiled for cytokine composition. Adoptively transferred T cells were immunophenotyped with spectral flow cytometry.Ex vivo expansion of T cells with DCs primed using PBNP-PTT-generated OC cell lysate produced a pool of CD8+ T cells with enhanced IFNγ and TNFα secretion in tumor coculture compared to nonspecifically expanded T cells. PBNP-PTT-expanded T cells exhibited greater tumor cell killing at increasing effector-to-target ratios and did not demonstrate off-target IFNγ secretion. Tumor-bearing female C57Bl6 mice receiving OC-expanded T cells lived significantly longer and exhibited decreased tumor burden compared to mice receiving nonspecific T cells. Adoptively transferred T cells expanded with PBNP-PTT lysate also persisted longer in vivo with maintained activation in the ascites, and synergized with concurrent epigenetic therapy to further prolong survival. *Ex vivo* expansion methods using PBNP-PTT were also applied to healthy human blood donors to generate human T cells that demonstrate potent activation when challenged with human OC cell lines. In summary, we developed a novel method of engineering T cells *ex vivo* for specificity against ovarian cancer using nanoparticle photothermal therapy. This study is the first to harness PBNP-PTT *ex vivo* to demonstrate antitumor activity in vivo using an autologous mouse model of ovarian cancer.

#5613 RenTCR-derived MAGEA1-specific TCRs demonstrated superior peptide sensitivity and potent antitumor activity *in vitro* and *in vivo*.

Yi Yang, Yabo Zhang, Jiawei Yao

Biocytogen, Waltham, MA

Background: MAGEA1, a cancer-testis antigen, is broadly expressed in solid tumors such as HCC and NSCLC, but is restricted to the testis in normal tissues, making it an ideal therapeutic target. TCR therapies against MAGEA1 are in preclinical/early clinical stages. Conventional strategies for TCR discovery typically rely on isolation from donor PBMCs or patient TILs. In contrast, Biocytogen's proprietary RenTCR platform enables the generation of TCRs using TCR/MHC humanized mouse models. Lacking thymic negative selection to human antigens, this platform facilitates the identification of TCRs exhibiting higher reactivity and specificity.

Method: RenTCR mice (HLA-A*02:01) were immunized with full-length MAGEA1 mRNA. PBMCs or splenocytes were isolated and stimulated *in vitro* with artificially modified antigen-presenting cells (APCs) presenting MAGEA1. Activated antigen-specific CD8+ T cells were then sorted. Single cells were sorted by FACS for reverse transcription, amplification, and sequencing to obtain TCR sequences. Initial TCR screening used a Jurkat reporter assay for binding. Positive TCRs were transduced into primary human T cells and co-cultured with HLA-A2.1+/MAGEA1+ tumor cells to assess killing and cytokine release. Functional TCR candidates underwent off-target risk assessment, with final anti-tumor efficacy validated in CDX models using NDG mice.

Results: Immunization of 20 mice yielded a total of 80 binding-positive TCRs. The majority of these TCRs mediated potent cytotoxic activity *in vitro*. Assessment of functional avidity showed that TCRs derived from RenTCR mice recognized target peptides with superior sensitivity compared to human donor-derived TCRs. No cross-reactivity was detected in the candidate TCRs. All candidate TCRs demonstrated efficacy by inducing tumor regression in NDG mice bearing HLA-A2.1+/MAGEA1+ tumors.

Conclusion: The RenTCR platform enables the generation of T cell receptors (TCRs) with higher reactivity and specificity. TCRs derived from RenTCR mice exhibited better peptide sensitivity than human donor-derived TCRs. The candidate TCRs demonstrated excellent antitumor activity both *in vitro* and *in vivo*.

#5614 RenTCR-derived natural MAGE-A4-specific TCRs outperformed affinity-enhanced TCRs in antitumor efficacy.

Yi Yang, Yong Wang, Yabo Zhang, Jiawei Yao

Biocytogen, Waltham, MA

Background: MAGE-A4 is a clinically validated target highly expressed in multiple solid tumors, but its expression in healthy tissues is restricted to the testis and placenta. TCR-T cell therapies targeting MAGE-A4 show promising efficacy in synovial sarcoma but exhibit limited efficacy in other solid tumors. Biocytogen's proprietary TCR discovery platform, RenTCR, showed advantages including lower costs and higher efficiency in screening high-reactivity TCRs. Using this platform, we successfully identified TCRs against MAGE-A4 with high reactivity, high specificity, and superior anti-tumor activity.

Methods: TCRs targeting MAGE-A4 were identified using the RenTCR platform. Reporter cell lines were used to rapidly screen reactive TCRs, followed by TCR transduction into primary human T cells to evaluate cytotoxicity, IFN-γ release, and peptide sensitivity. Candidate TCRs underwent cross-reactivity screening and X-scan analysis for safety assessment. To assess *in vivo* antitumor efficacy, NDG mice bearing MAGE-A4^{+} HLA-A2.1^{+} human tumor xenografts were administered human primary T cells transduced via lentiviral vectors with candidate TCRs.
Results: The RenTCR platform identified TCRs targeting two distinct epitopes of MAGE-A4. Two TCRs demonstrated excellent cytotoxicity, IFN-γ release, and specificity *in vitro*. The candidate TCRs also induced tumor regression *in vivo*. RenTCR Platform-derived natural TCRs exhibited better antitumor activity than clinical-stage affinity-enhanced TCRs.
Conclusion: These findings highlight the therapeutic potential of two MAGE-A4-targeting TCR candidates as an effective strategy for treating melanoma, lung cancer, and other solid tumors expressing MAGE-A4.

#5615 ALK-specific TCR-T cells showed potent and specific activity in ALK-positive anaplastic large cell lymphoma.

Simone Piane[1], Carmen Mecca[1], Nirmala Tilija Pun[1], Ana Azambuja[1], Luca Alessandri[2], Phuc Bao Chi Nguyen[1], Elisa Bergaggio[1], Gabriele Saccu[1], Alessandro Gasparetto[1], Haley Ohlson[1], Claudia Voena[2], Marcos Simoes-Costa[1], Roberto Chiarle[1]

[1]Boston Children's Hospital, Boston, MA,[2]Dept. Biomedical Sciences and Human Oncology, University of Torino, Torino, Italy

Introduction: Anaplastic Lymphoma Kinase (ALK)-positive Anaplastic Large Cell Lymphoma (ALCL) is a rare subtype of T-cell lymphoma driven by nucleophosmin 1 (NPM1)-ALK fusion protein. Treatment with standard chemotherapy or ALK tyrosine kinase inhibitor crizotinib is highly effective; however, a significant portion of patients still experience relapses or refractory disease, highlighting the need for innovative therapeutic options. Our group has recently identified two ALK-specific T cell receptors targeting the human ALK peptide RPRPSQPSSL presented by HLA-B*07:02 (B7) and demonstrated specific and robust anti-tumor activity of ALK.TCR-T cells (ALK.TCR-T) in ALK+ non-small cell lung cancer [Mecca et al, Cancer res, 2024]. In this work, we aimed to address the efficacy of ALK.TCR-T in multiple models of ALK+ ALCL.

Methods: Two ALK-specific TCRs were retrovirally transduced into human CD3+ T cells to generate ALK.TCR-T1 and ALK.TCR-T2. The anti-tumor activity of ALK.TCR-T was tested both *in vitro* and *in vivo* against a panel of crizotinib-sensitive and crizotinib-resistant ALK+ ALCL models. The specificity of peptide-MHC recognition was evaluated by employing ALK+/B7+, ALK+/B7-, and ALK-/B7+ cells. For *in vivo* studies, NSG mice were injected intravenously with ALK+ ALCL cell lines, and, after engraftment, treated with ALK.TCR-T, alone or in combination with crizotinib. Mice received 50mg/kg crizotinib by oral gavage for 10 days. Tumor growth was evaluated weekly by bioluminescence imaging.

