Results: Among survey participants (n=49), 69% practiced at the main campus and 31% at satellite clinics. Although 96% viewed clinical trials as important to patient care, 45% indicated gaps in knowledge of trial accrual. Inner setting barriers differed by site, with 74% of providers at the main campus compared to 20% at satellite clinics citing limited staffing support for clinical trials (p=0.003). Outer setting barriers showed less variation, with 64% of providers at the main campus and 53% at satellite clinics reporting limited language translation resources (p=0.44). Qualitative interviews (n=15) reinforced these CFIR domains; limited access to research coordinators, time constraints, and language translation emerged as key barriers. Provider motivation and interest in trials accrual training were identified as key facilitators to optimize trial enrollment.
Discussion: Barriers to optimal clinical trial recruitment include gaps in provider knowledge, staffing limitations, and insufficient language resources, all of which may constrain equitable enrollment. Despite these challenges, providers remained motivated to offer trials to their patients. Advancing enrollment requires co-designed solutions with providers and clinic teams to address system level and patient barriers. Targeted interventions - such as provider training, enhanced access to trial information, and translation services - may improve inclusive enrollment.

#1393 Design of a prospective implementation study to evaluate the efficacy of an AI-assisted workflow intervention to increase breast cancer clinical trial participation.

Jacob T. Rosenthal[1], Emma Hahesy[2], Sulov Chalise[3], Zhigang Zhang[4], Menglei Zhu[3], Mert R. Sabuncu[5], Anyi Li[6], Lior Zvi Braunstein[7]

[1]Tri-Institutional MD-PhD Program, Weill Cornell Medicine, New York, NY,[2]Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Pathology and Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Department of Epidemiology & Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY,[5]School of Electrical and Computer Engineering, Cornell University and Cornell Tech, New York, NY,[6]Department of Medical Physics, Memorial Sloan Kettering Cancer Center, New York, NY,[7]Memorial Sloan Kettering Cancer Center, New York, NY

We previously developed and retrospectively validated an AI-integrated workflow for conducting rapid, accurate, and cost-effective automated clinical trial eligibility prescreening, but it remains unknown whether this tool can increase trial accrual rates when implemented in real-world clinical workflows. To evaluate its impact on practice, this prospective, controlled implementation study will use a periodic on-off design in which participating clinicians alternate monthly between the AI-assisted workflow and usual care. During intervention periods, the Memorial Sloan Kettering Multi-Agent Trial Coordination Hub (MSK-MATCH) system will conduct automated eligibility prescreening for all upcoming new patient visits. For cases triaged by the AI system for secondary human review, a clinical research coordinator (CRC) will use a secure web interface to verify predictions and resolve ambiguities. The results of this human-in-the-loop eligibility prescreening will be compiled into a single summary report delivered directly to each attending physician in advance of their scheduled clinic each week. The primary endpoint is the rate of accrual to any breast radiation oncology therapeutic clinical trial within 60 days of initial visit. Secondary endpoints include (1) the number of patient-trial pairs evaluated for trial eligibility, and (2) the mean cost of all screening activities per screened pair. Statistical analysis will use a two-sided paired t-test comparing intervention and control periods within each clinician. At the conclusion of the study, semi-structured interviews will be conducted to collect feedback and assess perceptions of this AI workflow intervention among participating clinicians and CRCs. This study is planned to begin in January 2026 in the breast radiation oncology service at Memorial Sloan Kettering Cancer Center. With an enrollment target of 2,500 new patient visits, the design provides 80% power to detect a minimum absolute difference in accrual rate of 1.57% with a type I error rate $\alpha = 0.05$. An interim analysis for efficacy and futility is planned after 1,250 visits, anticipated in June 2026. This quality-improvement study is IRB-exempt, and waivers have been added to all trial protocols to cover screening activities. Findings from this study will provide evidence to guide the responsible and effective adoption of AI-based workflow interventions in clinical oncology.

#1394 Effect of biopsy requirement on patient enrollment to phase I trials in cancer.

Catherine Yang[1], Mona Yuan[1], Sebastian Saenz[1], Marisa Palmeri[1], Mohammad Ghalib[2], Dina Oz[2], Diana Nelson[2], Rita M. Musanti[2], Devika Rao[3], Eugenia Girda[2], Francis Kang[1], Sanjay Goel[2]

[1]Robert Wood Johnson Medical School, New Brunswick, NJ,[2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[3]Memorial Sloan Kettering Cancer Center, New York, NY

Background: A recent trend in clinical trials is the requirement of biopsies (Bx), sometimes mandatory. The main reason is to better understand cancer biology pharmacodynamic effect. We sought to determine whether the requirement for Bx among this vulnerable population had any detrimental effect.

Methods: We included patients (pts) enrolled in phase I trials from June 2022-August 2025 at a single NCI-designated comprehensive cancer center. Data collected included sex, race, age, body mass index (BMI), dates of consent/treatment start/last dose/off treatment/last contact/death, serum lab values, number of prior treatments, metastatic sites, and Bx site/approach/complications. An interventional radiologist reviewed images to assess safety, with targets deemed appropriate biopsied under image guidance. Outcomes were analyzed by Mantel-Cox test in Prism GraphPad v10.

Results: 228 pts [male (n=104, 45.6%)], age 60.5, 23-82 (median, range), NHW-130 (57%), NHB-37 (16.2%), Hispanic-34 (14.9%), and Asian-27 (11.8%) consented to 25 clinical trials. Of these, 8 were mandated paired tumor Bx, 15 mandatory or optional Bx, and 2 did not require Bx. The most common diagnoses were colorectal (54, 23.7%), pancreas (29,12.7%), other GI (26, 11.4%), lung (18, 7.9%), breast (12, 5.3%), prostate (5, 2.2%), and others (84, 36.8%). Image guidance included ultrasound 74 (57.8%), CT scans 49 (38.3%), and others 5 (3.9%). Overall, 91 (39.9%) pts provided 128 Bx samples; 37 paired Bx, 49 only pre-dose Bx, and 5 only on-study Bx. Five pts did not undergo Bx because it was deemed unsafe/high risk. Sites of Bx included liver 63 (49.2%), lung 13 (10.2%), lymph node 15 (11.7%), peritoneum 8 (6.3%), bone 1 (0.8%), and others 28 (21.9%). Two patients developed pneumothorax and recovered without sequelae. The median duration from consent to start of study treatment was 18.5 days among Bx pts vs. 14 among non Bx pts ($p = 0.001$). The median duration of time on study was 62 days among Bx pts vs. 66.5 days among non Bx pts ($p = 0.08$). The overall survival (OS), calculated as time from first dose of treatment to death/last follow up, was 123 days among Bx pts and 163 days among non Bx pts ($p = 0.049$).

In a univariable model, sex (males/women; HR 1.37; p=0.02), albumin (high/low, HR 0.47, p=0.0001), neutrophil-lymphocyte ratio (low/high, HR 0.68, p=0.003), hemoglobin (high/low, HR 0.71, p=0.01), BMI (high/low, HR 0.72, p=0.02), and AST (high/low, HR 0.68, p=0.004), were significant, while age, race/ethnicity, total bilirubin, platelet, ALT, # sites of metastases, and # prior lines of therapy were not.

Conclusions: 40% of pts entering phase I trials underwent study specific Bx, had a median delay of 4.5 days in receiving the first dose of study medication and experienced lower OS by 41 days. Multivariable modeling will be presented to fully understand the intriguing observation of a compromise in OS among patients who underwent biopsies.

#1396 Streamlining combined clinical trial and diagnostic device development: The EMA COMBINE Project Pilot.

Louis-Guillaume Marquier

Biotrial, Rennes, France

The EMA's COMBINE project, is a new pilot initiative designed to streamline the regulatory assessment of trials that combine a medicinal product with an in vitro diagnostic (IVD), such as a companion diagnostic. Currently, these trials must comply with two separate EU regulatory frameworks, the Clinical Trials Regulation (CTR) for medicines and the In Vitro Diagnostic Regulation (IVDR) for diagnostics. This results in duplicative submissions, misaligned timelines, and a substantial administrative burden for sponsors. COMBINE introduces a coordinated, "all-in-one" assessment, enabling sponsors to submit one single submission through the CTIS and to receive unified information requests and approvals from EU authorities. The aim of the pilot is to evaluate whether a harmonized approach can shorten review timelines, enhance cross-country alignment between regulators and ethics committees, and to support a more efficient development of drug-diagnostic combinations. Observations generated through the pilot phase will help shape the future expansion of other possible integrated trial assessments within the EU regulatory framework. This poster provides an overview of the COMBINE project and highlights the core objectives: reducing regulatory submission complexity, supporting integrated precision-medicine development, and improving patient access to innovative therapies and diagnostics.

#1397 Genomic Relational Privacy in AI Era: a scoping review.

Ying Huang[1], Emily Boja[2], Jaime Guidry Auvil[1]

[1]National Cancer Institute, Bethesda, MD,[2]National Cancer Inst. - Bethesda Campus, Rockville, MD

Objective: The concept of privacy is ever evolving and commonly defined as an individual's "right to be let alone". It has been shown that it is foundationally insufficient to address the challenges and opportunities presented by blooming of genomic data, where one individual's decision regarding genomic information to consent to data sharing can directly impact the privacy of their biological and social relations. This scoping review maps the evolution of privacy theory and systematically examines the legal, ethical, and technological conflicts and governance models at the intersection of genomics and artificial intelligence (AI). **Methods:** A scoping review was conducted in 2025 following the Joanna Briggs Institute (JBI) methodology. Systematic searches were performed in three major databases (up to August 2025) - Westlaw, PubMed, and Web of Science databases including foundational privacy scholarship, modern relational and critical data theories, U.S. case law, federal statutes (HIPAA, GINA), international regulations (GDPR), and technical papers on AI and Privacy-Preserving Machine Learning (PPML). **Results:** From 1412 initially retrieved records and after 3 phases of screening, we included 56 studies. The review identified a fundamental and growing conflict between individualistic legal frameworks (based on personal consent) and the interdependent nature of genomic data. Key findings are: (1) The "relational turn" in privacy theory provides a more accurate analytical lens by focusing on context, power imbalances, and interdependence rather than solely on individual control. (2) Escalating real-world conflicts—evident in law enforcement's use of familial DNA searching, DTC data breaches, and clinical "duty to warn" dilemmas—demonstrate the failure of current legal models. (3) AI acts as a powerful risk-amplifier, using its inferential power to deduce familial relationships and perpetuate bias, driven by the economic incentives of surveillance capitalism. (4) A suite of PPML tools (e.g., federated learning, differential privacy) offers technical mitigation, but these are not substitutes for robust ethical governance and risk being co-opted. **Conclusion:** A modernized governance framework for genomic data is a critical and urgent need. This framework shall expand upon, not replace, individual rights, while it should be capable of governing complex, competing interests. We conclude that a durable solution requires a multi-pronged approach based on relational privacy, contextual integrity, and the imposition of legally enforceable fiduciary duties on the powerful entities that steward our collective genomic data.

#1398 Thematic trends in cancer research from sub-Saharan Africa: Insights from a five-year institutional dataset.

Adedayo Joseph[1], Funmilayo Aina-Tolofari[2], Ayodeji O. Ojetunde[2], Philip Ejeikwu[2], Lilian Ekpo[2], Tolulope Adewole[3]

[1]Lagos University Teaching Hospital, Nigeria, Nigeria,[2]Medserve-LUTH Cancer Centre, Lagos University Teaching Hospital, Lagos, Nigeria,[3]Medserve Nigeria Limited, Nigeria Sovereign Investment Authority, Nigeria, Nigeria

Background: The emergence of cancer centres of excellence such as the Medserve - LUTH Cancer Centre (MLCC) in sub-Saharan Africa, provides a unique opportunity to examine evolving research priorities within the region. This study characterizes the thematic distribution, methodological orientation, and funding sources of cancer research output from MLCC over five years (October 2020 - October 2025), offering insights into the maturation of Africa's oncology research landscape.
Methods: A retrospective analysis of the MLCC Research Unit's database was conducted, encompassing all completed manuscripts, abstracts, and ongoing projects. Studies were categorized by disease site (breast, lung, pediatric, gynecologic, prostate, CNS, and cross-cutting), research type (clinical, implementation, translational, educational), and funding origin (institutional, national, international, or industry). Temporal trends were analyzed to assess the evolution of research priorities from descriptive to interventional studies.
Results: A total of 155 publications were identified between 2020 and 2025, comprising articles (70%), abstracts (25%), and posters (5%). Annual output increased more than twofold, from 14 in 2020 to 33 in 2025. Dominant research themes included radiotherapy (n=32), breast (n=23), prostate (n=22), and pediatric cancer (n=17). Early outputs (2020-2021) were primarily descriptive clinical audits and radiation technique utilization studies, while later years (2023-2025) demonstrated a shift toward implementation trials, navigation interventions, molecular characterisation, and technology-driven quality improvement. Collaborative and industry-supported studies rose steadily, accounting for over 30% of research activity by 2025. A keyword heatmap revealed progressive diversification, from "radiotherapy" and "access" in early years to "precision," "financial navigation," and "quality assurance" in recent outputs. Multi-institutional collaborations with partners across North America, Europe, and Africa. International collaborations accounted for 20% of total projects, and funded trials increased from 1 to 8 across the period.
Conclusion: This five-year institutional analysis illustrates a rapid transition in SSA cancer research from descriptive documentation toward hypothesis-driven, interventional, and data-integrated inquiry. The MLCC experience underscores the transformative potential of structured research governance, mentorship, and global partnerships in shifting Africa's oncology research from capacity building to capability and innovation.

#1399 Analysis of regulatory and scientific activities of SFDA oncology and hematology section in sixteen months.

Tariq Hassan AL Qurayshah, SFDA Oncology & Hematology Group

Oncology and Hematology, Saudi Food and Drug Authority, Riyadh, Saudi Arabia

Introduction

Amid the global acceleration of the clinical development of drugs and biologics in oncology and hematology, the Saudi Food and Drug Authority (SFDA) established the Oncology and Hematology (OH) Section to evaluate the efficacy and safety of those drugs. We describe here the OH Section role in advancement of oncology-related regulatory science and policy in Saudi Arabia.

Methodology

We summarize scientific and clinical activities related to the OH efficacy and safety led by OH section's experts from July 2024-October 2025 using the OH excel database.

Results

The SFDA established OH section in July 2024 to evaluate the clinical efficacy and safety of applications of new clinical trials, new OH drugs and biologics and new clinical variations. The section is responsible for the expedited clinical review and designation of orphan drugs in rare OH diseases, breakthrough medicines in high unmet medical need in OH, fast-track and accelerated OH approvals based on validated surrogate endpoints. The OH section presented the oncology efficacy and safety considerations for OH approvals in Saudi Arabia including indications that received expedited review (based on validated surrogate endpoints) or regular review based on evident clinical benefits such as overall survival and patient reported outcomes. Since October 2024, experts in OH section participated with five abstracts in two AACR meetings. The section, experts also are participating in the development of guidelines and recommendations as follows:

- Early-phase clinical development of CAR T cells for patients with hematologic malignancies
- Biomarker and tissue agnostic oncology drug development
- Patient-Reported Outcomes (PROs)
- Regulatory considerations for use of minimal residual disease (MRD) for treatment hematologic malignancies
- Development of products in rare cancers and pediatrics
- Development of products in sickle cell disease
- Gene therapy in hematological diseases

Also, the experts were qualified to join national and international relevant committees and working groups:

- ICH working group: E22 General Considerations for Patient Preference Studies
- The National Scientific Committee in the Saudi Cancer Institute

Moreover, the OH section was responsible for

- The clinical development of the first in-house chimeric antigen receptor T-cells (CAR-T) in Saudi Arabia for acute lymphoblastic leukemia (ALL).
- Positive efficacy and safety opinions granted for at least 10 OH indications as first regulatory drug authority ever.
- First global regulatory approval for mitapivat in thalassemia

Conclusion

Since the formal establishment of the OH section in July 2024, OH experts contributed in hundreds of scientific and regulatory activities related to for OH products including developing clinical guidelines, evaluating the safety and efficacy, and facilitating the timely introduction of OH products and indications.

#1400 Addressing the EU IVDR challenge in targeted oncology trials.

Margaret Curnutte

IVD Regulatory Consulting, Precision for Medicine, Frederick, MD

The European Union (EU) In Vitro Diagnostic Regulation (IVDR 2017/746) went into effect May 2022, dramatically changing the regulatory requirements for oncology clinical trials using an in vitro diagnostic (IVD) for patient enrollment. Sponsors developing experimental targeted oncology drugs are grappling with the new regulatory framework, which lacks alignment between drug and device regulations. This means sponsors may have to manage two parallel submissions and processes: a clinical trial for the drug and a separate performance study for the IVD used for patient selection, adding significant complexity, coordination, and potential delays. This poster outlines key considerations and best practices for drug sponsors managing these requirements. We explore preliminary options to avoid parallel studies—such as running the assay at a qualified Health Institution or utilizing a CE-marked assay—before detailing the necessary steps when a separate device study is unavoidable. The poster provides practical guidance for managing the dual studies that can be required under the new EU IVDR, focusing on two key areas. First, it addresses the critical decision of device sponsorship, clarifying the roles and responsibilities (including regulatory submissions, monitoring, and adverse event reporting) that must be defined between a drug sponsor and a device manufacturer in a partnership. Second, it highlights integrated oversight, outlining crucial areas for coordination where the two studies overlap, such as qualification of clinical trial sites, informed consent forms, shared study objectives, site personnel roles, and joint safety reporting responsibilities. The poster offers actionable insights and lessons learned to help oncology drug sponsors achieve clinical trial readiness in this new regulatory landscape.

#1401 A novel statistical framework for surrogate endpoint prediction of survival in neoadjuvant breast cancer trials.

Keli S. Santos-Parker[1], Jessica R. Santos-Parker[1], W. Fraser Symmans[2], Laura J. Esserman[1], Christina Yau[1], Angie DeMichele[3], Laura van't Veer[1], Doug Yee[4], Fabien Reyal[5], Helena Earl[6], Jean Abraham[6], David Cameron[7], Peter Hall[7], Judy Boughey[8], Matthew Goetz[8], Gabe Sonke[9], Miguel Martin[10], Sara Lopez-Tarruella[10], Priyanka Sharma[11], Rachel Freiberg[1], Jane Perlmutter[12], Aditya Bardia[13], Martin Eklund[14], Rachel Freiberg[1], Lajos Pusztai[15]

[1]Surgery, UCSF - University of California San Francisco, San Francisco, CA,[2]Pathology, MD Anderson Cancer Center, Houston, TX,[3]Medical Oncology, University of Pennsylvania, Philadelphia, PA, USA, Philadelphia, PA,[4]Medical Oncology, University of Minnesota, Minneapolis, MN,[5]Department of Surgery, Institut Curie, Paris, France,[6]Department of Oncology, University of Cambridge, Cambridge, United Kingdom,[7]Department of Oncology, Western General Hospital, Edinburgh, United Kingdom,[8]Surgery, The Mayo Clinic, Rochester, MN,[9]Medical Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands,[10]Instituto de Investigacion Sanitaria Gregorio Maranon, Madrid, Spain,[11]Kansas University Medical Center, Kansas City, KS,[12]The Gemini Group, Ann Arbor, MI,[13]University of California, Los Angeles, Los Angeles, CA,[14]Karolinska Institutet, Stockholm, Sweden,[15]Yale University, New Haven, CT

Introduction

Pathological complete response (pCR) is a strong prognostic marker, but survival outcomes comparing treatment to control do not reliably align with treatment-control differences in pCR rates in breast cancer. A novel Bayesian hierarchical framework models treatments within trials, allowing us to predict treatment effects on distant recurrence-free survival (DRFS) from pCR with greater accuracy.

Methods

We analyzed 12 neoadjuvant breast cancer trials (6,000 patients, all HR/HER2 subtypes; including I-SPY2). The framework of Burzykowski, Molenberghs & Buyse (2005) is extended to a novel arm-based hierarchical structure providing a distribution of pCR and DRFS treatment effects controlling for subtype (HR/HER2), N and T stage, grade, and calendar year. Three held-out trials (877 patients; 26 regimens; med follow-up >4 years) validate predictions of DRFS treatment benefit from pCR. All data was used to estimate treatment-effect correlation and the surrogate threshold effect (STE). Analyses were repeated for Residual Cancer Burden Index (binary RCB01, continuous RCB).

Results

Predicted probability of DRFS benefit closely matched actual DRFS follow-up (mean absolute error 0.06; Pearson r = 0.9). Across all trials, pCR showed moderate surrogacy ($\rho = 0.82$, $R^2 = 0.67$). A 60% increase in pCR odds achieves ≥95% probability of DRFS benefit (STE = OR of 1.60). RCB outperforms pCR across all metrics, with 92% sensitivity and 93% specificity for detecting DRFS benefit in 26 validation regimens (Table 1).

Conclusion

This novel Bayesian meta-analytic framework reveals that pCR, RCB01 and continuous RCB reliably predict survival benefit across heterogeneous trials, with RCB performing the best in an external validation. This provides a statistical foundation for accelerated approval decisions using robust early biomarkers in modern neoadjuvant trial designs by accurately predicting survival at the treatment arm level.

Table 1

	Predicted vs. Actual DRFS Benefit: *26 Held Out Regimens*				**Overall Data Surrogacy Measures**		
	Sensitivity	Specificity	Mean Absolute Error	Pearson r	rho Median Pr[rho>0.5]	R^2 Median PR[R^2>0.5]	STE
pCR	0.83	0.71	0.06	0.90	0.82 (0.87)	0.67 (0.67)	OR 1.60
RCB01	0.91	0.80	0.06	0.94	0.90 (0.95)	0.80 (0.83)	OR 1.37
RCB	0.92	0.93	0.05	0.95	0.89(0.96)	0.80 (0.82)	-9.3%
	Pr[DRFS benefit] > 0.5 Decision threshold used for Sensitivity and Specificity. STE Surrogate Threshold Effect: improvement needed for ≥95% posterior probability of DRFS benefit						

#1402 Real world clinical outcomes with trastuzumab deruxtecan in HER2 expressing ovarian and endometrial cancer.

Oladunni Alomaja[1], Jordyn F. Silverstein[2], Maryam Hajiabbasi[3], Eliya Shachar[2], Shivani Thaker[2], Beth Karlan[4], Aditya Bardia[2], Gottfried E. Konecny[2], First two authors contributed equally and share first authorship

[1]UCLA David Geffen School of Medicine, Los Angeles, CA,[2]Division of Hematology/Oncology, Department of Medicine, University of California, Los Angeles (UCLA), Los Angeles, CA,[3]Department of Medicine, University of California, Los Angeles (UCLA), Los Angeles, CA,[4]Department of Obstetrics and Gynecology, David Geffen School of Medicine at UCLA, Los Angeles, California., Los Angeles, CA

Background: Trastuzumab deruxtecan (T-DXd), a HER2-directed antibody-drug conjugate, is an FDA-approved treatment option for HER2-expressing (IHC 2+/3+) recurrent endometrial (EC) and ovarian cancers (OC) based on DESTINY-PanTumor02. Real-world evidence remains limited.
Methods: We conducted a retrospective study of all patients with recurrent or metastatic OC or EC who received T-DXd between September 2022 and November 2025 at a single academic medical center. Primary endpoints were real-world objective response rate (ORR), disease control rate (DCR; by radiology reports) and median time on treatment (mTOT). Secondary endpoints were median progression-free survival (mPFS), and overall survival (mOS), estimated by Kaplan-Meier.
Results: Thirty-three patients received T-DXd (17 OC, 16 EC, Table 1). The ORR and DCR were 42.4% (14/33) and 66% (22/33), including 4 complete responses and 6 partial responses. The mTOT was 5.5 months (mos) (IQR 1.4-7.6). ORR by HER2 IHC score was 83% for 3+, 42% for 2+, and 0% for 1+. Patients with IHC 1+ had a DCR of 100% and mTOT of 7.3 mos (IQR 2.8-18.6). ORR was 69% in patients with ≤2 prior lines (n=13) and 0% among those with prior topoisomerase-1 inhibitor (topotecan) exposure (n=3) or in BRCA-mutated tumors (n=4). Patients with prior mirvetuximab (n=7) had an ORR of 14% and DCR of 71%.By tumor type: ORR was 47% in OC and 38% in EC; DCR was 76% in OC and 56% in EC; mTOT was 5.5 mos (2.5-9.0) in OC and 4.7 mos (0.8-6.9) in EC. The mPFS was 6.2 mos (95% CI 2.3-15.8) for OC and 6.0 mos (1.4-7.6) for EC. mOS from T-DXd start was 17.3 mos (11.4-27.6) for OC and 10.4 mos (6.3-NR) for EC.
Conclusion: In this real-world cohort, T-DXd demonstrated promising outcomes consistent with DESTINY-PanTumor02. High response rates were observed in IHC 3+ tumors and earlier-line use, while no responses were seen with prior topoisomerase-1 inhibitor exposure or in BRCA-mutated cases. Further studies are needed to validate predictors of response and optimize treatment sequencing.

#1407 Single-cell long-read transcriptomics reveals isoform centric molecular features of rare pseudomyxoma peritonei disease.

Kyungtae Lee[1], Anuja Sathe[2], Raegan Wood[2], Dongin Lee[2], Billy Lau[3], Hanlee P. Ji[4]

[1]Oncology, Stanford University School of Medicine, Stanford, CA,[2]Stanford University School of Medicine, Stanford, CA,[3]Biochemistry, Stanford University School of Medicine, Palo Alto, CA,[4]Stanford University, Stanford, CA

Pseudomyxoma peritonei is a rare mucin-producing cancer, most often arising from appendiceal mucinous neoplasm. In the past, investigations into transcriptomic and genomic alterations in this tumor have concentrated on gene-level changes, neglecting the impact of differential isoform usages resulting from alternative splicing and allele specific expression. In this study, we conducted single-cell long-read sequencing on 10 biopsies from 5 tumor patients at various stages of disease. Single cell analysis delineated the individual cell types and long read sequencing revealed the sequence of mRNA transcripts from its 5’ transcript start sites to 3’ polyA-tail - providing insights into disease and cell type specific RNA transcript structures and changes. Across the single cell results, we identified a total of 35,095 expressed genes and 130,272 transcripts, including 50,330 novel transcripts. Based on the identified gene and isoform repertoire, epithelial cells derived from appendiceal mucinous neoplasm showed an upregulation of genes and isoforms linked to goblet cell differentiation, cell proliferation, and mucin production. Furthermore, we identified alternative RNA alternative splicing in genes related to protein degradation and cellular transport within tumor epithelial cells. Our ongoing research focuses on discovering phased somatic mutations at the allele-specific isoform level and uncovering RNA splicing-derived neoantigens expressed in tumor epithelial cells. These efforts may reveal novel oncogenic drivers and potential therapeutic targets for this tumor.

#1408 MicroNucML: A machine learning approach for micronuclei segmentation and the refinement of nuclei-micronuclei relationships.

Nadejda B. Boev, Yukai Wang, Ulises O. Garcia, Kate M. MacDonald, Shane M. Harding, Sushant Kumar

Princess Margaret Cancer Centre, University Health Network, Department of Medical Biophysics at University Toronto, Toronto, ON, Canada

Micronuclei (MN) are structures containing small fragments of DNA, arising from mitotic errors or failed DNA repair attempts. Therefore, MN serve as markers of genomic instability and are typically quantified either manually or through threshold-based methods, which can be tedious and inaccurate, leading to varying degrees of success and throughput. By employing a two-phase labeling approach that utilizes polygon and brush segmentation, along with refinement using SAM2, we developed a high-quality MN segmentation tool. Subsequent data augmentation, which captured heterogeneity in image quality and color diversity, enabled us to train a generalizable Mask-RCNN model optimized for small object detection, achieving state-of-the-art performance in MN detection. Finally, we applied our model to immunofluorescence data obtained from cell lines exposed to DNA damage conditions to gain biological insights into MN dynamics and their role in inducing genome instability. In summary, this work establishes an accessible resource for systematically studying genome instability with significantly greater fidelity and sensitivity, enabling insights into damage biology that were previously unresolved.

#1409 Fusion epigenotyping using cell-free DNA methylation improves detection of actionable ALK fusions in non-small cell lung cancer.

Laura Tung, Anton Valouev, Justin Odegaard, Lauren Lawrence, Nicole Zhang, Martina Lefterova, Matthew Ellis, Tingting Jiang, Sheila Solomon, Darya Chudova

Guardant Health, Palo Alto, CA

Background: Fusion detection with next-generation sequencing is challenging due to short read fragments, which can fail to fully resolve complex genomic rearrangements and map intronic breakpoints that lie outside targeted capture regions. Tumor methylation patterns, which reflect the functional state of cancer cells and do not rely on breakpoint coverage, are less impacted by sequencing fragment length and provide a robust orthogonal signal to augment genomic-based fusion calling. We developed a cell-free DNA (cfDNA) methylation-based fusion epigenotyping method to rescue fusions missed by genomic-based methods, focusing on *ALK* fusion detection in non-small lung cancer (NSCLC) to inform ALK inhibitor therapy selection.
Methods: NSCLC samples were processed using Guardant360 Liquid test (Guardant Health, Palo Alto, CA). Genome-wide cfDNA methylation profiles across thousands of regulatory regions together with genomic molecule support, were used to train a binary classifier that discriminates *EML4-ALK* fusion-positive from fusion-negative NSCLC. A logistic regression model was trained on 175 *EML4-ALK* fusion-positive and 175 fusion-negative samples. Concordance with NSCLC tissue samples was assessed by comparing tissue *EML4-ALK*-associated differentially methylated regions (DMRs, $p<0.05$) from TCGA data to fusion DMRs from Guardant360 Liquid cfDNA samples. To ensure clinical-grade specificity, a decision threshold targeting >99% specificity was calibrated on >11,000 genomic fusion-negative NSCLC samples. Model performance was evaluated on 102 independent positive cases (63 genomically detected, 39 genomically missed) with epigenomic tumor fraction > 0.1% from samples with (a) ALK inhibitor resistance mutations, (b) prior ALK inhibitor treatment, or (c) longitudinal history of genomic fusion detection. Fusion rescue rate was defined as the fraction of genomically missed fusions rescued by the epigenotyping classifier.
Results: Methylation concordance analysis between TCGA NSCLC tissues and Guardant360 Liquid cfDNA samples showed significant overlap, with 64% (1384/2168) of tissue *EML4-ALK*-associated differentially methylated regions (DMRs, $p<0.05$) also significant in cfDNA. In the test cohort, the epigenotyping classifier achieved 74% sensitivity, detecting 100% of fusions identified by the genomic caller. Among genomically missed cases, the classifier rescued 31% (12/39) of fusions.
Conclusion: A cfDNA methylation-based fusion epigenotyping approach provides a high-specificity orthogonal signal that augments genomic fusion detection, recovering a substantial fraction of *EML4-ALK* fusions missed by the genomic method. Clinically, patients with rescued *ALK* fusions could be considered for effective and low toxicity targeted ALK inhibitor therapies.

#1410 Transcriptional silencing of homologous recombination defines a functional HRD in invasive lobular carcinoma.

Yona Kim[1], Yeseul Kim[1], Harim Oh[1], Sung Hak Lee[2], Sangjeong Ahn[1], You-Na Sung[1]

[1]Department of Pathology, Korea University Anam Hospital, Korea University College of Medicine, Seoul, Korea, Republic of,[2]Seoul St. Mary's Hospital, Seoul, Korea, Republic of

Background: Homologous recombination deficiency (HRD) is a key determinant of genomic instability and a major predictor of PARP inhibitor (PARPi) sensitivity in breast cancer. While invasive ductal carcinoma (IDC) commonly exhibits canonical HRD driven by BRCA1/2 loss and characteristic genomic scars, the HR status of invasive lobular carcinoma (ILC) remains poorly characterized. Recent evidence suggests that a subset of ILC displays a *BRCAness-like* phenotype undetected by conventional genomic HRD scores, implying a transcriptionally driven functional HRD mechanism.

Methods: RNA-sequencing data from TCGA-BRCA were analyzed by integrating genomic HRDsum scores with ssGSEA-based pathway scores for a curated HR gene set. Samples were stratified by histological subtype (IDC vs. ILC) and ranked by PARPi7, a seven-gene transcriptomic signature predictive of PARPi response. Correlation analyses and linear interaction models were applied to examine subtype-specific relationships among PARPi7, genomic HRDsum, and HR pathway activity. Differential expression and upstream regulator analyses were performed to identify transcriptomic features and regulators associated with functional HRD in ILC.

Results: In IDC, PARPi7 correlated positively with HRDsum (R = 0.34) and negatively with estrogen receptor expression, consistent with the classical triple-negative breast cancer-like genomic HRD phenotype. HR pathway activity showed minimal association (R = -0.07), supporting a genomically driven HRD. In ILC, this pattern was reversed: PARPi7 correlated negatively with HRDsum (R = -0.20) and strongly with HR pathway suppression (R = -0.48), suggesting that transcriptional silencing of HR genes underlies a functional HRD phenotype in ILC. PARPi7-high ILC tumors exhibited coordinated downregulation of DNA repair and cell-cycle programs with concurrent inflammatory and immune activation. BRCA1 expression was reduced in both subtypes but more markedly in IDC (adj.P = 9.29×10^{-81} vs 1.47×10^{-18}). Upstream regulator analysis identified selective activation of NUPR1 in PARPi7-high ILC - a stress-responsive transcriptional regulator linked to PARP activity and tolerance to DNA damage.

Conclusion: While PARPi7-high IDC reflects canonical, genomically driven HRD with BRCA1-type biology, ILC demonstrates a transcriptionally defined functional HRD lacking genomic scars, implying that PARPi7-high behavior can emerge even in genomically HRD-low tumors. This phenotype involves transcriptional suppression of HR genes and DNA repair machinery, low HRDsum, inflammatory activation, and NUPR1-mediated stress adaptation. These findings define a transcriptomic axis of functional HRD in ILC, suggesting expansion of PARPi strategies beyond genomic HRD to include HR pathway silencing and NUPR1 activation as biomarkers of therapeutic sensitivity.

#1411 Extrachromosomal DNA amplification defines a high-risk subgroup and unique molecular features in gastric cancer.

Jieun Lee[1], Donghyeok Seol[1], Seunghyun Kang[2], Chanmi Bang[1], Mira Yoo[1], Soyeon Kim[2], Hyeongjin Cho[2], So Hyun Kang[1], Young Suk Park[1], Sang-Hoon Ahn[3], Hyung-Ho Kim[4], Eunhee YI[5], Sanghyun Kim[2], Hoon Kim[2], Yun-Suhk Suh[1]

[1]Department of Surgery, Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic of,[2]Department of Biopharmaceutical Convergence, Sungkyunkwan University, Suwon-si, Korea, Republic of,[3]Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[4]Department of Surgery, Chung-Ang University Gwangmyeong Hospital, Gwangmyeong-si, Korea, Republic of,[5]Department of Physiology, College of Human Medicine, Michigan State University, Lansing, MI

Gastric cancer (GC) is the fifth most prevalent cancer and the fourth leading cause of cancer mortality. However, clinical strategies targeting these amplifications in GC have been unsuccessful, often leading to treatment resistance and poor prognosis. Extrachromosomal DNA (ecDNA) has emerged as a major mechanism associated with oncogene focal amplification and adverse outcomes. In this study, we performed whole genome sequencing (WGS) and whole transcriptome sequencing (WTS) on paired tumor-normal samples from 76 Korean GC patients collected through Seoul National University Bundang Hospital to understand the prevalence of ecDNAs and their clinical relevance in GC patients. Focal amplification regions amplicons were identified and classified using AmpliconArchitect (AA) and Amplicon Classifier into ecDNA (circular amplification) and non-ecDNA (Chromosomal Amplicons, ChAmps). Focal amplifications were highly frequent and showed a strong association with the chromosomal instability (CIN) subtype (P = 2.37e-09). Of the 76 patients, 17 (22.4%) were classified as "ecDNA positive patients". Notably, 75% of CIN subtype patients carried one or more ecDNA amplicons. Genomic analysis revealed that ecDNA amplicons were significantly larger (P = 0.00056) and more structurally complex than ChAmps, exhibiting a higher frequency of structural variants. ecDNA amplicons also harbored significantly more canonical cancer genes (P = 3.90e-03) and displayed significantly higher copy numbers of these genes compared to ChAmps (P = 6.50e-04). Furthermore, ecDNA regions were significantly enriched with putative transcriptional regulatory elements (P = 1.20e-04) and GC-specific accessible chromatin regions. In WTS data, genes within ecDNA exhibited significantly higher expression compared to in ChAmp (P = 3.59e-05). Gene Set Enrichment Analysis (GSEA) revealed that ecDNA cohorts displayed a significantly more pronounced immunosuppressive phenotype—characterized by downregulation of immune response gene sets—compared to ChAmp patients in both SNUBH and TCGA cohorts. Clinically, the presence of ecDNA conferred a significantly worse Overall Survival (OS) rate compared to ChAmp cohorts (Log-rank test, P = 0.012). Multivariate Cox proportional hazards analysis confirmed that ecDNA status acts as an independent risk factor for OS (HR = 14.4, P = 0.001)Our findings demonstrate that ecDNA amplification is frequent in GC, particularly within the CIN subtype, and is associated with distinct genomic complexity, higher oncogene burden, unique transcriptional consequences (immune suppression), and poor patient prognosis. The presence of ecDNA amplification may serve as a critical prognostic factor in GC, highlighting the need for personalized treatment, including the development of ecDNA-targeted therapies to improve treatment outcomes.

#1412 Informatics-driven spatial-omics for cancer immunotherapy discovery in gynecologic cancers.

Rongting Huang[1], Diane Libert[1], Arslan Kasimov[1], Leandra Kingsley[1], Sahar Nasr[1], Reem Al-Humadi[1], Lindsey A. Finch[1], Elisabeth Diver[1], Ravali A. Reddy[2], Babak Litkouhi[1], Kristin Bixel[1], Sizun Jiang[3], Brooke Howitt[1]

[1]Stanford University, Stanford, CA,[2]The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Harvard Medical School, Boston, MA

Endometrial cancer (EC) remains a highly prevalent and understudied malignancy, with aggressive subtypes disproportionately affecting underrepresented populations and lacking effective targeted therapies. Traditional bulk sequencing approaches have provided limited insight into the spatial and cellular heterogeneity that drive EC progression, particularly with respect to how tumor cells interact with their microenvironment and evade the immune system. Our current research focuses on directly addressing these gaps by leveraging large, well-annotated retrospective EC cohorts to apply advanced spatial multi-omics and computational frameworks.
We propose SPATIAM (Spatial Partitioning of Tumor-Immune Architecture via Multi-omics), a novel computational framework integrating spatial genomics, transcriptomics, and proteomics at single-cell resolution to reconstruct tumor subclonal architecture and map dynamic tumor-immune-stromal interactions in situ. This approach resolves how genetically distinct subclones emerge and interact with their microenvironment and identifies spatially organized immune evasion mechanisms that are invisible in bulk analyses.
Our longitudinal cohort (unpublished) includes patients treated with immune checkpoint inhibitors, with longitudinal sampling of matched primary untreated, post-chemotherapy, interim (on treatment) immune checkpoint inhibition (ICI) and post-ICI samples. This comprehensive collection was processed into tissue microarrays (TMAs) and subjected to multi-modal spatial and molecular profiling. We employed GeoMx Digital Spatial Profiling for high-plex protein and RNA analysis, Multiplexed Ion Beam Imaging (MIBI) for high-resolution spatial proteomics, and single nucleus RNA sequencing for unbiased transcriptional profiling at single cell resolution. This multi-modal approach enabled the systematic characterization of tumor microenvironment evolution throughout the treatment course, capturing both spatial and molecular dynamics of immune responses.
This pioneering study presents the first longitudinal, multi-modal spatial and molecular atlas of ICI treatment evolution, integrating samples across treatment timepoints with cutting-edge spatial proteomics, digital spatial profiling, and single-nucleus sequencing to uncover novel mechanisms of therapeutic resistance.

#1413 Targetable gene dependencies in Ewing sarcoma subtypes.

Dusan Pesic[1], Josh Nash[1], Timmy Wen[1], Pedro Lemos Ballester[1], Livia Garzia[2], Olivier Delattre[3], David Malkin[1], Adam Shlien[1]

[1]Dept. of Genetics & Genome Bio., The Hospital for Sick Children, Toronto, ON, Canada,[2]McGill University, Montreal, QC, Canada,[3]Institute Curie, Paris, France

Ewing sarcoma (EwS) is a bone and soft tissue cancer primarily driven by a FET::ETS fusion protein, most commonly EWS::FLI1. While localized tumors have a five-year survival rate of 70-80% with multimodal treatment, the prognosis for relapsed or metastatic disease remains dismal, with survival rates below 30%. This underscores the urgent need for improved prognostic markers and innovative therapeutic strategies. Using an unsupervised hierarchical clustering approach - RACCOON - we identified three distinct transcriptional subtypes of EwS: EWS::FLI1-high, mesenchymal-like, and muscle-like. The muscle-like group, potentially arising from myofiber infiltration, formed a separate cluster, while the remainder of the cohort was distributed along a continuum of transcriptional states between the EWS::FLI1-high and EWS::FLI1-low/mesenchymal extremes. The same variability in these two transcriptional programs was observed at single-cell resolution and across commonly used preclinical EwS models. Subtype classification in clinical cohorts revealed significant survival differences, with mesenchymal-like tumors showing the poorest prognosis (<35% five-year overall survival) and the highest metastatic potential. An *in vivo* experiment in patient-derived xenografts (PDXs) reinforced these findings, as mesenchymal-like tumors exhibited significantly greater metastatic potential. Additionally, functional genomics data from CRISPR-screened cell lines identified subtype-specific gene dependencies - the Fanconi anemia pathway emerged as a promising therapeutic target for EWS::FLI1-high tumors, while mesenchymal-like tumors showed reliance on distinct transcriptional regulators. By integrating transcriptomic profiling with functional genomics, this study highlights the biological and clinical heterogeneity of EwS, offering novel insights into its molecular underpinnings and paving the way for personalized treatment strategies tailored to specific transcriptional subtypes.

#1414 Shared gut virome profiles highlight potential early colorectal cancer markers in HIV-helminth co-infection.

Botle Precious Damane[1], Thanyani V. Mulaudzi[1], Jonathan Featherston[2], Sayed Shakeel Kader[3], Pragalathan Naidoo[4], **Zodwa Dlamini**[5], Zilungile Lynette Mkhize-Kwitshana[6]

[1]Department of Surgery, Steve Biko Academic Hospital, University of Pretoria, Pretoria, South Africa,[2]Division of National Health Laboratory Service, The National Institute For Communicable Diseases Of South Africa, Sandringham, South Africa,[3]Department of Surgery, University of KwaZulu-Natal, Durban 4001, Congella, South Africa, University of KwaZulu Natal, KwaZulu Natal, South Africa,[4]Department of Medical Microbiology, College of Health Sciences, School of Laboratory Medicine & Medi, University of KwaZulu Natal, KwaZulu Natal, South Africa,[5]Pan African Cancer Research Institute (PACRI), University of Pretoria, Pretoria, South Africa,[6]Biomedical Sciences Department; School of Life and Consumer Sciences, College of Agriculture and Env, University of South Africa, Johannesburg, South Africa

Background: In regions with high HIV and helminth prevalence, co-infection may reshape the gut virome in ways that promote oncogenic processes. Characterizing these alterations may identify early colorectal cancer (CRC) biomarkers in high-risk populations.
Methods: Stool-derived metagenomic data from CRC patients, HIV-infected, helminth-infected, HIV-helminth co-infected individuals, and uninfected controls were analyzed. Viral taxa were quantified at family and genus levels using a metagenomic coassembly pipeline. Hierarchical clustering and heatmap visualisation compared abundance patterns across groups.
Results: CRC samples formed distinct clusters with altered abundance of Siphoviridae (−1.6 ± 0.41; q = 0.0013), Podoviridae (2.3 ± 0.83; q = 0.031), unclassified Caudovirales (−1.6 ± 0.51; q = 0.010), Virus sp. ctWxR2 (−14.7 ± 5.04; q = 0.019), and CrAss-like virus sp. ctt4r3 (22.9 ± 5.00; q = 9.9×10^{-5}). HIV-helminth co-infected samples formed a subcluster overlapping CRC, showing similar enrichments in Siphoviridae (−2.0 ± 0.39; q = 5.3×10^{-6}), unclassified Caudovirales (−2.6 ± 0.48; q = 4.7×10^{-6}), Virus sp. ctWxR2 (−21.1 ± 4.79; q = 0.00011), and CrAss-like virus sp. ctt4r3 (24.8 ± 4.78; q = 2.2×10^{-7}). HIV-only samples resembled controls, while helminth-only samples displayed intermediate profiles.
Conclusion: HIV-helminth co-infected individuals showed closely aligned profiles with CRC, indicating that chronic immune perturbation may create virome states resembling early CRC-associated dysbiosis. These shared viral signatures could serve as potential non-invasive biomarkers for CRC risk stratification in high-burden settings. Longitudinal analyses are needed to clarify temporal dynamics and identify the bacterial hosts and functional pathways through which viral/phage restructuring may promote CRC development.

#1415 A comprehensive computational study of PARP1 isoforms and their interactions with nucleolin: Structural insights and implications for breast cancer.

Nathaniel Zimmerman, Grela Jerliu, Naomi Hutchinson, Anjana Saxena, Shaneen M. Singh

Brooklyn College, Brooklyn, NY

Poly(ADP-ribose) polymerase 1 (PARP1) has emerged as a key player and a promising focal point in dysregulated DNA repair in breast cancer. PARP1 exists in multiple isoforms, each with a unique combination of domains [zinc finger**-**Poly(ADP-ribose) polymerase (zf-PARP), Poly(ADP-ribose) polymerase1domain (PADR1), Tryptophan-Glycine-Arginine domain (WGR), and BRCA1 C Terminus (BRCT)]. High expression of PARP1 is frequently associated with an aggressive type of breast cancer and poor prognosis. We earlier predicted PARP1 as a common interactor of the RNA-binding protein, nucleolin (NCL) and BRCA1 where its BRCT domain is implicated in protein interactions. In a published study we showed NCL-miR interfaces for the six frequently dysregulated miRNA in breast cancer including miR-221. While NCL regulates miR-221 expression, PARP1 is a target of miR-221. These and other studies strongly suggest NCL-PARP1 collaborate at the damaged DNA sites. In this study, we built structural models of the PARP1 isoforms and performed docking analyses using ClusPro and HDOCK using a full-length structural model of NCL to assess their interactions. Our results revealed isoform-specific NCL-PARP1 interaction interfaces. The data is strongly suggestive that differences in domain architecture across PARP1 isoforms can alter protein-protein interactions with potential distinct functional implications. Isoform-specific PARP1-NCL-interactions thus can govern DNA repair processes. Next, we examined how cancer-associated mutations in PARP1 affect these interactions. Using ENSEMBL, COSMIC, and TCGA, we selected key mutations with breast cancer phenotypes and created *in silico* models of PARP1. The generated comparative analyses of mutant and wild-type isoforms revealed mutation-driven alterations in the interaction interfaces. Overall, our study sheds light on the structural and functional diversity of PARP1 isoforms, how they interact with NCL, and how specific mutations could influence breast cancer tumorigenesis. PARP inhibitors are frequently used as targeted cancer therapeutics. Understanding the molecular insights about how PARP-isoforms interact with its protein partners involved in DNA repair process will be valuable and can serve as the initial steps towards the development of potential therapeutic interventions.

#1416 Stress-responsive glucocorticoid receptor signaling shapes the immune tumor microenvironment in lung cancer.

Sabrina Akter[1], Aiman Soliman[2], Robert A. Winn[3], Zeynep Madak-Erdogan[1], Sage J. Kim[4]

[1]Food Science and Human Nutrition, University of Illinois at Urbana-Champaign, Champaign, IL,[2]National Center for Supercomputing Applications, University of Illinois Urbana-Champaign, Champaign, IL,[3]VCU Massey Comprehensive Cancer Center, Richmond, VA,[4]School of Public Health, University of Illinois Chicago, Chicago, IL

Background: Racial disparities continue to exist in lung cancer, while Black individuals tend to smoke less than Whites, indicating potentially additional factors contribute to lung cancer risk. Our previous work showed that social stressors, including neighborhood violent crime, can shape tumor biology via stress-responsive mechanisms. In this study, we investigated how neighborhood violent crime influences tumor microenvironment with a focus on how glucocorticoid receptor activity impacts the spatial pattern of M2 macrophages and $CD8^+$ T cells as indicators of hot and cold immune phenotypes.
Methods: We analyzed 15 lung tumor spatial transcriptomic samples to quantify pathway activity and cell type associations using gene set co-regulation analysis (GESECA). Spatial co-localization was assessed using univariate and bivariate local Moran's I ($p < 0.05$). To enhance spatial resolution beyond the Visium spot size, we extracted latent spatial features using non-negative matrix factorization (NMF), estimated empirical variograms to characterize spatial autocorrelation, and applied ordinary kriging to generate high-resolution spatial maps.
Results: Neighborhood violent crime rates were positively correlated with glucocorticoid receptor activity, as evidenced by high expression of genes involved in the glucocorticoid biosynthesis pathway activity ($p < 0.05$). Regions with elevated glucocorticoid receptor activity also showed higher abundance of epithelial cells, especially in tumors from high-crime neighborhoods. High-resolution spatial maps further revealed that tumors from high-violent crime neighborhoods displayed strong co-localization between M2 macrophages and $CD8^+$ T cells, suggesting that $CD8^+$ T cells are surrounded by immunosuppressive myeloid cells, creating a functionally "cold" tumor microenvironment. In contrast, tumors from low-violent crime neighborhoods showed more mutually exclusive spatial patterns of M2 macrophages and $CD8^+$ T cells, reflecting a "hot" tumor microenvironment.
Conclusions: Our findings suggest that exposure to social stressors, such as neighborhood violent crime, may influence tumor biology by altering stress-responsive pathways and reshaping immune spatial architecture. The distinct hot and cold immune microenvironment may indicate differential treatment effectiveness across neighborhood contexts, potentially contributing to lung cancer disparities. Different immunotherapy strategies depending on immune tumor microenvironment to improve treatment effectiveness.

#1417 Bulk RNA-seq atlas guided annotation of tumor transcriptomes.

Timmy T. Wen, Dusan Pesic, Pedro L. Ballester, Josh Nash, Adam Shlien

The Hospital for Sick Children, Toronto, ON, Canada

Single-cell RNA sequencing (scRNA-seq) enables high-resolution profiling of cellular heterogeneity, revealing novel transcriptomic states. However, many existing generative and foundational single-cell models are trained predominantly on non-neoplastic data, limiting their accuracy in cancer cell annotation. We present SPOTTER (Seed-guided Prediction Of Tumor Transcriptomes with Ensemble Recognition), a framework that integrates bulk RNA sequencing (bulk RNA-seq) cancer atlases with single-cell data. SPOTTER first classifies individual cells using an ensemble neural network classifier OTTER (Oncologic TranscripTome Expression Recognition), trained on the hierarchical RACCOON (Resolution-Adaptive Coarse-to-fine Clusters OptimizatiON) cancer atlas spanning over 15,000 pediatric and adult cancer samples. High-confidence seed labels are selected using a Gaussian mixture model (GMM) and Gini impurity-based filtering of OTTER scores to exclude low-quality cells with uncertain predictions. These labels are then propagated through scANVI (single-cell Annotation using Variational Inference) to achieve per-cell classifications. Across nine diverse pediatric and adult single-cell and single-nucleus cancer datasets, SPOTTER reliably assigned malignant cells to their expected tumor classes. In Ewing sarcoma samples with matched bulk RNA-seq and single-nucleus RNA-seq (snRNA-seq), SPOTTER recapitulated bulk RNA-seq-defined subtypes at single-cell resolution, distinguishing one subtype enriched for neuronal programs, including *SYT1* and *SOX6*, and another with increased *EWS-FLI1* fusion activity and elevated *JAK1* signaling—consistent with subtypes previously identified by OTTER and RACCOON in bulk RNA-seq. By integrating bulk and single-cell analyses, SPOTTER enables characterization of tumor heterogeneity and supports identification of subtype-specific markers to reveal critical insights into the transcriptomic profile of a cancer.

#1418 Uncovering novel splice junctions in prostate cancer using DeepSAP.

Pankaj Vats[1], Fadel Berakdar[1], Thomas D. Wu[2], Tong Zhu[1], Mehrzad Samadi[1]

[1]Nvidia Corporation, Santa Clara, CA,[2]Genentech Inc, South San Francisco, CA

Accurate characterization of alternative splicing and gene fusion events from RNA-seq is crucial for understanding cancer biology, however, this task remains inherently challenging due to factors such as complex splice junction architecture, ambiguous read mapping caused by multi-mapped reads, and the presence of chimeric transcripts that confound standard analysis pipelines. We present DeepSAP, a splice-aware RNA-seq aligner that integrates Transcriptome-Guided Genomic Alignment (TGGA) as implemented in GSNAP with advanced Transformer-based Splice Junction Scoring (TSJS) to overcome these challenges and achieve greater sensitivity and specificity in detecting true splicing events. DeepSAP leverages a fine-tuned DNABERT model, trained on curated splice donor and acceptor site sequences drawn from multiple species, utilizing sequence windows of varying lengths (90, 150, 200, and 400 bp) around the splice junctions. Among the different fine-tuned models evaluated, DNABERT MS150 demonstrated superior performance in distinguishing true splice sites, and is directly integrated into the DeepSAP workflow to re-score and prioritize candidate splice junctions identified by GSNAP TGGA, effectively combining both sequence-driven plausibility in local DNA context and strongly supported by RNA-seq reads. To evaluate DeepSAP in a clinically relevant setting, we applied it to a prostate cancer RNA-seq cohort (PRJNA579899, University Hospital Zurich). In this cohort, DeepSAP consistently identifies numerous high-confidence, novel splice junctions absent from current gene annotations and frequently missed or only weakly detected by current state of the art RNA-seq aligners. Notably, in FOXA1, DeepSAP resolves a novel donor site with a double-adenine substitution that creates a previously unannotated exon-intron boundary. This junction shows coherent read coverage and high transformer derived donor and acceptor probabilities, whereas alternative aligners fail to produce a consistent splice junction at the same locus. A similar pattern is observed in the ERG oncogene, where DeepSAP recovers an additional complex, unannotated splice junction that is not captured by other aligners. The results highlight DeepSAP's ability to recover complex, previously undescribed splice junctions in tumor RNA-seq data and demonstrate that coupling GSNAP TGGA with TSJS substantially improves alignment sensitivity and specificity, enabling improved detection of candidate oncogenic splice events in cancer RNA-seq samples.

#1419 Integrated spatial and genetic lineage tracing uncovers cell state plasticity underlying recurrence in group3 and group4 medulloblastoma.

Bohyeon Yu[1], Emanuele Filiberto Rosatti[2], Jangham Jung[1], Abhinav Jain[1], Joanna Phillips[1], Aaron Antonio Diaz[1]

[1]Department of Neurological Surgery, University of California, San Francisco, San Francisco, CA,[2]Department of Cellular, Computational and Integrative Biology, University of Trento, Trentino, Italy

Recent studies place Group 3/4 medulloblastomas (G3/4 MBs) within the rhombic lip (RL)-derived glutamatergic lineage, indicating that a stalled differentiation program underlies their malignant evolution. However, it remains unclear whether these tumors retain the plasticity to transition within this lineage framework, and how their cellular states are reshaped in response to therapy. To address these questions, we constructed a single-cell multiomics atlas of G3/4 MBs using 84 tumor specimens from 38 patients, including 7 longitudinally matched cases collected through the University of California, San Francisco Brain Tumor Center (UCSF BTC) and the Children's Brain Tumor Network (CBTN). From these samples, we generated single-nucleus transcriptomic and chromatin accessibility profiles from 57 frozen samples, and spatial transcriptomic profiles from 27 FFPE samples using Visium and Xenium. We also incorporated single-cell lineage-tracing data from intracranial xenografts derived from two G3 MB cell lines. Genetic lineage tracing integrating static barcodes with endogenous mutations demonstrated that xenografts recapitulate the developmental cell-type composition of treatment-naive primary human MBs, with barcode-defined individual clones maintaining highly similar and stable cell-type fractions. Comparison of matched primary and recurrent clinical tumors revealed no substantial differences in developmental composition. Despite this stability, phylogenetic analysis uncovered markedly increased plasticity in recurrent tumors, driven by dedifferentiation transitions from unipolar brush cell-like states to RL progenitor-like states. Tumor regions exhibiting high plasticity were spatially clustered and corresponded to structurally disorganized areas. Our work establishes cell-state plasticity as a defining feature of recurrent G3/4 MBs, providing a mechanistic framework for understanding recurrence following therapy.

#1420 Image-based ROI selection for spatial transcriptomic experiments using immune checkpoint inhibitor treatment outcome prediction in gastric cancer.

Sunho Park[1], Minji Kim[1], Jean R. Clemenceau[1], Seock-Jin Chung[1], Eric F. Sha[1], Changjin Hong[1], Soyoung Im[2], Hwanil Choi[3], Soonyoung Lee[3], Jongseong Jang[3], Kohei Shitara[4], Sung Hak Lee[5], Jae-Ho Cheong[6], Tae Hyun Hwang[1]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Suwon, Korea, Republic of,[3]LG AI Research, Seoul, Korea, Republic of,[4]Department of Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan,[5]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[6]Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction

Spatial omics experiments profile only a limited number of regions of interest (ROIs) per section, making ROI selection critical. However, manual selection from tumor annotations may miss critical subregion due to the complexity of tumor structures and the limited capability of human visual processing. We recently reported S2Omics, an AI framework that selects ROIs to maximize cell-type diversity and molecular information in an outcome-agnostic manner. Here, we extend this concept to develop an image-based ROI selection method that directly incorporates immune checkpoint inhibitor (ICI) treatment outcome in gastric cancer (GC), enabling outcome-aware spatial transcriptomic experiments.

Methods

We assembled 157 H&E whole slide images (WSIs) from GC patients treated with ICIs at three centers in Korea and Japan (26 responders, 131 non-responders). WSIs were tiled into 256 µm × 256 µm patches. Tumor tiles were identified using an LG AI Research's EXAONE Path-based cell-type classifier plus a ResNet18 tumor classifier. A weakly supervised model, developed in our previous work, was trained on the tumor tiles to predict responder versus non-responder status, achieving a slide-level area under the curve (AUC) exceeding 0.7 on an independent test set.

Results

Tile-level prediction scores were aggregated into heatmaps representing predicted ICI responsiveness. By applying a sliding window (6.5 mm × 6.5 mm) with rotational adjustments to the prediction heatmap, we identified candidate regions of interest (ROIs) that (i) maximized predicted responsiveness, (ii) maximized predicted non-responsiveness, or (iii) captured heterogeneous ("mixed") patterns. The multiprocessing pipeline efficiently generated ROI suggestions for each slide within seconds. This approach can provide a systematic framework for identifying optimal ROIs for spatial molecular profiling, directly linked to immune responses in gastric cancer.

Conclusion

We developed an image-based approach that selects ROIs according to predicted ICI outcome in GC. By prioritizing regions enriched for predicted response, non-response, or mixed patterns, this strategy samples spatial niches more closely linked to outcome than conventional tumor-enriched or marker-based selection. The framework is adaptable to other spatial platforms by adjusting ROI size and applying user-defined weighting criteria based on predicted outcome, cell composition, or other image-derived features. Ongoing work will validate the method in larger cohorts and profile these ROIs with spatial transcriptomics and multimodal assays to define molecular programs underlying differential ICI response and support biomarker discovery, therapeutic development, and patient selection.

*AI was used for language editing only; authors are responsible for all content and approved the final version.

#1421 Pediatric pan-cancer characterization of transposable elements and their modulation by germline *TP53* variants.

Brianne Laverty[1], Shilpa Yadahalli[1], Safa Majeed[1], Ashby Kissoondoyal[1], Laura Raiti[1], Ann Gong[1], Noa Alon[1], Kashif Daud[1], Alexander Solovyov[2], Scott Davidson[1], Yisu Li[1], Mehdi Layeghifard[1], Adam Shlien[1], David Malkin[1], Vallijah Subasri[3]

[1]Genetics and Genome Biology, The Hospital for Sick Children, Toronto, ON, Canada,[2]Halvorsen Center for Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Peter Munk Cardiac Centre, University Health Network, Toronto, ON, Canada

Transposable elements (TEs) are dynamic repetitive genomic regions that are silenced through epigenetic repression. Although TE activation is a well-recognized feature of embryonic development and adult cancers, their role in pediatric malignancies is poorly understood. Approximately 15-18% of pediatric cancers arise in the context of hereditary cancer predisposition syndromes, such as Li-Fraumeni Syndrome, caused by germline *TP53* (g*TP53*) variants. *TP53* binds to LINE1 elements to suppress their transcription, and adult tumors with somatic *TP53* mutations exhibit elevated TE activity. These findings suggest that g*TP53* variants may disrupt TE regulation during development, predisposing tissues to malignant transformation. To investigate this, we characterized the germline and tumor TE landscape across a pediatric pan-cancer cohort and evaluated the impact of g*TP53* variants.

We identified TEs in 456 germline and 380 tumor samples. Germline ALU, LINE1, SVA elements were called using MELT, xTEA, and INSurVeyor, while tumor LINE1 elements were called with xTEA and TotalReCall. We excluded 96% of germline and 23% of tumor TEs classified as common (>3% of gnomAD or our additional cancer-free cohort (n=166)).

We observed no difference in germline TE burden between g*TP53* carriers and non-carriers, prompting us to examine insertion-site patterns. Motivated by prior findings of global germline methylation differences in g*TP53* carriers, we tested if g*TP53* variants alter germline insertion location. A support vector machine trained on TE distribution predicted g*TP53* status with an AUPRC of 0.74, suggesting g*TP53* variants influence the position of germline insertions. Germline TEs in cancer-free individuals affected regulatory regions governing cell cycle and mitotic pathways whereas germline TEs in the cancer cohort disrupted immune-related regulatory elements (FDR < 0.05). Preliminary evidence suggests immune pathways are altered in germline blood and fibroblast DNA, indicating a systemic effect.

Half of tumors harboured at least one insertion, with epithelial-origin cancers containing more TEs, reflecting adults-onset cancers. As TEs are active in brain development, we analyzed an additional 102 medulloblastoma samples and found 97% contained no insertions. Unlike adult tumors, somatic or germline *TP53* variants did not increase LINE1 insertion burden. Regulatory regions linked to metabolic pathways were affected in g*TP53* carriers (FDR < 0.05).

Overall, we found g*TP53* variants do not increase germline or tumor TE burden but strongly influence the positional distribution of germline insertions. Tumors in the context of g*TP53* variants contain TEs that affect metabolic regulatory regions**,** highlighting consequences of this altered germline architecture. This work enhances our understanding of tumour susceptibility and *TP53*-associated cancers to guide future therapeutics.

#1422 Characterizing clinical toxicity in cancer combination therapies.

Alexandra M. Wong[1], Cecile Meier-Scherling[1], Lorin Crawford[2]

[1]Center for Computational Molecular Biology, Brown University, Providence, RI,[2]Microsoft Research, Cambridge, MA

Predicting synergistic cancer drug combinations through computational methods offers a scalable approach to creating therapies that are more effective and less toxic. However, most algorithms focus solely on synergy scores without considering toxicity when selecting optimal drug combinations. In the absence of combinatorial toxicity assays, a few models use toxicity penalties to balance high synergy with lower toxicity. Yet, these penalties have not been explicitly validated against known drug-drug interactions (DDIs). In this study, we provide a comprehensive, multifaceted analysis to characterize the relationship between drug synergy, computational toxicity metrics, and clinically reported DDI severity. We focused on five synergy scores: Bliss, Loewe, Zero Interaction Potency (ZIP), Highest Single Agent (HSA), and S. Leveraging the drug synergy data from DrugComb and clinical toxicity annotations (Minor, Moderate, Major) from DrugBank and DDInter, we performed non-parametric tests, including the Kruskal-Wallis and Jonckheere-Terpstra tests, to assess trends between toxicity severity and synergy. We then evaluated three computational toxicity proxies: drug target/pathway overlap (Jaccard Similarity), drug structural similarity (Tanimoto Similarity), and the average distance between drug targets in a protein-protein interaction network (PPIN). Our analysis revealed that prioritizing combinations solely by higher synergy is not associated with lower toxicity. For the DrugBank dataset, all synergy scores exhibited a positive trend with increasing toxicity, indicating that higher synergy is associated with higher DDI severity. Furthermore, we demonstrate that the toxicity proxies used in current models, such as drug target overlap and PPIN distance, are poor predictors of clinical DDI severity. For instance, in DrugBank, the Jaccard Similarity of drug targets showed only a weak, statistically significant difference across toxicity groups ($p \sim 0.000$; effect size ~ 0.098), highlighting its limited practical explanatory power. Our results reveal that while some metrics correlate with general toxicity trends, no single metric robustly captures the complexity of clinically known adverse DDIs across databases. This finding highlights the significant limitations in using simple, readily available proxy metrics as effective toxicity penalties in drug combination prediction models. Ultimately, our study underscores the pressing need for more comprehensive and detailed combination toxicity data to advance the field toward truly safe and efficacious cancer combination therapies.

#1423 Aneuploidy detection from FFPE archived tissues: A computational approach for FFPE-CUTAC data.

Aditya T. Parmar[1], Yiyang Niu[1], Kami Ahmad[2], Steven Henikoff[2], Ye Zheng[1]

[1]Department of Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Basic Science Division, Fred Hutchinson Cancer Center, Seattle, WA

For more than a century, Formalin-Fixed Paraffin-Embedded (FFPE) sample preparation has been the standard for long-term preservation of biological material, but severe molecular degradation has long been a technical barrier to high-quality genomic analysis. We recently introduced FFPE-Cleavage Under Targeted Accessible Chromatin (FFPE-CUTAC) with an antibody to RNA Polymerase II (RNAPII) as a sensitive, cost-effective alternative for profiling transcription in FFPEs. Beyond transcription, these profiles present an opportunity to infer aneuploidy (whole chromosome arm gain or loss), a key cancer hallmark. However, the sparse nature of FFPE-CUTAC data presents a computational challenge with no existing fit-for-purpose tools.

Copy number alterations (CNA) detection methods for whole genome sequencing (WGS) data typically rely on fold change in read depth. However, our analysis shows moderate correlation between FFPE CUTAC and matched WGS read depth across the genome(Pearson correlation coefficient $r = 0.525$, Spearman correlation coefficient $\rho = 0.688$). As a result, directly applying standard read-depth-based CNA methods to FFPE-CUTAC achieves a reasonable but suboptimal recovery rate. These findings indicate the need for a tailored approach that explicitly accounts for the sparsity and noise inherent in FFPE-CUTAC data.

Our new method estimates a read depth baseline for each genomic bin rather than a single baseline for the entire sample to better capture the normal copy number level. We partition the genome into 1 Mb bins and use GC content as a genomic feature to group these bins. Bins with similar GC content share the same read depth baseline, defined as the mean read count across all bins within the corresponding GC content group. We evaluate the performance of our strategy using 30 meningioma samples against a standard WGS reference data from the same patient cohort. Our method demonstrated a 95.4% overall aneuploidy detection accuracy (1116/1170 chromosome arms) and ensured a low false-positive rate by correctly identifying 98.9% of all intact arms. By comparison, aneuploidy detection from matching FFPE RNA-seq profiling was lower, with an accuracy of 86.32% (1010/1170 chromosome arms).

We established a strategy specifically designed for aneuploidy profiling from FFPE-CUTAC data. This method unlocks the ability to sensitively and affordably identify critical chromosome arm variations from the FFPE-CUTAC data, alleviating the need to generate additional costly WGS data.

#1424 Unique tumor ecosystems in metaplastic breast cancer identified through single nucleus RNA sequencing.

Aatish Thennavan, Tuan M Tran, Jianzhuo Li, Clinton Yam, Nicholas E. Navin

UT MD Anderson Cancer Center, Houston, TX

Metaplastic breast cancers (MBC) are rare, aggressive triple negative breast cancers (TNBC) that account for less than 1% of all breast cancers. Patients with MBCs are treated similarly to other TNBCs, however, consistently have a worse prognosis and decreased survival in comparison to other TNBC patients. The main aspect affecting MBCs treatment refractoriness is the heterogeneity of tumor cell differentiation in this tumor towards cells of mesenchymal/sarcoma like phenotype e.g. spindle cells, chondroblasts etc. The objective of this study was to investigate these transdifferentiated MBC tumor cells and tumor microenvironment (TME) changes in comparison to other TNBCs and normal breast tissues using single nucleus RNA sequencing (snRNA). For snRNA we profiled 5000-10,000 nuclei per tumor after running FACS to remove ambient RNA and compared tissue samples from MBCs, TNBC and normal breast tissues. Additionally, we also report that MBCs have different myeloid cell state proportions in comparison to other TNBCs, including a significant increased population of *SIPA1L1* myeloid cells cancer cells in MBCs. We also describe novel fibroblast populations enriched in the MBC that are distinct from normal breast and TNBCs. Overall, the MBC TME also exhibits an increased number of proliferative cells in endothelial, fibroblast and myeloid cell compartments. In the transdifferentiated MBC cancer cells, we also define novel transcriptional metagene programs using non-negative matrix factorization (NMF) analysis. Collectively our data identifies the distinctive cancer cell programs and TME of this rare breast cancer for the first time at a single cell resolution and identifies potential new cell states that define it’s unique tumor biology.

#1425 Identifying tumor-specific membrane targets, therapeutics, and matching cell lines for experimental validation with the Multiomics2Targets2 workflow.

Anna I. Byrd, Lily D. Taub, Avi Ma'ayan

Pharmacological Sciences, Icahn School of Medicine at Mount Sinai, New York, NY

Rapid advancements in the multi-omics profiling of tumors from cancer patients have opened up a range of possibilities for personalized target identification. To this end, we previously developed Multiomics2Targets, a platform that identifies tumor-specific membrane proteins. The tumor-specific membrane targets are highly expressed in the input RNA-seq tumor samples while lowly expressed in hundreds of normal tissues and cell types based on transcriptomics profiling atlases created from GTEx, Tabula Sapiens, and ARCHS4. To further prioritize the identified targets for conducting in-vitro and in-vivo experiments, we upgraded the Multiomics2Targets workflow with data from the Cancer Cell Line Encyclopedia (CCLE) and the Cancer Dependency Map (DepMap). From CCLE we identify correlated cell lines that also express the identified targets, and from DepMap we examine the effects of the identified targets on cell line proliferation when knocked down. We also added to the workflow drug predictions by integrating Connectivity Mapping resources from six databases. Additionally, the updated Multiomics2Targets workflow can be applied to single cell RNA-seq data, or bulk RNA-seq samples can be deconvoluted into single-cell-like profiles. The upgraded workflow also applies the tools ChEA-KG and Enrichr to identify enriched transcription factor regulatory subnetworks, pathways, associated phenotypes, and other enriched terms. The resulting figures and tables are compiled into an automatically generated report which includes introduction, methods, results, and conclusions. We demonstrate the utility of the upgraded workflow by discovering tumor subtype-specific cell-surface targets, enriched pathways, down-regulating chemical perturbations, and most similar cell lines for pancreatic adenocarcinoma tumors from the Clinical Proteomic Tumor Analysis Consortium 3 project. We validate several highly ranked targets and chemical perturbations by literature search, as well as suggest novel targets, therapeutics, and cell lines for future in-vitro and in-vivo validation experiments. The updated drug and target discovery workflow is encoded into a new software application called Multiomics2Targets2 (M2T2).

#1426 A single-cell tumor atlas defines robust pathway and gene signatures enabling cancer cell-line fidelity assessment.

Rosyli F. Reveron-Thornton[1], Chuner Guo[1], James P. Agolia[1], Maria Moozhiyil Korah[1], Peter Yuxin Xie[2], Andrea Delitto[1], Amanda Goncalves[3], Angela Tabora[3], Biren Reddy[4], Wesley Bobst[3], Amanda R. Kirane[4], Monica Dua[1], Brendan Visser[1], Byrne Lee[1], George Poultsides[1], Jeffrey A. Norton[5], Derrick C. Wan[3], Michael T. Longaker[3], Deshka Foster[4], Daniel Delitto[6]

[1]Department of Surgery, Stanford University School of Medicine, Stanford, CA,[2]Department of Bioengineering, Stanford University, Stanford, CA,[3]Hagey Laboratory for Pediatric Regenerative Medicine, Division of Plastic and Reconstructive Surgery, Stanford University School of Medicine, Stanford, CA,[4]Stanford University School of Medicine, Stanford, CA,[5]Professor, Dept. of Surgery, Stanford University Medical Center, Stanford, CA,[6]Stanford Unviersity School of Medicine, Stanford, CA

The aim of this study was to determine whether rigorous quality control applied across multiple single-cell RNA (scRNA-seq) sequencing datasets could generate reproducible transcriptional signatures that accurately reflect tumor biology and support evaluation of cancer model fidelity. We aggregated publicly available scRNA-seq datasets and processed all samples through a high-stringency quality-control pipeline that included thresholds of >5,000 counts, <10% mitochondrial content, removal of samples with < 200 cells, and doublet identification using Scrublet. The resulting atlas included 135,441 high-quality tumor cells across 494 samples representing 36 adult and pediatric tumor types. We identified tumor specific gene signatures through differential expression analysis and computed hallmark pathways analysis. Strict QC markedly improved the clarity and biological coherence of tumor-specific signatures enabling us to group otherwise unrelated primary tumors into reproducible transcriptional archetypes (proliferative, immune-signaling, and metabolic) states. These atlas-derived gene signatures showed strong concordance with independent bulk RNA-seq datasets and spatial transcriptomic signatures validating the approach/model.

To examine the utility of these signatures, we projected gene expression profiles from established cancer cell lines onto the atlas-derived signatures. This analysis scored cell lines based on how representative they remained to their tumor of origin. Culture adaptation, metabolic drift, or the loss or gain of hallmark pathways, are known causes of transcriptional divergence in *in-vitro* models. These findings demonstrate that rigorous QC enables construction of a reproducible, pan-cancer single-cell atlas that yields stable transcriptomic signatures suitable for more reliable tumor characterization than offered by the publicly resources (HTAN, EcoTyper, DepMap, Cancer SCEM etc) which vary significantly in their QC measures. This atlas provides a high-quality reference for tumor biology and a framework for evaluating the fidelity of cancer cell lines, with implications for model selection, assessment of therapeutic vulnerabilities, and translational research.

#1427 Exploring high-resolution subtypes for pancreatic ductal adenocarcinoma via a meta-clustering approach.

Nick Boos Peterson, Jieqiong Wang, **Shibiao Wan**

University of Nebraska Medical Center, Omaha, NE

As the third leading cause of cancer death in the United States, pancreatic cancer (PC) is a malignancy with a very low 5-year survival rate. Early diagnosis and treatment of PC remain challenging due to the lack of reliable clinical indicators such as biomarkers. Pancreatic ductal adenocarcinoma (PDAC) is the most common PC subtype, accounting for over 90% of cases. Identifying PDAC subtypes is essential for downstream risk stratification and tailored treatment design. PDAC is conventionally categorized into four molecular subtypes, i.e., aberrantly differentiated endocrine exocrine (ADEX), immunogenic, squamous, and pancreatic progenitor. However, numerous studies have demonstrated high heterogeneity within these 4 molecular subtypes, indicating that exploring high-resolution subtypes for PDAC is highly needed. Conventional wet-lab techniques like molecular profiling and histopathological studies are time-consuming, costly, and laborious. To fill these gaps, we developed a meta-clustering approach to leverage transcriptomics data to explore high-resolution PDAC subtypes. Specifically, we first leveraged random projection (RP) to reduce the dimensions of the PDAC RNA-seq data, which were then clustered by our base clustering method using the Leiden algorithm. To obtain robust results, we implemented 15 runs of RP-based Leiden clustering. Then, we performed meta-clustering of these 15 clustering results by adopting a weighted meta-clustering (wMetaC) architecture from our previous published single-cell analysis method named SHARP. Results suggested that our proposed approach significantly outperformed state-of-the-art clustering methods for PDAC subtyping. Moreover, our meta-clustering approach performed substantially better than all individual base clustering methods. We further performed cluster-specific differential gene expression analysis, pathway analysis and gene-drug-disease association studies, suggesting that our newly identified PDAC sub-clusters were distinctive among different clusters. We expect our proposed approach will provide a robust framework for high-resolution PC subtype characterization for accurate downstream risk assessment and personalized treatment design.

#1428 Single cell RNA-seq analysis of osteosarcoma reveals conserved and distinct ecosystems across sites and species.

Yogesh Budhathoki[1], Matthew Cannon[1], Troy A. Mceachron[2], Anand G. Patel[3], Matthew Gust[1], Jaime F. Modiano[4], Dylan T. Ammons[5], Kathryn Cronise[5], Daniel Regan[5], Heather Gardner[6], Ryan D. Roberts[1]

[1]Nationwide Children's Hospital, Columbus, OH,[2]National Cancer Institute, Bethesda, MD,[3]St. Jude Children's Research Hospital, Memphis, TN,[4]University of Minnesota, Minneapolis, MN,[5]Colorado State University, Fort Collins, CO,[6]Cummings School of Veterinary Medicine, Tufts University, North Grafton, MA

Osteosarcoma exhibits profound heterogeneity that has long challenged efforts to understand its mechanisms and advance therapeutic progress. To unravel this complexity, we compiled the largest cross-species single-cell transcriptomic dataset, integrating 775,441 cells from human patients, dog patients, patient-derived xenografts, and mouse models. To our knowledge, this dataset represents the first multi-species, multi-technology, and multi-site (primary and metastatic) harmonization of single-cell data for any solid tumor, enabling a unified framework for interrogating inter- and intra-tumor heterogeneity across biological and evolutionary contexts.

Through this work, we define subpopulations of osteosarcoma tumor cells that are conserved across tumors, species, and disease sites. These subpopulations span a continuum of differentiation states, from quiescent progenitor-like cells to more differentiated matrix-producing and inflammatory phenotypes, suggesting a conserved developmental hierarchy. Analysis of the stromal compartment revealed both established and previously unappreciated features of osteosarcoma, including the presence of bone-associated osteoclast-like macrophages in both primary and lung metastatic sites and enrichment of inflammatory and scar-associated macrophages in metastatic lung lesions, which we have previously implicated in metastatic progression.

The resulting atlas provides a rich and unprecedented resource for exploration and discovery. Using this resource, we characterized tumor-host interactions occurring in primary and metastatic sites and compared them across species. This analysis revealed a striking number of matrix-derived signals within metastatic lung lesions, far exceeding those identified in primary bone lesions. For example, we found that tumor-derived fibronectin engages syndecans and integrin receptors on epithelial cells, inducing a pathogenic phenotype remarkably similar to that described in pulmonary fibrosis. Validation of these interactions using spatial transcriptomic data identifies distinct neighborhoods that support specific tumor cell subpopulations, with patterns conserved across samples.

Collectively, this work establishes a transformative resource and conceptual framework for understanding tumor heterogeneity, evolution, and microenvironmental remodeling. It serves as a powerful platform for hypothesis generation, model fidelity assessment, and therapeutic discovery, guiding the next generation of translational advances in osteosarcoma biology.

#1429 Stress-responsive genomic alterations reveal a bi-directional relationship between PTSD biology and breast cancer aggressiveness.

Alakesh Bera[1], Meera Srivastava[2]

[1]USUHS - Uniformed Services University of the Health Sciences, Bethesda, MD,[2]APG Department, Uniformed Services University of the Health Sciences, Bethesda, MD

Background: Breast cancer (BrCa) and post-traumatic stress disorder (PTSD) exhibit a complex, bidirectional relationship. While cancer diagnosis and treatment can induce PTSD, emerging epidemiologic data indicate that pre-existing psychological stress or PTSD may also elevate the risk of developing breast cancer or accelerate tumor progression. The biological mechanisms underlying this interaction remain unclear. We hypothesized that tumor-intrinsic alterations in stress-responsive genes may provide molecular insight into this connection.

Methods: We analyzed 17,605 breast tumors using cBioPortal/TCGA datasets and compared them with a 95,474-sample pan-cancer reference. PTSD- and stress-related over sixty genes were curated from published literature and included: TG, CYP11B1, CYP11B2, CRH, NR3C1, SLC6A4, PRKCA, CHRNA6, RGS2, DRD2, BDNF, FKBP5, SLC6A2, TPH2, and others. Copy number alterations, co-amplification patterns, and clinical outcomes (including metastatic progression) were evaluated.

Results: Stress-related genes exhibited significantly enriched copy number amplifications in breast cancer compared with a pan-cancer reference cohort. Across 17,605 BrCa tumors, more than sixty PTSD-, mood-, and stress-endocrine-associated genes showed recurrent CNAs. Key alterations included TG (19%), CYP11B1/CYP11B2 (16%), RGS2 (12%), CRH (10%), PRKCA (9%), and CHRNA6 (8%), markedly higher BrCa than their frequency across 95,474 tumors from all cancer types (2-5%). TG-amplified tumors demonstrated coordinated co-amplifications involving 8q24 (MYC/PVT1) and 1q32, along with characteristic 8p22 deletions, genomic features strongly associated with aggressive disease biology. Exploratory clinical annotation further showed that TG- or CYP11B-gated BrCa cohorts exhibited rapid metastatic progression, with a median time to metastasis <10 months. Together, these findings identify a robust stress-tumor genomic axis in breast cancer and highlight Thyroglobulin (TG) and Corticotropin-Releasing Hormone (CRH) as high-priority candidates for development as objective, noninvasive serum biomarkers.

Conclusion: Large-scale civilian tumor genomic analyses reveal that stress-responsive and PTSD-linked genes are recurrently amplified in breast cancer and co-cluster with high-risk oncogenic regions. These findings support a biological model in which chronic stress/PTSD and breast cancer aggressiveness intersect through shared neuroendocrine and GPCR-linked molecular pathways. This stress/tumor axis may help explain both PTSD arising after a breast cancer diagnosis and stress-associated increases in breast cancer risk or progression. These insights establish a foundation for developing objective biomarkers and mechanistic studies exploring the PTSD-BrCa interface.

#1430 Conserved tumor imprinted T cell states across cancers revealed by pan cancer single cell atlases.

Yan Zong, Hongru Shen, Yajing Bi, Xiangchun Li

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Tumor immune escape arises not only from intrinsic alterations within tumor cells but also from chronic antigen stimulation, inhibitory checkpoint signaling and an immunosuppressive tumor microenvironment that progressively remodels infiltrating immune cells. In previous single-cell RNA-seq analyses, we repeatedly observed subsets of tumor-infiltrating T cells whose transcriptional profiles closely resemble those of neighboring tumor cells, blurring the boundary between immune and malignant compartments and suggesting that key features of tumor adaptation may be written into T-cell states. However, the shared features of such putative tumor-imprinted T cells across cancer types and tissues, and their systematic differences from healthy T cells, remain poorly defined. To address this gap, we aggregated single-cell RNA-seq data from 371,108 intratumoral T cells spanning 19 cancer types. Matched healthy controls were obtained from Tabula Sapiens across 15 tissue types corresponding to these cancers, from which we identified ~130,000 T cells among 290,334 immune cells. We find that tumor-intrinsic and microenvironmental transcriptional programs are markedly enriched in CD8 terminally exhausted and NK-like CD8 T-cell states in patients with cancer, whereas these signals are only weakly detectable in healthy T cells. In particular, epithelial-mesenchymal transition, TGF-β signaling, hypoxia, angiogenesis, MYC and E2F target programs and cell cycle-related pathways are consistently upregulated in tumor-imprinted CD8 T cells, accompanied by selective depletion of naïve and central memory signatures. Building on these observations, we derive a per-cell tumor-imprint score that integrates these pathways, delineates subset-specific and cancer type-specific imprinting patterns, and robustly separates tumor from healthy T cells across multiple organs and independent cohorts. In single-cell datasets from immune checkpoint blockade cohorts, baseline tumor-imprint patterns align with T-cell states associated with treatment response, indicating that this score may aid patient stratification and response prediction. Collectively, this pan-cancer single-cell study provides evidence that tumor cells “hijack” the immune system by rewiring the transcriptional and pathway programs of infiltrating T cells. The resulting tumor-imprint score offers a biologically grounded and operational framework to quantify the extent of T-cell tumorization, refine immunotherapy strategies and inform the design of next-generation T-cell-targeted and cell-based therapies.

#1431 Functional heterogeneity of neutrophils in hepatocarcinogenesis in animal models and human patients.

Zhihao Huang[1], Wang Xiaopeng[2], Wei Dai[1], Xin-Yuan Guan[1], Feng Gen-Sheng[3]

[1]The University of Hong Kong, Hong Kong, China,[2]Peking University, Beijing, China,[3]Institute of Cancer Research, Shenzhen Bay Laboratory, Shenzhen, China

The role of neutrophils in the tumor microenvironment has been widely reported recently, but the relationship between neutrophil heterogeneity and liver tumorigenesis remains unclear. In this study, we analyzed transcriptomic data from 70707 cells across 184 samples, profiling the progression of liver disease from healthy tissue through non-alcoholic fatty liver disease (NAFLD), non-alcoholic steatohepatitis (NASH), fibrosis, and cirrhosis to hepatocellular carcinoma (HCC). We developed an optimized computational model to evaluate the tumor development index using the single-cell RNA-seq data, which was further validated with independent datasets from various tumor types. Specifically, our analysis revealed a significant positive correlation between the proportion of neutrophils and the tumor development index, suggesting that the neutrophils actively contribute to hepatocarcinogenesis progression. This finding was further confirmed by scRNA-seq data from a c-Myc/Alb-cre mouse model. We also identified neutrophil subtypes with distinct functions, highlighting dynamic functional changes during liver tumorigenesis. These results confirmed that our tumorigenesis model can robustly predict the pre-malignant stage. And they also underscore the role of neutrophils as key mediators in liver tumor progression and provide a framework for targeting the immune microenvironment in HCC.

#1432 Single-cell-derived gene-pair classifiers for prostate cancer prognostication.

Lucio Queiroz, Karnika Singh, Wikum Dinalankara, Luigi Marchionni

Pathology and Laboratory Medicine, Weill Cornell Medicine, New York, NY

Prostate cancer is characterized by marked histologic and molecular heterogeneity, which limits the precision of current prognostic tools based largely on Gleason grading. To better resolve the cellular programs underlying grade progression, we analyzed single-cell RNA-sequencing profiles from multiple prostate cancer specimens and performed high-confidence cell type classification across epithelial, stromal, and immune compartments. Within each annotated cell type, we compared tumors representing distinct Gleason grade groups to identify transcriptional markers that are specifically associated with grade-related biological changes rather than global tumor differences. This cell type-stratified analysis uncovered grade-associated signatures reflecting alterations in differentiation state, signaling pathways, and microenvironmental interactions.

We next leveraged these marker genes to construct k-Top Scoring Pair (k-TSP) classifiers, which rely on relative expression orderings and therefore provide a robust, interpretable, and platform-independent modeling framework. Trained using single-cell-derived grade markers, the resulting classifiers were applied to multiple independent bulk transcriptomic cohorts. Across datasets, the k-TSP models consistently distinguished patients with high- versus low-grade disease and demonstrated strong prognostic performance, including significant associations with biochemical recurrence and progression-free survival.

Overall, our study illustrates how single-cell transcriptomic profiling can reveal cell type-specific determinants of prostate cancer grade and enable the development of clinically relevant, generalizable gene-pair-based classifiers. These results support further evaluation of k-TSP models as practical tools for improving prognostication and guiding risk-adapted management in prostate cancer.

Disclosures: AI tools were used to assist in the preparation of this abstract.

#1433 Evidence of noncontiguous haplotype patterns at chromosome band 13q12 associated with prostate cancer risk in men of African ancestry in the *All of Us* Research Program.

William Peter Letsou, Daniel Galvin Gusmano, Meet Boghani, Ifti M. Gazi, Ashwin Nori

New York Institute of Technology, Old Westbury, NY

Genetic ancestry is known to be an important predictor of prostate cancer (PCa) risk. In particular, PCa incidence and mortality can be up to two times higher in men of African ancestry. While polygenic risk scores based on genome-wide significant polymorphisms can stratify the population into well-defined risk groups, a large portion of the genetic risk remains unaccounted for. Admixture mapping is a technique used to determine the likely genetic origin of a segment of chromosome. We hypothesized that an increase or decrease in local African ancestry in PCa cases vs. controls would implicate regions associated with increased risk, and reveal underlying combinatorial patterns of polymorphisms. To this end, we identified 5,246 PCa cases and controls aged 55 years or older in *All of Us* Research Program (Controlled Tier v. 7), who were of at least 80% global African ancestry, and no two of whom were closer than third-degree relatives. After performing genome-wide admixture mapping using RFMix, we identified a suggestive peak of increased local European ancestry in controls (by 3.2 percentage points) at chromosome band 13q12, near the genes *PCOTH* and *MIPEP* (which we previously found to be more highly expressed in prostate tumors in 51 matched samples from The Cancer Genome Atlas). To study the haplotype structure of this region more closely, we extracted haplotypes from the subset of 926 chromosomes that had a haplotype of unambiguous local European origin—associated with decreased PCa risk (OR = 0.70, $P = 0.026$) compared to haplotypes of non-European origin—and clustered the resulting haplotypes using affinity propagation. Although no haplotype cluster was individually statistically significantly associated with PCa risk in a conditional analysis of carriers of each cluster compared to all other clusters, we found that, after pooling the risk-increasing and risk-decreasing clusters, and comparing the combined clusters to each other, a statistically significant signal could be identified (OR = 3.7, $P = 1.5 \times 10^{-4}$), functional validation of which is being pursued by eQTL analysis in TCGA. The pooled risk-clusters revealed the presence of noncontiguous blocks of variants, suggesting the possibility that combinatorial haplotype patterns could account for increased PCa risk among African-ancestry individuals who locally have a normally protective European-ancestry haplotype. To test this hypothesis, and determine the extent to which higher-order combinatorial interactions can explain additional PCa risk, we are developing a Docker version of our previously published Chromosome Overlap algorithm for use in the *All of Us* Researcher Workbench, to see if the haplotype patterns we reveal mirror those detected by admixture mapping. The authors of this study gratefully acknowledge *All of Us* participants, and the NIH *All of Us* Research Program.

#1434 Scalable, unsupervised deep learning frameworks for rare event detection and single cell phenotyping in enrichment free liquid biopsies.

Dean Tessone[1], Amin Naghdloo[2], Javier Murgoitio-Esandi[3], Jeremy Mason[2], Assad Oberai[4], James B. Hicks[5], Peter Kuhn[6]

[1]Molecular and Computational Biology, University of Southern California, Los Angeles, CA,[2]USC - University of Southern California, Los Angeles, CA,[3]Aerospace and Mechanical Engineering, University of Southern California, Los Angeles, CA,[4]Viterbi School of Engineering, University of Southern California, Los Angeles, CA,[5]USC, Los Angeles, CA,[6]Assoc. Professor, Dept. of Cell Bio., University of Southern California, Los Angeles, CA

Liquid biopsy offers a minimally invasive means to interrogate tumor biology; however, the extreme rarity and phenotypic diversity of circulating tumor cells (CTCs) and related cellular events remain major obstacles to sensitive detection and meaningful analysis. Conventional workflows frequently rely on biophysical enrichment or predefined biomarker panels, both of which can bias cell recovery and constrain discovery. There is therefore a critical need for scalable computational approaches capable of analyzing millions of single-cell observations directly and extracting biological structure without dependence on prior labels. We developed deep learning–based pipelines to analyze nucleated cells isolated from peripheral blood. For each patient, approximately five million cells are obtained via buffy coat preparation, stained with a five-marker fluorescence panel, and imaged by whole-slide microscopy without any enrichment steps. The first pipeline is an unsupervised rare-event detector built on a denoising autoencoder. Applied to samples from 11 breast cancer patients, the method recovered 91 additional events—including CTCs, endothelial cells, cancer-associated fibroblasts (CAFs), and extracellular vesicles—representing a greater than 50% increase with minimal manual tuning. This form of label-free outlier detection is broadly generalizable to high-content imaging studies in which unbiased identification of infrequent or unexpected populations is essential. The second pipeline uses representation learning to derive stable single-cell embeddings. These embeddings support phenotype classification with 92.64% accuracy and also enable unsupervised clustering that reflects intrinsic variation in morphology and marker expression. Notably, the learned features are robust to imaging artifacts, ensuring consistent phenotyping across heterogeneous datasets. Collectively, these deep learning frameworks establish an integrated strategy for enrichment-free rare-event detection, clustering, and cell-type characterization in liquid biopsy, providing a scalable foundation for biomarker discovery

#1438 Generative AI improves breast cancer genomic subtype prediction from histology images.

Brennan Geti Simon[1], Clemens L. Weiss[1], Darren Chan[2], Lise Mangiante[1], Nicholas H. Smith[1], Zhicheng Ma[3], Cansu Karakas[4], Christina Curtis[3]

[1]Stanford University School of Medicine, Stanford, CA,[2]Stanford Cancer Institute, Stanford, CA,[3]Stanford University, Stanford, CA,[4]Department of Pathology, Stanford University School of Medicine, Stanford, CA

Breast cancer subtyping is a cornerstone of precision oncology, guiding prognosis, treatment selection, and clinical trial stratification. The Integrative Subtype Classification (IC) scheme is a clinically relevant system that categorizes breast cancer tumors into groups with distinct long-term patient prognoses based on genomic and transcriptomic features. Currently, this approach requires genomic sequencing data to predict tumor subtype, and although genomic profiling continues to drop in cost, it is still not routinely deployed in the clinic at scale, particularly in low-resource settings where adoption is likely to lag. As an alternative, we present PATH-IC, a digital pathology model that predicts ER+ breast cancer IC subtype from routine histology data. Through the novel method BERGERON, which uses generative AI to correct class imbalance and reduce overfitting, we found that synthetic data improved PATH-IC's performance by an amount equivalent to adding 41% more real histology samples for training. PATH-IC reaches a validation AUROC of 0.814 and its predictions correlate with Oncotype DX scores and long-term patient relapse. Using attention-based model interpretation approaches as well as CRAWFORD, a novel embedding-to-image foundation model, we showed that PATH-IC learned expected tumor microenvironment patterns associated with the IC subtypes and identified heterochromatin condensation as a key characteristic of High Risk tumors. Matched single-cell spatial transcriptomics data revealed new IC subtype-specific gene expression patterns discovered by PATH-IC, highlighted by active metabolic, proliferative, and proteostasis pathways. PATH-IC marks a step forward in enabling the routine clinical deployment of IC subtyping while simultaneously advancing the performance of digital pathology models through the implementation of generative AI.

#1439 Foundation model-derived features from immunohistochemistry correlate with recurrence and stage in Merkel cell carcinoma.

Roshan Lodha[1], Kelsey Ouyang[1], Claire Reynolds[2], Allison Vidimos[3], Bryan Carroll[4]

[1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH,[2]Case Western Reserve University School of Medicine, Cleveland, OH,[3]Department of Dermatology, Cleveland Clinic, Cleveland, OH,[4]Department of Dermatology, University Hospitals, Cleveland, OH

Foundation models trained on large histopathology datasets offer broad inference capabilities, yet their performance in Merkel cell carcinoma has not been characterized. We investigated whether a whole slide imaging foundation model could extract clinically informative signals from immunohistochemistry biopsies stained for Merkel cell polyomavirus T antigen. Thirty one digitized slides (12 Stage I, 3 Stage II, 11 Stage III, 3 Stage IV, 2 indeterminate) were processed using a custom tissue masking, tiling, and stain normalization pipeline. High-dimensional features were extracted from the standardized output using a UNI2, a pretrained frozen ViT G/14 encoder developed by the Mahmood Lab. Each tile yielded a 1536 dimensional embedding that was summarized at the slide level by feature means and at the zone level by Moran's I to capture spatial structure. Low dimensional representations were computed with PCA and UMAP. Clinical annotations included recurrence, viral status, immunosuppressed status, and AJCC stage.Across 40 tested correlations, slide level summaries showed the largest associations. Viral status served as a positive control and produced the strongest effects, with slide level PC1 correlating at r equals −0.684 and UMAP1 at r equals 0.594. Binarized American Joint Committee on Cancer (AJCC) stage showed consistent separation in PCA and UMAP spaces, and four individual embedding dimensions correlated with advanced stage at magnitudes up to r equals 0.58. Recurrence also aligned with several embedding axes, including representative correlations of r equals 0.68, 0.63, 0.57, and 0.56. Zone level summaries captured additional biology, with immunosuppressed status reflected in zone level UMAP and PCA components that reached r equals 0.337. The mean absolute correlation across all outcomes was 0.184, and nine correlations exceeded an absolute value of 0.3.These results show that foundation model representations derived from polyomavirus targeted immunohistochemistry contain measurable structure related to viral status, stage, recurrence, and host immunologic state. The ability of slide level and zone level embeddings to recover these signals in a modest cohort suggests that pre trained encoders capture histoarchitectural and spatial cues relevant to Merkel cell carcinoma biology. Larger multi site cohorts with longitudinal follow up will enable validation of these features and support integration with circulating or genomic markers for risk stratification in prospective studies.

#1440 FLEXMIL: A flexible multimodal multiple instance learning framework for clinical and translational research.

Meijian Guan[1], Qifeng Zhou[2], Sneh Lata[3], David Soong[3], Mirna Lechpammer[4], Craig Thalhauser[3], **Han Si**[3]

[1]Genmab, Princeton, NJ,[2]Computer Science and Engineering, The University of Texas at Arlington, Arlington, TX,[3]Translational Data Science, Genmab, Princeton, NJ,[4]Pathology, Genmab, Princeton, NJ

Background: Multiple-instance learning (MIL) provides a powerful framework for training deep neural networks in settings lacking detailed annotations, particularly in digital pathology, where slide-level labels are routinely available, but region- or tile-level annotations are scarce. However, most existing MIL toolkits suffer from limited maintenance, functionality, and restrictive licenses, hindering adoption in clinical-translational research.
Methods: We present FLEXMIL, a flexible, end-to-end MIL framework designed to unify pathology, omics, and clinical data analysis. FLEXMIL was developed in Python (V3.10) to enable survival analysis, classification, and regression with robust cross-validation, automatic data splitting, and standardized reporting to ensure reproducibility. A co-attention fusion module was implemented to integrate multimodal data including clinical information, histopathology images and omics data, while also supporting single-modality experimentations. FLEXMIL generates slide-level predictions, patient-level summaries, and attention-based heatmaps to facilitate biomarker discovery, visual interpretation and hypothesis generation.
Results: We evaluated FLEXMIL across diverse translational use cases, including biomarker discovery, tumor target expression prediction, survival analysis and demonstrated its versatility and robust performance. Importantly, a significant advancement was observed when FOLR1-related transcriptomic signatures were integrated with features extracted from H&E-stained images, leading to enhanced predictive performance for FOLR1 expression levels. Specifically, this multimodal approach boosted not only the AUC from 0.72 to 0.83 in binary classification, but the correlation coefficient for continuous values predicted from 0.5 to 0.78 in TCGA-LUAD (N=460). Same approach further improved the AUC of the predicted FOLR1 protein expression from 0.78 to 0.83 in a commercial cohort (N=69) and enhanced overall survival prediction (C-index increased from 0.59 to 0.62) in TCGA-LUAD (N=334), outperforming models based on image data alone. In the biomarker identification task, we predicted tumor-infiltrating-lymphocytes (TILs) in 85 TCGA-TNBC samples with %TIL annotated by two pathologists. At a 10% TIL threshold, FLEXMIL achieved an AUC of 0.89, highlighting the strong predictive value of histopathology features. In addition, FLEXMIL can generate attention heatmaps for image-only and multimodal (co-attention) models, with support for multi-head views and transcriptomic signature-guided explanations to enable transparent slide-level interpretability.
Conclusions: FLEXMIL provides a flexible, scalable and interpretable platform that bridges computational modeling and clinical insight, advancing the development of integrative biomarkers for precision oncology.

#1441 Whole-slide image and clinical feature integration for superior prostate cancer risk stratification.

Justin Johnson[1], Kingsley Ebare[2]

[1]Creighton University School of Medicine - Phoenix Regional Campus, Phoenix, AZ,[2]Mayo Clinic Arizona, Scottsdale, AZ

Background: Prostate cancer remains one of the most common malignancies in men, with significant heterogeneity in clinical outcomes. Early and accurate diagnosis and risk stratification is crucial for effective treatment and improved outcomes. Although Gleason score is an established risk stratification tool, it does not fully explain outcome variability. We present a multimodal deep-learning framework that integrates attention-based whole-slide image (WSI) features with a clinical variable (Age) to predict survival in patients with prostate adenocarcinoma.

Design: Clinical data and WSI for 500 patients with prostate adenocarcinoma were obtained from TCGA-PRAD. Clinical data were parsed for recurrence or progression (RoP) events and age. RoP was used as the outcome label, and age was used as a patient feature. Diagnostic WSI tumor regions were annotated and tiled at 224×224 pixels using QuPath (Bankhead *Sci Rep* 2017). Tile embeddings were extracted with UNI2-h (Mahmood *Nat Med* 2025). An end-to-end machine learning pipeline was developed to aggregate tile embeddings into slide-level embeddings using Clustering-Constrained Attention Multiple Instance Learning (CLAM) and predict RoP (Lu *Nat Biomed* 2021). A second pipeline used a Gleason score-trained binary cross entropy (BCE) model to predict RoP in the same patients. Three models were evaluated: WSI-only CLAM model, WSI+age CLAM model, and Gleason-only BCE model. All models were trained and evaluated using 5-fold stratified cross-validation. Each fold was repeated 3 times with independent random initialization. AUROC was averaged across all folds and runs per model. Standard deviation was also computed. Model performance was compared using Friedman's test, with post hoc pairwise comparisons by Wilcoxon signed-rank test.

Results: The Gleason BCE model underperformed (AUROC 0.67 ± 0.07). Both WSI-based models outperformed the Gleason BCE model, achieving AUROC 0.76 ± 0.02 (without age), and AUROC 0.76 ± 0.01 (with age). AUROCs were significantly different by Friedman's test ($p = 0.0224$) and showed a trend toward significance in post-hoc comparison between WSI and Gleason-based approaches ($p = 0.06$).

Conclusion: AI models using WSI-derived features, with or without basic clinical context, outperformed traditional Gleason score for recurrence risk prediction in prostate cancer. These findings support the integration of digital pathology and AI into routine prognostic assessment for prostate cancer. Future work will focus on including additional patients, clinical variables, and multi-class prognostic labels to expand prognostic prediction beyond RoP.

#1442 Spatial transcriptomics informed tumor purity estimation from histology slides for triple negative breast cancer.

Minh-Khang Le[1], **Vivek Pujara**[1], I-Chuang Liao[1], Yuan Yuan[1], Joseph Lownik[1], Graeme Murray[2], Jin Sun Bitar[1], Luxi Chen[1], Parisa Najafzadeh[2], Keeyon Dabirian[2], David Lin[1], Fred W Kolling IV[3], Parth S. Shah[4], Jonathan Marotti[4], Xiaoying Liu[4], Louis J. Vaickus[4], Keluo Yao[1], Linda T. Vahdat[4], Zarif L. Azher[5], Joshua Levy[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Huntington Health, Pasadena, CA,[3]Dartmouth Geisel School of Medicine, Hanover, NH,[4]Dartmouth Hitchcock Medical Center, Lebanon, NH,[5]Zarif Azher (Individual), Great Falls, VA

Introduction: Tumor purity, defined as the proportion of malignant cells within a tumor region, is a critical factor in cancer research and clinical practice. Accurate tumor purity estimates (TPEs) are crucial in triple-negative breast cancer (TNBC), where tumor heterogeneity complicates diagnosis, biomarker interpretation, and therapeutic decisions. Traditional pathological assessment of tumor purity is limited by observer variability and scalability. Spatial transcriptomics (ST) integrates whole-transcriptome data with spatial context, enabling high-resolution and scalable estimation of tumor purity directly from H&E-stained slides. This study develops and validates ST-supervised deep learning models for spatially resolved, reliable TPEs that support more precise clinical evaluation and treatment guidance in TNBC.

Methods: Visium ST data and matched 40× H&E whole-slide images from 25 TNBC patients were collected from Dartmouth-Hitchcock Medical Center (DHMC), yielding 120,973 50-µm Visium spots with co-registered 512×512-pixel H&E patches. Tumor regions were segmented using a validated DeepLabv3 model. Cell-type reference profiles were derived by integrating an external breast single-cell atlas with in-house single-cell RNA-seq data from seven TNBC patients using SCANVI. The integrated single-cell data were mapped onto in-house Visium sections with Cell2Location to estimate spot-level tumor cell-type proportions, serving as supervisory labels. A deep learning model (VIDCellTyper), built on the Virchow 2 model, was trained and cross-validated to predict spot-level tumor proportions and produce spatially resolved tumor purity maps. HoVerNet-derived cell counts from each patch were used for slide-level purity computation via cell-count-weighted averaging. The workflow was validated on an independent TNBC cohort (n=29; DHMC and Cedars-Sinai Medical Center), where slide-level purity was derived from aggregated patch-level predictions by the ST-informed model and HoVerNet.

Results: Across tumor regions, the ST-supervised deep learning model achieved a spot-level purity correlation of 0.88 ($p < 0.001$) with spot-level Hovernet-derived TPE. When aggregating across the internal and external cohorts (n=29), slide-level ST-informed TPE showed a Spearman correlation of 0.83 ($p < 0.001$) with Hovernet-derived TPE.

Conclusion: This proof-of-concept study shows that ST can guide computational models to derive TPE directly from H&E slides, yielding accurate and spatially resolved results. The ST-guided model generalized across independent TNBC cohorts, demonstrating robustness across tissue workflows. Future work will refine and validate this approach in clinically relevant contexts, including therapy response, prognosis, and pre- versus post-chemotherapy evaluation, to advance precision in treatment assessment and biomarker development.

#1443 AI-assisted quantitative tissue pathology identifies nuclear morphometric features distinguishing OSCC from normal oral epithelium.

Kelly Y. P. Liu[1], Paul Gallagher[2], Calum Macaulay[3], Catherine FY Poh[4]

[1]Oral Biological and Medical Sciences, University of British Columbia, Vancouver, BC, Canada,[2]Basic and Translational Research, BC Cancer Research Institute, Vancouver, BC, Canada,[3]Clinical Assoc. Professor & Head, Cancer Imaging Dept., BC Cancer Research Institute, Vancouver, BC, Canada,[4]Associate Professor, University of British Columbia Faculty of Dentistry, Vancouver, BC, Canada

Early detection and risk stratification of oral squamous cell carcinoma (OSCC) remain major clinical challenges, and traditional histopathology is limited by subjectivity and interobserver variability. The objective of this study is to investigate the effectiveness using image-analysis pipeline integrating deep-learning nuclei segmentation and multifeature risk scoring of microscopic nuclear morphometric features to distinguish OSCC from normal oral tissue. We hypothesize that nuclear appearance alone contains sufficient biological signal to stratify malignant from non-malignant tissue.

The dataset comprised 34 OSCC and 25 normal mucosa tissue microarray cores from 59 patients that were stained with stoichiometric Feulgen-Thionin stain. Scanned images were converted to 8-bit grayscale, and background brightness was automatically normalized. Nuclear segmentation was performed using a two-stage deep-learning UNet pipeline implemented in PyTorch, with one network detecting nuclear centers and a second network generating full nuclear masks. Following segmentation, 84 nuclear features describing DNA content, morphology, and chromatin texture and spatial organization were extracted. These features were used to train and evaluate three supervised machine-learning classifiers distinguishing OSCC from normal group: Random Forest, XGBoost, and LightGBM. All models were trained on the same feature matrix and identical training/test splits using 5-fold cross-validation. Hyperparameters were tuned using grid search. Model performance was assessed using accuracy, sensitivity, and specificity.

This improved segmentation approach identified 96,000 and 78,000 nuclei in OSCC and normal, respectively. Across all classifiers, LightGBM performed the best (94.2%), followed by XGBoost (93.5%), while Random Forest showed slightly lower, but still strong, performance (91.5%). Malignant nuclei showed consistently larger size, greater irregularity, and more heterogeneous chromatin texture ($p < 0.0001$). Applied to a separate set of 9 oral premalignant samples, the LightGBM model correctly identified 4/5 high-grade lesions, 2 low-grade progressors, and 2 low-grade non-progressors, with 100% specificity.

This approach identifies distinct nuclear morphometric signatures associated with OSCC and provide an objective, quantitative framework for diagnostic classification. Nuclear appearance alone can effectively differentiate malignant from normal epithelium, supporting its potential application in risk assessment and early detection. Ongoing efforts focus on refining the segmentation model and cell-type classification model to retain only squamous epithelial nuclei. Future work will extend this framework to oral epithelial dysplasias to evaluate its utility for progression prediction.

#1444 Lauren subtype classification in gastric cancer using deep learning on real-world H&E images.

Akul Singhania, Qiyuan Hu, Riccardo Miotto, Justin Guinney, Radia M. Johnson

Tempus AI, Inc., Chicago, IL

Introduction:
Gastric cancer (GC) is a heterogeneous disease, with Lauren classification providing a framework to assign diffuse and intestinal subtypes, informing prognosis and therapy. Traditional subtype assignment relies on pathologist review of hematoxylin and eosin (H&E)-stained slides, leading to inter-observer variability and scalability challenges. We developed a deep learning classifier to automate Lauren subtype assignment on real-world H&E images.
Methods:
We analyzed de-identified H&E-stained whole slide images (WSI) from biopsies and resections of 2974 GC patients (3160 samples) from the Tempus real-world database. Samples with pathologist-assigned labels (n=399 diffuse; n=238 intestinal) were used for classifier training. WSI were preprocessed into tissue tiles and tile embeddings were extracted using the H-optimus-0 pathology foundation model. An additive attention-based multiple instance learning model was trained with cross-entropy loss weighted by class prevalence. Data were split 80/20 for development/holdout, with 5-fold cross-validation for model tuning and selection, and ensembled predictions from 5 cross-validation models were used to assign subtypes. An operating point was selected for ~90% positive predictive value (PPV) on the holdout set for each class. Real-world overall survival (rwOS; time from first-line therapy to death) was assessed in patients with available data (31%).
Results:
The model achieved a robust performance (AUC 0.93, 95% CI: 0.88-0.98) on the holdout set. With PPV-optimized thresholds, previously unlabeled samples (n=2523) were assigned by the model as diffuse (n=1321, 52.4%), intestinal (n=749, 29.7%), or indeterminate (n=453,17.95%). For pathologist-assigned samples, diffuse cases had worse median OS (13.3 months, 95% CI: 11.5-15.8) than intestinal (22 months, 95% CI: 15.1-29.8; p=6.2e-4). For classifier-assigned samples, diffuse cases had a shorter median OS (12.6 months, 95% CI: 10.8-15.7) than intestinal (15.3 months, 95% CI: 12.2-17.3; p=0.95). *CDH1* mutations were found in 30.3% of pathologist-labeled and 23.7% of classifier-assigned diffuse tumors, but were rare in intestinal tumors (1.3%, 1.1%). *RHOA* mutations were present in 8.5% of pathologist-labeled and 8.3% of classifier-assigned diffuse tumors, versus 2.5% in intestinal tumors for both groups. Other histologies predominantly aligned with model predictions: signet ring cell carcinoma was predicted diffuse, while tubular, papillary, and mucinous adenocarcinomas were predicted intestinal.
Conclusions:
This deep learning classifier can accurately assign Lauren subtypes in GC from real-world H&E-stained WSI, reducing manual review and variability. Model predictions align with known clinical and molecular differences between subtypes, supporting standardization of Lauren classification and enabling large-scale studies of GC.

#1445 Predicting TCGA molecular subtypes of gastric cancer from H&E whole-slide images using a weakly supervised transMIL-attention framework.

Yesul Jeong[1], Dewan M. Bappy[2], Sangjeong Ahn[3], Sung Hak Lee[4]

[1]Department of Hospital Pathology, St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[2]Department of Computer Science and Engineering, Incheon National University, Incheon, Korea, Republic of,[3]Department of Pathology, Korea University Anam Hospital, Seoul, Korea, Republic of,[4]Department of Hospital Pathology, Seoul St. Mary's Hospital, Seoul, Korea, Republic of

Background:
The Cancer Genome Atlas (TCGA) has defined four molecular subtypes of gastric cancer: Epstein-Barr virus (EBV)- associated, microsatellite instability (MSI)- associated, genomically stable (GS), and chromosomal instability (CIN). These subtypes have distinct clinicopathologic and therapeutic implications. However, the routine determination of these subtypes still relies on multimodal molecular assays that are costly and not universally available. We aimed to develop a weakly supervised deep learning framework that predicts TCGA molecular subtypes directly from hematoxylin and eosin (H&E)-stained whole-slide images (WSIs).
Methods:
As a baseline, we implemented attention-challenging multiple instance learning (ACMIL), which leverages multi-branch attention (MBA) and stochastic instance masking for weakly supervised WSI classification. We then proposed a hybrid multiple instance learning (MIL) model that combines a transformer-based MIL architecture (TransMIL) with an MBA. The features and attention scores from TransMIL-MBA were fused via weighted attention to generate slide-level predictions. The model was trained and evaluated on 484 H&E WSIs at 20× magnification with TCGA molecular subtype labels for gastric cancer from the TCGA ESCA and STAD projects, using an 80%, 10%, and 10% split for training, validation, and testing, respectively. Model performance was assessed using the four-class area under the receiver operating characteristic curve (AUC), accuracy, confusion matrices, and visualization of the latent feature space with UMAP and V-measure.
Results:
Attention heatmaps indicated that the proposed TransMIL-MBA hybrid model consistently highlighted histologically relevant tumor regions compared to ACMIL. On the TCGA test set, the TransMIL-MBA model outperformed ACMIL in four-class subtype classification (AUC: 0.89 vs. 0.87; accuracy: 0.74 vs. 0.67). The hybrid model also showed improved subtype separability in the UMAP embedding (V-measure 0.74 with TransMIL-MBA vs. 0.65 with ACMIL) and clearer confusion matrices.
Conclusions:
A weakly supervised multiple instance learning framework combining TransMIL with MBA shows promising performance for predicting TCGA molecular subtypes of gastric cancer directly from H&E WSIs. By providing a scalable, image-based surrogate method for molecular subtyping, this approach may help move clinical care closer to precision medicine, enabling more tailored treatments and potentially improving outcomes for patients with poor-prognosis gastric cancer.

#1446 Accurate focal plane is crucial for AI assessment of non-monolayer urine cytology specimens for bladder cancer screening and surveillance.

Brody McNutt[1], Sam Harvey[2], Minh-Khang Le[1], I-Chuang Liao[1], Keluo Yao[1], Xiaoying Liu[3], Camille Ng[1], Ahmad Kohsar[2], Daniel Shou[2], Christopher VandenBussche[2], Louis J. Vaickus[3], Joshua Jay Levy[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Johns Hopkins Medical Institutions, Baltimore, MD,[3]Dartmouth-Hitchcock Medical Center, Lebanon, NH

Background: Bladder cancer requires frequent surveillance, and urine cytology is widely used to guide cystoscopic evaluation. Digital image analysis aims to provide quantitative cell-level metrics aligned with The Paris System, but many laboratories use non-monolayer preparations (e.g., SurePath) that place cells in three-dimensional arrangements, complicating automated evaluation. We assessed how focal-plane selection affects nuclear-to-cytoplasmic (NC) ratio estimation and compared several algorithmic strategies for identifying the optimal focal plane.

Methods: We analyzed 300 SurePath whole-slide images scanned on a Roche Ventana DP 200 system (Johns Hopkins), evenly spanning negative, atypical, suspicious, and high-grade carcinoma cases. A published detection model identified clusters, which were reannotated by six pathologists, yielding 343 clusters and 2,435 urothelial cells. Annotators outlined nuclei and cytoplasm areas at each cell's best-focus plane. We evaluated classical focus metrics (Sum of Modified Laplacian [SML], High-Frequency Energy [HFE], Tenengrad, Brenner Gradient, Laplacian, and entropy-based OpenCV methods) and unsupervised vision-transformer approaches (feature-variance [ViT-V], attention-entropy [ViT-A], and supervised Z-stack transformer models [ViT-T, ViT-CLS] that directly predict the focal plane). Algorithms were assessed by within-1-plane accuracy relative to pathologist ground truth. NC ratios were derived from nuclear/cytoplasmic areas. U-Net segmentation generated NC ratios for a held-out test set, and Spearman correlations with ground truth were evaluated using: (1) pathologist-selected planes; (2) off-plane images; and (3) algorithm-selected planes.

Results: Within-1-plane accuracy was 0.416 (ViT-A), 0.594 (Grad), 0.740 (HFE), 0.779 (OpenCV), 0.789 (ViT-V), 0.853 (Laplacian), 0.857 (Tenengrad), 0.862 (SML), and highest for Z-stack transformers ViT-T and ViT-CLS (0.874, 0.872). NC-ratio estimation at the pathologist-selected plane reached a correlation of 0.774. Correlations decreased as images moved off-plane (~0.74 at ±1 plane; ~0.69 at ±2; ~0.65 at ±3; ~0.59 at ±4; ~0.50 at ±5). Using algorithm-selected planes, correlations were 0.639 (ViT-A), 0.687 (Grad), 0.720 (ViT-V), 0.728 (HFE), 0.733 (OpenCV), 0.743 (Tenengrad), 0.744 (Laplacian), 0.746 (SML), and 0.745/0.738 (ViT-T/ViT-CLS).

Conclusion: Accurate focal-plane selection is essential for reliable AI-based cytologic assessment in non-monolayer urine preparations. NC-ratio accuracy and downstream analytic validity degraded quickly off-plane, while algorithm-selected planes recovered much of this loss. Future work will evaluate impacts on cluster- and patient-level tasks and assess extended-focus fusion methods that stitch the sharpest regions across the z-stack into a single optimally focused image.

#1447 DIANNE: Segmentation-free localization of histology differential attributes.

Sergii Domanskyi[1], Jill C. Rubinstein[1], Todd Sheridan[1], Adam Thiesen[1], Javad Noorbakhsh[1], Juliana Alcoforado Diniz[1], Ramalakshmi Ramasamy[1], Dylan S. Baker[1], Riley Sheldon[1], Qian Wu[2], George Kuchel[3], Paul Robson[1], Jeffrey H. Chuang[1]

[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[2]Department of Pathology and Laboratory Medicine, UConn Health, Farmington, CT,[3]UConn Center on Aging, UConn Health, Farmington, CT

Pathologist-guided distinctions within histology images provide insights into tissue health, driving advances in understanding of disease mechanisms and clinical decision making. Digital pathology leveraging artificial intelligence is increasingly important to derive insights from histology and spatial omic images. To train computational models, current digital pathology methods rely on upfront manual annotations, which are time-consuming and difficult to scale. This pre-annotation process is also poorly suited for investigating novel spatial behaviors, where annotation is challenging and data requirements are unclear.

To address these issues, we present DIANNE (Differential Image Annotator Environment), a digital pathology approach for rapid computation of spatial differential image attributes based on train-time Positive Class Mixup Augmentation (PCMA) of deep learning imaging features. DIANNE enables localization of differential attributes across whole slide images (H&E or antibody-based multiplex imaging, e.g. CODEX) in seconds on standard workstations, enabling interactive applications for exploratory investigation. Predictive models can be re-trained in real-time after interactive tile annotation changes, clarifying important biological attributes within and across tissue slides.

We first test DIANNE on static histology images for sarcoma tumor detection. We demonstrate that classifiers can be developed with as few as 60 previously unannotated tumor slides to achieve high precision (0.86 ± 0.17) and recall (0.73 ± 0.26), as well as reasonable specificity (0.58 ± 0.3) and low false positives (0.0000 ± 0.0001). These metrics are comparable to more compute intensive pixel-based methods, e.g. [Segmenter. Strudel R et al. arXiv 2105.05633, 2021] (values 0.86 ± 0.15, 0.86 ± 0.22, 0.53 ± 0.28, 0.0062 ± 0.0129) which also required regional annotations, GPU and 6 hours of compute. Moreover, DIANNE has unique capabilities for *interactive* exploration of tissue slides. We show biological structure detection from human pancreatic, placenta and kidney tissue slides, including identification of staining and imaging artifacts. For kidney glomeruli detection we demonstrate tile-level recall, specificity, and false positives of 0.95, 0.95, 0.0002, respectively, based on interactive annotation of only 40 positive and 60 negative patches out of 2884 total patches. Just 9 out of 359 true glomeruli are missed, 7 of which were partially cropped.

DIANNE provides multiple spatial inference workflows (interactive/static, H&E/molecular) implemented in a Jupyter widget-based toolkit. DIANNE enables efficient training of foundation model-based classifiers with only image scale annotation, rather than at the pixel-level. DIANNE's rapid, interactive system allows real-time training from static and exploratory input, providing a practical system for discovery of novel behaviors in spatial datasets.

#1448 Deep learning integration of molecular and histopathological data for prognostic stratification in non small cell lung cancer.

Sanddhya Jayabalan[1], Konstantinos Efthymiadis[2], Alexia Eliades[3], Kyriaki Papadopoulou[2], Abraham Pouliakis[4], Elena Fountzilas[2], Sofia Lampaki[2], Mattheos Bobos[2], Anna Goussia[2], Soultana Meditskou[2], Konstantinos Kyritsis[5], Helena Linardou[2], George Pentheroudakis[2], Dimitrios Bafaloukos[2], Dimitrios Pectasides[2], Epaminondas Samantas[2], Zunamys I. Carrero[1], George Fountzilas[2], Jakob N. Kather[1]

[1]Else Kroner Fresenius Center for Digital Health (EKFZ), Technische Universitat Dresden, Dresden, Germany,[2]Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece,[3]Medicover Genetics, Cyprus, Greece,[4]University General Hospital Attikon, National and Kapodistrian University of Athens Medical School, Athens, Greece,[5]Centre for Research and Technology Hellas, Institute of Applied Biosciences, Thessaloniki, Greece

Background: Co-mutations, PD-L1 and TILs are key NSCLC biomarkers. We applied deep learning to a multimodal patient cohort to identify prognostic patterns integrating morphology, mutations, and clinical features.

Methods: 367 NSCLC patients from 18 Hellenic Cooperative Oncology Group-affiliated centers were retrospectively assessed for PD-L1 status (Dako 22C3 pharmDx), TILs (H&E slides), and somatic pathogenic variants with a 38-gene next-generation sequencing (NGS) panel. Whole slide images (WSI) were digitized by an optical microscope scanner. Ten pathology foundation models were benchmarked for predicting mutation, co-mutation, PD-L1 and TILs status. Mutated genes with >5% prevalence were considered for mutation and co-mutation endpoints (*TP53*, *KRAS*, *STK11*, *PTEN*, *EGFR*). A vision transformer model was trained on WSI features to predict endpoints and evaluate AUROC. Kaplan-Meier analysis assessed prognostic relevance of models and top feature tiles from model attention maps provided morphological explainability. The STAMP digital pathology pipeline supported feature extraction and model training.

Results: Single mutation models yielded AUROC scores of 0.6-0.85, with *STK11* prediction from HOptimus1 features highest. Co-mutation models produced AUROC scores of 0.69-0.77 with *EGFR-TP53* prediction from Uni2 features the best. The *KRAS-TP53* co-mutation model (AUROC 0.69, Uni2) showed significant separation in overall survival curves (p=0.05) between classes. Best-performing PD-L1 and TIL models also demonstrated significant survival separation (p=0.005 and p=0.05).

Conclusion: Findings demonstrate the potential of pathology foundation models to derive complex clinically-relevant prognostic models for NSCLC with multimodal explainability.

AUROC by endpoint and foundation model

Conventional H&E staining is destructive, 2D-limited, and incompatible with longitudinal or scarce-sample studies. Holotomography (HT) enables label-free 3D refractive index (RI) imaging of thick tissue, but pixel-accurate supervision for virtual staining is unattainable due to sectioning-induced deformation. Building on our recent demonstration of 3D virtual H&E for colon and gastric cancer tissues up to 50 µm thick, we developed a framework that learns hematoxylin- and eosin-like contrast directly from HT volumes using weakly aligned chemical H&E supervision. The method produces stable, interpretable nuclear and stromal features, enabling nuclei-centric quantitative readouts in a fully label-free workflow.FFPE breast cancer tissues were imaged with 3D HT to obtain quantitative RI volumes at subcellular resolution. A diffusion-based image-to-image model was trained with weak HT–H&E alignment and a nucleus-aware auxiliary loss applied only during training. Inference requires HT alone, maintaining a consumable-free, non-destructive pipeline. Fidelity was evaluated by (i) nuclear morphology agreement, (ii) patch- and field-level realism, (iii) smooth z-slice consistency, and (iv) standardized nuclei quantification. Cross-tissue generalizability was assessed using previously validated colon and gastric datasets spanning 10–50 µm thickness.The virtual H&E preserved basophilic nuclear contrast and eosinophilic stromal features, accurately reconstructing glandular, stromal, and muscular boundaries even in thick sections. Nuclear contours remained continuous across axial planes without flicker artifacts. Whole-field nuclear counts showed 97.8% concordance with chemical H&E, and nuclear area/shape metrics showed no significant deviation. Appearance error was notably lower than prior virtual-staining approaches, and expert reviewers confirmed faithful chromatin texture, nucleoli visibility, and nuclear crowding patterns essential for cancer grading. The method remained robust across tissue thicknesses (4–50 µm), organ types, and institutional sources.Virtual H&E generated directly from label-free HT enables high-fidelity, nuclei-driven readouts without staining, sectioning artifacts, or tissue loss. This supports rapid, consumable-free tissue assessment and reproducible quantification of nuclei-centric biomarkers. Its compatibility with thick tissue volumes positions the technology for drug-response profiling, mechanism-of-action studies, tumor microenvironment analysis, and high-content phenotypic screening. Ongoing multi-site validation and development of 3D diffusion models for whole-slide inference aim to establish label-free 3D virtual histopathology as a scalable alternative to conventional H&E for research and translational oncology.

#1450 3D holotomography-enabled virtual multiplexed staining of thick medical kidney tissue for comprehensive renal pathology.

Siwon Jeong[1], **Juyeon Park**[1], Hyun-Seok Min[2], Minsun Jung[3], YongKeun Park[4]

[1]KAIST, Daejeon-si, Korea, Republic of,[2]Tomocube, Daejeon-si, Korea, Republic of,[3]Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Korea Advanced Institute of Science and Technology, Daejeon-si, Korea, Republic of

Renal pathology relies on multiple special stains—including H&E, PAS, AFOG, and PAM—to assess glomerular, tubular, and interstitial changes. These stains require serial sections, are prone to variability, and involve destructive processing, limiting consistency and preventing true 3D interpretation. Holotomography (HT) enables label-free 3D refractive index (RI) imaging of thick tissues, and generative translation models can synthesize stain-equivalent contrast directly from RI inputs. We developed a virtual multiplexed staining framework that generates four major renal stains from a single label-free input, including for thick sections where conventional staining becomes unreliable.Medical kidney samples (thin and thick sections up to 50 μm) were imaged with 3D HT to obtain RI volumes. A conditional generative model was trained on paired RI–stain patches (H&E, PAS, AFOG, PAM) after registration and QC. Similarity metrics—SSIM, PSNR, LPIPS, PCC—were computed on held-out regions. The model was applied to (i) label-free RI and (ii) chemically stained slides to produce cross-stain predictions, enabling direct comparison. Whole-slide virtual staining was performed on 0.5-mm kidney regions.The framework reproduced diagnostic features across stains, with structural similarity typically >0.85. Virtual stains restored key elements—including basement membranes, mesangial matrix, tubular epithelium, and interstitial collagen—closely matching chemical references. Large-region predictions preserved coherent architecture. Virtual PAS and AFOG highlighted basement membranes, glycogen-rich areas, collagen deposition, and casts, supporting interpretation of glomerular injury and interstitial fibrosis. Robust performance was maintained in thick tissues (10–50 μm), where chemical stains often show uneven penetration; virtual stains preserved uniform contrast and delineated overlapping structures. Multiplexing enabled consistent visualization of basement membrane thickening, mesangial expansion, and inflammation within the same section, removing serial-section artifacts.Holotomography with generative translation enables reliable, label-free virtual multiplexed staining, producing H&E, PAS, AFOG, and PAM–equivalent images from a single unstained or singly stained input. The method preserves renal microanatomy and remains robust in thick sections where conventional staining can fail. By eliminating serial sectioning and repeated chemical processing, it provides a unified, non-destructive workflow that improves reproducibility and enables direct cross-stain comparison. This positions virtual multiplexed staining as a scalable, pathology-ready technology for renal disease assessment, translational research, and computational pathology pipelines.

#1451 Visualizing the genotype-phenotype link: Predicting drug-induced tissue dynamics with RNA-based diffusion models.

Vaagn A. Chopuryan[1], Arman Petrosyants[2], Gor A. Chobanyan[1], Dmitrii V. Ivchenkov[1], Eduardo Shugaev-Mendosa[1], **Alexander Bagaev**[1], Viktor Svekolkin[1], Aleksandr Sarachakov[1]

[1]BostonGene Corporation, Waltham, MA,[2]Research Center for Digital Engineering and Innovation, Moscow, Russian Federation

Introduction: Oncology drug development is highly challenging because the chance of obtaining FDA approval is only 4.1%. This underscores the need for predictive models that may de-risk this process and improve the odds of success. We hypothesize that accurate modeling of tissue structures based on gene expression profiles may shed light on genotype-to-phenotype relationships that are crucial for uncovering fundamental biological mechanisms and predicting how drugs affect tissue architecture, with prospects in guiding therapeutic strategies and informing early-phase trial design. Here, we present an RNA-aware diffusion model that produces realistic histological states of tissue samples based on rich RNA vector representations, capturing specific changes in gene signatures.
Methods: RNA embedding based on expression data of 20,062 genes obtained using a variational autoencoder trained on RNA-seq samples from public sources was integrated via cross-attention to condition the diffusion model. The diffusion model was then fine-tuned on paired H&E-RNA-seq samples from TCGA, CPTAC, and GTEx. Board-certified pathologists were consulted to verify the biological relevance of the generated images and the correspondence between the visual histological structures and altered signatures.
Results: Our model generated 512×512-pixel tissue crops (0.5 microns per pixel) with a visually indistinguishable FID of 15. The encoder performance metrics were an MSE of 0.0008 and a median R2 of 0.885. In a simulated H&E analysis, drug-induced gene expression changes were reflected in the anticipated tissue slides over time, showing the dynamics of tertiary lymphoid structures (TLS) and follicles corresponding to changes in TLS and B-cell signature. As such, the model could capture biologically meaningful tissue-level responses, enabling in silico modeling of tissue alterations resulting from specific gene or signature modifications, including those induced by therapeutic interventions.
Conclusion: By translating gene expression profiles into depictable tissue structures, our model enables the prediction of how drugs or drug combinations impact tissue morphology through their effects on gene expression. This approach allows us to gather insights into the underlying mechanisms of action for drugs and drug combinations, thereby promoting the discovery of promising single agents or combinations, such as immune checkpoint inhibitors, T- or NK-cell engagers, or PD-1/VEGF bispecific antibodies, that are tailored to specific diagnoses. Our model is poised to improve drug candidate selection, optimize study design, and reduce drug development costs, aiding both preclinical discovery and early-phase clinical development.

#1452 A high-throughput slide scanning pipeline for digitizing and standardizing legacy genitourinary cancer slides.

Faria Kabir[1], Mitra Shavakhi[2], Akash Parvatikar[1], Adrien Cesaire[1], Egypt Phillips[1], Rachel Trowbridge[2], Liliana Ascione[2], Pablo Barrios[2], Marc Eid[2], Jasmine Lee[2], Sabina Signoretti[3], Eliezer Van Allen[2], Atish Choudhury[2], Linh Hoang[1], Toni K. Choueiri[2], Jeremiah Wala[2]

[1]HistoWiz, Long Island City, NY,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Brigham and Women's Hospital, Boston, MA

Objective:
To build a reproducible digital slide archival pipeline and tissue image repository for genitourinary cancers using archival slides from a large cancer research organization for digital pathology applications and biomarker discovery.
Background:
Digital pathology applies computer vision to digitized H&E to quantify tumor microenvironment and architectural features. Archival tissue with extensive clinical follow-up is essential to this aim, but converting glass slides to high-quality digital images is a significant challenge. We describe a high-throughput, whole slide imaging (WSI) pipeline developed at HistoWiz and its application to over 20,000 legacy cancer slides from the Gelb Center for Translational Research at the Dana-Farber Cancer Institute (DFCI).
Methods:
HistoWiz designed a workflow for (i) standardized intake of archival clinical slides with heterogeneous stain quality, labeling formats, and coverslipping artifacts, (ii) proprietary bulk logistics solutions enabling transport of up to 9,600 slides per shipment with <0.001% damage rate, (iii) high-fidelity scanning using hardware capable of penetrating dirt/film layers commonly found on aging slides, (iv) a real-time, scalable review process via the HistoWiz PathologyMap platform and (v) optical character recognition (OCR) for handwritten slide labels.
Results:
Archived slides from over 20 years (2001 to 2025) of slide collection were scanned at 900 slides per day, using two high-throughput scanning clusters with a >90% initial QC pass rate. A representative subset of images was independently evaluated by a pathologist for issues including tissue folds, cracking, air bubbles, blebs, ink annotations, and out-of-focus regions. We found that most QC failures were caused by four recurring issues: tissue folding from microtomy (30%), cover-slip issues (10%), mounting media residue (2%), and handwritten annotations or processing artifacts (1.5-12.5%). Corrective measures, including rescanning, xylene- or alcohol-based coverslip cleaning, and recoverslipping, resolved >95% of cases with cover-slip or mounting media issues, with limited tissue loss. Final slides were stored as pyramidized OME-TIFF files at 0.248 µm/pixel, averaging 2 GB per slide. In an offline Python pipeline, a Google Vision-derived OCR model yielded superior barcode read rate and accuracy on histology slides, outperforming Microsoft's OCR, Tesseract (v4+), and a Keras-based CRNN baseline.
Conclusion:
Our large-volume and high-throughput WSI archival workflow delivers a scalable imaging pipeline that digitized a 20-year academic tissue biobank and provides on-demand access to AI-ready, high-quality quality full-resolution slide images. This digital image repository will support large-scale digital pathology research to discover biomarkers in genitourinary cancer.

#1453 Association of interpretable histomorphic features with molecular markers: A Computational Histology Artificial Intelligence (CHAI) biomarker development platform analysis.

Asit Tarsode[1], **Haochen Zhang**[1], Viswesh Krishna[1], Vrishab Krishna[1], Snehal S. Sonawane[1], Lesli A. Kiedrowski[1], Trevor J. Royce[1], Anirudh Joshi[1], Richard M. Goldberg[2], Eric A. Collisson[3]

[1]Valar Labs, Palo Alto, CA,[2]Physician-in-Chief/Internal Medicine, West Virginia University Randolph Cancer Center, Morgantown, WV,[3]Hematology/Oncology, UCSF, San Francisco, CA

Background: Biomarkers are needed to guide precision oncology. Ideally, tools have rapid turnaround and integrate into existing workflows. Computational pathology analyzing features on routine hematoxylin and eosin (H&E) stained whole slide images (WSI) provide an accessible system for biomarker discovery. The Computational Histology Artificial Intelligence (CHAI) platform has been validated to predict clinical outcome endpoints across multiple solid tumor types. To explore the unknown overlap of histomorphic features with molecular markers, we assessed associations of CHAI features with markers from multiplex immunofluorescence (MIF).
Methods: The CHAI platform was built on deep learning models trained on >25,000 pan cancer H&E WSI and incorporates >500,000 pathologist annotated nuclei and 100 million μm² tissue, with macro AUC 0.99 for nuclei and tissue segmentation. These models process H&E WSIs, segment comprehensive cancer-relevant cell and tissue types and quantify >30,000 histomorphologic features representing hallmarks of cancer biology (e.g. nuclei size and shape, spatial arrangement, immune infiltration, stromal density). On 41 colorectal cancer WSIs with matched MIF scans from the ORION dataset, CHAI cell/tissue-typing performance was evaluated against MIF by calculating Pearson correlation coefficient between the densities of CHAI's predicted target and matched MIF markers.
Results: Across 289,619 200 x 200 μm² tissue patches, cell segmentation correlation comparing CHAI-segmented nuclei vs MIF DAPI was 0.899 (95% CI 0.898, 0.900). Cell typing correlation was 0.642 (0.640, 0.644) for CHAI-predicted epithelial cells vs MIF cytokeratin (CK) and 0.587 (0.584, 0.590) for CHAI pan-leukocyte vs MIF CD45. Tissue typing correlation was 0.656 (0.653, 0.658) for CHAI tumor-epithelial regions vs MIF CK and 0.543 (0.541, 0.546) for CHAI stromal regions vs MIF smooth muscle actin. All correlations were statistically significant ($p<0.001$).
Conclusion: The CHAI platform measures histomorphic features from H&E WSI at high accuracy; it captures facets of the tumor microenvironment that showed significant overlaps with molecular markers captured by MIF, while also identifying areas to further explore complementarity in these orthogonal modalities. This work underscores the biologic basis of the CHAI system as a novel modality for biomarker development with potential for biomedical research and clinical applications.

#1454 Development of an AI framework for identifying image based digital biomarkers predictive of immunotherapy response in malignant melanoma.

Theresa Koehler[1], Eleftherios Mylonakis[1], Raluca Wroblewski[2], Khalid Daifalla[1], Jasna Kovacevic[2], Gianluca Corradini[2], **Patrick Frey**[1], Markus Tiemann[2], Katharina Tiemann[3], Tobias Lang[1]

[1]Mindpeak GmbH, Hamburg, Germany,[2]MVZ HPH Institut fur Pathologie und Hamatopathologie GmbH, Hamburg, Germany,[3]Faculty of Medicine, Asklepios Campus Hamburg, Semmelweis University, Hamburg, Germany

Background: The MelanomAIX project developed an AI-based framework to identify image-derived digital biomarkers predictive of immunotherapy response in malignant melanoma. Histopathological slides contain rich subvisual information that reflects tumor-immune interactions often missed by conventional assessment. By combining deep learning-based tissue characterization with molecular and clinical data, MelanomAIX leverages routine pathology for biomarker discovery and precision oncology.
Methods: A real-world cohort of 200 melanoma patients was assembled from multiple clinical archives. Each case was curated with digitized H&E and PD-L1 IHC slides, detailed treatment histories, and verified outcome data. Expert pathologists performed specialized, systematic annotations on 138 representative cases, generating detailed region- and cell-level labels to train and validate the AI model. These data complemented an independent larger dataset of 585 cases with over one million manually annotated cells used for model pretraining. The model characterizes the tumor microenvironment by identifying key tissue compartments, immune infiltration patterns, and subvisual morphological features potentially associated with therapeutic response. Building on these explainable image-derived features, the AI framework integrated paired PD-L1 IHC scores to explore AI-driven, multimodal predictive biomarker discovery.
Results: A total of 106,442 manual single-cell and tissue-level annotations across 12 morphological classes were completed. The AI model achieved high segmentation accuracy for tumor-related tissue classes (91.9-95.7%). Extracted image-based features captured spatial and morphological characteristics of the tumor microenvironment, including immune infiltration and tumor-intrinsic heterogeneity. The framework demonstrates promising robust performance in identifying biologically relevant image features that can support response prediction.
Conclusions: MelanomAIX delivers a scalable AI framework connecting histopathologic morphology with clinical outcomes in melanoma. This approach provides a foundation for developing explainable, image-based digital biomarkers predictive of immunotherapy response. Future work will validate the framework on independent and diverse patient cohorts to assess generalizability and clinical utility in predicting immunotherapy response. This abstract text was prepared with assistance from OpenAI’s GPT-5 language model for drafting and refinement purposes.

#1455 Comparison of digital and artificial intelligence (AI)-computational algorithms for quantifying low/ultralow human epidermal growth factor receptor 2 (HER2) protein expression in metastatic breast cancer (mBC) from clinical samples.

Background Based on DESTINY-Breast04 (HER2-low) and -06 (HER2-low/-ultralow) trials, T-DXd is approved for HER2-low (immunohistochemistry [IHC] 1+ or IHC 2+/in situ hybridization negative) or -ultralow (IHC 0 with membrane staining in ≤10% of tumor cells) mBC. Whole slide images (WSIs) from mBC biopsy samples scored HER2 IHC 0/1+ were rescored by pathologists and using digital pathology (DP) to evaluate concordance.

Methods This retrospective real-world evidence study included 384 WSIs collected 2020-2023, stained with PATHWAY HER2 (4B5) assay scored as HER2 IHC 0 (n = 246) or 1+ (n = 138). Three pathologists each performed 2 blinded readings per WSI using 2023 ASCO/CAP guidelines; if readings differed, a reconciled score was used. Consensus was agreement by ≥2 of 3 pathologists. The same WSIs were analysed with 4 AI-computational DP tools in development. Concordance vs manual consensus was measured by overall percentage agreement (OPA) and Cohen κ, with review time recorded.

Results Of 384 WSIs, 375 had aligned HER2 IHC scores by pathologist review; 9 had discordance. Among consensus cases, 2/3 agreement occurred in 154 WSIs (41.1%) and 3/3 in 221 (58.9%); 81 (21.6%) WSIs were reclassified as IHC 0 absent membrane staining, 85 (22.7%) as IHC 0 with membrane staining, 203 (51.4%) as IHC 1+, and 6 (1.6%) as IHC 2+. HER2 IHC rescoring results with the 4 DP tools are shown in Table 1. OPA (95% CI) between consensus and DP-assisted scores across all HER2 IHC score categories was 74% (69-78%), 73% (68-77%), 69% (64-74%), and 55% (50-60%). Cohen κ (95% CI) ranged from 0.33-0.59. Median review times were shorter with DP vs manual review.

Conclusion Preliminary analysis suggests integrating AI-computational DP tools into HER2 IHC clinical workflows may reduce pathologist review time. Further analysis is underway to assess concordance of DP tools with manual scoring.

Table 1. HER2 IHC Re-scores (including HER2-low/ultralow) of WSIs and Median Time to Review

#1456 Paletrra^{TM} AI: Automated phenotyping of multiplex immunofluorescence datasets via information maximizing self-training.

Kevin Gallagher[1], Jiong Fei[1], Judy Kuo[1], Maryam Rohafza[1], Mitchell P. Levesque[2], Julia M. Martinez-Gomez[2], Marianne Thio[1], Erinn A. Parnell[1], Qingyan Au[1], Harry Nunns[1]

[1]NeoGenomics Laboratories, Inc., Aliso Viejo, CA,[2]University Hospital of Zurich, Schlieren, Switzerland

Multiplex immunofluorescence (mIF) is a powerful tool for profiling dozens of biomarkers from a single tissue section. Customized mIF panels enable oncology researchers to phenotype cells within the tumor microenvironment, interrogate activation status of immune cells, quantify expression levels of biomarker targets, and explore the spatial organization of cells. Yet, analysis of large mIF datasets remains a bottleneck, largely due to the difficulty of accurately phenotyping single cells across large tissues. The incorporation of deep-learning algorithms into mIF analysis pipelines has helped overcome some limitations of traditional intensity gating by using stain morphology to add robustness to intensity variation, spatial spillover, and tissue artifacts. However, these deep-learning algorithms are costly to develop from a data volume and/or annotation perspective, often requiring fine-tuning on manual labels from target datasets to achieve acceptable performance. Therefore, there is demand for algorithms that efficiently generalize across batches, mIF panels, and tissue types. Here, we present a label-free framework for adapting a pretrained single-channel feature extractor into a mIF whole panel classifier capable of zero-shot cell phenotyping. Our source model is a single-channel feature extractor trained on 20 million annotations spanning over 40 biomarker classes, with text conditioning to encode marker-specific interpretations. We adapt this model into a whole panel classifier by introducing both single-marker binary heads and a multi-marker phenotyping head, jointly trained through self-distillation to enforce per-channel consistency while promoting information maximization across the multiplexed panel. This strategy preserves interpretable single-marker classification while leveraging cross-channel context for accurate and scalable phenotyping of mIF datasets. We applied this framework to 27 FFPE samples stained with a 17-marker mIF TME panel using the Paletrra^{TM} (NeoGenomics Laboratories, Inc) platform. The samples are from a cohort of metastatic melanoma patients treated with pembrolizumab, with our analysis revealing significant differences in immune populations between non-responders and responders. Notably, we showed that our framework achieved higher cell phenotyping accuracy and reduced errors from common mIF issues such as batch effects and spatial spillover, as compared to other mIF image analysis techniques. Overall, our method provides a lightweight, automated method for adapting pretrained mIF algorithms to new panels with strong zero-shot performance to novel biomarkers.

#1457 Prediction of gene expression and molecular pathway activity from H&E whole slide images in non-small cell lung cancer.

Mina Khoshdeli[1], Muhammad Sohaib[2], Mohammed Qutaish[1], Mahesh Bachu[1], Matthew Loya[1], Prianka Chohan[1], Omar Jabado[1], Craig Thalhauser[1], Mirna Lechpammer[1], **David Soong**[1]

[1]Genmab, Princeton, NJ,[2]Electrical and Biomedical Engineering, University of Nevada, Reno, Reno, NV

Predicting transcriptomic profiles from hematoxylin & eosin (H&E) whole slide images (WSIs) remains a challenging but highly desirable task. This is driven by three main factors: (1) H&E WSIs are widely available across patient populations; (2) they are significantly more cost-effective than RNA sequencing; and (3) inferring such information from H&E images can help preserve limited tissue for more critical diagnostic and prognostic tests. Prior studies have explored a variety of models to address this problem and demonstrated potential in predicting genes in key cancer processes. In this study, we developed a two-stage framework that employed state-of-the-art foundation models for patient-level feature extraction, and leveraged robust machine learning methods for efficient model training. Comprehensive evaluation of these models was performed on a carefully curated internal dataset of 67 commercial non-small cell lung cancer (NSCLC) patient samples with matched RNA-seq.

Gigapath, a large-scale pathology foundation model pre-trained on over 170,000 WSIs, was used to extract patch and patient level visual embeddings from H&E-stained NSCLC. Each slide was divided into 256×256 pixel patches, with Gigapath embeddings aggregated via an attention mechanism (LongNet) into slide-level representations. Several regression models were evaluated to predict numerical gene expression and pathway levels from these slide-level embeddings. Ground truth pathway activity was computed using normalized enrichment scores for 50 Hallmark gene sets by single-sample gene set enrichment analysis on the RNA-seq data. Models were trained on 425 slides from The Cancer Genome Atlas Lung -Adenocarcinoma (TCGA-LUAD) cohort and evaluated on the independent dataset of 67 slides. Model performance was assessed using Spearman correlation.

The Gigapath-Random Forest regressor model demonstrated strongest predictive performance across several Hallmark pathways, such as Unfolded Protein Response ($\rho = 0.70$), MTORC1 Signaling ($\rho = 0.69$), and Epithelial-Mesenchymal Transition (EMT) ($\rho = 0.67$). These pathways are not only critical to NSCLC biology but also exhibit distinct histological signatures such as cytoplasmic stress, fibrotic remodeling, and nuclear morphological alterations. The framework was further extended to predict expression levels of individual genes using the same slide-level feature representations. Preliminary results indicate that out of 17,719 expressed genes, 2,223 can be predicted with a Spearman correlation greater than 0.4. These findings demonstrated that pathology foundation models can be efficiently integrated with regression models to capture diverse transcriptomic activities directly from histological imaging features, providing a generalizable framework for biomarker discovery and the development of personalized cancer therapies.

#1458 Deep learning of H&E slides adds prognostic value beyond IASLC grading in non-mucinous lung adenocarcinoma among never-smokers.

Background: Lung cancer in never smokers (LCINS) most often presents as non-mucinous adenocarcinoma. The International Association for the Study of Lung Cancer (IASLC) system is the current standard for histologic grading, but its use is limited by interobserver variability, time-intensive manual assessment, and limited scalability. We evaluated whether a deep learning model applied to routine hematoxylin and eosin (H&E) slides could predict overall survival and improve prognostic stratification beyond conventional histologic grading.**Methods:** We analyzed 595 stage I-III whole-slide images from the Sherlock-Lung study, each from a unique patient. For the full cohort, median follow-up was 37 months (range 1-120 months); 55 deaths occurred by 5 years and 102 deaths by 10 years from diagnosis, out of 190 events overall. Data were split into training (n=409), internal cross-validation (n=45), and held-out validation (n=141) sets. A convolutional neural network generated continuous patient-level risk scores from H&E images, which were dichotomized into high-risk (n=34) and low-risk (n=107) groups in the validation cohort using the Youden index. Prognostic discrimination for overall survival in the validation set was assessed using time-dependent AUCs and Cox models. We compared AUCs for 5- and 10-year survival probabilities estimated from IASLC grade and deep-learning risks in univariate analyses and based on the following Cox models: (1) baseline (age, sex, ancestry, tumor stage) + IASLC grade; (2) baseline + deep learning; (3) baseline + IASLC grade + deep learning. **Results:** Deep learning yielded higher AUCs than IASLC grade for 5 year (0.84 [0.76-0.92] vs 0.70 [0.62-0.78]; p=0.01) and 10 years overall survival (0.75 [0.61-0.90] vs 0.64 [0.48-0.79]; p=0.59). In multivariable analyses, at 5 years the AUCs were 0.79 for baseline + IASLC, 0.86 for baseline + deep learning ($p<0.01$ vs baseline + IASLC), and 0.87 for the full model (better than simpler models, p=0.04); at 10 years the corresponding AUCs were 0.82, 0.86, and 0.87, with no statistically significant differences overall (p=0.63), possibly reflecting fewer late events. In a Cox model for 5 years of follow-up the deep-learning low-risk group had improved overall survival versus the high-risk group (HR 0.31, 95% CI 0.13-0.76).**Conclusions:** Deep learning on routine H&E slides provides prognostic information independent of IASLC grade in LCINS. Integrating deep learning with grade and clinical factors improves overall survival prediction, supporting AI-augmented pathology for precision risk stratification and personalized treatment/surveillance in non-mucinous lung adenocarcinoma among never-smokers.

#1462 Cell type-specific somatic variants captured from single-cell RNA sequencing underlie transcriptional programs in pre-malignant blood.

Jasmine Ryu Won Kang[1], Mawusse Agbessi[2], June Kim[1], Ido Nofech-Mozes[1], Marie-Julie Fave[3], Philip Awadalla[4]

[1]University of Toronto, Toronto, ON, Canada,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]Concordia University, Montreal, QC, Canada,[4]University of Oxford, Oxford, United Kingdom

Background: Somatic variants in blood and their prognostic potential in hematological malignancy are well-established in the context of clonal hematopoiesis (CH), but their functional impacts on global gene expression and transcriptional programs remain understudied. We conducted associations between frequently occurring somatic variants, both within and outside of known cancer driver genes, and transcriptional programs to understand phenotypic consequences of genetic mosaicism in blood at the molecular level.
Methods: Single-cell RNA sequencing (scRNAseq), bulk ATAC-sequencing (ATAC-seq), and RipTide whole-genome sequencing (WGS) were conducted on a cohort of 400 samples within the Ontario Health Study. These samples were stratified according to age (<45 or >65 years) and the Intermountain Risk Score (low-risk or high-risk), which is strongly correlated with all-cause mortality. Somatic variants were identified per cell type in each sample with scRNAseq, filtering out germline variants identified with ATAC-seq and RipTide WGS. Cell type-specific gene expression modules were extracted using Hotspot, and pseudobulk profiles were scored for the usage of each module. Linear regressions were conducted to predict module scores for each cell type given somatic variant carrier status and adjusted for covariates.
Results: We identified 6 somatic variants in B cells and 10 in naive T cells which occurred at least 15 times across the cohort. In B cells, somatic variants in AFF3 and IL3RA associated with an upregulation of Module I (AFF3: OR=1.26, adj(p)=0.067; IL3RA: OR=1.26, adj(p)=0.076), which is increased in low-risk samples compared to high-risk (adj(p)=0.020). The variant allele frequency (VAF) of AFF3 somatic variants in B cells was correlated with an upregulation of Module C (ρ=0.510, p=0.0055), which is enriched for heat shock response terms with gene set enrichment analysis. In Naive T cells, MIR4426 VAF correlated with an upregulation of Module H (ρ=0.694, p=4.8e-4), which is increased in young samples compared to aged samples (adj(p)=4.7e-29).
Conclusions: We described how somatic variants shape the landscape of cell type-specific transcriptional programs in blood across 400 individuals. Interestingly, we identified hits in AFF3, of which gene fusion events are well-described in acute lymphoblastic leukemia, and in IL3RA, whose increased expression is an established feature of acute myeloid leukemia. Further work is needed to correlate transcriptional program usage with incident hematological malignancy outcomes.

#1463 DNA methylation driven clonal splicing neoantigens predict immunotherapy response in lung cancer.

Sadegh Saghafinia[1], Carla Castignani[1], Amirhossein Ghorbanpour[2], Carlos Marinez-Ruiz[1], Francisco Gimeno-Valiente[3], Ariana Huebner[1], Cristina Naceur-Lombardelli2[3], Raju Veeriah[3], Mariam Jamal-Hanjani[4], Alan Hackshaw[3], Nnennaya Kanu[3], Charles Swanton[1], Crispin Hiley[1]

[1]The Francis Crick Institute, London, United Kingdom,[2]Agora Cancer Research Center, Lausanne, Switzerland,[3]University College London (UCL), London, United Kingdom,[4]University College London (UCL) Cancer Institute, London, United Kingdom

Immunotherapy has transformed the treatment landscape for previously untreatable cancers, yet its effectiveness is typically associated with high tumour mutational burden. However, additional biological processes can generate immunogenic antigens independently of DNA mutations. Alternative splicing, a major mechanism of transcriptome diversification, can produce cancer-specific isoforms that give rise to neoantigens. Emerging evidence suggests that splicing-derived neoantigens may arise from coordinated dysregulation of splicing factors, including epigenetic alterations such as DNA methylation. Here, we developed an integrated multi-omics framework that combines paired methylome and transcriptome data to identify cancer-specific, splicing-derived epitopes driven by DNA-methylation changes at gene loci. We applied this framework to the DARWIN II cohort of non-small cell lung cancer (NSCLC) patients treated with immune checkpoint inhibitors (CPI), leveraging multi-region paired RRBS and RNA-seq data from 256 tumour regions across 72 patients. Using this approach, we uncovered a compendium of recurrent clonal splicing-derived neoantigens linked to DNA-methylation alterations, several of which were predictive of clinical benefit from CPI therapy. Our findings demonstrate that DNA methylation-mediated splicing regulation represents a source of clonal neoantigens in lung cancer, providing new avenues for patient stratification and informing future vaccine and immunotherapy development.

#1464 CELLama-Perturb: A virtual cell modeling approach for mapping drug sensitivity across spatial tumor heterogeneity.

Haenara Shin, Jeongbin Park, Dongjoo Lee, Hongyoon Choi

Portrai, Inc., Seoul, Korea, Republic of

Background
Predicting how anticancer drugs reshape cellular states in real tissue remains challenging. Perturbation datasets with transcriptomic profiling enable in vitro models of drug response, but how such models transfer to the human tumor microenvironment and capture spatial heterogeneity is unclear. There is a need for frameworks that integrate large-scale perturbation screens with spatial transcriptomics to map intratumoral variation in drug sensitivity.
Method
We developed CELLama-Perturb, a perturbation modeling framework that builds on CELLama-derived foundation embeddings generated by a sentence-transformer cell-embedding strategy. A memory-mapped data pipeline enabled large-scale training on the Tahoe-100M resource. Drug effects were learned from (i) DepMap PRISM drug-sensitivity profiles to model viability responses across cell lines and (ii) paired perturbed transcriptomes used to predict ranked lists of top differentially expressed genes. Drug identity, dose, and cellular state were embedded jointly, and a cross-attention architecture modeled drug-cell interactions. Trained models were then transferred to single-cell and spatial transcriptomics datasets from human tumors to infer spatially resolved drug-sensitivity maps from baseline gene expression.
Results
Across PRISM-derived models, CELLama embeddings captured biologically meaningful expression structure and enabled consistent prediction of drug sensitivity in held-out cell lines, with positive correlations between predicted and observed responses. For gene-expression perturbation tasks, the CELLama-based model accurately reconstructed ranked perturbed-gene profiles (nDCG@16=0.314, MRR=0.660, Recall@16=0.272), corresponding to ~4-5 true perturbed genes among the top 16 predictions out of 17,739 genes. Predicted top-gene sets aligned with experimentally observed differentially expressed genes, indicating that the model encodes transcriptional context relevant to downstream perturbation effects. Applied to lung cancer spatial transcriptomics, CELLama-Perturb produced high-resolution drug-sensitivity maps that revealed marked intratumoral heterogeneity; for example, regions predicted to be sensitive to tubulin inhibitors were spatially distinct from those sensitive to topoisomerase inhibitors, highlighting drug-class-specific vulnerability patterns within the same tumor.
Conclusion
CELLama-Perturb provides a foundation-model-based approach for projecting learned perturbation effects from in vitro systems into complex tissue environments. By generating spatially resolved drug-sensitivity maps, this framework enables virtual cell-to-tissue assessment of therapeutic response and supports refined decisions on drug modality selection, including antibody-drug conjugate payload prioritization.

#1465 Expression-based immune-phenotyping ML model predict ICI response and long-term clinic benefit in lung adenocarcinoma.

Ki Wook Lee[1], Hyun Woo Park[1], Han-En Lo[1], Sehhoon Park[2], Balachandran Manavalan[1], Young-Jun Jeon[1]

[1]Sungkyunkwan University, Suwon, Korea, Republic of,[2]Samsung Medical Center, Seoul, Korea, Republic of

Immune checkpoint inhibitors (ICIs) have transformed the treatment landscape of lung cancer, yet only a subset of patients derive durable clinical benefit, and reliable predictive biomarkers remain limited. To address this challenge, we developed a transcriptome-based artificial intelligence (AI) framework that predicts both ICI response and long-term clinical benefit by leveraging immune phenotype (IP) in lung adenocarcinoma (LUAD). Transcriptomic profiles of 359 TCGA-LUAD samples annotated with IP classes derived from whole-slide images (WSIs) were used to identify immune infiltration-associated AI-informed genes (AIGs) through tree-based classifiers. These features were subsequently trained across 14 machine learning algorithms to classify immune-infiltrated (IF) versus non-infiltrated (non-IF) tumors, followed by ensemble refinement. The resulting AIGs were then applied to ICI-treated LUAD cohorts (N=300) to construct a progression-free survival (PFS) prediction model reflecting long-term therapeutic benefit. The immune phenotyping model achieved strong predictive performance with AUCs of 0.907 in training, 0.810 in the independent test set (N=90), and 0.842 in external validation (N=76). Notably, immune phenotyping based on this model outperformed image-based prediction methods such as Lunit-SCOPE and PD-L1 tumor proportion score (TPS), achieving AUCs of 0.933 for the 1%<TPS<50% subgroup and 0.809 for TPS>50%, compared to 0.733 and 0.559, respectively. The PFS prediction model showed a high correlation between predicted and observed PFS (R = 0.94), and risk scores derived from this model demonstrated excellent predictive accuracy for ICI response (AUCs of 0.964 in training and 0.887 and 0.849 in two external validations). Biological interpretability was further supported by single-cell RNA-seq analysis, which revealed that model-derived genes were enriched in T cell activation and exhaustion compartments, reflecting immune activation linked to therapeutic response. This integrated framework demonstrates dual predictive capacity for short-term ICI response and long-term clinical benefit, offering a biologically interpretable and clinically scalable transcriptome-based platform with strong translational potential in precision immuno-oncology.

#1466 CellNeighbor: A transcriptional atlas of patient tumors and cell line models to inform preclinical model selection.

Caitlin M. A. Simopoulos, Gabrielle Persad, Otto Morris, Carlos A. Origel Marmolejo, Laura M. Richards, Kelly M. Biette

Recursion, Salt Lake City, UT

Preclinical scientists typically select cell line models for compound activity assays based on molecular profiles that support a drug program's hypothesis. However, extensive *in vitro* culturing of these cell lines can influence genetic changes in these models raising concerns about whether these models still represent the patient tumors from which they were derived. To address this translational gap, we developed CellNeighbor, a computational framework that guides model selection by contextualizing cell lines within the landscape of real-world patient transcriptomic data. Building on the established Celligner framework (1), we explicitly identified and removed tumor microenvironment-related gene expression variability before integrating cell line and patient profiles with Harmony (2). Then, we integrated transcriptomic profiles from DepMap (3,4) with patient tumor data from The Cancer Genome Atlas (TCGA) and deidentified patient tumor data from Tempus, creating a unified transcriptomic map of cell lines and tumors. Within this map, we employ a symmetric nearest neighbor approach to identify "patient neighborhoods" centered around each cell line to characterize cell lines most transcriptionally similar to patient tumors. In addition, we have developed novel metrics, such as a neighborhood-tissue homogeneity score, to quantify the confidence of these associations for use in objective and automated decision making. We can now rank cell lines by their transcriptional similarity to neighborhoods of real patient tumors to increase the likelihood that model lines remain representative of the intended patient population. The integrated clinical and molecular data layers produce a cell line-to-patient map that enables cell line selection tailored to specific patient populations. In conclusion, CellNeighbor offers a robust method to identify cell line models that closely resemble patient tumors, ultimately aiming to increase the translatability of preclinical discoveries into clinical applications.

#1467 Mechanism-aware cancer therapy planning with group-relative policy optimization on a multimodal oncology foundation model.

Eric E. Schadt, Jackson Stokes, Lihua Zhao, Jason Chin, Jonathan Tyler, Lijia Sun, Lauren Beck, Duo Xu, Aviva G. Beckmann, Iker Huerga

Pathos AI, New York, NY

Modern multimodal oncology foundation models (OFMs) can predict patient trajectories and simulate treatment effects from clinical, genomic, transcriptomic, and histologic data, but they remain largely black boxes: they rarely explain which mechanisms drive risk or how to modulate those mechanisms with feasible interventions.

We trained a multimodal OFM on over 1.2 million cancer patients with longitudinal clinical records, tumor DNA and RNA sequencing, and H&E imaging. The model learns a joint latent representation of each patient's evolving disease state and can forecast outcomes and simulate counterfactual treatment trajectories. We then added a mechanism-aware reasoning layer that turns the OFM from a predictor into an engine for mechanism-based therapy design.

Our key innovation is group-relative policy optimization (GRPO), a reinforcement-learning framework that links mechanism states inferred by the OFM (e.g., pathway activation patterns and resistance programs), a drug intervention space built from curated drug-target relationships and perturbation signatures, and an explicit clinical reward. Rather than optimizing an abstract objective for a single patient, we define the reward as improvement in predicted outcomes for cohorts of patients who share similar disease state and driver mechanisms. For each disease context, we identify mechanisms associated with poor outcome, link them to candidate drugs and observed outcomes in real-world data, and then use GRPO to evaluate policies (sets of mechanism-level interventions) by asking whether applying a policy to that cohort improves predicted survival or delays progression relative to matched standard-of-care controls. This group-relative reward stabilizes learning, avoids overfitting to idiosyncratic outliers, and aligns the learned policies with how clinicians naturally reason about "patients like these."

To make outputs biologically and clinically interpretable, we map proposed mechanism shifts to existing drugs and combinations, to mechanism-defined patient clusters whose outcomes are driven by similar latent programs, and to de novo mechanism opportunities where the optimal policy improves outcomes but no current drug fully explains the effect, flagging potential targets for discovery.

Across multiple indications, GRPO recovers known mechanism-therapy relationships, identifies patient subgroups whose outcomes are improved when therapies they receive align with GRPO-suggested mechanism policies compared with matched patients receiving discordant therapies, and proposes novel mechanism-therapy hypotheses involving combined or sequential modulation of programs that are not jointly targeted today. This turns a large-scale OFM into a mechanism-aware decision engine that reasons about resistance and treatment opportunities in the same latent space used for outcome prediction.

#1468 Germline whole exome sequencing implicates homologous recombination repair pathway genes as risk factors in SMARCB1 deficient renal medullary phenotypes without sickle hemoglobinopathies.

Pankaj Kumar Chauhan[1], Panayiotis Kontoyiannis[1], Evan von Eschenbach[1], Jessica P. Cheng[1], Susan S. Thomas[1], Luigi Perelli[2], Christopher J. Logothetis[1], Daria Melikhova[3], Lev Bedniagin[3], Michael Hensley[3], Nizar M. Tannir[1], Pavlos Msaouel[4]

[1]Department of Genitourinary Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Cancer Biology, UT MD Anderson Cancer Center, Houston, TX,[3]BostonGene Corporation, Waltham, MA,[4]Genitourinary Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

Renal medullary carcinoma (RMC) is a highly aggressive, SMARCB1-deficient kidney cancer classically arising in young individuals of African descent with sickle hemoglobinopathies, most commonly sickle cell trait, due to germline *HBB* variants. Very rare SMARCB1-deficient cases without sickle hemoglobinopathies are classified as renal cell carcinoma, unclassified with medullary phenotype (RCCU-MP). Apart from confirming sickle hemoglobinopathies, there is no established role for germline testing in RMC or RCCU-MP, and germline risk factors for RCCU-MP remain undefined. We performed an integrated germline whole-exome sequencing (WES) and bulk RNA sequencing (RNA-Seq) on 11 patients with RCCU-MP and compared them with 23 patients with canonical RMC associated with sickle hemoglobinopathies (sickle cell trait, n=22; sickle cell-C disease, n=1) and with disease-control cohorts of clear cell RCC (ccRCC; n=11) and chromophobe RCC (chRCC; n=11). RCCU-MP harbored pathogenic germline loss-of-function protein-truncating variants (PTVs) in homologous recombination repair (HRR) pathway genes in 2 of 11 cases (~18%): *ATM* (W2960*, affecting the PIKKc_ATM domain) and *RAD50* (E696*, affecting the Rad50_zn_hook domain). No germline pathogenic HRR pathway PTVs were found in RMC, ccRCC, or chRCC. Furthermore, aside from the expected HBB variants defining sickle hemoglobinopathies in the RMC cohort, no additional germline alterations associated with other hemoglobinopathies - including α-thalassemia and α/β-hemoglobinopathies (*KLF1, ATRX, HBG1, HBS1L, MYB, HBD, HBA1, HBA2, HBG2, HBZ* and *BCL11A*) - were detected in any specific cohort. RNA-Seq cellular deconvolution techniques such as ssGSEA tumor micro-environment (TME) reconstruction and Kassandra cellular deconvolution showed microenvironment with high enrichment for B cells, CD4 and CD8 T cells, and low presence of endothelial cells in both RMC and RCCU-MP cases. These data represent, to our knowledge, the largest germline analysis to date spanning both RMC and RCCU-MP and nominate HRR pathway disruption as a potential germline susceptibility signal specifically for RCCU-MP. Defining HRR-linked germline risk in RCCU-MP refines patient selection for genetic counseling and lays the groundwork for mechanistic and therapeutic studies in SMARCB1-deficient medullary kidney cancers beyond sickle hemoglobinopathies. The ChatGPT-5.1 was used to improve readability and language, and after using this tool, the content was reviewed and edited as needed.

#1469 Multi-omics profiling of neuroblastoma identifies immunological biomarkers associated with higher risk of relapse: Results from the MICCHADO study.

Antonio Colaprico[1], Alexandra Saint-Charles[1], Stelly Ballet[2], Charles Bobin[1], Joffrey Alves-Gasnier[1], Valery Attignon[3], Nathalie Droin[1], Ana Lalanne[4], Doriane Gorret[4], Lydie Cassard[5], Imene Hezam[6], Yasmine Iddir[1], Anthony Ferrari[7], Elnaz Saberi Ansari[1], Gaelle Pierron[2], Julien Masliah-Planchon[2], Angela Bellini[1], Nathalie Chaput[5], Charlotte Butterworth[1], Benoit Dumont[3], Olivier Lantz[4], Olivier Delattre[1], Nadege Corradini[3], Claudia Pasqualini[6], **Gudrun Schleiermacher**[1]

BACKGROUND: Neuroblastoma (NB) risk stratification relies on clinical and molecular features, though few molecular markers inform therapeutic interventions. Leveraging multi-omics approaches, we sought to identify biomarkers associated with relapse.
AIMSTo characterize molecular and immunological features associated with relapse inhigh-risk NB (HR-NB), (MYCN-amplified or metastatic >12 months), and correlate findingswith clinical outcomes to identify relapse mechanisms and therapeutic opportunities.
METHODS: For 197 NB patients (145 HR-NB, 52 low/intermediate-risk) in the MICCHADOprogram (NCT03496402, a 600-pediatric patients pancancer cohort), tumor and sequentialblood samples were analyzed using paired tumor/germline whole exome sequencing(WES), bulk RNA sequencing, sequential plasma cell-free DNA (cfDNA) analysis, and bloodflow cytometry by FACS. We assessed DNA alterations, transcriptomic subtypes,stemness, immune infiltration, and blood biomarkers.
RESULTS: In HR-NB higher cfDNA and ctDNA levels were observed at diagnosis compared to non-HR. In addition to previously known genetic features (including MYCN, DDX1 and NBAS amplification, copy number alterations as well as recurrent SNVs), sequential cfDNA analyses identified novel alterations at relapse, including ALK, RAS-MAPK or CDKN2A/B. Transcriptomic profiling revealed a higher stemness index in HR-NB and in patients who experienced relapse, suggesting that a higher stemness index at diagnosis may predict relapse risk. Immune deconvolution of RNAseq from diagnostic samples revealed that patients who experienced relapse had higher levels of CD4+ memory T-cells, but lower natural killer (NK)Cells. Peripheral blood flow cytometry revealed, as expected, more T-cells in younger patients and a significant decrease in CD3+, CD4+, CD8+ T-cells, and NK cells from diagnosis to treatment and relapse.
CONCLUSIONS: Multi-omics profiling of NB identified novel immune biomarkersassociated with relapse. A higher stemness index suggests more undifferentiated, relapse-prone tumors. Immune profiling revealed T-cell and NK cell changes, highlighting the need for integrated molecular and immune profiling in targeted therapies.

#1470 Selecting representative histologic sections for cost-efficient 3D spatial transcriptomics and tumor microenvironment reconstruction.

Minh-Khang Le[1], James Evans[2], Harsimran Kaur[2], Sojung Lee[2], Vivek Pujara[1], Alan Joey Simmons[2], Seungwoo Kang[2], Jai Mehta[3], Louis J. Vaickus[4], Ken Lau[2], Joshua Jay Levy[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Vanderbilt University School of Medicine, Nashville, TN,[3]University of Tennessee Knoxville, Knoxville, TN,[4]Dartmouth-Hitchcock Medical Center, Lebanon, NH

Background: Three-dimensional spatial transcriptomics (ST) is essential for characterizing tumor-microenvironment (TME) heterogeneity but profiling every serial section is cost-prohibitive. Prior work has explored selecting subsets of sections for imputing ST at interleaved positions. However, these approaches do not identify which sections to profile to most efficiently preserve the 3D architecture. An optimal strategy must reinforce high-confidence inference in regions with similar composition while ensuring inclusion of morphologically distinct areas. We developed a computational framework to select histologic sections that optimally preserve 3D TME structure while minimizing the number requiring ST profiling.

Methods: Four 3-mm FFPE colorectal cancer cores (two per patient) were collected to capture tumor-stroma interfaces and tertiary lymphoid structures. ~300 serial 5-µm H&E sections per core (~1500 µm depth) were imaged at 40x resolution; sections with sufficient tissue were retained (reported tissue loss at: TL 1150 µm, TR 350 µm, BL 1005 µm, BR 1100 µm). Retained sections were co-registered with VALIS. Eleven tissue classes—including tumor, desmoplastic stroma (DS), necrosis, smooth muscle, immune aggregates, and mucosa—were segmented using a graph neural network. For each section, we extracted Prov-GigaPath embeddings and tissue class area proportions. Pairwise similarities, incorporating histology features and z-distance, informed a facility location submodular optimization algorithm to select k representative sections (k=3-30). Selected subsets were used to reconstruct 3D TME structure via class-specific α-shape meshes and voxelization. Reconstruction fidelity was assessed using voxelized intersection-over-union (IoU) relative to full-section reconstructions.

Results: Cores differed in composition—TL: normal mucosa 50%, smooth muscle 26%, stroma 11%, DS 10%; TR: tumor 49%, DS 49%; BL: smooth muscle 43%, tumor 32%, stroma 23%, inflammation 2%; BR: smooth muscle 71%, DS 14%, stroma 11%, tumor 3%. Weighted IoU increased with k; mixed-effects models showed each section improved IoU by 0.014 ($p<2\times10^{-16}$), with core-specific slopes TL 0.015, TR 0.019, BL 0.016, BR 0.013. Saturation occurred at TL 18, TR 12, BL 17, BR 16 sections, with maximum weighted IoUs of 0.49, 0.64, 0.68, and 0.50. Class-specific IoUs correlated with tissue class prevalence ($\rho=0.81$, $p=3.6\times10^{-5}$), with abundant classes reconstructing best.

Conclusion: Section-selection algorithms can identify small subsets of H&E sections that preserve 3D TME structure for cost-efficient ST profiling. Although reconstruction fidelity reflects tissue class abundance, 15-20 sections sufficiently capture 3D architecture. Future work will refine selection strategies and integrate selected ST sections with interleaved H&E sections to enhance 3D reconstruction.

#1471 Unsupervised learning with MORPHAEUS enhances conventional tissue spatial phenotyping.

Elias Pavlatos[1], **Benjamin Tate**[1], Gregory Joseph Baker[2], Joanna Pucilowska[1]

[1]Immune Monitoring and Cancer Omics Services, OHSU Knight Cancer Institute, Portland, OR,[2]Division of Oncological Sciences, OHSU Knight Cancer Institute, Portland, OR

Introduction: Identifying unique cell phenotypes in cyclic immunofluorescence (cycIF) images is typically achieved through manual gating or unsupervised clustering of segmented cells based on marker expression profiles. While effective, segmentation-based methods are limited by predefined thresholds and cell type classification schemes. MORPHAEUS is a new Python-based software that infers cell types and multicellular structures directly from pixel-level imaging data using the variational autoencoder (VAE) deep learning architecture. This method enables unsupervised identification of cellular and morphological patterns without relying on image segmentation. Here, we compared segmentation-based phenotyping with MORPHAEUS-derived cell type classifications in a liver metastasis from a patient with PDAC imaged for 32 markers on the Lunaphore COMET platform.
Methods: Cell segmentation was performed on DAPI-counterstained nuclei using the U-net algorithm in Visiopharm. Mean per-cell marker intensities were quantified, and cell types were assigned based on a nested classification scheme using binary thresholding and prior biological knowledge. For MORPHAEUS analysis, 9x9µm image patches centered on nuclear centroids were extracted and stored in Zarr file format for VAE model training. Image patch encoding containing information on marker intensity, morphology, and local neighborhood contexture were clustered using Leiden community detection to identify cell types.
Results: MORPHAEUS identified several clusters consistent with those identified by manual gating, including a cluster with high CD3, CD8, CD69, and CD103 expression corresponding to tissue-resident memory CD8+ T cells. Clusters enriched for PanCK were consistent with tumor cells, with a subset co-expressing Ki67 indicative of proliferating tumor. MORPHAEUS also revealed novel clusters not captured by manual classification, including one with unexpected co-expression of CD4 and CD11C. Inspection of the primary image revealed that this cluster represented cell-cell interactions involving CD4+ T helper cells and CD11C+ dendritic cells, consistent with their known cooperative roles in antigen recognition.
Conclusions: Traditional classification provides a robust framework for quantifying predefined cell populations, but its reliance on manual gating and fixed marker definitions limits the discovery of novel or context-dependent phenotypes. MORPHAEUS offers a complementary, unsupervised approach capable of identifying rare and previously uncharacterized cell states as well as biologically meaningful spatial interactions that may be missed by conventional segmentation-driven analyses. These findings underscore the value of pixel-level deep learning as a powerful adjunct to traditional spatial phenotyping, enabling deeper insights into tissue organization and biomarker discovery.

#1472 AI-derived nuclear morphometrics as a novel prognostic indicator in lung adenocarcinoma.

Bokyung Ahn[1], Hee Sang Hwang[1], Hyun-Jung Sung[1], Se Jin Jang[2], Pil-Jong Kim[3], Heounjeong Go[1]

[1]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]Asan Medical Center, University of Ulsan College of Medicine,, Seoul, Korea, Republic of,[3]Seoul National University, Seoul, Korea, Republic of

Background: In lung adenocarcinoma (LUAD), prognostication has largely relied on architectural features, including predominant invasive pattern and tumor invasive size. However, the prognostic relevance of nuclear morphology relatively remains underexplored in LUAD. Using AI-based cell morphology analyzer, this study aimed to systematically quantify various nuclear morphometrics of LUAD and evaluate its prognostic significance.
Method: Whole slide images of surgically resected LUAD cases (n = 160) were retrieved, and CellViT was applied to extract nuclear-level morphometric features. From the generated contours, 114 features—including area, bounding-box area, convex-hull area, Feret diameter, maximum major/minor axis length, aspect ratio, circularity, form factor, eccentricity, compactness, solidity, orientation angle, and fractal dimension—were computed. Case-level features were generated for orientation-related features using orientation variance and entropy of orientation variance, and for all other variables using the median, IQR (interquartile range), IQR-based coefficient of variation, histogram entropy and quantiles (Q10, Q20, Q80, and Q90). Univariate Cox models for disease-specific survival (DSS) and recurrence-free survival (RFS) were fitted using these case-level features.
Results: Multiple nuclear contour features, including maximum Feret diameter, perimeter, major axis length, bounding-box area, and convex-hull area, were significant prognostic factors for both DSS (107/114, 93.9%) and RFS (28/114, 24.6%).
Discussion: These findings demonstrate that nuclear morphometrics can have prognostic implication in LUAD. Incorporating AI-based nuclear features into current grading or risk-stratification frameworks may improve prognostic precision and reduce dependence on subjective visual assessment. AI-driven nuclear shape profiling holds promise as a complementary biomarker in lung cancer pathology.

Univariable analysis of various nuclear morphometrics of LUAD

Disease specific survival feature	Adjusted P-value	Recurrence free survival feature	Adjusted P-value
Maximum Feret diameter_q90	<0.001	Major axis length_q90	<0.001
Perimeter_q90	<0.001	Maximum Feret diameter_q90	<0.001
Major axis length_q90	<0.001	Perimeter_q90	<0.001
Area_bbox_q90	<0.001	Area_bbox_q90	0.001
Area_convex_q90	<0.001	Area_convex_q90	0.003

#1473 Local indicators of spatial association bioinformatics analysis identifies animmunosuppressive zone at the liver tumor margin.

Yoshiki Nonaka[1], Kanae Echizen[1], Tomonori Kamiya[1], Maho Tsuda[1], Yoshimi Yukawa-Muto[1], Hideki Fujii[1], Ryo Takahashi[2], Takahiro Kodama[2], Naoko Ohtani[1]

[1]Osaka Metropolitan University, Osaka, Japan,[2]Osaka University, Suita, Japan

Immune checkpoint inhibitor therapy has shown effectiveness across several cancer types. However, immune checkpoint inhibitor therapy has limited efficacy for MASLD and MASH associated hepatocellular carcinoma, suggesting that the anti tumor immune response in the tumor microenvironment of MASLD and MASH associated hepatocellular carcinoma may differ from that in other cancers. Therefore, understanding the mechanisms behind MASLD and MASH hepatocellular carcinoma pathogenesis and identifying novel therapeutic targets is essential. Although immune checkpoint inhibitor monotherapy has shown limited efficacy, its combination with agents targeting cancer progression pathways may enhance anti tumor effects. In this study, to elucidate tumor promoting pathways in MASLD and MASH associated hepatocellular carcinoma, we aimed to comprehensively characterize the transcriptomic landscape of cancer cells and stromal cells within the tumor microenvironment. We performed single cell RNA sequencing on 63 samples from 45 hepatocellular carcinoma patients and 8 healthy donors, as well as spatial transcriptomics analysis on 6 samples from 5 patients with non viral hepatocellular carcinoma. Deconvolution analysis of the spatial transcriptomics data revealed that COL1A1 high cancer associated fibroblasts and TIMP1 high cancer associated fibroblasts were enriched at the inner margin of the tumor nodule. In this region, regulatory T cells, monocytes, and SPP1 high macrophages were predominantly co localized with cancer associated fibroblasts, which was determined by local indicators of spatial association analysis. These observations suggest that, in addition to histological wall thickening, the fibrotic tumor margin forms a functionally immunosuppressive niche in MASH associated hepatocellular carcinoma. In this presentation, we will highlight the distinct features of this fibrotic inner margin zone and discuss their therapeutic potential for MASLD and MASH associated hepatocellular carcinoma.

#1475 An evidence-based tool to systematically identify potential adverse drug-drug interactions.

Meetali Sinha, Ansu Kumar, Rajeev K, Vandana Nair, Liptimayee Behura, Deepak Lala, **James Wingrove**

Cellworks Group, Inc., South San Francisco, CA

Background: Combination therapy is routine in oncology, although it may be associated with adverse drug-drug interactions (DDIs). Machine-learning (ML) and Artificial Intelligence (AI) based tools have been applied to this problem, however they often lack predictive rationales. We have leveraged published data, including FDA drug label information, to create a rule-based tool designed to identify and classify potential drug-drug interaction candidates based on shared gene mechanisms, mechanistic impact, and supporting clinical evidence.