Results: *In vitro killing assays* demonstrated that both ALK.TCR-T selectively recognize and eliminate 80-100% of ALK+/B7+ ALCL, while no killing occurred in ALK+/B7- or ALK-/B7+ models, confirming that ALK.TCR-T specifically target the ALK peptide RPRPSQPSSL presented by HLA-B*07:02. Moreover, ALK-TCR-T were equally effective in killing crizotinib-resistant ALCL cells, independently of the mechanism driving the resistance to crizotinib. Interestingly, the combination of ALK.TCR-T and crizotinib potentiated the killing of crizotinib-sensitive ALK+ ALCL even at unfavorable E:T ratios (1:5 and 1:10).A single treatment with ALK.TCR-T significantly slowed tumor growth in an ALK+/B7+ systemic tumor model and increased the survival of mice, compared to treatment with irrelevant TCR-T cells. The combined treatment with ALK.TCR-T and crizotinib resulted in a further enhancement of tumor regression and mouse survival, with 50% (5/10) mice with no evidence of tumor 40 days after ALK.TCR-T injection.

Conclusions: We demonstrated that ALK.TCR-T show specific and potent anti-tumor activity against multiple ALK+ ALCL models both *in vitro* and *in vivo*. The combination of ALK.TCR-T and crizotinib further potentiate the ability of ALK.TCR-T to control tumor growth and extend the survival of mice. These results lay the basis for developing a novel immunotherapy strategy for patients with ALK+ ALCL.

#5616 Tumor necrosis factor-alpha armed TCR-T and CAR-T cells for solid tumors provide superior anticancer activity in the absence of toxicity.

Cole W. Peters[1], Miriam Valenzuela Cardenas[2], Moe Kawakami[2], Jaden Nguyen[2], Allison Flores[2], Andrew Dinh[2], Stephen Ma[2], Daniel G. Chen[3], Valerie Rezek[3], Scott Kitchen[3], Katie M. Campbell[1], Melissa Lechner[3], **Theodore Scott Nowicki**[2]

[1]UCLA - University of California Los Angeles, Los Angeles, CA,[2]Pediatric Oncology, University of California, Los Angeles, Los Angeles, CA,[3]University of California, Los Angeles, Los Angeles, CA

Background: TCR-T and CAR-T cells directed against tumor-specific antigens are associated with robust initial clinical responses which are often not durable against solid tumors, demonstrating an urgent need for more potent cell therapy products. We created TNF-alpha (TNF-a) armed variants of TCR-T and CAR-T cells to test their effectiveness and toxicity against a variety of solid tumors.
Methods: Lentiviral vectors encoding the TCR/CAR of interest with or without a supplemental copy of TNF-a were generated for NY-ESO-1 TCR, HPV-16 E7 TCR, and GD2 CAR. Mock, conventional TCR/CAR, and TNF-a armed TCR/CAR T-cells were co-cultured with nRFP-transduced tumor cells expressing the corresponding tumor antigen and appropriate HLA-A haplotype for the TCR-T cells (A375/M257-A2 melanoma cells for NY-ESO-1, 4050/CaSki cervical carcinoma cells for HPV-16 E7, and 143B/G292 osteosarcoma cells for GD2). Cells were subjected to repetitive stimulation assays to assess tumor killing efficiency in the setting of chronic antigen exposure. In parallel, in vivo tumor challenges were performed using humanized NSG mouse xenografts treated with mock, conventional TCR/CAR, or TNF-a-armed TCR/CAR T-cells. Mice were subjected to end of study necropsies to assess end-organ toxicity. T-cell phenotypes in circulation and intratumorally were assessed via flow cytometry, while serum cytokines were assessed weekly via multiplex sandwich ELISA. Tumors were also subjected to spatial transcriptomic analysis via CosMx.
Results: In vitro, TNF-a-armed TCR/CAR T-cells displayed significantly increased tumor cell killing and significantly increased secretion of TNF-alpha both initially and over time, exclusively in a tumor antigen-dependent manner. In vivo, TNF-a-armed TCR/CAR T-cells displayed superior tumor control and mouse survival compared to the corresponding conventional TCR/CAR. Importantly, this superior tumor control occurred in the absence of any systemic increases in TNF-a or IL-6, systemic toxicity (temperature, weight, body condition score), as well as without any differences in end-organ inflammatory damage/lymphocytic infiltration. Tumors treated with TNF-a-armed TCR/CAR T-cells displayed significantly increased T-cell infiltration, as well as significant reductions in intratumoral MDSCs, CD4 Tregs and Th2 cells and associated cytokines, while tumor cells displayed significant increases in TNF-a signaling, and significant decreases in IL-10 immunosuppressive pathways arising from the Tregs.
Conclusions: TNF-a-armed TCR/CAR-T cells possess superior antitumor efficacy against a wide variety of solid tumors, in the absence of any systemic toxicity, due to the antigen-dependent nature of the increased TNF secretion. This is due to both increased local TNF-a secretion and antitumor effector activity, as well as decreased Treg activity within the tumor.

#5617 Humanized antibody Fab-TCR T cells targeting GPC2 effectively regress neuroblastoma via enhanced TCR signaling and sustained cytotoxicity.

Mingyu Huo[1], Alex Quan[1], Dan Li[1], Laura E. Hutchins[1], Constanza Rodriguez[1], Jangsuk Oh[1], Hsi-En Tsao[1], Madeline Spetz[1], Elijah Edmondson[2], Dana Ashworth[3], Rui Zheng[3], Jing Zhou[3], Jinyun Chen[4], Jingbao Liu[4], Guangyan Xiong[4], Hongbing Zhang[4], Cheng Liu[4], Rosa Nguyen[1], Nan Li[1], Mitchell Ho[1]

[1]NIH/NCI, Bethesda, MD,[2]Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Spatomics LLC, Guilford, CT,[4]Eureka Therapeutics Inc., Emeryville, CA

Background and Significance: Chimeric antigen receptor (CAR) T cell therapy has revolutionized the treatment of hematologic cancers but remains less effective against solid tumors, where heterogeneous antigen expression poses a major barrier to efficacy. Neuroblastoma, a pediatric solid tumor with poor survival rates in high-risk patients, often expresses glypican-2 (GPC2), a promising yet variably expressed surface antigen. To overcome these challenges, we engineered antibody-T cell receptors (AbTCRs) that combine antibody-based antigen recognition with the signaling machinery of γ/δ T cell receptors, aiming to promote more physiological activation and sustained antitumor activity in GPC2-positive neuroblastoma.
Methods: We developed AbTCRs containing anti-GPC2 Fab fragments (humanized CT3 or murine CT3) fused to γ/δ TCR constant regions and a co-stimulatory domain, CD30. Primary human T cells were transduced with these constructs and tested through in vitro tumor-killing assays, repeated cytotoxicity tests, western blotting, and in vivo xenograft models bearing GPC2 neuroblastoma (IMR5, NBEB, LAN1, and SH-SY5Y) tumors. The LAN1 and SH-SY5Y models have low GPC2 antigen density, enabling evaluation of efficacy under stringent antigen conditions.
Results: We found strong anti-tumor effects in humanized CT3 AbTCR-T cells, including significant tumor reduction and complete responses in multiple xenograft models. Tumors from mice administered with humanized CT3 AbTCR-T cells showed notably augmented infiltration of $CD8^+$ and $CD8^+CD27^+$ T cells, consistent with enhanced effector persistence. Humanized CT3 AbTCR-T cells demonstrated downregulation of exhaustion markers PD1, LAG3, and TIM3 and an enriched less-differentiated Tscm subset, as assessed by peripheral blood testing. These cells maintained lower PD1 levels after prolonged coculture with tumor cells, and retained cytotoxic activity in second- and third-round killing assays. Mechanistically, upon tumor engagement, hCT3 AbTCRs elicited more robust TCR signaling, evidenced by higher NFAT nuclear translocation and greater phosphorylation of key TCR pathway proteins.
Conclusion: Humanized CT3 AbTCR T cells exhibit durable and potent antitumor effects against low-GPC2 neuroblastoma by combining antibody specificity with physiological TCR signaling. Their enhanced TCR signaling, reduced exhaustion, and sustained cytotoxic ability suggest that AbTCR T cells represent a promising next-generation cellular therapy for solid tumors with heterogeneous or low antigen expression.