Design: A proprietary database was developed and curated from the FDA drug labels of 338 approved drugs (271 small molecules and 67 biologics), capturing detailed information on drug-gene and drug-drug interactions. A rule-based Drug-Drug Interaction (DDI) assessment tool was then developed based on shared gene mechanisms, mechanistic impact, and supported clinical evidence. The performance of the tool was evaluated in 2 independent data sets.

Results: The tool was first tested using a curated set of known DDI-positive and DDI-negative drug pairs, (20 DDI-positive, 10 DDI-negative) yielding 100 percent accuracy. A second set of 544 drug pairs predicted to have efficacy based on a mechanistic model (Cellworks) was then assessed, with 6.8% pairs (37/544) predicted to be DDI-positive. Of these, 34 pairs shared a common gene and showed a clear victim-perpetrator relationship, indicating a strong mechanistic link for possible interactions, while the 3 additional DDI-positive pairs (Fluorouracil, Oxaliplatin; Carboplatin, Nab-Paclitaxel; Trastuzumab, Paclitaxel) showed clinical evidence of interaction in the absence of shared genes. Evaluation of ClinicalTrials.gov showed that 7 of these pairs (18.9%) had failed clinical development due toxicity-related findings. 460 (93%) of the DDI-negative drug pairs lacked shared gene pathways, mechanistic relationships, and clinical corroboration.

Conclusions: Developed specifically for oncology applications, the tool couples FDA label data and clinical information relevant to cancer treatment with mechanistic insights, providing a method to predict and mitigate toxicity risks arising from drug combinations. Future studies will aim to prospectively validate the tool.

#1476 Improve spatial transcriptomic data with integrated hybrid transformer and graph convolutional networks.

Steven Yan[1], Limin Jiang[1], **Yan Guo**[2]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]University of Miami, Miami, FL

Spatial transcriptomics technologies have revolutionized genomics by enabling the measurement of gene expression while preserving the spatial context of cells within tissues. However, their utility is limited by restricted gene coverage and high operational costs. To overcome these challenges, we previously developed generative AI approaches for imputing gene expression [1] and DNA methylation [2]. Building on this foundation, we now present TransGCN, a hybrid neural network model that integrates transformer architectures with graph convolutional networks to enhance spatial transcriptomic datasets through high-fidelity gene expression imputation. For example, TransGCN can expand a 500-gene Xenium panel to more than 1,500 to 2,000 genes. We systematically evaluated TransGCN across three leading spatial transcriptomic platforms: 10x Genomics Visium HD, Xenium, and Bruker CosMx, and six tissue types, including lung, brain, breast, skin, colon, and ovarian. Beyond previously leveraged features (e.g., 3D chromatin interactions from Hi-C, biological pathways, transcription factor networks, and protein-protein interactions), we incorporated spatial and housekeeping features derived from scRNA-seq (19,363 cells) and bulk RNA-seq (418,074 samples). Compared with existing imputation tools, TransGCN consistently achieved higher accuracy while enabling the recovery of a broader gene set, thereby substantially extending the analytical power of spatial transcriptomics.

#1477 Lysosomal routing geometry drives immunosuppressive secretion in triple negative breast cancer.

Sudhanshu Sharma, Manoj K. Mishra

Cancer Research Center, Department of Biological Sciences, Alabama State University, Montgomery, AL

Triple-negative breast cancer (TNBC) shows markedly elevated secretory activity, which contributes to a highly immunosuppressive tumor microenvironment. Lysosomes are central to both degradation and regulated secretion, but how their routing choices influence cytokine release has not been well explored. To investigate this, we developed a Subcellular Causal Geometry Model (SCGM) that maps nanoscale lysosomal routing behavior and identifies patterns in TNBC cells associated with the production of immunosuppressive cytokines. SCGM brings together lysosomal proteomics, LAMP1/LAMP2 vesicle distributions, RAB-GTPase interaction profiles, and intracellular pH gradients derived from patient samples. The mapping of the vesicle-routing paths using a geometry-aware transformer revealed several patterns. Acidic microdomains appeared more fragmented, V-ATPase activity shifted, and the interaction between RAB27A and LAMP1 shifted in a consistent way. To determine the biological impact of these changes, we compared them with cytokine levels, trends in macrophage polarization, exosome characteristics, and interferon-response markers. We also ran perturbation simulations for LAMP1, CTSB, ATP6V1C1, RAB27A, and RAB7A, and evaluated their influence through a geometry-informed Shapley ranking. These findings revealed three distinct routing programs, including a secretory-dominant state, a degradative state, and a recycling-oriented state. The secretory pattern showed fragmented acidic microdomains, stronger interactions between RAB27A and LAMP1, and faster vesicle fusion. Tumors associated with this state released higher levels of TGF-β1, IL-10, galectin-3, and CXCL12 (macro-AUC 0.95) and exhibited nearly fourfold higher M2-like macrophage polarization along with reduced antigen-presenting capacity. Perturbation modeling suggested that reducing RAB27A function could lower immunosuppressive cytokine release by almost two-thirds. Disrupting LAMP1 destabilized the secretory routing framework, and ATP6V1C1 inhibition shifted tumors toward a more immune-activating phenotype. CTSB, RAB7A, ATP6V0A1, and the LAMP1→RAB27A transition repeatedly emerged as major regulators. Taken together, these results outline an unrecognized lysosomal-routing architecture that shapes immunosuppressive cytokine release in TNBC and point to lysosomal geometry as a potential biomarker and intervention point for reshaping the TNBC immune environment.

#1478 Unifying molecular structure and cellular morphology to enhance drug-target interaction modeling in cancer.

Ying-Ju Lai, Yu-Chiao Chiu

UPMC Hillman Cancer Center, Pittsburgh, PA

Accurate drug–target interaction (DTI) prediction is critical for accelerating drug discovery and uncovering therapeutic mechanisms. However, the vast combinatorial space of chemical compounds and protein targets, coupled with the complex nonlinear relationships that govern their interactions, presents significant experimental challenges. Existing computational approaches rely heavily on molecular features, often overlooking perturbation-induced morphological phenotypes and lacking a unified representation that connects molecular properties to responses. To address these limitations, we propose a two-stage contrastive learning framework that integrates structural information of drugs and proteins with cellular morphological profiles derived from the Cell Painting high-content screening into a unified multimodal embedding space. In stage one, two modality-specific contrastive learning models were trained independently: a structure-based model that aligns embeddings of drug structures with protein sequences, and an image-based model that aligns morphological embeddings derived from Cell Painting assays of drug and gene knockout perturbations. In stage two, these modality-specific embeddings were further integrated through cross-modal contrastive learning to construct a shared embedding space that jointly encodes drug structures, protein sequences, and their corresponding cellular morphological profiles. Both embedding spaces from stage 1 (structure- and image-based models) effectively aligned annotated drug–target pairs more closely while pushing non-interacting pairs apart. These models yielded correlation differences of 0.4 and 0.3, respectively, as measured by cosine similarity. In the final unified embedding space, coherent clusters emerged among drugs, targets, and their associated morphological embeddings for known DTI pairs, demonstrating successful cross-modal alignment. Among the top-ranking DTI pairs, gedatolisib and *PIK3CB* showed a similarity of 0.95, consistent with the drug's known activity as a PI3K/mTOR pathway inhibitor. Overall, high-similarity DTI pairs often involved aromatic and heterocyclic compounds whose physicochemical properties closely matched the binding preferences of targets like G protein-coupled receptors (GPCRs) (e.g., *CHRM4*) and kinases (e.g., *PIK3CB*). These patterns align with studies showing that GPCR and kinase ligands share characteristic structural features that facilitate binding. In contrast, low-similarity ones involved molecules whose size, polarity, or geometry posed challenges for targets such as metabolic enzymes and heme-binding proteins. Overall, this study highlights the promise of integrating molecular and morphological representations via contrastive learning, providing a powerful framework for advancing DTI modeling and precision cancer therapeutic discovery.

#1479 CAB: A confidence-aware sequence model enabling high-throughput prediction of mutation-driven binding affinity change in antibody-based cancer therapeutics.

Yuanfei Sun[1], Bing Jiang[1], Huiping Liu[2]

[1]Utah Tech University, St. George, UT,[2]Northwestern University - Chicago, Chicago, IL

Background: Computational prediction of antibody-antigen (Ab-Ag) affinity is increasinglyimportant for designing tumor-targeting therapeutics, enabling rapid in-silico affinity maturation,and optimization of formats such as bispecifics and ADC. However, existing models are trainedalmost exclusively on positive binding cases with measurable affinity, creating a positive-casebias that limits their ability to recognize true loss-of-binding events and often yields unreliableaffinity predictions for Ab-Ag pairs that are experimentally non-binding.

Method: To avoid challenges in predicting accurate structures for mutated proteins, we adopteda sequence-to-function framework and fine-tuned sequence-only protein language models (e.g.,ESM2, DPLM) for mutation-level affinity prediction. We incorporated the AbAgym dataset(~335k measurements) to address the under-representation of weak and non-binding cases. Tobetter separate binding from non-binding regimes, we added a sequence-pair contrastivelearning stage using validated binders as positives and randomly sampled non-binders asnegatives. After contrastive pretraining, we jointly optimized an affinity-change regression headand an AlphaFold-inspired confidence-score head to capture prediction uncertainty and flaglikely non-binders. This combined contrastive and multi-task strategy improves mutation-levelsensitivity and strengthens detection of loss-of-binding events essential for anti-tumor antibodydiscovery.

Result: CAB enabled high-throughput in-silico screening of antibody mutation libraries and wasevaluated on both viral and tumor-associated antigen systems. For SARS-CoV-2 RBD, CABrapidly prioritized thousands of CDR variants and identified high-confidence mutations predictedto yield >10-fold affinity improvements, successfully recovering redesigns known from deepmutational scanning. For tumor targets such as HER2 and Plexin-B2, CAB similarly selected tophigh-confidence mutations with enhanced predicted affinity, consistent with experimentallyengineered antibodies.

Discussion: Unlike conventional models that output a single affinity estimate regardless ofreliability, CAB's confidence head enables explicit identification of low-confidence, likely non-binding variants, addressing a critical limitation of current prediction frameworks. This improvesthe trustworthiness of virtual screening and reduces false-positive redesigns. CAB provides anefficient computational engine for identification of promising variants against tumor-associatedantigens in cancer immunotherapy.

#1480 Transcriptional condensates at super-enhancers mediate pH-dependent transcriptional control in innate immunity.

Shengyuan Wang[1], Zhongyang Wu[2], Zhe Zhong[3], Zhenjia Wang[1], Xu Zhou[2], **Chongzhi Zang**[1]

[1]University of Virginia, Charlottesville, VA,[2]Boston Children's Hospital, Boston, MA,[3]Harvard University, Boston, MA

Tissue acidification is a common feature of hypoxia, inflammation and solid tumor. Acidic pH regulates innate immune response in macrophages by weakening BRD4-containing transcriptional condensates. Yet how disruption of transcriptional condensates leads to gene-specific regulation of immune programs remain unclear. Here, we integrated ATAC-seq, ChIP-seq, and RNA-seq of primary murine macrophages and performed integrative epigenomics analyses to identify transcriptional regulators (TRs) with pH-sensitive regulatory potential and association to BRD4-dependent transcriptional condensates. We determined pH-dependent super-enhancers (SEs) based on dynamic extended profiles of BRD4 binding and H3K27ac marks under pH perturbation. We found RELA, IRF family, and STAT family as candidate TRs enriched at BRD4-associated, pH-sensitive SE regions, particularly in response to LPS stimulation in macrophages. RELA and IRF3 preferentially occupied BRD4-associated and pH-sensitive SEs, and displayed markedly reduced binding under acidic conditions, aligning with BRD4 occupancy change. Correspondingly, immune-response genes within BRD4-associated, pH-sensitive SE regions, including *Ch25h*, *Il20rb*, *Slc2a6*, and *Ifit* family, were significantly higher expressed at pH 7.4 than at pH 6.5. Additionally, analysis of TCGA data for colorectal cancer revealed that chromatin accessibility at potential RELA or IRF binding sites within SEs had significantly elevated association with patient survival, indicating the clinical relevance of TR binding at transcriptional condensates in human cancer. Together, these results reveal a set of TRs involved in BRD4-associated, pH-sensitive transcriptional condensates that coordinate macrophage gene activation under physiological conditions, providing mechanistic insight into how acidic stress modulates transcriptional condensates in immune responses and tumor microenvironment.

#1481 Integrative analysis identifies potential proteomic intermediates associated with renal cell carcinoma and its risk factors.

Ibrahim Hossain Sajal[1], Andrew J. Song[1], Kevin M. Brown[2], Mitchell J. Machiela[2], Peter Kraft[2], Stephen J. Chanock[3], Mark P. Purdue[2], Diptavo Dutta[2]

[1]Integrative Tumor Epidemiology Branch, Division of Cancer Epidemiology & Genetics, National Cancer Institute, Rockville, MD,[2]Division of Cancer Epidemiology & Genetics, National Cancer Institute, Rockville, MD,[3]Sect. Head & Director, CGF/ATC, National Cancer Institute, Rockville, MD

Background: Renal cell carcinoma (RCC), the predominant form of kidney cancer, is influenced by several risk factors (RFs) including obesity, hypertension, and smoking. However, the molecular mechanisms linking these RFs to RCC remain unclear.
Methods: We investigated plasma proteins (PP) as potential intermediates of markers of the effects of RFs on RCC using two-stage Mendelian randomization (TSMR) approach. In stage 1, we identified PPs associated with each of the 19 RFs evaluated (e.g., anthropometric traits, blood pressure, smoking behavior, blood cell counts, and kidney function), leveraging summary-level proteogenetic data on PPs from the UK Biobank Pharma Proteomics Project (N=34,557). In stage 2, we evaluated the effects of these RF-associated PPs on RCC, using the largest-to-date RCC GWAS (N = 864,690; cases=29,020).
Results: Among 2,940 PPs, 2,339 were significantly associated (P<1.7E-05) with at least one of the 19 RFs. Of these, 33 showed a significant effect on RCC (FDR<5%) with 28 mapping outside RCC GWAS loci. Using multivariable MR, we estimated mediation effects of associated PPs, finding that proteins such as CDA and PILRB mediated up to 17.41% of BMI's effect on RCC, and APOL1 mediated 2.76% of white blood cell's effect. Convergent evidence from multiple in silico analyses with cis-MR, colocalization, and TCGA differential expression further prioritized TYMP, UMOD and USP28 as key protein intermediaries of the RF effects on RCC. TYMP and USP28, inversely associated with RCC risk, showed immune-related and tumor-suppressive effects, while UMOD was positively associated, potentially linking renal dysfunction to carcinogenesis. Functional annotation revealed enhancer activity and transcription factor (HIF) binding near these proteins.
Conclusion: Our approach and results identify molecular intermediates that may link epidemiologic risk factors to RCC and highlight actionable candidates for laboratory investigation.

Prioritized PPs associated to RCC and at least one RF, with results from multiple in-silico analyses

#1482 A deep learning-based multimodal integration framework for clinical outcome prediction.

Baoyi Zhang[1], Helen Tian[2], Thanh Bui[1], Yookyung Christy Choi[3], Mona H. Cai[3], Peter Ansell[4], Aditee Shrotre[5], Steven Chirieleison[5], Kevin Kolahi[5], Xi Zhao[1], Josue Samayoa[1], Weilong Zhao[1]

[1]Quantitative Medicine and Genomics, AbbVie, South San Francisco, CA,[2]Computer Science and Mathematics, The University of Chicago, Chicago, IL,[3]Global Epidemiology, AbbVie, North Chicago, IL,[4]Precision Medicine Oncology, AbbVie, North Chicago, IL,[5]Precision Medicine Pathology, AbbVie, South San Francisco, CA

In oncology, a diverse range of advanced approaches, including medical imaging, genomic and transcriptomic profiling, and clinical data analysis, are utilized to comprehensively characterize each patient's tumor. This integrative strategy provides actionable insights that inform personalized care plans and therapeutic decisions, ultimately aiming to optimize patient outcomes. However, practical challenges persist, including how to integrate unstructured imaging data and address missing data modalities.Here, we present a new deep learning based, multimodal integration framework to address these challenges. Our approach incorporates a single modal loss, calculated between each modal representation and the patient's clinical outcome, which encourages the model to learn more clinical outcome relevant features from each modality. Furthermore, a mutual information estimator is implemented to enable the model to explore exclusive features within each data modality. For multimodal fusion, we leveraged a transformer architecture to combine different modalities' embeddings into unified patient-level representations. In our study, we specifically focused on whole slide images, gene expression and mutation. We utilized TCGA non-small cell lung cancer (NSCLC) data (n=989) to develop our model for predicting overall survival (OS), and validated its performance in three independent datasets: CPTAC (n=208), ConcertAI RWD360® linked Caris datasets (ConcertAI/Caris: n=2176), City of hope (COH, n=84). We observed high and robust performance across the four datasets (TCGA: 0.64 ± 0.03; CPTAC: 0.60 ± 0.04; ConcertAI/Caris: 0.59 ± 0.03; COH: 0.61 ± 0.04) using C-index as the evaluation metric. Further evaluating survival association in the three independent datasets indicated significant prognostic values of our model in both univariable (CPTAC: HR = 3.29, p = 0.007; ConcertAI/Caris: HR = 1.50, p = 5e-6; COH: HR = 3.16, p = 0.008) and multivariable (CPTAC: HR = 2.72, p = 0.03; ConcertAI/Caris: HR = 1.40, p = 0.002; COH: HR = 3.81, p = 0.02) Cox proportional hazards model after adjusting for known prognostic clinical factors.To interpret our model, we applied integrated gradients method to understand each feature's contribution to model output. Specifically, we identified 349 core OS-related genes in NSCLC, enriching in cancer-related pathways such as epithelial mesenchymal transition, focal adhesion and TNFA signaling via NFKB. Stratifying patient cohorts by treatment types allowed us to further identify exclusive genes per treatment. As a result, we identified 11 exclusive genes for immunotherapy, with enrichment in immune-related and metabolism pathways.In summary, we developed a multimodal integration framework that predicts clinical outcomes with high and robust performance. Interpretating our framework reveals potential prognostic and predictive markers to advance therapeutic development.

#1483 Cleaved ATP5A1 mediates a poly(ADP-ribose)-dependent regulatory axis for R-Loop homeostasis under oxidative stress.

Aniruddha Mukherjee[1], Kaveri Goel[1], Weiqi Lei[1], Nicholas Hill[1], Rory Greer[2], Yuhua Song[3], Neil Pfister[1]

[1]Radiation Oncology, University of Alabama at Birmingham, Birmingham, AL,[2]Biomedical Engineering, University of Alabama at Birmingham, Birmingham, AL,[3]Associate Professor, Dept. of Biomedical Eng., University of Alabama at Birmingham, Birmingham, AL

Oxidative stress-induced DNA damage potentiates accumulation of R-loops, DNA:RNA hybrid structures with a displaced DNA strand that are resolved in a poly (ADP-ribose) (PAR)-dependent manner via PARP family enzymes. PARylation orchestrates recruitment of DNA repair factors during the oxidative stress response, in addition to multiple mitochondrial proteins also playing a role to protect the nuclear genome. We previously identified cleaved ATP5A1, a mitochondrial stress-responsive proteoform, as an interactor of R-loop resolving proteins including DHX9 and hnRNPU using immunoprecipitation/mass spectrometry (IP/MS) approach. We further investigated its PAR-dependent role in R-loop regulation using *in vitro* assays, cell culture, molecular dynamics (MD) simulation, and RNA-seq approaches in Calu-1, a non-small cell lung cancer cell model. To identify the bioactive R-loop resolving isoform of ATP5A1, mass spectrometry peptide fragments from Peptide Atlas were analyzed to identify potential calpain cleavage sites (cleavage windows that span multiple amino acids). Bioinformatic analyses predicted residue 135 as the primary cleavage site, validated by western blot and MD stability profiles. AlphaFold3 structure prediction and MD simulations demonstrated stable interactions of PAR chains with cleaved ATP5A1 (residues 135-553), with RMSD 0.2-0.3 nm and RMSF of stable residues ranging 0.1-0.2 nm, including ADPR monomers and polymers. IP/MS confirmed PARylation of transiently expressed ATP5A1(135-553) following ionizing radiation-induced oxidative stress. Slot blot was used to quantify R-loops in wild-type, ATP5A1 knockout, and cleaved ATP5A1 rescue conditions. RNA-seq of control and ATP5A1 knock-out (KO) cells identified differentially expressed genes enriching for cellular metabolism, DNA repair, and proliferation/cell cycle pathways in a cleaved ATP5A1-linked R-loop response signature. These findings identify cleaved ATP5A1 as a PAR-interacting protein that modulates R-loop homeostasis under oxidative stress, linking mitochondrial retrograde signaling to nuclear stress responses and revealing a potential R-loop therapeutic target in cancers with dysregulated oxidative stress signaling.

#1484 p-EMT transitional hub and its DC2-macrophage niche define recurrence in oral squamous cell carcinoma.

Yongjoon Jin[1], Jeong-Yeon Ji[2], Hyojung Lee[1], Na-yeon Kim[1], Eun-Jae Chung[3], Jong-Il Kim[4]

[1]Department of Biomedical Science, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Department of Otorhinolaryngology-Head and Neck Surgerys, Seoul National University Bundang Hospital, Gyeonggi-do, Korea, Republic of,[3]Department of Otorhinolaryngology-Head and Neck Surgery, Seoul National University Hospital, Seoul, Korea, Republic of,[4]SNU Medicine, Seoul, Korea, Republic of

Background: Partial epithelial-to-mesenchymal transition (p-EMT) is increasingly recognized as a critical driver of invasion and recurrence in OSCC, yet the spatially defined ecosystems and lineage trajectories that sustain p-EMT remain unknown.
Methods: We analyzed 40 tumor-edge TMA cores from 14 patients using Xenium 5k spatial transcriptomics and integrated two-year clinical outcomes (14 non-recurrence, 26 recurrence). Complementary snRNA-seq from 8 matched patients (4 non-recurrence, 4 recurrence) enabled epithelial subclustering, lineage/ontogeny modeling, ligand-receptor inference, and spatial neighborhood reconstruction.
Results: snRNA-seq uncovered a distinctly enriched p-EMT epithelial state (p-EMT_C2) defined by ECM-remodeling genes (MMP11, POSTN, COL11A1), CAF-like markers (PDGFRB, THY1, FAP), and pro-invasive regulators. p-EMT_C2 was significantly expanded in recurrence tumors. Spatial mapping revealed that p-EMT_C2 forms a discrete “transitional zone” positioned between differentiated core epithelium and highly invasive edge cells—a zone that was preferentially amplified in recurrence lesions. Pseudotime reconstruction demonstrated that p-EMT_C2 represents a central branching hub along the core-to-edge invasion trajectory, functionally linking epithelial differentiation to edge aggressiveness.
Strikingly, p-EMT_C2 was embedded within a recurrence-specific multicellular niche composed of DC2 dendritic cells and a pro-metastatic macrophage subset (Macrophage_C1). This tri-cellular niche exhibited strong spatial co-occurrence in recurrence cores. Macrophage_C1 expressed IL1A, IL6, HBEGF, THBS1, VEGFC, DKK1, PTHLH, and FOSL1, while DC2 cells displayed complementary pro-invasive signatures. Ligand-receptor analysis revealed dense reciprocal signaling among the three populations, suggesting that DC2 and Macrophage_C1 collaboratively reinforce and stabilize the p-EMT hub state.
Conclusions: We identify p-EMT_C2 as a transcriptionally and spatially central hub that orchestrates the transition from differentiated epithelium to invasive edge states in OSCC. Its tight association with DC2 and pro-metastatic macrophages defines a recurrence-specific invasive ecosystem. These findings nominate the p-EMT_C2-DC2-macrophage axis as a mechanistically grounded therapeutic target for disrupting the emergence of recurrence in OSCC.

#1485 Multimodal AI for patient subtype discovery in LUSC using real-world data.

Swati Kaushik, Mark Carty, Akul Singhania, Justin Guinney, Radia Johnson

Tempus AI, Inc., Chicago, IL

Introduction: Lung squamous cell carcinoma (LUSC) remains a significant therapeutic challenge due to patient tumor heterogeneity and lack of predictive biomarkers. Prior subtype identification efforts, limited to single-modality data (e.g. gene expression), fail to capture the full spectrum of LUSC's molecular complexity. To define clinically actionable vulnerabilities, we employed a multimodal AI approach integrating gene expression, copy number variation (CNV), and mutation data derived from Tempus real-world data to identify LUSC molecular subtypes, providing a biological landscape essential for improved treatments.

Methods: We analyzed de-identified clinico-genomic records from LUSC patients profiled with Tempus (xT) DNA and RNA (xR) assays. For molecular subtyping, we developed a multimodal autoencoder integrating gene expression, CNV, and mutation profiles from 4,973 tumors of the trachea, bronchus, and lung. Modality-specific encoders were trained and joint embeddings were obtained by averaging and aligning latent spaces with a distance loss to ensure coherent representation across modalities. K-means clustering was applied to joint embeddings to define patient subtypes, which were then functionally characterized via molecular enrichment. Real-world overall survival (rwOS) analysis was performed to assess the clinical and prognostic relevance of the identified subtypes.

Results: The multimodal autoencoder accurately reconstructed all three modalities with low reconstruction errors. Seven distinct subtypes of LUSC were identified with significant differences in rwOS ($p=0.02$). Subtype C1 (12.5% cases) exhibited the lowest median survival (11.7 months; 95% CI 9.4-16.3) and activation of EMT and TGF-β signaling pathways, known to be associated with adverse outcomes, contrasting with subtype C5 (9.5% cases) with the highest median survival (22.4 months; 95% CI 13.28- 31.5). Subtypes derived from joint embeddings showed enrichment for known driver genes, thereby defining distinct molecular characteristics. NFE2L2 mutations were enriched ($p<0.05$) in subtypes C3 (28%) and C7 (29%). RB1 mutations were prevalent in C2 (11%) and C5 (14%), while NF1 mutations were observed in subtypes C1 (15%) and C6 (12%). SOX2 and PIK3CA amplifications are known to be enriched in the classical subtypes (C3, C7). In addition, we identified multiple cluster-specific alterations (e.g. FGF19, CCND1 in C3; ETV5, BCL6 in C7) highlighting extensive intra-subtype heterogeneity. The resulting multimodal subtypes validated established TCGA classifications while providing a significantly deeper molecular resolution by uncovering previously uncaptured intra-subtype variability.

Conclusions: This study validated the potential of multimodal omic integration for high-resolution patient subtyping, establishing a critical foundation for developing integrative AI frameworks to accelerate precision oncology.

#1486 From animals to computational oncology: Digital twins as ethical enablers of next-generation bone metastasis research.

Luca Marsilio[1], Stefan Maksimovic[2], Elisa Serafini[3], Alice Maccarini[1], Sergio Barrios[2], Pietro Cerveri[4], Stefano Casarin[3], **Eleonora Dondossola**[2]

[1]Politecnico di Milano, Milano, Italy,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Houston Methodist, Houston, TX,[4]Politecnico di Milano, milano, Italy

Bone metastasis (BM) is a lethal consequence for advanced prostate and renal cancer patients, contributing significantly to morbidity, elevated mortality risk, and substantial healthcare burden. In vivo biological experiments provide evidence of the cellular mechanisms supporting cancer progression and therapy response, but they are limited in addressing the multi-parameter complexity of BM in a time-cost effective manner and pose ethical concerns about harm and distress. In silico computational models, instead, can explore an unlimited number of experimental combinations avoiding time and resource consumption, providing a valuable alternative to investigate disease biology and microenvironment interactions. Accordingly, this work introduces digital twins to monitor BM progression, response to therapy and impact on bone mechanical properties. By combining three-dimensional multiphoton microscopy and in silico modeling, we generated in vivo inspired, spatially explicit, multicellular A(BM)²s (Agent-Based Models of BM) replicating tumor growth, angiogenesis, and bone resorption. We rigorously retrieved driving coefficients using in vivo data from prostate and kidney tumors and calibrated them through a random forest regressor algorithm to adhere to the in vivo growth rate. We further conducted robust double verification by simulating both the anti-angiogenic effects of cabozantinib and the anti-resorptive effects of zoledronic acid. Our results highlight the predictive character of our A(BM)² in anticipating therapeutic outcomes and increasing our understanding of the complex dynamics of BM. In parallel, we developed a digital twin for mechanical testing of long bones and vertebrae that integrates finite element analysis with micro-CT-derived bone geometry and material properties. Computational compression tests revealed increased fragility in trabecular bone following treatment with the bone-targeting agent Radium-223, whereas three-point bending tests showed no fragility in cortical bone post-treatment. However, they did reveal significantly increased fragility after osteolysis occurred, indicating that these complementary approaches provide a comprehensive understanding of bone mechanical integrity. Overall, our digital twin approach provides a transformative platform to dissect tumor progression, predict therapy response, and evaluate the consequences on bone mechanics. By enabling these insights in silico, we aim to significantly reduce dependence on animal models, directly supporting and strengthening the 3Rs principle.

#1487 Spatial microdomains from histology reveal multi-omic biomarkers for enhanced idiopathic pulmonary fibrosis diagnosis.

Raymond Yan[1], Brian Falkenstein[1], A. Burak Tosun[1], Filippo Pullara[1], **S. Chakra Chennubhotla**[2]

[1]PredxBio, Inc., Pittsburgh, PA,[2]PredxBio, Inc. / University of Pittsburgh, Pittsburgh, PA

Background: Idiopathic pulmonary fibrosis (IPF) is characterized by progressive alveolar injury and extensive tissue remodeling that generate pronounced spatial heterogeneity across affected lung regions. Distinct pathological programs often coexist within adjacent microenvironments, reflecting cellular interactions and molecular circuits that drive disease progression. Although histologic assessment of H&E-stained biopsies remains central to clinical diagnosis, current evaluations lack quantitative measures that connect visual pathology to underlying biology. Integrating spatial transcriptomics with quantitative histologic features enables higher-resolution characterization of heterogeneous disease regions and provides molecular context essential for accurate diagnostic interpretation.
Methods: We applied a multi-omic analytic workflow using the SpaceIQ™ platform to the publicly available Xenium H&E and spatial transcriptomics dataset reported by Vannan et al., Nat. Genet. 2025. Unbiased cell typing was performed on H&E images and spatially aligned to cell-resolved gene expression. Spatial microdomains were derived from differential organization of inferred cell populations in IPF versus healthy tissue. Gene-feature associations were computed to identify molecular markers linked to pathology-associated microdomains. Candidate biomarkers were evaluated in an independent Visium dataset from Mayr et al., Sci. Adv. 2023 to assess reproducibility across platforms and cohorts.
Results: Unbiased H&E-derived cell typing revealed finer structural organization within pathologist-annotated regions and captured subregional distinctions in fibrotic and non-fibrotic compartments. Spatial microdomains identified from cell-type arrangements distinguished IPF-specific architectural patterns and yielded gene signatures associated with epithelial dysregulation, inflammatory macrophages, and extracellular matrix remodeling. These signatures showed consistent enrichment in corresponding molecular niches within the validation cohort. Cross-cohort mapping further demonstrated reproducible cell-type differences and implicated conserved pathways involved in epithelial stress responses, fibroblast activation, and tissue remodeling.
Conclusions: Integrating quantitative histologic features with spatial transcriptomics provides a robust framework for linking visual pathology to molecular mechanisms in IPF. Histology-derived microdomains reveal reproducible biological programs across independent cohorts and support the identification of clinically relevant biomarkers. This multi-omic approach enables more objective, biologically grounded interpretation of heterogeneous fibrotic regions and has the potential to improve diagnostic evaluation and patient stratification in IPF.

#1488 Structure-guided dual targeting of EZH2 and dopamine D1 receptor suppresses TNBC growth and metastasis.

Francesco Drago[1], Libere Ndacayisaba[2], Xilal Y. Rima[3], Gautam Sarathy[1], Deborah Ramsey[4], Gwen Fewell[4], Senthil Saravanamuthu[2], Sanjay Gupta[5], Giovanni Nigita[1], Eduardo Reategu[3], Pierre Giglio[6], Christian Rolfo[1], Eswar Shankar[1]

[1]Division of Medical Oncology, Department of Internal Medicine, Wexner Medical Center, The Ohio State University, Columbus, OH,[2]ONS BIO LLC, Cleveland, OH,[3]Department of Chemical and Biomolecular Engineering, The Ohio State University, Columbus, Ohio, Columbus, OH,[4]SYNVIVO INC., Huntsville, AL,[5]Department of Urology, School of Medicine, Case Western Reserve University, Cleveland, OH,[6]9Department of Neurology, School of Medicine, Wexner Medical Center, The Ohio State University, Columbus, OH

Triple-negative breast cancer (TNBC) is an aggressive subtype with high relapse rates and limited therapies, emphasizing the need for mechanism-based strategies. EZH2, the catalytic subunit of PRC2, drives TNBC proliferation, metastasis, and chemoresistance, while dopamine D1 receptor (D1R) activation induces apoptosis, autophagy, and invasion inhibition. Immunohistochemistry confirmed strong EZH2 expression and elevated H3K27me3, but catalytic inhibition alone is insufficient due to non-enzymatic functions. We hypothesized that dual targeting of EZH2 and D1R would synergistically suppress TNBC by disrupting the EZH2-D1R axis. Computational modeling using a full-length AlphaFold EZH2 structure and three ligands (GSK126, A77636, SKF38393) identified canonical and cryptic binding pockets via PocketMiner and Fpocket, revealing the SET domain as the primary high-affinity site. DiffDock docking showed stable, high-affinity binding of GSK126, while A77636 and SKF38393 displayed dynamic, less-specific interactions. Molecular dynamics simulations over 100 ns confirmed GSK126's stability and persistent contacts at key residues (624, 684, 686), providing mechanistic insight. Immunoprecipitation validated an EZH2-D1R interaction, and D1R knockdown reduced combination efficacy. Experimentally, combination therapy reduced 2D cell viability (CI = 0.24). In droplet-based tumor spheroids (TSIMS), GSK126 + A77636 decreased spheroid diameter by 62% and induced necrosis without apoptosis, with confocal imaging showing EZH2 degradation, H3K27me3 loss, and cytoskeletal disruption. EZH2 knockout cells failed to form spheroids. In a vascularized SynTumor organ-on-chip model, the combination reduced circulating tumor cells by 50% within 96 hours, demonstrating suppression of metastatic spread. Together, these silico-guided and experimental findings establish a translationally actionable dual-target strategy that synergistically inhibits TNBC growth and metastasis. (Supported by DOD: W81XWH2010065, Eswar Shankar.).

#1489 STniche: An approach to identify functional niches in the tumor microenvironment from spatial transcriptomics.

Sasi Arunachalam[1], Oscar Ospina[2], Alex C. Soupir[3], Xiaoqing Yu[3], Brooke L. Fridley[1]

[1]Children's Mercy Research Institute, Kansas City, MO,[2]John Hopkins All Children's Hospital, St. Petersburg, FL,[3]Moffitt Cancer Center, Tampa, FL

Background: Spatial transcriptomics preserves spatial context in the tumor microenvironment (TME), enabling precise mapping of cellular interactions and immune architecture. However, translating these data into functional niche maps remains difficult. We developed STniche, an integrated framework that identifies spatially coherent and biologically interpretable functional niches that link local transcriptomic activity to tissue organization.

Methods: STniche assigns functional phenotypes to spots or cells using pathway signatures, incorporates spatial dependency between neighboring cells with local Moran's I, and detects spatial niches via Gaussian model-based clustering. The optimal number of niches is selected by BIC. We applied STniche to the Meylan et al. (2022) clear cell renal cell carcinoma (ccRCC) dataset containing pathology-annotated tertiary lymphoid structures (TLS). Across ten tumor sections, we used a curated TLS meta-pathway integrating five coordinated programs—chemokine signaling, lymphotoxin axis, antigen presentation, germinal-center B-cell activation, and dendritic-cell maturation—to capture core molecular processes of TLS biology. STniche-identified TLS niches were compared with pathology annotations.

Results: STniche was able to identify spatially coherent functional immune niches corresponding to TLS. TLS meta-pathway-defined clusters showed strong agreement with pathologist annotations, with mean concordance of 0.39 (range 0.28-0.56) and mean relative symmetry of 0.64 (range 0.36-0.96). On average, ~42% of STniche-defined spots overlapped pathology-confirmed TLS, and the clusters captured ~42% of all TLS-positive spots. These findings demonstrate that STniche reliably recovers functional TLS microenvironments directly from spatial transcriptomic data, providing a quantitative and unsupervised framework for immune niche discovery

Conclusion: STniche provides a statistically rigorous and biologically interpretable framework for discovering functional spatial niches in tumor tissues. Its ability to detect TLS-enriched immune architectures highlights potential applications in understanding prognosis, immunobiology, and therapeutic response. Further benchmarking is ongoing.

#1490 A single cell-based protein activity landscape for human small cell lung cancer.

Lucas ZhongMing Hu[1], Anish Thomas[2], Andrea Califano[1]

[1]Columbia University, New York, NY,[2]National Cancer Institute, Bethesda, MD

Small cell lung cancer (SCLC) is a lethal malignancy characterized by rapid metastasis, profound intra-tumor heterogeneity (ITH), and an immunosuppressive tumor immune microenvironment (TIME). The underlying biology of SCLC is poorly understood, and treatment options remain limited. To overcome this, we performed a systematic analysis on a large collection of single-cell RNA-Seq-based SCLC human sample cohort to define the gene regulatory networks and master regulators (MR) driving SCLC ITH and TIME composition. We constructed a single-cell transcriptomic atlas of 182,189 cells from 41 fresh patient-derived SCLC samples (primary and metastatic sites). Tumor and immune cells were cataloged and clustered. To move beyond transcriptional states, we reverse-engineered patient- and cluster-specific regulatory networks using ARACNe and inferred protein activity for >6,500 regulatory and signaling proteins via metaVIPER. This protein activity landscape was used to deconvolute ITH and TIME architecture. The OncoTreat algorithm identified FDA-approved drugs that invert MR activity in matched SCLC cell lines, with subsequent *in vivo* validation. Our protein activity analysis identified distinct, translationally relevant SCLC tumor and TIME subpopulations governed by specific MR programs. In tumor cells, we defined a proliferative "Tumor Checkpoint" module of MRs as a key determinant of this aggressive disease. Within the TIME, we discovered immune subpopulations with unique biological properties. A genome-wide drug perturbation screen identified potent agents that effectively abrogate the activity of tumor-specific MRs. These candidates demonstrated significant efficacy in inducing tumor cell death in preclinical *in vivo* models. We present the largest single-cell protein activity atlas of SCLC, providing a high-resolution view of the regulatory networks underlying its ITH and TIME. We computationally derived and preclinically validated novel therapeutic strategies that target master regulators of distinct tumor and immune subpopulations, offering a promising path to overcome therapeutic resistance in SCLC.

#1494 Study on acquisition timing of *KRAS* mutations in the pancreatic ductal epithelium.

Tomonori Hirano[1], Yasuhide Takeuch[2], Kazuyuki Nagai[3], Takayuki Anazawa[4], Sachiko Minamiguchi[5], Hiroshi Seno[6], Seishi Ogawa[1], Nobuyuki Kakiuchi[1]

[1]Department of Pathology and Tumor Biology, Graduate School of Medicine, Kyoto University, Kyoto, Japan,[2]Department of Diagnostic Pathology, Graduate School of Medicine, Kyoto University, Kyoto, Japan,[3]Department of Surgery, Graduate School of Medicine, Kyoto University, Kyoto, Japan,[4]Department of surgery, division of gastroenterological surgery, Sapporo Medical University, Hokkaido, Japan,[5]Department of Diagnostic Pathology, Fujita Health University School of Medicine, Aichi, Japan,[6]Department of Gastroenterology and Hepatology, Graduate School of Medicine, Kyoto University, Kyoto, Japan

[Introduction] Pancreatic cancer is a highly aggressive malignancy with a poor prognosis, underscoring the need for early diagnosis *KRAS* mutations are among the earliest genetic events in pancreatic carcinogenesis, but the timing of *KRAS* mutation acquisition in the pancreatic ductal epithelium remains unclear.
[Methods] From surgical specimens, we collected non-neoplastic pancreatic tissues distant from the macroscopic tumor, from which pancreatic duct-derived organoids were established. Paired tumor/normal DNA was extracted and subjected to whole-exome sequencing (WES). Phylogenetic trees were reconstructed based on shared somatic mutations. In patients with pancreatic cancer or intraductal papillary mucinous neoplasm (IPMN), WES was also performed on DNA from formalin-fixed, paraffin-embedded (FFPE) tumor tissue to assess relationships between cancer and non-cancerous *KRAS*-mutant clones. In a subset of bulk organoids, single cell-derived organoids were further established to determine mutation accumulation rates.
[Results] We analyzed 430 organoid samples from patients with (n=25) and without (n=23) pancreatic cancer. A median of 33 mutations per sample was identified. Eighteen *KRAS* mutations were detected in 16 cancer patients compared with four in four non-cancer controls, indicating a higher prevalence and wider distribution of *KRAS*-mutant clones in cancer patients. Phylogenetic analysis showed that 13 of 22 *KRAS* mutations mapped to the major trunk, which typically spread into multiple (n=6 on average) branches, whereas *KRAS*-wild-type clones rarely extended to multiple branches, suggesting more localized expansion. We further analyzed 56 single-cell-derived organoids from 19 cases, of which 7 harbored *KRAS* mutations. In *KRAS*-wild-type cells, the mutational burden positively correlated with age with a rate of 0.29 mutations per exome per year. KRAS-mutant cells carried significantly more mutations than wild-type cells, suggesting an increased mutation rate after KRAS activation. Based on this mutation rate, we estimated that these *KRAS* mutations were acquired between 21 and 44 years of age. Among 16 cases with *KRAS*-mutant PDAC or IPMN, we analyzed 8 FFPE tumors. In one patient with metachronous intraductal papillary mucinous carcinoma, the primary tumor, recurrent tumor, and *KRAS*-mutant organoid clone all arose from a common ancestral clone. Phylogenetic analysis indicated that a clone shared by the primary and recurrent tumors first branched from this ancestor and subsequently gave rise to both lesions. In other cases, *KRAS*-mutant clones in non-neoplastic ducts were phylogenetically independent of the cancer clone, indicating parallel evolution of multiple KRAS-mutant lineages.
[Conclusions] We elucidated the evolutionary history of clones in non-cancerous pancreatic ductal epithelium. These findings improve our understanding of the early events in pancreatic carcinogenesis.

#1495 A novel, deep learning -based filtering tool for enhanced detection of technical artifacts in whole-genome sequencing data.

Julian Gascoyne[1], David Benjamin[2], Juan Gallegos[1], Lee T. Lichtenstein[2], Sachet Shukla[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Broad Institute, Cambridge, MA

Artifactual variants obfuscate the already difficult task of somatic variant calling by mimicking some qualities of low variant allele fraction (VAF) mutations in this low signal-to-noise ratio regime. Statistical callers cannot cover the entire landscape of artifacts, leaving a critical gap. While deep learning tools for variant calling exist, they generally consume enormous amounts of labeled training data, are expensive to run, and can be overfit to a single sequencing technology. Here we present and benchmark Permutect, a lightweight deep learning-based variant caller for identifying artifactual variants across sequencing technologies and genomes. Permutect combines an artifact model for technological context and posterior model for biological context, respectively, allowing it to learn the characteristics not only for the technology but additionally the particularities of a given lab environment. The tool leverages the inherent non-orderedness of a set of reads (and thus their permutation invariance) to ascribe a probability for being a technical artifact. Permutect is therefore a lightweight deep learning model which can use as little as a single (unlabeled) genome for training thereby addressing the shortcomings of existing statistical and deep-learning callers. We tested this novel tool by training on four Genome-in-a-Bottle samples and benchmarking it against Mutect2, Strelka2, and DeepSomatic across well-established callsets: the ICGC Dream Challenge Sets 1-4 and SEquencing Quality Control Phase 2 (SEQC2) HiSeq and NovaSeq replicates. Permutect is an effective and precise tool for filtering, particularly in the paired Tumor-Normal (TN) setting. It achieved the highest mean Precision score (0.928) and the highest mean F1 score (0.899) in the Dream TN cohort, demonstrating superior overall balanced performance relative to its traditional competitors. Performance remained high and consistent across SeqC2 data (e.g., F1 score of 0.941 on HiSeq TN); we exclude scores from DeepSomatic, which was trained on that same data. While the precision of all tools are depressed in the Tumor-Only (TO) setting, it maintains a strong mean Recall (0.810) comparable to that of Mutect2 (0.811) in Dream TO. Though all callers struggled in the TO context, our findings show that Permutect's performance is competitive, and often superior, to established methods, highlighting its potential to address the pervasive issue of artifactual variants. Further work is being done to extend the domain of Permutect to whole-exome and long read sequencing and other improvements such as including the tri-nucleotide context about a variant will further refine the tool to address the shortcomings seen in the TO setting. In doing so, we expect Permutect to enhance downstream genomic analysis with applications ranging from clinical molecular pathology to the design of personalized immunotherapies.

#1496 Long-read sequencing of 15 Ewing sarcoma cell lines uncovers extensive GGAA microsatellite variation shaping the landscape of EWSR1::FLI1 binding.

Andrew Song[1], Xin Li[1], Egor Dolzhenko[2], Helene Neyret Kahn[3], Kristine Jones[1], Difei Wang[1], Komal Jain[1], Aubrey Hubbard[1], Olivia Lee[1], Stephen Chanock[1], Diptavo Dutta[1], Olivier Delattre[3], **Mitchell J. Machiela**[1]

[1]National Cancer Institute, Rockville, MD,[2]PacBio, Menlo Park, CA,[3]INSERM U1330, Children's Oncology Research Unit, PSL Research University, SIREDO Oncology Center, Institut Curie Research Center, Paris, France

Ewing sarcoma (EwS) is a rare, aggressive bone and soft tissue tumor occurring primarily in adolescents and young adults. EwS is defined by acquired chromosomal translocations between a member of the FET gene family and an ETS transcription factor (e.g., EWSR1::FLI1 in >85% of cases) that bind GGAA repetitive sequences and rewire local transcriptional activity. Germline variation in GGAA microsatellite allele length and motif purity can alter binding of EWSR1::FLI1 and disrupt the ability to dysregulate core driver genes. Further investigation into the molecular features underlying these germline-somatic interactions may yield new insights into the genetic etiology of Ewing sarcoma.

We performed whole-genome PacBio Revio HiFi sequencing on high molecular weight DNA extracted from 15 EwS cell lines positive for EWSR1::FLI1 to characterize germline variation in GGAA microsatellites genome-wide. We implemented a custom TRGT pipeline to call microsatellites containing at least 3 GGAA motifs utilizing a genomic repeat library and hidden Markov models. To investigate genomic features that could enhance EWSR1::FLI1 binding, we utilized linear mixed models incorporating PacBio data on microsatellite allele calls and DNA methylation with chromatin accessibility and ChIP-seq of EWSR1::FLI1 binding from the Ewing Sarcoma Cell Line Atlas (ESCLA).

In total, 39,319 GGAA microsatellites were characterized, with notable variation observed in microsatellite length (median=16 bp, interquartile range=13-51) and purity of GGAA motifs (mean=93.4%, standard deviation=9.2%). Allelic variation was present between cell lines with a mean of 4 alleles and a maximum of all 30 haplotypes exhibiting a different allele. Increased microsatellite length was the strongest predictor of EWSR1::FLI1 binding (beta=0.711, 95% CI=0.703,0.719), followed by reduced DNA methylation (beta=-0.023, 95% CI=-0.024,-0.022) and increased H3K27ac measures of open chromatin (beta=0.154, 95% CI=0.138-0.170). Analyses of established core EwS genes dysregulated by EWSR1::FLI1 are underway to identify specific microsatellites and allelic combinations that promote EWSR1::FLI1-altered expression of these genes.

Together, germline data from long-read whole-genome sequencing and multi-omic profiles from the ESCLA enable integrative analyses for disentangling germline-somatic interactions that alter EWSR1::FLI1 binding and downstream transcriptional regulation.

#1497 Long-read RNA-Seq reveals a novel isoform landscape of *SRSF2*-mutant chronic myelomonocytic leukemia.

Nickolas Steinauer, Terra Lasho, Christy Finke, Pankaj Pradeep, Jenna Fernandez, Alejandro Ferrer, Moritz Binder, Abhishek Mangaonkar, Mrinal M. Patnaik

Mayo Clinic Hospital-Rochester, Rochester, MN

While missense somatic mutations in the serine/arginine rich splicing factor 2 (*SRSF2*) occur early in the clonal development of myeloid neoplasms, they are uniquely enriched in chronic myelomonocytic leukemia (CMML), an MDS/MPN overlap neoplasm, where their estimated prevalence is ~50%. Short-read RNA-sequencing experiments have demonstrated that missense alterations of the proline 95 residue hotspot (*SRSF2*^{P95}) globally dysregulate exon inclusion, though the full transcript structures induced by such alternative splicing events remain uncharacterized. Given the striking enrichment of *SRSF2* mutations in CMML, we hypothesized that there exist unique splicing alterations contributing to the biology of this disease, and sought to profile the landscape of alternative transcription induced by *SRSF2* mutations in CMML using long-read RNA-Seq. We conducted bulk long-read RNA-Seq on bone marrow mononuclear cells from 5 CMML patients with *SRSF2*^{P95H} (n=3) and *SRSF2*^{P95L} (n=2) mutations, with VAFs ranging 20-48%, along with 5 CMML splicing factor wildtype patients. Libraries were prepared with the Pacbio Kinnex full-length RNA kit and sequenced on a Revio SPRQ sequencer. Reads were processed and aligned using the IsoSeq pipeline, and isoform collapsing, quality control, reference comparison, and quantification were performed with IsoQuant and SQANTI3. Differential transcript and gene expression was assessed with DESeq2, while differential transcript usage was assessed with the DRIM-Seq and stageR packages. After long-read collapsing and quality control, we identified 255,505 unique transcript isoforms, of which 14,845 (~5.8%) were novel to the reference transcriptome annotation (GENCODE v39). We identified 23 transcripts differentially expressed in *SRSF2*-mutant samples, including 9 novel transcripts, the majority of which (n=7) were upregulated in *SRSF2*-mutant cases. A higher number of transcripts (n=80) and genes (n=65) demonstrated significant changes in proportional transcript usage. Among transcripts with increased expression and usage in *SRSF2*-mutant cases, we identified a novel transcript of the gene *YBX1*, which encodes an RNA- and DNA-binding transcription factor required for cell survival and self-renewal in myeloid neoplasms. This novel transcript, which we termed *YBX1ΔEx4*, has an in-frame loss of exon 4, and is predicted to encode a full-length protein missing a 30 amino acid region of the cold-shock (DNA-binding) domain. Using short read RNA-Seq data from an additional 29 CMML patients, as well as an independent dataset (GSE251806) comprising 43 blast-phase CMML patients, we confirmed increased exclusion of *YBX1* exon 4 in *SRSF2*-mutant cases, with an even greater loss of exon 4 in blast-phase SRSF2-mutant cases. We hypothesize an important role of this isoform in CMML disease progression and are currently performing functional studies to characterize the effect of *YBX1ΔEx4*.

#1498 A generalizable software framework for ultra-rapid sequence analysis and its application in enabling 1 day deep multi-omic data analysis turnaround for brain cancer precision oncology.

Anders Pitman[1], David Bean[2], **Yi Qiao**[2]

[1]Human Genetics, University of Utah School of Medicine, Salt Lake City, UT,[2]Biomedical Informatics, University of Utah School of Medicine, Salt Lake City, UT

BACKGROUND: Pediatric brain cancer patients in relapse lack standard-of-care options and experience poor clinical outcome; and adult glioblastoma is simultaneously the most commonly diagnosed central nervous system malignancy and the most deadly. While they stand to benefit the most from precision-guided, personalized therapy selection supported by multi-omic tumor profiling, they also experience an extremely short post-surgery window-of-opportunity to identify and acquire likely effective drugs. This short clinical timeframe precludes clinical trials utilizing next generation sequencing (NGS) tumor profiling techniques from being designed, as the vast amount of data produced by tumor-normal pair whole genome DNA sequencing and tumor single cell RNA sequencing cannot be analyzed in time using current prevailing methods.
METHODS: We look towards graphics processing unit (GPU) accelerated computation to significantly speed up sequence analysis. We utilize both existing acceleration efforts (most notably the GPU version of BWA-MEM and STAR alignment algorithms as part of the NVIDIA Parabrick package) as well as accelerated versions of software we developed for which no GPU versions currently exist (FreeBayes short variant and FACETS copy number variant calling algorithms). We focus both on result equivalency to the unaccelerated versions, as well as code reusability so that additional software can be ported to GPU platforms by others with ease.
RESULTS: Using the HG008 tumor normal pair from Genome In A Bottle as a test case (2x150bp Illumina NovaSeq 6000, 150X normal and 190X tumor nominal coverage), our pipeline spent < 2 hours in sequence alignment, and < 30 minutes in variant calling and annotation using readily available computer hardware. As a result, the entire sequence analysis workflow can be finished within 1 working day, and produces an annotated variant call set ready for expert review, molecular tumor board discussion, and therapy selection. We further tested our approach on an in-house pediatric brain dataset consisting of 16 patients and both DNA and scRNA sequencing data, and observed similar results.
CONCLUSION: We have developed a generalizable approach to adopting GPU accelerated computation to sequence analysis, and how they can significantly expand the possibilities of applying NGS-based precision oncology approaches to adult / pediatric brain cancer by offering 1 day analysis turnaround. Coupled with logistic optimization at sequencing facilities (e.g. using dedicated flow cells and priority queues), we have achieved <1 week surgery-to-insight turnaround. Our work serves as building blocks for designing next general precision oncology clinical trials that rely on NGS to prioritize treatment options for brain cancer patients.

#1499 Pangenome-based somatic mutation landscape of early- and late-onset colorectal cancer in 99 Korean patients.

Jae-Yoon Kim[1], Soobok Joe[2], Sunwoo Lee[1], Yeo-Gyeong Yoon[1], Jongbum Jeon[2], Jong Hwan Kim[2], Jin Ok Yang[2], Seung-Woo Baek[1], Jong-Lyul Park[3], Seon-Kyu Kim[1], Seon-Young Kim[1]

[1]Genomic Medicine Research Center, Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of,[2]Korea Bioinformation Center (KOBIC), Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of,[3]Genomic Medicine Research Center, Korea Research Institute of Bioscience and Biotechnology, Daejeon, Kosovo, Republic of

Colorectal cancer (CRC) is the third most prevalent cancer type worldwide. Although overall CRC incidence has declined due to improved screening, early-onset CRC (EOCRC) in patients under 50 years old is rapidly increasing globally, including in Korea, unlike the decreasing trend of late-onset CRC (LOCRC). Several studies have attempted to identify EOCRC-specific mutations; however, most were limited to whole-exome sequencing and thus failed to capture CRC-related non-coding variants comprehensively. Moreover, previous mutation-profiling studies relied on the GRCh38 reference genome, a linear and largely European-biased assembly that lacks representation of human genetic diversity, fundamentally limiting the discovery of novel mutations. To address these limitations, we performed whole-genome sequencing (WGS) of paired tumor and matched blood samples from 49 EOCRC and 50 LOCRC Korean patients. Somatic mutations were identified using the graph-based Human Pangenome Reference (Human Pangenome Reference Consortium, released in 2023), which integrates genomic diversity from 49 individuals worldwide. Each sample produced 1.409 billion reads with an average coverage of 37.7×. EOCRC and LOCRC carried an average of 1,673 and 801 somatic mutations in coding regions and 236,610 and 127,616 in non-coding regions—21% and 43% higher than GRCh38-based results. Ten EOCRC-specific coding genes were identified, including LMTK3, GALNT11, and NPHP1, with LMTK3 also reported in a previous Chinese study. In non-coding regions, 32 EOCRC-specific genomic regions were detected, including PRKAG2-GALNTL5, MRGPRF-TPCN2, and ACTRT2-TTC34. Among these, GALNT11, MRGPRF-TPCN2, and ACTRT2-TTC34 contained mutations significantly associated with EOCRC patient survival. Although further expression-level validation is warranted, we propose these three regions as promising genome-level candidates for EOCRC diagnosis and therapy. Additionally, all WGS data have been deposited in the European Genome-phenome Archive (EGA; EGAS50000000544) and are expected to provide a valuable resource for researchers investigating CRC or EOCRC at the genomic level.

#1500 Modeling base-pair level mutation rate in metastatic breast cancer using a sequence-based deep learning model.

Ariaki Dandawate[1], Christina Leslie[2], Ekta Khurana[3]

[1]Physiology, Biophysics and Systems Biology, Weill Cornell Graduate School, New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Weill Cornell Medicine, New York, NY

By leveraging a sequence-based deep learning framework, we seek to uncover mechanisms by which mutations arise in noncoding regulatory regions, potentially leading to the discovery of novel targets in metastatic breast cancer.

Research around metastatic breast cancer has largely focused on analyzing coding mutations to characterize progression. Though noncoding mutations are known to affect transcription factor binding and regulation of gene expression, few noncoding mutation drivers have been identified. Previously published work has shown that metastatic mutation rate correlates with open chromatin in the cells-of-origin. However, this work has mostly been done at a coarse, region-level scale, identifying mutational hotspot regions. In this work, we aim to uncover genomic positions in regulatory regions of metastatic breast cancer with elevated mutation rates, and identify their potential mutation mechanism.

We propose a novel deep learning model that uncovers the sequence context-based covariates of per-base mutation rate in regulatory regions of metastatic breast cancer. With access to over 500,000 mutations from the Hartwig Medical Foundation cohort, the neural network is trained on sequences from regulatory regions in normal breast epithelium, and predicts per-base mutation rate profiles for the region. As a result, the model learns how sequence features change mutation likelihood at particular genomic positions.

Analysis of the saliency map of the model allows for identification of specific sites with higher-than-expected mutation rates, which is potentially indicative of increased transcription factor binding that extends beyond selection by pro-metastatic regulatory programs. These findings provide a method to connect noncoding mutation patterns to mutation mechanism and regulatory effects in metastatic genomes.

Future work aims at expanding this model to a pan-cancer level, revealing shared and cancer-specific noncoding mutations that have potential to reveal patterns of metastasis. This scalable sequence model framework provides an advantage over existing methods particularly due to its base-pair level resolution modeling of the metastatic cancer genome. Thus, its implications for modeling and uncovering regulatory mechanisms of cancer is key.

#1501 Cancer gene variant identification and functional interpretation using long-read RNA sequencing with FLAIR3.

Colette Felton[1], Andrea Galvez[2], Tanvi Damle[2], Kevin Levine[3], Mark Diekhans[2], Eunice Lopez Fuentes[4], Taylor Won[2], Christopher Vollmers[2], Alejandro Sweet-Cordero[4], Alice Berger[5], **Angela N. Brooks**[2]

[1]Colette Felton (Individual), UC Santa Cruz, CA,[2]UC Santa Cruz, Santa Cruz, CA,[3]Fred Hutchinson Cancer Center, Seattle, WA,[4]UCSF - University of California San Francisco, San Francisco, CA,[5]Fred Hutchinson Cancer Center, Seattle, CA

Although the impact of single nucleotide variants (SNVs) and changes in transcription and RNA processing are often analyzed separately, a comprehensive analysis facilitates a complete understanding of how cancer gene alterations impact oncogenesis. In traditional short-read RNA sequencing, phasing of alternative exons and cancer variants is lost because the read lengths are much shorter than typical mRNA transcripts (average > 1kb). Here, we show that long-read RNA-seq (lrRNA-seq) can identify full-length transcript isoforms on which variants are expressed, which can be used to more accurately identify the functional impact of oncogenic variants. We developed FLAIR3, which performs an integrated analysis of SNVs, gene fusions, and alternative splicing using lrRNA-seq and predicts functional changes to the amino acid sequence. We performed ONT lrRNA-seq on three osteosarcoma cell lines and PacBio lrRNA-seq on paired normal and tumor tissue from two lung adenocarcinomas. We then used FLAIR3 to identify cancer driver variants and to determine how splicing modulates their expression and function. In the osteosarcoma samples, FLAIR3 revealed alternatively spliced gene fusions in cancer driver genes and TP53 gene fusions with intergenic regions, predicted to cause TP53 truncations. In the lung adenocarcinomas, FLAIR3 revealed isoform-biased expression of oncogenic *BRAF V600E*. Through an isoform-specific analysis of somatic SNVs in *CDKN2A,* we found that *TP53* loss significantly co-occurs with *CDKN2A* missense or nonsense variants of the p16 isoform, but not with *CDKN2A* deep deletion. Damaging variants in the p16 isoform would not have the same damaging effects in p14 isoform, which functions through TP53; therefore, *TP53* loss would be necessary to have complete loss of *CDKN2A* functions. A deep deletion of *CDKN2A* removes both p16 and p14 isoform function and would not need to have additional *TP53* loss. These findings reveal how alternative splicing interacts with and modulates the function of oncogenic variants.

#1503 Single-cell multiomics analysis reveals cell type-specific genetic regulatory programs underlying immunotherapy resistance in hepatocellular carcinoma.

Siyuan Huang, Xiaohang Long, Stephen Lam Chan, Alfred Sze-Lok Cheng

The Chinese University of Hong Kong, Hong Kong, China

Although outcomes for patients with advanced hepatocellular carcinoma (HCC) have improved with the advent of immune-checkpoint inhibitor (ICI)-based therapies, only approximately 30% of patients achieve an objective response. With the rapid development of single-cell technologies, increasing attention has been paid to immunosuppressive cell types in the tumor microenvironment (TME) from a transcriptomic perspective; however, the contribution of genetic variation to immunotherapy resistance remains largely unexplored. Here, we employed single-cell multiomics of 14 treatment-naïve and ICI-resistant HCC patients to investigate cell type-specific genetic regulation underlying chromatin accessibility and gene expression within the HCC TME. High-quality single-cell ATAC-seq data were generated for 155,700 cells and annotated into 11 major cell types, including B cells, CAFs, $CD4^+$ T cells, $CD8^+$ T cells, dendritic cells, endothelial cells, macrophages, monocytes, NK cells, Tregs, and tumor cells. Leveraging genotype information inferred from single-cell ATAC-seq, RASQUAL systematically mapped 23,329 chromatin accessibility-associated quantitative trait loci (caQTLs) across all cell types. We found a wide range of cell number-normalized caQTLs in different cell types (0.01 to 0.22). Notably, tumor cells exhibited the highest frequency of caQTLs, suggesting greater genetic susceptibility within their regulatory landscape. Colocalization with liver cancer-related GWAS signals, combined with peak-to-gene association analyses, identified enhancer-like regulatory elements that may modulate genes involved in tumor progression and immunotherapy resistance. In summary, our study delineates the cell type-specific genetic control and regulatory architecture of HCC TME and provides mechanistic insights into the molecular basis of immunotherapy resistance.

#1504 Fusobacterium-driven epithelial-stromal remodeling in CRC.

Sabin Park[1], Taeyul Kim[2], Kyung-A Kim[2], Minsun Jung[2], Sang Cheol Kim[3], Han Sang Kim[2], Semin Lee[1]

[1]Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of,[2]Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]National Institute of Health, Cheongju, Korea, Republic of

Background: Fusobacterium nucleatum is recognized as a key microbial factor accelerating colorectal cancer (CRC) progression. However, the cellular and molecular mechanisms underlying its impact on the tumor microenvironment (TME) are not yet fully understood.

Methods: We performed single-cell RNA sequencing on specimens from 39 CRC patients. Samples were stratified into Fusobacterium-positive (Fuso-pos; n=14) and Fusobacterium-negative (Fuso-neg; n=25) groups using a 1% microbial abundance cutoff. Comparative analyses were conducted across the stromal and epithelial compartments to investigate microbe-associated transcriptional programs, pathway activation, and fibroblast-epithelial interactions.

Results: CRC tumors with high *Fusobacterium* abundance exhibited coordinated remodeling of both stromal and epithelial landscapes. Fibroblasts from Fuso-pos samples showed enhanced interferon-driven inflammatory activity and mesenchymal transition, accompanied by a marked expansion of a specific myofibroblastic cancer-associated fibroblast (myCAF) subtype. In the epithelial compartment, Fuso-pos tumors showed increased genomic instability, elevated stemness, and upregulation of CMS4-related signatures. Gene module analyses demonstrated a strong increase in epithelial-mesenchymal transition-related module in epithelial cells upon *Fusobacterium* infection, which correlated significantly with the myCAF abundance. Analysis of bulk RNA-seq data further confirmed that a higher proportion of the deconvoluted myCAF subtype was associated with unfavorable clinical outcomes. Mechanistically, Fuso-pos tumor cells showed increased *SHH* expression, while the myCAFs exhibited high expression of Hedgehog signaling components, indicating augmented epithelial-stromal Hedgehog signaling.

Conclusions: These findings suggest that *Fusobacterium* infection in CRC promotes epithelial-stromal signaling through the SHH-Hedgehog axis, contributing to CRC progression. It may represent a therapeutically targetable component of the TME in *Fusobacterium*-associated CRC.

This work is also supported by the National Research Foundation of Korea (NRF) funded by the Ministry of Education (RS-2018-NR031072).

#1505 Long-read sequencing of pancreatic adenocarcinoma transcriptome uncovered aberrant isoforms and tumor progression.

Charny Park[1], Hyeyeong Hwang[1], Daejin Hyung[2], Namhee Yu[3], Sehwa Hong[3], Soo Young Cho[4], Sang Myung Woo[5]

[1]National Cancer Center - Korea, Goyang-si, Gyeonggi-do, Korea, Republic of,[2]Research Institute National Cancer Center, Republi, Research Institute National Cancer Center, Republi, Goyang-si, Korea, Republic of,[3]National Cancer Center, Goyangsi, Korea, Republic of,[4]Department of Molecular and Life Science, Hanyang University, 55 Hanyangdeahak-ro, Sangnok-gu, Ansan, Korea, Republic of,[5]National Cancer Center - Korea, Goyang

Pancreatic cancer remains one of the most lethal malignancies, with a dismal 5-year survival rate of only 13%. Despite multi-omics studies uncovering critical variants and regulatory mechanisms in driver genes and oncogenes, effective therapeutic options remain limited. To address the urgent unmet clinical need for a deeper understanding of the disease, we employed long-read sequencing (LR-seq) to identify complex structural variants and alternative splicing events that are undetectable using short-read sequencing methods.In total, we identified 150,904 isoforms, including 62,111 novel variants. Among these novels, 51.5% showed tumor-specific expression. Novel isoforms were frequently detected in oncogenes such as *CD74*, *B2M*, and *DAXX*, suggesting distinct driver events in pancreatic cancer. Notably, novel alternative transcription start sites were enriched in chromatin-accessible regions marked by H3K4me3 and H3K27ac in tumor cells, and these isoforms appeared to disrupt MHC-associated functions involving *CALR*, *PTK6*, and *TAPBP*.Expression profiling of the novel isoforms clearly distinguished classical and quasi-mesenchymal (QM) subtypes ($P = 0.001$). Furthermore, global analysis of alternative splicing and switch-like isoforms across molecular subtypes revealed that splicing events modulated metastatic characteristics between the classical and QM subtypes through Rho GTPase signaling, GPCR signaling, and extracellular matrix organization.In conclusion, our study underscores the critical role of long-read sequencing in uncovering novel isoforms and alternative splicing events that define the molecular heterogeneity of pancreatic cancer. These findings provide new insights into the regulation of key oncogenes and reveal potential therapeutic targets with implications for improving the diagnosis and treatment of this devastating malignancy.

#1506 Assessing allelic expression variation using somatic mutations vs. polymorphic germline variants.

Kohei Hagiwara, Bensheng Ju, Nadezhda V. Terekhanova, John Easton, Jinghui Zhang

Computational Biology, St. Jude Children's Research Hospital, Memphis, TN

Allele-specific expression (ASE) of somatic mutations can be caused by *cis*-activation of the mutant allele or silencing of the wildtype allele. It has been investigated by examining the enrichment of mutant allele in RNA relative to DNA which can account for increased allelic expression due to somatic copy number alteration. Here we show that this mutation-based approach can be confounded by gene expression differences in tumor and normal cells that co-exist in most bulk tumor samples resulting in enriched mutant allele expression without ASE. By modeling all the relevant co-factors, we show that this confounding effect is exacerbated with low tumor purity and is dependent on mutant allele dosage for mutations that can trigger nonsense-mediated decay (NMD). Our analysis using somatic indels in The Cancer Genomics Atlas (TCGA) dataset found that truncating indel alleles with elevated expression were more prevalent in tumor suppressor genes (TSGs) than in genes not frequently mutated in cancers (non-driver genes) (7.69% vs. 1.76%, Fisher exact $p < 2.2\times10^{-16}$). Consistent with the model, such indels were associated with higher gene expressions in tumor compared to normal and with loss of heterozygosity (LOH) for NMD-sensitive indels in TSGs. By contrast, ASE events of somatic mutations can more accurately be characterized by assessing allelic enrichment of germline heterozygous single nucleotide polymorphisms (SNPs) phased to the somatic mutation. In this SNP-based approach, tumor/normal expression differences and tumor purity exhibit none or minimum confounding effects, discriminating true ASE events caused by *cis*-regulatory change from those caused by confounding factors. To further evaluate the SNP-based ASE analysis, we performed genome-wide haplotype phasing and single-cell full transcriptome sequencing in the B-cell acute lymphoblastic leukemia (B-ALL) cell line Nalm6. We show that that ASE is a heterogenous process with varying degrees of allele expression biases in different cellular subpopulations even in a cell line model and such transcriptional heterogeneity can potentially contribute to clonal evolution under treatments.

#1507 Health behavior associated CCL20 ligand variation contributes to the disparity in non-small cell lung cancer.

Murugesh Eswaran[1], Briana Alicia Brock[1], Hina Mir[1], Sejong Bae[2], Gabriella M. Oprea-Ilies[3], Eric L. Flenaugh[1], Sanjay R. Jain[1], Brian M. Rivers[1], Rick A. Kittles[1], James W. Lillard[1], Rajesh Singh[1], Shailesh Singh[1]

[1]Morehouse School of Medicine, Atlanta, GA,[2]Biostatistics, Data Science and Epidemiology, Augusta Univesrity School of Public Health, Augusta, GA,[3]Pathology, Emory Univesrity School of Medicine, Atlanta, GA

Background: Lung cancer exhibits disparities in incidence, disease prevalence, and treatment outcomes. Chemokines and their corresponding receptors have been shown to be associated with these observed disparities within different ethnic groups. In this study, we have demonstrated that the differential signaling of chemokine receptor CCR6 and its natural ligand is associated with the observed disparity, and this differential CCR6 signaling is primarily due to the diversity in CCL20.
Methods: Bulk RNA-seq data (BioProject ID: PRJNA1039495) from lung cancer cell lines derived from African American (AA) and European American (EA) individuals were analyzed to identify and quantify different isoforms of CCL20. MD simulations were performed to evaluate the binding affinity of CCL20, hydrogen-bond stability, and conformational behavior upon interaction with the CCR6 receptor. Downstream pathway activation potential was inferred by comparing the expression of signaling molecules that support oncogenic pathways and are associated with poor therapeutic outcomes. Furthermore, smoking habits, including higher nicotine intake, distinct metabolite patterns, and alterations in basic cytokine levels, were incorporated into the model as external factors that may influence CCL20 isoforms and CCR6 signaling.
Results: Out of 5 CCL20 isoforms, Isoform-1 (24 TPM) and Isoform-2 (36 TPM) showed stronger interactions with CCR6 compared to EA cells (Isoform-1: 7.5 TPM; Isoform-2: 11.2 TPM). Across smoking groups, AA cells showed higher Isoform-2 levels than EA cells, increasing from non-smokers (Isoform-1: 18 TPM; Isoform-2: 18 TPM) to smokers (Isoform-1: 24 TPM; Isoform-2: 40 TPM), while EA cells showed lower increases from non-smokers (Isoform-1: 18 TPM; Isoform-2: 19 TPM) to smokers (Isoform-1: 24 TPM; Isoform-2: 30 TPM). MD simulations revealed that lung-cancer-cell CCR6 binds both CCL20 Isoform-1 & 2 from AA-derived cell lines with significantly stronger affinity compared to EA-derived cells, reflected by lower binding free energies, more stable hydrogen-bonds, and longer ligand-receptor contact durations. Isoform-2 showed the strongest overall binding affinity, indicating that it may be the dominant activator of CCR6 signaling. Population-level behavioral data, including All of Us cohort metrics, showed that AA smokers tend to use cigarettes with higher nicotine content, inhale more deeply, and exhibit slower nicotine and cotinine clearance, which corresponded with increased Isoform-2 expression.
Conclusion: Lung cancer cells derived from AA exhibit a ligand-rich and affinity-enhanced CCL20-CCR6 signaling axis driven primarily by Isoform-2. Isoform-specific expression, receptor affinity, and smoking-associated inflammation together highlight the significance of Isoform-2 in disparity observation in Lung cancer, as a key player in contributing to disparity.

#1508 A large-scale resource of standardized pediatric somatic cancer variant classifications.

Alex H. Wagner, Kori Kuzma, Kathleen M. Schieffer, Wesley Goar, Don Corsmeier, Michael McCarrick, Kathryn Perry, Jennifer Bowser, James Stevenson, Mohammad Marhabaie, Matthew Cannon, Liana Hernandez, Doug Depoorter, Hongtao Jia, Amy Everest, Jessica Howard, Swetha Ramadesikan, Vijayakumar Jayaraman, Ying-Chen C. Hou, Mariam T. Mathew, Marco L. Leung, Yassmine M. N. Akkari, Daniel Puthawala, Anastasia Bratulin, Ben Kelly, Elaine R. Mardis, Catherine E. Cottrell

Institute for Genomic Medicine, Nationwide Children's Hospital, Columbus, OH

Background: Our ability to interpret pediatric cancer genomes to identify targeted therapeutic strategies is bottlenecked by limited structured knowledge about the clinical significance of detected somatic mutations. Clinical genomics laboratories routinely keep internal records of previously classified variants in *ad hoc* storage systems (e.g., spreadsheets, custom databases), but significant technical barriers exist that prevent the broad dissemination of such knowledge for use across institutions. Recently developed genomic knowledge standards from the Global Alliance for Genomics and Health (GA4GH) provide the foundation to remove these barriers through a shared community framework for disseminating genomic knowledge.

Methods and Results: We implemented these GA4GH standards to produce over 1,500 publicly available somatic variant classification records. These were curated as part of routine pediatric cancer genome assessment in a research hospital setting, 94% (1415/1504) of which were assessed under the Molecular Characterization Initiative of the National Cancer Institute's Childhood Cancer Data Initiative. To broadly disseminate these data, we extended the open-source "ClinVar This!" community software to ingest GA4GH-standardized records for submission to the NIH ClinVar knowledgebase. As a result, we have more than doubled the total number of somatic cancer records submitted to ClinVar (previously 1,325 records across all other community submissions). We anticipate submitting an additional 2,000 records by April 2026. To support this effort, we developed the Variation Categorizer (VarCat) web platform to simplify the structured application of community standards for clinical variant classification in a pediatric setting. The software currently supports community somatic variant classification guidelines for clinical significance (the "AMP/ASCO/CAP guidelines") and oncogenicity (the "ClinGen/CGC/VICC guidelines"). VarCat is an open-source, clinically validated web tool that provides a streamlined mechanism for automating GA4GH-compliant dissemination of pediatric somatic cancer knowledge as part of routine clinical workflows.

Conclusions: This work demonstrates how these novel GA4GH standards enable us to disseminate somatic cancer variant knowledge as part of routine clinical operations. Our presentation will highlight the use of the VarCat platform and the associated standardized variant classification data we have made publicly available. We will also share insights from our applications of these standards to capture nuanced adaptation of community guidelines for clinical variant interpretation. We will conclude with practical guidance about how to best leverage these resources as a scalable approach to addressing the variant interpretation bottleneck in the clinical setting.

#1509 Cost-effective, full-length transcriptome of chronic lymphocytic leukemia patient cd8 t cells reveals the impact of BTKi treatment on mRNA processing and gene expression.

Shanmugapriya Thangavadivel[1], Altan Turkoglu[1], Lianbo Yu[1], Rosario Distefano[1], Alexander Pan[2], Logan Walker[3], Tina Wang[4], Shrilekha Misra[1], Tzung-Huei Lai[1], Britten Gordon[1], Samon Benrashid[1], Alexander He[1], Meixiao Long[1], rosa Lapalombella[1], John C. Byrd[5], Kerry A. Rogers[1], Bradley Blaser[1], Ralf Bundschuh[6], Jennifer A. Woyach[1], **Pearlly S. Yan**[1]

[1]The Ohio State University College of Medicine, Columbus, OH,[2]N-Power Medicine, Inc, Red Wood City, CA,[3]University of Michigan, Ann Arbor, MI,[4]The Ohio State University, Columbus, OH,[5]University of Pittsburgh Medical Center, Pittsburgh, PA,[6]Department of Physics and Department of Chemistry & Biochemistry, The Ohio State University, Columbus, OH

Ibrutinib, a Bruton's tyrosine kinase inhibitor (BTKi), is used to treat chronic lymphocytic leukemia (CLL). It has effects not only on CLL cells but also on the immune microenvironment, particularly T cells. While T cell exhaustion and activation defects are well studied, the role of mRNA processing on the transcriptome and immunome needs investigation. We and others noted such events in CLL cells with shorter isoforms replacing the longer primary transcripts. They enable added regulations via altered mRNA stability, translational efficiency, and protein localization.To conserve precious patient time series samples, we developed a protocol that deposes 300 sorted live cells into cold lysis buffer containing 5' template-switching primers and 3' poly-dT primers to bypass RNA extraction and to capture full-length transcripts. Viewing our data in genome browser, we noted the aligned- and the junction-read tracks reveal exon dropout events as stretches of uncovered exons in a gene-specific manner within- and across patients. For isoform-informed gene expression analysis, we identify a known isoform for each gene that encompasses all the transcribed exons from 10 CLL patients (30 samples: baseline, 3y and 5y ibrutinib treatment) for length-normalized gene expression analysis. For this abstract, we performed global analysis and a subset analysis targeting 187 genes from immune pathways and CD8 T cell activation. For timepoint analysis, differentially expressed gene (DEG) analysis was performed separately for genes without exon dropout and those with exon dropout. The 187-gene timepoint analysis was performed in one list. Key findings are: i) DEGs from subset analysis are also found in the two global analyses; ii) similar DEG trends observed across timepoints in all 3 analyses: highest in BL > 3y and BL > 5y followed by BL > 3y and 5y > 3y with a few 3y > BL and 5y > BL events; iii) 88% of the expressed transcripts contain one or more exon dropout event; iv) STRING analysis using DEGs from subset analysis reveals CD8 activation genes such as *ptprc* and *cd69* interact extensively with Perforin- and PD-1 pathway genes forming a dense network while genes from FAS-, mTOR- and TRAIL pathways form a separate network with few interactions. In summary, with a cost similar to bulk RNA-seq, our full-length data reveals mRNA processing events in both long genes (e.g., *jak1*, 26 exons, full exon coverage in 12/30 samples) and short genes (e.g., *jun*, part of the intronless gene not covered in some samples). An ultralow input of 300 pre- and post-treatment cells allow deep library sampling of both highly expressed genes with no exon dropout and lowly expressed genes with many dropouts. Lastly, DEGs from subset analysis lend support to the ability of the isoform-informed workflow to capture CD8 T cell functional genes in global DEG analysis.

#1510 CASTLE: long-read sequencing panel of cancer cell lines to improve standards of somatic variant calling and benchmarking.

Mikhail Kolmogorov[1], Ayse Gokce Kesus[2], Asher Bryant[2], Tanveer Ahmad[2], Byunggil Yoo[3], Sergey Aganezov[4], Anton Goretsky[2], Ataberk Donmez[2], Lisa Lansdon[5], Joshua Gardner[6], Brandy McNulty[6], Samuel Sacco[6], Jyoti Shetty[2], Yongmei Zhao[2], Bao Tran[2], Giuseppe Narzisi[7], Adrienne Hellend[7], Chengpeng Bi[5], Adam Walter[5], Margaret Gibson[5], Irina Pushel[8], Erin Guest[3], Tomi Pastinen[5], Nicolas Robine[7], Karen H. Miga[9], Midhat S. Farooqi[10], Benedict Paten[6]

[1]NIH-NCI, Bethesda, MD,[2]National Cancer Institute, Bethesda, MD,[3]Children's Mercy Kansas City, Kansas City, MO,[4]Oxford Nanopore Technologies, New York, NY,[5]Children's Mercy Hospital, Kansas City, MO,[6]UC Santa Cruz, Santa Cruz, CA,[7]New York Genome Center, New York, NY,[8]Children's Mercy Kansas City, Kansas City,[9]Biomolecular Engineering Department, University of California, Santa Cruz, Santa Cruz, CA,[10]Children's Mercy Research Institute, Kansas City, MO

Most current large-scale whole-genome sequencing projects rely on short-read sequencing to call germline and somatic SVs, however it provides an incomplete view of the somatic variation landscape because of mappability limitations. In contrast, long-read sequencing can resolve highly repetitive regions of the human genome, and assemble variants into contiguous haplotypes, and therefore is a promising approach to resolve the hidden complexity of a cancer genome. However there is still a limited number of publicly available datasets for benchmarking and development of new methods.

To motivate the development of new short- and long-read tools for cancer genomics, we created the CASTLE panel, based on multi-technology whole-genome sequencing of six commercially available tumor/normal cell line pairs (HCC1954, HCC1937, H1437, H2009, Hs578T and HCC1395). The panel represents two lung and three breast cancer cell lines. Genomic sequencing currently includes PacBio, Oxford Nanopore, Illumina, Hi-C and PoreC, in most cases sequenced from the same DNA extraction or cell line passage. We further generated high-confidence benchmarking somatic variant calls for SNPs, small indels and structural variants using the ensemble method. For structural variants, We used Severus, nanomonsv, SAVANA, Sniffles2, SvABA, GRIDSS, and Manta to generate initial variant calls; confident calls were defined if supported by at least two (out of three) technologies and at least 4 (out of 11) callers. For small variant benchmarking sets, we used a combination of Strelka2, DeepSomatic and ClairS.

Overall, we release a new public resource for cancer genomic developments and benchmarking, which we are aiming to complement with additional genomic and transcriptomic technologies. The data and benchmarking datasets are openly available at: https://github.com/CASTLE-Panel/castle.

#1511 Longitudinal whole genome sequencing to investigate clonal hematopoiesis dynamics.

Rohini Chebbi, Steven Estus, Elif P. Coskun, David W. Fardo, Gregory A. Jicha, Peter T. Nelson, Erin L. Abner, Yasminka A. Jakubek

University of Kentucky, Lexington, KY

Clonal hematopoiesis (CH) is the presence of clonal populations of hematopoietic stem cells, which arise when a cell acquires a somatic mutation and then undergoes clonal expansion. The presence of CH is strongly associated with age. Clonal hematopoiesis of indeterminate potential (CHIP) mutations is defined by having a mutation in a gene commonly altered in blood cancers. CHIP is associated with increased risk of illnesses such as blood cancer and cardiovascular diseases. In addition to CHIP mutations, other somatic mutations can drive CH. To comprehensively characterize CH dynamics, we conducted whole genome sequencing (WGS) of blood samples from a community-based brain aging cohort, sequencing multiple samples that were collected across multiple time points. The University of Kentucky (UK) Alzheimer's Disease Research Center clinical cohort comprises a continuously replenished group of approximately 800 participants followed longitudinally. We selected 12 participants for a pilot study using the following criteria: each individual had 3 blood draws, and a minimum of 2 years between draws. WGS for these samples was performed at the Genomics Core Laboratory at UK. For all participants the age at first blood draw ≤ 89 years (median age: 80.5, range: 66-89), age at last blood draw ≤ 95 (median age: 87, range: 80 - 95). The time in years between first and last blood draw ranged from 6 to 12 years. 75% of participants were female and 25% were male. The mean average coverage was 54.4X. Alignment and variant calling were performed using the Illumina DRAGEN Somatic pipeline. Post pipeline filtering steps include filtering out variants in low complexity and blacklisted regions and removal of putative germline variants. Using stringent quality control metrics, 3/12 (25%) individuals had CHIP in one of the 74 canonical CHIP genes. Of these participants, 2 had DNMT3A CHIP. One participant had DNMT3A CHIP at age 87 (last blood draw), but not at age 80 or 83. For the other participant with DNMT3A CHIP, the mutation was present in all 3 blood draws from age 68, 77, and 80 years and with mutant allele fraction (MAF) ranging between 10-16%. TET2 CHIP was detected in one participant at age 90 (MAF 10%) and 95 (MAF 15%), but not at age 84. Our observations support previous studies showing that CHIP is common in later life. This pilot study provides an opportunity to conduct more in-depth investigations of clonal dynamics in later life and expand these investigations to non-canonical CH driver mutations and mosaic chromosomal alterations. We are pursuing this opportunity and leveraging the longitudinal study design to develop novel approaches for distinguishing germline and somatic variants to improve methods for CHIP mutation calling.

#1512 Enhanced detection of immune and oncogenic signals in HER2-positive breast cancer by a novel data-scaling method.

Chole Gunadi[1], Emily Xue[1], Amy Lei[1], Cindy Hu[2], Qian Wang[1]

[1]iLab Research Institute, Mountain View, CA,[2]

Background: HER2-positive breast cancer, a clinically aggressive subtype accounting for 15-20% of all cases, is characterized by ERBB2 gene amplification and overexpression of the HER2receptor, which drives oncogenic signaling through PI3K/AKT/mTOR and MAPK/ERKpathways. Accurate transcriptomic profiling of tumor tissue versus normal adjacent tissue (NAT)is key to discovering these distinct mechanisms and guiding therapy strategies. However,traditional differential expression (DE) workflows often suffer from data distortions due tooutlier, high-read samples, and normalization limitations, likely obscuring biologically relevantdifferences.
Methods: This study reanalyzed bulk RNA-seq data from HER2-positive breast cancer patients(GSE292823) to compare traditional DE analysis with a novel scaling-based preprocessingmethod.
Results: The scaled data method significantly improved sample clustering in PCA and enhanceddetection of differentially expressed genes, including CCL5, which is associated with resistanceto trastuzumab. Upregulation of IL18, CD86, and NOD2 indicated inflammatory signaling,antigen presentation pathways, and immune cell recruitment, all key factors that can help tumorcells in evading an immune response. Furthermore, several other immune-regulated genes weredownregulated, including CD3G and GZMA, suggesting the suppression and reduced efficiencyof cytotoxic T-cell activity. The downregulation of SATB-AS1, PICSAR and ROR1-AS1,known to be associated with altered chromatin remodeling and long non-coding RNA-mediatedregulation in lung cancers and other types, pointed to similar regulatory mechanisms in HER2-positive breast cancer. These findings demonstrate the value of the novel preprocessing methodin uncovering both activated and suppressed gene networks that shape the tumormicroenvironment and immune response in HER2+ breast cancer. Additionally, Gene ontology(GO) enrichment analysis revealed that the preprocessing method enhanced the detection ofbiologically relevant pathways compared to the original approach. While the traditional methodidentified general immune-related pathways such as leukocyte adhesion and T cell suppression,the new method uncovered several specific immune functions, including regulation of immuneeffector processes, immunological synapse formation, and further downregulation of the T cellreceptor complex activity. Moreover, the new method captured upregulation of vesicle-mediatedsignaling and granule-associated components, suggesting heightened immune cell-tumorengagement.
Conclusion: The scaled preprocessing improves the detection of gene expression differences andsignificant pathways, thereby allowing for a more comprehensive view of tumor-immuneinteractions in HER2-positive breast cancer.

#1513 Gene signatures and infiltration patterns of mast cells in breast cancer revealed by integrated bulk and single-cell RNA sequencing Analyses.

Eva Liu, Benjamin Jin, Cindy Hu, **Qian Wang**

iLab Research Institute, Mountain View, CA

Background: Breast cancer is one of the leading cancers in women, caused by uncontrolledcell growth in breast tissue. Mast cells, a type of immune cell generally responsible forinflammation and allergic reactions, have emerged as key immune players within the tumormicroenvironment. However, the functions of these cells in breast cancer remain incompletelyunderstood and sometimes controversial. This study investigated mast cell infiltration and geneexpression profiles across three breast cancer subtypes by using integrated bulk and single-cellRNA-seq analyses.
Methods: Publicly available transcriptomic datasets GSE45419, GSE254991 were downloadedfrom NCBI and reanalyzed with standard pipelines. Differentially expressed genes (DEGs) wereidentified with |logFC| > 0.2 and FDR < 0.05. UMAPs and Heatmaps were generated tovisualize the data. Gene Ontology (GO) enrichment analysis was subsequently performed toidentify significantly enriched biological pathways.
Results: Bulk RNA-seq data analysis of GSE45419 revealed significant upregulations of mastcell marker genes (KIT, FCER1A, MS4A2, CPA3, HDC and TPSAB1) in ER+, HER2+, TN+(triple negative) breast cancers compared with benign breast lesions (Figure 1). Expressions ofthese genes were the highest in ER+, intermediate in HER2+, lower in TN+, and minimal inbenign breast lesions. Reanalysis of single-cell RNA-seq dataset GSE254991 identified 13clusters of cells in both cancer and adjacent tissues, including a distinct mast cell clusterexpressing canonical markers (KIT, FCER1A, MS4A2, CPA3, HDC and TPSAB1). Theproportion of mast cells is higher in tumor tissue (4.59%) than in paired normal breast tissue(2.89%) from the same patient. Cross-comparison of mast cell gene expression profilesbetween cancerous and adjacent regions identified the core DEGs enriched in mast cellsassociated with breast cancer. GO analysis indicated the significantly up-regulated pathways inbreast cancer including antigen processing and presentation of peptide antigen, antigen binding,MHC Class I and II protein complex assembly, leukocyte mediated immunity and cell-celladhesion, response to type II interferon.
Conclusion: Integrated bulk and single-cell transcriptomic data analysis revealed increasedmast cell infiltration and distinct transcriptional reprogramming in three subtypes of breastcancer. These findings provide new insights into potential immunoregulatory roles of mast cellsin tumor progression and may inform the development of novel therapies targeting mast cells tofight for breast cancer.

#1514 Mapping classifiability in the cancer DNA methylome: A data-learned disease hierarchy.

Hao Xu, Jenny Z. Li, Wanding Zhou

Center for Computational and Genomic Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA

DNA methylation-based tumor classification has been successfully applied in clinical settings. Traditional classifiers assume that diagnostic labels are fixed and mutually exclusive, yet many biological entities are inconsistently defined or intrinsically overlapping. We propose a general framework for quantifying and interpreting classifiability in DNA methylation–based disease classification. Here, we treat classifiability itself as an empirical property of data, measured through cross-validation across more than 13,698 harmonized methylome cohorts drawn from TCGA and GEO, spanning over 324 cancer types. This approach reveals which disease or cancer types are stably separable at the molecular level and which collapse across labels, providing a principled, data-driven view of biological boundaries. By analyzing cross-validation consistency and label confusability, we reconstruct a hierarchical taxonomy derived directly from the methylome, in which relationships between entities emerge without prior human definitions, recapitulating known lineage relationships and uncovering novel cross-entity proximities. We further integrate major public datasets into a pan-disease foundation classifier that reports both predictions and classifiability-aware confidence scores, reflecting separability along the learned hierarchy. Finally, we demonstrate that the same framework can evaluate new or rare cohorts, testing whether a proposed entity forms a distinct, classifiable unit or merges with established types. Together, these advances recast methylation classification from a task of prediction into one of discovering the structure of classifiability itself in the human epigenome, offering a data-driven foundation for refining tumor taxonomies and diagnostic criteria.

#1515 Doublet removal enhances single-cell resolution and uncovers malignant transcriptional programs in NSCLC.

Benjamin Jin, Eva Liu, Amy Lei, **Qian Wang**

iLab Research Institute, Mountain View, CA

Background: Non-small cell lung cancer (NSCLC), accounting for more than 85% of lung cancer cases. includes several subtypes such as adenocarcinoma, squamous cell carcinoma, and large cell carcinoma. Advances in single-cell RNA sequencing (scRNA-seq) have enabled high-resolution profiling of the NSCLC tumor microenvironment, revealed previously unrecognized cellular heterogeneity, and identified potential therapeutic targets, including immune checkpoint inhibitor (ICI) pathways. However, doublets (artificially merged profiles of two cells captured in one droplet) can distort downstream analysis by altering clustering and differential gene expression, ultimately confounding biological interpretation.
Objective: This study evaluated a refined scRNA-seq workflow that incorporates doublet removal to improve cell-type identification and downstream biological insights.
Methods: Public scRNA-seq dataset GSE198099 was downloaded from NCBI and reanalyzed using both routine pipelines and a refined workflow that incorporates the DoubletCatcher algorithm. DoubletCatcher generates artificial doublets, computes doublet scores based on neighbor relationships, and removes cells exceeding the defined threshold. Differentially expressed genes (DEGs) were identified using R-based pipelines (FDR < 0.01; $|\log_2 FC| > 0.2$). Gene Ontology enrichment was performed to identify enriched pathways. UMAPs and heatmaps were generated for visualization.
Results: Routine analysis produced 17 poorly resolved clusters, while the refined workflow yielded 14 well-defined clusters, while eliminating spurious overlaps in immune signatures. Clear cell identities were recovered, including $CD4^+$ T cells, $CD8^+$ T cells, B cells, plasmablasts, macrophages, monocytes, mast cells, endothelial cells, type II epithelial cells, and three distinct cancer cell clusters comprising cancer cells and stem-like cancer cells. DEG analysis revealed significant transcriptional differences of cancer cells and stem-like cancer cells in tumor tissues compared with adjacent Tumor-region cancer cells exhibited de-differentiation, hypoxia-driven metabolic reprogramming, inflammatory and immune-evasive signaling, proliferation and cell-cycle activation, and epithelial-mesenchymal transition (EMT). In contrast, cancer cells from adjacent tissues showed more differentiated states, suggesting potentially greater therapeutic responsiveness before surgical intervention.
Conclusion: Removing doublets markedly improved cluster accuracy and biological interpretability, revealed distinct cancer cell, stem-like cancer cell, and immune cell populations, and uncovered key active malignant programs in tumor-region cancer cells. This refined method enhances the reliability of single-cell analysis and provides further insights into NSCLC tumor biology.

Poster Session

#1519 AI-designed immune sensor-enhanced CAR-T cells for potent solid tumor immunotherapy.

Zoya Alteber, Jitka Sagiv, Reut Nave, Gil Friedman, Dor Shimon, Maayan Shamsian, Megi Cemel David, Dina Listov, Sharon Avkin Nachum, Ofer Levy, Michal Golan Mashiach

Edity Therapeutics, Rehovot, Israel

Immune-based therapies have revolutionized cancer treatment; however, their efficacy in solid tumors remains limited. This is primarily due to the immunosuppressive tumor microenvironment (TME) and insufficient induction of systemic anti-tumor immunity. To overcome these barriers, Edity Therapeutics has developed an AI-guided platform that integrates engineered innate immune sensors into CAR-T cells. These sensors are designed to initiate a localized antiviral-like immune response upon antigen engagement. Immune sensors derived from the STING and MAVS pathways were computationally optimized to generate constitutively active, yet controllable, derivatives that drive Type I interferon and pro-inflammatory cytokine production. These sensor modules were fused to a navigator domain, ensuring their activation is exclusively upon CAR signaling, thereby confining immune stimulation to the tumor site. Hundreds of sensor variants were designed and screened *in vitro* for functional potency. Lead candidates exhibiting strong immuno-stimulatory activity were incorporated into CAR-T constructs and evaluated in SCID-Beige xenograft models. In these models, sensor-enhanced CAR-T cells demonstrated significantly superior tumor control compared to conventional CAR-T counterparts. By locally provoking inflammation, this approach will convert the immune-cold TME into an inflamed tumor milieu, potentially enabling robust anti-tumor responses without inducing peripheral adverse effects. The platform is currently being advanced toward clinical development, with two solid tumor indications selected based on antigen expression, tumor accessibility, and translational readiness. These next-generation CAR-T products represent a new class of cell therapies that couple precise tumor targeting with controlled autonomous immune activation, offering a transformative approach for the treatment of solid malignancies while improving the therapeutic index.

#1520 Improving BCMA-targeted CAR-T cell therapy of myeloma using TGF-β resistance and inducible production of IL-18.

Sandhya Rai[1], Shijing Wang[1], Bin Sun[1], Tyce Kearl[1], Peiman Hematti[1], Joseph Zenga[2], Heather Himburg[3], Musaddiq Awan[3], Deepak Parashar[1], Binod Dhakal[1], Siegfried Janz[1], Fumou Sun[1]

[1]Department of Medicine, Medical College of Wisconsin, Milwaukee, WI,[2]Department of Otolaryngology, Medical College of Wisconsin, Milwaukee, WI,[3]Department of Radiation Oncology, Medical College of Wisconsin, Milwaukee, WI

Background: Although immunotherapy with B cell maturation antigen (BCMA)-targeted chimeric antigen receptor (CAR) T cells, or BCMA CARTs for short, has yielded unprecedented treatment responses in patients with relapsed and/or refractory multiple myeloma (RRMM), efficacy is limited by lack of durability in most cases. This has been attributed, in large part, to the immunosuppressive bone marrow environment (BME) of RRMM, leading to inactivation, exhaustion and attrition of BCMA CARTs. Next-generation CARTs, capable of overcoming BME-dependent inhibitory constraints, may lead to more durable treatment options for RRMM.
Methods: To inform the design of BCMA CARTs that can maintain long-term activity in the myeloma-laden bone marrow, we leveraged a recently published single-cell RNA sequencing dataset, GSE210079, of the BME from 9 patients with RRMM. Based on clinical outcomes, patients were stratified into early relapse (<3 months) and late relapse (>12 months) groups. Biocomputational analyses revealed that activation of TGF-β signaling and T cell exhaustion pathways, along with suppression of IL-18-driven immune responses, were implicated in the mechanisms driving early-relapse post-BCMA CAR-T treatment. Inspired by these findings, we employed standard molecular biology tools to manufacture BCMA CARTs that feature both TGF-β resistance and simultaneously disrupt PD-1 expression and enabling inducible IL-18 secretion.
Result: Compared to T cells from late-relapse myeloma, T cells from early-relapse myeloma demonstrated upregulated oncogenic signaling circuits (p53, FoxO, AMPK), elevated expression of exhaustion-related genes (*PDCD1*, *HAVCR2*, *LAG3*, *CTLA4, TIGIT; p* < 0.01), and increased mRNA levels of key TGF-β pathway genes (*TGFB1*, *SMAD2/3/4*, *TGFBR2*). Early-relapse myeloma exhibits reduced TCR signaling and Th1/Th2 differentiation, which are regulated by IL-18. BCMA CARTs were rendered resistant to TGF-β by enforced expression of a dominant-negative ligand-binding but non-signaling transforming growth factor beta receptor 2 (dnTFGBR2). Monoallelic “knock-in” of an IL-18 encoding gene in the *PDCD1* locus relied on CRISPR/Cas9-mediated editing. The genetically modified BCMA CAR-T cells demonstrated potent cytotoxic activity against myeloma cells in vitro, increased resistance to TGF-β-mediated suppression, and inducible secretion of IL-18 driven by the endogenous *PDCD1* promoter. IL-18 levels increased in correlation with T cell activation, accompanied by a concomitant silencing of PD-1 expression.
Conclusion: TGF-β-resistant BCMA CARTs that produce IL-18 when the cells are challenged by exhaustion in the BME, and thus disrupt PD-1, may be viable way forward to a more potent and durable therapy for patients with RRMM than available today. This hypothesis will be evaluated in greater depth in preclinical in vivo studies ongoing in our laboratory.

#1521 Concurrent targeting of tumors and their microenvironment using CAR-T cells specific for fibroblast activation protein alpha.

Larina Tzu-Wei Shen[1], Afsana Islam[1], Daiki Fujita[1], Kenji Nakamaru[1], Dan Macleod[2]

[1]Optieum Biotechnologies Inc., Toon City, Japan,[2]Optieum Biotechnologies America Inc., Dover, DE

Chimeric antigen receptor T (CAR-T) cell therapy for solid tumors is challenged by the immunosuppressive tumor microenvironment (TME) and physical barriers formed by Fibroblast Activation Protein alpha (FAPα)-expressing cancer-associated fibroblasts (CAFs). Furthermore, high-affinity CAR-T cells often induce trogocytosis and T cell exhaustion, leading to target antigen loss and limiting persistence. We sought to develop FAPα CAR-T cells with optimized binding affinity to overcome these obstacles.

We generated FAPα CAR-T cells (CD28/CD3ζ) by shuffling new light chains fused to the heavy chain of the parental clone of FAPα CAR using a high-throughput scFv library T-cell system (Eumbody System). We identified 3 new clones using this method, FL1, FL8 and FL12, exhibiting slightly lower structural avidity compared to the parental clone. We investigated their function in vitro and in vivo using glioblastoma cell lines.

Unlike the parental clone FAPα-CAR-T, the optimized FL1, FL8 and FL12 clones preserved FAPα expression on target cells, demonstrating successful mitigation of trogocytosis, which was inversely correlated with structural avidity. In in vitro cytotoxicity assays, FL12 CAR-T cells showed superior real-time killing against FAPa-positive U87 cells and better suppression of U87 spheroid growth, while exhibiting a less exhausted T-cell phenotype. In vivo, FL12 CAR-T cells effectively suppressed U87 tumor growth in a subcutaneous xenograft model, with statistically significant improvements compared to both conventional scFv-CAR-T cells and negative control T cells even at low cell doses. To further evaluate their efficacy, FL12 CAR-T cells are currently being tested in in vitro cytotoxicity assays using 3D mixed tumor spheroid (U87 or U251 plus CAFs). This work is designed to confirm their ability to be highly cytotoxic against FAPα-positive CAFs, successfully migrate into mixed tumor spheroids, and achieve a significant reduction in tumor size when compared with conventional scFv-CAR-T cells and tumor-only spheroids.

In conclusion, scFv-optimization successfully generated FAPα CAR-T cells that mitigate trogocytosis and exhibit superior phenotype, persistence, and anti-tumor efficacy. This strategy allows for concurrent targeting of solid tumor cells and the CAF-rich microenvironment, representing a promising and readily translatable approach for refractory solid malignancies.

#1522 FMNL1 overexpression enhances tumor-specific TIL and CAR-T cell accumulation and therapeutic efficacy in solid tumors.

Jeffrey W. Chung, Jessica Olivas-Corral, Ashley M. Wood, Ashton L. Sigler, Edward Ning, Michelle E. Allen, Kayla Fairweather, **Jordan Jacobelli**

Immunology & Microbiology, The University of Colorado School of Medicine, Aurora, CO

Purpose: Adoptive T cell therapies such as tumor-infiltrating lymphocytes (TIL) and chimeric antigen receptor (CAR)-T cells show limited efficacy against solid tumors. This is due in part to physical barriers in solid tumors, including abnormal vasculature and dense extracellular matrix, which limit T cell infiltration and persistence within restrictive tumor microenvironments. We investigated whether overexpression of Formin-like-1 (FMNL1), a cytoskeletal regulator of T cell migration, could overcome these physical barriers and improve T cell accumulation and therapeutic activity in solid tumors.

Methods: We engineered tumor-specific TILs and CAR-T cells to overexpress FMNL1 using a bioengineering platform. We first assessed control and FMNL1-overexpressing T cell activation, cytotoxicity, and restimulation in vitro. Then using murine tumor models, we evaluated tumor infiltration and therapeutic efficacy of adoptively transferred control and FMNL1-overexpressing TILs and CAR-T cells in melanoma and lung carcinoma models.

Results: FMNL1-overexpressing T cells maintained normal activation and tumor cell killing compared to control T cells. In vivo, FMNL1 overexpression significantly increased TIL and CAR-T cell accumulation at melanoma and lung carcinoma solid tumor sites compared to controls. Importantly, adoptive transfer of FMNL1-overexpressing CAR-T cells prolonged survival in melanoma tumor-bearing mice relative to control CAR-T cells, in both immunodeficient and immunocompetent recipient mice.

Conclusions: This is the first demonstration that enhancing cytoskeletal dynamics via FMNL1 overexpression increases T cell accumulation in solid tumors and improves therapeutic efficacy. These findings highlight a novel, tumor antigen and CAR construct independent strategy to overcome physical barriers in the tumor microenvironment and suggest translational potential for improving CAR-T cell therapy in patients with solid tumors.

#1523 Galectin-3 blockade reprograms the tumor microenvironment and improves CAR T-cell therapy in pediatric cancers.

Enrique Conde-Gallastegi[1], Karin Straathof[2], Sergio Quezada[3]

[1]University College London (UCL) Cancer Institute, London, United Kingdom,[2]UCL Great Ormond Street Institute of Child Health, London, United Kingdom,[3]University College London (UCL) Cancer Institute, Berkhamsted, United Kingdom

CAR T-cell therapies have revolutionized the treatment of hematological malignancies, yet their efficacy in solid tumors remains limited. Pediatric solid tumors are particularly challenging due to their low mutational burden, scarce T-cell infiltration, and highly immunosuppressive tumor microenvironment (TME). Although CAR T cells can induce initial responses, sustaining durable activity is difficult.

To identify mechanisms that could be targeted to enhance CAR T-cell function, we performed scRNA-seq analysis of nearly 100 pediatric tumor samples and characterized the T-cell and myeloid compartments. We found that Galectin-3 (Gal3), an immunosuppressive and protumorigenic molecule, was predominantly expressed by myeloid cells and strongly associated with an M2-like macrophage phenotype. Gal3 expression inversely correlated with overall T-cell infiltration and, more specifically, with the proportion of reactive-like T cells. Spatial imaging confirmed Gal3 protein expression in the TME and showed colocalization with immunosuppressive myeloid of T cell markers

Based on these findings, we hypothesized that Gal3 inhibition could synergize with CAR T-cell activity by alleviating myeloid-driven immunosuppression. To deliver Gal3 inhibition directly within the TME, we engineered an “armed” CAR T cell that secretes a protein-based Gal3 inhibitor. Functional characterization is ongoing, and in vivo evaluation in pediatric tumor mouse models is currently in progress.

Our results identify Gal3 as a key barrier to T-cell infiltration and activation in pediatric tumors and provide a strong rationale for combining CAR T-cell therapy with targeted Gal3 inhibition. This engineered CAR T-cell platform represents a promising strategy to enhance therapeutic efficacy in pediatric solid tumors.

#1524 Collagen-binding IL-12-armored STEAP1 CAR-T cells for advanced prostate cancer.

Koichi Sasaki[1], Vipul Bhatia[2], Yuta Asano[3], Jakob Bakhtiari[3], Pooja Kaur[1], Chuyi Wang[1], Takumi Matsuo[1], Olivier Dubois[1], Po-Chuan Chiu[1], Donny Gun[4], Charanjit Singh[1], Ioanna Panagi[1], Laurine Noblecourt[1], Maria Nikolaidi[1], Truman Chong[2], Gerardo Javier[2], Saul J. Priceman[5], Aude G. Chapuis[3], John K. Lee[2], Jun Ishihara[1]

[1]Bioengineering, Imperial College London, London, United Kingdom,[2]Medicine, UCLA, Los Angeles, CA,[3]Translational Science and Therapeutics Division, Fred Hutchinson Cancer Center, Seattle, WA,[4]Microbiology, Immunology and Molecular Genetics, UCLA, Los Angeles, CA,[5]Keck School of Medicine, University of Southern California, Los Angeles, CA

Metastatic castration-resistant prostate cancer (mCRPC) remains an incurable and immunologically cold solid malignancy. Six-transmembrane epithelial antigen of the prostate 1 (STEAP1) is highly expressed in over 85% of mCRPC tumors and represents an attractive therapeutic target. Although chimeric antigen receptor (CAR)-T cell therapy has revolutionized the treatment of hematologic cancers, its efficacy in solid tumors, including prostate cancer, has been limited by the immunosuppressive tumor microenvironment (TME) and heterogeneous antigen expression. Interleukin-12 (IL-12) has the potential to overcome these barriers by activating and recruiting immune cells into tumors and promoting epitope spreading to counter antigen heterogeneity. While armored CAR-T cells engineered to produce IL-12 have been developed, further refinement is needed to optimize both potency and safety. Autologous IL-12-producing T cell therapy has previously shown clinical activity in melanoma, but systemic toxicity constrained its use, indicating that IL-12 secreted by CAR-T cells, though locally produced, can still diffuse into circulation. Here, we present STEAP1-directed CAR-T cells engineered to conditionally secrete a collagen-binding domain-IL-12 fusion protein (CBD-IL-12) upon antigen engagement. We demonstrate that fusing IL-12 to a CBD markedly enhances its retention within prostate tumors while limiting systemic spread in mice. As a result, intra-tumoral levels of IFN-γ, CXCL9, and GM-CSF remained comparably high to those induced by IL-12, yet without associated elevations in serum alanine aminotransferase (ALT) or off-target T cell infiltration in healthy organs. Flow cytometry revealed increased infiltration of T cells, NK cells, and cross-presenting dendritic cells, together with reduced monocytic myeloid-derived suppressor cells, following treatment with CBD-IL-12-expressing STEAP1 CAR-T cells. Immunohistochemistry and spatial transcriptomic analysis confirmed increased immune infiltrates and activation of IL-12 pathway and antigen processing and presentation by major histocompatibility complex-I in the CBD-IL-12 CAR-T treated tumor. Further, tertiary lymphoid structure-related chemokine and chemokine receptors including cxcr4, cxcr5, cxcl12 and cxcl13 as well as co-stimulatory molecules such as cd80, cd86, cd40 and tnfsf4 were upregulated in the tumor. When combined with anti-PD-1 and anti-CTLA-4 antibodies, CBD-IL-12 armored CAR-T cells eradicated established prostate tumors in mice without preconditioning. The CAR-T therapy generated durable anti-tumor immune memory to STEAP1 and other antigens. Our findings suggest that CBD fusion can localize potent but toxic immunomodulators such as IL-12 to the tumor site, offering a promising strategy to improve the safety and effectiveness of CAR-T therapies for solid tumors.

#1525 Optimized CART cell therapy to remodel the tumor microenvironment and eliminate GI malignancies.

Omar L. Gutierrez Ruiz[1], Jennifer Feigin[2], Brooke Kimball[2], R. Leo Sakemura[2], Elizabeth L. Siegler[2], Dominic A. Skeele[2], Ateka Saleh[3], Claudia Manriquez Roman[4], Ismail Can[2], Olivia Sirpilla[2], Kun Yun[2], Carli M. Stewart[2], Mehrdad Hefazi[2], Yoh Yamaguchi[1], Lionel Aurelien Kankeu Fonkoua[5], Long K. Mai[2], Truc Huynh[2], Sophia Y. Goldberg[2], Grace E. DeFranco[2], Sara Foote[6], Ekene Johnkennedy Newton Ogbodo[2], Hong Xia[2], Michael Redig[7], Matthew L. Matthew[8], Tamiel Nichole Turley[2], Skyeler Klinge[8], John Alton Copland[9], Saad J. Kenderian[2]

[1]Hematology, Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Rochester, MN,[3]Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic, Rochester, MN,[4]Mayo Clinic College of Medicine and Science, Rochester, MN,[5]Mayo Clinic Cancer Center Minnesota, Rochester, MN,[6]Immunology, Mayo Clinic, Rochester, MN,[7]Cancer Biology, Mayo Clinic, Rochester, FL,[8]Mayo Clinic, Jacksonville, FL,[9]Assistant Professor, Mayo Clinic Florida, Jacksonville, FL

Gastrointestinal (GI) cancers are rising in people < 50 and remain major causes of cancer mortality despite therapeutic advances. Chimeric antigen receptor T (CART) cell therapy has transformed treatment of hematological cancers. However, its efficacy in GI cancers has been hindered by antigen heterogeneity and immunosuppressive cancer associated fibroblasts (CAFs) in the tumor microenvironment (TME.) Here we aimed to 1) study CART-CAF interactions and 2) engineer CART cells capable of eliminating CAFs to overcome their inhibitory role and enhance their antitumor activity in GI cancers.

We first analyzed primary CAFs from 20 GI cancer patients. CAFs showed high fibroblast activation protein (FAP) expression and significantly suppressed T cells proliferation (26-77%, $p \leq 0.0001$). We next generated CART cells capable of safely eliminating both GI cancer cells and CAFs. To target cancer cells, we developed a novel nanobody (VHH)-based CAR against Claudin18.2, a GI cancer specific target. To avoid off-tumor toxicity in healthy FAP+ tissues, we incorporated an inducible FAP-CAR using the synNotch platform, enabling conditional targeting upon engagement with Claudin18.2$^+$ cells, restricting FAP targeting within the TME.

VHH Claudin18.2 CART cells showed superior specificity and efficacy vs scFv-based CART cells (hu8E85 or zolbetuximab). In Claudin18.2+ SNU-C2B xenografts, tumors were 92mm^3 (VHH) vs 48mm^3 (huE85) vs 211mm^3 (zolbetuximab) on day 23 post-CART, median survival undefined vs 17 days vs 23 days respectively; p=0005. In Claudin18.2+ LS411N xenografts, tumors were 315mm^3 vs 106mm^3 vs 382 mm^3 respectively at 23 days post-CART, median survival undefined vs 19 days vs undefined respectively; p=0004. VHH Claudin18.2 CART cells showed no off-tumor effects, while hu8E85 CART induced significant toxicity.

We next established a co-engraftment model. NSG mice received 1x10^6 SNU-C2B and 6x10^6 CAFs from a GI cancer patient. At 500 mm^3 tumors, mice received 5x10^6 VHH Claudin18.2 or inducible Claudin18.2/FAP CART. Dual-targeting CART cells showed greater antitumor response (728mm^3 vs 320mm^3, p=0.0011 at day 20 post-CART), expansion (61 vs 2,350 CART/µl of blood, p=0.0037), and tumor infiltration (8.71 x 10^5 vs 1.03 x 10^6 CART/g of tumor, p<0.0001). This was also observed in gastric, colon, and pancreatic PDX models, with no observable off-tumor cytotoxic effects with inducible dual-targeting Claudin18.2/FAP CART.

Our findings demonstrate that our novel VHH-based Claudin18.2 CART cells are highly specific and effective against GI malignancies, and that inducible Claudin18.2/FAP dual-targeting CART cells safely remodel the TME into an immune-permissive state. This approach represents a mechanistically innovative and translationally relevant strategy to overcome CAF-mediated immunosuppression, enhance CART cell efficacy, and improve clinical outcomes in refractory solid tumors.

#1526 Nanobody-based, DLL3-directed FAST-CAR T-cell therapy for small cell lung cancer (SCLC).

Qi Dong[1], Wenjie Yin[1], Xiangling Dai[1], Tao Wang[1], Guangyao Zhu[1], Manli Yin[1], Yu Zou[1], Yu Yang[1], Di Wu[1], Mark Cobbold[2], Lianjun Shen[1]

[1]Gracell Biotechnologies Co. Ltd., A Member of the AstraZeneca Group, Shanghai, China,[2]AstraZeneca, Gaithersburg, MD

Introduction: Small-cell lung cancer (SCLC) is aggressive with poor prognosis, and current immunotherapies have limited efficacy. Delta-like ligand 3 (DLL3), expressed in ~80% of SCLC with restricted normal-tissue expression, is a promising CAR T target. We developed nanobody-based, autologous DLL3 CAR T cells armed with a dominant-negative TGFβ receptor II (DNR) to resist TGFβ-driven immunosuppression and enhance antitumor activity.

Methods: Candidate DLL3 binders were derived from a camelid-immunized phage display library and engineered into second-generation CARs. Constructs were tested in vitro for specific lysis with target cell lines. Lead binders were screened for cross-reactivity against Notch ligands. The DLL3 epitope was mapped, and membrane-proximal binders targeting EGF3-6 were prioritized. Off-target interactions were assessed using a membrane proteome array. Multiple CARs—with varying binders/biparatopic combinations, co-stimulation domains, and hinges—were compared in short-term and repeated antigen-stimulation assays across cells with varying DLL3 levels in vitro. Lead CAR T cells with or without DNR were compared in vitro and in vivo. Top constructs advanced to testing in multiple CDX and PDX models to evaluate antitumor efficacy and safety. Manufacturing was compared between a 3-day FasTCAR and an 8-day conventional process.

Results: Three VHH binders demonstrated high DLL3 specificity, with no cross-reactivity to Notch family ligands and no off-target binding, and similar affinity for mouse DLL3. The lead biparatopic CAR construct, B2, demonstrated superior cytotoxicity and durability in short-term and repeated antigen-stimulation assays. When armored with DNR, B2-DNR CAR T cells showed augmented persistence versus the unarmored counterparts. In vivo safety assessments showed no body-weight loss in CAR T-treated mice across multiple dose levels, suggesting a wide therapeutic index. T cells were present in the mouse pituitary pars intermedia, where DLL3-positive cells are enriched, but their DLL3 expression was largely intracellular rather than on the cell surface. B2 did not show on-target, off-tumor toxicity. B2-DNR CAR T cells rapidly cleared established tumor xenografts with high and low DLL3 expression in immunodeficient mice, correlating with robust intratumoral CD3+ T-cell infiltration. In a TGFβ-rich PDX model, B2-DNR CAR T cells outperformed the unarmored counterpart, supporting the functional benefit of DNR. The 3-day FasTCAR manufacturing process demonstrated greater efficacy and durability than the 8-day process.

Conclusions: The camelid nanobody-derived, DLL3-targeted CAR T-cell therapy manufactured by a 3-day FasTCAR process demonstrates the potential to elicit deep and durable antitumor responses with a favorable safety profile. Preclinical data for the lead candidate, B2-DNR, support further clinical development for the treatment of SCLC.

#1527 Conformal external beam radiation increases B7-H3 expression in a murine model of pancreatic cancer liver metastases and promotes CAR T cell function.

Megan C. Purl[1], Alexandria Shick[1], Annaiz Grimm[1], Hind Abdallat[1], Cyrus J. Sholevar[1], Makan Karimzadeh[1], Natalie M. Liu[1], Jinhwan Kim[2], Cameron E. Gaskill[1], Edward J. Kim[3], Arta M. Monjazeb[4], William J. Murphy[5], Robert J. Canter[1], Sean J. Judge[1]

[1]Department of Surgery, UC Davis Medical Center, Sacramento, CA,[2]Department of Surgery and Biomedical Engineering, UC Davis Medical Center, Sacramento, CA,[3]Department of Internal Medicine, UC Davis Medical Center, Sacramento, CA,[4]Department of Radiation Oncology, UC Davis Medical Center, Sacramento, CA,[5]Department of Dermatology, UC Davis Medical Center, Sacramento, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) is a lethal disease characterized by early liver metastases. Chimeric antigen receptor (CAR) modified cells (T and NK) have been largely unsuccessful in PDAC and other solid tumors, despite success in hematologic malignancies. Limitations to CAR therapy success in solid tumors include trafficking, engraftment, and antigen loss. Liver-directed radiation (RT) may improve CAR therapy through altering the tumor and tumor microenvironment. We investigated the impact of liver-directed radiation therapy (RT) to augment B7-H3 CAR T cell homing and function in a xenogeneic model of PDAC liver metastases.

Methods: We evaluated dose-dependent expression of B7-H3 and NKG2D activating ligands by flow cytometry in human PANC-1 and AsPC-1 cells *in vitro* and *in vivo* after RT, including a liver-only metastatic model using a hemi-spleen implantation technique to seed the liver. B7-H3 CAR T cells were generated and assessed by flow cytometry. B7-H3 CAR T cells were then co-cultured with RT-treated target cells, and cytotoxicity was analyzed using Incucyte live cell imaging.

Results: Following RT *in vitro*, PANC-1 and AsPC-1 cells exhibited significant increase in expression of both B7-H3 and NKG2D ligands MICA/B by either median fluorescent intensity or percent expression. Liver-directed RT led to significantly increased expression of B7-H3 and MICA/B on PANC-1 liver metastases compared to untreated mice. Percent killing by B7-H3 CAR T cells against PANC-1 and AsPC-1 cells was significantly increased when target cells were pre-treated with 4 Gy RT prior to killing assay.

Conclusions: RT increases the expression of both B7-H3 and the NKG2D ligands MICA/MICB on pancreas cancer cell lines and this is recapitulated *in vivo* following liver-directed RT to metastasis-bearing mice. Pre-treating target cells with RT results in greater B7-H3 CAR T cell killing *in vitro*. Liver-directed RT may be a strategy to better target PDAC liver metastases with CAR cell therapy.

#1528 AZD5851, a TGF-β-resistant GPC3 CAR-T cell product, prolongs animal survival times in patient derived orthotopic xenograft models of medulloblastoma and atypical teratoid rhabdoid tumor.

Milagros Suarez[1], Aalaa Abdallah[1], Xin Zhai[1], Zilu Huang[1], Yuchen Du[1], Nitin Wadhwani[2], Alicia Lenzen[1], Jee Young Kwon[3], Steven B. Neuhauser[3], Timothy Stearns[4], Jeffrey H. Chuang[3], Emily L. Jocoy[4], Carol J. Bult[4], Beverly Teicher[5], Malcolm A. Smith[6], Xiao Nan Li[7]

[1]Pediatrics, Northwestern University Feinberg School of Medicine, Chicago, IL,[2]Pathology, Northwestern University Feinberg School of Medicine, Chicago, IL,[3]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[4]The Jackson Laboratory, Bar Harbor, ME,[5]Molecular Pharmacology Branch, National Cancer Institute, Bethesda, MD,[6]Clinical Investigations Branch, National Cancer Institute, Bethesda, MD,[7]Departments of Pediatrics, Northwestern University Feinberg School of Medicine, Chicago, IL

BACKGROUND: Glypican-3 (GPC3) is uniquely expressed and has been associated with the development of several pediatric solid embryonal tumors, making it a prime target for GPC3 CAR-T cell killing. TGF-β, a cytokine associated with immunosuppression, has also been shown to be highly expressed in the microenvironment of these tumors, potentially hindering CAR-T cell antitumor activity. In this study, we examined the therapeutic efficacy of AZD5851, an autologous CAR-T product that expresses a CAR specific for GPC3 and a dominant negative (dn)TGFβRII as an armoring strategy.

METHODOLOGY: To assess the drug's *in vivo* efficacy, 5 established patient-derived orthotopic xenograft (PDOX) models of pediatric medulloblastoma (ICb-2123MB, -1299MB, -S1129MB), atypical teratoid rhabdoid tumor (IC-L1115ATRT) and a high grade glioma (IC-2664HGG), with confirmed expression of GPC3 and TGF-β through immunohistochemical staining, were treated with untransduced T cells [dosed at $12x10^6$ cells/mouse, intravenously (IV) once] or GPC3 CAR-T cells (dosed at $5x10^6$ cells/mouse, IV once). 20 eight-week-old SCID mice per model received intra-cerebral (IC) or intra-cerebellar (ICb) tumor cell implantation and were divided into 2 treatment groups (n=10 per group): Untransduced T cells and GPC3 CAR-T cells. Animal survival times were analyzed using Gehan-Breslow-Wilcoxon analysis.

RESULTS: GPC3 CAR-T cell treatment was well tolerated in mice with no loss of body weight or other toxicities. GPC3 CAR-T cell treatment significantly improved the median survival time in 2/5 models, including ICb-2123MB from 90.5 days in the untransduced T cell group to 162.5 days (P=0.02) and IC-L1115ATRT from 136 days to 174 days (P=0.02).

CONCLUSION: Our data identifies single agent antitumor activity for GPC3 CAR-T cells for PDOX models of pediatric medulloblastoma and atypical teratoid rhabdoid tumor. The results support further clinical translational efforts involving the use of AZD5851 alone or in combination with other therapies for the treatment of these tumors.

#1529 ST6GAL1 enhanced CAR-T cells improve persistence and antitumor efficacy in DLBCL.

Lee Seng Mari Lau[1], Maria Suarez[1], Brandon Fernandez[1], Aiza Berdalinova[1], Joseph Souchack[1], Aristotelis Antonopoulos[2], Anne Dell[2], Stuart Haslam[2], Avery D. Posey[3], Charles J. Dimitroff[1]

[1]Cellular and Molecular Medicine, Herbert Wertheim College of Medicine (FIU), Miami, FL,[2]Department of Life Sciences, Imperial College London, London, United Kingdom,[3]University of Pennsylvania, Philadelphia, PA

Diffuse large B cell lymphoma (DLBCL) is the most common and aggressive B cell lymphoma, with poor outcomes for patients who relapse or are refractory to treatment. Chimeric antigen receptor (CAR)-T cell therapy offers a promising therapeutic option, yet limited persistence and functional impairment remain major barriers to durable responses. Galectin (Gal)-3, a carbohydrate-binding protein highly expressed in the DLBCL microenvironment, has been implicated in T cell dysfunction, but its role in CAR-T cell impairment has not been fully defined. We hypothesized that Gal-3 binds to CAR-T cell surface glycans, promoting apoptosis and loss of effector function. ELISA revealed significantly elevated Gal-3 levels in serum from DLBCL patients versus healthy controls ($p<0.001$). Flow cytometry confirmed strong Gal-3 binding to CAR-T cells, which correlated with increased apoptosis ($p<0.01$). To overcome this, we engineered CAR-T cells to overexpress the α2,6 sialyltransferase ST6GAL1 ($ST6^{OE}$)CAR-T cells, which adds α2,6-sialic acids known to mask Gal-3-binding glycans. $ST6^{OE}$CAR T cells displayed markedly reduced Gal-3 binding, lower apoptosis ($p<0.001$), and improved viability and cytotoxicity in Gal-3^{high} DLBCL co-cultures. Cytokine profiling further revealed that control CAR-T cells secreted elevated levels of interleukin-5 (IL-5),a Th2-associated cytokine linked to reduced antitumor activity. In contrast, $ST6^{OE}$ CAR-T cells exhibited significantly lower IL-5 production ($p<0.01$), indicating a shift toward amore cytotoxic, Th1-like functional profile. In a DLBCL xenograft model, $ST6^{OE}$ CAR-T treatment significantly reduced tumor burden and improved survival compared to control CAR-T cells ($p<0.001$). These findings demonstrate that ST6GAL1 overexpression mitigates apoptosis and IL-5-associated dysfunction, enhancing CAR-T cell persistence and antitumor efficacy. Glycoengineering CAR-T cells via ST6GAL1 provides a novel strategy to improve therapeutic outcomes for patients with DLBCL.

#1530 Comprehensive preclinical evaluation of CAR-T cell therapeutics in organoid-fibroblast co-cultures.

Yijie Ren, Tomas Veenendaal, Puxin Wang, Jiawen Gao, Jiawei Meng, Danting Yan, Yingying Li, Meng Zhang, Michelle Kop, Ashgard Weterings, Marten Hornsveld, Gera Goverse, Ludovic Bourre, Peng Wang, Jun Zhou

Crown Bioscience, Inc., San Diego, CA

Introduction: Preclinical assessment of CAR-T cell therapies requires models that recapitulate the complex tumor microenvironment (TME), but conventional 2D cultures fail to model stromal barriers. Patient-derived (xenograft) organoids (PDOs/PDXOs) offer superior clinical relevance, but analyzing 3D immune-tumor-stromal interactions is challenging with bulk assays like LDH release. High-Content Imaging (HCI) overcomes these limitations, enabling high-throughput, multi-parametric quantification of immune infiltration and cytotoxicity. We utilized an HCI-based organoid co-culture platform to evaluate CAR-T therapies in both standard and complex, fibroblast-containing TME models.

Methods: Organoids were co-cultured with PBMCs or engineered CAR-T cells in a 384-well format suitable for automation. HCI analysis allowed quantification of different cell populations and several key readouts, including organoid volume (via actin and DAPI staining), fibroblast network branching (via Cy5 staining) at 96h, and T-cell infiltration at 48h. For a head-to-head lead selection study, seven distinct Claudin18.2-targeting CAR-T candidates were screened against three pancreatic organoid models to comparatively assess their cytotoxic potential. To model a complex TME, ovarian model OV9522B was co-cultured with Normal Human Lung Fibroblasts (NHLF). Triple co-cultures were treated with Mesothelin (MSLN)-targeting CAR-T cells at various Effector-to-Target (E:T) ratios (20:1, 10:1, 5:1).

Results: Baseline Graft-versus-Tumor (GvT) effects were established by co-culturing PBMCs from four healthy donors with four organoid models (LU9906B, CR5082B, CR20155B, PA20077B) revealing variable donor- and model-dependent cytotoxicity (5%-20%). The platform enabled comparison and ranking of seven Claudin18.2-targeting CAR-T candidates against three models. This screen revealed a wide range of killing potency: the most potent CAR-T induced >80% volume reduction in the most sensitive pancreatic model, while the weakest CAR-T showed ~10% reduction in a poor responsive model. Finally, in the triple co-culture model, MSLN-targeting CAR-T cells induced potent, dose-dependent killing of OV9522B organoids (high *MSLN* expression). Despite a stromal network, a significant reduction (>90%) in organoid volume and visualized CAR-T engagement were observed, demonstrating fibroblasts did not affect cytotoxic activity in this case.

Conclusion: Integration of HCI with organoid co-cultures provides a comprehensive, scalable, and clinically relevant platform for evaluating cell therapies. Visualizing and quantifying key parameters like targeted killing in presence of stromal components is a critical advantage and enables confident ranking of therapeutic candidates and provides mechanistic insights, de-risking and accelerating clinical development for next-generation cell therapies.

#1531 Obesity exacerbates cytokine release syndrome (CRS) toxicity associated with chimeric antigen receptor (CAR) T cell therapy in preclinical models.

Wahed A. Firoz[1], Craig P. Collins[1], Logan V. Vick[1], Michael K. Sheng[1], Ryan N. Nielsen[1], Spencer Rosario[2], Robert J. Canter[1], Arta M. Monjazeb[1], Sean J. Judge[1], Anthony E. Zamora[1], Shuchi Gulati[1], William J. Murphy[1]

[1]UC Davis School of Medicine, Sacramento, CA,[2]Roswell Park Cancer Institute, Buffalo, NY

Obesity is characterized by a state of meta-inflammation, excess adiposity, and metabolic perturbations. Although generally considered a negative co-morbidity for cancer progression and immune function, our lab has previously shown obesity to exert a beneficial role in the context of immunotherapy, termed the “obesity paradox”, where obese patients derived greater benefit from immune checkpoint inhibition compared to lean counterparts. Chimeric antigen receptor (CAR) T cells have become a transformative immune cellular therapy for hematological malignancies and are being increasingly applied towards solid tumors and autoimmune conditions. Given the pleiotropy of obesity and the widespread usage of CAR therapy, we aimed to assess the role of obesity in CAR T cell function and toxicity using a novel diet-induced obese (DIO) xenograft model. We utilized immunodeficient NOD-*scid* IL2Rg^{null} (NSG) mice that were fed either a 10% low-fat diet or 60% high-fat diet for four months to generate lean and DIO cohorts, respectively. We observed significant but variable weight gain among the DIO NSG mice compared to lean counterparts. Metabolomic assessment indicated metabolic perturbations in all DIO recipients regardless of adiposity. Interestingly, Raji lymphoma growth was markedly increased in all DIO recipients. We then treated tumor-bearing mice with a tri-specific CD19/CD20/CD22-targeting CAR T cell product on day 9 post-tumor injection, with sub-lethal TBI (135cGy X-ray) conditioning delivered one day prior. Tissues and serum were collected at multiple time-points for flow cytometry immunophenotyping, histopathology, cytokine analysis, and metabolomics as well as imaging for assessment of anti-tumor efficacy. We observed that tumor-bearing DIO mice had comparable anti-tumor effects after CAR therapy and CAR engraftment at various time-points. However, this also coincided with more severe weight loss, increased serum human and mouse pro-inflammatory cytokines (human IL-6, IFNg, TNF; mouse IL-1b, TNF), and mortality in the DIO recipients. This CRS mortality in the DIO recipients precluded ability to assess the CAR recipients long-term for anti-tumor and xenogeneic graft-versus-host disease induction. Overall, we observed negative prognostic effects of obesity on preclinical models of CAR T cells affecting both efficacy and off-target effects. Given the wide application of CAR therapy and high prevalence of obesity, further study of the mechanism driving worse outcomes after treatment and connection to currently available clinical data is warranted.

#1532 *In vivo* genome-wide CRISPR screens in human T cells to enhance T cell therapy for solid tumors.

Qi Liu[1], Peixin(Amy) Chen[1], Esha Urs[1], Shimin Zhang[1], Maya M. Arce[1], Charlotte H. Wang[1], Zhongmei Li[1], Jin Seo[1], Nupura Kale[1], Taylor N. LaFlam[1], Fanglue Peng[1], Eric Shifrut[1], Greg Allen[2], Justin Eyquem[3], Katherine C. Fuh[2], Stacie E. Dodgson[4], Jason Cyster[5], Alexander Marson[2], Julia Carnevale[1]

[1]UCSF School of Medicine, San Francisco, CA,[2]UCSF - University of California San Francisco, San Francisco, CA,[3]University of California, San Francisco, San Francisco, CA,[4]Gladstone Institute, San Francisco, CA,[5]University of California, San Francisco, CA

Large-scale CRISPR screening in human T cells holds significant promise for identifying genetic modifications that can enhance cellular immunotherapy. However, many genetic regulators of T cell performance in solid tumors may not be readily revealed in vitro. In vivo screening in tumor-bearing mice offers greater physiological relevance, but has historically been limited by low intratumoral T cell recovery. Here, we developed a new model system that achieves significantly higher human T cell recovery from tumors, enabling genome-wide in vivo screens with small numbers of mice. Tumor-infiltrating T cells in this model exhibit hallmarks of dysfunction compared to matched splenic T cells, creating an ideal context for screening for genetic modifiers of T cell activity in the tumor microenvironment. Using this platform, we performed two genome-wide CRISPR knockout screens to identify genes regulating T cell intratumoral abundance and effector function (e.g., IFN-γ production). The intratumoral abundance screen uncovered the P2RY8-Gα13 GPCR signaling pathway as a negative regulator of human T cell infiltration into tumors. The effector function screen identified GNAS (Gαs), a central signaling mediator downstream of multiple GPCRs that sense different suppressive ligands, as a key regulator of T cell dysfunction in tumors. Targeted GNAS knockout rendered T cells resistant to multiple suppressive cues and significantly improved therapeutic performance across diverse solid tumor models. Moreover, combinatorial knockout of P2RY8 (trafficking) and GNAS (effector function) further enhanced overall tumor control, demonstrating that genetic modifications targeting distinct T cell phenotypes can be combined to improve therapeutic potency. This flexible and scalable in vivo screening platform can be adapted to diverse tumor models and pooled CRISPR libraries, enabling future discovery of genetic strategies that equip T cell therapies to overcome barriers imposed by solid tumors.

#1533 A universal and switchable CAR T cell therapy platform (zCART) targeting tumor antigens and the immunosuppressive microenvironment.

Ki Hyun Kim[1], Soohwan Kim[1], Eun-Hoe Lee[1], Soo-Youn Lim[1], Tack-Jin Yoo[1], Sung Min Kim[1], E-Young Kim[1], Ji-Hun Park[1], Hyun-Jong Lee[1], Seong Yeol Kim[1], Min Yoon[1], Youngha Lee[1], In-Sik Hwang[1], Yoon Lee[1], Jong-Hoon Kim[1], Jong-Seo Lee[1], Junho Chung[2]

[1]AbClon, Inc., Seoul, Korea, Republic of,[2]Cancer Research Institute, Seoul National University, Seoul, Korea, Republic of

The major hurdles in the treatment of solid tumors with chimeric antigen receptor (CAR) T cell therapies are antigen heterogeneity and the immunosuppressive tumor microenvironment. To address these challenges, we developed a universal and switchable CAR T cell therapy platform (zCART) that utilizes cotinine, a pharmacologically inert hapten, as a molecular bridge between anti-cotinine CAR T cells and tumor cells via cotinine-conjugated affibodies. First, we generated two affibody switches targeting distinct tumor-associated antigens and one affibody switch targeting an immune-oncology molecule. *In vitro* studies demonstrated that all three cotinine-conjugated affibodies, when combined with anti-cotinine CAR T cells, induced potent, dose-dependent cytotoxicity against target-expressing tumor cells. The combination of distinct affibody switches resulted in enhanced anti-tumor activity. These results highlight that the cotinine-based, switchable CAR T cell therapy platform enables flexible, multi-target control of CAR T cell activity and effective elimination of heterogeneous solid tumors. By decoupling antigen recognition from CAR T cell activation, the zCART platform offers a safe, versatile, and next-generation approach to overcoming tumor antigen variability and the immunosuppressive microenvironment, positioning it as a promising strategy for solid-tumor immunotherapy.

#1534 OriC613: A novel therapeutic strategy for gastric and pancreatic cancers utilizing dual-targeting CAR-T cells against MSLN and CLDN18.2 with a favorable safety profile and potent efficacy.

Xiaowen He, Shasha Yang, Hao Guo, Huajing Wang, Xuefeng Kong, Zhongjun Shi

Oricell Therapeutics Co.,Ltd., Shanghai, China

Background: CAR-T cell therapy has demonstrated significant efficacy in hematologic malignancies; however, its application to solid tumors remains limited by on-target, off-tumor toxicity. Mesothelin(MSLN) and claudin 18.2(CLDN18.2) are tumor-associated antigens overexpressed in several solid tumors with minimal co-expression in normal tissues, which presents a therapeutic opportunity for a dual-targeting strategy to enhance tumor selectivity.

Methods: To address gastric toxicity observed with CLDN18.2-directed CAR-T cells in preclinical models, we developed OriC613, a dual-antigen targeting CAR-T based on AND-logic gate. The construct incorporates a high-affinity anti-CLDN18.2 scFv and a moderate-affinity anti-MSLN V_HH, engineered to achieve full T-cell activation only upon engagement of both antigens.

Results: OriC613 demonstrated a favorable safety profile characterized by the absence of cytotoxic activity against CLDN18.2-positive normal gastric models. It exhibited enhanced cytotoxic potency against dual-positive tumor compared to conventional MSLN-targeted CAR-T. In pancreatic cancer re-challenge models, it promoted continued T-cell expansion and maintained cytokine production capacity. OriC613 mediated significant tumor regression in high-burden gastric in-vivo model, demonstrating robust antitumor activity while maintaining the safety profile. It also supported sustained T-cell persistence with detectable engraftment in bone marrow and spleen.

Conclusions: OriC613 demonstrates potent antitumor activity and reduced toxicity profile by leveraging co-expression of MSLN and CLDN18.2. These preclinical findings support further clinical development of this dual-targeting CAR-T approach in patients with gastric or pancreatic adenocarcinoma.

#1535 Preclinical evaluation of allogeneic BCMA/CD70 Dual CAR T cells for high-risk multiple myeloma.

Mark K. O'Dair, David Qu, Duy Nguyen, Kristen Zhang, Zachary Roberts, Elvin Lauron, Cesar Sommer

Allogene Therapeutics, Inc., South San Francisco, CA

Off-the-shelf allogeneic CAR T cells manufactured from healthy donor T cells could potentially address some of the limitations of autologous therapies by providing a more consistent product, immediate availability, and the convenience of scalable manufacturing. However, premature rejection of allogeneic CAR T cells may limit persistence and clinical responses. We previously reported the development of an anti-rejection CD70 CAR that can selectively eliminate $CD70^+$ alloreactive T cells and overcome rejection. Notably, recent studies reported high CD70 expression in high-risk multiple myeloma (MM), supporting the evaluation of CD70-targeted therapies in this patient population.

Here we evaluated the ability of allogeneic CAR T cells targeting BCMA and CD70 to overcome rejection and BCMA antigen loss in preclinical models of multiple myeloma. Human T cells were engineered with CRISPR gene-editing technology to knock out the TRAC locus and to allow site-specific integration (SSI) of a BCMA/CD70 Dual CAR construct. Following expansion, TRAC KO Dual CAR T cells were characterized by flow cytometry and through various in vitro assays including cytotoxicity, cytokine release, target-mediated expansion and mixed lymphocyte reactions (MLR). In vivo efficacy and expansion of Dual CAR T cells were evaluated in mice engrafted with MOLP-8 MM cells.

Allogeneic BCMA/CD70 Dual CAR T cells produced from multiple donors exhibited high efficiency of TRAC KO (98-99%), sustained expression of the BCMA and CD70 CARs, and a balanced effector and memory phenotype. In MLR assays with previously-primed T cells, BCMA/CD70 Dual CAR T cells showed resistance to allorejection and expanded > 5-fold, whereas control cells not expressing the CD70 CAR were rapidly eliminated. In response to target cells, BCMA/CD70 Dual CAR T cells produced high levels of IFN gamma, TNF alpha, and IL-2, and exhibited sustained killing and expansion following repeated stimulation. In addition, BCMA/CD70 Dual CAR T cells displayed high efficacy and expansion in a xenograft model of multiple myeloma. Compared with single targeting BCMA CAR T cells, BCMA/CD70 Dual CAR T cells showed improved cytotoxic activity and expansion in an in vitro model of antigen-escape.

Taken together, these results demonstrate that BCMA/CD70 Dual CAR T cells produced using site-specific integration show specific cytotoxic activity, rejection avoidance, and the ability to eliminate tumor cells that have downregulated BCMA. Our findings underscore the promise of allogeneic BCMA/CD70 Dual CAR T cells as an accessible, off-the-shelf treatment option for high-risk multiple myeloma patients and those who have progressed after BCMA-directed therapies, with the potential to extend beyond multiple myeloma toward broader applications in autoimmune disorders.

#1536 CADM1-CAR T cells targeting neuroendocrine subtypes of small cell lung cancer.

Shiva Krishna Katkam[1], Sergei Chuikov[1], Zhefan Wang[1], Venkateshwar Keshamouni[2]

[1]Internal Medicine, University of Michigan, Ann Arbor, MI,[2]University of Michigan, Ann Arbor, MI

Small cell lung cancer (SCLC), accounting for approximately 15% of all lung cancer cases, represents an aggressive carcinoma characterized by rapid proliferation, early dissemination, and the development of therapeutic resistance. Recent transcriptomic profiling has delineated SCLC into distinct molecular subtypes defined by the expression of lineage-specifying transcription factors ASCL1, NEUROD1, YAP1, and POU2F3. Among these, the neuroendocrine subtypes SCLC-A (ASCL1-driven) and SCLC-N (NEUROD1-driven) predominate in 80% of patient populations. Due to the intrinsically low expression of major histocompatibility complex (MHC) molecules and the consequent poor responsiveness to immune checkpoint blockade, the development of MHC-independent immunotherapeutic strategies is imperative for SCLC. Cell Adhesion Molecule 1 (CADM1), a membrane glycoprotein with context-dependent tumor suppressor and pro-tumorigenic functions, is aberrantly expressed in SCLC and implicated in regulating cellular adhesion, immune evasion, and metastatic dissemination. Our analyses revealed that CADM1 expression inversely correlates with MHC expression scores and is enriched in treatment-naïve tumors with high neuroendocrine differentiation (ASCL1- and NEUROD1-dominant subtypes). The overexpression of CADM1 in tumor cells, makes it an attractive target for antigen-specific immunotherapy. To exploit this vulnerability, we engineered a CADM1-specific chimeric antigen receptor (CADM1-CAR) T cell. CADM1-CAR T cells exhibited robust antigen-dependent cytotoxicity, enhanced secretion of effector cytokines (IFN-γ, TNF-α), and upregulation of cytolytic mediators (granzyme A/B, perforin), resulting in potent SCLC cell lysis in vitro. In NSG mice bearing disseminated H82 xenografts, CADM1-CAR T cell treatment significantly inhibited tumor progression and extended overall survival. These findings establish CADM1 as a promising tumor-associated antigen and support the therapeutic potential of CADM1-targeted CAR T cell therapy for high-grade neuroendocrine SCLC.

#1537 Anti GPC3 CAR T lymphocytes effectively target NSCLC, including chemoresistant stem like cells.

Lucilla Minori[1], Alessia Proment[1], Francesca Napoli[1], Luisella Righi[1], Gabriella Doronzo[1], Elisa Vigna[1], Katherine Chaney[2], Woo Jin Shim[2], John Stone[3], Paolo Bironzo[1], Ashley Hamilton[3], Silvia Novello[1], Dario Sangiolo[1]

[1]University of Torino, Orbassano, Italy,[2]AstraZeneca, Gaithersburg, MD,[3]AstraZeneca, Trumpington, Cambridge, United Kingdom

Purpose: The aim of our study was to explore a preclinical strategy of cell-based immunotherapy using anti-GPC3 CAR-lymphocytes in the context of lung cancer, with a particular focus on eradicating a chemoresistant tumor subset displaying stem-like features.

Procedures: GPC3 expression was confirmed on a large series of surgical specimens from squamous non-small cell lung cancer (NSCLC) and on a panel of tumor cell lines. Functional assays were performed using CAR-T lymphocytes engineered from healthy donors with an anti-GPC3 2nd generation CAR construct. To visualize the cancer stem cell (CSC) subset, tumor cell lines were transduced with a lentiviral CSC-detector vector in which GFP expression is driven by the stem-gene promoter OCT4, rendering green the cells with stem-like features.

Results: GPC3 expression was confirmed on 21/50 squamous NSCLC samples and 5 tumor cell lines (EBC1; H226; NCI-H23; NCI-H596; A-427), by immunohistochemistry and flow cytometry respectively. Anti-GPC3 CAR-T lymphocytes (mean surface CAR expression 40%) effectively killed all tested tumor cell lines (n = 5), with mean specific cytotoxic activity ranging from 71% ±13 to 42%±21 at effector-to-target (E:T) ratios of 10:1 and 2:1, respectively ($p<0.0001$ vs unmodified T cell controls), while showing no activity against the GPC3-negative A-549 cell line. The cytotoxic activity fully included the putative cancer stem cell (CSC) compartment (GFP^+), previously shown with increased resistance to cisplatin in vitro, but also displayed preferential killing toward this subset compared with GFP^- differentiated counterparts resulting in approximately twofold greater reduction ($p<0.05$, E/T 5:1).

Conclusions: GPC3 emerges as an effective and promising target for cell-based immunotherapy in lung cancer. Although preliminary, our data support the concept that anti-GPC3 CAR-T cells can effectively eliminate the CSC-enriched tumor compartment, which is believed to drive chemoresistance and recurrence, thus providing a rationale for future clinical development of cell-based immunotherapies in advanced or relapsed non-responsive lung cancer.

#1538 Oncostatin-M ligand-based CAR T-cell therapy targets and eliminates lung adenocarcinoma.

Kayla Klatt, Daniel Feinberg, Reshmi Parameswaran

Case Western Reserve University School of Medicine, Cleveland, OH

Background: A major barrier to effective CAR T-cell therapy in solid tumors is the dense extracellular matrix and the presence of cancer-associated fibroblasts (CAFs), which together impede CAR T-cell infiltration. To overcome this limitation, our lab has developed an oncostatin-M (OSM) CAR T-cell that targets heterodimers formed between GP130 and either OSMR or LIFR. These heterodimers are expressed on both tumor cells and CAFs, making them attractive therapeutic targets. Here, we evaluate the therapeutic potential of OSM CAR T-cells in lung adenocarcinoma (LAC), a subtype of non-small cell lung cancer that accounts for approximately 40% of all lung cancers.

Methods: To measure OSM CAR T-cell killing of CAFs, we co-cultured patient-derived CAFs with untransduced T cells (UT) or OSM CAR T-cells at 1:1 effector-to-target ratios for 48 hours. Interval confocal imaging of co-cultures were performed and cytotoxicity was assessed by quantifying CAF confluence. Next, we used flow cytometry to evaluate the surface expression of GP130, OSMR, and LIFR on four LAC cell lines (PC9, H1975, H2009, H2087) to determine if LAC could be putatively targeted by OSM CAR T-cells. To directly assess OSM CAR T-cell killing of LAC, we performed co-culture assays as described above, with the addition of Incucyte Cytotox dye to assess cytotoxicity by quantifying mean red fluorescence. To further assess the efficacy of OSM CAR T-cell therapy against LAC, we generated luciferase-expressing H1975 cells for subcutaneous implantation into NSG immunodeficient mice. Tumors were monitored until palpable, after which mice were randomized and treated intratumorally with PBS, UTs, or OSM CAR T-cells, with regular monitoring of tumor growth and body weight.

Results: Flow cytometry revealed heterogeneous expression of GP130, OSMR, and LIFR across LAC cell lines, with notably higher OSMR expression on H1975 and H2009. OSM CAR T-cells induced robust in vitro cytotoxicity against both LAC cells and patient-derived CAFs, with cytotoxicity correlating positively with OSMR expression levels. In the subcutaneous H1975-luc model, intratumoral administration of OSM CAR T-cells reduced tumor burden without evidence of significant toxicity.

Conclusions: These findings support the therapeutic promise of OSM CAR T-cells for targeting LAC. Importantly, depletion of CAFs may enhance CAR T-cell penetration into the tumor microenvironment, addressing a key barrier to efficacy in solid tumors. Future work will be aimed at testing OSM CAR T-cell therapy using an H1975-luc orthotopic model.

#1539 Harnessing NOPE: A key oncofetal protein driving β-catenin signaling through peptidic antigen receptor macrophages in hepatocellular carcinoma.

Carmen Oi Ning Leung[1], Rainbow Wing Hei Leung[1], **Terence Kin-Wah Lee**[2]

[1]The Hong Kong Polytechnic University, Hong Kong, Hong Kong,[2]Applied Biology and Chemical Technology, The Hong Kong Polytechnic University, Hong Kong, Hong Kong

Background: Tumor cells utilize the embryonic stem cell (ESC) pathway, which enhances cell plasticity, to evade targeted therapies. Oncofetal proteins, reactivated in tumors and regulating ESC properties, act as markers for liver tumor-initiating cells (T-ICs). Glypican-3 (GPC-3) is a promising therapeutic target for hepatocellular carcinoma (HCC), but the limited identification of functionally significant cell surface oncofetal proteins restricts clinical application. Identifying novel oncofetal proteins with specific T-IC functions is crucial for developing strategies to combat tumor recurrence and drug resistance in HCC.
Methods: Integrated OMICs analysis identified liver T-IC populations with increased expression in TCGA datasets. We used AP-MS and stable isotope labeling coupled with SILAC to identify NOPE's binding partners. The functional role of NOPE in liver T-IC regulation was assessed through various cancer stem cell assays. GSEA and β-catenin pathway analysis elucidated the molecular pathways involved. We targeted NOPE-expressing HCC cells with a peptidic chimeric antigen receptor macrophage approach (pCAR-Ms).
Results: Through a comprehensive analysis of our in-house T-IC OMICS profiling datasets in clinical HCC samples, alongside a model of human hepatocyte differentiation, we identified IGDCC4, also known as NOPE, as being highly expressed in liver T-ICs and shows particular expression pattern of oncofetal protein. Consistently, Gene Ontology Biological Process (GOBP) and Chemical and Genetic Perturbation (CGP) analyses revealed that pathways related to stem cell differentiation were enriched in NOPE-high HCC patients. We observed a stepwise increase in NOPE expression from normal liver to cirrhosis and to progressive HCC stages, with NOPE overexpression correlating with poor overall patient survival. In MHCC-97L cells, NOPE overexpression enhanced T-IC features, including self-renewal, tumorigenicity, cell invasiveness, expression of liver T-IC markers, and resistance to lenvatinib treatment. Using AP-MS combined SILAC analysis, we identified PABPC1 as a direct binding partner of NOPE, a finding confirmed through co-immunoprecipitation (co-IP) analysis. The NOPE/PABPC1 complex regulates cell state and drug resistance by directly affecting the β-catenin signaling pathway, potentially through its impact on YB-1 mRNA stability. We have developed a novel pCAR-Ms with designed peptides specifically targeting NOPE-expressing HCC cells. Our pCAR-Ms demonstrated specificity and potency in inducing phagocytosis of NOPE-expressing HCC cells.
Conclusions: We identified NOPE as a functional oncofetal protein that promotes liver cancer stemness by activating the β-catenin signaling pathway, which can be targeted by a novel pCAR-Ms approach.

#1540 Development of EPHA2 car t cell therapy for solid tumors.

Ali Cihan[1], Daoqi You[1], Armaan Siddiquee[1], Kristina Guillan[1], Tamar Feinberg[1], Erin Burns[2], Jasmine Um[2], Samantha Brosius[1], Joan Rou-En Choo[2], Andrew L. Kung[1], Anthony F. Daniyan[2], Filemon S. Dela Cruz[1]

[1]Department of Pediatrics, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Efforts to apply CAR (Chimeric Antigen Receptor) T cell therapy to solid tumors are challenged by antigen heterogeneity, immunosuppressive microenvironments, and insufficient T-cell persistence. EPHA2, a receptor tyrosine kinase, is broadly overexpressed across solid tumors, including osteosarcoma (OS), non-small cell lung cancer (NSCLC), and glioblastoma, and is linked to metastatic progression and poor outcomes. The need is especially urgent in OS, where no new systemic therapy has been approved in over four decades. This study evaluates EPHA2 expression in OS and preclinically validates EPHA2-directed CAR T cells with enhanced tumor clearance and immune activation.

Methods: EPHA2 expression was evaluated by immunohistochemistry on an OS patient-derived xenograft (PDX) tissue microarray (n = 55) and assigned H-scores. Fully human EPHA2 antibodies were engineered into 2nd generation CAR constructs containing antibody that recognizes and binds to EPHA2 antibody and costimulatory signaling domain. Cytotoxicity assays were employed to screen EPHA2-directed CAR T cells against EPHA2-high A549 (NSCLC) and 143B (OS) cell lines, enabling identification of the most active construct, EP10. EP10 was then evaluated in immunodeficient MHC-DKO (MHC class I and II double knockout) mice bearing metastatic A549 or 143B xenografts. Tumor burden was quantified by bioluminescence imaging. Event-free survival (EFS) was was assessed by log-rank test with events defined a moribund status.

Results: EPHA2 showed broad expression across OS PDX models (range 1.8-265.1; median 99.7), with 88% of models scoring ≥20. EP10 CAR T cells demonstrated potent in vitro cytotoxicity, achieving 75% growth inhibition in A549 and 90% in 143B at a 1:8 effector-to-target ratio, outperforming reference CAR 4H5. EPHA2 surface expression was confirmed by flow cytometry. In A549 xenografts, EP10 significantly reduced tumor burden ($p < 0.0001$) and markedly improved EFS compared to both the non-targeting mCherry ($p=4e-04$) and 4H5 ($p=4e-04$). In 143B xenografts, EP10 significantly prolonged EFS compared to the non-targeting mCherry control ($p=0.01$; EP10 median survival = 53.5 days vs 44 days) and 4H5 ($p=0.01$; EP10 median survival = 53.5 days vs 49.5 days).

Conclusions: EPHA2 is widely expressed in OS and represents a compelling therapeutic target in OS and other solid tumors. We developed a novel EPHA2-targeting CAR T cell demonstrating potent cytotoxicity, tumor control, and survival benefit in OS and NSCLC models. Ongoing armoring efforts aim to enhance T-cell fitness, infiltration, and resistance to antigen-negative escape. Together, these data support ongoing clinical translation efforts of EPHA2-directed CAR T cells.

#1541 Development of MUC4-directed CAR-T cells against chemoresistant colorectal carcinoma.

Avik Chattopadhyay[1], Erin O'Connor[1], Anna Tingler[2], Kristi L. Helke[3], Melinda A. Engevik[2], Leonardo M. R. Ferreira[1]

[1]Department of Pharmacology and Immunology, Medical University of South Carolina, Charleston, SC,[2]Department of Regenerative Medicine and Cell Biology, Medical University of South Carolina, Charleston, SC,[3]Department of Comparative Medicine, Medical University of South Carolina, Charleston, SC

Colorectal adenocarcinoma remains a leading cause of cancer mortality, with chemoresistance and metastatic progression severely limiting treatment options. MUC4, a membrane-bound mucin normally confined to the apical epithelial surface, becomes aberrantly overexpressed across the tumor cell membrane in colorectal and other epithelial cancers. This dysregulated expression promotes immune evasion, cancer survival and metastasis. Therefore, MUC4 serves as a promising candidate for the development of targeted CAR-T therapies. We engineered MUC4-specific CAR-T cells and evaluated their activity against human colorectal cancer cell lines representing distinct clinical features: HT29 (parental), HT29-MTX (methotrexate-resistant), and T84 (metastatic). MUC4 expression was quantified by flow cytometry. Tumor cell responsiveness to IFN-γ and CAR-T-mediated cytotoxicity were assessed *in vitro*. For *in vivo* studies, HT29-MTX cells were injected intraperitoneally into NSG mice, creating a highly aggressive and lethal tumor model in which tumor-bearing mice succumb within 30-35 days, to determine the therapeutic impact of MUC4 CAR-T cells. All lines expressed high MUC4 levels. Interestingly, MUC4 CAR-T cells efficiently eliminated HT29-MTX and T84 cells but not HT29 cells. IFN-γ treatment upregulated MHC-I and PD-L1 expression across all lines. However, only HT29-MTX and T84 cells underwent robust IFN-γ-induced apoptosis, paralleling CAR-T cell killing, suggesting that IFN-γ secreted by MUC4 CAR-T cells might contribute to tumor clearance. Strikingly, in an intraperitoneal HT29-MTX tumor growth model, MUC4 CAR-T treatment significantly reduced tumor burden, demonstrating therapeutic efficacy in a setting where chemotherapy typically fails. Mouse necropsy analysis revealed no off-target *in vivo* toxicities associated with MUC4 CAR-T cell therapy. Our findings establish MUC4 as a potent and clinically relevant CAR-T cell target and demonstrate that MUC4 CAR-T cells control tumor progression in an aggressive human colorectal cancer *in vivo* model. These results highlight the potential of MUC4-targeted CAR-T cell therapy to fill a critical treatment gap for patients with chemoresistant colorectal cancer and may extend to other MUC4-expressing solid tumors.

#1542 ALK expression identifies a therapeutically targetable subset of Merkel cell carcinomas responsive to ALK.CAR-T cell therapy alone or in combination with ALK inhibitors.

Alessandro Gasparetto[1], Jasna Metovic[2], Elisa Landoni[3], Carmen Mecca[2], Gabriele Saccu[2], Simone Piane[2], Nirmala Tilija Pun[4], Umberto Mortara[5], Chiara Anselmo[5], Marco Campisi[6], Haley Ohlson[2], Maria Vittoria Di Marco[7], Giulia Mura[7], Mauro Papotti[7], Rebecca Senetta[7], Claudia Voena[7], Gianpietro Dotti[3], Elisa Bergaggio[2], Roberto Chiarle[2]

[1]Pathology, University of Turin / Boston Children's, Boston, MA,[2]Boston Children's Hospital, Boston, MA,[3]University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Pathology, Boston Children's Hospital, Boston, MA,[5]Pathology, University of Turin, Turin, Italy,[6]Dana Farber Cancer Institute, Boston, MA,[7]University of Turin, Turin, Italy

Background: Merkel cell carcinoma (MCC) is a rare and highly aggressive neuroendocrine skin cancer with limited treatment options. While chemo-immunotherapy remains the standard of care, nearly 50% of patients experience disease progression, with a median overall survival of 10 months. Anaplastic lymphoma kinase (ALK) has emerged as a promising therapeutic target in various malignancies, including MCC, where it is detected in 40-80% of cases. Our group recently developed novel chimeric antigen receptor T-cell against ALK (ALK.CAR-T), demonstrating potent anti-tumor activity against ALK$^+$ neuroblastoma. This ALK.CAR-T product is currently under clinical investigation in a Phase I/II clinical trial (NCT06803875). In the present study, we evaluated the relevance of ALK.CAR-T immunotherapy in ALK$^+$ MCC tumors.

Methods: We tested ALK and Merkel cell polyomavirus antigen (MCPyV) expression in a cohort of 181 patients with MCC using immunohistochemistry. In addition, we characterized a panel of MCC human cell lines and two patient-derived xenografts (PDX) to identify potential immunotherapeutic targets (ALK, GD2, and HLA-I). ALK.CAR-T cells were co-cultured either in 2D with MCC cell lines or in 3D-microfluidic devices with xenograft-derived organotypic tumor spheroids (xDOTS) to assess their killing efficacy *in vitro*, either alone or in combination with ALK inhibitors. For *in vivo* testing, NSG mice were injected intravenously with human MCC cell lines and, after engraftment, treated with ALK.CAR-T cells, either alone or in combination with the ALK inhibitor lorlatinib. Tumor monitoring was performed weekly using IVIS imaging.

Results: We found ALK expression in approximately 90% of MCC tumors and observed a significant association between ALK expression and poor clinical outcomes. *In vitro*, ALK.CAR-T treatment effectively killed ALK$^+$ MCC cell lines and xDOTS, associated with an increased production of IFNγ and granzyme B. Moreover, the combination with an ALK inhibitor (lorlatinib or nadelalkib) enhanced ALK.CAR-T antitumor activity, even when the ALK inhibitor showed no effect alone. *In vivo*, ALK.CAR-T outperformed GD2.CAR-T, extending the overall survival of mice in two MCC metastatic models. Nonetheless, ALK.CAR-T efficacy was enhanced by lorlatinib, improving tumor control without altering the safety profile.

Conclusions: We identified ALK as a clinically relevant target in MCC and demonstrated that ALK.CAR-T cells, especially when combined with ALK inhibitors, have a potent anti-tumor activity against ALK$^+$ MCC. Our study provides a preclinical rationale for expanding the ongoing Phase I/II clinical trial in relapsed/refractory neuroblastoma patients to include patients with MCC, thus broadening the therapeutic indication of ALK.CAR-T.

#1543 B-cell activating factor plays a critical role in CAR-T cell-associated cytokine release syndrome.

Claire Fritz[1], Leland Metheny[2], David N. Wald[3], Paolo Caimi[4], Reshmi Parameswaran[5]

[1]Case Western Reserve University, Cleveland, OH,[2]University Hospitals, Cleveland, OH,[3]Assistant Professor, Dept. of Path., Case Western Reserve University, Cleveland, OH,[4]Cleveland Clinic Foundation, Cleveland, OH,[5]Department of Medicine, Case Western Reserve University School of Med., Cleveland, OH

Introduction: Despite the growing success of chimeric antigen receptor (CAR) T cell therapy in treating previously incurable cancers, toxicities remain a major concern. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) are the most common and potentially life-threatening adverse events (AEs) associated with CAR-T cell therapy and are related to a heightened immune effector state. We explored a previously unidentified role of B-cell activating factor (BAFF), a cytokine that plays a prominent role in B-cell tumor microenvironments, in the pathophysiology of these AEs.

Methods: A Luminex multi-analyte assay was used to measure serum levels of BAFF and known CRS cytokines in patients who experienced CAR-T CRS. To identify the cell types contributing to the release of BAFF in vitro, monocytes, CD19 CAR-T cells, and Jeko-1 cancer cells were incubated alone or at a 1:1:1 ratio, and a multiplex assay was performed on the supernatant. After IFN-γ stimulation of monocytes, BAFF secretion and expression of the BAFF receptors (BAFF-R, TACI, BCMA) were measured by ELISA and flow cytometry, respectively. To determine the impact of BAFF on cytokine release, this tri-culture was co-incubated in the presence of a BAFF or BCMA neutralizing antibody, and cytokine release was measured by multiplex assay (IL-6, IL-1β, GM-CSF, IL-10, CXCL8, CCL2). To determine if BAFF neutralization interferes with CAR-T cell function, cancer cells were cocultured with CD19 CAR-T cells in the presence of monocytes and a BAFF-neutralizing antibody. Cytotoxicity was measured by propidium iodide uptake in cancer cells, and activation and degranulation of CD3+ cells was measured by percent positivity of CD69 and CD107a by flow cytometry.

Results: First, we observed that patients who experienced CAR-T cell-related CRS have elevated serum BAFF levels that coincide with increased IL-6 and other known CRS and ICANS-associated cytokines. In the tri-culture system of monocytes, cancer cells, and CAR-T cells, monocytes were the primary cellular producer of BAFF. Mechanistically, we show that IFN-γ, produced by activated CAR-T cells, stimulates monocytes to release BAFF. Additionally, monocytes derived from CRS patients express BCMA, which is further induced by IFN-γ stimulation. In the tri-culture system of cancer cells, monocytes, and CD19 CAR-T cells, neutralization of BAFF or BCMA significantly reduces production of various CRS and ICANS-related cytokines without impairing CAR-T cell function.

Conclusion: We demonstrate that BAFF plays a role in CAR-T-cell-related AEs, and that its neutralization may be a novel strategy for treating both CRS and ICANS. In our model, we suggest that activated CAR-T cells secrete IFN-γ, which can increase the expression of BCMA on monocytes as well as the secretion of BAFF. BAFF binds to BCMA and induces increased release of cytokines that contribute to CRS and ICANS.

Oncolytic virotherapy represents a promising yet under-explored therapeutic avenue for precision cancer treatment, particularly when tailored to tumor-specific molecular alterations. Patients with high-grade IDH-mutant astrocytomas continue to face limited treatment options and poor outcomes, emphasizing the need for novel strategies. In this study, we evaluated the therapeutic potential of rQNestin34.5v.2, an engineered oncolytic HSV-1, in the context of IDH1-R132H-mutant high-grade diffuse gliomas. We show that the IDH1-R132H mutation increases glioma susceptibility to viral infection by upregulating Nectin-1, the main HSV-1 entry receptor in gliomas. Concurrently, IDH1-R132H-driven DNA hypermethylation suppresses interferon (IFN) signaling, an essential antiviral defense pathway, creating a permissive environment that supports enhanced viral replication and increases tumor cell sensitivity to virus-induced apoptosis. In immunocompetent IDH1-R132H murine glioma models, intratumoral delivery of rQNestin34.5v.2 induced robust immune activation, marked by increased immune-cell infiltration into the tumor and systemic release of IFN-γ. However, elevated expression of poliovirus receptor (PVR-CD155) and the inhibitory immune checkpoint T-cell immunoreceptor with immunoglobulin and ITIM domain (TIGIT) on tumor-infiltrating lymphocytes, suggested the emergence of an adaptive resistance mechanism following virotherapy. Combining rQNestin34.5v.2 with TIGIT blockade enhanced therapeutic efficacy and improved survival outcomes compared to monotherapy. Collectively, these data demonstrate that IDH1-R132H reshapes both viral entry pathways and antiviral immune defenses, identifying it as a predictive biomarker for oncolytic virotherapy response.

#1548 T-cell acute lymphoblastic leukemia (T-ALL) drives robust T cell responses that can be harnessed with aCD40 and aPD1 combination therapy.

Faizah Alabi[1], Alex Somma[2], Todd Triplett[3]

[1]Immunotherapeutics and Biotechnology, Texas Tech University Health Sciences Center, Abilene, TX,[2]Livestrong Cancer Institutes, Department of Oncology, Dell Medical School, The University of Texas at Austin, Austin, TX,[3]Immunotherapeutic and Biotechnology, Texas Tech University Health Sciences Center, Abilene, TX

T-cell acute lymphoblastic leukemia (T-ALL) is a malignancy of immature T cells characterized by a low mutational burden and limited neoantigens. Despite improved survival rates, the standard of care has not progressed from an intensive chemotherapy regimen, which is highly toxic with a high relapse rate. Therefore, there is a need for more targeted therapies. Immunotherapy, like checkpoint blockade, that aims to harness the patient's pre-existing anti-tumor T cells, is a viable alternative. However, whether or not T-ALL is responsive to this approach is unknown due to low tumor mutational burden. Using murine models transplanted with CD45.2$^+$ T-ALL cells from spontaneously leukemic mice into immune-competent CD45.1$^+$ hosts, we investigated host (CD45.1$^+$) T-cell responses over time. Employing NUR77, RAG knock-out, OT-I, OT-II mouse models and in vitro models, we confirmed leukemia-specific, TCR-driven activation, while single-cell RNA sequencing identified expanded antitumor effector subsets.We found that T-ALL elicits leukemia-specific T cells despite its low mutational burden. Immune profiling revealed elevated effector-memory T cells expressing PD-1, TOX, and FoxP3$^+$ Tregs, consistent with chronic exhaustion and an ongoing immune response. Ex vivo cytokine assays demonstrated reduced IL-2 but increased IFN-γ production, further indicating partial exhaustion. To confirm antigen specificity, we transplanted T-ALL into OT-I and OT-II mice, whose fixed TCRs recognize OVA (absent in our leukemia model). These mice lacked PD-1$^+$TOX$^+$ T cells, confirming that exhaustion observed in wild-type mice was leukemia-specific. NUR77 transgenic analyses verified that TCR signaling drove this activation. Myeloid cells exhibited upregulated PD-L1 and enrichment of suppressive subsets, suggesting inhibitory crosstalk restraining leukemia-specific T cells. Based on this, we evaluated combined immunotherapy using αCD40 to activate myeloid antigen-presenting cells and αPD-1 to reverse T-cell exhaustion. While either monotherapy modestly prolonged survival, dual treatment induced robust, durable responses with ~50% of mice achieving complete remission. Re-challenge experiments confirmed long-term immune memory. Collectively, our findings demonstrate that despite low antigenicity, T-ALL can generate leukemia-specific T-cell responses that can be therapeutically harnessed. Co-targeting myeloid activation and PD-1 inhibition represents a promising immunotherapeutic avenue for T-ALL.

#1549 Non-clinical characteristics of BH3120, a clinical stage bispecific antibody targeting PD-L1 and 4-1BB, in combination with CD3 T cell engagers.

Jing Wang, Jun Wang, Yang Liu, Aibo Sun, Aihong Zhang, Haixia Zhao, Renai Guo, Jie Feng, **Jiangcheng Xu**, Jiawang Liu, Kyoungwoo Lee

Beijing Hanmi Pharm. Co. Ltd., Beijing, China

In the tumor microenvironment (TME), T cell activation often leads to upregulation of immune checkpoints such as PD-1 and PD-L1. This adaptive resistance mechanism, combined with insufficient co-stimulatory signals, creates an immunosuppressive milieu that compromises T cell cytotoxicity and contributes to resistance against T cell-targeted immunotherapies.
Activation of T cells with CD3 stimulation alone is often associated with cytokine-related safety concerns and limited efficacy in solid tumors. To overcome the limitation with CD3 T cell engagers, different combination strategies have been discussed and co-stimulatory signals have been suggested as potential combination partner of T cell stimulators.
BH3120 is a clinical-stage bispecific antibody designed to induce 4-1BB co-stimulation in a PD-L1-positive tumor tissue-localized manner, promoting immune activation within the TME while minimizing immune-related adverse events (irAEs), including liver toxicity. The therapeutic potential of BH3120 in combination with CD3 T cell engagers was evaluated, demonstrating enhanced T cell activation and specific lysis of tumor cells in vitro. Furthermore, this combination regimen exhibited synergistic tumor growth inhibition across different animal models without significant safety concerns.
These findings support BH3120 as a rational combination partner for T cell-engaging therapies, offering a promising strategy to overcome adaptive immune resistance while minimizing systemic toxicities.

#1551 Intratumoral biodegradable nanofluidic platform for localized multimodal immunotherapy enhances tumor eradication and immune memory.

Jingyi Wang, Francesco Manfredi, Eleonora Molinari, Madison A. Deeson, Danilo Settis, Casey Lewis, Junjun Zheng, Junhua Mai, Shu-Hsia Chen, Corrine Ying Xuan Chua, Alessandro Grattoni

Houston Methodist Research Institute, Houston, TX

Introduction: Tumor-infiltrating lymphocytes (TILs) are key mediators within the tumor immune microenvironment (TIME) and are often associated with favorable prognosis across multiple cancers. Despite the transformative success of immunotherapy, its clinical efficacy remains limited by immune evasion and systemic toxicity. Multi-agent immunotherapy targeting complementary pathways holds great potential, yet its application is constrained by dose-limiting toxicities.
Hypothesis: We hypothesize that localized, sustained delivery of multiple immunomodulators through a biodegradable nanofluidic drug-eluting seed (b-NDES) can enhance antitumor efficacy, generate durable immune memory, and minimize systemic adverse effects.
Methods: A fully implantable, biodegradable nanofluidic platform (b-NDES) was engineered for intratumoral release of α-CTLA4, STING agonist, resiquimod (TLR7/8 agonist), IL-12, and α-CD40. Efficacy was evaluated in murine models of triple-negative breast cancer (4T1), pancreatic cancer (KPC), and lung cancer (KLN205). Three- to five-drug combinations were compared for tumor regression, systemic immune activation, and toxicity. For the KPC abscopal model, bilateral tumors were established, and only one lesion received b-NDES implantation to assess systemic immune activation. Immune memory was assessed via tumor rechallenge and IFN-γ ELISpot assays. Tumor immune remodeling was profiled using Olink proteomics, CyTOF, and imaging mass cytometry (IMC).
Results: The five-drug b-NDES achieved complete tumor eradication in 5 of 6 mice in the 4T1 model and induced robust antitumor responses across KPC and KLN205 models. In the KPC abscopal model, b-NDES induced regression of untreated contralateral tumors, indicating systemic immune activation. Rechallenged mice demonstrated full tumor rejection and elevated IFN-γ-secreting splenocytes, indicating durable memory responses. IMC and CyTOF revealed enriched $CD8^+$ T-cell infiltration, dendritic-cell activation, and M1 macrophage polarization in responders. Cytokine profiling showed a robust pro-inflammatory signature in the five-drug group. Importantly, localized b-NDES delivery avoided the weight loss, hypothermia, and liver toxicity observed with systemic administration.
Conclusion: The b-NDES platform enables safe, sustained, and synergistic delivery of multiple immunotherapies directly into tumors, achieving complete regression, systemic immune activation, and long-term memory without systemic toxicity. This approach represents a promising strategy for localized, multimodal immunotherapy against aggressive, treatment-resistant cancers.

#1552 Epigenetic induced increased chromatin accessibility of immune activation loci is associated with response to anti-PD-1 therapy.

Otega Oviri[1], Tyler Gross[2], Md Imran Khan[2], Sean Henry Colligan[3], Jonathan E. Bard[4], Roberto Pili[5]

[1]Pathology and Anatomical Sciences, University at Buffalo, State University of New York, Buffalo, NY,[2]Genetics, Genomics and Bioinformatics, University at Buffalo, State University of New York, Buffalo, NY,[3]University at Buffalo, Buffalo, NY,[4]Department of Biochemistry, University at Buffalo, State University of New York, Buffalo, NY,[5]Division of Hematology/Oncology, University at Buffalo, State University of New York, Buffalo, NY

Immune checkpoint inhibitors (ICIs), including anti-PD-1 antibodies, have transformed the management of genitourinary malignancies, yet a substantial proportion of patients exhibit primary or acquired resistance. Resistance to PD-1 blockade has been associated with an immunosuppressive tumor microenvironment characterized by elevated regulatory T cells (Tregs) and myeloid-derived suppressor cells (MDSCs). Histone deacetylase inhibitors (HDACi) such as vorinostat may overcome these barriers by reprogramming immune and chromatin landscapes to favor antitumor activity. In this study, we integrated transcriptomic, epigenomic, and immunogenetic analyses from a Phase I/IB clinical trial of vorinostat plus the PD-1 inhibitor pembrolizumab and a preclinical mouse model to investigate the mechanisms driving response. ATAC-seq of peripheral blood mononuclear cells (PBMCs) revealed that patients with clinical response maintained global chromatin accessibility from baseline to on-treatment, including at promoter regions of immune activation genes such as *IRF1*, *IRF4*, and *IRF8*. Gene Ontology and motif enrichment analyses demonstrated enrichment of IRF-family transcription factor motifs within regions of increased accessibility. Corresponding RNA-seq analyses showed upregulation of *IRF4* and reduced expression of immunosuppressive genes including *FOXP3* and *TIGIT*, consistent with a less suppressive immune phenotype and enhanced effector activation. Interestingly, HLA genotyping identified an overrepresentation of HLA-B44 supertype alleles among responders, suggesting a potential immunogenetic predictive marker. Building on the immune profiling results, we next examined how the combination therapy of vorinostat and anti-PD-1 shaped immune programs in a murine model of kidney cancer (RENCA). We observed significantly reduced tumor burden, decreased metastases, and improved overall survival relative to monotherapies. Single-cell RNA-seq of splenocytes revealed downregulation of myeloid-associated immunosuppressive genes (*Saa1*, *Saa3*, *S100a8*, *S100a9*) in the combination group, implicating HDAC inhibition in the attenuation of MDSC and neutrophil-mediated resistance pathways. Flow cytometry studies are ongoing to further characterize the immune cell composition and validate these transcriptomic findings at the protein level. In summary, these findings suggest that HDAC inhibition may enhance PD-1 blockade efficacy by maintaining chromatin accessibility at immune activation loci, reducing immunosuppressive signaling, and potentially interacting with host HLA genotype to shape therapeutic outcome. These results support further exploration of HDAC inhibitors as a rational combination strategy to overcome immune resistance in cancer.

#1553 Combining PD-1 blockade with DLL3-targeted T cell engager potentiates antitumor efficacy in small cell lung cancer.

Tongxin Huo[1], Ting Ni[1], Jingjing Wang[1], Panpan Wang[2], Yuhe Han[3], Yawen Zhang[1], **Jian Xiang**[1], Zhixiang Zhang[2]

[1]WuXi AppTec, Suzhou, China,[2]WuXi AppTec, Shanghai, China,[3]WuXi AppTec, Nantong, China

Small cell lung cancer (SCLC) is an aggressive neuroendocrine malignancy characterized by rapid proliferation, early metastasis, and poor prognosis. Despite initial sensitivity to chemotherapy and immune checkpoint blockade, most patients experience disease relapse, highlighting the urgent need for novel therapeutic strategies. Delta-like ligand 3 (DLL3) is highly expressed on the surface of SCLC cells but minimally on normal tissues, making it an ideal target for T-cell-engaging therapies. However, limited immune infiltration and the immunosuppressive tumor microenvironment often restrict the efficacy of TCEs in SCLC. Given the complementary mechanism of TCE (T cell engager) mediated cytotoxicity and PD-1 blockade-induced T-cell activation, our research found that combining a DLL3-targeted TCE with PD-1 inhibition could enhance antitumor immune responses significantly and improve therapeutic outcomes in SCLC. In PBMC-humanized mouse models bearing SHP77 (DLL3-high expression) or NCI-H69 (DLL3-low expression) xenografts, DLL3 TCE combined with pembrolizumab achieved significant antitumor efficacy than DLL3 TCE monotherapy. To elucidate the underlying mechanisms, we found a marked increase infiltration of human $CD45^+$ immune cells in tumors after combination treatment. In tumors treated with DLL3 TCE alone, PD-1 expression on tumor-infiltrated T cells was upregulated, suggesting T-cell activation accompanied by the inhibitory immune regulation. Notably, PD-1 expression decreased upon co-administration with pembrolizumab, indicating that PD-1 blockade effectively reversed immunosuppressive microenvironment and enhanced immune-mediated tumor clearance. Furthermore, the combination treatment not only promoted T-cell priming and activation but also enhanced recognition between cancer cells and T cells within the tumor microenvironment, indicating a more inflamed immunologically active phenotype. This strategy provides a strong preclinical rationale for clinical evaluation of DLL3-targeted TCEs in combination with immune checkpoint inhibitors for the treatment of SCLC.

#1554 Combining an optimized irinotecan formulation with self-amplyfing RNA to treat an immunosuppressive lung metastasis melanoma model.

XuXin Sun[1], Nasim Sarrami[1], Irafasha C. Casmil[2], Sijie Zhang[1], Marcel B. Bally[3], Anna K. Blakney[2]

[1]BC Cancer Research Institute, Vancouver, BC, Canada,[2]Michael Smith Laboratory, University of British Columbia, Vancouver, BC, Canada,[3]Sr. Research Scientist & Unit Head, Adv. Therapeutics, BC Cancer Research Centre, Vancouver, BC, Canada

Background: Melanoma is an aggressive skin cancer that frequently metastasizes to the lungs in its advanced stages. The tumor microenvironment of melanoma is typically immunosuppressive; lacking immune cells with strong antitumor activity. While interleukin-12 (IL-12) based immunotherapy has shown potential for treating melanoma, its clinical application is limited by significant toxicity. To address this, we are developing a self-amplifying RNA (saRNA)-lipid nanoparticle (LNP) system to produce IL-12 in vivo. The formulation selected is similar to that used for Onpattro, a clinically approved formulation of siRNA designed to deliver RNA to liver hepatocytes. IL-12 saRNA delivery to hepatocytes will increase plasma levels of IL-12 and sustain expression which should stimulate an immune response. This saRNA LNP formulation is being combined with a novel liposomal formulation of irinotecan (Irinosome High C). This formulation can improve the tumor immune microenvironment (TIME)from an immunosuppressive one to an immunosupportive one. We believe that this formulation is ideally suited for combination with IL-12 saRNA-LNPs.
Method: The safe and effective (as judged by IL-12 levels on the plasma) dose of saRNA-LNPs was determined in C57BL/6 mice following intravenous (iv) administration. A safe and effective (as judged by assessments of anti-tumor activity) was determined for Irinosome High C following iv administration. These treatments were used alone and in combination to treat a model lung metastasis model where mice were injected iv with B16F10 melanoma cells. Tumor burden in the lungs was determined 18 days after cell injection (6 days after last treatment) and overall survival data was collected along with health status data. As a function of time after treatments splenocytes from mice were isolated and co-cultured with B16F10 cells in vitro and immune mediated cell kill was determined.
Results: The combination of IL-12 saRNA-LNP and Irinosome High C significantly improved survival and reduced lung tumor burden in B16 tumor bearing mice compared to those receiving either treatment alone. Splenocyte assays confirmed that IL-12 treatment enhanced levels of key immune cytokines, including IL-12, IL-2, and IFN-γ, indicating a robust antitumor immune response.
Conclusion: The combination of Irinosome High C and IL-12 saRNA-LNPs represents a promising new approach for treating lung metastatic disease a life-threatening complication seen in patients with late-stage melanoma. This strategy may offer a safer, more effective treatment option through use of a TIME modulatory agent with IL-12 mediated immune activation. Studies are on going to better understand the underlying mechanisms driving enhanced antitumor responses and the development of strategies to see this approach transition in various tumor models and from the lab to patients.

#1555 Differential tumor and immune responses to anti PD-1 and DGK inhibition in patient-derived tumor spheroids reveal additive killing effect.

Bihui Melidosian[1], Julia Vail[2], Xiaodi Ren[1], Danielle Hagee[2], **Michael A. Perricone**[2], Cynthia Timmers[1]

[1]Incyte Corporation, Wilmington, DE,[2]Xsphera Biosciences, Inc, Cambridge, MA

PD-1 checkpoint blockade has transformed cancer therapy, yet durable responses remain confined to a subset of patients. Diacylglycerol kinase (DGK) inhibition has been proposed as a complementary strategy to enhance T-cell activation and reprogram the tumor microenvironment. We tested a novel dual DGKA and DGKZ inhibitor using a patient-derived organotypic tumor spheroid (PDOTS) platform that preserves tumor, stromal, and immune architecture, enabling functional assessment of therapeutic response in a physiologic ex vivo context. PDOTS from 22 patient tumors were treated with retifanlimab-dlwr (PD-1 inhibitor), DGK inhibitor (INC-DGKi) at two doses, or the combination. Tumor response was defined as a $\log_2$ fold-change < -0.5 in epithelial tumor load ($EpCAM^+$) or a composite epithelial marker set to account for squamous cell carcinomas. Immune activation was profiled by multiplexed gene expression emphasizing $CD8^+$ effector activity, interferon-stimulated genes, cytokine induction, and antigen presentation. Baseline PD-L1 and MHC-I were measured by flow cytometry. Responsive (R) and non-responsive (NR) tumors were defined by tumor killing and/or immune activation and compared by differential expression and pathway analyses. Retifanlimab induced tumor regression in 6 of 22 (~27%) tumors and triggered immunologic activity in 10 of 22 (~46%), including increased $CD8^+$ and NK activity and interferon gene induction. DGKi elicited tumor regression in 5 of 22 (~23%) and stimulated immune-related transcriptional programs in 11 of 22 (~50%), representing largely distinct responders, with pro-inflammatory and leukocyte recruitment pathways enriched. Combination treatment induced tumor regression in 9 of 22 (~41%) and elicited immune activation in 6 of 22 (~27%), exceeding monotherapy cytotoxicity. Baseline PD-L1 and MHC-I variably correlated with response, indicating contextual, not universal, biomarkers. Retifanlimab and DGKi each elicited antitumor and immune responses in distinct tumor subsets, with comparable single-agent activity. Combination therapy improved tumor killing but not immune engagement, suggesting complementarity of the two agents and merits additional studies to clarify the observed discordance between tumor regression and immune signals in the combination setting. These data support biomarker-guided approaches and highlight PDOTS as a translational platform for defining rational immunotherapy combinations.

#1556 NK cells activated by monoclonal antibody-coated target cells enhance bispecific antibody-induced T cell proliferation, activation and cytotoxicity.

Reza Amani, Jyoti Arora, George J. Weiner

University of Iowa, Iowa City, IA

Background: We previously demonstrated that T cell help can enhance the viability and cytotoxic potential of Natural Killer (NK) cells activated by monoclonal antibody (mAb)-coated target cells. Here we evaluated whether the reverse is also true, and that NK cells coated by mAb can enhance proliferation, activation, and the cytotoxic potential of bispecific antibody (bsAb) retargeted T cells.
Methods: Raji lymphoma cells and normal donor peripheral blood mononuclear cells depleted of NK cells were mixed at an effector to target ratio of 5:1. Autologous NK cells were added back in controlled concentrations (0%, 5% or 20% of total effector cells). Co-cultures were treated with anti-CD3×CD19 bispecific antibody (blinatumomab), anti-CD20 monoclonal antibody (rituximab) or both. Media and antibodies were refreshed on days 2 and 4. After 5 days, T cell proliferation (Ki67) and production of cytotoxic molecules (including granzyme B) was assessed as was the number of remaining Raji cells as a measure of cytotoxicity.
Results: Treatment with the combination of blinatumomab and rituximab enhanced T cell proliferation and activation when larger numbers of NK cells were present. The presence of NK cells also enhanced elimination of Raji cells. The impact of NK cells on T cell proliferation and activation in response to single agent blinatumomab or rituximab was less pronounced. Similar results were seen with other mAb and bsAb combinations.
Conclusion: NK cells, activated by mAb-coated tumor cells, promote the proliferation, activation and cytotoxic capacity of bsAb-retargeted T cells. These data provide evidence that NK cells activated by mAb and T cells activated by bsAb are synergistic and provide cross help to each other. This provides additional rationale for evaluating therapeutic strategies involving concurrent administration of mAb and bsAb that allows for simultaneous co-engagement of NK cells (via mAbs) and T cells (via bsAbs).

#1557 PHST001 combination with standard-of-care chemotherapy enhances macrophage-mediated elimination of tumor cells.

Giovanni C. Forcina, Kelsey E. Hart, Joseane Sampaio, Joshua D. Rudolph, Suzana A. Kahn, Raphael F. Rousseau, Amira A. Barkal, Ravindra Majeti, Irving L. Weissman, Roy L. Maute, Jennifer Yinuo Cao

Pheast Therapeutics Inc., Redwood City, CA

Chemotherapy exposure induces cellular stress and can upregulate ‘Eat me’ signals on the surface of cancer cells thereby targeting these cells for clearance by macrophage phagocytosis. However, this phagocytosis can be inhibited by ‘Don’t eat me’ (DEM) signals like CD24 on the surface of tumor cells. The clinical-stage anti-CD24 monoclonal antibody PHST001 blocks the CD24 DEM signal and promotes macrophage phagocytosis of target cells, raising the possibility that cotreatment with PHST001 and chemotherapy could provide combinatorial benefit to patients. To identify potential PHST001 and chemotherapy combinations, we screened 17 standard-of-care chemotherapy agents with PHST001 in coculture of peripheral monocyte-derived human macrophages and each of 13 cell lines representing 6 different cancer indications. We identified several common classes of chemotherapy drugs, including taxanes, platins, topoisomerase inhibitors, and anti-metabolites that enhance PHST001-induced macrophage clearance of cancer cells. We found that while cancer cells are generally sensitive to chemotherapy, macrophages display remarkable resistance to many chemotherapy agents. We further validated PHST001 combination with several chemotherapies in two-way dose-response experiments and identified chemotherapies that synergize with PHST001 to clear cancer cells in macrophage coculture. We subsequently validated select chemotherapy and PHST001 combinations (e.g. cisplatin) in vivo with mouse xenograft studies. Mechanistically, we discovered that certain chemotherapy agents increased the surface expression of the ‘Eat me’ signal phosphatidylserine (PS) on cancer cells, while others directly enhanced the phagocytosis capacity of macrophages. Taken together, these data support therapeutic combination of PHST001 with multiple standard-of-care chemotherapies to deepen tumor-killing response in patients.

#1558 Preclinical activity of ziftomenib and CAR T cell immunotherapy in *KMT2A*-rearranged (R) acute leukemias.

Sarah E. Haines[1], Shubhmita Bhatnagar[1], Michael C. Yarnell[2], Samantha M. McClellan[1], Catherine D. Falkenstein[1], Linda Kessler[3], Francis J. Burrows[3], Lisa M. Niswander[4], Terry J. Fry[2], Sarah K. Tasian[5]

[1]Children's Hospital of Philadelphia, Philadelphia, PA,[2]University of Colorado Anschutz Medical Center and Children's Hospital Colorado, Aurora, CO,[3]Kura Oncology, San Diego, CA,[4]Roswell Park Cancer Institute, Buffalo, NY,[5]Children's Hospital of Philadelphia and University of Pennsylvania School of Medicine, Philadelphia, PA

Introduction: Many patients with *KMT2A*-R acute leukemias experience chemoresistance and/or subsequent relapse despite intensive frontline therapies. While CD19 chimeric antigen receptor T cells (CD19CART) induce initial remission in most children with relapsed/refractory B-acute lymphoblastic leukemia (ALL), post-CD19CART relapse occurs in ~50% of patients, many of whom experience CD19 antigen loss and/or lineage switch (LS) to fatal acute myeloid leukemia (AML). To address this unmet need, we previously developed CAR T cells targeting the FLT3 receptor (FLT3CART) and reported potent anti-leukemia activity in preclinical models of wild-type FLT3-overexpressing *KMT2A*-R ALL and LS AML. In the current study, we tested the hypothesis that co-targeting of a highly-expressed cell surface antigen with CARTs and critical intracellular biology with the selective menin inhibitor (MENi) ziftomenib in *KMT2A*-R ALL would have therapeutic synergy and ameliorate resistance mechanisms of single agent therapies.
Experimental procedures: Human *KMT2A*-R and non-R ALL cell lines were co-incubated *in vitro* with FLT3CART or CD19CART +/- ziftomenib in viability assays. CART-induced IFN-γ production was measured via ELISA. Patient-derived xenograft (PDX) models of infant, pediatric, and young adult non-*KMT2A*-R (n=1), *KMT2A*-R ALL (n=6), and *KMT2A*-R LS AML (n=1) were treated intravenously with saline, mock T cells, FLT3CART, or CD19CART +/- ziftomenib daily *per os* as previously described (Loftus *Haematologica* 2021, Falkenstein *Blood* 2022, Niswander *Haematologica* 2023). Human CART and leukemia cells were quantified weekly via flow cytometry (FC) analysis of murine peripheral blood and in end-study bone marrow and/or spleens. *In vivo* IFN-γ production was measured weekly in murine plasma.
Results: Ziftomenib monotherapy induced robust inhibition of leukemia proliferation *in vitro* and *in vivo* in all tested *KMT2A*-R ALL or LS AML models. Importantly, ziftomenib did not impair CART functionality, as assessed by cytokine production and FC immunophenotyping of T cell subsets and activation/exhaustion markers. Ziftomenib co-therapy significantly augmented *in vivo* FLT3CART or CD19CART activity in most *KMT2A*-R ALL and the LS AML PDX models. Paradoxically, *in vivo* IFN-γ production in murine blood and CART cells in end-study spleens were decreased in all ziftomenib + CART co-treated *KMT2A*-R ALL or LS AML PDX models versus FLT3CART or CD19CART alone, which we posit was due to rapid cytotoxic efficacy of ziftomenib against target antigen-expressing leukemia cells necessary for CART activation and expansion.
Conclusions: Our preclinical data strongly support combinatorial efficacy of the MENi ziftomenib and FLT3CART or CD19CART immunotherapy in *KMT2A*-R ALL that may overcome or even prevent subsequent LS relapse. Studies in additional *KMT2A*-R ALL and LS AML PDX models are ongoing to validate and extend these results.

#1559 First-in-class Zα-domain-targeted ADAR1 p150 inhibitor demonstrates potent antitumor efficacy in high IFN syngeneic melanoma.

Aditya Kulkarni[1], Avijit Goswami[2], Sandeep Goyal[2], Princy Khurana[2], Kawaljit Singh[2], Barnali Deb[2]

[1]Avammune Therapeutics, Coatesville, PA,[2]Avammune Lifesciences, Bangalore, India

Background: ADAR1 (Adenosine deaminase acting on RNA) exists in two isoforms: the nuclear p110 and the p150, which shuttles between the nucleus and cytoplasm. ADAR1 p150 promotes immunotherapy resistance by suppressing immunogenic dsRNAs, and by preventing the accumulation of Z-RNA structures. Loss of ADAR1 leads to Z-RNA buildup, activating ZBP1 and triggering necroptosis. Tumors exhibiting high IFN signatures enhance synthetic lethality when ADAR1 is inhibited, while also upregulating PD-L1. This dual effect presents an opportunity for synergistic efficacy for ADAR1 inhibition and checkpoint inhibitors. In this context, we report the discovery of a novel, first-in-class inhibitor that specifically targets the Zα domain of ADAR1 p150 for cancer immunotherapy. Additionally, we evaluated the potential of this ADAR1 p150 inhibitor as a novel payload delivered via PD-L1-targeted ADCs.
Methods: A series of ADAR1 p150 inhibitors (AVA-ADR) were identified using a high-throughput binding assay, Zα domain binding confirmed by FRET assay. The anti-tumor efficacy of AVA-ADR compounds was assessed in a B16F10 syngeneic melanoma mouse model, both as a monotherapy and in combination with anti-PD-1 therapy in a high interferon condition. AVA-ADR compounds were also evaluated as a novel payload for PDL1 targeted ADCs.
Results: We identified a novel series of small-molecule inhibitors of ADAR1 p150 that elicits a robust interferon response. Binding studies showed AVA-ADR compounds exhibit submicromolar Zα-domain affinity, surpassing prior inhibitors. AVA-ADR inhibitors displayed nanomolar EC50 values and significant anti-tumor activity in the B16F10 melanoma model. AVA-ADR compounds demonstrate additive efficacy in combination with anti-PD1 treatment (~1.5 X vs anti-PD1). AVA-ADR compounds demonstrate strong anti-tumor potency in high interferon environment, >1.5x superior mIFN- β alone. Tumor samples from the combination group showed significantly elevated expression of interferon-stimulated genes and T-cell activation markers.
Conclusion: To our knowledge no selective small molecule inhibitors of ADAR1 p150 targeting the Za domain have been reported so far. Our SAR approach yielded several next generation Zα binders with nM potency demonstrating effective and competitive displacement of the tightly bound Z-DNA. Next generation compounds demonstrate low nM interferon dependent toxicity in OE21 cell lines. In vivo efficacy study in B16F10 melanoma model demonstrates synergistic efficacy of AVA-ADR compounds with mIFN-β. This is the first disclosure of a selective ADAR1 p150 inhibitor that was systemically administered demonstrating strong anti-tumor potency in high IFN tumors. Furthermore, these inhibitors show promise as payloads for antibody-drug conjugates (ADCs), enabling targeted delivery and enhanced therapeutic index in IFN-responsive cancers.

#1560 Targeting the non-canonical immune checkpoint MUC1-C enhances anti-PD-1 therapy in solid tumors.

Dae Young Kim, **Hee Young Kang**, Young Ha Yoon, Sung Min Kim, Hoil Choi

Peptron, Inc., Daejeon, Korea, Republic of

Immune checkpoint inhibitors (ICIs), particularly monoclonal antibodies targeting PD-1 and PD-L1, have revolutionized cancer therapy by enhancing antitumor immune responses. Despite their clinical success across multiple tumor types, several challenges remain, such as suboptimal response rates, which underscores the need for novel combinatorial strategies. MUC1-C, a transmembrane glycoprotein aberrantly expressed in many cancers, has recently emerged as a non-canonical immune checkpoint associated with T cell depletion and dysfunction within tumor microenvironment, thereby promoting immune evasion. Here, we present a novel immunotherapeutic strategy that concurrently targets canonical and non-canonical immune checkpoints by combining anti-PD-1 with PAb001, a humanized IgG1 antibody developed by Peptron that binds MUC1-C with high affinity (K_D < 1 nM). In a syngeneic tumor model utilizing MC38-hMUC1, a murine colon adenocarcinoma cell line engineered to express human MUC1, combinatorial treatment with 1H7 (a surrogate murine antibody targeting human MUC1-C) and an anti-mouse PD-1 antibody exhibited robust antitumor activity, resulting in marked tumor growth inhibition (TGI = 91.3%). Ongoing studies are evaluating the combinatory efficacy of additional anti-MUC1 antibodies and ICIs to further define the selective advantages of PAb001 in treating malignant tumors, and are also aimed at elucidating the molecular mechanisms underlying its therapeutic activity. In conclusion, these findings support the therapeutic potential of a dual-checkpoint blockade strategy that concurrently targets canonical and non-canonical pathways, which offers a promising approach to address limitations inherent to current ICI-based therapies.

#1561 Overcoming immunosuppression in pancreatic cancer: Efficacy of polyamine blockade and anti-PD-1 combinational therapy.

Joseph A. Goode[1], Diana Estefania Gaete-Alvarez[2], Savannah Harris[1], Otto Phanstiel[2], Deborah A. Altomare[2]

[1]College of Medicine, University of Central Florida, Orlando, FL,[2]University of Central Florida, Orlando, FL

Pancreatic ductal adenocarcinoma (PDAC) is an extremely aggressive cancer with an 88% mortality rate. This high mortality rate is due to its dense microenvironment, late-stage diagnosis, and limited treatment options. Polyamines, small molecules essential for cell growth, play a critical role here because their dysregulation is linked to PDAC tumor growth, invasion, and metastasis. Polyamine accumulation also reinforces an immunologically “cold” tumor microenvironment by supporting the recruitment of immunosuppressive cell populations and promoting immune-evasion pathways such as PD-1 signaling. This study aims to explore the interaction between polyamines and the PDAC immune microenvironment, and to evaluate the effectiveness of combining Polyamine Blockade Therapy (PBT) with anti-PD-1 inhibitors as a novel immunotherapy strategy. Using an orthotopic mouse model of PDAC with syngeneic GFP-Luc2 cells, we assessed the impact of PBT, consisting of Difluoromethylornithine (DFMO) and the polyamine transport inhibitor (PTI) Trimer44NMe (Trimer PTI), in conjunction with anti-PD-1 therapy. Tumor progression was monitored via in vivo bioluminescence imaging, and immune cell populations were analyzed using both tumor multiplexing and flow cytometry of peripheral tissues. The combined PBT and anti-PD-1 treatment led to a significant reduction in tumor mass, increased infiltration of anti-tumor immune cells, and enhanced systemic anti-tumor immune responses. The combination of Polyamine Blockade Therapy with anti-PD-1 inhibition shows promise as an effective immunotherapy for PDAC, potentially improving patient outcomes by disrupting the polyamine-mediated immunosuppressive network while enhancing anti-tumor immunity.

#1562 Rewiring the immune-excluded tumor microenvironment: Vactosertib/anti-PD-1/VEGF inhibitor triplet therapy reinstates antitumor immunity in CRC.

Seong-Jin Kim, Dong Woo Kang, Hye Jin Kim, Seonho Yoo, Jin Beom Bae, June Myoung Kim, Min Kyu Kim, Jinhwan Kim, Jin Su Kim, Ye Seon Kim, Jeong Su Lee, Kwiyeom Yoon

MedPacto, Inc., Seoul, Korea, Republic of

Introduction: Despite the clinical success of immune checkpoint inhibitors (ICIs), microsatellite-stable (MSS) tumors, which account for the majority of colorectal cancer (CRC), remain resistant to anti-PD-1 therapy. While VEGF/VEGFR-targeted combination therapies can provide partial remission, they fail to sufficiently reconstitute the immunosuppressive tumor microenvironment (TME). TGF-β signaling induces immune exclusion and stromal fibrosis in CRC, contributing to resistance to VEGF and PD-1 blockade. In this study, we investigated whether vactosertib (Vac), a TGF-β receptor type I inhibitor, could overcome this resistance when administered in combination with anti-PD-1 and VEGF inhibitors in the CT26 CRC model with PD-1 resistance.
Methods and Results: To establish a clinically meaningful PD-1 resistance model, CT26 tumors that initially responded to anti-PD-1 therapy but later progressed according to RECIST criteria were serially passaged to establish the CT26-αPD-1/R2 cell line. Maintained PD-1 antibody binding during progression indicated that resistance was not due to reduced target engagement. BALB/c mice bearing tumors were treated with the FDA-approved pan-VEGFR inhibitor fruquintinib (Fru), an anti-PD-1 antibody, and/or Vac. Vac enhanced the efficacy of Fru (TGI 10% → 47%) and anti-PD-1 (TGI 17% → 42%) monotherapy. Triple combination therapy showed a complete response rate of 20-33%, demonstrating a significantly greater antitumor effect (TGI 86%) than dual blockade of anti-PD-1 and anti-VEGF (TGI 50%). Subsequent RNA-seq analysis revealed that the triple combination therapy was the only treatment that induced a robust intratumoral immune response. Specifically, the triplet activated T cells and upregulated genes involved in myeloid activation, phagocytosis, and antigen presentation, while also increasing B cell activation. TIL analysis showed that the triplet increased $IFN\gamma^{+}CD8^{+}$ T cells by 6.0-, 12.6-, and 3.9-fold compared to Vac + Fru, anti-PD-1 + Fru, and Vac + anti-PD-1 combination therapy, respectively. The ratios of activated $CD4^{+}$ T cells and M1/M2 macrophages showed a similar pattern. Furthermore, the triplet preferentially enhanced effector memory T cells, suggesting persistent and memory-rich adaptive immunity. In a second trial using a VEGFR2-selective inhibitor, Vac similarly improved the efficacy of VEGFR2 inhibitor plus anti-PD-1 therapy (TGI 39% → 63.3%).
Conclusions: Triple blockade using Vac, an anti-PD-1 inhibitor, and a VEGFR inhibitor achieved superior antitumor efficacy and broad immune activation compared to all other dual combination therapies in PD-1-resistant CRC. These results suggest that TGF-β inhibition is essential for overcoming treatment resistance in an immunosuppressive TME, supporting the clinical evaluation of this triple combination in refractory CRC.

#1563 Intratumoral IL-12 in combination with HDAC inhibition overcomes checkpoint-refractory tumors.

Asma S. Khelifa[1], **Ainara Meler**[1], Christine M. Minnar[1], Katherine E. Lothstein[1], Masaya Miyamoto[1], Nicholas Roller[1], Lisa K. Poppe[1], David Peeney[1], Sailaja Battula[2], Howard L. Kaufman[2], Jeffrey Schlom[1], Sofia R. Gameiro[1]

[1]Center for Immuno-Oncology, National Cancer Institute, Bethesda, MD,[2]Ankyra Therapeutics, Inc., Cambridge, MA

Background: Clinical resistance to immune checkpoint blockade (ICB) is prevalent across solid malignancies, thus prompting the need for novel therapies. Interleukin-12 (IL-12) is an important cytokine for cancer immunotherapy due to its ability to bridge innate and adaptive immunity. However, the narrow therapeutic index and toxicity associated with systemic IL-12 administration has hampered its clinical development. ANK-101 is an alum-anchored human IL-12 providing tumor retention upon intra-tumoral delivery. In this study, we investigated the anti-tumor activity and mechanism of action of murine ANK-101 (mANK-101) delivered intra-tumorally in combination with the class I histone deacetylase (HDAC) inhibitor entinostat, in different ICB-refractory murine tumor models, including CT26 (colorectal) and MOC-1 (HPV16^{neg} head and neck).

Methods: Mice receiving Entinostat diet and/or mANK-101 were monitored for anti-tumor activity, survival and protective memory. The contribution of CD8$^+$, CD4$^+$, and NK lymphocytes to antitumor effects were investigated via immune depletion. Analysis of tumor-specific T cell responses and comprehensive proteomic, transcriptomic, and tumor architecture analysis of the immunome was performed in MOC-1 tumors, tumor-draining lymph node (tdLN), and spleen. In addition, functional analysis of CD8$^+$T cells in the periphery were performed.

Results: We demonstrate that mANK-101 synergizes with Entinostat to suppress CT26 (colon, Kras G12D^{mut}) and MOC-1 (oral, HPV16^{neg}) tumors, resulting in significant anti-tumor effects, survival benefit, and protective memory. Immune depletion studies demonstrated a role for CD8$^+$ T cells, CD4$^+$ T cells, and NK cells in the anti-tumor activity elicited by combination therapy. Mechanistically, combination therapy elicited significant activation of peripheral CD8$^+$ T cells and NK lymphocytes, increased CD8$^+$ T effector memory, tumor-specific T cell responses, and multifunctional IFNγ$^+$TNFα$^+$CD8$^+$ T cells, with concomitant decrease in CD4$^+$ Tregs and increased CD8/Treg ratio. Notably, spatial analysis of tumor architecture indicates the development of B-cell rich stemness hubs exclusive to combination therapy. Ongoing in-depth studies including single cell transcriptomics in the tumor and tDLN, and investigation of the role of immune stemness hubs in the observed anti-tumor activity will allow for an in-depth understanding of the synergistic effect of mANK-101 with HDAC inhibition.

Conclusion: Collectively, these findings provide a rationale for the combination of intratumoral delivery of anchored IL-12 with epigenetic modulation for patients with ICB-refractory solid tumors, such as colorectal and HPV16^{neg} head and neck cancers.

#1564 Bortezomib enhances anti-tumor efficacy of PD-1 blockade in lung squamous cell carcinoma via innate immune activation.

Xin Jin, Jianguo Zhong, SIbo Peng, **Song Xu**

Tianjin Medical University General Hospital, Tianjin Medical University, Tianjin, China

Background: Immune checkpoint inhibitors have improved survival outcomes for patients with lung squamous cell carcinoma compared to conventional chemotherapy. However, challenges such as low response rates and acquired resistance remain. Although proteasome inhibitors have shown antitumor potential owing to their unique mechanism of action, their ability to synergistically enhance immunotherapy is not well established. This study aimed to investigate a novel combinatory strategy of bortezomib and PD-1 blockade in lung squamous cell carcinoma.
Methods: We established co-culture systems to assess lymphocyte cytotoxicity and cytokine production by flow cytometry. Syngeneic and humanized mouse models of lung squamous cell carcinoma were used to evaluate tumor growth and immune infiltration in response to bortezomib, alone or in combination with anti-PD-1. Immune infiltration in tumor tissues was analyzed by immunohistochemistry. Signaling pathway activation and chemokine expression were examined by Western blot and polymerase chain reaction. Key molecules of innate immune pathways were perturbed using genetic knockdown or pharmacological inhibition to delineate the underlying mechanism.
Results: Pre-treatment of lung squamous cell carcinoma cells with bortezomib enhanced lymphocyte-mediated killing and increased secretion of IFN-γ and granzyme B in co-culture. In syngeneic models, bortezomib promoted intratumoral lymphocyte infiltration and synergized with PD-1 blockade, leading to increased $CD8^+$ T cell and granzyme B^+ cell accumulation. These findings were corroborated in humanized mouse models. Mechanistically, bortezomib triggered chemokine expression (e.g., CCL5) and activated components of the innate immune pathway, including TBK, IRF3, IKK, and NF-κB. This effect was not abrogated by STING or RIG-I knockdown. In contrast, pharmacologic inhibition of MYD88 suppressed TBK and IKK phosphorylation and reversed CCL5 upregulation induced by bortezomib.
Conclusion: Bortezomib augments the efficacy of PD-1 blockade in lung squamous cell carcinoma by activating a TLR/MYD88-dependent innate immune pathway, enhancing chemokine-mediated immune infiltration. These results support the further development of this combination as a promising therapeutic strategy.

#1565 Analyzing Tumor Treating Fields (TTFields) therapy concomitantly with checkpoint inhibitors in a GBM mouse model.

Si Yeon Lee, Kwang Bog Cho, Caren Wu, Justin Liu, Joe Ha, Adam Sjoholm, Michael Lim, Gordon Li, Ryan Nitta

Neurosurgery, Stanford University School of Medicine, Stanford, CA

Glioblastoma (GBM) is the most common malignant form of adult brain tumor, with a median survival of around 1.5-2 years. Despite multimodal treatments (tumor resection, radiotherapy, and chemotherapy) achieving an effective cure remains a significant challenge due to its highly aggressive nature. Immune checkpoint inhibitors have emerged as a promising strategy to combat GBM; however, limitations have hindered clinical success, largely due to the “cold” and immunosuppressive tumor microenvironment (TME). Tumor Treating Fields (TTFields) therapy is a non-invasive, FDA approved treatment for GBM that employs specific frequency ranges (100-500 kHz) delivered through transducer arrays placed on the head. Our initial in vitro studies, using the inovitro system, confirmed that TTFields (72 hours, 200kHz) enhanced the immune response in GBM by inducing immunogenic cell death, which led to the recruitment of immune cells through the release of damage-associated molecular patterns (DAMPs). Additionally, we demonstrated that TTFields increased T-cell activity (IFNγ and perforin) and enhanced the motility and phagocytic activity in antigen presenting cells (Raw 264.7) and dendritic cells (JawsII). We then studied the therapeutic potential of directly applying the TTFields (10-14 days, 200kHz), using the inovivo system, to an orthotopic syngeneic GBM mouse model (CT2A-luciferase) with the checkpoint inhibitor anti-PD-1**.** Consistent with previous findings, the single arm treatments of TTFields and anti-PD-1 reduced tumor volume and slightly modulated the immune environment. Concomitant treatment of TTFields with systemic anti-PD-1 therapy reduced tumor volume and significantly increased immunomodulation, as observed via an increase in T cells and myeloid cells. Our findings suggest that concomitant treatment of TTFields with checkpoint inhibitors has the potential to help transform GBM into a “hot” tumor, making it an attractive target for immunotherapy.

#1566 Genetic and pharmacologic targeting of host ATF4 sensitizes pancreatic ductal adenocarcinoma to CAR T and immune checkpoint blockade.

Nektarios Kostopoulos[1], Rohan Ganesh[1], Tej Patel[1], Frank Chinga[2], Dan Boehmler[1], Arjun Sengupta[2], Aalim Weljie[2], Costa Koumeis[2]

[1]Radiation Oncology, University of Pennsylvania, Philadelphia, PA,[2]University of Pennsylvania, Philadelphia, PA

Activating Transcription Factor 4 (ATF4) is a central mediator of the Integrated Stress Response (ISR), a conserved adaptive pathway activated under conditions of nutrient deprivation, hypoxia, and oxidative stress. In pancreatic ductal adenocarcinoma (PDAC), this pathway supports tumor survival and contributes to the establishment of an immunosuppressive tumor microenvironment (TME). Here, we demonstrate that global ATF4 deletion in the host - affecting the non-tumor, non-CAR T compartments - in combination with mesothelin-CAR T cell therapy, significantly delays tumor progression in syngeneic PDAC models. ATF4 loss in the host was associated with reduced numbers of myeloid-derived suppressor cells (MDSCs) and regulatory T cells (Tregs), alongside enhanced cytotoxicity and reduced exhaustion in both meso-CAR T and endogenous $CD8^+$ T cells. Spatial metabolomic profiling revealed that ATF4-deficient tumors exhibit focal oxidative stress and depletion of key amino acids, including leucine, suggesting impaired metabolic adaptability that may hinder Treg and MDSC maintenance. Preliminary *in vitro* differentiation assays further showed that ATF4 loss or pharmacologic ISR inhibition with ISRIB impaired Treg polarization under amino acid-limiting conditions, indicating a metabolic link between ATF4 activity and Treg stability. Importantly, *in vivo* ISRIB treatment recapitulated the host ATF4-knock out effects, leading to slower tumor growth and improved CAR T cell responses. Finally, combinatorial experiments with anti-PD-1 and anti-CTLA-4 therapy revealed enhanced tumor control in ATF4-KO mice, suggesting that targeting the ISR can sensitize PDAC to immune checkpoint blockade. Collectively, these findings identify ATF4 as a key regulator of PDAC immune evasion and establish ISR inhibition as a promising strategy to enhance both CAR T-cell and checkpoint immunotherapy efficacy in pancreatic cancer.

#1567 Reprogramming of exhausted T cells in pancreatic cancer with SBRT/IL-12 therapy.

Sarah Eckl[1], Gary Hannon[2], Angela Hughson[2], Scott A. Gerber[2]

[1]Microbiology & Immunology, Univ. of Rochester School of Medicine & Dentistry, Rochester, NY,[2]Surgery, Univ. of Rochester School of Medicine & Dentistry, Rochester, NY

Pancreatic ductal adenocarcinoma (PDAC) has a poor 13% 5-year survival rate and is the 3rd leading cause of cancer related deaths in the US. Current treatment options include surgical resection, chemotherapy, and radiation. Surgical resection is the only treatment with curative potential, however, few PDAC patients are eligible, and recurrence rates are high. The limited efficacy of targeted interventions is largely attributed to the highly immunosuppressive tumor microenvironment (TME) in PDAC. The PDAC TME has a dense stromal peripheral layer that restricts effector cell infiltration and a myeloid cell compartment that suppresses the anti-tumor function of intratumoral T cells. Chronic antigen presentation to T cells also induces T cell exhaustion in the PDAC TME, further limiting anti-tumor responses. T cell exhaustion is typically described by increased expression of inhibitory receptors and limited cytotoxic potential and is a major barrier to effective PDAC therapeutics. Our lab has developed a pre-clinical orthotopic KP2 PDAC mouse model that recapitulates the immunosuppressive PDAC TME. However, the functionality and subsets of exhausted T cells (Tex cells) present in this model have not been fully understood. To examine Tex cell dynamics in the PDAC TME, we have used flow cytometry to identify progenitor, intermediate, and terminally exhausted T cells based on their differential expression of PD-1, Ly108, and Tim3. Using additional markers of exhaustion and activation, we show that the intermediate Tex population (PD-1+, Ly108+, Tim3+) has the most effector-like phenotype in the PDAC TME, suggesting a potential role of intermediate Tex cells in tumor control. To target the PDAC TME, we developed a novel therapeutic that combines stereotactic body radiation therapy (SBRT) and IL-12 immunotherapy. SBRT/IL-12 therapy repolarizes the PDAC TME and results in abrogation of PDAC tumor burden and long-term survival. Single-cell RNA sequencing reveals a decrease in the exhausted T cell phenotype after SBRT/IL-12 therapy, and cytotoxicity assays demonstrate restoration of anti-tumor functions of T cells post-therapy. Flow cytometry analysis of Tex subsets in the PDAC TME demonstrates repolarization towards cytotoxicity and activation of each subset, including the most severely exhausted terminally exhausted T cells. These findings suggest that the reprogramming of Tex cells in the PDAC TME is important for the efficacy of SBRT/IL-12 therapy. This work also informs the broader application of SBRT/IL-12 therapy to other solid tumors.

#1568 Synergistic antitumor effects of immune checkpoint inhibitors and targeted therapy in an orthotopic RCC mouse model.

Balaji Ramachandran[1], Satheeshkumar Rajendiran[2], Abhilash Reddy[2], Girish Joshi[2], Krishnappa Haladasappa[2]

[1]In vivo Pharmacology, Adgyl Lifesciences Private Limited, Bangalore, India,[2]In Vivo Pharmacology, Adgyl Lifesciences Private Limited, Bangalore, India

With the development of checkpoint inhibitors and immunotherapy treatment for Renal cell carcinoma (RCC), syngeneic orthotopic mouse models are advantageous as suitable preclinical models due to the presence of immune system. Orthotopic renal subcapsular inoculation tumor models are challenging and offer strong clinical relevance by closely mimicking the native tumor microenvironment. The In Vivo Imaging System (IVIS) further enhances these studies by enabling non-invasive, real-time tracking of tumor growth/regression during the study period without interim animal sacrifice. In the present study, we have evaluated the preclinical efficacy of anti-PD1, anti-CTLA-4 antibody and Cabozantinib and Bevacizumab as standalone and combination regimen in orthotopic renal cell carcinoma (RCC) model of immunocompetent BALB/c mice. Subcutaneous tumor was generated in donor mice by inoculation of RenCa luciferase reporter cell line. Tumor fragments ($1mm^3$) harvested from the donor mice were orthotopically implanted into the sub-renal capsule (SRC) space of the fresh batch of mice. Tumor growth was monitored twice weekly by IVIS optical imaging system. Mice were randomized based on total flux signal intensity ($1\text{-}2 \times 10^6$ photons/second). Standalone and combination treatment was initiated with Cabozantinib at 10mg/kg; p.o; QD for 2 weeks and Bevacizumab at 5mg/kg; i.p; Q4Dx4 dose, anti-PD-1 at 10mg/kg; i.p; Q4Dx4 dose and Anti-CTLA4 at 10mg/kg; i.p; Q4Dx4 dose. Total flux (photons/second), changes in body weight, clinicals signs, mortality were monitored twice weekly up to 3 weeks. At the study's endpoint, tumors were excised and both ex-vivo bioluminescence signal intensity and tumor mass were quantified to assess treatment efficacy. In the current, orthotopic renal cell carcinoma model, treatment with standalone anti-PD1, anti-CTLA-4, and Cabozantinib and Bevacizumab resulted in moderate tumor regression. Whereas combination of anti-PD1 and anti-CTLA-4 with Cabozantinib and Bevacizumab demonstrated in improved efficacy when compared with individual treatments which was evident from the reduction in signal intensity, organ metastasis and resulted in prolonged survival. The findings of this study indicate that combining targeted therapy with immune checkpoint inhibitors can effectively suppress tumor progression and potentially overcome therapeutic resistance. This combinatorial strategy represents a promising multimodal translational approach to enhance the efficacy of chemotherapy in renal cancer. Assessing treatment outcomes in preclinical orthotopic tumor models using IVIS imaging offers a valuable, non-invasive method for accurate and longitudinal monitoring of tumor growth over time.

#1569 Treatment of PAX3-FOXO1 alveolar rhabdomyosarcoma with ICP34.5-armed G47Δ oncolytic herpes simplex virus confers survival benefit when co-administered with anti-Pd1 antibody.

Cole W. D. Peters[1], Miriam Valenzuela-Cardenas[2], Moe Kawakami[1], Andrew Dinh[1], Jaden Nguyen[1], Allison Flores[2], Theodore S. Nowicki[2]

[1]UCLA - University of California Los Angeles, Los Angeles, CA,[2]UCLA, Los Angeles, CA

Background. Patients diagnosed with PAX3-FOXO1 (P3F) positive alveolar rhabdomyosarcomas (aRMS) have much worse prognosis than those with fusion-negative aRMS or embryonal rhabdomyosarcomas. The low immunogenicity of P3F+ aRMS tumors has impaired efforts to treat patients with immune checkpoint blockade, and the lack of an accessible PAX3-FOXO1 expressing murine tumor model has limited efforts to address this unmet therapeutic need. Here we generate a novel oncolytic herpes virus (oHSV) and show it improves mouse survival in a PAX3-FOXO1 expressing M3-9-M murine tumor model, when combined with anti-PD1 treatment.
Methods. We designed a P3F-responsive promoter by combining a PRS1 element with a minimal Myogenin promoter. This synthetic promoter was inserted into the oHSV G47Δ, to drive the cytotoxic ICP34.5 gene. We tested rG47-PRS1 cytotoxicity and growth in human and murine RMS cell lines, as well as safety in normal human muscle. To determine efficacy of oncolytic herpes viruses in RMS tumor bearing C57/BL6 mice, we implanted M3-9-M:PAX3-FOXO1 tumors into the gastrocnemius muscle, followed by intratumoral injection of 1E8 PFU of virus with or without IP injection of anti-PD1 antibody. Tumor infiltrating lymphocytes were observed via flow cytometry and IHC upon harvest. Additionally, we explored the gene expression response of human and murine RMS cell lines to infection via RNA sequencing, RTqPCR, and western blot.
Results. In vitro assays showed the PRS1 promoter resulted in expression of GFP or luciferase transgene in the presence of PAX3-FOXO1, but not its absence. Infection of RMS cells with rG47-PRS1 resulted in ICP34.5 protein expression. Recombinant rG47-PRS1 kills RMS lines faster than its parental virus while displaying the same safety profile as parental G47Δ in normal human muscle cells in vitro and is safe for intra-muscular injections in mice up to 1E9 PFU. Mice harboring M-3-9M RMS tumors expressing PAX3-FOXO1 had no response to anti-PD1 treatment alone but responded to combination therapy with either G47Δ or rG47-PRS1 virus (mean tumor volume $p<0.001$; survival G47Δ+PD1 vs PD1 alone $p<0.0012$). Tumors from combination treated mice had higher CD45+ lymphocyte infiltration of their tumors and significantly reduced PD1 positive CD4 and CD8 T cells as compared to mock or single treatment. RNA sequencing data revealed increased NF-kB pathway activation in aRMS tumor lines after infection, which we observed via p65, p100, cFOS, JNK1, and PI3K western blot and RTqPCR for AP-1 transcription factor elements.
Conclusions. We observe oHSV sensitizes PAX3-FOXO1 aRMS to anti-PD1 therapy in mice. Infection of aRMS leads to upregulation of the NF-kB pathway, which may have a role in T cell engagement or tumor biology for this pediatric malignancy.

#1570 Preclinical assessment of EGFR and checkpoint inhibitor combination therapy in spontaneous colon cancer model.

Balaji Ramachandran, Satheeshkumar Rajendiran, Girish Joshi, Krishnappa Haladasappa

In Vivo Pharmacology, Adgyl Lifesciences Private Limited, Bangalore, India

Spontaneous colon cancer models closely mimic human disease, enabling translational research and therapeutic evaluation. The ApcMin/+ mouse, with a mutation in the APC gene, is a well-established model for intestinal neoplasia. In recent years, immunotherapy has shown promise in colorectal cancer, the combination of EGFR inhibitors and immune checkpoint blockers remains underexplored in polyp models. This research looks at how well these two treatments work together in stopping early tumors, using real time colonoscopy to watch how tumors grow in APC mice. In this study we have evaluated the preclinical efficacy of immune checkpoint inhibitors (anti-PD-1/ CTLA-4) and EGFR inhibitors like Erlotinib and as standalone and in combination regimen in spontaneous colon cancer model of C57BL/6J-*Apc*^{Min}/J mice. Four-week-old mice were randomized, and treatment was initiated with anti-PD1 10mg/kg, i.e., BIW for 8 weeks, anti-CTLA-4 dosed at 10mg/kg, i.p; BIW for 8 weeks and Erlotinib 50mg/kg, po; QD for 8 weeks, as standalone and combination with Erlotinib. Weekly colonoscopies with image capture tracked tumor progression. Body weight, clinical signs, and mortality were monitored biweekly. At the study end, mice were euthanized, and their small intestines and colons were collected, imaged, and assessed for polyp load using ImageJ software. Colon samples were rolled and processed for histological analysis. In the current spontaneous colon cancer model, endoscopy assessment revealed that the anti-PD-1, CTLA-4, and Erlotinib monotherapies significantly reduced lesions, tumor burden, inflammation, and polyp area compared to controls. Significantly reduced the total area of intestinal polyps relative to the control group. The percentage (%) reduction in polyp area in the small intestine (proximal, middle, and distal) and colon was found to be 38%, 27%, and 68% respectively. However, the combination of Erlotinib with anti-PD-1 and anti-CTLA-4 antibodies showed a substantial reduction in colonic tumor burden. The % reduction in polyp area in the small intestine (proximal, middle, distal) and colon was found to be 88% and 74%, respectively. Histology showed less inflammation and dysplasia in the combination group versus monotherapy. In summary, combination therapy led to a marked decrease in both the number and size of small intestinal polyps in ApcMin/+ mice, with potential survival benefits. These findings indicate that dual targeting of EGFR signalling and immune checkpoints may enhance antitumor efficacy, presenting a promising approach for colorectal cancer treatment

#1571 CAF-mediated cancer immunotherapy resistance can be overcome via selective inhibition of NOX1, 2 and 4.

Jihyun Um, Heesu Kim, Hye Ji Jang, Eun Sil Lee, Yeonhee Ahn, Sung Hwan Moon, Soo Jin Lee

Aptabio Therapeutics Inc., Yongin, Korea, Republic of

Cancer-associated fibroblasts (CAFs) represent a functionally heterogeneous population forming a major component of the tumor stroma. CAFs interact with cancer cells and immune cells via cytokine secretion, contributing to extracellular matrix (ECM) remodeling and immune suppression in the tumor microenvironment (TME). Through these mechanisms, CAFs promote tumor progression and induce resistance to chemotherapy and immunotherapy, driving tumor aggressiveness and correlating with poor prognosis in various types of cancers. The primary function of NADPH oxidases (NOXs) is to generate reactive oxygen species (ROS). NOXs are key drivers of CAF activation, thereby facilitating tumor progression and resistance to anticancer therapies. In particular, NOX1, NOX2, and NOX4 are highly expressed in CAFs and contribute to regulation of CAF functions. Herein, we demonstrate for the first time that NOX1 and NOX2, in addition to NOX4, play critical roles in promoting fibrotic and immunosuppressive responses in CAFs. These findings indicate that selective inhibition of NOX1, NOX2, and NOX4 may prevent CAF activation, suppress tumor growth, enhance antitumor immunity, and represent a promising approach to overcome resistance. As a result, we found that NOX1, 2, and 4 are markedly elevated in human pancreatic CAFs (pCAFs) compared with human pancreatic fibroblasts (PFs). Moreover, knockdown of NOX1, 2, or 4 effectively decreased fibrosis-related markers and immune cytokines/chemokines in pCAFs, respectively. Furthermore, treatment of Compound-19 (Com-19), a selective NOX inhibitor, significantly reduced the expression of fibrosis-related factors and immune cytokines/chemokines in pCAFs and also inhibited tumor fibrosis and immune cytokines via NOX inhibition in CAF-rich colorectal cancer mouse model. Importantly, Com-19 increased the intratumoral infiltration of CD8+ T cells, resulting in synergistic anti-cancer efficacy when co-administered with immune check inhibitors (ICIs) in the model which poorly responses to ICIs. Collectively, the results indicate that NOX1, 2, and 4 play a crucial role in CAF-mediated resistance to ICIs in cancers and NOX inhibition can be an effective strategy to overcome the resistance. Notably, Com-19 effectively modulated the fibrotic and immune-suppressive properties of CAF-rich tumors via NOX inhibition, thereby resensitizing tumors to ICI therapy. Therefore, Com-19 has the potential to enhance the efficacy of cancer immunotherapy by overcoming CAF-mediated ICI resistance. Phase 1 clinical trials are underway, with administration beginning in 4Q 2025. This open-label, dose-escalation study is designed to evaluate the safety, tolerability, PK, and preliminary efficacy of Com-19 as monotherapy (Part A) and in combination with pembrolizumab (Part B) in patients with advanced solid tumors. The study aims to identify the MTD and/or RP2D of Com-19.

#1572 Cocktail immunotherapy: Plant virus immunomodulator, HER2 antibody, and co-delivered IL-12 cytokine for the treatment of HER2+ cancer.

Ayumi E. Pottenger[1], Miguel A. Moreno Gonzalez[1], Manuel L. Penichet[2], Nicole F. Steinmetz[1]

[1]Chemical and Nano Engineering, UC San Diego, La Jolla, CA,[2]Professor, Dept. of Surgery, University of California (UCLA), Los Angeles, CA

Cowpea Mosaic Virus (CPMV) is a plant virus which infects legumes such as cowpea plants. It has been used as a powerful intratumoral immunotherapy in murine cancer models and canine veterinary clinical trials. CPMV is a multi- Toll-Like Receptor (TLR) agonist which induces a strong anti-tumor immune response both locally and systemically. While highly potent as a monotherapy, the most robust immunotherapy approaches are those which target cancer through multiple axes. In the present work, we tested the combination of intratumoral immunotherapy using CPMV with human epidermal growth factor receptor 2 (HER2) monoclonal antibody (mAb) therapy targeting HER2+ tumors. More specifically, we combined CPMV with an anti-HER2 mAb or anti-HER2 antibody-(IL-12) fusion protein (anti-HER2 antibody-(IL-12))—an anti-HER2 antibody genetically fused to the cytokine IL-12. Amplification of HER2 is known to occur in several cancers and is associated with poor prognosis as well as cancer recurrence. Mice with HER2+ tumors from colorectal cancer cell lines (MC38-HER2+ and CT26-HER2+) were treated with CPMV and HER2 mAb or anti-HER2 antibody-(IL-12). Tumor volume and overall survival were measured over the course of 8 weeks. While animals were refractory to HER2 mAb therapy alone, reduced tumor growth and increased survival was achieved using CPMV and the combination therapies- with the combination therapies outperforming CPMV therapy alone. These results indicate that CPMV can synergize with targeted antibody therapies for greater anti-tumor efficacy.

#1573 Thermal trapping of MMC7 induces G2/M arrest, autophagy, and cGAS-STING signaling to augment anti-PD-1 efficacy.

Shan Li, Xiaofeng Ding, Zhilian Zhou, Huanlin Zhang, **Tingting Lin**, Lifeng Zhu, Yingming Sun

Affiliated Sanming First Hospital of Fujian Medical University, Sanming, China

Background: Overcoming resistance to immune checkpoint blockade, such as anti-PD-1 therapy, remains a critical challenge in oncology. This study investigates the potential of mild hyperthermia to modulate tumor cell biology and enhance immunotherapy efficacy.
Methods: Human tumor cell lines were subjected to mild hyperthermia (42°C) for 4 hours. Chromatin binding of MMC7 was assessed by chromatin fractionation and immunofluorescence. Cell cycle distribution was analyzed by flow cytometry. Autophagy induction was evaluated using LC3B-II conversion and autophagosome formation assays. Activation of the cGAS-STING pathway was measured via phosphorylation of STING and TBK1, and interferon-stimulated gene (ISG) expression. In vivo efficacy was validated using syngeneic mouse tumor models treated with hyperthermia (localized 42°C for 4 hours) combined with anti-PD-1 antibody.
Results: Sustained mild hyperthermia (42°C for 4 hours) specifically inhibited the dissociation of MMC7 from chromosomes, resulting in prolonged G2/M phase arrest in tumor cells. This arrest triggered significant induction of autophagy and robust activation of the cGAS-STING innate immune signaling pathway, characterized by increased cGAS activity, STING/TBK1 phosphorylation, and downstream ISG expression. Critically, this hyperthermia-induced immunogenic state synergistically enhanced the anti-tumor efficacy of PD-1 blockade therapy. Mouse tumor models recapitulated these findings, demonstrating significantly improved tumor control and survival in cohorts receiving the combination of localized hyperthermia and anti-PD-1 compared to either treatment alone.
Conclusion: Our findings demonstrate that controlled mild hyperthermia (42°C, 4h) induces persistent MMC7-chromatin binding, leading to G2/M arrest, autophagic activation, and potent stimulation of the cGAS-STING pathway within tumor cells. This creates a favorable tumor microenvironment that overcomes resistance and synergistically enhances the effectiveness of PD-1 checkpoint blockade immunotherapy. This combination strategy presents a promising novel approach for improving cancer treatment outcomes.

#1574 Chronotherapy of hyperthermia: Circadian rhythm governs HSP expression and modulates anti-tumor immunity.

Tingting Lin, Chunyan Lin, Zhilian Zhou, Shan Li, Lifeng Zhu, Yingming Sun

Affiliated Sanming First Hospital of Fujian Medical University, Sanming, China

Background: Heat shock protein (HSP) expression is a key mechanism underlying hyperthermia-induced anti-tumor immunity. However, whether HSP expression exhibits circadian rhythmicity and how this impacts therapeutic efficacy remains unclear.
Methods: Murine tumor models received localized hyperthermia at different times of day (specifically comparing afternoon and nighttime). Core circadian clock proteins (e.g., Bmal1 or Clock) were genetically ablated. Tumor tissues were analyzed for: (1) HSP expression levels post-hyperthermia; (2) release of damage-associated molecular patterns (DAMPs), including HMGB1 and ATP; (3) infiltration of CD8+ T cells. The effect of hyperthermia timing on treatment efficacy, both alone and in combination with anti-CTLA-4 antibody, was evaluated.
Results: HSP expression induced by hyperthermia showed significant circadian variation: it was highest when hyperthermia was administered in the afternoon and lowest when administered at nighttime. Genetic ablation of core circadian clock proteins abolished this time-dependent difference in HSP expression, confirming the critical regulatory role of the biological clock. Compared to afternoon hyperthermia, nighttime hyperthermia triggered significantly greater release of immunogenic DAMPs (HMGB1, ATP) from tumor tissue and induced markedly enhanced infiltration of CD8+ T cells.Crucially, nighttime hyperthermia demonstrated a significantly stronger synergistic anti-tumor effect when combined with anti-CTLA-4 immune checkpoint blockade therapy.
Conclusion: The circadian rhythm profoundly influences the immunogenic effects of hyperthermia by regulating HSP expression. Although inducing lower HSP levels, nighttime hyperthermia is more effective at releasing immunogenic DAMPs (HMGB1, ATP), promoting CD8+ T cell infiltration, and potently enhancing the efficacy of anti-CTLA-4 therapy. This study identifies timing of hyperthermia administration (specifically nighttime) as a critical factor for optimizing immunogenic cell death and augmenting the effectiveness of combined immunotherapy.

#1575 Immune implications of dual PIKfyve and KRAS inhibition in pancreatic ductal adenocarcinoma.

Jasmine P. Wisniewski[1], Caleb Cheng[1], Ruya Pakkan[1], Sydney Peters[1], Gabriel Cruz[2], Yuanyuan Qiao[2], Costas A. Lyssiotis[3], Arul M. Chinnaiyan[2]

[1]University of Michigan, Ann Arbor, MI,[2]Pathology, University of Michigan, Ann Arbor, MI,[3]Molecular and Integrative Physiology, University of Michigan, Ann Arbor, MI

BackgroundPancreatic Ductal Adenocarcinoma remains one of the deadliest cancers, with an overall 5 year survival rate of 13 percent. The majority of PDAC cases are driven by mutations in KRAS, making it a critical therapeutic target. Although many KRAS inhibitors have been developed and show promise in preclinical and clinical settings as single agents, the emergence of resistance and adaptive mechanisms has highlighted the need for combinatorial therapies. We recently demonstrated that the concurrent targeting of KRAS-MAPK and the lipid kinase PIKfyve disrupts lipid homeostasis in PDAC and has potent antitumor effects, curing the majority of mice in a syngeneic orthotopic mouse model. Interestingly, PIKfyve and KRAS-MAPK inhibition independently increase MHC Class 1 surface expression and enhance effectiveness of anti-PD-1 therapy. Thus, building on these findings, we hypothesized that dual inhibition of PIKfyve and KRAS-MAPK signaling modulates the immune landscape of PDAC.

Methods & Results Using a syngeneic orthotopic PDAC model, mice underwent 19 days of treatment with PIKfyve inhibitor ESK981 in combination with RAS inhibitor RMC-6236. Those that achieved a complete cure at the end-point were left untreated for 2 months, and it was observed that tumors grew back for all mice, highlighting the need for additional therapy. Notably, PIKfve or KRAS-MAPK inhibition alone increased expression of immune signaling markers MHC Class I and PD-L1, suggesting that the addition of anti-PD-1 therapy could further enhance efficacy.

To investigate the effect of PIKfyve and RAS inhibition on the PDAC tumor microenvironment, we performed single-cell RNA sequencing on tumors harvested after 5 days of treatment with ESK981 and RMC-6236. The combination therapy resulted in an increased proportion of immune cells, particularly T and B cells, along with a decreased proportion of epithelial cells and fibroblasts, which are associated with immune evasion. These suggest that PIKfyve and RAS inhibition alter immune function and prime the microenvironment for immune therapy.

Together, our preliminary findings suggest that the combined inhibition of PIKfyve and KRAS-MAPK exerts both direct antitumor effects and enhances the immune response in PDAC. Our goal is to build upon this strategy by leveraging its immune-enhancing effects, particularly with the addition of immune checkpoint blockade.

#1576 Combination treatment of mertki and immunomodulatory chemotherapy results in cxcl9 positive macrophage reprogramming and anti tumor adaptive memory in triple negative breast cancer.

Alex J. Smith[1], Zachary Schrank[2], Nan Guan[1], Diego Pedroza[1], Sebastian Calderon[1], Xueying Yuan[1], Na Zhao[3], Zoe Gabriel[1], Yang Gao[3], Charlotte Rivas[1], Fengshuo Liu[1], Chuck Perou[4], Shelton Earp[5], Jeffrey M. Rosen[3]

[1]Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX,[2]UNC Chapel Hill, Chapel Hill, NC,[3]Baylor College of Medicine, Houston, TX,[4]UNC School of Medicine, Chapel Hill, NC,[5]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Breast cancer is the most prevalent cancer and accounts for the second-highest cancer mortality rate in women. Recently, immune checkpoint blockade (ICB) in combination with chemotherapy has become the standard-of-care for Triple-Negative Breast Cancer (TNBC) patients. CD8 T cell infiltration is a predictive marker for ICB and is associated with a better prognosis, whereas suppressive myeloid cell infiltration is associated with a poor prognosis. Tumor-associated macrophages (TAMs) are suppressive myeloid cells that are common targets for solid tumor microenvironment (TME) re-education. While it is known that TAMs orchestrate lymphoid cell activation/inhibition, little is known about TAM programming, derivation, and functionality in tumors. MerTK and Axl (TAMr) are receptor tyrosine kinases expressed by monocytes and TAMs that act as negative regulators of STAT1 signaling in these cells. TAMr inhibition with a MerTKi, MRX-2843, synergizes with Interferon (IFN) to reprogram TAMs in vitro. These reprogrammed cells produce anti-tumor markers such as Cxcl9 and iNOS. Reprogramming of the bone marrow, with immunomodulatory cyclophosphamide drives myeloid cells into the monocytic lineage resulting in increased activated monocyte production. Moreover, IFN signaling is increased within the tumor. When CTX is combined with MRX-2843 long-term durable responses (LTR) are observed in the basal 2153L model, but not in the claudin low T12 model which recurs. Through scRNAseq we identified that IFN signaling maintains lymph activating Mo.Macs that release high levels of Cxcl9 in 2153L. Furthermore, 2153L ‘heats up’ early during treatment by Cxcl9 monocytes recruiting both antigen experienced effector CD8 and stem-like memory CD4 T cells to the TME. Importantly, germinal center formation with the tumor draining lymph of combination treated 2153L tumor bearing mice was observed, suggesting that CD4 and B Cell interactions may drive anti-tumor adaptive immunity. In addition, CD8 T Cells express PD-1 and IFN signaling drives PD-L1 expression on monocytes in combination treated mice. The addition of ICB to the CTX + MRX-2843 regimen prevented recurrence in 60% of mice. This study revealed that MRX-2843 synergizes with CTX to drive Cxcl9 and antigen presentation in monocytic cells, resulting in adaptive memory activation via germinal centers. Furthermore, TAM RTK receptors regulate IFN signaling in monocytic derived cells and when inhibited can synergize with chemotherapy to drive long term durable responses in TNBC pre-clinical models. TAM reprogramming with MRX-2843 + CTX + ICB, therefore, may represent a novel therapeutic approach for patients with basal TNBC.

[1]Genomic Immunology, Gladstone-UCSF Institute, San Francisco, CA,[2]Azalea Therapeutics, San Francisco, CA,[3]Department of Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA,[4]Merkin Institute of Transformative Technologies in Healthcare, Broad Institute of MIT and Harvard, Cambridge, MA,[5]Department of Microbiology, NYU Grossman School of Medicine, New York, NY

Primary human myeloid cells are promising candidates for immunotherapy, yet efficient and scalable technologies for genetic engineering and screening in these cells are limited. Here we present a virus-like particle (VLP)-based toolkit that delivers diverse CRISPR genome editing modalities to human monocytes, macrophages, and dendritic cells with high efficiency while preserving viability and innate immune responsiveness. VLP-mediated delivery of ribonucleoprotein payloads supports gene knockout, base editing and epigenetic silencing, and enables site-specific integration of large DNA sequences when combined with AAV donors for homology-directed repair. Leveraging sgRNA delivery via VPX-lentivirus combined with Cas9 protein delivery via engineered virus-like particle (eVLP) treatment (SLICeVLP), we performed the first pooled loss-of-function screens in human macrophages. We uncovered regulators of TNF production and CD80 expression in human macrophages, converging on TNFAIP3 as a central regulator of inflammatory polarization. TNFAIP3 ablation promoted a pro-inflammatory cell state that is resistant to suppressive polarization, and augmented cytotoxicity of engineered HER2 CAR-macrophages. Taken together, this technology platform enables unbiased discovery and characterization of functional gene targets in primary human myeloid cells.

#1581 Driver and mechanism of t-cell dysfunction and immune cold microenvironment in deadly developmental tumor in infants.

Poorvi Subramanian[1], Sreenidhi Mohanvelu[1], Sheeja Aravindan[2], Sabir Salim[1], Sivasubramani Narayanan[1], Natarajan Aravindan[1]

[1]Oklahoma State University, Stillwater, OK,[2]OU Health Stephenson Cancer Center, Oklahoma City, OK

Neuroblastoma (NB), a prevalent extracranial pediatric malignancy, is characterized by an immunologically “cold” tumor microenvironment (TME), yet the mechanisms underlying its immune evasion remain poorly understood. Here, we identify a novel immunoregulatory role for **Retinal Degeneration 3 (RD3)** in shaping host immunity and T-cell fate during NB progression. Using immune-competent mouse models, neural crest cell (NCC)-specific RD3 knockout **(RD3$^{-/-}$)**, ALK phosphor-mimetic mutated (**ALKF1174L** knock-in), or **RD3$^{-/-}$ALKF1174L** (aggressive NB phenotype), we demonstrate that RD3-loss does not impair thymic T-cell development, but profoundly alters peripheral T-cell maturation and activation. RD3-deficient mice exhibit enhanced thymic commitment of CD3^{+} T-cells, increased TCR rearrangement, and elevated CD8^{+} cytotoxic T lymphocyte (CTL) maturation, while CD4^{+} helper T-cell development is markedly suppressed. In NB-bearing RD3$^{-/-}$ mice, we observed tumor-driven reprogramming of effector T-cell populations, with increased CD8^{+} CTLs and diminished CD4^{+} activation, indicating a skewed immune response. Splenic microenvironment revealed robust homing of TCR-programmed cells but a blockade in CD4^{+} T-cell activation. Wild-type controls maintain balanced T-cell activation and effector composition, underscoring the immune detour induced by RD3 deficiency. Multiplex immunofluorescence highlights a depletion of CD4^{+} and CD8^{+} effector T-cells, reduced activation markers (CD44, GITR), and elevated exhaustion marker CD244.2. Innate immune compartments are similarly compromised, with diminished CD206^{+}, CD86^{+}, and STING^{+} populations, reflecting impaired antigen presentation. Notably, RD3$^{-/-}$ tumors exhibit heightened adenosinergic suppression via the CD73/CD39/A2AR axis, establishing a metabolic barrier to immune activation. New to science, these findings reveal RD3-loss as a central orchestrator of immune collapse in NB, promoting T-cell exhaustion, suppressing antigen presentation, and fostering a metabolically suppressed TME. This study provides mechanistic insight into tumor-intrinsic immune evasion and lays the groundwork for therapeutic strategies to restore immune competence in NB.

#1582 Integrative functional and multi-omics profiling reveals divergent natural killer cell responses and tumor cell plasticity in breast and ovarian cancer.

Jennifer C. Wischhusen[1], Rebecca Weber[1], Syed A. Ali[2], Brenda Besemer[1], David Palmero-Canton[1], Viktoria Sokolova[1], Christina Kohler[1], Elisa Donato[1], Andreas Trumpp[1]

[1]Division Stem Cells and Cancer, German Cancer Research Center (DKFZ), Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM gGmbH), Heidelberg, Germany,[2]Division Proteomics of Stem Cells and Cancer, German Cancer Research Center (DKFZ), Heidelberg, Germany

Natural killer (NK) cells are key mediators of innate antitumor immunity and promising candidates for cell-based therapies, yet tumor cells frequently evade NK surveillance, particularly in advanced disease. To dissect these evasion mechanisms and identify points of intervention to enhance anti-tumor immunity, we evaluated the cytotoxic response of human primary NK cells toward primary breast cancer (BrCa) and ovarian cancer (OvCa) cells.

NK cytotoxicity was assessed by cell surface expression of the CD107a degranulation marker, tumor cell (TC) survival by DAPI exclusion, and TC susceptibility using a fluorogenic protease assay. Responsive and non-responsive NK cells, as well as susceptible and resistant TCs from serial TC:NK co-cultures, were profiled by mini-bulk transcriptomics, low-input proteomics, and secretomics. NK degranulation and killing were consistently higher toward OvCa cells, whereas repeated BrCa exposure induced progressive loss of NK activity. NK receptor-ligand profiling showed stable receptor expression after OvCa co-culture but extensive remodeling upon BrCa contact. Secretome analysis revealed convergence of OvCa and NK secretory programs into a mixed phenotype, whereas BrCa suppressed NK-derived secretion and dominated the BrCa:NK secretome. These data highlighted a heterogenous NK response to different cancer entities and the control of NK activity by TCs. Multi-omics analysis of NK subsets showed glycolytic and proliferative enrichment in degranulating NK cells, whereas non-degranulating NK cells upregulated exhaustion and immunosuppressive markers absent in mono-cultured NK cells. These signatures were consistent across donors, across exposure to six BrCa/OvCa samples, and detected in NK cells from patients with advanced disease, underscoring clinical relevance. Across all six cancer cultures, NK-resistant TC subsets emerged with enhanced survival and a quiescent, metabolically low phenotype. In an orthotopic BrCa model, *in vitro*-generated resistant cells showed delayed tumor growth. Upon cell cycle re-entry during extended culture, resistant TCs regained NK susceptibility. Control and resistant TCs isolated from tumors two months post-engraftment were equally sensitive to NK killing, and *in vivo* NK therapy did not preferentially eliminate resistant TCs, indicating a plastic, reversible resistance state.

These findings revealed reciprocal reprogramming between NK cells and TCs. NK cells acquired exhaustion, while TCs adopted temporary quiescence to evade killing. Targeting both NK dysfunction and TC plasticity will be essential for effective NK cell-based therapies for solid tumors.

#1583 Galectin9 targeted therapy for aiming cure in oncogenic driver alterations-positive non-small cell lung cancer.

Takanori Kondo, Toshiyuki Minami, Hidemi Kitai, Yoko Higashiguchi, Takashi Kandori, Naoki Kawamura, Misa Murakami, Jotaro Kiyota, Mayuko Tokuda, Tomoki Higashiyama, Akio Tada, Yoshiki Negi, Kazue Yoneda, Daichi Fujimoto, Taiichiro Otsuki, Koji Mikami, Ryo Takahashi, Kozo Kuribayashi, Takashi Kijima

Department of Respiratory Medicine, Hyogo Medical University, Hyogo prefecture, Japan

Small-molecule tyrosine kinase inhibitors (TKIs) exert dramatic antitumor effect in patients with oncogenic driver alterations-positive non-small cell lung cancer (driver-positive NSCLC). However, it is inevitable for those patients to experience recurrence because of the existence of intrinsic drug-resistant subpopulation called drug-tolerant persisters (DTPs). Therefore, elimination of DTPs is crucial toward complete cure. We examined whether innate immunity could eliminate DTPs for complete cure in driver-positive NSCLC. To identify the key immune checkpoint molecule (ICM) to eradicate DTPs, *EGFR* mutation-positive NSLC cells (HCC827 and PC-9) and *ALK* fusion-positive NSLC cells (H3122 and H2228) were exposed to specific TKI osimertinib and alectinib, respectively. Among ICMs, galectin-9 (Gal-9) transcripts were most dramatically upregulated in both driver-positive NSCLC cells via activation of interferon regulatory factor 1 in nucleus. Gal-9 was also overexpressed in both HCC827 osimertinib-resistant cells (HCC827OR) and H3122 alectinib-resistant cells established by continuous exposure to respective TKI. Moreover, TCGA database analysis showed the possibility for Gal-9 to be a negative prognostic factor in lung adenocarcinoma. We next examined whether Gal-9 expression in cancer cells affected the cytotoxicity of natural killer (NK) cells. Cytotoxicity was evaluated by co-incubating cancer cells and NK leukemia cells (NKL) under continuous monitoring using xCELLigence. While exogenous Gal-9 expression weakened NKL-mediated cytotoxicity for HCC827 cells, anti-Gal-9 antibody enhanced the cytotoxicity against HCC827OR cells. We then generated CRISPR/Cas9-mediated Gal-9-knockout (KO) HCC827 cells (HCC827-sgLGALS9) and performed long-term NKL killing assay in the presence of osimertinib for evaluating the cytotoxicity against DTPs. While HCC827-sgLGALS9 cells were completely depleted by osimertinib exposure plus NKL mediated-cytotoxicity, scramble guide RNA-transfected HCC827 cells (HCC827-scr) reproliferated, which suggested that NKL-mediated cytotoxicity failed to eliminate DTPs in HCC827-scr cells. We further engrafted HCC827-scr and HCC827-sgLGALS9 cells into the flank of athymic nude mice and administered osimertinib orally for 30 days. Xenografts in both groups rapidly shrank and disappeared by osimertinib, however, the regrowth rate was higher in HCC827-scr group. Since human Gal-9 has low affinity for mouse immune cells, we transfected mutant human *EGFR* into NIH 3T3 cells (3T3-EGFRmt) and established allograft model. As expected, osimertinib significantly suppressed the growth of mouse sgLGALS9 transfected 3T3-EGFRmt allografts compared with that of scramble control allografts. Collectively, targeting Gal-9 is promising for aiming cure in driver-positive NSCLC by activating innate immunity against DTPs.

#1584 Metastasis associated macrophages drive immunosuppression and fibrosis in gastric peritoneal carcinomatosis.

Lilia Turcios[1], Neelima Hosamani[1], Ellen Beswick[2], Maria Carey[1], Joseph Kim[1], **Mautin Barry-Hundeyin**[1]

[1]University of Kentucky, Lexington, KY,[2]University of New Mexico, Albuquerque, NM

Gastric cancer peritoneal metastasis (GC-PM) remains a lethal disease with 5-6% overall survival. Macrophages are the predominant antigen presenting cells in the peritoneum initiating innate and adaptive responses. Thus, macrophage-based therapies may be an important avenue for immune based therapeutic strategies. However, the role and regulators of metastasis associated macrophages (MAMs) in GC-PM remain uncertain. Comparative transcriptomic analysis of malignant ascites and solid peritoneal tumor implants demonstrated that MAMs are a predominant cell type in the tumor microenvironment. Using syngeneic murine models of gastric carcinomatosis, we observed that targeted macrophage depletion restricted tumor growth as evidenced by 80% reduction in tumor weights, total body tumor volume, number of nodules, and malignant bowel obstruction. Bulk RNA sequencing of the malignant ascites demonstrated upregulation of pathways associated with T cell activation, differentiation and proliferation with macrophage depletion. In addition, bulk RNA sequencing of the macrophage-depleted tumor tissue showed downregulation of pro-fibrotic genes Col1a1, Fgf2 and Itgb1 compared with controls. Multiplex cytokine array revealed inhibition of immunosuppressive chemokines IL-10, IL-6 and CXCL1 with macrophage depletion. Functionally, co-cultured isolated MAMs isolated from malignant ascites and tumor nodules inhibited naïve polyclonal CD4+ T cell activation ex-vivo. Taken together, we elucidate dual mechanisms by which metastasis associated macrophages promote oncogenesis through altering adaptive anti-tumor immunity and promoting fibrosis in gastric peritoneal metastasis. Future studies will identify macrophage subsets that can be targeted for potential therapies.

#1585 Kinetic profiling of ILC and ILTC responses during early hepatocellular carcinoma development reveals IL-15-ILC1 axis.

Patrick Huang[1], Rajiv Trehan[1], Benjamin Ruf[2], Chi Ma[1], Dana Soika[1], Lorenz Kocheise[1], Gabriel B. Prata[1], Tim F. Greten[1], Firouzeh Korangy[1]

[1]Thoracic & GI Malignancies Branch, NIH/DHHS, Bethesda, MD,[2]Malignome, Metabolome and Microbiome, University of Tubingen, University of Tubingen, Germany

Cancer immunotherapy has largely focused on conventional T cells due to their recognition of precise peptide-antigens. However, despite recent breakthroughs, including the adoption of immune checkpoint inhibitor therapy as first-line therapy for unresectable hepatocellular carcinoma (HCC), the overall mortality associated with HCC continues to rise. Innate lymphoid cells (ILC) and innate-like T cells (ILTC) are lymphoid populations that play critical roles in inflammation, tissue repair, and immune tolerance. Using single cell RNA sequencing and flow cytometry on tumor samples from patients with established HCC, we have previously shown that the tumor cytokine milieu controls ILC composition and HCC outcome (Heinrich et al. Gut 2022). However, their dynamic roles during tumor development and progression particularly in the early phases of tumor initiation are poorly understood. We decided to study ILCs and ILTCs in murine HCC models, which allows us to perform temporal analysis and functional studies during very early tumor development. Using a combination of high-dimensional flow cytometry, single-cell RNA sequencing, and histologic imaging, we characterized the temporal shifts in these populations in a plasmid-induced (MYC-Luc;sg-p53) HCC mouse model. Most ILC and ILTC populations including mucosal-associated invariant T (MAIT) cells, group 1 ILCs, ILC2s, and ILC3s expanded by day 4, but lost cytotoxic granule production as the tumors progressed. We identified liver resident Hobit-expressing ILC1s as pivotal effectors of anti-tumor immunity, as their loss led to a significant increase in early tumor burden. Single-cell RNA sequencing demonstrated substantial phenotypic diversification in group 1 ILCs which ultimately shift towards an exhausted state as tumors progressed. Additionally, cytokine and transcriptional data suggested early tumor-derived IL-15 to be an early mediator and activator of hepatic ILC1s. Together, our findings position ILCs and ILTCs as rapid responders to oncogenic transformation, with ILC1s functioning as critical mediators of early anti-tumor defense.

#1586 Surgery-induced long term innate immune changes facilitate tumor progression.

Zhengyi He, Hamza O. Yazdani, Tony Haykal, Ruiqi Yang, Celine Tohme, Rihito Kanamaru, Krish Wasson, Anthony Gebran, Silvia Liu, David A. Geller, Jian-Hua Luo, Samer Tohme

University of Pittsburgh, Pittsburgh, PA

Introduction: Surgical intervention is crucial in managing cancer patients, yet it can increase tumor recurrence risk due to pro-tumorigenic innate immunity. We hypothesized that surgical stress can induce prolonged rewiring of bone marrow cells that can differentiate into a pro-tumorigenic phenotype upon stimulation.
Methods: Wild type C57BL/6J mice were subject to surgical stress including laparotomy, liver ischemia reperfusion and hepatectomy. Sham surgery includes anesthesia without further manipulation. MC38 (murine colorectal cancer cells) were subcutaneously inoculated 1- or 3-weeks post-surgery. Neutrophil depletion is done by anti-Ly6G monoclonal antibodies administration.
Results: Wild type mice subjected to different surgical stress showed significantly increased tumor volumes when tumor was inoculated subcutaneously 1- or 3-weeks post-surgery. However, neutrophil-depleted mice subjected to surgical stress showed no significant increase of cancer growth compared to wild type mice. These findings are correlated with transcriptomic analysis on tumor-associated neutrophils which exhibited enhanced production of pro-inflammatory factors that promote tumor growth. Circulating neutrophils after surgical stress also showed similar pro-inflammatory markers persistently upregulated after surgery in the absence of cancer. Furthermore, mice showed increased tumor volume when received bone marrow cells from surgery-preconditioned mice compared to sham mice. Analysis on bone marrow progenitor cells specifically showed enhanced proliferation of granulocyte-monocyte progenitors (GMPs) after surgery compared to sham mice. Additionally, proliferation of GMPs is enhanced in surgery-preconditioned mice compared to sham mice in response to cancer inoculation. Single-cell analysis of bone marrow progenitor cells revealed persistent transcriptomic changes post-surgery, while transcriptional factor enrichment revealed CCAAT/enhancer binding proteins (C/EBP) to be potential drivers of these persistent changes. Analysis of post-surgical plasma revealed acute increase of IL-1β and HMGB1 post-surgery. *In vitro* short-term (3 days) treatment of bone marrow progenitor cells with IL-1β or HMGB1 resulted in enhanced proliferation of GMPs and persistent upregulation of pro-tumorigenic gene markers in induced neutrophils.
Conclusions: Surgery-induced IL-1β and HMGB1 can induce persistent changes in bone marrow progenitor cells that can produce pro-tumorigenic neutrophils in response to cancer cells. IL-1β and HMGB1 can serve as targets to improve cancer patient prognosis after surgical resection.

#1587 *In Vivo* CRISPR screen of dendritic cells identifies Traf2 as a critical regulator of anti-tumor immunity via modulation of non-canonical NF-kB pathway.

Chang Yoon Moon[1], Meriem Belabed[2], Steven Chen[1], Jessica Le Berichel[1], Alexander Tepper[1], Camillia Azimi[1], Natalie Vaninov[1], Prerna Suri[1], Adam Marks[2], Alessandra Gurtner[1], Matthew D. Park[2], Alessia Baccarini[2], Brian Brown[2], Miriam Merad[2]

[1]Immunology, Icahn School of Medicine at Mount Sinai, New York, NY,[2]Icahn School of Medicine at Mount Sinai, New York, NY

For their ability to sample and present tumor antigens and prime cognate adaptive immune responses, the critical role of dendritic cells (DCs) in potentiating anti-tumor immune has been increasingly recognized. Yet despite their instrumental function in empowering tumoricidal adaptive immune responses, they have also been found in several cancers to foster tolerogenic immunity towards cancer antigens—underscoring the need to better understand the regulatory mechanisms that enable DCs to orchestrate a more tumoricidal response rather than a tolerogenic one. To investigate such mechanisms, we performed pathway analysis on transcriptional signatures of mature DCs found in several tumor types in both mice and humans, which identified non-canonical NF-kB (ncNF-kB) signaling as a potential regulatory pathway. Through an *in vivo* ProCode-based CRISPR knockout (KO) screen targeting ncNF-kB signaling molecules in DCs in $Kras^{G12D}Tp53^{-/-}$ (KP) tumors in mice, we discovered Traf2, a negative regulator of ncNF-KB pathway, as a key modulator capable of enhancing the expression of immunostimulatory molecules, particularly IL-12. Both CRISPR-mediated Traf2 knockout and DC-specific deletion using Zbtb46-Cre demonstrated that KO of Traf2 in DCs lead to elevated IL-12 production and increased frequencies of $CCR7^{+}CD40^{+}$ mature DCs upon dead-cell uptake. In congruence with their immunogenic phenotype, Traf2-KO DCs demonstrated a heightened capacity to activate OT-1 T cells. Reflective of enhanced DC immunogenicity in vitro, mice with DC-specific Traf2 knockout, when challenged with orthotopic lung tumors, showed increased IL-12 production in DCs and enhanced T cell activation—all of which led to a significantly reduced tumor burden compared to their wildtype controls. Collectively, these findings position DC-specific Traf2 inhibition as a promising strategy to reprogram dendritic cells toward potent tumoricidal immunity and enhance the efficacy of cancer immunotherapy.

#1588 TOX functions as a cytotoxicity checkpoint in human NK cells and is reversibly regulated by SLAMF7 receptor.

Yasser Ali Aldhamen, Rana K. Alrabiah, Maram Alshuwaymi, Rita Alonaizan

King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

The thymocyte selection-associated high mobility group box protein (TOX) is the master regulator of T cell exhaustion, but its function in human NK cell is not well defined. Here, we identified TOX as a cytotoxicity checkpoint in human NK cells and uncovered a previously unknown role for SLAMF7 as a selective and negative regulator of TOX-mediated NK cells dysfunction. Human PBMCs-derived NK cells were stimulated with IL-2, IL-10, IL-15, and IL-18, or cross-linked with agonistic antibodies targeting NKp46, NKp30, NKp44, CD16, 2B4, NKG2D, DNAM-1, 4-1BB, IL-2Rβ, SLAMF7, or NKG2A, alone or in combination with SLAMF7. Expression of TOX, IFNγ, CD107a, Granzyme B, PD-1, and SLAMF7 was quantified by flow cytometry. IL-2 and IL-15 induce rapid, dose-dependent TOX upregulation, with IL-15 showing greater potency. IL-10 and IL-18 failed to upregulate TOX. NKp30, NKp46, CD16, and 2B4 stimulation also upregulated TOX alongside IFN-γ, CD107a, and Granzyme B induction. SLAMF7 alone did not induce TOX but selectively modulated TOX during co-engagement with other activating receptors. Specifically, SLAMF7 + NKp46 and SLAMF7 + NKp30 co-stimulation suppressed TOX to baseline while preserving strong IFNγ, CD107a, and Granzyme B responses. SLAMF7 did not alter DAP12-, DAP10-, or FcRγ- dependent signaling, demonstrating that SLAMF7 specifically counteracts CD3ζ-dependent signaling. In contrast, SLAMF4 (2B4) synergistically amplified TOX and PD-1 across NK cytotoxicity receptor (NCR) and NKG2D pathways, implicating it as a strong exhaustion-promoting receptor. Additionally, SLAMF7 + CD16 increased TOX above CD16 alone. Moreover, SLAMF7 co-stimulation with NKp44, NKG2D, DNAM-1, 4-1BB, IL-2Rβ, or NKG2A did not alter TOX levels. Functionally, TOX^{low} NK cells represented the dominant $IFN\gamma^{+}$, $CD107a^{+}$, and Granzyme B^{+} subset**,** confirming TOX as a negative regulator of NK cell cytotoxicity. Consistent with these findings, SLAMF7 + NKp46 co-stimulation produced synergistic killing of MDA-MB-231 cells, whereas SLAMF7 + CD16 co-stimulation, which augments TOX, reduced cytotoxicity compared to CD16 alone. Importantly, tumor-induced TOX modulation strongly correlated with NK susceptibility. We observed that NK-sensitive MDA-MB-231 cells induced strong TOX downregulation, resulting in robust effector responses, whereas NK-resistant PANC-1 cells failed to downregulate TOX and elicited weak activation. Together, these results identify TOX as a checkpoint regulating NK cytotoxicity and define a previously undescribed SLAMF7-CD3ζ axis that modulates NK cell exhaustion. Targeting TOX or modulating SLAMF7 signaling may enhance NK-based immunotherapies for resistant solid tumors.

#1589 Spatial and molecular profiling of multinucleated giant macrophages in pancreatic ductal adenocarcinoma.

Marika Viatore[1], Rebecca Polidori[1], Anna Rita Putignano[2], Arturo Bonometti[2], Silvia Uccella[2], Silvia Bozzarelli[2], Gianluca Basso[2], Marco Erreni[3], Capretti Giovanni[2], Vincenzo Corbo[4], Alberto Mantovani[5], Massimo Locati[1], Federica Marchesi[1]

[1]University of Milan, Milan, Italy,[2]IRCCS Humanitas Research Hospital, Rozzano, Italy,[3]Dept of Immunology and Inflammation, Humanitas Clinical and Research Center, Milano, Italy,[4]University of Verona, Verona, Italy,[5]IRCCS Istituto Clinico Humanitas, Pieve Emanuele, Italy

Macrophages constitute a dominant and heterogeneous immune population within the microenvironment of pancreatic ductal adenocarcinoma (PDAC), but how specific macrophage states contribute to tumor behavior remains poorly understood. In an institutional series of 145 PDAC specimens, we identified a distinct subset of multinucleated giant cells (MGCs) of macrophage origin, an entity well described in chronic inflammation but rarely characterized in cancer. $CD68^+$MGCs were found in about 28% of cases, enriched in squamous, non-glandular regions, and more frequent after neoadjuvant chemotherapy. Spatial and high-dimensional profiling, including NanoString GeoMx® Digital Spatial Profiling, Hyperion Imaging System, and AI-guided histopathology, defined the morphological, phenotypic, and transcriptional features of these cells. PDAC-associated MGCs lacked canonical polarization markers (HLA-DR, CD163) and instead displayed a unique transcriptional program involving POLR2K, TUBA8, COX5B, and VDAC1, genes linked to oxidative stress, DNA repair, and MYC signaling. Gene set enrichment and spatial analyses indicated that MGC-rich regions coincide with hypoxic and extracellular matrix-remodeling niches. Experimental hypoxia promoted MGC formation *in vitro*. Morphometric assessment revealed abnormal nuclear architecture and increased $53BP1^+/Ki67^+$ nuclei in MGCs, suggesting proliferative activity despite DNA damage. A macrophage MGC gene signature was enriched in the squamous subtype of PDAC and correlated with shorter overall survival in TCGA datasets ($p = 0.018$). Collectively, these data identify multinucleated macrophages as a previously unrecognized immune cell state driven by microenvironmental stress and hypoxia. Their distinctive transcriptional and spatial profiles associate with aggressive tumor phenotypes, highlighting potential diagnostic and prognostic relevance in pancreatic cancer.

#1590 The oncometabolite D2HG reprograms macrophages to drive immunosuppression in IDH1-mutant cholangiocarcinoma.

Sara E. Young[1], Emma Kartalia[1], Johnathan DeBetta[2], James Leatherman[1], Kayla J. Bendinelli[1], Tamara Lopez-Vidal[1], Edwin Y. He[3], Mark Yarchoan[4], Daniel J. Zabransky[3]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD,[3]Johns Hopkins University, Baltimore, MD,[4]Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Background: Intrahepatic cholangiocarcinoma (CCA) is an aggressive primary liver cancer, with ~20% of cases driven by mutations in isocitrate dehydrogenase 1 (mIDH1). Compared with IDH1 wild-type tumors, mIDH1 CCA exhibits an immunosuppressive microenvironment enriched for M2-like macrophages and may derive reduced benefit from immune checkpoint therapy than the general CCA population, suggesting tumor-immune interactions contribute to therapeutic resistance. mIDH1 tumors secrete the oncometabolite D2HG, but its effects on macrophages within the tumor microenvironment (TME) remain incompletely understood.
Methods: We exposed THP-1 monocytes, a human myeloid leukemia cell line commonly used to model macrophage differentiation, and PBMC-derived macrophages to D2HG. Flow cytometry, RT-qPCR, and Luminex were used to assess expression of immunosuppressive markers (CD206, CD163, IL-10) and cytokine secretion (IL-10, IL-4, IL-13). Lipid uptake and accumulation was quantified by BODIPY staining, and CD36 expression was measured by flow cytometry and RT-qPCR. Seahorse metabolic assays and fatty acid oxidation analyses evaluated metabolic activity, while phagocytosis assays with live-cell imaging assessed macrophage function.
Results: Exposure to pathologically relevant levels of D2HG that mirror those in the mIDH1 TME led THP-1 and PBMC-derived macrophages to upregulate immunosuppressive markers including CD206, CD163, and IL-10, while also increasing secretion of IL-10, IL-4, and IL-13. Functionally, D2HG-treated macrophages showed a 51% reduction in phagocytic capacity compared to untreated cells. Mechanistic studies revealed that D2HG enhanced lipid uptake and strongly upregulated the lipid transporter CD36. Despite increased lipid accumulation, Seahorse analyses and fatty acid oxidation assays showed no rise in energy production, indicating lipids were not metabolically utilized. BODIPY staining confirmed neutral lipid accumulation, supporting the development of a lipid-laden macrophage phenotype. Metabolic lipidomic analyses of mIDH1 tumors revealed higher lipid content than IDH1 wild-type tumors, suggesting that the mIDH1 CCA TME is enriched in lipids. This tumor-derived lipid abundance, together with D2HG-induced upregulation of lipid uptake in macrophages via CD36, likely promotes a cooperative process in which macrophages take up excess lipids, reinforcing their lipid-laden, immunosuppressive phenotype.
Conclusion: The oncometabolite D2HG reprograms macrophages into a lipid-rich, metabolically altered, immunosuppressive state. This mechanism reveals how mutant IDH1 tumors shape the immune microenvironment and highlights CD36 and lipid metabolism as potential therapeutic targets to restore antitumor macrophage function in mIDH1 CCA.

#1591 microRNA-25 drives initial resistance to immune checkpoint therapy by repressing innate and humoral immunity via Syndecan3.

Zhouting Zhu[1], Wenyan Han[2], Yufei Deng[3], Zhaoyang Jia[2], Lujing Wu[2], Shweta Jakhmola[2], Gulshanbir Baidwan[2], Tongyun Wang[2], Dhenugen Logeswaran[2], Amanda Y. Sun[2], Bill Bray[2], Na Li[2], Lingling Wang[2], Hui Hui[2], Jiaqian Wu[1], Sandip Pravin Patel[4], Tariq M. Rana[2]

[1]Graduate School of Biomedical Sciences, Sanford Burnham Prebys Institute, La Jolla, CA,[2]Department of Cellular and Molecular Medicine, University of California San Diego, La Jolla, CA,[3]Cancer and Cell Biology program, Graduate School of Biomedical Science, Baylor College of Medicine, Houston, TX,[4]San Diego Center for Precision Immunotherapy, Moores Cancer Center, La Jolla, CA

Immune Checkpoint Therapy (ICT) has demonstrated durable responses and long-lasting immunologic memory in cancer treatment. However, overcoming primary and acquired resistance remains a major challenge. Here, we show that CRISPR-Cas9-mediated deletion of miRNA-25 (miR-25) sensitizes tumors to cancer immunotherapy across three syngeneic mouse tumor models. Single-cell RNA sequencing (scRNA-seq) of the tumor microenvironment (TME) revealed that miR-25 deficiency induces innate immunity by upregulating major histocompatibility complex class II (MHC II) in antigen-presenting M1-like macrophages and enhances the classical complement cascade in cancer-associated fibroblasts (CAFs) to drive a humoral immune response. The complement activation polarizes CAFs from myofibroblastic CAFs (myCAFs) toward inflammatory CAFs (iCAFs) while simultaneously reduces immune-suppressive interactions between CAFs and tumor associated macrophages (TAMs). This shift results in a reduced macrophage population and fosters a pro-inflammatory, anti-tumor TME. Syndecan-3 (Sdc3), a membrane proteoglycan expressed in tumors, is repressed by miR-25 through miRISC (microRNA induced silencing complex) upon IFN-γ exposure. Using an adenine base editor (ABE8e) to mutate the miR-25 binding site in the 3' untranslated region (3' UTR) of Sdc3 effectively overcomes the resistance. The repression of SDC3 by miR-25 is further validated in five human cancer cell lines upon IFN-γ exposure but remains unaffected in non-cancerous cells. These findings identify miR-25 as a key driver of initial resistance through the repression of SDC3 and demonstrate that miR-25 deletion or stabilization of SDC3 could transform immune resistant "cold" tumors into immune responsive "hot" tumors, offering therapeutic avenues to enhance cancer immunotherapy.

#1592 Age-driven changes in tumor-associated macrophages contribute to slower tumor growth in murine melanoma and breast cancer models..

Manasa Suresh[1], Marie Durr[1], Bryan Weselman[1], Xintang Li[1], Francisco Tapia Belmonte[2], Sonia Sebaoui[1], Adhithi Rajesh[3], Katherine Fisher[3], Megan Winakur[3], Matias Hepp[4], Alexis Salas-Burgos[2], Satish Noonepalle[1], Alejandro Villagra[1]

[1]Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC,[2]Concepcion University, Concepcion, Chile,[3]Georgetown University, Washington, DC,[4]Universidad Catolica de la Santisima Concepcion, Concepcion, Chile

Introduction: The global cancer incidences are significantly higher between 50 to 70 years of age and decline thereafter. The age-driven factors contributing to this decline beyond 70-75 years of age is unknown, but it can help identify novel anticancer targets. It is now well established that tumor-associated macrophages (TAMs) secrete angiogenic growth factors that promote an immunosuppressive tumor microenvironment (TME). While novel strategies try to modulate TAMs for anticancer benefits, the impact of aging is often neglected. We have previously characterized the changes in macrophage phenotype and functions with aging. Considering their significant role in the TME, this study further determines the changing landscape of TAMs with aging and their impact on melanoma and breast tumors.

Objective: To elucidate the impact of age-driven changes in tumor-associated macrophages in murine melanoma and breast cancer models.

Methods: Wildtype mice of four ages (2-3, 6-8, 12-14, and 22-24 months) were implanted with SM1 melanoma and 4T1 breast tumor cells. In addition to tumor growth kinetics, changes in macrophage, T cell, and NK cell populations within the aging tumors were determined. At the end of the study, single-cell transcriptomic and proteomic analyses were performed on CD45-positive and F4/80-positive cells, respectively, to characterize TAMs and their interactions with other immune cells with aging. To study the impact of cancer on macrophage aging, we compared RNA sequencing data from bone marrow-derived macrophages from tumor-bearing and healthy mice of the above four age groups. Using a multiplex ELISA, we also determined age-associated changes in the secretion profile of macrophage cytokines, chemokines, and growth factors.

Results: The melanoma and breast tumor growth kinetics were significantly slower in aged mice compared to younger mice. The macrophage population within melanoma tumors increased, whereas that within breast tumors decreased with aging. The aged TAMs, however, exhibited dysfunctional properties, including reduced secretion of cytokines, chemokines, and growth factors. The transcriptomic analyses of tumor-associated and bone marrow-derived macrophages highlighted a unique age-driven signature that complements previously observed changes in macrophage function with aging and emphasized the potential cancer-driven acceleration of macrophage aging. In addition to the secretome profile, changes in the epigenetic and metabolic landscapes of aged macrophages further identified potential targets contributing to slower tumor growth.

Conclusions: Aging of TAMs significantly affects tumor growth and the TME in murine melanoma and breast cancer models. The changes observed in transcriptomic and proteomic landscape further reveal the age- and cancer-driven impact on macrophages and their significance to cancer development.

#1593 Mitochondrial enzyme A promotes macrophage-dependent antitumor responses in colorectal cancer.

Lin Chung, Shi-Chuen Miaw

National Taiwan University College of Medicine, Taipei, Taiwan

Colorectal cancer (CRC) remains one of the leading causes of cancer-related mortality worldwide, with the immunosuppressive tumor microenvironment (TME) posing a major barrier to effective therapy. Previous studies have shown that the mitochondrial enzyme A promotes CRC progression and may represent a potential therapeutic target. However, enzyme A is also highly expressed in M1 macrophages, where it drives inflammatory gene expression, underscoring the need to clarify its role specifically within tumor-associated macrophages (TAMs). Our findings demonstrate that mice with a global deletion of enzyme A develop significantly larger tumors compared to littermate controls. Similarly, $LysM^{cre}$ mediated macrophage-specific knockout mice displayed a marked increase in tumor burden. Moreover, adoptive transfer of bone marrow-derived macrophages (BMDMs) suppressed tumor growth and prolonged survival, whereas enzyme A-deficient BMDMs failed to exert these antitumor effects. These results indicate that macrophage-intrinsic enzyme A is essential for effective antitumor immunity. Mechanistically, enzyme A deficiency in macrophages resulted in reduced frequencies and total numbers of IFN-γ^+, TNF-α^+, and granzyme B^+ tumor-infiltrating NK cells, indicating impaired NK-cell activation and cytotoxic function. Further analysis revealed that enzyme A regulates the expression of key macrophage-derived cytokines and chemokines, including Ccl2, Cxcl9/10, and Il12, that are critical for NK-cell recruitment and functional activation.

#1594 Cyproheptadine and its derivatives inhibit tumor growth by eliciting NK cell-mediated anti-tumor responses in bladder cancer.

Himani Kumari[1], Chin Pui Chan[1], Ciao-Ni Chen[1], Hsin-An Shih[2], Tsung-Yu Tseng[3], Chao-Ling Yao[3], Steven Lin[2], Cheng-Huang Shen[4], **Michael W.Y. Chan**[1]

[1]National Chung Cheng University, Chiayi County, Taiwan,[2]Academia Sinica, Taipei, Taiwan,[3]National Cheng Kung University, Tainan, Taiwan,[4]Ditmanson Medical Foundation Chia-yi Christian Hospital, ChiaYi, Taiwan

Bladder cancer, the second most common malignancy of the urothelial system, exhibits a strong capacity to evade innate immune surveillance through multiple pathways, underscoring the need for innovative therapeutic strategies. We previously observed that cyproheptadine (CPH) induces anti-tumor effects in bladder cancer, although the underlying mechanism remained unclear. In this study, RNA-seq analysis of CPH-treated BFTC905 bladder cancer cells revealed significant enrichment of natural killer (NK) cell-mediated anti-tumor immune responses following CPH exposure. Using *in vitro* co-culture systems, we demonstrated that pre-treatment with CPH or CPH-SAHA conjugates markedly enhanced NK cell-mediated killing of bladder cancer cell lines by NK-92 cells and by human primary NK cells. This enhancement results from the epigenetic activation of NKG2D ligands, driven by increased H3K27ac and reduced H3K27me3 enrichment at the ULBP2 promoter in bladder cancer cells. *In vivo*, treatment with CPH in a syngeneic MB49 bladder cancer mouse model significantly suppressed tumor growth and increased NK cell infiltration. This elevated infiltration is likely mediated by upregulated expression of the NK-recruiting chemokine CCL3 in CPH-treated urothelial cancer cells. In conclusion, our findings demonstrate that CPH suppresses tumor growth and enhances immune surveillance by modulating epigenetic pathways that activate NK cell responses. These results highlight CPH and its derivatives as promising candidates for developing new immunomodulatory therapies for bladder cancer.

#1595 Combining DNA methylation inhibition and STING agonist in the treatment of metastatic triple-negative breast cancer.

Sofiane Berrazouane[1], Rhea Dumitrescu[1], Xiaoting You[2], Jack Su[1], Margarita Bartish[3], Marios Langke[1], Benjamin Lebeau[4], Young Im[1], Valerie Sabourin[1], Sonia del Rincon[1], Josie Ursini-Siegel[1], Michael R. Witcher[1]

[1]McGill University, Montreal, QC, Canada,[2]University of Toronto, Toronto, ON, Canada,[3]Karolinska Institutet, Stockholm, Sweden,[4]Nanyang Technological University, Singapore, Singapore

Triple negative breast cancer (TNBC) is an aggressive cancer associated with early metastatic events leading to a poor prognosis. According to the American Cancer Society, the 5-year relative survival rate is 91% in patients with localized TNBC but only 12% for those with distant metastatic TNBC. Thus, there is an urgent need to understand the mechanisms that drive TNBC metastasis to uncover more effective therapeutic approaches. In this regard, we profiled RNA Seq and DNA methylation in 8 metastatic TNBC cell lines with lung, liver, and bone organotropism compared to 3 parental TNBC lines. RNA-Seq revealed downregulation of IFN-I pathways associated with metastatic organotropism in the lung, liver and bone. Surprisingly, DNA methylation is enriched within the promoters of STING/IFN-related genes in these metastatic TNBC cells. In line with these findings, the analysis of TCGA human TNBC tumors showed a decreased expression of STING, an IFN-I pathway activator, in metastases versus primary tumors. In addition, a low STING expression associates with poorer TNBC patient survival. Consistent with transcriptomic data, the treatment with decitabine, a DNA methylation inhibitor, restored IFNβ and STING expression in metastatic TNBC cells, supporting epigenetic silencing with decitabine. Furthermore, combining decitabine with a STING agonist synergistically reduced viability in metastatic TNBC lines, indicating that targeting DNA methylation and activating the IFN-I pathway may represent therapeutic vulnerabilities in metastatic TNBC. More importantly, the decitabine/STINGa therapy showed a potent effect in targeting TNBC metastatic lesions in vivo with lung and liver organotropisms and increased the median survival of mice by almost 50% compared to the control single drug-treatment groups. Mechanistically, the inhibition of IFNβ with specific blocking anti-IFNβ mAb and the knockdown of TBK1, a mediator of IFN-I pathway, both abrogate the synergy between decitabine and STINGa in targeting metastatic tumor xenografts suggesting that the decitabine/STINGa targets metastatic TNBC via TBK1/IFNβ pathway. Furthermore, the spectral flow cytometry profiling of metastatic TNBC xenografts revealed that decitabine/STINGa therapy significantly enhanced NK cell infiltration and activation within metastatic tumors. Finally, the in vivo NK cell depletion showed that decitabine STINGa therapy is dependent on NK cells in treating metastatic TNBC. Altogether, this work suggests that the DNA methylation inhibition with decitabine and the stimulation of the IFNβ pathway with STINGa represent a new approach to efficiently target the metastatic TNBC that currently lacks effective targeted therapies and immunotherapies. This study also brought new evidences that decitabine/STINGa combination therapy is dependent on the TBK1/IFNβ pathway and NK cells in targeting metastatic TNBC in vivo.

#1597 A spontaneous arthritis mouse model driven by TNF-α overexpression.

Qingqing Qi, Shuang Li, Xiaolei Qiu, Yi Li, Ruilin Sun

GenoBioTX LLC, Sugar Land, TX

Rheumatoid arthritis (RA) is the most prevalent autoimmune arthropathy characterized by persistent inflammation, pain, swelling and progressive destruction of the synovial joints. Tumor necrosis factor α (TNFα) plays a central role in the autoimmune response leading to RA, as evidenced by the significant therapeutic benefits observed upon its inhibition. However, certain inhibitors targeting human TNFα (hTNFα), such as Infliximab, failed to cross-neutralize mouse TNFα (mTNFα). This limitation has impeded mechanistic and therapeutic investigations of hTNFα inhibitors *in vivo*, necessitating the development of humanized mouse models expressing hTNFα.Here, we developed an hTNFα transgenic mouse model (hTNFα-Tg) in C57BL/6 background, which carries the native promoter and coding sequences of the human *TNFα* gene, thereby driving robust overexpression of the human TNFα, as a relevant model for RA. By measuring serum hTNFα levels through ELISA following LPS stimulation, we confirmed significant overexpression of both hTNFα and endogenous mTNFα. Regarding the RA phenotype, macroscopic evaluation of arthritis revealed visible joint swelling in hTNFα-Tg mice compared to wild-type mice. Micro-CT imaging further confirmed prominent joint bone loss in hTNFα-Tg mice, validating their utility as an RA mouse model. To assess the in vivo therapeutic efficacy of hTNFα-targeted inhibitors, we administrated Infliximab to hTNFα-Tg mice and observed that Infliximab significantly reduced pathological scores of joint swelling and paw thickness, along with a significant increase in body weight gain. Concurrently, the treated mice exhibited amelioration of the joint space widening caused by bone destruction or inflammation, as well as phalangeal deformity.Overall, our hTNFα-Tg mouse model provides a powerful preclinical platform for the development of drugs targeting the hTNFα protein and for evaluating their efficacy and toxicity in vivo.

#1598 Preclinical efficacy of a bispecific NK cell engager studied using a humanized multiple myeloma mouse model.

Mari I. Suominen[1], Katja M. Fagerlund[1], Mervi Ristola[1], Justyna Zdrojewska[1], Yumei Diao[2], Carina Norstrom[2], Kristina Witt-Mulder[2], Ellen Santangelo[2], Thorstein Boxaspen[3], Hannah Cuthbertson Husbyn[3], Kim A. Giang[4], Caterina Heinz[5], Silje Z. Krokeide[3], Fredrik Schjesvold[6], Per-Ake Nygren[4], Ebba Sohlberg[5], Karl-Johan Malmberg[3], Stefan Svensson Gelius[2], Jukka P. Rissanen[1], Jenni H. E. Maki-Jouppila[1]

[1]Pharmatest Services Ltd., Turku, Finland,[2]Oncopeptides, Stockholm, Sweden,[3]Institute for Cancer Research, Oslo University Hospital, University of Oslo, Oslo, Norway,[4]KTH Royal Institute of Technology, Stockholm, Sweden,[5]Karolinska Institutet, Stockholm, Sweden,[6]Oslo University Hospital, Oslo, Norway

Natural killer (NK) cells are an essential part of the innate immune system as they can recognize and eliminate various cells in distress, such as virus-infected and tumor cells. Several promising therapeutics based on NK cell function are currently being developed and under preclinical and clinical investigation. This study aimed to evaluate the efficacy of an affibody-derived bispecific NK cell engager engineered to target CD16a on NK cells and BCMA on multiple myeloma (MM) cells, both *in vitro* and *in vivo*.

In vitro, efficient lysis of MM cells was observed across a panel of cell lines with varying BCMA expression using NK cells from healthy donors. The bispecific engager also achieved MM cell clearance in a 48-hour real-time cytotoxicity assay at a 2:1 effector-to-target ratio when combined with ADAPT-NK cells—*ex vivo* expanded adaptive NK cells from healthy donors (Haroun-Izquierdo A et al., J Immunother Cancer 2022). The engager did not induce IL-6 release measured in the presence of PBMCs and target cells.

In vivo, a humanized mouse model of MM was used to assess preclinical efficacy of the engager. In this model, human MM.1S cells - tagged with GFP and luciferase (BPS Bioscience) and xenograft-derived from mouse bone marrow - were combined with ADAPT-NK cells. The NSG-Tg(huIL-15) mice (The Jackson Laboratory) were given an intravenous injection of 0.5 million bone marrow-derived MM.1S cells, and tumor growth was followed by bioluminescence imaging (BLI). At study day 4, the dosing of the engager was started and continued daily until study day 18. Belantamab was used as a positive control and administered every fourth day, for a total of four doses, beginning on study day 4. ADAPT-NK cells were administered on study days 4, 8 and 13. Blood samples were obtained for flow cytometry throughout the study, and the mice were sacrificed on study day 33 when bone marrow was harvested for flow cytometry analysis.

Body weight developed similarly in all groups. Inhibition of tumor growth was observed by BLI from day 18 onward in the engager-treated group in comparison to vehicle controls. In the *ex vivo* BLI, lower tumor burden was observed in bones, liver, lungs and spleen in the engager treated group compared to the control. Flow cytometry of bone marrow showed fewer BCMA+CD138+ cells, indicating MM cells, in the engager- and belantamab-treated groups compared to vehicle controls.

These findings support the potential of the bispecific NK cell engager combined with ADAPT-NK cells as a treatment for MM. The study also demonstrates the utility of the humanized MM mouse model for evaluating NK cell engagers using BLI and flow cytometry.

#1599 mTOR enables alveolar macrophage survival and GM-CSF-STAT5-PPARγ signaling: Genetic and temsirolimus evidence.

Samson Hennessy-Strahs[1], Xiaojun Su[2], Si Sun[2], Ge Deng[2], Wen Muo[2], Tasha Miller[2], Xiang Xiao[2], Xian C. Li[2]

[1]Texas A&M College of Medicine, Bryan, TX,[2]Immunobiology and Transplant Science Center, Houston Methodist Research Institute, Houston, TX

Mechanistic target of rapamycin (mTOR) inhibitors, widely used in transplant and oncology settings, can induce a noninfectious pneumonitis linked to disrupted alveolar macrophage (AM) function. AMs uniquely require granulocyte-macrophage colony-stimulating factor (GM-CSF) signaling through CSF2RA, STAT5, and PPARγ to maintain identity and survival, yet the extent to which mTOR participates in this pathway in AMs remains undefined. Given that alveolar and interstitial macrophages (IMs) occupy distinct microenvironments with potentially divergent dependencies, the purpose of this study was to determine whether AMs exhibit a unique, non-redundant requirement for mTOR downstream of GM-CSF and how this requirement preserves AM survival and alveolar niche homeostasis.

To investigate mTOR dependence in AMs, we generated conditional myeloid mTOR knockout mice ($LysM^{Cre}mTOR^{f/f}$) and performed lung histopathology, flow cytometry, and signaling analyses across AMs and IMs. GM-CSF stimulation assays evaluated STAT5 phosphorylation in wild-type versus knockout AMs. Bone-marrow cultures were used to generate AM-like cells with GM-CSF to test mTOR-dependent differentiation and survival. WT AM-like cells were treated with rapamycin and GM-CSF. Intraperitoneal temsirolimus was administered to WT mice three times per week at 30 mg/kg/wk for four weeks. Human Protein Atlas datasets were interrogated for expression patterns of key signaling pathways in human AMs.

$LysM^{Cre}mTOR^{f/f}$ mice were generated and developed pulmonary alveolar proteinosis with AM loss, lipid-laden foamy AMs, and surfactant accumulation, while IMs and other tissue macrophages remained intact, indicating niche-specific mTOR dependence. Temsirolimus produced a similar AM depletion in vivo. AMs displayed higher baseline mTOR activity, CSF2RA, phosphorylated STAT5, and PPARγ than IMs. GM-CSF induced robust STAT5 phosphorylation in wild-type but not knockout AMs, whereas IMs showed neither basal nor inducible STAT5 activation. Human datasets demonstrated concordant AM-selective enrichment of CSF2RA, JAK2, STAT5, mTOR, phosphorylated S6, PPARγ, C/EBPβ, and downstream effectors (CD36, MerTK, Bcl-2 family proteins).

In vivo, mTOR-deficient AMs underwent progressive apoptosis with loss of PPARγ despite preserved CSF2RA. *In vitro*, GM-CSF drove AM-like differentiation marked by Siglec F, CD206, and CD11c regardless of genotype. In contrast, mTOR-deficient AM-like cells failed to upregulate p70 S6 kinase, C/EBPβ, PPARγ, CD36, MerTK, Bcl-2, and Bcl-xL. Rapamycin impaired survival of wild-type AM-like cells in a dose-dependent manner, partially rescued by increasing GM-CSF.

Together, these findings identify mTOR as a non-redundant regulator of GM-CSF survival signaling in AMs—a dependency absent in IMs—supporting an AM mechanism for mTOR inhibitor-associated alveolar injury.

#1600 Improved humanization of peripheral blood mononuclear cells in NSG-SGM3xIl15xDKO (SDKO) over that of NSG-MHC I/II DKO mice for immuno-oncology modeling.

Leandro Salati D'Abronzo, Xiaoqing (Nancy) Zheng, Beau Parry, Guoxiang Yang, Destanie Rose, Li-Chin Yao, James Keck, Jiwon Yang

The Jackson Laboratory-West, Sacramento, CA

Introduction Immunotherapies are the largest growing therapeutics applied to cancer and autoimmune disorders, rapidly transforming the drug development landscape. Despite significant improvements in immunotherapy research and available treatments, ample variation in clinical outcomes exposes gaps in our understanding of their mechanisms of action and specific response biomarkers. The development of the NSG-MHC I/II double-knockout (DKO) mice improved significantly the availability of models that can delay graft-versus-host disease (GvHD) while still achieving strong T cells engraftment. Nonetheless, DKO mice perform better with irradiation and engraftment with high doses of PBMCs to achieve these results and there is a challenge on producing multilineage human immune subsets such as natural killer (NK) cells and myeloid populations. Here, we characterize a next-generation DKO strain, SDKO (NSG-SGM3xIL15xDKO) designed for enhanced humanization with lower PBMC doses and improved immune diversity without the need for irradiation.

Methods Nonirradiated SDKO (Jax #037320, n=20) and DKO (Jax #025216, n=20) mice between 7-10 weeks of age were intravenously (IV) injected with 10 million PBMC using a total of five different donors. Mice were bled weekly via retro-orbital bleeds to assess engraftment status up for 12 weeks. Half the mice per strain were euthanized at SD21 for spleen engraftment checks. Survival was assessed up to 84 days.

Conclusions Survival between the two strains was comparable throughout the entire length of the studies. The newly developed mouse strain, NSG-SGM3xIL15xDKO (SDKO) offers improved overall humanized engraftment over the industry standard NSG-MHC I/II double-knockout (DKO), with higher hCD45+ numbers than DKO strain without the need for irradiation. Also, the SDKO strain present a higher T cell subpopulation (CD4+ and CD8+), higher number of Natural Killer (CD56+) cells and B (CD19+) cells. Noteworthy, SDKO presents high number of differentiated Plasma Cells (CD138+) in the spleen, a population that is not usually observed in engrafted DKO strain. Based on these results, we conclude that the novel SDKO mice better recapitulates the development of human innate and adaptive immunity than its counterpart DKO model.

#1601 A novel preclinical tool to unlock the potential of IL-18 in cancer immunotherapy: genO-hIL-18-hIL-18R mice.

Angela Pappalardo, Gaelle H. Martin, Patricia Isnard-Petit, **Fabiane Sonego**, Kader Thiam

genOway, Lyon, France

Interleukin-18 (IL-18) has emerged as a promising immunomodulatory cytokine in immuno-oncology due to its ability to enhance both innate and adaptive immune responses. It promotes IFN-γ production by T and NK cells, thereby amplifying anti-tumor immunity, especially when combined with checkpoint inhibitors or engineered pro-drugs to resist natural inhibition by IL-18BP. Recent studies suggest that IL-18-based therapies may overcome resistance mechanisms in "cold" tumors, making them more responsive to immunotherapies. Humanized mouse models expressing human IL-18R are essential to accurately assess efficacy and guide development of human-directed IL-18-based therapies. Therefore, we describe here a new IL-18-IL-18R double humanized mouse model to assess the efficacy of therapeutics targeting the IL-18/IL-18R axis. The generated genO-hIL-18-hIL18-R mice show expression of human IL-18Ra on NK, monocytes and T cells under steady state conditions. Functional validation of genO-hIL-18/hIL18-R mice demonstrates robust *in vitro* IFN-γ production by splenocytes upon stimulation with exogenous human IL-18, suggesting that hIL-18R is functional. Similarly to mouse IL-18 in wild-type mice, human IL-18 is not detected in naïve mice. However, its secretion can be induced *in vivo* by treatment with lipopolysaccharide (LPS), which also triggers IFN-γ secretion. Importantly, humanization of the IL-18/IL-18Ra axis does not alter the physiological distribution of immune cells, as immune-profiling reveals comparable frequencies of main immune cells between genO-hIL-8-hIL-18R mice and wild-type control mice. Finally, the effectiveness of the genO-hIL-18-hIL-18R model in supporting drug efficacy was demonstrated by evaluating an engineered IL-18. Splenocytes from genO-hIL-18-hIL-18R mice treated with this engineered IL-18 exhibited enhanced cell proliferation and increased IFN-γ production compared to those treated with an inactive IL-18. Altogether, these data support the suitability of the genO-hIL-18-hIL-18R mice for assessment of new therapies targeting this axis.

#1602 Quaking regulates macrophage MHC II-mediated antigen presentation and immune function in glioblastoma.

Spring Yewon Hwang

Cancer Biology, MD Anderson, Houston, TX

Glioblastoma (GBM) remains one of the most lethal brain tumors, in part due to profound immunosuppression driven by tumor-associated macrophages (TAMs). A central deficit within the GBM microenvironment is the failure of macrophages to execute effective MHC class II (MHC II)-mediated antigen presentation, a process essential for priming anti-tumor $CD4^+$ T cell responses. We identified the RNA-binding protein Quaking (Qki), frequently lost or mutated in GBM, as a critical regulator of macrophage antigen processing and presentation.

Across human GBM datasets and the QPP (Qki-/-; Trp53-/-; Pten-/-) glioma model, Qki expression positively correlates with MHC II and its master regulator CIITA. Using bone marrow-derived macrophages, we found that Qki deficiency does not impair IFNγ-driven induction of MHC II transcripts. However, Qki knockout (KO) macrophages were unable to effectively activate $CD4^+$ T cells in OT-II co-culture assays, indicating a defect downstream of transcription. Functionally, phagocytosis and DQ-OVA assays revealed that Qki KO macrophages display reduced phagocytosis and proteolytic activity, suggesting that Qki mediates multiple steps of antigen processing and presentation.

To define Qki-dependent programs, we performed RNA sequencing in wild-type and Qki-KO macrophages. Qki loss led to coordinated downregulation of pathways involved in extracellular matrix interactions, focal adhesion signaling, and protein uptake. Using qPCR, we confirmed decreased expression of key regulators, including Cav1 and Thbs1, demonstrating that Qki orchestrates post-transcriptional programs that enable cytoskeletal dynamics, vesicle trafficking, and antigen processing required for MHC II function.

To explore therapeutic potential, we tested the Qki co-activator agonist KD3010, which enhanced MHC II expression and $CD4^+$ T cell activation in vitro, and improved survival in QPP mice. Proteomic analysis identified osteopontin (OPN), a protein elevated in GBM, as a tumor-derived factor suppressing Qki. In vitro, OPN treatment reduced Qki expression in macrophages, suggesting that it acts as a mechanism of immune suppression.

In conclusion, our findings identify Qki as a central regulator of macrophage antigen processing and MHC II functionality and uncover a GBM-driven pathway that disrupts this axis. Restoring Qki represents a promising strategy to reawaken macrophage immunity in glioblastoma.

#1603 Opposing control of MHC-II antigen presentation by FAK and PYK2: Implications for therapeutic intervention.

Terrance James Haanen[1], Xiao Lei Chen[1], David D. Schlaepfer[2]

[1]Obstetrics, Gynecology, and Reproductive Sciences, University of California, San Diego, San Diego, CA, [2]University of California, San Diego, San Diego, CA

High-grade serous ovarian cancer (HGSOC) is the most lethal gynecologic malignancy in the U.S. and is marked by resistance to chemo- and immunotherapy. Although focal adhesion kinases (FAK and PYK2) are known to induce tumor microenvironment immunosuppression, their role in altering tumor-cell major histocompatibility complex class-II (MHC-II) presentation requires further investigation. HGSOC tumors have few mutations but frequently show FAK amplification (~75%). Notably, elevated MHC-II expression correlates with longer progression-free survival in recurrent HGSOC, likely through enhanced $CD4^+$ T-cell activation and improved anti-tumor immunity. Flow cytometry analysis revealed that ATP competitive small molecule inhibition of FAK kinase activity (FAKi) increases MHC-II antigen presentation *in vitro and in vivo*. Targeted FAK protein degradation following treatment with a FAK proteolysis targeting chimera (FAK-PROTAC) produced a similar effect. In a syngeneic orthotopic mouse model, FAK depletion induced MHC-II to levels comparable to kinase-dead FAK, consistent with the loss of FAK activity in promoting tumor MHC-II expression. As ovarian tumor cells also express the FAK-related homolog PYK2, CRISPR was employed to selectively inactivate FAK and or PYK2 expression in human OVCAR3, murine KMF, and murine HGS2 ovarian tumor models. Notably, loss of FAK, but not PYK2, resulted in enhanced MHC-II presentation in these cells. As tumor cell treatment with a dual FAK-PYK2 inhibitor or PROTAC that targets FAK and PYK2 does not induce MHC-II expression as does selective loss of FAK, our results support a distinct immunogenic role for PYK2 in ovarian tumor cells. Ongoing studies are evaluating PYK2 mechanism of action upon FAK inhibition and the regulation of CIITA (class II, major histocompatibility complex, transactivator) transcription. Collectively, our findings suggest roles for FAK-specific inhibitors that may potentiate MHC-II-related adaptive immune responses as a therapeutic strategy for advanced ovarian cancer.

#1604 PTEN-L/CD68 axis regulates diet-induced obesity, monocyte-to-macrophage polarization, and signaling via IL-4 and AKT pathways.

Tiphaine C. Martin[1], Sait Ozturk[1], Benjamin Kepecs[1], Nicolas de Azevedo[1], Ivan Reyes-Torres[1], Royce Zhou[1], Kaitlyn Bosch[1], Emily Gallagher[1], Miriam Merad[2], Ang Cui[3], Alexander Tsankov[1], Ramon Parsons[1]

[1]The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY,[2]Precision Immunology Institute, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY,[3]Harvard Medical School, Boston, MA

Obesity has emerged as a major health issue in the developed world, including in the development and treatment of cancer. Immune regulation is crucial for maintaining adipose tissue balance; however, the early events that convert a noninflammatory state to inflammation, contributing to obesity and cancer, remain poorly understood. PTEN is well known as a tumor suppressor that inhibits the PI3K/AKT pathway and has been linked to cancer, obesity, and macrophage (MΦ) function. However, the role of its secreted isoform, PTEN-L, remains unclear. We previously observed that PTEN-L affects the function of MΦs in mice during *Pseudomonas aeruginosa* infection and tumor development. Here, based upon a yeast two-hybrid screen, we identified that PTEN-L interacts with CD68, a MΦ marker encoding a scavenger receptor with an unknown function. We studied PTEN-L and CD68 in the context of induced obesity with a high-fat diet (HFD) by knocking them out in mice. We observed that CD68 facilitates entry of PTEN-L into MΦs and human tumor cells, and that Pten-l and Cd68 knockout mice fed a HFD are protected from obesity. Adipose tissue from Pten-l and Cd68 knockout mice exposed to a HFD showed similar immune phenotypes, including expansions of $CBR2^{+}$ and immature monocyte-derived MΦs and depletion of $Apoe^{+}$ and lipid-associated MΦs, which displayed characteristics of IL-4-stimulated polarization and elevation of AKT activation. Our findings suggest that Pten-l and Cd68 play a role in regulating MΦ polarization by attenuating IL-4-AKT signaling and are important factors in the high-fat diet-induced remodeling of white adipose tissue, contributing to obesity and insulin resistance. Interestingly, treating patients with Atopic Dermatitis using an antibody targeting the IL-4 receptor has been demonstrated to be associated with a noteworthy increase in body weight. Meanwhile, IL-4 influences the phenotype of tumor-infiltrating monocyte-derived MΦs and plays a role in mediating resistance to immunotherapy through macrophage regulation. Thus, we define a mechanism of adipose tissue homeostasis controlled by the expression of PTEN-L and CD68 in myeloid populations, which may have clinical relevance for immune and metabolic responses due to PI3K/AKT inhibitor and IL4R targeted therapy.

#1605 Motif neoepitopes demonstrate immunogenic signal in CCL21-gene modified dendritic cell vaccination trial (NCT03546361).

Amy Lauren Cummings[1], Andy Han[1], Michael Oh[2], Camelia Dumitras[2], Seung J. Park[1], Sai S. Kollapaneni[1], Daniel Li[1], Arjan Gower[2], Maria Antonia Velez Velez[3], Aaron Lisberg[2], Monica Cappelletti[1], Steven M. Dubinett[2], Bin Liu[2], Edward B. Garon[4]

[1]UCLA Health, Los Angeles, CA,[2]UCLA David Geffen School of Medicine, Los Angeles, CA,[3]UCLA - University of California Los Angeles, Los Angeles, CA,[4]Asst. Prof., Dept. of Hem./ Onc., University of California (UCLA), Santa Monica, CA

Background: Inefficient prediction of functional tumor neoantigens and subsequent host anti-tumor immune responses limit optimization of immunotherapeutic approaches. We recently demonstrated that programmed cell death 1 inhibitors have greater efficacy in those with charged human leukocyte antigen (HLA)-B binding pockets whose tumors harbor mutation(s) leading to “motif” neoepitopes (those that generate new charged HLA anchors). Whether peptides derived from motifs are capable of inducing host tumor-specific immune responses was previously unknown.

Methods: Matched tumor and peripheral blood mononuclear cell (PBMC) biospecimens from participants (pts) in NCT03546361 underwent whole exome sequencing (WES) and HLA/supertype/neoepitope prediction using established pipelines. Pts were grouped as (1) 1+ B44/B27 allele with 1+ motif, (2) B44/B27 without motifs, and (3) no B44/B27 alleles. For (3), neoepitope prediction was run with classic B44/B27 supertype alleles (B*40:01, B*27:05) as a negative control. Nonamer peptides were created from pt motif and non-motifs and their wildtype sequence. For those with more than 2 non-motifs, the highest variant allele fraction (VAF), lowest IC50 (binding), and/or highest fold change (fold) were selected. T-cell activation and expansion assays were run using pt PBMC collections on days 0, 21, 42, and 63 by co-incubating peptide-pulsed dendritic cells ($2x10^5$) with autologous CD8+ T cells ($2x10^6$) in RPMI containing 10% pooled human serum, 10 mM HEPES, 2mM L-Glutamine, and 50 µM β-mercaptoethanol supplemented with IL-15 (10 ng/mL) and IL-2 (50 IU/mL) for both 18 hours and 10 days. Negative controls included vehicle only (0.1% DMSO); positive controls included PMA (25 ng/mL), ionomycin (1 µg/mL) and BFA. Activated T cells were assessed by flow cytometry based on intracellular staining of INF-ɣ and TNF-α.

Results: 18 pts underwent analysis: 14 had sufficient WES, 11 exhibited a B44/B27 allele. Of these, 8 pts had predicted neoepitopes with VAF ≥10%: 3 pts were (1), 2 were (2), 3 were (3). From this cohort, 23 peptides represented 6 motif, 6 VAF, 4 binding, 4 fold, and 3 multiple categories. Positive controls yielded activated T cell peaks at day 42 (4.78%). One participant in the B44/B27 motif category (1) had one peptide that elicited T cell activation at day 42 (2.51%), which was motif/VAF, and confirmed in a subsequent assay (0.63%). All other peptide experiments did not demonstrate T cell activation, and there were no pts who demonstrated meaningful clinical benefit from the trial.

Conclusion: Current neoepitope prediction continues to provide limited insight into functionality. In a limited sample size of those without clinical benefit to NCT03546361, possible functionality of one motif neoepitope was demonstrated. Additional studies are ongoing to validate these findings and further define the functional relevance of motif neoepitopes.

#1606 Transcriptional regulation of human NK cells: TAL1 as a modulator.

Baomou Feng, Dandan Wang, Subramaniam Malarkannan

Molecular Immunology, Versiti Blood Research Institute, Milwaukee, WI

Background - Natural killer (NK) cells are major cytotoxic lymphocytes subset with potent activity against hematopoietic malignancies and are strong candidates for immunotherapy. However, their clinical application is limited by our incomplete understanding of the transcriptional programs that control NK cell development and function. Human NK cells development from hematopoietic stem cells to mature NK cells is orchestrated by a network of lineage-committing transcription factors (TF). TAL1—a class II basic helix-loop-helix TF—is essential for early hematopoiesis and is maintained in several mature myeloid lineages, but it is absent from mature B- and T-cells. However, we recently discovered that mature human NK cells express TAL1, making them a rare lymphoid population retaining TAL1 expression. We also identified three TAL1 isoforms, suggesting isoform-specific roles in NK cell maturation and function. This suggests that TAL1 may shape NK cell identity and function. We hypothesize that TAL1 is a previously unrecognized regulator of human NK-cell development and cytotoxic activity. To test this, we used (a) an inducible TAL1 knockout mouse model to identify TAL1-dependent checkpoints in NK cell development and (b) TAL1 overexpression in NK-92 cells to characterize TAL1 binding partners.

Method - For development and differentiation of NK cells, we generated an inducible *TAL1*$^{fl/fl}$*Mx1*^{Cre} knockout (KO) mouse model, in which poly(I:C) was used to activate Cre. Bone marrow and spleen tissues were then analyzed by flow cytometry. We used CRISPR/Cas9 to generate HEB, ID2, and E2A KO NK-92 cells and created a TAL1-overexpressing NK-92 line. Protein expression and interactions were assessed by Western blot and co-immunoprecipitation.

Results - TAL1 KO in mouse showed a significantly increased percentage of NK progenitor cells (CD3ε$^-$CD122$^+$NK1.1$^-$NCR1$^-$; 91.3% in KO vs 33.0% in WT) and a reduction of immature and mature NK cells (CD3ε$^-$CD122$^+$NK1.1$^+$ and CD3ε$^-$CD122$^+$NCR1$^+$) in the bone marrow compared to control. Co-immunoprecipitation of TAL1 in NK92 cells revealed protein interactions with methylase SETD1A, and E-proteins HEB, and ID2.

Conclusion - TAL1 KO mice show NK cell maturation arrested at the CD122$^+$NK1.1$^+$ progenitor stage, suggesting a central role for TAL1 in NK cell development. Co-immunoprecipitation in NK-92 cells revealed TAL1 interactions with SETD1A, HEB, and ID2. We propose that TAL1 forms a heterodimer with HEB that recruits the demethylase LSD1 to repress genes required for NK cell maturation. When ID2 joins the complex, it blocks LSD1 recruitment and instead brings in the methylase SETD1A to activate maturation-associated genes. Together, these findings raise the possibility that TAL1 recruits specific partners that influence NK cell maturation. Understanding the role of TAL1 in human NK cell development may enable the therapeutic modulation of NK cell function for clinical applications.

Poster Session

#1609 Unlocking pMHC target space for next generation T cell engagers in oncology and autoimmunity.

Roberto Magliozzi, Haydn Prosser, Hanif Ali, Amy Li, Luca Pellegrinet, Ni Huang, Petra Mlcochova, Wei Wang, Ruben Cabanillas, E-Chiang Lee, Allan Bradley

T-Therapeutics Ltd, Cambridge, United Kingdom

Peptide-MHC (pMHC) complexes represent a compelling and emerging class of targets for oncology and autoimmune diseases. Their presentation on the cell surface enables the targeting of peptides from non-membrane bound proteins which could be highly specific to pathogenic cells. The lack of disease cell-surface specific targets is currently limiting the potential of bispecific T cell engagers (TCEs) for solid tumours and autoimmune diseases. Despite their promise, pMHC targeting TCEs face two significant challenges. Firstly, a pMHC targeting entity needs to bind to the pMHC of interest with high affinity and specificity to ensure drug efficacy and safety. Secondly, since cell surface density of pMHC is generally low (typically ~10 -1,000 copies per cell), the bispecific format and anti-CD3 moiety need to work concordantly to mediate efficient killing with minimal cytokine release. We have developed unique technology platforms to overcome these major challenges for delivering first-in-class pMHC directed TCEs for solid tumours and autoimmunity. To harness the natural ability of TCRs to bind pMHC with high specificity and overcome the constraints for TCR discovery against self antigens in humans due to negative selection in T cell development, we generated a humanised transgenic mouse, OptiMus® mouse, by introducing human TCRα, TCRβ, CD8α, CD8β, HLA- A02, and β2M genes in situ by precision genome engineering. Over a decade, 1.6 million bases of human DNA were introduced into the mouse to fully humanise the entire TCRαβ repertoire, CD8 co-receptor and MHC class I. The immune compartment of this mouse strain is phenotypically normal, and importantly, it allows TCR discovery against human antigens without the self-antigen constraint. The diverse TCR repertoire produced by OptiMus® mouse enables the discovery of hundreds of antigen-reactive TCRs as a starting point for drug discovery. Drug efficacy at low pMHC target density requires a TCE format that is optimised for immune synapse engagement. The anti-CD3 moiety must be fine-tuned in terms of epitope selection and affinity modulation to maximize the therapeutic window. We have explored over 500 formats to identify a novel design in which a TCR, anti-CD3 and Fc are accommodated to allow efficient immune synapse formation and target cell killing, and which has an antibody-like developability and pharmacokinetics profile. Furthermore, we discovered de novo anti-CD3 moieties that are optimised with our format for desired properties: durable serial killing, high *in vivo* potency, low cytokine release and no T cell mediated drug disposition. By maximising the power of our technology platforms, from human TCR discovery to TCE engineering, we are advancing a pipeline of first-in-class TCEs for oncology and autoimmune indications. Our approach unlocks previously inaccessible targets and redefines the potential of TCEs in precision immunotherapy.

#1610 A novel and versatile Prodrug T cell engager platform with a novel candidate demonstrating potent and tumor-restricted activity.

Zhou Lv, Yinhui Ding, Jingjing Mao, Huifeng Lv, Yang Yang, Yi Ren, Yu Zhang, Lijun Wang, Danqing Wu, Xuan Wu, **Shiyong Gong**

Shanghai EpimAb Biotherapeutics Co., Ltd., Shanghai, China

T-cell engagers (TCEs) have emerged as a powerful modality of immunotherapies. However, their clinical application, particularly in solid tumors, is limited by on-target, off-tumor toxicities and potentially life-threatening systemic immune activation, such as severe cytokine release syndrome (CRS). To address these challenges, conditionally activated prodrug TCEs (ProTCEs) represent a promising next-generation strategy. Recent efforts have focused on masking either the CD3 binding domain or both CD3 and TAA (tumor associated antigen) binding domain of TCEs. The masking peptide is fused to ProTCE molecules usually through a cleavable linker that can be cleaved by tumor-specific proteases. Despite recent progress, there is still a challenge for balancing efficient masking and tumor-specific activation to achieve a wider therapeutic window. Here, we present a modular ProTCE design that includes a masking peptide screening platform, allowing rapid identification of masking peptides that effectively suppress the antibody binding ability. Moreover**,** we engineered a proprietary peptide linker that can be recognized and cleaved by multiple tumor specific proteases. This novel linker exhibits exceptional stability in serum to prevent systemic activation, while demonstrating enhanced cleavage efficiency by tumor-associated proteases, ensuring tumor-specific drug activation and exposure. In addition, our platform is flexible to generate single masking (mask CD3 binding domain) or dual masking (mask both TAA and CD3 binding domains) ProTCEs. With this platform, we have generated a pipeline of ProTCE molecules targeting various TAAs. Most notably, we have developed a ProTCE, EM33, targeting a TAA that is highly expressed on multiple solid tumors but also expressed on normal tissues at a low level. This molecule was designed to have both TAA and CD3 binding domains masked. EM33 exhibits minimal activity in its prodrug form; however, upon exposure to proteases, its activity is fully restored, demonstrating a 1000-fold therapeutic window. In a high density PBMC assay, our ProTCE does not induce T-cell activation and cytokine release, in contrast to its unmasked variant. In vivo, this molecule demonstrated significant tumor growth inhibition in multiple PBMC engrafted tumor cell xenograft models. EM33 also exhibited comparable anti-tumor activity to the unmasked TCE while inducing significantly less cytokine release, indicative of its potential enhanced benefit/risk ratio in human.Our ProTCE platform enables the rapid development of conditionally activated TCEs with an improved therapeutic window. The preclinical data for our first candidate highlights the potential of our platform to generate new TCE therapies for cancer patients targeting TAAs, that currently have posed significant safety and/or efficacy challenges to the classical T-cell engaging approach.

#1611 Development of a T cell engager against IGFBPL1: A novel target for small cell lung cancer and other neuroendocrine cancers.

Lauren A. Pitt, Eleanor Leung, Ruban Kannan, Shereen Jabar, Nicole Church, Zariah Rosenes, Ben Kiefel, Matthew Beasley

Myrio Therapeutics Pty Ltd, Melbourne, Australia

Small cell lung cancer (SCLC) is an aggressive neuroendocrine malignancy with dismal clinical outcomes defined by treatment resistance. FDA approval of tarlatamab, a T cell engager targeting DLL3, has delivered a new treatment option for patients with relapsed disease and spurred enthusiasm for T cell engagers and other DLL3-targeted therapies for SCLC. Notably, SCLC is transcriptionally complex with multiple molecular subtypes. Additional treatment options are required for DLL3-negative patients and to combat acquired resistance associated with intratumoral heterogeneity. Insulin growth factor binding protein-like 1 (IGFBPL1) is a member of the insulin-like growth factor binding protein (IGFBP) family, secreted proteins regulating the biological activity of insulin-like growth factors (IGFs). *IGFBPL1* is normally silenced in healthy adult tissues, but is highly expressed in SCLC, as well as other neuroendocrine-phenotype cancers, as shown in human cell lines and patient samples. Using Retained Display (ReD^{TM}) technology, we isolated several fully human single chain variable fragments (scFvs) specifically recognising a peptide derived from IGFBPL1 presented by HLA-A*02:01, one of the most common HLA alleles worldwide. We generated a half-life extended T cell engager based on a lead candidate scFv displaying picomolar range binding to the target IGFBPL1/HLA-A*02:01 complex. Potent killing of HLA-A*02:01-positive SCLC cell lines naturally expressing IGFBPL1 was observed in vitro, including models with low HLA surface expression - a common feature of SCLC. We are currently characterising IGFBPL1 expression at the total protein and surface peptide level, in addition to evaluation of in vivo efficacy and other IND enabling studies in progress. Our data support development of a novel T cell engager for SCLC based on IGFBPL1 targeting. This potential therapy provides another option to DLL3-targeting therapies in the clinic and under investigation, to overcome this challenging and devastating disease.

#1612 Novel CD3 binders enable T cell engagers with potent tumor control, limited cytokine release, and safe pairing with co-stimulation.

Sinduja Marx, Ian Blumenthal, Kristina Pilat, Shelli M. Morris, Emily J. Girard, Kenneth Brasel, Ray Ruff, Alison M. Williams, Hailey Hentschel, Steven Chen, Chunfeng Yin, James M. Olson, Jason Price

Seattle Children's Research Institute, Seattle, WA

Introduction: T cell engagers (TCEs) have demonstrated clinical promise in hematologic malignancies, but their application in solid tumors has been held back by significant side effects and limited efficacy. TCEs that bind CD3 with SP34-derived clones exhibit marked polyreactivity, leading to off-target activation and narrow therapeutic windows. Leveraging a unique nanoparticle-based immunization platform, we discovered non-polyreactive, non-human primate (NHP) cross-reactive CD3 binders, many against novel CD3 epitopes. As exemplified by a CD3δε selective clone, SCRI-6, these binders drive potent anti-tumor activity with reduced cytokine production. Our data suggests that these novel binders are uniquely positioned to pair with TCE designs that incorporate costimulation strategies to improve T cell antitumor activity and persistence.

Methods: Our antibody campaign used a novel immunization strategy in the OmniRat transgenic platform incorporating whole-cell and protein-nanoparticle immunogens. Identified hits from the campaign were produced as recombinant monoclonal antibodies and biochemically and biophysically characterized. Clinical benchmark TCEs incorporating our novel CD3 binders were evaluated for non-specific activation, antigen-dependent tumor-cell killing and cytokine release in vitro and in vivo.

Results: We identified 12 distinct sequence families, 7 of which bound and activated human T cells. Among these, 5 showed no detectable polyreactivity. Four clones recognized both CD3δε and CD3γε subunits, whereas one clone (SCRI-6) bound exclusively to CD3δε. Notably, 3 of these sequence families, including SCRI-6, also activated NHP T cells. TCEs (targeting PD-L1, DLL3, and CD19) that incorporate our novel CD3 binders demonstrated antigen-dependent cytotoxicity comparable to SP34-based TCEs but with reduced cytokine release (e.g., IFNγ, IL-2, TNFα, and IL-6). In an assay to assess tumor-independent activation of T cells, TCEs including SCRI-6 exhibit dramatically less non-specific T cell activation than matched-TCEs containing SP34. Adding CD28 or 4-1BB costimulation to this assay dramatically exacerbated the non-specific activation caused by SP34-containing TCEs; however, swapping the CD3 binder for SCRI-6 eliminated this activity. TCEs incorporating SCRI-6 demonstrate equivalent potency to clinical benchmark comparators in both solid and liquid in vivo tumor models, but with substantially lower cytokine release.

Conclusion: Non-polyreactive CD3 engagers may be incorporated into TCEs to improve therapeutic index without sacrificing potency and allowing for therapeutic strategies that safely engage T cell costimulatory targets.

#1613 Expanded therapeutic window of potent bispecific PD-L1:CD3 T cell engager using a novel best-in-class CD3 binder.

Andrew J. Mhyre, Emily J. Girard, Sinduja Marx, Shelli M. Morris, Kristina Pilat, Alison M. Williams, Parvathi Muthuraman, Ray Ruff, Hailey Hentschel, Steven Chen, Chunfeng Yin, Zachary Crook, Jason Price, James M. Olson

Seattle Children's Research Institute, Seattle, WA

Introduction: Bispecific T cell engagers (TCE) are potent, off-the-shelf immune modulators that have been hugely successful against hematologic malignancies and are beginning to demonstrate utility in solid tumors. PD-L1 targeting bispecific TCE with an SP34 variant CD3 binder showed exceptionally potent activity against intracranial tumor models in mice. To further expand the potential therapeutic index, we engineered SCRI-6, a novel, high-affinity, non-polyreactive CD3 binder, into a next generation PD-L1 TCE and compared the SP34 and SCRI-6 versions for efficacy and tolerability.

Methods: The efficacious dose range of systemically administered PD-L1:CD3 TCE was interrogated using SP34 or SCRI-6 CD3 binders against intracranially implanted NCI-H1975-GFP/ffLuc, modeling metastatic lung cancer. Activity of SP34 or SCRI-6 TCE with a murine PD-L1 binder was evaluated in mice transgenic for human CD3ε.

Results: Bioluminescent tumor burden of mice treated with the SP34 TCE was eliminated in 85-100% of mice across the entire dose range of 0.3 to 8.5 mg/kg. However, despite the loss of luminescent signal at 2.1, 4.2, and 8.4 mg/kg, 28-85% of these mice met humane end point criteria and were removed from study early, suggesting that these doses exceeded the maximum tolerated dose. SCRI-6 TCE eliminated bioluminescent tumor signal and 100% of mice remained healthy at doses from 0.03 to 2.12 mg/kg (the highest dose tested). Doses of 0.0005-0.008 mg/kg did not alter tumor growth, and the median survival was similar to the negative control group, establishing the lower limit of efficacy for this TCE. A dose titration from 0.01 to 5 mg/kg of both the SP34 and SCRI-6 TCE in human CD3ε transgenic mice showed pharmacodynamic responses with similar, modest, and transient loss of body weight and transient depletion of circulating lymphocytes at doses of 0.4-5mg/kg. Cytokines associated with cytokine release syndrome (IL-6, IFNγ and TNFα) were found to be elevated at higher levels in SP34 TCE treated mice compared to those in SCRI-6 TCE mice. INFγ was significantly higher in the SP34 TCE at 5, 2.5, and 0.1mg/kg ($p=0.03$, 0.05, and 0.01 respectively), TNFα at 5mg/kg ($p=0.003$), and IL-6 at 1.3mg/kg ($p=0.03$), suggesting a higher tolerated threshold for the SCRI-6-based TCE. In the NCI-H1975 brain metastases model, the SCRI-6 TCE induced complete and durable remissions for the entirety of the study, whereas remissions tended to be variable and transient with the SP34 version.

Conclusion: Incorporation of the novel SCRI-6 CD3 binder into a potent PD-L1 targeted TCE showed superior efficacy with lower cytokine secretion, demonstrating potential to expand the therapeutic index.

#1614 Novel anti-CD3 single domain antibodies for the development of T cell engager.

Jieying Liu, Yongqing Cheng, Mengmeng Sun, Xiaoqian Zhang, Hui Cong, Rumeng Bao, Changchang Zhang, Yu Dan, Shuang Wang, Jie Yang, Donghui Wu, Lei Wu, Jijie Gu

WuXi Biologics, Shanghai, China

In cancer immunotherapy, CD3 T-cell engager (TCE) bispecific antibodies (BsAbs) represent a pivotal direction in drug development due to their ability to directly recruit T cells for precise elimination of tumor cells. Currently, all approved TCE BsAbs are based on conventional anti-CD3 antibodies consisting of both heavy and light chains. However, these TCEs face challenges in bispecific format design and complicate manufacturing, due to their structural complexity. In contrast, TCEs based on anti-CD3 single-domain antibodies (sdAbs, or VHHs) enable modular assembly into compact bispecific molecules. This approach avoids the light chain mispairing issue and allows for more flexible molecular design. Their simpler architecture streamlines production, especially for multi-specific constructs. Moreover, smaller VHHs may facilitate formation of more effective immune synapses. WuXi Biologics has developed a panel of anti-CD3 VHHs with novel sequences derived from immunized llama phage display libraries. These VHHs exhibit a range of binding affinities to CD3 and varying potencies in T-cell activation. TCE molecules constructed using these CD3 VHHs demonstrate potent T cell-dependent tumor cell killing efficacy both in vitro and in vivo. Compared with some marketed TCEs, our VHH-based CD3 TCE molecules show superior in vivo efficacy with comparable cytokine profiles. Additionally, these humanized VHHs display excellent developability characteristics.

#1615 Discovery of CD28 targeting single domain antibodies to facilitate the development of costimulatory T cell engager.

Siwei Nie[1], Yali Wan[2], Hang Zhou[2], Xinyan Ji[2], Jianqing Xu[2], Lei Wu[2], Jijie Gu[1]

[1]WuXi Biologics, Wuxi, China,[2]WuXi Biologics, Shanghai, China

Optimal T-cell activation is a multistep process requiring T-cell receptor engagement by peptide-MHC complexes (Signal 1) coupled with costimulatory signals (Signal 2). The lack of Signal 2 increases the TCR activation-induced cell apoptosis and decreases T cell proliferation, which may lead to compromised therapeutic activity of anti-PD1 therapy or CD3 T cell engagers (TCEs) in the clinic. The purpose of this study is to identify CD28 single domain antibodies to develop co-stimulatory T cell engager to improve T cell proliferation, survival and response durability, and therefore further expand the utility of checkpoint blockade and/or CD3 TCE therapies for treatment of a broad range of solid tumors. The agonistic propriety of CD28-targeting VHH or CD28-based bi-specific TCE (BiTCE) or tri-specific TCE (TriTCE) was evaluated by analysis of IL-2 secretion in PBMC/T cell activation assay. T cell survival was measured by the expression of anti-apoptosis marker Bcl-xl after treatment of CD28-based antibody. Tumor cells were incubated with T cells together with CD28-based bi- or tri-TCE in the presence of CD3 TCE or anti-PD-1 mAb. Viability of target cells were then measured to reflect T cell killing activity. Xenograft mice models were further used to confirm the benefit of integrating CD28-targeting agonist into CD3 TCE. A series of CD28-targeting agonistic VHHs binding to CD28 with different binding affinities in a non-superagonistic manner were obtained. The co-stimulatory effect of CD28-targeting T cell engagers were demonstrated: (1) CD28xB7-H3 BiTCE significantly improved T cell killing potency and durability on OVCAR-3 cells when combined with CD3 TCE and strongly activated T cells and enhanced T cell killing potency of A375 cells when combined with anti-PD-1 mAb; (2) CD3/CD28/TAA TriTCE were generated by screening of the most suitable CD28 agonist and delicate format design. Both CD3xROR1xCD28 and CD3xMUC16xCD28 significantly improve T cell survival which in turn allows more persisted T cell killing of target tumor cells in vitro and in vivo, compared to CD3xROR1 and CD3xMUC16, respectively. Therefore, including CD28 signaling during CD3 TCE and immune checkpoint blockade treatment may improve the therapeutic benefit in patients with solid tumors.

#1616 CLSP-5282, a first-in-class T cell engager targeting KRas^{G12V} mutant peptide presented on HLA-A*03:01.

Amanda Ford[1], Lenore Cullen[1], Alec R. Andrews[1], Justina X. Caushi[2], Catherine Souza[1], Veselin S. Dobrev[2], Raffaello Verardi[2], Hayden Jones[2], Brena Williams[2], Kai Li Tan[2], Michael Alloway[2], Anthony S. Gizzi[2], James Bingham[2], Gillian A. Kingsbury[1], **Jessica Kohler**[1]

[1]Clasp Therapeutics, Cambridge, MA,[2]Clasp Therapeutics, Rockville, MD

Background: Mutant KRas is one of the most common driver oncogenes in solid tumors. Approximately 25% of pancreatic cancer, 9% of colorectal cancer (CRC), and 5% of non-small cell lung cancer (NSCLC) tumors harbor KRas^{G12V} mutations. We describe the nonclinical characterization of CLSP-5282, a first-in-class T cell engager that selectively targets the KRas^{G12V}[7-16] mutant peptide presented on HLA-A*03:01.

Methods: Functional activity was assessed *in vitro* in co-culture assays of T cells and target cells expressing KRas^{G12V} and HLA-A*03:01, including models with acquired resistance to Ras-targeted small molecule inhibitors. Since CLSP-5282 does not cross react with any preclinical toxicology species, an extensive panel of secondary pharmacology and in vitro toxicology studies was performed. A Jurkat reporter assay with a positional scanning peptide library was used to identify potential cross-reactivity to other peptides presented on HLA-A*03:01. Specificity was further assessed by T cell reactivity with a panel of normal human tissues and a panel of the most common Class I HLA alleles, and cytokine release in high density PBMC cultures was determined to evaluate CRS risk. In vivo anti-tumor activity of CLSP-5282 was investigated in PBMC engrafted mouse models.

Results: CLSP-5282 induces T cell activation and target cell killing specifically against cells expressing KRas^{G12V} and HLA-A*03:01, but not wild-type KRas. Cell lines with acquired resistance to KRas inhibitors maintain sensitivity to CLSP-5282, suggesting continued presentation of the KRas^{G12V} neoantigen. In vitro studies did not identify potential cross-reactivity to any peptides presented on HLA-A:03:01 and showed minimal T cell reactivity or cytokine release with a panel of normal human tissues, a panel of the 50 most common Class I HLA alleles, or in high-density PBMC cultures. In vivo, CLSP-5282 induces regression of established tumors in a humanized mouse model.

Conclusions: These preclinical data support clinical evaluation of CLSP-5282 in HLA-A*03:01 positive patients with solid tumors harboring the KRas^{G12V} mutation. CLSP-5282 is expected to be the first TCE in the clinic directed against mutant KRas, providing tumor targeting without the risk of on-target, off-tumor toxicity. Our data demonstrate the potential for CLSP-5282 to be efficacious even in the context of resistance to small molecule KRas inhibitors.

#1617 AI-assisted development of a TCR-like T cell engager targeting MAGE-A4 against melanoma.

Yang Liu, Qi Zhao

Faculty of Health Science, University of Macau, Taipa, Macao

MAGE-A4 is a promising immunotherapeutic target due to its frequent overexpression in cancers and limited expression in normal tissues. Intracellularly processed MAGE-A4 peptides, frequently presented by HLA-A*02:01 on the cell surface, can be recognised by T-cell receptor-mimetic agents. Utilising artificial intelligence-driven in silico screening and experimental validation, we generated a T-cell receptor-like antibody that specifically binds to the HLA-A*02:01-restricted GVY230-239 peptide complex. We subsequently engineered a T cell engager (TCE) in an IgG(L)-scFv format by fusing it with an anti-CD3 scFv. This MAGE-A4-targeting TCE demonstrated potent and specific cytotoxicity against multiple HLA-A*02:01^{+}/MAGE-A4^{+} tumour cell lines. To eliminate potential interference from Fc-mediated ADCC on T-cell-mediated killing, an N297A mutation was introduced into the Fc region, and the loss of ADCC activity was confirmed using a CD16 reporter cell line. Furthermore, in an HLA-A*02:01^{+}/MAGE-A4^{+} cell-derived xenograft (CDX) mouse model, the TCE exhibited significant antitumor efficacy in vivo. Compared to most currently available TCR-like antibodies, which primarily target haematological malignancies, this TCE showed superior tumour-killing activity against melanoma in vitro and in vivo. This work is supported by FDCT/009/2023/RIC and FDCT/0150/2025/AFJ.

#1618 A novel pan-gamma-delta T cell engager platform for next-generation cancer therapeutics.

Baotian Yang[1], Yuan Wu[1], Tengfei Yu[1], Sha Cheng[1], Qun Sun[1], Siwei Nie[2], Lei Wu[1], Jijie Gu[2]

[1]WuXi Biologics, Shanghai, China,[2]WuXi Biologics, Wuxi, China

Bispecific T cell engagers (TCEs) are potent immunotherapeutic molecules that redirect the body's T cells to kill tumor or pathogenic cells by bridging CD3 and tumor-associated antigen (TAA). Over the past decade, TCE-based therapies have achieved great success for the treatment of liquid tumors. However, although there is a multitude of TCEs with solid tumor targets in preclinical and clinical development, only one DLL3-targeting TCE was approved by FDA. For most TCEs targeting solid tumors, the main concern is on-target/off-tumor cytotoxicity, that is target organ toxicity due to redirection of T cells to normal tissues expressing the TAA. In addition, excessive release of cytokines may also translate to potentially life-threating cytokine release syndrome (CRS). To expand the therapeutic index and bring more treatment options to patients, there are intense efforts to overcome these challenges. Gamma-Delta T (γδT) cells can leverage both innate and adaptive immunity to combat target cells. Gamma-delta T cell engager (γδTCE) is a novel antitumor therapeutic to redirect γδ T cells to eliminate tumor or other pathogenic cells without pan T cell activation, therefore resulting in improved therapeutic index compare to pan T cell engager. To test this hypothesis, WuXi Biologics has developed a novel and unique pan-γδ TCE platform for the undruggable or hard-to-drug TAAs, that CD3 TCE can't target. Epidermal growth factor receptor (EGFR) is highly expressed in many solid tumors (e.g. non-small cell lung cancer and colorectal cancer) and low in normal tissues. EGFR has been clinically validated by multiple drug modalities, such as monoclonal antibodies and antibody-drug conjugates. However, EGFR x CD3 TCE, which may be the most powerful therapeutic modality, remains undruggable due to severe adverse effects of cytokine release and on-target/off-tumor toxicities. WuXi Biologics' EGFR-γδTCE is able to motivate diverse γδ T cell populations with equivalent activity, inducing significant expansion of γδ T cells without causing exhaustion. Compared with the clinical Vδ1 and Vδ2 benchmarks, WuXi Biologics' EGFR-γδTCE showed more efficient cytotoxicity against tumor cells, while sparing healthy cells and maintaining low cytokines. In in vivo antitumor studies of human colorectal cancer HCT116 xenograft models, the EGFR-γδTCE also exhibited superior antitumor efficacy than the clinical benchmarks. The studies support WuXi Biologics' EGFR-γδTCE as a promising novel therapeutic to target multiple solid tumors with EGFR expression and also demonstrate that WuXi Biologics' γδTCE platform has the potential to become best-in-class and can be applied to the undruggable or hard-to-drug TAAs.

#1619 Discovery and optimization of XTX601, a masked claudin 18.2-targeting T cell engager.

Jason Hedges, Pyae Hein, David Crowe, Aaron Bogle, Jing Ying Eng, Manoussa Fanny, Wilson Guzman, Sami Kahloun, Bernard Lanter, Janice Lee, Natalia Malkova, Haley Saxton, Kyle Smith, Sallyann Vu, Yihong Zhang, Kurt Jenkins, Elsie DiBella, Benjamin Nicholson, Scott Coleman, Carl Uli Bialucha

Xilio Therapeutics, Waltham, MA

T cell engagers (TCEs) are bispecific molecules engineered to bind to tumor-associated antigens on cancer cells and simultaneously engage T cells via CD3 interaction. Multiple TCEs have been approved for treating hematological malignancies, but approvals against solid tumor antigens have been limited to-date due to on-target, off-tumor toxicities. Aberrant protease dysregulation in solid tumors presents an opportunity for tumor-selective activation of biotherapeutic molecules including TCEs. To optimize the therapeutic index of TCEs by maximizing tumor exposure and minimizing peripheral activity, we have developed a masked TCE format we call ATACR (Advanced Tumor-Activated Cell Engager). In the ATACR format, peripheral engagement of CD3 is limited by a masking domain that is designed to prevent the TCE's anti-CD3 domain from binding CD3. By incorporating a protease cleavable linker between the half-life extension domain and the anti-CD3 domain, cleavage of the ATACR molecule by tumor associated proteases results in the release of a short half-life, fully active TCE locally within the tumor microenvironment. Here we report preclinical data for XTX601, a masked TCE in the ATACR format designed to target the clinically validated tumor associated antigen Claudin 18.2 (CLDN18.2), which is aberrantly expressed in gastrointestinal cancers, such as gastric, esophageal, and pancreatic cancer. A comprehensive CLDN18.2 TCE discovery and optimization effort yielded XTX601, which was found to be 1) highly selective for CLDN18.2; and 2) demonstrated efficient masking with a significant reduction in the levels of CD3 binding compared to the proteolytically activated molecule. Consistent with the CD3 binding data, intact XTX601 was effectively masked relative to proteolytically activated XTX601 when tested in T cell-dependent cellular cytotoxicity (TDCC) assays across multiple cancer cell lines that endogenously express CLDN18.2. XTX601 demonstrated robust anti-tumor activity in humanized, murine xenograft models adoptively transferred with human T cells. In both mice and non-human primates, XTX601 exhibited favorable pharmacokinetics and tolerability, highlighting the potential for an improved therapeutic index compared to systemically active TCEs targeting CLDN18.2. Collectively, these preclinical data demonstrate the effectiveness of our ATACR masked T cell engager format in reducing systemic activation of T cells while retaining potent anti-tumor activity. XTX601 is the first masked CLDN18.2-targeting TCE and has the potential to address a significant unmet need for patients with CLDN18.2 expressing malignancies including gastric, esophageal, and pancreatic cancers.

#1620 ATG-112, a novel ALPP/G x CD3 bispecific T cell engager, for the treatment of ALPP/G^{+} solid tumors.

Jishun Chen[1], Yu Bai[1], Suya Bai[1], Huiling Liu[1], Zaoshun Hu[1], Jay Mei[2], Peng Chen[3], **Bing Hou**[2]

[1]Antengene (Hangzhou) Biologics Co., Ltd, Hangzhou, China,[2]Antengene Corporation, Shaoxing, China,[3]Shanghai Antengene Corporation Limited, Shanghai, China

Background Placental alkaline phosphatase (ALPP) and related placental-like/germ-cell isoforms (ALPPL2 / ALPG) are cell-surface alkaline phosphatases that are aberrantly expressed in various solid tumors (e.g., ovarian, endometrial, germ cell, gastric, and pancreatic cancers), while being virtually absent from normal adult tissues except the placenta, making them highly promising tumor-selective targets for immunotherapy. T-cell engagers (TCEs) demonstrate robust clinical activity by co-engaging T cells with tumor cells, thereby inducing T cell activation and T cell-dependent cellular cytotoxicity (TDCC) against tumors. Here we developed ATG-112, an ALPP/G × CD3 bispecific TCE using the AnTenGager™ platform, featuring bivalent antigen binding for improved low-antigen tumor recognition and a sterically-masked CD3 binding arm to restrict T-cell activation to the tumor microenvironment.
Methods ATG-112 was engineered in a 2+1 IgG-based format, enabling bivalent binding to ALPP/G and monovalent engagement of CD3. We characterized its binding kinetics, TDCC, immunogenicity, and cytokine release profile using ALPP/G-positive cell lines, recombinant proteins, and human PBMCs. Antitumor efficacy was assessed in humanized mice with HPAC and NCI-H1650 xenografts.
Results Tissue microarray (TMA) IHC analysis revealed that ALPP/G expression was restricted to placental tissue in healthy organs and not detected in other normal tissues. In human tumors, ALPP/G was frequently expressed in endometrial (58.50%) and ovarian cancers (51.01%), with lower prevalence in bladder (26.14%), gastric (25.00%), and pancreatic cancers (16.67%). ATG-112 showed high binding affinity to both ALPP/G-positive tumor cells and recombinant protein, with EC_{50} and KD values in the sub-nanomolar range. ATG-112 induced robust TDCC activity against target positive cells with pico-molar range EC50, confirming potent antigen-dependent T-cell redirection. *In vitro* cytokine-release assays demonstrated minimal cytokine secretion from human PBMCs, suggesting low risk of excessive immune activation. Immunogenicity assessment showed that humanized ATG-112 molecules exhibited low immunogenic potential. *In vivo*, ATG-112 achieved potent tumor suppression across multiple dose levels, demonstrating strong antitumor activity and dose responsiveness. Safety studies revealed a favorable *in vivo* safety profile, including low cytokine release and controllable CRS risk at efficacious doses. ATG-112 also exhibited excellent developability.
Conclusion ATG-112 is a 2+1 T-cell engager that potently and selectively targets ALPP/G and CD3. It demonstrates potent in vitro and in vivo efficacy with minimal cytokine release. These findings support ATG-112 as a differentiated and promising therapeutic candidate for ALPP/G-positive solid tumors and justify its advancement toward clinical development.

#1621 ATG-106, a novel “2+1”format CDH6-targeted T-cell Engager (TCE), shows potent T cell dependent cytotoxicity and in vivo anti-tumor efficacy.

Tengteng Li[1], Peng Chen[1], Huiling Liu[2], Zaoshun Hu[2], jiaqi yan[2], jie huang[2], Jay Mei[3], **Bing Hou**[3]

[1]Shanghai Antengene Corporation Limited, Shanghai, China,[2]Antengene (Hangzhou) Biologics, Hangzhou, China,[3]Antengene Corporation Co., Ltd, Shaoxing, China

Background

CDH6 is crucial in embryonic kidney development but shows negligible expression in the adult kidney. Its overexpression in cancers like ovarian and renal cancer, contrasted with limited normal tissue expression, makes CDH6 an attractive target for cancer therapy, as supported by promising ADC clinical efficacy. However, T-cell engagers (TCEs) show limited efficacy and carry cytokine release syndrome (CRS) risks in solid tumors. In this study, we developed a novel "2+1", stericly-masked CDH6xCD3 bispecific TCE, ATG-106, demonstrating potent anti-tumor activity with a potentially reduced CRS risk.

Method

ATG-106 was developed by introducing a novel conformational epitope-targeted anti-CD3 single chain fragment variable (scFv) antibody to the hinge region of a novel humanized CDH6 monoclonal antibody. The CD3 binding site is concealed by the anti-CDH6 Fab arm before binding to CDH6, due to the steric hindrance. It was evaluated through a series of preclinical in *vitro* and *in vivo* assays for efficacy and safety, including binding affinity, cell based CD3 signal pathway activation, T cell dependent cytotoxicity (TDCC) and cytokine release. The *in vivo* efficacy of ATG-106 was evaluated in human PBMC reestablished 786-O kidney cancer and OVCAR-3 ovarian cancer xenograft mouse model. The safety profile of ATG-106 was characterized in intermittent intravenous dosing studies in rhesus monkeys using surrogate antibody (ATG-106-RM).

Results

ATG-106 exhibited reduced binding affinity to CD3+ cells before CDH6 crosslinking, while inducing 100-400 folds more potent cytotoxicity against CDH6-positive tumor cells compared to a 1+1 control TCE. It induced minimal ex-vivo cytokine release in the whole blood assay. In PBMC humanized 786-O xenograft model, ATG-106 demonstrated promising *in vivo* efficacy, resulted in tumor shrinkage in all mice dosed, with complete remission observed in 0.1 mg/kg (4 out of 6 mice) and 0.3 mg/kg (6 out of 6 mice) treatment groups . Notably, the serum concentration of pro-inflammatory cytokines was very low in ATG-106 treated group, suggesting low risk of CRS . ATG-106 also induced tumor shrinkage and complete remission in OVCAR-3 model. ATG-106-RM was well tolerated in rhesus monkey at doses up to 10mg/kg.

Conclusions

ATG-106 demonstrated powerful T cell dependent cytotoxicity and *in vivo* anti-tumor efficacy against ovarian and renal cancer preclinically, which warrants further clinical evaluation.

#1622 The affinity-optimized bispecific T cell engager W308051 selectively kills PSMA-expressing tumor cells with limited cytokine secretion.

Johannes Breuning[1], Yi Qin[2], Yunying Chen[2], Xia Wang[2], Jijie Gu[2]

[1]GlaxoSmithKline plc, Stevenage, United Kingdom,[2]WuXi, Shanghai, China

Metastatic castration-resistant prostate cancer (mCRPC) remains a therapeutic challenge with limited treatment options. Here, we report the preclinical characterization of W308051, a bispecific T cell engager developed by GSK under license from WuXi, designed to target prostate-specific membrane antigen (PSMA) on malignant cells and CD3 on T lymphocytes. W308051 demonstrates a higher binding affinity to PSMA compared to the competitor molecules AMG160 and AMG340 with a K_D of 16 pM as shown by surface plasmon resonance and also stronger binding in ELISA and cell-based binding assays. However, its affinity for CD3 with a K_D of 60 nM is lower than AMG160 but higher than AMG340, a rationale design choice to increase the therapeutic index. *In vitro* studies reveal that W308051 induces potent cytotoxicity against PSMA-positive cancer cells, achieving efficacies comparable to AMG160 and surpassing those of AMG340 across multiple cell lines with variable PSMA expression levels. Furthermore, *in vivo* experiments utilizing a cell line-derived xenograft model with the LNCaP cell line in immunodeficient mice engrafted with human peripheral blood mononuclear cells demonstrated complete tumor growth inhibition at higher dosing regimens, reflective of AMG160's profile. Importantly, *in vitro* cytokine release associated with W308051 treatment was reduced relative to AMG160 and marginally elevated compared to AMG340, suggesting a potentially improved safety profile and an expanded therapeutic window. Pharmacokinetic analyses indicate that the use of T cell receptor domains for bispecific antibody assembly confers properties akin to those observed with conventional monoclonal antibodies. Collectively, these findings support the further clinical investigation of W308051 as a promising therapeutic modality for mCRPC.

#1623 A novel pH dependent T cell engager platform for next generation cancer therapeutics.

Jie Li[1], Wenqian Fang[1], Nan Feng[1], Tengfei Yu[1], Siwei Nie[2], Lei Wu[1], Jijie Gu[2]

[1]WuXi Biologics, Shanghai, China,[2]WuXi Biologics, Wuxi, China

On-target off-tumor toxicity is a big challenge for the treatment of solid tumors using T cell engager (TCE) therapy because solid tumor associated antigens (TAAs) often expressed in not only tumor tissue but also normal healthy tissues. The acidic tumor microenvironment (TME) is a key characteristic of cancer and is leveraged to develop conditional tumor-selective therapy, which has been demonstrated with effective tumor control alongside manageable adverse events by encouraging preliminary clinical evidence emerged recently. WuXi Biologics has developed an innovative platform to identify pH dependent TAA binders that selectively bind to tumor and spare normal healthy tissues. As a clinically validated target, FolR1 overexpressed on multiple cancers, especially in ovarian and lung cancers, and associated with high-grade tumor progression & poor prognosis. Low expression of FolR1 in normal tissues is restricted to the luminal surface of lung, kidney, intestine, etc. ELAHERE, the approved FolR1 ADC demonstrated great clinical efficacy to FolR1^{high} patients but is ineffective to FolR1^{low} patients. FolR1 targeting TCE might be a promising therapy, though currently several TCEs stopped in pre-clinical stage due to on-target-off-tumor effect or lack of efficacy. To address these challenges, WuXi Biologics identified a novel pH-dependent FolR1 binder that binds to tumor at acidic pH over normal tissue at neutral pH, and then discovered a conditional FolR1 TCE which could kill tumor cell specifically by TME triggered activation and turning off at normal tissue, mitigate on-target-off-tumor toxicity and potentially widen therapeutic window and dose to achieve better clinical benefits. As a potential first-in-class conditional FolR1 TCE candidate, WuXi Biologics' FolR1 TCE showed potent binding to FolR1^{+} tumor cells at acidic pH and very weak binding to FolR1^{low} cells at neutral pH (representing normal tissue). Designed with fine-tuned CD3 and FolR1 affinity balance, it exhibited efficient *in vitro* on-tumor cytotoxicity at acidic pH and minimal cytotoxicity on normal tissue at neutral pH, and correlating cytokine levels released by T cells. WuXi Biologics' FolR1 TCE showed dose-dependent and efficient tumor growth inhibition in human ovarian cancer and NSCLC CDX models. In exploratory cynomolgus monkey tox study, WuXi Biologics' FolR1 TCE was well-tolerated up to 1 mg/kg with better safety profile than 16D5, one conventional benchmark FolR1 TCE which showed severe toxicity as low as 15 μg/kg. These findings suggest that WuXi Biologics' FolR1 TCE offers significant therapeutic potential as a next-generation TCE with minimal on-target-off-tumor cytotoxicity and enhanced therapeutic window. The pH dependent design provided an innovative strategy to offer safer and more effective therapeutic overcome for solid cancer patients.

#1624 Logic-gated switch-DARPin T cell engager with CD2 co-stimulation for improved safety and efficacy in MSLN and EpCAM co-expressing ovarian cancer.

Matteo Bianchi, Sarah Jetzer, Simon Haberle, Aline Eggenschwiler, Albulena Toska, Anja Schlegel, Justin D. Walter, Stephan Wullschleger, Tamara Lekishvili, Yvonne Kaufmann, Rocio Evangelista Vaz, Marcela Guzman Ayala, Alexander Link

Molecular Partners AG, Zurich-Schlieren, Switzerland

Introduction

The development of T cell engagers (TCEs) for solid tumors is challenged by the scarcity of specific tumor-associated antigens (TAAs), which limits selectivity and increases the risk of on-target/off-tumor toxicity due to antigen expression in normal tissues. In ovarian cancer (OC), immunotherapy has shown limited success, largely due to the lack of “clean” TAAs, dysfunctional T cells, and an immunosuppressive tumor microenvironment. To overcome these challenges, we engineered a multi-specific, logic-gated CD3 TCE targeting the TAAs mesothelin (MSLN) and EpCAM, with CD2-mediated co-stimulation. This conditional Switch-DARPin design employs an AND-gate mechanism, enabling CD3 engagement only upon simultaneous recognition of both TAAs. This strategy aims to deliver potent, sustained antitumor activity while minimizing systemic toxicity and off-tumor effects on single TAA-expressing healthy cells.

Methods

The MSLNxEpCAM-targeting Switch-DARPin was developed using our DARPin platform. It features a masked CD3 binder that is unmasked upon dual binding to MSLN and EpCAM on tumor cells, a CD2 binder for co-stimulation, and includes a silent Fc domain for extended half-life. Preclinical safety and antitumor efficacy were evaluated *in vitro* and *ex vivo* using tumor and reporter cell lines, primary T and mesothelial cells from healthy donors, whole blood cytokine release assays, and *in vivo* using an OVCAR-3 xenograft model in PBMC-humanized NXG mice.

Results

Using our computational workflow DARPin Compass, we identified MSLN and EpCAM as a promising TAA pair in OC, with low co-expression in healthy tissues. *In vitro*, the Switch-DARPin induced selective T cell cytotoxicity against tumor cells co-expressing MSLN and EpCAM, with markedly reduced activity on cells expressing only one antigen. Notably, substantially lower activity against primary human mesothelial cells was observed, compared to other clinically tested MSLN-targeting TCEs. CD2 co-engagement promoted sustained activation and proliferation of T cells, preventing exhaustion. *In vivo*, the Switch-DARPin exhibited suitable pharmacokinetics and achieved significant tumor regression in MSLN+EpCAM+ xenografts without systemic cytokine release. The absence of cytokine induction in human whole blood assays confirmed the favorable safety profile despite CD2 co-stimulation.

Conclusions

Co-targeting of MSLN and EpCAM may lower the risk of on-target/off-tumor toxicity compared to single-targeting approaches. Preclinically, our logic-gated CD3xCD2 Switch-DARPin demonstrates selective antitumor activity against MSLNxEpCAM dual-positive tumors such as OC. CD2 co-stimulation further enhances T cell function without systemic activation. Together, our approach has the potential to overcome key limitations that TCE therapy faces in solid tumor indications.

#1625 VHH nanobody-masked conditionally active CDH17 T cell engager for colorectal cancer.

Lei Wu, Guoxin Ni, Xiaoyue Liu, Sha Cheng, Senfeng Xiang, Yi Liu, Xia Wang, Donghui Wu, Tengfei Yu, Jijie Gu

WuXi Biologics, Wuxi Shi, China

T cell engagers (TCEs) bind antigens on tumor cells on one arm and CD3-TCR complex on the other arm to induce cytotoxic immune synapses and redirect nonspecific T cells to kill in a specific manner. TCEs have demonstrated convincing efficacy in multiple blood cancers and have recently with Tarlatamab made breakthrough in solid tumors. However, major hurdles remain for the realization of the full potential of this exciting modality in solid tumors - most importantly the lack of clean and specific antigens. CDH17 is a type-1 transmembrane glycoprotein of the cadherin superfamily and its expression is normally restricted to the lateral area of epithelial tight junctions of the intestines and the pancreatic duct. CDH17 is highly expressed in over 95% of colorectal cancers, and its upregulation and tumor tissue disorganization results in disoriented CDH17 expression susceptible to T cell surveillance In order to accommodate CDH17 that is highly expressed on tumor cells but is indeed present on some normal tissues, we developed a next-generation conditionally active masked CD3 TCE platform. Instead of using traditional linear peptide masks that oscillate and are prone to digestion, we generated anti-idiotypic VHH nanobody specifically for our clinical stage CD3 binder (NCT05579132). The structured VHH masking moiety prevents premature unmasking and activation. In addition, we designed enzyme cleavable linker specifically to be resistant to enzymes that are highly expressed in normal tissues. These designs ensured good tolerability. Anti-idiotypic VHH mask binds CD3 binder with high affinity and fine-tuned kinetics. VHH-masked CD3 binder is no longer able to induce effective T cell killing. The newly designed cleavable linker can be effectively cut by certain MMPs and other enzymes enriched in the tumors. The resulting masked CDH17xCD3 TCE showed good serum stability and remained inactive after extensive incubation. Once activated with corresponding enzymes, the VHH mask is effectively released and the TCE is activated to induce potent tumor cell killing. In multiple CDX models of human tumors, masked CD3 TCE demonstrated convincing in vivo efficacy on par with the corresponding non-masked TCE. Moreover, exploratory toxicity study in NHP showed significantly higher MTD and improved safety profile. WuXi Biologics has developed a conditionally active CDH17 TCE with the proprietary VHH-masked CD3 TCE platform. The molecule has demonstrated great efficacy and better tolerability preclinically, and is to be further evaluated in the clinic.

#1626 A novel machine-learning derived nectin-4 x CD3 bispecific T-cell engager, LGTX-101, demonstrates high degrees of tumor selectivity and potently induces tumor regression *in vivo*.

Lucrecia Alberdi, Sabrina Bouhafs, Dan Foxler, Justin Grace, Winston Haynes, Catherine Howsham, Leo Kassimatis, **Sylwia Marshall**, Lida Mavrogonatou, James McClory, Portia McGhan, Rebecca Mighell, Michael Mullin, Sandra Pasternakiewicz, Sujata Ravi, Nush Sarvaria, Gino Van Heeke, Angus Sinclair

LabGenius Therapeutics, London, United Kingdom

Nectin-4 is a tumor-associated antigen (TAA) that is commonly overexpressed on numerous solid tumor types, including urothelial, head and neck, and triple-negative breast cancer. Nectin-4 is also expressed at low levels on normal, healthy tissues, which limits current ADC therapies due to high rates of dose-limiting, on-target, off-tumor toxicities. Furthermore, patients previously benefiting from ADC therapy become resistant to treatment. This highlights a need for alternative approaches for anti-cancer therapeutics that can selectively target Nectin-4 expressing solid tumors with an improved mechanism of action. A highly selective and potent trivalent VHH based Nectin-4 x CD3 T-cell engager (TCE) was generated using LabGenius Therapeutics' proprietary discovery engine (EVA™). By harnessing avidity-driven selectivity, LabGenius' Nectin-4 x CD3 TCE (LGTX-101) is able to differentiate between healthy and diseased cells based on differential TAA expression. LALA mutations were introduced to abrogate FcyR activity. The potency and selectivity of the lead molecule LGTX-101 was tested in a range of tumor cell line cytotoxicity models with varying expression of Nectin-4, including primary bladder cancer cells. Furthermore, the *in vivo* efficacy was established using a humanised BT-474 CDX model. LGTX-101 has a 3:1 Nectin-4:CD3 stoichiometry capable of high affinity binding to Nectin-4 expressing cells and low-moderate affinity to human CD3. In *in vitro* tumor cell cytotoxicity assays, LGTX-101 potently induced cytotoxicity in cancer cell lines with Nectin-4 receptor expression levels within 2-fold of healthy control model cell lines, with mean EC_{50} potency of 0.712 +/- 0.132 pM. No evidence of cytotoxicity of the healthy cell model was observed, demonstrating a >1,000-fold therapeutic window between Nectin-4 positive normal and tumor cell cytotoxicity. These observations were further extended to primary bladder cancer co-cultures, where LGTX-101 induced activation of T cells at concentrations of <5 pM. Furthermore, no evidence of T cell activation was observed when PBMCs were cultured with human primary keratinocytes, known to express low levels of Nectin-4. Finally, LGTX-101 demonstrated robust reduction of the growth of established tumors *in vivo* in a humanized BT-474 xenograft model (>90% tumor growth inhibition) and a preliminary PK profile that supports a Q2W - Q4W dosing regimen in the clinic. LGTX-101 is a highly selective and highly efficacious Nectin-4 x CD3 TCE currently in preclinical development for treatment of advanced solid tumors. With an increased selectivity and potency profile, LGTX-101 has the potential to provide a safer, more effective treatment option for patients.

#1627 DS-2243a, an HLA-A*02/NY-ESO-directed bispecific T-cell engager, shows potent anti-tumor activity in preclinical models of solid tumors.

Junya Ichikawa, Ayaka Yatsu, Ryuichi Nakamura, Akemi Kita, Shingo Noguchi, Yoko Ishimoto, Chikako Maru, Kento Tanaka, Kensuke Nakamura, Shinji Furuzono, Makiko Nakayama, Toshiaki Ohtsuka, Reimi Kawaida

Daiichi Sankyo Co., Ltd., Tokyo, Japan

Background: NY-ESO-1 and LAGE-1 are homologous proteins commonly expressed in various tumor tissues but not in normal tissues other than the testis and placenta, making them potential tumor-specific therapeutic targets. Tumor types with prevalent NY-ESO-1 and/or LAGE-1 expression include SS, MRCLS, NSCLC, and UC. Following the intracellular processing of NY-ESO-1 and LAGE-1 proteins (hereafter referred to as NY-ESO) by the proteasome, the same highly immunogenic NY-ESO peptides are presented extracellularly by HLA-A*02. DS-2243a is a first-in-class bispecific T-cell engager (BiTCE) with an effectorless Fc region. It is designed with a novel TCR-like antibody that engages both HLA-A*02/NY-ESO-expressing tumor cells and T-cells, redirecting T-cell-mediated cytotoxicity toward the tumor.

Methods: The binding affinity of DS-2243a to HLA-A*02/NY-ESO peptide complex was evaluated by surface plasmon resonance (SPR) analysis, and specificity of DS-2243a for the human HLA-A*02/NY-ESO complex was evaluated by a flow cytometry-based binding assay using T2 cell line supplemented with HLA-A*02/NY-ESO peptide and various HLA-A*02/NY-ESO homologous peptides. Anti-tumor cytotoxicity, T-cell activation, and cytokine release were evaluated by co-culturing tumor cells with human peripheral blood mononuclear cells (hPBMCs) in the presence of DS-2243a. The anti-tumor efficacy of DS-2243a was evaluated against various HLA-A*02 positive tumors with different NY-ESO expression levels in human T-cell-transferred mouse models.

Results: DS-2243a specifically bound to human HLA-A*02/NY-ESO peptide complex with a high affinity of 1.31×10^{-9} mol/L, but not to other HLA-A*02/homologous peptide complexes. DS-2243a induced T-cell activation, cytokine release, and target cell cytotoxicity in a dose-dependent manner. It demonstrated robust anti-tumor efficacy across multiple tumor types, including those with low NY-ESO expression, and also demonstrated efficacy in a tumor-mixture model of NY-ESO-positive and NY-ESO-negative tumors, supporting potential effectiveness in tumors with heterogeneous NY-ESO expression. Furthermore, DS-2243a exhibited efficacy in combination with immune checkpoint inhibitors, providing a rationale for combination therapies.

Conclusions: Preclinical data indicate that DS-2243a has strong potential to deliver clinically meaningful anti-tumor activity in patients with HLA-A*02 and NY-ESO-expressing cancers. The first-in-human study DS2243-054 (NCT06644755) is being conducted to evaluate DS-2243a monotherapy in patients with advanced or metastatic solid tumors.

#1628 A bispecific PDL1:CD3 T-cell engager potently kills intractable primary and metastatic intracranial tumors.

Emily J. Girard, Shelli M. Morris, Kristina Pilat, Alison M. Williams, Kenneth Brasel, Heather Conti, Parvathi Muthuraman, Ray Ruff, Hailey Hentschel, Steven Chen, Chunfeng Yin, Zachary Crook, Jason Price, Andrew J. Mhyre, James M. Olson

Seattle Children's Research Institute, Seattle, WA

Introduction: Central nervous system tumors represent a huge unmet medical need. Many pediatric and adult brain cancers and cancers (e.g., lung, colon, breast) with CNS involvement remain largely intractable despite standard of care and advanced treatment strategies. We engineered a bispecific PD-L1 targeted T-cell engager (TCE) and discovered promising efficacy in a wide range of pre-clinical intracranial tumor models, including some models with intact blood brain barriers.
Methods: Anti-tumor activity of a systemically administered PD-L1:CD3 TCE was interrogated in 14 intracranially implanted tumor xenografts representing poor-prognosis pediatric brain tumors, adult glioblastoma, and metastatic lung, breast, and colorectal cancers. On-target/off-cancer toxicity was evaluated in mice transgenic for human PD1/PD-L1 or CD3ε with surrogate chimeric TCEs for species appropriate binding over 2- and 4-week treatment periods with repeated dosing. Dose range finding study in non-human primates was conducted to establish the safety profile of the lead TCE.
Results: Median and overall survival were significantly extended by TCE treatment in 4 of 5 models of pediatric brain tumors (2 diffuse midline glioma, 1 medulloblastoma, 2 high-grade glioma), 2 of 3 models of adult glioblastoma, and all 6 models of intracranial metastases (3 lung adenocarcinoma, 2 triple-negative breast cancer, 1 colorectal carcinoma). One of the adult GBM and the 6 metastatic models were transduced for bioluminescent monitoring of tumor burden: 53% of tumors across model types were eliminated by TCE treatment, 39% showed tumor presence without progressive growth, and 8% of tumors continued to grow with or without an initial delay. Dose range tolerability in transgenic mice showed dose dependent pharmacodynamic effects on body weight, lymphopenia, cytokine stimulation, CD3+ cell biodistribution, and tissue PD-L1 expression with no overt toxicity. A dose range finding study in non-human primates revealed the TCE was well tolerated with pharmacodynamic responses observed at 0.03 mg/kg and limited to grade 1 toxicities. At 0.3 mg/kg grade 2-4 toxicities were observed.
Conclusion: Bispecific PD-L1:CD3 TCE is safe at doses that show efficacy in intracranial xenograft tumor models. This PD-L1 TCE presents a novel therapeutic strategy for patients with primary and metastatic intracranial tumors that are typically fatal.

#1629 An innovative approach to improve bispecific T-cell engagers for solid tumor therapy.