#5618 KRASG12V- and CTAG1B-targeted TCR-T cells from phage TCR library suppress colorectal and esophageal tumors.

Obed Boadi Amissah[1], Wenfang Chen[2], Zhiyuan Li[2], Gloria Bora Kim[1]

[1]Mayo Clinic Arizona, Scottsdale, AZ,[2]Guangzhou Institutes of Biomedicine and Health, Chinese Academy of Sciences, Guangzhou, China

Background: Colorectal cancer (CRC) remains a leading cause of cancer-associated mortality and is difficult to treat due to therapy resistance and limited durable responses. Esophageal cancer (EC) is similarly challenging, exhibiting highly aggressive and metastatic behavior that contribute to its poor prognosis. Adoptive TCR-engineered T cell (TCR-T) therapies show promise in these settings, but their efficacy is limited by suboptimal antigen specificity and an immunosuppressive tumor microenvironment (TME). To address these barriers, we isolated high-affinity TCRs from a phage-displayed TCR library targeting KRASG12V neoantigen in CRC and CTAG1B cancer/testis antigen (CTA) in EC.

Methods: KRASG12V$_{(8\text{-}16)}$/HLA-A11:01-restricted and CTAG1B$_{(157\text{-}165)}$/HLA-A02:01-restricted TCRs were isolated from an optimized phage-displayed TCR library generated from healthy donor CD8$^+$ T cells through high-throughput biopanning. Binders were screened against antigen-family peptides and irrelevant controls by phage ELISA to eliminate cross-reactivity. Binding affinities were measured by SPR. Antigen-specific TCRs (asTCRs) were cloned into lentiviral vectors and transduced into primary human T cells. TCR-T function was assessed using peptide-pulsed T2 cells and KRASG12V$^+$ or CTAG1B$^+$ tumor cells through LDH-release cytotoxicity and cytokine secretion assays. Normal human cells were used to evaluate off-target toxicity. *In vivo* antitumor activity was tested in NOD/SCID-IL2rγ$^{-/-}$ xenografts with histological confirmation of TCR-T infiltration.

Results: Next-generation sequencing confirmed that the 10^9-scale library contained >90% functional genes and >80% sequence diversity. Three high-affinity TCRs were identified for each antigen (K_D as low as 1.07 μM). These TCRs exhibited strict antigen specificity with no detectable cross-reactivity. TCR-T cells expressing asTCRs showed potent antigen-dependent cytotoxicity against KRASG12V$^+$/HLA-A11:01$^+$ colorectal and CTAG1B$^+$/HLA-A02:01$^+$ esophageal tumor cells (up to 80% lysis, $p<0.01$), accompanied by robust IFN-γ and TNF-α secretion (>1000 pg/mL, $p<0.01$). No killing was observed against any of seven healthy cell types. TCR-T cells remained effective at low effector-to-target ratios and maintained stable proliferation and effector-memory phenotypes. In xenograft models, KRAS- and CTAG1B-targeted TCR-T cells induced significant tumor regression compared to unmodified T cell controls ($p<0.05$), with increased effector TCR-T infiltration, and reduced antigen escape.

Conclusions: This work establishes a rapid and robust platform for isolating potent, safe, antigen-specific TCRs targeting both oncogenic driver mutation (KRASG12V) and an immunogenic CTA (CTAG1B). TCR-T cells demonstrated strong antitumor activity *in vitro* and *in vivo*, supporting the translational potential of this approach for solid tumor treatment.

#5619 First-in-class anaplastic lymphoma kinase (ALK)-specific TCR-T cells induce potent and selective antitumor immunity across ALK-driven human cancers.

Carmen Mecca[1], Simone Piane[1], Nirmala Tilija Pun[1], Ana Azambuja[1], Luca Alessandri[2], Rafael Blasco[1], Chi Nguyen Puc Bao[1], Elisa Bergaggio[1], Gabriele Saccu[1], Alessandro Gasparetto[1], Haley Ohlson[1], David A. Barbie[3], Ellis L. Reinherz[4], Marcos Simoes-Costa[1], Roberto Chiarle[1]

[1]Pathology, Boston Children's Hospital, Boston, MA,[2]Universita Degli Studi di Torino, Turin, Italy,[3]Lowe Center Thoracic Oncology, Dana Farber Cancer Institute, Boston, MA,[4]Department of Medical Oncology, Dana Farber Cancer Institute, Boston, MA

Introduction: Anaplastic Lymphoma Kinase (ALK) tyrosine kinase inhibitors (TKIs) have dramatically improved outcomes for patients with ALK-rearranged non-small cell lung cancer (NSCLC) and other ALK-positive (ALK+) cancer types. However, the near-universal emergence of resistance underscores an urgent need for new, durable therapeutic strategies. Leveraging our prior identification of the ALK-derived peptide RPRPSQPSSL presented by HLA-B*07:02 (PMID: 37430060), we aimed to develop ALK-specific TCR-engineered T cells (ALK.TCR-T) that can selectively recognize and eliminate ALK-driven tumors.

Methods: HLA-B*07:02 transgenic mice were vaccinated with the RPRPSQPSSL peptide. After two priming and two booster injections, $CD137^{+}/CD8^{+}$ T cells were sorted and subjected to single-cell sequencing for TCR discovery. The most expanded TCR clonotypes were then cloned and retrovirally transduced into human T cells to generate ALK.TCR-T cells. The anti-tumor activity of ALK.TCR-T cells was evaluated against various models of ALK+ tumors both *in vitro* and *in vivo*.

Results: From twelve dominant clonotypes, six ALK-specific TCRs were identified. Two (ALK.TCR-1 and ALK.TCR-2) demonstrated >95% ALK-dextramer binding. Notably, ALK.TCR-2 bound the ALK-dextramer also in $CD4^{+}$ T cells, indicating co-receptor-independent peptide-MHC recognition. Both TCRs mediated robust, antigen-specific cytotoxicity against ALK+/HLA-B*07:02+ cell lines, with no activity against mismatched targets. Engineering either EML4;ALK variant 3 or HLA-B*07:02 into non-expressing cells restored potent killing, confirming strict peptide-MHC specificity. *In vivo*, a single infusion of ALK.TCR-1 or ALK.TCR-2 markedly suppressed tumor growth and extended survival in a metastatic ALK+/HLA-B*07:02+ NSCLC model. Treated animals exhibited near-complete tumor clearance by day 7 post-ALK.TCR-T infusion, while control mice experienced progressive disease. Remarkably, in a metastatic ALK+/HLA-B*07:02+ neuroblastoma model, 70% (7/10) of mice achieved complete, durable responses (>100 days tumor-free) without evidence of on-target/off-tumor or off-target toxicity.

Conclusion: We report the first generation of ALK-specific TCR-T cells targeting the naturally presented ALK peptide RPRPSQPSSL in the context of HLA-B*07:02. ALK.TCR-T cells display potency, selectivity, and safety across multiple ALK-driven tumor models, providing a strong rationale for advancing ALK.TCR-T cell therapy into clinical development.