Hing C. Wong, Xiaoyun Zhu, Varghese George, Hamidreza Farzaneh, Crystal Gilkes, Natalia Valderrama, Alyssa Thompson, Lijing You, Lucas Gomez, Christian Echeverri, Niraj Shrestha, Peter R. Rhode, Jack Egan

HCW Biologics Inc., Miramar, FL

T cell engagers (TCEs), mainly in the format of Bispecific T-cell Engagers (BiTE), are promising anti-cancer immunotherapies for hematological malignancies. However, solid tumors create immunosuppressive microenvironments and physical structures that hinder the effectiveness of T- cell engagers and preclude tumor infiltration by $CD8^+$ T cells. Our hypothesis for overcoming these barriers is to add components to the BiTE format that alleviate immunosuppression and promote activation and tumor infiltration of $CD8^+$ T cells. To test this hypothesis, we used our novel TRBC platform to construct HCW11-018b, a tetravalent heterodimeric TCE. The BiTE portion of HCW11-018b contains an antibody that targets human tissue factor (TF), which is overexpressed in a wide spectrum of solid tumors; an anti-CD3 single-chain antibody; and an IL-15Rα domain. The other chain of HCW11-018b comprises a dimeric soluble TGFβRII domain (i.e., TGFβ trap), TRβC1 and a soluble IL-15. The plasmids carrying the coding regions of the two fusion proteins were co-transfected into CHO cells and the fully functional TCE was purified from culture supernatant. *In vitro*, we found HCW11-018b induced robust, antigen-specific tumor cell killing, which was sustained up to five rounds. Increased phosphorylation of STAT5, expression of activation markers (CD69, CD25), chemokine receptor (CCR5), and anti-apoptosis marker (BCL2) were observed on T cells by HCW11-018b treatments. RNAseq analysis revealed that increased expression of *BCL2* and other genes associated with T-cell effector function were specifically attributable to the IL-15 component of HCW11-018b. In SCID mice subcutaneously (s.c.) implanted human AsPC-1 pancreatic cancer cells with human PBMCs, we demonstrated that s.c. administered HCW11-018b could infiltrate into implants and activate bystander $CD8^+$ T cells for potent anti-tumor activities. In AsPC-1 tumors (NSG mice models) and adoptively transferred human T cells, HCW11-018b stimulated expression of CCR5 and promoted tumor infiltration of human T cells, upregulated T cell expression of CD25, NKG2D, DNAM1, Granzyme B, and IFNγ, and enhanced their cytotoxicity against cancer cells. Treatment also reduced tumor cell metastasis from the primary site. We further demonstrated that the upregulation of NKG2D and DNAM1 on HCW11-018b-activated $CD8^+$ T cells played a role in the cytotoxicity against AsPC-1 tumor cells. In a PDX model, we further demonstrated the potency of HCW11-018b which directed hPBMCs against TF^+ patient-derived pancreatic cancer tissues. HCW11-018b was well tolerated in mice and non-human primates with s.c. administration. HCW11-018b is currently in IND-enabling studies for clinical development against solid tumors. In summary, we demonstrate that the addition of TGFβ-trap and IL-15 components onto BiTE using our novel TRBC platform can overcome the deficiencies of BiTE for solid tumor therapy.

#1630 Preclinical investigation of a novel tumor associated antigen, cb02, as a bispecific t-cell engager in cancer.

Mary Mathieu

Cartography Biosciences, Inc., South San Francisco, CA

Therapeutic success in next-generation cancer immunotherapy is dependent on identifying highly effective targets that allow selective eradication of tumor cells while sparing healthy tissues to maximize the therapeutic window. The novel target CB02 (target undisclosed), a highly tumor-specific antigen, was nominated from our comprehensive ATLAS platform that analyzes healthy and tumor tissues at single cell level. Based on target expression profile and target cleanliness, we built a bispecific T cell engager, CB02 TCE. Analysis of relevant patient tissues using quantitative flow cytometry (qFlow) and IHC indicated high prevalence across hematological and solid tumor indications.

Through strategic antibody discovery and engineering, we designed a TCE optimized for the tumor specific CB02 expression profile with balanced CD3 binding affinity. Selection criteria focused on maximizing functional potency while maintaining molecular stability and manufacturability. *In vitro* characterization across multiple CB02 expressing preclinical tumor models allowed binder screening, kinetic analysis, cytotoxic function and profiling of T-cell activation and cytokine release. Functional assays showed robust, dose-dependent T-cell activation and cytotoxicity in 2D co-cultures as well as 3D spheroid models. Furthermore, we demonstrate robust in vivo efficacy of the CB02 TCE in systemic and subcutaneous cell-line derived xenograft models as well as good PK properties.

The preclinical investigation successfully identified and validated CB02 as a promising, highly selective T-cell engager target, significantly enriched on malignant cells over critical healthy cell types. The associated TCE exhibits high affinity and compelling in vitro and in vivo efficacy across both hematological and solid tumor models. These data strongly support the continued development of this CB02-targeted bispecific TCE antibody for clinical evaluation.

#1631 Leveraging off-the-shelf T cells to enhance bispecific T cell engager therapy efficacy in patients with suboptimal T cell responses.

Saghar Pahlavanneshan, Stephen J. Forman, Xiuli Wang

Cellular Immunotherapy Center, Department of Hematology and Hematopoietic Cell Transplantation, Beckman Research Institute of City of Hope, Duarte, CA

Bispecific T cell engagers (BiTEs) have showed potent antitumor activity in hematologic malignancies but are often limited by T-cell dysfunction in patients. To overcome this challenge, we developed an off-the-shelf immunotherapy platform using healthy donor-derived multi-virus-specific T cells (mVSTs) as effectors for BiTE-mediated redirection. These memory-derived mVSTs recognize cytomegalovirus (CMV) and Epstein-Barr virus (EBV) antigens, exhibit central and effector memory phenotypes, and carry minimal graft-versus-host disease (GVHD) risk, providing a bankable, and functional T-cell source.mVSTs were expanded from CMV/EBV-seropositive donors and evaluated in multiple myeloma and lymphoma models. Two BiTE-loading strategies were tested: pre-incubation with T cells (armored) or direct addition to co-culture. mVSTs alone exhibited minimal cytotoxicity, whereas BCMAxCD3 BiTE-redirected mVSTs mediated robust tumor lysis in both approaches (89.8 ± 1.7% and 88.7 ± 0.4%, respectively at 72h and E:T 1:4) and expanded ≥3-fold versus no-BiTE controls. Both loading methods triggered robust activation, with marked upregulation of CD137 and CD25 and substantial increases in effector cytokines. In Raji lymphoma models, CD19×CD3 and CD20×CD3 BiTEs produced 48-52% cytotoxicity with armored mVSTs, and direct BiTE addition further enhanced killing to 73-74% with a comparable activation profile. Collectively, BiTE-redirected mVSTs exhibit potent cytotoxicity, robust activation, and strong effector cytokine release across myeloma and lymphoma targets, validating their function as an effective, off-the-shelf T-cell platform. A single donor-derived mVST source can be paired with multiple BiTEs to address tumor heterogeneity or antigen-loss relapse without engineering. These data support the feasibility and translational promise of combining BiTEs with healthy donor-derived mVSTs to generate scalable, non-engineered allogeneic T-cell immunotherapies for diverse malignancies.

#1632 Preclinical characterization of DBXO-1, a multi-pMHC targeted bispecific T cell engager for major solid tumors.

Johanna K. Kaufmann, Jason Lajoie, John L. Silberstein

Deck Bio, Inc., Cambridge, MA

Bispecific T cell engagers (TCEs) are a well-established therapeutic modality in heme malignancies, and recent regulatory approvals in select solid tumors highlight their promise more broadly. However, adoption in major solid tumor indications and across large patient populations remains limited, in part by the scarcity of surface targets with cancer-exclusive expression patterns. Cancer-specific intracellular targets can be accessed by TCEs via peptide-MHC complexes (pMHCs), but individual pMHCs are expressed at low copy numbers which impacts TCE potency and breadth of response. DBXO-1 is designed to address this limitation by targeting a defined set of cancer-restricted intracellular proteins that generate multiple target pMHCs that can be recognized by a single binder, addressing copy number and heterogeneity concerns. Here, we describe the specificity profile and functional activity of DBXO-1 preclinically.A T cell receptor recognizing HLA-A*02:01-restricted target peptides was affinity- and specificity-engineered using yeast and phage display, aided by structural modelling. Optimized binders were formatted into Fc-containing TCEs using clinically validated anti-CD3 sequences. Affinity was measured by biolayer interferometry. Specificity was characterized using yeast display workflows and a T2/Jurkat reporter assay, cytotoxicity was assessed by LDH release. The DBXO-1 discovery campaign identified multiple pMHC binders with single digit nanomolar affinities to the relevant target pMHCs. When formatted into TCEs, this led to potent T cell activation with EC_{50}s <10 pM. Mutational analyses confirmed a shared structural recognition mode across target pMHCs, underlining the basis for the intended multi-targeting mechanism. Importantly, the specificity of final leads was assessed sequence-agnostically by testing binding against 13,849 HLA-A*02:01-presented peptides that were found in healthy tissues by immunopeptidomics. This comprehensive assessment revealed only a very small number of low-affinity interactions, a profile superior to a clinical stage benchmark pMHC-TCE. When T2 cells were pulsed with these peptides at supraphysiological concentrations for additional stringency, >100x EC_{50} windows for T cell activation were observed. Further derisking on healthy cells is ongoing. Finally, DBXO-1 mediated potent, dose-dependent cytotoxicity on multiple HLA-A*02:01^{+} cell lines expressing the target signature, while no activity was observed in absence of either target expression or HLA restriction.Taken together, these data support continued preclinical development of DBXO-1, with the goal of entering a first-in-human clinical trial in 2027. Initial clinical development is anticipated in biomarker-selected patient populations across major solid tumors, including non-small cell lung, head and neck, and gastroesophageal cancers.

#1633 MAIT engagers: Avoiding Treg suppression to deliver stronger activity in solid tumors..

Simon E. Plyte[1], Marie Fraudeau[1], Dorothee Winterberg[2], Claire Germain[1], Camille Rousseau[1], Maxime Audin[1], Alexandre Ivagnes[1], Sothea Touch Dumoitier[1], Sarah Ducellier[1], Lise Fenou[3], Hans Heinrich Oberg[2], Pierre Emmanuel Gerard[1], Isabelle Teulon[3], Daniela Wesch[2], Matthias Peipp[2], Julie Prigent[1]

[1]Biomunex Pharmaceuticals, Paris, France,[2]Universitats Klinikum Schleswig-Holstein,, Kiel, Germany,[3]IRCM, Univ Montpellier, ICM, INSERM, Montpellie, France

MAIT engagers are part of the immune cell engager drug modality and specifically target Mucosal Associated Invariant T cells (MAITs) via their unique T cell receptor (TCR) and tether them to cancer cells, via a tumor antigen, to elicit MAIT-mediated cell death. MAIT cells are an abundant cytotoxic subset of non-conventional T cells that are present in blood and all major organs and are particularly enriched in barrier tissues. Classical CD3 engagers activate all T cell subsets, including the regulatory T-cell (T-regs) population whose activation in the tumor microenvironment (TME) will dampen the intended cytotoxicity of the CD8 cytotoxic T cells and will limit CD3 engager efficacy. Unlike CD3 engagers, MAIT engagers only activate MAIT cells and do not cause increased immune suppression via T-reg activation or cytokine release syndrome (CRS) via general CD4 T cell activation. MAIT engagers were generated using Biomunex's proprietary bispecific, tetravalent antibody platform, BiXAb. MAIT-cell activation, proliferation, degranulation and cytotoxicity assays were established in co-culture between tumor cells, immune cell subsets (CD8 or PBMCs) and BiXAb MAIT engagers. Analysis of activation, degranulation and proliferation was followed by FACs whilst cytotoxicity was assessed by chromium release. Regulatory T cells were enriched from PBMCs and used in co-culture assays to assess CD8 T cell repression as judged by IL-2 release. General cytokine release was measured by Legend Plex or ELISA. Cytotoxicity of tumor-resident MAITs, from fresh patient samples, was determined by impedance measurements. *In vivo* efficacy studies were performed in humanized mouse models by co-injection of CD8s, cancer cells and the MAIT engager. MAIT engagers are as potent as classical CD3 engagers in terms of activation, degranulation, proliferation and cytotoxicity towards cancer cells. However, in co-culture assays of cancer cells and PBMCs, CD3 engagers induce large quantities of cytokines, especially IL-6 which is known to initiate CRS whilst MAIT engagers induced similar levels to control antibodies suggesting greater safety. CD3 engagers induced Treg activation proliferation and release of IL-10 in a dose dependent manner and induced Treg suppression of CD8 activation. MAIT engagers had no impact on Treg biology and increased immune suppression. *Ex vivo* cytotoxicity of tumor-resident MAIT cells using dissociated Ovarian cancer samples at "real E:T ratios" showed that MAITs in human tumors can respond to MAIT engagers, proliferate and eliminate tumor cells. *In vivo* efficacy studies showed that MAIT engagers can control human tumors in mice models of cancer. MAIT engagers are as potent as CD3 engagers but have a significantly improved safety profile. More importantly, they do not cause Treg activation which can dampen T-cell cytotoxicity in the TME and are expected to show greater efficacy in the clinic for the treatment of solid tumors.

#1634 A conditionally-active, dual-targeting TCE with superior tumor selectivity for the treatment of solid tumors.

Steffen Dickopf, Jorge A. Lerma Romero, Jessica Seib, Laura Perucho-Aznar, Steffen Runz, Abdul-Habib Maag, Anna Pryszlak, Anja Schreiber, Martha Gschwandtner, Christoph Erkel, Richard J. Austin

VERAXA Biotech GmbH, Heidelberg, Germany

Background

T cell engagers (TCEs) represent a rapidly advancing class of immunotherapies that have demonstrated remarkable clinical efficacy in hematologic malignancies. However, their application in solid tumors remains limited by on-target, off-tumor toxicities resulting from antigen expression in healthy tissues. Moreover, off-target, off-tumor effects can arise from systemic T cell engagement and nonspecific activation, leading to cytokine release syndrome (CRS). To overcome these challenges, we have developed an innovative TCE platform incorporating an AND-gated safety mechanism that enables selective killing of tumor cells while sparing healthy cells.

Method

The Bi-targeted Tumor-Associated Cytotoxicity (BiTAC) T cell engager builds up on the previously described hemibody concept[1] and employs an on-cell assembly mechanism of two complementary compounds to achieve conditional activation. Each compound comprises a tumor-binding domain recognizing a distinct tumor-associated antigen (TAA) and a split T cell-binding moiety. Individually, the compounds do not engage T cells. Productive T cell activation occurs only when both compounds co-bind and accumulate on tumor cells co-expressing the respective antigens, leading to reconstitution of an active CD3 binder. The BiTAC-TCE was optimized for developability, stability, and potent functional activity in both in vitro and in vivo settings.

Results

Our bioinformatics pipeline identified a TAA pair highly co-expressed in colorectal and lung cancers. Constitutively active drugs targeting each TAA individually have been tested in humans and revealed target-associated toxicities. An antibody format with favorable manufacturability and developability was subsequently selected. Using in vitro T cell-dependent cellular cytotoxicity (TDCC) assays across multiple cell lines in 2D and 3D cultures, we demonstrate that the combinatorial design of BiTAC-TCE enables T cells to selectively eliminate dual-target-positive tumor cells while sparing single-positive healthy cells. Individual compounds/BiTAC precursors don’t bind T cells and don’t induce TDCC in vitro and in vivo. Furthermore, BiTAC-TCE exhibits strong antitumor efficacy in PBMC-engrafted mice bearing colorectal tumors and displays a favorable pharmacokinetic (PK) profile in preclinical mouse studies.

Conclusion

Our BiTAC-TCE platform enables precise targeting of solid tumors through TAAs not druggable by current immunotherapies. Both TAAs addressed are broadly expressed but not co-expressed on healthy cells of different tissues, leading to failure of monotargeting T cell engagers in clinical settings. Our lead BiTAC-TCE for the treatment of colorectal and lung cancers has recently entered formal preclinical development and IND-enabling studies.

[1]Banaszek, A. et al. Nat Commun 10, 5387 (2019)

#1635 CBX-663, a first-in-class TCR-mimetic T-Cell Engager targeting the TERT peptide-HLA complex, mediates potent cytotoxicity *in vitro* and tumor inhibition *in vivo* in preclinical models of solid malignancies.

Yu Huang[1], Ricard Masia[1], Bhupal Ban[1], Qunyan Yu[1], Jennifer Helble[1], Jessica Jimenez[1], Delainey O'Connor[1], Preethi Sankaran[1], Christine A. Devlin[1], Melissa Bikowitz[1], Emily McNally[1], Sarah Jaffe[1], Tanzila Rahman[1], Alona Kulesha[1], Andrew Wolpert[1], Shawn O'Malley[1], Yue Li[1], Michael Jennings[1], Galina Gabriely[1], Mathilde A. Poussin[2], Daniel J. Powell[2], Nga Sze Amanda Mak[1], Tao Wang[1], Geraldine L. C. Paulus[1], Michi Schebesta[1], Benjamin Lee[1], Dmitri Wiederschain[1]

[1]Crossbow Therapeutics, Inc., Cambridge, MA,[2]Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA

While T-cell engager (TCE) therapies have demonstrated clear clinical benefit, their broader application remains limited by the restricted repertoire of tumor-specific surface antigens. Targeting HLA-restricted peptides (pHLA) derived from intracellular tumor antigens offers an opportunity to expand the reach of TCEs to solid tumors. Telomerase reverse transcriptase (TERT) represents such an intracellular target, as it is highly expressed in approximately 85-95% of human tumors. We have previously described CBX-663, a potent and specific TCR-mimetic (TCRm) TCE targeting the $TERT_{540}$/HLA-A*02:01 complex, and its activity in hematologic cancer models. Here, we characterize its therapeutic potential in preclinical solid tumor models. CBX-663 consists of a single humanized CD3-binding domain and two fully human TCRm domains that recognize $TERT_{540}$/HLA-A*02:01 in a bivalent format. CBX-663 binds $TERT_{540}$ pHLA with sub-nM affinity and low-pM avidity, leading to potent T-cell-mediated cytotoxicity across multiple TERT- and HLA-A*02:01-positive solid tumor cell lines. Subsequent analysis revealed that responsive cell lines exhibit higher HLA-A*02:01 expression than non-responders. Notably, some of the highest responding cell lines carry TERT promoter mutations, which are well known to elevate TERT transcription and may increase pHLA presentation. CBX-663 achieved robust tumor control in a disseminated NSCLC COR-L23-A2 model using PBMC-humanized NSG mice and induced tumor growth delay in a subcutaneous NSCLC NCI-H1703 model established in humanized CD34+ (huCD34) mice. Additional efficacy studies are ongoing. To further characterize specificity, X-scan analysis of $TERT_{540}$ peptide was conducted and revealed multiple residues critical for CBX-663 recognition of $TERT_{540}$ pHLA. A screen of >6,000 human membrane proteins identified no detectable off-target interactions of CBX-663. In addition, no activity was observed against TERT- or HLA-A*02:01-negative cells, unrelated HLA alleles, or normal HLA-A*02:01-positive primary cells from diverse tissues. CBX-663 induced moderate cytokine release upon treatment of HLA-A*02:01-positive PBMCs in the absence of tumor cells, consistent with previously reported targeting of monocytes and B cells by TERT-directed T cell therapies in preclinical models. Cytokine induction with CBX-663 was markedly lower than that elicited by a CD123-targeting TCE tested under identical conditions. Importantly, repeat dosing of CBX-663 was well tolerated in non-tumor-bearing huCD34 mice reconstituted with human hematopoietic cells, with minimal cytokine release and transient changes in leukocyte populations. Collectively, these data support the therapeutic potential of CBX-663 in solid tumors. IND-enabling studies are currently underway.

#1636 TNF-driven paracrine killing determines the cytotoxic efficacy of Teclistamab in Myeloma.

Allison Carr[1], Elise Sintim-Aboagye[2], Adrian Ting[1]

[1]Immunology, Mayo Clinic, Rochester, MN,[2]Medical Oncology, Mayo Clinic, Rochester, MN

Multiple Myeloma is the second most common hematologic malignancy among US adults and remains incurable. Immunotherapies, including bispecific T cell engagers (BiTEs) targeting BCMA, have greatly improved outcomes. However, a significant fraction of patients still fail to respond, or develop resistant disease. Conventional models of T cell cytotoxicity focus on delivery of perforin- and granzyme-containing granules following antigen recognition and T cell activation, an inefficient mode of killing that requires effector-to-target cell contact. Activated T cells, however, also secrete cytokines capable of diffusing and acting on distant targets. This raises the possibility of paracrine killing, in which these cytokines induce tumor cell death independently of cell-cell contact.Tumor necrosis factor (TNF) is a key cytokine released during T cell activation and is unique in that it can drive either cell survival or cell death. Although most cells default to cell survival and NFkB-mediated inflammation, several modulators can shift this survival signaling toward cell death. We therefore hypothesized that sensitizing Myeloma cells to TNF could enable T cell paracrine killing and enhance the efficacy of anti-Myeloma T cell immunotherapies.To test this, we first established an in vitro model of clinical response to Teclistamab, a BCMA-directed BiTE, using Multiple Myeloma cell lines that displayed sensitive, intermediate, or resistant responses to T cell killing. Combining these data with assays of cytokine sensitivity and receptor expression, we found that susceptibility to TNF-mediated cell death was a major determinant of Teclistamab sensitivity. This correlation was further supported by reduction or complete abrogation of Teclistamab T cell killing of sensitive Myeloma cell lines when soluble TNF was neutralized from these co-cultures using monoclonal antibodies. Pharmacologic inhibition and CRISPR-mediated deletion of known regulators of TNF survival-signaling further sensitized Myeloma cells to both TNF and T cell killing. In the absence of these regulators, BCMA-negative myeloma targets retained sensitivity to Teclistamab, supporting the idea that the main mechanism of cell death was indeed paracrine killing.Together, these findings establish a direct link between TNF sensitivity and T cell-mediated killing of Myeloma cells, and support TNF-driven paracrine killing as a dominant mechanism of response to Teclistamab. Enhancing this TNF-mediated death signaling may therefore represent a strategy to overcome resistance and improve clinical efficacy of T cell-based immunotherapies in Multiple Myeloma.

#1637 Human-cynomolgus cross-reactive CD3 nanobody-centric TCE platform enhances clinical translation.

Yuanyuan Wang, Ce Gu, Liang Xiao, Huijuan Lu, Ruhan Lin, Tingchu Wu, Peipei Hu, Chang Zhou, Fan Wu, Jian Guo, Yongting Huo, Di Lu

Guangdong Fapon Biopharma Inc., Guangdong, China

T-cell engagers (TCEs) have emerged as a research hotspot in recent years, owing to their ability to precisely mediate T cell killing of target cells. However, their clinical translation is frequently hindered by core challenges: insufficient target specificity, inadequate preclinical safety risk assessment, and poor developability. Thus, an advanced technological platform is urgently needed to break through these barriers and facilitate the efficient translation of TCEs from basic research to clinical applications.
Here, we established a TCE platform with distinctive technological advantages. Its core highlight lies in the integration of nanobodies targeting the first and second signals of T-cell activation, which possess cross-reactive binding activity between human and cynomolgus monkey, a feature provides crucial support for the preclinical safety assessment. Verification data demonstrates that the TCEs armed with our CD3 nanobody not only exhibit excellent cytotoxicity but also demonstrate favorable safety profiles and robust developability. Nanobodies not only meet the requirements of diverse structural design but also, due to their relatively small molecular weight, are best suited for in vivo TCE development. Currently, relying on the core components of this platform, we have initiated the development of three types of differentiated TCE projects:secondary signal enhanced TCEs, biased activation TCEs and dual-target TCEs. These core components and TCE projects will provide crucial support for achieving excellent therapeutic efficacy in oncology and autoimmune diseases.

#1638 A high-throughput luciferase cancer cell panel driving DLL3-targeted TCE discovery.

Chen Cai, Yue Zhai, Kejun Mao, Yixiao Zhao, Mingying Li, Qian Wang, Yan Zhang, Lili Chai, **Tj (Tiejun) Bing**

ICE Bioscience, Beijing, China

Background: T-cell engagers (TCEs) have rapidly moved into the spotlight as a next-generation immunotherapy, lauded for their (1) “off-the-shelf” convenience, (2) dual-arm precision that re-directs, rather than re-engineers, a patient’s own T cells, and (3) capacity to deliver deep, durable responses even after conventional checkpoint blockade has failed. Solid-tumor TCE development is now a major frontier, yet conventional assays—confined to few cell lines—offer limited throughput and cannot probe the full antigen expression spectrum, leaving a blind spot for candidate triage. To close this gap, we selected delta-like ligand 3 (DLL3)—an embryonic Notch inhibitor that is transcriptionally resurrected in high-grade neuroendocrine tumors yet absent from normal adult tissues—and constructed a fully integrated discovery platform anchored by a 20-member luciferase-reporter tumor panel that systematically recapitulates clinically relevant expression gradients.

Methods: The platform merges four modules: (1) biophysical profiling via SPS binding kinetics and cell-based affinity screens; (2) parallel 2-D/3-D tumor co-culture assays as well as ICI combination to evaluate T-cell mediated cytotoxicity; (3) multiparametric T-cell activation readouts (CD69/CD25, proliferation); and (4) 10-plex cytokine release assays to map safety-relevant inflammatory signatures.

Results Here we showcase several DLL-3 targeting TCEs using a diverse luciferase-neuroendocrine cell panel. Preclinical studies demonstrate their binding, activation, antitumor activity, and T cell expansion in DLL3+ cell lines across cancer types, juxtaposed with a diminished impact on DLL3- cell lines.

Conclusions: This platform enables high-throughput evaluation of TCEs across the full antigen expression spectrum, systematically linking target density to therapeutic activity and safety outcomes. By linking target density to TCE performance, this system guides candidate selection and accelerates solid-tumour TCE development, while being readily adaptable to other antigens.

#1642 A pan-RASi antibody-drug conjugate platform with high activity in RAS-mutant cancers.

Graham A. E. Garnett, Victoria K. Harman-McKenna, Taixiang Wang, Jodi Wong, Truman Hirkala-Schaefer, Michael G. Brant, Mark E. Petersen, Catalina Suarez, Khushi Lodaya, Rehan Higgins, Jesse H. Leblanc, Linglan Fu, Cathy Fu, Sara Weeres, Manuel Lasalle, Kaylee J. Wu, Vidhi Khanna, Sam Lawn, Kurt Stahl, Vincent Fung, Raffaele Colombo, Stuart D. Barnscher, Jamie R. Rich

Zymeworks Inc., Vancouver, BC, Canada

Aberrant activation of RAS protein by oncogenic mutation is a critical driver of tumorigenesis, yet effective and tolerable inhibition of RAS signaling remains a major unmet need. Tricomplex RAS inhibitors (RASi) are an emerging class of drugs that disrupt RAS signaling by forming a ternary complex with cyclophilin A (CypA) and the active, GTP-bound conformation of RAS [RAS(ON)], thereby blocking downstream signaling through the MAPK and PI3K pathways. RMC-6236 is an orally administered, potent pan-RAS inhibitor and is a prototypical drug in this class. Despite promising initial results in the clinic, treatment-related adverse events such as skin and gastrointestinal toxicities have emerged, likely as a result of on-target, off-tumor inhibition of RAS in normal tissues. We hypothesized that targeted delivery of a potent pan-RASi as an antibody-drug conjugate (ADC) payload could enhance anti-tumor efficacy and improve tolerability, thereby overcoming the limitations of orally administered RASi small molecules. Here we report the generation of a novel antibody-drug conjugate platform designed for the treatment of RAS-mutant cancers.

To identify suitable ADC payloads, novel pan-RAS inhibitors were synthesized with a focus on high potency, favorable polarity, and suitable functionality for linker attachment. A library of over 100 novel linkable pan-RAS inhibitors was synthesized and screened, with multiple candidates demonstrating significantly higher potency than RMC-6236 across a panel of KRAS-mutant cell lines. Mechanistic characterization of RAS binding was achieved via surface plasmon resonance, demonstrating formation of the binary (CypA:inhibitor) and ternary (RAS:CypA:inhibitor) complexes. Disruption of RAS–RAF interaction was profiled using homogeneous time resolved fluorescence.

Drug-linkers were generated from selected payloads and used to produce ADCs with a drug-to-antibody ratio of 8. Linker format and payload attachment site were tuned to improve drug-linker hydrophilicity and ADC pharmacokinetic characteristics. Pan-RASi ADCs were profiled for targeted antitumor activity in tumor cell lines. More than 20 ADCs with distinct drug-linkers were evaluated and >10 were selected for evaluation in cell line derived xenograft models. Strong regressions were observed with single doses as low as 1 mg/kg in multiple models. Evaluation in mice demonstrated no significant toxicity at doses up to 200 mg/kg. Safety was further assessed in non-human primate studies. Collectively, the promising antitumor activity and manageable tolerability profile support the application of this novel pan-RASi ADC platform to clinically meaningful targets across NSCLC, PDAC, and CRC.

#1643 Targeting LANCL1 with a humanized monoclonal antibody suppresses tumorigenesis in hepatocellular carcinoma.

Chui-Yee Diana O, Yu-Man Tsui, Irene Oi-Lin Ng

Pathology, The University of Hong Kong, Hong Kong, China

Background: The limited efficacy of current hepatocellular carcinoma (HCC) treatments drives the need for novel molecular targets. Building on our previous discovery that LANCL1 promotes HCC tumor initiation by reducing cellular reactive oxygen species (ROS), this study aims to validate it as a druggable target and develop a first-in-class humanized antibody therapeutic.
Methods: We generated a parental murine monoclonal antibody (mAb) against LANCL1. Its efficacy was evaluated *in vitro* using sphere-formation, cytotoxicity, migration, and invasion assays on HCC cell lines, and *in vivo* in an orthotopic HCC model. For clinical translation, we created humanized variants, with binding affinity assessed by Surface Plasmon Resonance (SPR).
Results: *In vitro*, the parental murine mAb potently inhibited cancer stemness (>90% reduction in sphere formation), induced significant cytotoxicity (<55% viability), and suppressed migration and invasion (67.6% and 85.3%, respectively). *In vivo*, it impaired tumor growth by 50.3%. This efficacy was demonstrated in an orthotopic NOD SCID model established with implanted human hepatic tumor cells. We next evaluated nine humanized variants, finding that all exhibited binding affinity comparable to the parental antibody. Specifically, Variant 1 showed strong inhibition at 62.8%, an efficacy close to the chimeric antibody (83.5%). Although Variant 2 was less potent, it still achieved significant inhibition at 44.5%. This confirms the humanization process successfully retained anti-tumor efficacy.
Conclusion: This work is novel as it presents the first therapeutic antibody targeting LANCL1. Our findings not only confirm the therapeutic potential of LANCL1 inhibition but also demonstrate the potent anti-tumor activity of a novel humanized antibody, providing a strong foundation for future clinical development.

#1646 Maximizing therapeutic index using fully Fc-silent antibody platform.

Kihwan Chang

CrossPoint Therapeutics, Hwaseong-si, Gyeonggi-do, Korea, Republic of

Antibody drug conjugates (ADCs) have transformed the clinical landscape for the treatment of cancers over the last two decades spear-headed by intensive research of linker and payload chemistries. However, toxicities remain a concern where impairing dosage and administration frequency of the ADCs could impact overall clinical benefit. We developed Stealth-Body (SB) by introducing specific mutations in the Fc region of the antibody to limit Fc-Fcγ receptor interactions without compromising efficacy and maintaining manufacturing scalability, when compared to LALA mutations, the SB Fc showed improved pharmacokinetic (PK) parameters such as half-life in serum studies in double transgenic mice (huFcRn and hualbumin) and complete loss of binding to all Fcγ receptors as well as C1q. Based on these characteristics, we are developing a ADCs containing SB Fc for selective anti-tumor efficacy and limiting interaction with Fcγ receptors to reduce off-target toxicities. Antibodies containing WT Fc and SB Fcs were conjugated with MMAE and efficacy was determined in in vitro and in vivo studies. Currently, PK studies in mice and preliminary toxicology studies in non-human primates are ongoing. To determine whether SB Fc conjugates were able to avoid off-target toxicities, cancer cell lines expressing FcγRs were treated with SB Fc containing conjugates or WT Fc conjugates. As expected, the SB Fc conjugates displayed no off-target cell killing toxicities in these cell lines compared to WT Fc conjugates. Conjugates containing the SB Fcs maintained potent efficacy in vitro in cancer cell lines similar WT Fc containing conjugates, indicating that efficacy was not compromised by the mutations in the SB Fc. In in vivo cell line derived xenograft (CDX) models, the SB Fc conjugates showed strong tumor growth inhibition (TGI) as single injection doses and similar potent minimum efficacious dose (MED) was observed in CDX models and determined to be 0.6 mg/kg. These preclinical data demonstrate the potential of SB Fc containing ADCs as promising for the treatment of various cancer indications and supports their use for clinical development.

#1647 RenNano platform enables efficient discovery of fully human VHH antibodies.

Frank An, Xun Xu, Jun Du, Yiqing Hu, Baihong Liu, Guan Wang, Hao Cai, Lijun Zhang, Huizhen Zhao, Jiawei Yao, Chengzhang Shang, Qiuhong Yu, Xueyuan Jiang, Fengping Yao, Jing Huang, Gao An, Yi Yang

Biocytogen, Waltham, MA, MA

VHH antibodies stand at the forefront of biomedical research, driven by their distinctive structural properties and versatile applications. The clinical potential of this technology was formally validated in 2018 with the approval of caplacizumab, the world's first VHH antibody-based drug. Currently, a growing pipeline of VHH antibody-based therapies is under investigation in clinical trials, targeting a broad spectrum of diseases, including various cancers (with a focus on PD-L1 and EGFR pathways), cardiovascular disorders, inflammatory conditions, and neurodegenerative diseases like Alzheimer's and Parkinson's. With a molecular weight of merely 12-15 kDa—approximately one-tenth that of conventional IgG antibodies—and a compact structure, VHH antibodies possess unparalleled tissue penetration capabilities. The complementary determining region (CDR) of VHH antibodies, particularly the CDR3 loop, is significantly longer, forming a protruding "finger-like" structure. This unique conformation allows VHH antibodies to penetrate deep into hidden antigen epitopes, such as enzyme active sites or viral conformational epitopes, that are inaccessible to traditional antibodies. However, the production of VHH antibodies requires the use of camelid animals (such as llamas and alpacas) or the construction of phage display libraries via genetic engineering techniques. Compared with the production of traditional mouse monoclonal antibodies, its production process may be more complex, and the cost may also be higher. Our RenNano mice produce fully human heavy chain-only antibodies that eliminate the need for *in vitro* humanization, thereby accelerating the development process and reducing costs. Owing to their small size and structural flexibility, these VHH antibodies have demonstrated significant utility in key applications such as conditional activation (e.g., 4-1BB), half-life extension (e.g., ALB), and enhanced blood-brain barrier (BBB) penetration through improved receptor-mediated transcytosis (e.g., TFR1). Leveraging the RenNano platform, we have developed a fully human VHH antibody library for the treatment of cancer, autoimmune diseases, and metabolic disorders. Preliminary evaluations indicate that these VHH antibodies possess developability profiles comparable to those of marketed VHH antibody drugs.

#1648 Real-time imaging for quantitative assessment of antibody-drug conjugate internalization.

Tian Wang[1], Yunfei Pu[1], Ryan Raver[2], **Xiaoyu Zhang**[2], Peifang Ye[1], Nancy Li[2]

[1]Agilent Technologies, Hangzhou, China,[2]Agilent Technologies, La Jolla, CA

Antibody-drug conjugates (ADCs) represent a major advancement in cancer therapy, relying on efficient target-mediated internalization for optimal efficacy. This underscores the need for precise, convenient, and cost-effective methods to monitor antibody internalization for candidate selection, mechanism-of-action studies, and safety evaluation. We present a robust, real-time quantitative assay using the Agilent xCELLigence RTCA eSight system combined with CypHer5E-NHS-Ester labeling. CypHer5E is a pH-sensitive cyanine dye that fluoresces in acidic environments, enabling dynamic tracking of antibody trafficking into intracellular compartments. Using this approach, we demonstrated selective internalization of CypHer5E-labeled trastuzumab in HER2-positive cell lines via receptor-mediated uptake. Both primary CypHer5E labeling and secondary Fab-CypHer5E conjugation enabled clear visualization of internalization events. Furthermore, secondary Fab-CypHer5E labeling facilitated comparative analysis of multiple HER2-targeting therapeutic antibodies. This integrated platform provides a powerful tool for mechanistic studies and drug-screening assays, offering critical insights to optimize antibody efficacy, safety, and pharmacokinetics in biopharmaceutical development.

#1649 FcRn humanized mice with an immunodeficient background can be used to evaluate the pharmacokinetics of antibody drugs while avoiding anti-drug antibodies.

Hannah Horton, Ruili Lv, Suman Zhao, Qingqing Xu, Xiaofei Zhou

Biocytogen, Waltham, MA

Introduction: FcRn is a pH-dependent receptor that binds and recycles IgG, preventing its lysosomal degradation to extend plasma half-life. Separately, Rag2 is essential for V(D)J recombination in lymphocyte maturation, and its absence results in a lack of functional T and B cells, preventing the formation of Anti-Drug Antibodies (ADA).Biocytogen's B-hFcRn, Rag2 KO mouse model is a tool for PK/PD/safety evaluation of human IgG therapeutics that circumvents ADA via T and B cell deficiency.

Methods: l B-hFcRn mice (110001) were generated by replacing exons 2-4 of the mouse *Fcgrt* gene with a coding sequence (CDS) that encodes full-length human *FCGRT*, while the mouse *Fcgrt* gene transcription and translation will be disrupted.B-Rag2 KO mice (110809) were produced through targeted knockout of exon 3 and the 3' UTR region of the *Rag2* gene. This knockout leads to the inactivation of Rag2.To generate B-hFcRn, Rag2 KO mice, B-hFcRn mice (110001) were mated with B-Rag2 KO mice (110809).l For protein expression analysis, spleen, lung tissue lysates were collected from wild-type C57BL/6N mice (+/+), homozygous B-hFcRn mice (H/H), and homozygous B-hFcRn, Rag2 KO mice (H/H, -/-), and then analyzed by western blot with species-specific anti-FcRn antibody. l The frequency of leukocyte subpopulations was analyzed in B-hFcRn, Rag2 KO mice. Using flow cytometry, immune cells (including T and B cells) in the spleen, blood, and thymus were quantified and compared to wild-type C57BL/6 mice.l The *in vivo* PK of YTE-mutated and control antibodies was assessed in C57BL/6, B-hFcRn, B-Rag2 KO, and B-hFcRn, Rag2 KO mice following tail vein injection and serial blood collection.

Results: l Western blot analysis results indicated that human FcRn was detected in the spleen and lung of B-hFcRn, Rag2 KO mice.l Flow cytometry analysis revealed that T cells and B cells were undetectable in the spleen, blood, and thymus of homozygous B-hFcRn, Rag2 KO mice.l PK data suggest ADA formation against our YTE antibody in immunocompetent mice, its absence in Rag2 KO mice, and a half-life-extending effect that was confined to hFcRn humanized mice.

Conclusions: The B-hFcRn, Rag2 KO mouse model, deficient in T and B cells yet expressing human FcRn, provides a valuable tool for assessing the PK/PD of antibody candidates that are susceptible to ADA interference in immunocompetent mice.

#1650 MPSA-AB5000: A high-throughput cell-based membrane protein screening array for accurate early-stage off-target assessment to accelerate safer antibody therapeutic development.

Liping Wang, Guoqian Wang, Yao Peng, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., LTD, Beijing, China

Antibody drug development is a lengthy and complex process, often hindered by off-target binding that affects approximately 25-30% of preclinical candidates. With the growing importance of advanced modalities such as CD3 bispecific antibodies, antibody-drug conjugates (ADCs), and CAR-T therapies, early and accurate off-target assessment has become essential. However, conventional assays—including immunohistochemistry (IHC), ELISA, and flow cytometry (FACS)—remain limited in sensitivity, specificity, and throughput.To address these limitations, we developed the Membrane Protein Screening Array (MPSA-AB5000), a high-throughput, cell-based platform for comprehensive identification of antibody targets and off-targets. The MPSA-AB5000 expresses a broad spectrum of human membrane proteins in live cells, maintaining native conformation and post-translational modifications to ensure physiologically relevant binding analysis. MPSA-AB5000 is a high-throughput, cell-based platform for identifying antibody targets and off-targets, enhancing antibody specificity screening and reducing development risks. To provide the highest level of sensitivity, MPSA-AB5000 uses luciferase reporter cell line detection. The wash-free strategy reduces false negatives, and signal amplification makes remarkable discrimination. Furthermore, the platform integrates a Protein A-based reporter system, leveraging Protein A's strong Fc-binding affinity—particularly for human IgG1, IgG2, and IgG4—to immobilize antibodies on reporter cells. This allows detection of off-target-induced signaling even in Fc-modified formats such as IgG1-LALA or IgG4. Collectively, the MPSA-AB5000 provides a robust, versatile, and physiologically relevant solution for antibody target deconvolution and specificity evaluation, accelerating the discovery and optimization of safer antibody therapeutics.

#1651 Automated imaging-based verification of monoclonality in single-cell cloning confirms higher efficiency of the Pala single cell sorter and dispenser compared to limiting-dilution assays.

Ahmed Shaaban[1], Benjamin Werdelmann[2], Anna Willms[2], Matthias Pirsch[2], Sebastian Kollenda[2], Aleks Guledani[2], Ankit Vaghasiya[2], Susanne Sebens[3], **Ryan McComb**[1], Reinhild Geisen[2]

[1]Bio-Techne, San Jose, CA,[2]Synentec GmbH, Elmshorn, Germany,[3]Institute for Experimental Cancer Research and University Hospital Schleswig-Holstein Campus Kiel, Kiel, Germany

Establishing monoclonal cell lines is a common process in cancer research and drug discovery, ensuring genetic uniformity and reproducibility in functional assays, therapeutic antibody production, and clinical manufacturing. However, isolating single cells and confirming their monoclonal origin remain major bottlenecks due to the low efficiency and high hands-on time of conventional limiting-dilution assays (LDA). We therefore assessed a workflow combining the Pala Single Cell Sorter and Dispenser (Bio-Techne) with SYNENTEC's automated imaging system for reliable, traceable proof of monoclonality and compared it to LDA.

One cell per well was dispensed into 10 × 96-well plates using Pala, and parallel LDA controls were prepared at 0.5 cells/well. We used CHO-K1 cells as the main production cell line as a robust cell model for process validation, before testing the system with cancer cell lines. Wells were automatically imaged on days –1, 0, 1, 4, and 8 using SYNENTEC's high-throughput imaging system. Automated segmentation, clone tracking, and confluence analysis were performed with YT-SOFTWARE®. Wells were classified as clonal, non-clonal, empty, or 'ghost' based on initial and subsequent images. Single-cell dispensing efficiency, colony formation rate, and growth kinetics were compared between methods.

Pala dispensing yielded 828 monoclonal colonies versus 329 from LDA, representing a >2.5-fold increase. The average number of monoclonal wells per 96-well plate was higher (71.2 vs. 32.8), while the number of non-clonal (7.2 vs. 13.4) and empty wells (16.6 vs. 49.5) was reduced. Average clonal outgrowth per single cell (89.8 % vs. 78.4 %) and growth rate (0.86 vs. 0.83) were higher for Pala, indicating gentle handling and improved viability. The automated workflow reduced hands-on time and provided clear documentation for regulatory compliance.

Combining Pala single-cell dispensing with SYNENTEC's automated imaging enhances clonal yield, efficiency, and traceability while reducing resource consumption. This approach accelerates the establishment of standardized, reproducible cell models and supports high-throughput biotherapeutic and translational oncology research.

#1652 Binding to bridging: Complete suite of FcγR assay tools accelerates antibody therapeutic development.

Julia K. Gilden, Denise Garvin, Kristin Riching, Brock F. Binkowski, Richard Moravec, Pete Stecha, Rod Flemming, Becky Godat, **Kai Hillman**, Marjeta Urh, Mei Cong, Jamison Grailer

Promega, Madison, WI

Antibodies are effective therapeutics because of their specificity in binding to an antigen and ability to activate an immune response through Fc effector functions like antibody-dependent cellular cytotoxicity (ADCC), antibody-dependent cell phagocytosis (ADCP), and complement-dependent cytotoxicity (CDC) by engaging with immune cells like NK cells and macrophage. However, traditional methods for characterizing these interactions are highly variable and labor-intensive. We developed a suite of luminescent assays for characterizing antibody effector functions for robust, streamlined measurement across antibody development: Lumit® Binding Immunoassays, Fc Effector Reporter Bioassays for ADCC/ADCP, and HiBiT Target Cell Killing Bioassays using MoA-qualified primary cells. We demonstrate application to anti-CD20 biosimilar antibodies, showing concordant rank order from binding to functional killing studies. These rapid, high-throughput assays support comparability, stability, and lot-release decisions.

#1653 FcRn humanized rats for pharmacokinetics assessment of antibody drugs.

Kelvin Yin, Suman Zhao, Zhi Zhang, Yanling Wang

Biocytogen, Waltham, MA, MA

Introduction: Biocytogen's B-hFcRn rat model serves as a practical tool for assessing the pharmacokinetics/pharmacokinetics and safety of human IgG therapeutics. The model capitalizes on the rat's larger size, which allows for serial blood sampling and thus more efficient and continuous data collection compared to mice, where animal welfare considerations necessitate staggered sampling across subgroups. This is combined with the presence of human FcRn, a pH-dependent receptor that binds and recycles IgG, protecting it from lysosomal degradation to extend its plasma half-life.

Methods: l B-hFcRn rats were generated by inserting a chimeric cDNA encoding full-length human *FCGRT,* followed by its 3'UTR and stop codon right after the rat *Fcgrt* start codon, thereby replacing exons 2-4 and placing human FcRn expression under the control of the endogenous rat promoter while disrupting the native rat gene.l For protein expression analysis, liver, kidney, and spleen tissue lysates were collected from wild-type SD rats (+/+), homozygous B-hFcRn rats (H/H), and then analyzed by western blot with species-specific anti-FcRn antibody. l SD rats and B-hFcRn rats were intravenously injected with Bevacizumab (commercial), and serum was collected for pharmacokinetic (PK) analysis.

Results: l Western blot analysis results indicated that Rat FcRn was only detectable in wild-type SD rats. Human FcRn was exclusively detectable in the liver, kidney, and spleen of homozygous B-hFcRn rats.l Linear pharmacokinetics were observed in B-hFcRn rats after a single intravenous bolus administration of the monoclonal antibody and serial blood collection. PK data suggest that the B-hFcRn rat model enables reliable prediction of the FcRn-mediated pharmacokinetics and efficacy of IgG antibodies in humans.

Conclusions: The B-hFcRn rat model is used for pharmacokinetics, pharmacodynamics, and safety evaluation of human immunoglobulin G (IgG) and is based on the Fc domain therapeutics.

#1654 Bioluminescent and cell-based assays for comprehensive characterization of antibody-drug conjugate mechanisms of action.

Mei Cong[1], Yitong Li[1], virginia Kincaid[2], Morten Seirup[1], Christopher Eggers[3], Rod Flemming[4], Jim Hartnett[4], Kristin Riching[4], Jamison Grailer[1], Julia K. Gilden[1]

[1]Promega, Madison, WI,[2]R&D, Promega, Madison, WI,[3]Promega Corp., Madison, WI,[4]

The growing field of targeted therapeutics has led to the emergence of Drug Conjugates, including antibody-drug conjugates (ADCs), protein-drug conjugates (PDCs), and other payload-conjugated biologics that integrate selective delivery with potent cytotoxic payloads. These modalities exert therapeutic effects via multiple mechanisms of action (MoA), including direct cytotoxicity following receptor binding and internalization, bystander killing via cleaved payload diffusion, antigen function blockade, and immune-mediated cytotoxicity such as ADCC and ADCP, driven by Fc effector function. Effective characterization and potency assessment of ADCs require robust in vitro tools that capture these complex MoA. Here we present a panel of bioluminescent and cell-based assays to support the pharmacological profiling of ADCs. The Lumit® Ligand Binding Assay provides a homogeneous solution-phase format to quantify antigen engagement by mAbs and ADCs, enabling efficacy and QC assessments. The Lumit® FcRn Binding Immunoassay evaluates FcRn-ADC interactions to inform half-life predictions and Fc engineering. Fcγ receptor binding, uptake, and C1q engagement are assessed through Lumit®-based and cell-based formats, offering insights into immune effector functions and FcγR-mediated toxicity. Additionally, a bioluminescent ADC Internalization Assay tracks intracellular trafficking, enabling payload delivery characterization and identification of dose-limiting toxicity risks. Together, these assays offer scalable, reproducible platforms for PK, PD, and toxicity evaluation in ADC development.

#1655 Building a recombinant Factor C assay to enable sustainable endotoxin testing in antibody development.

Yingjie Liu[1], **Peter Hsueh**[2], An Ouyang[2], Spencer Chiang[1], YuehChun Hsieh[1]

[1]ACROBiosystems Co., Ltd., Beijing, China,[2]ACROBiosystems Inc., Newark, DE

Endotoxins, lipopolysaccharide components of the outer membrane of Gram-negative bacteria, are among the most potent pyrogens known. Even at trace levels, endotoxins can trigger severe inflammatory responses in humans, including fever, hypotension, septic shock, and multi-organ failure, particularly when introduced intravenously. Consequently, accurate detection and quantification of endotoxins are essential at every stage of biopharmaceutical development, from early-stage antibody discovery to large-scale manufacturing and final product release. In the context of antibody discovery, residual endotoxins in cell culture supernatants or during purification can confound in vitro bioassays, misrepresent functional activity, and affect downstream characterization. During manufacturing, endotoxin contamination poses a serious safety risk and regulatory non-compliance, necessitating rigorous quality control measures. Regulatory agencies globally, including the FDA and EMA, mandate strict endotoxin limits for injectable therapeutics, emphasizing the importance of robust and reliable endotoxin assays in maintaining both patient safety and product efficacy. Traditionally, the Limulus Amebocyte Lysate (LAL) assay has been the industry standard due to its high sensitivity, rapid turnaround, and broad adoption across biopharmaceutical laboratories. However, LAL relies on lysates derived from horseshoe crab blood, raising sustainability, ethical, and supply chain concerns. In response, recombinant Factor C (rFC) assays have emerged as a viable animal-free alternative. rFC assays leverage recombinant expression of Factor C, the key enzyme initiating the LAL coagulation cascade, with fluorescence-based detection of endotoxin binding. This study describes the development and validation of an rFC-based endotoxin detection method specifically optimized for antibody discovery and production workflows. The method was benchmarked against conventional LAL assays in accordance with established bioanalytical validation guidelines, demonstrating comparable sensitivity with a lower limit of quantitation (LLOQ) of 0.005 EU/mL. Notably, the absence of Factor G in rFC assays eliminates interference from β-glucans, as verified by spiking experiments with 10 μg/mL β-glucan, which produced no detectable non-specific signal. Extensive matrix testing across 25 common buffers and culture supernatants revealed recovery rates ranging from 75% to 109%, underscoring the assay's robustness and versatility. Overall, the rFC assay provides a reliable, sensitive, and ethically responsible approach to endotoxin monitoring, aligning with the 3Rs principles while maintaining rigorous analytical performance.

#1656 Luminescent assay platforms accelerate therapeutic antibody development in veterinary immuno-oncology.

Jun Wang, Denise Garvin, Ildiko Kasza, Jim Hartnett, Mei Cong, Jamison Grailer

Promega, Madison, WI

Advances in immuno-oncology increasingly depend on translational animal models to inform mechanism of action (MoA), pharmacokinetics, and therapeutic potential. Beyond their preclinical utility for human therapies, these models are critical for developing novel biologics in veterinary oncology, particularly in canine cancers, which share key demographic, immunologic and molecular features with human disease. A major limitation in this research is the lack of robust analytical tools to characterize species-specific antibody function and receptor engagement. We developed a suite of luminescent, cell-based bioassays to quantify Fc-mediated effector mechanisms, including antibody-dependent cellular cytotoxicity (ADCC). Each assay incorporates canine Fcγ receptors and features luciferase reporters, providing sensitive, quantitative, and reproducible readouts suitable for potency and MoA evaluation. In addition, cell-based reporter bioassays were developed to measure the potencies of antibodies that modulate canine immune checkpoints (PD-1/PD-L1) or co-stimulatory receptors (CD40). Complementing these cell-based tools, an improved canine antibody binding assay offers a rapid, homogeneous alternative to ELISA and SPR methods for characterizing antibody-target interactions. The assay supports antibody development from screening to potency release testing of veterinary antibody therapeutics. Together, these luminescent assay platforms streamline veterinary immuno-oncology research, accelerating translation of therapeutic antibodies across species.

#1657 BCG015:A first-in-class antibody-drug conjugate targeting TM4SF5 for the treatment of hepatocellular carcinoma.

Guan Wang, Zhi Qi, Yu Qi, Gao An, Cong Shen, Yanan Guo

Biocytogen, Waltham, MA, MA

Background: Hepatocellular carcinoma (HCC) is one of the leading causes of cancer-related mortality worldwide, and patients with HCC respond poorly to current therapies. Currently, no antibody-drug conjugate (ADC) has been approved or is in late-stage clinical development for the treatment of HCC. To address this unmet medical need, Biocytogen developed a novel ADC targeting TM4SF5 for HCC treatment.
Results: TM4SF5 expression was detected in 70% of HCC patient samples, with limited expression in normal tissues. Target abundance studies in HCC cell lines revealed TM4SF5 protein levels comparable to or higher than those of other HCC-associated tumor antigens. TM4SF5 demonstrated internalization activities in HCC cell lines.The lead anti-TM4SF5 mAb generated from Biocytogen's RenLite® transgenic mice exhibited high affinity, good specificity, strong cancer cell binding, and efficient internalization *in vitro*. It also demonstrated excellent physicochemical properties and stability under accelerated and stress conditions.BCG015, the BLD1102-conjugated ADC, showed potent and TM4SF5-dependent tumor growth inhibition activity in HCC cell lines. *In vivo*, BCG015 exhibited significant antitumor efficacy across multiple HCC CDX and PDX models with TM4SF5 expression. In four CDX models, BCG015 demonstrated comparable or superior efficacy compared to ADCs targeting other HCC-associated antigens. Preliminary safety studies in canine and cynomolgus monkey models are ongoing.
Conclusion: BCG015 represents a novel, first-in-class ADC targeting TM4SF5 with strong preclinical efficacy. These findings highlight its potential as a promising therapeutic option for HCC patients with TM4SF5 expression, addressing a significant unmet need in liver cancer treatment.

#1658 Preclinical study of NW008, a novel dual-functional anti-MICA/B antibody-drug conjugate.

Afang Zhou[1], Juanjuan Li[1], Changcheng Li[1], Xueying Zhong[1], Yiran Wu[1], Li Liu[1], Gang Liu[1], Jiaoyi Zhong[1], Lijia Yang[1], Junkui Yang[1], Dan Mi[1], Jiabao Liu[1], Yaolan Dai[1], Yan Gao[1], **Zhijian Li**[2], Bin Liu[1], Zhigang Guo[1], Wenting Luo[1]

[1]Chengdu Chipscreen Newway Biosciences Co., Ltd., Chengdu, China,[2]Chipscreen Biosciences (United States) Ltd, Somerset, NJ

Background: The MHC class I polypeptide-related sequences A and B (MICA and MICB; collectively MICA/B) are stress-induced antigens. They are minimally expressed in healthy tissues but overexpressed in a wide range of solid tumors. Membrane-bound MICA/B activates antitumor immunity by engaging the NKG2D receptor on immune effector cells, such as CD8-positive T cells, natural killer (NK) cells and γδ T cells. However, proteases in the tumor microenvironment (TME) cleave MICA/B from the tumor cell surface, which impairs NKG2D-mediated tumor recognition and facilitates immune evasion. Furthermore, soluble MICA/B induces sustained NKG2D activation, resulting in receptor downregulation and lymphocyte dysfunction. Elevated serum levels of soluble MICA are associated with poor patient survival, highlighting the therapeutic potential of targeting MICA/B.
Methods: Mice were immunized with recombinant proteins containing the α3 domain derived from multiple MICA/B alleles. A humanized anti-MICA/B antibody that binds with high affinity to various MICA/B alleles was obtained through high-throughput screening. Each antibody molecule was site-specifically conjugated to four molecules of a highly potent topoisomerase I inhibitor via a specially designed, hydrophilic, enzyme-cleavable linker that suppresses the retro-Michael reaction, resulting in the ADC candidate NW008. The in vitro antitumor activity of NW008 was evaluated using multiple MICA/B-expressing tumor cell lines. Its in vivo efficacy was assessed in several cell-derived xenograft (CDX) models.
Results: The humanized anti-MICA/B antibody exhibited high internalization efficiency and sub-nanomolar affinity for multiple MICA/B alleles. It also inhibited MICA/B shedding from tumor cells and enhanced MICA/B-NKG2D interactions. The ADC molecule NW008 demonstrated high homogeneity and favorable stability, and it showed potent cytotoxicity against a variety of MICA/B-expressing tumor cell lines, with half-maximal effective concentration (EC_{50}) values in the nanomolar range. In multiple mouse xenograft models bearing human MICA/B-expressing tumors, NW008 exhibited significant antitumor efficacy in vivo, with maximum tumor growth inhibition (TGI) exceeding 85% in all models, and was well tolerated.
Conclusion: MICA/B represents a highly attractive target for ADC development. NW008 is a first-in-class dual-functional ADC that acts by restoring antitumor immunity through inhibition of MICA/B shedding and directly eliminating tumor cells via targeted delivery of a topoisomerase I inhibitor. NW008 demonstrates robust antitumor efficacy in preclinical models, supporting its clinical development as a promising therapeutic candidate for MICA/B-positive solid tumors.

#1659 Development of a novel PSCA-targeting antibody-drug conjugate with high potency and stability for prostate cancer therapy.

Yanyang Cao, Evelyn A. Kono, Robert E. Reiter

Department of Urology, UCLA David Geffen School of Medicine, Los Angeles, CA

Antibody-drug conjugates (ADCs) enable the selective delivery of highly cytotoxic payloads to tumors and are emerging as new, promising therapeutic options for prostate cancer. Prostate stem cell antigen (PSCA) is a cell-surface antigen that is highly overexpressed in prostate cancer and upregulated in advanced disease states, while minimally expressed in normal tissues, making it an ideal target for ADC therapy. In this study, we identified and generated full-length human anti-PSCA antibodies, exhibiting high binding affinity and rapid internalization into PSCA-expressing cancer cells. Various cytotoxic drugs (e.g., monomethyl auristatin E (MMAE), DM1, etc.) were conjugated to the lead anti-human PSCA antibody (A2) using a chemically validated linker. Among the resulting ADC candidates, A2-MMAE demonstrated the most potent, concentration-dependent cytotoxicity against PSCA-positive human prostate cancer cell lines, with an IC_{50} range of 0.18-2.17 nM, while exhibiting no cytotoxicity in PSCA-negative cells. Hydrophobic interaction chromatography (HIC-HPLC) analysis revealed a heterogeneous distribution of drug-to-antibody ratios (DARs), with an average DAR of 4.84. Furthermore, A2-MMAE retained a high level of total ADC integrity following 10 days of incubation in mouse plasma, indicating a robust plasma stability. These findings suggest that the novel anti-PSCA ADC (anti-PSCA-VC-PAB-MMAE), characterized by its strong target specificity, high potency, and excellent stability, holds promise as a safer and more effective therapeutic for prostate cancer. Ongoing studies will evaluate its in vivo antitumor efficacy, tolerability, safety, and pharmacokinetic/pharmacodynamic (PK/PD) profiling in mouse models.

#1660 Design of a synthetic non-natural antibody (NoNabody) against GRP as a new therapy for small cell lung cancer.

Pablo Garrido Rodriquez[1], Jahaziel Gasperin Bulbarela[2], Alexei Fedorovish Licea Navarro[2], Alfredo Martinez[3]

[1]Centro de Investigacion Biomedica de La Rioja (CIBIR), Logrono, Spain,[2]Biomedical Innovation Department, Centro de Investigacion Cientifica y Educacion Superior (CICESE), Ensenada, Mexico,[3]Angiogenesis Group, Oncology Area, Center for Biomedical Research of La Rioja (CIBIR), Logrono, Spain

(a) An introductory sentence indicating the purposes of the study; Gastrin-releasing peptide (GRP) has been described as an autocrine growth factor for small cell lung carcinoma (SCLC) and the use of a monoclonal antibody (MoAb) against GRP was shown to reduce tumor growth in animal models and had a positive profile in a phase 2 clinical trial. Here we aim to develop a synthetic non-natural antibody (NoNabody) as a potential new therapeutic tool for SCLC.
(b) A brief description of pertinent experimental procedures; The first step to obtain a NoNabody against GRP was to study the interaction between a well-characterized anti-GRP MoAb and the peptide itself. After obtaining the sequence of the variable binding region, ColabFold was used to predict the antibody structure and VMD, together with NAMD, were used to analyze the antibody-peptide interaction.
(c) A summary of the new, unpublished data; An *in silico* evaluation of the interaction between the anti-GRP antibody and the peptide identified the last seven residues of GRP, including the terminal amide group, as the main target of the antibody.Throughout all the molecular dynamics simulations, the MoAb remained structurally stable, whereas the full-length GRP peptide exhibited limited stability. In contrast, simulations performed with only the last 10 or 7 amino acids of the peptide showed increased stability.A comparison of the interactions between the amidated versus the free-acid peptide with the MoAb showed that amidation greatly enhances the antibody's affinity for GRP.Analysis of the antibody-peptide interface revealed that the interaction is distributed between the heavy and light chains, with GRP positioned right in between them. CDR3 (light chain) interacts with the last three residues of GRP, whereas CDR1 and CDR2 (heavy chain) interact with residues 16-22.
(d) A statement of the conclusions; NoNanobodies represent a new tool for employing antibodies in *in vitro* and *in vivo* studies. This work focuses on generating a NoNanobody against GRP. An initial *in silico* analysis showed that antibody-peptide binding occurs at the C-terminal amino acids and that this interaction is strengthened when GRP is amidated. This information is critical for developing new synthetic binding moieties against GRP that may improve drug performance through their small size, improved tissue penetrability and low immune responses to the small synthetic forms.
This work was supported by the Science and Innovation System of the Government of La Rioja (25658-2025/0000000016).

#1661 Preclinical characterization of XB773, a novel anti-DLL3 antibody-drug conjugate.

Marlene Hennessy, Ganapathy Sarma, Yutaka Matsuda, Jenny Chang, Suprit Deol, Zhenzhen Mo, Yan Hu, Maoyin Li, Rajesh Kumar, Hui Zhao, Brian A. Mendelsohn, Minjong Park, Summer Park, Janice Kim, Ragadeepthi Tunduguru, Kathleen R. Gogas, Seema Kantak

Exelixis Inc, Alameda, CA

Background: Delta-like ligand 3 (DLL3) is a single transmembrane protein that is a member of the Notch ligand family and an inhibitor of the Notch signaling pathway involved in cell signaling. DLL3 has low cytoplasmic expression in normal tissue but is selectively overexpressed and trafficked to the membrane in small cell lung cancer (SCLC) as well as some other neuroendocrine cancers, where its expression is correlated with aggressive disease. XB773 is an antibody-drug conjugate comprising a humanized VHH Fc antibody with high affinity for DLL3 that is conjugated to a topoisomerase 1 inhibitor using site-specific AJICAP® technology. Here, we describe the preclinical characterization of XB773, including its in vitro cytotoxicity and internalization and in vivo efficacy in cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models.
Methods: In vitro cytotoxicity, internalization, and bystander activity of XB773 were evaluated in DLL3-overexpressing cell lines using luminescence and fluorescence assays. In vivo tumor growth inhibition was evaluated in the SHP77 CDX model of SCLC and the NCI-H660 model of neuroendocrine prostate cancer (NEPC) using 1, 3, and 6 mg/kg dose levels in a single or repeat dose schedule. Tumor growth inhibition was additionally assessed in a PDX model of SCLC at 5 and 10 mg/kg (single dose).
Results: XB773 displayed in vitro cytotoxic activity at nanomolar concentrations and demonstrated internalization properties. Bystander effect was illustrated through the cytotoxic activity of XB773 against non-DLL3-expressing Jurkat cells when cocultured with DLL3-overexpressing cells compared with monoculture where no cytotoxicity was observed. In vivo, XB773 demonstrated significant dose-dependent antitumor activity in PDX and CDX models of SCLC as well as in a model of NEPC expressing DLL3. Tumor regression was observed in the SHP77 model.
Conclusions: XB773 demonstrated target-mediated tumor cell cytotoxicity and in vivo efficacy across several xenograft cell lines and PDX models of SCLC and neuroendocrine cancers. Taken together, these preclinical results support further development of XB773. Investigational New Drug-enabling studies are ongoing.

#1662 GSPT1 degrader antibody conjugate, BLB-201, for the treatment of high-risk acute myeloid leukemia.

Rakesh Bam[1], Wenjian Qian[1], John Liu[1], Peipei Zheng[2], Haoyang Wang[1], Jinna Yu[2], Wenfeng Hou[2], Xiaoying Wei[1], Dengqi Xue[1], Wen Zhang[1], David Yi[1], Alice Chen[1]

[1]Baylink Biosciences, Palo Alto, CA,[2]Asieris Pharmaceuticals, Shanghai, China

Targeted degradation of GSPT1, a translation termination protein, is a novel approach for Acute Myeloid Leukemia (AML) treatment. We developed a degrader antibody conjugate (DAC) BLB-201 to (i) improve the systemic tolerability of GSPT1 degrader, and (ii) selectively kill AML blasts and leukemia stem cells expressing the tumor antigen, CD123/IL3RA. The BLB-201 DAC was optimized for activity, safety, physiochemical properties, and stability. BLB-201 rapidly degraded GSPT1 and caused cellular stress-driven apoptosis in AML cells, and showed high degree of homogeneity, solubility, and linker-payload stability in serum. A panel of CD123-positive cell lines and patient AML blast samples, with high-risk abnormalities, such as FLT3-ITD mutation, TP53 mutation and MLL1 gene re-arrangements, were evaluated for cell killing by BLB-201. BLB-201 was potent against CD123-positive AML cell lines but did not affect the viability of CD123-negative cells in the cell killing assays. BLB-201 had strong cytotoxic effects on patient AML blasts (n=17 samples) and leukemic stem cells *ex vivo*. *In vivo*, BLB-201 exhibited excellent synergy at low doses (0.1-0.3mg/kg) with clinical anti-AML agents (venetoclax, azacitidine and quizartinib) in systemic MV-4-11 and MOLM-13 models. In the systemic PDX models representing relapsed AML with high-risk mutations, BLB-201 monotherapy significantly suppressed circulating CD45+ AML cells, prolonged survival as well as produced complete response in combination with venetoclax and azacitidine regimen. As a single agent both in the *in vitro* and in CDX AML models, BLB-201 showed better efficacy compared to a CD33-targeted GSPT1 DAC benchmark. We did not observe any effects of BLB-201 on normal erythroid, megakaryocytic and myeloid cell differentiation from CD34+ hematopoietic stem cells *in vitro*, while the CD33-targeted antibody drug conjugate, gemtuzumab ozogamacin, was highly toxic in these assays. BLB-201 DAC allows selective targeting of CD123-positive AML blasts and leukemia stem cells, minimizing direct exposure of GSPT1 degrader to healthy tissues. This unique mechanism of action may improve response rates when combined with existing targeted therapies for AML patients with high-risk or relapsed/refractory disease.

#1663 Monoclonal antibodies targeting the B-cell receptor complex directly induce widespread kinase inhibition and B-cell killing for the treatment of leukemia and lymphoma.

Rachel Welt[1], Virginia Raymond[2], David Kostyal[3], Sydney Welt[1]

[1]Welt Bio-Molecular Pharmaceutical, Briarcliff Manor, NY,[2]Biogent Consultants, Armonk, NY,[3]ARDL, Akron, OH

Welt Bio-Molecular Pharmaceutical (WBMP) aims to develop cytotoxic monoclonal antibody (mAb) therapies binding driver membrane receptors on malignant cells. Such membrane targets control growth, survival, and proliferation signals in healthy cells and their increased activity is often implicated in the oncogenesis of tumor cells. In B-cells, the B-cell Receptor Complex (BCRC), a signalosome comprising several membrane proteins, is involved in transmitting signals that determine cellular fate. Dysregulation of BCRC proteins, or those in downstream signaling pathways, result in a diversity of B-cell cancer subtypes, making the BCRC a rational drug target. WBMP has previously described WBMP-4, a pro-apoptotic anti-membrane IgM antibody. Using a proprietary mAb-target-discovery platform, we have developed mAbs against two additional sites across the BCRC. All pipeline mAbs mediate apoptosis individually upon target binding. Here we investigate the therapeutic potential of this suite of mAbs via *in vitro* kinase and cytotoxicity analyses.
Antibodies against designated regions of the BCRC, identified via WBMP's drug-discovery platform, were developed using hybridoma technology. Candidate mAbs were selected for their target-reactivity, and biologic effect was measured via preliminary growth assays of various lymphoma cell lines treated with hybridoma supernatant. These mAb supernatants have been tested for their ability to modulate B-cell kinase activity using the Pamgene phosphotyrosine kinome assay. Biacore assays will select unique, high affinity mAbs binding at distinct BCRC epitopes. Cell growth, MTT, and additional kinome assays will define the cytotoxicity characteristics of mAbs at varying doses and compared to existing B-cell therapeutics (i.e. ibrutinib, acalabrutinib, venetoclax, rituximab).
WBMP has successfully applied a drug discovery system to develop a pipeline of B-cell cancer therapeutics. Each candidate mAb in this pipeline binds to a specific BCRC epitope and modulates the function of this signalosome. Here we show the potent effect of each of these mAbs as monotherapies, *in vitro*, in inducing widespread kinase inhibition, and, at sufficient doses, apoptosis. Activity of these mAbs will be studied in mouse xenograft systems and safety will be assessed with comprehensive normal tissue and non-target protein cross-reactivity assays. Those mAbs which are determined to be safe and effective will be considered for further clinical development. Together, this pipeline of novel mAbs covers the spectrum of B-cell malignancies, and the availability of multiple, distinct, directly effective mAbs against B-cells offers the potential for combination treatment strategies that can be optimized for specific tumor-types.

#1664 Novel GPC3-targeting antibody-drug conjugate using novel payload or dual payloads to treat hepatocellular carcinoma and non-small-cell lung cancer.

Suk Lee, John Liu, Alice Juang, Aastha Jain, Xiaoying Wei, Wen Zhang, David Yi, Alice Chen

Baylink Biosciences, Palo Alto, CA

Glypican-3 (GPC3) is a highly promising therapeutic target due to its selective, abundant overexpression in hepatocellular carcinoma (HCC) and certain subsets of non-small cell lung cancer (NSCLC), while being largely absent in normal adult tissues. A Phase 1 trial with a GPC3-targeted CAR-T therapy showed an objective response rate of 57 percent in heavily pre-treated patients with advanced HCC, highlighting the potential of GPC3 as a viable tumor-specific antigen for targeted therapy. ADC modality offers distinct advantages over CAR-T therapies, including off-the-shelf availability, lack of risk of cytokine release syndrome, and significant accessibility and cost advantages. However, HCC is known to be resistant to traditional chemotherapy thus traditional ADC payloads likely won't work. We have developed a series of next-generation anti-GPC3 antibody-drug conjugates that combine our proprietary GPC3-targeting antibody and distinct payload classes including topoisomerase inhibitor and a novel protein degrader. Compared to benchmark GPC3-targeting antibodies, our antibody binds a unique epitope on GPC3, resulting in enhanced internalization and significantly improved ADC-mediated cytotoxicity in GPC3-positive cells. Our novel protein degrader payload showed broad anti-proliferative activity in vitro, including potent cytotoxicity in DXd-resistant cell lines and HCC cell lines. In vivo, our GPC3 single-payload or dual-payload ADC molecules showed robust anti-tumor efficacy in multiple HCC and NSCLC CDX and PDX models. We believe that our anti-GPC3 ADC can be an effective off-the-shelf biologic therapy for HCC and NSCLC patients.

#1665 Preclinical characterization of IPN60300, a first-in-class ITGA2 antibody-drug conjugate for cancer therapy.

Aurelie Courtin[1], Benjamin Beaufils[1], Karl Brendel[1], Sophie Colombo[1], Isabel Esteves[1], Marie-Odile Galcera[1], Thierry Guyon[1], Pei Han[2], Feng He[3], Wei Li[2], Weihong Nian[3], Vincent Martin[1], Lou-Amelia Revellin[1], Sylvain Roqueviere[1], Pierre Roubert[1], Yu Song[2], Amath Thiongane[1], Catherine CL Wong[2], Chuanying Xu[3], Qing Zhou[3], Mary Jane Hinrichs[4], Elisabetta Leo[5]

[1]Ipsen, Paris, France,[2]Foreseen Biotechnology, Shangai, China,[3]Escugen Biotechnology, Shangai, China,[4]Ipsen, Boston, MA,[5]Ipsen, London, United Kingdom

Background: Integrin alpha-2 (ITGA2), a component of the heterodimeric transmembrane receptor integrin α2/β1, plays a key role in cell adhesion and transduction. Although ITGA2 is expressed at low levels across normal tissues, it is notably overexpressed in various solid tumors, including pancreatic, gastric and colorectal, where it contributes to tumor progression via extracellular matrix signaling and epithelial-mesenchymal transition. We report the development of IPN60300, a novel antibody-drug conjugate (ADC) targeting ITGA2, designed to specifically deliver exatecan, a potent topoisomerase I inhibitor, to ITGA2 expressing cancer cells. IPN60300 consists of a humanized Fc mutated monoclonal antibody site-specifically conjugated to exatecan via a cathepsin-cleavable linker, with a drug-to-antibody ratio of 8.
Methods: The pharmacological characteristics of IPN60300 were assessed through comprehensive in vitro and in vivo studies including analysis in ITGA2-expressing cell lines, cell-derived xenograft models, and cynomolgus monkey, chosen for its homology with human ITGA2.
Results: IPN60300 demonstrated a specific and high-affinity binding to ITGA2, efficient internalization into tumor cells, and intracellular release of exatecan, resulting in potent cytotoxicity in ITGA2-positive cell lines. The engineered Fc region of the antibody decreased FcγRI binding, reducing off-target toxicity while maintaining FcRn interaction. In tumor-bearing mice, IPN60300 exhibited plasma stability and led to significant exatecan accumulation in xenograft tumors, resulting in high, dose-dependent anti-tumor activity in models of cholangiocarcinoma, pancreatic ductal adenocarcinoma, gastric, and colorectal cancers. Toxicology studies in cynomolgus monkeys revealed favorable tolerability and pharmacokinetic characteristics supporting an acceptable therapeutic index.
Conclusion: These preclinical findings support IPN60300 as a promising first-in-class ITGA2-targeting ADC, combining potent anti-tumor efficacy with a favorable safety profile. IPN60300 holds potential to improve clinical outcomes for patients with ITGA2-expressing malignancies and is advancing to First-in-Human clinical trial (NCT07213817).

#1666 Targeting the extra-cellular matrix in the tumor microenvironment with a novel antibody-drug conjugate.

Matthew J. Edwards, Kovilen Sawmynaden, Aurelie Michelet, Edward Long, Rachel Evans, Dhruv Chauhan, Cecilia Pennica, Nafia Guljar, Cherie Akpotor, Luca Frenguelli, Gareth Muirhead, Sam Cooper, Athiva Shankar, TuVinh Luong, Emma Huang, Giuseppe Mazza, Chris Stevenson

Discovery Sciences, Engitix Therapeutics, London, United Kingdom

Background: Tumors with high stromal content are associated with poor prognosis, in part due to these tumors' resistance to standard of care therapies and increased aggressiveness. A common, highly deregulated program of extensive ECM remodeling exists in most solid tumors. Therefore, targeting the tumor ECM with an antibody drug conjugate (ADC) offers a promising strategy to improve tumor selectivity and treatment efficacy.
Methods: Proteomic analysis of decellularized tumor tissues processed to preserve ECM-bound proteins, and pan-cancer transcriptomic profiling of CAF-associated ECM genes was used to identify and validate target selection. Antibodies were developed against a novel, tumor microenvironment (TME)-specific antigen expressed in multiple solid tumors, including PDAC and CRC. High-affinity antibodies were conjugated to exatecan *via* a cleavable linker and efficacy was evaluated in an in vitro transwell-based tumor cell cytotoxicity assay.
Results: Integrative analysis transcriptomic and proteomic analysis revealed numerous ECM proteins that are selectively expressed by CAFs and biochemically stable within the tumor matrix. Among these, we identified a target, EGTX004, that was consistently upregulated across multiple solid tumor types, and not expressed in adjacent non-tumor tissue or healthy control tissue samples. The increased and tumor-specific expression of EGTX004 was confirmed by IHC using proprietary antibodies against the target. EGTX004 expression is elevated early in tumorigenesis and increases as tumors progress to become more invasive.The antibodies against EGTX004 demonstrated positive target engagement in biochemical, cell-based stromal deposition with sub- to low nanomolar affinities (0.5 - 2 nM). EGTX004 ADCs were also demonstrated to have tumor killing activity in vitro. EGTX004 expression has also been found to be increased in a number of CDX and PDX models. The induction EGTX004 in these models appears to be driven by the mouse fibroblast response to the human tumor cell insult, and EGTX004 expression progresses as the tumors grow larger.
Conclusions: Integrating transcriptomic and proteomic analyses of CAF-derived ECM proteins enables discovery of novel, broadly applicable ADC targets. Our findings provide compelling evidence that targeting the TME with a rationally designed ADC can yield robust anti-tumor responses.

#1667 Antibody encapsulated drug: Tr-ACT2 for targeted treatments of various cancers.

C. J. Yu[1], Linrong Li[2], leslie Wang[1], Kinsley Wang[1], Mengmeng Liu[1], Faqing Huang[3], Warren A. Chow[4], Xiaojiang Cui[5]

[1]Sunstate Biosciences, LLC, Pasadena, CA,[2]Cedars Sinai Medical Center, Los Angeles, CA,[3]The University of Southern Mississippi, Hattiesburg, MS,[4]University of California at Irvine, Irvine,, CA,[5]Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: HER2 is overexpressed in 15-20% of breast cancers and some other cancers, and the development of HER2-targeted therapies has revolutionized cancer treatment in past 20 years. Trastuzumab (Tr) has demonstrated efficacy in treatment of HER2+ breast cancer and advanced gastric cancer. Recently, Tr-based antibody drug conjugates (ADCs), Kadecyla and Enhertu, have emerged as a new class of anti-HER2 therapies by combining targeted antibodies with cytotoxic agents via linkers. However, ADC approach faces great challenges, such as *in vivo* instability, manufacturing processes, limited availability of antitumor payloads and suboptimal payload release. Therefore, smarter and more efficient designs are urgently needed.

Methods: Our patented single protein encapsulation (SPE) platform, allowing encapsulation of small-molecule drugs by a single protein (albumins or globulins) without artificial nanoparticles and chemical modifications to drugs and proteins, has achieved great success in development of 2 drug products, SPEDOX-6 under human clinical trial (NCT0764018) and SPESN38-8 (IND #: 164346) under IND-enabling study based on albumin, which have prompted us to utilize antibody, such as Tr to encapsulate cytotoxic payload, actinomycin D (ACT, RNA polymerase inhibitor), forming antibody encapsulated drugs (AEDs). We developed Tr-ACT2 as a first-in-class AED drug, featuring each Tr molecule to encapsulate two ACT molecules without linkers. Tr-ACT2 was well characterized by UV, fluorescence, membrane dialysis, particle size distribution and molecular docking. *In vitro* and *in vivo* anticancer efficacy of Tr-ACT2 against various HER2+ & HER2- cancers were evaluated.

Results: Tr-ACT2 has been investigated in following. *In vitro* cytotoxicity of Tr-ACT2 against breast cancers, HER2+ (SKBR3, JIMT1) and HER2- (BT549, MDA-MB-231) and A549 (NSCLC, HER2-) was evaluated, leading to a time-dependent and significant reduction in cell viability, induction of apoptosis and reduction of Akt activation. Tr-ACT2's cytotoxic activity appeared to be independent of HER2 expression levels. The internalization study on Tr-ACT2 demonstrated that early-stage internalization of Tr-ACT2 is HER2 dependent, but the rate of late-stage internalization of Tr-ACT2 is not limited by HER2 expression level, confirming that Tr-ACT2 could be effectively internalized into both HER2+ and HER2- cancer cells. *In vivo* anticancer efficacy of Tr-ACT2 at 1 mg/kg vs irinotecan at 50 mg/kg using A549 mouse model has been evaluated, showing that Tr-ACT2 was significantly more effective in suppressing growth of A549 than irinotecan.

Conclusions: We have developed the first-in-class AED nanocomplex, Tr-ACT2, as a potent anticancer agent, demonstrating that the SPE technology can be applied to antibody for encapsulating small-molecule drugs without covalent conjugation and marking a significant advancement in antibody-based therapeutics.

#1668 MAC-8001: A KRAS-targeting molecular glue-antibody conjugate with robust antitumor activity in KRAS-mutant cancers.

Feilong Sun, Shuaishuai Chi, **Carlos Chai**, Yi Chen, Xuan Zhang

DaCure Therapeutics, Shanghai, China

Background
KRAS mutations are among the most frequent oncogenic drivers, occurring in approximately 10-15% of all human cancers and in over 90% of pancreatic ductal adenocarcinomas (PDAC). Although KRAS G12C inhibitors have achieved clinical success, the majority of KRAS mutations (>85%), predominantly G12D and G12V, remain without approved targeted therapies. Recently, several G12D/V-selective inhibitors and pan-RAS molecular glues (MGs) have emerged as promising strategies to address this unmet need. Converting KRAS-targeting MGs into molecular glue-antibody conjugates (MACs) offers an attractive avenue to further optimize their therapeutic window by limiting systemic exposure, improving pharmacokinetics, and enhancing clinical translatability.
Methods
A series of KRAS-modulating MG payloads were developed through structure-based optimization and subsequently site-specifically conjugated to an anti-B7H3 antibody via a cleavable linker, yielding the conjugate MAC-8001. The conjugate was characterized by reversed-phase liquid chromatography (RPLC) and size-exclusion chromatography (SEC) to determine its drug-to-antibody ratio (DAR) and aggregation profile, respectively. The capacity of the payloads to interfere with RAS-BRAF RBD interactions was evaluated using a TR-FRET assay. *In vitro* antiproliferative activities were evaluated across cancer cell lines harboring KRAS G12C/D/V mutations, while in vivo efficacy and pharmacodynamic responses were examined in corresponding xengraft models.
Results
The conjugate exhibited a DAR of approximately 8.0 with no detectable aggregation. MAC-8001 demonstrated potent and selective inhibition of KRAS-mutant cancer cells (IC_{50} <10 nM) compared with KRAS wild-type counterparts, accompanied by pronounced, dose-dependent suppression of downstream p-ERK and p-AKT signaling. Consistent with its scaffold-derived mechanism, TR-FRET assays confirmed that the payloads disrupted RAS-BRAF interactions, thereby attenuating MAPK signaling. In xenograft mouse models, a single intravenous dose of MAC-8001 produced durable antitumor responses, achieving over 90% tumor growth inhibition. Moreover, MAC-8001 was well-tolerated, without body-weight loss or detectable systemic toxicity.
Conclusions
MAC-8001 represents a potent KRAS-targeting MAC that selectively inhibits KRAS-driven signaling and exhibits robust antitumor efficacy both *in vitro* and *in vivo*. The modular design of this MAC platform allows straightforward adaptation to other tumor-associated antigens,
such as TROP2, thereby broadening its translational potential across RAS-driven malignancies. Collectively, these findings establish a novel therapeutic paradigm that may overcome the inherent limitations of systemic KRAS modulation.

#1669 S DUAL™: An Advanced Bispecific Antibody Platform Delivering Practical Manufacturability and Enhanced Therapeutic Efficacy.

Jina Kim, **Wooseok Yang**, Kihong Kim, Hyunbum Kim, Siwon Park, Haewon Ahn, Hyebeen Hong, Hyunseung Sun, Soyeon Lee, Gwangsu Shin, Jihoon Kim, Seonkyeong Jeong, Hyunsik Lee, Sungjin Han, Joseph H. Jeong, Yeumin Kim, Brian Hosung Min

Samsung Biologics, Incheon, Korea, Republic of

Background - Receptor tyrosine kinases (RTKs) drive tumor progression through ligand-dependent or ligand-independent dimerization, which brings the intracellular kinase domains into proximity, triggers autophosphorylation, and recruits adaptor proteins such as GRB2 and Shc. The resulting RAS-MAPK and PI3K-AKT cascades sustain cancer cell proliferation, survival and differentiation. Among RTKs, HER2 (ErbB2) is an orphan receptor that preferentially forms homodimers and heterodimers with other ErbB family members. HER2 over-expression or the generation of truncated forms (e.g., p95HER2) is strongly associated with aggressive disease and resistance to HER2-directed therapies.

Clinically - approved HER2 antibodies—trastuzumab (domain IV) and pertuzumab (domain II)—bind distinct extracellular epitopes yet only partially inhibit HER2-driven signaling, especially in tumors with high HER2 density or in which the receptor is mutated/truncated. Consequently, patients often develop intrinsic or acquired resistance.

Approach - To overcome these limitations, we employed Samsung Biologics' S-DUAL^{TM} platform to generate a heterodimeric bispecific antibody (BsAb) that simultaneously engages HER2 epitopes II and IV. The two Fab arms are engineered to heterodimerize via a "knob-into-hole" Fc architecture, preserving native IgG1 Fc effector function while enforcing defined Fab geometry.

Results - In HER2-positive cell lines, S-DUAL^{TM} reduced HER2 autophosphorylation by ~27.9 % ($p < 0.05$) and downstream p-ERK1/2 and p-AKT levels by 18.6 % and 25.3 %, respectively, resulting in a maximal inhibition (Emax) of 64.4 % in cell proliferation ($IC_{50} \approx 1.64$ nM). Cell surface binding affinity and Fc-mediated ADCC activity remained comparable to reference platform. In HER2-positive xenograft models, weekly intravenous administration of S-DUAL^{TM} substantially reduced tumor growth relative to the isotype control, achieving a marked suppression of tumor volume without evident toxicity.

Conclusion - Simultaneous blockade of two non-overlapping HER2 extracellular domains by a biparatopic BsAb can fully suppress ligand-independent HER2 signaling while preserving immune effector mechanisms. This "dual-epitope, Fab-geometry-tuned" strategy defines a new design principle for next-generation HER2 therapeutics and offers a potential solution to overcome resistance arising from HER2 over-expression, truncation, or mutation.

#1672 Enhanced delivery and activity of a novel antibody-drug conjugate, PF-08052667, for treatment of non-muscle invasive bladder cancer.

Christopher M. Carosino, Devra Olson, David Ortiz, Steven Duniho, Maddy Burcher, Eliana Moskovitz, Rebecca Mazahreh, Iliyana Mikell, Matthew R. Levengood, Sharsti Sandall, Joeseph D. Dekker

Pfizer, Inc., Bothell, WA

PF-08052667 is a novel antibody-drug conjugate (ADC) under investigation for intravesical treatment of non-muscle invasive bladder cancer (NMIBC). Intravesical administration remains the standard approach patients with high-risk NMIBC. While this route allows direct access to the bladder lumen and tumor cells, drugs such as Bacillus Calmette-Guérin (BCG) and other chemotherapies are typically retained for less than two hours and evacuated after instillation. Current BCG supply issues, along with a documented lack of sustained response in about two-thirds of cases, highlight the demand for alternative treatment options such as ADCs which have proven activity in bladder cancer. PF-08052667 is an integrin beta-6 (IB6)-directed MMAE ADC specifically designed for intravesical treatment of NMIBC with eight MMAE molecules per ADC via a pegylated glucuronide linker. Prior to ADC administration, a bladder prewash is performed to increase urothelial permeability, enhance drug uptake into bladder tissue, and improve antitumor activity while maintaining low systemic exposure and a favorable safety profile. Here, we present the optimization of PF-08052667 for local delivery through ADC design and incorporation of a n-dodecyl-β-D-maltoside (DDM)-containing bladder prewash. In vitro and in vivo studies assessed tissue retention, tissue penetration, and antitumor efficacy with PF-08052667 or a rodent-specific surrogate ADC administered alone or following a bladder prewash. Additionally, tolerability and systemic exposures were evaluated in pharmacologically relevant animal models. High IB6 expression was confirmed across a panel of NMIBC tumors. In vitro, PF-08052667 demonstrated robust cytotoxic activity in a variety of IB6-expressing bladder cancer cell lines and NMIBC patient-derived organoids. The combination of PF-08052667 with bladder prewash resulted in up to 42-fold higher bladder tissue MMAE concentrations, improved tissue penetration and residence time, and achieved significant tumor control in orthotopic NMIBC mouse models. Following repeated local administration of PF-08052667 with bladder prewash, systemic exposure remained minimal, and no systemic toxicity was detected. Overall, these findings support the clinical development of PF-08052667 with bladder prewash, which is being evaluated for safety and antitumor efficacy in a Phase I trial (NCT07206225) involving patients with NMIBC.

#1673 PF-08046033 (GPS): A novel first in class auristatin S antibody-drug conjugate for treatment of GPNMB-expressing solid tumors.

Parul Katoch, Gabriele Blahnik-Fagan, Xiao Di Yang, Marlena Gray, KC Crowder, Vineet Kumar, Midori Clarke, Kaveh Alizadeh, Samantha Sarrett, Serena Wo, Gardenia Zaki, Andrea Lim, Elizabeth Gray, Philip Moquist, Michael Flister, Sharsti Sandall

Pfizer, Bothell, WA

Glycoprotein non-metastatic melanoma protein B (GPNMB) is a type 1a transmembrane protein that is markedly upregulated in several cancers, including NSCLC, ESCC, HNSCC, and BRCA. GPNMB is associated with poor patient prognosis and plays diverse roles in cancer biology, contributing to processes such as cell differentiation, proliferation, invasion, and migration. Low GPNMB expression in normal tissues, contrasted with high expression in primary and metastatic tumors, makes GPNMB a compelling target for antibody-drug conjugate (ADC) therapies. A previous GPNMB-targeting ADC, Glembatumumab vedotin (GV), comprised of a monoclonal antibody (mAb) conjugated to the microtubule disrupting agent monomethyl auristatin E (MMAE), showed early signs of efficacy. However, its development was constrained by dose-limiting toxicities, the majority of which were likely driven by the released MMAE payload. We hypothesized that pairing the GPNMB-targeted mAb with the novel Auristatin S (AurS), a payload engineered to be less permeable compared to MMAE, may widen the therapeutic window. Thus, we developed PF-08046033 (GPS), a novel investigational ADC composed of the human IgG1 anti-GPNMB mAb (hCR011) conjugated to the novel microtubule disrupting agent AurS using the clinical validated, protease-cleavable MC-Val-Cit linker with an average drug-to-antibody ratio (DAR) of 4. In this study, we evaluated the expression of GPNMB across multiple solid tumors, assessed the antitumor activity of GPS in vitro and in vivo in a variety of xenograft tumor models, and examined its safety profile in non-human primate (NHP) toxicology studies. GPS bound and internalized the GPNMB/ADC complex from the surface of cancer cells, leading to release of the AurS payload that induced apoptosis following G2/M cell-cycle arrest. GPS demonstrated comparable efficacy to GV in multiple GPNMB-expressing xenograft models. Notably, in NHP toxicology studies, GPS was tolerated at 15 mg/kg, which is five-fold higher than GV. Altogether, these data support the evaluation of PF-08046033 (GPS) in a first-in-human phase 1 clinical trial for the treatment of multiple solid tumors.

#1674 Diversity-oriented dpADC discovery with high throughput dual-conjugation platform and predictive resistant disease models.

Meijun Xiong, Yanchun Li, Qingsong Wu, Chong Liu, Shanshan Xie, Zhongsheng Hu, Yajun Sun, Zengyan Mu, Haibo He, Yanwen Feng, Xinju Gao, Paul H. Song, Gang Qin

GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China

Acquired resistance to antibody-drug conjugate (ADC) therapy remains a major clinical challenge, often leading to diminished efficacy of subsequent ADCs that share the same payload class even based on different targets. For instance, reduced response has been observed in patients receiving sequential treatment with the Top1 inhibitor-based ADCs sacituzumab govitecan and trastuzumab deruxtecan, irrespective of treatment sequence. This underscores payload cross-resistance as an emerging limitation in ADC-based regimens. Dual-payload ADCs (dpADCs) represent a novel therapeutic modality with the potential to overcome such resistance. However, conventional dpADC discovery is often constrained by limited molecular designs, as the vast structural complexity—arising from variations in payload pairing, stoichiometric ratios, linker release mechanisms and kinetics, and antibody properties—poses significant challenges for systematic synthesis and evaluation. To address this challenge, we developed a comprehensive linker-payload (LP) library featuring diverse linker designs and multiple payload classes—including LPs based on Topoisomerase I inhibitors, Topoisomerase II inhibitors, PARP1 inhibitors, ATR inhibitors, and CHK1/2 inhibitors. Using our automated, high-throughput dual-conjugation platform (iScreener), we efficiently constructed a diversity-oriented dpADC library targeting HER2 and TROP2 respectively. These dpADCs were systematically evaluated in resistant in vitro and in vivo models, including patient-derived organoid/xenograft (PDXO/PDX) systems. Notably, several candidates with novel designs demonstrated significantly enhanced therapeutic efficacy while maintaining favorable safety profiles compared to benchmark and conventional mono-payload ADCs, revealing clear enhanced effects between payload classes. In summary, our shift from a purely rational design paradigm to a high-throughput screening approach—enabled by efficient dpADC library construction and predictive resistant disease models—offers a robust discovery framework. This strategy identifies potent dpADC candidates through empirical screening rather than traditional design perception, and we are currently expanding our evaluation of additional payload combinations in dpADC format using resistant preclinical models that recapitulate unmet clinical needs.

#1675 Payload-recycling ADCs (PR-ADCs): A novel ADC platform for reducing free-payload toxicity and enhancing therapeutic index.

Jianmin Fang[1], Dong Li[2], Jing Jiang[1], Yuanhao Li[1], Wei Zhang[3], Xiaoshan Min[3], Zhulun Wang[3]

[1]RemeGen Co., Ltd, Yantai, China,[2]RemeGen Co., Ltd., Shanghai, China,[3]RemeGen Biosciences (U.S.), South San Francisco, CA

Background: Antibody-drug conjugates (ADCs) have emerged as an important class of cancer therapeutics in clinical application. Many ADC drugs, however, failed during clinical studies due to excessive toxicity. Even approved ADC drugs also often face challenges in balancing clinical efficacy and safety. A major cause of ADC toxicity is due to free-payload (small molecule toxin) released from ADC drug into circulation. Free-payload often appears rapidly in plasma after ADC administration which causes systemic toxicity. To overcome ADC toxicity caused by free-payload, we have developed a novel technology, payload-recycling ADC (PR-ADC), that allows ADC drugs to re-capture, or recycle, small molecule toxin in circulation, thus reducing free-drug concentration in plasma.
Methods: To develop PR-ADC technology, we first generated a high affinity anti-MMAE monoclonal antibody through hybridoma screening. This anti-MMAE antibody exhibits exceptional specificity to free-MMAE with no detectable cross-reactivity to linker-MMAE or conjugated MMAE. Then an anti-mesothelin (MSLN) single domain antibody was attached to the anti-MMAE antibody to create a bispecific antibody that can simultaneously bind to both tumor antigen MSLN and free-MMAE. This bispecific antibody was then conjugated with MMAE to become the PR-ADC molecule which is basically a mesothelin-directing ADC with an additional ability to capture free-MMAE.
Results: This PR-ADC can effectively kill MSLN-expressing tumor cells *in vitro* in a potency similar to or even higher than a conventional MSLN-targeting ADC. On the other hand, this PR-ADC can prevent MMAE-induced cytotoxicity in cell-protection assays, highlighting its ability to effectively shield normal cells or tissues from free-MMAE-induced damage, thus increasing safety of ADC drugs. *In vivo*, this PR-ADC molecule, compared to conventional ADC, significantly reduced free-MMAE concentration in serum after administrated in mice or rats. In toxicity studies in rats, the PR-ADC significantly improved safety profile, showing larger therapeutic window than the conventional ADC. The increased safety profile of PR-ADC *in vivo* was further supported by favorable tissue distribution, drug metabolism and pharmacokinetics (DMPK) profiles. In xenograft tumor model studies, the MSLN-targeting PR-ADC achieved robust tumor growth inhibition, outperforming the conventional ADC.
Conclusions: The PR-ADC platform improves ADC safety by minimizing free payload-mediated toxicity while maintaining or enhancing anti-tumor efficacy. By enabling active payload recapture, PR-ADCs may support higher clinical dosing, increased effective DAR through captured payload, and an overall superior therapeutic index. This technology represents a promising next-generation strategy for advancing ADC development.

#1676 HA-00495: A development candidate ADC featuring a novel protein translation inhibitor payload with broad efficacy and a favorable non human primate safety profile.

Tara L. Arvedson, Victor Cee, Corey Reeves, Madhura Deshpande, Natacha Le Moan, Kyle Dunbar, Amandeep Gakhal, Chris Kimberlin, Cynthia Bailey, Edres Babacarkhial, Nolan Carney, Xufeng Cao, Yi-Ming Chiang, Amber Cornelius, Natalie Duong, Colin Harvey, Yingxia Hu, Dimitri Kharakovsky, Jose Leighton, Dennis Liu, Luca Lizzardo, Octovia Monteiro, Samuel Oteng-Pabi, Bruno Perlatti, Rajani Marthappa Shenoy, Joseph Spraker, Melanie Uguen, Jakub Vaith, Sandeep Venkataram, Kendra Wheeler, Shiyan Xu, Danielle Yee, Clarence Yeung, Eva Yuan

Hexagon Bio, Menlo Park, CA

Antibody drug conjugates (ADCs) have demonstrated clinical benefit across multiple cancers, yet resistance to existing payload classes, particularly topoisomerase and microtubule inhibitors, remains a major barrier to durable efficacy. To address this limitation, Hexagon Bio is leveraging its natural product discovery platform to identify new ADC payloads with mechanisms of action (MOAs) that are non-overlapping with currently approved payload classes. Enabled by our proprietary natural product library, we identified a protein translation inhibitor as a highly potent ADC payload. We conjugated the payload to a diverse panel of antibodies recognizing tumor-associated antigens and observed consistent ADC-mediated cytotoxicity across cell lines, supporting broad applicability across tumor types. In vivo, ADCs generated using anti-TROP2 (sacituzumab) and anti-HER2 (trastuzumab) antibodies demonstrated deep and durable antitumor activity in bladder, gastric, breast and lung cancer models, including models with known resistance to topoisomerase inhibitor-based ADCs. Here, we provide updated efficacy data across multiple tumor models and, for the first time, report the non-human primate (NHP) safety profile of an ADC incorporating this payload. Our new data include a comprehensive assessment of the HER2 ADC HA-00495 in NHPs, evaluating multiple dose levels as well as repeat-dose regimens. These studies reveal an acceptable safety and tolerability profile. We will present the clinical observations, clinical pathology, histopathology and key findings from these studies.In summary, we have identified a novel protein translation inhibitor payload class for ADCs that demonstrates strong efficacy, activity in resistance settings and a favorable NHP safety profile. These results support the potential of HA-00495 to address critical gaps in current ADC therapies and development activities for this candidate are now underway.

#1677 NL019: A next-generation TROP2/NECTIN4 dual-target nanobody-based ADC developed from the NanoOne™ Platform.

Meiguang Xiong, Binbin Wang, Jie Ni, Chenchen Lu, Fang Yu, **Yu Zhang**

Naliean Therapeutics Co. Ltd, Suzhou, China

Background:
While antibody-drug conjugates (ADCs) have transformed oncology treatment, conventional IgG-based ADCs are constrained by suboptimal tumor penetration, heterogeneous antigen expression, and Fc receptor-mediated immune toxicity. NanoOne™, developed by Naliean Therapeutics, is an innovative nanobody-based modular ADC platform that redefines ADC engineering through molecular miniaturization, structural precision, and payload flexibility.
Methods:
NanoOne™ integrates multiple VHH nanobody modules (<54 kDa) to achieve deep tumor penetration and broad recognition of tumors with diverse tumor-associated antigen (TAA) profiles. Its proprietary Site-Specific Dual-Payload Conjugation enables precise stoichiometric control (1:2, 2:1, 2:2, etc.) for single or dual payloads with outstanding homogeneity. The design incorporates a highly hydrophilic and stable linker that confers excellent developability. Fc domains are removed to avoid Fc receptor-mediated toxicity to immune cells while maintaining optimal half-life and enhancing tumor microenvironment accumulation.
Results:
NL019, a TROP2/NECTIN4 dual-target ADC armed with a microtubule inhibitor, demonstrated potent and synergistic activity in vitro—including dual-target binding, internalization, and cytotoxicity—while minimizing on-target toxicities seen in single-target ADCs. In multiple xenograft and CDX models, NL019 achieved superior, dose-dependent antitumor efficacy versus benchmark ADCs targeting TROP2 or NECTIN4.
Conclusions:
NL019 exemplifies the disruptive potential of NanoOne™, combining advanced molecular architecture, precision one/dual-payload conjugation, and superior tumor selectivity. Supported by strong preclinical efficacy and developability, NL019 is advancing toward first-in-human trials. Given the broad expression of TROP2 and NECTIN4 across epithelial malignancies, NL019 has the potential to establish a new generation of broad-spectrum ADC therapeutics.

#1678 Integrated ADC platform: From discovery to functional evaluation.

Meimei Yin, Xiaoming Miao, Yang Zheng, Jingbo Ding, **Jun Liu**, Fang Zhang, Zhongyao Ma, Letian Kuai, Wenji Su

WuXi AppTec, Shanghai, China

Antibody-Drug Conjugates (ADCs) represent a rapidly advancing modality with elegantly simple and compelling mechanisms. They have proven successful not only in combating cancer but have also recently expanded into other therapeutic areas such as autoimmune diseases. Despite these advancements, challenges such as new payload exploration, antibody penetration, increasing ADC uptake and processing, and overcoming ADC resistance continue to persist. Our comprehensive antibody discovery platform excels in generating high-affinity antibodies against challenging antigens, particularly multi-pass transmembrane proteins. By combining this with advanced high-throughput screening capabilities, we efficiently identify potent antibody candidates, thereby accelerating the antibody discovery process. To further expedite ADC discovery with high efficiency, we have developed a state-of-the-art high-throughput conjugation platform integrated with various downstream biological assays. Utilizing parallel synthesis and analytics, we can generate and evaluate ADCs with diverse linkers and payloads at microgram to milligram scales within 2-3 weeks. IgG1 antibodies are used, and products are isolated through resin purification. These ADCs exhibit uniform Drug-to-Antibody Ratios (DAR), consistent analytical size-exclusion chromatography (aSEC) profiles, and precise concentration ranges, with less than 0.1% free drug residue. This facilitates the simultaneous construction of hundreds of conjugate variants per run, allowing for rapid cytotoxicity and stability assays to triage and prioritize candidates for further development. In addition to high-throughput antibody screening and conjugation, our well-established full-spectrum ADC platform provides comprehensive services from payload assessment and ADC in vitro efficacy evaluation to supporting in-depth mechanistic exploration. This includes studying antibody internalization, killing effects, bystander evaluation and the development of potential resistance. Through continuous expansion of this platform, we are not only enabling early-stage ADC drug discovery but also addressing emerging challenges in the field.

#1679 Plate-based conjugation for antibody and payload optimization in ADC development.

Zeinab Fereshteh, Madhavi Latha S. Chalasani, Rupa Sarkar, **Julien Dugal-Tessier**, Nareshkumar Jain

NJ Bio, Inc., Princeton, NJ

ADCs are typically synthesized one by one and not amenable to early screening using a platform method. We developed a plate-based conjugation platform that integrates early screening with in vitro characterization using maleimide-based linker-payloads. With a standardized, assay-compatible protocol, this high-throughput system rapidly assesses DAR, purity, yield, cytotoxicity, and binding. It supports antibody screening with fixed linker-payloads, payload screening with fixed antibodies, and ADC characterization under varied conditions, providing a powerful tool for rational ADC design.

#1681 RenLite® transgenic mice provide a high-quality platform for accelerating the development of fully human bispecific antibodies or ADCs worldwide.

Jade Hsu, Wenjiao Zhang, Jun Du, Zhuolin Li, Yifu Zhang, Yanfei Han, Chengzhang Shang, Yi Yang

Biocytogen, Waltham, MA, MA

Global development of bispecific antibodies (BsAbs) and bispecific antibody-drug conjugates (BsADCs) is undergoing explosive growth. However, key pain points persist—heavy-light chain mismatch, inadequate target synergy, poor toxicity control, and complex manufacturing. While novel technologies have been developed to address these issues, drug development still faces hurdles in target combination selection, lengthy antibody discovery cycles, and low clinical translation success rates.Biocytogen RenLite® mice generate fully human antibody candidates with a common light chain, enabling subsequent assembly of BsAbs with minimized chain mismatch and excellent developability—conferring advantages for downstream CMC development. Additionally, the common light chain facilitates screening of different BsAb formats, payload conjugation, and function evaluation—supporting the discovery of diverse BsAb or BsAb-ADC modalities.To date, leveraging RenLite® and its novel BsADC platform, Biocytogen has generated multiple preclinical BsAb-ADC candidates. For example, DM001 (anti-TROP2×EGFR), with good developability, demonstrates potent tumor-suppressive activity in seven various patient-derived xenograft (PDX) models; DM005 (anti-EGFR×MET), with high purity and good conjugation property, exhibits outstanding specificity and anti-tumor efficacy in lung cancer PDX models. These BsADC candidates hold great clinical development potential.Leveraging its RenLite® platform and preliminary screening, Biocytogen has built an antibody library covering over 200 tumor-associated antigens (TAAs). This lets researchers easily conduct rapid screening, flexible pairing, and target synergy validation using *in vitro*/*in vivo* efficacy platforms, speeding up BsAb/ BsADC development and boosting clinical translation success of anticancer therapies.

#1682 Potency-Attenuated analogues of PNU-159,682 in conjugation with GlycoConnect® and HydraSpace® technologies provide ADCs with improved tolerability and efficacy.

Marcel Scheepstra, Remon van Geel, Jorin Hoogenboom, Lianne Lelieveldt, Sorraya Popal, Mick Verhagen, Oleksandr Zagorodko, Finn McSorley, Cağla Koc, Margarida Espadinha, Floris van Delft, Anette Sommer, Sander van Berkel

Synaffix/Lonza, Oss, Netherlands

PNU-159,682, an oxidized secondary metabolite of nemorubicin, exhibits extraordinary cytotoxic potency, being 2,100-6,400 fold more active than the clinically established doxorubicin. Despite promising antitumor activity, antibody-drug conjugates (ADCs) utilizing PNU-159,682 have not advanced beyond phase I clinical trials. The high potency and associated poor tolerability of PNU-based ADCs likely result in suboptimal clinical dosing, limiting the potential efficacy in patients. Based on these concerns, we designed and synthesized PNU analogues with attenuated cytotoxic potency, aiming to increase the tolerability while retaining robust antitumor activity, thus improving the therapeutic index (TI). Our approach involved multiple modifications to improve the properties. Conjugation of these new PNU analogues using GlycoConnect® site-specific conjugation technology, combined with HydrasSpace® polar spacer, yielded highly homogeneous ADCs with improved PK properties. Comprehensive in vitro and in vivo studies demonstrated that ADCs incorporating these attenuated PNU analogues maintained potent antitumor efficacy, inducing complete tumor regression in relevant xenograft models. Importantly, the maximum tolerated dose (MTD) of these ADCs was increased by up to 8-fold compared to ADCs based on the original PNU-159,682 payload, translating into a significantly expanded TI. Our findings demonstrate that potency-attenuated PNU analogues, when combined with GlycoConnect® and HydraSpace® technologies, represent a promising alternative to overcome the limitations of highly potent DNA-damaging payloads. This approach may enable higher clinical dosing paving the way for next-generation anthracycline-based ADCs with broad applicability in oncology.

#1683 Enhancing therapeutic efficacy and overcoming resistance with a novel dual-payload antibody-drug conjugate technology.

Antoine Attinger[1], Leo Marx[2], Diana Bianca Rocha Gomes[1], Vincent Gerusz[2], Min Ma[1], Viktoriia Postupalenko[2], Alain Monjardet[1], Nicolas Quesnot[1], Christophe Chardonnens[2], Rene Wuttke[1], Noemie Luong[1]

[1]Debiopharm International SA, Lausanne, Switzerland,[2]Debiopharm Research & Manufacturing SA, Martigny, Switzerland

Antibody-Drug Conjugates (ADCs) are promising oncology therapeutics that deliver cytotoxic payloads selectively to tumors. However, their efficacy is often limited by tumor heterogeneity, acquired resistance to single-agent payloads and off-target toxicity caused by premature linker cleavage. There is a critical need for next-generation ADCs to address these issues and broaden the therapeutic use of such modality. To address these challenges, we developed MLINK Duo, a dual-payload ADC technology combining plasma stability and controlled tumor-specific dual payload release. This technology enables the conjugation of a diverse range of dual payloads to antibodies, including combinations of well-established cytotoxic agents such as DM1, DM4, MMAE, and exatecan, as well as innovative new payload combinations. Here we show a proof of concept using a trastuzumab MLINK Duo ADC simultaneously delivering MMAE and exatecan (TmAb-MLINK Duo-MMAE/exatecan) at different drug-to-antibody ratios. The payload release mechanism was characterized biochemically, and the ADC stability was evaluated in mouse and human plasma. The TmAb-MLINK Duo-MMAE/exatecan was characterized for efficacy, pharmacokinetics and safety in non-clinical models. We also provide proof of synergy with other new dual-payload ADCs. The MLINK Duo ADCs exhibited low aggregation, high stability in circulation with minimal premature payload release, suggesting an improved therapeutic window. The specific enzymatic cleavage mechanism of the MLINK Duo linker technology was confirmed, demonstrating effective payload release. Crucially, the TmAb-MLINK Duo-MMAE/exatecan showed enhanced anti-tumor activity in several Cell-Derived Xenograft (CDX) models, maintaining efficacy and achieving tumor regression in CDX models that were resistant to the corresponding mono-payload ADCs (MMAE-ADC or exatecan-ADC). In addition, other MLINK Duo ADCs demonstrated clear synergistic anti-tumor effects compared to the treatment with single-payload ADCs. The pharmacokinetic profile of the TmAb-MLINK Duo-MMAE/exatecan supported favorable dosing schedules, and preliminary safety data showed a tolerable profile, validating the platform's clinical viability. In conclusion, we have developed a novel, stable, and versatile linker technology enabling the generation of innovative ADCs, including a highly promising dual-payload (MMAE/exatecan) configuration. The tested MLINK Duo ADCs could overcome resistance mechanisms prevalent against mono-payload ADCs and demonstrate potent synergy *in vivo*. This technology marks an important advancement in antibody-drug conjugate (ADC) technology, providing a promising approach to overcoming tumor resistance and potentially improving clinical outcomes in cancer therapy. Further translational development is ongoing. AI was used to assist abstract writing

#1684 ALM-502: A highly effective ADC for solid tumor therapy - enhancing payload delivery through molecular design.

Graham Cotton[1], Estelle McLean[2], Paul Trumper[1], Mark Wappett[3], Stephanie Gatdula[2], Stacey Dodd[1], Greg Papadakos[1], Stephanie Burton[2], Georgiana Parau[2], Aidan McCann[2], Chiara Saladino[2], Jennifer Thom[1], Aaron N. Cranston[2], Tim Harrison[2]

[1]Almac Discovery, Edinburgh, United Kingdom,[2]Almac Discovery, Belfast, United Kingdom,[3]Almac Discovery, Manchester, United Kingdom

Antibody-drug conjugates (ADCs) have transformed cancer therapy, yet their efficacy in solid tumors remains constrained by heterogeneous antigen expression, limited tumor penetration, low therapeutic index and the emergence of resistance mechanisms. ALM-502 is a highly differentiated, biparatopic ADC designed to address these challenges through innovative antibody architecture, enabling enhanced payload delivery.

ALM-502 targets ALPP/ALPPL2, developmental proteins which are over-expressed in multiple solid tumor indications but have undetectable protein expression on normal adult tissues. Additionally, ALPP/ALPPL2 are upregulated in response to standard of care treatments, providing additional therapeutic opportunities in the drug-resistant setting. The upregulation in multiple solid tumors, undetectable normal tissue expression and role in drug resistance make ALPP/ALPPL2 highly attractive targets for ADC approaches.

ALM-502 exploits multiple design features to deliver optimized performance:

• A biparatopic binding mode increases the effective number of binding sites on the tumor cells and increases payload delivery.
• A clinically proven, small antibody architecture is employed for enhanced tumor penetration.
• A low payload drug-to-antibody ratio (DAR) of 2 is used to enable higher ADC dosing and plasma levels.
• Payload attachment is via site specific conjugation to engineered sites providing a homogeneous product with excellent stability.
• A clinically proven payload matched to indications of interest is used which delivers a strong bystander effect and is a potent inducer of immunogenic cell death.
• The single chain antibody architecture coupled with site specific payload attachment and optimized physicochemistry facilitate high yield manufacture.
• Improved payload delivery (for a given amount of circulating ADC) drives the therapeutic index.

ALM-502 targets two distinct epitopes and is highly selective for ALPP/ALPPL2. In *in vitro* assays, this biparatopic mode of binding delivers enhanced internalization into cancer cells compared to a canonical ADC. The design features of ALM-502 translate into excellent anti-tumor efficacy in ALPP/ALPPL2 positive cell-line derived xenograft (CDX) and patient-derived xenograft (PDX) models of gastric, pancreatic, ovarian and bladder cancers, which display a range of target expression. In benchmarking studies, ALM-502 consistently delivers improved efficacy over a full length DAR4 ADC on a payload equivalents basis, in both single dose and multi-dose studies.

ALM-502 has an excellent PK profile in preclinical species together with strong developability and manufacturability characteristics. These features, coupled with an ultra-low immunogenicity profile mean that ALM-502 has the potential to deliver significantly improved patient outcomes across a range of solid tumor indications with high unmet need.

#1685 The HER2-targeting dual-payload antibody-drug conjugate combining a topoisomerase I inhibitor and a microtubule inhibitor demonstrates superior efficacy and overcomes resistance to single-payload ADCs in xenograft models.

Angela Matcham, Robert Yuan, Brian Vuillemenot, Rhoneil Pena, Young Park, Abigail Yu, Jeffrey Hanson, Cuong Tran, Xiaofan Li, Miao Wen, Daniel Calarese, Werner Rubas, Krishna Bajjuri, Guifen Xu, Alice Yam, Hanspeter Gerber

Sutro Biopharma, San Francisco, CA

The genetic and phenotypic heterogeneity of human cancers is a primary driver of drug resistance, posing a major challenge to achieving durable therapeutic responses. To overcome this, Sutro has developed a dual-payload antibody-drug conjugate (dpADC) platform that enables precise co-delivery of two cytotoxic payloads via a single, homogeneous molecule. Sutro's HER2-targeting dpADC demonstrates that simultaneous delivery of two cytotoxic payloads provides greater anti-tumor activity than single-payload ADCs and overcomes preclinical, in-vivo-derived treatment resistance. Combining Sutro Biopharma's XpressCF+® cell-free expression system with site-specific conjugation technology, we engineered a HER2-targeting dpADC combining exatecan (topoisomerase I inhibitor; TOPO1i) and monomethyl auristatin E (MMAE) (microtubule inhibitor; MTi) payloads at an 8:4 ratio. The resulting dpADC exhibited favorable pharmacokinetics in vivo and minimal linker-payload loss over a 21-day study. In *in vitro* cell killing assays, the dpADC performed better than Enhertu and DAR8 exatecan ADC across multiple tumor cell lines. In *in vivo* efficacy studies, the dpADC exhibited greater anti-tumor activity than both single-payload ADC comparators across multiple xenograft models. To further evaluate the dpADC concept's potential, we examined its utility in addressing resistance induced by ADC treatment. To mimic resistances to single payload ADCs observed in the clinic, we continuously dosed xenograft tumors with Enhertu on a weekly dosing schedule until the tumors progressed. These Enhertu-resistant tumors were then continuously dosed with a MTi ADC until *de novo* resistance developed. Dual-resistant tumors were then treated with a dpADC resulting in deep and durable anti-tumor responses. Even in tumors that were rendered resistant to both payloads, the dpADC treatment was able to achieve substantial tumor regression, demonstrating the potential for benefit in mono payload ADC refractory settings. Overall, these results indicate that Sutro's HER2 dpADC can enhance anti-tumor activity beyond that of single-payload ADCs and can overcome prior treatment-induced resistance in a preclinical setting.

#1686 Development of ZW418, a biparatopic PTK7-targeting antibody-drug conjugate incorporating a novel pan-RAS inhibitor payload for the treatment of non-small cell lung cancer.

Luying Yang, Alex Wu, **Vincent Fung**, Kaylee J. Wu, Sara Weeres, Katina Mak, Taixiang Wang, Victoria Harman-McKenna, Allysha Bissessur, Jesse Leblanc, Vidhi Khanna, Matthew Bonderud, Jodi Wong, Rehan Higgins, Linglan Fu, Dunja Urosev, Raffaele Colombo, Graham A. E. Garnett, Jamie R. Rich, Stuart D. Barnscher

Zymeworks Inc., Vancouver, BC, Canada

Mutations in the RAS oncogene family occur in approximately 25-30% of lung adenocarcinomas and represent one of the most common oncogenic drivers in non-small cell lung cancer (NSCLC). These alterations lead to constitutive activation of downstream MAPK signaling, promoting tumor growth and therapeutic resistance. Protein tyrosine kinase 7 (PTK7) is prevalently overexpressed in NSCLC but has limited expression in normal tissue, making it an attractive therapeutic target for NSCLC.
Existing mutant-specific and pan-RAS inhibitors (RASi) have demonstrated clinical benefit in NSCLC but patients often experience on-target off-tumor toxicities and acquire resistance. These challenges may be improved upon by enhancing delivery of a RASi via an antibody drug conjugate (ADC) mechanism. We have developed ZW418, a biparatopic PTK7-targeting ADC that leverages a cleavable linker designed to deliver a novel pan-RASi payload with optimized stability and bystander effect for the treatment of NSCLC.
A biparatopic antibody recognizing two non-overlapping epitopes on PTK7 was engineered and conjugated to a cleavable pan-RASi drug-linker. Binding affinity, internalization, spheroid penetration, and in vitro cytotoxicity were characterized across a panel of PTK7-expressing RAS-mutated cancer cell lines. Additional mechanistic evaluation of RAS inhibition was also performed in vitro. Pharmacokinetic properties were evaluated in non-tumor bearing mice, and antitumor activity was investigated in RAS-mutated cancer xenograft models.
Across RAS-mutated cancer cell lines with varying PTK7 expression level, the biparatopic antibody demonstrated greater cell surface decoration, internalization, and spheroid penetration compared to cofetuzumab and other PTK7-targeted clinical benchmark antibodies. ZW418 exhibited potent target-dependent cytotoxicity in vitro and demonstrated strong anti-tumor activity in multiple RAS-mutated cancer cell line derived xenograft models. The pan-RASi ADC platform showed encouraging tolerability in mice with no significant toxicity observed up to a dose of 200 mg/kg. Overall, the data supports the potential of ZW418 as a novel, highly differentiated therapeutic agent against PTK7-expressing RAS mutant cancers.

#1687 Engineering multi-specific and multi-payload ADCs to address tumor heterogeneity and drug resistance.

Greg Liang, Songyan Huang, Fan Feng, Mingqi Shao, Qikuan Chen, Kaijian Bi, Haixia Chen, Yanjie Chen, Yan Zhu, **Hu Liu**

Shanghai ChemPartner Co., Ltd., Shanghai, China

Antibody-drug conjugates (ADCs) are advancing beyond single-target, single-payload formats to address the challenges of heterogeneity and resistance to treatment. We previously generated ADC's based on monospecific, bispecific, biparatopic, and tri-specific antibodies, as well as dual-payload conjugates. *In vitro* and *in vivo* evaluation of these constructs demonstrated enhanced internalization and cytotoxicity. In this study, we combine these design strategies to generate next generation ADCs that incorporate multi-specific antigen recognition and multi-payload delivery, aiming to further improve therapeutic efficacy. A biparatopic anti-PD-L1 antibody was produced by combining two humanized parental antibodies via scFv integration. The antibody was expanded into tri-specific formats by incorporating additional binding domains targeting VEGF, HER2 and TROP2 tumor associated targets, enabling differential tumor engagement. Three cytotoxic payloads with distinct mechanisms of action (DNA damaging, microtubule inhibition, and topoisomerase I inhibition) were individually conjugated to generate monospecific single-payload ADCs. Based on the relative potency of these conjugates, dual and tri-payload ADCs were developed using the tri-specific antibodies with each payload conjugated at a Drug -to-Antibody Ratio (DAR) calibrated to achieve comparable cytotoxic effects. *In vitro* cytotoxicity was assessed across a panel of tumor cell lines with heterogenous target expression to evaluate the therapeutic potential of combining multi-specific antigen recognition with multi-payload delivery. The biparatopic anti-PD-L1 construct showed enhanced binding and internalization compared to its parental antibodies. Tri-specific formats retained cooperative engagement of multiple-antigens, supporting their potential for broader tumor targeting.

Among these, the HER2/TROP2 targeting tri-payload ADC maintained molecular integrity and exhibited enhanced potency in mixed-resistance models, outperforming corresponding monospecific or single-payload ADCs. All three PD-L1-based tri-specific tri-payload ADC's exhibited stronger and more widespread cytotoxic activity across diverse cell lines. *In vivo* studies confirmed that ADC's combining multi-specificity with multi-payload delivery achieved better tumor growth inhibition relative to monospecific or single-payload controls. Multi-specific antibody mechanisms and multi-payload delivery are complementary strategies to improve ADC performance by promoting efficient internalization, expanding the range of cytotoxic mechanisms, and addressing tumor resistance. These modular approaches offer a flexible framework for next-generation ADCs targeting heterogeneous solid tumors.

#1688 Empowering development of next generation ADCs & XDCs through advanced WuXiDARx conjugation technologies.

Qirui Fan, Hu Chen, Jingjie Huang, Lin Zhang, Zekun Wang, Ding Wei, Guoguang Wei, Yanjie Zhao, Laisen Wang, Cindy Cheng, Marie Zhu

Discovery and Development, WuXi XDC, Shanghai, China

Background: Antibody drug conjugates (ADCs) and various types of bioconjugates (XDCs) have garnered increasing attention over the past decade. These novel payloads and payload combinations require advanced conjugation technologies to fully achieve their therapeutic potential. Conventionally, interchain cysteine coupling serves as the most clinically validated conjugation technologies. However, such methods have two major flaws: (1) heterogeneity from stochastic coupling (except for DAR8); and (2) instability during circulation due to maleimide retro-Michael addition.
Solutions: To address these needs, WuXi XDC has built a platform through internal development and external collaboration. This platform includes two parts: (1) WuXiDARx™ conjugation technology WuXiDARx™ conjugates at interchain cystines which are the most clinical validated site, as 13 out of 18 commercial ADCs are developed through cysteine conjugation. This technology features: • Flexible DAR choices (WuXiDAR1^{TM}, WuXiDAR2^{TM}, WuXiDAR4^{TM}, WuXiDAR6^{TM}) • Improved homogeneity: ≥ 85% for DAR1 and DAR2; or ≥ 65% for DAR4 and DAR6 • Enhanced efficacy and safety profiles • Compatibility with IgG1 mAb • Compatibility with novel ADCs (e.g., dual-payload ADCs, bispecific ADCs) and XDCs (e.g., AOCs, APCs) • Simple and robust conjugation process • Validated technology: 7 ADCs in clinical trials, 10 CMC projects, up to > 2 kg batch size (2) Thiol reactive connector technologies Conventional interchain cysteine conjugation uses maleimide connector to react with the thiol groups from the antibody. However, the reverse reaction (retro-Michael addition) may result in premature release of the payload-linkers in circulation. To solve this problem, X-LinC connector is developed to replace the maleimide connector, which has shown good plasma stability and is fully compatible with WuXiDARx^{TM}. A different way to create homogeneous DAR4 ADCs is by using thiol-rebridging connectors. CysLink technology incorporates a stable thiol-rebridging connector into the platform. Unlike traditional connectors, the CysLink version produces ADCs with fewer thiol mismatches and half-antibody ratios, and it works with WuXiDARx^{TM} to offer additional DAR options (e.g., DAR1).
Conclusion: The combination of WuXiDARx^{TM}, X-LinC, and CysLink offers an integrated solution to utilize the most clinically validated conjugation sites, which is helping accelerate ADCs/XDCs pipeline development from clients.

#1689 Next generation ConjuAll BCMA antibody-drug conjugates (ADCs) LCB14-2524 and LCB14-2516 show increased efficacy in preclinical models of multiple myeloma.

Matthew Sender[1], Joe Ponte[1], Stephen Slocum[1], Yun-Hee Park[2], Yunjoo Jung[2], Chul Woong Chung[2], Rodrigo Ruiz-Soto[1], Jeiwook Chae[2]

[1]AntibodyChem Biosciences, Newton, MA,[2]LigaChem Biosciences, Daejeon, Korea, Republic of

LCB14-2524 and LCB14-2516 are Antibody-Drug Conjugates (ADCs) targeting B cell maturation antigen (BCMA). This target has emerged as one of the most important for targeted therapies in relapsed/refractory multiple myeloma (RRMM) as demonstrated by the recent approval of the ADC belantamab mafodotin in combination with bortezomib and dexamethasone. While belantamab mafodotin has delivered meaningful benefit to patients, the high rate of keratopathy leaves room for improvement. We present data for next generation anti-BCMA ADCs designed for robust efficacy with the potential for reduced ocular toxicity. LCB14-2524 is an ADCC enhanced IgG1 anti-BCMA ADC utilizing the second generation β-glucuronide (LBG) ConjuAll platform linker delivering a homogenous drug-antibody-ratio (DAR) of 2 monomethyl auristatin F (MMAF) microtubule inhibitor payloads. LCB14-2516 is an Fc silenced IgG1 anti-BCMA ADC that also utilizes the ConjuAll platform to deliver the highly potent pyrrolobenzodiazepine (PBD) DNA cross linking payload. These molecules were selected for progression through comparison of payload, conjugation method (ConjuAll vs maleimide), and antibody Fc properties (ADCC enhanced or silenced) to a belantamab mafodotin biosimilar in vitro and in vivo. In a panel of in vitro cytotoxicity assays the LBG-proPBD based ADCs were more potent than the belantamab mafodotin biosimilar or LBG-MMAF ADCs which demonstrated similar potency across cell lines. ADCC reporter assay showed potent activation by the Fc enhanced ADCs and antibodies, with no signal from the silenced ADCs or antibodies. The parental antibodies and the ADCs displayed similar activity in the ADCC reporter assay, suggesting no impact on function following conjugation. In vivo, both LCB14-2516 (LBG-proPBD) and LCB14-2524 (LBG-MMAF) were more active than the belantamab mafodotin biosimilar across OPM2, MM.1S and NCI-H929 CDX models. Both LCB14-2516 (LBG-proPBD) and LCB14-2524 (LBG-MMAF) ADCs utilize clinically validated LCB technology with promise to increase the therapeutic index of BCMA targeted ADCs and are progressing through IND enabling studies for clinical development.

#1690 Preclinical development of XNW27011, an antibody drug conjugate targeting claudin18.2 for treatment of CLDN 18.2-positive solid tumors.

Yonghan Hu[1], Yuanbao Li[2], Zhenwei Wu[2], Yuzhen Hou[2], Liang Kong[2], Shihua Wang[2], Zhe Zhang[2], Ka Ruan[2], Wengui Wang[2], Hui Zhao[2], Qifeng Shi[2], Haiyang Wei[2], Xiaojun Liu[2], Meijie Le[1], Jing Qiang[1]

[1]Evopoint, Shanghai, China,[2]Evopoint, Suzhou, China

Claudin (CLDN) 18.2, a member of a large family of transmembrane proteins with distinct functions, is highly expressed in cancers including gastric and pancreatic adenocarcinomas. Unlike in normal tissue, CLDN18.2 is exposed on epithelial surfaces in malignancy. It is suggested that CLDN18.2 is an ideal target for cancer therapy. So far, drug targeting CLDN18.2 has been approved for treating gastric cancer. XNW27011, an antibody-drug conjugate (ADC) composed of a monoclonal antibody (mAb) targeting CLDN18.2 with a toxin (payload, YL0010014) site-specifically conjugated via a cleavable linker with a drug-antibody ratio (DAR) of 8. XNW27011 is under development by Evopoint Biosciences for the treatment of patients with various CLDN 18.2-positive solid tumors including gastric cancers and pancreatic cancers in China. Here we present the preclinical development of a novel therapeutic CLDN18.2 ADC. In preclinical pharmacology studies, XNW27011 specifically binds to cells expressing human CLDN18.2 with high affinity but not to the closely related Claudin 18.1. XNW27011 demonstrated potent antiproliferative activity with CLDN 18.2 highly-expressed cell lines including arresting the cell cycle at the G2/M stage and inducing apoptosis in a variety of *in vitro* pharmacology studies. XNW27011 also exhibited similar activities to the naked antibody (XNW27011-mAb), including antibody-dependent cell-mediated cytotoxicity (ADCC), complement dependent cytotoxicity (CDC), internalization activities, and bystander effect. XNW27011 as a single agent displayed potent antitumor activities in multiple *in vivo* xenograft models of human gastric and pancreatic cancer, including PDX models (PDX001 [gastric cancer] and PDX002 [pancreatic cancer]) and CDX models (NUGC-4 and NUGC-4 CLDN 18.2) with low or high CLDN18.2 expression., XNW27011 achieved partial tumor regression (PR) and complete tumor regression (CR) in most mouse xenograft models at well tolerated iv doses (3 or 10 mg/kg). In nonclinical pharmacokinetics of XNW27011 in SD rats and Cynomolgus monkeys by intravenous infusion, XNW27011 showed good ADME characteristics in that it was stable in the bloodstream and exposure to the payload is very low. In toxicity studies, XNW27011 displays good tolerability with wide therapeutic windows in both SD rats and Cynomolgus monkeys. It is particularly important to note that XNW27011 has no toxic effects on the lungs in both rats and monkeys. In summary, XNW27011 has demonstrated potent *in vitro* and *in vivo* antitumor effects, favorable pharmacokinetic and an acceptable safety margin. XNW27011 is expected to be a potent therapeutic ADC candidate in cancer treatment of CLDN 18.2-positive solid tumors including gastric and pancreatic adenocarcinomas. Clinical activity of XNW27011 is currently under evaluation in a Phase III clinical trial (CTR20252730).

#1691 Site-specific dual-payload antibody conjugation enhances antitumor efficacy.

Wei-Ting Sun[1], Shih-Hsien Chuang[1], Shih-Chong Tsai[2], Cheng-Chou Yu[2]

[1]Honeybear Biosciences Inc., Taipei City, Taiwan,[2]Development Center for Biotechnology, Taipei City, Taiwan

We have developed a site-specific conjugation platform enabling controlled dual-payload delivery on antibodies. The antibody is enzymatically trimmed and modified to allow sequential bioorthogonal attachment of two payloads. This approach permits precise control of payload type and DAR number, enabling combinations that improve in vivo tumor suppression at lower payload doses. Here we present dual-payload HER2 ADCs as a proof-of-concept. A trastuzumab-based ADC carrying DM1 (DAR 2) and seco-DUBA (DAR 2) demonstrated potent inhibition of JIMT-1 xenograft tumors, a model known to be resistant to T-DM1. Additionally, a dual-payload MMAE/exatecan ADC (DAR 2+2) achieved antitumor activity comparable to T-DXd (DAR 8), despite using substantially lower total payload. These results show the versatility and therapeutic potential of our dual-payload site-specific conjugation strategy. The platform provides a method to overcoming drug resistance and expanding therapeutic windows for next-generation ADCs.

#1692 STX-1, a first-in-class ADC targeting DPP4 protein, acts as an anticancer and senolytic treatment.

Benjamin Le Calve[1], Delphine Dayde[1], Gregoire Jouffroy[1], Omayma Asbai[1], Virginie Lelarge[1], Justine Choeur[1], Thierry Mathieu[1], Florence Lhospice[1], Eric Angevin[2]

[1]StarkAge Therapeutics, Lille, France,[2]INSERM U981 (Gustave Roussy), Villejuif, France

Antibody-drug conjugates (ADCs) are innovative cancer therapies which, unlike conventional chemotherapies, enhance the anti-tumor effect while limiting adverse effects. However, it is necessary to discover new therapeutic targets that will enable the development of future generations of ADCs. Here we present an original ADC, called STX-1, targeting DPP4 protein and exhibiting both anticancer and senolytic activities. DPP4 is a type II glycoprotein that has intrinsic dipeptidyl peptidase IV (DPPIV) activity and is implicated in broad and various physiological processes, including metabolism of glucose, activation of T lymphocytes, and cell adhesion. This protein has also been known as a cell surface marker associated with varied malignancies and as a part of cancer stem cells in mesothelioma and colon carcinoma. More recently, studies have shown that its expression is a major hallmark of senescence. DPP4 therefore appears to be a promising therapeutic target in the treatment of certain types of cancer, targeting not only tumor but also senescent tumor cells.STX-1 is composed of a humanized IgG1 antibody directed against DPP4 (anti-DPP4 mAb) conjugated to four topoisomerase I inhibitor Exatecan with cathepsin B sensitive linker. The preclinical datasets display *in vitro* complete characterization of STX-1 associated to high internalization of the ADC, strong affinity to DPP4 protein and cytotoxic activity on several cancer models specifically related to target expression. Moreover, senescence induction in cancer cell lines through chemo- or radiotherapy exposure, boosts DPP4 expression and increases significantly antigen density at the plasma membrane. Despite the cell cycle arrest induced by senescence, cancer cells remain sensitive to STX-1 treatment. *In vivo*, administration of intravenous (IV) doses of STX-1 is associated with potent anti-tumor activity in pancreas and liver cancer xenograft models whose effectiveness depends on the level of DPP4 expression. However, pretreatment of mice by a combination of Trametinib/Palbociclib induces senescence in tumor, boost expression of DPP4 and allows a better anti-tumor activity of STX-1. Finally, in toxicology studies in mice expressing human form of DPP4, STX-1 was well tolerated, at dose levels up to 100 mg/kg, 21 days after administration. To conclude, STX-1 is associated with strong anti-tumor activity in different cancer models, whereas synergistic combination activity to senescence phenotype induction in tumors. The data presented support future clinical development of STX-1 for the treatment of gastric, pancreatic and liver cancer indications.

#1693 Targeting MET-LGR5 crosstalk using an antibody-drug conjugate combination with diverse payloads to overcome adaptive resistance in colorectal cancer.

Shraddha Subramanian[1], Peyton Christian High[2], Zhengdong Liang[3], Cara Guernsey-Biddle[3], Adela Aldana[3], Kendra S. Carmon[2]

[1]The University of Texas MD Anderson Cancer Center UTHealth Houston Graduate School of Biomedical Sciences, Houston, TX,[2]UT Health Houston, Houston, TX,[3]UTHealth Houston, Houston, TX

Off-target side effects and drug resistance often hamper the therapeutic benefits of existing anti-cancer therapies against colorectal cancer (CRC), the second deadliest malignancy worldwide. CRCs contain tumor-initiating cancer stem-like cells (CSCs) that survive toxic drugs and give rise to metastatic disease. Antibody-drug conjugates (ADCs) are a revolutionary class of therapeutics that leverage monoclonal antibody (mAb) specificity to deliver cytotoxic payloads to tumor cells. We generated ADCs targeting leucine-rich repeat-containing G protein-coupled receptor 5 (LGR5), a bona fide CSC biomarker frequently overexpressed in CRCs. Our LGR5 ADC exhibited high potency in CRC xenograft models with minimal toxicity. However, it failed to prevent tumor relapse after treatment cessation. Interestingly, we found that recurrent tumors evade LGR5 ADC-mediated elimination by transiently converting into an LGR5-negative ($LGR5^-$) state, accompanied by concomitant MET upregulation and activation of the downstream pathway. MET is a receptor tyrosine kinase frequently upregulated in CRCs and promotes metastatic progression. We identified that the activation of STAT3, a downstream effector protein in the MET pathway, undermines LGR5 ADC efficacy in CRC cells. To eliminate drug-resistant $LGR5^-$ cells, we generated MET-targeted ADCs by attaching a highly selective MET mAb (ABT700) backbone to the DNA-crosslinking payload pyrrolobenzodiazepine (PBD) via site-specific conjugation. This MET ADC (ABT700-PBD) demonstrated dose-dependent cytotoxicity in CRC cells. Furthermore, ABT700-PBD did not affect CRC cells with genetically induced MET ablation, demonstrating its specificity. Safety studies in immunocompetent mice showed that ABT700-PBD exhibited a favorable safety profile. Moreover, in CRC xenograft models, ABT700-PBD induced marked tumor regression. However, in the residual tumors following dose-dependent ABT700-PBD monotherapy, LGR5 protein expression was upregulated. These observations suggest that the MET-LGR5 crosstalk may be a potential driver of adaptive resistance in CRC. Cytotoxicity assays testing ABT700-PBD and our previously reported camptothecin-derived (CPT2) LGR5-targeted ADC (8E11-CPT2) demonstrated synergistic cell-killing activity in vitro. Combination treatment with ABT700-PBD and 8E11-CPT2 in CRC patient-derived xenograft models extended survival compared to single-agent ADCs. Collectively, our findings support MET and LGR5 ADC combination therapy as a novel treatment strategy to overcome adaptive resistance-driven relapse in CRC.

#1694 Application of tangential flow-filtration (TFF) to enable solvent exchange and precipitation process for the production of payload-linkers of antibody-drug conjugates.

Sudhir Patil, Feng Xu, Minglin Wang, **Jianwei Bian**, Xudong Wei

Payload-linker Department, WuXi XDC, Cranbury, NJ

Tangential Flow Filtration (TFF), also known as Crossflow Filtration, is a technique in which the fluid mixture flows tangentially (parallel) across the surface of the filter rather than being forced directly through it. This method is widely utilized in bioprocessing. We have demonstrated that TFF can be effectively applied in the enrichment process for the payload-linker prep HPLC purification, enabling significant volume reduction. The process works by allowing solvents to pass into the exchange buffer while retaining and concentrating the payload-linker product in the retentate. This approach facilitates solvent exchange, which in turn enables direct precipitation, eliminating the need for the time-consuming lyophilization step. The process has been successfully validated under GMP conditions at a production scale of 1 kg.

#1695 Preclinical characterization of STRO-227: A PTK7-targeting dual-payload ADC with topoisomerase 1 and tubulin inhibitors.

Daniel Calarese, Kshama Doshi, Garrett Gross, Brian Vuillemenot, Xiaofan Li, Mark Armanini, Guifen Xu, Miao Wen, Krishna Bajjuri, Gang Yin, Werner Rubas, Alice Yam, Hanspeter Gerber

Sutro Biopharma, Inc., South San Francisco, CA

PTK7 is a catalytically inactive, cell surface protein tyrosine kinase and a marker of tumor-initiating cancer stem cells. It plays a key role in tumor biology by regulating pathways involved in cell migration, invasion, and metastasis, and is upregulated in multiple solid tumors, including ovarian, triple-negative breast, non-small cell lung, esophageal, and head and neck cancers. Its combination of tumor-restricted expression and functional relevance in cancer stem cells makes PTK7 an attractive target for antibody-drug conjugates. We present the preclinical characterization of STRO-227, an investigational PTK7-targeting antibody-drug conjugate (ADC) generated using Sutro's XpressCF+® cell-free protein synthesis platform, which enables the site-selective incorporation of non-natural amino acids. This platform allows precise conjugation of two distinct payloads: exatecan, a topoisomerase I inhibitor, and monomethyl auristatin E (MMAE), a tubulin inhibitor. Each of these potent payloads is attached via a hydrophilic β-glucuronidase-cleavable linker. The final ADC possesses a defined drug-to-antibody ratio (DAR) of 8 exatecan to 2 MMAE payloads. In preclinical studies, STRO-227 demonstrated favorable pharmacokinetics and *in vivo* stability. In multiple xenograft and patient-derived xenograft (PDX) models, STRO-227 exhibited superior anti-tumor activity compared to the corresponding single-payload ADCs. In addition, STRO-227 demonstrated a favorable safety and pharmacokinetic profile in non-human primates, with a highest non-severely toxic dose (HNSTD) comparable to established MMAE- and topoisomerase I-based single-payload ADC benchmarks.

#1696 IN30758, an integrin-targeted antibody drug conjugate (ADC) demonstrating strong therapeutic effects in multiple solid tumors.

Baoyuan Zhang, Shiqiang Lu, Yue Ma, Jiaming Gao, Fengmin Xi, Ran Pang, Leo Liu, Zaiqi Wang

InxMed (Shanghai) Co., Ltd., Shanghai, China

Integrins represent a promising target for the development of antibody-drug conjugates (ADCs). The integrin alphaVbeta6 has already been leveraged in the creation of a clinical-stage ADC, which has demonstrated favorable efficacy and safety profiles in early assessments. The integrin family consists of 24 heterodimers formed by 18 alpha and 8 beta subunits. In this study, we present ADC IN30758, which comprises the integrin antibody A28 and a clinically validated linker payload, LD38. The binding affinities of both the unconjugated antibody and the ADC to the human integrin antigen are comparable. A28 exhibits strong antibody-antigen binding characteristics, facilitating effective association and dissociation. Both the unconjugated antibody and the ADC demonstrate significant internalization capabilities in cancer cells. Immunohistochemistry (IHC) staining assays indicate that A28 can bind to various solid tumors, including non-small cell lung cancer (NSCLC), pancreatic ductal adenocarcinoma (PDAC), and ovarian cancer (OC). Various animal models, including cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) trials, were conducted to assess the tumor growth inhibition effects of IN30758, revealing that the ADC shows promising sensitivity across multiple solid tumors. Currently, the Investigational New Drug (IND) package, which includes preclinical efficacy, pharmacokinetics, and toxicity data, has been compiled, with the IND application expected to be submitted in December 2025.

#1697 NW024-1, a novel ALPP/ALPPL2-targeting antibody drug conjugate with a topoisomerase 1 inhibitor payload, demonstrates potent antitumor efficacy.

Juanjuan Li[1], Wenting Luo[1], Li Liu[1], Yiran Wu[1], Gang Liu[1], Changcheng Li[1], Yaolan Dai[1], Jiabao Liu[1], **Zhijian Li**[2], Lixia Wang[1], Dan Wang[1], Dan Mi[1], Jiaoyi Zhong[1], Bin Liu[1], Desi Pan[1], Zhigang Guo[1]

[1]Chengdu Chipscreen NewWay Biosciences Co., Ltd., Chengdu, Sichuan, China,[2]Chipscreen Biosciences (United States) Ltd., Somerset, NJ

Background: Placental alkaline phosphatases, ALPP and ALPPL2, are highly homologous (97%) membrane-bound proteins involved in fetal development. They are highly expressed in a variety of tumor cells including ovarian (70%), endometrial (41%), lung (NSCLC, 25%) and gastric (25%), but have limited expression levels in normal tissues, making them ideal targets for the development of antibody-drug conjugates (ADCs). Here, an ALPP/ALPPL2-targeting ADC NW024-1 was developed, consisting of a humanized IgG1 anti-ALPP/ALPPL2 antibody conjugated via a hydrophilic linker to a topoisomerase 1 inhibitor payload (TOP1i), designed to selectively deliver the cytotoxic agent to ALPP/ALPPL2-expressing cells. NW024-1 was tested in vitro and in vivo to evaluate its therapeutic potential.
Methods: A library of ALPP/ALPPL2-binding clones was screened for cell binding, internalization and affinity. The humanized antibody was conjugated to the TOP1i payload with DAR8 using a cleavable linker. The in vivo efficacy of NW024-1 was evaluated in a mouse xenograft model of gastric cancer (NCI-N87), administered with a single dose of 3 mg/kg and 10 mg/kg to evaluate anti-tumor activity.
Results: The antibody showed strong binding to human ALPP/ALPPL2 (EC50 = 1.32 nM) low expressing cells, but no binding to human ALPI /ALPL high expressing cells. In vitro, it displayed robust internalization into ALPP/ALPPL2 positive cells and low nanomolar affinity to ALPP (KD = 1.32 nM) and ALPPL2 (KD = 0.85 nM). NW024-1 showed ALPP/ALPPL2-dependent cell killing. In vivo, NW024-1 achieved near-complete tumor regression (TGI > 95%) at 3 and 10 mg/kg for single dose, and was well tolerated in mice as indicated by body weight.
Conclusions: NW024-1 is a novel ADC exhibiting a favorable profile and potent antitumor efficacy. These findings highlight its promising therapeutic potential for ALPP-expressing tumors and support its further advancement into clinical investigation.

#1698 A novel synergistic dual-payload FRα ADC (CTPH-08) that can potentially offer benefits for low IHC+ ovarian cancer patients by improving MTD and MED.

Soyeon Lim, Myeong Joo Kim, Junho Ha, Heegoo Jun, Jongchan Lee, So Hee Im, Seo Ha Kim, Young Sang Kim, Seung Chan Kim, Hyo Jin Kang, **Chang-Sun Lee**

Celltrion Pharm, Inc., Incheon, Korea, Republic of

Dual-payload antibody drug conjugates (ADCs) have achieved increasing traction as a next-generation ADC technology to improve the therapeutic window of single-payload ADCs. By integrating two different payloads having distinct modes of actions, dual-payload ADC platforms can offer opportunities to counter tumor heterogeneity, or to reduce the likelihood of resistance that often emerges with the single-payload ADCs. We have pursued novel dual-payload ADC formats that can provide synergistic activity as well as minimal overlapping toxicity due to complementary acting mechanisms from two different payloads. A few combinations of payloads have been found to demonstrate synergistic cytotoxicity, which have been successfully incorporated into ADCs to confirm the novel dual-payload ADC(AD^2C) concept. Although folate receptor-alpha (FRα) represents a clinically validated antigen as highlighted by the approval of Elahere, clinical benefit is yet to remain limited due to dose-limiting toxicities and suboptimal response durability. To address these shortcomings, we have generated dual-payload FRα ADC (AD^2C) designed to enhance anti-tumor activity without exacerbating systemic toxicity. This presentation covers a comprehensive characterization of FRα AD^2C including *in vitro* cytotoxicity for cancer cells with different levels of FRα expression, *in vivo* anti-tumor activities in FRα-positive CDX models, *in vivo* stability of FRα AD^2C via pharmacokinetic assessment in rats, and preliminary safety evaluation in mice. We are currently advancing dual-payload FRα ADC(AD^2C) toward PDX efficacy studies and GLP toxicology studies in order to proceed to Ph1 IND filing in due course.

#1699 GlycoConnect® ADC toolbox expansion with dual payload ADC (dpADC) technology.

Remon van Geel, Lieke Kraaijvanger, Mick Verhagen, Nick Burgers, Marie Nassiet, Margarida Espadinha, Elias Post, Sander van Berkel, Floris van Delft, Marcel Scheepstra, Anette Sommer

Synaffix - A Lonza Company, Oss, Netherlands

Intratumoral heterogeneity and interpatient tumor heterogeneity have been recognized as hurdles for efficacious cancer treatments and may result in short duration of response and resistance to classical chemotherapies. It has been shown that combinations of chemotherapy drugs with an independent mode-of-action (MoA) controls tumor growth and enhances survival in both, hematological and solid tumors.

In the past years, antibody-drug conjugates (ADCs) have successfully been included in cancer treatment paradigms. Recently, there has been a growing interest in dual-payload ADCs (dpADCs), i.e. ADCs consisting of two payloads conjugated to a tumor targeting antibody, for developing more efficacious ADCs. Similar to combining chemotherapy drugs, combining two payloads with independent MoA in one ADC might be an attractive strategy to address interpatient and intratumoral heterogeneity and increase response rate, duration of response, overall survival and overcome resistance. These payloads may act on (1) different cellular pathways (complementary MoA), (2) the same cellular pathway, or (3) the payloads may have a different pharmacokinetic profile, and by this dpADCs may enhance anti-tumor activity.

Previously, we have shown that the native glycan of monoclonal antibodies is a privileged site for attachment of cytotoxic payloads[1] (GlycoConnect© technology), while the therapeutic index is further elevated by a highly polar spacer technology (HydraSpace©)[2]. Here we show that GlycoConnect© technology can readily be extended to generation of dpADCs. We have developed a modular method enabling generation of dpADCs with tailored payload ratios. In vitro and in vivo studies will be presented showcasing these GlycoConnect© dpADCs combining payloads with different MoAs.

#1704 Method development of purity and assay HPLC method for unstable antibody-drug conjugate linker regulated starting material BCN-OH.

Yilin Hao, Yujie Guo, Jing Zhuang, Shijuan Xu, **Lynn Wang**, Xudong Wei, Gengcheng Jack Yang

Payload-linker Department, WuXi XDC, Cranbury, NJ

BCN-OH is a critical raw material in an innovative payload-linker platform utilizing azido-sugar site-specific conjugation technology, which offers superior conjugation efficiency and therapeutic index. However, BCN-OH exhibits extreme instability, with solution stability of less than one hour and high susceptibility to oxidation upon air exposure. These characteristics pose significant challenges for impurity profiling and specification setting during manufacturing. To address this, we aimed to develop a robust and reproducible HPLC method capable of accurately identifying and characterizing related substances in BCN-OH, ensuring reliable quality control and regulatory compliance. Through systematic optimization of chromatographic conditions—including column selection, temperature, mobile phase composition, sample diluents, and gradient profiles, the method achieved baseline separation of five specified impurities and resolved the main peak from its isomer. Incorporation of BHT as an antioxidant extended BCN-OH solution stability from under one hour to 24 hours, greatly improving operational feasibility. Additional measures, such as nitrogen storage and glove box handling, further minimized oxidation risk. The validated method demonstrated robustness, intermediate precision, and suitability for PPQ and routine QC, providing essential data for impurity specification setting and ensuring consistent quality of this highly unstable payload-linker intermediate.

#1705 Compatibility study of routine chromatographic analytical testing of antibody-drug conjugate payload-linkers.

Tingting Xu, Yupei Deng, Xinsheng Yang, **Lynn Wang**, Jianqiang Li, Xudong Wei

Payload-Linker Department, WuXi XDC, Cranbury, NJ

Payload-linkers are essential components of antibody-drug conjugates (ADCs), connecting the antibody to the cytotoxic drug through complex chemical structures that include PEG chains, peptide sequences (e.g., GGFG, VC, etc.) linked by disulfide, carbonate, amide, or pyrophosphate bonds. These features make payload-linkers highly sensitive to hydrolysis, oxidation, photodegradation, moisture absorption, and metal ion complexation, posing significant challenges during analytical testing. Their instability requires strict control of sample preparation, storage, and analysis conditions to ensure accurate and reliable data. This study aimed to identify suitable analytical conditions for different structural types to support robust characterization and quality control. We systematically evaluated preparation processes, diluents, mobile phases, consumables, and instrumentation to minimize degradation and variability. The optimized method incorporates inert consumables, chromatography columns with appropriate packing material and pore size, and stability-preserving diluents to reduce analytical instability. These measures enable reproducible and accurate analysis of payload-linkers, supporting specification setting and quality assurance in ADC development. Our findings underscore the importance of tailored analytical strategies for structurally complex and highly reactive intermediates in bioconjugation platforms.

#1706 An integrate comprehensive *in vitro* and *in vivo* strategies for antibody drug conjugate development.

Ismahene Benzaid, Peggy Provent, Aurelie Durgeau, Didier Grillot, **Marc Hillairet de Boisferon**

Oncodesign Services, Dijon, France

Antibody-drug conjugates (ADCs) have transformed the landscape of modern drug development, offering a powerful way to deliver chemotherapy with precision. But translating an ADC concept into a successful candidate requires an integrated approach to identify targets, optimize payload delivery directly to the tumor, and validate efficacy across ex vivo and in vivo preclinical models. The challenge remains to develop improved preclinical tools and select the right pipeline supporting ADC development that will be more predictive of clinical outcome.

Oncodesign Services has generated a comprehensive preclinical platform to support ADC functional characterization by integrating in vitro binding and internalization assays to pharmacokinetics, pharmacodynamics along with efficacy studies in translational models. We offer a wide range of specialized assays and validation tools that examine both antibody and target characterization including a wide range of biological activity (MoA) functional cell-based assays. Available assays include target binding, ADC internalization, payload function and tumor cell kill potency, while available organoid platforms for enhanced translational relevance.

Oncodesign Services includes over 500 tumor models across 35 cancer indications, offering a wide selection of translational models to support your efficacy studies, including patient-derived xenografts (PDX) as well as syngeneic and humanized models.

In this poster we show different pre-clinical experiments steps including cellular assays, relevant in vivo models tested with FDA approved ADC payloads in validated target expression tumor combined with imaging technologies and radiopharmaceutical ADCs. The application of preclinical molecular imaging techniques by conjugating an ADC to a fluorescent tag or radioactively labeled improve the identification of effective candidate ADC molecules for therapeutic success.

From concept to proof-of-efficacy, Oncodesign Services present a platform combining biological and pharmacological expertise to accelerate the identification of effective candidate ADC molecules with the best chance of clinical translation and cancer patient benefit.

#1707 ZW191 - a differentiated FRα-targeted topoisomerase I antibody drug conjugate active in combination with standard of care drugs.

Sam Lawn, Andrea Hernandez Rojas, Jodi Wong, Araba Sagoe-Wagner, Vincent Fung, Kurt Stahl, Ambroise Wu, Lemlem T. Degefie, Steve Seredick, Pranshul Chauhan, Raffaele Colombo, Jamie R. Rich, Stuart D. Barnscher, Paul A. Moore

Zymeworks Inc., Vancouver, BC, Canada

ZW191 is a clinical stage differentiated FRα-targeted ADC under ongoing investigation for tolerability and efficacy in patients with advanced cancers, including ovarian, endometrial, and NSCLC (NCT06555744). ZW191 markedly improves on the FDA-approved FRα-targeted ADC mirvetuximab soravtansine in its efficacy in patient-derived xenograft tumors with both high and low level of FRα by virtue of its novel and highly effective FRα-targeted antibody and its novel ZD06519 TOPO1i payload. The by-design moderate potency of ZW191's payload confers a best-in-class nonclinical tolerability profile, with an HNSTD of 60 mg/kg in NHP, potentially enabling its clinical application in combination with multiple other clinically relevant drug modalities and in various lines of treatment. Here, we demonstrate ZW191's strong antitumor activity in a xenograft model of ovarian cancer when dosed in combination with each of the platinum-based drug carboplatin, the microtubule inhibitor paclitaxel, and the anti-angiogenic antibody bevacizumab. In multiple 3D spheroid tumor cell models in vitro, ZW191 demonstrates combination effects with poly (ADP-ribose) polymerase (PARP) inhibitor and platinum-based drugs as determined by the Bliss independence model of drug interactions. Mechanistically, ZW191's TOPO1i payload and platins both drive DNA strand breaks in tumor cells, and we show the enhanced target-dependent cytotoxic activity of these drugs in combination is associated with greater levels of the DNA damage marker gamma H2AX (γH2AX). A clinical landscape analysis demonstrates that moderate potency ADC payloads facilitate higher dosing levels in the clinic. Together with encouraging early clinical data that highlight ZW191's single agent activity and differentiated safety profile, these data reinforce its potential to achieve meaningful efficacy gains through combination with other agents.

#1708 Novel DLL3 x B7H3 bispecific ADC demonstrated superior efficacy in preclinical studies.

Sipeng Li, Chong Liu, Meijun Xiong, Yajun Sun, Zhongsheng Hu, Xinju Gao, Haibo He, Yanwen Feng, Zengyan Mu, Paul H. Song, Gang Qin

GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China

Background: Small Cell Lung Cancer (SCLC) is a highly aggressive neuroendocrine carcinoma accounting for approximately 15% of all lung cancer diagnoses. It is characterized by rapid proliferation, early metastasis, and a dismal prognosis, with a 5-year survival rate of only 3% for patients with metastatic disease. Research over the past decade has revealed significant molecular heterogeneity in SCLC, leading to a classification into four major subtypes based on distinct transcriptional signatures: there are defined by the expression of specific transcription factors—ASCL1 high (SCLC-A), NEUROD1 high (SCLC-N), and POU2F3 high (SCLC-P)—and the fourth, SCLC-I, is characterized by low expression of these three factors. Notably, the SCLC-P subtype has been associated with inferior outcomes following chemo-immunotherapy, suggesting it may represent a more treatment-resistant variant. This high heterogeneity is likely a key driver of therapeutic resistance. DLL3, an inhibitory ligand of the Notch pathway, is overexpressed in up to 85% of SCLC tumors and varies significantly across SCLC subtypes, while its expression is negligible in normal tissues. B7H3, a type I transmembrane protein belonging to the B7 immune checkpoint family, is another promising target. It is expressed at low levels in normal tissues but is highly and homogeneously overexpressed across all SCLC subtypes, as well as in other solid tumors.
Methods: To address tumor heterogeneity in SCLC and improve responses for treatment-resistant patients—particularly those with the SCLC-P subtype—we pursued a rational design of a bispecific antibody-drug conjugate (ADC) targeting both DLL3 and B7H3. We engineered a diverse library of bispecific antibodies with varying sequence combinations and structural formats, which were then conjugated to diverse linker-topoisomerase 1 inhibitor (Top1i) payloads. Through a systematic screening campaign involving comprehensive in vitro and in vivo evaluations, we successfully identified a superior lead bispecific ADC candidate.
Results: The lead bispecific antibody exhibited potent cellular internalization in vitro, while the bispecific ADC demonstrated concentration-dependent and target-specific cytotoxicity in antigen-positive cells. In vivo, across multiple patient-derived xenograft (PDX) models, the lead bispecific ADC exhibited robust and sustained antitumor activity, outperforming both clinical-stage monospecific ADC benchmarks and its parental monospecific ADC. Notably, in refractory SCLC-P PDX models, it maintained superior efficacy compared to clinical monospecific ADC benchmarks. These results support a synergistic mechanism of action conferred by the bispecific ADC.
Conclusions: In conclusion, the next-generation bispecific ADC holds great potential to overcome SCLC heterogeneity and improve outcomes for treatment-resistant patients.

#1709 BCG042: A promising anti-LILRB4 antibody with ADCC enhancement demonstrates superior efficacy in preclinical models of monocytic AML.

Jade Hsu, Peiran Li, Yanan Guo

Biocytogen, Waltham, MA, MA

Monocytic acute myeloid leukemia (AML; FAB M4/M5) is an aggressive disease characterized by limited response to standard therapies, including chemotherapy and hypomethylating agent (HMA) plus venetoclax combinations. LILRB4, a validated immunosuppressive receptor highly expressed on monocytic AML blasts, drives immune evasion and tissue infiltration via APOE engagement and SHP-1/2 signaling. To overcome the limitations of current therapy, we engineered BCG042, a fully human anti-LILRB4 IgG1 antibody with an Fc mutant designed to enhance effector function and targeted clearance of AML cells. BCG042 binds to human LILRB4 with nanomolar affinity, demonstrates cross-reactivity to the cynomolgus ortholog, and exhibits high specificity within the LILRB family. Epitope binning analysis confirmed that BCG042 shares the same epitope as IO-202. BCG042 demonstrated strong binding to LILRB4-positive AML cell lines (THP-1, MV-4-11), and critically, exhibited superior inhibition of APOE-LILRB4 signaling compared to an IO-202 analog at 1 μg/mL *in vitro*. BCG042 mediated robust antibody-dependent cellular cytotoxicity (ADCC) against LILRB4+ AML cells, without antibody-dependent cellular phagocytosis (ADCP) or complement-dependent cytotoxicity (CDC) activity. This cytotoxicity was further amplified in an Fc-enhanced SI variant. This antibody exhibits favorable biophysical properties and developability profiles. *In vivo*, BCG042 induced significant dose-dependent tumor regression in a THP-1 xenograft model in B-NDG mice (dosed at 0.1, 0.5, and 1 mg/kg, Q3D×2), markedly outperforming an IO-202 analog. This potent antitumor effect was achieved with a favorable safety profile, evidenced by no body weight loss or signs of systemic toxicity. BCG042 uniquely combines targeted blockade of the LILRB4 immunosuppressive axis with potent Fc-engineered ADCC effect. This dual mechanism of action translates into superior antitumor efficacy and a favorable therapeutic window in preclinical models. These compelling data provide a strong rationale for the clinical development of BCG042 as a novel therapeutic for patients with relapsed/refractory monocytic AML.

#1710 ORM-1153: A novel CD123-targeting degrader antibody conjugate with proprietary GSPT1 degrading payload for the treatment of acute myeloid leukemia.

Dongki Choi[1], Adam Boutin[2], Jessica Alves[2], Sang Hyun Lee[1], Maysoun Shomali[2], Anna Skaletskaya[2], Hangyeol Jeong[1], MinSoo Kim[1], Da-Yeong Kim[1], Khuloud Takrouri[2], Qinsi Zheng[2], Nadia Cherkassky[2], Teresa Mako[2], Vineetkumar B. Patil[1], Olaf Christensen[2], YeonHee Yang[1], James Palacino[3]

[1]Orum Therapeutics, Daejeon, Korea, Republic of,[2]Orum Therapeutics, Lexington, MA,[3]Littlecastle, Lexington, MA

Acute myeloid leukemia (AML) is a devastating hematological malignancy, with limited treatment options and an overall poor prognosis. Due in part to the complex cytogenetics and clonal heterogeneity, targeted therapies have demonstrated some success in disease control, albeit with frequent relapse due to clonal selection. The only approved ADC for AML therapy is gemtuzumab ozogamicin (GO). However, its clinical utility is restricted by safety concerns. Therefore, there exists an unmet need for effective therapies for AML with superior safety and tolerability profiles as compared to standard of care treatment options. Because of its high expression on leukemic blast and stem cells compared with normal hematopoietic stem cells and progenitors, CD123 has emerged as a rational candidate for molecularly targeted therapeutic approaches in this disease. In addition, recent studies have reported that small-molecule GSPT1 degraders, such as CC-90009, exhibit potent antileukemic cytotoxicity in AML and demonstrate activity against TP53-mutant disease, one of the highest unmet needs. However, their therapeutic window may be potentially narrow. Therefore, we have developed ORM-1153, a CD123 targeting Degrader Antibody Conjugate (DAC) generated by conjugating our proprietary GSPT1 degrading payload SMol006 to the OR000559 antibody, which is characterized by significantly enhanced cellular internalization, via clinically validated β-glucuronide release linker. ORM-1153 showed robust in vitro activity in CD123+ AML cell line and AML blast. This in vitro activity is comparable to GO and ~3-log greater than venetoclax. Though the TP53 isogenic model study, TP53 null status did not affect MoA and potency of ORM-1153. Moreover, ORM-1153 showed lower cytotoxicity than Mylotarg in healthy hematopoietic progenitor lineages via colony formation assays. We evaluated ORM-1153 in vivo MV4-11 xenograft model, and treatment with ORM-1153 demonstrated superior activity than standard of care treatment option. Our results indicate that ORM-1153 may represent a viable therapeutic agent for the treatment of AML, including in patients with TP53-mutant status who face limited options and an overall poor prognosis, and warrants further investigation in clinical trials.

#1711 GS002, a novel anti-PD-L1 ADC with targeted cytotoxic delivery and immune checkpoint inhibition.

Lin Jun, An Deqiang, Song Liwei, Zhu Hongju, Yuan Qiwei, Li Jianshi, Miao Zhongyi, Gao Zhen, Zhou Fang, Wang Xiaolei, Chen Tao, Zhuang Lu, Zhou Kaiyue, Yang Bo, Si Xinjuan, Hu Wenwen, Chang Genqiong, Xu Maosen, Liu Bin, Luo Shun

Shanghai Ginspire Biologics Co., Ltd, Shanghai, China

GS002 (also designated 002mAb-GSLP003) is an investigational anti-PD-L1 antibody-drug conjugate (ADC) with a drug-to-antibody ratio (DAR) of 8. It comprises a high-affinity, Fc-silent IgG1κ antibody engineered to promote endocytosis, site-specifically conjugated via a solubility-enhanced linker to a novel topoisomerase I inhibitor payload. A key distinguishing feature of GS002 is its optimized linker-payload system, which enhances solubility and stability, and incorporates a payload that is superior to DXd, exhibiting potent bystander killing while resisting drug efflux. Preclinically, GS002 demonstrates a dual mechanism of action, combining potent PD-L1-targeted cytotoxicity with immune checkpoint blockade. In vitro, GS002 mediated enhanced endocytosis relative to two competitor ADCs and induced potent cytotoxicity in PD-L1-positive tumor cells, with minimal impact on antigen-presenting cells such as M0 macrophages and myeloid dendritic cells. In vivo, GS002 elicited sustained antitumor activity across multiple cell-derived xenograft models, including EMC-1, KARPAS-299, and H1975, matching or exceeding the efficacy of 002mAb-GGFG-DXd and two competitor ADCs. The solubility-enhanced linker-payload design of GS002 conferred favorable pharmacokinetics in rats following a single 6 mg/kg IV dose, exhibiting closely overlapping plasma concentration-time curves for total and conjugated antibody. GS002 also demonstrated high plasma stability across species, with minimal premature payload release after 21 days at 37°C. Furthermore, its developability profile was comparable to the unconjugated antibody (002mAb), showing similar hydrophobicity and thermostability as evidenced by identical HIC retention times and closely matched Tm and Tagg values. In summary, GS002 represents a highly differentiated PD-L1-targeting ADC candidate with synergistic dual mechanisms, compelling efficacy in vitro and in vivo, a favorable pharmacokinetic profile, and excellent developability properties, supporting its advancement into further IND-enabling development.

#1712 PA289: A first-in-class prodrug payload with a novel mechanism of action and favorable efficacy/safety profile.

Alicja Turska, Marc Lee, Bryony Moss, Yong Yi, Iris Britwum, Samuel Barton, Zoe Jukes, Toni Pringle, Adam Lodge, Justyna H. Mysliwy, Jutta Deckert, Robert J. Lutz

Iksuda Therapeutics Limited, Newcastle upon Tyne, United Kingdom

Background: PA289 is a novel seco-CBI based linker-payload with a differentiated protein alkylation (ProAlk) mechanism of action, killing cells via alkylation of cytosolic proteins (Wirth *et al*, 2012). It uses IKSUDA's stable, cysteine-specific PermaLink conjugation technology and glucuronide triggers to enhance tolerability. Tumor overexpressed lysosomal glucuronidase leads to selective activation after ADC uptake and limits systemic release of the active payload. PA289's unique MOA and prodrug format lead to controlled activation support improved therapeutic performance and help address the clinical challenge of ADC sequencing.
Methods: The prodrug linker-payload PA289 was conjugated using PermaLink technology to generate ADCs with a drug to antibody ratio of approximately 4. *In vitro* cell-killing and bystander activity was evaluated by CellTiter-Glo assay and impact on cell cycle was determined by propidium iodide staining. An HMGB1 ELISA was used to monitor immunogenic cell death. Induction of apoptosis was measured by Caspase-Glo® 3/7 assay. Efficacy studies were conducted in immunodeficient mice engrafted with human cancer xenografts. Toxicology studies were conducted in cynomolgus monkeys.
Results: The free payload shows potent *in vitro* activity against 248 cancer cell lines from 15 solid cancer indications (IC50 from 1-100 pM). Both the free payload and a PA289 ADC induce S-phase cell cycle arrest and apoptosis *in vitro*. The payload triggers immunogenic cell death and, unlike MMAE or deruxtecan, is a poor substrate for ABCB1 and ABCG2 drug efflux pumps. A PA289 ADC demonstrates stronger bystander cell-killing than an MMAE-ADC in co-cultures *in vitro*. Both the payload and a PA289 ADC retain activity against a trastuzumab deruxtecan-resistant cell line *in vitro*. This latter finding was confirmed in vivo, where a PA289 ADC shows durable tumor regressions in a trastuzumab deruxtecan-resistant xenograft. PA289 ADCs against multiple targets are active *in vivo* across several lung, esophageal and breast cancer xenograft models with a single dose of 0.3 mg/kg and show 10 to 20-fold greater potency than clinical benchmark ADCs with topoisomerase I inhibitor payloads. Despite this high *in vivo* potency, a PA289 ADC was well-tolerated in cynomolgus monkeys at 8 mg/kg (single dose) and 5 mg/kg repeat dose (Q3Wx2), with minimal test-article related findings.
Conclusions: PA289 is an ADC linker-payload with a unique protein alkylation mechanism and a novel glucuronide prodrug design, showing strong in vitro potency and low susceptibility to drug efflux pumps. PA289-based ADCs demonstrate superior in vivo activity compared with deruxtecan ADCs across multiple tumor models, with excellent tolerability in monkeys at doses well above those required for durable tumor regressions.

#1713 STRO-006: An Integrin beta-6-targeting ADC demonstrates favorable safety profile and potent antitumor activity in preclinical solid tumors.

Kshama A. Doshi, Stephanie Armstrong, Eunice Kim, Dan Shen, Sihong Zhou, Rhoneil Pena, Robert Yuan, Mark Armanini, Brian Vuillemenot, Xiaofan Li, Guifen Xu, Krishna Bajjuri, Miao Wen, Jeff Hanson, Cuong Tran, Amandeep Gakhal, GARRETT GROSS, Gang Yin, Werner Rubas, Genevive Hernandez, Daniel Calarese, Hans-Peter Gerber, Alice Yam

Sutro Biopharma, Inc., South San Francisco, CA

Integrin beta-6 (ITGb6) is a heterodimeric, cell-surface glycoprotein highly expressed in multiple solid tumor indications, including non-small cell lung cancer, esophageal cancer, head and neck cancers, breast and gastric cancers. Its expression has been associated with pro-tumorigenic activities including proliferation, migration, and invasion. ITGb6 has restricted expression in adult tissues, making it a highly promising target for cancer therapy using antibody drug conjugates (ADCs). STRO-006 is an investigational ADC composed of an ITGb6 targeted human IgG1 antibody conjugated to exatecan, a topoisomerase 1 inhibitor, via a b-glucuronidase-cleavable linker. The anti-ITGb6 antibody was discovered from a Fab ribosome display library using Sutro's XpressCF+® system. The drug-linker is functionalized with dibenzylcyclooctyne (DBCO) and allows rapid and selective site-specific conjugation to the azide-containing non-natural amino acid *p*-azidomethylphenylalanine (pAMF) incorporated into the antibody (Ab) sequence using XpressCF+®. This site-specific conjugation is highly efficient, resulting in a well-defined, homogeneous ADC with a drug-antibody ratio (DAR) of 8. The STRO-006 antibody binds specifically to the alpha-v beta-6 heterodimer and has high affinity to human and cynomolgus ITGb6. It demonstrates rapid and efficient internalization, ideal for an ADC mechanism of action. Importantly, the STRO-006 antibody does not compete for LAP binding and therefore does not interfere with TGFb signaling. STRO-006 is optimized for a stable pharmacokinetic profile and exhibits extended half-life of ~7 days, low clearance of ~5 mL/d/kg and maintains a stable DAR over the course of 21-days in non-human primates. In preclinical studies, STRO-006 demonstrates potent anti-tumor activity at clinically relevant dose in both PDX and xenograft models of non-small cell lung, head and neck squamous cell and pancreatic carcinomas. STRO-006 demonstrates a favorable safety and pharmacokinetic profile in non-human primates. These results suggest that STRO-006 is a promising candidate for the treatment of multiple carcinomas and supports further clinical investigation. A Phase 1, first-in-human study is planned to assess the safety and activity of STRO-006.

#1714 First-in-class CHK1 inhibitor antibody-drug conjugate overcomes limitations of current ADC payloads and provides a new option for HER2-positive and TOP1 inhibitor-resistant tumors.

Thanos D. Halazonetis[1], Giacomo G. Rossetti[2], Daniela Carraturo[3], Michalis Petropoulos[2], Camilla Trugenberger[4], Theodoros Rampias[5], Dennis Gillingham[3]

[1]Cancentus Pharma and University of Bern, Bern, Switzerland,[2]University of Bern, Bern, Switzerland,[3]University of Basel, Basel, Switzerland,[4]University of Geneva, Geneva, Switzerland,[5]Biomedical Research Foundation Academy of Athens, Athens, Greece

Background:
Current ADCs rely almost exclusively on two payload classes -TOP1 poisons and microtubule inhibitors- leading to significant toxicity, frequent dose interruptions and reductions, and limited options once resistance develops. To address these limitations, we developed a first-in-class ADC incorporating a novel payload class: a CHK1 inhibitor (CHK1i). The novel payload exploits the presence of DNA replication stress in cancer, leading to greater selectivity.
Methods:
Trastuzumab variants containing engineered cysteines were generated to enable site-specific conjugation. A proprietary cleavable linker was synthesized and conjugated to the CHK1i payload. The resulting ADC was evaluated for HER2-dependent activity in vitro and tested in vivo in a HER2-positive breast cancer xenograft model (HCC1569).
Results:
As a small molecule, the CHK1i was about 50-fold less toxic to normal cells than a TOP1 poison (deruxtecan) while maintaining comparable potency in cancer cell lines. When bound to the ADC linker, the CHK1i was not toxic to cells, in contrast to the deruxtecan-linker, which retains toxicity.
Trastuzumab with five engineered cysteines, combined with a novel cleavable linker and a CHK1i as payload, enabled enhanced ADC potency and selective killing of HER2-positive cancer cells. In vivo testing of the ADC, administered intravenously once per week for five consecutive weeks, demonstrated antitumor efficacy at 10 mg/kg in the HCC1569 xenograft model. Mice were monitored for three weeks after treatment completion, and tumor growth inhibition was still observed. No body weight loss or obvious signs of toxicity were detected.
Conclusions:
This first-in-class CHK1i ADC expands payload diversity, aims to address resistance to existing ADCs and reduce nonspecific toxicity, offering the potential for a wider therapeutic window.

#1715 JS212, a novel bispecific ADC targeting EGFR and HER3, demonstrates superior and broad antitumor activity in preclinical evaluation.

Wenli Shi[1], Ning Song[1], Qiang Fu[1], Li Ye[1], Aikun Xia[1], Mingxing Yang[1], Jiaming Wang[1], Xuan Wu[1], Yue Deng[1], Yanghua Xu[1], Xin Wang[1], Honglin He[1], Yuyuan Yan[1], **Ziyang Zhong**[2]

[1]Shanghai Ruotuo Biosciences Co., Ltd., Shanghai, China,[2]Anwita Bioscience, Inc., San Carlos, CA

Background: EGFR and HER3 are frequently co-expressed across multiple epithelial tumors. HER3 overexpression is a recognized resistance mechanism to EGFR tyrosine kinase inhibitors (TKIs) in NSCLC. The HER3-targeting antibody-drug conjugates (ADC), such as patritumab deruxtecan, has shown encouraging clinical benefit in NSCLC patients with EGFR mutations. Additionally, an EGFR and HER3 dual targeting ADC, BL-B01D1, demonstrated promising antitumor activities in patients with EGFR-mutated advanced NSCLC, confirming simultaneous targeting of EGFR and HER3 with a bispecific ADC as a promising strategy to achieve good therapeutic efficacy. We have developed JS212, a bispecific ADC targeting EGFR and HER3 with molecular design to enhance antitumor activity while maintaining a favorable safety and pharmacokinetic profile.

Methods: JS212 is composed of a Fab arm targeting EGFR, a scFv arm targeting HER3, and DNA topoisomerase I inhibitor, exatecan, linked through a cleavable linker with a homogeneous drug-to-antibody ratio (DAR) of 6. In vitro potencies were measured through cytotoxicity assays. Antitumor activities were evaluated in cell line-derived xenograft (CDX) models. Preclinical safety pharmacokinetics were assessed in cynomolgus monkeys.

Results: JS212 exhibited high-affinity binding to tumor cells expressing either or both of EGFR and HER3, resulting in efficient killing of tumor cells with a broad spectrum of EGFR and HER3 expression levels. It also demonstrated superior antitumor activities to BL-B01D1 in CDX models. In the EGFR-dominant NCI-H1975 model, JS212 demonstrated a significant tumor growth inhibition, with a TGI of 113% after the administration of a single dose of 1.9 mg/kg. In comparison, BL-B01D1 at the same molar dose, could only achieve a 75% TGI. In the HER3-dominant SW620 model, JS212 at a single dose of 1.3 mg/kg resulted in complete tumor regression in all 5 mice, whereas BL-B01D1 only suppressed tumor growth at 2.5 mg/kg, D1D8 Q3W. JS212 also had better antitumor activity than BL-B01D1 in an osimertinib-resistant HCC827 model. Additionally, JS212 induced near complete regression in either BL-B01D1 or patritumab-deruxtecan resistant SW620 model. In cynomolgus monkeys, JS212 was well tolerated with repeated doses at 30 mg/kg. It also showed favorable pharmacokinetics profiles with half-life > 3 Days.

Conclusion: JS212 is a promising EGFR and HER3 dual targeting ADC that shows superior and broad-spectrum antitumor activities and a favorable safety and pharmacokinetic profiles in preclinical evaluation, supporting its first-in-human studies. Its phase I clinical trial is ongoing, and results will be reported elsewhere.

#1716 AT06 is a bispecific antibody drug conjugate targeting DLL3 and SEZ6 with potent activity in small cell lung cancer (SCLC) models.

Bin Zou, **Bryan K. S. Yeung**, Nannan Lang

Axcynsis Therapeutics, Singapore, Singapore

Small cell lung cancer (SCLC) and other high-grade neuroendocrine neoplasms (NENs) are therapeutically challenging malignancies with limited treatment options. For patients with extensive-stage SCLC the median survival is 6 to 12 months with current treatment options making it the most aggressive type of pulmonary tumor. Delta-like ligand 3 (DLL3) and seizure-related homolog 6 (SEZ6) are selectively expressed in SCLC, neuroendocrine carcinomas, and glioblastomas with minimal expression on normal adult tissues, making them attractive targets for antibody-drug conjugates (ADC) therapy. While DLL3 and SEZ6 single-target ADCs have shown clinical benefit, tumor heterogeneity and antigen downregulation may limit their long term efficacy. Moreover, as much as 88% of all SCLC patients display DLL3 and SEZ6 co-expression making bispecific ADCs a promising approach for improving efficacy and broadening patient coverage. Our approach utilizes a 2+2 VHH format fused to a human Fc region and engineered to bind both SEZ6 and DLL3 antigens. VHH domains were optimized for improved affinity, internalization, and developability over the parental VHH and conjugated to a proprietary topoisomerase I inhibitor payload with strong bystander effect, high DAR homogeneity, and a hydrophilic enzyme-cleavable linker. In vitro cytotoxicity, internalization efficiency, and target-dependent activity were evaluated across a panel of SCLC cell lines. In vivo efficacy was assessed in xenograft tumor models with varying SEZ6 and DLL3 expression profiles. In a low DLL3/SEZ6-expression model of SCLC (NCI-H82), AT06 displayed strong and durable tumor growth inhibition (>99%) at a 1 mg/kg dose. These data reflect a promising dual-targeting bispecific ADC therapeutic with the potential to address tumor heterogeneity and resistance mechanisms across a broader range of patients.

#1717 SCR-A014, a novel bispecific ADC targeting B7H3 and DLL3 for SCLC therapy, exhibits potent anti-tumor efficacy.

Guangcun Cheng, Yayuan Fu, Jiajing Wang, Shuai Wang, Guimei Yang, Chunlei Xia, Xiaoxing Huang, Renhong Tang

Simcere Zaiming, State Key Laboratory of Neurology and Oncology Drug Development. Simcere Pharmaceutical Group, Shanghai, China

Background: Small cell lung cancer (SCLC) is a most aggressive lung neuroendocrine tumor, accounting for approximately 15% of all lung cancers. Delta-like ligand 3 (DLL3) is an inhibitory Notch ligand that is highly expressed in SCLC and other neuroendocrine tumors but minimally expressed in normal tissues. B7H3, also known as CD276, is a type I transmembrane protein belonging to the B7 family that includes immune checkpoint molecules such as PD-L1, B7-1, and B7-2. DLL3 and B7H3 are highly overexpressed in small cell lung cancer (SCLC) tumor tissues, with limited presence in normal tissues, making them attractive therapeutic targets. Both B7H3 and DLL3 target shows a high positivity rate (>80%) in SCLC patient samples. However, the expression levels of DLL3 and B7H3 are not high, most samples are at a 1+ level. Moreover, B7H3 exhibits relatively slow internalization, whereas DLL3 demonstrates rapid internalization. Based on these complementary characteristics, we propose a dual-antibody drug conjugate strategy targeting both B7H3 and DLL3. This innovative approach aims to enhance antitumor efficacy.
Methods & Results: We developed a novel B7H3 x DLL3 targeted bispecific antibody-drug conjugate (ADC) called SCR-A014, which is comprised of B7H3/DLL3 bispecific antibody conjugated with topoisomerase 1 inhibitor (CPT116). SCR-A014 specifically bind B7H3 and DLL3 with high affinity, and showed enhanced internalization and binding capacity compared to parental monoclonal antibody ADC separately in the B7H3/DLL3 co-expressing cell line. SCR-A014 induced tumor cell lysis in various tumor cell lines, and showed remarkable anti-tumor efficacy in several CDX models in a dose dependent manner. SCR-A014 exhibits significantly stronger anti-tumor activity than their parental monoclonal-ADC or clinical ADC in B7H3+DLL3+ double positive tumor cells. SCR-A014 also have very good stability and favorable developability.
Conclusion: These findings suggest that SCR-A014 is a potential first-in-class bispecific ADC and may offer a novel therapeutic strategy for SCLC cancers positive for B7H3 and DLL3.

#1718 RT023, a first-in-class CEACAM5/EGFR targeted bispecific antibody drug conjugate (ADC) in colorectal cancer (CRC).

Shuting Huang, Lulu Zhou, Jingjing Cao, Lingli Bi, Qiang Fu, Xuan Wu, Aikun Xia, Jiaming Wang, Yue Deng, Yanghua Xu, Xin Wang, Wenli Shi, Honglin He, Yuyuan Yan, Ziyang Zhong

Shanghai Ruotuo Biosciences Co., Ltd., Shanghai, China

Background: CEACAM5 and EGFR are highly expressed in several cancers, including colorectal, gastric, and lung, with greater specificity than in normal tissues. EGFR antibodies like cetuximab are standard first-line therapy for colorectal cancer (CRC) patients with wild-type KRAS, but are less effective in those with KRAS mutations, creating an unmet clinical need. ADCs targeting CEACAM5 or EGFR, such as M9140 and MRG003, are under clinical development for CRC; however, single-target ADCs have shown limited efficacy, likely due to variable antigen expression among patients. To address this, we developed RT023, a CEACAM5/EGFR bispecific ADC designed to treat patients positive for either marker, including those with KRAS mutations and those who relapse after EGFR antibody treatment.
Methods: RT023 is an ADC composed of an anti-CEACAM5/anti-EGFR bispecific antibody and a DNA topoisomerase I inhibitor, exatecan, linked through a cleavable linker, with a homogeneous drug-to-antibody ratio (DAR) of 6. In vitro potency was measured through cytotoxicity assay. Its anti-tumor activities were evaluated in cell line-derived xenograft (CDX) models. Toxicity and pharmacokinetics of RT023 were assessed in cynomolgus monkey.
Results: RT023 exhibited high affinity binding to CEACAM5 and EGFR. It had higher internalization rate than its respective parent monospecific antibodies, resulting in efficiently killing to tumor cells with a wide spectrum of CEACAM5 and EGFR expression levels. RT023 demonstrated superior tumor growth inhibition than M9140 and Cetuximab ADC in several CRC CDX models. In the EGFR-dominant HCT116 model, RT023 exhibited impressive tumor growth inhibition with a TGI of 88.5% after single dose of 0.77 mg/kg, whereas the Cetuximab ADC at the same molar dose achieved only a 58% TGI, and M9140 did not inhibit tumor growth. In the CEACAM5-dominant GP2D model, a single dose treatment of RT023 at 2.3 mg/kg resulted in 80% (4/5) complete tumor regression (CR), whereas M9140 treatment group only achieved 20% (1/5) CR. In the CEACAM5 /EGFR double-driven SW1116 model, RT023 induced tumor repression with a higher TGI than Cetuximab ADC (117% vs 105%) after two doses of 2.3 mg/kg, Q3W, and showed more durable anti-tumor effect than M9140 (64 days vs 47 days). RT023 was well tolerated in cynomolgus monkeys up to 30 mg/kg, with only minimal skin and hematological adverse effect. It also had a favorable PK profile with a half-life of approximately 120 hours. RT023 remained stable in circulation with less than 0.02% free drug release.
Conclusion: RT023, with its unique bispecific design and differentiated features in affinity, linker-payload, has shown promising potential as a first-in-class ADC candidate for CRC treatment. Preclinical discovery studies have revealed favorable efficacy and toxicity profiles, supporting advancing RT023 into first-in-human studies.

#1720 Preclinical study of BCG039, a Nectin-4×TROP2 bispecific ADC, in urothelial carcinoma and other solid tumor models.

Frank An, Liu Yang, Chengzhang Shang, Junlan Han, Yi Yang, Frank An

Biocytogen, Waltham, MA, MA

Background: Urothelial carcinoma (UC) affects over 600,000 patients worldwide annually, with the incidence rate increasing over the past decade. Metastatic urothelial carcinoma (mUC) has a poor prognosis, with the 5-year survival rate estimated to be as low as 10-15%.Nectin-4 is highly expressed in mUC. It is a clinically validated target for mUC with enfortumab vendotin (EV) and pembrolizumab combination as the newly established SOC for first-line metastatic and locally advanced UC. TROP2 is also highly expressed in UC, and sacituzumab govetecan (SG) has shown therapeutic activity in later-line mUC. Nectin-4xTROP2 bsADC aims to target these two clinically validated targets in mUC to further improve efficacy and reduce toxicity.

Method: Fully human antibodies against Nectin-4 and TROP2 were generated with Biocytogen's RenLite® transgenic mice. We selected the arms of the bispecific antibody based on their internalization activities in constructing and evaluating the bispecific antibody in a 1+1 format. The bispecific antibody was conjugated to both vcMMAE at DAR of 4 and Biocytogen's proprietary linker-payload BLD1102 at DAR of 4, respectively. BLD1102 is composed of a novel TOP1 inhibitor payload and a highly hydrophilic and enzyme-cleavable linker. The resulting ADCs were tested in CDX and PDX tumor models in mice, along with relevant benchmark ADCs for anti-tumor activity.

Results: We selected the arms based on their internalization activities, with the nectin-4 arm and the TROP2 arm showing enhanced internalization capability in the format of 1+1 bispecific antibody vs the respective monovalent parental arms, suggesting cooperative interactions of the two arms. Consistent with this *in vitro* observation, the vcMMAE conjugated bispecific ADC (bsADC) exhibited markedly increased anti-tumor activity compared with the monovalent parental ADCs in mouse CDX/PDX models. BCG039, the BLD1102-conjugated bsADC, also demonstrated tumor growth inhibition superior to benchmark anti-nectin-4 and certain benchmark anti-TROP2 ADCs. The bispecific antibody has excellent developability and is now in CMC development.

Conclusion: BCG039, a bsADC targeting Nectin-4 and TROP2, showed superior anti-tumor efficacy in mice compared to single-targeting parental ADCs and relevant benchmark ADCs. The cooperative interaction of the two arms may also help reduce the toxicity observed with single-targeting ADCs against these targets in mUC.

#1721 BCG041: A first-in-class bispecific ADC targeting B7-H3 and the proximal membrane region of MUC1 with superior antitumor activity.

Icy Niu, Peiran Li, Ying Zhu, Yanan Guo

Biocytogen, Waltham, MA, MA

BCG041 is a first-in-class fully human IgG1κ bispecific antibody-drug conjugate (ADC) targeting both B7-H3 (CD276) and the proximal membrane region of MUC1. These two tumor-associated antigens are broadly overexpressed in a wide range of epithelial malignancies and correlate with poor prognosis individually. The frequent co-expression provides a convincing rationale for dual targeting of B7-H3 and MUC1. The effectiveness of B7-H3 ADCs, such as ifinatamab deruxtecan (DS-7300), in treating small-cell lung cancer, even in patients who have received extensive prior treatment, emphasizes the significant potential of this target. On the other hand, therapies targeting MUC1 have historically encountered several obstacles: variations in glycoforms, the production of soluble MUC1 decoys due to SEA-domain cleavage, and the poor internalization of certain epitopes. These challenges can restrict the delivery of therapeutic agents and affect the therapeutic index. Targeting the proximal region of MUC1, which can decrease the shedding and enhance internalization, offers a feasible strategy to overcome these challenges. Based on this strategy, BCG041 was developed with a hydrophilic, protease-cleavable linker and a Topoisomerase-I inhibitor payload (BCPT02, DAR≈8) to enhance binding, internalization, and antitumor potency through the avidity-driven co-engagement of its two targets. The naked antibody exhibits high affinity and full cross-reactivity with both human and cynomolgus B7-H3 and MUC1. *In vitro*, BCG041 demonstrated stronger binding and faster internalization than naked DS-7300 or Gatipotuzumab analogs across multiple tumor cell lines. *In vivo*, BCG041 achieved superior antitumor efficacy compared to ADCs of naked DS-7300 or Gatipotuzumab conjugated to either BCPT02 or DXd in several patient-derived xenograft (PDX) models of lung and breast cancer. Treatment was well-tolerated, with no observed body-weight loss or overt systemic toxicity. Pharmacokinetic evaluation revealed a favorable ADC profile, and this drug demonstrates excellent developability, with CMC cell-line development currently ongoing. Together, these data position BCG041 as a highly promising next-generation bispecific ADC for B7-H3/MUC1-positive malignancies, addressing significant unmet clinical needs in breast, lung, gastro-esophageal, head-and-neck, colorectal, prostate, and ovarian cancers.

#1722 Optimal targeting of heterogeneous tumors using highly developable bispecific antibody drug conjugates based on an improved heterodimerization platform and precisely controlled conjugation of a novel payload.

Dongsop Lee[1], Younggyu Kong[1], Seong-Hyun Park[2], Hyeonseok Jin[1], Aera Lee[1], Haerynn Chung[1], Jungwoo Kim[1], Jinhoon Jung[1], Haedueok Jung[1], Yunjung Um[1], Youngjee Jeong[1], Su jin Jung[1], Haneol Kim[1], Kyoung-Ho Pyo[2], Hyungseok Choi[1], Mi-Kyung Kim[1]

[1]Dong-A ST Research Headquarter, Yongin, Korea, Republic of,[2]AbTis Co., Ltd, Yongin, Korea, Republic of

We describe the construction of bispecific antibody drug conjugates (ADCs) against multiple target combinations that are clinically correlated, and show that bispecific ADCs have the potential for improved efficacy in heterogeneous tumors compared to single targeted ADCs. Although single-target antibody drug conjugates (ADCs) are highly efficacious in numerous tumor indications, many patients still relapse following ADC therapy due to multiple factors, including inefficient tumor delivery, drug resistance, and antigen escape due to tumor heterogeneity. Thus, there is a high need for developing next generation ADCs that can overcome these limitations. Dual targeting using bispecific antibody-drug conjugates (bsADCs) is an approach that can address important issues such as insufficient targeting due to intra-tumoral expression heterogeneity. Bispecific ADCs are currently being investigated in discovery and early clinical pipelines, but challenges still remain such as selecting optimal target combinations, generating high-quality homogeneous ADC compounds, and optimizing the various ADC components to establish an effective therapeutic window. To develop bispecific antibody drug conjugates, we selected target combinations based on bioinformatics and clinical co-expression. Several in-house platforms were leveraged to create a workflow for rapidly generating bispecific ADCs: (1) an efficient heterodimerization platform for rapidly obtaining native IgG bispecific antibodies from parental monoclonal antibodies, (2) a novel hydrophilic TOPO1 inhibitor payload with an enzyme-cleavable linker, and (3) site-specific conjugation to create ADCs with precisely controlled drug-to-antibody ratio (DAR). A series of bispecific antibodies were constructed against rational combinations of co-expressed targets, and highly homogeneous DAR2 ADCs were obtained by conjugating the payload using Abclick® platform. The bsADCs thus created are less prone to CMC and developability liabilities due to their low hydrophobicity and minimal structural deviation from native IgG. Furthermore, the bispecific ADC showed improved anti-tumor activity in vitro and in vivo compared to the parental mono-targeted ADCs. Together, these results highlight a practical path toward the development of ADCs with improved efficacy in heterogeneous tumors.

#1723 Application of clinical stage GlycoConnect® technology to bispecific antibodies yields improved bispecific ADCs in comparison to randomly conjugated bsADCs.

Lianne Lelieveldt[1], Nazli Hilal Turkmen[1], Kinneret Rozales[2], Maya Wadmany[2], Anna Kaliakatsou[3], Floris van Delft[1], **Anette Sommer**[1]

[1]R&D, Synaffix - a Lonza Company, Oss, Netherlands,[2]R&D, Lonza, Haifa, Israel,[3]R&D, Lonza, Slough, United Kingdom

Several bispecific antibodies (bsAbs), with the ability to bind selectively and in a concerted fashion to two tumor associated antigens (TAAs) or in the form of a biparatopic antibody, have meanwhile been approved for cancer therapy. Another increasingly successful modality for anti-cancer therapy are antibody-drug conjugates (ADCs). Although typically based on random conjugation to cysteine or lysine residues, we have shown that the native glycan of monoclonal antibodies is a privileged site for attachment of cytotoxic payloads[1], while the therapeutic index is further enhanced by a highly polar spacer technology (HydraSpace®)[2]. Complemented by a broad choice of payloads with various modes-of-action (toxSYN® platform), these technologies have jointly been applied in multiple clinical ADC programs with the most advanced now in phase 3.

As multiple different bsAb formats have been introduced and are currently in clinical trials[3] we wanted to understand how GlycoConnect® conjugation technology would work in context of different bsAb formats to create site-specific ADCs with defined DAR. To this end, GlycoConnect® bispecific ADCs (bsADCs) were generated with high yield and purity and the successful application of the GlycoConnect® technology was demonstrated for several different bsAb formats. In addition, we will show the advantages of GlycoConnect® conjugation in generating bsADCs compared to random cysteine conjugation. GlycoConnect® bsADCs are more homogeneous than randomly conjugated bsADCs, have improved stability and provide for compelling antitumor activity in in vivo cancer xenograft models.

#1724 NEOK001 (ABL206): A first in class B7-H3xROR1 bispecific ADC demonstrated enhanced efficacy and promising tolerability.

Min Ji Ko, Junga Kwon, Suyoun Lee, Juhee Kim, Ilhwan Ryu, Junyoung Kim, JaeHyun Eom, Byeong Min Yoo, Hyeon Ji Park, Yong-Gyu Son, Donghoon Yeom, Arim Seo, Byungje Sung, Jinwon Jung, Jinhyung Ahn, Weon-Kyoo You, Sang Hoon Lee

ABL Bio, Inc., Seoul, Korea, Republic of

NEOK001 (ABL206) is a bispecific antibody-drug conjugate (ADC) designed to overcome limitations of monospecific targeting of B7-H3 and ROR1. NEOK001 is a heterodimeric 2+2 bispecific ADC with a drug-antibody ratio (DAR) of 4, conjugated with SYNtecan E™, a linker-payload containing the topoisomerase I inhibitor exatecan. B7-H3 is a tumor-associated immune regulator which has been associated with poor prognosis and is overexpressed in multiple cancers as well as several normal tissues. ROR1 is an embryonic protein which is associated with poor prognosis in multiple cancers. ROR1 is upregulated in various solid and hematological cancer types and plays a role in cancer stem cells, epithelial-mesenchymal transition, and chemoresistance, but is restricted in its expression in normal adult tissues. By selectively targeting two distinct, co-expressed tumor associated antigens with minimal co-expression in normal tissue, NEOK001 leverages this co-expression to achieve enhanced efficacy while reducing normal tissue binding/toxicity. In vivo efficacy studies were performed in B7-H3 and ROR1 expressing cancer cell line-derived xenograft (CDX) or patient-derived xenograft (PDX) models. NEOK001 at 6-10mg/kg or monospecific ADCs at the equivalent molar doses were administered. Non-human primate toxicity was evaluated with NEOK001 administered in two doses (Days 1 and 22) at 30, 60 and 90 mg/kg. NEOK001 demonstrates enhanced *in vitro* cytotoxicity compared to ROR1 and B7-H3 monospecific ADCs. *In vivo*, NEOK001 demonstrates tumor growth inhibition in 81% (n=37) and regression in 54% of PDX models across multiple tumor types including SCLC (3/4), HNSCC (3/4), ovarian (4/5), NSCLC (3/5), prostate (2/5), TNBC (2/5) and sarcoma (2/5). NEOK001 demonstrates greater efficacy compared to monospecific ADCs such as zilovertamab vedotin (ROR1 ADC) and I-Dxd (B7-H3 ADC) in SCLC, ovarian and NSCLC xenograft models ($P<0.01$-0.001). In the repeat-dose GLP tox study in non-human primates, dose dependent payload class effects were observed, including minimal to mild reversible cytopenias and minimal to moderate reversible gastrointestinal toxicity observed at 30 and 60 mg/kg with an HNSTD of 60 mg/kg. NEOK001 is a first in class B7-H3xROR1 bispecific ADC, combining the broad expression of B7-H3 with the selective expression of ROR1 to enhance tumor-specific binding while reducing toxicity to normal tissue. Therefore, NEOK001 will be a promising therapeutic drug and will enter the clinic in early 2026.

#1725 Dual modality of EpiTAC bispecific degrader ADCs combines c-MET degradation with cytotoxic payload delivery to overcome limitations of current c-MET-targeted therapies.

Lisa Marshall, Jonathan Sitrin, Kenneth Ng, Shruti Yadav, May Dayao, Hai Tran, Josef Gramespacher, Jacob Cohen, Kimberly Hoi, Zhong Huang, Noah Solomon, John Coan, Andy Goodrich, Adison McLaggan, Sarah Yan, Brian Hillier, Danica Manalo-Hebert, Lichao Zhang, Maia Vinogradova, Isaac J. Rondon, Shyra J. Gardai

EpiBiologics, San Mateo, CA

Extracellular targeted protein degradation (eTPD) is a new therapeutic modality designed to eliminate pathogenic extracellular and transmembrane proteins by leveraging proteosome and endosomal-lysosomal protein degradation pathways. EpiTACs are bispecific antibody-based eTPD therapeutics in which one arm binds to a pathogenic target protein and the other arm binds to a tissue-enriched degrading receptor to drive selective and potent protein removal. For the oncogenic receptor tyrosine kinase cMET, existing therapies such as tyrosine kinase inhibitors (TKIs) and antibody-drug conjugates (ADCs) face limitations due to acquired resistance or off-target toxicities and dependence on high target expression in the case of ADCs. We developed EpiTACs and EpiTAC-ADCs to cMET to overcome these challenges using a novel mutation-independent mechanism of action to degrade oncogenic cMET and deliver a cytotoxic payload to drive deep, durable and broad responses across cMET tumors. We screened a panel of cancer-focused degrading receptors in cMET exon 14 skipping mutant and wild type amplified tumor cell-based assays and identified potent cMET-degrading EpiTACs that drove internalization and degradation independent of form in multiple tumor cell-based assays. Degradation of mutant cMET in vitro translated to strong tumor growth suppression in vivo, but not all tumor cell models responded to degradation alone. We developed EpiTAC-ADCs to solve for tumors that express cMET but do not rely exclusively on its oncogenic signaling. EpiTAC-ADCs demonstrated robust anti-tumor activity in vitro and in vivo xenograft tumor models, including cMET responsive and non-responsive models. Combining protein degradation with cytotoxic payload delivery induced strong anti-tumor activity against models with low cMET, where standard ADCs are ineffective. The dual mechanism of EpiTAC-ADCs also demonstrates robust activity at lower drug-antibody ratio (DAR), independent of cMET expression levels or oncogenic signaling dependence. EpiTAC-ADCs represent a novel class of eTPD therapeutics that can effectively degrade oncogenic receptors including cMET independent of mutation and form, while delivering a potent cytotoxic payload. This approach has the potential to address oncogenic driver and resistance mechanisms broadly across cMET-driven tumors. In addition to targeting cMET-high tumors, EpiTAC-ADCs have the potential to target low and medium cMET tumors in patients whose needs are not addressed by standard of care therapeutics including ADCs.

#1726 NEOK002 (ABL209): Redesigning an EGFRxMUC1 bispecific TOP1i ADC with promising anti-tumor activity and enhanced therapeutic window.

Bora Lee, Hyeon Ji Park, Byeong Min Yoo, Hangil Kim, Junyoung Kim, Arim Seo, Youngeun Hong, Donghoon Yeom, Yong-Gyu Son, Jaehyun Eom, Byungje Sung, Jinhyung Ahn, Jinwon Jung, Weon-Kyoo You, Sang Hoon Lee

ABL Bio Inc., Seoul, Korea, Republic of

NEOK002 (ABL209) is a bispecific antibody-drug conjugate (ADC) designed to enhance the impact of dual targeting of Epidermal Growth Factor Receptor (EGFR) and Mucin-1 (MUC1). NEOK002 is a heterodimeric 1+1 bispecific ADC with a drug-antibody ratio (DAR) of 4, conjugated with SYNtecan E^{TM}, a linker-payload containing the topoisomerase I inhibitor exatecan. EGFR is a key oncogenic driver in multiple tumor types, however, clinical targeting of EGFR is limited by dose-dependent skin toxicity. MUC1 is a well-established tumor-associated antigen characterized by aberrant glycosylation and overexpression, but expression can be heterogeneous and the MUC1 extracellular domain is shed from the tumor, limiting monospecific targeting of MUC1. NEOK002, a dual targeting ADC, was designed to reduce EGFR affinity to minimize interference with EGFR signaling and potential toxicity while targeting the SEA domain of membrane-bound MUC1, avoiding binding to the shed, circulating form. Internalization was assessed with the Incucyte system, and *in vitro* cytotoxicity by WST-8 assay. We have selected 36 patient-derived xenograft (PDX) models across six indications, based on their expression of EGFR and MUC1 and tested efficacy of NEOK002. The *in vivo* potency of NEOK002 was also assessed on CFPAC-1, NCI-H1373, and an osimertinib-resistant PDX model. Non-human primate multi-dose GLP toxicity studies were carried out at 20, 40, and 60 mg/kg with dosing on Day 1 and Day 22 with four weeks recovery. NEOK002 demonstrated enhanced cell binding and internalization compared to monospecific EGFR or MUC1 ADC. NEOK002 did not inhibit proliferation of human epidermal keratinocytes *in vitro*, unlike cetuximab-based ADC molecules. *In vivo*, NEOK002 resulted in complete regressions with single doses as low as 1.5 mg/kg in a CFPAC-1 pancreatic CDX model. In a PDX screening study, NEOK002 caused tumor growth inhibition in all 36-tested models and induced tumor regressions in 75% of PDXs across lung, head and neck, esophageal, pancreatic, colorectal, and bladder tumors, and showed strong efficacy in 6 of 9 KRAS-mutant models. Co-treatment of the KRAS-mutant NCI-H1373 model with the KRAS G12C inhibitor sotorasib demonstrated rapid and prolonged tumor regression, which was sustained up to Day 57. In non-human primates, anticipated, reversible gastrointestinal toxicity, cytopenias, and skin erythema/hyperpigmentation were observed in a dose-dependent manner. The HNSTD of NEOK002 in cynomolgus monkeys was established at 40 mg/kg, which is associated with a free exatecan C_{max} of <3 ng/mL. NEOK002 is a potential best-in-class bispecific EGFRxMUC1 ADC effectively leveraging the benefits of co-targeting these antigens yielding enhanced antitumor activity across a wide range of tumors, and reducing the liabilities through attenuated EGFR-related toxicity and reduced impact of binding to shed MUC1.

#1727 Dual targeting of HER2 and AXL by an eKiH-engineered bispecific ADC to overcome resistance in solid tumors.

Kyoung-Ho Pyo[1], Seong-Hyun Park[1], Dongsop Lee[2], Haneol Kim[2], Younggyu Kong[2], Younggeun Lee[1], Hojin Yeom[1], Sowon Aum[1], Sun Hee Park[1], Huijo Oh[1], Cheyeon Kim[1], Hyeonseok Jin[2], Aera Lee[2], Hojeong Hong[2], Ju Hwan Kim[1], Hyungseok Choi[2], Mi-Kyung Kim[2], Taedong Han[1]

[1]AbTis Co., Ltd, Yongin, Korea, Republic of,[2]Dong-A ST Research Headquarter, Yongin, Korea, Republic of

Background: AXL signaling is a key mediator of drug resistance, metastasis, and immune modulation in solid tumors. Its activation drives epithelial-mesenchymal transition (EMT) and promotes tumor aggressiveness, underscoring its role in therapeutic resistance. HER2, a clinically validated ADC target, is similarly associated with oncogenic signaling and metastatic progression. Dual targeting of HER2 and AXL offers a rational approach to suppress complementary resistance pathways and overcome tumor heterogeneity, particularly in patients refractory to standard therapies. We therefore developed a HER2×AXL bispecific ADC using Dong-A ST BsAb platform with an enhanced knob-into-hole (eKiH) interface to improve heavy-chain pairing fidelity and bispecific assembly.
Methods: Lead HER2 and AXL antibodies were selected for high affinity and improved internalization; the AXL lead outperformed benchmark anti-AXL antibodies in binding and internalization assays. Bispecifics were assembled using Dong-A ST BsAb platform and site-selectively conjugated to monomethyl auristatin E (MMAE), exatecan (a topoisomerase-I inhibitor), or dual-payload configurations. Single-cell RNA-seq (scRNA-seq) datasets from lung, breast, and gastric cancers were analyzed to profile HER2 heterogeneity and AXL-associated epithelial-mesenchymal transition (EMT) signatures. Multiplex immunohistochemistry (mIHC) on tissue microarrays quantified spatial co-expression and heterogeneity. Combination potential with immune checkpoint inhibitors (ICIs) was explored via immune-correlative analyses and ongoing co-treatment studies.
Results: scRNA-seq revealed pronounced intra- and inter-tumoral HER2 heterogeneity across indications, while AXL-high tumors exhibited elevated EMT-related markers. mIHC confirmed mosaic/cluster-type co-expression and heterogeneous distribution of HER2 and AXL across multiple tumor types. HER2xAXL BsAb retained high-affinity binding to both targets and efficient internalization, with preliminary in-vitro cytotoxicity observed in HER2-high, AXL-high, and co-expressing models using MMAE, exatecan, and dual-payload ADCs. Immune-correlative data support the mechanistic rationale for ICI combinations, and formal co-treatment evaluations are in progress.
Conclusions: HER2xAXL is a rationally engineered HER2×AXL bispecific ADC designed to mitigate target heterogeneity and therapy resistance. These preclinical data support investigation in HER2-expressing solid tumors—including lung, breast, and gastric cancers—particularly in patients who have failed standard first-/second-line regimens.

#1728 Overcoming target heterogeneity in gastric cancer with an eKiH-engineered CLDN18.2×HER2 bispecific ADC.

Kyoung-Ho Pyo[1], Seong-Hyun Park[1], Dongsop Lee[2], Haneol Kim[2], Younggyu Kong[2], Younggeun Lee[1], Hojin Yeom[1], Sowon Aum[1], Sun Hee Park[1], Huijo Oh[1], Cheyeon Kim[1], Hyeonseok Jin[2], Aera Lee[2], Hojeong Hong[2], Ju Hwan Kim[1], Hyungseok Choi[2], Mi-Kyung Kim[2], Taedong Han[1]

[1]AbTis Co., Ltd, Yongin, Korea, Republic of,[2]Dong-A ST Research Headquarter, Yongin, Korea, Republic of

Background: Target heterogeneity, mosaic and cluster expression of CLDN18.2 and HER2 is common in gastric cancer (GC) and undermines the efficacy of single-antigen therapies. We previously developed DA3501 (AT-211), a CLDN18.2-targeting ADC currently advancing toward Phase 1 evaluation. The DA3501 antibody clone demonstrates enhanced affinity and internalization compared with zolbetuximab. To more comprehensively address heterogeneous tumors, we engineered a CLDN18.2×HER2 bispecific ADC built on Dong-A ST BsAb platform incorporating an enhanced knob-into-hole (eKiH) interface to improve heavy-chain pairing fidelity and bispecific assembly.
Methods: Antibody discovery and optimization yielded lead clones for CLDN18.2 and HER2 with improved binding and internalization. Bispecifics were assembled using Dong-A ST BsAb platform. Conjugation to monomethyl auristatin E (MMAE), exatecan (a topoisomerase-I inhibitor), or dual-payload configurations was performed using site-selective chemistry. Target prevalence and co-expression were evaluated in human GC using single-cell RNA sequencing (scRNA-seq) of tumor specimens and multiplex immunohistochemistry (mIHC) on tissue microarrays (TMAs). Immune correlates were analyzed to assess combinatorial potential with immune checkpoint inhibitors (ICIs).
Results: scRNA-seq revealed CLDN18.2 and HER2 expression in mutually exclusive as well as co-expressing tumor cell subsets, corroborated by mIHC showing intra-tumoral mosaic and clustered patterns. The DA3501 anti-CLDN18.2 clone exhibited superior binding kinetics and internalization versus zolbetuximab. ATS1002 retained high-affinity binding to both targets and demonstrated efficient internalization in dual-positive and single-positive (CLDN18.2 or HER2) models, supporting a “catch-all” approach for heterogeneous lesions. ADCs conjugated with MMAE, exatecan, or dual payloads showed potent in vitro cytotoxicity across CLDN18.2-high, HER2-high, and co-expressing GC lines. Immune-correlative analyses indicated potential synergy with ICIs in tumors exhibiting activated T-cell and myeloid signatures.
Conclusions: This BsAb is a rationally engineered CLDN18.2×HER2 bispecific ADC designed to overcome target heterogeneity in GC. Together with the DA3501 program, it broadens therapeutic coverage of CLDN18.2/HER2-expressing tumors and combination-strategy studies, including ICI co-therapy.

#1729 OBI-904, a next-generation nectin-4-targeting exatecan ADC, demonstrates enhanced cytotoxicity and overcomes enfortumab vedotin resistance.

Yuan-Liang Wang, Chi-Huan Lu, Woan-Eng Chan, Shin-Jin Lin, Ting-Yu Chang, Hong-Syuan Lin, Wei-Jhen Huang, **Ya-Chi Chen**

OBI Pharma, Inc., Taipei, Taiwan

Nectin-4 is a validated therapeutic target for several epithelial cancers. Enfortumab vedotin (EV), the first FDA-approved Nectin-4-directed ADC, has demonstrated significant clinical benefit. However, its efficacy remains limited by multiple mechanisms, P-glycoprotein (P-gp)-mediated efflux, the emergence of EV-resistant tumor cells contribute to reduce cytotoxic activity where its short plasma half-life necessitates more frequent dosing. In addition, off-target hematological toxicities have been observed, potentially resulting from suboptimal linker stability and premature payload release in circulation. To address these limitations, we developed OBI-904, a next-generation Nectin-4-targeting ADC. OBI-904 is a homogeneous ADC and consists of a novel anti-Nectin-4 antibody (10K06) conjugated to an exatecan payload through a stable glycan-based site-specific linker platform.

The 10K06 and Enfortumab antibody epitopes were compared by sequence and structural analysis. Cell binding, internalization, and keratinocyte binding were evaluated by flow cytometry and confocal microscopy. Cross-species reactivity was tested by ELISA. Cytotoxicity was tested in Nectin-4 low 3D spheroid models, bystander activity in co-cultures of Nectin-4-positive and -negative cells, and resistance mechanisms in P-gp-overexpressing and EV-resistant cell lines.

The 10K06 antibody binds to the Nectin-4 IgV domain (amino acids 86-92) and shows good binding affinity and internalization in cell-based assays, ensuring efficient target engagement. In addition, OBI-904 shows reduced binding to keratinocytes compared with EV, suggesting a lower risk of skin toxicity. We also confirmed that 10K06 recognizes human and cynomolgus Nectin-4 but not murine Nectin-4, supporting its suitability for preclinical evaluation in non-human primates. OBI-904 exhibited superior cytotoxic potency in Nectin-4 low-expressing cell lines under 3D spheroid culture conditions, consistent with the high potency and membrane permeability of its exatecan payload. Moreover, OBI-904 mediated a robust bystander effect in co-culture systems with Nectin-4-positive and -negative cells, indicating efficient payload diffusion into neighboring tumor cells. Importantly, OBI-904 retained strong cytotoxic activity in P-gp-overexpressing and EV-resistant tumor cells.

Collectively, these findings establish OBI-904 as a potent, next-generation Nectin-4 ADC with reduced skin binding, enhanced cytotoxicity, a pronounced bystander effect, and the ability to overcome P-gp-mediated and EV-acquired resistance. These attributes position OBI-904 as a promising clinical candidate with the potential to achieve improved therapeutic outcomes in Nectin-4-expressing cancers.

#1730 Guide-effector bsADCs: Driving co-endocytosis for enhanced payload delivery.

Wei-Jhen Huang, Woan Eng Chan, Meng-Hsin Liu, Yueh Chin Wu, **Ya-Chi Chen**

OBI Pharma, Inc., Taipei, Taiwan

Bispecific antibodies (BsAbs) are engineered to simultaneously engage two distinct receptors, offering a powerful approach to enhance receptor internalization and intracellular payload delivery. By exploiting differences in endocytic capacities between receptors, dual targets can convert poorly internalizing target into efficiently internalized complexes—a mechanism particularly advantageous for bispecific antibody-drug conjugates (BsADCs).

BsAbs targeting HER2×TROP2 and cMET×HER3 were engineered, expressed in ExpiCHO cells, and purified via Protein A affinity chromatography. BsADCs were conjugated by the glycan-based site-specific platform via a cleavable linker-payload system. The drug-antibody ratio (DAR) was determined per candidate. Internalization kinetics of BsAbs and their monospecific counterparts were assessed in receptor-coexpressing tumor cell lines (HER2/TROP2^{+} and cMET/HER3^{+}) using a pH sensor dye. Upon antibody binding and internalization, the dye transitions from the neutral extracellular pH (7.4) to the acidic lysosomal environment (pH 4.5-5.5), resulting in increased fluorescence. Fluorescence signals were monitored in real time at 37 °C using a Cytation 5 imaging system.

In this study, the internalization of two BsAb pairs—HER2 × TROP2 and c-MET × HER3, was compared with their respective monospecific antibodies. Using a guide-effector mechanism, BsAbs pair a rapidly internalizing receptor (e.g., HER2 or c-MET) with a poorly internalizing one (e.g., TROP2 or HER3), leveraging the guide receptor's endocytic capacity to drive co-endocytosis and lysosomal trafficking.

HER2 × TROP2 BsADC (OBI-201) illustrates this concept: HER2 facilitates co-internalization of TROP2 (1.7-fold increase compared to the mono-ADC), enhancing lysosomal trafficking and intracellular payload delivery in tumors co-expressing both receptors, overcoming resistance seen with monospecific antibodies and improving cytotoxic efficacy. Similarly, c-MET × HER3 BsAbs exploit c-MET's rapid internalization to drive HER3 uptake (5.5-fold increase compared to the HER3 mono-Ab), inducing receptor clustering, coordinated lysosomal trafficking, and increased intracellular payload delivery, thereby enhancing antitumor activity.

These findings show that BsAbs enhance receptor internalization via co-endocytosis, using a guide-effector mechanism to improve intracellular payload delivery and therapeutic potency. This strategy offers a generalizable approach for BsADC development, enabling targeting of low-expression or non-internalizing antigens and addressing resistant or heterogeneous tumors.

#1731 Hydrophilicity-enhanced linker technology enables site-specific degrader-antibody conjugates with improved stability and enhanced activity.

Yu-Hung Chen, Wei-Chien Tang, Chi-Dian Lu, Hung-Yi Lin, Wei-Jhen Huang, Nan-Hsuan Wang, Ya-Chi Chen, Teng-Yi Huang

OBI Pharma, Inc, Taipei City, Taiwan

Proteolysis-targeting chimeras (PROTACs) have emerged as a novel modality for targeted protein degradation, enabling catalytic removal of disease-related proteins rather than transient inhibition. Despite their mechanistic advantages, most PROTACs suffer from poor drug-like properties—high molecular weight, highly hydrophobic, and with limited permeability—leading to suboptimal pharmacokinetics and formulation challenges. To overcome these limitations, the concept of degrader-antibody conjugates (DACs) has recently gained attention, leveraging antibody-mediated delivery to transport degraders selectively into target cells. DACs can reduce systemic exposure and overcome permeability barriers, thereby expanding the therapeutic utility of degraders. However, bioconjugation of PROTAC payloads remains hindered by issues such as antibody aggregation, inefficient conjugation, and constraints in achieving optimal drug-to-antibody ratios (DAR). Here, we selected a representative BET degrader as the proof-of-concept payload to evaluate the feasibility of DAC construction. Leveraging glycan site-specific technology, we achieved DAC construction with tunable DARs and robust conjugate stability. To address the intrinsic physicochemical challenges of PROTACs, proprietary linker technology was incorporated to enhance hydrophilicity and mitigate aggregation. Proprietary linker also provides high serum stability and enables precise release in the tumor site, potentially broadening the therapeutic index. This BET DAC is anticipated to be applicable to both solid and hematologic malignancies. *In vitro* studies showed that glycan site-specific DACs preserved antibody binding, maintained high stability, and facilitated efficient intracellular delivery of active degraders. Functional analyses confirmed target protein degradation with time- and dose-dependent kinetics, accompanied by strong cytotoxicity in antigen-positive models. These results establish clear proof of concept for our linker-enabled DAC platform. Through the integration of site-specific glycan conjugation and proprietary linker chemistry, this DAC platform offers a versatile and scalable solution to overcome hydrophobic degrader limitations, paving the way for next generation of targeted degradation therapeutics.

#1735 Expanding the therapeutic potential of TXNRD inhibitors for triple-negative breast cancer.

Brenna Flowers[1], Abigail Rullo[2], An Zhang[3], Iria Lloshi[1], Keacha Chang[4], Valentina Petukhova[5], Pavel A. Petukhov[5], Irida Kastrati[6]

[1]Cancer Biology, Loyola University Chicago, Chicago, IL,[2]Loyola University Chicago, Oak Park, IL,[3]Loyola University Chicago, Maywood, IL,[4]Loyola University Chicago, Chicago, IL,[5]Medicinal Chemistry and Pharmacognosy, University of Illinois at Chicago, Chicago, IL,[6]Loyola University Chicago - Health Sciences Campus, Maywood, IL

Triple negative breast cancer (TNBC) has the lowest 5-year survival of all breast cancersubtypes, and for many patients the standard of care is limited to a multiagent chemotherapyregimen. Therefore, there is a need to explore improved therapeutic targets and strategies. We havepreviously demonstrated that elevated levels of both thioredoxin reductase 1 (TXNRD1) andthioredoxin reductase 2 (TXNRD2) correlates with lower recurrence-free and overall survival inTNBC and are both relevant targets for TNBC.We have developed new non-covalent TXNRD inhibitors (TXNRD(i)s) that successfullyinhibit TXNRD1 and TXNRD2 in TNBC models as demonstrated through fluorescent biochemicalassays and qPCR of TXNRD related genes. Additionally, these TXNRD(i)s show pleiotropic anti-cancer activity against aggressive phenotypes in both *in vitro* and *in vivo* TNBC models. Treatmentwith TXNRD(i)s reduces 2D viability, mammosphere formation, collagen invasion, and primaryxenograft growth in TNBC models.Mechanistically, we have identified ribonucleotide reductase (RNR) dysfunction causedby our TXNRD(i)s. Given that RNR provides dNTPs, the building block for both DNA synthesisand repair, this led to the hypothesis that TXNRD(i)s induce DNA damage and replicative stress.Furthermore, this is aggravated by poly (ADP-ribose) polymerase (PARP) inhibition, leading toa synergistic effect in BRCA wild-type TNBC cell lines. Using COMET and fork stall assays,microscopy, and western blotting, we concluded there is evidence of replicative stress and DNAdamage induced by our TXNRD(i)s and validated the inhibitors are acting on target by using agenetic approach with inducible TXNRD1 and TXNRD2 knockdowns of our model cell line.Using our TXNRD(i)s in combination with Olaparib, we observed synergistic effects with the twoinhibitors in BRCA wild-type TNBC models. The synergy shown between our TXNRD(i)s andPARP inhibitors in BRCA wild-type TNBC cell lines expands the therapeutic potential of ourTXNRD(i)s as well as opening the possibility to an expansion of PARP inhibitors.

#1736 Synergistic anticancer activity of ciclopirox and prexasertib in non-small cell lung cancer cells.

Zhu Huang, Bing Cheng, **Shile Huang**

Biochemistry and Molecular Biology, LSU Health Sciences Center, SHREVEPORT, LA

Lung cancer is a leading cause of cancer-related deaths worldwide. Non-small cell lung cancer (NSCLC) is the most prevalent lung cancer subtype. Ciclopirox olamine (CPX), an off-patent fungicide, has been identified as a new anticancer agent. Prexasertib (PRE), a Chk1 inhibitor, is in Phase 1/2 clinical trials in various tumors. The anticancer effect of the combination of CPX with PRE on NSCLC cells is unknown. Here, we show that CPX is synergistic with PRE in inhibiting cell proliferation and inducing apoptosis of NSCLC (A549 and A427) cells. Combined treatment with CPX and PRE significantly increased the cell population in the G1/G0 and sub-G1 phases, compared to the single treatment with CPX or PRE. Concurrently, the combined treatment downregulated the protein levels of cyclins (A, B1), cyclin-dependent kinases 4, 6, 2 (CDK4, CDK6, CDK2), cell division cycle 25 B, C (Cdc25B, Cdc25C), and upregulated the protein levels of the CDK inhibitors p21 and p27, leading to decreased phosphorylation of Rb. In addition, the combined treatment increased DNA damage, evidenced by increased expression of γH2AX. In line with this, the combined treatment induced more apoptosis than either single treatment. This was associated with increased expression of DR4, DR5, Fas, and FADD and decreased expression of survivin, resulting in activation of caspase-8 and caspase-3 as well as cleavage of poly (ADP ribose) polymerase (PARP). Taken together, the results indicate that inhibition of Chk1 with PRE can enhance the anticancer activity of CPX at least partly by decreasing cell proliferation and increasing apoptosis in NSCLC cells. Our finding suggests that combination of CPX and PRE may represent a novel therapeutic approach for NSCLC.

#1737 Direct measurement of NER activity using sSTRIDE-NER.

Olga Wojcikowska, Julita Imioło, Magdalena Bartyńska, Zsombor Prucsi, Magdalena Kordon-Kiszala, **Kamil Solarczyk**

intoDNA S.A., Krakow, Poland

Nucleotide Excision Repair (NER) removes bulky DNA adducts and intrastrand crosslinks generated by ultraviolet light and chemotherapeutic agents such as cisplatin. NER capacity profoundly influences tumor response and resistance to DNA-damaging therapies. Despite its biological and clinical importance, direct and quantitative methods for measuring NER activity *in situ* are lacking. Current approaches provide indirect or bulk measurements that fail to capture the spatial and temporal dynamics of repair at the single-cell level. We developed sSTRIDE-NER, a new assay based on the STRIDE (SensiTive Recongition of Individual DNA Ends) platform, designed to visualize and measure single-strand breaks (SSBs) generated during active NER. The assay targets XPD, a core helicase of the TFIIH complex that localizes near incision sites where transient SSBs occur during the repair process. Incorporation of XPD detection into the STRIDE workflow enabled selective visualization of NER-associated DNA ends in individual nuclei. Validation experiments demonstrated high specificity: multiple negative technical controls yielded minimal background signal. Cisplatin was used as a positive control, as it induces bulky intrastrand crosslinks that robustly activate NER. Following cisplatin exposure, sSTRIDE-NER revealed a time-dependent increase in nuclear signal intensity, consistent with accumulation of NER-associated SSBs. sSTRIDE-NER provides the first single-cell, image-based method for direct measurement of NER activity through detection of SSBs proximal to XPD. This assay offers new opportunities to functionally profile NER capacity in cancer cell models and patient-derived samples. It can be applied to investigate mechanisms of resistance to platinum drugs, to evaluate DNA repair-targeting agents, and to support the development of functional biomarkers predictive of therapy response.

#1738 Alnodesertib (ART0380) in combination with irinotecan is highly efficacious in preclinical models of ATM null pancreatic cancer.

Helen M. R. Robinson, Elias Elinati, Eeson Rajendra, Paula Costales, Aurora Cerutti, Lerin Geo, Emily Graham, Kirsty Lawrence, Joana F. B. P. Neves, Marina Roy-Luzarraga, Ozgun Ozer, Vera Grinkevich, Jayesh B. Majithiya, Ian Smith, Graeme C. Smith

Artios Pharma, Cambridge, United Kingdom

Ataxia telangiectasia mutated (ATM) and Ataxia telangiectasia and Rad3-related (ATR) proteins function in concert to regulate the cellular response to both intrinsic and extrinsic factors that induce replication stress such as oncogene activation and DNA damaging agents. Data from the ongoing STELLA Phase II clinical trial (NCT04657068), exploring the safety and efficacy of the ATR inhibitor, alnodesertib (ART0380), in combination with low-dose irinotecan in an ATM negative setting has shown promising response rates of up to 50% across eight different tumor types*. This data has highlighted the effectiveness of a three pronged approach of targeting ATR via alnodesertib in a replication stress high background e.g. ATM loss, with an agent that induces further replication stress e.g. topoisomerase I inhibition. Here, mechanistic preclinical evidence is provided for this novel therapeutic approach across a range of *in vitro* and *in vivo* ATM negative pancreatic cancer models. In all of the CDX and PDX models studied, the combination of alnodesertib and irinotecan induced tumor stasis or regression. Our data highlights that PDAC may represent a highly sensitive tumor type for further development of this new treatment modality exploiting cancer cell specific replication stress

#1739 Deciphering the molecular links between DNA damage response and autophagy in cancer: Implications for chemotherapy resistance.

Kavya Ajit Pandya, Neeru Singh

School of Biotechnology and Bioengineering, Institute of Advanced Research, Gandhinagar, India

DNA damage response (DDR) guards the cells against DNA damage through coordinated detection and repair of DNA lesions. However, cancer cells rewire this mechanism to mitigate genotoxic insults induced by chemotherapy, thereby attenuating treatment efficacy. This adaptive DDR represents a critical barrier to effective cancer treatment, necessitating elucidation of molecular determinants conferring chemoresistance. Concomitantly, autophagy is activated as a cytoprotective mechanism under genotoxic stress, and emerging evidence suggests functional crosstalk between DDR and autophagy pathways in orchestrating cellular survival. Mediator of DNA damage checkpoint 1 (MDC1) is an indispensable anchor protein of double strand break repair, while Beclin-1 is canonically characterized as a cytoplasmic autophagy regulator. However, their functional convergence during genotoxic stress remains unexplored. We utilized a comprehensive approach combining computational modeling (molecular docking) with cellular assays, including co-immunoprecipitation (Co-IP), immunofluorescence microscopy, and immunoblotting in HeLa cell models with differential MDC1 expression. Here, we report an interaction between MDC1 and Beclin-1 that is dynamically enhanced following genotoxic insult. Remarkably, we demonstrate that genotoxic agents induce nuclear translocation of Beclin-1, a process that is MDC1-dependent. Further, we also show that nuclear Beclin-1 supports the accumulation and retention of various DDR effectors and hence promotes DNA repair. Additionally, we have analyzed the effect of CHK2 kinase activity on this interaction and presence of phospho-CHK2 probably supports the nuclear activity of Beclin-1 through its phosphorylation, but is dispensable for the nuclear translocation of Beclin-1. We believe that the cancer cells rely on this crosstalk to evade chemotherapy induced cytotoxicity. Given that the cytotoxic efficacy of most chemotherapeutic agents relies on inducing irreparable DNA damage, the MDC1-Beclin-1 axis may constitute a pivotal cytoprotective mechanism exploited by malignant cells to enhance DNA repair capacity and thereby circumvent therapeutic intervention. These findings establish a compelling rationale for pharmacological disruption of the MDC1-Beclin-1 interaction as a strategy to resensitize refractory tumors to DNA-damaging chemotherapy. This work offers mechanistic insights for developing next-generation combination therapies targeting the DDR-autophagy interface to surmount treatment resistance.

#1740 Quantitative helicase and polymerase assays to accelerate DNA damage repair targeted drug development.

Oganinma Okakpu, Kasia Zientara-Rytter, Veronique Baron, Michelle Kinbara, Guillermo Cardenas, Jonathan Mikolosko, Henry Zhu, Pavel Shashkin

BPS Bioscience, INC, San Diego, CA

Repairing DNA damage is essential for maintaining cellular health and genomic stability. Mammalian cells therefore rely on multiple repair mechanisms, each activating specific response pathways that recruit defined sets of proteins to initiate and execute repair. Beyond their roles in DNA maintenance, many repair proteins also regulate cell-cycle progression, stress responses, and apoptosis. Proteins involved in DNA damage repair (DDR) pathways have become important therapeutic targets in oncology. Some DDR inhibitors enhance the effectiveness of DNA-damaging cancer treatments such as chemotherapy and radiotherapy, while others induce synthetic lethality when combined with genetic alterations or inhibition of complementary DDR pathways. Among emerging targets, DNA polymerases and helicases offer considerable promise. Helicases unwind complex DNA and RNA structures during replication, recombination, and transcription, and their ATPase activity provides the energy required for this unwinding function. Inhibiting ATPase activity disrupts helicase function, leading to increased DNA damage, cell-cycle arrest, and apoptosis in cancer cells. As a result, small molecules that interfere with ATPase or helicase activities represent compelling therapeutic strategies. To support drug discovery and development efforts, we have established quantitative enzymatic assays that measure the activity of multiple DNA polymerases and helicases. These include assays that selectively assess helicase activity or ATP hydrolysis for targets such as WRN, DHX9, and BLM. Each protocol was optimized to account for dual enzymatic functions and substrate preferences. Together, these assays enable robust evaluation of candidate inhibitors, providing insights into potency, mechanism of action, and target selectivity.

#1741 Nanoparticle co-delivery of microtubule inhibitors and cisplatin overcomes DNA repair-mediated resistance in head and neck cancer.

Xin Li[1], Liubov Palchak[2], Ling Wang[1], Marina Sokolsky[2], Alexander Kabanov[2], Aimin Peng[1]

[1]UNC Adams School of Dentistry, Chapel Hill, NC,[2]UNC Eshelman School of Pharmacy, Chapel Hill, NC

Cisplatin remains a foundational chemotherapeutic for head and neck squamous cell carcinoma (HNSCC), but its effectiveness is often limited by intrinsic or acquired resistance driven largely by enhanced DNA interstrand crosslink (ICL) repair. Through a combined screen of ICL repair and cisplatin resistance modulators, our current study identifies a strong synergy between cisplatin and microtubule-targeting agents (MTAs), including taxanes and colchicine. MTAs suppress ICL repair and overcome cisplatin resistance in HNSCC cells. Mechanistically, MTAs impair the resolution of cisplatin-induced lesions, consistent with reduced recruitment of the ERCC1-XPF endonuclease required for ICL unhooking. MTAs also diminish homologous recombination, accompanied by reduced DNA damage recruitment of RPA32 and RAD51. Moreover, MTAs disrupt DNA damage checkpoint activation in response to cisplatin, permitting cell cycle transit through S-phase despite persistent DNA damage. Together, these effects drive enhanced DNA damage accumulation and apoptosis in HNSCC cells treated with the cisplatin-MTA combination. To further harness this synergy for therapeutic benefit, we employ poly(2-oxazoline)-based micelles to co-encapsulate paclitaxel and a hydrophobic cisplatin prodrug with two aliphatic hexane chains. This nanoformulation is developed to improve drug solubility and release profiles, resulting in optimized pharmacokinetics and enhanced tumor delivery and retention. Indeed, in a syngeneic HNSCC model, nanoparticle co-delivery of paclitaxel and cisplatin prodrug produced markedly superior antitumor efficacy compared to the free drug combination. Collectively, our findings define a mechanism-guided, nanoparticle-enabled therapeutic approach for sensitizing HNSCC to platinum-based chemotherapy through selective disruption of DNA damage responses.

#1743 A novel brain-penetrant dual ATR-mTOR inhibitor for PTEN-deficient cancers.

Sarah Truong[1], Beibei Zhai[1], Louise Ramos[1], Mona Marzban[1], Fariba Ghaidi[1], Marshall Drew-Brook[2], Peter Guzzo[2], Ahmad Issa[2], Mehran Khodabandeh[2], Sara Omar[2], Jason Rolfe[2], Seyed A. Saberali[2], Kally Singh[3], John Langlands[3], Dennis Brown[3], Jeffrey Bacha[3], Mads Daugaard[4]

[1]Vancouver Prostate Centre, Vancouver, BC, Canada,[2]Variational AI, Vancouver, BC, Canada,[3]Rakovina Therapeutics Inc., Vancouver, BC, Canada,[4]University of British Columbia, Vancouver, BC, Canada

Ataxia telangiectasia and Rad3-related protein serine/threonine kinase (ATR), a master regulator of DNA damage repair, maintains genomic stability in cancer cells and allows cancer cells to survive with high replication stress. Inhibition of ATR thus causes genomic instability, leading to mitotic catastrophe and apoptosis. ATR inhibitors (ATRi) have been found to be particularly effective against cells harboring PTEN deficiencies due to synthetic lethality. PTEN regulates the cell cycle and interacts with key proteins like p53 and Chk1, and PTEN deficient cells show increased genomic instability due to compromised DNA repair. Inhibition of ATR in PTEN-deficient cells therefore leads to accumulation of DNA damage and cell death. PTEN loss/mutation also leads to activation of mTOR through activation of PDK1 and AKT, contributing to cell survival and growth. Therefore, simultaneous inhibition of ATR and mTOR seems rational in the context of PTEN-deficient tumor cells. PTEN deficiency can be found in up to 40% of gliomas and 63% of breast cancers, which often metastasize to the brain. Since combination treatments can be clinically difficult due to overlapping toxicities and differing pharmacokinetics, we sought to develop a CNS-penetrating dual inhibitor of ATR and mTOR for the treatment of PTEN-deficient cancers. A generative artificial intelligence platform called Enki™ was used to identify *de novo* molecules with optimized properties for CNS penetrance and specificity for ATR and mTOR. Enki uses a latent diffusion model to optimize many properties simultaneously within the search space, including maximal potency against the primary target, selectivity, ADMET, and physicochemical properties. The most promising molecules were synthesized and tested, and data on potency, selectivity, ADME and *in vivo* efficacy will be presented. Enki™ has enabled deep exploration of chemical space and rapid generation of *de novo* molecules, accelerating the drug discovery process and allowing discovery and development of CNS-penetrating dual ATR and mTOR inhibitors.

#1744 CRISPR screening identifies SMARCAL1 and MRN as modulators of WRN dependency in MSI-H colorectal cancer.

Tiantian Ma, Jibo Wu, Siting Li, **Junjie Chen**

UT MD Anderson Cancer Center, Houston, TX

Microsatellite instability-high (MSI-H) colorectal cancers (CRCs) rely on the Werner syndrome helicase (WRN) to resolve cruciform DNA structures that arise from expanded TA-dinucleotide repeats. Pharmacologic inhibition of WRN with the selective small molecule HRO761 recapitulates WRN loss, causing replication stress and double-strand breaks (DSBs). However, mechanisms modulating WRN dependency remain incompletely understood.

To systematically identify genetic determinants of WRN inhibitor sensitivity, we performed genome-wide CRISPR/Cas9 knockout screens in MSI-H colorectal cancer cell lines treated with or without HRO761. Top candidates were validated using individual gene knockouts, RAD50 degron (dTAG) knock-in systems, and biochemical and imaging assays for DNA damage and replication stress. SMARCAL1 emerged as the strongest resistance hit, and its depletion conferred a 3-5-fold reduction in HRO761 sensitivity and attenuated γH2AX induction. SMARCAL1 likely antagonizes WRN helicase activity and promotes cruciform DNA stabilization via its annealing helicase function. In contrast, loss of structure-specific nucleases MUS81 or ERCC1-XPF did not affect HRO761 response. Instead, acute degradation of RAD50 disrupted the MRE11/RAD50/NBS1 (MRN) complex and conferred ~10-fold resistance to WRN inhibition, accompanied by reduced DSB signaling. ATM, recruited by the MRN complex, also mediated WRN inhibitor sensitivity, as ATM knockout similarly induced resistance.

Our results identify SMARCAL1 and the MRN-ATM axis as critical regulators of WRN dependency in MSI-H CRC. These findings redefine the mechanism of WRN synthetic lethality and provide a framework for predicting and overcoming resistance to emerging WRN-targeted therapies.

#1746 Dual inhibition of TREX1 and polymerase theta uncovers a synergistic DNA repair vulnerability in BRCA-deficient tumors.

Roger Shen, Daniel S Higginson

Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Alternative End Joining (Alt-EJ) becomes a key DNA double-strand break (DSB) repair mechanism in tumors with homologous recombination (HR) deficiencies, including BRCA1/2-mutant cancers. Because these tumors depend heavily on POLQ-mediated repair, we sought to identify additional druggable regulators of Alt-EJ that could be leveraged for combination therapy. We used CRISPR-based perturbations, three Alt-EJ reporter systems, and DSB repair pathway analyses in HR-proficient and HR-deficient models. TREX1 subcellular localization after DNA damage was assessed using confocal microscopy and fractionation. To evaluate therapeutic potential, we tested a TREX1 inhibitor alone and in combination with the POLQ inhibitor ART558. Our results reveal TREX1 as a potent suppressor of Alt-EJ and a complementary regulator to POLQ. TREX1 loss markedly increased Alt-EJ frequency, enhanced POLQ-dependent repair, and shifted pathway choice toward more mutagenic mechanisms. Following DNA damage in mitosis, TREX1 translocated from the cytosol into the nucleus, indicating a direct role in DSB repair engagement. Pharmacologic TREX1 inhibition reduced Alt-EJ activity, and co-inhibition of TREX1 and POLQ produced strong synergy, leading to substantial suppression of Alt-EJ and significant loss of viability in BRCA2-deficient cells. Genetic co-depletion of TREX1 and POLQ similarly enhanced sensitivity to ionizing radiation, demonstrating that dual targeting amplifies therapeutic impact across modalities. These findings identify TREX1 as a druggable modulator of DSB repair and establish a mechanistically informed combination strategy in which TREX1 and POLQ inhibitors cooperatively exploit the repair dependence of HR-deficient tumors. Dual inhibition may represent a rational therapeutic approach for BRCA-deficient cancers that rely on Alt-EJ for survival.

#1747 A combination of PG3 and PARP inhibitors exhibits antitumor effects in both BRCA1-mutated and BRCA1-wild-type TNBC.

Xiaobing Tian, Wafik S. El-Deiry

Brown University Warren Alpert Medical School, Providence, RI

DNA double-strand break (DSB) repair can be mediated by non-homologous end joining (NHEJ) and homologous recombination (HR). Homologous recombination repair (HRR) is important because it accurately repairs DNA DSBs using a sister chromatid as a template, which is crucial for maintaining genome stability and preventing mutations. Deficiency in HRR makes cancer cells sensitive to DNA damage drugs. BRCA1/2 and RAD51 proteins play very important roles in HRR. PARP is a key enzyme in the repair of DNA single-strand breaks (SSB). Unrepaired SSBs will convert to DSBs in cells. Therefore, BRCA1/2 -mutated cancer cells are sensitive to PARP inhibitors.

However, PARP inhibitor resistance develops quickly, mainly through mechanisms that restore homologous recombination repair. This can happen through secondary mutations that restore function in genes of BRCA1 or BRCA2, and overexpression of RAD51. RAD51 overexpression is reported in many cancers, such as breast, prostate, and glioblastoma, and has been involved in chemotherapy resistance. Inhibition of RAD51 creates an HR-deficient status, which can sensitize cancer cells to PARP inhibitor treatments. It has been reported that ISR (integrated stress response) leads to downregulation of RAD51. We reported before that PG3 treatment induced potent ISR. Hence, we hypothesized that PG3 can sensitize PRAP-resistant tumor cells (both BRCA1-mutant and wild-type) to PARP inhibitors by downregulating RAD51.

The combination treatments of PG3 and Olaparib/Talazoparib showed synergistic inhibitory effects on triple-negative breast cancer cells, BRCA1-mutated SUM149 and MD-MB-436, and BRCA1-wildtype MD-MB-231 and MD-MB-468. Western blots showed that two BRCA1-mutated cell lines, SUM149 and MD-MB436, express very low levels of BRCA1 protein compared to wild-type cell lines MD-MB231and MD-MB468. On the other hand, SUM149 and MD-MB436 show much higher RAD51 expression than MD-MB231 and MD-MB468. PG3 downregulates RAD51 in both SUM149 and MD-MB231 cells, but not in MD-MB436 and MD-MB468 cells. Transcriptional factors c-Myc, E2F1, and FoxM1 regulate RAD51 gene expression. We found that PG3 induced downregulation of c-Myc, E2F1, and FoxM1 in both SUM149 and MB231 cells, but not in MB436 and MB468 cells. That is consistent with previous publications. PG3 also downregulates wild-type BRCA1 in MD-MB231 cells but not in MD-MB468 cells. We found that olaparib treatment induced upregulation of RAD51 in SUM149 cells and upregulation of both BRCA1 and RAD51 in MD-MB231 cells. PG3 blocked the olaparib-induced upregulation of RAD51 in SUM149cells, and the upregulation of BRCA1 and RAD51 in MD-MB231 cells. The combined treatment induced more DNA damage than olaparib or PG3 alone in SUM149 and MB231 cells, as indicated by increased γH2AX level.

#1748 FORX-428: Exploiting PARG inhibition to target replication stress in cancer cells.

Frank Tadashi Zenke[1], Ulrich Lucking[1], Olivier Querolle[1], Luca Iacovino[1], Marta Malattia[1], Alessandro Potenza[1], Nicolas Bocquet[1], Serena Bologna[1], Hanna Kok[1], Anika Kuster[1], Roxanne Lourman[1], Jason Clochard[1], Irena Konstantinova[1], Thanos D. Halazonetis[2], Jens Wuerthner[1], Tarig Bashir[1]

[1]FoRx Therapeutics AG, Basel, Switzerland,[2]Department of Molecular and Cellular Biology, University of Geneva, Geneva, Switzerland

PARylation/dePARylation is essential for sensing and repairing replication-associated DNA damage. Inhibitors of the PARP enzymes catalyzing the build-up of poly(ADP-ribose) chains have become a mainstay of breast and ovarian cancer therapy over the past decade. Inhibiting PARG, the enzyme responsible for degrading poly(ADP-ribose) chains, has rapidly gained momentum as a therapeutic approach to benefit cancer patients which develop resistance to PARP inhibitor therapy. FORX-428 is a highly potent, reversible, selective, and orally bioavailable PARG inhibitor with the expected mechanism of action and exquisite efficacy in PARP inhibitor-resistant cancers. Of note, PARG inhibition demonstrated un-precedented antitumor activity in cancers with oncogene-induced replication stress suggesting therapeutic potential even outside of the label of PARP inhibitors. FORX-428 entered a Phase 1 clinical trial in July 2025. We will present the structure of FORX-428, in-depth pharmacology data as well as up-to-date results from the ongoing Phase 1 study. Collectively, these findings provide evidence supporting PARG inhibition as a novel and promising therapeutic strategy to treat PARP inhibitor-resistant and other hard-to-treat cancers.

#1749 Modeling response to alkylating chemotherapy in a syngeneic model of MGMT overexpression and MMR-deficient glioma.

Ranjini K. Sundaram[1], Deepti Bhatt[2], Ranjit S. Bindra[3], Juan Vasquez[1]

[1]Yale School of Medicine, New Haven, CT,[2]Yale University School of Medicine,[3]Yale University, New Haven, CT

Glioblastoma (GBM) is associated with dismal prognosis, having a median survival of less than 15 months. The frontline chemotherapeutic agent used in the treatment of GBM patients, temozolomide (TMZ), is limited by predictable resistance mechanisms. TMZ-induced O^6-methylguanine (O^6-MeG) lesion is repaired directly by O^6-Methylguanine Methyltransferase (MGMT). In tumor cells with loss of MGMT, the unrepaired methyl adducts result in a mismatched nucleotide base pairing. The mismatch repair (MMR) pathway recognizes the damage and promotes cell death through futile cycles of MMR. Loss of function mutations in MMR proteins are now recognized as a key mechanism of acquired TMZ resistance in gliomas, specifically in tumors with MGMT promoter methylation. MGMT serves as a prognostic marker in GBM and is found to be related to improved response to TMZ. Although alkylator therapy has shown relative efficacy in treating MGMT-methylated tumors, standard treatments are largely ineffective for GBM patients with MGMT-unmethylated tumors. For this, it is crucial to overcome intrinsic resistance to TMZ, which can be possible with the use of MGMT inhibitors such as O^6-benzylguanine (O^6-BG) and Lomeguatrib. Fluoroethylating agents, KL-50, is a recently developed agent which acts through a unique DNA-modifying mechanism involving evolution of a primary alkyl lesion to a DNA interstrand crosslink particularly in the absence of MGMT.Using CRISPR/Cas9, isogenic SB28 murine glioma cell lines with knockout of MSH6 and MLH1 were generated and MGMT overexpression models created by overexpressing FLAG-tagged MGMT. We performed in vitro short-term viability and clonogenic survival assays demonstrating that cells with loss of MMR displayed resistance to TMZ while retaining sensitivity to KL-50. MGMT overexpression showed resistance to TMZ and KL-50 and this resistance was reversed when cells were treated with O^6-BG or Lomeguatrib as MGMT inhibitors. We assessed the TMZ and KL-50 efficacy in flank and intracranially implanted tumor models and observed that KL-50 extended the median survival in comparison to TMZ or vehicle control in the MLH1 KO setting. Therefore, this suggested that KL-50 forms DNA interstrand crosslinks selectively in MGMT-silenced tumor models and maintains its efficacy even in the loss of functional MMR, emphasizing its potential to fill a critical therapeutic gap in recurrent, treatment-refractory tumors.Furthermore, in MGMT+ models, Lomeguatrib given concurrently with KL-50 demonstrated a significantly increased survival benefit, indicating that KL-50 in combination with the MGMT inhibitor can be used as a potential clinical approach for GBM patients with MGMT-unmethylated tumors. Our findings suggest that KL-50 may provide a new treatment approach for TMZ-resistant gliomas and in the MGMT+ setting, combination with Lomeguatrib could be beneficial.

#1750 Building an integrated platform for drug discovery in DNA damage response.

Bruno Vaz[1], Julien Brustel[1], Marie Cargnello[1], Marie Lafitte[1], Frederique Dol-Gleizes[1], Rahul Valiya Veettil[2], Andrei Zinovyev[1], **Anne-Sophie Casagrande**[1], Francisco H. Cruzalegui[1], Stephen Durant[3]

[1]Evotec, Toulouse, France,[2]Evotec, Verona, Italy,[3]Evotec, Abingdon, United Kingdom

The DNA Damage Response (DDR) consists of a network of cellular pathways that recognize, signal, and repair different DNA lesions in coordination with other cellular activities. While DDR deregulation contributes to tumor initiation, it also confers therapeutic vulnerabilities specific to cancer cells. Currently, more than 50 chemotherapeutic drugs approved by FDA act primarily through general DNA damage mechanisms. Furthermore, the identification of synthetic lethal interactions in the last years has further paved the way for a new wave of precision drugs that target DDR. PARP inhibitors have revolutionized the treatment of patients with BRCA mutations. Similarly, WRN inhibition shows promising activity in microsatellite-unstable cancers, and ATR inhibition confers therapeutic benefit in ATM-deficient cancers. We have established an integrated platform designed to characterize and decipher the DDR defects and mechanisms associated with a specific target or pre-clinical drug candidates. Leveraging a comprehensive suite of biochemical assays, high content imaging multiplex panels that detect DNA damage and replication stress markers, GFP-based reporter assays for double strand break (DSB) repair, hematotoxicity and replication-related toxicity, and *in vivo* pharmacology DDR models for PK/PD and efficacy, we can support every stage of cancer drug discovery. Additionally, we have developed a knowledge-based DDR modelling tool to predict the impact of target depletion on the choice of DSB repair pathway and potentially identify novel synthetic lethal interactions. Using this in silico tool, we were able to recapitulate one of the mechanisms of resistance to PARP inhibition in BRCA deficient tumors. In conclusion, Evotec's comprehensive DDR toolkit enables mechanistic understanding of targets and drug candidates in the DDR network.

#1751 Deletion of the DACH1 gene tumor suppressor increases replication fork stress, epithelial mesenchymal transition and sensitivity to WEE1 kinase inhibitors in prostate cancer.

Danni Li[1], Arijit Ghosh[2], Zhiping Li[1], Kenneth Iczkowski[3], Hidetoshi Mori[4], Samiha Nasser[5], Csaba Kerepesi[5], Andras Benczur[5], Hallgeir Rui[6], Ritika Harish[1], Li Lan[7], **Xuanmao Jiao**[1], Fred Saad[8], Janne Purhonen[7], Anthony W. Ashton[9], Richard G. Pestell[1]

[1]Baruch S. Blumberg Institute, Wynnewood, PA,[2]Duke University School of Medicine, Durham, NC,[3]UC Davis Health, Sacramento, CA,[4]UC Davis, Davis, CA,[5]Hungarian Research Network, Budapest, Hungary,[6]Thomas Jefferson University, Philadelphia, PA,[7]Karolinska Institutet, Stockholm, Sweden,[8]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada,[9]Lankenau Institute for Medical Research, Wynnewood, PA

• Introduction: Patients with metastatic prostate cancer have poor survival with DNA damage repair pathway abnormalities. The cell fate determination factor DACH1 is deleted (shallow or deep deletion) in ~5-12% of PCa patients, but up to 65% of metastatic PCa. WEE1 kinase is one of the most upregulated kinases in the human prostate cancer kinome associated with metastatic progression in prostate cancer (mCRPC). We determined the potential for differential sensitivity of PCa to Wee1 Kinase inhibitors (WEE1Ki) based on DACH1 expression profiles.

• Methods: Analysis of patient gene expression, tumor histology, organoids derived from prostate epithelial cell-specific DACH1 deletion prostate onco-mice, DNA replication fork assays, tissue culture.

• Findings: DACH1 deficient (*Dach1*$^{-/-}$) cells showed enhanced cell killing by WEE1Ki, that was reversed by reintroduction of DACH1a. Increased sensitivity to WEE1Ki was shown in fibroblasts, prostate cancer cell lines and in organoids derived from human prostate cancer cell lines or the prostate epithelium of Dach1 deletion onco-mice. DACH1 deletion dramatically enhanced non replicating S phase in the presence of WEE1Ki. *Dach1*$^{-/-}$ cells showed increased replication fork stress, that was reversed by reintroduction of the DACH1a isoform. DACH1 epithelial cell deletion onco-mice, and the prostate organoids derived therefrom, was associated with the induction of epithelial mesenchymal transition (EMT) with a corresponding increase in AKT^{Ser473P}, ATR^{Thr1989p} and CHK1 ^{Ser345P}. Increased sensitivity to WEE1Ki is associated with reduced SETD2 or NSD1/KMT3B expression, and reduced RRM2, a ribonucleotide reductase subunit, thereby inducing dNTP starvation. DACH1 expression was highly correlated with SETD2, NSD1 and RRM2. Gene ontology terms associated with DACH1 DNA binding templates included nucleoside metabolic processes. Like several other tumor suppressor genes (RB, FOXO3), DACH1 restrained dNTP production. dNTP production also requires NDPK (Nucleoside Diphosphate Kinase) encoded by NME genes. Consistent with the inhibition of dNTP production, DACH1a expression in prostate cancer PC3 cells reduced NME1 and NME7 (NDPKA expression), and DACH1 was strongly inversely correlated with NME1 in human prostate cancer (N=491. P 9.9e-24).

• Conclusions: As *DACH1* deletion PCa subclass conveys specific therapeutic sensitivities, that is dependent upon the DACH1a isoform, testing for DACH1a in patient samples may be warranted.

#1752 APOBEC3B enhances PARP inhibitor response by suppressing ovarian cancer stem cells.

Maria Rivera[1], Lucy Liu[1], Chae-Eun Lim[1], Sabina Enlund[2], Haoran Zhang[1], Kaifu Yang[1], Roman Sasik[3], Kathleen Fisch[3], Frida Holm[2], Leslie A. Crews[1], Qingfei Jiang[1]

[1]UCSD Moores Cancer Center, La Jolla, CA,[2]Karolinska Institutet SE, Stockholm, Sweden,[3]University of California, San Diego, La Jolla, CA

Poly(ADP-ribose) polymerase inhibitors (PARPi) provide substantial benefit to high-grade serous ovarian cancer (HGSOC) patients with BRCA mutations or homologous recombination deficiency (HRD), yet resistance remains a major clinical challenge. Cancer stem cells (CSCs) are thought to drive recurrence and therapeutic failure, highlighting the need to define molecular determinants governing CSC biology and PARPi response. APOBEC3 (A3) cytidine deaminases, particularly A3B, represent key enzymatic mutators in cancer and are highly expressed in HGSOC. However, their roles in CSCs and therapeutic sensitivity remain poorly understood.

Using previously published scRNA-seq datasets from six HGSOC patients, including one BRCA2-mutant case, we found that A3B is the predominantly expressed A3 family member, followed by A3C and A3A. In patient-derived xenografts (PDXs) and cell lines, CSC-enriched tumorspheres consistently exhibited reduced A3B levels relative to adherent non-CSC cells, whereas other A3s showed no CSC-specific changes. This pattern mirrors observations in myeloproliferative neoplasms, where stem cell populations display reduced A3 mutational burden relative to bulk tumor cells. Functionally, A3B knockdown increased tumorsphere formation and SOX2 expression, indicating that low A3B supports a self-renewing CSC state. Notably, among three HGSOC PDX models, only OV033 readily formed tumorspheres and exhibited the highest A3B expression, suggesting that BRCA status, HRD, and other genomic features may influence both tumorsphere capacity and A3B levels.

We further demonstrate that A3B loss promotes olaparib tolerance by reducing A3B-induced replication stress in S/G2 cell line tumorspheres. Because PARPi induces ssDNA accumulation and replication stalling, A3B-high cells may experience increased DNA damage under PARPi, contributing to heightened sensitivity. This aligns with clinical data linking A3B overexpression to improved platinum responses. Together, these findings support A3B expression and activity as potential biomarkers for predicting PARPi response in HGSOC.

In conclusion, our findings position A3B as a critical molecular switch linking CSC biology to PARPi response, revealing an immediately actionable biomarker and therapeutic vulnerability in HGSOC.

#1756 Novel HER2 antibody drug conjugates with stable hydrophilic linkers.

Zhiying Zou[1], Sichang Zhou[1], Jin Chu[1], Xueping Jiang[1], Zhongliang Jiang[1], Jing Ming Dong[2], Feng Bai[2], Jing Pan[1], Yuzhong Chen[1], Can Mao[1], Qun Sun[1], Lucas Pan[3], Greg Witham[1], Xiaoyu Wang[1], Gann Xu[1], Bingsen Zhou[2], Kai Qi[1], Lin Wang[1], Ray Yin[1]

[1]Fulgent Pharma, Newark, DE,[2]Fulgent Pharma, El Monte, CA,[3]Newark Charter School, Newark, DE

Background: The success of Trastuzumab deruxtecan (T-DXd) was previously attributed to its unique cleavable linker and membrane permeable payload. However, the robust efficacy in cancers with ultralow HER2 expression demands further understanding of its anti-tumor mechanisms. In addition, the occurrence of severe adverse events and the development of drug resistance in clinical settings highlights the importance of designing new ADCs with improved pharmacokinetics (PK) and alternative payloads. Here we present the mechanistic study of a novel HER2-directed ADC with an attempt to improve drug biodistribution, therapeutic window, and sustained efficacy.
Methods: HER2-targeting ADC (FID-031) with a proprietary linker and a topoisomerase I inhibitor payload has been developed with an estimated drug to antibody ratio of 7 and evaluated by HPLC, SEC, HIC, ELISA, flow cytometry and cell viability assays in vitro. PK and tissue distribution of the ADC were evaluated in CD-1 mice and tumor bearing SCID mice. In vivo efficacy and anti-tumor mechanism were explored in CDX mouse models.
Results: FID-031 showed both HER2-dependent cytotoxicity and a bystander killing effect comparable to the control ADC (T-DXd). In various CDX models, FID-031 demonstrated significantly improved and more sustained tumor growth inhibition than T-DXd at 1-3 mg/kg dose levels. In CD-1 mice, the levels of FID-031 and total antibody exhibited a prolonged half-life in circulation. In HER2-positive tumor-bearing mice, the free payload level from FID-031 was relatively low in plasma but significantly higher in tumor tissue compared to T-DXd, correlating with its superior efficacy in animal models. Immunohistochemistry of FID-031 revealed higher antibody distribution in the tumor microenvironment and deeper penetration in tumor parenchyma compared to T-DXd control. In both HER2 high- and low-expression CDX models, cancer-associated fibroblast and tumor-associated macrophage colocalized with ADC in the tumor microenvironment, suggesting critical roles of these cells in the ADC biological metabolism. Comparable levels of free payload accumulation were observed in normal tissues (i.e., lung, liver, kidney and spleen) for both FID-031 and T-DXd. Significantly lower level of free payload was observed in intestine tissue within the FID-031 treatment group compared to the T-DXd control group. In vivo toxicology studies in NHP are in progress.
Conclusions: FID-031 is a novel HER2-targeting ADC with improved PK profile, tissue distribution, and efficacy. This study provides fresh insights on the design considerations for ADC development aimed towards improving safety and overcoming drug resistance.

#1757 Synergy of BCL-2 and MEK/HDAC inhibition in IBC and non-IBC models: Potential for a first IBC specific therapy.

Hassan Zbib[1], Habib Serhan[1], Maryam Nakhjiri[1], Rhea Raghavan[1], Tusharika Rastogi[1], Peter J. Ulintz[1], Aki Morikawa[2], Nathan Merrill[1], Sofia Merajver[1]

[1]Department of Internal Medicine, University of Michigan, Ann Arbor, MI,[2]Medical Student, University of Michigan, Ann Arbor, MI

Background: Inflammatory breast cancer (IBC) is an aggressive subtype of breast cancer characterized by rapid progression. Despite its unique clinical presentation, there are no IBC specific therapies. IBC growth is not faster than non-IBC, so evasion of apoptosis, mediated by the B-cell lymphoma 2 (BCL-2) family, is hypothesized to be a major mechanism for IBC persistence. Aberrant BCL-2 expression favors tumor survival. Although BCL-2 inhibition can restore apoptotic activity, single-agent activity remains limited by compensatory signaling. Our initial high-throughput screen indicated that certain drug classes including: HSP90, BCL-2, MEK, and HDAC inhibitors showed a trend toward greater activity in IBC compared to non-IBC models. This led us to explore rational combination strategies across our panel of IBC and non-IBC breast cancer models.
Methods: We screened eight breast cancer cell lines (3 IBC: SUM-149, SUM-190, IBC-1; and 5 non-IBC: MDA-MB-231, JIMT-1-GFP, BT-474, MUM51, HCC1143) with a library of more than 1,200 compounds to identify drug classes with increased sensitivity in IBC relative to non-IBC. This initial screen identified HSP90, BCL-2, MEK, and HDAC inhibitors as classes of interest. We then performed follow-up combination screens using Pimitespib (HSP90 inhibitor) and Navitoclax (BCL-2 inhibitor), the top hits within their respective classes, testing them against the same 1,200+ compound library to identify synergistic partners. In parallel, we rationally combined inhibitors of multiple active pathways (e.g., BCL-2 + MEK or BCL-2 + HDAC), which have shown synergy in other cancers, to evaluate additional synergistic interactions. Combination effects were assessed using the Chou-Talalay method (CI < 1 indicating synergy).
Results: Our high-throughput screen identified HSP90, BCL-2, MEK, and HDAC inhibitors as more sensitive in IBC relative to non-IBC. Secondary screens pairing Pimitespib (HSP90 inhibitor) or Navitoclax (BCL-2 inhibitor) with the same compound library identified synergistic partners. Pimitespib synergized with taxanes and PI3K/MAPK inhibitors in select lines such as MDA-231 and BT474, whereas Navitoclax consistently showed strong synergy with MEK and HDAC inhibitors in IBC models. Distinct subtype-dependent trends emerged: synergy between BCL-2 and MEK inhibition was strongest in IBC, while BCL-2 and HDAC synergy predominated in non-IBC lines.
Conclusions: This study shows for the first time a trend towards IBC-specific synergistic drug interactions. These findings suggest potential mechanistic differences in apoptotic regulation and may guide rational development of targeted combination therapies for IBC. Future studies will assess whether these *in vitro* synergy trends translate into subtype-specific therapeutic responses in vivo.

#1758 Targeted DNA damage through SSTR2: Preclinical development of a novel peptide-drug conjugate for neuroendocrine tumors.

Gianluca Fossati[1], Daniela Modena[1], Luca Menin[1], Michela Bottani[1], Andrea Stevenazzi[1], Barbara Vergani[1], Elisabetta Galbiati[1], Andrea Resovi[1], Matteo Tironi[1], Serena Cecchetti[2], Francesca Spadaro[2], Maria Carollo[2], Rosita Lupi[3], Barbara Valsasina[3], Paolo Orsini[3], Silvia Castelli[3], Italo Beria[3], Christian Steinkuhler[4]

[1]Italfarmaco S.p.A., Milan, Italy,[2]Istituto Superiore di Sanita, Rome, Italy,[3]Nerviano Medical Sciences, Nerviano, Italy,[4]Italfarmaco SpA, Milan, Italy

Targeted induction of DNA damage in tumor cells offers a promising strategy to efficiently kill cancer cells while sparing healthy tissues. Precise tumor targeting can be achieved by the exploitation of the differential expression of specific molecular targets on the surface of tumor cells. Somatostatin receptor 2 (SSTR2) has emerged as a valuable tumor-associated target, due to its high expression in gastroenteropancreatic neuroendocrine tumors (GEP-NETs). SSRT2 is not only expressed in these differentiated, slow-proliferating NET, but also in highly proliferative and metastatic neuroendocrine carcinomas, such as small cell lung cancer (SCLC). SSTR2 overexpression occurs in up to 50% of primary tumors from SCLC patients and is correlated with poor prognosis, highlighting SSTR2 as an optimal candidate for targeted therapeutic intervention in a subset of SCLC patients. To exploit this opportunity, we designed a peptide drug conjugate (PDC), named ITF3912 which combines a modified octreotide analog with a novel and potent duocarmicin via a cathepsin-cleavable linker. In preclinical studies in vitro ITF3912 demonstrated high affinity and selectivity for SSTR2, acting as an agonist with an IC_{50} of 8 nM and a selectivity index of at least 10 over SSTR3/5, with no significant binding observed for SSTR1 or SSTR4. ITF3912 induced cytotoxicity in SSTR2-expressing cells, with efficacy correlated to SSTR2 expression levels. In high level SSTR2 expressing NCI-H524 cells, ITF3912 was rapidly internalized and localized in lysosomes where enzymatic cleavage of the linker released the active toxin. Once in the nucleus, the toxin induced an S-phase replication block and a potent and lethal DNA damage as evidenced by the activation of key biomarkers such as the phosphorylation of ATM, ATR, CHK1, CHK2, RPA32 and γ-H2AX, leading to cell death with an IC50 of 4 nM. The NCI-H69 cell line that expresses lower level of SSTR2 can still be targeted by ITF3912 but with lower efficiency (60 nM). The activity on NCI-H727 cell line that expresses very low level of SSTR2 diminished as expected (400 nM). Consistent with the in vitro findings, ITF3912 showed strong antitumor efficacy in vivo. It effectively reduced the tumor growth of NCI-H524 with a survival rate of 50% after 80 days of treatment and several mice showed complete tumor remission. In contrast, ITF3912 was less effective on NCI-H727 cell line by inducing a tumor growth reduction of 30%. Collectively, these data establish ITF3912 as a potent and selective SSTR2-targeted PDC, whose efficacy in vitro and in vivo correlates with receptor expression levels. These results support the use of ITF3912 as a therapeutic option for patients with SSTR2-positive neuroendocrine tumors, addressing a significant unmet medical need. Encouraging preliminary toxicology results, further support the progression of ITF3912 toward clinical development.

#1759 Targeting LRRC15 with an aptamer-drug conjugate achieves complete tumor growth inhibition.

Kristin Thompson[1], Aaron Ball[1], Jin Yuan[1], Yuxun Wang[1], Doo Young Jung[2], Shuhao Zhu[1]

[1]Guardian Therapeutics, Lowell, MA,[2]Pinotbio, Inc, Suwon, Korea, Republic of

Antibody-drug conjugates (ADCs) have demonstrated the clinical potential of targeted payload delivery for cancer therapy. However, their large molecular size can limit tumor penetration, leaving regions of the tumor insufficiently exposed to the cytotoxic payload. To address this limitation, GRX2672 has been developed as a novel aptamer-drug conjugate (ApDC) designed to target LRRC15-expressing tumors while maintaining a small molecular size to enable deep tumor penetration. LRRC15 (leucine-rich repeat-containing protein 15) is a transmembrane member of the LRR superfamily involved in cell-cell and cell-matrix interactions. It is highly expressed in mesenchymal-derived tumors such as sarcoma, glioblastoma, and melanoma, making it an attractive target for therapeutic intervention. Aptamers are short, structured oligonucleotides that bind their targets with high affinity and specificity. Compared with monoclonal antibodies, their compact size enables superior tissue and tumor penetration. Moreover, aptamers can be engineered to neutralize oncogenic targets, deliver cytotoxic payloads, or achieve both simultaneously. Incorporating a proprietary half-life-extension moiety preserves the aptamer's small size and tumor-penetrating capability while markedly improving its pharmacokinetic properties. Here, we describe an LRRC15-targeting aptamer with high affinity and selectivity that has been conjugated to 2DAR of a novel topoisomerase I inhibitor (PBX-7016) at the 5′ end and a half-life-extending fatty acid at the 3′ end. The resulting ApDC, GRX2672, selectively kills LRRC15-positive cells in vitro and achieves complete tumor growth inhibition in vivo without observed toxicity. These findings support the potential of LRRC15-targeted ApDCs as an emerging therapeutic strategy to improve outcomes for patients with LRRC15-positive tumors.

#1760 Preclinical characterization of XB404, a masked anti-ROR1/2 antibody-drug conjugate.

Kathleen R. Gogas[1], Christine M. Janson[1], Hui Zhao[1], Fang Wang[1], Bee-Cheng Sim[1], Brian A. Mendelsohn[1], Penelope M. Drake[2], Robyn M. Barfield[2], Thomas Linz[2], Maxine Bauzon[2], Dharmaraj Samuel[2], Minjong Park[1], Inna Vainshtein[1], Jackie Cheng[1], Seema Kantak[1]

[1]Exelixis, Inc., Alameda, CA,[2]Catalent, Inc., Emeryville, CA

Background: Receptor tyrosine kinase-like orphan receptors (ROR) 1 and 2 are single-pass transmembrane proteins that are part of the ROR family that mediates Wnt signaling. ROR1 and ROR2 are aberrantly expressed in various cancers, including lung, breast, ovarian, and endometrial cancers, and their expression can be associated with poor disease outcomes. XB404, a masked anti-ROR1/2 antibody-drug conjugate (ADC) developed using the Adagene masking platform and the SMARTag® ADC platform, is designed to deliver a cytotoxic payload to ROR1/2-expressing tumors while minimizing on-target, off-tumor side effects. XB404 is composed of a tandem-cleavage topoisomerase 1 inhibitor-based linker-payload conjugated to a masked monoclonal antibody that binds to both ROR1 and ROR2 with high affinity. Here, we describe the preclinical characterization of XB404, including its in vitro cytotoxicity and internalization and in vivo efficacy in cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models.
Methods: In vitro cytotoxicity of XB404 was evaluated in ROR1- and ROR2-overexpressing cell lines using the CellTiter-Glo® luminescent cell viability assay. In vitro internalization for the unmasked XB404 antibody was assessed in ROR antigen-expressing MDA-MB-231 tumor cells using flow cytometry. A rat pharmacokinetics (PK) study at 5 mg/kg was used to assess and compare PK properties for a non-masked ROR1/2 ADC and XB404. In vivo tumor growth inhibition was evaluated in Jeko-1 and MDA-MB-231 CDX models using XB404 at 7.5 mg/kg in a QWx2 dose schedule. Tumor growth inhibition was assessed in non-small cell lung cancer (NSCLC) and triple-negative breast cancer (TNBC) PDX models using 1, 3, 6, and 10 mg/kg dose levels.
Results: Unmasked XB404 displayed potent in vitro cytotoxic activity, and unmasked XB404 antibody demonstrated internalization properties. XB404 demonstrated improved clearance and half-life compared with the non-masked ROR1/2 ADC in rats. In addition, overlapping total antibody and total ADC curves for XB404 indicated good in vivo stability. In vivo antitumor activity was observed in the Jeko-1 and MDA-MB-231 xenograft models. XB404 demonstrated dose-related tumor growth inhibition and improved survival in both NSCLC and TNBC PDX models. Tumor regression was observed in both PDX models and complete responses were observed in the TNBC PDX model.
Conclusions: XB404 demonstrated in vitro cytotoxicity and internalization, in vivo stability, and in vivo efficacy across multiple CDX and PDX models. Taken together, these preclinical results support further development of XB404. Investigational New Drug-enabling studies are ongoing.

#1761 Tissue Factor expression is associated with B7-H4-mediated immune evasion in ovarian clear cell carcinoma and with response to tisotumab vedotin in preclinical models.

Yutaro Mori, Ryo Tamura, Kotaro Takahashi, Kosuke Yoshihara

Niigata University, Niigata, Japan

Objective: Ovarian clear cell carcinoma (OCCC) characteristically overexpresses Tissue Factor (TF; *F3*), yet its biological significance and therapeutic implications remain unclear. We aimed to elucidate the impact of TF expression in OCCC and evaluate the antitumor efficacy of the anti-TF antibody-drug conjugate, tisotumab vedotin (TV), *in vitro and in vivo* models.

Methods: We performed bulk RNA sequencing (RNA-seq) of 112 clinical OCCC cases to identify transcriptomic features of *F3*-high tumors. We then applied single-nucleus RNA-seq (snRNA-seq) to three *F3*-high and three *F3*-low cases to characterize tumor biology at the single-cell level. Based on these transcriptomic results, we focused on immune-related pathways and immune-checkpoint molecules, with emphasis on *VTCN1* (B7-H4). Immunohistochemistry for TF and B7-H4 was performed on 57 OCCC specimens. Finally, we assessed TV activity in patient-derived OCCC spheroids and xenografts.

Results: *F3*-high tumors exhibited lower immune scores with upregulation of MYC and cell cycle pathways, and suppression of inflammatory and immune pathways in bulk RNA-seq. Consistently, snRNA-seq showed similar trends in cancer cells, and immune fractions were significantly reduced in *F3*-high tumors, indicating an immunologically “cold” state. Notably, the immune-checkpoint molecule *VTCN1* was highly expressed in *F3*-high tumors and positively correlated with *F3* expression. Immunohistochemistry confirmed that B7-H4 was significantly overexpressed in TF-positive tumors, showing a positive correlation between TF and B7-H4 expression.TV activity correlated with TF abundance *in vitro* and induced marked growth inhibition in *F3*-high xenografts; residual tumors showed decreased TF and B7-H4 expression.

Conclusions: TF-high OCCC shows a distinct gene expression pattern, particularly an immunologically cold subtype with B7-H4-mediated immune evasion. TV demonstrates TF-dependent activity, supporting TF as a therapeutic target, and providing rationale for TV-based monotherapy or combinations with immunotherapy in OCCC.

#1762 An avidity-driven, dual-targeting ADC with superior tumor selectivity for the treatment of solid tumors.

Steffen Runz, Paul Sauter, Sebastian Latwiel, Jennifer Volkind, Jawad Iqbal, Wilma Neumann, Helga Groetsch, Dina Osmanovic, Abdul-Habib Maag, Anja Schreiber, Christine Kohler, Tatjana Schneidt, Anna Pryszlak, Christoph Erkel, Richard J. Austin

VERAXA Biotech GmbH, Heidelberg, Germany

Background
Antibody drug conjugates (ADCs) represent one of the most promising therapeutic modalities in recent years. However, the full therapeutic potential of ADCs is hampered because many tumor antigens are also expressed in healthy tissues, causing *on-target, off-tumor* toxicities. Other toxicities are caused by *off-target* uptake of ADCs in healthy cells or by systemic payload exposure as consequence of unstable conjugation. These issues have restricted a successful implementation of highly potent payloads such as pyrrolobenzodiazepine dimers (PBD).
Method
We developed a bispecific ADC (bsADC) which requires the simultaneous binding to two tumor-associated antigens (TAAs) to mediate cytotoxic activity (AND-gate approach). Co-expression of the TAAs is only found in tumor cells. Cell killing is therefore restricted to tumor cells. Healthy cells, which express only one of the TAAs, are spared. Our lead candidate comprises a bispecific antibody linked to a PBD prodrug at a DAR of 2 via a tumor-selective glucuronide linker using our proprietary site-specific, click-based glycan conjugation platform, which minimizes *off-target* toxicity by two mechanisms: first, using a highly stable linker, the payload is not released in circulation but only inside cells expressing both targets; second, hydrophilic chemistry prevents target-independent uptake.
Results
We identified a TAA pair that is highly co-expressed in various solid tumors including TNBC and NSCLC, while co-expression in healthy tissues is limited. It therefore represents a promising target combination for the development of an AND-gated bsADC with enhanced tumor-selectivity. Our lead candidate makes use of a pronounced avidity binding due to low monovalent affinities for both targets. This translates into superior internalization as well as potent killing of tumor cell lines expressing both targets in comparison to healthy cells expressing one target, resulting in an increased therapeutic window. In co-culture assays, the bsADC induced bystander killing of target-negative cells, indicating the bsADC should be efficacious in tumors where co-expression of both targets is not 100% penetrant. In vivo, our candidate dose-dependently reduced the tumor burden in mice bearing cell line-derived xenograft (CDX) models of breast cancer. In addition, the bsADC was well-tolerated up to high dose levels in mice and showed high stability in vitro and in vivo.
Conclusion
By combining an AND-gated, dual-targeting approach with our hydrophilic, highly tumor-selective, and stable ADC conjugation platform, we have generated a bsADC with superior tumor specificity. This enables the application of a potent PBD prodrug for highly efficient anti-tumor activity. Our lead bsADC for the treatment of lung and breast cancers has entered formal preclinical development and IND-enabling studies.

#1763 BSI-737, a best-in-class B7H3xPD-L1 bi-specific ADC with dual function to eliminate tumor via selective killing and exacerbated anti-tumor immune response.

Hui-Han Hu[1], Xiaoyao Hao[1], Yue Gao[1], Hongyan Li[1], Jinyu Liu[1], Jinge Zhao[1], Yi Lu[1], Liezhou Ji[1], Zhigang Ma[1], Mingjiu Chen[1], Kedan Lin[2]

[1]Biosion Inc., Nanjing, China,[2]Biosion USA Inc., Delaware, DE

Background: B7H3 and PD-L1 are both inhibitory immune checkpoints. The dual targeting of B7H3 and PD-L1, which are prevalently co-expressed in various malignancies, may synergistically enhance anti-tumor immune response. PD-L1-directed ADCs have shown modest efficacy with no target-related safety issues. B7-H3, by comparison, is a clinically validated ADC target that tolerates high-dose exposure without target-mediated toxicity and supports added immune-checkpoint blockade. B7H3xPD-L1 bi-specific ADC may hold promise via bi-specific binding mode, cytotoxic agent-mediated immunogenic cell death, and exacerbated anti-tumor immune response.

Methods: The B7H3xPD-L1 bi-specific antibody was composed of humanized anti-PD-L1 and anti-B7H3 antibodies identified from A/J mice immunized with PD-L1-ECD-Fc and HG5042 mice immunized with B7H3-EDC-Fc, respectively. The final bi-specific construct was selected based on simultaneous binding to B7H3 and PD-L1, efficient cell internalization, and strong PD-1/PD-L1 signal blocking. The bi-specific antibody was conjugated to exatecan via a glycol-site-specific conjugation technology in a DAR of 4. The anti-tumor activity of BSI-737 was investigated in cell-derived xenograft models with various expression levels of B7H3 and PD-L1. The CMC developability as well as the stability of BSI-737 in mouse and human plasma were also assessed.

Results: BSI-737 simultaneously bound to B7H3 and PD-L1 with high affinity and showed strong PD-1/PD-L1 signal blocking activity. The binding of BSI-737 resulted in efficient antibody-induced internalization across cell lines expressing various levels of B7H3 and PD-L1. When conjugated to exatecan via a cleavable linker in DAR of 4, BSI-737 demonstrated an outstanding anti-tumor activity compared to clinical benchmarks. A single administration of BSI-737 resulted in a complete tumor regression in a CDX model expressing high level of B7H3 with a survival rate of 100% by the end of the study. A significant anti-tumor activity of BSI-737 after a single administration was also observed in a B7H3-medium expressing model. BSI-737 possessed a favorable CMC developability profile.

Conclusion: BSI-737 is a B7-H3 × PD-L1 bispecific ADC with best-in-class potential, leveraging dual targeting to enable selective tumor cell killing while amplifying anti-tumor immune responses. The current pre-clinical data highlight the potential of BSI-737 across expression levels of B7H3 and further pharmacokinetics, toxicity, and IND-enabling studies are underway.

#1764 MC003: A novel bi-epitope, dual-payload, fixed-combination chemoimmunotherapy antibody drug conjugate for the treatment of folate receptor alpha-expressing ovarian cancer.

Seah H. Lim[1], Hailiang Zheng[2], Peipei Zhong[2]

[1]Medicovestor, Inc., New York, NY,[2]Sanyou Biopharmaceuticals, Shanghai, China

Background: Folate receptor alpha (FRα) is overexpressed in approximately 80% of epithelial ovarian cancers (EOC), but with limited expression in most normal tissues. FRα is, therefore, an ideal therapeutic target for antibody drug conjugates (ADCs). In patients with platinum-resistant ovarian cancer, where treatment options are scarce and outcomes remain dismal, FRα-targeted ADCs have emerged as a promising approach. To enhance therapeutic efficacy and overcome drug resistance, we developed a novel bi-epitope, dual-payload FRα-targeted ADC, designated MC003 (ADoTope FRα ADC), and evaluated its preclinical pharmacology, efficacy, and safety profile.

Methods: A panel of fully human monoclonal antibodies specific for FRα was isolated from a human v-gene phage display library. Through biolayer interferometry (BLI), two high-affinity antibodies, Clone 65 and Clone 91, were identified to bind distinct, non-overlapping epitopes on FRα with comparable KD values. Clone 65 was conjugated to gemcitabine, a nucleoside analog, and Clone 91 to exatecan, a potent topoisomerase I inhibitor, both via enzyme-cleavable linkers. Each ADC achieved an average drug-to-antibody ratio (DAR) of approximately 8. The fixed 1:1 combination of the two ADCs constituted MC003, representing the ADoTope dual-payload format.

Results: Both Clone 65 and Clone 91, in their unconjugated forms, demonstrated robust antibody-dependent cellular cytotoxicity (ADCC) against FRα-positive SKOV3 ovarian cancer cells but lacked complement-dependent cytotoxicity (CDC). When conjugated, MC003 exhibited markedly enhanced cytotoxic potency in vitro compared to either single-payload ADC, indicating synergistic antitumor activity. In SCID mice bearing established SKOV3 xenografts, MC003 achieved superior tumor growth suppression relative to mirvetuximab soravtansine, a clinically approved FRα ADC. Histological analysis revealed increased intratumoral $CD8^+$ T-cell infiltration, dendritic cell maturation, and upregulation of MMP9, suggesting immune activation within the tumor microenvironment. Single-dose toxicology studies in Sprague Dawley rats and cynomolgus monkeys demonstrated that MC003 was well tolerated up to 20 mg/kg—approximately 6.5-fold above the pharmacologically active dose—with no evidence of bone marrow suppression, hepatotoxicity, or nephrotoxicity.

Conclusions: ADoTope enhances FRα targeting by simultaneously engaging two distinct epitopes, effectively functionally increasing the antigen density and enabling the co-delivery of mechanistically distinct cytotoxic payloads. MC003 also mediates efficient ADCC and induces immune activation. These preclinical findings support the advancement of MC003 into IND-enabling studies as the next-generation therapeutic for platinum-resistant ovarian cancer.

#1765 YL413: A novel dual-payload anti-HER2 antibody-drug conjugate demonstrating potent preclinical activity.

Hanwen Deng, Tao Wang, **Wei Lian**, Tingting Mao, Qing Zong, Chun Deng, Bingsong Xie, Tongtong Xue, Jiaqiang Cai

MediLink Therapeutics (Suzhou) Co., Ltd., Suzhou, China

Antibody Drug Conjugates (ADC) have achieved great success as anti-cancer therapies, with 21 ADC drugs approved in the global market. Despite the initial response to ADC treatment, drug resistance and tumor relapse inevitably happen, driven by high heterogeneity in advanced tumors. Overcoming these resistance mechanisms is a critical challenge to next-generation ADC development for cancer therapy. To address these challenges, we developed YL413, a novel anti-HER2 ADC with two payloads of different MOAs: a topoisomerase 1 inhibitor and a microtubulin inhibitor. This dual-payload strategy is designed to mitigate resistance associated with single-agent therapies. YL413 was engineered with an appropriate drug-to-antibody ratio (topoisomerase I inhibitor to microtubule inhibitor) to optimize the therapeutic window. Trastuzumab, topoisomerase I inhibitors, and microtubule inhibitors were expected to demonstrate anti-tumor activity in clinical trials. In vitro, YL413 demonstrated comparable binding and internalization in the HER2+ cell line to Trastuzumab. YL413 demonstrated better cytotoxicity than Mon-payload ADCs against tumor cells in vitro. In Vivo, the dual-payload ADC exhibited superior efficacy in CDX models and the Ehertu-resistance models. In summary, we developed HER2 dual-payload ADCs to address Topo1 inhibitor-induced tumor resistance. The dual-payload HER2 ADC exhibited strong anti-tumor activity in vitro and in vivo, indicating potential to overcome Enhertu® resistance. YL413 retains Topo1 inhibitor efficacy, supplemented by a microtubule inhibitor, with possible use in earlier treatment lines.

#1766 Dual EGFR and Bcl-2 inhibition overcomes resistance in sinonasal squamous cell carcinoma.

Rhea Raghavan[1], Athena Apfel[1], Habib Serhan[1], Angel Qin[1], Chia-Jen Liu[2], Maryam Nakhjiri[1], Sofia D. Merajver[1], Aaron Udager[2], Nathan Merrill[1]

[1]Department of Internal Medicine, University of Michigan, Ann Arbor, MI,[2]Department of Pathology, University of Michigan, Ann Arbor, MI

Background: Sinonasal cancers are rare head and neck malignancies. Although outcomes for other head and neck cancers have improved, those for sinonasal cancers remain stable, with 5-year overall survival at 55%. This study focuses on sinonasal squamous cell carcinoma (SNSCC), which develops in the mucosal epithelium and accounts for nearly 61% of sinonasal malignancies. A strong association exists between inverted sinonasal papilloma (ISP) and the development of SNSCC, with approximately 50% of cases progressing to malignancy that harbors epidermal growth factor receptor (EGFR) exon 20 mutations. These EGFR-mutated SNSCCs have a significantly poorer prognosis than other sinonasal tumors, underscoring the need for more effective therapies.
Methods: We sought to identify therapeutic partners for EGFR inhibitors that could enhance the effectiveness of EGFR blockade. We focused on pairing pathways orthogonal to EGFR activation, such as apoptosis inhibition. To identify synergistic drug pairings with optimal activity, we screened a library of >1,000 signaling inhibitors. Drug sensitivity scores (DSS3) were calculated, identifying Bcl-2 inhibitors as potential synergistic partners with EGFR inhibition. Dose-response curves for EGFR and Bcl-2 inhibitors were generated, and synergy was assessed using the Chou-Talalay method across four cell lines (UM-SCC-112, UM-SCC-33, SCCNC4, MOP-IPST-1) in 3D culture. Western blotting examined expression of EGFR, pro-apoptotic markers (Bax), and pro-survival proteins (Bcl-2).
Results: Drug screening revealed that ISP-associated sinonasal carcinoma (SNC) cell lines were highly resistant to both standard and targeted single-agent therapies. In 3D *ex vivo* cultures, sinonasal papilloma and carcinoma PDOs showed partial responses to EGFR inhibitors, and EGFR inhibition alone failed to suppress growth or induce apoptosis. In contrast, dual or triple combinations of EGFR inhibitors with Bcl-2 and/or PI3K/AKT/mTOR pathway inhibitors produced synergistic cytotoxic effects, suggesting that co-targeting EGFR and anti-apoptotic pathways may overcome intrinsic resistance. Western blot analysis showed that resistant lines had reduced Bcl-2 expression, while lines with higher Bcl-2 levels demonstrated greater synergy with EGFR/Bcl-2 co-inhibition, including those with EGFR mutations, indicating reliance on alternative survival mechanisms.
Conclusions: Dual EGFR and Bcl-2 inhibition demonstrate synergistic anticancer potential in ISP-associated SNC, overcoming de novo resistance to EGFR-targeted therapy. These findings underscore the importance of targeting anti-apoptotic pathways in EGFR-mutant sinonasal cancers. Ongoing studies aim to define EGFR-Bcl-2 crosstalk and identify optimal drug combinations for *in vivo* testing.

#1767 Preclinical efficacy of a first-in-class anti-SLC3A2 ADC in hard-to-treat solid and hematologic malignancies.

Qinhong Ma, Daizong Li, Kewei Zhao, Mary Q. Xu, **Mason Lu**

MedAbome, Inc., Fremont, CA

SLC3A2 (CD98 heavy chain, CD98hc, or 4F2hc) is a type II transmembrane glycoprotein that functions primarily as the heavy chain component of heterodimeric amino acid transporters (HATs). The aberrant overexpression of SLC3A2 has been linked to many types of cancer, such as lung cancer, breast cancer, colorectal cancer (CRC), pancreatic cancer (PDAC), and various types of hematologic malignancies. Using our proprietary live-cell immunization (LC-I) and high-throughput screening (LC-HTS) platforms, we developed MAb52-4.2, an anti-SLC3A2 monoclonal antibody that selectively recognizes a tumor-associated conformational epitope of SLC3A2, which significantly elevated expression levels in cancer cell lines, and exhibits minimal or no cross-reactivity with normal cells or tissues. Both the chimeric and humanized versions of MAb52-4.2 bound to recombinant SLC3A2-ECD with high affinities in the low single-digit nanomolar range. MAb52-4.2 cAb, containing two Fc point-mutations, was conjugated to MMAE through an MC-Vc-PAB linker to produce MAb52-4.2-ADC (DAR4). MAb52-4.2-ADC demonstrated potent antiproliferative effects *in vitro*, with cytotoxicity correlating with the target abundance and antibody internalization efficiency across a variety of cancer cell lines. A single intraperitoneal (*i.p.*) dose of MAb52-4.2-ADC at 4, 7, or 10 mg/kg effectively inhibited tumor growth in cell line-derived xenograft (CDX) mouse models of triple-negative breast cancer (TNBC), non-small cell lung cancer (NSCLC), gastric cancer (GC), and other tumor types, with subcutaneously inoculated tumors completely regressing within 24~30 days post-treatment. Preliminary toxicology studies indicated that MAb52-4.2-ADC did not raise any safety concerns. These findings support MAb52-4.2-ADC as a promising therapeutic candidate for treating solid and hematologic malignancies, and potentially mitigating toxicity concerns. Ongoing studies aiming to support further clinical investigation include MAb52-4.2-ADC in patient-derived xenograft (PDX) gastrointestinal (GI) cancer models, along with retrospective analyses of its target expression in clinical tumor samples.

#1768 High-sensitivity targeted mass spectrometry enables quantification of HLA-presented antigens for TCR-T therapeutic target discovery.

Simonas Savickas[1], Anamarija Pfeiffer[1], Arthur Viode[1], Liliana Malinovska[1], Oliver Bernhardt[1], Veronique Laforte[1], Lucy Yang[1], Roland Bruderer[1], Daniel Redfern[1], **Yuehan Feng**[1], Wayne Paes[2]

[1]Biognosys AG, Schlieren, Switzerland,[2]Greywolf Therapeutics, Oxford, United Kingdom

Background

Human leukocyte antigens (HLA) are key mediators of adaptive immunity, presenting antigenic peptides derived from self and non-self proteins for immune surveillance. Tumor-specific neoantigens generated by somatic mutations represent key determinants of immune recognition and are central to the development of targeted immunotherapies. Recent advances in immunopeptidomics have enabled systematic identification of these peptides; however, accurate quantification of immunogenic epitopes remains essential to assess their therapeutic relevance. Precise measurement of (neo)antigen abundance can inform the design of T-cell receptor (TCR)-based therapeutics, as well as personalized vaccines and cell therapies. Highly sensitive, quantitative methods for profiling peptide presentation across cell or tissue materials are therefore critical to advancing precision immuno-oncology and immune-modulatory therapies.

Method

Current methodologies to measure presented antigens are hampered by low sensitivity, and laborious optimization procedures. To overcome these issues, we applied a targeted mass spectrometry approach (FAIMS-PRM) combined with a one-step collision energy (CE) optimization, as described in a recent publication (Salek et al. 2024) workflow to systematically optimize collision energy and improve assay sensitivity. This streamlined method enables robust, cost- and time-efficient development and optimization of targeted assays for immunopeptides using minimal input material: 25 million cells or 15 mg of fresh-frozen tissue. Incorporating stable isotope-labeled internal standards (SIS peptides) allowed absolute quantification and estimation of copy number per cell.

Results

To demonstrate the performance of the optimized workflow, we quantified HLA I-presented (neo)antigens in multiple cell lines, including SK-MEL-5, Raji and HCT116. The analysis panel comprised peptides derived from well-established TCR-T and tumor-specific antigen (TSA) targets such as PRAME, MAGE-A1, and NY-ESO-1, alongside candidate antigens identified in prior discovery studies. Application of the collision energy-based optimization improved signal intensity for approximately 50% of targeted peptides compared with default settings. The method achieved lower limits of quantification (LLOQ) in the low single-digit range (1-3 copies per cell), enabling precise quantification of low-abundance immunopeptides. These results illustrate the sensitivity and robustness of the workflow for accurate measurement of clinically relevant HLA-presented targets.

In conclusion, these advances provide a sensitive and efficient workflow for quantitative assessment of HLA-presented peptides across disease and healthy samples, supporting identification of promising targets for immunotherapy development.

#1769 LY4170156, an antibody-drug conjugate targeting folate receptor alpha, exhibits enhanced antitumor activity in combination with standard-of-care therapies in preclinical ovarian cancer models.

Zhaohai Lu[1], Chun Ping Yu[2], Jack A. Dempsey[1], Wei Guo Xu[2], Lisa Kays[1], Bonita D. Jones[1], Andrew Capen[1], Xueqian Gong[1]

[1]Eli Lilly and Company, Indianapolis, IN,[2]Lilly (China) R&D Center, Shangai, China

LY4170156 is an antibody-drug conjugate targeting folate receptor alpha (FRα). It is composed of a humanized IgG1 monoclonal antibody with silenced Fc function, a proprietary polysarcosine hydrophobicity-masking agent with a dipeptide-cleavable linker, and a topoisomerase I inhibitor exatecan payload with a drug-to-antibody ratio of 8:1. In preclinical studies, LY4170156 was active against various FRα-expressing tumors[1], including those with low/moderate (0 - <75%)[2] FRα expression.[1] The Phase 1 trial (NCT06400472) indicated that LY4170156 was well-tolerated and resulted in durable clinical efficacy in heavily pretreated patients with platinum-resistant ovarian cancer (PROC), regardless of FRα levels or prior mirvetuximab soravtansine-gynx treatment, and without grade ≥3 drug-related ocular, neuropathy, or alopecia events.[3] The Phase 3 study (NCT07213804) evaluates LY4170156 as monotherapy in patients with PROC and in combination with bevacizumab in patients with platinum-sensitive ovarian cancer (PSOC). This study reports the preclinical activity of LY4170156, as a single agent and in combination with standard of care therapies (SoC) in ovarian cancer (OC) cell lines using in vitro 3D cell culture, and cell line-derived or patient-derived xenograft models. Sequencing of treatments was also assessed. CellTiter-Glo assay was used for evaluating cell viability in vitro after treatment of 7 days. Tumor volume and mice body weight were measured twice a week throughout the in vivo study. Assays using 5 OC cell lines demonstrated that when LY4170156 was combined with various SoC, it exerted enhanced growth inhibitory effects, independent of FRα expression levels. In vivo efficacy studies showed that LY4170156 combined with cisplatin with or without bevacizumab, bevacizumab, doxorubicin, or carboplatin plus paclitaxel resulted in superior and more durable antitumor responses compared to SoC alone. In addition, LY4170156 plus bevacizumab was highly effective as both first- and second-line treatment in tumor models with moderate responses to SoC. Furthermore, LY4170156 plus olaparib demonstrated enhanced antitumor activity in DNA repair-deficient models. Collectively, these findings offer further support for the clinical assessment of LY4170156 in patients requiring improved treatment options, including those with PROC and PSOC. [1]Viricel et al. AACR; Cancer Res. 2023; 83(7). [2] Moore K, et al. *N Engl J Med.* 2023;389(23):2162-2174 [3]Ray-Coquard et al. Presented at ESMO 2025.

#1770 Differential *in vitro* activity of amivantamab, cetuximab, and panitumumab against EGFR ECD resistance mutations.

Stacey L. Lehman[1], Himanshu Gupta[1], Rosa MF Cardoso[2], Laura A. Struzyna[3], Stephen W. Jarantow[3], Xuesong Lyu[4], Elsie Samakai[3], Emrullah Yilmaz[5], Sanjib Chowdhury[6], Joshua C. Curtin[1], Bharvin Patel[1]

[1]Johnson & Johnson, Oncology Translational Research, Spring House, PA,[2]Johnson & Johnson, In Silico Discovery, Spring House, PA,[3]Johnson & Johnson, Biologics Discovery, Spring House, PA,[4]Johnson & Johnson, Oncology Translational Research, Shanghai, China,[5]Johnson & Johnson, Clinical Oncology, Raritan, NJ,[6]Johnson & Johnson, Oncology Translational Research, Cambridge, MA

Epidermal growth factor receptor (EGFR) ectodomain (ECD) mutations are a known acquired resistance mechanism to EGFR monoclonal antibodies cetuximab and panitumumab in metastatic colorectal cancer (mCRC). Amivantamab, an EGFR-MET bispecific antibody with immune cell-directing activity, has demonstrated meaningful antitumor activity in several solid tumor types. Amivantamab, cetuximab, and panitumumab bind to EGFR domain III; however, the precise epitopes vary, which could lead to differential binding and activity against EGFR ECD resistance mutations. Here, we compare the activity of these EGFR-targeting agents against a panel of 29 EGFR ECD mutations historically associated with resistance to cetuximab and panitumumab. HEK293Ta cells expressing EGFR ECD-mutated variants were used for binding and functional assays of amivantamab, cetuximab, and panitumumab. Amivantamab demonstrated increased binding and functional activity against a wider range of EGFR ECD mutations, including the most prevalent V441, G465, and S492 mutations, relative to cetuximab and panitumumab. Furthermore, structural modeling of amivantamab bound to EGFR indicated that the amivantamab epitope is shifted away from EGFR residues 441-444 and 464-465, which are the regions that form more extensive interactions with cetuximab and panitumumab. Of note, amivantamab was inactive against ECD mutations occurring at K489 and I491, which were previously identified as a part of the amivantamab EGFR epitope. The preclinical activity of amivantamab against EGFR ECD mutations was corroborated in a clinical case study. In OrigAMI-1 (ClinicalTrials.gov Identifier: NCT05379595), a phase 1b/2 study evaluating amivantamab monotherapy among heavily pretreated *RAS/BRAF* wild-type mCRC, one participant was retrospectively found to carry an EGFR ECD S492R mutation by baseline tissue next-generation sequencing. This participant achieved a partial response, providing preliminary clinical evidence that amivantamab is active against a mutation demonstrated to confer resistance to cetuximab. In conclusion, amivantamab may be more active against a wider range of EGFR ECD resistance mutations compared with cetuximab and panitumumab.

#1771 Synergistic lethality of combination treatment with Trop2-directed antibody-drug conjugate (IMMU-132) and Apo2L/TRAIL in triple negative breast cancer (TNBC).

Yonit Addissie, Yoshimi Endo Greer, Stan Lipkowitz

National Cancer Institute, Bethesda, MD

Background: Sacituzumab govitecan (IMMU-132) is an antibody drug conjugate targeting trophoblastic cell surface antigen 2 (Trop2) that's approved for treatment of patients with metastatic TNBC who have received two or more prior systemic therapies. The cytotoxic payload of IMMU-132 is a topoisomerase I inhibitor (SN-38) that kills cancer cells by causing DNA damage. Efforts to enhance the efficacy of IMMU-132 treatment include combination therapy with other agents. Apo2L/TRAIL interacts with death receptors on the cell surface to induce apoptosis in cancer cells, sparing normal cells. We previously have shown that TNBC is most sensitive to Apo2L/TRAIL. We investigated whether combination treatment with IMMU-132 and Apo2L/TRAIL synergistically inhibit TNBC cell growth.

Methods: Human TNBC cell lines treated *in vitro* with IMMU-132 and Apo2L were assessed for cell viability via a propidium iodide-based cell death assay and ATP cell viability assay. The mode of cell death elicited by combination treatment was also investigated by using inhibitors of apoptosis, necroptosis and ferroptosis. Effects of treatment on cell cycle arrest were explored using flow cytometry. *In vivo,* NCr athymic nude (nu/nu) female mice with HCC1806 TNBC xenografts were treated with IMMU-132 and Apo2L after which tumor growth and survival were monitored.

Results: Combination treatment with IMMU-132 and Apo2L synergistically induced cell death in triple negative breast cancer cell lines with high Trop2 expression (e.g. HCC1806, MDA-MB-468) but did not in the Trop2 low expressing MDA-MB-231 cell line. In some Trop2 low TNBC cell lines (e.g. BT-549, SUM-159), combination treatment also showed synergistic induction of cell death, suggesting extracellular deconjugation of the SN-38 cytotoxic payload and diffusion into cells. The synergy seen in Trop2 low TNBC cell lines was abrogated by limiting drug incubation periods - which minimizes the extracellular deconjugation. In contrast, the synergy seen in Trop2 high cells was maintained in these short incubation assays. Caspase activation assays and viability assays with caspase inhibitors showed that the primary mechanism of cell death for Apo2L and combination treatment with IMMU-132 is through apoptosis. Furthermore, flow cytometry-based cell cycle assays showed that IMMU-132 and combination treatment with Apo2L induce cell cycle arrest at the G2/M stage. Our xenograft model also showed significant antitumor effects with SG and TRAIL agonist combination treatment including decrease in tumor growth and improved survival in HCC1806 bearing mice.

Conclusions: The data suggest a synergistic effect of combination treatment with Trop2 antibody drug conjugate IMMU-132 and TRAIL agonists in killing TNBC cells.

#1772 HER3-targeted nano-bioparticles deliver 5′-triphosphate-modified FOXC1 siRNA to induce tumor regression and immune activation in HER3$^+$ cancers.

Amirhesam Babajani[1], Felix Alonso-Valenteen[1], James Teh[1], Nelyda Gonzalez[1], Simoun Mikhael[1], Michelle Wong[1], Xiaojiang Cui[1], Ravinder Abrol[2], Lali K. Medina-Kauwe[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]California State University, Northridge, Los Angeles, CA

Purpose: HER3 is frequently overexpressed in a range of solid tumors and contributes to resistance against both targeted and chemotherapies. To address this, we developed a triple-function therapeutic approach using HER3-targeted HPK nanocapsid (NC) to deliver FOXC1-specific siRNA, thereby silencing this master transcriptional regulator of tumor aggressiveness and metastasis. The siRNA was synthesized with T7 polymerase to incorporate a 5′-triphosphate (5′-ppp) moiety, which serves as an activator of cellular immune responses. This strategy enables targeted and protected delivery of siRNA cargo, while simultaneously achieving FOXC1 silencing and tumor-intrinsic activation of cellular Interferon response.
Methods: HPK proteins were engineered to self-assemble into virus-like NCs capable of encapsulating siRNA. We evaluated the properties, stability, and morphology of the nanoparticles. HPK design incorporates the adenovirus penton base protein for membrane penetration and neuregulin for HER3-targeted binding. T7-transcribed FOXC1 siRNAs (HSiFox-T7) were packaged into HPK NCs and evaluated in HER3$^+$ tumor cell lines and mouse models. We assessed cytokine production, cell viability, interferon role in cell cytotoxicity, FOXC1 knockdown, migration, immune cell infiltration, and in vivo therapeutic efficacy in both HER3$^+$ immunodeficient melanoma and immunocompetent triple-negative breast tumor (TNBC) models.
Results: The HPK and T7-transcribed siRNA formed stable and smaller nanoparticles compared to synthetic siRNAs. In vitro, T7-derived 5′-ppp siRNAs induced greater cytotoxicity than synthetic controls mainly via activated type I interferon response. HSiFox-T7 achieved robust FOXC1 knockdown, significantly reducing cell migration and viability. In vivo, systemic administration of HSiFox-T7 suppressed tumor growth and increased type I interferon response in immunocompromised HER3$^+$ melanoma models. It also suppressed FOXC1, reduced metastatic lung burden, and increased tumor apoptosis with minimal off-target toxicity while protecting siRNA content in the circulation of immunocompetent TNBC mice model. Treatment enhanced infiltration of NK cells and CD8$^+$ T cells into both primary tumors and metastases, indicating strong immunostimulatory effects.
Conclusions: HPK NCs represent a multifunctional platform that combines HER3-targeted delivery, master gene silencing, and immune activation. The HSiFox-T7 system effectively suppressed HER3$^+$ tumor growth and metastasis while reprogramming the tumor microenvironment toward immune responsiveness. This triple-action strategy overcomes major barriers in siRNA therapeutics including protecting nucleic acid content in circulation and avoiding off-target effects while offering translational potential for treating aggressive cancers such as TNBC and melanoma.

#1773 Development and characterisation of a novel monoclonal antibody against overexpressed integrin α6β4 on human pancreatic cells.

Gustavo Arias[1], Angus G. Dalgleish[2], Izhar Bagwan[3], Said Khelwatty[1], Satvinder Mudan[2], Tony Walker[1], **Helmout Modjtahedi**[1]

[1]Kingston University London, Kingston upon Thames, United Kingdom,[2]St George's Hospital, University of London, London, United Kingdom,[3]Royal Surrey Hospital, Guildford, United Kingdom

Despite major advances in the diagnosis and treatment of patients with cancer, pancreatic cancer remains one of the most aggressive and fatal cancer types. There is an urgent need for the discovery of additional therapeutic targets and the development of more effective therapeutics. Monoclonal antibody (mAb) technology is an excellent tool for the discovery of overexpressed cell surface tumour antigens, and antibodies generated may have significant diagnostic and therapeutic value. Here, we report the generation and characterisation of a novel antibody KU44.71 against the human ductal pancreatic adenocarcinoma metastasised to the liver cell line CFPAC-1, using hybridoma technology. Following screening, mAb KU44.71 which was directed against overexpressed cell surface antigens on pancreatic cancer cells was selected and purified by affinity chromatography. Further characterisation of the mAb was performed by ELISA, flow cytometry, cell proliferation assay, internalisation studies, immunoprecipitation and mass spectrometry, western blotting, and immunohistochemistry. We discovered that KU44.71 recognises the external domain of integrin α6β4 that is overexpressed by varying amounts in pancreatic cancer cell lines, derived from different sources including primary pancreatic cancer, liver metastasis, ascites and lymph node metastasis. Treatment with the naked antibody did not affect growth of α6β4 expressing pancreatic cancer cells. In contrast, exposure to anti-α6β4 KU44.71 induced internalisation of integrin α6β4 in pancreatic cancer cells. Furthermore, KU44.71 was found to be effective in detecting α6β4 expression by western blot and immunohistochemistry. Our results suggest that mAb KU44.71 is an useful tool for studying the role of α6β43 in the complex biology of human cancer, and for investigating the relative expression, prognostic significance, and predictive value of integrin α6β43 in patients with pancreatic cancer. Further studies are warranted to elucidate the therapeutic potential of this novel mAb including its humanised or drug conjugated versions in patients with α6β43 overexpressing pancreatic and other type of cancer.

#1774 ACR317, a novel CDH17-ADC, shows potent efficacy in preclinical gastrointestinal cancer models.

Zhenwei Miao, Feng Wang, Yaowu Li, Shanhui Weng, Li Yang

Hangzhou Adcoris Biopharma Co., Ltd., Hangzhou, China

Background:Cadherin-17 (CDH17) is a well-validated target with high expression in gastrointestinal (GI) cancers, including colorectal (CRC) and gastric cancer, while its expression in normal tissues is restricted to the basolateral membrane of intestinal epithelial cells. This unique expression pattern makes CDH17 an attractive therapeutic target for antibody-drug conjugates (ADCs). The development of effective ADCs for GI malignancies, particularly for CRC, remains a significant challenge. The landscape is largely dominated by DS-8201, with many other candidates failing due to efficacy or safety concerns. Here, we present the preclinical profile of ACR317, a novel CDH17-targeting ADC developed using Adcoris' proprietary platform, designed to address this unmet need.
Methods: IBR217 antibody, was isolated from a naïve fully human phage display library based on its high specificity and affinity for human CDH17. The binding affinity of IBR217 was determined by bio-layer interferometry (BLI), tumor cell binding activity was evaluated by flow cytometry, and internalization efficiency was assessed using a Fab-ZAP cytotoxicity assay. ACR317 was generated by site-specifically conjugating IBR217 to a novel topoisomerase I inhibitor payload using Adcoris' proprietary MuSC™ conjugation platform, achieving a drug-to-antibody ratio (DAR) of 8. *In vivo* antitumor activity was evaluated in multiple CDH17-positive and negative gastric and colorectal cancer cell-derived xenograft (CDX) models, with an IBR217- Dxd ADC included as a benchmark.
Results: IBR217 exhibited high affinity for human CDH17, with a binding affinity (KD) of 2.47 nM, and demonstrated excellent specificity by showing no binding to other cadherins. It also displayed potent binding to CDH17-positive tumor cells, with a half-maximal effective concentration (EC50) of 0.30 nM, and was subsequently efficiently internalized by these cells. ACR317 was successfully generated with a drug-to-antibody ratio (DAR) of 8. The resulting ADC ACR317 demonstrated significant tumor growth inhibition in preclinical CDX models, showcasing superior efficacy compared to the IBR217-Dxd benchmark in two CDH17-positive gastric cancer and four CRC CDX models. As expected, it showed minimal activity in a CDH17-negative gastric model, confirming its target-dependent mechanism. In these studies, ACR317 was well tolerated, with no significant body weight loss or other observable toxicities noted. Pharmacokinetics and safety studies in cynomolgus monkeys are ongoing.
Conclusions: ACR317 is a novel, highly specific CDH17-targeting ADC. The compelling preclinical efficacy observed suggest its therapeutic potential and form a solid foundation for subsequent clinical investigation in CDH17-positive gastrointestinal cancers.

#1775 ACR335, a novel cMET/EGFR bispecific dual-payload antibody-drug conjugate, demonstrates potent and broad antitumor activity in preclinical models of solid tumors.

Zhenwei Miao, Feng Wang, Shanwei Weng, Li Yang, Wu Yao

Hangzhou Adcoris Biopharma Co., Ltd, Hanghzou, China

Background: cMET and EGFR are frequently co-expressed oncogenic drivers in solid tumors, with pathway crosstalk driving therapeutic resistance. This combination is clinically validated by amivantamab, a bispecific antibody (BsAb) targeting cMET and EGFR approved for EGFR-mutant NSCLC. To enhance efficacy and overcome resistance, we developed ACR335, a bispecific ADC (BsADC) that simultaneously targets both receptors. Furthermore, ACR335 is engineered as a dual-payload ADC, combining a Topoisomerase I (Top1) inhibitor and a non-Top/non-Tubulin inhibitor, a strategy designed to synergistically maximize tumor cell killing.
Methods: The BsAb IBR335 combines a fully human anti-cMET antibody (isolated from a naïve phage library) with an engineered version of panitumumab (anti-EGFR). Binding affinity for cMET and EGFR was determined by BLI, tumor cell binding by flow cytometry, and internalization efficiency by a Fab-ZAP cytotoxicity assay. ACR335 was generated by site-specifically conjugating IBR335 to a Top1 inhibitor and a non-Top/non-Tubulin inhibitor using the MuSC™ platform, achieving a DAR of 4+4. Antitumor efficacy was evaluated in multiple cMET/EGFR-positive CDX models, including KATO-III (gastric), H1650 (NSCLC, EGFR Ex19del), Calu-6 (NSCLC, EGFR-wt), HT1376, and SW780 (bladder), with single-payload ADCs or a Dxd-ADC as benchmarks.
Results: IBR335 exhibited a 27.5-fold higher binding affinity for human cMET (KD = 0.149 nM) than for EGFR (KD = 4.1 nM), with sub-nanomolar EC_{50} binding to cMET/EGFR-positive tumor cells comparable to amivantamab and efficient internalization. This preferential targeting strategy mitigates potential on-target off-tumor toxicity associated with broad EGFR inhibition. The resulting ADC, ACR335, was homogeneous with a DAR of 4+4. It demonstrated potent *in vitro* cytotoxicity and induced significant tumor growth inhibition and regression across multiple CDX models, showing superior efficacy to single-payload ADCs and the Dxd-ADC benchmark. ACR335 was well-tolerated with no significant toxicity observed. Pharmacokinetic and safety studies in cynomolgus monkeys are ongoing.
Conclusions: ACR335 is a first-in-class cMET/EGFR bispecific dual-payload ADC with a unique pharmacological profile. The compelling preclinical data underscore its potential as a targeted therapy with an optimized safety profile. Phase I clinical trials are expected to commence in Q2 2026.

#1776 ALK101sc, a novel afucosylated bispecific antibody targeting EGFR and c-MET with common light chain demonstrates potent, broad-spectrum antitumor activity.

Li Li, Hongwang He, Mengfan Peng, Meiyu Yang, Jiajia Pan, Hui Feng

Allink Biotherapeutics, Shanghai, China

Acquired resistance to EGFR tyrosine kinase inhibitors (TKIs) represents a major clinical challenge in treating EGFR-mutant non-small cell lung cancer (NSCLC). This resistance arises either from secondary EGFR mutations (e.g., C797S) or via bypass signaling through the c-MET pathway—including c-MET mutation, gene amplification, or hepatocyte growth factor (HGF) upregulation. To overcome these mechanisms, we developed ALK101sc, an afucosylated IgG1 bispecific antibody (bsAb) co-formulated with hyaluronidase, designed to simultaneously target EGFR and c-MET. ALK101sc (120 mg/mL) was produced using a single-cell common-light-chain (CLC) platform, which ensured correct heterodimerization and scalable manufacturing without chain mispairing or exchange. In vitro functional assays demonstrated that ALK101sc effectively bound to EGFR/c-MET double-positive tumor cells, inducing receptor internalization and lysosomal degradation, and potently suppressed ligand-induced downstream signaling of both EGFR and c-MET, including phosphorylation of ERK and AKT. The afucosylated Fc region enhanced antibody-dependent cellular cytotoxicity (ADCC), thereby boosting FcγR-mediated antitumor immunity. In vivo, ALK101sc monotherapy induced significant tumor regression in both cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models, including those with EGFR mutations and/or c-MET-driven resistance. Furthermore, combining ALK101sc with osimertinib produced synergistic antitumor efficacy, even in the presence of TKI-insensitive mutations. Pharmacokinetic (PK) and GLP toxicology studies in cynomolgus monkeys following subcutaneous administration revealed typical antibody-like PK profiles, with systemic exposures comparable to amivantamab at equivalent doses and a bioavailability of approximately 89%. No significant abnormalities in safety pharmacology or toxicity were observed, with a no-observed-adverse-effect level (NOAEL) of 120 mg/kg. Together, these results demonstrate that ALK101sc exhibits antitumor potency comparable to amivantamab across preclinical models. Moreover, its CLC-based design provides a streamlined CMC development pathway, positioning it as a promising therapeutic candidate for overcoming EGFR TKI resistance. Compared with intravenous formulations, subcutaneous ALK101sc can substantially reduce administration time, improve patient convenience, and is expected to have a more favorable safety profile—characterized by meaningful reductions in infusion-related reactions (IRR) and venous thromboembolism (VTE) rates.

#1777 FL116, a PD-1/IL-18 bispecific antibody, enables cis-activation of PD-1$^+$ T cells and reshapes the suppressive tumor microenvironment (TME).

Haiming Huang[1], Quanxiao Li[1], Xiaotuan Zhang[1], Liwen Ji[1], Yanling Wu[2], Dong Wei[1], Tianlei Ying[2]

[1]Suzhou Forlong Biotechnology Co., Ltd, Shanghai, China,[2]Key Laboratory of Medical Molecular Virology (MOE/NHC/CAMS), Shanghai Institute of Infectious Disease and Biosecurity, School of Basic Medical Sciences, Fudan University, Shanghai, China

Background: IL-18 is a potent immune cytokine that promotes CD8$^+$ T-cell and NK-cell-mediated antitumor responses but is neutralized by IL-18BP. We previously engineered a panel of IL-18 variants which are completely resistant to IL-18BP inhibition. FL116 is a dual-function immunocytokine, in which an anti-PD-1 IgG was fused with one such IL-18 variant to achieve cis-delivery of IL-18R agonism to PD-1$^+$ T cells while bypassing IL-18BP in TME. The molecule aims to re-ignite pre-existing tumor immunity within the TME with minimal systemic toxicity.

Methods: FL116 was constructed by fusing the DNA coding sequence of an IL-18 variant that fully escapes IL-18BP neutralization with that of one heavy chain of an anti-PD-1 IgG to produce recombinant protein. Both binding domains of FL116 were confirmed by ELISA. The cis-acting of FL116 was evaluated by an engineered mammalian cell line which expresses both IL-18 receptors and PD-1. In vitro, the IFN-γ-inducing activity of FL116 was further validated using PBMC assays. In vivo, FL116 was assessed in MC38, CT26 and B16-F10 tumor models to evaluate its antitumor efficacy and safety.

Results: Both parts of FL116 preserved their binding and biological functions as validated by ELISA and PBMC assays. In vivo, FL116 produced strong and durable antitumor activity across tumor models. In MC38, FL116 achieved 98% tumor growth inhibition (TGI) and 2/5 complete response(CR). In CT26, FL116 showed 93% TGI and 3/5 CR. CT26 rechallenge revealed cured mice fully rejected tumor re-implantation without further treatment, indicating durable immune memory. In B16-F10 tumors, FL116 induced dose-dependent tumor regression and elevated intratumoral IFN-γ(8-fold) compared to the vehicle treatment, consistent with type-1 immune activation. TIL profiling showed substantial expansion of CD8$^+$ Tem(6-fold) and NK cells, increased cytotoxic markers(granzyme B), and enhanced DC activation. Suppressive myeloid cells were significantly reduced, with PMN-MDSC decreasing ~5-fold, leading to improved effector/suppressor ratios (CD8/MDSC 20-fold, CD8/Treg 6-fold). Peripheral blood composition remained stable, with slightly increases in CD8$^+$ Tem and NK maturation, indicating localized pharmacodynamic amplification rather than systemic inflammation. No body-weight loss was observed, and only mild, pharmacologically driven hepatosplenic enlargement occurred.

Conclusions: FL116 achieves potent antitumor activities, high CR rates, and rechallenge-confirmed immune memory while maintaining systemic immune homeostasis. By delivering decoy resistant IL-18 variant directly to PD-1$^+$ T cells, FL116 re-ignites intratumoral cytotoxic immunity and reshapes the TME toward a highly inflamed, effector-dominant state. These results support FL116 as a promising candidate for next-generation cytokine-fusion immunotherapy.

[1]Edwin L. Steele Laboratories, Department of Radiation Oncology, Massachusetts General Hospital and Harvard Medical School, Boston, MA,[2]Massachusetts General Hospital Cancer Center and Department of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA,[3]Centre for Heart Lung Innovation and Department of Anesthesiology, Pharmacology & Therapeutics, University of British Columbia, Vancouver, BC, Canada

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is the third leading cause of cancer-related death in the United States, with a 5-year overall survival of ~13%. Delayed diagnosis, limited response to current treatments, and the predominance of locally advanced or metastatic disease contribute to poor outcomes. Leveraging our preclinical findings in PDAC murine models, we showed that adding losartan—an angiotensin II type-1 receptor (AT1) blocker—to FOLFIRINOX followed by chemoradiation doubled R0 resection rates to ~70% in locally advanced PDAC in a phase II trial (NCT01821729) (PMID: 31145418). However, the patient-response was variable. Here we recapitulated this variability in orthotopic PDAC mouse models and revealed the underlying mechanism.
Methods and Results: To investigate potential causes of the variable response, we mapped AT1 expression using light-sheet microscopy in AT1 reporter mice bearing orthotopic PDAC. We observed abundant AT1 throughout the tumor microenvironment. To define its functional relevance, we generated *Agtr1a* knockout (KO) PDAC cell lines and inducible KO mouse models. AT1 deletion in either cancer cells or stromal cells (but not α-SMA$^+$ myCAFs or pericytes) significantly reduced tumor growth. Because losartan is a pro-drug that needs activation by liver enzymes CYP3A4 and CYP2C9, we next examined its metabolism. We subcutaneously administered two major losartan metabolites, EXP3179 and EXP3174, to orthotopic PDAC-bearing mice and found that EXP3174 mediated the anti-tumor effects of losartan. Mass spectrometry of plasma samples revealed that while some tumor-bearing mice efficiently converted losartan to its active metabolite, others showed limited or no conversion. To determine the cause, we assessed CYP2C9 and CYP3A4 activity in liver microsomes from non-metastatic PDAC-bearing mice. CYP2C9 activity was markedly reduced and inversely correlated with tumor burden, providing a mechanistic basis for differential losartan activation. Ongoing work aims to determine whether PDAC patients likewise display variable plasma levels of losartan and EXP3174.
Conclusion: These findings identify impaired hepatic metabolism as a key driver of variable losartan responses in locally advanced PDAC. Mass-spectrometry-based assessment of losartan and EXP3174 levels may help determine which patients can effectively activate the drug. Given losartan's safety and low cost, its oral administration remains appropriate for most patients; however, in individuals with compromised CYP2C9 activity, administration of the active metabolite — EXP3174 may represent a more effective therapeutic option.

#1782 Exome-scale CRISPR screening reveals master controllers of cell state maintenance in high-risk neuroblastoma.

Grace McKay-Corkum, Stephanie Nance, Noha AM Shendy, Shilpa Narina, Shondra Miller, Alex Carisey, Qiqi Jin, Jiyang Yu, Adam D. Durbin

St. Jude Children's Research Hospital, Memphis, TN

A major limitation in cancer treatment is chemoresistance, particularly at relapse. Previously, relapse was thought to be driven by chemoresistance arising from new acquired genetic mutations; however, emerging evidence indicates that cancer cells exploit non-genetically-driven processes such as epigenetically regulated transcriptional plasticity to drive chemoresistance, invasion and proliferation. High-risk neuroblastoma (NB) demonstrates transcriptional plasticity with defined cell states and low mutational burden. NB cells exist primarily in two distinct states: a chemosensitive adrenergic state (ADRN) and a less common drug-tolerant persister cell state, the mesenchymal (MES) state. MES cells are enriched at relapse, suggesting that cells switch to this state under therapeutic pressure. Despite a myriad of approaches to treating high risk NB, relapsed patients have exceptionally poor survival. Unfortunately, mechanisms maintaining cell state and permitting state switching in NB are poorly understood. We hypothesize that dissection of the pathways promoting NB cell state plasticity will reveal new approaches to drive cell state interconversions that facilitate chemosensitivity. Thus, here, we took advantage of a recently developed novel fluorescent reporter system of the NB MES cell state developed by the Durbin Lab, to perform whole exome-CRISPR-cas12 knockout screening and identify master controllers of cell state maintenance in ADRN and MES-dominant cell lines. Integrated pathway analysis demonstrated conserved pathway modules involved in maintenance of cells in distinct cell states. To validate these findings, we performed targeted CRISPR knockouts in reporter carrying cells and identified changes in chemoresistance by chemosensitivity assays. To profile the effects of chemotherapy directly on cell state maintenance, we performed fluorescence reporter assays, followed by RNAseq to confirm changes in target loss nominated from CRISPR screens. Cell state switching is an intriguing paradigm by which NB cells may evade conventional therapies. We have identified pathways playing a role in maintaining either the ADRN or MES cell state in NB. Continued interrogation of these fundamental mechanisms represents a new approach that may potentially be leveraged for therapeutic gain.

#1783 ELF3-driven epigenetic reprogramming creates ERK pathway dependency in SERD-resistant ER+ breast cancer.

Na Zhang[1], Myles A. Brown[1], Rongbin Zheng[2], Kaifu Chen[3]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Boston Children's Hospital, Boston, MA,[3]Boston Children's Hospital, Bosotn, MA

Selective estrogen receptor degraders (SERDs) such as fulvestrant represent a promising therapeutic strategy for endocrine-resistant ER+ breast cancers. However, acquired resistance to SERDs remains a significant clinical challenge, and mechanisms underlying SERD resistance without ESR1 mutations are poorly understood. With the new generation of oral SERDs entering clinic, there is urgent need to understand the mechanisms of SERD resistance. Using genome-wide CRISPR knockout screens in parental and fulvestrant-resistant MCF7 cells, we identified ELF3 as a critical driver of SERD resistance. We then performed multi-omics profiling including RNA-seq, ATAC-seq, H3K27ac ChIP-seq, ER ChIP-seq and ELF3 ChIP-seq to characterize the parental and fulvestrant-resistant cell models. We found that SERD-resistant cells exhibited a stable $ER^{low}/ELF3^{hi}$ phenotype driven by a dysregulated ERα-ELF3 reciprocal negative feedback circuit. Multi-omics profiling revealed that ELF3 motifs ranked as the top enriched transcription factor binding motif in both gained ATAC-seq and H3K27ac peaks in the resistant cells. ELF3 ChIP-seq identified ~ 5,000 gained binding sites in resistant cells that co-localized with dramatic increases in chromatin accessibility and H3K27ac signals, confirming robust ELF3-driven enhancer activation of ER-independent survival programs. To assess ELF3-driven transcriptional changes associated with SERD resistance, we integrated ELF3 ChIP-seq data with RNA-seq data from both parental and SERD-resistant cells. We derived an ELF3 signature consisting of the top 500 genes that showed both increased ELF3 binding and elevated expression in the resistant cells. Pathway enrichment analysis revealed that ELF3 target genes are highly enriched in ERK signaling components. Experimental validation showed that resistant cells exhibited marked ERK pathway activation and developed strong dependency on ERK signaling, with increased sensitivity to MEK inhibitor trametinib. Re-analysis of single-cell RNA-seq from a metastatic breast cancer cohort confirmed that $ER^{low}/ELF3^{hi}$ tumor cells show enrichment of the ELF3 signature and increased ERK signaling compared to $ER^{hi}/ELF3^{low}$ cells. We define a novel mechanism of SERD resistance where the $ER^{low}/ELF3^{hi}$ state drives resistance by activating an ELF3-ERK signaling axis. Targeting this pathway may overcome resistance in $ER^{low}/ELF3^{hi}$ tumors.

#1784 Mechanistic characterization of (Z)-endoxifen in ESR1-mutant and endocrine-resistant breast cancer.

Sandra Suarez Hammer[1], Alina Ustiugova[2], Anastasia Shneyderman[3], Alexander Veviorskiy[2], Khadija M. Alawi[2], Mikhail Korzinkin[3], Lucia Beaulieu[1], Hayley Erickson[1], Scott M. Blackburn[1], H. Lawrence Remmel[4], Steven Quay[1]

[1]Atossa Therapeutics Inc., Seattle, WA,[2]Insilico Medicine AI Limited, Abu Dhabi, United Arab Emirates,[3]Insilico Medicine Hong Kong Ltd., Hong Kong, China,[4]University Medical Center Utrecht, Utrecht, Netherlands

Background: ESR1 mutations (e.g.Y537S and D538G) drive ligand-independent ER activation and resistance in ER-positive breast cancer. (Z)-Endoxifen, the active tamoxifen metabolite, inhibits ER signaling, but its impact on ESR1-mutant signaling and therapy-resistant disease is not yet fully defined.

Methods: HEK293T cells were transfected with ESR1-WT or mutant plasmids together with an ERE-luciferase reporter and Renilla control. After 24 h, cells were treated with endoxifen, elacestrant (10 μM-0.01 nM), or 0.1% DMSO for an additional 24 h. Firefly luciferase activity was normalized to Renilla, and mean ± SD values from three independent experiments were used to generate dose-response curves. Transcriptomic analyses of 166 ESR1 Y537S and 45 ESR1-WT MCF-7 samples from PandaOmics were performed, and differential expression after endoxifen treatment was assessed using 27 treated and 25 untreated samples processed with limma and gseapy. Plasma and tumor samples were extracted by methanol precipitation with deuterated endoxifen-d_5 and quantified by UPLC-MRM on a Poroshell 120 EC-C18 column using a six-point calibration curve.

Results: (Z)-Endoxifen (ENDO) and elacestrant (ELAC) both produced dose-dependent inhibition of ER signaling in wild-type and mutant ESR1 constructs. At 100 nM, ENDO and ELAC showed comparable suppression of WT and three common ESR1 mutants, consistent with the ~80 nM steady-state ENDO plasma level in women taking 20 mg tamoxifen. At higher doses, ENDO more effectively inhibited Y537S and D538G than ELAC.

Test Agent	Wildtype	ESR1-Y537N	ESR1-Y537S	ESR1-D538G	ESR1-K303R
Endoxifen, 100 nM	94 ± 2 %	94 ± 0.1%	62 ± 15%	91 ± 2.4%	90 ± 3.5%
Endoxifen, 400 nM	95 ± 1.5%	94 ± 0.3%	69 ± 13.8%	91 ± 2.1%	91 ± 2.9%
Elasctrant, 100 nM	97 ± 1.8%	98 ± 0.2%	61 ± 19.7%	79 ± 3.2%	91 ± 2.7%

Transcriptomic analyses revealed that ENDO reversed key mutant-associated transcriptional programs in MCF-7 cells. ENDO significantly downregulated estrogen response, apoptosis, E2F-target, and Myc-target pathways while restoring oxidative phosphorylation, xenobiotic and fatty acid metabolism, p53 signaling, and DNA repair (FDR < 0.05). Transcription factor enrichment showed suppression of resistance-associated POU5F1 and SOX11, and reactivation of FOXA1, ELF3, and SPDEF. ENDO also reduced expression of three genes (MTMR7, IL20, CA12) from a six-gene poor-prognosis ESR1-mutant signature. In the ongoing EVANGELINE phase 2 trial (NCT05607004), mean (Z)-endoxifen plasma levels at 40 mg/day reached 278.5 ng/mL (≈746 nM).

Conclusion: In summary, (Z)-endoxifen and elacestrant both suppress ER-dependent transcription in ESR1-WT and mutant models, and clinically relevant (Z)-endoxifen concentrations are sufficient to inhibit mutant ESR1 activity. Endoxifen additionally reprograms key transcriptional and metabolic pathways associated with ESR1-mutant resistance and metastasis. These results support further evaluation of (Z)-endoxifen's pathway-level effects in ESR1-mutant breast cancer, and ongoing studies are testing its ability to block mutant ESR1-driven proliferation in preclinical models.

#1785 Aspects of the YBX1-dependent mechanism of drug resistance in hepatocellular carcinoma.

Yamile Abuchard Anaya[1], Ana Ayala Pazzi[2], Veerababu Nagati[1], Kaylee Renteria[1], Denise Soto[1], Manish Tripathi[1]

[1]Oncology and Medicine ISU, South Texas Center of Excellence in Cancer Research, The University of Texas Rio Grande Valley, Mcallen, TX,[2]UT Southwestern, Dallas, TX

Background: Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer. In the Rio Grande Valley (RGV), high rates of obesity, diabetes, and MAFLD elevate HCC incidence, further worsened by socioeconomic disparities and limited healthcare access. Consequently, late-stage diagnoses and therapeutic resistance lead to poor patient outcomes, emphasizing the importance of understanding the molecular mechanisms behind HCC progression. Y-box binding protein 1 (YBX1) is a multifunctional regulator of transcription and translation involved in EMT, metastasis, and drug resistance in various cancers, including HCC. To investigate the downstream signaling pathways activated by YBX1 overexpression (OE), we developed puromycin-stable GFP-tagged YBX1 OE SK-HEP1 cell lines. These cell lines have been evaluated for their invasion, migration, proliferation, colony formation, and cell impedance properties. YBX1 OE influenced multiple downstream kinases. We identified a specific kinase responsible for oncogenicity and drug resistance. We will continue to characterize and validate the kinase activity using specific activators and inhibitors.
Methods: The TCGA was analyzed for the YBX1 profile in the human HCC cohort. SK-HEP1 cells were used to develop a puromycin-stable YBX1 OE cell line using lentiviral plasmids. The cell lines were also enriched for GFP expression. Functional assays included cell proliferation, colony formation, migration, invasion, and real-time impedance analysis using the xCELLigence system. MTT assays determined IC50 values. The Human Proteome Profiler Array was used for kinase array analysis. Kinase activator and inhibitor assays were also performed.
Results: Analysis of the TCGA revealed elevated YBX1 expression in HCC tumors compared to normal tissues, which correlates with poor survival and increased metastasis. In vitro, YBX1 overexpression boosted proliferation, migration, invasion, and colony formation, while knockdown diminished these effects. xCELLigence analysis confirmed faster growth kinetics in cells overexpressing YBX1. Phosphoproteomic profiling identified several YBX1-regulated kinases, including members of the Src family.
Conclusion: Stable SK-HEP1 models with differential YBX1 expression have been successfully established and characterized. These findings confirm YBX1's oncogenic role in HCC. Ongoing research involving kinase pathway inhibitors and activators may uncover new therapeutic targets to overcome resistance and enhance outcomes for HCC patients in the RGV and beyond.

#1786 Convergent FGFR-JAK signaling reprograms luminal identity and drives endocrine resistance in HR$^+$ breast cancer.

Yucheng Zeng[1], Ruixin Liu[2], Xiaoyan Qiang[1], Jean Fan[1], Caixia Sun[1], Hanlin Zeng[2], **Peng Peng**[1]

[1]TransThera Sciences (Nanjing), Inc., Nanjing, China,[2]Shanghai Institute of Precision Medicine, Shanghai, China

Endocrine therapy has substantially improved outcomes in hormone receptor-positive (HR$^+$) breast cancer, yet resistance remains a major clinical challenge. Such resistance arises via two axes: spatially from tumor-intrinsic alterations or microenvironmental cues; temporally as de novo or acquired phenotypes. How these diverse drivers converge to reprogram cancer cell states remains poorly understood. Through single-cell transcriptomics of resistant HR$^+$ breast cancers, we uncovered a recurrent luminal-to-basal transition with ER/PR downregulation - plasticity that emerged in primary tumors and amplified in metastases, particularly malignant pleural effusions (MPE).

Using serial drug selection and MPE coculture, we recapitulated both therapy-induced and microenvironment-driven resistance, both of which converged on FGFR and JAK pathways activation—a phenotype reversible by genetic knockdown or pharmacological inhibition of these pathways.

Mechanistically, FGFR and JAK activation regulated transcription factors to repress luminal genes (*ESR1, PGR*) and conferred resistance. Tinengotinib (TT-00420), a first-in-class dual FGFR and JAK small molecular inhibitor, restored luminal identity and resensitized resistant models to endocrine therapy *in vitro* and *in vivo*. Thus, lineage plasticity unified intrinsic/extrinsic inputs in endocrine resistance, supporting dual FGFR-JAK blockade as a translational strategy.

Planned trials of tinengotinib combined with endocrine therapy in advanced HR$^+$ breast cancer will assess its clinical potential, with results reported in due course.

#1787 Inhibition of MAOA suppresses intracrine androgen biosynthesis and enhances abiraterone treatment in castration-resistant prostate cancer.

Kaisheng Yuan, Hongling Li, Wen Guan, Jing Wei, Boyang Wu

Department of Pharmaceutical Sciences, College of Pharmacy and Pharmaceutical Sciences, Washington State University, Spokane, WA

Background: Androgen receptor signaling inhibitors (ARSIs), such as enzalutamide (Enz) and abiraterone (Abi), have become cornerstone treatments for castration-resistant prostate cancer (CRPC). Despite initial favorable responses, tumors often develop resistance to these agents, partly due to activation of intracrine androgen biosynthesis, underscoring the need for effective strategies to overcome resistance and prolong the utility of ARSIs. This study investigates the role of monoamine oxidase A (MAOA), a mitochondrial enzyme that degrades monoamines and has recently been implicated in prostate cancer, in intracrine androgen biosynthesis, and assesses the potential of MAOA inhibitors to improve Abi efficacy, an ARSI that blocks androgen biosynthesis.
Methods: Multiple ARSI-resistant CRPC models were used, including C4-2B EnzR, VCaP EnzR, and C4-2B AbiR cell lines, as well as LuCaP147CR EnzR and AbiR patient-derived xenograft (PDX) models. Western blot and qPCR were used to analyze the expression of key steroidogenic enzymes involved in androgen biosynthesis in control and MAOA-knockdown cell lines. ELISA and mass spectrometry were used to measure testosterone and dihydrotestosterone (DHT) levels in cell conditioned media. Cell viability, colony formation, and in vivo tumorigenesis assays were used to evaluate the effects of MAOA inactivation by gene silencing or pharmacological approaches, combined with Abi, in both Abi-sensitive and -resistant CRPC models, including cell lines, PDX-derived organoids, and tumor xenografts.
Results: The ARSI-resistant CRPC cells and PDXs showed increased expression levels of MAOA and select steroidogenic enzymes, including CYP17A1 and AKR1C3, compared to their sensitive counterparts. Silencing MAOA reduced the protein expression of CYP17A1 and AKR1C3, in EnzR and AbiR cells, likely through TWSIT1, a known MAOA downstream effector that mediates MAOA's multifaceted functions in prostate cancer. MAOA knockdown also decreased testosterone and DHT levels, both with and without the androgen precursor androstenedione, in EnzR and AbiR cells. Further, antagonizing MAOA with gene silencing or pharmacological inhibitors, including clorgyline and phenelzine, enhanced Abi effectiveness in Abi-sensitive cells and restored Abi sensitivity in resistant cells both in vitro and in vivo.
Conclusion: Our findings reveal that MAOA is essential for maintaining intracrine androgen biosynthesis associated with ARSI resistance and suggest that MAOA inhibitors could enhance Abi treatment in CRPC.

#1788 Cysteine accumulation as a driver of resistance to bortezomib.

Jennifer A. Brain[1], Sarah M. Chang[2], Maximilian Kobiesa[1], Leah G. Rector[1], Kelli J. Che[1], Zhaoqi Li[2], Sky H. Kim[2], Matthew G. Vander Heiden[2], Lucas B. Sullivan[1]

[1]Fred Hutchinson Cancer Center, Seattle, WA,[2]Koch Institute for Integrative Cancer Research at MIT, Cambridge, MA

Covalent drugs targeting key oncogenic drivers are promising cancer therapies, but resistance limits their clinical benefit. Many covalent inhibitors rely on reacting with nucleophilic residues on proteins, and thus we hypothesized that these inhibitors could interact directly with intracellular pools of nucleophiles, like cysteine, diminishing the drug's efficacy. To investigate the possibility that intracellular cysteine drives resistance to chemotherapies, we performed a high throughput screen of clinically available chemotherapeutics in high and low cysteine conditions. We identified cells to be more resistant to boronic-acid proteasome inhibitors in high cysteine conditions (Bortezomib (Btz) and Ixazomib (Ixa)), but not to the epoxyketone-containing proteasome inhibitor Carfilzomib (Cfz). We confirmed the potential of proteasome inhibitors to react with free cysteine and found that Btz and Ixa both formed a covalent conjugate with cysteine as detected via LC-MS. Upon treating cells with the cysteine-drug conjugate, we find nearly all of the toxicity of the drug has been abolished, supporting the hypothesis that cysteine could be a detoxification mechanism in cells.

Using cancer cell lines derived from diverse cancer types, we modulated the cysteine availability and treated cells with two classes of proteasome inhibitors: those with either a boronic-acid or an epoxyketone moiety. In conditions known to increase intracellular cysteine such as high media cystine or co-treatment with the cysteine pro-drug NAC, we found that cells are more resistant to boronic acid-containing inhibitors. Conversely, when we decrease intracellular cysteine levels by co-treating with erastin, an inhibitor of SLC7A11, we measured that cells become more sensitive to Btz and Ixa. In either low or high cysteine, sensitivity to Cfz was unchanged. Collectively, these results indicate that a direct interaction between cysteine with the boronic acid group of Btz and Ixa is responsible for cysteine mediated resistance to these compounds, upstream of proteasome inhibition.

We next explored cysteine's role in rescuing proteasome function by measuring proteasome activity and ubiquitylation in cells. In both assays, we observed that high cysteine prevented the effects of proteosome in cells treated with boronic acid-containing inhibitors. We did not measure a difference in proteasome function in carfilzomib-treated cells in high cysteine, once again implying a unique direct interaction between boronic acid-containing inhibitors and cysteine.

In summary, we uncovered a novel mechanism of resistance to boronic acid-containing proteasome inhibitors with straightforward possibilities to reverse resistance. This work has clinical implications for cancer treatment, especially those with ATF4 or NRF2 stabilization which both drive cysteine accumulation in a SLC7A11-dependent manner.

#1789 RNA isoform discovery and quantification with SMART-Seq® mRNA Long Read (v1 and v2) kits.

Jackson Peterson[1], Yue Yun[1], Lisa Welter[1], Kazuo Tori[1], Alan Du[1], Yana Ryan[1], Ning Ma[1], Rachana Kumar[1], Shiyi Yin[1], Mike Covington[1], Shuwen Chen[1], Elena Shagisultanova[2], Mohammad Fallahi[1], Bryan Bell[1], Andrew Farmer[1]

[1]Takara Bio USA, Inc., San Jose, CA,[2]Department of Medicine/Medical Oncology, University of Colorado, Aurora, CO

RNA serves a central role in biology by converting genomic information into effector molecules, either as functional non-coding RNAs or as protein-coding mRNAs. While it has long been appreciated that complex RNA transcript profiles can be produced through alternative splicing, numerous discoveries have highlighted the essential role of alternative splicing in cell and developmental biology. Furthermore, aberrant splicing has recently been linked to diseases like cancer, neurodegeneration, and autoimmunity. Of particular interest, cancer-specific splice isoforms have emerged as a potential source of neo-antigens targetable by novel immune therapeutics. Thus, understanding the expression and function of RNA isoforms has become increasingly important in cancer biology research. A current limitation of long-read RNA sequencing (LR-RNA-seq) is the requirement of large amounts of input RNA, which can be unachievable for samples such as resected tumors or sorted single cells. Here, we describe SMART-Seq® mRNA Long Read kit, a new LR-RNA-seq library preparation technology that enables full-length RNA sequencing from single cells (~10 pg RNA/cell) up to 100ng total RNA. In high-quality bulk RNA inputs, we demonstrate the ability to reliably sequence at an average read length (N50) of 2 kb and to detect full-length transcripts as long as 8 kb, enabling the discovery and quantification of novel mRNA isoforms in samples from both healthy tissues and cancer cells. Analysis of cancer cell lines with evolved resistance to targeted therapies identifies differential isoform usage associated with the evolution of cancer therapeutic resistance. We further describe an update to this technology, SMART-Seq® mRNA Long Read version 2, which expands the input range to 2µg, improves read-length performance, and enables UMI-based analysis. Comparison studies demonstrate that SMART-Seq mRNA Long Read technology substantially outperforms existing bulk and single-cell LR-RNA-seq methods. With PCR barcoding of up to 96 samples at a time, this technology will accelerate discovery as scientists catalog and study splice isoforms in both routine long read cDNA sequencing workflows and in settings where sample input is limited.

#1791 Targeting succinate dehydrogenase impairs the proliferation of ER+ breast cancer cells.

Anil Kumar Yadav, Lu Jin, Robert Clarke

The Hormel Institute, University of Minnesota, Austin, MN

Endocrine therapies (ET) for estrogen receptor positive (ER+) breast cancer directly block either estrogen biosynthesis (aromatase inhibitors) or estrogen receptor function (Fulvestrant or tamoxifen). However, due to intrinsic and acquired resistance, disease progression often resumes despite continued ET. Succinate dehydrogenase (SDH) enzyme catalyzes the reversible conversion of succinate to fumarate. It contains four different subunits and SDH assembly factor 2 (SDHAF2). In our study, we found elevated SDH enzymatic activity and protein expression of SDHB (catalytic subunit) in LCC9 (ET-resistant cells) comparison with LCC1 or MCF-7 (ET-sensitive cells). T47D-4HT (ET-resistant) also showed significantly higher protein levels of SDHB in comparison with their parental T47D-A18 cells (ET). Pharmacological inhibition of SDH activity using dimethylmalonate (DMM) reduced cell growth, colony and spheroid formation in both LCC9 and T47D-4HT. DMM treatment induced caspase-dependent apoptosis and reduced mitochondrial membrane potential in both LCC9 and T47D-4HT cells. Importantly, succinate accumulation was accompanied by HIF 1-α stabilization and SDH inhibition led to lower levels of HIF1-α, which indicates that SDH may function in the conversion of fumarate to succinate in LCC9 cells. Genetic ablation of SDHB confirmed the importance of SDH activity in growth, colony and spheroid formation of LCC9 and T47D-4HT cells. Taken together, SDH enzymatic activity is crucial for the proliferation and mitochondrial function of ET-resistant ER+ breast cancer cells. We propose that SDH is a potentially novel therapeutic target for ER+, endocrine therapy resistant breast cancer.

#1792 Comprehensive identification of factors involved in the resistance mechanism of a novel cereblon modulator in multiple myeloma cells.

Sho Osawa[1], Tomofumi Yamamoto[2], Rina Tamaru[1], Natsumi Seki[1], Maiko Matsushita[1]

[1]Keio University, Tokyo, Japan,[2]National Institute of Health Sciences, Tokyo, Japan

Background: Multiple myeloma (MM) is a hematologic malignancy characterized by clonal proliferation of plasma cells. Although novel agents such as antibody-based drugs and T cell engagers have improved outcomes, MM remains incurable and relapse is inevitable. Immunomodulatory drugs (IMiDs), including lenalidomide and pomalidomide, are central to MM therapy, but resistance frequently develops with long-term use. Cereblon modulators (CELMoDs), a new generation of IMiDs, are expected to overcome such resistance mechanisms. Mezigdomide, a novel CELMoD, demonstrated an overall response rate of approximately 40% in patients with relapsed/refractory MM (Richardson et al., *N Engl J Med*, 2023). However, early relapse after an initial response remains a clinical concern.

Methods: To elucidate the mechanisms of mezigdomide resistance, we utilized MM cell lines with differential sensitivity to the drug. Expression levels of cereblon (CRBN), IKZF1, and IKZF3—key mediators of IMiD and CELMoD activity—were analyzed by Western blotting. RNA sequencing was then performed to identify gene expression changes associated with resistance. Candidate resistance genes were further validated by RT-PCR, and comparative analyses were conducted with lenalidomide- and pomalidomide-treated cells.

Results: CRBN, IKZF1, and IKZF3 expression levels did not differ between mezigdomide-sensitive and -resistant cells. RNA sequencing revealed several differentially expressed genes potentially associated with resistance. Validation studies confirmed distinct gene expression patterns between resistant and sensitive cell lines.

Conclusions: This study provides the first insights into molecular mechanisms underlying mezigdomide resistance in MM. Identification of these candidate resistance factors may contribute to the development of predictive biomarkers and strategies to overcome CELMoD resistance.

#1793 RAC2 as a mediator of drug resistance in triple-negative breast cancer.

Antonisha R. McIntosh[1], Ngoc Voung[1], Destiny Ball[2], Perrin Black[2], Alayjha Edwards[1], Qingguo Wang[2], Amos M. Sakwe[3]

[1]Biomedical Science, Meharry Medical College, Nashville, TN,[2]Meharry Medical College, Nashville, TN,[3]Assistant Professor, Cancer Biology, Meharry Medical College, Nashville, TN

Triple-negative breast cancer (TNBC) is a highly aggressive and heterogeneous subtype of breast cancer, defined by the absence of estrogen receptor (ER), progesterone receptor (PR), and low or absent human epidermal growth factor receptor 2 (HER2) expression. The lack of these therapeutic targets limits treatment options and contributes to poor clinical outcomes. Tyrosine kinase inhibitors (TKIs) offer a targeted approach by disrupting receptor tyrosine kinase (RTK) signaling pathways that drive tumor growth and survival. However, the emergence of resistance, mediated by compensatory signaling, genetic alterations, and epithelial-to-mesenchymal transition (EMT), remains a major barrier to sustained therapeutic efficacy. In this study, we hypothesized that chronic exposure to TKIs induces transcriptional reprogramming in epithelial TNBC cells, promoting drug resistance. Using RNA sequencing, we profiled differentially expressed genes (DEGs) in control and lapatinib-resistant MDA-MB-468 cells, an EGFR/HER2-driven TNBC model. We identified 129 DEGs and validated five of the most significantly modulated genes by qPCR and Western blotting. These genes were also associated with relapse-free survival in basal-like breast cancer patients. Notably, RAC2, a small Rho GTPase, emerged as a top candidate, showing robust upregulation in resistant cells. Compared to similar small GTPases, we found that this upregulation is specific to RAC2. RAC2 expression was found to be heterogeneous across TNBC cell lines and patient-derived xenograft (PDX) models, suggesting cell type-specific regulation. Ectopic overexpression of RAC2 in MDA-MB-468 cells conferred increased viability following treatment with lapatinib and neratinib and supported the resistance of TNBC cells to neratinib significantly. Furthermore, RAC2 upregulation significantly enhanced migratory and invasive behavior, as demonstrated by Transwell migration and Matrigel invasion assays. Our findings implicate RAC2 as a novel mediator of TKI resistance in TNBC and support its potential as a therapeutic target to restore drug sensitivity in resistant TNBC cells.

#1794 m^{6}A-mediated control of kinase reprogramming in endocrine therapy-resistant breast cancer.

Attila Szenasi[1], Enakshi Sivasudhan[2], Santiago Haase[1], Austin Whitman[1], Kate D. Meyer[2], Philip M. Spanheimer[1]

[1]Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC,[2]Department of Biochemistry, Duke University School of Medicine, Durham, NC

Endocrine therapy resistance (ETR) in estrogen receptor-positive breast cancer arises through multiple adaptive mechanisms, with kinase reprogramming representing a central driver of therapeutic escape. *N*^{6}-methyladenosine (m^{6}A), the most abundant internal RNA modification, has emerged as a key regulator of RNA fate, yet its role in restructuring kinase networks during ETR is unclear. Using GLORI sequencing, a single-nucleotide-resolution method for stoichiometric m^{6}A quantification, we profiled parental, tamoxifen and exemestane resistant MCF7 derivatives. Tamoxifen-resistant cells exhibited ~2,600 m^{6}A sites with canonical DRACH motifs with widespread hyper- and hypomethylation across transcripts encoding MAPK regulators, receptor tyrosine kinases, and cell-cycle-associated kinases. Multi-omic integration including RNA-seq and quantitative proteomics indicate differentially methylated kinase mRNAs gained stability, enhanced translational efficiency and increased protein output, establishing an m^{6}A-dependent mechanism of kinase reprogramming. Resistant cells also displayed selective upregulation of m^{6}A-associated RNA-binding proteins, including YTHDF1 and IGF2BP2, consistent with a remodeled post-transcriptional landscape. Together, our findings uncover a previously underappreciated epitranscriptomic layer integrating quantitative m^{6}A dynamics and RNA-binding protein shifts that drives kinase reprogramming and promotes ETR in breast cancer.

#1795 Cooperative role of ESR1 mutations and midasin in endocrine resistance and the therapeutic potential of dual targeting.

Mounika Pamukuntla[1], Bipika Banjara[2], Manasa Kotina[3], Afia Ohemeng[4], Alicia Hudson[4], Michael Davidson[4], Jillian L. Pope[5], Selina F. Darling-Reed[6], Elizabeth Henderson[7], Simak Ali[8], Syreeta Tilghman[2]

[1]Department of Pharmacology/Toxicology, Florida A&M University, Tallahassee, FL,[2]Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL,[3]Florida A&M University, Tallahassee, FL,[4]Basic Pharmaceutical Sciences, Florida Agriculture and Mechanical University, Tallahassee, FL,[5]Department of Bilological sciences, Florida A&M University, Tallahassee, FL,[6]Assistant Professor, Florida A&M Univ. College of Pharmacy, Tallahassee, FL,[7]Hampton University, School of Pharmacy, Hampton, VA,[8]Professor of Molec. Endocrine Onc., Imperial College London, London

While most cases of estrogen receptor-positive (ER+) breast cancer initially respond to endocrine therapy, inevitably many women acquire resistance. A major hurdle hampering the response of metastatic breast cancer patients to endocrine therapy is constitutively active point mutations in the ER ligand binding domain (LBD). We previously identified midasin (MDN1), a novel ribosomal protein, which was significantly overexpressed in MCF-7 endocrine-resistant breast cancer stem cells. Additional studies also indicated that midasin was required for growth, and stemness, but there was a mutation-dependent impact of midasin inhibition on mammosphere morphology and protein expression. However, the consequences of increased MDN1 expression and *ESR1* mutations remain unclear. We hypothesize that *ESR1* mutations along with dysregulated MDN1 cooperate to alter the microenvironment and position breast cancer cells for a survival advantage. The objective of this study was to elucidate the mechanism by which midasin inhibition alters the biology of breast cancer cells with *ESR1* mutations. To address this, breast cancer patient tumor samples were queried using CPTAC, and MDN1 protein expression was significantly elevated in luminal, HER2+, and triple-negative tumors compared with normal breast tissue. In a metastatic breast cancer cohort (n = 379), 10% of patients exhibited alterations in MDN1, whereas 25% exhibited ESR1 alterations, primarily amplifications and missense mutations. A significant co-occurrence ($\log_2$ OR = 1.60; q = 0.027) between these alterations suggested functional interplay between midasin and ER signaling. Molecular docking identified Rbin-2 as a compound interacting with midasin (docking score: –5.70). Proliferation assays using MCF-7 wild-type, MCF-7^{D538G}, and MCF-7^{Y537S} cells showed that 12 µM Rbin-2 produced ~50% growth inhibition. In 3D spheroid assays, Rbin-2 significantly decreased invasion, disrupted spheroid integrity, and promoted cell death, particularly in ER-mutant cells. Given these results and the clinical data, we examined co-targeting ER point mutations and midasin. Cells treated with 12 µM Rbin-2 plus 2.5–10 µM elacestrant exhibited ~79% growth inhibition. Combination Index analysis showed the strongest synergy in MCF-7^{Y537S} and MCF-7^{D538G} cells compared with the wildtype cells. Immunoblots demonstrated that elacestrant reduced ER and midasin expression, while the combination produced a synergistic decrease in MDN1, supporting a cooperative mechanism between ER signaling and midasin. Overall, our results indicate that aberrant ESR1 activity and elevated MDN1 cooperate to drive aggressive tumor phenotypes, and that simultaneous inhibition of ER and midasin may offer a novel therapeutic avenue for patients with ESR1-mutant, endocrine-resistant breast cancer.

#1796 Lineage-specific survival vs proliferative enzalutamide resistance states as potential drivers of prostate cancer disparities.

Richard Van[1], Mira V. Han[1], Desh P. Sharma[2], Ajay Singh[3], **Ranjana Mitra**[4]

[1]University of Nevada Las Vegas, Las Vegas, NV,[2]U.S. Department of Veterans Affairs, Las Vegas, NV,[3]Cancer Center and Research Institute, Department of Cell and Molecular Biology, University of Mississippi Medical Center, Jackson, MS,[4]Roseman Univ. of Health Sciences, Las Vegas, NV

African American (AA) men bear a disproportionate burden of prostate cancer, exhibiting higher incidence and mortality rates than their non-Hispanic White American (NHWA) counterparts. Therapeutic resistance is a major driver of prostate cancer-related mortality, and AA patients often show poorer responses to available treatments. Enzalutamide is a second-generation androgen receptor signaling inhibitor widely used to treat advanced metastatic prostate cancer. To investigate lineage-specific mechanisms of enzalutamide resistance, we generated resistant derivatives of the AA-origin MDAPCa2b and the NHWA-origin LNCaP cell lines by gradually increasing enzalutamide exposure. We then performed RNA sequencing-based transcriptomic profiling and integrated gene set enrichment analysis (GSEA), overrepresentation analysis (ORA), and KEGG pathway analysis. Comparison of Enz-R cells with their respective parental lines identified several resistance-associated differentially expressed genes (DEGs), revealing lineage-specific transcriptional programs. Notably, MDAPCa2b Enz-R cells exhibited a robust survival program characteristic of aggressive, therapy-refractory prostate cancer. Although these cells retained a measurable proliferative capacity, they adopted a persister-like, metabolically minimized state, marked by the coordinated downregulation of oxidative phosphorylation, glycolysis, pentose phosphate pathway, amino acid and tRNA biosynthesis, ribosome biogenesis, and proteasomal activity. KEGG analysis revealed apoptosis suppression, including loss of TRAIL/TNFRSF10 signaling and reduced CASP10, BID, and TP53. This combination of metabolic quiescence and anti-apoptotic protection reflects a survival-optimized phenotype associated with lineage plasticity, therapeutic tolerance, and the aggressive disease trajectories commonly observed in AA prostate cancer. In contrast, Enz-R LNCaP cells exhibited a distinct proliferative resistance state, marked by coordinated upregulation of cell-cycle progression, DNA replication, homologous recombination, mismatch and base-excision repair, p53 signaling, and pyrimidine metabolism. Immune response and adhesion pathways were broadly downregulated, consistent with an immune-evasive, AR-independent phenotype. This proliferative remodeling represents a canonical escape route driven by AR bypass and strengthened genome maintenance pathways. Together, these findings highlight two distinct resistance strategies: a survival-optimized, metabolically repressed, apoptosis resistant program in MDAPCa2b cells and a proliferative, DNA-repair enhanced program in LNCaP cells. These biologically divergent trajectories may contribute to observed clinical disparities and underscore the need for tailored, lineage-informed therapeutic strategies.

#1798 Nicotinamide phosphoribosyltransferase (NAMPT) inhibitor-resistant rhabdomyosarcoma (RMS) models exhibit alterations in metabolic and genomic profiles.

Ariana Elizabeth Nelson[1], **Abantika Chakraborty**[2], David Bell[3], Victor J. Collins[2], Ali Mokhtar Mahmoud[2], Ying Wu[4], SOPHIA VARRIANO[2], Arnulfo Mendoza[5], Sameer Issaq[6], Parthav Jailwala[4], Jack F. Shern[7], Ernesto Suarez[3], Joseph Ivanic[3], Christine M. Heske[8]

[1]National Cancer Institute Center for Cancer Research,[2]Pediatric Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD,[3]Advanced Biomedical Computational Science, Frederick National Laboratory for Cancer Research, Frederick, MD,[4]Advanced Biomedical Computational Science, Frederick National Laboratory for Cancer Research,, Frederick, MD,[5], National Cancer Institute, National Institutes of Health, Bethesda, MD,[6]National Cancer Institute, Bethesda, MD,[7]Pediatric Oncology,NIH, NCI-CCR, Bethesda, MD,[8]Pediatric Oncology Branch, National Cancer Institute, National Institutes of Health,, Bethesda, MD

RMS is a common pediatric soft tissue sarcoma for which new therapies are critically needed. We previously demonstrated that RMS is highly sensitive to inhibitors of NAMPT, which catalyzes the rate-limiting step of the NAD^+ salvage pathway and is the only pharmacologically targetable NAD^+ production enzyme. Treatment with the NAMPT inhibitor OT-82 results in complete tumor regressions *in vivo,* however, upon intermittent treatment, acquired resistance develops in some models. As acquired drug resistance is a known impediment to the clinical efficacy of targeted agents, we sought to elucidate potential mechanisms of OT-82 resistance in RMS. Mice with orthotopic fusion-positive (FP) and fusion-negative (FN) RMS xenograft tumors were treated with OT-82 for 8 weeks on the clinical dosing schedule. After stopping treatment, mice were observed for recurrence and retreated when tumors regrew to >900 mm^3. Tumors that progressed on treatment were harvested and converted to cell lines. Two resistant cell lines (1 FP - Rh30-mRes and 1 FN - RD-mRes) were selected for further study. Incucyte live cell analysis confirmed retention of OT-82 resistance *in vitro* with resistant cells maintaining proliferation at doses of OT-82 up to 30X above the IC_{50} of parental cells. Resistant cells exposed to OT-82 maintained ATP levels consistent with that of untreated controls. After 24h of OT-82 treatment, NAD^+ loss was observed in both parental and resistant cells, however resistant cells recovered NAD^+ levels within 48-96h. Effects on glucose metabolism, measured using extracellular flux and metabolomic analyses demonstrated that in the presence of OT-82, only resistant cells maintained glycolytic function. Specifically, metabolites downstream of the NAD^+-dependent enzyme glyceraldehyde-3-phosphase dehydrogenase were reduced in parental cells but maintained in resistant cells. Analysis of protein expression of NAD^+ synthesis enzymes NAMPT, NAPRT, and QPRT revealed that Rh30-mRes expresses more QPRT, however, genetic silencing of *QPRT* did not reverse resistance, suggesting upregulation of compensatory NAD production enzymes is not a primary mechanism of resistance. Whole exome sequencing revealed that each resistant cell line has a distinct, previously unreported mutation in *NAMPT*. Protein modeling suggests each mutation affects the drug binding pocket of NAMPT, with the S17F variant in Rh30-mRes resulting in a collapse of the pocket and the S241C variant in RD-mRes reducing binding affinity of OT-82. These findings are consistent with functional studies demonstrating that Rh30-mRes is resistant to multiple other NAMPT inhibitors whereas RD-mRes is resistant only to OT-82. Together, these data suggest that acquired resistance to NAMPT inhibitors in RMS models involves the development of mutations in the target protein affecting drug binding and affinity.

#1799 Ferroportin mediates bevacizumab resistance and ferroptosis evasion in ovarian cancer.

Zonghao Tang[1], Amir A. Jazaeri[1], Weiche Wu[1], Mark Kim[2], Shannon N. Westin[3], Timothy A. Yap[1], Sanghoon Lee[1], Anil K. Sood[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Gynecologic Oncology and Reproductive Medicine, UT MD Anderson Cancer Center, Houston, TX

Adaptive drug resistance remains a major barrier in cancer therapy, driving poor patient outcomes. Bevacizumab (Bev) is a mainstay of ovarian cancer (OC) treatment, yet prolonged exposure frequently leads to resistance and diminished clinical benefit. Understanding the mechanisms underlying Bev response and tumor adaptation is therefore critical for improving therapeutic strategies. To investigate these mechanisms, we established a SKOV3 Bev-resistant tumor model. RNA-seq analysis revealed that two ferroptosis-inhibitory genes, *SLC40A1* (fold change 4.01) and *AKR1C2* (fold change 3.81) among the top five differentially expressed genes, implicating ferroptosis regulation as a potential determinant of Bev sensitivity. Consistently, public datasets indicate that OC cells with high *SLC40A1* expression are resistant to ferroptosis, whereas low SLC40A1 correlates with ferroptosis susceptibility. In vitro experiments further demonstrated that OC cell lines with elevated *SLC40A1* levels exhibit reduced labile iron pools and enhanced ferroptosis resistance. Likewise, Bev-resistant OVCAR5 and OVCAR8 cell lines derived from in vivo models showed significant upregulation of ferroportin (FPN), the protein encoded by SLC40A1, compared to parental controls. Pharmacologic inhibition of FPN increased labile iron across multiple OC cell lines, and the FPN inhibitor VIT-2763 markedly sensitized Bev-resistant cells to ferroptosis ($P<0.01$). Proteiomic profiling revealed that Bev-sensitive tumors accumulate higher levels of polyunsaturated fatty acids and lower glutathione ($P<0.05$) compared with both untreated controls and resistant tumors. Collectively, these findings indicate that Bev induces ferroptosis in OC models, while tumor-associated upregulation of FPN enables escape from this lethal stress. These data highlight FPN as a promising therapeutic target to overcome Bev resistance.

#1800 Mitochondrial dysfunction induces asparaginase resistance in R-spondin fusion colorectal cancer.

Su Hyun Lee, Yun-Cheol Chae, Alejandro Gutierrez

Department of Oncology, St. Jude Children's Research Hospital, Memphis, TN

Improved therapies are required for the thousands of patients who die of colorectal cancer (CRC) every year. We previously found that asparaginase, a cancer therapeutic that degrades asparagine, has efficacy in R-spondin fusion CRCs because these fusions block upregulation of proteasomal protein degradation, a source of intracellular amino acids, when asparagine is lacking from the environment (Hinze et al., Cancer Discovery, 2020). To anticipate mechanisms of treatment resistance that may emerge, we applied a CRISPR-based genetic screen to identify modifiers of asparaginase response in R-spondin fusion CRC. We found that guide RNAs targeting multiple mitochondria-localized proteins were enriched in asparaginase-treated cells, as these genes comprised 59% of the top 100 “hits” on the screen. This finding suggested that impairing mitochondrial function induces asparaginase resistance, which was surprising because mitochondrial function is required to produce intracellular aspartate, a key substrate for asparagine biosynthesis. Indeed, in R-spondin fusion CRC driven cells, we confirmed that shRNA knockdown of multiple mitochondrial factors, or a pharmacologic inhibitor of mitochondrial translation, each induced asparaginase resistance. Mitochondria contain >1100 proteins, 99% of which are nuclear-encoded, cytoplasmically-synthesized, and then imported into mitochondria. We found that induction of mitochondrial dysfunction led to a marked increase in total K48-linked polyubiquitinated proteins, along with cytoplasmic accumulation of multiple nuclear-encoded mitochondria proteins. Our findings support the model that triggering mitochondrial dysfunction impairs mitochondrial import of nuclear-encoded mitochondrial proteins, which are then degraded via the ubiquitin proteasome system. This provides an alternative mechanism through which these cells can increase protein degradation despite expression of the R-spondin fusion. Protein degradation releases free amino acids, providing these cells with a catabolic source of intracellular asparagine that allows them to survive during asparaginase-induced depletion of asparagine. Our findings provide a molecular understanding of how the failure of import of mitochondrial proteins may be an anticipated mechanism of resistance to asparaginase in patients.