#5620 Development of T cell receptor (TCR) based cellular therapy for fibrolamellar HCC uncovers role of TCR in CD4 T cell differentiation.

Kayla J. Bendinelli[1], Allison M. Kirk[2], Marina Baretti[3], Abigail M. Gottschall[1], Heng-Chung Kung[1], Jeric Peter Hernandez[4], Waqar Arif[3], Julie Nauroth[3], Jennifer Durham[3], Christopher Thoburn[3], Amanda Huff[3], Neeha Zaidi[5], Alexei Hernandez[3], Hassan Jamaleddine[6], Timothy N. West[6], Justin McCallen[5], George Coukos[7], Alexandre Harari[8], Challice L. Bonifant[3], Elizabeth Jaffee[3], Won Jin Ho[3], Gregoire Altan-Bonnet[6], Paul G. Thomas[9], Mark Yarchoan[10]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Host-Microbe Interactions, St. Jude Children's Research Hospital, Memphis, TN,[3]Johns Hopkins University, Baltimore, MD,[4]JOHNS HOPKINS UNIVERSITY, Baltimore, MD,[5]Oncology, Johns Hopkins Hospital, Baltimore, MD,[6]National Cancer Institute, Bethesda, MD,[7]UNIL University of Lausanne, Lausanne, Switzerland,[8]Harari (Individual), Lausanne, Switzerland,[9]Fred Hutchinson Cancer Center, Seattle, WA,[10]Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Background: Fibrolamellar carcinoma (FLC) is a rare and often lethal liver cancer that primarily affects children and young adults. There is no approved systemic therapy for FLC. The FLC transcriptome is defined by an in-frame fusion of exon 1 of *DNAJB1* with exons 2-10 of *PRKACA*, resulting in expression of the chimeric oncoprotein DNAJ-PKAc. Direct pharmacologic inhibition of this oncoprotein has been infeasible due to unacceptable on-target toxicity. However, the shared, tumor-specific expression of DNAJ-PKAc presents an opportunity for neoantigen-targeted immunotherapy.

Methods: We are conducting an ongoing clinical trial of a peptide vaccine targeting DNAJ-PKAc in combination with immune checkpoint inhibitors. We used single-cell sequencing and functional assays to identify DNAJ-PKAc-specific T cell receptors (TCRs) from peptide-expanded peripheral blood cells of trial participants. We characterized their HLA restriction, avidity, cytotoxicity, cytokine profiles, and differentiation phenotypes using co-culture systems.

Results: We identified seven $CD4^+$ TCRs that recognize DNAJ-PKAc in the context of HLA-DRB1*13:01 (n=2) or HLA-DRB3*01:01 (n=5). When introduced into healthy donor T cells and co-cultured with tumor cells expressing the corresponding HLA allele, these TCRs exhibited variable functional avidity, cytokine production, differentiation, and cytotoxic activity against DNAJ-PKAc-pulsed targets. Among them, JHU12-TCR2 (*HLA-DRB3*01:01-restricted*) mediated the strongest cytokine production and tumor cell killing despite only moderate avidity. Consistent with this, JHU12-TCR2 showed the greatest *in vivo* expansion in the original patient, who achieved a near-complete response to immunotherapy. In contrast, a fusion-specific TCR identified from a non-responder, JHU8-TCR2, that shares sequence similarities and clusters with JHU12-TCR2, demonstrated limited cytotoxicity *in vitro*. Interestingly, although all TCRs recognized the same antigen in matched donor T cells, they drove divergent helper T cell differentiation programs. For example, JHU12-TCR2 favored Th1/Th17 polarization with minimal Treg induction, whereas JHU8-TCR2 promoted a Th2-biased phenotype.

Conclusions: We identified and functionally characterized multiple $CD4^+$ TCRs specific for the DNAJ-PKAc oncoprotein, highlighting their potential utility as the basis for TCR-based therapy in FLC. A clinical trial of JHU12-TCR2-based TCR therapy for patients with FLC and HLA-DRB3*01:01 is in development. These findings also suggest that variation in vaccine-induced TCR repertoires may contribute to differences in clinical response, and that intrinsic biophysical or signaling properties of individual TCRs can shape the differentiation fate of $CD4^+$ T cells expressing them.

#5621 The GPC3-targeting hYP7 antibody-based gamma/delta TCR-T cell therapy for overcoming antigen mutation and heterogeneity in liver cancer.

Dan Li[1], Tianyuzhou Liang[1], Hsi-En Tsao[1], Zhijian Duan[1], Laura E. Hutchins[1], Madilyn Gaydos[1], Iris Yang[1], Elijah Edmondson[1], Xiaoshan Wang[2], Rui Zheng[2], Jing Zhou[2], Chin-Hsien (Emily) Tai[1], Jing Bian[1], Maggie Cam[1], Hongbing Zhang[3], Cheng Liu[3], Mitchell Ho[1]

[1]National Cancer Institute, Bethesda, MD,[2]Spatomics, Guilford, CT,[3]Eureka Therapeutics, Inc, Emeryville, CA

Antigen mutation and heterogeneous expression remain major barriers to effective antibody- and chimeric antigen receptor (CAR)-based immunotherapies for hepatocellular carcinoma (HCC). Glypican-3 (GPC3) exhibits variable surface density and epitope alteration in advanced or recurrent HCC tumors. To address these clinically relevant obstacles, we developed a modular antibody-based γ/δ T-cell receptor (γδAbTCR) platform that integrates antibody specificity with intrinsic TCR-CD3 signaling to enhance tumor recognition under conditions of antigen variation. Using two GPC3 antibodies recognizing distinct epitopes (hYP7 and HN3), we generated four γδAbTCR constructs—hYP7-hYP7, hYP7-HN3, HN3-hYP7, and HN3-HN3—and evaluated their functional properties in primary human T cells. Among these, hYP7-hYP7 γδAbTCR-T cells demonstrated the strongest antigen binding and cytotoxic activity against Hep3B and other GPC3$^+$ HCC models, particularly those with low or heterogeneous antigen density. In vivo, hYP7-hYP7 T cells showed superior tumor infiltration, persistence, and control of large, established xenografts compared with other configurations. Mechanistic studies revealed that the hYP7-hYP7 γδAbTCR architecture couples enhanced antigen-binding avidity with coordinated TCR-CD3 and CD30 signaling, leading to potent NF-κB and NFAT activation and rapid induction of caspase-mediated apoptosis in tumor cells. These findings establish hYP7-hYP7 as a lead γδAbTCR design that overcomes the limitations of antigen heterogeneity and mutation in liver cancer, providing a promising framework for next-generation T-cell therapies targeting liver cancer.

#5622 Development of allogeneic TCR-mimic activating gdT (TAG-T) cells targeting KRAS^{G12D}/HLA-A*11 pMHC for undruggable KRAS-mutated cancers.

Chia-Chun Chao[1], Hsin-Yu Chang[2], Wei-Ze Hong[1], Jhen-Yu Chen[3], Yi-Wen Jiang[3], K.S. Clifford Chao[3], Kevin Chih-Yang Huang[3]

[1]NDV Therapeutics Corp., HsinChu City, Taiwan,[2]National Yang Ming Chiao Tung University, HsinChu City, Taiwan,[3]China Medical University, Taichung City, Taiwan

The therapeutic antibodies are at the vanguard of the most promising cancer treatments. Whereas conventional therapeutic antibodies have been limited to extracellular antigens, T cell receptor mimic (TCRm) antibodies can target intracellular antigens presented by cell surface major histocompatibility complex (MHC) proteins. We successfully obtained KRAS^{G12D}/HLA-A*11-specific TCRm antibodies from a phage display using a human scFv library. The affinity and target binding specificity of TCRms was validated by SPR and flow cytometry. Then, the KRAS^{G12D}/HLA-A*11-specific TAG receptor was designed as a double-chain, TCR-based construct, with the KRAS^{G12D}/HLA-A*11-specific TCRm fused to the N-terminus of the human TCR-Cγ and TCR-Cδ chain with Furin-P2A linker sequence. *In vitro* and *in vivo* cytotoxicity assays demonstrated that the KRAS^{G12D}/HLA-A*11-specific TAG-T cells exhibited high cytotoxic activity against KRAS^{G12D}/HLA-A*11-positive cells. Furthermore, TAG-T cells engineered with a co-stimulatory domain and a chimeric switching receptor (CSR) showed the highest anticancer activity and proliferation both *in vitro* and *in vivo*. Therefore, our results demonstrate that the TCRm-based TAG-T platform targeting KRAS^{G12D}/HLA-A*11 represents a novel and promising allogeneic cell therapy strategy for patients with KRAS-G12D-positive cancers.