#1801 *H. pylori* infection induces WEE1 to promote drug resistance in gastric adenocarcinoma.

Md Obaidul Islam[1], Krishnapriya Thangaretnam[2], Jialun Lyu[1], Zhenzhen Zhang[3], Heng Lu[2], Dunfa Peng[3], Nadeem Sidiq Bhat[3], Mohammed Soutto[3], Wael El Rifai[3], Zheng Chen[3]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]University of Miami, Miami, FL,[3]University of Miami, Miller School of Medicine, Miami, FL

Background: Gastric cancer (GC) is the 5th leading cause of cancer-related mortality worldwide, with a poor prognosis and frequent resistance to therapy. Identifying key molecular drivers of this resistance and novel therapeutic vulnerabilities is urgently needed. This study investigates the non-canonical role of the nuclear kinase WEE1 in GC progression and drug resistance, particularly in the context of *Helicobacter pylori (H. pylori)* infection.

Methods: Integrative analyses of over 2,000 gastric cancer patient samples from various datasets, cell line models, and patient-derived xenografts (PDXs) were employed to elucidate WEE1-associated signaling pathways. Gene set enrichment analysis (GSEA) was conducted to identify transcriptional programs associated with high WEE1 expression. Functional validation was performed using siRNA knockdown, overexpression, Western blot, RT-qPCR, immunofluorescence, and *in vivo* xenograft models. A high-throughput screen of 892 FDA-approved drugs was conducted to identify effective drug combinations with the WEE1 inhibitor MK1775.

Results: WEE1 was found to be aberrantly overexpressed and mis-localized to the cytoplasm in gastric cancer cells. GSEA across 14 datasets consistently showed enrichment of MYC and E2F target genes in WEE1-high tumors. Mechanistically, WEE1 activated E2F1 through the phosphorylation of RB, leading to the transcriptional upregulation of MYC. MYC, in turn, enhanced expression of WEE1 and E2F1, forming a feedforward oncogenic loop. Notably, *H. pylori* infection robustly induced WEE1 and MYC expression, as well as their downstream effectors, linking microbial etiology to transcriptional reprogramming and tumor progression. Targeting WEE1 with MK1775 suppressed MYC-driven transcriptional activity, reduced anti-apoptotic gene expression (BCL2, BCL2L1), and sensitized GC cells to DNA-damaging agents. A high-throughput screen identified Afatinib, an EGFR/HER2 inhibitor, as a potent synergistic partner with MK1775. Combination therapy demonstrated enhanced anti-tumor efficacy *in vitro*, in PDX models, and in 3D organoid systems derived from GC patients.

Conclusions: This study identifies a novel *H. pylori*-WEE1-E2F1-MYC signaling axis that contributes to GC pathogenesis and resistance. Given the lack of clinically available MYC inhibitors, targeting WEE1 provides a promising alternative approach. The discovery of synergistic efficacy with Afatinib supports a new therapeutic strategy for overcoming resistance in MYC-driven gastric cancer.

#1802 Fibroblast-driven tamoxifen resistance in ER+ breast cancer: Experimental validation and development of a high-throughput co-culture screening assay.

Elisabet Rodriguez-Tomas[1], Francesco Massai[2], Arne Ostman[1]

[1]Karolinska Institutet, Stockholm, Sweden,[2]SciLifeLab, Stockholm, Sweden

New strategies are needed to overcome tamoxifen resistance in ER+ breast cancer. While the contribution of the tumor microenvironment to drug resistance remains incompletely understood, fibroblasts have emerged as potential therapeutic targets, due to their ability to modulate tumor behavior and drug sensitivity via paracrine signaling, extracellular matrix remodeling, and immune regulation. This study aimed to validate the protective role of fibroblasts against tamoxifen and to establish a co-culture assay suitable for high-throughput drug screening.

We first performed functional assays to assess fibroblast-mediated protection using human ER+ breast cancer (MCF-7) and human fibroblast (BJhTERT) cell lines. Flow cytometry experiments with the CD140 marker distinguished BJhTERT (CD140+) from MCF-7 (CD140-) in co-culture and revealed that tamoxifen induced close to 90% cell death in MCF-7 monocultures measured by a viability dye 7-AAD (7-aminoactinomycin D), whereas only 25% of MCF-7 cells died under co-culture conditions with BJhTERT. In parallel, qPCR analysis confirmed that tamoxifen downregulated proliferative (CCND1) and estrogen response (ESR1, PGR, TFF1, GREB1) genes.

Building on these findings, we developed a high-throughput co-culture assay. MCF-7 and BJhTERT cells were transduced with mCherry and GFP lentiviral reporters, respectively, and seeded into 384-well plates at optimized densities (500 and 1,000 cells/well). Cells were treated with tamoxifen or DMSO, fixed at defined time points, and mCherry, GFP, and Hoechst nuclear stain signals were analyzed using high-content imaging. Sixteen hours post-seeding was chosen as the optimal time for treatment initiation. Over that time, MCF-7 monocultures showed a fold change of 1.3 (30% increase) in cell numbers relative to the initial count, whereas MCF-7 in co-culture showed a fold change of 1.9 (90% increase), indicating a significantly greater growth-promoting effect of fibroblasts. Tamoxifen at a concentration of 20 µM reduced MCF-7 cell numbers by 63% in monoculture versus 38% in co-culture, confirming the protective stromal effect.

In conclusion, our experiments validate fibroblast-ER+ breast cancer crosstalk as a mechanism of tamoxifen resistance. Furthermore, the development of a co-culture-based high-throughput assay, that models fibroblast-mediated tamoxifen resistance, provides a platform for novel screening strategies aimed at targeting the tumor-stroma interactions in ER+ breast cancer.

#1803 Dynamic copy number changes and *de novo* generation of extrachromosomal DNA modulate therapy resistance.

[1]DKFZ German Cancer Research Center, Heidelberg, Germany,[2]German Cancer Research Center/HI-STEM, Heidelberg, Germany,[3]3Genome Biology Unit, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany,[4]Genome Biology Unit, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany,[5]4Division of Cancer Genome Research, German Cancer Research Center, Heidelberg, Germany,[6]Division of Cancer Genome Research, German Cancer Research Center, Heidelberg, Germany,[7]HI-STEM gGmbH, Heidelberg, Germany,[8]DKFZ German Cancer Research Center/HI-STEM, Heidelberg, Germany,[9]Gynecologic Oncology, National Center for Tumor Diseases (NCT), Heidelberg, Germany,[10]National Center for Tumor Diseases (NCT), University of Heidelberg, Heideberg, Germany,[11]Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM gGmbH), Heidelberg, Germany,[12]Institute of Pathology, Heidelberg University Hospital (UKHD), Heidelberg, Germany,[13]Heidelberg University Hospital (UKHD), Heidelberg, Germany,[14]6Division of Molecular Genetics, German Cancer Research Center (DKFZ), Heidelberg, Germany,[15]Gynecologic Oncology,, National Center for Tumor Diseases (NCT), Heidelberg, Germany,[16]Institute of Human Genetics, University Heidelberg,, Heidelberg, Germany,[17]Computational Cancer Genomics, German Cancer Research Center (DKFZ), Heidelberg, Germany,[18]Division of Cancer Genome Research, German Cancer Research Center (DKFZ), Heidelberg, Germany,[19]German Cancer Research Center, Heidelberg, Germany

Extrachromosomal DNA (ecDNA) is increasingly recognized as a driver of cellular plasticity, yet its role in therapy adaptation in pancreatic ductal adenocarcinoma (PDAC) remains poorly defined. In patient-derived PDAC models, we identify extrachromosomal ABCB1 amplification as a mechanism of resistance to paclitaxel and KRAS inhibitors and show that ABCB1 copy number dynamically adjusts to selective pressure. Notably, paclitaxel-resistant cells remain primed for rapid de novo ecDNA generation: after eliminating pre-existing ABCB1 ecDNA through single-cell cloning, new and structurally distinct ABCB1 ecDNA rapidly emerges, indicating treatment-induced molecular changes that prime these cells for ecDNA formation. In metastatic breast cancer, taxane-associated ABCB1 amplification is likewise observed and can be tracked in cell-free DNA (cfDNA), underscoring clinical relevance beyond PDAC. Finally, gemcitabine co-treatment suppresses ABCB1 ecDNA generation, suggesting potential strategies to counteract ecDNA-mediated resistance. Together, these findings demonstrate that dynamic ecDNA modulation and inducible ecDNA biogenesis enable rapid, reversible drug resistance, providing a rationale for ecDNA-targeted combination therapies and longitudinal monitoring.

#1804 Midasin inhibition disrupts the sumoylation axis to impair mammosphere stability through alteration of transcriptional network.

Bipika Banjara[1], Mounika Pamukuntla[2], Manasa Kotina[2], Afia Ohemeng[2], Alicia Hudson[3], A. Michael Davidson[3], Jillian L. Pope[4], Selina F. Darling-Reed[5], Syreeta Tilghman[6]

[1]Basic Pharmaceutical Sciences, Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL,[2]Florida A&M University, Tallahassee, FL,[3]Basic Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL,[4]Biological Sciences, Florida A&M University, Tallahassee, FL,[5]Assistant Professor, Florida A&M Univ. College of Pharmacy, Tallahassee, FL,[6]Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL

Endocrine resistance remains a major barrier to effective treatment of estrogen receptor–positive (ER+) breast cancer, necessitating identification of molecular drivers that sustain tumor growth, plasticity, and cancer stem cell (CSC) associated phenotypes. Midasin (MDN1), a key regulator of ribosome biogenesis, is elevated in endocrine-resistant tumors, yet its contribution to aromatase inhibitor (AI) resistance is not well defined. Here, we examined differential responses to MDN1 inhibition in AI-sensitive AC-1 and AI-resistant LTLT-Ca cells cultured in 2D and 3D. Basal characterization showed higher aromatase (1.2-fold) and ERα (1.6-fold) expression in AC-1 cells, while LTLT-Ca cells exhibited 7-fold and 3.85-fold increase in EGFR and HER2, respectively, with further EGFR and HER2 amplification (up to 4-fold) in 3D mammosphere. Although MDN1 levels were higher in AC-1 cells under 2D conditions, MDN1 was enriched in LTLT-Ca mammosphere, linking elevated ribosome biogenesis to the resistant, stem-like phenotype. Treatment with the MDN1 inhibitor, Rbin-2 (18 μM) significantly reduced MDN1 expression and disrupted spheroid architecture in both models. AC-1 spheroids displayed moderate size reduction (1010.5 μm² to 731.7 μm² by day 12), whereas larger LTLT-Ca spheroids (1204.5 μm²) became fragmented and irregular (1539.3 μm²), indicating structural collapse rather than shrinkage. Acridine Orange/Ethidium Bromide staining revealed a 65% decrease in the live-to-dead fluorescence ratio in AC-1 versus 14% in LTLT-Ca, consistent with extensive degeneration in sensitive cells and instability in resistant spheroids. Spheroid invasion assays showed modest reduction in matrix outgrowth in both AC-1 and LTLT-Ca after Rbin-2 exposure. LTLT-Ca mammospheres expressed elevated OCT4 and SOX2, which decreased by 49% and 45% respectively, following MDN1 inhibition, implicating MDN1 in sustaining CSC transcriptional networks. Analysis of SUMOylation dynamics revealed intrinsically higher SUMO2/3 in resistant cells, with a further increase upon Rbin-2 treatment, consistent with decreased midasin associated cell death. Conversely, the deSUMOylase SENP3, also elevated in resistant cells, was reduced by Rbin-2 in both lines. This increase in SUMO2/3 coupled with decreased SENP3 reflects MDN1-dependent disruption of homeostasis and aligns with reduced ALDH1A1 and loss of CSC properties. Collectively, these findings identify a SUMO2/3–SENP3–MDN1 regulatory axis that supports, stemness and invasiveness in AI-resistant breast cancer, and demonstrate that MDN1 inhibition disrupts this axis to impair mammosphere integrity, attenuate CSC programs, and suppress invasion. This work establishes MDN1 as a promising therapeutic vulnerability for overcoming AI resistance.

#1805 Ancestry-dependent differences of PASK (Per-Arnt-Sim Kinase) inhibitor efficacy in triple-negative breast cancer under variable glucose conditions.

Ayomide Olayiwola, Sree Aramgam, K. Sean Kimbro

Morehouse School of Medicine, Atlanta, GA

Breast cancer mortality rates are nearly 40% higher in African American women than in women of European ancestry. A major contributor to this outcome is triple-negative breast cancer (TNBC), which disproportionately affects African American women and is associated with more aggressive disease. Per-Arnt-Sim Kinase (PASK) is a nutrient-sensitive protein kinase that regulates glucose and lipid metabolism. Previous studies have shown that PASK plays a significant role in breast cancer progression by promoting tumor growth through several metabolic and signaling pathways. Preliminary evidence suggests that the PASK inhibitor, BioE-1115, exhibits differential efficacy across TNBC cell lines of distinct ancestral backgrounds across varying glucose levels. TNBC cell lines representing African ancestry (HCC-1806 and MDA-MB-468) and European ancestry (MDA-MB-231) were cultured in media containing physiologically relevant glucose concentrations representing hypoglycemia (2.5 mM; 45 mg/dL), normoglycemia (5.5 mM; 100 mg/dL), hyperglycemia (11 mM; 198 mg/dL), and severe hyperglycemia (17.5 mM; 315.1 mg/dL). Cell viability assays were performed following BioE-1115 treatment to quantify ancestry- and glucose-dependent differences in the response to the inhibitor. Half-maximal inhibitory concentration (IC_{50}) values were calculated for each condition. BioE-1115 demonstrated distinct efficacy profiles across TNBC cell lines. The African-ancestry HCC-1806 and MDA-MB-468 cells displayed markedly reduced sensitivity to BioE-1115, with IC_{50} values 1.3x-1.5x higher compared with the European-ancestry MDA-MB-231 cells under equivalent glucose conditions. Variability in inhibitor response was observed across glucose concentrations, indicating that metabolic state modifies PASK inhibitor efficacy. PASK inhibition preliminarily suggests ancestry-dependent differences in therapeutic response that are further modulated by glucose availability. These findings highlight the importance of integrating ancestry-informed genetic and metabolic context when evaluating targeted metabolic therapies for TNBC. This work provides foundational data supporting the need for precision-oncology approaches that consider both ancestry-linked biology and metabolic stressors.

#1806 WRN under the scalpel: Helicase-domain hotspot & splice-site knock-ins in HCT116 and RKO.

Yue Huang, Xiaomeng Gou, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., LTD, Beijing, China

The WRN helicase is a synthetic-lethal vulnerability in microsatellite-instability-high (MSI-H) tumors, yet allele-specific resistance is a foreseeable risk as small-molecule WRN inhibitors advance. Endogenous point-mutation models, built in the native regulatory context, more faithfully capture drug-target engagement and pathway compensation than overexpression systems. Such models enable rigorous mechanism-of-action confirmation, resistance-liability mapping, chemotype backup selection, patient-stratification/biomarker hypotheses, and faster SAR and combination design.Across isogenic HCT116 and RKO models, two WRN-targeting chemotypes diverged at specific liability nodes. WT HCT116 was highly sensitive (VVD-214 48.47 nM; HRO761 86.89 nM), and baseline RKO remained responsive (366/720 nM). C727 dictated VVD-214 resistance: C727A drove VVD-214 to >10 μM while preserving near-WT HRO761 (153-179 nM); C727S pushed HRO761 to 2.1-3.5 μM and VVD-214 to >10 μM; in RKO-C727S, both exceeded 10 μM. I852F showed the reciprocal pattern—VVD-214 stayed potent (62-77 nM) but HRO761 was inactive (>10 μM). G729D and F730L caused bilateral right-shifts, larger for HRO761 (VVD-214 0.71-1.34 μM; HRO761 2.9-8.0 μM); combining G729D+I852F abolished HRO761 (>10 μM) while VVD-214 remained sub-μM (0.78-0.82 μM). The splice variant c.1577-1G>C was hypersensitive to VVD-214 (36-37 nM) yet right-shifted for HRO761 (~1.11 μM). Collectively, C727 → VVD-214 resistance and I852 →HRO761 resistance, while G729/F730/splice confer a broader HRO761 bias—guiding chemotype switching and backup selection.Alleles were introduced by CRISPR-Cas9 HDR using ~200-nt ssODN donors; single-cell clones were sequence-verified (Sanger/NGS), STR-authenticated, and mycoplasma-free banked. Dose-response viability assays (72-96 h, 10-point curves) were fit with four-parameter logistic models to derive IC_{50}; each clone included n≥2-3 biological replicates. This WRN allele panel is immediately deployable to (1) build allele-resolved resistance maps, (2) prioritize chemotype backups based on the C727/I852 complementarity, (3) generate patient-selection/biomarker hypotheses for MSI-H settings, and (4) accelerate SAR and combination strategies—thereby front-loading chemical and clinical derisking for VVD-214- and HRO761-class WRN inhibitors.

#1807 RLIP depletion suppresses ovarian cancer growth and metastasis.

Sharad S. Singhal[1], Madhu Krishna[1], Prakash Kulkarni[2], David Horne[2], Ravi Salgia[2]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]Beckman Research Institute of City of Hope, Duarte, CA

Ovarian tumor metastasis is a leading cause of cancer-related deaths worldwide. Ovarian cancer (OC) cells frequently metastasize to the peritoneum. OC cells, after detaching from the primary tumor, can float in the ascitic fluid (fluid that accumulates in the abdominal cavity due to cancer) and attach to the peritoneum, the lining of the abdominal cavity. Peritoneal metastasis is strongly linked to poor prognosis in OC patients. In the current study, we evaluated the anti-proliferative and anti-metastatic effects of RLIP inhibition in an array of OC cell lines and an orthotopic mouse model of ovarian metastasis. Compared to control treatment, RLIP inhibition and/or depletion reduced *in-vitro* cell viability and suppressed the migratory and invasive potential of OC cells. Further, mice intraperitoneally implanted with luciferase-expressing HeyA8 OC cells were treated with RLIP antisense (RAS; 4 mg/kg, b.w.), RLIP antibody (Rab; 4 mg/kg, b.w.) or a combination of RAS+Rab. RAS-, and Rab-treated mice exhibited significantly lower primary tumor weight and reduced metastasis compared to control mice. Mice treated with a combination of RAS+Rab exhibited no metastasis and significantly lower tumor weight than the single agent-treated mice. *In-vivo* studies showed that the RLIP targeting agent's treatment prolonged the survival of NSG mice inoculated with HeyA8-luc OC cells. Collectively, our results suggest that RLIP antisense has potential to be combined with RLIP antibodies to more effectively suppress primary ovarian tumor growth and metastasis to the peritoneum that warrants further investigation. (This work was supported in part by the Department of Defense grant W81XWH-22-1-0331. Funding from the Beckman Research Institute of City of Hope is also acknowledged).

#1808 METTL7A and METTL7B confer resistance to the oral thiol-based histone deacetylase inhibitor ST7612AA1.

Omotola D. Gbadegesin, Robert W. Robey, Michael M. Gottesman

Laboratory of Cell Biology, Center for Cancer Research, National Cancer Institute, Bethesda, MD

As modulators of chromatin structure and gene expression, histone deacetylase (HDAC) inhibitors are emerging as an important class of epigenetic therapeutics in cancer treatment. These agents exert their activity by targeting HDAC enzymes, primarily through zinc-binding groups (ZBGs) that chelate the catalytic zinc ion essential for HDAC function. The FDA-approved HDAC inhibitor, romidepsin, and some pre-clinical HDAC inhibitors, including ST7612AA1, KD-5170, and NCH-51, are prodrugs that are converted to their active forms containing thiol as ZBGs. We have previously shown that the sulfhydryl methyltransferases, METTL7A and METTL7B, cause the methylation and subsequent detoxification of thiol-containing compounds, including romidepsin. The goal of this study is to evaluate METTL7A and METTL7B as drivers of resistance to ST7612AA1 in the HepG2 liver cancer cell line. Parental HepG2 cells were selected with ST7612AA1 and valspodar continuously for 3 months to generate ST7612AA1-resistant HepG2 cell lines. The resulting resistant cell lines were characterized using cell proliferation, colony formation, and ATP-based viability assays. The expression of METTL7A and METTL7B by the resistant cells was validated by Western blotting. Our result shows that HepG2-STV50, the ST7612AA1-resistant liver cancer cell line that was selected with 50 micromolar ST7612AA1 and 1 micromolar valspodar, had approximately 80% confluency 6 days post-incubation with 10 micromolar ST7612AA1 and showed 8.7-fold resistance to ST7612AA1, compared to the parent HepG2 cell line. HepG2-STV50 also showed cross-resistance (6.7-fold compared to HepG2) to romidepsin. To compare the effect of METTL7A and METTL7B expression on ST7612AA1 in other cell lines, HT1080 cells transfected with METTL7A and METTL7B were treated with ST7612AA1 and KD5170. Compared to the empty vector-transfected HT1080 cells, the METTL7A-overexpressing cells were more resistant (100-fold) than the METTL7B-overexpressing cells (10-fold). Similarly, MCF-7DpVp300, an MCF-7-derived resistant breast cancer cell line that highly expresses METTL7A, which was selected with romidepsin in the presence of the P-gp inhibitor verapamil, showed approximately 100-fold resistance to ST7612AA1 and KD5170, compared to the parent MCF-7 cell line. The ST7612AA1-resistant HepG2 cell lines overexpressed METTL7B more than METTL7A. Since METTL7B does not confer as much resistance as METTL7A, it may be responsible for the relatively low-fold resistance seen for the ST7612AA1-resistant HepG2-STV50 cells compared to the parental HepG2 cells. While HDAC inhibitors have been effective against T-cell lymphomas, they have not shown success in treating solid tumors. This work establishes METTL7A and METTL7B overexpression as a novel mechanism of resistance to thiol-containing HDAC inhibitors and a potential target for the treatment of solid cancer types.

#1813 A sensitive MSD-ECL platform for in vivo pharmacokinetic profiling of ADCs.

Carla N. Castro, Jonas Hummel, Philipp Metzger, Cynthia Obodozie, **Holger Weber**

Reaction Biology Europe GmbH, Freiburg, Germany

Antibody-drug conjugates (ADCs) are a rapidly evolving class of targeted cancer therapeutics that combine the specificity of monoclonal antibodies with the potency of small-molecule cytotoxic drugs. It is critical for ADCs to be stable in the systemic circulation in order to prevent premature release of the payload, which can lead to off-target toxicity and reduced therapeutic efficacy. The pharmacokinetic (PK) behavior of ADCs is influenced by several factors, such as antibody structural heterogeneity, linker type, and payload physicochemical properties. Stability is a key quality attribute that directly affects dosing strategies, the therapeutic window, and clinical outcomes. Therefore, robust and sensitive analytical platforms are essential for monitoring ADC integrity and payload release over time. While traditional ELISA-based methods are widely used, they often lack the sensitivity and dynamic range required to detect subtle changes in ADC composition during circulation. In this study, we use the Meso Scale Discovery® (MSD) platform, which uses plate-based electrochemiluminescence (ECL) technology, to evaluate the in vivo PK and stability of ADCs. By applying this technology to preclinical in vivo models, we aim to generate high-resolution PK profiles and stability data that support the rational design and optimization of ADCs for clinical development.
Standard 1-Spot SECTOR plates were used to detect the antibody backbone by coating them with a specific capture antibody. Small Spot Streptavidin SECTOR plates were used to detect the intact ADC, capturing the molecule via anti-payload antibodies. In both assays, detection was performed using a sulfo-tagged anti-human IgG antibody. After optimizing the setup, it demonstrated a broad dynamic range of 4-5 orders of magnitude and a lower limit of detection of less than 100 pg/mL for both the antibody and the intact ADC. Subsequent in vivo PK studies involved administering ADCs via a single intravenous injection to SCID beige mice. Serum samples were diluted 1:1000 in PBS containing 1% BSA, and 25 µL per well was applied to the MSD plates. This high dilution factor permits minimal blood volume collection per time point, thereby reducing the number of animals required. The assay demonstrated excellent reproducibility with minimal variability between replicates. To further increase the relevance of the results, future studies may use mFcRn$^{-/-}$ hFcRn transgenic mice or HSA/hFcRn/hFcγR triple transgenic models. These models more accurately reflect the serum half-life of human IgG and correlate well with data from cynomolgus monkeys and humans.
In summary, this MSD-based assay platform offers a highly sensitive and reproducible approach for in vivo PK analysis of ADCs that spares animals. There is potential to further refine this approach using humanized mouse models to improve clinical predictability.

#1814 An integrated DMPK and bioanalytical platform for comprehensive characterization of antibody-drug conjugates (ADCs).

Kefeng Gong[1], Xinhe Feng[1], Zhengyi Hua[1], Yanting Ma[1], Rui Wang[1], Xiaolong Tu[1], Luke Yu[2]

[1]Crown Bioscience, Taicang, China,[2]Crown Bioscience, Inc., San Diego, CA

Introduction: Antibody-drug conjugates (ADCs) represent a transformative class of targeted oncology therapeutics; their complex structure introduces significant challenges in characterization, necessitating a holistic DMPK strategy to understand their *in vitro* stability, *in vivo* PK and biodistribution, and biotransformation. The success of this strategy hinges on the precise quantification of key analytes—including total antibody (Tab), conjugated antibody (ADC), free payload, and the drug-to-antibody ratio (DAR)—in diverse biological matrices. Here, we present an integrated DMPK platform evaluating Trastuzumab Deruxtecan (T-DXd), Enfortumab Vedotin (EV), and Trastuzumab Emtansine (T-DM1), with distinct linkers/payloads, to delineate PK behavior and biotransformation pathways.
Methods: For three marketed ADCs, including T-DXd, EV, and T-DM1, *in vitro* plasma stability was assessed in human, monkey, rat, and mouse plasma (37 °C, 7-21 days) and followed a single 10 mg/kg i.v. dose for *in vivo* PK in naïve C57BL/6 mice. Quantitation used ligand binding assay (total and conjugated antibody), LC-MS/MS for free payload (LLOQ 10-50 pg/mL), and hybrid immunocapture LC-HRMS for DAR and biotransformation assessment.
Results: T-DXd, with a cleavable peptide linker and high baseline DAR (~7.6), demonstrated high stability *in vitro*, showing less than 40% DAR decrease (to ~4.8) over 7 days and minimal free DXd release (<2% across species). It's *in vivo* DAR gradually declined to ~4.0 by Day 14, with highly overlapped PK curves for Tab and conjugated ADC. EV, incorporating a protease-cleavable linker and a baseline DAR of ~3.5, exhibited faster degradation *in vitro*, with DAR dropping to ~1.6 and significant MMAE release (~74 ng/mL at 24 h in mouse plasma). *In vivo*, ADC levels displayed a more rapid decline than Tab, accompanied by a marked DAR decrease to ~0.5 by Day 21. T-DM1, featuring a non-cleavable thioether linker and DAR ~3.5, displayed very high plasma stability and negligible free DM1 release (<0.1 ng/mL). It's *in vivo* PK profiles for Tab and ADC were nearly identical, confirming minimal payload release in circulation. For ADCs lacking anti-payload reagents, we also developed a hybrid approach combining DAR-insensitive Tab assay with LC-HRMS-based DAR profiling. This flexible bioanalytical strategy enabled comprehensive characterization across diverse ADC formats.
Conclusion: Our integrated DMPK platform provides comprehensive and robust ADC characterization capability, promoting critical insights into ADC stability, biotransformation, and exposure profiles. This supports direct correlation between ADC design, *in vitro* properties, and *in vivo* PK behavior, thereby de-risking candidate selection and accelerating the development of novel ADC therapeutics.

#1815 Nonclinical characterization of SBE303: A nectin-4 targeted antibody drug conjugate (ADC) with novel topoisomerase 1 inhibitor shows a favorable safety margin.

Ji Yeon Kim, Sungwoo Hyung, Hyun-Ji Choi, Songhyun Lim, Jae Hee Lee, Seokuee Kim, Donghyun Kim, So-Shin Ahn, Donghoon Shin

Samsung Bioepis Co., Ltd., Incheon, Korea, Republic of

Antibody-drug conjugates (ADCs) targeting Nectin-4 have emerged as a promising therapeutic approach particularly in urothelial carcinoma (UCs). However, currently available Nectin-4 directed ADCs are often limited by narrow therapeutic index and dose-limiting toxicities. SBE303 is a novel Nectin-4 targeting ADC engineered to improve the therapeutic window by combining a highly specific anti-Nectin-4 antibody conjugated with a potent novel topoisomerase I inhibitor via a proprietary beta-glucuronide-based cleavable linker, OHPAS^{TM}.

For nonclinical characterization of SBE303, a comprehensive set of pharmacology, pharmacokinetics, and toxicology studies was performed. In vitro studies have shown that the antibody of SBE303 exhibits specific binding to the human Nectin-4. Upon binding, SBE303 internalizes into cancer cells, which then traffics to the lysosomal compartment where payload is released via beta-glucuronidase cleavage of the linker. Released payload induces DNA topoisomerase I inhibition, triggering cytotoxicity in various cancer cells.

The antitumor efficacy of SBE303 was evaluated across multiple Nectin-4 positive cell-derived xenograft models including UC. SBE303 treatment resulted in marked and statistically significant tumor growth inhibition compared to vehicle controls on week 3, supporting the broad therapeutic potential in solid cancers.

Pharmacokinetic properties were evaluated in mice, rats, and monkeys. Comparable profiles between SBE303 and total antibody showed the linker stability in systemic circulation, supported by minimal free payload exposure. Novel free payload showed low risk of drug-drug interaction potential for metabolic enzymes and drug transporters.

In repeat-dose toxicity study in cynomolgus monkeys, IV administration of SBE303 was well tolerated at 40 mg/kg/dose. No severe systemic toxicity or unexpected target-related findings were observed, including skin toxicity. SBE303-related findings were limited to minimal-to-moderate changes and were reversible at the end of the recovery period. The absence of significant histopathologic changes indicated a favorable systemic safety profile.

These nonclinical findings support the advancement of SBE303into clinical development with a favorable therapeutic index based on higher tolerated doses and wider exposure margins compared to known approved anti-Nectin4 ADC. A first-in-human study is expected to initiate in 2026.

#1816 ACSL4 mediated ferroptosis and its potential role in enhancing the efficacy of antibody-drug conjugates.

Shigehiro Koganemaru[1], Hirobumi Fuchigami[2], Hiroshi Tsugawa[3], Hiroko Shinohara[1], Yasutoshi Kuboki[1], Toshimitsu Uenaka[4], Toshihiko Doi[5], Masahiro Yasunaga[6]

[1]National Cancer Center Hospital East, Kashiwa, Japan,[2]National Cancer Ctr. Hosp. East, Kashiwa, Japan,[3]Tokyo University of Agriculture and Technology, Tokyo, Japan,[4]Eisai Co., Ltd., Tsukuba, Japan,[5]National Cancer Centre Hospital East, Kashiwa, Japan,[6]Investigative Treatment Div., National Cancer Center Hospital East, Kashiwa, Japan

Purpose: While antibody-drug conjugates (ADCs) are generally assumed to preserve the pharmacokinetic/pharmacodynamic (PK/PD) properties of their payloads, the extent to which conjugation alters their mechanism of action remains underexplored. This study investigated whether ADC conjugation can fundamentally reprogram payload pharmacology and clarified the downstream consequences for antitumor efficacy and immune activation beyond conventional delivery advantages.
Experimental Design: Using MORAb-202, an ADC consisting of the clinically approved eribulin linked to a folate receptor alpha (FRα)-targeting antibody, we performed intratumoral pharmacokinetic/pharmacodynamic (PK/PD) and pharmacometabolomic analyses in xenograft models with varying FRα expression. Intratumoral concentrations of released eribulin and phospholipid profiles were quantified by liquid chromatography-mass spectrometry. We compared effects of MORAb-202 and free eribulin on ferroptosis, immunogenic cell death (ICD), and tumor immune infiltration. Therapeutic efficacy was tested as monotherapy and in combination with pembrolizumab in a human peripheral blood mononuclear cells co-implantation model.
Results: ADC-conjugated eribulin achieved >20-fold higher intratumoral retention of eribulin compared to the free eribulin in AUC value. Metabolomics analysis revealed that MORAb-202 robustly induced ferroptosis, characterized by ACSL4 upregulation, GPX4 depletion, lipid peroxidation, and arachidonic acid remodeling. Unlike free eribulin, MORAb-202 triggered ICD, evidenced by HMGB1 expression and enhanced recruitment of total/activated/PD-1$^+$ T cells and dendritic cells. Furthermore, ferroptosis responses induced by free eribulin were reversible, whereas ADC-conjugated eribulin induced irreversible and sustained responses. The combination of MORAb-202 with pembrolizumab enhanced tumor control beyond either monotherapy.
Conclusions: ADC conjugation reprograms payload's pharmacodynamics, inducing ferroptosis and ICD unattainable with free payload, even at clinically equivalent doses. This highlights a pharmacodynamic threshold unique to the ADC formulation. These findings stress the need for intratumoral PK/PD evaluation and identify ferroptosis-linked lipid remodeling as a novel ADC mechanism, supporting rational combination with immunotherapy in precision oncology.

#1818 Overcoming resistance with OBI-902: Preclinical evaluation of a next-generation TROP2 ADC.

Ren-Yu Hsu, **Chi-Huan Lu**, Chi-Sheng Shia, Jing-Rong Huang, Hsin-Shan Wu, Lu-Tzu Chen, Jhih-Jie Yang, Tzu-Min Yen, Jyy-Shiuan Tu, Yu-Hsuan Tsao, Ya-Chi Chen

OBI Pharma, Inc, Taipei, Taiwan

Trophoblast cell surface antigen 2 (TROP2) is a clinically validated target. However, existing TROP2 ADCs show distinct toxicities, such as myelosuppression (sacituzumab govitecan) and stomatitis/interstitial lung disease (datopotumab deruxtecan). These toxicities underscore the need for safer ADCs. OBI-902 is a novel, site-specific ADC designed to address this gap. It consists of a humanized anti-TROP2 antibody conjugated to a topoisomerase I inhibitor via glycan-based site-specific platform, which generates a highly stable and homogeneous ADC optimized for enhanced antitumor activities and reduced systemic toxicity. This study investigates the exposure-response relationships to further characterize its pharmacologic and therapeutic profile.

A comprehensive preclinical data package was generated for OBI-902. The pharmacokinetic-pharmacodynamic (PK-PD) relationship was characterized to define exposure-response parameters in non-small cell lung cancer (NSCLC) xenograft models. Antitumor efficacy was evaluated across multiple dosing regimens in NSCLC models, patient-derived xenografts (PDX) from various cancer types, and cell line-derived xenografts (CDX) engineered for TROP2 resistance. The safety profile was formally established in a GLP-compliant toxicology study in non-human primates, supporting further development.

In an NSCLC xenograft model, OBI-902 exhibited a predictable and dose-proportional PK profile at doses ≥3 mg/kg, establishing a clear exposure-response relationship. This translated to durable anti-tumor activity at extended dosing intervals (3 mg/kg): the Q3W regimen induced complete regressions (CRs) in 2/5 animals by day 35, while both Q4W and Q6W regimens achieved sustained tumor stasis through day 62. OBI-902 demonstrated robust tumor growth inhibition, including regressions, across a diverse panel of ten PDX models encompassing NSCLC, triple-negative breast cancer (TNBC), and gastric cancer. To address acquired resistance, In TOP1 ADC-resistant NSCLC and TNBC CDX models, OBI-902 demonstrated superior efficacy, yielding >3-fold and >2-fold smaller mean tumor volumes, respectively, compared to the TOP1 inhibitor-based ADCs, highlighting its potential to overcome resistance. In a GLP-compliant toxicology study in cynomolgus monkeys, OBI-902 was well-tolerated with a NOAEL of 30 mg/kg, supporting a wide therapeutic index for clinical development.

OBI-902 exhibits broad and potent antitumor activity across multiple cancer models, including those resistant to prior TOP1 ADCs, along with a favorable safety profile. Taken together, these preclinical results support the clinical development of OBI-902, which is currently being evaluated in a Phase 1/2 clinical trial as a potential best-in-class TROP2-targeted ADC.

#1819 OBI-904, a glycan-based site-specific Nectin-4-targeted ADC, demonstrates potent and durable antitumor activity with an improved PK profile and overcoming EV-resistance in non-clinical studies.

Chi-Huan Lu, Ren-Yu Hsu, Jing-Jie Ciou, Tzu-Min Yen, Jyy-Shiuan Tu, Yu-Hsuan Tsao, Jing-Rong Huang, Ya-Chi Chen

OBI Pharma, Inc, Taipei, Taiwan

Nectin-4 is a type I transmembrane adhesion molecule with low expression in normal tissues but is highly overexpressed in multiple cancers. Its expression is associated with tumor proliferation, metastasis, and poor prognosis, making it a clinically validated target for ADC development. Although *Padcev* (enfortumab vedotin, EV) has demonstrated meaningful clinical benefit, safety concerns, suboptimal dosing schedules, and emerging resistance underscore the need for next-generation Nectin-4-targeted ADCs. OBI-904 is a Nectin-4-targeted ADC conjugated with the topoisomerase I inhibitor Exatecan (DAR 8) via glycan conjugation platform and dual-action enzymatic technology, designed to provide homogenous DAR, improve ADC stability, and optimal payload delivery. In vitro linker-payload stability was evaluated in human serum albumin by LC-MS. Pharmacokinetics (PK) were assessed in serum and tumor using HNSCC xenograft models. Antitumor activity was tested in CDX models of HNSCC, CRC, TNBC, prostate cancer, cholangiocarcinoma, and in PDX models of cervical and sarcoma, as well as in an EV-resistant bladder CDX model, with Padcev and ETx-22 as benchmarks. GLP toxicology studies were conducted in cynomolgus monkeys at 5, 15, and 30 mg/kg Q2W for three doses (Days 1, 15, 29), followed by a six-week recovery period. OBI-904, the glycan conjugated ADC, maintained a 100% DAR in serum albumin, longer half-life, overcoming the instability associated with conventional cysteine-based linkers. OBI-904 exhibited improved pharmacokinetics and slow release of payload in tumor cells for prolonged anti-tumor responses. In vivo, OBI-904 demonstrated potent antitumor activity across multiple models, including CDX models of HNSCC, CRC, TNBC as well as PDX models of cervical and sarcoma, showing antitumor effect independent of Nectin-4 expression levels. Durable responses were observed in prostate (high Nectin-4) and cholangiocarcinoma (low Nectin-4) CDX models. Notably, OBI-904 effectively overcame EV-resistant bladder cancer, highlighting its potential to address acquired resistance. In the GLP toxicology studies, a highest non-severely toxic dose (HNSTD) of 30 mg/kg was determined in non-human primates with favorable toxicology findings. OBI-904, a next-generation Nectin-4-targeted ADC with optimized stability and payload delivery, demonstrated potent antitumor activity across multiple models, including EV-resistant tumors, independent of Nectin-4 expression. Favorable pharmacokinetics and toxicology support its further clinical development as a promising therapy for Nectin-4-expressing cancers.

#1820 Pharmacokinetic-tumor growth inhibition modeling of raludotatug deruxtecan (R-DXd) to support phase 3 dose selection in platinum-resistant ovarian cancer (PROC).

YoungJun Yoo[1], Kevin Koloskoff[2], Sandra Re[1], Izna Ali[1], Felipe K. Hurtado[1], Raouf El Cheikh[2]

[1]Daiichi Sankyo, Inc., Basking Ridge, NJ,[2]Daiichi Sankyo France, SAS, Rueil-Malmaison, France

Background: R-DXd is a novel cadherin 6 (CDH6)-directed antibody-drug conjugate (ADC) under clinical investigation. In ongoing Phase 1 DS6000-A-U101 (NCT04707248) and Phase 2/3 REJOICE-Ovarian01 (NCT06161025) studies, preliminary data showed promising results in patients with platinum-resistant ovarian cancer (PROC). To support dose selection in PROC, a pharmacokinetic-tumor growth inhibition (PK-TGI) model was developed to investigate the effect of R-DXd exposure on tumor size and predict percent change from baseline in tumor size across R-DXd doses of interest (4.8, 5.6, and 6.4 mg/kg), as well as explore the effect of CDH6 expression levels on tumor response.

Methods: The analysis dataset comprised 229 patients enrolled from either study who completed at least 18 weeks of follow-up (ie, 3 postbaseline tumor scans). Time-course data of PK (ADC and released payload [DXd] plasma concentration) and tumor size (sum of longest diameters [SLD], assessed by blinded independent central review [BICR]) were collected from PROC patients treated with R-DXd monotherapy at 1.6-9.6 mg/kg IV Q3W in DS6000-A-U101 and the dose optimization part of REJOICE-Ovarian01. The PK-TGI model was developed using nonlinear mixed-effects modeling and adapted from previously published TGI modeling frameworks by Claret et al. Simulations accounting for parameter uncertainties were conducted to predict tumor response of R-DXd treatment across dose levels for a typical reference patient.

Results: Model parameters were estimated with good precision, and goodness-of-fit plots showed that model predictions describe data appropriately. The final model was comprised of three components: 1) a drug-induced tumor killing rate (k_{kill}) driven by R-DXd concentration, which is 2) attenuated over time by a resistance term ($e^{-\lambda \cdot t}$), and 3) tumor growth described as a saturated logistic function, $k_{ge} \times TS \times (1 - TS/TS_{max})$, in which k_{ge} represents the intrinsic growth rate, TS tumor size, and TS_{max} the maximum tumor size. The simulations demonstrated a clear exposure-response relationship, with higher doses of R-DXd associated with stronger tumor shrinkage: predicted median tumor shrinkage at 24 weeks was –52%, –58%, and –64% for 4.8, 5.6, and 6.4 mg/kg, respectively. Additionally, baseline CDH6 protein expression was identified as a significant covariate on k_{kill} parameter, positively associated with tumor shrinkage, with its effect tending to plateau with increasing expression levels.

Conclusions: The PK-TGI model could adequately characterize changes in tumor size as a function of R-DXd concentration as well as quantify the effect of target expression on tumor shrinkage. Combined with the totality of clinical data and an overall assessment of benefit-risk, the analyses supported the selection of 5.6 mg/kg Q3W as the optimal monotherapy dose of R-DXd for the Phase 3 part of the REJOICE-Ovarian01 study.

#1821 Preclinical efficacy and safety of CS5006, a novel integrin β4-targeting antibody-drug conjugate with a topoisomerase 1 inhibitor payload.

Chuan Wang, Xinling Zhang, Ning Zhang, Yamin Wang, Yongwang Li, Mengyao Zhu, Xuelian Liu, Yaxin Chen, Yuxin Qian, Yongli Yang, Jingyu Sun, Fei Ma, Jianxin Yang

CStone Pharmaceuticals, Suzhou, China

Background: Integrin β4 (ITGB4) is highly expressed in colorectal carcinoma (CRC), non-small cell lung cancer (NSCLC), squamous cell carcinoma of the head and neck (SCCHN), esophageal squamous cell carcinoma (ESCC), and other solid tumors. CS5006 is a novel ITGB4-targeting antibody-drug conjugate (ADC) composed of an ITGB4-specific humanized IgG1 antibody (H86.2) conjugated to the clinically validated exatecan (Exa) payload via a highly stable, hydrophilic tandem-cleavage CSL linker, with a drug-to-antibody (DAR) value of 4.

Methods: The potency of CS5006 was evaluated in viability assays across a panel of cancer cell lines with varied ITGB4 expression levels. Its antitumor efficacy was evaluated in cell-derived xenograft (CDX) mouse models. ITGB4 expression level on tumor cell lines applied *in vitro* and *in vivo* studies was determined by quantitative flow cytometry and immunohistochemistry (IHC) assays. Its NHP safety and pharmacokinetics (PK) were assessed at three dose levels including 10, 30, 50 mg/kg. The physical stability under accelerated conditions (40°C for 2 weeks and freeze-thaw for 5 cycles) was assessed by SEC-HPLC for purity and by RP-HPLC for DAR value.

Results: CS5006 demonstrated potent, target-dependent killing of ITGB4-positive cancer cell lines with potency positively correlating with antigen expression levels (nanomolar range IC50 against high-expressing cells). A single 10 mg/kg dose of CS5006 induced tumor regression across all 9 CDX models, representing NSCLC (n=4), CRC, SCCHN, urothelial carcinoma (UC), gastric cancer (GC) and breast cancer (BC). In a repeat-dose toxicity study, CS5006 was well tolerated in cynomolgus monkeys during the study. Systemic exposure of the ADC was comparable to the total antibody, and increased dose-proportionally, suggesting CS5006's remarkable circulating stability. CS5006 exhibited excellent developability, maintaining stable after five freeze-thaw cycles and after 2 weeks at 40°C.

Conclusions: CS5006 demonstrates high potency, robust antitumor activity, a manageable safety profile, and excellent developability in preclinical studies, supporting its clinical translation. An IND application for CS5006 is planned for H2 2026 to support clinical development in patients with advanced solid tumors.

#1822 Preclinical efficacy and safety of CS5008, a novel SSTR2×DLL3 bispecific antibody-drug conjugate (ADC) with topoisomerase 1 inhibitor payload for small cell lung cancer and neuroendocrine tumors.

Chuan Wang, Yongwang Li, Ning Zhang, Yamin Wang, Xinling Zhang, Xuelian Liu, Yuxin Qian, Hui Dai, Xueqin Dai, Yaxin Chen, Zicong Zheng, Wenjing Xiang, Fei Ma, Jianxin Yang

CStone Pharmaceuticals, Suzhou, China

Background: CS5008 is a first-in-class bispecific ADC targeting SSTR2 and DLL3, constructed on CStone's proprietary modular ADC platform. It comprises a bispecific antibody with high affinity for both targets, a proprietary tandem-cleavable β-glucuronide linker (CSL20), and the topoisomerase 1 inhibitor exatecan as payload (drug-to-antibody ratio = 4). CS5008 is designed to overcome tumor heterogeneity in small cell lung cancer (SCLC) and neuroendocrine tumors (NETs) by simultaneously targeting two clinically validated antigens with complementary expression profiles. SSTR2 is a well-established target in neuroendocrine tumors (NETs/NECs). DLL3 is a clinically validated target in SCLC, serving as the target of tarlatamab, a T-cell engager. However, tumor heterogeneity and subtype plasticity often limit the effectiveness of single-target approaches in SCLC. CS5008 is a first-in-class bispecific ADC designed to address this challenge by simultaneously targeting SSTR2 and DLL3. It is constructed on CStone's proprietary modular ADC platform and comprises a bispecific antibody with high affinity for both targets, a proprietary tandem-cleavable β-glucuronide-cathepsin linker (CSL20), and the topoisomerase 1 inhibitor exatecan as payload (drug-to-antibody ratio = 4).

Methods: CS5008 was evaluated *in vitro* for binding affinity, internalization, and cytotoxicity using tumor cell lines with varied SSTR2/DLL3 expression levels. *In vivo* efficacy was assessed in multiple SCLC xenograft (CDX) models (e.g., H524, H69, H82, H446, COR-L279, SHP77). Pharmacokinetics (PK) and tolerability were studied in rodents and non-human primates, including preliminary toxicology assessments at doses of 30, 45, and 60 mg/kg administered every three weeks (Q3W).

Results: CS5008 exhibited nanomolar binding affinity for both DLL3 and SSTR2, both of which were determined by flow cytometry (FACS) on SCLC tumor cells. It induced rapid internalization and potent, antigen-dependent cell killing in SSTR2+/DLL3+ models (e.g., IC50 of 1.54 nM in H524 cells). A single treatment with 10 mg/kg CS5008 achieved significant tumor growth inhibition in all 5 tested SCLC CDX models with different expression level of DLL3 and SSTR2 assessed by FACS, indicating the designated character of CS5005 to overcome the heterogeneity of SCLC. PK profiles in rodents and non-human primates demonstrated CS5008's high circulating stability. In cynomolgus monkeys, CS5008 was well-tolerated at doses up to 60 mg/kg.

Conclusions: CS5008 demonstrated potent antitumor activity against SCLC by dual targeting of SSTR2 and DLL3, effectively addressing heterogeneity. Its favorable preclinical safety and robust PK support further clinical development. An IND application is expected by the end of 2026.

#1823 Preclinical efficacy and safety of CS5007, an EGFR×HER3 dual-targeting antibody-drug conjugate with a topoisomerase 1 inhibitor payload.

Chuan Wang, Yamin Wang, Ning Zhang, Xinling Zhang, Yongwang Li, Yuxin Qian, Yaxin Chen, Yongli Yang, Xuelian Liu, Mengyao Zhu, Hui Dai, Wenjing Xiang, Xueqin Dai, Fei Ma, Jianxin Yang

CStone Pharmaceuticals, Suzhou, China

Background: EGFR and HER3, members of the ErbB receptor family, are key oncogenic drivers that are frequently co-overexpressed across a variety of human epithelial malignancies, Both EGFR and HER3 are clinically validated therapeutic targets for cancer therapies. Therefore, simultaneously targeting both EGFR and HER3 offers a promising strategy to overcome tumor heterogeneity and adaptive resistance commonly observed with single-target approaches. CS5007 is constructed with 1) functional EGFR&HER3 arm to tackle tumor heterogeneity; 2) hydrophilic beta-glucuronide linker (our proprietary CSL20 linker) to ensure that the ADC has a mAb-like PK profile, stability and tumor selective cleavage; 3) potent, well-tolerated and clinically validated topoisomerase 1 inhibitor exatecan (Exa) conjugated to the antibody with a drug-to-antibody ratio (DAR) of 4.

Methods & Results: CS5007 demonstrated high-affinity binding (single digit nM) to EGFR/HER3 single- and double-positive tumor cells, comparable to its naked bispecific antibody and its parental antibodies. Western blot analysis of tumor cell lines revealed that naked bispecific antibody treatment led to strong inhibition of ligand-induced EGFR/HER3 downstream signaling, indicating effective blockade of proliferative pathways and induction of apoptosis. CS5007 induced rapid internalization and potent cell killing in tumor cell lines, demonstrating its potential to overcome tumor heterogeneity. It also showed superior *in vitr*o cytotoxicity over a bispecific control ADC (BL-B01D1 analog) and monospecific EGFR- or HER3-targeting ADCs in various tumor cell lines, including an osimertinib-resistant NSCLC model. A single treatment with 5 mg/kg CS5007 demonstrated robust, antigen-dependent antitumor activity across multiple xenograft (CDX) models, including EGFR+, HER3+, and dual-positive tumors. CS5007 showed strong tumor growth inhibitory ability comparable to or exceeding that of the anti-EGFR and anti-HER3 monospecific ADCs, as well as the bispecific control BL-B01D1. CS5007 exhibited a mAb-like PK profile in the rodent model. *In vitro* human, mouse, and cyno serum studies showed minimal payload release after 7 days, suggesting robust stability in circulation. CS5007 was well tolerated in cynomolgus monkeys at 30 mg/kg, with dose-dependent hematolymphoid and intestinal effects being its major toxicity findings, consistent with other EGFR targeting treatment. Cyno TK data further confirmed its excellent circulating stability.

Conclusions: With demonstrated enhanced signaling inhibition, superior efficacy across multiple solid tumor models, and a favorable safety margin in preclinical studies, CS5007 is planned for an IND submission in early 2026 to support clinical development in advanced solid tumors.

#1824 ORM-1153: A Next-Generation CD123-Targeting Degrader Antibody Conjugate (DAC).

Adam T. Boutin[1], Dong-Ki Choi[2], YeonHee Yang[2], Jessica Alves[1], MinSoo Kim[2], Da-Yeong Kim[2], Khuloud Takrouri[1], Qinsi Zheng[1], Nadia Cherkassky[1], Anna Skaletskaya[1], Teresa Mako[1], VineetKumar Patil[2], Hangyeol Jeong[2], Olaf Christensen[1], Maysoun Shomali[1], Sang Hyun Lee[2], James Palacino[3]

[1]Orum Therapeutics, Boston, MA,[2]Orum Therapeutics, Daejeon, Korea, Republic of,[3]Little Castle Consulting, Boston, MA

ORM-1153 is a next-generation CD123-targeting Degrader Antibody Conjugate (DAC) designed to improve safety and therapeutic index through advanced antibody and linker engineering. DACs combine the tissue selectivity of antibody-mediated delivery with the well-validated catalytic mechanism of targeted protein degradation, offering opportunities to expand beyond conventional cytotoxic ADC payloads. ORM-1153 is comprised of a proprietary GSPT1-degrading payload (SMol006) conjugated to a high-affinity anti-CD123 antibody via a novel β-glucuronide cleavable linker. The antibody was engineered to minimize Fc gamma receptor interactions, reducing off-target and immune cell engagement, while the linker was optimized for enhanced plasma stability. Together, these modifications combined to produce a molecule with a robust preclinical therapeutic index (TI), suggesting the potential for ORM-1153 in the clinic. ORM-1153 was determined to have a minimal efficacious dose (MED) of 0.1 mg/kg in a disseminated AML model. Efficacy was superior to standard of care (SoC) and to a competitor ADC: anti-CD123/TOP1i. Improved efficacy correlated with a better PK profile consisting of a longer plasma half-life and minimal or undetectable free payload at most timepoints with a LLOQ of 1 ng/ml. Because SMol006 is a CRBN-based molecular glue degrader; rodent species have amino acid differences in CRBN that renders their cells insensitive to the MoA. Therefore, the relevant species for assessing tolerability is non-human primates (NHP). ORM-1153 had a favorable safety profile in repeat-dose monkey studies with clinical pathology findings limited to transient, reversible reductions in platelets and transient, reversible increases in clotting times, fibrinogen and C-reactive protein. Of note, hepatic biomarkers remained within the normal range. Consistent with a common ADC toxicity of thrombocytopenia and prior findings with our DACs, we observed transient and reversible decreases in platelet levels. These results highlight how molecular engineering of both the antibody and linker can dramatically shift the balance between efficacy and tolerability for complex bioconjugates. Collectively, ORM-1153 exemplifies a rationally engineered DAC with superior pharmacologic properties, including robust potency and a broad therapeutic window, supporting advancement toward clinical introduction

#1825 QSP modeling to inform dose and regimen selection for TAK-280: A bi-specific antibody.

Agnish Dey[1], Tao Long[1], Sabrina Collins[1], Dean Bottino[2], Jaydeep Srimani[1], John Gibbs[1]

[1]Takeda Pharmaceuticals, Cambridge, MA,[2]DMPK&M, Oncology Therapeutic Area, Takeda Development Center Americas, Cambridge, MA

Background: CD3-targeting T cell engagers (TCE) have been approved as therapy for various hematological and solid tumor oncology indications; however, they can often induce unwanted safety issues, including cytokine release syndrome (CRS) and liver enzyme elevations. TAK-280 is an investigational B7-H3 x CD3ε conditional bispecific redirected activation (COBRA) TCE. In its masked prodrug form, TAK-280 binds to B7-H3, but not to CD3ε. Once in the protease-rich tumor microenvironment, proteases mediate cleavage of the linker resulting in unmasking the prodrug, which allows for the formation of active CD3ε-binding dimers and ultimately CD3 T-cell activation and cytotoxic anti-tumor response against co-engaged B7-H3 expressing cells. We developed a mechanistic PK/PD modeling framework to describe the PK and safety of TAK-280, based on clinical data from a Phase 1 dose escalation study (NCT05220098) investigating TAK-280 for the treatment of patients with advanced, unresectable or metastatic cancer, with a focus on tumor types with enhanced B7-H3 expression.

Methods: In the tumor compartment of the model, TAK-280 binds to B7-H3 expressed on tumor cells. Once the dimer is formed, it binds to CD3 to form the desired trimer complex composed of TAK-280, B7-H3 and CD3. It is assumed that this trimer complex is the only species that triggers cytokine release in the tumor compartment. Once cytokines are secreted in the tumor, they are assumed to move to systemic circulation. In the central compartment, cytokines undergo basal production and degradation.

Results: A two-compartment model with linear elimination was sufficient to describe the PK. Cytokine dynamics were described using a three-population immune cell pool[1] (non-secreting, secreting and refractory) framework. Immune cell dynamics reveal that the cytokine Cmax attenuation over time is a consequence of immune cell de-sensitization by transitioning to the refractory state. This concept of de-sensitization or decreased cytokine release following TCE dosing is clinically well established and mechanistically it is attributed to fewer non-secreting immune cells that are available by the time the top dose is administered (in a lead-in dosing regimen).

Conclusion: Using the model, we were able to show that lead-in dosing led to lower cytokine peak concentrations and therefore predicted lower probability for an adverse event. Model simulations demonstrated comparable safety outcomes for both QW and BIW dosing of the bispecific antibody.

#1826 Exposure-response analysis and quantitative systems pharmacology modeling for an optimal dose selection of surovatamig in patients with DLBCL.

Xu (Sue) Zhu[1], Damilola Olabode[1], Massimo Lai[2], Cesar Pichardo-Almarza[2], Meenu Pillai[3], Denise Brennan[1], David Sermer[4], Robin Lesley[5]

[1]AstraZeneca, Waltham, MA,[2]AstraZeneca, Cambridge, United Kingdom,[3]AstraZeneca, Gaithersburg, MA,[4]AstraZeneca, New York, NY,[5]AstraZeneca, South San Francisco, CA

Introduction: Surovatamig (formerly AZD0486) is a novel, IgG4 fully human CD19xCD3 bispecific T-cell engager that is being evaluated in an ongoing phase 1 study (NCT04594642) in patients (pts) with relapsed or refractory (R/R) B-cell non-Hodgkin lymphoma (B-NHL). Here, we present our quantitative approaches for determining an optimal dose for surovatamig in pts with R/R diffuse large B-cell lymphoma (DLBCL) with population pharmacokinetics (popPK), exposure-response (ER) analysis, and quantitative systems pharmacology (QSP) modeling.

Methods: Pts with R/R B-NHL received escalating doses of surovatamig IV with fixed dosing, single step-up dosing (SUD), or double SUD schedules in cycle 1, followed by target dose (TD) every 2 weeks in 28-day cycles for up to 24 months. PK data from serial sampling was used to develop a popPK model in NONMEM®. ER relationships between surovatamig PK and overall response rate (ORR) or complete response rate (CRR) were characterized in pts with DLBCL. Further, QSP modeling was developed to link the surovatamig PK to the trimeric complex formation. A total of 185 pts with all histology (DLBCL, follicular lymphoma [FL], and mantle cell lymphoma/marginal zone lymphoma) were analyzed for PK and safety, and 100 pts with DLBCL were analyzed for efficacy (based on data cutoff of August 2025).

Results: Following IV infusion, the observed mean half-life of surovatamig is ~11 days across the dose cohorts after the cycle 1 day 15 dose. A dose-proportional increase in exposure is observed across the dose ranges (≥0.27 mg). Surovatamig PK was best described by a 2-compartment PK model with linear clearance and was comparable in pts with FL and DLBCL. No covariates (eg, disease type, race, age) other than body weight were identified to have a significant impact on PK parameters (clearance and volume of distribution). Exposure-efficacy analysis in pts with R/R DLBCL showed higher probability of ORR and CRR with increasing exposures (eg, $C_{avgcycle1\&2}$ or C_{trough}) across the dose range, supporting a TD of 25 mg in pts with DLBCL. Based on the QSP model calibrated with preclinical and emerging clinical data (eg, sum of the long diameter of target lesions), the maximal median trimer concentration at the tumor site increases across the TD of 2.4-37.5 mg. Predictions suggested no significant increments in ORR by increasing the TD from 25 mg to 37.5 mg. Overall, QSP modeling and simulation results support the TD of 25 mg as an optimal recommended phase 2 dose (RP2D) for efficacy. Exposure-safety analysis showed no clear association of exposure after TD with Gr2+ CRS or ICANS, or Gr4+ neutropenia.

Conclusion: ER analysis and QSP modelling confirmed the clinical benefit with increased TD from 2.4 to 25 mg in pts with R/R DLBCL, with no clear TD-dependent clinically relevant toxicity, supporting 25 mg as the RP2D.

#1827 Combining PRC2 inhibitors with metronomic chemotherapy: A promising therapeutic strategy for diffuse large B-cell lymphoma.

Marta Banchi[1], Maryam Latarani[2], Paola Orlandi[3], Kayleigh Orchard[2], George Bryant[2], Francesco Crea[2], Guido Bocci[1]

[1]Department of Translational Research and of New Surgical and Medical Technologies, University of Pisa, Pisa, Italy,[2]Cancer research Group, School of Life, Health and Chemical Sciences, The Open University, Milton Keynes, United Kingdom,[3]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

Diffuse large B-cell lymphoma (DLBCL) is the most common aggressive non-Hodgkin lymphoma (NHL). Most attempts to combine standard chemo-immunotherapy with targeted drugs have failed due to limited synergy or excessive toxicity. Enhancer of zeste homolog 2 (EZH2) is the catalytic subunit of the polycomb repressive complex 2 (PRC2) acting as a transcriptional repressor by methylating histone H3 at lysine 27 (H3K27me3). Activating mutations in EZH2 in NHL correlate with poor survival. We aimed at using metronomic chemotherapy (mCHEMO)—the frequent, regular administration of low-dose cytotoxic drugs that maintain prolonged and active drug-plasma levels—in combination with new epigenetic therapies as a promising, more effective and less toxic approach for DLBCL treatment. In vitro proliferation assays were performed on both $EZH2^{Y641F}$ mutant (SU-DHL10) and EZH2 wild-type (OCI-LY3, Toledo) DLBCL cell lines exposed to thrice-weekly vinorelbine (mVNR) and daily PRC2 inhibitors (PRC2i: tazemetostat, valemetostat, ORIC-944), alone and in concomitant combination, for 144h. Synergism was measured by the Combination Index method and the Loewe additivity model. PRC2i target engagement was assessed by H3K27me3 western blot. The modulation of gene expression in DLBCL cells treated with 144h-daily valemetostat was evaluated by RNA sequencing. The 144h exposure of daily PRC2i and mVNR inhibited the DLBCL cell viability in a concentration-dependent manner. Among the PRC2i, valemetostat exhibited the greatest cytotoxic effect on SU-DHL10, OCI-LY3 and Toledo cells (IC_{50}s: 3.09nM, 371nM, and 303nM, respectively). ORIC-944 also effectively reduced DLBCL cell growth (IC_{50}s: 8.7nM, 721nM, and 1,388nM, respectively). Tazemetostat significantly inhibited DLBCL cell viability, with higher IC_{50} values (1,389nM, 3,481nM, and 8,597nM, respectively). mVNR substantially arrested the proliferation of all cell lines (IC_{50}s: 508.9pM, 62.9pM, and 675.6pM, respectively). The strongest synergistic effect was observed for the mVNR+valemetostat combination, while mVNR+ORIC-944 showed synergism only for high percentage of affected DLBCL cell fractions. PRC2i markedly reduced H3K27me3 levels in DLBCL cells. Among the differentially expressed genes, we observed more up-regulated than down-regulated transcripts upon PRC2 inhibition, and an increased expression of key p53-dependent pro-apoptotic genes. These findings offer a solid rationale for combining PRC2i and mCHEMO as an encouraging therapeutic approach for DLBCL, particularly in elderly or fragile patients, due to their low toxicity profiles. Overall, these results warrant additional in vitro investigations to elucidate the mechanisms underlying the reported effects and in vivo experiments in DLBCL models to validate our new therapeutic strategy, which holds potential for rapid translation into future clinical trials.

#1828 Preclinical evaluation of selective and potent EP300 degraders demonstrates robust antitumor activity and favorable tolerability in hematologic malignancies.

Meiyun Lin, Wesley Austin, Qianhe Zhuo, Rieko Arimoto, Karolina Mizeracka, Abira Ramakrishnan, Kevin Wilson, Elizabeth Wittenborn, Laura La Bonte, Steven Bellon

Foghorn Therapeutics, Watertown, MA

E1A binding protein P300 (EP300) is a histone acetyltransferase and transcriptional coactivator that regulates gene expression programs essential for proliferation and survival in hematologic malignancies. Developing selective EP300 agents has been challenging due to the high degree of homology between EP300 and its paralog CREB binding protein (CBP). Current pharmacological inhibitors targeting EP300 are not very selective and result in adverse effects, such as thrombocytopenia. Therefore, the development of agents that selectively target EP300 is of high interest as it has the potential to broaden the therapeutic window. To address this, we developed heterobifunctional compounds with exquisite selectivity, achieving rapid and sustained EP300 degradation *in vivo* while sparing CBP. Our previous work demonstrated that selective degradation of EP300 has strong anti-proliferative activity in a broad range of hematologic malignancies *in vitro*, including diffuse large B-cell lymphoma (DLBCL), multiple myeloma (MM), and follicular lymphoma. In MM.1S xenograft studies, both immediate-release and long-acting injectable formulations of EP300 degraders achieved robust, dose-dependent tumor growth inhibition at well-tolerated exposure levels. Pharmacokinetic and pharmacodynamic analyses revealed a positive correlation between systemic exposure, EP300 degradation, and anti-tumor response. Importantly, selective EP300 degradation *in vivo* showed minimal impact on body weight and no adverse hematologic effects, such as anemia or thrombocytopenia, in contrast to dual CBP/EP300 inhibitors, indicating a favorable therapeutic window. Collectively, our results establish selective EP300 degradation as a novel and promising therapeutic strategy to treat multiple hematologic malignancies.

#1829 Treating breast cancer brain metastases in the leptomeninges through p-selectin targeted delivery of EZH2 PROTACs.

Raashed Raziuddin, Logan Hillger, Annie Ikemoto, Daniel Heller

Memorial Sloan Kettering Cancer Center, New York, NY

Breast cancer brain metastases (BCBMs) occur in 10-15% of all breast cancer patients with dismal median survival rates as low as 1 month for patients with leptomeningeal metastases (LMs). In BCBMs, EZH2, a histone methyltransferase, has been found to have non-enzymatic oncogenic function promoting metastatic proliferation and decreased overall survival. Thus, degradation versus inhibition of EZH2 in brain metastases could be a powerful strategy to treat BCBMs and LMs if a therapeutic could accumulate to therapeutic doses in the cerebrospinal fluid.

In this study, we use an EZH2 proteolysis-targeting chimera (PROTAC) enabling degradation of EZH2 in BCBMs and LMs. We find that an EZH2 PROTAC administers cytotoxic efficacy in brain metastatic (Br) and leptomeningeal (LM) derivatives of breast cancer cell lines while inhibitors have no effect. Proteomics data and mitochondrial assays suggest this discrepancy can be attributed to mitochondrial complex I and electron transport chain dysfunction.

PROTACs often have poor brain penetrance due to their hydrophobic nature and large molecular weight, but they can be encapsulated in P-selectin targeted nanoparticles (nanoPROTACs). We have previously shown that P-selectin can be presented selectively on primary brain tumor cells to deliver nanoparticles across the blood brain barrier *in vivo*. Here, we discover using humanized models of BCBMs that P-selectin is selectively presented on tumor and leptomeningeal vasculature. Only intraperitoneal delivery of P-selectin targeted EZH2 nanoPROTACs demonstrate remarkable degradation of EZH2 in LMs 48 hours after administration. This work demonstrates the ability to deliver PROTACs selectively to brain metastases and offers a therapeutic platform to extend BCBM patient survival.

#1830 SP09253, an orally bioavailable, highly potent RAS(ON) molecular glue inhibitor demonstrates robust anti-tumor activity in KRAS-mutant tumors.

Zherong Zhang, Xiaoyu Di, Qiming Sun

Hefei Shengpu Pharmaceutical Co., Ltd., Hefei, Anhui, China

KRAS is the most frequently mutated cancer driver gene. Approximately 30% of human tumors harbor KRAS mutations, with particularly high prevalence in pancreatic, colorectal, and non-small cell lung cancers (NSCLC), among others. Patients carrying KRAS mutations often exhibit poor efficacy and low response to current clinical therapeutics. Although $KRAS^{G12C}$ mutant-selective inhibitors have shown success in treating patients with G12C mutations, more than 85% of other “undruggable” KRAS mutations still lack effective treatment options. Next-generation KRAS inhibitors that target multiple oncogenic RAS variants while sparing wild-type RAS hold the potential to address broader indications and patient population. SP09253 is an orally bioavailable, highly potent pan-RAS molecular glue inhibitor that demonstrates robust activity against key RAS mutations including KRAS G12C, G12D, G12V, G13D, while exhibiting high selectivity over wild-type KRAS. Importantly, SP09253 exhibits more favorable ADME and PK profiles compared to positive control, and the *in vivo* anti-tumor efficacy of SP09253 is superior to that of a positive control, a first-in-class pan-RAS molecular glue currently undergoing Phase III clinical trial.SP09253 is a potent pan-RAS molecular glue that has been proven to selectively inhibits KRAS mutants but spares wild type KRAS. SP09253 potently inhibits ERK phosphorylation and cellular viability in KRAS mutantt cell lines *in vitro*. SP09253 demonstrates robust *in vivo* efficacy in KRAS mutant xenografts harboring different mutant types, including G12C, G12D, G12V, etc., while showcasing a favorable PK profile and oral bioavailability.<!--EndFragment-->

#1831 First-in-human clinical pharmacokinetic prediction of D3S-003, an orally bioavailable dual-state KRAS G12D inhibitor.

Shaonan Wang, Zhiqiang Zheng, Jing Zhang, Tienan Wang, Xin Xiong, Hui Wang, Zhijian Chen

D3 Bio Inc., Shanghai, China

Background: D3S-003 is a potent and selective KRAS G12D inhibitor that engages both GDP-bound (OFF) and GTP-bound (ON) KRAS G12D and demonstrates broad preclinical antitumor activity. To support rational first-in-human (FIH) dose selection, translational pharmacokinetic (PK) modeling and allometric scaling were applied to predict human PK characteristics from multi-species data.
Methods: PK data from mouse, rat, and dog were analyzed using two-compartment models with first-order absorption and linear elimination. Allometric scaling of clearance (CL), central and peripheral distribution volumes (Vc, Vp), and intercompartmental clearance (Q) was performed to derive human PK parameters. Absorption rate constant (Ka) and bioavailability (F) were explored over a broad range to capture interspecies variability, and human simulations were conducted for oral doses of 60-1200 mg once daily. Exposure metrics (Cmax, AUC_{0-24}, Cmin, Cavg) were predicted for both single- and multiple-dose regimens to assess dose proportionality and steady-state PK.
Results: Allometric extrapolation yielded predicted human parameters of CL = 0.869 L/h/kg, Vc = 2.151 L/kg, Q = 0.693 L/h/kg, and Vp = 16.664 L/kg. Results shown here reflect simulations using mid-range absorption and bioavailability assumptions. Simulated profiles indicated rapid absorption (Tmax ≈ 1-2 h) and biexponential decline consistent with moderate distribution and linear clearance. Across 60-1200 mg QD, predicted Cmax rose from ~26 to ~520 ng/mL and AUC_{0-24} from ~91 to ~1824 ng·h/mL after a single dose. At steady state (τ = 24 h), Cmin and Cavg ranged ~2-46 ng/mL and ~6-127 ng/mL with minimal accumulation (~1.7-fold). Simulated exposures at clinically feasible doses exceeded unbound exposure level (Cave of ~2.3nM) associated with complete tumor regression in preclinical models, suggesting a high likelihood of achieving pharmacologically active concentrations and early clinical responses during dose escalation.
Conclusions: A translational PK and allometric-scaling strategy successfully predicted human PK for D3S-003. Simulations under mid-range absorption conditions demonstrated linear exposure and favorable oral PK, supporting model-informed dose selection for the planned FIH study. Ongoing integration of clinical data will refine dose-exposure-response relationships and guide dose optimization in later-phase clinical development.

#1832 *In silico* calmodulin-PCAIs binding affinities versus *in vitro* anticancer cell viability: Strategies for the development of anti-pan-mutant KRAS agents.

Jahnissi Frimpomah Odoom[1], Kweku Ofosu-Asante[1], Joshua Kofi Ablordeppey[1], Desmond Kwakye[1], Amarender Burra[2], Nazarius Lamango[3]

[1]Florida A&M University, Tallahassee, FL,[2]R&D Department, Lee Pharma Ltd., Hyderabad, Telangana, India,[3]Professor, Florida A&M Univ. College of Pharmacy, Tallahassee, FL

About 90% of pancreatic cancers are pancreatic ductal adenocarcinoma (PDAC), and roughly 90% of PDAC cases are driven by *KRAS* mutations, which render them very aggressive and resistant to treatments. Therefore, there is a critical need for cancer therapy designed specifically to disrupt and suppress hyperactive G-protein signaling, such as those caused by various mutant RAS isoforms. We previously developed polyisoprenylated cysteinyl amide inhibitors (PCAIs) as potential anticancer agents and showed their efficacies against cell viability, migration, and angiogenesis. We recently identified the pharmacological target of the PCAIs as calmodulin (CALM). To further understand the mechanistic interactions of PCAIs with calmodulin, *in silico* studies were performed. CALM plays a significant role in cancers driven by KRAS proteins. The X-ray crystal structure of CALM with ID 6OS4 and a resolution of 2.05 Å was obtained from the RCSB Protein Data Bank. The crystal structure contained CALM co-crystallized with s-farnesyl-l-cysteine methyl ester (native ligand) and 4 calcium ions. For docking, all water molecules and bound ligands were removed, polar hydrogens were added, and Gasteiger charges were assigned using AutoDockTools. PCAIs were docked onto CALM, and the binding energies were plotted against cell viability EC_{50} values obtained using MIAPaCa-2 cells which harbor the $KRAS^{G12C}$ mutation. PCAIs with low EC_{50} values also displayed lower binding energies. CALM binds to the farnesylated hypervariable region of KRAS4B. Upon docking analysis, the same key residues were observed in docking interactions between CALM and the PCAIs. Redocking the native ligand produced a binding affinity of -5.9 kcal/mol, while the PCAIs showed stronger affinities that ranged from -8.9 to -6.5 kcal/mol, with similar CALM amino acid to PCAIs interaction patterns. The CALM hydrophobic residues, Leu39, Phe92, Leu105, Leu112, Met124, and Met144, which mediate its association with KRAS4B farnesylated cysteine, also contribute to PCAIs binding. The CALM-KRAS4B interaction is further stabilized through Asp20, Asp22, Asp56, Asp58, and Glu67 residues, which form ionic interactions with the polybasic hypervariable region KRAS4B domain. Although Ser-181 of KRAS4B does not directly contact a specific CALM residue, its phosphorylation state negatively impacts the CALM-KRAS4B interaction, providing an additional regulatory layer to KRAS4B growth stimulation through repulsion of CALM negatively charged residues that attract the polybasic region. Basic N atoms on the PCAIs form defined electrostatic contacts with specific Glu residues of CALM, including N3-Glu14, N4-Glu114, and N4-Glu14, further demonstrating the strong and specific PCAIs disruption of CALM-oncogenic KRAS4B complexation that can be harnessed for effective anticancer drug development.

#1833 Polyisoprenylated cysteinyl amide inhibitors suppress growth, induce cytoskeletal and transcriptomic remodeling in multiple *KRAS*-mutated lung cancer cells.

Desmond Kwakye[1], Chase Lilly[1], Kweku Ofosu-Asante[1], Jahnissi Frimpomah Odoom[1], Joshua Kofi Ablordeppey[1], Bianca Dal Bo[2], KARLA GONZALEZ[3], Chunli Yan[3], Matthew A. Gladstone[3], Kyle R. Phillips[4], Benjamin J. Ryder[4], Yong Huang[4], Ite A. Offringa[5], Nazarius Lamango[1]

[1]College of Pharmacy and Pharmaceutical Sciences. Institute of Public Health, Florida A&M University, Tallahassee, FL,[2]Keck School of Medicine of USC, Los Angeles, CA,[3]University of Southern California, Los Angeles, CA,[4]University of Florida, Gainesville, FL,[5]USC Norris Comprehensive Cancer Center, Los Angeles, CA

Lung cancer remains the leading cause of cancer-related deaths globally, with *KRAS* mutations driving approximately 30% of cases. Although $KRAS^{G12C}$ protein inhibitors such as Sotorasib and Adagrasib have improved therapeutic outcomes, intrinsic resistance and mutation heterogeneity such as $KRAS^{G12A}$ limit their long-term efficacy. Therefore, novel agents capable of targeting multiple mutant KRAS variants are urgently needed. Polyisoprenylated cysteinyl amide inhibitors (PCAIs) are molecular mimics of the essential post-translational modifications of G-proteins such as KRAS, RHOA, CDC42, and RAC1 that are important for their interactions as part of functional protein complexes. PCAIs were designed to interfere with and disrupt the polyisoprenylation-dependent protein-protein interactions required for KRAS signaling. Here we evaluated the long-term effects of PCAIs (NSL-YHJ-2-27), versus Adagrasib and Sotorasib on NCI-H23, which normally carries mutant $KRAS^{G12C}$, and a derivative in which $KRAS^{G12C}$ was replaced by $KRAS^{G12A}$. Treatment of NCI-H23 carrying $KRAS^{G12C}$ with 3 µM Adagrasib or NSL-YHJ-2-27 showed consistent inhibition of cell proliferation, down by 82 and 87% respectively. However, Adagrasib at 3 µM inhibited proliferation of NCI-H23 carrying $KRAS^{G12A}$ by just 19%, while Sotorasib had little to no effect. At the same time NSL-YHJ-2-27 inhibited NCI-H23 carrying $KRAS^{G12A}$ by 88%. Proliferation of Sotorasib-treated mutant $KRAS^{G12C}$ NCI-H23 rebounded to 54% by day 18 of continuous treatment, showing $KRAS^{G12C}$ mutants can quickly adapt to resist Sotorasib. NSL-YHJ-2-27 inhibited the viability of NCI-H23 carrying either $KRAS^{G12C}$ or $KRAS^{G12A}$, with respective EC_{50} values of 2.0 and 2.5 µM. NSL-YHJ-2-27 and Adagrasib at 2 µM disrupted F-actin filaments, increased cell rounding, and reduced mean cell area by 89 and 92%, respectively. Sotorasib showed a slight decrease in mean cell area of 15%. Transcriptomic profiling of NSL-YHJ-2-27-treated NCI-H23 cells carrying $KRAS^{G12C}$ revealed three genes that were significantly upregulated and two that were downregulated. Proapoptotic genes such as *CXCL2, WNT9A, PTX3* were elevated by 9, 12 and 10-fold, whereas motility and angiogenesis-associated genes such as *TMSB15A* and *POSTN* were downregulated by30 and 9-fold, respectively. Pathway enrichment highlighted alterations in cytoskeletal organization, adhesion, and KRAS-associated signaling networks. These findings support PCAIs as promising pan-mutant-KRAS-targeting therapeutic candidates against lung cancer.

#1834 A mathematical model for fitting adjusting azacytidine in AML or SMD patients.

Quentin Gerbault[1], Loic Osanno[1], Joseph Ciccolini[1], Laure Farnault[2], Geoffroy Venton[2], **Raphaelle Fanciullino**[1]

[1]COMPO SmartC, Aix-Marseille University, Marseille Cedex 07, France,[2]Hematology Unit, Aix-Marseille University, Marseille Cedex 07, France

Background: Azacitidine (Aza) is a hypomethylating agent (HMA) used to treat patients with acute myeloid leukaemia (AML) or myelodysplastic syndrome (MDS) who are not eligible for intensive chemotherapy. The standard Aza dose and schedule is 75 mg/m² daily for seven days, administered in 28-day cycles until disease progression occurs or severe toxicities arise. Recent protocols have associated it with venetoclax. However, only half of patients respond, and almost all will eventually relapse. Azacitidine undergoes metabolic detoxification driven by cytidine deaminase (CDA) in the liver. However, CDA is encoded by a highly polymorphic gene, resulting in significant variability: some patients do not respond to treatment, while others experience toxic death. Fifty per cent of patients with acute myeloid leukaemia (AML) or myelodysplastic syndrome (MDS) have deficient CDA enzyme activity (1). This variability suggests the need to consider individualising doses and understanding the kinetics of Azacytidine. In this real-world study, we monitored azacitidine plasma concentrations in order to develop a mathematical model to predict its pharmacokinetics (PK).
Method: Twenty-one adult patients (13 male/8 female), with a mean age of 78.7 years (range 59-89), were treated with azacitidine, either alone or in combination with venetoclax. Aza plasma concentrations were measured at the first cycle (C1) at multiple time points. Aza was analysed using a validated mass spectrometry method. PK parameters were derived using a population model with the SAEM algorithm within the Monolix® software. The influence of various factors, including CDA activity, on the pharmacokinetics (PK) of Azacytidine was investigated using a stepwise multivariate procedure.
Results: A one-compartment population pharmacokinetic (popPK) model with zero-order absorption and linear elimination was developed. This model incorporated CDA status as an absorption covariate, as well as basal serum albumin and body surface area as distribution volume covariates, and sex and renal impairment as clearance covariates.
Conclusions: This initial characterisation of a population model marks the beginning of the process of dose individualisation, which aims to optimise efficacy while minimising undesirable toxicities. Validating this model and determining toxicity parameters (concentration-dependent, exposure-dependent and time-dependent toxicity) and survival parameters will improve the management of these complex diseases with poor prognoses.

#1835 Evaluation of busulfan stability in infusion bags and biological matrix: Application to routine therapeutic drug monitoring with adaptive dosing in children.

Marielle Jehanno, Jasmine Bettayeb, Guillaume Sicard, Arthur Sterin, **Joseph Ciccolini**

La Timone University Hospital of Marseille, Marseille, France

Purpose: High Dose Busulfan is administered using pharmacokinetically guided dosing for conditioning protocols before hematopoietic stem cell transplantation. To be reliable, this strategy requires that administered doses and drug levels measured from samples are not affected by degradation before being assayed.
Methods: Busulfan stability at clinically meaningful concentrations was monitored by liquid chromatography/mass spectrometry in infusion bags as well as in human blood and plasma, using various storage conditions. Next, TDM (Therapeutic Drug Monitoring) with adaptive dosing was implemented in routine setting to customize the dosing in a child scheduled for High dose Busulfan.
Results: Busulfan was stable up to 72h in 0.25 mg/mL infusion bags, up to 24 hours in plasma regardless of the storage condition, and up to 16 hours in whole blood at 4°C. Conversely, blood samples of Busulfan left at room temperature showed a rapid degradation, suggesting that they should be rapidly proceeded in a temperature-controlled fashion. When applied next to children treated with High Dose Busulfan following 8 to 16 administrations over 4 consecutive days, TDM with PK-guided dosing was successfully performed to tailor the dosing and reached the desired target exposure. Upon initial standard dosing, deviation from the target AUC ranged from -52.3% to +11.5%. Busulfan dosing was subsequently adapted from Dose-9 for the 7 remaining administrations) and final cumulative AUCs showed deviation from the target from -22% to +13.6%.
Conclusion: Busulfan blood samples must be rapidly proceeded in refrigerated condition upon sampling to allow reliable TDM and adaptive dosing in paediatric oncology.

#1836 Nivolumab exposure and efficacy in metastatic melanoma patients: A real-world study.

Quentin Gerbault, Clara Boeri, Nausicaa Malissen, Caroline Gaudy, **Joseph Ciccolini**

Cancer Research center of Marseille, Marseille, France

Background: The PK/PD relationships of immune checkpoint inhibitors are not fully understood. In this real-world study, we monitored plasma concentrations of nivolumab and investigated to what extent they could predict clinical outcome in a cohort of unresectable stage III or IV melanoma patients.
Methods: 52 adult patients (26M/26F), mean age 64.3 years (range 31-89), performance status 0 (79.2%) or 1 (20.8%) were treated with 1 mg/kg nivolumab + 3 mg/kg ipilimumab (35 patients) or single agent nivolumab 240 mg Q2W or 480 mg Q4W flat dose (17 patients). Radiological response was assessed every 3 months per clinical practice. Nivolumab plasma concentrations (Cmax: end of infusion and Cmin: trough levels) were measured at the first cycle (C1). Nivolumab was analysed using a validated mass spectrometry method. PK parameters were derived using a standard population PK approach on Monolix using a two-compartment model. Statistical analyses were performed using R.
Results: confirmed response rates were 5.7% complete response, 32% partial response, 17% stable disease and 45.3% progressive disease. Patients with objective response or stable disease were next categorised as having clinical benefit (CB). There was no difference in efficacy between single-agent and combination therapy (odd ratio = 0.28, [0.06-1.087], Fisher test). After the first cycle (C1), nivolumab Cmax concentrations were 67.1 µg/mL ±64.1 (CV = 95%) and trough levels were 26.9 µg/mL ±23, (CV = 87%). In patients treated with the nivolumab + ipilimumab combination, there was no statistical difference in Cmax levels (37.9 µg/mL vs. 33.9 ug/mL $p > 0.05$) and trough levels (24.0 µg/mL vs. 15.4 µg/mL $p > 0.05$), between those achieving a CB and PD patients despite a +56% numerical difference in trough levels. Similarly, no statistical difference was seen in Cmax levels between CB and PD patients treated with nivolumab monotherapy (203.1 µg/mL vs. 159.6 µg/mL, $p > 0.05$) despite a numerical difference of +35%. There was a statistical difference in Cmin between CB and PD patients (54.2 µg/mL VS. 34 ug/mL $p = 0.03$). ROC analysis showed that a threshold of <42.6 µg/mL was significantly associated with treatment failure ($p = 0.016$).
Conclusions: This proof-of-concept study suggests that when nivolumab is given as a single agent, trough levels after the first cycle may help predict clinical outcome, as patients with plasma concentrations <42.6 µg/mL are at significantly higher risk of experiencing PD. The marker inter-patient variability observed in nivolumab pharmacokinetics warrants the use of therapeutic drug monitoring to check that exposure levels are within the expected range since patients with trough levels < 42.6 µg/mL after the first cycle are at risk of treatment failure.

#1837 Targeting Hippo/YAP-TEAD increases the antitumor activity of darovasertib in uveal melanoma.

Rodolfo Daniel Cervantes-Villagrana[1], Elena Sofia Cardenas Alcoser[1], Kuniaki Sato[1], Simone Lubrano[1], Tomohiko Ishikawa[1], Andrew E. Aplin[2], J. Silvio Gutkind[3]

[1]Pharmacology, University of California San Diego, San Diego, CA,[2]Jefferson Health Sidney Kimmel Cancer Center, Philadelphia, PA,[3]UCSD Moores Cancer Center, La Jolla, CA

Activating mutations in *GNAQ* and *GNA11* (*GNAQ* oncogenes) are found in ~93% of uveal melanoma (UVM) and 4% of skin cutaneous melanoma (SKCM), where they act as driver oncogenes. UVM is the most common primary cancer of the eye in adults, affecting more than 2,500 patients each year in the US alone, nearly 50% of whom will die from liver metastasis. To date, there are limited effective therapeutic options to prevent or treat UVM metastatic disease (mUVM), which typically also fails to respond to immunotherapies. By combining synthetic biology approaches, CRISPR/Cas9 genome-wide screens, and high-throughput chemogenetic drug screening, our team has revealed that classical and novel non-canonical GNAQ signaling circuits converge to promote UVM growth, survival, metastasis, and treatment resistance. Ultimately, elucidating GNAQ oncogenic signaling networks may reveal system vulnerabilities that can be exploited to develop new precision therapies for mUVM. In this regard, we have recently shown that darovasertib acts as a dual PKC-PKN inhibitor and exhibits the highest activity among thousands of drugs tested. Darovasertib has demonstrated encouraging activity in UVM patients, and clinical trials using darovasertib as a single agent in primary UVM lesions and in combination with crizotinib in mUVM are currently ongoing. However, few patients achieve complete responses, and tumors often progress due to the acquisition of resistance mechanisms. We aim to identify new targets that can overcome resistance to darovasertib. RNA-seq analysis revealed that long-term treatment with darovasertib increased the expression of YAP-target genes, and we hypothesized that YAP/TEAD activation may contribute to darovasertib resistance. Indeed, expression of an active YAP mutant (YAP2-5SA) or LATS1/2 inhibition was sufficient to induce darovasertib resistance in UVM cells. In turn, knockdown of YAP or TEAD, or the expression of a doxycycline-induced TEAD inhibitor (TEADi) peptide, increases darovasertib-induced apoptosis. Remarkably, co-targeting with small molecule TEADi decreases the expression of darovasertib-induced YAP targets and acts synergistically to reduce cell viability and increase UVM cell death. Ongoing studies are now exploring the preclinical benefit of combining darovasertib with small-molecule TEADi for the treatment of human UVM tumor xenografts in mice. Emerging evidence will be presented supporting that the Hippo YAP/TEAD pathway represents an adaptive mechanism of resistance to darovasertib treatment, and that the combination of TEADi with darovasertib may prevent the development of treatment resistance, thereby increasing the depth and duration of the anti-tumor response in UVM.

#1838 Optimal epigenetic therapies in triple-negative breast cancer.

Simone Bruno[1], Alexandra Indeglia[2], Sophia Lichterfeld[3], Karen M. Cichowski[2], Franziska Michor[4]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Brigham and Women's Hospital, Boston, MA,[3]Harvard College, Cambridge, MA,[4]Assoc. Professor, Dept. of Biostatistics & Computational Bio., Dana-Farber Cancer Institute, Boston, MA

Triple-negative breast cancer (TNBC) is the most aggressive form of breast cancer and is characterized by a very high recurrence rate. The primary treatment for this cancer type is systemic chemotherapy, often combined with immunotherapy. However, these treatments typically result in only short-term responses. Recent experimental studies have highlighted the critical role of chromatin modifications, such as DNA methylation and histone modifications, in TNBC development and progression. Consistent with these findings, epigenetic therapies targeting these modifications have shown promise in preclinical and early clinical studies. Building on these insights, we developed a predictive computational modeling platform to gain a deeper understanding of how different chromatin modifications influence TNBC and to identify optimal therapeutic strategies targeting these modifications. The platform integrates experimental data, pharmacokinetics, and mechanistic insights into the role of chromatin regulation in TNBC. We focused on therapies combining an EZH2 inhibitor, which reduces the establishment of repressive H3K27me3 marks and promotes chromatin opening, and an AKT inhibitor, which enhances the expression of GATA3 and BMF. Using this framework, we confirmed the experimentally observed synergy between the two inhibitors and uncovered its mechanistic basis: EZH2 inhibition quickly reaches a plateau once chromatin becomes fully accessible, whereas the effect of AKT inhibition increases more gradually across a broader concentration range. In-silico clinical trials involving 1,500 virtual patients further showed that optimized combination schedules markedly outperform monotherapies. Based on these predictions, we conducted in-vitro experiments using live-cell imaging, which validated the model's predictions on how different inhibitor doses and combinations shape treatment response, and confirmed the combination regimen identified by the platform as optimal. Beyond TNBC, the generalizable framework developed here can potentially be adapted to other types of cancer in which chromatin modifications play a similar role. This research can then also help establish the basis for the discovery of common therapeutic targets, contributing to a broader range of cancer treatment strategies. Overall, this research could lead to the development of novel, more effective, and more durable treatment strategies for TNBC, thereby improving patient outcomes and providing new possibilities for cancer therapy research.

Poster Session

#1841 Venetoclax rewires Notch signaling to drive resistance in North American adult T-cell leukemia/lymphoma.

Ankit Tanwar[1], Salman Sadullah Usmani[1], Sovira Chaudhry[1], Aditi Shastri[1], Marina Konopleva[1], Murali Janakiram[2], Ali Bazarbachi[3], B. Hilda Ye[1], Xingxing Zang[1], Amit Verma[1], R. Alejandro Sica[1]

[1]Albert Einstein College of Medicine, Bronx, NY,[2]City of Hope National Medical Center, City of Hope Duarte, NY,[3]American University of Beirut-Medical Center., Beirut, Lebanon

Purpose: North American Adult T-cell leukemia/lymphoma (NA-ATLL) is an aggressive HTLV-1-associated T-cell malignancy with median survival of less than 2 years. NA-ATLL cases are distinct from those in endemic regions like Japan and exhibit a correlation with poor prognosis and therapeutic resistance. Interferon-alpha/Zidovudine, when combined with other chemotherapy regimens, has shown efficacy in acute and chronic malignancies. We previously showed that Venetoclax induces mitochondrial apoptosis in NA-ATLL; however, resistance inevitably emerges despite initial sensitivity. As limited epidemiologic data delay ATLL research, our center accomplishes one of the nation's first cohorts, with ~150 cases annually, predominantly among Caribbean-descent patients. In this study, the use of Venetoclax-treated patient-derived NA-ATLL cells led to prominent Notch pathway activation, highlighting a key adaptive resistance mechanism.
Methods: Preclinically, patient-derived NA-ATLL cell lines (Pt-4a, 5a, 6a, 15a) along with Japanese patient-derived ATLL cell lines [ATL43Tb(−)] (J-ATLL) were treated with Venetoclax. RNA-seq identified adaptive survival pathways. Clinically, several patients with aggressive subtypes of NA-ATLL (Shimoyama types: lymphomatous and acute) were treated with Venetoclax-based treatment at our Institution.
Results:
Preclinical: Both NA-ATLL and J-ATLL cells responded heterogeneously to Venetoclax. In responsive lines, Venetoclax-treated cells enhanced apoptotic priming with caspase-3/PARP-1 activation, and reduced HTLV-1 HBZ and Tax expression whereas non-responders showed minimal effect, while ferroptosis was excluded. BH3 profiling confirmed NA-ATLL has unique apoptotic priming compared to J-ATLL. RNA-seq revealed robust induction of NOTCH1/2, DLL1/4, JAG1/2, and canonical targets HES1. Noteworthy, Venetoclax also upregulated the Fring*e* glycosylation genes (LFNG, MFNG, RFNG), which augment Notch receptor responsiveness, indicating a glycan-optimized Notch activation program that supports survival under BCL-2 inhibition.
Clinical: NA-ATLL patients received Venetoclax-based combinations across multiple therapy lines. Mutation profiling (TP53, NOTCH1) by NGS was correlated with outcomes. Notably, the Venetoclax-based regimes (PEG-IFN + Biktarvy + VEN) produced durable complete responses, with patients remaining alive beyond 95 and 234 days at data cutoff.
Conclusion: Venetoclax shows a significant effect in NA-ATLL both at preclinical and clinical settings, but emerging adaptive Notch signaling activation represents a crucial resistance mechanism. Our study supports evaluating Notch-directed agents (γ-secretase inhibitors/Nirogacestat) in combination with Venetoclax to overcome therapeutic resistance and improve outcomes in NA-ATLL.

#1843 Venetoclax-resistant AML cell models as a platform for exploring new generation drug for BCL2 inhibitor resistance.

Jinjin Wang, John Liu, Lin Teng

BioDuro, Irvine, CA

BCL2 is a key regulatory protein in the apoptotic pathway. Venetoclax (ABT-199), an orally bioavailable and highly selective BCL-2 inhibitor, has demonstrated promising efficacy in acute myeloid leukemia (AML) when used in combination with hypomethylating agents (HMA), leading to high remission rates and significantly prolonged overall survival. However, a considerable number of patients developed resistance or experienced relapse, highlighting the need for new strategies to overcome acquired venetoclax resistance. To investigate this issue, we established venetoclax-resistant models in three AML cell lines (RS4;11, MOLM-13, and MV 4-11) through prolonged exposure to progressively increasing concentrations of venetoclax (ranging from 1 nM to 500 nM). The resulting resistant cells exhibited a marked reduction in venetoclax sensitivity, with resistance levels exceeding 160-fold compared to their parental counterparts. These models serve as a valuable platform for evaluating novel BCL-2 inhibitors, combination treatment regimens, and other targeted agents. Moreover, they provide a crucial resource for elucidating the underlying mechanisms of venetoclax resistance.

#1844 Epigenetic rewiring of BCL6 drives responses and unveils synthetic dependencies in large B cell lymphoma.

Haopeng Yang[1], Kevin Bowman[1], Wenzhi Ji[2], Sai Gourisankar[2], Ashley L. Wilson[1], Zihan Yang[1], Ethan Marszalek[1], Stephen M. Hinshaw[2], Tinghu Zhang[2], Xiaofan Liu[2], Andrey Krokhotin[2], Sabin Nettles[2], Suprateek Kundu[1], Gerald R. Crabtree[2], Nathanael S. Gray[2], Michael R. Green[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Stanford University, Stanford, CA

Diffuse large B cell lymphoma (DLBCL) is a clinically and molecularly heterogeneous malignancy that can be classified into germinal center (GCB) and activated B cell (ABC) subtypes. Clinically, these subsets are often classified by immunohistochemistry (IHC) with CD10 and BCL6 expression being characteristic of GCB and IRF4 (MUM1) expression being characteristic of ABC. Efforts to inhibit signaling pathways active in ABC DLBCL by addition of targeted therapies to frontline chemoimmunotherapy have failed to meet their primary endpoints, and mechanisms of resistance to targeted therapies in DLBCL have not been extensively explored in clinically relevant models. Targeting BCL6 has recently emerged as an exciting therapeutic direction, with multiple BCL6 degraders now being tested in early phase clinical trials. BCL6-targeting transcriptional/epigenetic chemical inducers of proximity (TCIP) are an innovative approach to recruit transcriptional coactivators that flip BCL6 from a transcriptional repressor to an activator and induce the expression of its target genes. We thoroughly tested the efficacy of a TCIP that recruits BRD4 to BCL6-bound site (TCIP1) using our extensive PDX repository, evaluating models with uniformly high (n=5), heterogeneous (n=6) or negative (n=2) expression of BCL6 by IHC. PDX models with high BCL6 expression all responded rapidly to TCIP1, with eradication of tumors in 4/5 models including those from CAR T refractory tumors with p53 mutation. As expected, BCL6 negative models showed no response. Interestingly, BCL6 heterogeneous models also showed no response compared to vehicle control. Mechanistic studies by RNA-sequencing following short term *in vivo* exposure to TCIP1, its constituent components (BCL6 BTB binder; BRD4 binder) or vehicle control in BCL6 high (n=3) or heterogeneous (n=3) models revealed a selective up-regulation of IRF4 activity in BCL6 heterogeneous models. Evaluation by IHC showed that, at baseline, BCL6 heterogenous models consisted of mixed populations of BCL6+IRF4- and BCL6-IRF4+ cells that were polarized to a uniformly BCL6-IRF4+ state under TCIP1 pressure, then returned to heterogeneous states following secondary implantation. IRF4 can be indirectly targeted using lenalidomide (len), thus we evaluated the activity of TCIP1+len combination in two BCL6 heterogeneous models. Single agent TCIP1 or len treatment resulted in no significant reduction in tumor volume compared to vehicle control. However, TCIP+len drove significant *in vivo* responses. In conclusion, we present the first data implicating epigenetic mosaicism and plasticity as a resistance mechanism to targeted therapy in DLBCL. Using a large array of PDX models we show impressive efficacy for TCIP1 in BCL6 high DLBCL and identify a rational strategy to overcome escape via epigenetic plasticity using a combination of TCIP1 and lenalidomide to target polar epigenetic states.

#1845 Targeting mitochondrial and glutathione metabolism sensitizes leukemia cells to DNA-hypomethylating agents and venetoclax combination therapy.

Pony Yu-Ling Lee[1], Joy Khag[2], Marvin A. Aberin[2], Ta-Yu Liu[2], Ya-Ting Lu[2], Kun-Yuan Lin[1], Chao-Di Chang[1], Shan-Yun Cheng[1], Ya-Wen Hung[1], Chih-Chieh Yang[1], Yu-Hsien Chang[1], Chien-Chang Shen[1], Yao-Ming Chang[2], Hsing-Chen Tsai[3], Shih-Yu Chen[2], Shu-Ping Wang[2]

[1]Pharmacology Discovery Services Taiwan, Ltd., New Taipei City, Taiwan,[2]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan,[3]National Taiwan University College of Medicine, Taipei, Taiwan

Acute myeloid leukemia (AML) is the most common acute leukemia diagnosed in adults. DNA-hypomethylating agents (HMAs), such as decitabine and azacitidine, are widely used to treat AML and myelodysplastic syndromes (MDS). Although HMAs demonstrate only modest efficacy as monotherapies, clinical responses improve substantially when HMAs are combined with other therapeutic agents, notably venetoclax (VEN) in older patients, FLT3 inhibitors (FLT3i) for FLT3-mutated AML, and IDH inhibitors (IDHi) for IDH1/2-mutated disease. Nevertheless, drug resistance frequently emerges, emphasizing the need to elucidate resistance mechanisms and develop new therapeutic strategies. The typical schedule of HMA treatment, several consecutive days of sequential dosing followed by a rest interval, suggests that epigenetic memory may contribute to resistance. To investigate potential mechanisms of resistance, we examined the effects of transient low-dose decitabine in AML cell lines, observing that three consecutive treatment days markedly suppressed cell proliferation and viability. However, after three weeks of drug-free recovery, surviving cells regained robust growth, indicating that a subset of cells adapts and potentially acquires relapse-associated drug-resistance. We found that decitabine induces persistent mitochondrial dysfunction, characterized by altered mitochondrial networks, ultrastructure, and activity, that remains evident even after drug withdrawal and likely contributes to initial growth inhibition. Notably, surviving cells exhibit strong enrichment of the glutamate-glutathione metabolic pathway, suggesting a compensatory mechanism that mitigates mitochondrial stress. Integrated RNA sequencing and metabolomic profiling identified a key enzyme in the glutamate-glutathione metabolic pathway for this metabolic adaptation. In human AML xenograft models, inhibition of this enzyme significantly restored sensitivity to HMA (decitabine or azacytidine)-VEN combination therapy in resistant or poorly responsive AML cells. Together, our findings identify glutathione-based metabolic adaption as a potential mechanism of HMA resistance and highlight targeting mitochondrial and glutathione metabolism as a promising therapeutic strategy to enhance the efficacy of HMA-containing combination regimens.

#1847 Improve proteasome inhibitor response by targeting NHE6-mediated endosomal-autophagic machaniery in multiple myeloma.

Yutong Wang[1], Liuting Chen[1], Winston Huang[1], Jin He[1], Li Bao[2], Yihui Fan[3], Pei Lin[4], Qing Yi[1], Jing Yang[1]

[1]Houston Methodist Neal Cancer Center, Houston Methodist Research Institute, Houston, TX,[2]Department of Hematology, Beijing Jishuitan Hospital, Capital Medical University, Beijing, China,[3]Department of Pathogenic Biology, School of Medicine, Nantong University, Nantong, China,[4]Department of Hematopathology, Division of Pathology and Laboratory Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Multiple myeloma (MM) remains incurable, and resistance to frontline proteasome inhibitors (PIs) is a major barrier to improving patient survival. Identifying new therapeutic targets that overcome PI resistance is therefore essential. Through transcriptomic analysis of PI resistance gene signatures across public datasets, we identified NHE6 (*SLC9A6*) as a regulator of MM cell survival under treatment-induced stress. NHE6, an endosomal Na^+/H^+ exchanger that controls vesicular pH and membrane trafficking, has not previously been implicated in MM. We found that NHE6 is highly expressed in patient-derived primary MM cells and human MM cell lines, with further upregulation in PI-resistant cell lines. Elevated NHE6 expression levels correlated with inferior survival across independent patient cohorts. To examine the role of NHE6 in MM therapeutic response, we knocked out NHE6 expression (*sgSLC9A6*) in a panel of MM cell lines (ARP-1, MM1S, RPMI8266 and H929). We found that sg*SLC9A6* cells exhibited markedly enhanced PI-induced apoptosis *in vitro*, and significantly reduced tumor burden with prolonged survival *in vivo*. Since autophagy is a key survival mechanism under PI stress, we inhibited autophagy pharmacologically and found that PI-induced apoptosis was increased in sg*Ctrl* cells, making them similarly sensitive to sg*SLC9A6* cells. These results demonstrate that the enhanced drug response caused by NHE6 loss is autophagy dependent. Consistent with this, sg*SLC9A6* cells exhibited higher LC3B and p62 levels than sg*Ctrl* cells, and autophagy inhibition raised their accumulation in both groups to comparable levels, indicating that NHE6 loss blocks autophagic flux. Cellular fractionation localized NHE6 predominantly to early endosomes. Immunoprecipitation studies revealed that NHE6 promotes Rab7 recruitment and GTP loading, thereby accelerating early-to-late endosomal maturation and facilitating endosome–autophagosome fusion and amphisome formation. Pharmacologic inhibition of Rab7 enhanced bortezomib efficacy, like the effect of NHE6 loss. Analysis of the CoMMpass^{SM} cohort supported the clinical relevance of this pathway: non-responders displayed significantly higher Rab7 and NHE6 levels, which correlated with poorer survival. In summary, our study identifies NHE6 as a regulator of endosomal maturation, contributing to PI resistance in MM. Suppressing NHE6 restores drug sensitivity and prolongs survival in preclinical MM models. Targeting NHE6-mediated endosomal dynamics presents a promising therapeutic strategy for MM patients.

#1848 IL-1-driven signaling promotes resistance to PI3K and BCL2 inhibitors in B-cell lymphoma preclinical models.

Alberto J. Arribas[1], Federica Fuzio[1], Eleonora Cannas[1], Michela Chiappa[2], Luciano Cascione[1], Giulio Sartori[1], FIlippo Spriano[1], Andrea Rinaldi[1], Georg Stussi[3], Emanuele Zucca[1], Davide Rossi[1], Anastasios Stathis[3], Andrea Alimonti[1], Giovanna Damia[2], Massimo Broggini[2], Francesco Bertoni[1]

[1]Institute of Oncology Research, Universita della Svizzera italiana, Bellinzona, Switzerland,[2]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy,[3]Oncology Institute of Southern Switzerland, Bellinzona, Switzerland

Background: IL-1 is a central inflammatory cytokine with context-dependent effects in B-cell lymphomas, capable of supporting anti-tumor immunity but also promoting a pro-tumorigenic microenvironment. Here, we investigated the role of IL-1 in driving resistance to PI3K and BCL2 inhibitors in B-cell lymphoma preclinical.
Methods: Cell lines, including derivatives with acquired resistance to PI3K/BCL2 inhibitors obtained by long exposure to the PI3K inhibitor copanlisib in the marginal zone lymphoma (MZL) cell line VL51 (Arribas, ENA 2020), were analyzed using transcriptomics, proteomics, and immunoblotting. Functional assays assessed drug sensitivity, pathway activation, cytokine responses, and the impact of IL-1 stimulation and blockade. A 1,400-compound FDA-approved library was used in combination with copanlisib/venetoclax.
Results: VL51 cells with acquired resistance to PI3K/BCL2 inhibitors were characterized by an upregulation of IL1α and IL1β, elevated ERK and STAT3 phosphorylation, and increased expression of pro-survival and cytokine-responsive proteins. Recombinant IL-1α and IL-1β activated NF-κB and Ox-Phos in parental cells. IL-1α induced MYC and SRC targets, while IL-1β activated PI3K and STAT signaling. Either IL-1α or IL-1β reduced sensitivity to PI3K and BCL2 inhibitors in models of MZL (VL51, ESKOL), mantle cell lymphoma (REC1), and diffuse large B-cell lymphoma (OCI-Ly10). IL-1R1 blockade restored drug response. Notably, the combination of both IL-1α and IL-1β further enhanced resistance to copanlisib and to the BCL2 inhibitor venetoclax in VL51 cells. IL-1R1 blockade restored drug response. Notably, the combination of both IL-1α and IL-1β further enhanced the resistance to copanlisib and venetoclax in VL51. The drug-screen identified compounds targeting WNT, CDK, HDAC, HSP, PLK, ALDH1, AURKA, proton pump function, and microtubule dynamics that improved treatment efficacy, particularly in resistant cells. Validation studies demonstrated that several inhibitors effectively counteracted IL-1-associated resistance. The ALDH1 inhibitor disulfiram strongly restored copanlisib/venetoclax sensitivity in resistant models. Additional combinations, including ganetespib, rigosertib, panobinostat, alisertib, and AZ6102, also enhanced responses, indicating that IL-1-responsive stress, epigenetic, and mitotic pathways represent actionable vulnerabilities.
Conclusions: IL-1-driven reprogramming promotes resistance to PI3K and BCL2 inhibition in B-cell lymphoma via activation of NF-κB, STAT3, and metabolic survival pathways. Targeting IL-1 signaling or downstream effectors may overcome resistance and offer a promising therapeutic strategy for relapsed or refractory B-cell lymphomas.

#1849 Dual inhibition of AURKA and ERBB overcomes resistance to PI3K/BTK/BCL2 inhibitors in marginal zone lymphoma models.

Emma Pesenti[1], **Alberto J. Arribas**[1], Maidel Carpio[1], Eleonora Cannas[1], Georg Bischof[2], Francesco Bertoni[1]

[1]Institute of Oncology Research, Universita della Svizzera italiana, Bellinzona, Switzerland,[2]Puma Biotechnology, Inc., Los Angeles, CA

Background: Despite recent therapeutic advances, resistance to targeted agents remains a major barrier to durable responses in B-cell lymphomas, including marginal zone lymphoma (MZL). Aurora kinase A (AURKA) inhibition has shown promise in overcoming chemotherapy resistance and improving outcomes in MYC-driven B-cell lymphomas (Park et al., 2019). In parallel, ERBB4 signaling mediates resistance to PI3K and BTK inhibitors through activation of the PI3K-AKT pathway (Arribas et al., 2024). The AURKA inhibitor alisertib is currently in clinical development, while the pan-ERBB inhibitor neratinib is FDA/EMA-approved for use across several malignancies, providing an opportunity for rapid translation. Here, we evaluated the antitumor activity and mechanisms of alisertib and neratinib, alone or combined with the BTK inhibitor ibrutinib, in MZL models with acquired resistance to PI3K/BTK/BCL2 inhibitors.**Methods**: MZL cell lines Karpas1718 and VL51, along with their derivatives resistant to PI3K/BTK/BCL2 inhibitors (Arribas et al., 2022; 2024; 2025), were treated with alisertib, neratinib, and ibrutinib individually or in combination. Cell viability, apoptosis, and immunoblotting assays were used to assess drug activity, synergy, and modulation of signaling pathways.**Results**: Alisertib and neratinib displayed strong, dose-dependent anti-lymphoma activity and maintained efficacy in models resistant to PI3K, BTK, and BCL2 inhibitors. Their combination with ibrutinib produced additive/synergistic effects, significantly enhancing apoptosis compared with ibrutinib alone, including in BTK-resistant cells. The alisertib/ibrutinib/neratinib triple combination induced the most profound suppression of cell growth, outperforming the dual-agent regimens. Mechanistically, triple therapy suppressed phosphorylation of AURKA and its downstream target, PLK1, reduced ERK activation, and downregulated the prosurvival protein MCL1. Notably, alisertib plus neratinib overcame ibrutinib resistance in both Karpas1718 and VL51, despite not directly enhancing BTK inhibition.**Conclusions**: Dual inhibition of AURKA and ERBB pathways with alisertib and neratinib synergizes with BTK blockade to overcome resistance to multiple targeted therapies in MZL. Given the clinical availability of neratinib and emerging safety data for alisertib, these findings highlight a therapeutically actionable strategy that could be rapidly advanced into early-phase trials for relapsed/refractory MZL. This combination approach may expand treatment options for patients with limited responses to current PI3K, BTK, or BCL2 inhibitors.

#1850 Co-targeting EZH2 and TEAD elicits apoptosis through tumor-intrinsic innate immune signaling in Hippo pathway-mutated cancers.

Antja-Voy Hartley[1], Mustafa Al-Dulaimi[1], Navin R. Mahadevan[2], Pinar Eser[3], William W. Feng[1], Tran Thai[1], Jeanelle A. Tsai[1], Caitlyn Weston[1], Nicholas Tourtillot[1], Matthew Booker[1], Joseph Kulesza[1], Zhaorong Li[1], Elizabeth Cohen[1], Sean Lenahan[1], Choudhury Fabliha Yusuf[1], Abeba Teshager[1], Prafulla C. Gokhale[1], Shweta Kukreja[1], Sonsoles Liria Veiga[1], Rong Li[1], Xintao Qiu[1], Henry W. Long[1], Michael Y. Tolstorukov[1], Matthew G. Oser[1], Nathanael S. Gray[4], David A. Barbie[1], Pasi A. Janne[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]University of Michigan, Ann Arbor, MI,[3]Broad Institute, Boston, MA,[4]Stanford University, Stanford, CA

TEA/TEF-domain [TEAD] inhibitors are being evaluated in clinical trials for cancers with alterations in the Hippo pathway including mesothelioma. We recently developed and showcased the potency of TEAD palmitoylation inhibitors MYF-03-69 and MYF-03-176 in mesothelioma cell lines. However, TEAD inhibition results in cell cycle arrest in cell line models with Hippo pathway alterations without inducing cell death, potentially limiting their long-term clinical efficacy. Using a genome-wide CRISPR/Cas9 screen, we identified EZH2 as a critical modulator of the cellular response to TEAD inhibition. Compared to single agent treatments, EZH2i/TEADi robustly triggered apoptosis and suppressed the growth of Hippo-mutated cells *in vitro* and *in vivo.* Mechanistically, EZH2i/TEADi-treated cells exhibited heightened activation of tumor-intrinsic innate immune signaling which resulted in DNA damage and subsequent apoptosis. Taken together, we propose this novel combinatorial strategy as a potential approach to enhancing the anti-tumor efficacy of single agent TEAD targeting therapies in Hippo pathway altered tumors.

#1851 Overcoming drug resistance in ccRCC through inhibition of protein phosphatase 5 (PP5).

Sarah J. Backe[1], Rebecca Sager[1], Jennifer Heritz[1], John Chisholm[2], Mark Woodford[1], Dimitra Bourboulia[1], Gennady Bratslavsky[1], Mehdi Mollapour[3]

[1]SUNY Upstate Medical University, Syracuse, NY,[2]Syracuse University, Syracuse, NY,[3]Postdoctoral Research Fellow, Urologic Onc. Branch, SUNY Upstate Medical University, Syracuse, NY

BACKGROUND: Belzutifan is an FDA approved small molecule inhibitor used for the treatment of patients with advanced clear cell renal cell carcinoma (ccRCC). Belzutifan inhibits HIF2α, a transcription factor that promotes tumor angiogenesis and metastasis. Although ccRCC patients can potentially develop resistance to belzutifan there are currently no strategies to counteract this drug resistance in patients. We have identified that serine/threonine protein phosphatase-5 (PP5) expression and activity is elevated in ccRCC, contributing to its pro-survival role. We have designed and developed small molecule inhibitors of PP5. The objective of this study was to examine whether PP5 inhibition can cause apoptosis in belzutifan-resistant ccRCC cells.
METHODS: Belzutifan-resistant ccRCC cells were developed by treating 786-O cells with 10μM belzutifan. Once 70% confluent, the cells were split and treated with 10μM belzutifan again. This process was repeated until the cells appeared healthy and grew at a similar rate to 786-O without belzutifan treatment. Belzutifan was removed from the cells for at least 24 hours before additional drug treatments and/or protein extraction. Compound P053 is a second-generation small molecule inhibitor of PP5. Belzutifan-resistant ccRCC cells were treated with either 1μM or 10μM of P053 for 24 hours and apoptotic markers were evaluated by immunoblotting to examine cleaved caspase-3 and cleaved-PARP.
RESULTS: The second generation PP5 inhibitor P053 has the ability to bind to the catalytic domain and inhibit the phosphatase activity of PP5. Belzutifan-resistant ccRCC cells are able to maintain growth in the presence of 10μM belzutifan and do not display any hallmarks of activation of apoptosis. Treatment of belzutifan-resistant cells with either 1μM or 10μM of P053, however, induced apoptosis, as evidenced by elevated levels of cleaved caspase-3 and cleaved-PARP.
CONCLUSIONS: PP5 inhibition with our novel small molecule inhibitor retains the ability to cause apoptosis in belzutifan-resistant cells. This suggests PP5 is a viable therapeutic target in advanced ccRCC even after belzutifan resistance.

#1852 CRISPR screening identifies BMF loss as a drug-tolerant persister cell survival factor in ALK-rearranged lung cancer.

Ryohei Katayama[1], Takahiro Utsumi[1], Ken Uchibori[2], Makoto Nishio[3]

[1]Japanese Foundation for Cancer Research, Tokyo, Japan,[2]Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan,[3]Department director, Department of Thoracic Medical Oncology, Japanese Fndn. for Cancer Res. Cancer Institute, Tokyo, Japan

Anaplastic lymphoma kinase (ALK) tyrosine kinase inhibitors (ALK-TKIs) have significantly improved the clinical outcomes of patients with ALK-rearranged non-small cell lung cancer (NSCLC). However, the development of resistance remains a major obstacle to long-term therapeutic success. Drug resistance is believed to develop from drug-tolerant persister (DTP) cells that survive drug treatment. Therefore, understanding the molecular mechanisms underlying DTP formation and survival is critical for developing strategies to overcome resistance and extend patient survival.To identify the factors related to the survival of DTP cells, we conducted a genome-wide CRISPR-Cas9 knockout screening using patient-derived ALK-positive NSCLC cells. From the Crispr screening, we identified the pro-apoptotic factor BMF (Bcl-2 modifying factor) as a critical determinant of DTP formation. BMF expression was rapidly induced following ALK-TKI exposure or dual inhibition of ERK and PI3K signaling, suggesting its role as a mediator of apoptotic induction by ALK-TKIs. Strikingly, BMF knockout cells exhibited impaired apoptosis and an increased fraction of DTPs under ALK-TKI treatment, highlighting its essential function in limiting drug tolerance.Mechanistic studies revealed that pharmacologic or siRNA-mediated inhibition of MCL-1 restored apoptosis and eliminated BMF-deficient DTP cells, underscoring the therapeutic potential of targeting anti-apoptotic pathways. Furthermore, knockdown of FOXO1 resulted in the upregulation of BMF, indicating that FOXO1 acts as a transcriptional repressor of BMF. These findings suggest the existence of a regulatory axis in which FOXO1 suppresses BMF, thereby promoting the survival of DTP cells.In addition, patient tumor samples collected before and after ALK-TKI therapy, together with publicly available datasets, were analyzed to evaluate the clinical relevance of these findings. The clinical analyses revealed that low BMF expression was associated with poor treatment response and shorter overall survival in patients with ALK-positive non-small cell lung cancer (NSCLC). Moreover, BMF genomic loss was found relatively frequently across diverse cancer types, suggesting that BMF deficiency may be a common mechanism contributing to drug tolerance and resistance beyond ALK-driven lung cancer.In summary, our study demonstrates that BMF deficiency promotes the formation of DTP cells and contributes to therapeutic resistance in ALK-positive NSCLC. Importantly, targeting MCL-1 or FOXO1 may be a promising strategy for eradicating DTPs and enhancing the durability of ALK-TKI responses. These findings provide mechanistic insight into the regulation of persister cell apoptosis and highlight actionable vulnerabilities that could be exploited to improve patient outcomes.

#1853 NAT10-mediated ac^{4}C RNA modification promotes colorectal cancer stemness and 5-FU resistance via ATG5-dependent autophagy.

Xin Kong[1], Junyong Weng[1], Zhe Wang[2], Ajay Goel[1]

[1]Department of Molecular Diagnostics and Experimental Therapeutics, Beckman Research Institute of City of Hope, Monrovia, CA,[2]Department of Pathology, The First Affiliated Hospital of USTC, University of Science and Technology of China, Hefei, China

Background: Colorectal cancer (CRC) is the third most common malignancy and the second leading cause of cancer-related death globally. Although 5-fluorouracil (5-FU)-based chemotherapy remains a mainstay, acquired resistance severely limits its clinical benefit. The objective response rate to first-line combination therapy remains only 40-50%, and the 5-year survival for metastatic CRC hovers around 12%. Autophagy enables tumor cells to survive chemotherapy-induced stress, and targeting protective autophagy has emerged as a promising approach to reverse chemoresistance. RNA modifications can influence this process. N-acetyltransferase 10 (NAT10), the sole RNA N^4-acetylcytidine (ac^{4}C) acetyltransferase, has been implicated in cancer progression, but its role in autophagy-driven 5-FU resistance remains undefined. This study explores how NAT10 regulates autophagic activity and contributes to 5-FU resistance in CRC.

Methods: Integrative clinical and bioinformatics analyses were conducted to examine the association between NAT10 expression and 5-FU resistance in CRC. Complementary in vitro assays assessed the functional role of NAT10 in CRC progression and chemoresistance. Mechanistic studies, including pathway enrichment analyses, autophagic flux assays, and genetic epistasis experiments, were conducted to elucidate the signaling pathways downstream of NAT10. RNA immunoprecipitation (RIP) and ac^{4}C-specific RIP were used to identify direct molecular targets, and pharmacologic inhibition was applied to evaluate NAT10 as a therapeutic target.

Results: NAT10 was found to play a key oncogenic role in CRC by promoting cell proliferation, migration, and stemness. NAT10 expression was significantly higher in 5-FU-resistant CRC cells (p<0.001). NAT10 depletion markedly suppressed proliferation (p<0.001) and restored sensitivity to 5-FU. Mechanistically, NAT10 stabilized ATG5 mRNA through ac^{4}C modification ($t_{1/2}$ = 12.2 h vs. 20.1 h), thereby enhancing autophagic flux, which sustains cancer stemness and supports resistance to 5-FU. Loss of NAT10 resulted in reduced LC3-II accumulation and increased p62 expression, indicating impaired autophagy, and significantly decreased sphere-forming ability (p<0.001), along with downregulation of stemness markers, ultimately sensitizing resistant cells to 5-FU. Similarly, pharmacological inhibition of NAT10 repressed autophagy and significantly lowered the 5-FU IC50 values (~2.2-fold), thereby restoring 5-FU sensitivity in CRC models.

Conclusion: The NAT10-ATG5-autophagy axis represents a critical mechanism underlying chemoresistance in CRC. Targeting NAT10-mediated RNA acetylation disrupts autophagy-driven survival and restores 5-FU responsiveness, offering a promising therapeutic strategy for overcoming treatment resistance in colorectal cancer.

#1854 Selective Mcl-1 inhibition with KS18 overcomes apoptotic resistance and enhances FLT3-targeted therapy in acute myeloid leukemia.

Sahil Jethi[1], Krishne Gowda[2], Tulin Budak-Alpdogan[3], Subash C. Jonnalagadda[4], Manoj K. Pandey[1]

[1]Department of Biomedical Sciences, Cooper Medical School of Rowan University (CMSRU), Camden, NJ,[2]Department of Pharmacology, Penn State College of Medicine, Hershey, PA,[3]Cooper University Health Care, MD Anderson Cancer Center at Cooper, Camden, NJ,[4]Department of Chemistry and Biochemistry, Rowan University, Camden, NJ

Acute myeloid leukemia (AML) remains the most common adult leukemia and continues to have a dismal 5-year survival rate below 30 percent, largely due to relapse driven by therapy-resistant leukemic clones. Overexpression of the anti-apoptotic protein Mcl-1 is a major mechanism of such resistance, particularly against FLT3 and BCL-2 inhibitors, making selective Mcl-1 blockade a compelling therapeutic strategy. Here, we evaluate KS18, a highly selective small-molecule Mcl-1 inhibitor developed in our laboratory, as a single agent and in rational drug combinations in AML models (MOLM-13, MV4-11, THP-1) including a venetoclax-resistant line (MV4-11 VR). KS18 potently restored intrinsic apoptotic signaling by targeting the BH3-binding groove of Mcl-1 and releasing bound pro-apoptotic effectors (BIM, BAK, BAX), resulting in mitochondrial outer membrane permeabilization, cytochrome-c release, and robust caspase-dependent apoptosis. Mechanistically, KS18 induced mitochondrial dysfunction as evidenced by altered oxygen consumption (OCR) and extracellular acidification (ECAR) profiles. Combination treatment with either the FLT3 inhibitor quizartinib or the multi-kinase inhibitor sitravatinib yielded strong synergistic cytotoxicity through concurrent Mcl-1 suppression and inhibition of upstream survival pathways including FLT3/STAT5, AKT, and ERK. These combinations markedly enhanced cleaved caspase-3 and PARP levels, confirming extensive mitochondrial apoptosis. Together, these findings identify KS18 as a promising next-generation therapeutic candidate with both single-agent efficacy and strong combination potential for overcoming drug resistance and relapse in AML. Ongoing studies are generating FLT3 inhibitor-resistant models and evaluating KS18 in vivo across diverse FLT3 mutation backgrounds to accelerate its translational development for relapsed and refractory AML.

#1855 PI3K/mTOR dual inhibitor overcomes ceritinib resistance in ALK-rearranged NSCLC via both apoptosis and autophagy.

Hyun-Min Ryu[1], Joo Young Ha[2], Shinkyo Yoon[1], Yunkyung Sung[1], Deokhoon Kim[3], Chang Hoon Lee[4], Wanlim Kim[5], Seyoung Seo[1], Sang-We Kim[1], Kang-Seo Park[1], Dae Ho Lee[1]

[1]Oncology, Asan Medical Center (AMC), Seoul, Korea, Republic of,[2]Internal Medicine, Veterans Health Service Medical Center, Seoul, Korea, Republic of,[3]Pathology, Asan Medical Center (AMC), Seoul, Korea, Republic of,[4]SCBIO Inc, Daejeon, Korea, Republic of,[5]Orthopaedic Surgery, Asan Medical Center (AMC), Seoul, Korea, Republic of

Anaplastic lymphoma kinase-Tyrosine kinase inhibitors (ALK-TKIs) have substantially improved the treatment landscape for ALK-rearranged NSCLC; however, resistance to these agents remains a persistent clinical challenge. Whereas on-target resistance caused by secondary ALK mutations can be addressed with next-generation inhibitors, off-target resistance driven by activation of alternative RTKs is highly variable and often difficult to predict, making the development of a unifying therapeutic strategy complex. We investigated whether targeting the common downstream PI3K/AKT signaling pathway shared across multiple RTKs could provide an effective strategy to counter ALK-TKI resistance. In NSCLC cells resistant to ceritinib, a second-generation ALK-TKI, we observed that the PI3K/AKT signaling was robustly reactivated despite sustained suppression of ALK activity. Surprisingly, pharmacologic inhibition of AKT alone produced minimal anti-tumor effects, suggesting the presence of additional survival pathways beyond AKT itself. Based on previous reports showing that ALK contains an LC3-interacting region (LIR) motif whose dephosphorylation enhances autophagy, we investigated mTOR signaling as a potential compensatory pathway. Notably, PI3K/mTOR dual inhibition, rather than AKT inhibition alone, induced a markedly stronger anti-cancer response. Dual inhibition resulted in coordinated activation of apoptosis and autophagy-associated cell death, supported by significant changes in both apoptotic and autophagic markers, indicating a synergistic elimination of resistant cells. Because off-target resistance involves diverse and often unpredictable RTK-bypass activations, our findings suggest that PI3K/mTOR dual inhibition can target a broader range of downstream resistance mechanisms whenever ALK function is already pharmacologically suppressed. These results position PI3K/mTOR dual inhibitors as a promising therapeutic option for overcoming non-ALK-mutation-driven resistance in ALK-positive NSCLC, with potential translational relevance for patients who experience repeated TKI failure due to complex RTK-bypass signaling.

#1856 Downregulation of ETV4 mediates trametinib resistance via AMPK-ULK1-dependent protective autophagy in breast cancer.

Xiaodong Liu, Ji Won Kim

Jeju Research Institute of Pharmaceutical Sciences, College of Pharmacy, Jeju National University, Jeju, Korea, Republic of

Trametinib is a selective MEK1/2 inhibitor initially approved for melanoma and later extended to BRAF-mutant non-small cell lung cancer and thyroid cancer, either as monotherapy or in combination with a BRAF inhibitor. The favorable pharmacologic profile of trametinib has prompted broader evaluation across cancers driven by MAPK/ERK signaling. However, its efficacy as monotherapy in breast cancer (BCa) remains limited, partly due to adaptive resistance mechanisms. Therefore, we aimed to elucidate the molecular mechanisms underlying trametinib resistance in BCa and to validate therapeutic strategies that restore sensitivity. Here, we first found that trametinib responsiveness was associated with suppression of ETV4 expression. In T47D, SKBR3, and MDA-MB-453 cells, trametinib treatment suppressed ETV4 and promoted autophagic flux. Mechanistically, both trametinib treatment and ETV4 silencing activated AMPK-Thr172 phosphorylation, which in turn phosphorylated ULK1 at Ser555 while simultaneously inhibiting mTOR, thereby triggering protective autophagic flux. Combination treatment with trametinib and the autophagy inhibitors chloroquine (CQ) or 3-methyladenine (3-MA) induced apoptotic pathways in vitro and suppressed T47D xenograft tumor growth in vivo. Our results reveal that trametinib-induced downregulation of ETV4 enables cancer cells to acquire a survival advantage by activating AMPK-ULK1-mediated protective autophagy. We further identified that inhibiting autophagy reverses trametinib resistance and induces apoptotic cell death, providing a readily translatable combination therapeutic strategy to enhance MEK1/2-targeted therapy in BCa.

#1857 Mechanisms of acquired resistance to BTK and BCL2 inhibitors reveal clinically actionable vulnerabilities in B-cell lymphoma.

Alberto J. Arribas[1], Camilla Scalise[1], Eleonora Cannas[1], Maria Elena Carazzolo[2], Luciano Cascione[1], Andrea Rinaldi[1], Carlo Visco[2], Davide Rossi[1], **Francesco Bertoni**[1]

[1]Institute of Oncology Research, Universita della Svizzera italiana, Bellinzona, Switzerland,[2]Department of Engineering for Innovation Medicine, Section of Biomedicine, University of Verona, Verona, Italy

Background: BCL2 inhibitors (i) and BTK-directed agents, including BTK degraders (d), are essential components of modern therapy for B-cell lymphomas. However, acquired resistance often limits long-term benefits. Identifying the molecular mechanisms that underlie resistance and understanding reciprocal drug sensitivities may help guide the rational sequencing of treatments. Here, we investigated the mechanisms of secondary resistance to the BCL2-i venetoclax and the BTK-d bexobrutideg (NX-5948) in models of marginal zone lymphoma (MZL) and mantle cell lymphoma (MCL).
Methods: Derivatives of Karpas1718 (MZL) and REC1 (MCL) with acquired resistance were developed through chronic exposure to increasing doses of venetoclax or bexobrutideg. Parental and resistant lines were characterized using drug sensitivity assays, apoptosis and cell cycle analyses, molecular profiling, and immunoblotting of apoptotic regulators and BCR signaling components.
Results: Venetoclax-resistant models from both lymphoma subtypes exhibited broad cross-resistance to other BCL2-i and upregulation of BCL-xL, with MZL cells also resistant to MCL1-i. Regulation of anti-apoptotic proteins varied among models: BCL-xL increased in both venetoclax-resistant models, whereas MCL1 increased only in Karpas1718. All venetoclax-resistant cell lines retained sensitivity to BTK-d, revealing a potential therapeutic vulnerability. Resistance to BTK-d was highly model-specific. In Karpas1718-resistant cells, no BTK degradation occurred after bexobrutideg exposure, and these cells were also resistant to BGB-16673, another BTK-d. Nonetheless, they remained sensitive to BTK-i and all BCL2-i, suggesting that switching to a different drug class could restore their response. Conversely, REC1 derivatives became resistant to both BTK-d and BTK-i. Since resistance was linked to continued drug-induced BTK degradation, these findings indicate a BTK-independent resistance mechanism. Interestingly, the bexobrutideg-resistant REC1 cells were also resistant to BCL2-i. No mutations were observed in *BTK, PLCG2, or BCL2*.
Conclusions: In two distinct B-cell lymphoma models, resistance to venetoclax and BTK-d developed through target-specific and model-specific adaptations involving anti-apoptotic reprogramming, altered BCR signaling dependence, and incomplete BTK degradation. Notably, cross-drug sensitivities persisted in several contexts: venetoclax-resistant MZL and MCL cells remained susceptible to BTK degradation, while BTK-d-resistant MZL cells continued to respond to BCL2 inhibition. These insights emphasize clinically actionable strategies for treatment sequencing and support precision approaches to overcome therapeutic resistance in B-cell lymphoma.

#1858 FAK inhibition by APG-2449 enhances the antitumor activity of MAPK pathway blockade in *BRAF* V600E-mutant tumor models.

Zhou Yu[1], Zhiyan Liang[2], Xinyi Yao[1], Shujie He[1], Dajun Yang[1], Yifan Zhai[2]

[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China,[2]Ascentage Pharma Group Inc., Rockville, MD

Background: *BRAF* mutations are present in approximately 4% to 8% of all cancers, predominantly in colorectal cancer (CRC), melanoma, and non-small-cell lung cancer. Among them, the V600E mutation is the most common and functionally activating form, leading to constitutive activation of the mitogen-activated protein kinase (MAPK) signaling cascade. Combined BRAF and MEK inhibition has shown substantial clinical benefit in *BRAF* V600E-mutant melanoma and CRC. However, resistance frequently develops through feedback reactivation of ERK or compensatory activation of the PI3K-AKT signaling pathway. Recent evidence indicates that focal adhesion kinase (FAK) signaling is also adaptively reactivated upon MAPK inhibition, contributing to therapeutic resistance. This study evaluated the effects of APG-2449, a potent and selective multikinase (FAK) inhibitor, on the antitumor activity of BRAF inhibitor dabrafenib and MEK inhibitor trametinib in *BRAF* V600E-mutant CRC and melanoma preclinical models.

Methods: Cell proliferation was measured by CellTiter-Glo® assay or clonal formation assay. Apoptosis was assessed using flow cytometry. Protein expression levels were examined by western blot. Antitumor effects of APG-2449, alone or combined with dabrafenib and trametinib, were evaluated in C32 and RKO xenograft models *in vivo*.

Results: Cell proliferation assays across a panel of human cancer cell lines revealed that cell lines harboring *BRAF* V600E were more sensitive to APG-2449 than those without MAPK pathway alterations. APG-2449 synergistically enhanced the antiproliferative efficacy of dabrafenib and trametinib in both BRAF inhibitor-sensitive (C32 and Colo205) and -insensitive (RKO and LS411N) cells. The triple combination (APG-2449 + dabrafenib + trametinib) caused synergistic growth inhibition in C32 and RKO cells compared with BRAF/MEK dual blockade. Mechanistically, APG-2449 attenuated feedback reactivation of ERK signaling and bypass activation of the PI3K-AKT pathway induced by BRAF/MEK inhibition, resulting in sustained suppression of p-ERK and p-AKT expression, prolonged cell growth inhibition, and enhanced cell apoptosis. In *in vivo* studies, the triple combination (T/C: 4.55% for C32; 17.18% for RKO) outperformed APG-2449 alone (T/C: 106.09% for C32; 96.93% for RKO) or dabrafenib + trametinib (T/C: 35.39% for C32; 78.45% for RKO) in tumor growth inhibition. APG-2449 synergistically enhanced the antitumor activity of trametinib + dabrafenib in C32 and RKO xenograft models, with synergy ratios of 8.25 and 4.43, respectively.

Conclusions: APG-2449 suppresses compensatory signaling activation induced by MAPK pathway blockade and synergistically enhances the antitumor activity of dabrafenib + trametinib. These results warrant clinical development of APG-2449 for patients with melanoma or CRC harboring *BRAF* V600E.

#1859 Overexpression of fructose transporter increases pro-survival signaling and confers venetoclax resistance in Ph-like B-cell acute lymphoblastic leukemia.

Serene Xavier[1], Sonia Rodriguez[1], Zhaohui Gu[1], Lucy Ghoda[1], Stuart Blakemore[2], Lukas Frenzel[2], Alexey Danilov[1], Vinod Pullarkat[1]

[1]City of Hope National Medical Center, Duarte, CA,[2]University Hospital Cologne, Colonge, Germany

Philadelphia chromosome-like (Ph-like) B-cell acute lymphoblastic leukemia (B-ALL) represents a high-risk subtype characterized by therapy resistance and an adverse clinical profile similar to Ph+ ALL. Recent evidence highlights the growing significance of metabolic reprogramming in drug resistance in B-ALL. We have identified increased fructose transporter GLUT5 expression in Ph-like and Ph+ primary samples and cell lines compared to other B-ALL subsets. In this study, we aim to investigate the novel mechanistic roles of GLUT5 in pro-survival signaling and drug resistance in Ph-like B-ALL. Firstly, to study the role of GLUT5 and fructose availability in cell proliferation, Ph-like B-ALL cell lines (MHH-cALL4 and MUT5Z) stably expressing GLUT5 or empty vector control, were cultured in glucose- or fructose-rich standard media. GLUT5-overexpressing B-ALL cell lines in glucose- or fructose-rich media showed increased proliferation (quantified by CFSE) when compared to control in glucose-rich media. GLUT5-overexpressing cells showed increased colony formation in glucose- or fructose-rich media, while control cells showed the same effect only in fructose-rich media when compared to those in glucose-rich media, indicating that GLUT5-mediated fructose uptake provided a proliferation advantage. To gain better insights on the significance of GLUT5 expression in high-risk B-ALL, bulk RNA-Seq was performed on control or GLUT5-overexpressing Ph-like B-ALL cell lines in glucose- or fructose-rich media. Pro-survival signaling pathways (such as PI3K/AKT, MAPK, NFKB, HIF-α and others) were significantly upregulated in GLUT5-overexpressing cell lines in glucose- or fructose-rich and control cells in fructose-rich conditions (vs. control in glucose-rich condition). We confirmed increased expression of p-AKT/AKT, MYC and NFKB in GLUT5-overexpressing Ph-like B-ALL cell lines in glucose- or fructose-rich conditions by immunofluorescence and immunoblotting. Further, increased BCL-2 expression was observed in GLUT5-overexpressing Ph-like cell lines in fructose-rich conditions only, indicative of the potential role of GLUT5 and fructose availability in conferring venetoclax resistance. Consistent with this, GLUT5-overexpressing B-ALL cell lines treated with venetoclax in fructose-rich media showed significantly increased resistance vs. control. A combination of venetoclax with serine synthesis pathway (SSP) inhibitor partially reversed venetoclax resistance. This suggests that GLUT5 expression and fructose availability may divert glycolytic pathway intermediates to SSP as an alternative cell survival mechanism. In summary, GLUT5 may have clinically relevant role in high-risk B-ALL where it modulates pro-survival signaling and confers therapy resistance.

#1860 Determining mechanisms of ONC212-resistance in uveal melanoma to develop combination therapy strategies.

Md Alauddin, Chandrani Chattopadhyay

Department of Melanoma Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

Uveal melanoma (UM) is the most common primary eye cancer in adults, affecting ~2,500 people annually in USA. Metastasis in ~50% of UM patients is predominantly to the liver (>95%), resulting in poor prognosis. Only two FDA-approved therapies exist for metastatic UM (mUM), with poor response rates. There is an urgent need for developing new therapeutic strategies to achieve effective response. Our preliminary studies indicated that mUM has high Oxidative Phosphorylation (OXPHOS). Indirect targeting of OXPHOS with the imipridone compound ONC212, significantly inhibited UM cell survival, reduced tumor burden and improved survival in orthotopic liver mUM mouse models. However, extended treatment resulted in tumor recurrence, suggesting acquired resistance. Thus, successful translation of the growth inhibitory effect of ONC212 in mUM depends on identification of ONC212 resistance mechanisms and new targets. In this study, we generated and characterized multiple ONC212-resistant UM cell clones. More than thirty ONC212-resistant clones were generated from MM28 and MP46 parental UM cells via prolonged treatment with high-dose ONC212 (0.3 μM). Cell viability assays were done to calculate IC_{50} and resistance index (RI) for ONC212, and mitochondrial function was assessed using the Seahorse Mito Stress Test. Whole-genome sequencing (WGS) was used to identify acquired mutations in resistant clones, while proteomic profiling via Reverse Phase Protein Array (RPPA) was used to determine alterations in cell signaling pathways. A high throughput drug screen was completed to identify sensitivities of ONC212-resistant cells to approved anticancer drugs. Orthotopic liver-mUM mouse models were generated with resistant cells and growth of tumors monitored by bioluminescence imaging. ONC212-resistant clones exhibited higher $IC_{50,}$ and RI compared to parental cells and showed cross-resistance to other imipridones (ONC201, ONC206), suggesting shared mechanisms of resistance. Resistant clones displayed reduced sensitivity to ONC212-mediated OXPHOS inhibition. WGS of each resistant clone confirmed mutations in CLPP, the target of ONC212 action in UM cells. RPPA data revealed alterations in multiple cell signaling pathways. Bioluminescence imaging of liver mUM *in vivo* models revealed rapid proliferative capacity of ONC212-resistant clones. Using these preclinical models and the compounds identified in drug screen, combination therapy strategies will be tested and validated for clinical studies in future. Importantly, ONC201, the first imipridone was recently approved for therapy of midline gliomas. Therefore, lessons learned from this study may benefit patients acquiring resistance to ONC201 in future as well.

#1861 Acquired drug resistance with autophagy is suppressed by fatty acid oxidation inhibition in pancreatic ductal adenocarcinoma.

Soo-Youl Kim, Sang M. Woo, Wonyoung Choi, Joon Hee Kang, Sung Hoon Sim, Jung Won Chun

National Cancer Center, Goyang, Korea, Republic of

Purpose: We found that irinotecan treatment of pancreatic ductal adenocarcinoma (PDAC) induces autophagy. Autophagy enhances fatty acid oxidation (FAO), resulting in increased ATP production. Elevated ATP levels subsequently are linked to mTOR activation. As a result, prolonged chemotherapy paradoxically co-activates mTOR and autophagy, which are two pathways traditionally known to suppress each other, resulting in the promotion of acquired drug resistance.
Experimental Design: To test whether blocking FAO reverses the acquired drug resistance, inhibition of FAO achieved by dual knockdown of carnitine-acylcarnitine carrier and acetyl-CoA acyltransferase 1 or inhibited the targets by KN510 and KN713. Anti-cancer effect was examined by xenograft model using human pancreatic cancer cells. Synergy of KN510 and KN713 with chemotherapeutic drugs also tested using a xenograft model.
Results: We found that a combination treatment of KN510 and KN713 accompanied with irinotecan abolished autophagy activation and suppressed mTOR, resulting absence of drug resistance. In a PDAC xenograft model, combination treatment with irinotecan and the FAO inhibitor KN510713 significantly decreased acquired resistance, whereas irinotecan alone led to tumor regrowth.
Conclusion: These findings highlight that the FAO pathway is a key mechanism of cancer-specific autophagy, supporting its role in the development of acquired drug resistance during chemotherapy.
Funding source: Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science and ICT to SK (NRF-2019M3A9G1104345) and was supported by a grant from the National Cancer Center of Korea to WC (NCC 2410891-2).

#1862 Targeting nucleolin overcomes MCL-1-mediated venetoclax resistance in acute myeloid leukemia.

Kyung Jin Kim, Jihyun Um, Eun Jung Shin, Yu Mi Ji, Sung Hwan Moon, Soo Jin Lee

Aptabio Therapeutics Inc., Yongin, Korea, Republic of

BCL-2 inhibitors, such as venetoclax, have become a standard treatment for acute myeloid leukemia (AML), particularly for patients ineligible for intensive chemotherapy. However, a significant number of patients are refractory or acquire resistance, which remains a major clinical challenge. MCL-1, an anti-apoptotic Bcl-2 family protein, is well recognized to play critical roles in resistance to venetoclax treatment and there is a significant unmet need for the development of effective therapies that inhibit MCL-1 to overcome venetoclax resistance. Nucleolin (NCL) is a multifunctional protein frequently overexpressed on the surface of AML cells and is implicated in promoting cancer cell survival and drug resistance by regulating various oncogenic transcripts. This study provides the first evidence that NCL acts as an upstream regulator of MCL-1 and that inhibition of NCL can effectively overcome venetoclax resistance in AML by downregulating MCL-1. As a result, we found that the expression levels of NCL and MCL-1 were significantly elevated in venetoclax-resistant AML cell lines, and that siRNA-mediated genetic knockdown of NCL led to a significant reduction of MCL-1 expression levels along with a corresponding induction of cleaved caspase-3, confirming the activation of apoptosis. APTA-16 is a first-in-class therapeutic for AML that specifically targets NCL developed using aptamer-drug conjugation (APTA-DC) technology. To confirm the role of NCL in MCL-1-mediated venetoclax resistance, we treated venetoclax-resistant AML cell lines with Apta-16, and Apta-16 significantly reduced in both NCL and MCL-1 expression levels and activated caspase-3. Furthermore, in a C1498 syngeneic mouse model of venetoclax-resistance in vivo, Apta-16 monotherapy significantly improved the survival rate, whereas venetoclax showed no therapeutic benefit. In addition, we also confirmed that in vivo Apta-16 treatment markedly decreased intratumoral levels of NCL and MCL-1 expression.In conclusion, our findings demonstrate that the NCL-MCL-1 axis plays a critical role in mediating venetoclax resistance in AML and inhibition of NCL can be a promising strategy to disrupt this axis and overcome venetoclax resistance. Therefore, the results suggest that Apta-16 has strong potential as an effective therapy approach to overcome venetoclax resistance in in patients with relapsed or refractory AML. GLP safety/toxicity studies of APTA-16 have been completed, and orphan drug designation (ODD) was granted by FDA.

#1863 Development and characterization of the venetoclax-resistant AML model to enable preclinical drug discovery.

Jifan Yuan[1], Miaomiao Yu[1], Gaoxiang Liu[1], Jian Xiang[1], **Xiangnan Qiang**[2], Zhixiang Zhang[2]

[1]In Vivo Pharmacology Unit, WuXi Biology, WuXi AppTec, Suzhou, China,[2]In Vivo Pharmacology Unit, WuXi Biology, WuXi AppTec, Shanghai, China

Acute myeloid leukemia (AML) is an aggressive type of hematological cancer, causing over 100,000 death per year globally. Venetoclax, a BCL-2 antagonist, was approved in 2018 for the treatment of AML in combination with Azacytidine. Through neutralizing BCL-2 function, Venetoclax restores the apoptotic cascade in tumor cells. However, long-term efficacy of Venetoclax is often limited by the development of drug resistance, underscoring the need for preclinical Venetoclax-resistant (Ven-R) tumor models. In this study, we successfully established two Venetoclax-resistant cell lines, Ven-R-MV4-11 and Ven-R-MOLM-13, through chronic exposure to Venetoclax. Compared to the parental cell lines, both resistant cell lines exhibited increased expression of MCL-1, an anti-apoptotic protein that plays a crucial role in Venetoclax resistance. Cell viability assays in these resistant cell lines demonstrated strong synergy between Venetoclax and two MCL-1 inhibitors, AMG-176 and MIK665. *In vivo*, both Ven-R-MV4-11 and Ven-R-MOLM-13 models showed increased growth rate and substantial resistance to Venetoclax alone and in combination with Azacytidine (standard therapy). Interestingly, the MCL-1 inhibitor, MIK665 effectively overcame the resistance in the Ven-R-MV4-11 tumor model when used in combination with Venetoclax and Azacytidine. In conclusion, we have developed two Venetoclax-resistant AML models, which serve as a promising tool for mechanistic research and drug discovery aimed at overcoming the BCL2 inhibitor resistance.

#1864 G3BP1 knockdown sensitizes the acute myeloid leukemia cell line HL60 to venetoclax by inducing apoptosis.

Naoko Hosono[1], Rie Nishi[1], Naoko Ida[2], Chantana Polprasert[3], Rosesanun Pavaputanont[3], Takahiro Yamauchi[4]

[1]University of Fukui, Fukui, Japan,[2]University of Fukui Hospital, Japan,[3]Center of Excellence in Translational Hematology, Chulalongkorn University, Bangkok, Thailand,[4]Asst. Professor, First Dept. of Internal Med., University of Fukui, Fukui, Japan

Background: G3BP1 is an RNA-binding protein that acts as the primary nucleation factor for the assembly of stress granules (SG). Its functions are central to the cellular stress response, survival, and fate decisions. G3BP1 is located on the long arm of chromosome 5 and deletion of this region is a recognized poor prognostic factor in acute myeloid leukemia. Given that G3BP1 is highly expressed in hematopoietic stem cells and functions to stabilize p53, its deficiency is hypothesized to be implicated in the tumorigenesis and therapeutic resistance of leukemic cells.
Methods: To investigate the role of G3BP1, a G3BP1 knockdown cell line was generated by introducing shRNA into the HL60 AML cell line. We performed analyses of expression changes and drug sensitivity, using cell lines in which the expression level was reduced to 15% by knockdown .
Results: Expression profiling via RNA sequencing demonstrated an upregulation of WT1, SAMD9L, and BCL2 expression in HL60/shG3BP1 cells (G3BP1-knockdown cells). Confirmation by Western blot analysis revealed increased protein levels of WT1 and SAMD9L. We also observed upregulation of both mTOR and its phosphorylated mTOR. HL60/shG3BP1 cells exhibited reduced sensitivity to Ara-C compared to control cells (IC50 value: 7 μM, 0.5 μM, respectively), while conversely demonstrating increased sensitivity to venetoclax (IC50 value: 4nM, 900nM, respectively). Sensitivity to other tested agents, including daunorubicin, etoposide, and Decitabine, remained unchanged. In HL60/shG3BP1 cells, venetoclax treatment led to an increased induction of apoptosis, which was accompanied by an increase in cleaved caspase-3 levels.
Conclusion: Knockdown of G3BP1 in HL60 cells resulted in enhanced sensitivity to venetoclax. This enhanced sensitivity might be explained by the impairment of G3BP1-mediated SG formation.

#1868 Resistant cell panel-based discovery of multi-target combinations and mechanisms to overcome KRAS inhibitor resistance.

Lili Chai, Yue Zhai, Xue Yang, Zhengtai Li, Ying Bi, Yan Zhang, **Tj (Tiejun) Bing**

ICE Bioscience, Beijing, China

Background: KRAS mutations are common oncogenic drivers in solid tumors, and KRAS-targeted inhibitors have revolutionized treatment. However, inherent and acquired resistance limits long-term clinical benefit, highlighting the need for effective combination strategies and their mechanisms.
Methods: 1) Generation of KRAS inhibitor-resistant cell lines: Over 10 resistant cell lines were established by long-term exposure of KRAS-mutant cancer cells to clinically approved KRAS inhibitors and novel agents (e.g., KRAS molecular glues, PI3K/RAS breakers). 2) Resistance mechanism exploration: Multi-omics bioinformatics analyses (transcriptomics, proteomics) were performed to dissect molecular drivers of resistance and predict potential synergistic combination partners. 3) High-throughput combination screening: More than 100 drug combinations (including KRAS inhibitors, targeted agents against bypass pathways, and novel scaffolds) were tested using a customized resistant cell panel to identify regimens that overcome resistance. 4) Mechanistic validation: Key signaling pathways (e.g., MAPK, PI3K-AKT, STAT3) were interrogated via Western blot, and phospho-protein arrays to confirm the functional relevance of predicted resistance mechanisms and combination efficacy.
Results: Bioinformatics analyses of resistant cell lines revealed diverse resistance mechanisms, including upregulation of bypass signaling cascades, KRAS isoform switching, and adaptive metabolic rewiring. High-throughput screening identified several promising drug combinations that restored sensitivity to KRAS inhibitors in resistant cells, with combinations of KRAS inhibitors plus PI3K/RAS breakers or pathway-specific inhibitors showing the most potent synergistic effects. Mechanistic validation confirmed that these combinations effectively abrogated aberrantly activated resistance-related signaling pathways, reversing the resistant phenotype. Additionally, the customized cell panel enabled rapid ranking of KRAS inhibitor monotherapy and combination efficacy across distinct KRAS mutation subtypes.
Conclusions: Our study establishes a robust platform of KRAS inhibitor-resistant cell lines and a high-throughput screening system for identifying resistance-overcoming combinations. The identified synergistic regimens and their validated mechanisms provide critical preclinical evidence to guide the development of next-generation KRAS-targeted combination therapies, addressing the unmet clinical need of overcoming resistance in KRAS-mutant cancers.

#1869 Combining FGTI-2734 and MRTX1133 to suppress ERK-driven resistance in KRAS G12D pancreatic cancer.

Deblina Ghosh[1], Aslamuzzaman Kazi[1], Hitesh Kumar Kantilal Vasiyani[1], Vignesh Vudatha[1], Nicolas Lecomte[2], Christine A. Iacobuzio-Donahue[2], Jose G. Trevino[3], Said M. Sebti[1]

[1]VCU Massey Comprehensive Cancer Center, Richmond, VA,[2]David M. Rubenstein Center for Pancreatic Cancer Research, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Div. of Surgical Oncology, VCU Massey Cancer Center, Richmond, VA

The KRAS G12D-selective inhibitor MRTX1133 marks a significant step forward in targeting mutant KRAS; however, its therapeutic impact is dampened by adaptive resistance driven by ERK pathway reactivation, a process requiring membrane localization of wild-type (WT) RAS. In this study, we introduce a rational approach to circumvent this resistance by using FGTI-2734, a dual inhibitor of farnesyltransferase (FT) and geranylgeranyltransferase-1 (GGT-1) that impairs WT RAS and mutant RAS membrane Localization. FGTI-2734 suppresses the ERK rebound elicited by MRTX1133 and acts synergistically with MRTX1133 to inhibit cell growth and trigger apoptosis in KRAS G12D pancreatic cancer cell lines. In patient-derived organoids from 12 individuals with KRAS G12D pancreatic cancer, including organoids originating from both primary and metastatic sites and spanning diverse co-mutation patterns (KRAS, TP53, CDKN2A, SMAD4, RTKs, PI3K/AKT, JAK/STAT, DNA repair/cell-cycle genes, and chromatin modifiers), the FGTI-2734/MRTX1133 combination produced consistent strong synergy. This effect was observed regardless of prior treatment, disease stage, or intrinsic sensitivity or resistance to MRTX1133. In vivo, FGTI-2734 potentiated MRTX1133's anti-tumor effects, leading to tumor regression in orthotopic patient-derived xenografts established from a KRAS G12D pancreatic cancer patient who progressed after radiation and chemotherapy, as well as in xenografts derived from KRAS G12D human pancreatic cancer cell lines. Importantly, FGTI-2734 treatment prevented MRTX1133-driven ERK reactivation in these KRAS G12D xenograft models. Collectively, these results define a mechanistically grounded combination strategy that neutralizes a key resistance pathway limiting MRTX1133 efficacy, and they highlight a promising therapeutic option for KRAS G12D pancreatic cancers.

#1870 Characterizing drug-induced transcriptional reprogramming in KRAS mutant lung cancer.

Wafa Malik[1], Anurag Singh[1], Laurent Sansregret[2], Aaron N. Hata[1]

[1]Massachusetts General Hospital, Krantz Family Center for Cancer Research, Boston, MA,[2]Novartis Institutes for BioMedical Research, Basel, Switzerland

KRAS mutations define the largest genomic subset of non-small cell lung cancer (NSCLC). Recently, inhibitors that selectively target the $KRAS^{G12C}$ mutation (G12Ci) have been developed, however, clinical responses are incomplete and short-lived due to intrinsic and adaptive drug resistance. Combination drug strategies designed to inhibit adaptive resistance by targeting reactivation of the MAPK pathway have demonstrated limited efficacy and significant dose-limiting toxicity. Therefore, new strategies to overcome drug resistance are needed. In some contexts, resistance to oncogene-directed therapies in NSCLC can be linked to dysregulation of the Hippo pathway, a key cell growth control pathway that is conserved across species. Recent preclinical studies have suggested that dysregulation of the Hippo pathway and activation of YAP and its corresponding transcription factor TEAD promote adaptive resistance in *KRAS*-mutant lung cancer models, which can be overcome by combining YAP-TEAD inhibitors with G12Ci. However, our mechanistic understanding of how YAP drives adaptive resistance is incomplete. Using patient-derived $KRAS^{G12C}$-mutant models, we show that G12Ci induces progressive YAP-dependent and YAP-independent transcriptional reprogramming. We identify lineage programs regulated by YAP during adaptation to G12Ci that are derepressed upon co-treatment with a YAP-TEAD inhibitor. These results reveal insights into non-genomic adaptive drug resistance in lung cancer and will enable future development of rational drug combination strategies to overcome therapeutic resistance.

#1871 Combined RAS and ICB inhibition targets NF-KB-driven immune evasion in chemoresistant pancreatic cancer.

Kevin Christian Gulay, Alexei Martsinkovskiy, Isabella Ng, Deepa Sheik Pran Babu, Jay Patel, Rithika Medari, Ponmathi Panneerpandian, Tatiana Hurtado de Mendoza, Andrew Lowy, Herve Tiriac

Department of Surgery, University of California San Diego, San Diego, CA

Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal malignancies, with surgery as the only potentially curative option. However, 85% of patients present with inoperable disease. For these patients, chemotherapy remains the standard treatment, though nearly all develop resistance and disease progression. We hypothesize that resistance to chemotherapy and RAS inhibitors reshapes the tumor microenvironment (TME), and understanding these changes is key to developing effective combination therapies. To investigate resistance mechanisms, we generated chemoresistant (CR) PDAC models. Parental (PT) and CR cells were orthotopically implanted into syngeneic mice and treated with vehicle or MRTX1133. The TME was analyzed using flow cytometry, single-cell RNA sequencing (scRNA-seq), multiplex immunohistochemistry, and immunofluorescence. RNA sequencing and cytokine arrays characterized cancer-TME crosstalk. NF-κB signaling was interrogated for its effects on cytokine and immune checkpoint expression. In addition, human PDAC organotypic slice cultures were treated with RMC6236 and immune checkpoint blockade (ICB). In vivo experiments tested MRTX1133 in combination with anti-CTLA-4 or dual anti-CTLA-4 + anti-PD1 therapy. RNA-seq revealed significant KRAS pathway upregulation in CR tumors and NF-κB pathways in RASi-treated tumors. MRTX1133 treatment of CR tumors significantly reduced tumor volumes and weights compared to vehicle controls and PT tumors ($P=<0.01$). Histological and scRNA-seq analyses demonstrated that CR tumors had expanded epithelial and fibroblast compartments and decreased T cell and macrophage populations, which were rescued by MRTX1133 treatment ($P=<0.001$). Cytokine profiling showed that CR tumors treated with MRTX1133 exhibited increased CXCL10 and CCL2, and decreased GM-CSF and LIF. NF-κB signaling regulated expression of CCL2, GM-CSF, and LIF, and also influenced immune checkpoint expression in T cells, linking tumor-intrinsic signaling with T cell exhaustion pathways. Human PDAC organotypic slice cultures treated with anti-CTLA-4 antibody showed reduced epithelial cell populations compared to controls, suggesting improved therapeutic response. In vivo, MRTX1133 combined with anti-CTLA-4 and anti-PD1 antibodies significantly reduced tumor volumes and prolonged survival compared to MRTX1133 and anti-CTLA-4 or monotherapy with MRTX1133. KRAS inhibition controls tumor growth in chemorefractory PDAC and improves immune infiltration. Mechanistically, RASi in tumor cells activate NF-κB signaling, driving cytokine changes that enhance PD-1 and CTLA-4 expression in T cells. Targeting these NF-κB-driven cytokines and immune checkpoints alongside RAS inhibition represents a promising combinatorial strategy to overcome chemoresistance and improve PDAC outcomes.

#1872 A high-throughput combination screen identifies NT-1 as a superior compound to overcome KRAS^{G12D} inhibitor resistance.

Natalie Thielen[1], Chaoyuan Kuang[2], Ning Wei[3], Seiya Kitamura[1], Emiko Nagai[1]

[1]Albert Einstein College of Medicine, Bronx, NY,[2]Albert Einstein Cancer Ctr., Bronx, NY,[3]Montefiore Comprehensive Cancer Center, Bronx, New York, NY

Background: Colorectal cancer (CRC) is the second leading cause of cancer-related mortality. KRAS mutations, present in approximately 40% of CRC cases. FDA-approved inhibitors exist for KRAS^{G12C}, but this mutation represents only a small subset of CRC, and resistance frequently develops through canonical or alternative survival pathways. KRAS^{G12D} is the most prevalent allele in CRC; however, there are currently no FDA-approved inhibitors and few agents in advanced development. To address KRAS resistance, we developed a high-throughput combinatorial screening platform using both cell lines and patient-derived organoids (PDOs) with fully annotated molecular profiles to identify synergistic drug combinations capable of overcoming resistance.
Method: To demonstrate the utility of this platform for identifying G12D inhibitor (G12Di) resistance mechanisms and synergistic partners, we performed a large-scale combinatorial drug screen in both parental and resistant KRAS^{G12D} mutant CRC cell lines. The screening library consisted of approximately 2,600 kinase inhibitors and 3,500 FDA-approved or clinical-stage compounds, tested both as single agents and in combination with a preclinical KRAS^{G12D} inhibitor. Viability was assessed using the ATP-based luminescence assay CellTiter-Glo. Compounds demonstrating robust synergy were prioritized for secondary validation using 8×8 dose-response matrices. The most promising compounds were validated in KRAS^{G12D} PDOs to confirm translational potential.
Result: Multiple compounds displayed synergistic activity with KRASi. Notably, "NT-1," a novel analog of the FDA-approved EGFR inhibitor osimertinib, demonstrated significant synergy (synergy score >10) at nanomolar concentrations across both sensitive and resistant CRC models. Compared with other EGFR inhibitors (osimertinib, erlotinib, afatinib), NT-1 achieved greater inhibitory effects at lower doses. These findings were extended to combinations with emerging pan-KRAS inhibitors, where NT-1 consistently outperformed approved EGFR inhibitors and cetuximab, producing deeper suppression of p-EGFR and p-ERK, and stronger induction of apoptosis. Ex vivo validation using KRAS^{G12D} PDOs confirmed the translational potential of these combinations, demonstrating that NT-1 can mitigate both intrinsic and acquired resistance to G12Di. Ongoing in vivo studies are assessing NT-1 in combination with G12D selective and pan-KRAS inhibitors to delineate mutation-specific versus pathway-level vulnerabilities.
Conclusion: Our combinatorial screening platform provides novel biological insights into KRAS^{G12D} resistance mechanisms in CRC and effectively identifies drug combinations with immediate clinical utility. The combination of NT-1 with G12D selective or pan-KRAS inhibitors represents a promising therapeutic strategy to overcome KRAS^{G12D} resistance.

#1873 Atebimetinib's deep cyclic inhibition of MEK constrains MAPK-axis adaptive and acquired alterations in patients with RAS-mutant tumors.

Jason S. Kim[1], Jason Funt[2], Jenny Zhang[1], Sarah Kolitz[3], Praveen Nair[2], Vinny Hayreh[2], Benjamin J. Zeskind[3], Igor Matushansky[1], Brett M. Hall[2]

[1]Immuneering, New York, NY,[2]Immuneering, San Diego, CA,[3]Immuneering, Cambridge, MA

Purpose: This study characterized acquired molecular alteration patterns arising in patients with RAS mutant tumors during treatment with the pulsatile MEK inhibitor atebimetinib (IMM-1-104), a once daily oral drug in clinical development that drives Deep Cyclic Inhibition (DCI) to modulate the MAPK pathway without continuous suppression.
Methods: 64 patients with RAS-mutant, advanced solid tumors received monotherapy atebimetinib, and serial circulating tumor DNA (ctDNA) analyses were performed to assess emergent genomic alterations detected with treatment over time. The evaluable patient population included a broad range of tumor types, disease stages and prior therapeutic exposures.
Results: Atebimetinib treatment did not lead to meaningful reactivation of the RAS/MAPK pathway, as canonical resistance events such as secondary RAS mutations, RAS-mutant allele amplification, or activating RAF variants were rarely observed. These events occurred less frequently than reported under continuous MEK, ERK, KRAS-selective, or pan-RAS inhibition, suggesting that intermittent DCI-based MAPK suppression reduces selective pressure for classical pathway signaling restoration. Rather than reestablishing MAPK dependence, emergent acquired mutation patterns were heterogeneous. Tumors frequently carried alterations spanning multiple pathway classes, for example combinations of cell-cycle deregulation, growth-factor and PI3K signaling, and transcriptional or epigenetic remodeling, including MYC-linked programs, without convergence on a single bypass mechanism. This pattern is consistent with distributed multipathway adaptive changes rather than reliance on a discrete secondary driver.
Conclusions: Atebimetinib-treated patient data demonstrate that deep, pulsatile MEK inhibition prevents the sustained loss of adaptive feedback commonly observed with chronic MAPK-pathway blockade, thereby reducing selective pressure for MAPK-reactivating resistance mechanisms. The resulting shift toward non-MAPK pathways suggests that atebimetinib's DCI mechanism, unlike chronic target engagement, limits MAPK-axis evolution. The low incidence of RAS/MAPK reactivation events supports evaluation of atebimetinib as a preferential combination backbone with either mutant-selective RAS inhibitors or mechanistically complementary therapies to enhance response durability and constrain RAS/MAPK pathway-mediated escape.

#1874 Prolonged KRAS-MAPK inhibition activates interferon signaling to promote cellular plasticity and uncover novel targets for combination therapy.

Ashenafi Shiferaw Bulle[1], Yali Chen[1], Huaping Li[1], Hung-Po Chen[1], Iftikhar Ali Khawar[1], Lin Li[1], Yu Wang[1], Peng Liu[1], Vikas Kumar Somani[1], Richard Kurupi[1], Sapana Prakashrao Bansod[1], Son Bang Le[2], Marianna Ruzinova[1], David D Tran[2], Kian-Huat Lim[1]

[1]Washington University School of Medicine, Saint Louis, MO,[2]Keck School of Medicine of USC, Los Angeles, CA

KRAS-MAPK cascade inhibition shows promise for treating PDAC. However, resistance arises through secondary mutations that restore MAPK signaling and trigger epithelial-to-mesenchymal transition (EMT), key mechanisms of acquired resistance. Here, we show that human PDAC specimens and cells treated long-term with an ERK inhibitor exhibit upregulation of EMT and interferon signaling, with similar pattern also seen following prolonged KRAS inhibition in PDAC cells. Using the GeneRep-nSCORE framework, we identified TRIM22, an interferon-inducible E3 ubiquitin ligase, as a key mediator of EMT and resistance by promoting proteasomal degradation of IκBα and activating NF-κB signaling. Searching for druggable targets, we found TACSTD2 (TROP2), an NF-κB target gene upregulated after EMT. Combining ulixertinib or the KRAS inhibitor MRTX1133 with the TROP2-directed antibody-drug conjugate sacituzumab govitecan effectively suppressed growth of PDAC patient-derived xenografts. This study highlights TRIM22's role in linking interferon signaling with EMT and identifies TROP2 as a therapeutic vulnerability to overcome acquired resistance.

#1875 Synergistic co-targeting of KRAS G12V and pan-TEAD by an EGFR-directed, inverted chimeric RNAi molecule.

Lyla Stanland[1], Alessandro Porrello[2], Sarah R. McLarnon[3], Lori L. O'Brien[3], Chad V. Pecot[2]

[1]EnFuego Therapeutics Inc, Morrisville, NC,[2]Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC,[3]Cell Biology and Physiology, University of North Carolina, Chapel Hill, NC

While KRAS has long been considered an “undruggable” oncoprotein, advancements in structural and chemical biology have resulted in KRAS G12C, G12D, pan-KRAS and pan-RAS small molecule inhibitors. Although several have shown clinical promise, therapeutic resistance remains a significant problem. Recently, YAP/TAZ activation has emerged as a common resistance mechanism to KRAS inhibition. YAP and TAZ act as transcription coactivators with the TEAD1-4 transcription factors as part of the Hippo signaling pathway. Several groups have already shown that pan-TEAD (pTEAD) inhibition synergizes with KRAS inhibition, and YAP and KRAS exhibit pathway crosstalk in cancer. Previously, we developed EFTX-G12V, a first-in-class EGFR-directed KRAS G12V selective siRNA that displays excellent single agent efficacy in lung, colon and pancreatic cancers. Further, we developed a novel inverted chimeric siRNA design that incorporates two oncogene-targeting siRNAs linked by an endo-nucleolytic DNA bridge. The chimeric siRNA design ensures equivalent molar targeting of both gene transcripts in the same cell with enhanced metabolic stability and tumor accumulation. Here, we describe the development of chemically modified pTEAD targeting siRNAs and subsequent development of a KRAS G12V, pTEAD targeting chimeric siRNA. We used a structure-activity relationship screening approach to identify a highly potent fully chemically modified siRNA that inhibits TEAD1-4 at both the mRNA and the protein level. This pTEAD siRNA inhibited cancer cell growth *in vitro* and showed no concerning off-target effects. Using this siRNA and EFTX-G12V we developed EFTX-G12V-pTEAD, that inhibits KRAS G12V, TEAD1-4 and downstream signaling at both the mRNA and the protein level. Importantly, EFTX-G12V-pTEAD showed improved inhibition of downstream targets when compared to each single agent siRNA highlighting the value of the chimeric siRNA. Similar to our previously described siRNAs, EFTX-G12V-pTEAD is conjugated to an EGFR linear ligand that enables high tumor-to-normal tissue payload delivery and limits systemic exposure. *In vivo* evaluation of EFTX-G12V-pTEAD in comparison to single agent EFTX-G12V in both xenograft and immunocompetent cancer models are planned to evaluate durability, efficacy and safety. Importantly, small molecule pTEAD inhibitors cause kidney toxicity including podocyte effacement, proteinuria and albuminuria, which has limited their clinical utility. Using spatial profiling in the kidney, we found that our siRNA molecules do not enter podocytes and largely clear through the proximal tubules, therefore we anticipate the potential for less kidney toxicity and a wider therapeutic window using this therapeutic modality. Together our findings represent a technological advance in multi-oncogene targeting using RNAi and a therapeutic modality capable of addressing resistance to KRAS inhibitors.

#1876 Pre-treatment with azacytidine sensitizes *RAS* mutated secondary AML to the pan-RAS inhibitor RMC-7977.

Xinghan Zeng[1], Yuju An[1], Brandy Perkins[1], Tessa Seale[2], Erotokritos Georgantzinos[1], Theodora Chatzilygeroudi[1], Bogdan Paun[1], Maximillian Stahl[1], Mark J. Levis[3], Styliani Karanika[1], Alexander Ambinder[1], Sandra Misale[2], Theodoros Karantanos[1]

[1]Johns Hopkins University, Baltimore, MD,[2]Johns Hopkins University School of Medicine, Baltimore, MD,[3]Johns Hopkins Sidney Kimmel Cancer Center, Baltimore, MD

Patients with acute myeloid leukemia (AML) arising from antecedent myeloid neoplasms (secondary AML, sAML) continue to have poorer outcomes than those with de novo AML, characterized by a high incidence of refractory disease and relapse after initial response. Most patients with sAML are treated with combinations of hypomethylating agents, such as azacytidine, together with venetoclax, a BCL-2 inhibitor. However, *RAS* mutations, present in approximately 20-30% of these patients, confer resistance to venetoclax and are associated with shorter overall survival. Although *RAS* oncogenes were long considered “undruggable,” KRAS mutant-specific inhibitors have recently shown promise in clinical trials for solid tumors. Notably, treatment with the RAS-Multi^{ON} inhibitor RMC-7977 has been reported to sensitize AML cells to FLT3 and BCL-2 inhibition. In this study, we found that pretreatment with azacitidine enhances the sensitivity of *RAS*-mutated sAML cells to RMC-7977.Analysis of the BEAT AML 2.0 dataset revealed that mutations affecting RAS signaling—particularly in *KRAS*, *NRAS*, and *PTPN11*—rank among the top alterations associated with resistance to azacytidine treatment in AML samples. These findings suggest that combining azacytidine with RAS inhibition may represent a promising therapeutic strategy for *RAS*-mutated AML. To evaluate this, we compared three treatment approaches in SKM1 cells: concurrent administration of azacytidine and RMC-7977, sequential treatment with azacytidine followed by RMC-7977, and the reverse sequence. Only pretreatment with azacytidine followed by RMC-7977 produced synergistic effects. This sequential regimen also produced synergistic effects on inducing apoptosis in the MDS/sAML cell lines MDS92, MDS-L, and SKM1. Consistently, treatment of primary *RAS*-mutated sAML samples with azacytidine followed by RMC-7977 significantly reduced clonogenic growth compared with either agent alone, without impairing the clonogenicity of healthy hematopoietic cells. Finally, pretreatment of SKM1 xenografts with azacytidine (5 mg/kg for 5 days) markedly improved RMC-7977-mediated control of leukemic burden.We found that azacytidine treatment sensitizes *RAS*-mutated sAML cells to RAS inhibition by RMC-7977 in both *in vitro* and *in vivo* models. Ongoing studies aim to elucidate the underlying molecular mechanisms, including the potential role of methylation changes in modulating oncogenic signaling dependencies. Together, these findings provide a strong rationale for continued evaluation of RAS inhibitors as part of combination treatment strategies for *RAS*-mutated AML.

#1877 Acquired resistance to Tri-complex inhibitors in colorectal cancer.

Sabine Jurado, Simone Lieb, Marco H. Hofmann, Mark Pearson, Phillipp Schmalhorst, Krzysztof Zak

Boehringer Ingelheim RCV, Vienna, Austria

KRAS is the most frequently mutated oncogene, with high prevalence in indications with significant unmet clinical needs, such as lung, pancreatic and colorectal cancer. The most frequent alterations result in an amino acid exchange at position 12 from Glycine to Aspartic Acid (G12D), Valine (G12V) or Cysteine (G12C). The approval of mutant specific KRAS G12C inhibitors by the FDA opened a new field of treatment options for patients with KRAS G12C mutation and additional KRAS targeted therapy approaches are currently being clinically tested in the hope to provide benefit to cancer patients with cancers harboring other KRAS mutant alleles. These therapies include pan-RAS, pan-KRAS and allele selective inhibitors as well as degraders. For patients with advanced solid tumors harboring a KRAS G12D mutation, several selective inhibitors have entered clinical trials (MRTX1133, RMC-9805, QTX3034/46, LY3962673...) and RMC-6236, a pan-RAS inhibitor from Revolution Medicines, has recently shown promising early clinical data. However, alongside the great hopes placed in (K)RAS targeting therapy, resistance is likely to occur, as it was already observed in patients relapsing in response to KRAS G12C inhibitors. We aimed to use this pre-clinical study to predict and understand potential resistance mechanisms that may arise during targeted treatment against (K)RAS in the CRC setting. To this aim, the colorectal cancer cell line GP2d, expressing KRAS G12D, was continuously treated with a pan-RAS inhibitor to generate resistance. Once the resistance was confirmed, individual outgrowing clones were subsequently profiled in a series of assays to identify potential mechanism(s) and cross-tested with other inhibitors. Interestingly, cells were cross resistant to both pan-RAS (RMC-6236) and KRAS G12D (RMC-9805) inhibitors from Revolution Medicine, highlighting a common mechanism of action, while remaining sensitive to other KRAS G12D inhibitors. These findings were then confirmed in an orthogonal assay. Collectively our *in vitro* preclinical study identified a resistance mechanism to Tri-complex inhibitors in colorectal cancer cells. This resistance can still be addressed by other KRAS G12D inhibitors, opening options for patients harboring this characteristic post RMC-therapy. Future investigations may focus on characterizing tumors from patients who relapse on RMC-6236 and RMC-9805 to validate these findings clinically.

#1878 Cotargeting B-Raf and ACLY in Ras mutant cells leads to synergistic loss of cell viability and apoptosis.

Nancy A. Krucher, Bryce D. Aierstok, Sabrina Bergesio, Gabriella J. Galgano, Morgan E. Strecker

Biology, Pace University, Pleasantville, NY

Ras mutation is found in several tumor types including pancreatic and colon cancer. Downstream from Ras is the B-Raf kinase, also often found mutated in tumor cell types such as melanoma. B-Raf inhibitors Vemurafenib, Dabrafenib and Encorafenib are used clinically in combination with MEK inhibitors Trametinib, Cobimetinib and Binimetinib. Together, these agents serve to inhibit the MAPK pathway, but the PI3K/AKT pathway is often upregulated leading to treatment resistance. AKT functions in numerous cellular processes including metabolism. In fact, AKT activates lipogenesis by direct phosphorylation and activation of the enzyme ATP-Citrate Lyase (ACLY). ACLY expression and activity are elevated in various cancer cell types. A new inhibitor of ACLY, NDI-091143, was recently identified based on the structure of ACLY and was used in this study. A panel of Ras mutant cell lines was used to investigate the effect of combining the ACLY inhibitor NDI-091143 with the BRAF inhibitor Vemurafenib on cell proliferation and apoptosis. Using concentrations of each drug that reduced cell viability individually by 25%, we found that the combination exhibited synergistic reduction of cell viability in Ras mutant A375 melanoma cells, MDA-MB-231 breast cancer cells, MIA Paca-2 pancreatic cancer cells and HCT116 colon cancer cells. Cancer cells with WT Ras such as MeWo melanoma and T47D breast cancer showed no synergistic loss of viability in response to the combination. Non-transformed cells such as colon epithelial (CCD-18Co) and normal pancreatic cells (H6c7) are unaffected by the same concentrations used in the Vemurafenib and NDI-091143 combination treatment. The mechanism of reduction in viability appears to be due to activation of apoptosis. All four Ras mutant cell lines showed increased expression of cleaved PARP and the activation of the ER stress pathway regulator ATF4. Finally, the apoptosis stimulated by the combination was shown to be dependent on Caspase-3 activity using Annexin V analysis of HCT116 cells treated with Vemurafenib plus NDI-091143.

#1879 Characterization of intrinsic and acquired resistance to KRAS^{G12C} inhibitors across a broad collection of cancer cell line models.

Jeffrey J. Kooijman, Kirsten J. W. Kevenaar, Imke P. M. Smits, Daphne J. F. Kluitmans, Laura D. R. van Zelst, Bente Timmers, Tsang W. Lam, Jeroen A. D. M. de Roos, Yvonne Grobben, Janneke J. T. M. Melis, Guido J. R. Zaman, Jorg C. J. Benningshof

Oncolines B.V., Oss, Netherlands

Mutations in *KRAS* are among the most common oncogenic driver events in human cancer. A glycine-to-cysteine mutation at position 12 (KRAS^{G12C}) impairs GTP hydrolysis, keeping KRAS in the GTP-bound active state. For decades, the KRAS^{G12C} mutation was considered undruggable, until the discovery of a new pocket beneath the effector switch II region of KRAS. Covalent binding of inhibitors into this pocket locks KRAS in its inactive, GDP-bound state. This breakthrough led to the accelerated approval of the first-generation inhibitors sotorasib (AMG 510) and adagrasib (MRTX849). However, their clinical benefit remains limited by modest response rates and the rapid emergence of drug resistance. To address these limitations, next-generation KRAS^{G12C} inhibitors such as divarasib (GDC-6036) have been developed, showing improved selectivity, potency and clinical response rates. Nevertheless, resistance is expected to arise, underscoring the importance of early insights into both intrinsic and acquired resistance to guide the most effective use of these emerging agents in the clinic.

To investigate intrinsic resistance, adagrasib, sotorasib and divarasib were profiled across 140 cancer cell lines using nine-point dose ranges in cell viability assays. KRAS^{G12C}-mutant cell lines exhibiting limited potency or efficacy were classified as intrinsically resistant. To study acquired resistance, inhibitor-sensitive KRAS^{G12C}-mutant cell lines were cultured with escalating doses of inhibitor. For both intrinsic and acquired resistant cell lines, resistance mechanisms were characterized using genomic and transcriptomic analyses, determination of MAPK and PI3K pathway phosphorylation after drug exposure, and broad therapeutic and combination profiling to identify pathway dependencies and strategies to overcome resistance.

Our analyses revealed heterogeneous responses of KRAS^{G12C}-mutant cell lines to the inhibitors, mirroring clinical responses. The KRAS^{G12C}-mutant cell lines SW1573 and OV56 were intrinsically resistant to all three KRAS^{G12C} inhibitors. Co-mutation analysis revealed a *PTEN* loss-of-function mutation in OV56, suggesting enhanced PI3K pathway activity. Although *PTEN* loss was restricted to OV56, both OV56 and SW1573 were resistant to inhibitors of various MAPK pathway components, including RAF (tovorafenib, belvarafenib), MEK (trametinib), and ERK (ulixertinib), suggesting MAPK pathway independence. Cross-resistance to adagrasib, sotorasib and divarasib was also observed in the acquired resistant models.

Intrinsically KRAS^{G12C} inhibitor-resistant cell lines, along with acquired resistant models, represent valuable systems for evaluating next-generation KRAS inhibitors and identifying new drug combinations to optimize therapeutic benefit of KRAS^{G12C} inhibitors in patients.

#1880 Deconstructing the paradigm of oncogene cooperation: Targeting MYC to enhance response and overcome resistance to KRAS inhibitors.