#5623 Novel mechanism for eliminating tumor collagens to boost efficacy by attIL12-TIL therapy in PDX sarcoma models.

Jiemiao Hu[1], Harjeet Singh[1], Yining Jin[1], Wendong Zhang[1], Jian Wang[1], Xueqing Xia[1], Neeta Somaiah[2], Richard Gorlick[1], Shulin Li[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Assistant Professor, UT MD Anderson Cancer Center, Houston, TX

Tumor-targeted T-cell therapies of various types have been booming, but T-cell therapy is limited by its inability to penetrate the collagen barrier that “stuffed” within tumors and surrounding tumors/tumor cells. Compared to normal human tissues, sarcoma tissues exhibited significantly higher density of collagens and extracellular matrix (ECM) determined via bulk RNAseq and Masson’s trichrome staining. The destruction of tumor collagen is significant because collagen does not only suppresse T cells but also contributes to the formation of the extracellular matrix. In this study, for the first time, we used three pairs of autologous sarcoma patient-derived xenograft (PDX) and autologous tumor infiltrating T cells (TILs) models to discover that CCKAR directly boosts collagen production by tumor cells in vitro and in vivo. attIL12-modified TILs disabled collagen production from CCKAR-high autologous tumor cells in vitro and in vivo. This attIL12-TILs induced disruption of tumor cell derived collagen production required a simultaneous interaction between two signaling pathways: 1) the CSV on autologous tumor cells, which is targeted by attIL12, and 2) HLA-TCR on attIL12-TILs; when either interaction was abrogated, collagen production and CCKAR expression were not shut down. Mechanistically, the dual signaling activation between attIL12-TILs and autologous tumor cells synergistically induced super high IFNγ production in tumors, which in combination with CCKAR downregulation reduced collagen expression through suppression of both TGFβ-stimulated SMAD activation and CCKAR-AKT signaling. Diminishing collagen expression from tumor cells significantly increased T-cell infiltration and improved tumor growth inhibition in PDX sarcomas. This study revealed for the first time that CCKAR, which is highly expressed in immunotherapy resistant sarcomas, may serve as a novel target for reducing tumor collagens. attIL12 modification mediated collagen disrupting reversed the lost tumor penetration function of TILs post ex vivo expansion, resulting in sarcoma tumor regression that TILs alone fail to achieve. Thus, this attIL12-TIL therapy holds great clinical potential for boosting T-cell infiltration in high-grade, collagen-rich tumors.

#5624 Clinical strategies to enhance the efficacy of tumor-infiltrating lymphocyte (TIL) therapy using preclinical models.

Asraa Ahmed[1], Jonathan F. Khan[2], Sadna Budhu[2], Jedd D. Wolchok[2], Taha Merghoub[2]

[1]Pharmacology, Weill Cornell Grad. School of Medical Sci., New York, NY,[2]Sandra and Edward Meyer Cancer Center, Weill Cornell Medical College, New York, NY

Advanced metastatic melanoma refractory to immune checkpoint blockade (ICB) remains exceedingly difficult to treat, highlighting the need for alternative immunotherapeutic strategies. Due to the immunosuppressive mechanisms within the tumor microenvironment (TME), the infiltration and effector function of tumor-associated antigen (TAA) and neoantigen-specific CD4+ and CD8+ tumor-infiltrating lymphocytes (TILs) are limited, allowing the tumor to escape immune surveillance and hinder the endogenous immune response. Adoptive cell therapy (ACT) of autologous, ex-vivo expanded TILs was recently approved as a second line of therapy for advanced metastatic melanoma patients refractory to ICB. Despite positive responses observed in a subset of patients, many fail to respond, highlighting the urgent, unmet need to identify strategies which improve TIL-ACT efficacy. We have shown that a lower precursor frequency of self-antigen-specific CD8+ T cells enhances the quality of the antitumor response, whereas self-antigen-specific CD4+ T cells are susceptible to exhaustion at the same frequencies. These preliminary findings suggest that clonal abundance plays a critical role in determining T cell functional state—an unexplored area in the context of TIL therapy efficacy. ICB reinvigorates exhausted T cells under certain conditions, however, whether ICB can also reprogram exhaustion that arises as a consequence of dysregulated precursor frequency or subset composition is unknown. We hypothesize the efficacy of TIL therapy is determined by antigen-specific precursor frequency and T cell subset composition, and combining TIL-ACT with ICB will reprogram the exhausted T cells to sustain the hostile TME. To investigate this, we transferred varied precursor frequencies of neoantigen and tumor associated antigen-specific CD4+ and CD8+ T cells into tumor-bearing mice. Preliminarily, we have found antigen-specific CD4+ T cells to modestly enhance the anti-tumor response to ACT, however, this effect is not mediated through effector function and tumor control. This suggests that antigen-specific CD4+ T cells provide a helper role in ACT products. Next, we have shown upregulated immune checkpoint expression on ex vivo expanded TILs using flow cytometry and aim to assess combinatorial strategies with ICB to improve anti-tumor immune response. Further, we aim to investigate how precursor frequency and CD8+/CD4+ T cell ratio impacts TIL-ACT response by spiking in exogenous transgenic, antigen-specific T cells in the TIL product at varied frequencies.

#5625 Epigenetic reprogramming of T cell exhaustion.

Tsunghan Hsieh, Ruomin Xin, Enchong Zhao, Xiao Tian

Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA

During tumor progression, T cells are recruited to the tumor microenvironment (TME), where T cells experience hypoxia, nutrient deprivation, immunosuppressive cytokines, and continuous stimulation by tumor antigens. These harsh conditions drive global epigenetic remodeling of T cells and promote their transition into a state of T cell exhaustion, characterized by impaired capacity in proliferation, reduced production of proinflammatory cytokines, and diminished self-renewal. Immune checkpoint blockade (ICB) treatment has revolutionized cancer therapy; however, it fails to reprogram the exhaustion-associated epigenetic landscape and therefore only partially restores T cell functions. Here, we aim to prevent T cell exhaustion by targeting this epigenetic landscape through ectopic expression of epigenetic reprogramming factors (ERFs). To this end, we first generated a mouse model with inducible ERF expression, isolated CD8+ T cells, and cultured them under hypoxic conditions with continuous stimulation, to mimic the TME. Under these conditions, ectopic expression of ERF factors significantly downregulates expression of exhaustion markers such as Tim3. We next assessed whether ERF-mediated reprogramming can restore the T cell function. In vitro, ERF-reprogrammed T cells exhibit increased durability compared to non-reprogrammed control T cells in response to exhaustion signals. In vivo, ERF-reprogrammed T cells, when transferred into tumor-bearing mice, significantly delays the tumor growth compared with transfer of non-ERF-expressing control T cells. Transcriptomics profiling further reveals that ERF reprogramming upregulates the genes involved in T cell activation, proliferation, and epigenetic remodeling. Collectively, these data support ERF-mediated reprogramming of T cells as a promising strategy to reshape the entrenched exhaustion-associated epigenetic landscape and restore T cell functions, with the potential to improve adoptive cell transfer (ACT)-based therapy such as Tumor-Infiltrating Lymphocytes (TIL) and Chimeric Antigen Receptor (CAR) T therapy.

#5626 Combination epigenetic therapy unmasks non-canonical neoantigens to improve adoptive T cell therapy in ovarian cancer.

Jose A. Colina[1], Katherine B. Chiappinelli[1], Erin E. Grundy[1], Conrad Russell Y. Cruz[2]

[1]The George Washington University, Washington DC, DC,[2]Children's National Health System, Washington, DC

Immunotherapy has revolutionized cancer treatment across a range of malignancies, yet its efficacy in ovarian cancer (OC) has remained limited due to low tumor mutational burden and limited neoantigen availability. While current immunotherapy strategies have struggled to achieve durable responses, adoptive T cell therapy (ATT) combined with epigenetic therapies that expand the antigenic landscape present a promising avenue to overcome the inherent challenges of immune resistance in OC. Epigenetic remodeling can increase tumor immunogenicity as well as de-repress “cryptic antigens”, that are normally transcriptionally silent yet selectively expressed in malignant cells. These cryptic antigens arise from mis-splicing, alternative open reading frames, and endogenous retroelements that generate HLA-restricted peptides recognizable by T cells. Their selective expression in cancer cells and immunogenicity highlight the actionability of these non-canonical targets for immunotherapy. We treated four OC cell lines with DNA methyltransferase and histone deacetylase inhibitors and identified a reproducible subset of upregulated protein-coding cryptic antigens, including endogenous retroviruses (ERVs) and other endogenous retroelements. We then generated an overlapping peptide library spanning the identified targets to prime and expand T cells from PBMCs of healthy donors. The resultant T cell products demonstrated robust proliferation, antigen-specific cytokine production, and high-avidity responses across multiple peptide pools. Functional avidity assays confirmed specific recognition of epigenetically induced antigen targets. These results demonstrate that epigenetic therapy can uncover a previously inaccessible tumor-specific antigen pool in OC and enable the generation of potent T cell products directed against these cryptic antigens. Leveraging epigenetic induction of cryptic antigen expression may thus provide path a to expand the target landscape for ATT and improve therapeutic efficacy in ovarian cancer.

#5627 Intermittent cyclophosphamide and vinorelbine combined with anti-PD-1 induce transferable T-cell-mediated antitumor immunity and long-term memory in TNBC mouse models.

Stefania Orecchioni[1], D'Ambrosio Lorenzo[2], Davide Lombardi[3], Anna Vaccari[3], Paola Nistico'[4], Francesco Bertolini[3], **Paolo Falvo**[3]

[1]European Institute Of Oncology, Milano, Italy,[2]Tumor Immunology and Immunotherapy Unit, IRCCS-Regina Elena National Cancer Institute, Rome, Italy,[3]IEO - European Institute of Oncology, Milan, Italy,[4]IRCCS-Regina Elena National Cancer Institute, Rome, Italy

Cell-based immunotherapies offer a powerful means to harness treatment-induced antitumor immunity for durable tumor control. We previously developed a Triple-Therapy (TT) regimen combining vinorelbine-mediated activation of antigen-presenting cells (APCs) with cyclophosphamide-driven induction of TCF1$^+$ stem-cell-like T cells (scTs), markedly enhancing anti-PD-1 efficacy in resistant tumor models. The TT protocol consists of three intermittent doses of vinorelbine, and cyclophosphamide administered every six days, together with five anti-PD-1 doses delivered every two days.In a Non-Hodgkin Lymphoma (NHL) model, TT not only achieved strong tumor regression but also conferred long-term immunological memory, as evidenced by protection upon tumor rechallenge. Extending these findings to triple-negative breast cancer (TNBC), TT induced comparable antitumor activity. To determine whether TT-elicited immunity could be adoptively transferred, immunocompetent BALB/c mice bearing 4T1 TNBC were treated with TT, and immune tissues—including blood, spleen, and lymph nodes—were collected and transferred into syngeneic BALB/c nude mice inoculated with the same tumor.Strikingly, transfer of peripheral blood from TT-treated donors significantly delayed tumor growth, indicating that circulating immune cells are sufficient to convey protection. In contrast, lymphocyte depletion abolished this effect. Selective ablation of CD4$^+$ or CD8$^+$ T cells—performed either by flow cytometric sorting or using neutralizing antibodies—also eliminated the therapeutic benefit, confirming their essential role in the transferable antitumor response.Overall, these findings demonstrate that TT induces systemic, memory-forming T-cell responses capable of mediating cell-transferable tumor control. Current work focuses on identifying the tumor antigens recognized by TT-induced T cells, with the ultimate goal of developing targeted therapeutic vaccines to extend these benefits to broader patient populations.

#5631 TCX-201, a novel ADC targeting a specific tumor-associated carbohydrate antigen (TACA) with excellent preclinical efficacy, PK and safety profile in solid tumor models.

Matthias Ocker, Francesco Muraca, Stephan Grunwald, Wiebke Winkler, Karla E. G. Soto, Carolin Lange, Jean Engela, Peter Sondermann

Tacalyx GmbH, Berlin, Germany

Tumor-associated carbohydrate antigens (TACAs) are defined oligosaccharide structures that are expressed on the surface of cancer cells. They are derived from changes in glycosylation pathways associated with malignancy, which lead to overproduced or aberrant structures, and represent a still unexplored target class for cancer therapy. We have generated specific antibodies against several of these difficult to target antigens and obtained a high affinity, fully humanized monoclonal antibody (mAb), TCX-201, against one of these TACAs, highly expressed across a broad range of cancer indications, including various gastrointestinal cancer types as well as NSCLC. This mAb shows superior internalization, affinity, and specificity for the target compared to the available benchmark, as assessed by glycan array, flow cytometry, and immunohistochemistry or immunofluorescence. Three ADC-variants were created by conjugation with MMAE (DAR 4), Exatecan (DAR 8), and Deruxtecan (Dxd, DAR 8) via a cleavable linker and were subsequently analyzed regarding their potency. *In vitro* studies showed effective killing of various pancreatic and colon cancer cell lines expressing different levels of the TACA (e.g. HuP-T4 (high expressing, IC50 of 0.3 nM), Capan-2 (heterogeneous expression, IC50 of 1.03 nM), Colo-205 (high expressing, IC50 of 0.013 nM), LS180 (medium expressing, IC50 of 4.7 nM). Moreover, high efficacy was observed for the tested payloads in different xenograft models with weekly iv administration: Capan-2 pancreatic cancer (reaching T/C of 16% and 6% at 3 and 7 mg/kg MMAE, respectively and T/C of 27% with 7 mg/kg Dxd) and Colo-205 colorectal cancer reaching T/C of 3% with 7 mg/kg MMAE. In addition to CDX models, PDX *in vitro* screening on PDAC and CRC models showed highly effective killing in 5/8 PDAC PDX and 2/5 CRC PDX with TCX-201 MMAE. These results, coupled with a favorable PK and safety profile make this ADC a first-in-class molecule for the treatment of various solid tumors that express different levels of the target structure.In conclusion, our antibody represents a new promising treatment option for different cancer indications and can be effectively employed as an ADC using different payloads.

#5632 Enhancing dual-payload ADC discovery projects by overcoming heterogeneity and resistance through dual-payload innovation.