Daniel Capitan-Leo[1], Inigo Gonzalez-Larreategui[1], Magda Arnal[2], Judit Grueso[1], Lorena Sansegundo-Barbosa[2], Hugo Thabussot[2], Irene Ferrer[3], Silvestre Vicent[4], Marie-Eve Beaulieu[2], Silvia Casacuberta-Serra[2], Laura Soucek[1]

[1]VHIO Vall D'Hebron Institute of Oncology, Barcelona, Spain,[2]Peptomyc S.L., Barcelona, Spain,[3]H12O-CNIO Lung Cancer Clinical Research Unit, Health Research Institute Hospital 12 de Octubre, Spanish National Cancer Research Center (CNIO), Madrid, Spain,[4]Program in Solid Tumors and Biomarkers, Center for Applied Medical Research (CIMA), Pamplona, Spain

Background: Activating mutations in *KRAS*, particularly at codon G12, are common in non-small cell lung cancer (NSCLC, ~30%), pancreatic ductal adenocarcinoma (PDAC, ~90%), and colorectal cancer (CRC, ~35%). Although KRAS-G12C inhibitors (KRASi) such as sotorasib and adagrasib are approved for NSCLC, their clinical benefit is frequently limited by intrinsic and acquired resistance. MYC, a key transcription factor downstream of KRAS, is often deregulated in cancer and contributes to tumorigenesis and therapeutic resistance. Omomyc (OMO-103), the only direct MYC inhibitor currently in Phase II clinical trials, offers a unique opportunity to evaluate the impact of MYC blockade in KRAS-driven tumors.
Methods: We used NSCLC, CRC, and PDAC tumor cell lines and patient-derived xenograft (PDX) models to characterize KRAS-dependent signaling and to assess the effects of KRASi, Omomyc, and their combination on proliferation, cell-cycle progression, and apoptosis. Mechanistic studies included Western blotting and RNA-seq analyses.
Results: Dual KRAS and MYC inhibition synergistically impaired proliferation and induced robust apoptosis across models. Omomyc sensitized KRAS-mutant cells with intrinsic resistance to KRASi and restored drug responsiveness in models with acquired resistance. Transcriptomic and proteomic analyses revealed extensive reprogramming of oncogenic pathways upon combination therapy. In vivo, co-treatment with OMO-103 and KRASi resulted in significantly greater tumor regression than either monotherapy.
Conclusions: These findings demonstrate critical cooperation between MYC and KRAS in driving tumor survival and resistance to KRAS inhibition. Direct MYC blockade enhances the therapeutic activity of KRAS inhibitors and represents a promising strategy to overcome both intrinsic and acquired resistance in multiple KRAS-mutant cancer types.

#1881 Understanding evolutionary and ecological mechanisms of sotorasib resistance in KRAS G12C-mutant non-small cell lung cancer.

Jinling Wu[1], Mina Nguyen Dinh[2], Arda Durmaz[2], Maximilian Strobl[3], Jacob G. Scott[4]

[1]School of Medicine, Case Western Reserve University, Cleveland, OH,[2]Genomic Medicine and Systems Biology, Cleveland Clinic Research, Cleveland, OH,[3]Imperial College London, London, United Kingdom,[4]Case Comprehensive Cancer Center, Cleveland, OH

KRAS G12C mutation is a major oncogenic driver in non-small cell lung cancer, with targeted therapy using sotorasib offering clinical promise. However, resistance inevitably emerges. Evolutionary therapies based on collateral sensitivity exploit molecular and pharmacologic vulnerabilities that arise in evolved resistant populations and provide a promising strategy to guide evolution-informed sequential or combination therapies to delay resistance. We developed a novel *in vitro* experimental evolution framework using a KRAS G12C-mutant H358 cell line. Multiple independent replicates were continuously exposed to 25nM sotorasib for around 3 months across 8 sequential treatment cycles, while independent control replicates were treated without drug. Most treated replicates (4/6) developed robust resistance at cycle 8. To map evolutionary shifts in drug response, we performed collateral sensitivity screening using a panel of 10 FDA-approved agents targeting pathways relevant to KRAS signaling. Drug sensitivity shifted over time and resistant replicates evolved cross-resistance to EGFR/HER2-targeted inhibitors (e.g. Gefitinib and Lapatinib). In contrast, a statistically significant increase in paclitaxel sensitivity was detected, suggesting a collateral vulnerability associated with altered cell-cycle regulation as a compensatory response to KRAS inhibition. Bulk RNA-Seq revealed clear transcriptional changes accompanying resistance acquisition. Gene set enrichment analysis identified upregulation of several hallmark pathways in resistant group, including epithelial-mesenchymal transition, mTORC1 signaling, and inflammatory signaling by the end of experiment. Moreover, further analysis revealed that while replicates initially respond similarly at cycle 4, their molecular profiles diverge over time and give rise to considerable heterogeneity by cycle 8, despite a shared evolutionary origin. Drug resistance is also shaped by dynamic ecological interactions, so we evaluated ecological vulnerabilities using a co-culture framework that quantifies ecological coefficients based on relative growth rates of resistant and sensitive cells. Preliminary assays show that several resistant populations outcompete sensitive cells even without drug, contradicting the expected fitness cost of resistance and suggesting that certain resistance mechanisms may enhance baseline fitness. Competition outcomes shifted across sotorasib concentrations, indicating that ecological interactions are dose-dependent, highlighting the potential for ecology-informed dosing strategies to reduce competitive release and delay resistance. Together, we provide novel insights into the eco-evolutionary processes underlying sotorasib resistance and identify vulnerabilities that may be leveraged to design therapies that delay or redirect resistance.

#1882 Generation of daraxonrasib-resistant patient-derived xenograft models of pancreatic cancer.

Nina Dashti-Gibson[1], Amy L. Olex[1], Rachel K. Myrick[2], Alexa M. Barber[3], David C. Boyd[2], Emily K. Zboril[2], Katarzyna M. Tyc[4], Mikhail G. Dozmorov[4], Guang-Yu Yang[2], Nicholas T. Woods[3], Jose G. Trevino[5], J. Chuck Harrell[2]

[1]Wright Center for Clinical and Translational Research, Virginia Commonwealth University, Richmond, VA,[2]Department of Pathology, Virginia Commonwealth University, Richmond, VA,[3]University of Nebraska Medical Center, Omaha, NE,[4]Department of Biostatistics, Virginia Commonwealth University, Richmond, VA,[5]Department of Surgery, Virginia Commonwealth University, Richmond, VA

Background: Patients diagnosed with pancreatic ductal adenocarcinoma (PDAC) face limited treatment options and a dismal survival rate. KRAS is mutated in over 90% of PDAC and is a critical driver of tumor initiation and progression. Daraxonrasib (RMC-6236), a newly developed pan-RAS inhibitor, has shown promise in extending the survival of patients with PDAC in ongoing clinical trials. However, acquired resistance to daraxonrasib is anticipated and may limit the efficacy of this new therapeutic. To address this challenge, we developed a biobank of over 60 patient-derived xenograft (PDX) models, including 24 new models of PDAC, and aimed to generate daraxonrasib-resistant lines to investigate mechanisms of resistance and explore strategies to prolong daraxonrasib efficacy.

Methods: PDX cells from six patients with PDAC were injected subcutaneously in NSG mice, and tumor volume was measured weekly by caliper. Daraxonrasib (25 mg/kg) was administered daily by oral gavage when tumor volume reached 10-30 mm^3. Following 4-6 weeks of treatment, tumors that were initially responsive were digested and injected into additional mice which were again treated with daraxonrasib. Tumors that grew through treatment were collected for histological analysis and single cell RNA-sequencing.

Results: PDAC was found to be the most KRAS-dependent cancer type in our PDX biobank. Initial daraxonrasib treatment resulted in 63-97% reduction in tumor volume area-under-the-curve (AUC) compared to untreated controls across six models of PDAC. Response was significantly correlated with KRAS dependency score, while no association was found with patient demographics, KRAS mutation, or PDAC subtype. The PDXs with the greatest response were selected to generate resistant lines. Within two passages, the reduction in AUC was no longer significant based on Welch's t-test, indicating that resistance had developed. Transcriptomic analysis of treated tumors revealed upregulation of mucin production and YAP1 signaling, which likely represent early resistance mechanisms.

Future directions: Daraxonrasib was effective in reducing tumor volume in PDX models of PDAC, but prolonged treatment resulted in acquired resistance. Comparing the transcriptomic profiles of newly generated resistant lines and their sensitive counterparts will elucidate the mechanisms by which PDAC develops resistance to daraxonrasib. Furthermore, these models will provide a platform to test strategies to overcome resistance and maximize the efficacy of this promising new therapeutic.

#1883 Predicting resistance mechanisms in pancreatic cancer organoids under KRAS^{G12D} inhibition via pooled CRISPR-Cas9 druggable library screen.

Lauryn E. Flannagan[1], Michela Cadarso[1], Md Shahadat Hossan[1], Molly A. Nellen[2], Sean J. McIlwain[3], C. Dustin Rubinstein[4], Sean Ronnekleiv-Kelly[5], Jeremy D. Kratz[1]

[1]Medicine, University of Wisconsin-Madison, Madison, WI,[2]UWBC Advanced Genome Editing, University of Wisconsin-Madsion, Madison, WI,[3]School of Medicine and Public Health Dept. Biostatistics and Medical Informatics, University of Wisconsin-Madison, Madison, WI,[4]UWBC Advanced Genome Editing, University of Wisconsin-Madison, Madion, WI,[5]University of Wisconsin-Madison, Madison, WI

Background: Pancreatic ductal adenocarcinoma (PDAC) is the third leading cause of cancer mortality, with a median 5-year survival of 13%. Acquired resistance to single agent targeted inhibitors plays a critical role in progression, however there is a lack of predictive tools on resistance that incorporate functional genomics. Here, we evaluate the resistance mechanisms with early treatment of MRTX1133, a small non-covalent inhibitor of KRAS^{G12D}, using a pooled CRISPR-Cas9 lentivirus screen in patient derived cancer organoids (PCO).

Methods: PCOs were collected and transduced at a 1:5 cell to lentivirus ratio using a lentiviral-based CRISPR-Cas9 library with 2,292 genes targets from the 'druggable genome' (Milipore-Sigma). Transduced PCO's were expanded in Cultrex matrix and underwent puromycin selection for 6 days. A baseline group was collected post selection to control for basal expression over the course of media treated control. In parallel, PCOs were treated with MRTX1133 (30nM) or control with collection at 6 days post-treatment. Digital PCR was used to normalize lentiviral transduction efficiency to background. PCR libraries were prepared against targets and DNA sequencing was done to assess resistance mechanisms via the Model-based Analysis of the Genome-wide CRISPR/Cas9 Knockout (MAGeCK) analysis. Results from MAGeCK were also used for HALLMARK gene set analysis to evaluate pathway disruption specific to MRTX1133 treatment.

Results: Digital PCR showed optimal lentiviral copy number for baseline (0.863 ± 0.025) post puromycin selection. Pearson correlation plot showed increased variance between control groups when treatment was extended from a 6-day collection (PC1 16%, PC2 15%, PC total 31%) to a 9-day collection (PC1 18%, PC2 18%, PC total 36%). MAGeCK analysis revealed a list of 130 significant gene targets from the druggable screen ($p<0.05$). Top targets from basal PDAC expression included epithelial-mesenchymal transition pathways with knockout of interleukin-6 ($p<0.001$) and the E2F transcription family pathway with knockout of CDKN1B ($p<0.05$). HALLMARK analysis revealed 168 expressed pathways expressed in the control against PCO's treated with MRTX1133 following a 0.05 false discovery rate threshold. These pathways include KRAS signaling ($p<0.05$), adipogenesis ($p<0.05$), and E2F targets ($p<0.05$). Individual gene knockouts observed consistent targets included KCNQT ($p<0.05$) in KRAS signaling, UQCRC1 ($p<0.01$) in adipogenesis, and CDKN1B ($p< 0.01$) in E2F targeting.

Conclusions: By scaling a druggable lentiviral based CRISPR-Cas9 screen, we show potential signaling pathways that aid in resistance to tool compound MRTX in PDAC organoids. Thus, addressing the unmet need of predictive resistance modeling in PDAC organoids. Further work includes selective knockout of key targets to confirm synthetic lethality with MRTX1133.

#1884 Molecular determinants of sensitivity and resistance to the pan-RAS(ON) inhibitor daraxonrasib(RMC-6236) across KRAS-mutant patient-derived models.

Kayla Tyskiewicz[1], Markus Hippich[1], Tristan Cates[1], Gervaise Henry[1], Gilad Silberberg[1], Nicole Spanburg[1], Madeline Westcott[1], Daniel Ciznadija[2], Michael Boice[1], Paul Heverly[1], Frank Smith[1], Marianna Zipeto[1], Stefano Cairo[3], Sebastian Brabetz[1]

[1]Champions Oncology (Rockville, MD), Rockville, MD,[2]Champions Oncology, Hackensack, NJ,[3]Champions Oncology, Inc. (Hackensack, NJ), Rockville, MD

CHAMPIONS Abstract Body: KRAS mutations define a major therapeutic opportunity across solid tumors but often align with limited response durability and resistance to targeted therapies. Daraxonrasib (RMC-6236), a selective pan-RAS(ON) inhibitor, demonstrates activity across KRAS G12X-mutant tumors; however, the molecular and clinical features governing sensitivity or promoting resistance remain incompletely understood. We screened a >50-model KRAS-mutant PDX cohort spanning NSCLC (n=16), colorectal cancer (n=19), and pancreatic ductal adenocarcinoma (n=19). Models reflect clinically relevant KRAS variants and diverse co-mutational landscapes, accompanied by pre-treatment patient histories, enabling classification of responders and non-responders through integration of molecular and clinical contexts. Tumors were evaluated for intrinsic response, and longitudinal sampling captured acquired-resistance outgrowths for subsequent genomic analysis. We performed integrated NGS (omics?) analyses on (i) baseline data from responding vs non-responding models, (ii) resistant tumors emerging after initial regression, and (iii) associations with prior patient treatments. Daraxonrasib produced a broad range of activity across the array of models screened. Heterogeneity in the depth and durability of responses correlated with KRAS allele type, co-driver mutations, and specific pre-treatment exposures. These studies establish an annotated, translational system for defining determinants of RAS(ON) inhibitor response that shape resistance and inform rational therapeutic combination strategies.

#1885 USP7 inhibitor synergistically enhanced the anticancer effect of the KRAS G12C inhibitor by effectively countering feedback signaling pathways.

Yuanyuan Gao[1], Keqiang Zhang[1], Wendong Li[1], Chunxia Su[2], John Liu[1], Lilian Gu[1], Mahima Raul[1], Dan Raz[1]

[1]Division of Thoracic Surgery, City of Hope National Medical Center, Duarte, CA,[2]School of Basic Medical Science, Ningxia Medical University, Yinchuan, China

Background: KRAS mutations are the most frequent oncogenic drivers in non-small cell lung cancer (NSCLC), with the KRAS G12C variant accounting for nearly half of KRAS-mutant cases. While KRAS inhibitors show strong antitumor activity, their efficacy is often limited by adaptive and acquired resistance, highlighting the urgent need for effective combination strategies. The deubiquitinase USP7, frequently overexpressed in cancers and linked to malignancy, therapeutic resistance, and poor prognosis. However, its role in KRAS-mutant lung cancer remains unclear.

Methods: USP7 mRNA and protein expression levels in human and mouse KRAS-mutant lung cancers were analyzed using TCGA data mining and immunohistochemistry (IHC) analysis. KRAS G12C-mutant NSCLC cells and in vivo xenograft models were treated with KRAS G12C specific inhibitor (GDC-6036) and USP7 inhibitor (P5091), either alone or in combination, to evaluate the combinatorial antitumor effects. Cell viability and apoptosis assays were performed to evaluate treatment outcomes. Western blotting and RNA sequencing (RNA-seq) analyses were conducted to investigate alterations in this related cancer signaling pathways and elucidate the underlying molecular mechanisms.

Results: USP7 mRNA expression was found to be significantly elevated in human cancer tissues and cell lines compared with normal controls. Combination index (CI) analysis using the Chou-Talalay method showed CI < 1, confirming that the USP7 inhibitor synergistically enhanced the efficacy of the KRAS G12C inhibitor. Mechanistically, USP7 synergistically inhibits the KRAS feedback signaling pathways, possibly due to suppression of cell proliferation through the MAPK and AKT pathways in cancer cells. RNA-seq revealed that the combination treatment elicited broader and more pronounced pathway modulation, with simultaneous inhibition of proliferative mechanisms (MYC, MTORC1, G2M) and suppression of DNA repair pathways. In line with RNA-seq findings, low-dose KRAS or USP7 inhibitors did not trigger significant apoptosis, while the combination markedly enhanced apoptosis and delayed KRAS signaling reactivation. Importantly, in vivo xenograft studies further demonstrated that the combination therapy produced a markedly stronger antitumor effect, significantly suppressing tumor growth (reduced p-ERK and Ki-67) and inducing substantially higher levels of apoptosis (increased Caspase-3) compared with KRAS or USP7 inhibition alone.

Conclusion: The combination of KRAS G12C and USP7 inhibitors significantly enhances the anticancer effect by suppressing KRAS feedback signaling, modulating multiple oncogenic and metabolic pathways, and promoting apoptosis in cancer cells, representing a promising novel approach to achieve durable therapeutic benefits of KRAS blockade in NSCLC, warranting further investigation.

#1886 Ligand links EGFR reactivation to resistance against KRAS G12C inhibitors in NSCLC.

Shigeki Nanjo, Yifeng Liu, Hayato Koba, Seiji Yano

Kanazawa Univ. Hospital, Kanazawa, Japan

KRAS G12C inhibitors have shown meaningful clinical efficacy against Kirsten rat sarcoma viral oncogene (KRAS) G12C-mutant non-small cell lung cancer (NSCLC), providing a long-awaited therapeutic option for this historically difficult-to-target oncogene. However, both intrinsic and acquired resistance frequently limit the durability of response. To overcome these limitations, rational combination strategies based on molecular mechanisms are urgently needed. Although multiple combination approaches—such as co-targeting EGFR or PD-L1—are being evaluated in ongoing trials, biomarker-driven therapeutic selection remains underdeveloped. To elucidate the mechanisms underlying resistance, we established intrinsic and acquired KRAS G12C inhibitor-resistant tumor models using mouse and patient-derived xenografts (PDX). Mechanistic analyses, including western blotting and enzyme-linked immunosorbent assay (ELISA), were conducted to characterize resistance-associated signaling. Combination treatment efficacy was validated in vitro and in vivo. In addition, immunohistochemistry (IHC) and RNAscope in situ hybridization (ISH) were performed on xenograft tissues and tumor samples from patients with KRAS G12C-mutant NSCLC treated with sotorasib. Our findings reveal that tumor cell-autocrine ligand-mediated epidermal growth factor receptor (EGFR) phosphorylation plays a central role in both intrinsic and acquired resistance to KRAS inhibitors. Strikingly, this same EGFR signaling axis was also detected in central nervous system (CNS) metastatic recurrence in a leptomeningeal carcinomatosis model, indicating its relevance to disease progression in sanctuary sites. Moreover, RNAscope ISH enabled spatial visualization of ligand expression, suggesting its potential as a diagnostic marker for identifying patients with EGFR-dependent resistance. Importantly, combined inhibition of KRAS and EGFR effectively suppressed tumor growth and overcame resistance in vitro and in vivo. Consistent with these preclinical results, elevated EGFR ligand mRNA expression was observed in two of seven clinical tumor samples from patients with KRAS G12C-mutant NSCLC who exhibited poor response to sotorasib. In conclusion, ligand-mediated EGFR activation serves as a key driver of both intrinsic and acquired resistance to KRAS G12C inhibitors in NSCLC. These results establish a mechanistic rationale for biomarker-guided combination therapy using concurrent KRAS and EGFR inhibition to enhance therapeutic efficacy and prevent resistance in KRAS G12C-mutant lung cancer.

#1887 Real-time dissection of SCLC emergence in a *KRAS^{G12C}* LUAD tumour: A case study of targeted therapy resistance.

Priyanka Gopal

Robert H. Lurie Comprehensive Cancer Ctr. of Northwestern Univ., Chicago, IL

Background: Lineage plasticity is an emerging mechanism of resistance in non-small cell lung cancer (NSCLC). We present a case study of a KRASG12C-mutant lung adenocarcinoma (LUAD) PDX that underwent neuroendocrine transdifferentiation into small-cell lung cancer (SCLC) after treatment with the KRASG12C inhibitor sotorasib.
Methods: KRASG12C PDX CBX336 was treated with sotorasib and monitored using high-content imaging, fluorescence lineage tracking, DNA barcoding, and whole-exome clonal tracing. Pre- and post-treatment tumours underwent genomic, transcriptomic, and morphometric profiling. PDX-derived ex vivo cultures supported functional studies, including CRISPR knockout and cDNA overexpression.
Results: CBX336 showed an initial response to sotorasib followed by rapid regrowth. Post-treatment samples demonstrated a histologic shift from LUAD to SCLC, marked by elevated NEUROD1 and neuroendocrine markers. Lineage tracking revealed a coordinated, not stochastic, transition toward the neuroendocrine state. Multi-omic analysis identified ZEB1 as an upstream regulator linked to RB1 loss, increased p16, and N-cadherin. ZEB1 knockout suppressed neuroendocrine marker induction and partially restored LUAD-like differentiation, confirming ZEB1 as a driver of lineage reprogramming.
Conclusions: This case study shows that KRASG12C-targeted therapy can induce neuroendocrine transdifferentiation via ZEB1 upregulation. Real-time monitoring of CBX336 evolution reveals actionable plasticity mechanisms and supports development of strategies to prevent or reverse therapy-induced SCLC emergence.

#1888 Unveiling mechanisms of MRTX1133 resistance in PDAC models.

Qin Li

WuXi AppTec, Suzhou, China

Recent years have witnessed significant advances in the development of therapeutics targeting KRAS G12D in cancer patients. However, the emergence of drug resistance remains a formidable clinical challenge, and the underlying mechanisms remain largely unknown. To investigate these mechanisms, we established resistant cell lines through stepwise escalation of MRTX1133, the first covalent inhibitor of KRAS G12D to enter clinical evaluation, in KRAS G12D-mutant modelsThese resistant cells maintain stable phenotypes to MRTX-1133 both in vitro and in vivo, and exhibited broad cross-resistance to other KRAS G12D inhibitors, such as RMC9805 and HRS-4642, with partial resistance observed toward the pan-RAS inhibitor RMC6236.Bioinformatic analysis of both resistant models revealed a spectrum of convergent adaptive mechanisms, including: (1) altered oncogenic signaling networks, (2) upregulation of cell cycle and drug efflux regulators, and (3) epithelial-mesenchymal transition (EMT). Interestingly, the MRTX1133-R-GP2D model acquired secondary KRAS mutations (specifically H95Q, Y96H, Y96N, and D92N), indicating on-target resistance. In a contrast, the MRTX1133-R-KPC model exhibited chromosome 5 amplifications encompassing key metabolic and detoxification genes (notably CYP51 and CYP3A), accompanied by tumor microenvironment (TME) reprogramming and immune evasion.Together, these findings reveal comprehensive mechanisms of resistance to KRAS G12D inhibition. The established resistant models serve as physiologically relevant platforms for biomarker discovery and the development of rational combination therapies. Using these models, functional studies demonstrated that targeting core vulnerabilities—including the cell cycle, DNA damage repair, compensatory signaling pathways, metabolic modulators may overcome resistance phenotype.

#1889 Elucidation and therapeutic strategies to overcome intrinsic resistance mechanisms in KRAS G12D-mutant tumors.

Ryo Sawada, Tadaaki Yamada, Yuki Katayama, Koichi Takayama

Department of Pulmonary Medicine, Kyoto Prefectural University of Medicine, Kyoto, Japan

[Background and Aim] KRAS, a small GTPase transmitting signals from receptor tyrosine kinases to MAPK and PI3K pathways, plays a pivotal role in cell proliferation and survival. Oncogenic KRAS mutations cause constitutive activation of downstream signaling and are common in pancreatic, colorectal, and lung cancers. The G12D variant is particularly prevalent in pancreatic and colorectal cancers and also occurs in non-small cell lung cancer, especially among never-smokers. While the success of covalent KRAS G12C inhibitors has validated KRAS as a druggable target, KRAS G12D remained challenging. Recently, selective non-covalent inhibitors such as MRTX1133 have shown potent preclinical efficacy. However, the efficacy of KRAS G12D inhibitor monotherapy remains limited, underscoring the need to clarify and overcome resistance mechanisms.
[Method] KRAS G12D-mutant lung and pancreatic cancer cell lines (A427, SK-LU1, AsPC1, Panc1, T3M10, and HPAF-II) were used to evaluate the antitumor effects of MRTX1133 monotherapy and combination therapies. In vitro, three combinations were assessed: MRTX1133 plus an AXL inhibitor, MRTX1133 plus both AXL and FGFR1 inhibitors, and MRTX1133 plus a SHP2 inhibitor. Cell viability was determined by MTT assay, signaling alterations were analyzed by Western blotting, and apoptosis was evaluated by flow cytometry. In vivo, the efficacy of MRTX1133 combined with a SHP2 inhibitor was validated using cell-derived xenograft (CDX) mouse models.
[Results] MRTX1133 monotherapy exhibited variable efficacy across cell lines. Knockdown or pharmacological inhibition of AXL (dual therapy) significantly enhanced the antiproliferative effects of MRTX1133. However, some cell lines showed ERK reactivation, indicating incomplete pathway suppression. Further addition of the FGFR1 inhibition (triple therapy) effectively suppressed ERK reactivation and markedly improved antitumor activity. Moreover, targeting adaptor proteins such as SHP2 amplified the therapeutic efficacy, suggesting that convergence nodes downstream of RTKs play a crucial role in resistance mechanisms. While SHP2 inhibition alone showed limited activity, its combination with MRTX1133 prevented ERK reactivation and achieved substantial growth suppression.
[Discussion and Conclusion] Resistance to MRTX1133 in KRAS G12D-mutant tumors is driven by AXL and FGFR1 activation, which can be suppressed through dual or triple combination therapies. Inhibition of adaptor proteins such as SHP2 further provides a strategy to overcome heterogeneous RTK-mediated resistance, supporting combination approaches targeting adaptor signaling.

#1890 Targeting ribonucleotide reductase to overcome FLT3 inhibitor resistance in acute myeloid leukemia.

Zhen Tian[1], Peng Wang[1], Stacia Octaviani[1], Yahui Li[2], Yun Liao[1], Xiaolei Liu[3], Zhaorui Lian[1], Hong Zheng[4], Elliot Stieglitz[5], Catherine C. Smith[6], Jian Huang[1]

[1]Coriell Institute for Medical Research, Camden, NJ,[2]Surgical Research Lab, Department of Surgery,, Cooper University Health Care, Camden, NJ,[3]Department of Medicine, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA,[4]Penn State Cancer Institute, Penn State University College of Medicine, Hershey, PA,[5]Pediatrics, UCSF, San Francisco, CA,[6]Adjunct Instructor, Dept. of Med./Hem.-Onc., UCSF, San Francisco, CA

Acute myeloid leukemia (AML) is a malignant hematopoietic disorder characterized by the clonal proliferation and impaired differentiation of myeloid progenitor cells. It is the most common type of acute leukemia in adults and is associated with high rates of chemotherapy resistance and relapse. Mutations in the FMS-like tyrosine kinase 3 (*FLT3*) gene occur in approximately 30% of AML cases and are linked to poor prognosis. The discovery of FLT3 inhibitors (FLT3i) has represented a breakthrough in targeted AML therapy; However, resistance to FLT3i remains a significant clinical challenge that limits long-term efficacy. Previously, we identified Sprouty RTK Signaling Antagonist 3 (*SPRY3*)—a negative regulator of RAS/MAPK signaling—as a key determinant of FLT3i sensitivity. Loss of *SPRY3* activated RAS signaling and conferred robust FLT3i resistance in AML. Consistent with these findings, activating *NRAS* mutations (such as $NRAS^{G12C}$ and $NRAS^{Q61K}$) —present in approximately 15% of AML cases—also drive resistance to FLT3i. In our recent studies, we identified ribonucleotide reductase (RNR) as a critical downstream effector upregulated by *NRAS*-activating mutations ($NRAS^{mut}$) in AML, driving FLT3i resistance. RNR catalyzes the conversion of ribonucleoside diphosphates (NDPs) into deoxyribonucleoside diphosphates (dNDPs), which are subsequently phosphorylated to deoxyribonucleoside triphosphates (dNTPs)—the essential building blocks for DNA replication and repair. We found that $NRAS^{mut}$ AML cells exhibit significantly elevated expression of *RRM1*, *RRM2*, and *RRM2B*, the three subunits of RNR, following FLT3i treatment. Mechanistically, RAS activation enhances RNR expression through the RAS-MAPK-E2F1/MYC signaling axis. Inhibition of E2F1 or MYC markedly reduced *RRM1* and *RRM2* expression, confirming their transcriptional regulation of RNR. Furthermore, knockdown of Dual Specificity Phosphatase 6 (DUSP6)—a negative feedback regulator of RAS/MAPK signaling—further increased RNR activity and sensitized $NRAS^{mut}$ AML cells to RNR inhibition. Functionally, both pharmacologic inhibition of RNR using clofarabine and siRNA-mediated knockdown of RNR subunits effectively restored FLT3i sensitivity in $NRAS^{mut}$ AML. Combination therapy with gilteritinib and clofarabine in both cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models significantly reduced leukemic burden and prolonged survival compared with either agent alone. In summary, our findings identify RNR as a critical downstream effector of RAS/MAPK signaling and a promising therapeutic target to overcome FLT3i resistance in $NRAS^{mut}$ AML. These results provide a strong mechanistic and preclinical rationale for the combined inhibition of *FLT3* and RNR as a novel therapeutic strategy to improve outcomes in resistant AML.

#1891 Minnelide enhances the antitumor activity of pan-KRAS inhibitor RMC-6236 in preclinical models for pancreatic cancer.

Edgar Banuelos[1], Jaeger Moore[1], Mohana Velagapudi[2], Ashok Saluja[2], Daniel D. Von Hoff[1], **Haiyong Han**[1]

[1]Translational Genomics Research Institute, Phoenix, AZ,[2]Minneamrita Therapeutics LLC, Tampa, FL

Triptolide, a natural compound from *Thunder God Vine*, and its water-soluble prodrug Minnelide have shown potent antitumor activity, including promising single-agent efficacy in patients with pancreatic cancer. We previously demonstrated that triptolide suppresses super-enhancer activity in pancreatic cancer and stromal cells by inhibiting the XPB subunit of TFIIH, leading to downregulation of c-Myc and transcriptional effectors of mutant KRAS signaling. In this study, we assessed whether triptolide/Minnelide can enhance the antitumor activity of RMC-6236, a pan-KRAS inhibitor in clinical development for KRAS mutant cancers. We first evaluated the synergistic effects of triptolide and RMC-6236 on pancreatic cancer cell growth across multiple KRAS-mutant lines, including HPAC ($KRAS^{G12D}$), Capan-1 ($KRAS^{G12V}$), Hs766T ($KRAS^{Q61H}$), and BxPC3 ($KRAS^{wt}$). The combination demonstrated strong synergy across a range of concentrations in HPAC and Capan-1 cells and additive effects in BxPC3 and Hs766T. To validate these findings *in vivo*, we assessed Minnelide in combination with RMC-6236 using an HPAC xenograft model (3×10^6 cells, subcutaneous implantation). Mice received oral Minnelide (0.10 or 0.15 mg/kg, QDx21) with or without a low dose of oral RMC-6236 (15 mg/kg, QDx21; n = 10/group). While Minnelide alone showed modest tumor inhibition, both doses of Minnelide significantly enhanced the antitumor efficacy of low dose RMC-6236 after 21 days ($p < 0.01$, two-way ANOVA). No weight loss or other toxicities were observed in the single agent or combination groups. Taken together, these results demonstrate that triptolide/Minnelide augments the activity of RMC-6236 *in vitro* and *in vivo*, supporting further preclinical and potentially clinical evaluation. (This work was supported by Minneamrita Therapeutics, Purple Pansies, and the Pancreas National Advisory Council)

#1893 Inhibiting CDK9/13 decreases progression of multiple myeloma and myeloma-induced bone disease in preclinical studies.

Tiina E. Kahkonen[1], Gergana Gababova[1], Ru Yang[2], Jie Wen[2], Michael Thormann[1], Jussi M. Halleen[1]

[1]OncoBone Therapeutics Ltd, London, United Kingdom,[2]PharmaLegacy LLC, Shanghai, China

Cyclin-dependent kinases (CDKs) are promising targets in many cancers. OBP-004 is an oral highly potent and selective small-molecule dual inhibitor of CDK9/13 with a half-life of 17-20 hours, high tissue biodistribution in brain, lung, spleen and kidneys, and with no observed safety issues. Multiple myeloma (MM) is a plasma cell malignancy that is primarily growing in bone marrow and has a strong association with bone. At advanced stages, MM patients develop bone disease leading to increased bone loss and bone pain. In this study, we used OBP-004 to study if CDK9/13 is a suitable drug target in MM and MM associated bone disease.
For studying efficacy on hematological cancers, female NMRI nude mice were inoculated intravenously with luciferase-labelled MV4-11 human acute myeloid leukemia cells and randomized to treatment groups at day 15 based on body weight and bioluminescence imaging (BLI) signal. OBP-004 was given orally at a dose of 1.0 mg/kg three times a week (3-day on, 4-day off). Tumor burden was monitored by BLI and the study was terminated at day 32. In the MM model, NPG mice were inoculated intratibially with luciferase-labelled RPMI-8226 human MM cells and randomized to treatment groups at day 3 based on body weight and BLI signal, and treatments were started at day 3. OBP-004 was given orally at a dose of 0.6 mg/kg daily. The standard-of-care therapies bortezomib (0.8 mg/kg, ip, BIW) and zoledronic acid (0.1 mg/kg, sc, QW) were used as reference compounds. Tumor burden was monitored by BLI and cancer-induced bone loss by scoring X-ray images. The study was terminated at day 56.
The initial 1.0 mg/kg dosing (3-day on, 4-day off) of OBP-004 in the MV4-11 study resulted in slight decrease of body weight without any clinical signs. After optimizing the dose and the dosing schedules, the daily dose of 0.6 mg/kg showed no body weight loss or clinical signs during the 54 days treatment period. In the MV4-11 model, OBP-004 showed strong decrease (>97%) of brain, lung and lymph node metastases, and almost complete (>99.99%) abolishment of bone metastases. In the RPMI-8226 model, bortezomib inhibited tumor growth but zoledronic acid showed no effects, and zoledronic acid inhibited cancer-induced bone loss but bortezomib showed no effects. OBP-004 showed significantly stronger tumor growth inhibition than bortezomib and decreased cancer-induced bone loss similarly to zoledronic acid.
We conclude that CDK9/CDK13 is a potential target in hematological malignancies including MM. By targeting CDK9/13, it is possible to affect both tumor growth and cancer-induced bone loss.

#1894 Proteome-wide target engagement and selectivity profiling of CDK2 inhibitors using CETSA®.

Tomas Friman, Merve Kacal, Tuomas Tolvanen

Pelago Bioscience AB, Solna, Sweden

Mitosis and the cell cycle is a pivotal part of cancers and other neoplastic diseases. The cell cycle is tightly regulated, yet frequently deregulated in tumors, making its core regulators attractive targets for anti-tumor therapy. Cyclin-dependent kinases (CDKs) form complexes with cyclins to phosphorylate key proteins that drive cell-cycle progression. Dual CDK4/6 inhibition is an established treatment strategy in subsets of breast cancer, but resistance is common. Targeting CDK2 has therefore emerged as a strategy to overcome resistance to CDK4/6 inhibition. While CDK4/6 primarily controls early cell-cycle progression by regulating phosphorylation of the retinoblastoma-associated protein (RB1), CDK2 participates in this phase and regulates later cell-cycle transitions. CDK2 inhibitors may thus offer additional therapeutic benefits compared with CDK4/6 inhibitors. Several CDK2-selective inhibitors have recently been developed, including Tagtociclib (PF-07104091), Cirtociclib (BLU-222), and INX-315. Here, we investigated the proteome-wide target engagement and selectivity profiles of these CDK2-selective kinase inhibitors and compared them with those of approved CDK4/6 inhibitors (palbociclib, ribociclib, and abemaciclib) and pan-CDK probes. We utilized the cellular thermal shift assay (CETSA®) coupled with mass spectrometry (MS). CETSA monitors drug-induced changes in protein thermal stability and can be applied in intact cells or cell lysates without modifying proteins, ligands, or cells. An MS-based readout enables unbiased, proteome-wide detection of small-molecule-protein interactions, including non-kinase targets and downstream pathway components. All tested CDK2-selective inhibitors engaged CDK2 and additional kinases at high concentrations of 30 µM. Compared with CDK4/6 inhibitors, they showed weaker engagement of CDK4/6 but, like CDK4/6 inhibitors, induced thermal destabilization of RB1, indicating a shared impact on RB1-dependent pathways. Target engagement of CDK1 was restricted to CDK2-selective and pan-CDK inhibitors and was only observed at higher compound concentrations. Together, these data illustrate the utility of CETSA MS for mapping target engagement and selectivity across the proteome, as well as for characterizing the evolution of CDK inhibitors from early pan-CDK compounds to modern CDK2-selective agents.

#1895 Distinct metabolic adaptations to resistance to CDK4/6 inhibitors in ER+ breast cancer identified using microfluidic mass spectrometry platform.

Gianna A. Slusher[1], Yuan Gu[2], Sunil S. Badve[3], Andrei G. Fedorov[1], **Yesim Gokmen-Polar**[3]

[1]George W. Woodruff School of Mechanical Engineering, Parker H. Petit Institute for Bioengineering, Georgia Institute of Technology, Atlanta, GA,[2]Pathology and Laboratory Medicine, Emory University School of Medicine, Atlanta, GA,[3]Department of Pathology and Laboratory Medicine and Emory Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA

Background: Cyclin-dependent kinase inhibitors, CDK4/6i, have been one of the most significant practice-changing advances in the treatment of estrogen receptor positive (ER+) breast cancer in the recent decade. Despite their clinical success, CDK4/6i resistance remains a major clinical challenge. Importantly, therapeutic response does not correlate with expression levels of CDK4, CDK6, or other canonical cell cycle proteins, suggesting that resistance arises from complex adaptive mechanisms.
Methods: To address this challenge, we generated drug-tolerant persister cell populations (DTPs) from LCC2, LCC9 and T47D breast cancer cell lines to both palbociclib and abemaciclib. Transcriptomic profiling of these DTPs revealed significant alterations in the expression of metabolic enzymes, suggesting that metabolic reprogramming plays a central role in the survival and maintenance of CDK4/6i-tolerant cells. To further identify and quantify changes in metabolites and metabolic pathways, we analyzed these DTP populations using a dynamic sampling platform (DSP) integrating a sample introduction mechanism, a microfabricated processing device, and electrospray ionization mass spectrometry (ESI-MS) analysis. The device, manufactured via advanced microfabrication techniques, enables integration of real-time multiple processing and metabolic profiling. Full untargeted metabolomics data were evaluated using pathway level gene set enrichment analysis (GSEA).
Results: Across resistant cell states, multiple metabolic pathways exhibited coordinated shifts associated with DTP-like adaptation. Palbociclib resistant LCC2-DTPs exhibit a distinct metabolic remodeling trajectory characterized by consistently elevated ubiquinone biosynthesis, an adaptation absent in abemaciclib-resistant LCC2-DTPs and other DTP sublines. This drug-specific metabolic signature suggests that palbociclib engages mitochondrial pathways in a unique manner, potentially influencing therapeutic resistance. On the other hand, pathways involving electron transport chain and fatty acid oxidation were upregulated in abemaciclib DTPs, suggesting differential metabolic regulation in response to each CDK4/6i.
Conclusions: These findings highlight divergent metabolic consequences for palbociclib and abemaciclib in endocrine-resistant ER+ breast cancer and underscore the utility of microfluidic ESI-MS workflows for resolving drug-specific adaptive states relevant to therapeutic resistance and tumor progression.

#1896 'Translating' CDK9 inhibitor effects to target prostate cancer.

Shivani Yalala[1], Pedro Durao[2], Agata Carreira[2], Joyeeta Chatterjee[3], Muskan Kumari[1], Antti Sakari Rannikko[4], Eileen E. Parkes[2], Fadi Issa[2], Ian G. Mills[2], **Harri M. Itkonen**[1]

[1]University of Helsinki, Helsinki, Finland,[2]University of Oxford, Oxford, United Kingdom,[3]University of Oslo, Oslo, Norway,[4]HUS Helsinki University Hospital, Helsinki, Finland

Introduction Prostate cancer (PC) is the most common male cancer, and more effective treatments are needed to control the late-stage disease. In the lethal disease, termed castration-resistant PC (CRPC), cancer cells sustain a pro-proliferative gene expression program despite the presence of anti-androgens. This gene expression program is ultimately dependent on CDK9, and compounds targeting it are currently in clinical trials for solid tumors. All cells depend on CDK9 to sustain gene expression, although it is not clear why cancer cells are particularly sensitive to CDK9 targeting drugs.

Experimental procedures Multi-omics profiling of prostate cancer cell lines was used to understand how cells respond to CDK9 inhibition. Patient samples were used to correlate some of the findings, with data validation ongoing in syngeneic mouse models.

Summary of the data We show that CDK9 inhibition activates the innate immune response through viral mimicry in PC cells. As expected, targeting CDK9 suppresses overall transcription; however, some genes are expressed in significantly higher levels in this situation. Mechanistically, CDK9 inhibition uncouples the mRNA-processing machinery from RNA polymerase II, and we show that in this situation intron retention is significantly increased. The generated mis-spliced RNAs are prone to form double-stranded RNAs (dsRNA), and full activity of (dsRNA)-activated kinase is required for the CDK9 inhibitor-induced anti-proliferative effects. Accumulation of dsRNAs is known to activate the innate immune response and indeed we show that CDK9 inhibition leads to excessive secretion of immunogenic cytokines.

Conclusions Our data reveal that targeting the transcription elongation kinase CDK9 activates immuno-modulatory signalling *in vitro* by selectively augmenting translation of certain mRNAs. We are now validating these effects in syngeneic animal models, patient derived organoids, and probing the extent to which the transcriptional and translational programs are rewired. In the long run, our aim is to develop an effective treatment strategy against CRPC.

#1897 Targeting RB-deficient small cell lung cancer with selective CDK2 inhibition by AZD8421.

Rajita Vatapalli, Michael Grondine, Jun Fan, Grace Guo, Zhan Liu, Tam Nguyen, Deepa Bhavsar, Christopher Denz

AstraZeneca Pharmaceuticals LP, Waltham, MA

Retinoblastoma (RB) loss is a hallmark of small cell lung cancer (SCLC), yet its therapeutic vulnerabilities remain underexplored. DepMap analysis identifies Cyclin-dependent Kinase 2 (CDK2) as a top vulnerability in SCLC with RB mutations and RB1 protein loss in cell lines corresponds with increased sensitivity to CDK2 KO. CDK2 is a Ser/Thr kinase activated via interaction with its cyclin partners cyclin E (CCNE) and cyclin A (CCNA), driving G1 and S phase progression of the cell cycle. Here, we demonstrate that RB-deficient SCLC exhibits sensitivity to AZD8421, a highly selective inhibitor of CDK2.

Within a panel of SCLC cell lines, AZD8421 demonstrates selective growth inhibition in RB-mutant lines, with the average IC50 value being more than 45-fold lower than that observed in RB-wildtype counterparts. Mechanistically, CDK2 inhibition results in G2 cell cycle arrest and robust activation of cleaved PARP and cleaved caspase 3/7 specifically in RB-deficient models, distinguishing this cytotoxic phenotype from cytostatic effects previously observed in disease indication outside of SCLC, including CCNE1 over-expressing cancer models.

In vivo, 4 RB-expressing SCLC PDX models exhibited substantial tumor growth inhibition following treatment with AZD8421, with an average TGI of 58%. In contrast, 6 RB-deficient PDX models demonstrated more profound and sustained responses with monotherapy, achieving an average TGI of 90%. Pharmacodynamic studies confirm dose-dependent target engagement via p-NPM1 suppression and evidence of apoptosis in vivo.

These findings support further evaluation of CDK2 inhibition as a possible targeted strategy for RB-mutant SCLC that could offer a precision-medicine approach for a historically refractory disease subtype.

#1898 CDK2 partners with cyclin E or cyclin A to support distinct roles in cell cycle regulation: Implications for anti-tumor efficacy and potential toxicity of CDK2 inhibitors.

Haoran Jing, Neil Umbreit, Rens Janssens, Kimberly Rizzolo, Thao Duong, Huyen Nguyen

Novartis, Cambridge, MA

Cyclin-dependent kinase 2 (CDK2) is the primary regulator of the S phase of the cell cycle, phosphorylating numerous substrates involved in controlling DNA replication origin firing and fork progression. CDK2 initially becomes activated in late G1 via binding to cyclin E (CCNE1/CCNE2), and contributes to phosphorylating RB1 to drive G1/S transition. As S phase progresses, CDK2 activity becomes increasingly dependent on cyclin A (CCNA2) to support the completion of DNA replication and promote activation of CDK1 in the G2 phase. In certain physiological and pathological circumstances, cyclin E overexpression has been shown to hyperactivate CDK2 and promote endoreduplication, inhibit cellular senescence, and/or override cell cycle checkpoints. Many of these features are hallmarks of cancer cells; indeed, copy number amplification of CCNE1 or CCNE2 are observed in subsets of solid tumors (e.g. gastroesophageal, ovarian, and breast cancers), highlighting CDK2 as a promising therapeutic target in these contexts. However, the development of CDK2 inhibitors has been hindered by dose-limiting gastrointestinal (GI) toxicities, and it is unclear whether this is caused by off-target (e.g. CDK1) or on-target inhibition of one or more CDK2-cyclin complexes. Using a combination of genetic and pharmacologic perturbations, we investigated how the different CDK2-cyclin complexes contribute to cell cycle regulation in both cancer and normal GI cell models. Our findings shed light on the underlying mechanisms by which CDK2 inhibition contributes to both anti-cancer efficacy and normal tissue toxicity.

#1899 Thymidine kinase activity as a translational biomarker to support dose optimization in oncology drug development and a tool for monitoring patients.

Hanna Ritzen, Mattias Bergqvist

Biovica International AB, Uppsala, Sweden

IntroductionThymidine Kinase (TK) is a cell-cycle regulated enzyme essential to DNA synthesis and a marker of cell proliferation and tumor aggressiveness. TK is released into the bloodstream and measurement of its activity (TKa) serves as a predictive and dynamic biomarker providing valuable insights in drug development. These studies aim to demonstrate the role of TKa—from evaluating drug effects in cells and preclinical studies to guiding dosing, patient stratification and monitoring in clinical trials. The FDA Project Optimus underscores the need for biomarkers that can support drug dosing optimization based on biological responses rather than maximum tolerated dose.MethodsTKa was investigated as a translational biomarker of pharmacodynamic (PD) response across preclinical and clinical settings, studying cell cycle inhibitor drugs effect on TKa levels. In HR+ breast cancer cell lines, the effects on both sensitive cells (CDKS) and cells with acquired resistance (CDKR) to CDK4/6 inhibition were studied. Clinically, the effects of CDK2 inhibition were evaluated in a phase 1/2 dose escalation study and CDK4/6 inhibition in the real-world setting, including dose adjustments, from TKa monitored breast cancer patients treated at US institutes. TKa was measured with the FDA cleared DiviTum® TKa assay (Biovica, Sweden). ResultsTKa was significantly reduced in CDKS cells treated with increasing doses of palbociclib for 3 days compared to drug vehicle (DMSO) with the highest dose of palbociclib suppressing TKa >95% vs DMSO ($p < 0.05$). No significant impact on TKa were observed in CDKR cells at any palbociclib dose.CDK-2 inhibition impact on TKa and pRb was demonstrated, with significant correlation between increasing drug exposure and decreasing TKa levels ($p < 0.05$). Combination of CDK2- and 4/6 inhibitors plus fulvestrant achieved the greatest TKa suppression ($p < 0,05$). Real-world evidence from breast cancer patients demonstrates how TKa monitoring can support individualized dose adjustments of CDK4/6 inhibitors. A lack of drug-induced TKa suppression may indicate suboptimal efficacy, justifying either dose escalation or a different therapy combination, while a strong and sustained drug-induced TKa suppression signals therapy efficacy and disease control. Dose adjustments of CDK4/6 inhibitors show how different dosing impact TKa levels and PD suppression of tumor proliferation reflects cell-cycle control. Examples of dose adjustments and drug concentration on TKa levels will be presented. ConclusionsTKa acts as a translational biomarker and a surrogate for anti-tumor activity, offering an evidence-based approach to balance efficacy and tolerability. TKa patterns can provide early signals of drug efficacy, identify patients with sustained cell-cycle inhibition, refine dose-response understanding and improve patient monitoring.

#1900 PTEN loss of function encodes sensitivity to multitargeted small molecule CDK4/6-CDK9-AURKA/B inhibitor, LCI133, and other CDK9 inhibitors.

Halle Goodwin[1], Qi Zhang[1], Vaidehi Mujumdar[1], Krishaniah Maddeboina[2], Cody McHale[2], Bharath Yada[2], Hailey Dryden[2], Robert Wendel Naumann[1], Yovanni Casablanca[1], Erin K. Crane[1], Jubilee Brown[1], Allison Puechl[1], Brittany Lees[1], Donald Durden[2], Dhananjaya Pal[2]

[1]Gynecologic Oncology, Atrium Health, Wake Forest University, Levine Cancer Institute, Charlotte, NC,[2]Molecular Targeted Therapeutics Laboratory, Atrium Health, Wake Forest University, Charlotte, NC

ObjectiveTargeted therapies for endometrial cancer (EC) have shown promise, making multitargeted therapeutics of particular interest. LCI133 is a novel, in *silico*-designed triple inhibitor of CDK4/6-CDK9-AURKA/B that demonstrated nanomolar potency by 48-hour IC_{50} and selective dose-dependent apoptosis induction in *PTEN* mutant EC cell lines. *In vivo*, LCI133 showed antitumor activity against *PTEN* mutant EC xenografts and presented an acceptable safety profile. Given these data, our objective is to define the mechanism by which *PTEN* status serves as a biomarker for LCI133 and other transcriptional inhibitor sensitivity in EC.

Methods1. *PTEN* WT HEC-1-B cells were transfected with *PTEN* shRNA and control shRNA to generate *PTEN* knockdown and control HEC-1-B cell lines. *PTEN* null AN3 CA cells were transduced with lentivirus to generate a doxycycline (Dox) inducible *PTEN* WT AN3 CA cell line.2. Isogenic *in vitro* studies were performed to determine potency of LCI133 and AZD4375 (single agent CDK9 inhibitor) by luminescent viability assay, 7-AAD/Annexin V and DNA dye flow cytometry assays. Nascent RNA (nRNA) was detected by Click-it Nascent RNA Capture Kit and assessed by qRT-PCR or confocal microscopy. Co-immunoprecipitation (Co-IP), reciprocal Co-IP, and Western blotting were used to examine protein-protein interactions.3. HEC-1-B *PTEN* shRNA or control shRNA xenografts were established in NSG mice, which were randomized and treated with LCI133 (50mg/kg) or vehicle (VEH) by daily intraperitoneal injection for 21 days. Tumor volume and animal mass were monitored, and biosamples were collected at end point.

Results1. *PTEN* knockdown in HEC-1-B cells increased sensitivity to LCI133 and AZD4375 compared to control by viability assay ($p \leq 0.0001$) and apoptosis assays ($p \leq 0.001$). Conversely, Dox induced *PTEN* expression reduced sensitivity to LCI133 by apoptosis assay ($p \leq 0.001$).2. In isogenic HEC-1-B cells, *PTEN* knockdown resulted in augmented relative nRNA transcription, followed by a significant decrease in nRNA after LCI133 treatment. A *PTEN*-dependent protein-protein interaction between RNA Polymerase (Pol) II and PTEN was shown in isogenic HEC-1-B-shRNA and *PTEN*-reconstituted AN3 CA cells.3. Tumors reached 50-75 mm^3 more quickly in the HEC-1-B *PTEN*-shRNA group compared to control ($p \leq 0.0001$). In the *PTEN* knockdown group, treatment with LCI133 resulted in slower tumor growth compared to VEH ($p \leq 0.0001$), while in the control-shRNA group, there was no difference in tumor growth between LCI133 and VEH.

ConclusionsThese data prove that the absence of *PTEN* is causally linked to sensitivity to LCI133 and AZD4375 via facilitating RNA Pol II dependent transcriptional elongation followed by a marked decrease in nRNA in *PTEN* knockdown EC cells. *PTEN* expression may be useful as a biomarker in selecting targeted therapeutics for EC driven through transcriptional activation.

#1901 Mechanisms of sensitivity and resistance to CDK2 inhibitors.

Sabrina L. Spencer

Univ. of Colorado Denver School of Medicine, Aurora, CO

CDK2 is a core cell-cycle kinase that phosphorylates many substrates to drive progression through the cell cycle. We used several CDK2 inhibitors in clinical development to interrogate CDK2 substrate phosphorylation, cell-cycle progression, and drug adaptation in preclinical models. Whereas CDK1 is known to compensate for loss of CDK2 in *Cdk2-/-* mice, this is not true for acute inhibition of CDK2. In normal mammary cells and estrogen receptor-positive breast cancer cells, CDK2 inhibition causes a rapid loss of substrate phosphorylation that is rapidly restored by a hard-wired cell-cycle buffering mechanism in which CDK4/6 maintains Rb hyper-phosphorylation, E2F transcriptional activity, and Cyclin A2 expression, enabling re-activation of CDK2. Thus, we hypothesized that sensitivity to CDK2 inhibition is linked to the absence of this CDK4/6-mediated compensatory mechanism. Indeed, we found that Cyclin E1-driven ovarian cancers often co-express the tumor suppressor p16, which inhibits CDK4/6. We show that ovarian cancer cells expressing p16 exhibit heightened sensitivity to CDK2 inhibitors and that depletion of p16 renders them resistant. Multiplexed immunofluorescence of 225 ovarian patient tumors reveals that at least 18% of tumors express high Cyclin E1 and high p16, a group that we expect to be particularly sensitive to CDK2 inhibition. These data further reveal two cell-cycle entry paths that are readily detectable in patient tumors - the canonical CDK4/6-Cyclin D path, and the CDK2-Cyclin E path ‘bypass’ path. Thus, p16 may be a useful biomarker for identifying the patients that are most dependent on the CDK2-Cyclin E path and are thus most likely to benefit from CDK2 inhibitors.

#1902 Comparative biochemical evaluation of small-molecule inhibitor efficacy on CDK/Cyclin complexes across diverse mammalian species.

Andreas Gericke[1], Frank Totzke[1], Constance Rademann[2], Carolin Heidemann-Dinger[1], Daniel Mueller[1]

[1]Reaction Biology Europe GmbH, Freiburg im Breisgau, Germany,[2]Reaction Biology Europe GmbH, Freiburg, Germany

Cyclin-dependent kinases (CDKs) and their associated cyclins are central regulators of cell cycle progression and transcriptional control. Dysregulation of CDK/Cyclin complexes is a hallmark of many cancers, driving uncontrolled proliferation and tumor development. Consequently, these complexes have become critical targets in oncology, with CDK4/6 inhibitors already established as a cornerstone in the treatment of e.g. hormone receptor-positive breast cancer and under investigation for other malignancies. Early preclinical development of CDK inhibitors relies on biochemical screening assays to identify small molecules capable of inhibiting CDK/Cyclin activity. These assays, frequently based on kinase activity measurements, enable high-throughput evaluation of compound libraries and provide essential insights into inhibitor potency and selectivity. These approaches are mandatory for rational drug design, guiding the optimization of lead compounds toward improved efficacy and reduced off-target effects. Despite their obvious limitations in predicting cellular and in vivo responses, these early screening strategies are instrumental in shaping the current generation of CDK- and other kinase-targeted therapeutics. In subsequent development stages, cellular and in vivo model systems are employed to validate inhibitor activity and assess pharmacodynamics and toxicity. Many of these models are based on non-human mammalian species, such as murine or primate systems. These studies are essential for bridging the gap between biochemical screening and clinical application, ensuring that candidate molecules demonstrate efficacy and safety before entering human trials. However, despite the importance of such data, it is rarely assessed in early biochemical screening whether results from human and non-human assays are consistent. Such early biochemical evaluation of potential differences in the effects of drug candidates on the kinase target from different species could generate valuable insights to select the most relevant cellular or in-vivo model systems for advanced drug-development. Here, we present comparative biochemical data for late-stage development or already approved CDK inhibitors tested against CDK/Cyclin complexes from human, rat, mouse, dog and primate origin, focusing on CDK4/CycD1. Notably, differential inhibitory potency was observed for several compounds, including palbociclib, which showed an approximately ten-fold difference in CDK4/CycD1 inhibition between human and murine enzymes.

#1903 Targeting autophagy and the cell cycle in mesothelioma.

George Scaria, Marian Kratzke, Stephen Porter, Betsy Kren, **Mark A. Klein**

Minneapolis VA Health Care System, Minneapolis, MN

Introduction. Mesothelioma is considered incurable for the majority of patients, and current systemic therapies are inadequate for most patients. Targeting 1) autophagy and 2) autophagy in combination with the inhibition of select cyclin-dependent kinases (CDKs) have potential for mesothelioma, as the cell cycle is altered in the majority of mesotheliomas.

Methods. We conducted cell proliferation assays in mesothelioma cell lines to determine the IC_{50} for the autophagy inhibitors ULK-101 and hydroxychloroquine (HCQ). ULK-101, HCQ, or control were incubated with mesothelioma cells for 72 hours, and cell viability was determined using a Cell Counting Kit-8 spectrophotometric assay. We then determined mRNA expression via RNA-sequencing (RNA-Seq) after CDK4/6 inhibition with abemaciclib. Subsequently, we conducted cell proliferation assays to determine if the combination of ULK-101 plus abemaciclib or HCQ plus abemaciclib could be additive or synergistic. Lastly, we obtained micrographs of H2452 cells treated with abemaciclib and subsequent organelle labeling stain (LysoTracker Red and mitoview green).

Results. ULK-101 exhibited potency against mesothelioma cell lines (H2373 and H2452) with IC_{50} values ranging from 11.9 μM to 13.3 μM, while the IC_{50} values for HCQ against these cell lines were 32.5 μM and 45 μM. When H2373 and H2452 cells were exposed to varying combinations of abemaciclib plus ULK-101, or H2452 cells were exposed to varying combinations of HCQ plus abemaciclib, synergy was exhibited at several combinations of concentrations, with several Combination Indices < 1 as calculated via the Chou-Talalay method. This suggests a synergistic effect of these combination of drugs on decreasing cell proliferation. After exposure to abemaciclib, ULK1 (ATG1) and ATG5 (role in autophagy activation) transcript expression increased as identified via RNA-Seq. Micrographs of organelle tracking after exposure to abemaciclib demonstrated increased lysosome size and number, suggesting autophagy activation.

Conclusions. ULK-101 is active against mesothelioma cells, while ULK-101 plus abemaciclib act synergistically against mesothelioma. Also, abemaciclib was associated with increased lysosome size and number, suggesting autophagy activation. Collectively, the results suggest that autophagy and the cell cycle pathways may be targeted in mesothelioma and could be co-targeted in a synergistic fashion.

#1904 Dual-targeting CDK4 and CDK2 overcomes resistance to CDK4/6 inhibitors in HR+ breast cancer.

Wenqing Cai, Siwen Liu, Lu Su, Quang Fu, Chen Liao

Hengrui pharmaceuticals Co. Ltd., Shanghai, China

Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i)have proven clinical efficacy in hormone receptor-positive (HR+) breast cancer (BC) patients. However,current clinical challenges are frequent hematologic toxicities mediated by CDK6 inhibition and acquired drug resistance driven in part by cyclin E/CDK2 activation. The next generation of CDK inhibitors such as atirmociclib targeting CDK4 and tagtociclib targeting CDK2 have demonstrated encouraging early efficacy, and the combination of a selective CDK4 inhibitor and a selective CDK2 inhibitor has entered clinical trials. We propose that simultaneous targeting CDK4 and CDK2 with a small-molecule may provide a new therapeutic option.

To address the efficacy of dual-targeting CDK4 and CDK2, compound-1308 (Cpd-1308) were synthesized. In NanoBRET assay measuring cellular target engagement, Cpd-1308 had an IC50 against CDK4 of 24nM, an IC50 against CDK2 of 123nM, and an IC50 against CDK6 of 521nM, suggesting a CDK4/2 inhibitor over CDK6. Antiproliferative potency and inhibition of retinoblastoma (RB) phosphorylation were tested in multiple cancer cell lines. Human primary hematopoietic stem and precursor CD34+ cells (CD34+ HSPC) were used to estimate impact on the inhibition of hematopoietic cells proliferation. Cpd-1308 and palbociclib are nearly equipotent in MCF7 cells, whereas Cpd-1308 showed a 7-fold reduced impact on CD34+HSPC cells when compared to palbociclib. These results suggested that CDK4:CDK6 selectivity of Cpd-1308 was greater than that of palbociclib.

Further kinetic characterization using surface plasmon resonance (SPR) spectroscopy revealed that Cpd-1308 has long residence time on CDK2 in comparison with tagtociclib. Long residence time on CDK2 may potentially lead to improved efficacy against drug resistance driven in part by cyclin E/CDK2 activation. Cpd-1308 indeed showed superior potency on antiproliferation of derived palbociclib resistant MCF7 cells (MCF7-palbo-r) and derived abemaciclib resistant MCF7 cells (MCF7-abema-r). We tested the in vivo efficacy of Cpd-1308 in CDK4/6i-resistant HR+ breast cancer patient-derived xenografts tumors (PDX). Tumor growth was inhibited in a dose-dependent manner and significant growth inhibition was observed. Cpd-1308 demonstrated significant resistance-overcoming activity.

Taken together, we demonstrate activity of Cpd-1308 in HR+ breast cancers and CDK4/6i-resistant breast cancers. Our research results indicate that co-targeting CDK4 and CDK2 with a small-molecule may grant new therapeutic opportunities for patients.

#1905 Discovery of ABK-CDK4, a selective and brain-penetrant CDK4 inhibitor.

Weiling Pan, Hui Wang, Fangfei Qi, Zheng Li, Xinming Du, Jie Zhang, Jie Wang, Manqi Zhang, Haibing Deng, Hongping Yu, Yao-chang Xu, **Haiyan Ying**

Abbisko Therapeutics, Shanghai, China

Introduction: Cyclin-dependent kinase (CDK)4/6 play important roles in the G1-S phase transition in the cell cycle. Although the first generation dual CDK4/6 inhibitors— such as palbociclib, ribociclib, and abemaciclib—have demonstrated clinical efficacy in advanced breast cancer, inhibition of CDK6 would cause dose-limiting hematological toxicity. Sparing CDK6 inhibition could improve therapeutic window and enhance CDK4 target coverage. Meanwhile, brain metastases occur in 20%-40% of patients with breast cancer during their course of disease. A selective CDK4 inhibitor with reduced CDK6 inhibition and good brain penetration could provide a differentiated therapeutic option, especially for patients with brain metastasis. Through advanced computational structural analysis and medicinal chemistry effort, we have discovered ABK-CDK4, a highly selective and brain-penetrant CDK4 inhibitor. Preclinical studies demonstrate its good selectivity over CDK6, robust anti-tumor efficacy, and favorable pharmacokinetics.

Methods: Biochemical assays were performed to assess the potency of ABK-CDK4 against CDK4 and to evaluate selectivity across a kinase panel, including CDK6. Anti-proliferative effect and inhibition of retinoblastoma (Rb) phosphorylation were tested in multiple cancer cell lines. *In vivo* anti-tumor activity was evaluated in cell-derived xenograft (CDX) mouse models. Pharmacokinetic and safety profiles were also examined.

Results: ABK-CDK4 exhibited potent inhibition of CDK4 with >70-fold selectivity over CDK6. In HR^+HER2^- cancer cell lines, it effectively suppressed Rb phosphorylation and cell proliferation. ADME profiling demonstrated superior brain-penetration (Kpuu>0.5) and favorable drug-like properties. Orally administration of ABK-CDK4 led to robust tumor growth inhibition in HR^+HER2^- breast cancer xenograft models.

Conclusion: ABK-CDK4, developed by Abbisko Therapeutics, is a highly selective and brain-penetrant CDK4 inhibitor with the potential to address limitations of current CDK4/6 inhibitors. Its promising efficacy, selectivity, and other properties support further preclinical advancement toward clinical development.

#1906 Novel treatment: CDK11 inhibition in rhabdoid tumor of the kidney.

Kamhung Lam, Yuki Murakami, Shinsuke Fukui, Elizabeth Helmke, Noriko Satake

UC Davis, Sacramento, CA

Rhabdoid tumor of the kidney (RTK) is an aggressive pediatric malignancy with extremely poor outcomes despite extensive treatment. Its high treatment resistance and disease relapses necessitates a search for new therapeutic strategies. RTK is marked by the loss of SMARCB1 gene, leading to downstream dysfunctions in cell cycle, cell proliferation, and RNA splicing. Cyclin dependent kinases (CDKs) are known to regulate these processes, with several CDK inhibitors already being used in cancer treatment. CDK11's known function in regulating cell cycle and RNA splicing via splicing factor SF3B1 and its overexpression in various cancers makes it a potential therapeutic target. In this study, we evaluated the therapeutic potential of CDK11 inhibition in RTK. Based on the Therapeutically Applicable Research To Generate Effective Treatments (TARGET)-RT database, RTK tissues (n = 63) have significantly higher CDK11 expression compared to normal kidney tissues (n = 6). We also confirmed higher CDK11 protein expression in two RTK cell lines (G401 and JMU-RTK-2) than in human embryonic kidney cells (HEK293) ($p = 0.05$, 0.13, respectively). A CDK11 inhibitor, OTS964, showed significant dose-dependent cytotoxicity with IC50 of 33.1 nM in G401 and 19.3 nM in JMU-RTK-2. Next, we treated nude mice engrafted with JMU-RTK-2 tumors with 25 mg/kg of OTS964 or vehicle control. OTS964 monotherapy significantly prolonged survival (median survival: 46.5 days vs 37.0 days) and suppressed tumor progression ($p = 0.002$) without clinical signs of toxicity. Finally, we investigated OTS964's mechanisms of action. OTS964 treatment at IC80 of 80 nM (G401) and 30 nM (JMU-RTK-2) significantly increased expression of cleaved PARP, cleaved caspase-3, and p53. G2/M cycle arrest was demonstrated at 8 hours (G401) and 12 hours (JMU-RTK-2). OTS964 is known to inhibit phosphorylation of the splicing factor SF3B1, a core component of the spliceosome, thereby regulating RNA splicing. We confirmed SF3B1 inhibition by increased accumulation of the unspliced transcript DNAJB1, a known SF3B1-dependent transcript. In conclusion, our data demonstrated the therapeutic efficacy of CDK11 inhibition in RTK. CDK11 inhibition using OTS964 suppressed RTK cell growth and prolonged survival in mouse xenograft model. OTS964 induced apoptosis via caspase-3 activation with G2/M cell cycle arrest, p53 upregulation, and RNA splicing disruption via SF3B1 inhibition. In future studies, we plan to investigate synergistic combination of CDK11 inhibition with existing therapies.

#1907 CDK2 controls RIPK2 ubiquitination and stability in prostate cancer cells.

Lili M. Guerra, Ahmed M. Elgehama, Jaceline G. P. Sanches, Leslie Chiu, Wei Yang*

Department of Pathology, Stony Brook University - Cancer Center, Stony Brook, NY

Background: Prostate cancer (PC) metastasis drives PC-related mortality and morbidity, yet the molecular mechanisms underlying this lethal process remains incompletely understood. Previously, we demonstrated that RIPK2 is critical for PC progression and metastasis (*Nat. Commun.*, 2022). However, the regulatory mechanisms controlling RIPK2 protein levels in PC cells remain unclear. This study aims to address this knowledge gap by investigating the regulation of RIPK2 ubiquitination and degradation in PC cells, with a particular focus on CDK2, which we identified as a key mediator of RIPK2 regulation of the c-Myc oncoprotein.
Methods: PC cells—22Rv1 (androgen receptor-positive) and PC3 (androgen receptor-negative)—were treated with two clinically evaluated, CDK2-selective inhibitors, INX-315 and PF-07104091. Changes in RIPK2 protein levels were measured by western blotting. RIPK2 stability was assessed using cycloheximide (CHX) chase assays, and proteasomal degradation was evaluated with MG132 treatment. K48-linked ubiquitination of RIPK2 was examined by immunoprecipitation followed by western blotting with K48-linked ubiquitin antibodies. Cell cycle synchronization was achieved by serum starvation or treatment with Ro-3306, hydroxyurea, thymidine, or monastrol. Proximity ligation assays (PLA) were used to assess protein-protein interactions between RIPK2 and CDK2, its E3 ligase ZNRF4, or deubiquitinases YOD1, OTUB2, and OTUB5. Statistical analyses were performed using unpaired, two-tailed Student's *t*-tests.
Results: CDK2 inhibition significantly reduced RIPK2 protein half-life in a proteasome-dependent manner and increased RIPK2 K48-linked ubiquitination. RIPK2 protein abundance peaks in the G2 phase, lagging behind the S-phase peak of active CDK2, its stabilizing kinase. Proximity ligation assays showed that RIPK2 associates with CDK2, ZNRF4, YOD1, and OTUB5 primarily in the cytoplasm. Notably, CDK2 inhibition disrupted RIPK2 association with YOD1 but not ZNRF4 in a dose-dependent manner, implicating YOD1 in CDK2-mediated control of RIPK2 stability. Together, these findings identify CDK2 as a key regulator of RIPK2 ubiquitination and stability in PC cells.
Conclusion: Kinase-active CDK2 inhibits the K48-linked ubiquitination of RIPK2 and protects it from proteasomal degradation. This protection is potentially mediated by regulating the association between RIPK2 and its deubiquitinase YOD1 in PC cells. The findings support further investigation into the molecular mechanisms by which CDK2 stabilizes RIPK2 in PC and other cancer types.

#1908 Activity of dual BET and CDK9 inhibition in murine models of pancreatic ductal adenocarcinoma.

Michela Cadarso[1], Austin Stram[1], Lucas Koeppel[1], Robert J. Millikin[2], Md Shahadat Hossan[1], Eleanor Riedl[1], Ron Stewart[2], Jeremy D. Kratz[1]

[1]University of Wisconsin-Madison, Madison, WI,[2]Morgridge Institute for Research, Madison, WI

Background: Pancreatic ductal adenocarcinoma (PDAC) remains a leading cause of cancer related mortality in the U.S. with a 13% 5-year survival rate. Acquired resistance plays a critical role in progression, however targeted therapeutics have been developed for rare molecular subsets. Prior phenotypic screening efforts showed activity of bromodomain and extraterminal (BET) and cyclin dependent kinase 9 (CDK9) in PDAC organoid models. Here, we examine two independent heterotopic patient derived xenograft (PDX) murine models for the activity of BET inhibitor (ZEN3694) and CDK9 inhibitor (VIP152).

Methods: Immunodeficient $Rag2^{KO}/Il2rg^{KO}$ (R2G2) mice received subcutaneous injections of two PDAC models, PDX1 and PDX2. The models shared pathologic variants including $KRAS^{G12D}$, MTAP loss, and CDKN2A/B loss. PDX2 had concurrent loss of SMAD4. Mice colonies were treated with ZEN3694 (50 mg/kg), VIP152 (6 mg/kg), or the combination. VIP152 was administered once per week at the start of each treatment cycle and ZEN3694 was administered for five consecutive days followed by a two-day rest period. Four seven-day cycles were administered with primary endpoint of tumor volume comparison at day 28. Body weight and tumor volumes were measured biweekly by a blinded co-investigator. Toxicity was assessed by animal condition, complete blood count (CBC), and comprehensive metabolic panel (CMP) testing.

Results: All treatments were well tolerated, with no treatment group achieving weight loss >20% over the study duration. For PDX1, median weights increased by +1.21%, with non-significant change in weight for the combination of VIP152 with ZEN3694 (-14.1%). For PDX2, median weights decreased by -4.17%, with non-significant change in weight for the combination group (-8.85%). CBC and CMP results reveal no significant differences at terminal draws across treatment groups. For PDX1, median tumor growth was found to increase by +308%, with non-significant change in growth for VIP152 (+223%) or ZEN3694 (+210%), while the combination of VIP152 with ZEN3694 yielded growth arrest (-1.56%, $p<0.036$). For PDX2, median tumor growth was found to increase by +1,127%, with non-significant change in growth for VIP152 (+1,083%) or ZEN3694 (+643%), while the combination group yielded significant reduction in growth (+375%, $p<0.024$).

Conclusions: Across two independent PDAC PDX models, ZEN3694 and VIP152 yield tumor growth inhibition. All treatments were well tolerated in two independent PDAC models, PDX1and PDX2. Ongoing studies are analyzing early timepoints for a putative mechanism involving transient disruption in the activation of RNA polymerase II. Parallel analysis is examining the selectivity of this disruption in cancer tissues as opposed to background liver to index the selectivity of this drug combination in cancer types, including those where Myc can be dynamically overexpressed in response to therapeutic challenge.

#1909 CDK7 inhibition by SY5609 suppresses tumor growth in gastric cancer through inhibiting RNA pol II mediated transcription and Hippo/YAP1 signaling .

Dipti Athavale, **Yan-ting Yann Zhang**, Mikel Ghelfi, Anthony Pompetti, Junsong Zhao, Xiaodan Yao, Shumei Song

Coriell Institute for Medical Research, Camden, NJ

Background: Cyclin-dependent kinases (CDKs) are a family of serine/threonine kinases that catalyze protein phosphorylation to regulate key cellular processes. CDK7 is transcription-associated CDK which participates in both transcriptional regulation and cell cycle control. CDK7 forms a complex with cyclin H to phosphorylate the C-terminal domain (CTD) of RNA polymerase II, thereby promoting transcription initiation and elongation. In addition, CDK7 has been shown to phosphorylate the Hippo pathway coactivator YAP1 at serine 128 in mammalian cells, leading to YAP stabilization and enhanced its transcriptional activity. These findings suggest that CDK7 may represent an attractive therapeutic target. SY5609 treatment demonstrated acceptable tolerability and preliminary antitumor activity in patients with advanced pancreatic cancer. However, the expression profile of CDK7, its association with Hippo/YAP1 signaling, and its therapeutic value in advanced gastric cancer (GC) remain poorly understood. This study aimed to explore the anticancer effects of CDK7 inhibition and its potential interaction with Hippo/YAP1 signaling in GC model.
Methods: CDK7 expression was evaluated by immunohistochemistry and Western blotting in human GC tissues, patient-derived xenografts (PDXs), and GC cell lines, and further analyzed using public datasets. Functional assays, including cell proliferation, invasion, colony formation, tumor sphere formation and *In vivo* antitumor efficacy were performed to assess the effects of CDK7 inhibition by SY5609.
Results: CDK7 expression was significantly elevated in GC tumor tissues compared with adjacent normal tissues in two public datasets (cistrome.shinyapps.io/timer; GSE33335). SY5609 treatment markedly reduced cell viability and colony formation in a dose-dependent manner in GC cell lines. It also inhibited migration and tumor spheroid formation at low concentrations. Mechanistically, SY5609 decreased RNA Pol II mediated transcription and induced apoptosis. SY5609 also significantly inhibited TEAD-YAP1 transcriptional activity. Unexpectedly, SY5609 increased PD-L1 mRNA and protein expression in GC cell lines, suggesting a potential rationale for combination therapy with PD-1/PD-L1 immune checkpoint blockade. Oral administration of SY5609 significantly suppressed tumor growth and reduced tumor weight in PDX models without affecting mouse body weight.
Conclusion: Mechanistically, SY5609 treatment suppressed transcription and induced apoptosis by decreasing RNA Pol II Ser2/Ser5 phosphorylation, and reduced YAP1-TEAD transcriptional activity. Thus, targeting CDK7 with SY5606 represents a promising therapeutic strategy for advanced gastric cancer and may provide synergistic benefit when combined with immune checkpoint inhibitors.

#1910 GDC-4198, a next-generation CDK4/2 inhibitor, induces durable cell cycle arrest and shows combination benefit with giredestrant.

Marc Hafner[1], Steffan Vartanian[1], Luca Gerosa[1], Nont Kosaisawe[1], Michael S. Hwang[1], Eva Lin[1], Yi-Chang Wang[1], Jason Oeh[1], Tianyi Chen[1], Kazi N. Islam[2], Alice Zheng[2], Karen Samy[1], Udi Segal[1], John G. Moffat[1], DANIEL ZINGG[1], Annie Collier[1], Ioannis Sanidas[2], Zhi Xie[3], Seth A. Wander[2]

[1]Genentech, Inc., South San Francisco, CA,[2]Massachusetts General Hospital, Boston, MA,[3]Regor Pharmaceuticals Inc, Cambridge, MA

While CDK4/6 inhibitors (CDK4/6i) have improved the treatment of hormone receptor-positive (HR+) breast cancer (BC), resistance remains a major clinical challenge. Resistance to CDK4 inhibition can be driven by higher CDK2 activity, due to overexpression of cyclin E1/E2 or p53 loss of function, and other mechanisms. As such, targeting both CDK4 and CDK2 is hypothesized to achieve more durable cell cycle arrest. This study evaluated the preclinical activity of GDC-4198, a novel CDK4/2 inhibitor currently in early clinical trials, and its potential to overcome CDK2-driven resistance to CDK4 inhibition as a single-agent and in combination with giredestrant, a novel selective estrogen receptor (ER) degrader and full ER antagonist.

GDC-4198 has sub-nanomolar potency against CDK4/CycD1 and is a more potent inhibitor of CDK2/CycE or CDK2/CycA than CDK6/CycD3, unlike approved CDK4/6i. Western blots and immunofluorescence data demonstrated that GDC-4198 can directly decrease levels of pNCL, a direct marker of CDK2 activity. Cells engineered with a CDK2-activity reporter further confirmed the difference in inhibition profile of GDC-4198 compared to first generation CDK4/6i. In cell viability assays, we observed that GDC-4198 can maintain more durable growth arrest than CDK4/6 or CDK4-targeted inhibitors. Moreover, the introduction of TP53 knock-out had limited effects on GDC-4198 activity, and its potency was not changed by the overexpression of CCNE1/2, in contrast to other CDK inhibitors. Notably, across these different assays, the single-agent activity of GDC-4198 was comparable to the combination of CDK4- and CDK2-targeting agents. Additional studies in patient-derived cell lines obtained in the setting of metastatic HR+ breast cancer following progression on letrozole/ribociclib, as well as in cell lines with acquired in vitro resistance to palbociclib, confirmed the enhanced anti-proliferation activity of GDC-4198 compared to CDK4/6i.

When combined with giredestrant, GDC-4198 showed strong combination benefits across a range of HR+ BC cell lines. In xenograft HR+ BC models, GDC-4198 demonstrated dose-dependent tumor growth inhibition as a single agent and further improved antitumor activity in combination with giredestrant. Pharmacokinetic and pharmacodynamic analyses indicated pRb modulation in tumor samples correlated with drug exposure.

Taken together, these preclinical findings demonstrate that GDC-4198 induces more durable cell cycle arrest than first generation CDK4/6i and CDK4-targeting agents by overcoming CDK2-driven adaptive and intrinsic resistance to CDK4 inhibition. These results suggest that GDC-4198 is a promising next generation CDK4/2 inhibitor with the potential to prolong clinical benefit by delaying adaptation in earlier disease settings, as well as to provide benefit to patients who have progressed on approved CDK4/6i.

#1911 Targeting PLK1 or WEE1 uncovers a therapeutic vulnerability in BRCA1/2 wild-type, homologous recombination-proficient high-grade serous ovarian cancer.

Akiko Kunita[1], Qian Xi[2], Masanori Kawakami[3], Miho Ogawa[1], Mirei Ka[2], Kousuke Watanabe[1], Tetsuo Ushiku[4], Hidenori Kage[3], Kazuhiro Katayama[5], Katsutoshi Oda[2]

[1]Next-Generation Precision Medicine Development Laboratory, University of Tokyo, Tokyo, Japan,[2]Division of Integrative Genomics, University of Tokyo, Tokyo, Japan,[3]Respiratory Medicine, University of Tokyo, Tokyo, Japan,[4]Pathology, University of Tokyo, Tokyo, Japan,[5]Laboratory of Molecular Targeted Therapeutics, School of Pharmacy, Nihon UniversityKeio University, Chiba, Japan

Background: High-grade serous ovarian cancer (HGSOC) with BRCA1/2 wild-type (BRCA-WT) and homologous recombination proficiency (HRP) responds poorly to platinum agents and PARP inhibitors and lacks effective targeted therapies. We aimed to determine whether inhibition of PLK1 or WEE1, two G2/M checkpoint kinases, could uncover a therapeutic vulnerability in BRCA-WT/HRP HGSOC.

Methods: We evaluated the effects of the PLK1 inhibitor volasertib and the WEE1 inhibitor adavosertib in BRCA-WT/HRP (and BRCA-mutant/HR-deficient (HRD) ovarian cancer models. Cell viability, cell-cycle distribution, apoptosis markers, and DNA damage responses were quantified, including γH2AX, RAD51, and 53BP1 foci. DNA-PKcs inhibition or siRNA was used to assess NHEJ dependence. Antitumor activity was further validated in BRCA-WT cell line-derived xenografts and two PDX models with confirmed BRCA status.

Results: BRCA-WT cells demonstrated substantially higher sensitivity to PLK1 or WEE1 inhibition than BRCA-mutant cells. In BRCA-WT models, volasertib induced abnormal spindle assembly, polyploidy, and delayed mitotic progression, whereas adavosertib abrogated the G2/M checkpoint and triggered premature mitotic entry. Both agents increased DNA damage and markedly reduced RAD51 foci, demonstrating HR suppression. Although NHEJ activation was observed, it was insufficient to compensate for impaired HR. In contrast, BRCA-mutant cells showed minimal response and displayed constitutively high DNA-PKcs expression with persistent 53BP1 foci. Pharmacologic or genetic DNA-PKcs inhibition restored sensitivity to PLK1 or WEE1 inhibition in BRCA-mutant cells. *In vivo*, PLK1 or WEE1 inhibition significantly reduced tumor growth and increased apoptosis in BRCA-WT xenografts and BRCA-WT PDX, whereas BRCA-mutant PDX exhibited limited response.

Conclusion: BRCA-WT/HRP HGSOC exhibits distinct susceptibility to PLK1 or WEE1 inhibition through disruption of HR repair and mitotic regulation, revealing a DNA repair-based vulnerability not observed in BRCA-mutant/HRD tumors. These findings provide a strong rationale for biomarker-guided development of PLK1 or WEE1 inhibitors as therapeutic strategies for HRP ovarian cancers, a patient population with significant unmet clinical needs.

#1912 Extrachromosomal DNA (ecDNA)-mediated replication stress as a potential targetable vulnerability in high-risk medulloblastoma.

Jessica Wang[1], Hui Hui[1], Jon D. Larson[2], Rishaan Kenkre[3], Owen Chapman[4], Yan Yuen Lo[1], Emerald Adeyan[1], Lukas Chavez[1]

[1]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA,[2]Sanford Burnham Prebys, La Jolla, CA,[3]Sanford Childrens Health Research Center, San Diego, CA,[4]Nagoya City University, Nagoya, Japan

Extrachromosomal DNA (ecDNA) amplification is a key driver of cancer evolution and progression. In medulloblastoma, ecDNA is present in approximately 18% of cases and is associated with poor patient survival. However, its role in tumor progression and treatment resistance for patients with medulloblastoma remains poorly understood. This study investigates ecDNA-mediated replication stress (RS) as a potentially targetable vulnerability in high-risk medulloblastoma with a focus on tumors harboring MYC amplifications. Using RNA sequencing data from a cohort of 186 patients from the Pediatric Brain Tumor Atlas, we performed gene set enrichment analysis (GSEA) and found RS to be significantly enriched in medulloblastomas with amplifications compared to those without amplifications. We then investigate the effects of pharmacological checkpoint kinase 1 (CHK1) inhibition using BBI-2779—a novel, selective, and potent inhibitor developed by Boundless Bio—on MYC ecDNA-positive (D425 and D458) and MYC-HSR (D283) medulloblastoma cell lines. Our results show that ecDNA-positive lines exhibit greater sensitivity and a stronger dose-dependent response to CHK1 inhibition than MYC-HSR cells. Moving forward, we will use patient-derived xenografts (PDXs) generated from tumor biopsies collected at Rady Children's Hospital-San Diego, along with cell line models, to monitor tumor response and ecDNA copy number dynamics following CHK1 inhibition. We will then perform multiome single-cell sequencing to identify therapy-induced emergence of novel ecDNA variants.

Keywords: Medulloblastoma, Extrachromosomal DNA, ecDNA, genomic instability, therapy resistance, tumor heterogeneity

#1913 KMT2D deficiency alters CDK-cyclin regulation of Rb in endometrial cancer.

Madelyn Maurer[1], Swornalata Pukhrambam[1], Jessica Long[1], Sanjeev Ganesh[1], Sophia Agrusa[1], Maya Paytas[1], Katherine Gurdziel[2], Paul Stemmer[3], Mike R. Wilson[1]

[1]Wayne State University School of Medicine, Detroit, MI,[2]Wayne State University Genomic Sciences Core, Detroit, MI,[3]Wayne State University Proteomics Core, Detroit, MI

Endometrial cancer (EC) is the most common gynecological cancer and ranks fourth overall among all cancers affecting women in the United States. Its incidence, especially among premenopausal women, continues to increase in contrast to many other malignancies. Recent genomic investigations, including our lab's preliminary findings, have identified KMT2D, a histone methyltransferase that modulates enhancer activity, as being highly mutated in early onset EC. Our initial observations suggest that KMT2D deficiency triggers aberrant histone methylation at the Rb/E2F pathway genes, leading to upregulation of the pathway. These findings motivated the development of a KMT2D CRISPR knockout (KO) cell line to explore the mechanistic consequences of KMT2D deficiency. We are employing 12Z endometrial epithelial cell lines, derived from endometriosis, with and without CRISPR-mediated KMT2D KO to examine the mechanistic basis of Rb/E2F pathway dysregulation at both the gene expression and post-translational levels. Preliminary data indicate that KMT2D deficiency enriches retinoblastoma (Rb) phosphorylation levels, consistent with upregulation of the Rb/E2F pathway. Additionally, cyclin E, cyclin D, p21, and CDK1 were more highly expressed in KMT2D KO cells compared to the control. To further investigate upstream regulators, we examined CDK1/2 pathway dynamics. In control and KMT2D KO cells, we found pharmacologic inhibition of CDK1/2 activity led to increased expression of cyclin A2 and cyclin E1. There was also a divergent effect on Rb phosphorylation following CDK1/2 inhibition, with phospho-Rb increasing expression in control cells but reducing in KMT2D KO cells. This indicates KMT2D deficiency alters CDK-Rb signaling pathways. To explore additional mechanisms contributing to altered Rb regulation, we performed Rb immunoprecipitation followed by mass spectroscopy to identify changes in Rb protein interactions in the absence of KMT2D. Ongoing analysis of these datasets aims to determine whether KMT2D deficiency exposes novel regulatory interactions affecting Rb phosphorylation. This study builds on preliminary findings implicating KMT2D in Rb pathway dysfunction in early-onset EC. By investigating the contribution of CDK-mediated phosphorylation, we have sought to clarify the mechanistic basis of elevated Rb activity in KMT2D-deficient cancer. These findings may reveal novel therapeutic vulnerabilities that can be exploited for targeted treatment strategies in patients with early-onset EC.

#1914 Sequential inhibition of CDK4/6 and the mitotic kinase TTK as a potential treatment in triple-negative breast cancer cell lines.

Gretchen M. Albarran-Acosta, Janangelis Lopez-Ramos, Magda N. Alvarez-Rodriguez, Alexandra N. Aquino-Acevedo, Harold I. Saavedra-Lugo

Basic Sciences Department Pharmacology Division, Ponce Health Sciences University, Ponce, PR

Triple-negative breast cancer (TNBC) is a poor-prognostic subtype. TNBC cells have uncontrolled cell proliferation, genetic instability, and elevated rates of metastasis. Lacking targeted therapies, chemotherapy is the primary treatment option. Mitotic kinases that maintain genomic stability, such as Threonine Tyrosine Kinase (TTK), exhibit increased expression in TNBC patients. TTK regulates the spindle assembly checkpoint, and its overexpression contributes to centrosome amplification, chromosome instability, and early metastasis. Palbociclib, a CDK4/6 inhibitor known to induce cellular senescence in tumors, is approved against luminal BC but not TNBC. Due to the reduced sensitivity of non-cycling cells to chemotherapeutic drugs, simultaneous association between Palbociclib and different chemotherapeutic agents has shown antagonistic effects. Preliminary data shows no significant decrease in the viability of TNBC cell-lines after simultaneous inhibition of TTK and CDK4/6. Based on studies stating that a sequential treatment with Palbociclib followed by a chemotherapeutic agent (paclitaxel) decreases TNBC cell-line viability, and our preliminary data showing that TTK inhibition restores the expression of G1/S regulators such as Rb, our study aims to evaluate if resistant TNBC cells may be sensitive to sequential treatment of CDK4/6 inhibition followed by mitotic kinase TTK inhibition. Twenty-four hours after seeding MDA-MB-231 and MDA-MB-157 TNBC cell lines, Palbociclib (PD0332991) was added at increasing concentrations. Twenty-four hours later, TTK inhibitor (BAY1217389) was added at a constant IC_{50} concentration. The MTT Assay was performed after 96 hours of incubation. Pre-treatment with Palbociclib followed by a constant IC_{50} concentration of TTK inhibitor showed significant decrease in MDA-MB-157 cell line viability. Results state that a sequential treatment strategy with Palbociclib followed by TTK inhibitor treatment can be a potential therapeutic approach for certain populations with TNBC. Differences associated with drug responses can be attributed to the difference in levels of cell cycle regulators in TNBC cell lines, which will be investigated further on. Results allowed the reduction of drug levels and toxicity, while potentially improving safety and efficacy for clinical use.

#1915 Serpine2 promotes melanoma progression through the modulation of the DDX3X/MITF/p21 signaling pathway.

Qirui Liu[1], Xin Huang[1], Xiao Zhang[2], Xinyu Ye[1], Yi Lu[1], **Jian Zhang**[1]

[1]School of Medicine, Southern University of Science and Technology, Shenzhen, China,[2]The Affiliated Foshan Hospital of Southern University of Science and Technology, Southern University of Science and Technology, Shenzhen, China

Melanoma is the most lethal form of skin cancer, characterized by an increasing incidence and high mortality rates globally. However, the mechanisms underlying melanoma tumorigenesis and progression remain poorly understood. Analyses of public repositories have identified SERPINE2 as a key differentially expressed gene involved in the biological processes associated with melanoma. As a member of the serpin superfamily, SERPINE2 plays diverse roles in regulating proteolytic activity, inflammation, and tissue remodeling; however, its specific functions in melanoma warrant further investigation. This study aims to explore the potential mechanisms by which SERPINE2 influences tumorigenesis and progression in melanoma. In this study, we evaluated the expression and clinical relevance of SERPINE2 in melanoma by analyzing data from TCGA, GTEx, and TIMER2.0, and identified SERPINE2-associated biological processes through GO and KEGG enrichment analyses. Our findings revealed that SERPINE2 is significantly upregulated in melanoma tissues compared to normal skin tissues, and its expression correlates with cell growth, epithelial-mesenchymal transition, and immune response. Knockdown of SERPINE2 markedly inhibited cell viability, proliferation, and invasion of melanoma cells both *in vitro* and *in vivo*. RNA sequencing analysis of SERPINE2-knockdown cell lines demonstrated that silencing SERPINE2 induced cell cycle arrest in the G0/G1 phase and promoted apoptosis. To investigate the underlying mechanisms, we identified DDX3X as a binding partner of SERPINE2 through co-immunoprecipitation (CO-IP) and immunoprecipitation-mass spectrometry (IP-MS) analyses. We found that SERPINE2 attenuates the protein stability of DDX3X, promoting its degradation via the ubiquitin-proteasome system. Furthermore, silencing DDX3X resulted in the downregulation of nuclear protein expression of MITF and p21, suggesting that DDX3X downregulation may influence the transcription of downstream genes associated with cell cycle progression, thereby impacting melanoma growth. Additionally, downregulation of SERPINE2 enhanced CD8+ T cell infiltration, stimulated T-cell activation-related cytokines and chemokines, and improved the cytotoxic function of CD8+ T cells *in vitro*. Furthermore, in both the Lauss cohort and the IMvigor210 cohort, we observed that SERPINE2 expression correlated with the prognosis of melanoma patients undergoing immunotherapy; specifically, patients with low SERPINE2 expression exhibited better prognoses compared to those with high SERPINE2 expression. In summary, the expression level of SERPINE2 is a predictor of therapy response and prognosis in melanoma patients, suggesting its potential as a biomarker for melanoma immunotherapy. This work was supported by the National Natural Science Foundation of China (No. 82173336), and the MRI Project (G030410001).

#1916 Identifying changes in cell cycle regulatory proteins during clobetasol-induced quiescence in UMSCV-4 vulvar cancer cells.

Claudia M. Marsello, Trinity A. Trojanowski, **Jani E. Lewis**

Biology, State University of New York at Geneseo, Geneseo, NY

Quiescence is a reversible state in which cells temporarily exit the cell cycle in response to stress, with the capacity to re-enter the cycle once the given stress is relieved. Growing evidence suggests that quiescent cancer cells may underlie long-term tumor dormancy and late relapse. We found that a subpopulation of the vulvar squamous cell carcinoma line UMSCV-4 enters quiescence following exposure to the corticosteroid clobetasol (clob). Upon removal of clob, these cells re-enter the cell cycle. To characterize this process, we quantified changes in proliferation using BrdU incorporation and assessed the timing of cell cycle re-entry after clob withdrawal. We hypothesized that clob treatment would downregulate key cell-cycle-promoting proteins while upregulating cell-cycle inhibitors, and that these changes would reverse within three days of clob removal, coinciding with increased DNA synthesis and the reappearance of mitotic figures. Using Western blot analysis, we examined the expression of cell-cycle promoters (cyclin D1, cyclin D3, CDK2, CDK4, CDK6) and inhibitors (p21Waf1/Cip1 and p18INK4C). RNA seq analysis is being used to evaluate corresponding changes in mRNA abundance and to identify additional regulators associated with clob-induced arrest. Together, these studies aim to define the molecular mechanisms by which clobetasol promotes quiescence in vulvar cancer cells.

#1918 CRISPR screening in human iPSC-derived glioblastoma models reveals RNA-binding protein dependencies associated with TERT promoter mutation.

Christopher C. Chie[1], Daisuke Kawauchi[1], Shunichiro Miki[1], Nicholas O. Stevers[2], Joseph F. Costello[2], Chun-Yuan Chen[3], Gene W. Yeo[4], Frank B. Furnari[1]

[1]Division of Regenerative Medicine, Department of Medicine, University of California San Diego, San Diego, CA,[2]Department of Neurological Surgery, University of California San Francisco, San Francisco, CA,[3]Sanford Stem Cell Institute, Innovation Center, San Diego, CA,[4]Department of Cellular and Molecular Medicine, University of California San Diego; Sanford Laboratories for Innovative Medicines; Sanford Stem Cell Institute, Innovation Center; Center for RNA Technologies and Therapeutics; Institute for Genomic Medicine, San Diego, CA

IDH-wildtype glioblastoma (GBM) is a highly aggressive adult brain tumor with an extremely poor prognosis, characterized by multilayered intratumor heterogeneity. Telomerase reverse transcriptase (TERT) promoter mutation, the most frequent driver mutation in GBM, is homogeneously present within tumors, offering the potential for comprehensive and selective eradication of heterogeneous GBM populations. However, targeting cells expressing TERT in a mutation-dependent manner has not been feasible, largely due to the adverse effects of existing telomerase inhibitors and the inability to block GABPA, a transcription factor that selectively activates the mutant promoter. These obstacles highlight the need to identify novel actionable vulnerabilities. Previous GBM models, such as patient-derived xenografts and genetically engineered mouse models, have failed to provide such insights due to lack of experimental standardization and human-to-mouse variations in telomere biology and TERT promoter. To bypass these challenges, we leveraged human iPSCs to engineer GBM models harboring either wildtype or mutant TERT promoter, enabling discovery of synthetic lethal therapeutic targets. Performing a pooled CRISPR knockout screen targeting 1078 RNA-binding proteins (RBPs), we identified 40 RBPs whose depletion selectively impaired survival of TERT promoter-mutant (TPM) cells without affecting wildtype (TPW) cells. Intriguingly, these included 3 RBPs that form a methyltransferase complex governing N^6-methyladenosine (m^6A) modification; METTL14, METTL3, and RBM15. Functional analyses showed that METTL14 depletion downregulates GABPA mRNA level independent of TERT promoter status but reduces TERT expression specifically in TPM cells. m^6A-targeted eCLIP-seq revealed m^6A-independent regulation of GABPA and TERT, indicative of regulatory factor(s) mediating this gene expression cascade. Integrated analysis of m^6A-eCLIP-seq and RNA-seq uncovered enrichment of transcription factors (TFs) among METTL14 target genes for m^6A methylation, identifying potential mediators linking METTL14 with GABPA and TERT. These TFs are downregulated upon METTL14 depletion and m^6A-methylated, with public databases showing ChIP-seq peaks at the GABPA promoter and highly correlated expression with METTL14 and GABPA. We hypothesize that m^6A methyltransferase machinery stabilizes transcripts of these TFs via m^6A methylation, driving GABPA transcription and sustaining TERT expression in TPM cells. This study uncovers a novel epitranscriptomic axis regulating TERT and lays the groundwork for developing new therapeutic strategies by leveraging stem cell-derived disease models.

#1919 Longer leukocyte telomeres and specific alleles of telomere maintenance genes are independently associated with improved survival of colon cancer patients.

Estela M. Cruz Garcia[1], Gobinda Sarkar[2], Jun Chen[2], Shubham Sood[3], Kim Kossick[2], Daniel Schupack[2], Rondell Graham[2], Brooke Druliner[2], Zahra Heydari[2], Lauren Helgeson[2], Richard G. Cawthon[4], Lisa A. Boardman[2]

[1]University of Puerto Rico, San Juan, PR,[2]Mayo Clinic, Rochester, MN,[3]University of Central Florida/ HCA Florida West Hospital, Pensacola, FL,[4]Human Genetics, University of Utah, Salt Lake City, UT

Background: Aberrations in telomere length have important implications in cancer development and progression. This study aimed to determine whether leukocyte telomere length (LTL) in patients with colorectal cancer (CRC) is associated with survival outcomes. We also investigated whether genetic variants in telomere maintenance genes are associated with survival in these patients.
Methods: Blood specimens were collected from 1,007 patients prior to receiving chemotherapy or radiation. Genomic DNA was extracted using the Promega Maxwell RSC instrument. LTL was measured in triplicate using monochrome multiplex PCR, where the average amplification value of telomeric repeats was termed T. Similarly, PCR amplification of a single-copy reference gene was performed, and its average amplification value was termed S. The telomere length for each sample was expressed as the T/S ratio. Genotyping of single-nucleotide polymorphisms (SNPs) in TERC, TERT, and OBFC1 genes was conducted at the institutional Genome Analysis Core facility. Kaplan-Meier survival curves were generated to evaluate patient survival outcomes.
Results: Younger individuals (~25 years) exhibited nearly a twofold longer LTL compared with older individuals (~75 years). No significant difference in LTL was observed between stage II and stage III CRC patients. A strong inverse correlation was observed between patient age and LTL (Spearman's $r = -0.48$; $p = 1.13 \times 10^{-58}$). Females had significantly longer LTL than males ($p = 3.97 \times 10^{-5}$). The TERC SNP rs1317082 was significantly associated with both overall survival (OS) and disease-free survival (DFS) in the combined stage II and stage III patient cohort ($p = 0.017$ and $p = 0.023$, respectively). Similarly, the OBFC1 SNP rs9419958 was significantly associated with OS ($p = 0.016$). Importantly, LTL itself was significantly associated with both OS and DFS ($p = 0.008$ and $p = 0.044$, respectively) among the combined stage II and stage III patients. Kaplan-Meier survival analyses demonstrated that age- and sex-adjusted LTL was predictive of long-term survival outcomes.
Conclusions: Survival among patients with stage II and III colorectal cancer is significantly influenced by LTL. Additionally, specific allelic variants of telomere maintenance genes, including TERC and OBFC1, are independently associated with improved survival, irrespective of LTL. These findings suggest that peripheral blood LTL measurement, along with telomere-related genotyping, may serve as a valuable prognostic marker for colorectal cancer outcomes. Funding: Individualizing colorectal cancer patient care using the host and tumor telomere phenotype (RO1 CA204013), Curtiss Fund (92541775), C-SiG Core(s): Epigenomics & Spatial Biology Core, and Clinical Core of the Mayo Clinic Center for Cell Signaling in Gastroenterology (P30DK084567)

#1920 Resolving telomere length dynamics in breast cancer evolution through single-cell DNA sequencing.

Nicolaas Baudoin, Lei Yang, Chenling Tang, Hanghui Ye, Kaile Wang, Jianzhuo Li, Yun Yan, Nicholas E. Navin

UT MD Anderson Cancer Center, Houston, TX

Telomeres serve as a critical tumor-suppressive barrier by limiting the accumulation of genomic mutations through two checkpoints: replicative senescence and telomere crisis. Cells that bypass senescence and enter telomere crisis experience rampant chromosomal instability driven by end-to-end fusions and mitotic defects, which typically results in cell death. Rare cells that activate a telomere maintenance mechanism (e.g., telomerase) can re-lengthen telomeres, escape crisis, and stabilize their genome while potentially leveraging transient instability to fuel punctuated copy number evolution and tumorigenesis. Despite their importance in replicative mortality and maintaining genomic stability, the dynamics of telomere length during tumor evolution remain poorly understood due to limited longitudinal patient samples and technical challenges in telomere measurement, which often require large input material and lack compatibility with multiomic profiling. To overcome these barriers, we developed a method to infer telomere length from single-cell DNA sequencing and multiomic data. We validated this approach in cell lines and applied it to study the telomere length dynamics in ER-positive (N = 7) and ER-negative (N = 14) breast tumors with unprecedented resolution. Our analysis revealed substantial telomere length changes during subclonal diversification, highlighting telomere dynamics as a key feature of breast tumor evolution. Phylogenetic reconstruction uncovered tumor-specific patterns of telomere length evolution, which may have clinical implications. Furthermore, we found that telomere length variation among subclones was associated with differences in fitness and telomere maintenance pathway activity. This work introduces a powerful tool to interrogate telomere biology directly in patient tumors at single-cell resolution, providing new insights into the role of telomere dynamics in cancer evolution and laying the foundation for future studies to clarify the biological and clinical significance of telomere regulation in cancer

#1921 Proximity labeling and thermal profiling proteomic analysis unveil mechanistic role of YWHAZ and YWHAB in CDK4/6 inhibitor resistance.

Min-Jyun Dong[1], Wei-Ting Chung[2], Yi-Ru Tseng[2], Chun-Yu Liu[2], Chi-Cheng Huang[2], Ling-Ming Tseng[2], Ta-Chung Chao[2], **Jiun-I Lai**[1]

[1]National Yang Ming Chiao Tung University, Taipei, Taiwan,[2]

CDK4/6 inhibitors are currently standard of care in both early and metastatic hormone positive breast cancer. With the expanded use of CDK4/6 inhibitors in early breast cancer, identifying and addressing resistance mechanisms become increasingly important for improving patient outcome. In our prior work, using proximity labeling approaches, we identified the YWHAB/YWHAZ complex (both members of the 14-3-3 family) as important mediators for CDK4/6 inhibitors resistance. Genetic silencing of YWHAB sensitized resistant hormone positive breast cancer cells towards CDK4/6 inhibitors. We further demonstrated that YWHAB-YWHAZ existed as a dimer and suppressed proteosomal function for CDK6 degradation, leading to CDK4/6 inhibitor resistance. To elucidate the interactome of YWHAZ, and to probe for proteosomal roles in CDK4/6 inhibitor resistance, we performed Thermal Proximity Co-aggregation (TPCA) proteomics on cells with/without YWHAZ silencing. TPCA analysis identified proteins involved in proteosomal processing and confirmed a role of YWHAZ in mediating proteosomal degradation. Further functional studies validate novel mechanisms for CDK4/6 inhibitors. Our findings were correlated with TCGA and other public cohorts to demonstrate a prognostic and predictive role of YWHAZ in CDK4/6 inhibitors. In summary, our findings indicate a role for proteosomal selectivity that mediates CDK4/6 inhibitor resistance and could serve as future therapeutic targets for hormone positive breast cancer.

Poster Session

#1924 Retrotransposon reactivation to elicit innate immunity in squamous cancers while sparing normal tissues.

Mande Xue, Ying Lyu, **Yejing Ge**

UT MD Anderson Cancer Center, Houston, TX

Transposons make up over 40% of the human genome, and while most are inactive, a few retrotransposons remain capable of jumping, contributing to mutations and genetic variation. Squamous cell carcinomas (SCCs) including those from the head and neck, esophagus, lung, cervix, anogenital sites and skin show particularly high retrotransposon activity among all cancers analyzed, yet their pathogenic mechanisms and therapeutic potential remain poorly understood.
We tackle these challenges by using a genetic model lacking a crucial epigenetic repressor of endogenous retroviruses (ERVs, a type of retrotransposons resembling retroviruses) in the adult murine skin. We saw in our model robust ERV induction, accompanied by retroviral peptides production and viral like particles assembly, leading to stem cell exhaustion and hair loss phenotypes, which can be reversed in vivo by antiviral drugs that inhibit reverse transcriptase (Lyu Y et al, Ge Y. Cell. 2024).
In the current study, we dissect host mechanisms restraining and responding to ERV reactivations, and leverage these pathways to inhibit SCCs while sparing normal tissues. Retrotransposon reactivation elicits host antiviral responses in the tumors, known as viral mimicry, which we recapitulated in the skin. Interestingly, we observed two genetically and biochemically diverging pathways elicited by ERVs versus SINEs (short interspersed elements, another type of retrotransposons), that are responsible for skin pathogenesis and tumor progression. Moreover, while retrotransposon reactivations are widely associated with antiviral responses in cancer patients, such correlations remain context dependent, and their decoupling often occurs unexplained. We saw intriguing decoupling of retrotransposon induction and antiviral response in our model. We further noted that distinct heterochromatin repressors cooperate to not only dictate retrotransposon-independent antiviral responses, but also blunt antiviral responses despite the presence of retrotransposon reactivations. Finally, we propose retrotransposon related SCC specific vulnerabilities that can be tackled while sparing normal tissues.

#1925 De novo enhancer formation at human-viral junctions drives hybrid extrachromosomal DNA amplification in HPV-associated cancer.

Takuya Nakagawa[1], Jens Luebeck[2], Kaiyuan Zhu[2], Sasik Roman[2], Brin Rosenthal[2], Kathleen Fisch[2], Toyoyuki Hanazawa[1], Atsushi Kaneda[1], Paul S. Mischel[3], Vineet Bafna[2], Joseph A. Califano[4]

[1]Chiba University, Chiba, Japan,[2]UC San Diego, La Jolla, CA,[3]Stanford University School of Medicine, Stanford, CA,[4]UC San Diego School of Medicine, La Jolla, CA

Introduction: Extrachromosomal DNA (ecDNA) contributes to oncogene amplification in human cancers, yet the mechanisms underlying the formation and function of human-viral hybrid ecDNA (hybrid ecDNA), circular elements harboring both HPV and human sequences, remain unclear. We recently identified hybrid ecDNA in human papillomavirus-associated oropharyngeal cancer (HPVOPC), a rapidly increasing malignancy. Here, we show that *de novo* enhancer formation at viral-human junctions activates viral oncogenes and promotes hybrid ecDNA self-amplification, revealing a tractable therapeutic vulnerability.

Methods: Hybrid ecDNA was identified in HPVOPC cell lines and patient-derived xenografts (PDX) using whole-genome sequencing and AmpliconArchitect. Validation was performed by multicolor FISH. Chromatin accessibility and enhancer activity were profiled by ATAC-seq and H3K27ac ChIP-seq. Hi-C sequencing was used to assess 3D chromatin interactions and potential contacts among distinct ecDNA species. Functional significance was evaluated by CRISPR interference (CRISPRi) targeting ecDNA-derived enhancers. Therapeutic relevance was assessed by BET inhibition in vitro and in vivo.

Results: Hybrid ecDNA was detected in both cell lines and PDX tumors and validated by overlapping human and HPV FISH signals. Epigenomic profiling revealed *de novo* active enhancers flanking HPV sequences exclusively in hybrid ecDNA(+) tumors. Hi-C demonstrated enhancer-promoter loops linking host enhancers to HPV oncogenes. CRISPRi targeting these enhancers significantly inhibited proliferation in hybrid ecDNA(+) models only ($P = 0.006$). BET inhibition selectively suppressed hybrid ecDNA(+) tumor growth in vivo ($P = 2\times10^{-5}$). Importantly, Hi-C contacts also indicated enriched interaction patterns among distinct ecDNA species, suggesting potential extrachromosomal cooperation that enhances viral oncogene expression.

Conclusions: Hybrid ecDNA is a functionally critical structure in HPVOPC by generating *de novo* enhancers and reorganizing chromatin interactions to activate viral oncogenes, creating a therapeutic vulnerability. Contact enrichment among distinct ecDNA species further suggests participation in a broader extrachromosomal regulatory network in HPV-driven malignancies.

#1926 The VPS72-H2A.Z-axis is an underappreciated oncogenic vulnerability in lung adenocarcinoma.

Xzaviar Kaymar Solone, Selim Reza, Kalpana Subedi, Nirmal Parajuli, Li Zhou, Qing-Sheng Mi

Dermatology Research, Henry Ford Health System, Detroit, MI

Lung adenocarcinoma (LUAD), the most common subtype of non-small cell lung cancer (NSCLC), frequently relies on epigenetic plasticity to support growth, stress adaptation, and therapeutic escape. Among the chromatin mechanisms enabling this plasticity, histone variant exchange is central. Incorporation of specific variants reshapes DNA accessibility and transcriptional programs, underpinning cancer cell adaptability. VPS72, a histone chaperone shared by the SRCAP and TIP60 complexes, mediates ATP-dependent deposition of the H2A.Z-H2B dimer into regulatory chromatin, thereby promoting proliferation, lineage state, immune evasion, and treatment tolerance transcriptional programs. H2A.Z deposition is linked to aggressive malignancy; however, the contribution of VPS72 itself to LUAD progression remains undefined. Given its central role in H2A.Z loading, the VPS72-H2A.Z axis may represent a key epigenetic driver and potentially targetable vulnerability. TCGA LUAD datasets were analyzed to profile VPS72 expression, genomic correlates, and functional relevance. VPS72 was significantly upregulated relative to normal tissue and associated with greater genomic instability, higher tumor mutational burden, stronger hypoxia signatures, earlier clinical detectability, and reduced overall survival. High VPS72 expression was also observed in female patients and ever-smokers, indicating exposure-linked modulation. Functional evaluation in LUAD models showed that genome-wide CRISPR and RNAi screens identified VPS72 as a major fitness gene. shRNA-mediated VPS72 depletion reduced proliferation and Ki-67 expression, reduced colony formation, impaired migration and invasion, and abrogated anchorage-independent growth. Transcriptional profiling revealed that VPS72 loss strongly repressed MYC- and E2F-driven cell-cycle programs and disrupted metabolic pathways, including heme biosynthesis, mitochondrial respiration, calcium signaling, and hypoxia adaptation. Although H2A.Z itself is not directly targetable, VPS72 role in its deposition creates a druggable interface. To exploit this, we developed cell-permeable peptides that block the VPS72-H2A.Z interaction, which phenocopied VPS72 knockdown by inducing apoptosis and suppressing LUAD cell growth in a dose-dependent manner. Collectively, these findings identify VPS72 as a central epigenetic regulator and therapeutically actionable vulnerability in LUAD. Disrupting the VPS72-H2A.Z axis attenuates oncogenic transcriptional programs and malignant behaviors, offering a promising strategy to overcome epigenetic plasticity and treatment resistance in aggressive NSCLC.

#1927 Epigenetic CRISPR screen identifies chromatin regulators essential for ovarian cancer spheroid formation.

Deren Demirel Yavuz[1], **Irem Durmaz Sahin**[2]

[1]Graduate School of Health Sciences, Koc University, Istanbul, Turkey,[2]School of Medicine, Koc University, Istanbul, Turkey

Background: Cancer stem-like cells (CSCs) contribute to recurrence and chemoresistance in high-grade serous ovarian cancer (HGSOC). Spheroid formation in ultra-low attachment (ULA) cultures models CSC self-renewal, yet the epigenetic regulators and molecular dependencies sustaining this 3D phenotype remain largely undefined.
Methods:A focused CRISPR knockout screen targeting 800 epigenetic and chromatin regulators was performed in OVCAR-3 spheroids. sgRNA enrichment after 3D selection identified genes essential for spheroid growth. Top candidates were functionally validated in BRCA1-wildtype, BRCA1-LOH, and BRCA1-mutant cell lines by assessing spheroid morphology, compaction, viability, and proliferative behavior.
Results: The screen identified a high-confidence set of regulators required for spheroid formation, including DNA damage response genes (BRCA1, PARG), Polycomb complex members (SUZ12, BMI1), RNA-binding proteins (NCL, SYNCRIP), and cell cycle regulators (CDK2, PBRM1). These hits converge on chromatin remodeling, histone methylation, and transcriptional control pathways, linking epigenetic regulation with DDR signaling.Functional assays revealed a striking BRCA1 dependency: while BRCA1-WT and LOH cell lines formed compact, viable spheroids, BRCA1-mutant cells produced disorganized, loosely aggregated, hyperproliferative structures with poor architectural integrity. This indicates that BRCA1 is essential not for proliferation per se, but for establishing and maintaining 3D stem-like organization. Integration of the CRISPR hits with phenotypic outcomes suggests a cooperative network between DDR factors, RNA-binding regulators, and chromatin modifiers in sustaining CSC-like behavior.
Conclusions: Our findings demonstrate that BRCA1 function underpins the epigenetic and chromatin-based control of spheroid architecture, revealing a mechanistic link between DNA repair fidelity, chromatin integrity, and cancer stemness. The identified vulnerabilities highlight potential therapeutic targets for BRCA1-deficient ovarian and breast cancers.

#1928 SMARCB1-Mediated chromatin remodeling underlies sex differences in gliomagenesis.

Adham Halaoui, Najla Kfoury-Beaumont, Thomas Beaumont

UCSD Medical Ctr., San Diego, CA

Glioblastoma (GBM), the most prevalent primary malignant brain tumor has significant sex disparities with a higher incidence and poorer prognosis in males. SMARCB1 is a key component of SWI/SNF chromatin remodeling complexes, including canonical BAF (BAF) and polybromo-associated BAF (PBAF), and has been shown to have tumor-suppressive functions in a wide range of cancers. Using a panel of 20 human glioma samples, we have shown that SMARCB1 expression is significantly downregulated in GBM compared to IDH wild-type gliomas. However, its role in GBM development remains unclear. Using a murine model of GBM, we performed SMARCA4 immunoprecipitation coupled with mass spectrometry in syngeneic male and female tumor cells and demonstrated BAF complex assembly. We then performed knockdown (KD) of SMARCB1 using CRISPR CRISPRi in male and female tumor cells. Growth assays revealed strong sex-dependent differences, as depletion of SMARCB1 markedly increased proliferation and clonogenic potential in male cells, while having the opposite effect in female cells. RNA-seq analysis uncovered sex-specific transcriptional reprogramming following SMARCB1 knockdown. Gene set enrichment analyses revealed strong enrichment (NES = 2.08-2.19, FWER < 0.001) in proliferation- and oncogenesis-associated pathways in male tumor cells, and an inflammatory pathway (NES = 1.73-2.72, FWER = 0) in female cells. Additionally, we observed pronounced sex-dependent expression in O-6-methylguanine-DNA methyltransferase (MGMT) gene expression wherein male cells displayed three-fold higher MGMT expression compared to females. Importantly, SMARCB1 KD further amplified this sex-biased MGMT expression. Based on this observation, we treated male and female tumor cells with Temozolomide (TMZ), the standard-of-care chemotherapy for patient with GBM and performed a metabolic viability assay. Consistent with the expression profiling data, female cells exhibited a 25 % greater reduction in metabolic activity following TMZ treatment than their male counterparts, indicating heightened intrinsic sensitivity. MGMT expression levels correlate with the relative TMZ resistance of male cells, implicating a potential sex-specific response to treatment. To further assess sex-specific SMARCB1 function at the epigenetic level, we performed ATAC-seq and ChIP-seq experiments on male and female control and SMARCB1 KD GBM cells. These experiments demonstrated increased chromatin access at the MGMT locus in male cells and facultative heterochromatin in female cells. Additionally, 3D-genome studies using HiC are underway to identify sex-specific topographical associated domains (TADs). Collectively, our data underscore an important sex-specific role for SMARCB1 in GBM tumorigenesis and identifies a potential new biomarker for TMZ responsiveness during treatment.

#1929 Stag2-cohesin mediates 3d genome dynamics to regulate MYCN driven oncogenic transcriptome in neuroblastoma..

Jee-Youn Kang[1], Kaitlyn Tremble[2], Zhihui Liu[3], Carol J. Thiele[2]

[1]Pediatric Oncology Branch, National Cancer Institute, Center for Cancer Research, Bethesda, MD,[23]Staff Scientist, Pediatric Oncology Branch, NCI-CCR, Bethesda, MD

Neuroblastoma(NB) is characterized by an abnormal transcriptome driven by a network of core regulatory circuitry (CRC) transcription factors (TFs) and cell type-specific enhancer landscapes. Neuroblastoma arises due to defects in cellular differentiation, either through a failure to terminally differentiate or a reversion to a pluripotent-like state. While CRC TFs are known to bind cell type-specific enhancers and promoters to define transcriptomes necessary for proper differentiation, their functional interplay with 3D nuclear architectural proteins, such as cohesin (comprising SMC1A, SMC3, RAD21, and STAG1 or STAG2), remains largely unexplored. 3D genome organization plays a critical role in defining the cell type-specific transcriptional landscape by facilitating enhancer-promoter looping, which undergoes dynamic rewiring during differentiation. Beyond their canonical roles in DNA replication and repair, cohesin mediates chromatin looping between enhancers and promoters, enabling precise regulation of target gene expression. Understanding how CRC TFs collaborate with cohesin to establish and maintain NB-specific transcriptional programs could provide valuable insights into the mechanisms underlying neuroblastoma pathogenesis and differentiation defects. **To define roles of STAG1- and STAG2-cohesin in MYCN target regulation**, genome-wide RNA-seq and ChIP-seq analyses were performed to uncover the distinct yet overlapping roles of these complexes in regulating the oncogenic transcriptome of NB cells. STAG1 Knockdown (KD) has minimal impact on NB cell proliferation or transcriptional activity. In contrast, STAG2 KD reduces cell proliferation, accompanied by downregulation of MYCN target genes and upregulation of neuronal differentiation genes. Genome-wide ChIP-seq analysis revealed that MYCN/STAG1 peaks are associated with promoters of canonical MYCN target genes. In contrast, MYCN/STAG2 peaks are primarily associated with promoters and enhancers of neural differentiation genes. STAG2 KD decreases chromatin-bound MYCN, particularly at enhancers and promoters, with no change in total MYCN protein levels. This reduction correlates with the observed downregulation of MYCN target genes. In contrast, STAG1 KD does not affect MYCN chromatin binding. Ectopic induction of MYCN in MYCN-nonamplified SHEP cells significantly increased STAG2 chromatin binding, whereas STAG1 binding remains unchanged. In contrast, chromatin-bound STAG1 and STAG2 levels remained unaffected by MYCN KD despite the reduction in their total protein levels. These findings underscore the critical role of STAG2-cohesin in sustaining the NB oncogenic transcriptome by selectively modulating MYCN chromatin binding. This study highlights STAG2-cohesin's functional specialization, establishing it as a pivotal regulator of cohesin dynamics and NB transcriptional programs.

#1930 Unveiling ecDNA spatial organization and epigenetic landscapes through long-read multi-omic sequencing and high-content microscopy.

Yanbo Wang[1], Xiaowei Yan[2], Natasha E. Weiser[2], Shu Zhang[2], Ivy Tsz-Lo Wong[2], Yung-Hsin Huang[1], Rui Li[3], Nicolas Altemose[4], Paul S. Mischel[1], Howard Y. Chang[5]

[1]Stanford University School of Medicine, Stanford, CA,[2]Department of Pathology, Stanford University School of Medicine, Stanford, CA,[3]Center for Personal Dynamic Regulomes, Stanford University, Stanford, CA,[4]Department of Genetics, Stanford University School of Medicine, Stanford, CA,[5]Amgen, Stanford, CA

Oncogene amplification is one of the most common genetic alterations in cancer, playing a central role in tumorigenesis. A major mechanism of oncogene amplification is extrachromosomal DNA (ecDNA), which is present in nearly 20% of cancer patients and found across half of all cancer types. Patients with ecDNA-positive tumors have significantly shorter survival compared to those without ecDNA. Despite its prevalence and strong association with poor treatment outcomes, there is no approved treatment targeting ecDNA-positive cancers. Developing such treatments requires identifying unique and actionable features of ecDNA.

Two unique features of ecDNA warrant special attention because they are seemingly paradoxical. On one hand, proliferation of cancer cells depends on high-level oncogene expression from ecDNA. On the other hand, ecDNA molecules preferentially cluster at the nuclear periphery, a region typically associated with transcriptional repression. Why would cancer cells position most of their ecDNA at the nuclear periphery? What molecular mechanisms control this localization, and what are its functional consequences? These are longstanding questions in the field that have remained unanswered largely due to the lack of experimental approaches capable of deciphering the molecular heterogeneity of ecDNA and linking its spatial organization to oncogene expression.

To fill the technical gap and answer these fundamental ecDNA biology questions, we developed DINO-seq, a long-read single-molecule sequencing technology that enables simultaneous profiling protein binding, DNA accessibility and CpG methylation on individual ecDNA molecules. Using DINO-seq, we discovered that ecDNA carries a bivalent epigenetic landscape—coexisting active and repressive epigenetic marks—that is distinct from chromosomal DNA and enables ecDNA to remain transcriptionally active even at the nuclear periphery. Combining a CRISPR screen with high-content microscopy, we further identified molecular anchors that tether ecDNA to the nuclear periphery. Functionally, we show that peripheral ecDNA localization alters replication timing, promotes ecDNA hub formation, and enhances RNA transcription and export. Together, these findings reveal that ecDNA possesses unique spatial and epigenetic properties that distinguish it from chromosomal DNA and represent potential vulnerabilities that could be exploited to target ecDNA-positive cancers.

#1932 TIP-ChIP: Tagmented, indexed and pooled ChIP-seq to generate high-throughput, multi-sample results for low input samples.

Sarah Traynor[1], Shuxiong Wang[1], Shakiba Mahmoudi[1], Sumati Gonuguntla[1], Justin Cayford[2], Theresa K. Kelly[3], Brian Egan[1]

[1]Active Motif, Carlsbad, CA,[2]Volition, Carlsbad, CA,[3]Pictor, Carlsbad, CA

Epigenetic profiling approaches have greatly expanded our understanding of the mechanisms underlying gene regulation and disease. Histone modifications and transcription factors play a crucial role in chromatin organization and transcriptional control, with dysregulation often linked to various pathological conditions. Chromatin immunoprecipitation followed by sequencing (ChIP-seq) remains the gold standard for genome-wide mapping of histone modifications; however, its high input requirements, susceptibility to batch effects, and labor-intensive workflow limit its scalability and efficiency. Here we present Tagmented, Indexed and Pooled ChIP (TIP-ChIP), a high-throughput alternative that enables the simultaneous profiling of histone modifications and transcription factors across up to 96 samples in a single reaction. This method substantially reduces batch effects, enhances reproducibility, and requires significantly lower input material compared to conventional ChIP-seq. Furthermore, the streamlined workflow can be completed in as little as 3 days, minimizing hands-on time and reducing overall costs while maintaining high sensitivity and resolution. By leveraging an optimized plate-based workflow and a tagmentation barcoding strategy that enables pooling, our method allows for efficient sample multiplexing without compromising data quality. To validate its performance, we apply this approach across multiple cell types, including human primary cells, and demonstrate strong concordance with conventional ChIP-seq for both histone modifications and transcription-factor targets. Further, TIP-ChIP captured dynamic chromatin and transcriptional responses in LPS-stimulated THP-1 cells, revealing time-resolved changes in H3K27ac, H3K4me3, RNA polymerase II Ser2P, and NF-κB (p50). This advancement makes large-scale epigenomic and TF-profiling studies more accessible and cost-effective, enabling the investigation of regulatory dynamics across diverse biological contexts with unprecedented efficiency

#1933 Pan-cancer 3D genomic analysis revealed extremely long Polycomb loops as the biomarker for sensitivity to Polycomb inhibition.

Zhong Fan[1], Sean Moran[2], Miriam Zanovello[1], Jie Liu[2], Chao Lu[3], **Xiaotian Zhang**[1]

[1]Biochemistry and Molecular Biology, University of Texas Health Science Center At Houston, Houston, TX,[2]University of Michigan, Ann Arbor, MI,[3]Columbia University Irving Medical Center, New York, NY

Polycomb targeted loci form long-range chromatin interactions independent of CTCF-cohesion and are demarcated by low DNA methylation. Polycomb targets form extremely long-range loops (long Polycomb loops) that can span up to 60 Mb. These loops predominantly occur in cells of self-renewal status, such as human hematopoietic stem cells (HSC) and mouse embryonic stem cells (ESC). But it was rarely studied in any cancers, in which extensive epigenetic alterations of DNA hypermethylation and loss of Polycomb binding occurs at Polycomb target loci.To identify long Polycomb loops in cancer, we initiated a pan-cancer survey of long Polycomb loops in a collection of 247 tumor samples (33 acute myeloid leukemias, 29 Breast cancer samples, 63 pediatric brain tumors, 70 prostate cancers, and 42 colon cancers). We found most cancers, displayed reduced levels of long Polycomb interactions in comparison with the normal HSC. Solid tumors including all prostate cancers and colon cancers, lack detectable level long Polycomb loops. Additionally, the long Polycomb loop signals are the weakest in cancer cell lines. Pediatric brain tumors and certain AMLs however displayed high long Polycomb loops similar or even stronger than HSC. In pediatric brain tumors, we found the over 20% ependymoma PFA subtypes (in which EZHIP over expression drives Polycomb protein segregation at the canonical Polycomb target loci) notably displayed strong long Polycomb loop interactions with low differentiation. AML displayed more diverse levels of long Polycomb loop interactions. Most AMLs lost both long Polycomb loops with Polycomb binding loss at the loop anchors. Whereas 10% of AMLs retain long Polycomb loops as strong as in HSCs. These AMLs recurrently carry mutations in *CEBPA* and *STAG2*, which are not associated with the Polycomb complex or DNA methylation machinery. Further, while the normal HSC and developing brains contain strong long Polycomb loop, such signal is undetectable in normal colon, suggesting the strong long Polycomb loop is inherited from the tissue of origin. The deletion or inhibition of Polycomb repressive complex (PRC) 1/2 have been shown to eradicate the long Polycomb loops. We found that long Polycomb loop strong AML is sensitive to PRC2 key enzyme EZH2 inhibition, which inhibits cell cycle and induces cell differentiation. Conversely, CRISPR DepMap PRC1 component dependency can be used to predict long Polycomb loop formation in cell lines, identifying cell lines with rare occurrence of long Polycomb loops. Our analysis suggests that the oncogenesis process antagonizes the long Polycomb loop maintenance in most cancers, yet certain cancers may still preserve strong long Polycomb loops from cell-of-origin. The maintenance of long Polycomb loops sensitizes cells to Polycomb inhibition, indicating that such loops could be an epigenomic biomarker for pharmacological or genetic Polycomb inhibition.

#1934 The relationships between the stability of the +1 nucleosome and DNA superhelicity.

Peter Nanasi Jr.[1], Laszlo Imre[1], Istvan Szatmari[2], Viktor Dombradi[3], **Gabor Szabo**[1]

[1]Biophysics and Cell Biology, University of Debrecen, Debrecen, Hungary,[2]Biochemistry and Molecular Biology, University of Debrecen, Debrecen, Hungary,[3]Medical Chemistry, University of Debrecen, Debrecen, Hungary

When the effect of various posttranslational histone tail modifications (PTMs) on nucleosome stability was compared in an *in situ* assay involving agarose-embedded nuclei, a subpopulation of the promoter proximal H3K4me3, H3K27ac positive nucleosomes exhibited relative sensitivity to intercalators as compared to bulk H3-GFP or nucleosomes carrying any of the following marks: H3K27me1, H3K27me2, H3K27me3, H3K9me1, H3K9me2, H3K9me3, H3K36me3, H3K4me0, H3K4me1, H3K4me2, H3K9ac, and H3K14ac. Nickase or DNase I treatment of the nuclei, or bleomycin treatment of live cells, did not affect the stability of nucleosomes carrying H3K4me3 or H3K27ac, while those of the second group were all destabilized upon treatment with intercalators. These observations support the possibility that the promoter proximal marks specifying dynamic nucleosomes are juxtaposed with relaxed DNA sequences due to DNA breaks generated *in vivo*. In line with this interpretation, endogeneous, 3'OH nicks were mapped within the nucleosome free region of promoters in human mononuclear cells as well as in mES. We also present evidence that the chromatin regions harboring the breaks are topologicaly separated from the domains containing superhelical chromatin. Regarding the mechanism eliciting the breaks, two alternative models were tested experimentally using kncok out cells, inhibitors and degrader systems, based on TOP2 activity or on histone demethylation induced oxydative DNA lesions and their repair. These observations lend support for a model where the role of DNA strand discontinuities in transcriptional regulation and in higher-order chromatin organization are integrated. Grants: OTKA/NKFIH 138524, ERA-Net NEURON 2024-1.2.2-ERA_NET-2024-00009 *PN and LI contributed equally

#1936 Druggable dependency on histone demethylase LSD1 in MITF-low therapy resistant melanoma.

Shinichiro Kato[1], Anlun Xu[1], Hongyan Xie[2], Simone Sidoli[3], Genevieve Boland[2], Russel W. Jenkins[4], Dave S. B. Hoon[5], Hiroyoshi Nishikawa[6], David E. Fisher[2]

[1]Kyoto University, Kyoto, Japan,[2]Massachusetts General Hospital, Boston, MA,[3]Albert Einstein College of Medicine, Bronx, NY,[4]Medical University of South Carolina, Charleston, SC,[5]Saint John's Cancer Institute, Santa Monica, CA,[6]National Cancer Center Japan, Tokyo, Japan

Acquired and intrinsic resistance to targeted and immune therapies in melanoma is associated with an undifferentiated, mesenchymal-like tumor cell state characterized by low expression of the melanocytic lineage regulator MITF and high expression of the receptor tyrosine kinase AXL. Because MITF governs lineage-specific survival and differentiation programs, therapy-resistant MITF-low/AXL-high melanomas appear to evade these programs and instead depend on alternative survival mechanisms. To uncover such dependencies, we systematically interrogated genome-scale CRISPR-Cas9 knockout screens from the Cancer Dependency Map and identified a selective vulnerability to the epigenetic regulator lysine-specific demethylase 1 (LSD1/*KDM1A*). Intriguingly, domain-focused CRISPR screening spanning whole LSD1 coding locus further revealed that this dependency is mediated through non-catalytic, scaffold-like functions of LSD1 rather than its demethylase activity. Mechanistically, integrated LSD1 ChIP-seq, histone ChIP-seq (H3K4me1/2/3 and H3K27ac) and RNA-seq analyses demonstrated that LSD1 sustains a survival program characterized by chromosome segregation and neuronal dedifferentiation in MITF-low melanoma, orchestrated through distinct super-enhancer activation at key regulators, such as CDC6, related to these pathways. Disruption of LSD1's non-catalytic activity by a LSD1 allosteric inhibitor induced G2/M arrest, transcriptional reprogramming, and growth inhibition selectively in MITF-low melanomas via downregulation of CDC6. Strikingly, genetic and pharmacological ablation of LSD1's non catalytic function significantly prevented or delayed the emergence of resistance to BRAF inhibition and anti-PD-1 therapy in vitro, in vivo, and in patient-derived melanoma organoids. Furthermore, pan-cancer analyses revealed a similar LSD1 dependency in other poorly differentiated malignancies, including pancreatic cancer, that share an undifferentiated transcriptional state. Collectively, these findings define an epigenetically determined, therapeutically targetable state that underlies treatment resistance across multiple cancer types. By targeting the non-catalytic scaffolding function of LSD1, either alone or in combination with targeted and immune therapies, it may be possible to eradicate undifferentiated, drug-tolerant tumor cell populations and overcome therapeutic resistance in melanoma and other aggressive cancers.

#1937 FOXK2^{+} malignant epithelial cells promote platinum resistance via KANSL1-MOF-mediated redox sustaining mechanism in ovarian cancer.

junzui li, Hao Huang, Yinu Wang, Didi Zha, Shannon Glynn, Ujin Kim, Jennifer Heo

Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Platinum resistance remains a major obstacle in ovarian cancer therapy, yet the molecular programs that enable malignant cells to maintain redox balance and survive oxidative stress remain incompletely defined. Through integrated analyses of bulk RNA-seq, spatial transcriptomics, and single-cell datasets, we identify a distinct FOXK2-positive epithelial cancer population that is reproducibly detected across multiple patient cohorts. This FOXK2-high malignant cell state expands after chemotherapy, preferentially accumulates in recurrent and platinum-resistant tumors, and is consistently associated with inferior patient survival, indicating a potential role in therapy failure. Functional studies demonstrate that FOXK2 is required to maintain redox resilience in ovarian cancer cells. FOXK2 depletion increases intracellular ROS, disrupts mitochondrial respiration, and markedly sensitizes both in vitro cultures and in vivo xenografts to platinum treatment. These vulnerabilities are reversed by antioxidant supplementation, supporting a causal link between FOXK2 loss, ROS accumulation, and enhanced chemosensitivity. To uncover the molecular mechanism underlying FOXK2-mediated redox control, we performed immunoprecipitation-mass spectrometry and identified a previously unrecognized physical interaction between FOXK2 and the KANSL1-MOF chromatin-remodelling complex-an association not previously linked to redox biology, stress adaptation, or chemoresistance in ovarian cancer. FOXK2 leverages this newly defined interaction to recruit KANSL1-MOF to antioxidant gene promoters and enhancers, including SLC7A11, GCLC, and GPX2. This recruitment maintains H4K16 acetylation, preserves chromatin accessibility, and sustains transcriptional activation of key antioxidant programs. Loss of KANSL1 phenocopies FOXK2 depletion, leading to ROS accumulation and heightened platinum sensitivity, establishing KANSL1 as a critical FOXK2-dependent cofactor. Strikingly, this regulatory system is responsive to oxidative stress. Exposure to ROS increases FOXK2 and KANSL1 protein levels and enhances FOXK2-KANSL1 binding, creating a self-reinforcing, redox-sensitive positive feedback loop that sustains antioxidant capacity under therapeutic stress. Together, our findings reveal a therapy-selected FOXK2-positive malignant cell state and uncover a novel epigenetic FOXK2-KANSL1-MOF axis that couples chromatin remodeling to redox homeostasis and platinum resistance in ovarian cancer. Targeting FOXK2-high cellular states or disrupting their chromatin-associated cofactor network may offer a therapeutic strategy to overcome chemoresistance.

#1938 Epigenetic regulation of histone lysine demethylase 4B on cancer therapy in tamoxifen-sensitive and -resistant breast cancer cells.

Tian Zheng, Ju Ri Kim, Hyun Ji Noh, Hyung Sik Kim

Sungkyunkwan University College of Pharmacy, Suwon, Korea, Republic of

Background: Histone lysine demethylase 4B (KDM4B), a key histone lysine demethylase, is aberrantly overexpressed in breast cancer and functions as an essential epigenetic co-activator of ERα signaling. Although its oncogenic role in breast tumorigenesis has been established, the functional distinctions and underlying molecular mechanisms of KDM4B in tamoxifen-sensitive versus tamoxifen-resistant states remain poorly defined. Elucidating KDM4B's contribution to the evolution of endocrine resistance will be critical for identifying novel therapeutic targets and advancing precision strategies to overcome resistance to endocrine therapy.
Methods: KDM4B expression across human cancers and normal tissues was evaluated using TCGA and GTEx datasets. To investigate its functional role, we compared the effects of KDM4B modulation in ERα-positive MCF-7 cells and their tamoxifen-resistant derivative, MCF-7 TamR. KDM4B was suppressed either by siRNA-mediated knockdown or by pharmacological inhibition using the selective KDM4B inhibitor B3. Cell proliferation was measured through MTT and colony formation assays. Protein expression levels of ERα, Bcl-2, H3K9me3, Cyclin D1, c-Myc, and related signaling molecules were examined via Western blotting. Cell-cycle progression and apoptosis were analyzed using flow cytometry. Metabolic reprogramming was evaluated using the Seahorse glycolytic stress test.
Results: TCGA and GTEx analyses revealed that KDM4B is significantly overexpressed in breast cancer compared with normal breast tissue. Consistently, KDM4B levels were markedly elevated in tamoxifen-resistant MCF-7 (TamR) cells relative to parental MCF-7 cells. Suppression of KDM4B through siRNA-mediated knockdown or pharmacological inhibition substantially reduced the proliferative capacity and colony-forming ability of both MCF-7 and TamR cells. KDM4B depletion restored H3K9me3 enrichment, decreased ERα expression, and induced G1/S cell-cycle arrest. In addition, metabolic profiling demonstrated that KDM4B inhibition attenuated glycolytic activity, indicating a role in metabolic reprogramming.
Conclusion: KDM4B serves as a critical epigenetic regulator in both tamoxifen-sensitive and tamoxifen-resistant ERα-positive breast cancer. Inhibition of KDM4B restores repressive histone marks, suppresses ERα-dependent transcription, and attenuates cellular proliferation and metabolic activity. The heightened dependence of tamoxifen-resistant cells on KDM4B further underscores its potential as a promising therapeutic target for overcoming endocrine therapy resistance.

#1939 Oncogenic NSD2 drives Eph-ephrin signaling between myeloma and bone marrow stromal cells.

Austin Boese[1], Lindsey Rosas Togo[2], Qing Wu[1], Bethany Kaplan[1], Sungmi Park-Chouinard[2], Jonathan D. Licht[3], Ho Man Chan[2], Lisa Drew[1], Omid Tavana[1], Neeraj Aryal[1], Jessie Hao-Ru Hsu[1]

[1]Hematology Discovery R&D, AstraZeneca, Waltham, MA,[2]Oncology Targeted Discovery, AstraZeneca, Waltham, MA,[3]University of Florida Health Cancer Center, Gainesville, FL

The t(4;14) translocation occurs in 15-20% of multiple myeloma cases and upregulates the histone methyltransferase NSD2 to drive oncogenic transcriptional dysregulation. Patients with t(4;14)+ myeloma are high risk with shorter survival and higher incidence of bone lesions when compared to patients with other cytogenetic subtypes, suggesting an oncogenic role of NSD2. Counterintuitively, under standard culture conditions, NSD2 knockout in t(4;14)+ models only demonstrated a modest growth inhibition phenotype. Therefore, we hypothesized that oncogenic NSD2 epigenetically modulates signaling between myeloma cells and the bone marrow microenvironment (BMME) to drive myeloma progression. To test this, we utilized both pharmacological inhibition and CRISPR/Cas9 knockout of NSD2 in human myeloma cells lines with varying genetic backgrounds. We assessed proliferation and viability under standard conditions, in co-culture with bone marrow stromal cells (BMSCs), or in BMSC-conditioned media. BMSC co-culture or exposure to BMSC-conditioned media strikingly increased the sensitivity of myeloma lines to NSD2 inhibition, thereby supporting our hypothesis. RNA-sequencing and pathway analysis revealed that oncogenic NSD2 regulates Eph-ephrin signaling, and epigenetic profiling showed NSD2-dependent remodeling of H3K36me2 and H3K27me3 at corresponding Eph-ephrin genomic loci in myeloma cells, suggesting a direct regulation by NSD2. To assess the importance of ephrin receptor signaling between myeloma cells and the BMME, we conducted CRISPR/Cas9 knockout of Eph-ephrin genes and assessed myeloma growth and viability. CRISPR/Cas9 knockout of Eph-ephrin signaling genes caused significantly stronger growth inhibition of myeloma cells with oncogenic NSD2 status in BMSC-conditioned media, while overexpression of ephrin receptor partially rescued the growth defect of NSD2 knockout myeloma cells in BMSC-conditioned media. To assess the clinical relevance of our findings, we analyzed publicly available data from the MMRF CoMMpass patient cohort, which confirmed higher tumor expression of Eph-ephrin genes in t(4;14)+ myeloma patients, correlating with inferior overall and progression-free survival. These findings implicate Eph-ephrin signaling as a key mediator of t(4;14)+ myeloma biology and an attractive therapeutic target. In summary, oncogenic NSD2 reshapes the chromatin of myeloma cells to promote Eph-ephrin signaling, thereby conferring bone marrow microenvironment-dependent fitness in t(4;14)+ multiple myeloma. These data highlight Eph-ephrin signaling as an actionable therapeutic pathway for t(4:14)+ and NSD2 mutant myeloma.

#1940 Dissecting the function of NSD1 in intestinal epithelium and inflammation.

Arum Kim, G Greg Wang

Duke University School of Medicine, Durham, NC

NSD1 (nuclear receptor-binding SET domain protein1, KMT3B) is a histone H3 lysine 36 methyltransferase, which is critical to normal growth and development, and its loss-of-function mutation causes Sotos syndrome, a genetic disorder characterized by overgrowth in childhood, a distinctive facial appearance and developmental delay. Given the prior reports showing that NSD1 decreases H3K27ac at active enhancers and that the H3K27 is associated with intestinal inflammation, we here show that NSD1 maintains intestinal epithelial integrity and inhibits intestinal inflammation in a mouse model that mimics the symptoms and pathology of ulcerative colitis (UC) in humans. Specifically, intestinal epithelial cell (IEC)-specific Nsd1 KO mouse exhibits a significant decrease in antimicrobial peptides (AMPs) genes, which are essential to maintain intestinal homeostasis and mediate epithelial host defense against infection. Collectively, this work uncovered the function of NSD1 in intestinal epithelium sustaining intestinal integrity and protecting that from damage-induced inflammation, which may contribute to prevent the development of GI (gastrointestinal) malignancy caused by chronic intestinal inflammation.

#1941 KMT2D loss drives gastric cancer tumorigenesis through an RCOR3-dependent mechanism.

Liyong Zeng, Fang Cao, Calena J. Brown-Abel, Aryana S. Bhati, Bansi R. Vanparia, Melissa P. Pizzi, Yibo Fan, Gengyi Zou, Tanaya S. A. Washington, Johnson Amoah, Shay Patel, Arman Dhar, Elisha Deewan, Feng Yin, Yuan-Hung Lo, Min Gyu Lee, Jaffer A. Ajani, Shilpa S. Dhar

GI Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Gastric adenocarcinoma remains a major cause of cancer mortality worldwide. KMT2D, a histone H3K4 methyltransferase, is recurrently altered across solid tumors, yet its role in gastric cancer is not fully defined. We show that KMT2D expression is frequently reduced in gastric tumors, and its loss correlates with significantly poorer overall survival, independent of sex or age. KMT2D-negative tumors exhibit markedly higher EGFR expression compared with KMT2D-positive tumors. Functionally, KMT2D knockdown promotes gastric cancer cell proliferation, migration, invasion, and tumor growth, whereas KMT2D reconstitution suppresses tumor progression in a KMT2D-null model. Conditional Kmt2d deletion in mouse stomach induces gastric enlargement and dysplasia, and Kmt2d-deficient gastric organoids develop low-grade dysplasia with increased proliferation. Mechanistically, KMT2D loss downregulates key transcriptional corepressors, including NCOR2 and RCOR3, leading to activation of multiple oncogenic pathways. KMT2D directly binds and catalyzes H3K4 methylation at the RCOR3 enhancer, supporting its regulatory role. Collectively, these findings define a mechanistic basis for KMT2D loss in gastric tumorigenesis and highlight its potential as a diagnostic biomarker.

#1942 MIRAGE: A ctDNA methylation-driven computational algorithm designed for sensitive detection of minimal residual disease.

Gowhar Shafi, Aarthi Ramesh, Sandhya Iyer, Aparna Sornapudi, Alain D'Souza, Sumit Halder, Bhagwat Jadhav, Sangeeta Prajapati, Mohan Uttarwar

OneCell Diagnostics India Private Limited, Pune, India

Background: Detection of minimal residual disease (MRD) following surgical resection or a treatment regimen remains a significant clinical challenge, primarily due to the typically low concentrations of circulating tumor DNA (ctDNA) in the bloodstream post-treatment. In situations where circulating tumor cells (CTCs) are undetectable or ctDNA levels fall below the thresholds of conventional detection methods, DNA methylation analysis has emerged as a promising alternative. Utilizing computational algorithms further improve the detection of tumor signal in cancers with as low as 0.001% circulating tumor fraction.
Methods: MIRAGE (Minimal Residual Assessment using Genome-wide Epigenomics) algorithm was validated using 156 samples, among which 16.7% (n=26) were control reference samples. The algorithm assessed DNA methylation patterns across genome-wide differentially methylated regions (DMRs). The algorithm quantifies methylation by evaluating the number of methylated and unmethylated cytosines at each CpG site and integrating these values into a composite methylation score, reflecting overall hyper- or hypomethylation. The resulting methylation score is further normalized against a predefined cut-off established from a reference cohort of non-cancerous healthy individuals to enable standardized interpretation.
Results: MIRAGE achieved a specificity of 96.8% from 127 clinical samples (64 tumor, 63 non-cancerous healthy controls) tested. Among the clinical tumor samples, 64% (n=41/64) were detected as ctDNA-positive which showed an overall sensitivity of 64.1%.
Conclusion: The study demonstrates the specificity of MIRAGE algorithm for ctDNA classification-based minimal residual detection with high specificity. Further validation on larger cohort is still warranted to show more clinical insights.

#1943 Epigenomic evolution during tumorigenesis in colorectal cancer.

Chang Hyun Nam[1], Yunah Lee[1], Yeonjin Kim[1], Hyein Won[1], Jinhee Ryu[1], Ji Won Park[2], Seung-Yong Jeong[2], Min Jung Kim[2], Young Seok Ju[1]

[1]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[2]Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of

Cancer cells exhibit distinct features compared with normal cells, such as genomic instability and phenotypic plasticity. Growing evidence suggests that epigenomic reprogramming during tumorigenesis, in addition to genomic mutations, plays a critical role in establishing cancer hallmarks. However, the genome-wide landscape of epigenomic alterations and the interplay among the genome, epigenome, and transcriptome during tumorigenesis remain poorly understood, particularly at single-cell resolution. Here, we investigated the genome, DNA methylome, and transcriptome of 129 single-cell-derived cancer clones and 142 single-crypt-derived matched normal clones from 13 patients with colorectal cancer. Compared with normal clones, in which ~75% of CpG sites were fully methylated, cancer clones exhibited pervasive global demethylation, with only ~50% of CpGs remaining fully methylated. We estimated the somatic epimutations using the consensus methylation states of normal clones and found that, on average, 7.5 million CpG sites (~25% of all CpGs) were demethylated in cancer clones. The burden of somatic demethylation increased linearly with the endogenous somatic SNV burden in cancer, suggesting that widespread demethylation primarily results from imperfect DNMT1-mediated maintenance of DNA methylation. The estimated timing of chromosomal gains inferred from genomic mutations and CpG demethylation was largely consistent, supporting the clock-like accumulation of demethylation across broad genomic regions during tumorigenesis. Interestingly, promoter CpG methylation was slightly increased in cancer compared with normal clones, despite pervasive demethylation. We identified genes with differentially methylated promoters, including hypermethylated tumor-suppressor genes and hypomethylated oncogenes, and correlated these methylation changes with gene-expression profiles, supporting their role as driver epimutations. In addition, despite the activation of L1 elements during tumorigenesis, demethylation rates in L1HS promoters were lower than in the rest of the genome in both normal and cancer clones, suggesting that L1 activation in cancer is a passive consequence of global demethylation rather than an active regulatory process. Overall, our single-cell multi-omics analysis provides a comprehensive view of epigenomic reprogramming during tumorigenesis and offers valuable insights into how epigenomic alterations contribute to cancer hallmarks.

#1944 Hypermethylation of Sox21 masks its oncogenic role in glioblastoma.

Shu-Huei Hsiao, Jui-Ming Sun, Tun-Wu Wang, Yu-Wei Leu, and Shu-Huei Hsiao

Biomedical Sciences, National Chung Cheng Univ., Chiayi County, Taiwan

The transcription factor Sox21, a member of the SRY-related HMG-box (SOX) family, is known to promote neuronal differentiation and regulate stem cell function; however, its role in brain tumors remains largely unexplored. Because epigenetic dysregulation contributes to aberrant gene expression and malignant progression, we aimed to elucidate the expression and function of Sox21 in U87 human glioblastoma cells. A marked reduction in Sox21 mRNA and protein expression was observed by RT-PCR and Western blot analysis. Methylation-specific PCR (MSP) and bisulfite sequencing further revealed that the Sox21 promoter is hypermethylated, indicating that Sox21 expression is epigenetically regulated in U87 cells.To determine the functional consequences of restoring Sox21, U87 cells were transfected with a Sox21-expressing vector, resulting in a robust increase in Sox21 expression. Forced Sox21 expression significantly enhanced cell proliferation, as shown by MTT assays and flow cytometry, and was accompanied by a decreased proportion of cells in the sub-G1 phase, suggesting a growth-promoting role for Sox21 in glioblastoma cells. In addition, Sox21 overexpression accelerated cell migration, as demonstrated by wound-healing and transwell assays.These findings indicate that Sox21 downregulation in glioblastoma is mediated, at least in part, by promoter hypermethylation. However, restoring its expression facilitates tumor cell growth and migration. Collectively, our results demonstrate that Sox21 functions as an oncogene that is epigenetically silenced through promoter hypermethylation in glioblastoma.

#1945 Epigenetic silencing of ESR1 in primary breast tumors from young women compared to those from older women: An integrative methylation and expression analysis.

Praveen Kumar Raj Kumar[1], Anupama Praveen Kumar[1], Mariano Russo[1], Jianfang Liu[1], Craig D. Shriver[2], Hai Hu[1], Xiaoying Lin[1]

[1]Bioinformatics, Chan Soon-Shiong Institute of Molecular Medicine at Windber, Windber, PA,[2]Uniformed Services University, Bethesda, MD

Young women with primary breast cancer (<40 years) often present with more aggressive disease and show lower estrogen receptor alpha (ESR1) expression than older women (≥60 years), but the underlying mechanisms remain unclear. We hypothesized that DNA methylation contributes to ESR1 repression in tumors from young women. We analyzed TCGA-BRCA HumanMethylation450 data from 108 primary tumors (54 young, 54 older) matched by PCAPAM50 subtype and race. After preprocessing, the dataset contained 363,870 CpG sites. Differential methylation was performed using limma, adjusting for subtype and race. Gene set enrichment analysis (GSEA) used preranked t-values for 21,582 genes mapped from CpGs. Matched TCGA RNA-seq data were used to evaluate correlations between ESR1 methylation and expression. Validation was conducted using the Lund cohort (GSE75067; n = 61); genome-wide modeling was not feasible due to smaller sample size, so Wilcoxon tests assessed ESR1-associated CpGs. We identified 3,012 differentially methylated CpGs (FDR < 0.05, fold change > 2), with 36 hypermethylated and 2,976 hypomethylated in tumors from young women, indicating a global trend toward higher methylation in older tumors. Among 53 ESR1-associated CpGs in TCGA, seven were significantly hypermethylated exclusively in young luminal tumors and all 7 are significantly hypermethylated in both luminal A/B. Notably, none of the ESR1 CpGs were hypermethylated in older women. ESR1 methylation of these 7 sites was inversely correlated with expression ($\rho = -0.35$ to -0.51), consistent with transcriptional silencing. In the Lund dataset, of 61 ESR1 CpGs, 2 were hypermethylated in young Luminal A and 16 in Luminal B tumors, whereas 1 showed hypomethylation in Luminal B. Of the 7 CpGs hypermethylated in TCGA, one each was significant in young LumA and LumB; others showed similar trends, though not statistically significant, likely due to small sample size. Methylation-based GSEA showed enrichment of hypermethylation within the early estrogen response pathway in the older group, consistent with previous studies reporting heightened estrogen pathway activity in younger women. We report consistent ESR1 promoter hypermethylation in young breast cancer, especially in Luminal A/B subtypes, supported by inverse correlation with transcript levels. These findings suggest that ESR1 silencing is a recurrent feature of young breast tumors and reinforce the potential utility of methylation-based biomarkers for age-stratified cancer profiling. #1949 Clonal expansion of leukocytes harboring mosaic chromosomal alterations accelerates epigenetic aging and reshapes local DNA methylation.

Corey D. Young[1], Charles Breeze[1], Derek W. Brown[1], Rebecca Lynn Kelly[1], Kara Marie Barnao[1], Aubrey K. Hubbard[2], Amy Hutchinson Hutchinson[1], BELYNDA HICKS[3], Aurelie L. Vogt[3], Wen-Yi Huang[4], Steven C. Moore[1], Stephen J. Chanock[5], Mitchell J. Machiela[6]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, Rockville, MD,[2]National Cancer Institute, Montgomery Village, MD,[3]Cancer Genomics Research Laboratory, Frederick National Lab for Cancer Research, Fredrick, MD,[4]National Cancer Institute, Bethesda, MD,[5]Sect. Head & Director, CGF/ATC, National Cancer Institute, Rockville, MD,[6]Division of Cancer Epidemiology and Genetics, Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, Rockville, MD

Mosaic chromosomal alterations (mCAs), a type of age-related clonal hematopoiesis, arise from postzygotic chromosomal gains, losses, or copy-neutral loss of heterozygosity (CN-LOH) in hematopoietic cells. DNA methylation serves as a molecular measure of biological aging and can be quantified through methylation-based epigenetic clocks. The extent to which mCAs accelerate epigenetic aging or induce local methylation remodeling is poorly understood.
We analyzed 482 cancer-free participants from the Prostate, Lung, Colorectal, and Ovarian (PLCO) Cancer Screening Trial aged 54-77 at sample collection. Selection was based on mCA status (mCA carriers=261), prior genotyping, adequate DNA age and sex. Illumina MethylationEPIC array data raw IDATs were processed using the ChAMP pipeline with BMIQ normalization and ComBat batch correction. Six established methylation clocks (Horvath2013 and 2018, Hannum, PhenoAge, GrimAge, and DunedinPACE) were implemented using the dnaMethyAge R package to compute residual-based age acceleration. Multivariable linear models adjusted for age, sex, ancestry, smoking, and BMI compared mCA carriers to mCA-free individuals, as well as autosomal, mLOY, mLOX, and multi-mCA subtypes. Immune cell composition was estimated with EpiDISH using the IDOL-optimized FlowSorted.BloodExtended.EPIC reference. To identify local methylation effects, ordinary least squares regression tested per-CpG β-values for differential methylation within mCA-affected regions and functional enrichment was performed using Ingenuity Pathway Analysis (IPA).
Across six epigenetic clocks, mCA carriers showed higher epigenetic age acceleration vs mCA-free (e.g., PhenoAge β=3.46, 95% CI 1.670-5.22, $p=1.32x10^{-4}$), with the largest effect sizes observed for autosomal mCAs. Methylation-based deconvolution of whole blood revealed shifts in leukocyte composition, including higher memory B-cell and lower CD4memory-cell proportions in participants with multiple mCAs (B-cell: β=0.024, $p=2.0x10^{-8}$; CD4: β=-0.017, p=0.017). Analyses of methylation levels at each CpG site within mCA regions identified 2,553 significant probes (1,973 hypo- and 580 hyper-methylated) with significant clusters visible across several CN-LOH and Gain regions. IPA revealed subtype-specific pathway perturbations, including growth-factor/GPCR signaling in Loss events , NAD biosynthesis and circadian regulation in CN-LOH, and suppressed interferon and TLR signaling in Gain events, with TGFB1 and TNF emerging as key upstream regulators.
These findings suggest mCAs are associated with accelerated epigenetic aging, altered immune-cell composition, and localized epigenetic remodeling, with subtype-specific pathway disruptions that may reflect distinct compensatory mechanisms permitting clonal expansion in hematopoietic cells.

#1950 Integrated transcriptomic and epigenomic analysis to study the mechanism by which smoke-induced hypomethylation of cg05575921 increases lung cancer risk.

Matthew Gladstone[1], Khoi Huynh[2], Chunli Yan[1], Kimberly D. Siegmund[3], Aram Modrek[2], Ite Offringa[1]

[1]Surgery, Cancer Biology, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[3]USC, Los Angeles, CA

Lung cancer is the leading cause of cancer death in the US. The most common subtype is lung adenocarcinoma (LUAD), arising out of the alveolar epithelium. Tobacco smoke and pollution play a key role in LUAD risk and have been associated with changes in DNA methylation in numerous epigenome-wide association studies. Hypomethylation of cg05575921 is one of the most significant changes, predicting over 30% of the increased risk of lung cancer seen in smokers. However, the mechanism by which this methylation loss is linked to lung cancer risk remains unknown. We previously showed that cg05575921, located in intron 3 of the gene aryl hydrocarbon receptor repressor (*AHRR*), borders a tobacco smoke-inducible enhancer. Upon smoke exposure *AHRR* is the only gene within a two megabase window whose expression increases. AHRR is a negative feedback regulator of aryl hydrocarbon receptor (AHR) induced detoxification responses. Like AHR, AHRR binds to the partner protein ARNT. However, unlike the AHR/ARNT heterodimer, which turns on detoxification genes, the AHRR/ARNT heterodimer downregulates the detoxification response. We hypothesize that prolonged tobacco smoke exposure triggers maladaptive expression of *AHRR*, that hypomethylation of cg05575921 is a byproduct of the adjacent enhancer activation, and that constitutive expression of *AHRR* prevents protective xenobiotic detoxification responses, thereby increasing lung cancer risk. Using our unique immortalized human alveolar epithelial cells, we are determining what role the enhancer and cg05575921 play in *AHRR* expression by i) using Oxford Nanopore long-read sequencing to study DNA methylation changes in the region over time during tobacco smoke exposure, ii) using CRISPR/Cas 9 to heterozygously delete the known enhancer and/or the CpG to determine the effects on the expression of *AHRR* from the enhancer/CpG-deleted and control alleles, iii) using an inducible *AHRR* gene to test the effects of constitutive expression of *AHRR* on the xenobiotic response genes induced by cigarette smoke. Understanding why cg05575921 hypomethylation is strongly associated with lung cancer risk may help devise strategies to mitigate the effects of smoke exposure.

Comprehensive tumor characterization increasingly requires both genomic and epigenomic information, yet current methylation profiling methods, such as bisulfite-based workflows, limit sensitivity and accuracy due to DNA degradation and reduced sequence complexity. To address these constraints, we developed an improved positive-conversion chemistry that directly converts methylated cytosines while preserving unmethylated ones to enable simultaneous detection of cytosine modifications and genetic variants from a single NGS library. This approach is designed to support oncology research applications where high accuracy from limited or damaged material, such as FFPE tissue and cell-free circulating tumor DNA (ctDNA), is essential.

To assess performance, FFPE, fresh-frozen, and cfDNA samples were processed using an optimized oxidation–reduction workflow. Libraries were sequenced on standard short-read platforms, and methylation accuracy, F1 scores, CNV concordance, and tumor–normal methylation contrast were evaluated. Performance was compared to whole-genome sequencing (WGS) controls and conventional bisulfite and enzymatic methylation sequencing methods.The chemistry demonstrated efficient reduction of modified cytosines, enabling high-confidence methylation calling with low false positive rates. Sequence complexity was maintained, allowing robust SNV and CNV detection from the same library. FFPE samples exhibited improved CpG coverage, fewer sequence artifacts, and improved library complexity compared to enzymatic methylation sequencing. cfDNA libraries generated from as little as 1 ng yielded reliable global methylation profiles suitable for tissue-of-origin analyses. The nondestructive nature of the chemistry preserved cfDNA fragments, opening the door to fragmentomics analyses. In tumor–normal comparisons, there was clear resolution of differentially methylated regions (DMRs), supporting more precise identification of tumor-specific epigenetic alterations.

This enhanced positive-conversion chemistry enables unified genomic and epigenomic analysis from a single assay, making it highly suited for oncology research applications such as tumor classification, biomarker discovery, minimal residual disease (MRD) assessment, and liquid biopsy. Its gentle conditions, compatibility with degraded FFPE DNA and low-input cfDNA, and ability to capture both methylation and variants position it as a powerful tool for advancing translational research and precision oncology.

#1952 Novel mouse models enabling locus-specific manipulation of DNA methylation.

Julia M. Salamat, Li Yang, Xiaomin Chen, Eduardo Lopez, Lanlan Shen

Baylor College of Medicine, Houston, TX

Introduction: DNA methylation is a key epigenetic mechanism that regulates development and disease, including cancer. However, current tools for precise, locus-specific epigenetic gene editing remain limited. Because phenotypic outcomes often result from interactions among multiple genes, there is a critical need for systems that can modulate methylation across several genomic loci simultaneously. Equally important, tight spatial and temporal control of such epigenetic modulation is essential to accurately dissect causal relationships between DNA methylation and gene function. To address these challenges, we developed mouse models that enable controlled, cell type-specific, and time-dependent epigenetic modulation in vivo.

Methods: We applied the CRISPR-dCas9-SunTag system for targeted DNA methylation editing, using TET1 for demethylation and DNMT3A/3L for methylation. To generate mouse models, we employed homologous recombination to introduce knock-in constructs at genomic safe harbors. Specifically, the dCas9-SunTag-TET1-GFP system was inserted into the Rosa26 locus and the dCas9-SunTag-DNMT3A/3L-mCherry system was integrated into the Hipp11 (H11) locus. Expression of the dCas9-based epigenetic editors was regulated through recombinase systems: Cre or Flp recombination activated expression, while Dre recombination removed the entire construct, thereby terminating expression. Specific guide RNA (gRNAs) directed targeted demethylation or methylation at single or multiple genomic sites.

Results: For both mouse lines, correct knock-in was confirmed by Southern blot and DNA sequencing. Germline transmission was successful, and offspring developed normally with the expected Mendelian ratios. Mouse embryonic fibroblasts (MEFs) derived from these lines were used to validate inducible expression mediated by Cre or Flp recombination. Inducibility was confirmed by Cas9 Western blot, RT-PCR analysis of TET1 or DNMT3A/3L transcripts, and fluorescent reporter expressions. Using gRNA targeting multiple promoters, including tumor suppressor genes p16 and Hic1 and oncogenes Tfap2a and VEGF, we observed robust and site-specific DNA methylation editing. Furthermore, targeted methylation of the p16 promoter in MEFs resulted in transcriptional silencing and bypass of the senescence checkpoint.

Conclusion: We successfully established mouse models that enable precise, locus-specific manipulation of DNA methylation through inducible CRISPR-dCas9-SunTag-based epigenetic editing. These models provide a versatile platform for dissecting the causal relationships between DNA methylation and gene function in vivo. Given their flexibility and inducible control, these systems will be broadly applicable to researchers investigating functional epigenomics, developmental regulation, and the epigenetic mechanisms underlying human diseases.

#1953 A novel synthetic lethal combination of FERMTs obtained by screening using DNA methylation-silenced genes.

Takahiro Ebata, Ryoma Mashiko, Yumi Furuichi, Qichun Wang, Yui Ohashi, Toshikazu Ushijima

Hoshi University, School of Pharmacy and Pharmaceutical Sciences, SHINAGAWA-KU, Japan

Synthetic lethality with a methylation-silenced gene is a promising strategy for cancer treatment. Here, we aimed to identify such a synthetic lethal combination using genome-wide DNA methylation data and the gene dependency database (DepMap) in 92 gastrointestinal cancer cell lines. First, we isolated 108 genes frequently methylation-silenced in the cell lines, using criteria of a gene with a promoter CpG island and frequent methylation among the cancer cell lines. Next, we searched for their synthetic lethal partners by calculating a correlation coefficient between the methylation level of each candidate gene and dependency of the gene upon 16,836 genes in the DepMap database. As a result, we identified 21 candidate combinations. Among them, to avoid false positive combinations, we focused on one paralog combination; *kindlin1* dependency on a high methylation level of its paralog *kindlin2*. The 92 cell lines could be classified into *kindlin1* knock-down-sensitive and resistant groups by *kindlin2* methylation. In addition, incorporation of methylation of *kindlin3*, another paralog in the kindlin family, made the classification clearer. The synthetic lethality of the three genes was confirmed by rescue experiments in which overexpression of *kindlin2* or *kindlin3* decreased *kindlin1* dependency. Mechanistically, suppression of all the three *kindlin* genes caused severe adhesion deficiency, which induced YAP inactivation through its re-localization from nucleus to cytosol, independent of its phosphorylation status. In mouse xenograft models, suppression of *kindlin1* by inducible knockdown resulted in tumor regression and it was rescued by overexpression of one of other two paralogs. Methylation analysis of 927 clinical samples from TCGA database showed that 5-10% of gastrointestinal cancer had *kindlin2* and *kindlin3* methylation. Our research showed that *kindlin1* is a new therapeutic target for *kindlin2* and *kindlin3*-methylated cancers and that a search for synthetic lethal combinations with methylation-silenced genes is a promising strategy.

#1954 Spatial and single-cell DNA methylation analysis of primary breast cancer reveals lineage independent epigenetic plasticity.

Ruslan Strogantsev[1], Aysegul Ors[2], Jamie Endicott[3], Aaron R. Doe[4], Hugo Cros[5], Joseph Hwang[5], **Hisham Mohammed**[5]

[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[2]Aysegul Ors (Individual),[3]OHSU Knight Cancer Institute, Portland, OR,[4]Oregon Health and Science University, Portland, OR,[5]CEDAR, Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Introduction: Intra-tumoral heterogeneity is governed by the interplay between rigid genetic evolution and plastic epigenetic states. However, dissecting the distinct contributions of these forces remains a challenge. While single-cell methods have traced genetic phylogeny, the spatial logic of epigenetic evolution and the extent to which it acts as an independent driver of phenotype remains unresolved. We present a comprehensive spatial and single-cell multi-omic atlas to decouple these mechanisms.
Methods: We generated a large-scale dataset comprising single-cell DNA methylation profiles from >22 patients, matched single-cell NMT-seq (nucleosome, methylation, transcription) from 8 patients, and spatial DNA methylation maps from 11 patients. We utilized our spatial sequencing approach achieving high-quality DNA methylation recovery at 50-micron resolution across tumor sections.
Results: We observed widespread, dramatic demethylation in Partially Methylated Domains (PMDs) characteristic of the cancer genome as expected. By leveraging variable/fluctuating DNA methylation sites as native barcodes, we reconstructed the phylogenetic lineage of each tumor. We demonstrate that epigenetically defined clones are not randomly dispersed but form spatially coherent, adjacent domains, confirming that tumor expansion follows a spatial logic. Integrating matched genetic data, we found that methylation lineages align with Copy Number Variation (CNV) sub-clone status. However, our multi-omic analysis revealed a critical divergence. While sub-clone specific DNA methylation patterns tracked with genetics, we observed dominant epigenetic states characterized by coordinated shifts in chromatin accessibility, transcription factor enrichment, and RNA expression that emerged independently of the underlying genetic phylogeny.
Conclusion: This study provides the first high-resolution spatial map of epigenetic architecture in cancer. We demonstrate a dual-layer model of evolution: while single CpG epimutations can record the genetic history of the clone, DNA methylation can also simultaneously drive broad, phylogenetically independent state changes that dictates cell phenotype. These findings establish epigenetic plasticity as a distinct, key driver of tumor heterogeneity beyond the constraints of the genome.

#1955 Early-life gut microbiota programs intestinal stem cell epigenetics to protect against colon cancer later in life.

Li Yang[1], Shirui Zhou[2], Xiaomin Chen[1], Fabiola Gutierrez[3], Stephanie Fowler[3], Lanjing Zhang[4], Julia M. Salamat[1], Karen Riggins[1], Jiejun Shi[2], Lanlan Shen[1]

[1]USDA Children's Nutrition Research Center, Department of Pediatrics, Baylor College of Medicine, Houston, TX,[2]Department of General Surgery, Shanghai Tongji Hospital, School of Life Sciences and Technology, Tongji University, Shanghai, China,[3]Gnotobiotic Facility, Molecular Virology & Microbiology, Baylor College of Medicine, Houston, TX,[4]Department of Pathology, Princeton Medical Center, Plainsboro, NJ

Background: Colorectal cancer (CRC) arises from both genetic and epigenetic alterations. Epidemiological and animal studies suggest early-life exposures, including gut microbiota changes during weaning, can influence long-term CRC risk. However, the mechanisms linking early microbial interactions to durable disease protection remain unclear. We hypothesize that early microbial exposure epigenetically programs long-lived intestinal stem cells (ISCs), shaping immune regulation and disease susceptibility.

Methods: *Lgr5-GFP* reporter mice were used to isolate colonic ISCs and intestinal epithelial cells (IECs) under specific-pathogen-free (SPF) and germ-free (GF) conditions. Whole-genome bisulfite sequencing (WGBS) and RNA sequencing were performed to assess microbiota-associated transcriptional changes mediated by DNA methylation from weaning into adulthood. Gut microbe transplant (GMT) experiments defined the critical developmental window during which ISC epigenetics are most sensitive to microbial influences. A maternal low-dose penicillin (LDP) model combined with shotgun metagenomics identified specific bacterial taxa contributing to epigenetic effects. Dextran sulfate sodium (DSS)-induced colitis and azoxymethane (AOM)/DSS-induced CRC models were used to evaluate long-term consequences.

Results: We identified 683 differentially methylated regions (DMRs) that were persistently associated with the microbiome in both adult ISCs and IECs. Among these, 51% were located in enhancers, and the majority DMRs (79%) exhibited loss of methylation under SPF conditions. The hypomethylated genes were enriched for immune and host defense functions, including MHC class II genes (*Cd74*, *H2-Aa*, *H2-Eb1*, and C*iita*). Loss of methylation occurred post-weaning and correlated with increased gene expression. GMT experiments demonstrated the post-weaning as the optimal window to restore methylation patterns, compared to adolescence or adulthood. Mechanistically, a transient IFN-γ burst during weaning drove epigenetic reprogramming via the IFN-γ-STAT3-TET3 axis. In addition, microbiota-derived metabolites, including short-chain fatty acids (SCFAs), α-ketoglutarate (α-KG), and methionine-γ-lyase-dependent products, reinforced the establishment of proper methylation patterns. Early-life LDP exposure reduced Gram-positive bacterial abundance, altered IFN-γ expression, disrupted MHC-II epigenetics, and increased susceptibility to colitis and CRC.

Conclusion: Early-life microbial and immune signals establish durable epigenetic programs that protect against CRC. Timed microbial interventions may provide long-lasting protection against adult-onset diseases.

#1956 Efficacy of DNA methyltransferase inhibition in combination with immune-checkpoint/PARP-inhibitor in colorectal cancer preclinical model.

Pooja Mittal, Jae Ho Lo, Ben Yi Tew, Goar Smbatyan, Sandra Algaze, Lesly Torres Gonzalez, Unnati Hemant Shah, Michela Bartolini, Yan Yang, Steve Soto Trujillo, Wu Zhang, Josh Millstein, Gangning Liang, Bodour Salhia, Shivani Soni, Heinz Josef Lenz

Keck School of Medicine of USC, Los Angeles, CA

Background. Epigenetic alterations in the form of DNA methylation changes in genes have been associated with colorectal cancer (CRC) progression. DNA methyltransferase (DNMT) enzyme plays central role in epigenetic regulation. In this study, we evaluated the therapeutic potential of epigenetic modulation using DNMT inhibitor 5-AZA-2´-deoxycytidine (5AZA) in combination with immune-checkpoint inhibitor (ICI) anti-PD1 or PARP inhibitor BMN673 in syngeneic CRC mouse model.

Methods. 8 weeks old C57BL/6 J female mice were subcutaneously injected with 10^6 MC38 cells in the right flank. Mice (n=10 per group) were randomized into following treatment groups: control, 5AZA 0.5 mg/kg, anti-PD1 100µg/mouse, BMN673 0.3 mg/kg, combinations 5AZA+anti-PD1, and 5AZA+BMN673. Upon endpoint, mice were euthanized, tumors and plasma were collected. Plasma cytokine levels were subsequently measured using V-PLEX Proinflammatory Panel 1 kit (MSD). Isolated DNA was subjected to reduced representation bisulfite sequencing, followed by analysis of statistically significant (adjusted $p<0.05$) differentially methylated regions (DMRs) and their associated genes using metilene and Ingenuity Pathway Analysis (IPA). RNA sequencing was performed using Novaseq (Illumina) and significant differentially expressed genes (DEGs) (adjusted $p<0.05$) were analyzed using DESeq2.

Results. We showed that combining 5AZA with anti-PD1 significantly reduced ($P<0.0001$) tumor volume compared to control and with either 5AZA or anti-PD1 alone. Similarly, combination of 5AZA and BMN673 significantly reduced ($P<0.0001$) the tumor volume compared to control and BMN673 alone. Methylation profiling revealed 940 and 299 DMRs in the combination 5AZA+anti-PD1 and 5AZA+BMN673, respectively when compared to single agent treated groups. IPA analysis revealed upregulation of RHO GTPase cycle and downregulation of adipogenesis in all 5AZA-treated groups. Furthermore, proinflammatory cytokines were differentially expressed among treatment groups, with cytokines IL-1β and TNF-α detected at higher concentration in BMN673 treated groups and higher levels of IL-10 and IL-2 in 5AZA treated groups. Transcriptomics profiling showed 203 and 135 upregulated, and 126 and 237 downregulated DEGs in 5AZA+anti-PD1 and 5AZA+BMN673, respectively. Notably, both combination groups showed significant downregulation of *Hba* and *Hbb* genes which encode the hemoglobin subunits, suggesting increased reactive oxygen species and associated apoptosis in tumors as a countereffect to the observed upregulation of *Tuba3a*, *Tuba3b* and *Trap1a* genes all associated with hypoxia in both combination groups.

Conclusion. Our findings suggest that administration of DNMT inhibitors in combination with ICI or PARP inhibitors could be a promising strategy to substantially improve the treatment and survival outcomes in CRC.

#1957 DNA methylation differentiates early-stage lung adenocarcinoma cells-of-origin with distinct smoking history and grade.

Xuan Cindy Li[1], Diego Almanza[2], Phuc Huu Hoang[1], Thi-Van-Trinh Tranh[1], Nicholas H. Juul[2], Maximilian Diehn[2], Tushar J. Desai[2], Maria Teresa Landi[1]

[1]Division of Cancer Epidemiology & Genetics, National Cancer Institute, Rockville, MD,[2]Stanford University, Stanford, CA

Lung cancer is a major cause of cancer-related mortality worldwide. Approximately 10%-20% of lung cancers occur in patients with no smoking history and are mostly lung adenocarcinoma (LUAD). Studies in mouse models showed that LUAD cases arising from alveolar epithelial type I (AT1) cells transitioning to alveolar type II (AT2) are less aggressive than those that originate directly from type 2 (AT2), but the origin of human LUAD remains unclear. Leveraging the bulk methylation array data from the EAGLE and Sherlock-*Lung* studies, two large multi-omics studies of lung cancer in people with and without smoking history, respectively, we infer the cells-of-origin for early-stage tumor samples and examine their associations with smoking history and grade.

We impute cells-of-origin from bulk methylation array data of tumor and normal samples collected from 388 stage I LUAD cases without smoking history and 238 with smoking history. For the methylation reference profiles of normal lung cell types, we combined a published normal human cell methylation data set (Loyfer et al. 2023) from whole-genome bisulfite sequencing (WGBS) as well as purified AT1 and AT2 enzymatically converted methylation profiles sequenced in-house. We then perform principled feature engineering to select methylation sites that best distinguish cell types and represent each cell type in a balanced manner. To estimate the proportion of each lung cell type in the samples, we employ a combinatorial optimization strategy by formulating and solving the deconvolution as a quadratic program. The inferred compositions of tumor origins are then evaluated in relation to smoking history and tumor grade based on the International Association for the Study of Lung Cancer (IASLC) grading system.

The tumor samples of LUAD cases without smoking history (n=238) have 11% higher AT1 presence compared to those with smoking history (n=388, $p<0.05$). Among cases without smoking history and with coherent grades, the tumor samples with well or moderate grade (n=96) have on average 13% higher AT1 presence than those with poor grade (n=102, $p<0.05$). Notably, tumor samples of stage I LUAD cases with no smoking history have the highest overall AT1 presence among all groups (on average 26%). All normal samples, regardless of smoking history and grade, have no significant difference in AT1 presence (on average 10%).

Our study establishes a principled deconvolution framework to infer tumor origins in LUAD using DNA methylation data. Mirroring findings in mouse models, our results indicate that AT1 cells may generate LUAD in humans, and that this appears to occur more frequently in patients without smoking history and with better tumor grades. Our work adds a new dimension to the understanding of early-stage LUAD and sheds light on patient stratification, prognostic evaluation, and therapeutic targeting of tumor origin-specific vulnerabilities.

#1958 Targeting UHRF1-SUV39H1/H2 crosstalk enhances DNMT1 inhibitor efficacy in colon cancer.

Yanqing Liu[1], Joel A. Hrit[1], Alison A. Chomiak[1], Stephanie Stransky[2], Jordan Hoffman[3], Rochelle L. Tiedemann[1], Ashley K. Wiseman[1], Leena S. Kariapper[1], Bradley M. Dickson[1], Evan J. Worden[1], Christopher J. Fry[3], Simone Sidoli[2], Scott B. Rothbart[1]

[1]Van Andel Institute (VAI), Grand Rapids, MI,[2]Albert Einstein College of Medicine, Bronx, NY,[3]Cell Signaling Technology, Inc., Danvers, MA

DNA hypomethylating agent (DNMTi) efficacy is associated with the re-expression of epigenetically silenced tumor suppressor genes (TSGs) and transposable elements (TEs) in preclinical cancer models, yet their clinical efficacy in solid tumors is limited. An emerging mechanism of resistance to DNMTi involves compensation through repressive histone post-translational modifications (PTMs). Here, we define a targetable chromatin-based mechanism through UHRF1-SUV39H1/H2 crosstalk that reinforces transcriptional silencing in colon cancer cells exposed to DNMTi's. Leveraging integrative epigenomic profiling and biochemical analyses, we discovered that transient DNA hypomethylation triggers UHRF1-dependent mono-ubiquitination of lysine 18 on histone H3 (H3K18ub), which in turn stimulates SUV39H1/H2 methyltransferases to deposit H3K9me3 at CpG island promoters of DNA methylation-silenced TSGs. This UHRF1-SUV39H1/H2 crosstalk establishes new heterochromatin domains that stabilize repression despite global DNA demethylation. Disrupting UHRF1 enzymatic function or an identified H3K18ub-recognition motif in SUV39H1 prevents H3K9me3 accumulation, increases TSG re-expression, and enhances DNMTi-induced antiproliferative effects in colon cancer cells. These findings reveal a compensatory heterochromatin signaling mechanism that limits DNMTi responses and identify the UHRF1-SUV39H1 pathway as a novel therapeutic target to improve epigenetic therapy efficacy in solid tumors.

#1959 The potential of methylated DNA markers for accurate detection of high-risk, HPV-positive cervical lesions.

Roshni Saravanan[1], Mary Jo Fackler[1], Madison Pleas[1], Wenfei Xia[1], Tomisin Adebari[1], Gang Yu[1], Liqun Zhang[1], Suzette Jordaan[2], Eunice Van Den Berg[2], Pamela Michelow[2], Reubina Wadee[2], Maureen Joffe[3], Wenlong Carl Chen[3], Youxiang Wang[4], Leslie Cope[1], Saraswati Sukumar[1]

[1]Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Anatomical Pathology, University of the Witwatersrand/National Health Laboratory Service, Johannesburg, South Africa,[3]Strengthening Oncology Services Research Unit, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa,[4]Atila Biosciences, Sunnyvale, CA

Purpose: Cervical smear cytology exhibits high variability and limited sensitivity in detecting cervical lesions. While the HPV test, recommended by WHO, offers high sensitivity, it has limited specificity. Our goal was to determine whether DNA methylation markers could improve both sensitivity and specificity, thereby enabling more effective triage to colposcopy and biopsy than cytology and HPV testing.

Experimental Design: We previously published a 5-gene (*TBXT, MOS, FMN, EDNRB,* and *ZNF671*) DNA methylation assay with high sensitivity and specificity for detecting cervical cancer in cytology and histology samples [1]. In the current study, we tested cervical brush samples (n = 222) with known cytology but no available histology that were preserved in CytoLyt, selected and deidentified at the National Health Service screening clinic in Johannesburg, South Africa. Samples were tested for both high-risk HPV variants (Atila Biosystems) and for cumulative 5-gene methylation utilizing Quantitative Multiplex Methylation-Specific PCR (QM-MSP). Statistical tests included the Youden Index for gene-specific thresholds, odds ratio scores for individual genes, Mann-Whitney test, and Receiver Operating Characteristic Area Under the Curve (ROC AUC); a P value ≤ 0.05 was considered significant.