Ying Meng, Lili Chai, Wei Liu, Xue Yang, Min Kang, Rui Song, Zhengtai Li, Yan Zhang, Zhiwei Bao, Ying Bi, Yixiao Zhao, Wange Fan, Xiao Li, Li Li, **Tiejun Bing**

ICE Bioscience, Beijing, China

Dual-payload antibody-drug conjugates (ADCs) have emerged as an innovative promising next-generation ADC format, delivering two cytotoxic agents to enhance efficacy through synergistic effects, mitigate resistance, without an accompanying increase in toxicity risk, aiming to address the challenge of poor-responsive cancers and rapid patient relapses. The success of dual-payload ADCs hinges on the appropriate dual-payload combination.DNA-damage response (DDR) inhibitors are increasingly being evaluated as payloads for ADCs, with Topoisomerase 1 (Top 1) inhibitors being the most commonly used class. Top 1 inhibition traps DNA breaks at replication forks, simultaneously blocking the DDR pathway severs the repair escape route, leading to replication catastrophe and selective synthetic-lethal cell death.To identify a rationally designed dual-payload combination that overcomes tumor heterogeneity and conventional resistance of colorectal cancer (CRC), synergistic pairs of Top 1 inhibitors and a group of DDR inhibitors with different mechanisms were screened and evaluated. Single payload activities were first investigated in CRC cell panel, and dual-payload combination synergies were then assessed in some selected CRC cell lines and ADC-related drug-resistant cell lines. A pair of Top 1 inhibitor + CHK inhibitor combination showed significant potent synergy in CRC cell lines and ADC-related drug-resistant cell lines with 2D and 3D cytotoxicity evaluation models. Mechanistic studies of this combination were further explored with cell cycle and apoptosis studies, WB of biomarkers, as well as RNA-Sequencing, revealing that the synergy stemmed from coordinated cell cycle arrest and enhanced apoptosis induction, supported by transcriptomic profiling of DDR pathways. Critically, the dual-payload combination showed no increased toxicity in a group of healthy human cell lines and limited or additive hematotoxicity in the in vitro CD34+ HSPCs myeloid progenitor cell proliferation and differentiation assays, indicating a potentially improved therapeutic window. These study strategies and findings accelerate dual-payload ADC innovative research, especially in the stage of proof of concept for dual-payload combination as a promising strategy to overcome cancer heterogeneity and resistance

#5633 YB-811, a novel antibody drug conjugate targeting the tumor-selective human neuronal pentraxin receptor shows pronounced efficacy in experimental tumor models.

Peter Schiemann[1], Michel Janicot[1], Gunther Wennemuth[2], Mykola Lyndin[2]

[1]Ymmunobio AG, Riehen, Switzerland,[2]University Hospital Essen, Essen, Germany

The human neuronal pentraxin receptor (NPTXR) gene encodes a type II transmembrane protein that functions as a trans-synaptic organizer and anchors neuronal pentraxin complexes to plasma membranes in a subset of neuronal cells of the hippocampus and cerebral cortex. Beside its synaptic functions in the brain, NPTXR is not present in other organs and therefore does not have any physiological role; hence *NPTXR*$^{-/-}$mice showed no abnormalities in reproduction, development, metabolism, or motor function. Recent immunohistochemistry studies performed with a fully humanized monoclonal antibody (YB-800) targeting NPTXR with high affinity have revealed expression of membrane-associated NPTXR protein in a wide variety of solid tumors (but not in adjacent healthy tissues and healthy tissue samples) with a high prevalence (up to 98%) and H-scores (up to 300); e.g., in bladder, cervix, non-TNBC, NSCLC, and pancreas tumor samples. These results strongly support the rationale for the design of a YB-800-based antibody drug conjugate (ADC) as novel option for safe therapeutic intervention in Oncology. A novel ADC (YB-811) was engineered with YB-800 linked to 4 monomethylauristatin F molecules (*via* non-cleavable linkers), and 4 exatecan molecules (*via* cleavable linkers). YB-811 was evaluated in multiple experimental tumor models in both cell-based assays and *in vivo* tumor studies. Results clearly indicate concentration- and time-dependent effect on tumor cell proliferation and survival, as well as pronounced anti-tumor activity - tumor growth inhibition/regression - in established tumor-bearing athymic mice. Taken together, these results strongly support further exploration of the potential therapeutic benefit of YB-811.

#5634 KY102, a novel Glypican 3-targeting nanobody drug conjugate bearing a topoisomerase 1 inhibitor payload demonstrates compelling preclinical activity in hepatocellular carcinoma models.

Haikun Shi

Hangzhou kunyu pharmaceutical, Hangzhou, China

Background: Glypican-3(GPC3), a cell-surface oncofetal glycoprotein highly expressed in hepatocellular carcinoma (HCC) with minimal presence in normal adult tissues. KY102 is a nanobody-drug conjugate (NDC)targeting human GPC3, composed of a monovalent nanobody covalently conjugated to a topoisomerase 1 inhibitor, DXD. via a maleimide anchor and a glycyl glycyl phenylalanyl glycine (GGFG)- aminomethyl (AM) cleavable linker at a drug to nanobody ratio (DAR) of 3.
Materials and Methods: Extensive functional characterization was performed to assess the mechanism of action and therapeutic potential of the KY102 (NDC) at DARs of 3.
1.Nanobody binding to human,cynomolgus monkey rat and mouse GPC3 was assessed by biolayer interferometry (BLI) and flow cytometry(FACs).
2.Am assessment of off-target binding, and target specificity was conducted using 177-Lu labeled Nanobody in normal and cell line derived animalmodel.
3.KY102 nanobody internalization in GPC3-expressing tumor cell lines was assessed by flow cytometry.
4.In vitro KY102 (NDC) cytotoxicity against tumor monolayers was assessed in a panel of HCC cell lines.
5.Tumor cell co-culture assays were also performed to assess bystander-mediated cell killing by KY102.
6.Anti-tumor activity of KY102 was investigated in a panel of cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) mouse models representing a range of GPC3 expression.
7.The tolerability of KY102 was assessed in a single dose and repeat-dose (4 doses; once every weeks) non-GLP toxicology study in a cell line-derived xenograft (CDX) in mice.
Results:
1.The KY102 nanobody backbone demonstrated pico-molar binding affinity to both human, cynomolgus monkey, rat and mouse GPC3, and strong binding to target-expressing cancer cell lines.
2.Rapid internalization of KY102 nanobody was observed in GPC3-expressing HCC cell lines.
3.KY102 exhibited potent and target-specific cytotoxicity in a panel of HCC cells cultured either in monolayer.
4.KY102 showed effective bystander-mediated killing of GPC3 negative cancer cells when in co-culture with GPC3 positive cancer cells.
5.A single administration of KY102 (2.5mg/kg and 5.0 mg/kg) resulted in robust tumor growth inhibition of a panel of CDX and PDX models representing a range of GPC3-expression.
6.A single dose and a repeat-dose mouse toxicology study of KY102 showed encouraging tolerability at 30, and 60 mg/kg dose levels.
7.A dose-dependent nanobody pharmacokinetics at 2.5 mg/kg, and 5 mg/kg dose levels, without the maximum tolerated dose (MTD) determined.
Conclusions: Overall, these results support the potential of KY102 as a novel therapeutic agent against GPC3-bearing cancers including HCC. An IND application is anticipated in 2026. No conflict of interest

#5635 Rational design of a bispecific ADC targeting ITGB4 and TROP2 for co-expressing solid tumors.

Mi Young Cha, **Jiyoung Lee**, Hyunkyung Yu, Hyunuk Kim, Youngeun Ha, Bu-Nam Jeon, Seungmin Byun, Kitae Park, Mira Kim, Han-Sol Kim, Wuhwui An, Hyonam Kim, Sang-Gyun Kim, Hansoo Park

Genome & Company, Suwon-si, Korea, Republic of

Integrin beta 4 (ITGB4) was identified as a promising tumor-specific antigen through the GNOCLE™ platform. ITGB4 is highly expressed in head & neck, colorectal, esophageal, and other solid tumors, but shows minimal expression in matched normal tissues by immunohistochemistry, supporting a favorable therapeutic window. ITGB4 promotes epithelial detachment, migration, and invasion, and its high expression is associated with therapy resistance and poor prognosis. Target profiling further revealed the frequent co-expression of ITGB4 and TROP2 in multiple cancers, including pancreatic, lung, bladder, and HER2-negative breast cancers, with minimal overlap in normal tissues, supporting the tumor-selective potential of ITGB4/TROP2 co-targeting. TROP2-targeting antibody-drug conjugates (ADCs) have been actively developed, with several already approved for the treatment of solid tumors. However, relatively high TROP2 expression in normal epithelia can drive on-target/off-tumor toxicity, thereby restricting the therapeutic index of TROP2-targeting ADCs. This highlights an unmet need for strategies that preserve the antitumor benefit of TROP2 targeting while improving tumor selectivity. Leveraging the complementary biology of ITGB4 and TROP2, we designed a bispecific ADC targeting ITGB4 and TROP2 to preferentially deliver cytotoxic payloads to dual-positive cancer cells, thereby increasing therapeutic effect and expanding the therapeutic window. To construct the bispecific antibody, we combined the variable region of sacituzumab with our humanized anti-ITGB4 antibody, GENA-120B17. Guided by target affinity and relative expression, we generated 1+1 and 2+2 valency formats to optimize efficacy and selectivity. The bispecific antibodies showed enhanced internalization in TROP2/ITGB4 double-positive cancer cells compared with sacituzumab or GENA-120B17, without increased uptake in target-negative cancer cells or normal cells. These bispecific antibodies were then conjugated, via a hydrophilic, cleavable linker (LinkerE) designed to reduce retro-Michael elimination, to either a topoisomerase I inhibitor or a microtubule inhibitor. The resulting bispecific ADCs exhibited superior in vitro cytotoxicity in double-positive cancer cell lines relative to the corresponding monospecific ADCs, while maintaining a safer profile in normal cells. In conclusion, this bispecific ADC design broadens the therapeutic index and offers a safer, more effective treatment approach that addresses key limitations of existing TROP2-targeted ADC therapies.

#5636 Preclinical evaluation of LM-338: An innovative anti-STn antibody drug conjugate for solid tumors.

Jin Li, Junwei Yang, Yuan Li, Te Du, Xia Qin, Da Fei, Lei Shi, **Wei Cao**

LaNova Medicines, Shanghai, China

Background: Sialyl-Thomsen-nouveau(STn)antigen is a truncated O-glycan generated by early sialylation of the Tn antigen. While with limited expression in normal tissues, STn is overexpressed in numerous human carcinomas, including ovarian, breast, bladder, cervical, colon, pancreatic and lung cancers. LM-338, a STn-targeted antibody-drug conjugate (ADC), is comprised of a humanized monoclonal antibody (LM-138) conjugated to a topoisomerase I inhibitor via a cleavable linker, with a drug-antibody ratio of 4.
Methods: Target binding activity of LM-338 was assessed by flow cytometry. Internalization was evaluated using a pH-sensitive dye. Binding specificity was evaluated using glycan array. Cytotoxic and bystander effects were measured using CellTiter-Glo luminescent cell viability assay. In vivo anti-tumor activity of LM-338 was examined in several STn-positive cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models. Immunohistochemistry was used to assess STn expression in tumor tissues. Toxicity was evaluated inrepeated-dose toxicity study in rhesus monkeys.
Results: LM-338 showed high binding activity and specificity to STn with minimal cross-reactivity to sialyl-T-antigen. LM-338 bound to and was internalized by STn-positive tumor cells in a dose-dependent manner, resulting in potent cytotoxic and bystander effects in vitro. *In vivo*, LM-338 (3 or 6 mg/kg) induced significan tumor growth inhibition or regression across multiple CDX and PDX models (ovarian, colorectal and lung cancers), with superior efficacy as compared to a DXd-conjugated comparator. LM-338 was well tolerated in non-human primates at dosed up to 60 mg/kg.
Conclusion: LM-338, an anti-STn ADC, demonstrated potent anti-tumor activityacross several solid tumor models with favorable preclinical tolerability. These findings support further clinical development of LM-338 for patients with STn-expressingmalignancies.
Keywords: STn, antibody-drug conjugate, LM-338, solid tuomrs, ovarian cancer, colorectal cancer, lung cancer
Disclosure: The study was funded by LaNova Medicines Limited, China.

#5637 A novel EGFR and B7H3 dual-targeted antibody-drug conjugate (ADC) for the treatment of solid tumors.

Mingkun Zhang[1], Xuguo Zhu[1], Jun Wang[2], Jing Zhao[1]

[1]NeoMab Biotechnology Co,. Ltd, Suzhou, China,[2]GemPharmatech LLC., San Diego, CA

Background: EGFR (also known as HER1) is an epidermal growth factor receptor involved in tumor progression, and its overexpression in approximately 70% of colorectal cancer (CRC), 60% of lung cancers, and over 90% of head and neck squamous cell carcinoma (HNSCC). B7H3 belongs to the B7 immunoregulatory family. B7H3 is overexpressed on a wide range of solid tumors such as lung cancers, gastrointestinal cancers and gynecological cancers, but its expression is absent or low in normal tissues. Therefore, dual targeting of both EGFR and B7H3 can achieve better therapeutical efficacy. EGFR/B7H3-ADCs are novel bispecific Antibody-drug Conjugates (ADCs), composed of fully human anti-EGFR/B7H3 bispecific antibodies (BsAbs) conjugated to TOP1i payload via cleavable linker.
Methods: the fully human monoclonal antibodies were derived from transgenic mouse model NeoMab mice. Flow cytometry was performed to examine binding of ADCs to tumor cells. In addition, we used pHrodo conjugated to ADCs to detect internalization activity in tumor cells. CTG (CellTiter-Glo®) assay was employed to measure cell viability. In immunodeficient mice, xenograft model was generated to assess the tumor growth inhibition of ADCs.
Results: EGFR/B7H3-ADCs showed stronger binding to tumor cells than EGFR-ADC and B7H3-ADC. Besides, EGFR/B7H3-ADCs displayed superior internalization activity. More importantly, our EGFR/B7H3-ADCs suppressed tumor growth more effectively than EGFR-ADC and B7H3-ADC in CDX mouse model.
Conclusion: our EGFR/B7H3-ADCs show potential therapeutic promise in patients with EGFR or B7H3 positive tumors. This study provides crucial rationale for supporting the further development of our novel dual-targeted Antibody-drug Conjugates (ADCs).

#5638 A first-in-class photo-responsive EGFR-ADC drives ROS-mediated, energy-dependent tumor eradication in preclinical models.

Wentao Shang[1], Hua Shang[2], Josie Cai[2], Vicky Qin[2], Lyan Chen[2], Xiaobo Zhang[1]

[1]School of Basic Medicine and Clinical Pharmacy, China Pharmaceutical University, Nanjing, China,[2]Shanghai Biophy Biological Pharmaceutical Co., Ltd., Shanghai, China

Light-activated antibody-drug conjugates (ADCs) represent an emerging class of precision therapeutics that enable spatial and temporal control of cytotoxicity. By restricting payload activation to illuminated tumor sites, this modality can enhance local potency while limiting systemic toxicity. We developed Cetuximab-I21-2, a next-generation EGFR-targeted ADC incorporating a Heloporfin-derived photosensitizer engineered for high singlet-oxygen yield, serum stability, and rapid photochemical activation upon exposure to red light near 650 nm. This architecture integrates receptor-mediated tumor localization with externally programmable activation, enabling precise, on-demand cytotoxicity.