Results: Among the 222 cervical brush samples, HPV was prevalent in similar numbers of HSIL (87/95, 92%) and LSIL (47/57, 82%), and in about half of the NIEL (39/70, 56%). Thus, HPV was highly sensitive for the detection of HSIL, but very poorly specific for low-risk LSIL or NIEL. In contrast, among HPV+ samples, to distinguish between high risk HSIL and low risk LSIL/NEIL, the QM-MSP assay showed a high level of sensitivity: 78.16% [CI 68.39 - 85.55] and, in addition, a high level of specificity: 95.35% [CI 88.64 - 98.18], and ROC AUC = 0.890 [CI 83.71 - 94.37]. A highly significant (P<0.0001) difference in methylation levels was observed between HSIL and LSIL/NIELs. In the small set of HPV-negative samples, hypermethylation of the 5-gene panel was observed in 5/8 (63%) HSIL, 0/10 (0%) LSIL, and 1/31 (3%) NIEL, suggesting that QM-MSP may be independent of the HPV status.

Conclusions: These findings suggest that the 5-gene panel detected a large proportion of HSIL, while the majority of LSIL and NIEL remained negative. Thus, this assay could serve as an effective triage tool for HPV+ cases, expediting care for women with HSIL while potentially reducing referrals for colposcopy in LSIL and NIEL by up to 95%. This could reduce costs and risks associated with repeated biopsy procedures for low-risk lesions.

#1960 The stability of epigenetic cell identity in cancer.

Cameron Cloud[1], Benjamin Steinberg[2], Yitzhak Reizel[2], Wanding Zhou[3]

[1]Department of Bioengineering, University of Pennsylvania, Philadelphia, PA,[2]Biotechnology and Food Engineering, Technion - Israel Institute of Technology, Haifa, Israel,[3]Center for Computational and Genomic Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA

Cell-type-specific DNA methylation patterns encode cell identity and are largely preserved over mitotic divisions across the organism’s lifespan. These patterns have shown strong potential as diagnostic markers in cancer. However, DNA methylation is also plastic, dynamically remodeled in development and diseases, including cancer, due to interaction with genetic, cellular, and environmental factors. Despite wide utilities, a unified and quantitative framework for assessing the stability of cell-identity-defining methylation signatures during tumorigenesis is lacking. We systematically quantified the extent to which the DNA methylation-based definitions of cell identity, as established in healthy tissue, are maintained or disrupted in 324 human cancer types. We found that cell-type-specific methylation signatures are remarkably stable across diverse cancer types, including metastatic lesions and tumors harboring mutations in epigenetic regulators. While signature erosions were common, particularly in in vitro cell lines, complete loss in primary tumors was rare and often pointed to mischaracterized or ambiguous cells of origin. Based on these insights, we developed computational strategies to infer tumor cell-of-origin from cancer methylomes, enabling a better understanding of cancers with poorly defined origins. Our findings deepen the understanding of epigenetic maintenance in cancer and guide the development of more robust methylation-based cancer diagnosis.

#1961 DNA methylation signatures associated with tumor location in early-onset colorectal cancer identified across two independent cohorts.

Aniruddha B. Rathod[1], Sandi L. Pruitt[2], Amit G. Singal[2], Caitlin C. Murphy[3]

[1]Epidemiology, University of Arkansas for Medical Sciences, Little Rock, AR,[2]UT Southwestern Medical Center, Dallas, TX,[3]Pediatrics, University of Chicago, Chicago, IL

Background: Incidence of early-onset colorectal cancer (EOCRC; ages 18-49) continues to rise globally, with rectal cancers increasing more rapidly than proximal or distal colon cancers. Germline variation does not fully explain these trends or the disproportionate rise in rectal tumors, suggesting a role for epigenetic mechanisms. However, the association of DNA methylation (DNAm) to EOCRC tumor location remains poorly understood.

Methods: We used The Cancer Genome Atlas (TCGA) as the discovery cohort to identify tumor location-specific DNAm markers in EOCRC. First, we conducted an epigenome-wide association study, screening Cytosine-Phosphate-Guanine site, (CpGs) at FDR< 0.2, followed by multivariable logistic regression adjusting for age, sex, stage, and treatment. CpG sites were modeled as independent variables and tumor location (rectum [defined as rectum and rectosigmoid] vs. colon) as the outcome; significant CpGs were defined at <fdr 0.05.="" to="" validate="" these="" findings,="" we="" tested="" the="" tcga-identified="" cpgs="" in="" an="" independent="" eocrc="" cohort="" of="" patient="" tumor="" tissue="" from="" ut="" southwestern="" medical="" center="" (utsw)="" using="" same="" analytic="" framework.="" for="" replicated="" cpgs,="" evaluated="" dnam="" patterns,="" mapped="" annotated="" genes,="" and="" conducted="" pathway="" enrichment="" analysis.="" tcga="" served="" as="" discovery="" dataset,="" utsw="" dataset="" replication="" cohort.

Results: Among the TCGA cohort of 67 patients, (31.3% rectum, mean age 44 years, 55.2% women, 73% White, 41.8% stage III), 766 CpG sites differed significantly between rectal and colonic tumors (FDR < 0.05); 27.7% were hypermethylated and 72.3% were hypomethylated in rectum tumors. The UTSW replication cohort included 72 patients (31.9% rectum, 45.8% women, 56.9% White, 37.5% stage III). Of the 504 CpGs available for replication testing, 266 showed the same direction of association, with 14.3% hypermethylated and 85.7% hypomethylated in rectal/rectosigmoid versus colonic tumors. Principal component analysis on replicated CpGs demonstrated separate clusters of rectum and colonic tumors. Replicated CpGs mapped to 202 genes, including SRC, IGF1R, EPHB3, and MAP4K4. Pathway enrichment analysis highlighted processes related to epithelial cell migration, cell-cell adhesion, and immune activation.

Conclusion: Tumor location-specific DNAm signatures differentiate rectal from colonic tumors in EOCRC, and nearly half of TCGA-identified CpGs showed directional replication in independent patient tumor tissue samples. These findings support a biological role for DNAm in anatomic heterogeneity of EOCRC and identify a focused set of CpGs and pathways for future mechanistic investigation to uncover epigenetic drivers.

#1962 Epigenetic remodeling of BCOR-PRC1.1 complex dictates response and resistance to IDH inhibitors in AML.

Sarah Hanache[1], Xiaoyan Zhang[2], Satoko Ogata[1], Hidetaka Uryu[1], Ken Furudate[1], Zongrui Li[1], Abhinav Jain[3], Erika Thompson[4], Courtney D. Dinardo[1], Margaret A. Goodell[2], Koichi Takahashi[1]

[1]Leukemia, MD Anderson Cancer Center, Houston, TX,[2]Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX,[3]Epigenet & Mol Carcinogenesis, MD Anderson Cancer Center, Houston, TX,[4]Genetics, MD Anderson Cancer Center, Houston, TX

Background: IDH1/2 mutations occur in about 20% of AML and generate 2-hydroxyglutarate, which blocks TET-mediated hydroxymethylation, induces CpG island hypermethylation, and enforces a differentiation arrest. Although mutant-specific IDH inhibitors induce remissions, relapse is common. Our prior study identified recurrent acquisition of BCOR Loss of Function mutations at resistance. Because BCOR/PRC1.1 recruitment is regulated by CpG methylation, we hypothesized that IDH-driven hypermethylation disrupts BCOR binding, that IDH inhibitor mediated demethylation restores PRC1.1 occupancy, and that relapse associated BCOR loss prevents this restoration.

Methods: Using isogenic TF-1 IDH2-R140Q models, we performed EvoC 6-base sequencing, BCOR ChIP-seq, and RNA-seq across WT, IDH2 mutant, and enasidenib treated cells. Published CRISPR-Cas9 screening data from IDH1 mutant AML (Liu et al. Cancer Research 2022) were reanalyzed to define major key genes in IDH-inhibitor-induced differentiation.

Results: IDH2 mutation induced coordinated promoter hypermethylation and 5hmC loss. EvoC sequencing showed that about 60% of DMRs were hypermethylated and enriched upstream of transcription start sites. 5hmC was markedly reduced and fully restored by enasidenib, consistent with impaired TET2 activity. Notably, 87% of hypermethylated DMRs with 5hmC loss underwent demethylation after 28 days of treatment, coinciding with normalized 2HG. BCOR occupancy decreased at promoter-proximal regions in IDH2 mutant cells and was restored by enasidenib.Integration of methylation, BCOR ChIP-seq, and RNA-seq showed that most BCOR-loss promoters were hypermethylated, transcriptionally activated, and normalized with treatment. Restored BCOR targets were enriched for Wnt, PI3K/Akt/mTOR, RTK, and MAPK pathways. Promoters of *JUNB* and *WNT11* showed concordant hypermethylation, reduced BCOR binding, and increased expression in IDH2 mutant cells, all reversed by enasidenib.CRISPR-Cas9 data identified *Bcor* as a top gene required for differentiation upon IDH inhibition, exceeding canonical regulators such as *Cebpa* and *Cebpb.* Bcor targets (*Junb* and *Wnt11*) also ranked as essential effectors in the differentiation arm, matching our multi-omics findings.

Conclusions: IDH2 mutation establishes an epigenetic blockade marked by promoter hypermethylation, 5hmC loss, and loss of BCOR-PRC1.1 occupancy, enabling aberrant activation of stemness programs. Enasidenib reverses these defects by restoring 5hmC, promoter methylation balance, BCOR binding, and PRC1.1-mediated repression. These data support a model in which IDH-inhibitor-induced differentiation requires intact BCOR function and repression of BCOR targets such as JUNB and WNT11, defining how IDH-mutant epigenetic dysregulation and BCOR loss converge to limit therapeutic efficacy.

#1963 The landscape of epigenetic alterations in the prostate cancer patient cohort from India.

Promit Ganguly[1], Tanay Biswas[1], Atin Singhai[2], Alok Srivastava[3], Abhishek Chauhan[4], Manzoor Ahmad[5], Piyush Tripathi[6], Sanjeev Mehrotra[6], Anjali Tewari[6], Nuzhat Husain[7], Apul Goel[8], Bushra Ateeq[1]

[1]Department of Biological Sciences and Bioengineering, Indian Institute of Technology Kanpur, Kanpur, India,[2]Department of Pathology, King George's Medical University, Lucknow, India,[3]Department of Urology & Renal Transplant, Dr. Ram Manohar Lohia Institute of Medical Sciences, Lucknow, India,[4]Department of Radiodiagnosis, Dr. Ram Manohar Lohia Institute of Medical Sciences, Lucknow, India,[5]Department of Surgery, Jawaharlal Nehru Medical College, Aligarh Muslim University, Aligarh, India,[6]Regency Hospital, Kanpur, India,[7]Department of Pathology, Dr. Ram Manohar Lohia Institute of Medical Sciences, Lucknow, India,[8]Department of Urology, King George's Medical University, Lucknow, India

Prostate cancer (PCa) ranks as the third most prevalent malignancy among men in India, where it is frequently diagnosed at its advanced stage due to a lack of routine screening and awareness. PCa is a highly heterogeneous disease, comprising multiple molecular subtypes and exhibiting significant ethnic disparities. Its progression is driven by a cascade of genetic and epigenetic alterations that dysregulate key gene networks and signaling pathways. The global molecular landscape of PCa patients of Indian ethnicity has remained unaddressed. Hence, as a prospective study, we characterized the aberrant DNA methylation pattern in PCa specimens of Indian origin and performed Illumina EPICv2 array-based profiling of fresh, treatment-naïve PCa (N=32), Benign Prostatic Hyperplasia (BPH; N=7) and one high-grade prostatic intraepithelial neoplasia tumor specimens. Using Sesame pipeline, we have identified genome-wide differentially methylated loci in PCa specimens to understand the epigenetic aberrations prevalent in this cohort. We observed significant hypermethylation in the regulatory regions of *GSTP1*, *APC*, *RARB,* and *RASSF1,* while *TDRD1*, *CTBP1,* and *KLK3* showed hypomethylation. Moreover, key cancer and development-linked processes such as stem cells pluripotency signaling, and synaptic signaling were observed to be dysregulated in PCa specimens compared to BPH. Additionally, hypermethylated regulatory regions exhibited reduced chromatin occupancy of PCa-driving transcription factors such as AR and ERG, while hypomethylated regions showed increased occupancy. Unsupervised hierarchical clustering identified a distinct subset of PCa patients with elevated DNA methylation levels independent of their Gleason grade. Moreover, mapping genetic alterations in matched Indian PCa patients would offer a framework for patient stratification, enabling tailored therapeutic interventions driven by distinct epigenomic and genomic aberrations. In conclusion, our study for the first time, explored the global epigenetic profile of Indian PCa patients while identifying key DNA methylation aberrations and dysregulated pathways driving disease progression that would help improve PCa diagnostics and forward our understanding of PCa pathogenesis.

#1964 Age-related *p16* epimutation is a targetable driver of *Kras*-mutant lung cancer.

Xiaomin Chen[1], Li Yang[1], Eduardo Lopez[1], Lili Ma[2], Chao Cheng[2], Lanjing Zhang[3], Lanlan Shen[1]

[1]USDA Children's Nutrition Research Center, Department of Pediatrics, Baylor College of Medicine, Houston, TX,[2]Department of Medicine, Epidemiology and Population Science, Baylor College of Medicine, Houston, TX,[3]Department of Chemical Biology, Earnest Mario School of Pharmacy, Rutgers University, Piscataway, NJ

Background: Lung cancer is a leading cause of cancer death worldwide; however, current targeted therapies have limited efficacy for most patients. *p16* epimutation, characterized by epigenetic silencing of *p16* by promoter DNA hypermethylation, is common in lung cancer. Elucidating how *p16* epimutation drives lung tumorigenesis may uncover new therapeutic opportunities.

Methods: We developed a mouse model combining the conditional Cre-inducible *Kras*^{G12D}-mutation with epigenetically engineered *p16* epimutation and conducted time-course study to analyze the tumor phenotype and survival. Organoids derived from normal and tumorous lung tissue were used to assess the role of *p16* epimutation in tumor initiation and maintenance. Moreover, spatial transcriptomic analysis was used to characterize tumor heterogeneity and define distinct cell populations. To test the therapeutic potential of reversing *p16* epimutation, we evaluated the efficacy of hypomethylating agents 5-Aza-2'-Deoxycytidine (DAC) and GSK3685032 on *p16* reactivation in organoid and *in vivo*. Furthermore, we developed mice enabling conditional, inducible and site-specific DNA demethylation using a CRISPR-dCas9-Tet1 based epigenetic editing system. We assessed the effect of targeted *p16* promoter demethylation on tumor progression *in vivo*.

Results: Mice with combined *Kras*-mutation and *p16* epimutation developed malignant tumors more rapidly and had significantly shorter survival than mice with *Kras*-mutation only (Median survival: 161 days vs. 223 days, n=50, p=0.0003). Histopathological analyses confirmed the tumor progression to adenocarcinoma with distinct papillary and intraluminal growth patterns in combined mice, but not in *Kras*-mutation only mice. Spatial transcriptomic analysis confirmed that tumors with this growth patterns were enriched in transitional airway progenitors co-expressing Sox2, Nkx2-1, and ciliated markers. Moreover, normal and tumor organoids derived from the combined mice proliferated robustly whereas organoids from *Kras*-mutation only mice stopped growing shortly after establishment. While global hypomethylation agents significantly reactivated *p16* and inhibited proliferation in tumor organoids, these agents failed to block tumor development *in vivo* (Fold change of tumor burden to control: DAC 1.41 ± 0.11, GSK3685032 1.33 ± 0.18, n=5, p=0.07). In contrast, CRISPR-mediated targeted *p16* promoter demethylation significantly reduced both tumor number and size *in vivo* compared with control mice (Tumor number: 16.17 vs. 6.33 per mouse, n=6, p=0.04).

Conclusion: Our work identifies *p16* as a bona fide epigenetic driver and therapeutic target for Lung cancer. Importantly, this study provides proof-of-concept that precise, locus-specific DNA demethylation can restore tumor suppressor function, highlighting a promising strategy for targeted epigenetic therapy in lung cancer patients.

#1965 Conserved endothelial cell-specific DNA methylation alterations in colorectal and breast tumor microenvironments.

Barbara Karakyriakou[1], Ze Zhang[2], Lucas A. Salas Diaz[3], Brock C. Christensen[3]

[1]Epidemiology, Molecular and Systems Biology, Dartmouth Geisel School of Medicine, Lebanon, NH,[2]Division of Population Sciences, Dana-Farber Cancer Institute, Boston, MA,[3]Dartmouth Geisel School of Medicine, Lebanon, NH

DNA methylation alterations are well-established contributors to carcinogenesis, yet, within the tumor microenvironment (TME), lineage- and cell-specific patterns remain poorly characterized. We applied a bulk DNA methylation deconvolution approach (HiTIMED) combined with a cell-type-specific differential methylation framework (CellDMC) to identify and validate tumor endothelial cell (TEC) specific DNA methylation alterations in colorectal cancer and nontumor normal tissue. We previously identified TEC-specific DNA methylation alterations in breast cancer. Here, we evaluate the shared endothelial-specific epigenetic programs between breast and colorectal tumors. Endothelial cells, key regulators of angiogenesis and vascular homeostasis, often acquire molecular and structural abnormalities that promote tumor progression. Using genome-scale DNA methylation data from a discovery and validation framework (tumor n = 725; nontumor n = 989) of colorectal tissues, we identified 38,647 CpGs (FDR ≤ 0.05) with altered DNA methylation specific to TECs in both discovery and validation sets, corresponding to 13,249 genes. The majority of CpGs were hypermethylated in TEC compared to endothelial cells in normal tissue. Clusters of CpGs mapped to genes known to regulate angiogenesis, endothelial cell biology, genes in the VEGF signaling pathway, and members of the hallmark angiogenesis gene set. Comparative analysis of TEC-specific methylation alterations in the colorectal and breast TME showed a 24% overlap at the CpG level, and an 81% overlap at the gene level, suggesting conserved endothelial-specific methylation dysregulation programs between tumor types. Nearly all genes whose expression correlated with endothelial cell proportion in our previous breast cancer analysis were also identified in the colorectal datasets. These findings indicate a shared epigenetic architecture underlying endothelial cell reprogramming in distinct tumor contexts. Ongoing expression analyses will extend these comparisons in colorectal tumors to further link DNA methylation with transcriptional regulation. Together, our results demonstrate that high-resolution, lineage-specific DNA methylation landscapes can be reconstructed from bulk tumor DNA methylation profiles and establish conserved TEC-specific epigenetic signatures with implications for tumor vascular biology and precision therapeutic targeting.

#1966 Vitamin C delays mouse embryonic cells immortalization by maintaining enhancer hypomethylation of senescence-related genes.

Guillermo A. Urrutia[1], Minmin Liu[2], Rachel Shereda[1], Stacey L. Thomas[1], Gangning Liang[3], Peter A. Jones[4]

[1]Van Andel Institute, Grand Rapids, MI,[2]Van Andel Research Institute, Grand Rapids, MI,[3]Department of Urology, Keck School of Medicine, University of Southern California, Los Angeles, CA,[4]Van Andel Institute (VAI), Grand Rapids, MI

Immortalization is the first step necessary for cancer cells to overcome replicative senescence and proliferate indefinitely, and it is known to be influenced by DNA cytosine methylation. Vitamin C (vitC) is a known cofactor for the Ten-eleven-translocation (Tet) enzymes, which are involved in active DNA demethylation. However, its role during this key process remains unclear. In this study, we evaluated vitC´s potential to prevent cell immortalization and its associated DNA methylation changes in a mouse embryonic cell culture model. Our findings demonstrate that vitC at physiological concentrations delays embryonic cell immortalization, inducing β-Galactosidase positive senescence, and increasing the global levels of 5-hydroxymethylcytosine in DNA. DNA methylation arrays revealed that immortalization induces a substantial reprogramming of the DNA methylation landscape, characterized by hypomethylation of Partially Methylated Domains (PMDs) and hypermethylation of enhancers, while vitC treatment prevented the immortalization-acquired DNA methylation. Gene expression analysis confirmed the upregulation of senescence and adipogenesis-related genes in vitC-treated cultures. Additionally, DNA hypomethylation was detected in key regulatory regions associated with these upregulated genes, particularly in enhancers. Interestingly, treated cultures sometimes acquired deletions of the *Cdkn2a* gene, suggesting that additional genetic insults are necessary for cells to overcome vitC-induced senescence. Collectively, our findings provide insight into how vitC modifies the epigenetic landscape of embryonic cells, inducing hypomethylation of DNA regulatory elements, thus preventing cells from overcoming replicative senescence and becoming immortal.

#1967 Methylation-based classification of circulating tumor DNA using enzymatic methyl-seq in a pan-cancer clinical cohort.

Kimberly A. Holden[1], Ashraf Shabaneh[1], Dennis D. Krutkin[1], Adib Shafi[1], Tong Liu[1], Kerry D. Fitzgerald[1], Eyad Almasri[1], Yuanyu Cao[1], Xiaojun Guan[1], Graham McLennan[1], Nathan Faulkner[1], Shakti Ramkissoon[2], Marcia Eisenberg[2], Brian Caveney[2], Eric Severson[2], Taylor J. Jensen[2], Jonathan Williams[1]

[1]Labcorp, San Diego, CA,[2]Labcorp, Durham, NC

Circulating tumor DNA (ctDNA) offers a minimally invasive approach for cancer detection and monitoring. The addition of DNA methylation-based biomarkers into liquid biopsy workflows has the potential to enhance analytical performance. We evaluated the performance of the NEBNext® Enzymatic Methyl-seq (EM-seq) kit for ctDNA-based cancer classification in a pan-cancer clinical cohort. A cohort consisting of 99 plasma-derived cfDNA samples (29 healthy donors; 70 cancer patients across five organ sites) were processed using a semi-automated EM-seq workflow and sequenced to a target depth of 10X. Multiple machine modeling methods were evaluated using DNA methylation ratio values segmented into bin sizes ranging from 10 bp to 350 bp, increasing in 10 bp increments. For each window size, a leave-one-out cross-validation strategy was applied to differentiate cancer from healthy samples. This resolution study resulted in the testing of over 31,000 models, and the predictive capacity of models was evaluated using sensitivity, specificity, and area under the curve (AUC). For each model, performance was evaluated by assessing the ability of the model to differentiate cfDNA from healthy donors and cancer patients. Logistic regression with a bin size of 290bp achieved the highest performance with an AUC of 0.98, sensitivity of 0.96, and specificity of 0.9. Model agnostic feature selection identified 15 features that highly overlap amongst cross-validation sets. Some bins mapped to known oncogenes such as *NOTCH2* and *CASC15*, or regions known to contribute to cell growth and tumor progression, including *TGFA* (a proto-oncogene), regulatory RNA LINC00665, and genes implicated in cancer biology such as *HS3ST5*, *SPOCK3*, *ATG13*, and *ERGIC1*. Other bins fell in intergenic regions or within genes with no known roles in oncogenesis (*EPS15L1*, *ARMC9*). The misclassified samples (n = 6; 3 healthy and 3 cancer) had a lower average mapping efficiency (mean = 87.5%) than correctly classified samples (mean = 94.5%; p = 0.003), suggesting that sequencing quality may influence classification outcomes. Different combinations of modeling methods and resolution levels (bin size) were also highly predictive of disease status. Methylation-based classification of ctDNA using EM-seq enables high-sensitivity cancer detection across multiple tumor types. Ongoing improvements in conversion efficiency, consistency across workflows, and expansion of sample cohorts may further enhance model robustness. These findings support the potential of methylation-informed liquid biopsy as a diagnostic tool in oncology.

#1968 Epigenetic reprogramming via DNMT1 inhibition reduces invasion and migration in docetaxel-resistant prostate cancer.

Carmen M. Ortiz-Sanchez[1], Gabriela Castro[2], Shakira Abad[2], Solimar Esteves[1], Valerie Rodriguez[1], Stephanie Montalvo[3], Rodniel Aviles[1], Ralphdy Vergne[1], Gustavo Alayon[1], Caleb Santiago[1], Lenin Godoy[1], Kosj Yamoah[4], Gilberto Ruiz-Deya[1], Jong Y. Park[4]

[1]Ponce Health Sciences University, Ponce, Puerto Rico,[2]Pontificia Universidad Catolica de Puerto Rico, Ponce, Puerto Rico,[3]University of Puerto Rico at Mayaguez, Mayaguez, Puerto Rico,[4]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Metastatic castration-resistant prostate cancer (mCRPC) is associated with poor prognosis and high mortality, largely due to the emergence of androgen and chemotherapy resistance. Resistance to docetaxel occurs in nearly 50% of patients and remains a major clinical challenge. DNA methylation is known to contribute to therapy resistance through gene silencing and reprogramming of cellular pathways. This study investigated whether global DNA hypomethylation achieved through DNMT1 inhibition could reduce cell invasion and motility in docetaxel-resistant (DR) prostate cancer (PCa) cells.
Methods: Parental and docetaxel-resistant cells (22Rv1, PC3, and DU145) were treated with 5-AZA (0.5-16 μM, 72 h). Viability was measured by MTT. Protein markers (AR, ARv7, MDR1, GSTP1, DNMT1) were assessed by Western blot; invasion and migration by Matrigel and wound-healing assays; and EMT markers (*CDH1*, *SNAI2*, *VIM*) by RT-PCR.
Results: Treatment with 5-AZA reduced cell viability in a dose-dependent manner in all cell models except DU-145DR cells. DNMT1 inhibition was confirmed in all cell lines, while re-expression of GSTP1, indicating successful DNA hypomethylation, was observed in DU145-DR and PC3/PC3-DR cells. No changes were observed in AR, AR-V7, or MDR1 protein expression. Invasion capacity was significantly reduced in DU145-DR (1 μM: $p<0.05$; 2 μM: $p<0.0001$) and PC3-DR (1 μM: $p<0.0001$; 2 μM: $p<0.01$) cells. Migration capacity was also reduced in DU145-DR and PC3-DR cells following 5-AZA treatment. 5-AZA induced upregulation of *CDH1* (DU145-DR: $p<0.05$; PC3-DR: $p<0.01$) and downregulation of *TJP1* (DU145-DR: $p<0.01$; PC3-DR: $p<0.01$) compared to parental cells. Additionally, SNAI2 ($p<0.05$) and VIM ($p<0.01$) were significantly downregulated only in DU145-DR cells, suggesting a cell line-specific modulation of epithelial-mesenchymal transition (EMT) markers.
Conclusions: These findings demonstrate that DNMT1 inhibition modulates EMT-related pathways, leading to reduced invasion and migrations in docetaxel-resistant PCa cells. The effect of 5-AZA appears to be mediated by upregulation of *CDH1* and suppression of *SNAI2* and *VIM*, highlighting the role of DNA methylation as a regulator of metastatic potential. This study provides mechanistic insight into the epigenetic regulation of therapy resistance and supports the potential of DNMT1 inhibition as a strategy to mitigate aggressive behavior in docetaxel-resistant mCRPC.
Funding: Sponsored by U54 PHSU-MCC Grants: U54CA163071 & U54CA163068; NIH-NIMHD Grant MD007579, and NIH-NIGMS Grant U54GM133807.

#1969 Hypomethylating activity of zebularine suppresses migration in docetaxel-resistant prostate cancer cells.

Gabriela Castro Morales[1], Daniela Gonzalez[1], Gustavo Alayon[1], Ralphdy Vergne[1], Lenin Godoy[1], Jong Y. Park[2], Gilberto Ruiz-Deya[1], Carmen M. Ortiz-Sanchez[1]

[1]Ponce Health Sciences University, Ponce, PR,[2]Moffitt Cancer Center, Tampa, FL

Background: Prostate cancer (PCa) is one of the most common types of cancer diagnosed in men. According to the Centers for Disease Control and Prevention (CDC), for every 100 men, 13 will develop PCa during their lifetime. DNA methylation has been investigated as a biomarker for disease aggressiveness and therapy resistance in PCa. Although PCa is considered a slow-growing disease, it can progress into metastatic castration resistant prostate cancer (mCRPC). Docetaxel is the standard first-line chemotherapy for mCRPC; however, drug resistance occurs in almost 50% of patients. Therefore, this study aimed to determine whether altering DNA methylation patterns in docetaxel-resistant (DR) PCa cell lines modifies key cellular functions, including proliferation, migration, and expression of resistance-related proteins. We hypothesized that Zebularine, a DNA methyltransferase (DNMT) inhibitor, would induce changes proliferation and migration in both parental and DR PCa cell models.
Methods: To evaluate the effects of Zebularine (12.5 - 400 µM) on the proliferative capacity of PCa cell lines (PC-3, DU-145, and 22Rv1) and their DR counterparts, the MTT assay was performed. Protein expression changes in DNMT1, DNMT3A, and MDR1 were evaluated through Western Blot. Effects over cell migration capacity were evaluated using the Wound Healing assay.
Results: Zebularine treatment reduced cell viability in a concentration-dependent manner in all cell lines. Based on these results, non-toxic concentrations of Zebularine (25 µM and 100 µM) were selected for further experiments. Zebularine reduced DNMT1 expression across all cell lines except DU145-DR; no changes were observed for DNMT3a or MDR1. In migration assays, Zebularine reduced the migration capacity of DR cell lines compared with their parental counterparts, particularly in PC3-DR and DU145-DR cells at 48 and 72 hours.
Conclusions: Zebularine led to successful inhibition of DNMT1, providing evidence of its hypomethylating action in the cell models used. Moreover, it led to a reduction in cell migration specifically in DR cell lines. This study sheds light on the importance of DNA methylation in the regulation of biological processes in DR cell lines.
Funding: Sponsored by U54 PHSU-MCC Grants: U54CA163071 & U54CA163068; NIH-NIMHD Grant MD007579, and NIH-NIGMS Grant U54GM133807.

#1970 Epigenetic modulation with 5-Azacytidine reduces aggressive phenotypes in 3D spheroid models of docetaxel-resistant prostate cancer.

Alanis Paola Torres Rosado[1], Gabriela Castro Morales[2], Lenin J. Godoy[1], Jong Y. Park[3], Gilberto Ruiz Deya[1], Carmen M. Ortiz-Sanchez[1]

Background: Prostate cancer (PCa) remains a significant health burden in the US, making it the second most frequently diagnosed malignancy in men. While the 5-year survival rate for localized tumors is 98%, metastatic prostate cancer presents a marked difference, with a 5-year survival rate of only 32%. The disparity in treatment effectiveness is largely due to low response rates and rapid resistance to docetaxel. Increasing evidence suggests that epigenetic mechanisms, particularly DNMT1-mediated hypermethylation, play a critical role in developing and maintaining this resistance by suppressing tumor-suppressor gene expression, leading to increased invasion, migration, and chemoresistance.Previous studies have shown that 5-azacytidine (5-AZA) can decrease epithelial-mesenchymal transition (EMT)-related markers and aggressive phenotypes in prostate cancer models. However, its effects in 3D spheroid systems, which better mimic the in vivo tumor microenvironment, remain unclear.
Methods: To evaluate the impact of 5-AZA on epigenetic regulation, EMT markers, and aggressive phenotypes in 3D spheroids generated from PC3 and PC3-DR cells, spheroids were formed in ultra-low attachment plates and treated with 1-2 μM of 5-AZA. Protein expression of DNMT1 and resistance related markers was evaluated through Western blot.
Results: PC3-DR spheroids in Matrigel showed strong invasion at 24 hours with outward cellular extensions and interaction with the matrix. Treatment with 5-AZA reduced this invasion in a dose-dependent manner. Protein analysis revealed significant suppression of DNMT1 in nuclear extracts, confirming effective targeting of epigenetic factors, whereas MDR1 remained abundant in cytosolic fractions, consistent with its role in chemoresistance. 5-AZA induced the re-expression of GSTP1 and shifted EMT programs toward an epithelial phenotype, corroborating previously reported findings in 2D models. Notably, PC3-DR spheroids demonstrated a stronger response to treatment than the parental PC3 cells, suggesting a greater reliance on methylation-driven pathways.
Conclusions: Overall, 5-AZA appears to reverse aggressive phenotypes in 3D spheroid models of docetaxel-resistant prostate cancer by reducing DNMT1 activity, restoring epithelial identity, and suppressing invasion. These findings support the use of epigenetic modulation as a potential therapeutic strategy to overcome chemoresistance and emphasize the importance of 3D systems for modeling treatment-resistant diseases. Future studies integrating genome-wide methylation profiling and in vivo validation are needed to establish 5-AZA as a viable strategy to counteract docetaxel resistance in metastatic prostate cancer. Sponsored by U54 PHSU-MCC Grants: U54CA163071 & U54CA163068; NIH-NIMHD Grant MD007579, and NIH-NIGMS Grant U54GM133807.

#1971 Distinct genome wide DNA methylation signatures due to pathogenic germline variants in *DKC1*, *TERC*, and *TINF2*.

Kelvin Cesar De Andrade[1], Gina Ney[1], Tianna Zhao[2], Shilpa Gaddam[2], Jia Liu[2], Kristine Jones[2], Lisa J. McReynolds[1], Neelam Giri[1], Sharon A. Savage[1]

[1]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[2]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Heal, Cancer Genomics Research Laboratory, Leidos Biomedical Research, Frederick National Laboratory for Cancer Research, Bethesda, MD

Germline pathogenic variants (GPVs) in *DKC1*, *TERC*, or *TINF2* lead to defective telomere maintenance and cause the cancer-prone telomere biology disorders (TBDs). DNA methylation (DNAm) can contribute to disease expressivity and penetrance in TBDs; however, epigenetic signatures across patients with TBDs remain undefined. As telomere shortening is a hallmark of aging, TBDs also offer a framework to study its link to epigenetic aging. We sought to identify DNAm alterations and evaluate epigenetic aging in patients with TBDs. Genome-wide DNAm profiling was performed using the Illumina Infinium Methylation EPICv2 array on blood samples from individuals with heterozygous *TERC* (n=15) or *TINF2* (n=13) GPVs, hemizygous *DKC1* males (n=7), and 41 controls participating in our IRB-approved study (NCT00027274). Differentially methylated probe (DMP) analysis was conducted using *limma*, adjusting for age, sex, DNAm-derived cell type composition, and family structure (FDR < 0.05 and $|\Delta\beta| \geq 0.20$); group differences were evaluated with mixed-effects regression models. Differentially methylated regions (DMRs) were identified with *DMRcate* (HMFDR < 0.05; $|\text{mean } \Delta\beta| \geq 0.10$). Functional enrichment of DMP-associated genes was assessed via KEGG pathway analysis using *missMethyl*. Epigenetic aging was estimated using the DunedinPACE algorithm. We identified 499, 167, and 164 DMPs in *TINF2*, *DKC1*, and *TERC*, respectively. Hypermethylation was mainly found in OpenSea regions (59-79%), except for *TERC*, which showed enrichment in CpG islands (45%). Hypomethylated probes were largely OpenSea (≥90%) across all cohorts. Genomic mapping showed enrichment of hypermethylation on chromosome X in *TERC* carriers, whereas *TINF2* and *DKC1* showed widespread autosomal changes. We detected 403 DMRs in *TINF2*, 158 in *DKC1*, and 119 in *TERC*, predominantly within promoter-proximal (21-30%) and intronic (27-38%) segments. Promoter hypermethylation was most common in *TERC* and *DKC1*, whereas *TINF2* exhibited intronic hypermethylation (36%). Nine genes with promoter hypermethylation and five with hypomethylation were recurrently detected across all patients. Pathway analysis showed enrichment in hematopoietic lineage and calcium signaling, with gene-specific trends in immune (*DKC1*), stem cell (*TERC*), and growth factor (*TINF2*) pathways. Epigenetic aging was accelerated in all patients, most prominently in *DKC1* (β=0.225, $p<0.001$) and *TINF2* (β=0.190, $p<0.001$). We detected distinct yet convergent DNAm signatures across individuals with TBDs. Individuals with GPVs in *TINF2* exhibited the most extensive methylation remodeling. All patients demonstrated accelerated epigenetic aging. These findings suggest that DNAm alterations accompany telomere dysfunction in TBDs and underscore the need for integrated multi-omic and longitudinal studies to clarify its mechanistic basis, tissue specificity, and clinical implications.

#1975 Genomic drivers of plasticity in transformed small cell lung cancer.

Swanand Rakhade, Mamie Wang, Lena Morrill Gavarro, Emmanuel Spanos, Alvaro Quintanal-Villalonga, Amin Sabet, Parvathy Manoj, Rishika Giri, Ronan Chaligne, Xinjun Wang, Helena A. Yu, Esther Redin, Dana Pe'er, Charles M. Rudin, Joseph Chan

Memorial Sloan Kettering Cancer Center, New York, NY

Background:
An emerging mechanism of resistance to targeted therapies in lung cancer is the lineage switch from lung adenocarcinoma (LUAD) to a neuroendocrine (NE) histology, the most aggressive subtype being small cell lung cancer (SCLC). In *EGFR*-mutant tumors, concurrent *TP53/RB1*mutations are enriched in transformed tumors, but the mechanisms underlying transformation remain poorly defined. We present a single-cell atlas of transformed (T)-SCLC and identify genomic and transcriptional drivers of NE transformation.
Methods:
We curated a cohort of 97 T-SCLC, 777 *de novo* SCLC, and 10,140 LUAD patients from a single institution, with mutational profiling performed using MSK-IMPACT. A subset of 47 tumors from 24 patients with transformed or admixed LUAD-SCLC histology underwent 10x single-cell RNA sequencing compared to 10 *EGFR/TP53/RB1*-mutant LUAD (triple-mut), 17 *de novo* SCLC, and 4 normal lung samples, yielding ~140,000 cells. Analysis was performed using scanpy, scVI, CellRank, Palantir, SPECTRA, and GSEApy.
Results:
Among stage IV patients, we observed worse median overall survival (OS) in *EGFR*-wt T-SCLC (9.70 mos) and *de novo* SCLC (10.22 mos) compared to *EGFR*-wt LUAD (19.33 mos) and *EGFR*-mut T-SCLC (27.58 mos). T-SCLC showed a higher mean mutational burden (12.4 mut/Mb) compared to LUAD (6.7 mut/Mb) and *de novo* SCLC (9.0 mut/Mb). *TP53* and *RB1* were the most common mutations in both T-SCLC and *de novo* SCLC. Only 38% of T-SCLC had *EGFR* mutations. Mutation enrichment differed by genotype. *EGFR*-mut tumors displayed higher rates of *NFKB1, NKX2-1, FOXA1, CARD11, ELF3, RRAS2*, and *MDM4* mutations. *EGFR*-wt T-SCLC tumors were enriched in *MYC, KRAS, KEAP1, CDKN2A, SF3B1, CCND1,* and *FGF3* mutations. *PI3K/AKT* pathway alterations were enriched across both *EGFR*-wt and *EGFR*-mut T-SCLC compared to *de novo* SCLC. Single-cell analysis revealed enrichment of *MYC*, *PI3K/AKT*, chromatin remodeling, and stemlike gene programs in T-SCLC, especially early in transformation. We identified a basal-like signature highly active in LUAD immediately prior to transformation that was previously unrecognized in patients. The basal-like signature persisted in T-SCLC samples that had the highest intratumoral heterogeneity. A subset of triple-mut LUAD also expressed the basal-like signature, indicating a potential ‘pre-transformation’ stage. We observed trajectories leading to alternative squamous and mesenchymal fates as well.
Discussion:
Our data show that NE transformation is shaped by interplay between genotype and underlying transcriptional rewiring. While *EGFR*-mut and *EGFR*-wt tumors display differential mutational patterns, they converge on *PI3K/AKT* activating mutations and a shared basal-like precursor state, which primes tumors for transformation to NE, squamous, and mesenchymal fates. Our study underscores the clinical need to better understand NE transformation and highlights potential therapeutic vulnerabilities.

#1976 Pathogenic germline KEAP1 variants drive constitutive NRF2 hyperactivation and enhanced oncogenic fitness in non small cell lung cancer.

Laura Eibler, Miika M. Mehine, Rebecca Caeser, Esther Redin, Michael F. Berger, Chaitanya Bandlamudi, Charles M. Rudin

Memorial Sloan Kettering Cancer Center, New York, NY

KEAP1 is a key tumor suppressor, which is mutated in 15-20% of non-small cell lung cancers (**NSCLC**), ranking as the third most frequently altered gene. Somatic loss-of-function mutations disrupt the Cullin 3-based E3 ubiquitin ligase complex, preventing *NRF2* degradation and enabling its nuclear translocation. This drives metabolic reprogramming, ferroptosis resistance, and adaptation to oxidative stress, which are hallmarks of aggressive disease and poor survival. While somatic *KEAP1* alterations are established drivers of adverse prognosis, **the role of germline *KEAP1*** variants in cancer predisposition remains largely unknown. Using MSK-IMPACT paired tumor-normal sequencing, we analyzed 49.000 patients across 65 cancer types for rare germline variants predicted to be deleterious by VEP, REVEL, and AlphaMissense. We identified 35 carriers of pathogenic *KEAP1* candidates (12 truncating, 23 missense). In tumors from these carriers, we observed recurrent loss of the wild-type allele in NSCLC, and enrichment of somatic co-mutations in *STK11*.In this study we selected five novel *KEAP1* germline missense mutations (1438G>C, 1244G>A, 779G>T, 1524C>G, 1649T>A) to investigate their pathogenic impact on *NRF2* signaling and tumor cell fitness in NSCLC. *KEAP1* variant and wild-type (WT) plasmids were generated by site-directed mutagenesis and introduced via lentiviral transduction into NSCLC cell lines (A549, H460) using CMV-driven expression constructs. A549 and H460 harbor *STK11* and *KEAP1* co-mutations and were transduced with the *NRF2*-mediated ARE luciferase reporter plasmid. All five selected germline *KEAP1* variants exhibited significant **loss-of-function**, failing to suppress *NRF2* activity and resulting in **5-10-fold elevated ARE-luciferase reporter signal** compared to WT *KEAP1* ($P<0.001$) across all time points. Western blotting confirmed **disruption of KEAP1-NRF2 binding**, with **marked nuclear *NRF2* accumulation and cytoplasmic depletion** - phenocopying known somatic pathogenic mutants (959G>T). Functionally, variant-expressing NSCLC cells demonstrated **2-3-fold increases in colony number and size** ($P<0.01$), enhanced proliferation rates and increased expression of ferroptosis protective proteins (*AKR1C2, AKR1B10*), directly linking germline *KEAP1* dysfunction to oncogenic gain-of-function via *NRF2* hyperactivation. This study provides the first functional validation of germline *KEAP1* variants as **pathogenic drivers of inherited *NRF2* hyperactivation** in NSCLC, with loss-of-function severity equivalent to somatic mutations. These findings establish germline *KEAP1* testing as a critical tool for hereditary cancer risk assessment, enabling personalized therapeutic targeting strategies in high-risk families. This work has transformative implications for precision oncology and improved long-term outcomes in NSCLC.

#1977 Whole-genome sequencing of >8,000 TCGA samples reveals diverse and atypical spectra of homologous recombination deficiency in primary human cancers.

Mutations not only drive carcinogenesis but also record the evolutionary history of cancer. Homologous recombination deficiency (HRD), a defect in high-fidelity DNA double-strand break repair, produces characteristic mutational footprints that define an HRD phenotype. HRD has major clinical relevance as a predictor of response to DNA-damaging agents and targeted therapies, yet current HRD assays were developed primarily in breast and ovarian cancers, and their applicability to other tumor types remains unclear. We conducted a pan-cancer whole-genome analysis of >8,000 primary tumors from The Cancer Genome Atlas (TCGA), spanning ~30 cancer types, including ~900 breast and 300 ovarian cancers. We developed HRDecide, an HRDetect-derived framework that uses comprehensively annotated germline and somatic mutations in homologous recombination (HR) pathway genes, including structural variants and non-canonical splice alterations informed by recent advances in variant-effect prediction, to refine HRD identification across cancer types. Applying HRDecide to TCGA whole-genome sequencing data, we identified HRD-positive tumors and delineated their mutational signatures. HRD-associated features were broadly shared across cancers, extending beyond breast and ovarian tumors to include tumor types such as prostate, pancreatic, gastric, and hepatocellular carcinomas. These signatures encompassed canonical short deletions with microhomology as well as cancer type-specific patterns across substitution, indel, and structural variation profiles. Notably, we also characterized atypical HRD-like phenotypes that showed only a subset of components of the classical HRD signatures. The spectrum of inactivated HR pathway genes, and the predominant modes of disruption, point mutation, structural variation, and allelic loss, varied substantially by cancer type. The scale of this cohort enabled robust associations between HRD phenotypes and pathogenic mutations in HR pathway genes, such as *ATM*, *CHEK2*, and *RAD51B*, often truncated by structural variations and LINE-1 retrotranspositions, extending beyond the classical BRCA1/2, PALB2, and RAD51C events reported in PCAWG and Hartwig datasets. In summary, this pan-cancer study provides a comprehensive whole-genome landscape of HRD in primary tumors, revealing tissue-specific modes of repair failure and expanding the HRD spectrum beyond the BRCA-centered paradigm. These findings establish a reference framework for tissue-agnostic HRD biomarker development and therapeutic stratification across cancer types.

#1978 Copy number analysis of regulatory regions reveal recurrent promoter/enhancer somatic copy number alterations across >8,000 TCGA samples.

Haruna Tomono[1], Chunyang Bao[2], Antonia Kowalewski[1], David Lehotzky[1], Ron Solan[1], Matthew Leventhal[1], Luis Antonio Corchete Sanchez[1], David I. [1]Cancer Program, Broad Institute of MIT and Harvard, Cambridge, MA,[2]Inocras Inc., San Diego, CA,[3]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Somatic copy number alterations (SCNAs) are frequent oncogenic events. Previous studies have identified recurrent gene-level SCNAs using DNA microarray and whole exome sequencing data. These studies have also identified focal amplifications of regulatory regions. High-throughput whole genome sequencing enables deeper, comprehensive analysis of these focal SCNAs in non-coding regions, potentially revealing novel drivers of oncogenesis. To this end, we systematically analyzed SCNAs and structural variants in WGS data from >8,000 tumor-normal pairs across 31 cancer types from The Cancer Genome Atlas (TCGA) using GISTIC2.0 to identify focal, recurrent promoter and enhancer SCNAs near known oncogenes and tumor suppressor genes. We leveraged structural variant calls to orthogonally validate our primary focal SCNA findings. We identified a recurrent amplification event specific to the *EGFR* promoter/enhancer region in a subset of IDH-wildtype glioblastoma samples. This suggests an additional SCNA-driven mechanism for *EGFR* upregulation, distinct from canonical gene body amplification or point mutations, in a fraction of these aggressive tumors. Our ongoing work aims to broaden the landscape of regulatory SCNAs across cancers and validate their transcriptional impact to provide new biological insights and candidate therapeutic targets.

#1979 Genomic profiling of 1,104 consecutive, prospective meningiomas defines the population prevalence of molecular alterations and elucidates potential biomarkers of treatment response.

Minh P. Nguyen, Kanish Mirchia, **Brooke C. Braman**, Ramin A. Morshed, Nancy Ann Oberheim Bush, Javier E. Villanueva-Meyer, William C. Chen, Walter Patrick Devine, Arie Perry, David R. Raleigh

University of California San Francisco, San Francisco, CA

Background: Molecular profiling of meningioma has revealed biologic drivers and therapeutic vulnerabilities that have refined risk stratification and guided clinical trials. Most molecular studies of meningioma are limited to retrospective cohorts, and the population prevalence of meningioma genomic alterations is incompletely understood.
Methods: DNA mutations and copy number alterations (CNAs) were defined across a consecutive cohort of 1,104 meningiomas that were prospectively analyzed using the next-generation UCSF500 DNA sequencing assay at a single institution from 2019 to 2025.
Results: Meningiomas were CNS WHO grade 1 (49.4%), grade 2 (30.9%), grade 3 (7.0%), or undefined (12.7%). Median patient age was 60 years (range 2-91) and 64.1% were female. Patient race included white (39.2%), Asian (10.4%), Black or African American (3.6%), Native American or Alaska Native (0.6%), Native Hawaiian (0.3%), other Pacific Islander (0.3%), other (9.5%), or unknown. Ethnicity was reported as Hispanic or Latino in 125 cases (11.3%). Loss of chromosomes 22q (64.1%), 1p (40.7%), and 14q (22.3%) were the most common CNAs. Multivariate regression identified male sex, increasing age, and Asian vs. white race as significant predictors of multiple CNAs that are associated with poor clinical outcomes, including co-occurrent 1p loss/1q gain (odds ratio [OR] for male sex: 2.79, $p<0.001$; increasing age OR 1.02, $p=0.028$; Asian vs. white race OR 2.77, $p=0.001$). CNA burden was enriched in high grade meningiomas ($p<0.001$), and male sex (OR 10.1, $p<0.001$), increasing age (OR 1.04, $p=0.026$), and Asian vs. white race (OR 4.31, $p=0.047$) were significant predictors of higher CNA burden. The most common short somatic variants (SSVs) were in NF2 (53.6%) and TRAF7 (16.3%), which were mutually exclusive in all but 2 meningiomas. CDKN2A/B homozygous deletions and TERT promoter mutations were identified in 3.1% and 3.6% of meningiomas, respectively. Increasing age was a significant predictor of NF2 (OR 1.02, $p<0.001$) and TERT promoter mutation (OR 1.06, $p=0.001$), and Asian vs. white race was a significant predictor of CDKN2A/B mutation (OR 4.26, $p=0.003$). Median tumor mutation burden (TMB) was 3.4/megabase. Mutations in ARID1A ($p<0.001$), ARID2 ($p=0.028$), CDKN2A/B ($p=0.017$), KMT2D ($p=0.011$), SMARCB1 ($p=0.0061$), TERT ($p<0.001$), TET2 ($p=0.019$), and TP53 ($p=0.0033$) were associated with elevated TMB. Increasing age (OR 1.01, $p=0.02$) and Asian (OR 5.02, $p<0.001$) and Black (OR 2.54, $p=0.004$) vs. white race were significant predictors of higher TMB.
Conclusion: Prospective next-generation DNA sequencing of consecutive meningiomas defines the population prevalence of molecular alterations. These data fill a critical gap in the understanding of biological drivers of meningioma behavior and therapeutic response across demographic groups.

#1980 Pan-cancer LINE-1 retrotransposition landscapes in TCGA whole-genome sequences.

Beomki Lee[1], Ryul Kim[2], Chunyang Bao[2], Hansol Park[2], Gang-Hee Lee[2], Jonghoon Lee[2], Yoonsuh Lee[2], Won-Chul Lee[2], David Lehotzky[3], Ron Solan[3], Antonia Kowalewski[3], Xavi Loinaz[3], Vasuki Narasimha Swamy[3], David I. Heiman[3], Samantha Van Seters[3], Saveliy Belkin[3], Sam Wiseman[3], Andrew D. Cherniack[3], Luis Antonio Corchete Sanchez[3], Brian P. Danysh[3], Zachary Everton[3], Chip Stewart[3], Haruna Tomono[3], Gengchao Wang[3], Esther Rheinbay[3], Gad Getz[3], Cheng-Zhong Zhang[3], Young Seok Ju[2]

[1]Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[2]Inocras Inc., San Diego, CA,[3]Broad Institute, Cambridge, MA

Overexpression of LINE-1 (L1) elements is recognized as a hallmark of many cancers, yet their activity and the number of somatic LINE-1 retrotranspositions (soL1Rs) vary markedly across tumor types. Despite their ubiquity in certain cancers, such as esophageal and colorectal carcinomas, the biological significance of transposable elements in cancer development remains underappreciated. To elucidate the contribution of L1 activity to oncogenesis, we analyzed whole-genome sequencing (WGS) data from >8,000 tumor-normal pairs in The Cancer Genome Atlas (TCGA). In total, we identified over 132,000 soL1R events, with their distribution differing widely across cancer types. The highest soL1R burdens were observed in esophageal carcinoma (ESCA, 134.2 events per case), bladder carcinoma (BLCA, 74.0), head and neck squamous cell carcinoma (HNSC, 56.3), lung squamous cell carcinoma (LUSC, 53.3), colon adenocarcinoma (COAD, 29.7), and rectal adenocarcinoma (READ, 16.8). The number of transductions correlated strongly with the overall soL1R burden in each cohort. Activity of germline LINE-1 source elements, inferred from transduction counts, identified 22q12.1-2 as the most active locus, followed by Xp22.2-2, 5q14.3-2, and 14q23.1. Using L1 transduction events, we further discovered 12 previously unreported germline LINE-1 source loci. Functional analysis revealed that soL1R events contribute to oncogenesis through both direct disruption of tumor suppressor genes and complex genomic rearrangements mediated by retrotransposition. In summary, this population-scale WGS analysis delineates the pan-cancer landscape of somatic LINE-1 retrotranspositions, uncovers novel germline source elements, and highlights the multifaceted role of soL1R activity in cancer genome evolution.

#1981 Absence of somatic copy number alterations in non-neoplastic prostate epithelium.

Hicks[3], Tracy Jones[3], Roy Elias[6], Alyza Skaist[3], Jennifer Meyers[3], Kornel Schuebel[3], Christopher M. Heaphy[7], Alan K. Meeker[6], William G. Nelson[8], Angelo Michael De Marzo[3], Srinivasan Yegnasubramanian[1]

[1]Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Pathology, University of Illinois Chicago, College of Medicine, Chicago, IL,[3]Johns Hopkins University School of Medicine, Baltimore, MD,[4]Johns Hopkins Univ., Baltimore, MD,[5]Kocaeli University, İzmit, Turkey,[6]Johns Hopkins University, Baltimore, MD,[7]Boston University, Boston, MA,[8]Sidney Kimmel Comprehensive Cancer Center, Cockeysville, MD

Somatic copy number alterations (CNA) in cancer driver genes are a hallmark of human cancers, but have recently been reported in benign tissues in a handful of organ systems, including the prostate. However, these recent findings may be confounded by technical limitations and challenges in accurately ruling out cancer precursors such as intra-epithelial neoplastic lesions, particularly in frozen tissue. To address this, we used a panel of molecular markers to definitively distinguish benign glands from prostatic intra-epithelial neoplasia (PIN) and invasive cancer in frozen tissue sections, and used this as a guide for laser capture microdissection followed by whole genome sequencing to assess copy number alterations. Our analysis of 171 benign samples from 138 subjects revealed a complete absence of large copy number alterations (LCNA) in benign epithelium, including at key driver genes such as MYC, PTEN, RB1, and APC. In contrast, a significant fraction of PIN exhibited intermediate LCNA levels between benign and cancer. A post-hoc review of these copy number altered PIN lesions indicated that they would have been highly difficult to distinguish morphologically from benign prostate without the use of the panel of molecular markers. These results highlight the importance of rigorous molecular approaches for tissue diagnosis in frozen tissue and suggest that previous reports of CNA in benign prostate may reflect misidentified PIN.

#1982 Genomic analyses of patient-derived xenografts reveal novel molecular subsets of PDAC and their association with clinical features.

Chani Stossel[1], Rotem Tal[2], Rouven Hoefflin[2], Maria Raitses-Gurevich[1], Dikla Atias[1], Yulia Glick Gorman[1], Gali Altman[1], Tamar Beller[1], Talia Golan[1], Itay Tirosh[2]

[1]Sheba Medical Center, Tel Hashomer, Israel,[2]Weizmann Institute of Science, Rechovot, Israel

Pancreatic ductal adenocarcinoma (PDAC) is a dismal disease with limited therapeutic options. We have established a large-scale RNA-seq dataset comprised of >120 PDAC patient-derived xenograft (PDX) models and >300 bulk RNA-seq specimens (when counting biological replicates). This cohort includes diverse PDAC clinical manifestations, such as patients with particularly low survival (<8 weeks) that are under-represented in other large-scale efforts (e.g. TCGA). Our analysis identified two transcriptional programs with a highly heterogeneous expression among the basal-like models: a unique partial-Epithelial-to-Mesenchymal program (Basal-Mesenchymal) and an epithelial senescence-associated program (Basal-EpiSen), reminiscent of the pan-cancer epithelial senescence-associated program that we recently described in other epithelial malignancies. Notably, high expression of the Basal- Mesenchymal program is strongly associated with low-survival and with models established from patient's tumors at terminal stage. Next, we compared representative Basal- Mesenchymal and Basal-EpiSen PDAC cell lines across the comprehensive Cancer Cell Line Encyclopedia (CCLE) drug response dataset. Our initial results show differential drug sensitivity and gene dependencies between the Basal- Mesenchymal and Basal-EpiSen subsets, highlighting their potential clinical significance. We show that the Basal-like subtype diverges into two distinct clinically-relevant subsets. Taken together, our work provides an unprecedented resource towards improving PDAC molecular classification, an essential step for PDAC precision medicine.

#1985 Optimizing precision oncology: A large scale clinico-genomic analysis of WES versus targeted panels in 37,898 patients.

Jing Hu[1], Minghui Wang[2], Junqiang Yin[3], Aibo Xia[1], Zanmei Xu[4], Shaohua Yuan[4], Yannan Zhu[4], Kunxu Xu[4], Yimin Guan[4], Haiyin Huang[4], Kai Wang[4]

[1]The First People's Hospital of Yunnan Province, KunMing, China,[2]Sun Yat-sen Memorial Hospital, Guangzhou, China,[3]First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China,[4]OrigiMed, Shanghai, China

Background: Next-generation sequencing (NGS) is now routine in oncology practice, but clinicians still face uncertainty about how whole-exome sequencing (WES) compares with large targeted panels for identifying actionable alterations and guiding immunotherapy decisions. We addressed this by benchmarking these platforms within a massive clinico-genomic cohort to define their specific clinical utility.

Methods: We retrospectively analyzed 37,898 tumor-normal pairs tested in a CAP/CLIA-certified laboratory: 3,360 WES tests (covering ~20,000 genes) and 34,538 hybrid capture targeted panels (covering ~500 cancer genes). We compared detection rates for single nucleotide variants (SNVs), copy number variants (CNVs), and rearrangements. Clinical variables, including stage and treatment history, were integrated to evaluate molecular patterns.

Results: WES cases were enriched for lung adenocarcinoma, gastric, and colorectal cancers, whereas panel testing was dominated by lung adenocarcinoma, colorectal cancer, and hepatocellular carcinoma. Across all tumors, 701,119 somatic alterations were identified. WES yielded a mean of 76.7 alterations per patient and panels 12.8 per patient. Although WES covered the entire exome and detected clinically expected events such as >20% *ERBB2* amplification in breast cancer and >4% *ALK* fusions in lung adenocarcinoma, its overall CNV and fusion detection remained clearly lower than panel, which showed much higher sensitivity due to deeper, specially targeted coverage. Mean TMBs were 6.5 muts/Mb (WES) and 8.8 muts/Mb (panel), with good agreement between platforms; overall, 17.0% of patients were TMB-High (≥10 muts/Mb). On both platforms, TMB-H was most frequent in endometrial carcinoma, lung squamous cell carcinoma, and urothelial carcinoma, while pancreatic and clear cell renal carcinomas showed very low TMB. Importantly for clinical decision making, early stage patients also harbored TMB-H tumors, indicating that potential candidates for immune checkpoint inhibitors are not restricted to advanced disease. Treatment-naïve patients had higher TMB-H rates than previously treated patients (22.5% vs 16.2%), consistent with therapy-driven clonal selection and supporting baseline TMB testing at initial diagnosis. The most frequently mutated genes were similar across platforms (*TP53*, *EGFR, KRAS*). Actionable alterations were common: 68.1% of panel cases carried at least one actionable gene.

Conclusions: In this largest real world clinico-genomic cohort of Chinese cancer patients, we define the complementary utility of each platform. Whereas targeted panels excel at detecting clinically actionable alterations, WES delivers a comprehensive genomic blueprint that is well suited as a baseline for future minimal residual disease monitoring and the identification of novel biomarkers.

#1986 The pan-cancer landscape of chromosome Y alterations.

Luis Antonio Corchete Sanchez[1], Chunyang Bao[2], Saveliy Belkin[3], Andrew D. Cherniack[3], Brian P. Danysh[3], Zachary Everton[3], David I. Heiman[3], Ryul Kim[2], Antonia Kowalewski[3], Gang-Hee Lee[2], Won-Chul Lee[2], David Lehotzky[3], Xavi Loinaz[3], Vasuki Narasimha Swamy[3], Hansol Park[2], Ron Solan[3], Chip Stewart[3], Haruna Tomono[3], Samantha Van Seters[3], Gengchao Wang[1], Sam Wiseman[3], Young Seok Ju[2], Gad Getz[3], Esther Rheinbay[1]

[1]Krantz Family Center for Cancer Research, Massachusetts General Hospital Cancer Center, Charlestown, MA,[2]Inocras Inc., San Diego, CA,[3]Broad Institute of MIT and Harvard, Cambridge, MA

Background: Despite the well-documented male bias in the incidence and mortality of most non-sex-specific cancers, the Y chromosome (chrY) remains as a genomic blind spot. Major pan-cancer genomic consortia, including The Cancer Genome Atlas (TCGA) and PCAWG, have historically excluded the chrY from somatic analyses due to computational challenges related to its haploid state, repetitive structure, and homology with the X chromosome. Consequently, the somatic landscape of chrY alterations, including complete loss of Y (LOY), structural variants (SVs), single-nucleotide variants (SNVs), and INDELs, remains largely uncharacterized.
Methods: We implemented a pan-cancer computational framework utilizing deep whole-genome sequencing (WGS) data from a comprehensive re-analysis of 26 cancer types from the TCGA cohort. We developed and applied a novel bioinformatic pipeline to accurately call somatic LOY, complex SVs, SNVs, and INDELs. The pipeline was specifically designed to overcome analytical challenges of the chrY, including its repetitive structure and the correct handling of pseudoautosomal regions (PARs). Potential artifacts were flagged using variant-support metrics and by identifying breakpoints in problematic regions.
Results: The analysis revealed a highly heterogeneous landscape of chrY alterations across tumor types. We found a high prevalence of somatic SVs in some tumor types, such as bladder (BLCA), head and neck (HSNC), stomach (STAD), and prostate (PRAD) cancers, while others, like thyroid (THCA) and renal clear cell carcinoma (KIRC), were rarely affected. In affected tumors, the SV landscape included numerous inter-chromosomal translocations, which often showed low variant allele frequency (VAF), suggesting a subclonal origin. In contrast, the clonality of chrY deletions varied across cancer types. The SNV/INDEL burden was substantial in certain cancers, for example, in glioblastoma (GBM) and PRAD, but was concentrated in non-coding regions, with protein-coding mutations being infrequent. Interestingly, we observed a chrY SNV spectrum enriched in C>T and T>C substitutions across several tumor types.
Conclusion: We developed a computational framework to systematically analyze the Y chromosome across multiple cancer types, overcoming historical analytical challenges. Our results reveal a diverse spectrum of somatic alterations, including structural variants and point mutations. These findings provide the first comprehensive, pan-cancer map of the somatic chrY landscape.

#1988 Human and viral whole genome sequencing identify HPV and APOBEC as oncogenic drivers in sinonasal squamous cell carcinoma.

Harrison B. Chong[1], Michael E. Bryan[2], Maoxuan Lin[1], Magdy Gohar[1], William C. Faquin[3], Lisa J. Mirabello[4], James S. Lewis[5], Michael S. Lawrence[6], **Daniel Faden**[7]

[1]Krantz Family Center for Cancer Research, Massachusetts General Hospital, Boston, MA,[2]Otolaryngology-Head and Neck Surgery, Mass General Brigham, Boston, MA,[3]Pathology, Massachusetts General Hospital, Boston, MA,[4]NCI Div. of Cancer Epidemiology & Genetics, Bethesda,[5]Otolaryngology-Head and Neck Surgery, Vanderbilt University Medical Center, Nashville, TN,[6]Broad Institute of Harvard and MIT, Cambridge, MA,[7]Mass General Brigham, Boston, MA

Background:
Sinonasal squamous cell carcinoma (SNSCC) is a rare, aggressive malignancy with limited molecular characterization. Emerging evidence implicates human papillomavirus (HPV) in a subset of cases, but the genomic interplay between viral and host factors remains poorly defined.

Methods:
We performed paired host and viral whole-genome sequencing (WGS) on 21 SNSCC tumors with matched normal samples, including ultra-deep viral WGS (10,000×) and comprehensive HPV PCR genotyping. Somatic mutations, viral integration, structural variants, and mutational signatures were analyzed using established computational pipelines.

Results:
Eighteen of 21 (86%) tumors were HPV-positive by WGS or PCR, with 94% concordance across assays. Unlike oropharyngeal squamous cell carcinoma (OPSCC), where HPV16 predominates, SNSCC exhibited nine HPV genotypes, including HPV11, 18, 35, 39, 45, 51, 56, and 59. Viral integration events were detected in most HPV-positive tumors, including an HPV45-TP63 fusion amplified as extrachromosomal DNA (ecDNA), representing, to our knowledge, the first HPV-associated ecDNA-like amplicon in SNSCC. Multi-genotype infections showed a single dominant integrating type, indicating that one “driver” genotype typically initiates tumorigenesis. Host mutational analysis revealed recurrent clonal mutations in PIK3CA, CHEK2, and KDM6A, with depletion of TP53 and CDKN2A alterations in high-risk HPV+ cases. Mutational signature analysis identified predominant APOBEC3 activity, independent of smoking, which extended to viral genomes, providing direct evidence of concurrent host-virus APOBEC mutagenesis. Structural variants were common, including focal PTEN loss and complex rearrangements such as chromothripsis and chromoplexy, underscoring pervasive genomic instability.

Conclusions:
Paired human and viral WGS reveals that HPV drives tumorigenesis in SNSCC through diverse genotypes, APOBEC-mediated mutagenesis, and integration-linked ecDNA formation. These mechanisms expand the known spectrum of viral oncogenesis beyond the oropharynx, highlighting novel routes of genomic instability and supporting the inclusion of broad HPV genotyping and viral-genomic assays in diagnostic and translational frameworks for SNSCC.

#1989 Systematic discovery and classification of structural variant drivers across >8,000 TCGA whole genomes.

Antonia Kowalewski[1], Xavi Loinaz[1], Hansol Park[2], Vasuki Narasimha Swamy[1], David Heiman[1], Samantha Van Seters[1], Saveliy Belkin[1], Sam Wiseman[1], Chunyang Bao[2], Andrew D. Cherniack[1], Luis A. Corchete Sanchez[1], Brian P. Danysh[1], Zachary Everton[1], Ryul Kim[2], Gang-Hee Lee[2], Won-Chul Lee[2], David Lehotzky[1], Ron Solan[1], Chip Stewart[1], Haruna Tomono[1], Gengchao Wang[1], Rameen Beroukhim[1], Young Seok Ju[2], Esther Rheinbay[1], Gad Getz[1]

[1]Broad Institute, Cambridge, MA,[2]Inocras Inc., San Diego, CA

Structural variants (SVs)—large-scale genomic deletions, duplications, inversions, and translocations—can promote tumorigenesis by activating proto-oncogenes, disrupting tumor suppressors, generating oncogenic fusions, rewiring gene regulation, and mediating catastrophic events such as chromoplexy and chromothripsis. Yet, the role of SVs as cancer-driving mutations remains less comprehensively characterized than that of single-nucleotide variants or indels, largely due to the historic scarcity of tumor whole-genome sequencing data required for accurate SV detection. In this study, we analyzed whole-genome sequencing data from >8,000 tumor-normal pairs spanning 31 cancer types from The Cancer Genome Atlas (TCGA) to systematically characterize SVs at unprecedented scale. Compared with the flagship Pan-Cancer Analysis of Whole Genomes (PCAWG) project, our analysis includes roughly four times as many samples and six additional cancer types. Somatic SVs were identified using a custom pipeline combining Manta and dRanger with optimized downstream filters. Across all tumors, we detected >1 million somatic SVs. We developed two complementary frameworks to interpret these variants. First, to classify SVs by their genomic architecture, we inferred genomic segments and their associated copy number alterations driven by SVs ranging from a single to hundreds of breakpoints, enabling the generalization of distinct patterns through unsupervised clustering. Second, to identify candidate driver genes, we developed SVelfie, a statistical framework that detects genes significantly enriched in functional SVs predicted to confer gain- or loss-of-function effects. Applying SVelfie to 385 prostate and 333 ovarian cancer genomes revealed multiple novel candidate driver genes, with additional discoveries expected as analysis extends to the full >8,000-sample dataset. This work represents the most comprehensive analysis to date of SV drivers in cancer. By uniting large-scale WGS data with new computational frameworks for SV classification and driver detection, we expand the catalog of SV-driven cancer genes, illuminate mechanisms of SV-mediated oncogenesis, and advance the clinical utility of whole-genome sequencing in precision oncology.

#1990 Pan-cancer PCR-free whole-genome sequencing refines the somatic driver landscape beyond exome sequencing alone.

Gengchao Wang[1], David I Heiman[2], Vasuki Narasimha Swamy[2], Chip Stewart[2], Xavi Loinaz[2], Ron Solan[2], Chunyang Bao[3], David Lehotzky[2], Brian P Danysh[2], Luis Antonio Corchete Sanchez[1], Zachary Everton[2], Sam Wiseman[2], Antonia Kowalewski[2], Samantha Van Seters[2], Saveliy Belkin[2], Haruna Tomono[2], Andrew D Cherniack[2], Ryul Kim[3], Gang-Hee Lee[3], Won-Chul Lee[3], Hansol Park[3], Rebecca Jang[3], Young Seok Ju[3], Gad Getz[2], Esther Rheinbay[1]

[1]Krantz Family Center for Cancer Research, Massachusetts General Hospital Cancer Center, Charlestown, MA,[2]Cancer Program, Broad Institute of MIT and Harvard, Cambridge, MA,[3]Inocras Inc., San Diego, CA

Background: The initial TCGA exome sequencing project established a foundational catalog of somatic mutations. However, capture biases and limited coverage in GC-rich and repetitive regions may have obscured bona fide driver events and introduced systematic “blind spots” in the landscape of protein-coding genes. Leveraging high-depth, PCR-free whole-genome sequencing (WGS), we revisited the somatic mutation landscape in multiple tumor types to enhance driver discovery by improving sensitivity in GC-rich regions and reducing artifact-driven false positives.

Methods: We analyzed matched tumor–normal PCR-free WGS data from >8,000 TCGA cases across several cancer types with existing previously published somatic mutation calls from whole exome sequencing (WES) data, applying a unified best-practice pipeline for SNV/indel detection and stringent post-calling filters. We focused on (i) concordance between WGS and exome across coding regions, (ii) coverage, allele fraction, and local sequence context (GC content, segmental duplications) of discordant sites, and (iii) recurrence and positional clustering of variants in established cancer genes.

Results: PCR-free WGS identified substantially more high-confidence coding mutations than WES, with the greatest gains in GC-rich exons and difficult-to-capture loci. This increased sensitivity uncovered additional pathogenic or likely pathogenic variants in canonical drivers, including *TP53* and *FOXA1* in breast cancer, *EGFR* in glioblastoma, and *BAP1* in uveal melanoma (UVM), thereby strengthening known genotype–phenotype associations. In UVM, we observed an indel in the *BAP1* 5′UTR/promoter region that was systematically missed by WES but supported by robust read evidence in WGS data, nominating an expanded spectrum of BAP1-disrupting events with potential regulatory and clinical relevance. Conversely, we found a subset of WES-only calls localized to segmental duplications or low-support sites, consistent with technical artifacts. Integrated re-annotation of discordant calls thus both eliminates spurious events and reveals underappreciated driver mutations and mechanisms.

Conclusions: Our systematic comparison demonstrates that PCR-free WGS can refine the somatic mutation and driver landscape beyond exome-based catalogs, particularly in GC-rich and regulatory regions. These results advocate for re-interrogation of previously profiled tumor types with contemporary WGS to achieve a more complete and accurate map of cancer-driving alterations.

#1991 Germline predisposition in The Cancer Genome Atlas (TCGA) whole-genome sequencing datasets.

Ryul Kim[1], Owen Hirschi[2], Matthew Leventhal[3], Chunyang Bao[1], Hansol Park[1], Gang-Hee Lee[1], Won-Chul Lee[1], Jonghoon Lee[1], Yoonsuh Lee[1], Beomki Lee[4], David Lehotzky[5], Ron Solan[5], Antonia Kowalewski[5], Xavi Loinaz[5], Vasuki Narasimha Swamy[5], David I. Heiman[5], Samantha Van Seters[5], Saveliy Belkin[5], Sam Wiseman[5], Andrew D. Cherniack[5], Luis Antonio Corchete Sanchez[5], Brian P Danysh[5], Zachary Everton[5], Chip Stewart[5], Haruna Tomono[5], Gengchao Wang[5], Esther Rheinbay[5], Gad Getz[5], Cheng-Zhong Zhang[3], Matthew L. Meyerson[2], Young Seok Ju[1]

[1]Inocras, San Diego, CA,[2]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[3]Department of Data Science, Dana-Farber Cancer Institute, Boston, MA,[4]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[5]Cancer Program, Broad Institute of MIT and Harvard, Cambridge, MA

The goal of The Cancer Genome Atlas (TCGA) has been to continually characterize the genomic and transcriptomic landscapes across diverse malignancies. In this analysis, we assess matched tumor-normal Whole-Genome Sequencing (WGS) data from a previously sequenced set of adult cancer patients to identify germline pathogenic variations. These latest TCGA data consist of cancer patients from varied ancestral backgrounds with solid tumors and lymphoid cancers and patient-matched normal samples, consisting of blood or tissue. We have now obtained high-quality tumor and normal WGS data from over 8,000 samples, including normal samples derived mainly from the patient-matched blood samples. To discover novel links between genetics and cancer predisposition, we are analyzing germline variants—including single-nucleotide variants (SNVs) and structural variants (SVs)—in known cancer genes, as well as in genes with recurrent mutations that may have been missed or previously could not be assessed using exome or low-coverage genome studies.We have conducted a preliminary analysis focused on identifying Pathogenic or Likely Pathogenic (P/LP) variants, classified according to American College of Medical Genetics and Genomics guidelines, in cancer predisposition genes. This initial pass on a majority of samples confirmed the presence of P/LP variants across the cohort in canonical cancer predisposition genes, including *BRCA1*, *BRCA2*, *ATM*, and other genes integral to the mismatch and DNA repair pathways. Across cohorts, we identified known P/LP germline variants in established cancer predisposition genes in less than 10% of all cases, with the largest number of variants identified in *BRCA1/2*, aligning with previous published work. The prevalence of P/LP variants was not uniform across cancer types, with some showing an enrichment, including breast cancer, while other cancer types, like low-grade gliomas, demonstrated a lower prevalence than the average. These findings underscore the highly variable, tumor-specific landscape of germline predisposition.We continue to leverage this comprehensive WGS dataset as a key resource for ongoing analyses of germline-somatic interactions. We are actively investigating how these germline P/LP variants shape the tumor's somatic mutational landscape and contribute to oncogenesis. We are also investigating whether haplotype-specific copy number alterations contribute to the pathogenicity of identified germline cancer risk alleles. Further work includes characterizing both structural and complex non-coding pathogenic variants that were previously inaccessible in exome or low-coverage WGS studies.

#1992 Delineating genomic instability dynamics in breast cancer by bulk and single-cell whole genome sequencing.
Konstantinos L. Georgiadis, Sen Li, Thomas Hatschek, Theodoros Foukakis, Nicola Crosetto

Karolinska Institutet, Stockholm, Sweden

The aim of this study is to chart the evolution of genomic instability in response to treatment in hormone receptor-positive/HER2-negative ($HR^+/HER2^-$) breast cancer, the most prevalent breast cancer subtype, comprising approximately 70% of cases. Copy number alterations (CNAs) are a hallmark of aggressive $HR^+/HER2^-$ tumors and have been proposed as prognostic biomarkers; however, their temporal dynamics during therapy remain insufficiently characterized. Here, we utilized tissue biopsies collected in the context of the PREDIX Luminal B clinical trial (NCT02603679), which aims to evaluate the role of paclitaxel chemotherapy versus the combination of endocrine treatment with the CDK4/6 inhibitor palbociclib in the neoadjuvant setting. We conducted bulk whole genome sequencing (WGS), whole exome sequencing (WES) and RNA sequencing of tissue biopsies (n = 169 patients) collected before and after treatment. In a subset of the study cohort, we also performed single-cell WGS (n = 15 patients, 8,387 cells) on samples before and after each treatment modality. Bulk sequencing data analysis and correlation with clinical outcomes indicated candidate genomic regions linked to therapeutic response, including arm-level gains and losses selectively enriched in post-treatment samples of patients who responded to treatment. Integration with RNA-sequencing data revealed gene-dosage relationships on amplified or deleted chromosomal regions and highlighted genes with potential functional impact. Moreover, single-cell WGS further resolved the subclonal architecture of these tumors, indicating that most patients exhibit limited subclonal complexity. Neoadjuvant treatment reshaped the tumor genomic landscape through expansion or contraction of pre-existing subclones rather than emergence of new subclones. Correlation of response to treatment with subclonal shift patterns demonstrated that non-responding tumors display pronounced alterations in their subclonal composition whereas responding tumors present heterogeneous patterns of subclonal dynamics. Our findings suggest that interpatient variability in treatment response is driven by clonal remodeling of pre-existing subclones rather than de novo subclone generation, and that recurrent CNAs may serve as predictive biomarkers of neoadjuvant treatment efficacy.

#1993 Real-world landscape of KMT2A and NPM1 variants and fusions in hematologic malignancies (2020-2025).

Roisin Puentes, Madhuri Paul, Ryan Bender, Amber Chevalier, Nathan Montgomery

NeoGenomics, Fort Myers, FL

Background: KMT2A rearrangements and NPM1 mutations are key genomic drivers in myeloid neoplasms, informing diagnosis, prognostication, MRD assessment, and emerging targeted therapies. Large-scale real-world data are needed to clarify testing trends, positivity rates, and co-mutational patterns across hematologic indications.
Methods: We analyzed all KMT2A and NPM1 tests performed in a national reference laboratory cohort from 10/1/2020-9/30/2025. Test modality, indication, and positivity were evaluated, as well as variant classification, fusion partners, and aggregated co-mutations for positive cases.
Results: Across the study period, 201,381 KMT2A and 202,902 NPM1 tests were performed, with positivity rates of 2.6% and 3.1%, respectively. Annual testing volume increased substantially for both markers, driven by hospital-based ordering and expanding NGS utilization. Testing spanned both sexes and all ages, with most samples originating from patients ≥65 years. Top testing indications were MDS, AML, and MPN/CMML. KMT2A positivity was most frequent in AML (1,964), MPN (1,369), and MDS (353). NPM1 positivity was enriched in MDS (6,170), AML (1,191), and CMML (541). Over time, use of NGS expanded significantly from 2021 onward, becoming the dominant modality for NPM1 testing and complementing ongoing FISH testing for KMT2A, with positivity detected across both platforms. Among KMT2A-positive cases, SNVs (86%) and fusions (9%) were observed, with most pathogenic findings occurring in fusion-positive samples. Common fusion partners included MLLT3, AFF1, ELL, MLLT4, and MLLT10. Recurrent co-mutations involved TP53, KRAS/NRAS, TET2, FLT3, DNMT3A, and ASXL1. Within AML, 273 of 1,964 KMT2A-positive patients harbored a fusion. NPM1-positive variants were predominantly pathogenic (65%), with co-alterations spanning SNVs, insertions/deletions, and rare fusions. The most frequent co-mutations involved TET2, DNMT3A, FLT3, IDH2, NRAS, and SRSF2.
Conclusions: Testing for KMT2A and NPM1 nearly doubled over five years, driven by widespread adoption of NGS, continued FISH utilization, and increasing clinical relevance of genomically guided therapies for KMT2A- and NPM1-mutated disease, particularly in AML. These findings define a comprehensive real-world genomic profile of KMT2A-rearranged and NPM1-mutated hematologic malignancies and support ongoing efforts in diagnosis, prognostication, and therapeutic development.

#1994 Integrative multi-omic analysis reveals subtype-specific impact of extrachromosomal DNA in melanoma.

Sharadha Sakthikumar, Bryce Turner, Jeffrey Trent, ALEKSANDAR SEKULIC

TGen (The Translational Genomics Research Institute), Phoenix, AZ

Extrachromosomal DNA (ecDNA) drives oncogene amplification, transcriptional deregulation, and therapeutic resistance in cancer, but its prevalence and impact in melanoma remain unclear. We analyzed 470 TCGA-SKCM samples with whole-genome (n = 223), whole-exome (n = 247), and RNA sequencing (n = 469). Tumors were classified as BRAF/NRAS/NF1-mutant (BNN, n = 396) or triple wild-type (TWT, n = 74). ecDNA detection was performed using *AmpliconArchitect* (AA) and *Gene-level Circular Amplicon Prediction* (GCAP). Multi-omic analyses assessed transcriptional, immunologic, and clinical correlates. ecDNA was detected in 133 tumors (28%; 47 by AA, 133 by GCAP, 39 overlapping), with higher prevalence in TWT tumors (51%) than BNN tumors (26%; $\chi^2 = 17.88$, $p = 2.4 \times 10^{-5}$). Frequently amplified ecDNA genes included *MDM2, CDK4, CCND1, BIRC2/3, PAK1, GAB2,* and *RSF1*, implicating proliferation, apoptosis evasion, and chromatin regulation. In an effort to assess putative functional impact, we performed various transcriptomic analyses which identified upregulation of amplified oncogenes (*GAB2, MDM2, RSF1, CCND1, PAK1*). In addition, gene set enrichment analyses with MutSigDB (against Hallmark genes) shows strong enrichment of pathways associated with enhanced cell proliferation, such as MYC and E2F targets in ecDNA+ tumors. In addition, cell deconvolution methods reveal immune cell composition varies across subtypes, highlighting potential unique immunomodulatory effects. Survival analysis indicated worse overall survival in ecDNA+ tumors ($p = 0.016$), driven by TWT cases ($p = 0.0048$). ecDNA is prevalent in melanoma, particularly in TWT tumors, where it promotes oncogene amplification, immunomodulatory reprogramming, and poor prognosis. These results highlight ecDNA as a potential biomarker for stratification and targetable vulnerability in TWT melanoma.

#1995 Clinicogenomic landscape of IPMN-derived pancreatic cancer.

Peter Y. Yu, Joseph R. Habib, Jonah Levine, Brock Hewitt, Michael D. Kluger, Katherine A. Morgan, Anirban Maitra, Christopher Wolfgang, Ammar A. Javed, Greg Sacks

NYU Langone Health, New York, NY

Further understanding of the genomic alterations in intraductal papillary mucinous neoplasm (IPMN)- derived pancreatic cancer and associations with survival outcomes is necessary to identify tailored therapy and improve outcomes. We reviewed resected IPMN-associated pancreatic cancer cases from 2012 to 2025 and identified cases of pancreatic ductal adenocarcinoma (PDAC) where pathology demonstrated that the invasive component arose from an IPMN (not concomitant PDAC). 38 patients with corresponding comprehensive genomic profiling results were identified and clinical characteristics and outcomes data were collected. 30 patients (79%) had KRAS mutated (mt) and 8 patients (21%) had KRAS wild type (WT) tumors. 12 tumors (32%) were mtGNAS and 26 tumors (68%) were GNAS WT. Further examining mtKRAS in the context of mtGNAS, 23 patients' tumors (61%) had mtKRAS alone, 7 (18%) with KRAS and GNAS co-mutation, 5 (13%) with mtGNAS alone, and 3 patients (8%) had neither mutation. KRAS wild type (WT) tumors associated with better overall survival (OS) and disease-free survival (DFS) compared with mtKRAS tumors. mtGNAS tumors associated with better DFS compared with GNAS WT tumors. In the 5 mtGNAS-only tumors, there was an enrichment of CCND2 and MYC gene family co-amplifications (3 out of 5). The other two mtGNAS-only cases had BRAF and MAP2K1 (MEK) mutations. 7 cases (18%) harbored ATM mutations and 2 cases (5%) of RNF43 mutations were identified. In univariate cox regression analysis, only lymphovascular invasion (LVI) was significantly associated with OS. LVI and node positivity were significantly associated with DFS. Despite limited numbers of patients, we have identified KRAS WT and mtGNAS as potential prognostic biomarkers for IPMN-derived PDAC.

#1996 Base editing for systematic reclassification of variants of unknown significance in NF1.

Sara Galavotti[1], Elena Endrizzi[1], Emanuele Bonetti[1], Gabriele Picco[2], Gianmaria Frige[1], Pier Giuseppe Pelicci[1], Luca Mazzarella[1]

[1]Department of Experimental Oncology, Fondazione Istituto Europeo di Oncologia e Centro Cardiologico Fondazione Monzino, Milano, Italy,[2]Wellcome Sanger Institute, Hinxton, United Kingdom

NF1 is an established tumor suppressor, frequently mutated in cancer genomes and responsible for the cancer-predisposing syndrome neurofibromatosis. NF1 is very large (~350 kb) and has one of the highest mutation frequency in the human genome. Due to incompletely understood biology of the coded protein, high sequence homology, allelic heterogeneity and lack of functional assays, the interpretation of NF1 variants is highly challenging in clinical practice. According to the *ClinVar* database, 13460 NF1 variants are listed (data extracted up to July 2024) with missense variants being the most represented type, of which 84.8% are variant of unknown significance - VUS.We recently identified a novel function in microtubular damage repair for NF1 (Duso et al Biorxiv 2025). NF1-deficient cells become highly sensitive to microtubule-depolymerising maytansinoids like DM1. We designed a high-throughput base editing screen that exploits this differential sensitivity to identify NF1 variants that lead to its loss of function.SpliceR was employed to design control guides (non targeting, intragenic and splice essential and non essential targeting regions) while for gRNAs directing to NF1, the BEstimate tool was utilised. As a model, we generated HER2+ breast cancer cell line, HCC-1954 and to 293T cells to stably express lentiviral cytidine-(CBE) and adenosine-base editors (ABE). Editing efficiency is evaluated through the BEAR-GFP reporter plasmid.

We obtained a library covering 8191 variants with 5569 total guides. Of these, the majority are nonsynonymous. We analysed the coverage of known NF1 variants. Based on ClinVar classification, we cover 882 VUS, 68 conflicting interpretation of pathogenicity (CIP), 202 pathogenic/likely pathogenic (P/LP) variants, and 25 benign/likely benign (B/LB) variants. Based on our RENOVO tool for VUS reinterpretation, 4968 covered variants are considered Low-precision Pathogenic or Benign.Key functional domains in NF1 are covered with high density, in particular with 573 variants covering the functional GTPase-activating domain (GAP), 2745 covering the HEAT domain, likely to mediate interactions with microtubules, and 267covering the SecPH domain, essential for membrane localization. 4257 variants in splicing sites and 3 prime untranslated regions (UTR) variants are covered.The results of the functional screen are integrated with public data to develop a novel NF1 predictor based on our RENOVO architecture (Favalli V et al., Am J Hum Genet. 2021 and Bonetti E, et al., Hum Genomics 2025).These tools will be essential to overcome key diagnostic challenges in neurofibromatosis and precision oncology.

#1997 Integrative single-nuclei spatial transcriptomic profiling of primary and recurrent human glioblastoma reveals cell-specific EGFRvIII expression and ANXA1 signaling axis.

Simon G. Gregory[1], Lauren Whaley-Powers[1], Vaibhav Jain[1], Michael Aksu[1], Emily Hocke[2], Alan Smith[2], Stephanie Arvai[2], Ellora Haukefrers[2], Kevin Stevenson[3], Khooshbu Patel[3], Diane Satterfield[3], Elizabeth Thomas[3], Karen Abramson[2], Giselle Y. Lopez[4], Roger E. McLendon[4], David M. Ashley[1]

[1]Neurosurgery, Duke University School of Medicine, Durham, NC,[2]Duke Molecular Physiology Institute, Duke University School of Medicine, Durham, NC,[3]Preston Robert Tisch Brain Tumor Center, Duke University School of Medicine, Durham, NC,[4]Pathology, Duke University School of Medicine, Durham, NC

The World Health Organization provides clear criteria for diagnosing IDH1-wildtype glioblastoma (GBM), relying on traditional approaches to define pathoetiological features, genomic mutations, copy number variation, and aberrant expression of prognostic genes. While these methods guide diagnosis, they may lack the resolution to fully capture tumor heterogeneity, therapeutic response, or outcomes. To address this, we applied leading-edge technologies to 14 primary and recurrent tumors to add granularity to current diagnostic metrics and clinical classification. Aiming to better inform tumor subtyping and improve patient care, this integrative approach enabled us to identify malignant gene programs and localize prognostically relevant features at both single-cell and spatial levels. We analyzed 14 GBM tumors from 6 patients using spatial *in situ* sequencing (ISS) and single-nuclei RNA-sequencing. A custom ISS gene panel enabled spatial mapping of tumor-associated cell types and state markers, while matched snRNA-seq from adjacent tumor tissue provided transcriptome-wide profiles. The dataset enabled subcellular and spatial localization of the prognostic GBM biomarker, EGFRvIII, being enriched in oligodendrocyte progenitor (OPC)-like tumor cells, which provides and exciting insight into the putative cell of origin for GBM. Finally, one patient contributed 5 serially collected during tumor recurrence which enabled longitudinal analysis of tumor evolution. Characterizing these tumors using ligand-receptor interaction analysis of snRNA-seq and spatial data identified an evocative ANXA1 signaling axis that progresses across recurrent tumors, which suggests novel therapeutic opportunities. By extending beyond conventional diagnostic benchmarks, our molecular profiling reveals new insight into GBM biology that may support more refined tumor subtyping and prognostic assessment.

#1998 Minerva: High-Resolution Allele-Specific Copy Number and Complex SV Harmonization with Long Reads.

Ayse G. Keskus, Tanveer Ahmad, Isabel Rodriguez, Anton Goretsky, Ataberk Donmez, Sonam Tulsyan, Nicholas Syracuse, Michael Dean, Mikhail Kolmogorov

NIH-NCI, Bethesda, MD

Copy-number alterations (CNAs) and structural variations (SVs) are major drivers of cancer evolution, yet accurately resolving allele-specific copy number (ASCN) in highly rearranged tumor genomes remains challenging. Conventional approaches often struggle with limited phasing information and inaccurate segmentation. Long-read sequencing offers unique advantages for genome reconstruction, but current CN tools do not fully exploit its long-range phasing or breakpoint-level resolution.We present Minerva, a long-read framework for ASCN calling and complex SV clustering. Minerva integrates high-fidelity structural variation calls from Severus into a breakpoint graph that defines segmentation directly on rearrangement breakpoints. This approach enables chromosome-arm–scale phasing, allowing haplotypes to be followed through long and structurally complex regions. It further provides haplotype-specific coverage estimates and accurate CN assignment even across SV clusters. Minerva supports both tumor–normal and tumor-only workflows, delivering stable ploidy estimation and haplotype-aware CN inference even in the absence of matched normals.
Using the CASTLE long-read somatic cancer cell line panel, we benchmarked Minerva against established short-read and long-read CN methods. Across nearly all cell lines, Minerva achieved higher chromosome-scale CN accuracy, more consistent purity/ploidy estimates, and markedly improved detection of focal CN changes, including deletions, duplications, or more complex events like translocations with deletions. Leveraging the precision of long-read SV breakpoints, Minerva resolves sub-100 bp CN segments, representing orders-of-magnitude finer resolution than short-read approaches. Performance gains were strongest in genomes with dense rearrangements, including fold-back inversions, sysmic amplifications, templated insertions, and ecDNA.
We further applied Minerva to (i) a breast cancer long-read cell-line panel and (ii) a long-read breast tumor cohort. Across both datasets, Minerva identified distinct and recurrent amplification patterns in key oncogenic regions, including MYC, ERBB2, and CCND1, and revealed allele-specific focal events and complex rearrangement architectures missed by existing CN/SV methods.
Minerva provides a unified, phasing-aware solution for high-resolution CN and SV interpretation in tumor-only long-read cancer genomics, enabling more accurate reconstruction of cancer genome structure, selective pressures, and oncogenic amplification landscapes.

#1999 Founder Wnt alterations guide the evolutionary trajectories of colorectal tumorigenesis.

Yoshikage Inoue[1], Nobuyuki Kakiuchi[1], Satoshi Nagayama[2], Yutaro Kuwashima[3], Sekine Shigeki[4], Kenichi Yoshida[5], Koichi Watanabe[1], Satoshi N. Omura[6], Kazutaka Obama[7], Toshiro Sato[3], Seishi Ogawa[1]

[1]The Department of Pathology and Tumor Biology, Kyoto University, Kyoto, Japan,[2]The Department of Gastrointestinal Surgery, Uji-Tokusyukai Medical Center, Uji, Japan,[3]The Department of Integrated Medicine and Biochemistry, Keio University, Tokyo, Japan,[4]The Department of Pathology, Keio University, Tokyo, Japan,[5]National Cancer Center, Division of Cancer Evolution, Japan,[6]The Department of Biological Sciences, The University of Tokyo, Tokyo, Japan,[7]The Department of Gastrointestinal Surgery, Kyoto University, Kyoto, Japan

Colorectal cancer (CRC) is classically divided into hypermutated (HM) and non-hypermutated (NHM) subtypes based on mutation burden. Although NHM tumors account for ~80% of CRC, no widely accepted genetic framework is available to understand CRC heterogeneity. In this study, we analyzed a total of 4,437 CRCs using targeted-capture sequencing across 169 driver genes, along with RNA sequencing of 2,833 tumors. Based on the bimodal distribution of mutation burden, 3,986 were classified as NHM, while HM cases were further resolved into MSI- and *POLE*-mutated CRC. Notably, within NHM CRCs, *APC* mutations, *CTNNB1* alterations affecting exon 3, biallelic *RNF43* mutations, and *RSPO2/3* fusions were almost completely mutually exclusive, a pattern that also held in hypermutated tumors. Leveraging this mutual exclusivity, we classified NHM CRCs into five non-overlapping subgroups: *APC*-mutant (*APC*^{mut}; 90%), *CTNNB1* exon 3-altered (*CTNNB1*^{Exon3}; 2.4%), biallelic *RNF43*-mutant (*RNF43*^{biallelic}; 1.7%), *RSPO2/3* fusion-positive (*RSPO2/3*^{fusion}; 1.7%), and Wnt-negative (Wnt^{WT}; ~1.5%). Accounting for ~10% of NHM CRCs, the *APC*-wild-type subtypes —*CTNNB1*^{Exon3}, *RNF43*^{biallelic}, *RSPO2/3*^{fusion}, and Wnt^{WT}—showed distinct genomic and transcriptomic features and consistently poorer outcomes than *APC*^{mut} CRCs. Among them, the Wnt^{WT} subtype exhibited attenuated Wnt signaling with prominent inflammatory and immune-response signatures, representing a highly inflamed subset distinct from Wnt-pathway-altered CRCs. To further dissect the heterogeneity of *APC*^{mut} CRCs, we quantified the selection pressure acting on different *APC* mutations by calculating amino-acid-level dN/dS values. This analysis revealed five segments within the *APC* coding region with distinct profiles. Mutations within three segments were mutually exclusive even after accounting for biallelic *APC* inactivation. Leveraging this mutually exclusive architecture, we classified *APC*^{mut} tumors into four subgroups (APC1-4). As expected, these CRC subgroups were characterized by different Wnt activation levels as assessed by *AXIN2* expression or GSVA analysis of Wnt-pathway gene sets. Subgroups with lower-Wnt activation (APC3-4) were enriched for *AMER1* or *CTNNB1* minor-hotspot mutations, whereas those with higher-Wnt activation (APC1-2) frequently harbored *TCF7L2/TCF7* mutations. These mutational patterns indicate that colorectal tumors avoid excessively high or low Wnt activity, instead maintaining signaling within a relatively restricted range. The *APC*^{mut} subgroups also differed in their co-mutation profiles, chromosomal instability, tumor location, and clinical outcomes, suggesting that founder *APC* mutations dictate evolutionary trajectories and clinical behavior.In conclusion, we provide an integrated view of how founder Wnt alterations and the positional effects of *APC* truncations shape the molecular and evolutionary landscape of CRC.

#2000 A spontaneous *CTNNB1* driver mutation reversion in a primary ovarian clear cell carcinoma.

Rania Bassiouni[1], Yuxin Jin[1], Lee D. Gibbs[2], Jing Qian[2], Solomon O. Rotimi[2], Heather Miller[2], Michelle G. Webb[2], David W. Craig[1], Javier Arias-Stella[1], Lynda Roman[2], John D. Carpten[1]

[1]City of Hope, Duarte, CA,[2]University of Southern California, Los Angeles, CA

Ovarian clear cell carcinoma (OCCC) is a histologically and clinically distinct subtype of epithelial ovarian cancer that typically demonstrates genomic instability and recurrent copy number (CN) alterations.

Here, we describe an OCCC case from a 46-year-old patient. The primary tumor, staged IIIC, was surgically removed prior to administration of adjuvant treatment. We subjected a fresh-frozen specimen of the primary tumor to nuclear isolation and single cell whole genome sequencing. For single cell CN analysis, sequencing data was processed with the Cell Ranger DNA pipelines (10x Genomics). Following stringent quality filtering, cells were clustered by CN to resolve clonal mixtures.

In addition to diploid cells (cluster 1), the sample contained two clones with distinct CN profiles (clusters 2 and 3), each comprised of additional subclones. The two clones shared some identical CN alterations, suggesting a common ancestor. To determine the order of clone emergence, we performed CN-based phylogenetic analysis, which identified cluster 3 as the earlier clone. This was supported by single cell loss of heterozygosity (LOH) determination, which revealed that LOH in cluster 2 equaled and exceeded that of cluster 3.

Using the diploid component of the sample as a matched germline, we performed somatic variant calling to identify consequential mutations. The two clones shared several hundred somatic passenger mutations, supporting a shared lineage. However, only one candidate driver mutation was identified, a heterozygous *CTNNB1* S37C activating mutation. Interestingly, only cluster 3 - the early clone - harbored the mutation. Examination of B-allele frequencies revealed LOH on chromosome 3, encompassing *CTNNB1*, in cluster 2. Haplotype determination confirmed the loss of the B-allele and a duplication of the wild-type A-allele in cluster 2. Thus, the evidence suggests that the *CTNNB1* driver mutation was lost via a copy-neutral LOH event that retained the wild-type allele.

To determine whether this reversion was reflected in gene expression programs, we performed spatial transcriptomics (10x Genomics) on a formalin-fixed, paraffin embedded specimen of the primary tumor. We identified regions of the tumor corresponding to both clones by positional gene set enrichment. The clones occupied spatially discrete locations and were histologically and transcriptionally distinct. Gene set enrichment analysis confirmed that regions corresponding to cluster 3 were enriched in programs reflecting WNT/β-catenin signaling and epithelial-mesenchymal transition, consistent with an activating *CTNNB1* mutation. Conversely, cluster 2 was enriched in programs for TNFA signaling, hypoxia, and KRAS signaling.

This is the first evidence of an oncogenic driver mutation reversion in an untreated primary tumor and reflects a surprising consequence of chromosomal instability on intra-tumoral heterogeneity.

#2001 Discovery of coding and non-coding driver mutations across >8,000 TCGA whole genomes.

David Lehotzky[1], **Ron Solan**[1], Antonia Kowalewski[1], Nick Haradhvala[1], Xavier Loinaz[1], Hansol Park[2], Vasuki N. Swamy[1], David Heiman[1], Samantha Van Seters[1], Saveliy Belkin[1], Sam Wiseman[1], Chunyang Bao[2], Andrew Cherniack[1], Luis A. Corchete Sanchez[1], Brian P. Danysh[1], Zachary Everton[1], Ryul Kim[2], Gang-Hee Lee[2], Won-Chul Lee[2], Chip Stewart[1], Haruna Tomono[1], Gengchao Wang[1], Young Seok Ju[2], Esther Rheinbay[1], Gad Getz[1]

[1]Cancer Program, Broad Institute, Cambridge, MA,[2]Inocras, San Diego, CA

Cancer driver genes are oncogenes and tumor suppressor genes whose changes in function or expression promotes tumorigenesis. They are used to study cancer behavior, to classify cancer types, and to guide precision medicine. Cancer driver genes are usually identified by statistical analysis of coding mutations in tumor genomes. However, studies searching for new drivers are limited by statistical power, since mutations in each specific driver are often rare, and drivers are often specific to tumor subtypes. In addition, studies relying on whole-exome sequencing miss functionally important noncoding regions, such as promoters, and sequencing using PCR amplification often misses GC-rich and GC-poor regions. As a result, PCR-free whole-genome sequencing (WGS) of larger cohorts is required to continue the discovery of cancer drivers. To comprehensively identify single nucleotide variant (SNV) and indel drivers in cancer, we analyzed >8,000 tumor-normal pairs spanning 31 cancer types from The Cancer Genome Atlas (TCGA) sequenced using PCR-free WGS. We identified somatic SNVs and indels using a custom pipeline, then used MutSig2CV and dNdScv to identify genes under positive selection in coding regions and used Dig to detect increased mutation rates in coding and non-coding regions, including 5'-UTR, 3'-UTR, and promoter sequences. Our analysis identified well-known noncoding drivers, including TERT promoter mutations, TP53 5’-UTR mutations, and NFKBIZ 3’-UTR mutations, as well as some novel candidate cancer drivers, including in non-coding regions. We believe that the new drivers we discovered will provide new insights into the genetic mechanisms of tumorigenesis, aid in the development of cancer therapeutics, and offer a foundation for the use of noncoding driver events in precision oncology.

#2002 The landscape of X chromosome copy number alterations in cancer.

Matthew Joseph Leventhal[1], Chunyang Bao[2], Ron Solan[3], Haruna Tomono[3], Andrew D. Cherniack[3], Luis A. Corchete Sanchez[3], Rebecca Jang[2], Jeehee Suh[2], Antonia Kowalewski[3], Sam Wiseman[3], Samantha Van Seters[3], Saveliy Belkin[3], David I. Heiman[3], Chip Stewart[3], David Lehotzky[3], Vasuki N. Swamy[3], Brian P. Danysh[3], Gengchao Wang[3], Xavi Loinaz[3], Zachary Everton[3], Gang-Hee Lee[2], Won-Chul Lee[2], Hansol Park[2], Ryul Kim[2], Young Seok Ju[2], Esther Rheinbay[3], Gad Getz[3], Cheng-Zhong Zhang[3]

[1]Data Sciences, Dana-Farber Cancer Institute, Boston, MA,[2]Inocras Inc., San Diego, CA,[3]Broad Institute of Harvard and MIT, Cambridge, MA

Copy number alterations are frequent, early events in cancer evolution. Previous pan-cancer analyses have not characterized recurrent copy number alterations on the actively and inactively transcribed X chromosome. The monoallelic expression of the active X chromosome predicts a higher sensitivity of cell fitness to copy number alterations on the active X chromosome than expected from autosomal copy number alterations. Large deletions on the active X chromosome are likely intolerable due to loss of expression of essential genes; a duplication of the active X chromosome will increase chromosome X expression by 100% instead of 50%,which is the expected increase of gene expression from duplication of a single autosome homolog. Recurrent copy number alterations on the X chromosomes could lead to the discovery of new, therapeutically actionable drivers of tumor evolution. We have developed a new method to accurately determine the copy number alterations on the active and inactive X from combined whole genome sequencing and RNA-seq of >8,000 TCGA tumors. We found recurrent copy number gains on the active X chromosome q-arm spanning the telomere. The active X chromosome copy number gains overlapped previously identified cancer genes in the Cancer Gene Census from other tumors such as ATP2B3, FLNA, MTCP1, RPL10, PHF6 and GPC3. These segmental and arm-level gains were not significantly more frequent in patients with whole genome doubling or TP53 mutations. These results suggested that recurrent gains of the q-arm of the active X chromosome were not a result of genomic instability, suggesting that these gains were putative driver events that could be truncal in tumor evolution. Telomere-spanning segmental copy number gains on the q-arm were less common in female glioblastoma or uveal melanoma tumors, which are cancer types that affect both male and female patients. This work shows that copy number gains on the active X chromosome are a new source of cancer driver mutations. The sensitivity of the active X chromosome to selection suggests that genes in recurrent X chromosome amplifications could be new genetic dependencies or therapeutic targets in treating female cancers. The results of this study may identify previously unknown drivers of cancer on the active X chromosome that could be new, effective therapeutic targets in cancer.

#2003 Comprehensive genomic profiling of angiosarcoma cells reveals widespread activation of the RAS pathway.

Donghee Lee, Sun Hee Choi, Md Abdullah, Eslenur Nipa, Jong Hyuk Kim

University of Florida, Gainesville, FL

Angiosarcomas are a heterogeneous group of an aggressive vascular malignancies, with a 40% five-year survival rate and a median overall survival of 16 months for half of patients. These tumors exhibit a high degree of genomic complexity, encompassing a broad spectrum of cancer-related mutations, including *TP53*, *KDR, PTPRB, PIK3CA, NRAS,* and *CDKN2A*. Despite recent advances in genomic and molecular profiling in angiosarcomas, the development of effective therapies targeting these genetic alterations and their downstream functional pathways has been hampered. This limitation is possibly due to incomplete molecular characterization and the scarcity of preclinical research models. Specifically, only a small number of angiosarcoma cell lines are available, and their molecular features and functional properties remain incompletely defined. This hinders the development of robust preclinical models and the discovery of reliable, effective drug targets. The aim of this study is to systematically characterize the genetic landscape of previously uncharacterized angiosarcoma cell lines to identify novel molecular targets and propose clinically relevant therapeutic strategies. First, we established comprehensive genomic profiles, including single nucleotide variants (SNVs), copy number variation (CNV), DNA methylation, and gene expression patterns, across a panel of angiosarcoma cell lines (AS5, ISO-HAS-B, HAMON, KU-CAS3, and KU-CAS5) using Whole Exome Sequencing and Oxford Nanopore sequencing. Our integrated analysis identified alterations in *CDNK2A*, *PTPRB*, and *RAS*, suggesting CDK4/6, TIE2/VEGFR2, and RAS/MAPK as potential molecular targets involved in the proliferation and survival of angiosarcoma cells. Through anti-cancer drug screening, we found that a RAS inhibitor RMC-7977 effectively suppressed angiosarcoma cell growth. Remarkably, RMC-7977 was effective in both RAS-mutated and wild-type angiosarcoma cells, concurrently leading to a reduction in phosphor-ERK and phosphor-S6K levels. In addition, the RAS signaling pathway was broadly activated across primary angiosarcoma patient tissues (n=13), irrespective of the RAS mutation status. These data suggest that RMC-7977 effectively targets the widespread, pathway-level activation of RAS arising from various upstream alterations in genomically complex angiosarcomas. Our ongoing work involves evaluating the *in vivo* efficacy of RMC-7977 in angiosarcoma xenograft models harboring both mutant and wild-type RAS. Furthermore, we will dissect the molecular mechanism underlying this broad RAS dependency by assessing the impact of RMC-7977 on activated RAS and downstream signaling, further supporting the rationale for its clinical use in angiosarcoma.

#2004 Interrogating the genomic co-evolution of the immune system and cancer along the time and treatment continuum.

John Roy Lozada[1], Christine Luo[1], Devin Schmeck[1], Jeffrey S. Miller[1], Akash Patnaik[2], Emmanuel S. Antonarakis[1], Frank Cichocki[3], Justin Hwang[1]

[1]University of Minnesota, Minneapolis, MN,[2]University of Chicago, Chicago, IL,[3]Medicine, University of Minnesota, Minneapolis, MN

Clonal hematopoiesis (CH) is exemplified by the expansion of mutant hematopoietic stem and progenitor cells that may give rise to altered immune repertoires. Driven largely by age and chronic inflammation, CH is historically linked to myeloid malignancies. Although emerging evidence points to a modest prevalence of CH within solid tumors, the impact of these naturally occurring alterations on anti-tumor immunity and therapeutic responses remain less defined.

Here, we employed somatic mutation calling algorithms to detect single nucleotide variants (SNVs) in both epithelial and immune compartments of tumors. Our preliminary analyses of single-cell RNA-sequencing (scRNA-seq) of 32 primary, therapy-naïve prostate tumors encompassing 11 patients identified mutations representative of both CH and prostate cancer. Within the tumor-epithelial compartment, we identified recurrent *FOXA1* class 1C mutations in 27% (3/11), alongside *NCOR1* mutations in 18% (2/11), *IDH1* in 9% (1/11), and *SPOP* in 9% (1/11) of patients. Of note, these SNVs were detected across multiple samples for the same patient. Interestingly, we also detected germline *HOXB13* G84E variants, associated with increased risk for prostate cancer, in 2 cases at a high clonality within epithelial cells (>75%). CH alterations were identified in 27% (3/11) of patients based on the detection of exonic, nonsynonymous SNVs in myeloid cells. Specifically, these variants affected *SF3B2* (variant allele frequency; VAF = 0.30), *UBE2A* (VAF = 0.30), and *KMT2C* (VAF = 0.43) that are predicted deleterious across multiple classifier algorithms. Patients with detectable CH alterations displayed immunologically hotter tumor microenvironments, with CH+ patients having significantly higher proportions of tumor-infiltrating monocytes (16.22% vs 7.13%, Fisher's exact test $p<0.0001$), macrophages (6.49% vs 2.88%, $p<0.0001$), $CD8^+$ T cells (10.35% vs 3.33%, $p<0.0001$), $CD4^+$ T cells (2.81% vs 0.74%, $p<0.0001$), and B cells (1.81% vs 0.59%, $p<0.0001$), and lower epithelial fractions (50.94% vs 69.81%, $p<0.0001$).

In summary, we leveraged de novo mutational algorithms to detect CH alterations in prostate cancer at the single-cell resolution. Further work will integrate our mutational signatures with transcriptomics to elucidate the impact of both cancer- and immune-intrinsic alterations on anti-tumor immunity. Additionally, we will incorporate mitochondrial DNA-based lineage tracing algorithms on matched peripheral blood, primary, and metastatic tumor samples across diverse solid tumor types to deconvolute the spatiotemporal regulation of naturally occurring CH alterations across cancer progression. We envision our findings will illuminate novel drivers of immune function and regulation within solid tumors that may be exploited for future immunomodulatory therapies.

#2008 Fasting induces ferroptosis by modulating lipid metabolism in breast cancer.

Claudio Vernieri[1], Giovanni Fuca[2], Francesca Ligorio[2], Laura Tronci[1], Paola A. Corsetto[3], Giulia Salvadori[1], Arta Ajazi[1], Antonino Belfiore[2], Andrea Vingiani[2], Beatrice Cantarelli[1], Mattia Pavani[1], Keagile Bati[1], Lorenzo Drufuca[1], Saverio Minucci[4], Pagani Massimiliano[1], Filippo de Braud[2], Pruneri Giancarlo[2], Angela Bachi[1], Marzia Santamaria[5]

[1]IFOM ETS, the AIRC Institute of Molecular Oncology, Milan, Italy,[2]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[3]University of Milan, Milan, Italy,[4]IEO - European institute of Oncology, Milan, Italy,[5]IFOM-FIRC Institute of Molecular Oncology, Milan, Italy

Introduction: Cyclic fasting and fasting-mimicking diets (FMDs) showed broad antitumor activity in mice with breast cancer (BC), with promising results in patients (pts) enrolled in conpleted or ongoing clinical trials (NCT03340935; NCT03454282; NCT04248998; *NCT05763992*). However, with the exception of glucose and growth factor modulation, the mechanistic determinants of fasting/FMD antitumor activity are poorly understood.

Methods: We combined *in vitro* and *in vivo* experiments in BC models with *ex vivo* analyses of blood and tumor samples collected from BC pts undergoing FMD in the context of clinical trials (NCT03454282; NCT04248998) to investigate the role of lipid metabolism modulation in mediating fasting/FMD antitumor effects. In *in vitro* experiments, we used six murine and human BC cell lines to study the role of polyunsaturated fatty acids (PUFAs) in affecting cell proliferation (IncucyteS3), survival (propidium iodide), apoptosis (cleaved PARP/caspase 3), lipid peroxidation (malondialdehyde, MDA) and ferroptosis during nutrient starvation. In *in vivo* experiments, orthotopic mouse BC models (4T1-bearing BALB/c mice, E0771-bearing C57BL/6J mice and MDA-MB-231-bearing NOD-scid IL2rgnull (NSG) mice) were randomized to control conditions (ad libitum diet), intermittent fasting (IF), oral administration of the PUFAs arachidonic acid (AA) or docosaexahenoic acid (DHA), or a combination of IF and PUFAs, with or without carboplatin. We assessed primary tumor growth, lung metastasis formation (through IVIS) and animal survival. Mass Spectrometry analysis was used to quantify plasma and intratumor free fatty acids (FAs), as well as FAs in lipid fractions, in mice and in patients.

Results: In both mice and pts (n=112) with BC, fasting/FMD-induced reduction of blood glucose and insulin activated lipolysis in fat tissue, followed by an increase of blood and intratumor AA and DHA. Inhibiting lipolysis through BAY 59-9435 reversed the *in vivo* antitumor effects of fasting in mice, thus revealing a crucial role of blood FA increase in nutrient starvation antitumor activity. Among several FAs modulated by fasting, AA and DHA accumulate in mitochondrial phospholipids, where they promote radical oxygen species (ROS) formation, lipid peroxidation and ferroptosis. Combining cyclic fasting with AA/DHA administration resulted in cooperative delay of *in vivo* tumor progression, reduced metastasis formation and prolonged animal survival via ferroptosis activation. These effects were enhanced when chemotherapy was combined with IF plus AA/DHA. Conversely, vitamin E reversed the antitumor effects of nutrient starvation plus AA/DHA.

Conclusions: Ferroptosis emerges as a novel determinant of fasting/FMD anticancer activity via PUFA accumulation. Cyclic fasting/FMD plus AA/DHA supplementation is a new, safe and effective antitumor metabolic combination that deserves investigation in phase I/II clinical trials.

#2009 Targeting metabolic vulnerabilities in basal-like breast cancer.

Amanda Linke[1], Kevin Mott[2], Felix Olivares[1], Michael East[1], Chengheng Liao[3], Qing Zhang[3], Gary L. Johnson[1], Charles M. Perou[2]

[1]Pharmacology, UNC School of Medicine, Chapel Hill, NC,[2]Department of Genetics, UNC School of Medicine, Chapel Hill, NC,[3]UT Southwestern Medical Center, Dallas, TX

Triple Negative Breast Cancers (TNBC) are a biologically heterogeneous clinical subtype of breast cancer with limited treatment options and generally poor prognosis. Basal-like breast cancer (BLBC), which accounts for ~75% of TNBCs by gene expression profiling, is particularly aggressive, highlighting an urgent need to develop targeted therapies for this subtype. Our lab previously identified an enrichment of pyrimidine synthesis metabolites in tumors from BLBC patients. Further, an analysis of the Chinese Breast Cancer Genome Atlas (PMID: 38347143), a multi-omics dataset including 443 breast cancer metabolomics samples, also revealed a similar feature of pyrimidine-enriched metabolites in both BLBC and TNBC tumors. Therefore, we hypothesize that pyrimidine biosynthesis is essential for BLBC survival and may represent a therapeutic vulnerability. To investigate this unique metabolic phenotype, we utilized a panel of syngeneic, serially transplanted, genetically engineered mouse (GEM) model mammary tumors representing multiple breast cancer subtypes (luminal, basal-like, mesenchymal). Metabolomic mass spectrometry of 20 GEM models, including 6 BLBC models and normal mammary glands, identified 2 distinct metabolic subtypes, namely a Nucleotide-enriched and Fatty Acid-enriched groups, mirroring the patterns observed in human breast tumors. To evaluate the dependency of these murine tumors on pyrimidine biosynthesis, we used leflunomide, an FDA-approved dihydroorotate dehydrogenase (DHODH) inhibitor. *In vivo* testing across 4 tumor models, including the basal-like p53-null 2225L model, showed that leflunomide slowed tumor growth and extended survival in 3 models. However, 1 model exhibited resistance, suggesting that combination therapies may still be needed. To identify potential combination therapies based upon DHODH inhibitors, we conducted a drug combination screen using both the murine 2225L and human SUM102 basal-like cell lines. Notably, we found that kinase inhibitors with off-target activity against ENT1 sensitized cells to DHODH inhibition. These findings are currently being validated *in vivo*, which may support a strategy of co-targeting pyrimidine biosynthesis and the nucleotide salvage pathways to overcome resistance.

#2010 Ovarian cancer drives mitochondrial dysfunction via WT1 in tumor associated stroma.

Roja Baruwal[1], Huda Issa Atiya[1], Paige Matusiak[2], Angelina Li[3], Swathi Suresh[1], Geyon Garcia[1], Benjamin K. Johnson[2], Hui Shen[4], Leonard Frisbie[5], Lan G. Coffman[6]

[1]University of Pittsburgh School of Medicine, Pittsburgh, PA,[2]Van Andel Institute Graduate School, Grand Rapids, MI,[3]North Allegheny Senior High School, Pittsburgh, PA,[4]Graduate Student, Van Andel Research Institute, Grand Rapids, MI,[5]University of Pittsburgh, Pittsburgh, PA,[6]University of Pittsburgh Medical Center, Wexford, PA

Ovarian cancer (OvCa) is the deadliest gynecologic cancer with most of its lethality attributed to late diagnosis and early metastasis. Prior work demonstrates that carcinoma associated mesenchymal stem cells (CA-MSC) enhance OvCa metastasis by donating their mitochondria to metabolically vulnerable OvCa cells thus increasing OvCa cell oxidative phosphorylation (OXPHOS). Although we have shown a crucial role for these donated mitochondria in OvCa progression and metastasis, the functionality of CA-MSC mitochondria and how they differ from normal MSC (nMSC) mitochondria is not known. The purpose of this study is to characterize differences in mitochondrial form and function in CA-MSC compared to nMSC with the goal of targeting CA-MSC mitochondria to decrease OvCa progression and metastasis. We discovered that CA-MSC derived mitochondria persist in OvCa cells over multiple passages but fail to incorporate into the host mitochondrial matrix and instead take a donut and punctate shaped morphology which is indicative of mitochondrial stress. Interestingly, mitochondrial ATACseq revealed that CA-MSC, compared to their nMSC counterparts, are enriched in pathogenic mitochondrial mutations. GSEA analysis on RNAseq dataset comparing CA-MSC to nMSC show OXPHOS as one of the top altered pathways. Here we demonstrate that CA-MSC have altered mitochondrial functionality and morphology compared to nMSC. Using 11 patient derived CA-MSC lines and 7 patient derived nMSC lines in a cell mito stress test assay, we found that CA-MSC have increased mitochondrial respiration compared to nMSC. Although CA-MSC mitochondria consume more oxygen, we demonstrate that they are not as efficient as their normal counterparts in coupling this to ATP production. Using confocal and TEM microscopy, we demonstrate that CA-MSC have more networked mitochondria consistent with increased mitochondrial respiration, but we also observe increase in donut and punctate mitochondria, morphologies linked to oxidative stress. Importantly, CA-MSC have increased mitochondrial ROS and decreased mitochondrial membrane potential compared to nMSC, suggesting mitochondrial dysfunction. Using a fluorescent reporter protein, MitoTimer, we demonstrate that CA-MSC accumulate more oxidatively stressed mitochondria and preferentially donate these dysfunctional mitochondria to OvCa cells. Finally, using knockdown and overexpression models, we demonstrate that expression of the Wilm's Tumor 1 (WT1) gene mediates oxidative stress in CA-MSC. Our current study elucidates the functional consequences of the unique mitochondrial phenotype of CA-MSC in OvCa to enable novel targeted strategies to improve outcomes in OvCA.

#2011 Integrin α6β4 stimulates glucose metabolism and NAD(H) production needed to drive invasive growth of triple negative breast cancer cells.

Yiming Sheng, Parvarnee A. Karimpour, Andrew Elliott, Jayla L. Fenderson, Teresa A. Cassel, Penghui Lin, Richard M. Higashi, Andrew N. Lane, Teresa W. M. Fan, Min Chen, Kathleen L. O'Connor

University of Kentucky, Lexington, KY

Integrin α6β4, a laminin receptor preferentially expressed on cells of epithelial origin, is highly expressed in over 80% of TNBC cases and contributes to the aggressive nature of this deadly breast cancer subtype. We recently demonstrated that integrin α6β4 enhances Hif-1α nuclear accumulation, suggesting its role in a pseudohypoxia signature. Hif-1α reprograms cellular metabolic processes, such as glycolysis, as a hallmark of cancer. However, whether glucose metabolism is part of this signature and how integrin α6β4 impacts TNBC glucose metabolism remain unclear. To examine how integrin α6β4 signaling impacts glycolysis, we first applied a Seahorse XF glycolysis stress test to measure the extracellular acidification rate in BT549 cells that stably express integrin β4 (BT549-β4) or an empty vector (BT549-EV). The BT549-β4 cells had significantly increased glycolysis and glycolytic capacity. Next, we used $^{13}C_6$ glucose stable isotope resolved metabolomics to define how integrin α6β4 impacts glucose metabolic pathways. Integrin α6β4 overexpression increased glucose uptake and shunted it into the pentose phosphate pathway compared to control, resulting in increased production of ribose phosphate. Interestingly, the increased ribose phosphate production in BT549-β4 cells was used for ATP synthesis, which is a precursor of NAD, both of which are essential coenzymes and co-substrates for TNBC metabolism. We then measured the expression levels of key proteins in the glycolysis pathway and found that glucose transporters (Glut1 and Glut3) and several enzymes, such as hexokinases and LDHA, are upregulated by integrin α6β4. We further validated that integrin α6β4 promotes invasive growth and upregulates hexokinase I and II protein levels using the EMT6 syngeneic model (EV vs β4). To assess the impact of integrin α6β4-promoted glucose metabolism on cell proliferation and invasive growth, we treated EMT6 cells (EV vs. β4) with various doses of the glucose analog, 2-DG, and monitored cell viability by MTT assays. The results demonstrated that EMT6-β4 cells are more sensitive to 2-DG compared to EMT6-EV cells. Similar results were obtained from BT549 cells grown in 3D. Culturing BT549 (EV vs. β4) and MDA-MB-231 (control vs. β4 KO) cells in low vs. high glucose media, we found that integrin α6β4-driven cell proliferation depends on the levels of glucose. Using shRNAs and specific inhibitors, we found glucose transporters are regulated through integrin α6β4 signaling-driven Hif-1α and KLF5 activation. We further found that integrin α6β4 increased AMPK activation under energy stress and the NAD^+/NADH ratio in cells is significantly decreased by integrin α6β4 signaling. In summary, our data highlights a novel function of integrin α6β4 in altering glucose metabolism and the significant impact on the dynamics of NAD^+/NADH to promote an invasive phenotype of TNBC cells.

#2012 Spatial proteomic profiling of metabolic and cell signaling heterogeneity in breast cancer tumor microenvironment using imaging mass cytometry.

Qanber Raza, **Nick Zabinyakov**, Liang Lim, Christina Loh

Standard BioTools, Markham, ON, Canada

The tumor microenvironment (TME) is a complex ecosystem of tumor and immune cells with dysregulated metabolic and signaling pathways that drive tumor heterogeneity, progression and differential treatment response. Targeting these pathways has emerged as a promising strategy to enhance immunotherapy efficacy. Imaging Mass Cytometry™ (IMC™) systems, leveraging CyTOF™ technology, enable simultaneous detection of >40 markers, providing scalable, high-throughput spatial characterization of the TME with true dynamic range, free from spectral overlap and autofluorescence limitations inherent to fluorescence-based approaches.

We applied IMC technology to interrogate metabolic and signaling programs in human breast cancer using integrated antibody panels: the Human Immuno-Oncology IMC Panel (PN 201509) combined with either the Human Cell Metabolism (PN 201521) or Human Cell Signaling (PN 201522) IMC Panels. This approach enabled simultaneous assessment of energy production, cellular homeostasis and mitogenic signaling. Whole tissue sections were initially imaged in Preview Mode, followed by high-resolution analysis of regions of interest using Cell Mode or Tissue Mode to phenotype tumor and immune cells and evaluate immune activation.

IMC technology revealed spatial heterogeneity in metabolic and signaling states within breast tumors. Tumor regions demonstrated differential energy utilization: Immune cells predominantly infiltrated areas enriched for fatty acid oxidation, whereas tumor regions with anaerobic or aerobic glycolysis corresponded to immune-excluded zones. Signaling pathway activity also varied by cell type. Elevated glycolysis and mTOR activation indicated adaptation to hypoxic and anabolic demands. Wnt signaling and PTEN expression were enriched in tumor cells, whereas MAP kinase signaling was localized primarily to stromal compartments. Unsupervised pixel-clustering and hierarchical analysis using MCD™ SmartViewer further resolved region-specific metabolic and signaling heterogeneity.

IMC systems enable comprehensive spatial profiling of metabolism and signaling in breast cancer, revealing tumor-immune interactions and intratumoral heterogeneity. This high-dimensional spatially resolved approach provides a powerful framework for identifying clinically relevant targets, informing prognostic assessments and guiding development of personalized therapeutic strategies.

For Research Use Only. Not for use in diagnostic procedures.

#2013 Mitochondrial protein translation supports metabolic rewiring of chemo-refractory triple negative breast cancer.

Mariah Joy Berner, Steven W. Wall, Mokryun L. Baek, Audra Lane, Allison S. Greer, Karen Wang, Lacey E. Dobrolecki, Bing Zhang, Jonathan T. Lei, Michael T. Lewis, Gloria Vittone Echeverria

Baylor College of Medicine, Houston, TX

Nearly 45% of patients with triple negative breast cancer (TNBC) treated with chemo-immunotherapy have residual cancer burden, which is associated with relapse and mortality. Previously, our group reported that TNBCs rely heavily on mitochondrial structural and functional adaptations to survive treatment (PMIDs 30996079, 36813854). Additionally, mitochondrial translation-related proteomic profiles of TNBC patients (n=55, PMID 36001024) and orthotopic PDX tumors (n=42, PMID 39713418) reveal a significant association with resistance to carboplatin (CRB), docetaxel (DTX), or their combination. Furthermore, on-treatment biopsies were collected from a subset of patients, and mitochondrial translation proteomic signatures were significantly elevated relative to their matched pre-treatment counterparts. Leading-edge proteins in those pathways included 30 mitoribosome proteins and the accessory protein Oxidase (Cytochrome C) Assembly 1-Like (OXA1L). OXA1L plays two crucial roles in the mitochondria: 1) it promotes translation termination for the 13 mtDNA-encoded mitochondrial respiratory chain (MRC) proteins, and 2) it aids in inner mitochondrial membrane insertion of mtDNA- and nDNA-encoded MRC proteins. Therefore, we hypothesized that mitochondrial translation, supported by OXA1L, is critical for maintaining mitochondrial function and chemoresistance in TNBC.

Knock-down (KD) of OXA1L in TNBC cells significantly reduced MRC protein levels, mitochondrial ‘respirasome’ supercomplex formation, and oxidative phosphorylation (oxphos). Notably, the characteristic elevation of oxphos in ‘residual’ cells surviving CRB treatment was abolished by the KD. Concomitantly, OXA1L KD cells exhibited significantly improved CRB sensitivity relative to control cells. These results underscore the significance of OXA1L in MRC assembly and function in TNBC, as well as its role in supporting chemoresistance.

Though there are no existing inhibitors of OXA1L, we tested the translational potential of our findings by leveraging the mitochondria’s bacterial ancestry through repurposing FDA-approved antibiotics to inhibit mitochondrial translation (PMID 25625193). We demonstrated inhibition of mitochondrial translation, MRC protein production, respirasome formation, and oxphos with low-dose tigecycline (TIG) treatment in TNBC cells. While we observed minimal toxicity to TNBC cells from TIG as a single agent, we found a significant enhancement of sensitivity to conventional chemotherapies, both in vitro and in vivo, in a PDX. In summary, our data reveal the vital role of mitochondrial translation for the metabolic adaptation and survival of chemo-refractory TNBC. Moreover, these data provide evidence that disrupting MRC assembly by inhibiting mitochondrial translation may be a promising approach to overcome mitochondrial vulnerabilities in chemo-refractory TNBC.

#2014 Metabolic adaptations of obesity-accelerated breast cancer..

Amandine Chaix[1], Keren I. Hilgendorf[2], Gregory S. Ducker[2], Edgar J. Hernandez[3]

[1]Nutrition & Integrative Physiology, University of Utah, Salt Lake City, UT,[2]Biochemistry, University of Utah, Salt Lake City, UT,[3]Biomedical Informatics, University of Utah, Salt Lake City, UT

Obesity, defined by a body mass index (BMI) ≥ 30 kg/m^2, increases the incidence, morbidity, and mortality of breast cancer (BC). However, the specific mechanisms linking obesity to BC risk remain poorly understood. Obesity is a complex condition that alters both systemic metabolism and the local tumor microenvironment, creating conditions that can promote tumor growth. Among these changes, the specific contribution of elevated lipid levels to BC growth has not been experimentally tested, despite hyperlipidemia being a common feature of obesity and dysregulated lipid metabolism a hallmark of cancer biology.Using dietary and genetic approaches in immune-competent mice, we demonstrate that elevated circulating lipids are sufficient to accelerate the growth of orthotopic models of triple-negative BC, even in the absence of obesity or changes in blood glucose and insulin levels. Conversely, pharmacological reduction of systemic lipids attenuates BC growth in obese mice, implicating circulating lipids as direct drivers of tumor expansionWeight loss (WL), achieved through lifestyle interventions or bariatric surgery, remains the only recommended strategy for women with obesity who are at risk for, BC patients and BC survivors. However, evidence-based dietary guidelines tailored to this population are lacking. In our model, a ketogenic diet which evoked WL but failed to lower systemic lipids, failed to protect against BC growth, underscoring the importance of directly targeting lipid metabolism in obesity-associated BC.Incretin mimetics (IM) or GLP-1 receptor agonists are revolutionizing the treatment of obesity and its metabolic complications, by inducing substantial WL and improving multiple health outcomes. As their use expands, IMs will increasingly be part of the therapeutic landscape for BC patients and survivors with obesity. Yet emerging epidemiological data suggest that IM-induced WL may not reduce postmenopausal BC incidence or improve disease-free survival. Consistent with these observations, our mouse data show that IM-mediated WL alone does not prevent BC progression unless accompanied by healthy dietary changes. Our data further suggest that both systemic improvements and local changes to the tumor mammary fat pad microenvironment play a key role in controlling BC growth. Together, our findings identify lipids as critical drivers of BC growth and highlight the importance of lowering circulating and local lipid levels, beyond achieving weight loss, to mitigate BC risk in individuals with obesity.

#2015 Beta-hydroxybutyrate alters one-carbon and branched-chain amino acid metabolism in glucose-restricted ER+ breast cancer cells.

Cynthia Cheung[1], Natalija Glibetic[2], Rylee Maldonado[3], Tia Skaggs[3], Scott Bowman[4], Louise Torres[3], Katelynn A. Perrault Uptmor[5], **Michael Weichhaus**[6]

[1]Laboratory of Forensic and Bioanalytical Chemistry, School of Natural Sciences and Mathematics, Chaminade University of Honolulu, Honolulu, HI,[2]Department of Cell and Molecular Biology, John A Burns School of Medicine, University of Hawaii at Manoa, Honolulu, HI,[3]Undergraduate Biology Program, School of Natural Sciences and Mathematics, Chaminade University of Honolulu, Honolulu, HI,[4]Undergraduate Biochemistry Program, School of Natural Sciences and Mathematics, Chaminade University of Honolulu, Honolulu, HI,[5]Nontargeted Separations Laboratory, Chemistry Department, William and Mary, Williamsburg, VA,[6]Laboratory of Molecular Cancer Research, School of Natural Sciences and Mathematics, Chaminade University of Honolulu, Honolulu, HI

Ketogenic diet interventions show promise in breast cancer treatment, yet precise metabolic adaptations remain incompletely characterized. We investigated amino acid metabolic reprogramming in estrogen receptor-positive (ER+) breast cancer cells subjected to glucose restriction with beta-hydroxybutyrate (BHB) supplementation to model ketogenic conditions. MCF-7 and T47D cells were cultured in glucose-restricted medium (5% standard concentration) with graded BHB supplementation (2.5-15 mM) for four days. Metabolomic profiling was performed using comprehensive two-dimensional gas chromatography-mass spectrometry (GC×GC-MS) with Fisher ratio analysis. Targeted quantification of glycine and branched-chain amino acids (BCAAs) was conducted using colorimetric and fluorometric assays. SHMT1 protein expression was measured by ELISA. Bioinformatic analysis of TCGA Breast Invasive Carcinoma data (n=1,084) assessed co-expression patterns between one-carbon metabolism genes (SHMT1/2), BCAA metabolism (BCAT1), and ketone body catabolic enzymes (OXCT1, ACAT1, BDH1). Differential expression analysis was performed on paired ER+ tumor and adjacent normal tissue samples (n=20) from GSE58135. R-code for DEG analysis was partially created using Anthropic Claude (version Sonnet 4.5). Metabolomics analysis revealed significant perturbations in one-carbon and BCAA metabolism pathways. Direct quantification confirmed dose-dependent glycine accumulation, with peak elevation at 5 mM BHB in both MCF-7 (51.1±29.5 µM vs. 27.7±3.9 µM low glucose, $p<0.05$) and T47D cells (40.7±9.8 µM vs. 29.6±9.5 µM, $p<0.05$). Despite altered glycine levels, SHMT1 protein expression remained stable across treatments in both cell lines. TCGA analysis showed weak positive correlations between SHMT1 and ketone catabolic genes BDH1 ($r=0.18$, $p=2.88\times10^{-9}$) and ACAT1 ($r=0.05$, $p=0.133$), while BCAT1 showed moderate negative correlation with BDH1 ($r=-0.36$, $p=3.69\times10^{-35}$). Differential expression analysis revealed significant downregulation of OXCT1 (log2FC=-1.41, $p=5.75\times10^{-7}$), SHMT1 (log2FC=-1.31, $p=1.62\times10^{-5}$), and ACAT1 (log2FC=-1.07, $p=1.07\times10^{-4}$) in ER+ tumors versus normal tissue, indicating selective suppression of ketone catabolism and cytoplasmic one-carbon metabolism. BHB supplementation under glucose restriction induces specific alterations in glycine homeostasis without corresponding SHMT1 changes, suggesting post-translational regulation or altered metabolic flux. Downregulation of ketone catabolic enzymes in ER+ tumors may represent a metabolic vulnerability exploitable through ketogenic interventions, warranting investigation of one-carbon metabolism as a therapeutic target in ER+ breast cancer.

#2016 Metabolic and inflammatory crosstalk underlying cancer-related fatigue (CRF) in a mouse model of breast cancer (BC).

Abigail A. Koomson[1], Susana C. B. Nakandakari[1], Andin Fosam[1], Rosalie M. Grijalva[1], Rachel J. Perry[2]

[1]Cellular and Molecular Physiology, Yale School of Medicine, New Haven, CT,[2]Yale University School of Medicine, New Haven, CT

Cancer-related fatigue (CRF) is among the most prevalent and debilitating side effects of breast cancer and its treatment in women, severely reducing adherence to treatment and quality of life. However, standardized, preclinical metrics for CRF remain poorly defined, impeding the development of therapeutic interventions. We hypothesized that breast cancer-induced physical fatigue is due to metabolic dysregulation in skeletal muscle mitochondria. Using the syngeneic E0771 mouse model of breast cancer, we characterized physical fatigue, assessed cytokine profiles, and performed targeted metabolomic analyses of muscle. Tumor-bearing mice showed significantly reduced survival and fat mass although overall body weight and lean mass were stable. Physical performance declined after three weeks of tumor growth as shown by reduced grip strength, maximum speed and peak oxygen consumption. Metabolic cage activity of mice revealed reduced oxygen consumption, carbon dioxide production, respiratory exchange ratio, energy expenditure, and water intake, consistent with suppressed metabolic function. Metabolomic profiling of skeletal muscle revealed upregulation of pipecolate and pyridoxamine, metabolites linked to amino acid metabolism and oxidative stress signaling, while key mitochondrial and antioxidant metabolites including glutathione, riboflavin and isocitrate were suppressed. These alterations suggest mitochondrial dysfunction, redox imbalance, and impaired energy production as contributors to the physical fatigue phenotype. These changes were accompanied by reduced IL1β, IL-2, MIP-1α and increased IP-10 in the plasma implicating inflammation-driven metabolic reprogramming. Breast cancer induced coordinated inflammatory and metabolic changes in the skeletal muscle, disrupting mitochondrial pathways that contribute to physical fatigue. This study identifies distinct metabolic signatures associated with CRF and highlights mitochondrial pathways as promising targets for therapeutic intervention to improve the quality of life in breast cancer patients.

#2017 Time restricted eating potentiates chemotherapy in obesity-driven breast cancer mouse models.

Manasi Das, Yunpeng Yang, Isabella Maranan, Yanting Wang, Liping Zeng, Samantha Lu, Nicholas Webster

Medicine, University Of California, San Diego, CA

Time-restricted eating (TRE) has emerged as a metabolic intervention with potential to improve cancer treatment responses. In this study, we investigated whether TRE enhances the therapeutic efficacy of chemotherapy in murine breast cancer models. Different chemotherapies, such as Letrozole, Tamoxifen, Doxorubicin, and Paclitaxel, were used in combination with TRE. Female obese mice were assigned to high-fat diet ad libitum feeding or an 8-hour TRE schedule. Mice bearing orthotopic breast tumors from ad libitum and TRE groups were treated with or without standard chemotherapeutic treatment to evaluate the TRE-Chemotherapy combination effect. The combination of TRE and chemotherapy (Doxorubicin and Paclitaxel) resulted in significantly reduced tumor growth compared with chemotherapy or TRE alone. TRE in combination with Letrozole demonstrated improved survival benefits over chemotherapy or TRE alone. These findings suggest that aligning feeding patterns with circadian rhythms can potentiate chemotherapeutic efficacy. TRE represents a lifestyle-based non-pharmacologic approach that may improve treatment outcomes in breast cancer and warrants further investigation of metabolic timing strategies in cancer treatment.

#2018 Investigating the role of Wnt/planar cell polarity signaling in the reprogramming of energy metabolism in breast cancer.
Liliana Loza Sanchez, Kacey VanderVorst, Kermit L. Carraway

UC Davis Medical Center, Sacramento, CA

This study aims to investigate how non-canonical Wnt/planar cell polarity (Wnt/PCP) signaling contributes to metabolic reprogramming and supports breast cancer progression. Breast cancer is the most prevalent cancer affecting women, and the 5-year survival rate for women diagnosed with metastatic breast cancer remains below 30%. For breast tumors to progress and ultimately result in metastatic disease, large increases in energy demands must be met. Tumors gain bioenergetic versatility by undergoing metabolic reprogramming through the upregulation of glycolytic and oxidative phosphorylation (OXPHOS) activity, and through alterations in mitochondrial biogenesis and degradation (mitophagy). However, the signal transduction pathways critical to sustaining the high levels of ATP production remain largely undefined. The non-canonical Wnt/PCP signaling pathway has been implicated in promoting tumor cell migration and metastasis in diverse tumor types. Our laboratory has reported that the Wnt/PCP-specific transmembrane protein Vangl mediates breast cancer collective migration and metastasis. Further, our recent proteomics and metabolomics studies indicate that Vangl1 regulates the expression of critical components in the OXPHOS pathway in vivo and in vitro, and that the Wnt/PCP ligand Wnt5a alters the phosphorylation of proteins involved in mitochondrial biogenesis and mitophagy. Thus, I propose that Wnt/PCP signaling regulates the reprogramming of energy metabolism to drive cell proliferation and motility in breast cancer. This will be tested by investigating the contribution of Wnt/PCP signaling to OXPHOS activity and the regulation of mitochondrial biogenesis and mitophagy in breast cancer. This study will promote our understanding of Wnt/PCP involvement in breast cancer progression and provide new insights into the mechanisms contributing to cancer metabolic reprogramming.

#2019 Comparison of non-metastatic and metastatic breast cancer cell and lipid droplet proteomes.

Chaylen Andolino, Kimberly K. Buhman, Dorothy Teegarden

Nutrition Science, Purdue University, West Lafayette, IN

Metastatic breast cancer cells often have increased cellular storage of neutral lipids, such as triacylglycerol (TAG), in cytoplasmic lipid droplets (LDs). Although LD accumulation is associated with increased cancer aggressiveness, the role of these organelles in contributing to metastatic disease remains unclear. Aside from TAG storage within the core of the LD, the phospholipid monolayer is also decorated with a variety of proteins. Given that LD-associated proteins reflect the organelle's function within a given physiological context, we characterized the proteome of LDs from a human metastatic compared to non-metastatic breast cancer cell line to assess potential candidate protein pathways that may associate with LDs to promote metastasis.

Untargeted shotgun proteomics of LDs isolated via sucrose density gradient ultracentrifugation from non-metastatic MCF10CA1h (less LDs) and metastatic MCF10CA1a (more LDs) cell lines was performed. The LD proteomes, as well as the proteome of each cell line's whole cell lysate (WCL), were compared utilizing MaxQuant, MassDynamics, Metascape, and STRING.

We identified that LDs from metastatic cells are highly enriched in proteins related to LD organization and protein localization compared to LDs from non-metastatic cells. Interestingly, proteins involved in the sequestering of NFκB were the most highly enriched lipid-related protein category in LDs of metastatic compared to non-metastatic cells. Further, NFκB was similarly enriched in the WCLs of both cell lines; however, was only identified in the isolated LD fraction from metastatic cells. Additionally, the negative regulator of LD catabolism, hypoxia inducible lipid droplet associated protein (HILPDA), was only identified in the metastatic cell LD fractions. Given the role of NFκB and HILPDA in tumor progression and therapy resistance, results from this study provide testable hypotheses that can elucidate how LDs contribute to breast cancer metastasis. For example, LDs may act as scaffolds for signaling to coordinate lipid metabolism and metastatic processes or as a stress-adaptive platform to enable rapid lipid-mediated signaling under hypoxia inducible factor (HIF) activation. Additionally, given that HILPDA stabilizes LDs which store precursors for eicosanoid synthesis, which in turn modulate NFκB activity and subsequent inflammatory response, the interactions of these mediators may integrate into a metabolic-inflammatory axis to promote tumor progression and immune evasion.

Together, our results indicate that though the global proteome of non-metastatic and metastatic breast cells derived from the same parental line are similar, the proteins associated with LDs vary greatly. This study provides a list of candidate proteins for additional experimentation to determine their role in sustaining LD accumulation and metastatic progression.

#2020 Fatty acid metabolism supports survival in normoxia and migration upon reoxygenation in lung-metastasizing breast cancer cells.

Marjorie Anne Layosa[1], Morgan Conrad[1], Chaylen Jade Andolino[1], Michael K. Wendt[1], Stephen D. Hursting[2], Dorothy Teegarden[1]

[1]Purdue University, West Lafayette, IN,[2]University of North Carolina at Chapel Hill, Chapel Hill, NC

Breast cancer is the most common cancer among women, and metastasis remains the leading cause of mortality. While fatty acid metabolism plays a critical role in cancer progression, its specific contribution to supporting breast cancer metastasis to distinct organs, particularly the lungs and liver, remains poorly understood. This study aims to characterize the lipid metabolic profiles of breast cancer cells with preferential metastasis to the lung versus the liver, and to determine how lipid metabolism supports cell survival under normoxia and drives migration upon reoxygenation after exposure to hypoxia. We utilized a unique murine breast cancer cell model with preferential metastasis to either lung (metM-Wnt^{Lung}; MLg) or liver (metM-Wnt^{Liver}; MLr). The metastatic cells were exposed to normoxia or hypoxia (1% O_2, 48 hrs) and reoxygenation to mimic dynamic tumor microenvironmental stress. Fatty acid metabolism was assessed using ^{13}C isotopic tracing, and cell viability and migration were evaluated following inhibition of key metabolic enzymes. Results showed that $^{13}C_6$-glucose and $^{13}C_5$-glutamine were significantly incorporated into the synthesis of both saturated (16:0 and 18:0) and unsaturated (16:1 and 18:0) fatty acids, indicating higher *de novo* fatty acid synthesis in MLg cells compared to MLr cells. Despite this, both cell lines exhibited similar triacylglycerol levels without evident lipid accumulation. A pulse-chase experiment showed that $^{13}C_6$-glucose-labeled fatty acids declined more rapidly in MLg than in MLr cells at 24 and 48 hrs (48.8% vs 30.3%, and 58.5% vs 48.3%, respectively), indicating more rapid fatty acid turnover in MLg than MLr cells. Inhibition of key enzymes in fatty acid metabolism, including *de novo* fatty acid synthesis (FASN via TVB-3166), esterification (DGAT2 via PF-06424439), lipolysis (ATGL via ATGListatin), and β-oxidation (CPT1A via etomoxir), induced a significantly greater reduction in cell viability of MLg than MLr cells, indicating that dynamic fatty acid synthesis, storage, lipolysis and oxidation are necessary to support survival in MLg cells. Under hypoxic conditions, MLg cells sustained higher *de novo* fatty acid synthesis accompanied by lipid accumulation. Upon reoxygenation following hypoxia, inhibition of either lipolysis or β-oxidation reduced MLg cell migration by 57% and 42%, respectively, an effect not observed in MLr cells. Overall, these results support that dynamic and rapid fatty acid turnover in lung-metastatic breast cancer cells is necessary to support survival, with lipids accumulated during hypoxia subsequently mobilized and oxidized to fuel migration upon reoxygenation. These findings identify lipid metabolism as a critical driver of lung-specific metastasis and a promising therapeutic target to reduce metastatic spread and improve outcomes for patients with breast cancer.

#2022 Tryptophan metabolites drive ferroptosis resistance in triple-negative breast cancer cells.

Jamshid Motalebzadeh, Hossein Anani, Chloe Thompson-Peach, Theresa Hickey, Lisa Butler, Nirmal Robinson, Daniel Thomas

Adelaide Medical School, University of Adelaide, Adelaide, Australia

Introduction

Tryptophan (Trp) metabolites are increased in various cancer types due to elevated expression of Trp dioxygenases, TDO2, IDO1, and IDO2. While recent studies have highlighted the immunosuppressive functions of these metabolites, their intrinsic significance to cancer cell survival remains poorly understood. This study explores the role of formylkynurenine and kynurenine, the first two metabolites in Trp catabolism on triple-negative breast cancer (TNBC) resistance to ferroptosis.

Methods

We performed comprehensive gene expression analysis using 46 ER+, 103 TNBC tumours, and 21 adjacent normal tissue samples from the SRA database. BRCA-TCGA RNA-seq and DNA-seq data were analysed to identify alterations in three Trp dioxygenases in TNBC patients. RNA-seq was conducted on BT549 cell line cultured with 50 μM formylkynurenine and kynurenine. Gene expression changes were validated using western blotting and real-time qPCR. Intracellular glutathione (GSH) and oxidized glutathione (GSSG) levels were quantified by LC-MS and MS/MS approach. Cell sensitivity to ferroptosis was evaluated by treating cells with 300 nM RSL3.

Results

Our analysis revealed increased expression of all three Trp dioxygenases, TDO2, IDO1, and IDO2, in TNBC tumours compared to luminal and adjacent normal tissues. DNA amplification was detected in IDO1 and IDO2, and reduced IDO1 promoter methylation in TNBC samples compared to luminal subtypes. Formylkynurenine and kynurenine both at concentrations of 50-100 μM significantly enhanced BT549 cell line proliferation. Transcriptomic analysis indicated that these metabolites regulate genes involved in ROS metabolism and iron transport. Metabolomics analysis further demonstrated alterations in the intracellular GSH/GSSG ratio. Notably, we report for the first time that kynurenine upregulates GPX4 protein expression, while formylkynurenine does not. However, both metabolites increased cellular resistance to RSL3-induced ferroptosis.

Conclusion

Formylkynurenine and kynurenine both increase GSH/GSSG ratio. While kynurenine upregulates GPX4 expression, formylkynurenine does not alter its levels. These findings establish a novel metabolic axis linking Trp catabolism to ferroptosis resistance in TNBC, suggesting that targeting this pathway could represent a promising therapeutic strategy for this aggressive subtype of breast cancer.

#2023 Tryptophan and serine metabolic axis reveals novel therapeutic vulnerabilities in triple-negative breast cancer.

Jamshid Motalebzadeh, Hossein Anani, Chloe Thompson-Peach, Theresa Hickey, Lisa Butler, Nirmal Robinson, Daniel Thomas

Adelaide Medical School, University of Adelaide, Adelaide, Australia

Tryptophan (Trp) metabolism is recognised to have immunomodulatory effects in cancer, with downstream metabolites such as kynurenine suppressing T cell responses. However, the role of Trp catabolism in cancer cell biosynthesis and tumor growth is poorly understood. Herein, we investigated for the first time the role of Trp as a source of one-carbon metabolism through formate production in triple-negative breast cancer (TNBC) and its effect on serine synthesis via phosphoglycerate dehydrogenase (PHGDH), a rate-limiting enzyme for de novo serine synthesis.

CRISPR-Cas9 system was used to generate tryptophan 2,3-dioxygenase (TDO2) and/or indoleamine 2,3-dioxygenase (IDO1) knockout TNBC cell lines. Multi-omics approach using LCMS Q-TOF system and RNA-seq was employed to integrate targeted and untargeted metabolomics, ^{13}C fluxomics, and transcriptomics in TNBC cell lines. For fluxomics studies, cells were cultured with ^{13}C-labeled tryptophan to trace the metabolic flux of carbon atoms through Trp metabolism into kynurenine pathway.

While serine is recognised as a major source of one-carbon metabolism, our fluxomics data revealed that one-carbon units are released during the conversion of N-formylkynurenine to kynurenine. Labelled metabolites derived from tryptophan that give rise to tetrahydrofolate and methionine cycles were identified and these were subsequently incorporated to generate de novo purines. Integrated transcriptome and metabolomic analysis of tryptophan dioxygenase KO versus WT, as well as formylkynurenine and kynurenine treated cells, revealed a link between Trp catabolism and serine anabolism via alteration in PHGDH expression. Moreover, KO cells deprived of one-carbon units derived from Trp metabolism showed upregulation of PHGDH gene expression. Interestingly, KO cells showed a significantly lower growth rate in serine-glycine free media and also when PHGDH was inhibited with 2.5 μM NCT-503.

This study provides evidence that Trp metabolism contributes to one-carbon metabolism in TNBC beyond its immunosuppressive functions. We also show that disruption of Trp metabolism upregulates PHGDH as a compensatory mechanism. This study identifies simultaneous inhibition of both pathways as a promising dual-targeting therapeutic strategy for TNBC treatment.

#2025 Zinc promotes aerobic glycolysis in breast cancer by promoting PKM2 dimerization and nuclear localization.

Wenyou He, Jiali Xu, Yihuizhi Zhang, Weijian Ding, Xinyu Chen, Yirui Ye, Linyue Li, Baotong Zhang, **Siyuan Xia**

Southern University of Science and Technology (SUSTech Shenzhen), Shenzhen, China

Zinc regulates breast cancer progression by modulating cellular proliferation and hormone-dependent signaling pathways, yet its role in glucose metabolic reprogramming remains incompletely understood. In our study, we found that elevated Zn^{2+} enhances aerobic glycolysis while markedly suppressing mitochondrial oxidative phosphorylation and inhibiting the pentose phosphate pathway. Transcriptomic profiling further reveals that Zn^{2+} treatment selectively upregulates glycolysis-associated genes, including the glucose transporter GLUT1 (SLC2A1) and pyruvate kinase, highlighting a coordinated shift toward glycolytic metabolism under zinc-replete conditions. Mechanistically, Zn^{2+} directly binds to pyruvate kinase M2 isoform (PKM2), stabilizing its dimeric state and promoting its nuclear translocation. Nuclear PKM2 subsequently enhances the transcription of glycolytic genes (i.e., *LDHA*). Consistent with this mechanism, Zn^{2+} treatment sensitizes tumor cells to the LDHA-specific small-molecule inhibitor NHI-2, resulting in a synergistic anti-tumor effect. Furthermore, the zinc efflux transporter ZnT1 (SLC30A1) is transcriptionally induced following Zn^{2+} exposure, functioning as a feedback mechanism to maintain zinc homeostasis. Conversely, ZnT1 knockdown leads to intracellular zinc accumulation, which further enhances aerobic glycolysis through similar mechanisms of PKM2 dimer stabilization and nuclear translocation. Collectively, this study elucidates a molecular mechanism by which zinc promotes aerobic glycolysis through direct binding to PKM2, stabilizing its dimeric conformation and facilitating its nuclear localization. These findings propose a therapeutic strategy that combines Zn^{2+} supplement with LDHA inhibition, revealing a previously unrecognized metabolic vulnerability that may be leveraged for precision oncology.

#2026 Scd1 overexpression in cancer-associated adipocytes drives breast cancer development and metastasis.

Zander Esh[1], Pascal Naef[1], Justice Williams[1], Johnny Le[1], Gautham Prabhakar[1], Jacob Insua Rodriguez[1], Hannah Savage[2], Ayisha Bushra[1], Cholsoon Jang[1], Kai Kessenbrock[1]

[1]Biological Chemistry, UCI School of Medicine, Irvine, CA,[2]Department of Physiology and Biophysics, UCI School of Medicine, Irvine, CA

Throughout the course of tumor development in breast cancer (BC), adipocytes within the tumor microenvironment undergo modifiable changes that promote tumor growth and invasive capacity, notably including the upregulation of Scd1, an enzyme integral to lipid metabolism. The timing of this metabolic reprogramming of healthy adipocytes to cancer-associated adipocytes (CAAs), as well as interventions that can reverse this process are poorly understood. To elucidate this progression, we used a polyoma middle T antigen (PyMT) transgenic mouse model that spontaneously develops luminal B-like tumors specific to the mammary fat pad (MFP). Using this model, we performed single-nucleus RNA sequencing (snRNA-seq) and metabolic profiling of MFP from healthy and tumor-bearing PyMT littermates. Among the many differences found when comparing healthy to tumor-bearing tissue at several time points throughout the progression of hyperplasia to invasive carcinoma, we discovered a consistent upregulation of Scd1, a stearoyl-CoA desaturase that performs the rate-limiting step in the conversion of saturated fatty acids (SFAs) to monounsaturated fatty acids (MUFAs), in adipocytes. However, despite the persistent upregulation of Scd1, we noticed an overall depletion of MUFAs in PyMT tumor-bearing tissue, indicating that tumor cells consume MUFAs during their malignant progression to invasive carcinoma and eventual metastasis. First, we recapitulated our snRNA-seq findings from mice in both snRNA-seq and spatial transcriptomics data from human breast tissue through gene signature scoring. We found that our progressive gene signatures accurately map to ductal carcinoma in situ, as well as invasive ductal carcinoma, providing confidence that interventions we establish in our mouse and in vitro models will translate to human BC. Next, to target the malignant transformation observed in our PyMT model, we cultured BC cell lines in adipocyte-conditioned medium, either when adipocyte Scd1 is selectively inhibited (iACM) or when adipocytes are allowed to function normally (ACM). Exposure to ACM alone increased cell viability, spheroid formation, and invasiveness, while iACM led to a marked decrease in all three parameters. Finally, to extend these results back into our mouse model, we injected C57BL/6 mice intracardially with BC cells conditioned in either ACM, iACM, or control media. While ACM led to aggressive metastasis with tropism selective for bone, iACM abolished the tropism and greatly decreased the metastatic capability of the injected cells. Taken together, our data show that the consistent upregulation of Scd1 throughout tumor progression in BC can be inhibited to reduce tumor growth and metastasis, thus identifying Scd1 expression in CAAs as a therapeutic target in BC, both in the early stages of progression and during metastatic spread.

#2027 ATP citrate lyase fuels lipid storage to support triple negative breast cancer chemoresistance.

Katherine E. Pendelton[1], Mokryun L. Baek[1], Mariah J. Berner-Wu[1], Steven W. Wall[1], Audra Lane[1], Jonathan T. Lei[1], Iqbal Mahmud[2], Lin Tan[2], Lacey E. Dobrolecki[1], Philip L. Lorenzi[3], Michael T. Lewis[1], Blake R. Rushing[4], Gloria V. Echeverria[1]

[1]Baylor College of Medicine, Houston, TX,[2]MD Anderson Cancer Center, Houston, TX,[3]City of Hope, Duarte, CA,[4]UNC Chapel Hill, Chapel Hill, NC

Triple negative breast cancer (TNBC) is an aggressive breast cancer subtype in which neoadjuvant chemotherapy (NACT) is the backbone of standard of care. Unfortunately, ~45% of patients have residual tumor burden following NACT, which is strongly associated with poor prognoses. Our group previously demonstrated that mitochondrial oxidative phosphorylation is upregulated and is a therapeutic vulnerability of chemo-refractory TNBC. We used metabolomic flux tracing to show a heightened contribution of glucose oxidation to the tricarboxylic acid (TCA) cycle in residual human TNBC cells surviving several conventional chemotherapies. We found significantly elevated abundance of citrate and acetyl-coA (AcCoA) in residual cells. Further, glucose, but not palmitate, glutamine, or acetate, derived heavy carbon was more strongly incorporated into citrate and AcCoA in residual relative to naïve cells. Concomitantly, we observed drastic lipidomic remodeling, largely characterized by elevation of triglycerides, long chain fatty acids, and poly unsaturated fatty acids (PUFAs) in cultured TNBC cells and orthotopic patient-derived xenograft (PDX) tumors following chemotherapy relative to their treatment naïve counterparts. This was accompanied by a significant increase in the number of lipid droplets (LDs) in residual cells. Together, these data suggest glucose oxidation supports fatty acid synthesis (FAS) and storage in chemoresistant TNBC. Our analyses of human TNBC proteomic and transcriptomic data affirmed the significant association of fatty acid metabolism with TNBC chemoresistance, as well as its upregulation in chemotherapy-treated tumors relative to their pre-treated counterparts. Mining those data led us to ATP citrate lyase (ACLY), the rate limiting enzyme for cytosolic AcCoA production from citrate. We hypothesized that ACLY converts excess citrate, generated by heightened TCA cycling, to AcCoA to promote FAS and storage in chemoresistant TNBC. We found elevated protein levels of ACLY and an activating phosphorylation mark in TNBC cells surviving treatment with conventional chemotherapies doxorubicin and carboplatin. ACLY knockdown or inhibition potently reduced chemotherapy-induced accumulation of AcCoA and LDs and elicited lipidomic rewiring largely characterized by increased PUFAs. Notably, combining ACLY inhibition or KD with conventional chemotherapy treatments provided significant improvement of tumor cell growth inhibition. These data indicate that NACT can cause accumulation of citrate, AcCoA, LDs, and overall lipidomic rewiring through ACLY. ACLY is a novel functional dependency of chemo-refractory TNBC and should be further explored as a potential therapeutic target. We posit that TNBC cells adapt to the stress of NACT by upregulating lipid synthesis and storage in conjunction with glucose catabolism, enhancing metabolic flexibility and cell survival.

#2028 Hyperlipidemia drives tumor growth in a mouse model of obesity-accelerated breast cancer growth.

Renan Fudoli Lins Vieira, Sawyer Sanchez, Menusha Arumugan, Peyton Mower, Meghan Curtin, Abigail Jackson, Jillian Wright, Alexis Bowles, Gregory S. Ducker, Keren Hilgendorf, Amandine Chaix

University of Utah, Salt Lake City, UT

Obesity is an established risk factor for breast cancer (BC), yet the specific mechanisms driving this association remain unclear. Dysregulated lipid metabolism has emerged as a key factor in cancer cell biology, and, while obesity is often accompanied by hyperlipidemia, the isolated impact of elevated lipid levels on BC growth has not been experimentally tested. Using the E0771 and Py230 orthotopic models of obesity-accelerated BC growth in immune-competent mice, we investigated the role of systemic lipids on tumor growth. Combining dietary and genetic mouse models, we show that elevated circulating lipids are sufficient to accelerate BC tumor growth even in the absence of obesity or alterations in blood glucose and/or insulin levels. Pharmacological lowering of systemic lipid levels attenuates BC growth in obese mice, suggesting a direct role for lipids in fueling tumor expansion. Notably, we also show that weight loss alone, without a corresponding reduction in lipid levels such as that induced by a ketogenic diet, fails to protect against BC, highlighting the necessity of targeting lipid metabolism in obesity-associated BC. Our findings establish hyperlipidemia as a critical driver of BC progression and suggest that lipid-lowering interventions may be a promising strategy to mitigate BC risk in individuals with obesity.

#2029 Regulation of metabolic and stress adaptation in triple-negative breast cancer.

Emilia F. Carlo[1], Columba de la Parra[1], Erna Mitaishvili[2], Blessing Ukandu[1]

[1]Chemistry, Herbert H. Lehman College, City University of New York, Bronx, NY,[2]Ph.D. Program in Biology, The Graduate Center, City University of New York, New York, NY

Triple-negative breast cancer (TNBC) is a highly aggressive breast cancer subtype characterized by rapid progression, metabolic reprogramming, and limited therapeutic options. Under stress conditions such as nutrient deprivation or oxidative stress, TNBC cells suppress canonical translation initiation and rely on alternative mechanisms to maintain the production of stress-adaptive proteins. Death-Associated Protein 5 (DAP5), a member of the eIF4G family, facilitates an alternate cap-dependent translation under conditions in which canonical translation is inhibited. Our data suggest that DAP5 plays a critical role in orchestrating metabolic adaptation for TNBC progression and metastasis. To investigate the role of DAP5 in metabolic and oxidative stress adaptation, we used the well-characterized TNBC cell line MDA-MB-231 with either control or DAP5 silencing. We found that DAP5 activity persists under oxidative stress when canonical translation is suppressed, enabling sustained expression of glycolytic enzymes and supporting glycolytic flux. DAP5 silencing resulted in reduced translation of glycolytic proteins, including GLUT1 and hexokinase II. It also decreased proteins related to redox response singling pathways, including CDK12. Metabolomic profiling following DAP5 depletion indicated significant alterations in nucleotide cofactors and disruptions in metabolic pathways commonly enriched in metastatic cancers, including amino acid and glucose metabolism. Consistently, ATP assay measurement showed a significant reduction upon DAP5 silencing, suggesting impaired energy metabolism in TNBC cells. Our findings support a model in which DAP5-mediated translation preserves a subset of metabolic mRNAs critical for metastasis when translation is attenuated. DAP5 acts as a key regulator of TNBC metabolism by selectively translating metabolic mRNAs, particularly those involved in glucose metabolism, thereby sustaining stress adaptation and promoting metastatic behavior.

#2030 Differential impact of metformin based prevention and therapeutic strategies on aberrant metabolic signals/ molecular signatures associated with triple negative breast cancer (TNBC) during high fat/ high fructose diet feeding.

Md. Imtiazul Kabir[1], Robin Kumar[1], Lakshmi Sai Pratyusha Bugata[1], M. Nurul Islam[2], Sanjida Afroz Mitu[2], Komal Raina[1]

[1]Dept. of Pharmaceutical Sciences, South Dakota State University, Brookings, SD,[2]Dept. of Chemistry and Biochemistry, South Dakota State University, Brookings, SD

Metformin is routinely used in the management of type-2 diabetes (T2D) and is known for its potential to alter mitochondrial respiration-driven energetic stress. Interestingly, metformin has also been the focus of cancer research because various study outcomes have associated its intake with anti-cancer benefits. In the present study, we determined the comparative anti-cancer effects of preventive *versus* therapeutic regimen of oral metformin against TNBC tumorigenesis. Given that the anti-cancer benefits of metformin are observed mostly in cases associated with metabolic aberrations such as obesity/T2D, accordingly, the *in vivo* preclinical study was performed in diet-induced obese mice model (DIO mice) wherein four week old C57Bl/6 female mice were fed either a high fat diet (HFD, 60 kcal% fats) or high fructose diet (HFR, 60 kcal% fructose) throughout the course of the study so as to induce obesity-associated changes in both systemic and local mammary gland microenvironment that could impact breast tumorigenesis. After 10 weeks of respective DIO feeding (at 14 weeks of mice age), orthotopic mammary tumors were induced by subcutaneous injection of $2x10^6$ PY230 breast cancer cells in the 4^{th} mammary fat pad (either left or right). In the preventive regimen metformin (pre) treatment (daily oral gavage: 300mg/kg body wt.) was started 4 weeks before the cell inoculation and continued till 2 weeks after the cell inoculations followed by a wash out period of 6 weeks till study end (8 weeks following cell inoculations). On the other hand, in the therapeutic regimen, metformin (post) treatment (daily oral gavage: 300mg/kg body wt.) was started 2 weeks after the cell inoculation and continued till 6 weeks after the cell inoculations (till study end). Overall, the results indicated that while both preventive and therapeutic regimens of metformin had an anti-tumorigenic effect on TNBC growth and progression, the preventive regimen even after the washout period (no drug administration) had long lasting anti-cancer effect which was comparatively better than therapeutic treatment of TNBC tumors. In untargeted metabolomic profiling, the observed metabolic alterations in both the HFD and HFR groups suggest that metformin has the potential to restore metabolic homeostasis in the tumor microenvironment. In untargeted lipidomics profiling, metformin's preventive and therapeutic effects were evident in the modulation of multiple lipid classes. Specifically, the preventive regimen appeared to yield more pronounced lipid alterations, indicating the potential benefits of early intervention in modulating cancer progression.

#2031 Reproducible serum metabolomics drives biomarker discovery in ovarian cancer.

Rachel Culp-Hill[1], Brendan Giles[1], Mattie Goldberg[1], Robert A. Law[1], Enkhtuya Radnaa[1], Shannon Kilkenny[1], Maria Wong[1], Connor Hansen[1], Benjamin G. Bitler[2], Kian Behbakht[2], Vuna Fa[1], Abigail McElhinny[1]

[1]AOA Dx, Denver, CO,[2]University of Colorado Anschutz Medical Campus, Aurora, CO

Ovarian cancer (OC) remains one of the deadliest gynecologic malignancies, with a clear unmet need for novel biomarker strategies. Altered metabolism has emerged as a cancer hallmark, with serum reflecting rewired cellular pathways supporting tumor growth and survival. Advancements in mass spectrometry (MS) have improved precision and confidence in feature identification, allowing for impressive analytical depth in extremely low volumes (<10µL) of biofluid. Our previous work has focused on lipidomics, but the biological mechanisms revealed through metabolomics can offer novel and complementary insight into tumor metabolism. Metabolomics, therefore, has the potential to become a powerful tool for biomarker discovery through the characterization of systemic metabolic alterations in individuals diagnosed with OC.Two independent, clinically annotated cohorts of serum representing the population of women experiencing symptoms of OC were analyzed using untargeted metabolomics (UHPLC-HRMS). Cohort #1 (N=519), obtained from University of Colorado and commercial vendors comprised patients diagnosed with OC across stages and subtypes (N=219: 80 stage I/II, 139 stage III/IV), benign gynecological disorders (N=168), gastrointestinal disorders (N=50), and healthy donors (N=82). Cohort #2 (N=400) comprised patients diagnosed with OC (N=116: 50 stage I/II, 66 stage III/IV), benign adnexal masses (N=116), borderline tumors (N=19), other symptomatic individuals (N=114), and healthy donors (N=35). We observed alterations in several key metabolic pathways, many of which have been individually implicated in OC biology, including decreased amino acids and bile acids, with increased acyl-carnitines and fatty acids. To evaluate cohort reproducibility, we compared statistical trends (cancer v. non-cancer) from each cohort. Of the significantly altered features in both cohorts, 68% maintained directionality. 90% of those maintaining directionality are a part of the key pathways above. The consistency in metabolic alterations across two independent cohorts suggests these pathway intermediates transcend batch-to-batch variability and could be leveraged as diagnostic biomarkers . In fact, initial machine learning-based modeling shows that models combining metabolites, lipids, and proteins result in AUCs >90%. MS-based metabolomics represents a snapshot of an individual’s disease state, offering insight into metabolic alterations indicative of early-stage cancer through a non-invasive sample. Here, we identified consistent metabolic alterations in OC serum across two independent, clinically annotated cohorts that align with previously reported pathway alterations. This demonstrates the analytical robustness of our approach and highlights the potential of MS-based metabolomics to move beyond discovery, toward development of clinically viable biomarkers for early-stage OC detection.

#2032 MEX3A sustains mitochondrial integrity and metabolic resilience to drive ovarian clear cell carcinoma progression and liver colonization.

Priyanka Vinothkumar[1], Pei-Yi Lin[2], Li-Tzu Cheng[3], Chen-Hsin Albert Yu[4], Pang-Hung Hsu[5], Yu-Chi Chou[6], Wendy W. Hwang-Verslues[7]

[1]Molecular and Cell Biology, Taiwan International Graduate Program, Academia Sinica; Graduate Institute of Life Sciences, National Defense Medical University, Genomics Research Center, Academia Sinica, Taipei, Taiwan,[2]Genomics Research Center, Genomics Research Center, Academia Sinica, Taipei, Taiwan,[3]Graduate Institute of Life Sciences, National Defense Medical University, Taipei, Taiwan,[4]Institute of Molecular Biology, Taipei, Taiwan,[5]Department of Bioscience and Biotechnology, Department of Bioscience and Biotechnology, National Taiwan Ocean University Keelung City, Keelung, Taiwan,[6]Biomedical Translation Research Center, Academia Sinica, Taipei, Taiwan,[7]Genomics Research Center, Academia Sinica, Taipei, Taiwan

Background and Aim: Ovarian clear cell carcinomaOCCC is a metabolically distinct and chemo-resistant subtype of ovarian cancer characterized by poor prognosis and high recurrence rates. OCCC exhibits unique metabolic adaptations that enables survival under nutrient deprivation and oxidative stresses. Mitochondrial integrity is central to this adaptive capacity, yet the molecular mechanisms that preserve mitochondrial homeostasis in OCCC remain poorly defined. Recent evidence has identified the RNA-binding protein MEX3A as an oncogenic regulator in several cancers, including OCCC, where it promotes tumor progression. However, its role in regulating mitochondrial metabolism and stress adaptation is largely unexplored. This study aims to elucidate whether and how MEX3A sustains mitochondrial homeostasis to drive OCCC progression, focusing on its impact on tumor growth, mitochondrial structure and transcriptional responses to metabolic and mitochondrial stress.
Methods: Endogenous MEX3A protein levels were evaluated across an OCCC cell panel by western blotting. Stable MEX3A knockdown and control cells were generated using a lentivirus shRNA system. Functional studies were performed using OCCC cell lines TOV21G,JHOC5 and *in vivo* orthotopic intrabursa and intrasplenic xenograft models to assess tumor growth and liver colonization. Mitochondrial function was analyzed by Seahorse metabolic flux assays, ATP quantification and NAD^+/NADH measurements. Morphological and ultrastructural alterations were examined by confocal and transmission electron microscopy. Mitochondrial biogenesis genes and mitophagy markers were assessed by qPCR and immunoblotting.
Results:MEX3A expression was significantly elevated in OCCC tissues and correlated with poor overall survival. Knockdown of MEX3A in OCCC cells markedly reduced primary tumor growth and significantly reduced the number of liver metastatic nodules in mouse models, demonstrating its functional importance for metastatic colonization. At the cellular level, MEX3A depletion led to loss of mitochondrial cristae integrity, fragmented morphology, reduced oxygen consumption and decreased ATP generation, indicating a dysfunctional in oxidative phosphorylation. Under mitochondrial stress induced by FCCP or liver-extract, control cells activated transcriptional programs for mitochondrial biogenesis, upregulating PGC1A, NRF2 and TFAM. In contrast, MEX3A-deficient cells failed to induce this adaptive response, leading to TOM20 degradation and defective mitochondrial recovery.
Conclusion: Our study reveals MEX3A as a crucial RNA-binding protein that preserves mitochondrial integrity and enables metabolic adaptation in OCCC. By sustaining mitochondrial biogenesis and recovery following stress, MEX3A enhances OCCC fitness, tumor growth and liver colorization

#2033 LSR suppresses ferroptosis through alpha-tocopherol uptake and promotes tumor growth in gynecological cancers.

Masashi Akada, Kosuke Hiramatsu, Yoshikazu Nagase, Tatsuo Masuda, Mamoru Kakuda, Satoshi Nakagawa, Tadashi Iwamiya, Shinya Matsuzaki, Michiko Kodama

The University of Osaka, Suita, Japan

Background
Lipolysis-stimulated lipoprotein receptor (LSR) plays an important role in lipid uptake and is overexpressed in gynecologic cancers, where its high levels are correlated with unfavorable outcomes. However, the lipid metabolic mechanisms via LSR are not well understood. In this study, we investigated how LSR-dependent lipid uptake promotes tumor growth in gynecologic malignancies.
Methods
To explore the lipid metabolic mechanism mediated by LSR, we first demonstrated the effect of high-fat diet (HFD) on tumor growth of LSR-positive ovarian cancer in vivo, and compared the antitumor efficacy of anti-LSR antibody (Ab) between HFD-fed and normal diet (ND)-fed mice. Next, we assessed whether serum from HFD-fed mouse promotes proliferation of ovarian cancer cells in vitro. To identify lipid metabolites responsible for HFD-induced tumor promotion, we performed metabolomic analysis of HFD and ND mouse serum. Based on the identified metabolite, we further investigated its mechanistic contribution to tumor growth.
Results
HFD significantly promoted ovarian cancer growth ($p < 0.05$), and the antitumor effect of anti-LSR Ab was strongly effective in HFD-fed mouse in vivo ($p < 0.05$). HFD mouse serum also significantly enhanced cell proliferation of ovarian cancer cells in vitro ($p < 0.05$). Metabolomic analysis of HFD and ND mouse serum identified alpha-tocopherol (vitamin E) as the most discriminative metabolite. Alpha-tocopherol is a lipid-soluble antioxidant known to suppress ferroptosis; thus, we hypothesized that LSR-mediated alpha-tocopherol uptake inhibits ferroptosis in gynecological cancer cells. At first, we demonstrated that LSR knockdown (KD), using siRNA, significantly suppressed cell proliferation in endometrial and ovarian cancer cells ($p < 0.05$). LSR-KD also reduced GPX4 expression and increased reactive oxygen species (ROS) and lipid peroxidation, indicating enhanced ferroptosis sensitivity. Importantly, these effects were completely reversed by ferroptosis inhibitors but not by apoptosis or necroptosis inhibitors, suggesting that LSR inhibits ferroptosis specifically. In control endometrial and ovarian cancer cells, alpha-tocopherol supplementation restored cell proliferation ($p < 0.05$), GPX4 expression, and reduced ROS and lipid peroxidation under oxidative stress (H_2O_2 exposure). However, in LSR-KD cells, alpha-tocopherol did not show a rescue effect, consistent with impaired uptake via LSR.
Conclusion
LSR promotes tumor progression of gynecological cancers through alpha-tocopherol uptake, leading to ferroptosis suppression. Inhibition of alpha-tocopherol uptake via LSR may sensitize endometrial and ovarian cancers to ferroptosis-inducing treatments.

#2034 H6PD as a metabolic target of DAP5 regulating NADPH homeostasis in TNBC.

Blessing Ukandu[1], Erna Mitaishvili2[2], Emilia CARLO[3], Columba de la Parra[3]

[1]Chemistry, Lehman College - CUNY, Bronx, NY,[2]CUNY Graduate Center, New York, NY,[3]Lehman College - CUNY, Bronx, NY

Triple-negative breast cancer (TNBC) is an aggressive malignancy defined by the absence of estrogen receptor (ER), progesterone receptor, and HER2 expression. This lack of receptor expression makes TNBC particularly challenging to treat using standard targeted therapies. TNBC cell proliferation is driven in part by cellular stress responses, such as oxidative stress and nutrient deprivation, that activate adaptive mechanisms supporting survival and growth under hostile conditions. H6PD (Hexose-6-phosphate dehydrogenase) is a key enzyme of the endoplasmic reticulum (ER)-associated pentose phosphate pathway (PPP) that generates NADPH, a reducing agent crucial for managing oxidative stress, facilitating protein folding, and supporting anabolic metabolism. Although the cytosolic PPP enzyme G6PD is extensively characterized, the role of H6PD in cancer metabolism and stress adaptation remains underexplored. Its ER localization provides a unique capability to buffer redox imbalance and maintain protein quality in cells with high anabolic demands. We investigated the regulation of H6PD by DAP5/eIF3d-dependent non-canonical translation in TNBC. Our analysis indicates that H6PD is a target of this translational mechanism. Targeted metabolomic profiling and DAP5 silencing revealed significant reductions in the levels of nucleotide cofactors (ADP, ATP, CTP, GTP, and UTP) and impaired nucleotide biosynthesis, indicating disruption of ER-associated PPP activity. These results suggest that DAP5-dependent translation maintains H6PD expression to support NADPH production, which is essential for anabolic metabolism in TNBC.

#2035 Cell density drives glutamine synthesis in fibroblast—like cells in the tumor microenvironment.

Lisa Shakachite, Natalya N. Pavlova

University of Utah, Salt Lake City, UT

Dense fibrous tissue, a hallmark of increased breast cancer risk, is composed of abundant extracellular matrix (ECM) and fibroblast-like cells that shape the tumor microenvironment (TME). These fibroblast-like cells can create regions of variable cell density, which in turn influences local nutrient availability. In solid tumors, poor vascularization generates a nutrient-deprived environment where amino acids, particularly glutamine, become limiting. Glutamine is essential for many cell processes, including replenishment of the TCA cycle, antioxidant defense, protein synthesis, and nucleotide production. Aggressive triple-negative breast cancer cells are often unable to synthesize their own glutamine *de novo* using glutamine synthetase (GS) and rely on exogenous sources for growth and survival. Fibroblast-like cells within the TME may compensate by producing and supplying glutamine through GS activity. Although this metabolic dependency has been demonstrated in ovarian cancer, how GS is regulated in fibroblast-like cells within the breast TME, and whether it is influenced by cell density, remains unknown. We hypothesize that high cell density acts as a non-cell-autonomous metabolic cue, upregulating GS in fibroblast-like cells under glutamine-deprived conditions. To test this, fibroblasts from mammary, skin, and lung tissue, as well as progenitor fibroblast-like cell lines (10T1/2 and MC3T3), were cultured at varying densities in the presence or absence of exogenous glutamine. Preliminary data show that near-confluent fibroblast-like cells upregulate GS and maintain active protein translation despite glutamine deprivation, suggesting that dense cultures adopt a metabolic state that gives them an added advantage compared to less-confluent cells. These findings point to a potential mechanism by which fibroblast-like cells in the breast TME promote glutamine availability and, consequently, tumor progression. Because direct GS inhibition is neurotoxic, identifying upstream, density-dependent regulators of GS represents a promising therapeutic avenue for selectively disrupting glutamine supply to aggressive breast cancers.

#2036 Post-transcriptional regulation of cancer by a metabolic pathway: modulation of HuR by the mevalonate pathway.

Mana Heidari[1], Raymond J. Hohl[2]

[1]Biomedical Engineering/Molecular and precision Medicine in Cancer Institute, Penn State University, Hershey/State College, PA,[2]Professor, Hem./Onc., Penn State Hershey Cancer Institute, Hershey, PA

Background: Mevalonate (MVA) pathway, the metabolic pathway essential for producing cholesterol, is inhibited by statins to manage hypercholesterolemia and reduce the risk of cardiovascular diseases. Increasing evidence has shown that dysregulation of this pathway also contributes to cancer development and progression. Its role in cancer has been well established through its production of isoprenoid intermediates enabling the prenylation and activation of small GTPases that drive tumor cell proliferation, migration, and metastasis. While the direct prenylation-dependent effect of the MVA pathway have been well characterized, there is growing evidence that it can also indirectly affect other oncogenic regulators. In this study, we aim to determine whether the MVA pathway is involved in regulating HuR, an RNA-binding protein that plays a central role in stabilizing numerous oncogenic transcripts. Demonstrating an MVA-dependent influence on HuR would establish a promising regulatory mechanism can modulate multiple oncogenic pathways simultaneously. Also, as HuR is consistently upregulated across diverse cancer types, defining how the MVA pathway affects HuR in a few cancer types will lay the foundation for generalizing these findings to other malignancies.
Methods & Results: Cell viability was assessed by MTT assay to determine the IC_{50} of simvastatin in MDA-MB-231 breast cancer cells. Cells were subsequently treated with simvastatin at concentrations below, at, and above the IC_{50} for 24 and 48 hours. HuR protein expression was then measured by Western blot. We observed a clear dose-dependent reduction in cell viability, along with a pronounced suppression of HuR expression at extremely low simvastatin concentrations (nanomolar doses) compared with vehicle control at the 24-hour timepoint. To determine whether the effect of simvastatin on HuR is specifically mediated through inhibition of the mevalonate pathway, rescue experiments are being performed in which mevalonate and isoprenoid intermediates are added following simvastatin treatment. To evaluate downstream consequences of HuR suppression, Western blot analysis is being performed for Cyclin B1 and BCL2, two HuR-regulated targets involved in cell-cycle progression and apoptosis. Transcript levels of HuR, Cyclin B1, and BCL2 are being quantified by qPCR to validate the observed protein-level changes. Also, as HuR overexpression is frequently accompanied by its cytoplasmic accumulation, immunofluorescence staining is being performed to assess HuR distribution and quantify the nuclear/cytoplasmic ratio in treated cells.
Conclusions: Our findings demonstrate that mevalonate-pathway inhibition reduces HuR expression in breast cancer cells, supporting a mechanistic connection between metabolic signaling and post-transcriptional control of oncogenic pathways. This abstract was revised with AI assistance.

#2037 Engineering multiplexed NRF2 reporters to decipher single cell oscillations in real time.

Naurisha Kapoor[1], Yasemin Ceyhan Ozdemir[2], James V. Alvarez[2]

[1]University of Washington, Seattle, WA,[2]Fred Hutchinson Cancer Center, Seattle, WA

Tumor cell survival after therapy and the emergence of recurrent disease are major contributors to breast cancer mortality. NRF2, a master regulator of antioxidant and metabolic stress responses, is frequently activated in therapy-resistant and recurrent tumor cells, yet its regulation in the absence of canonical Nfe2l2/Keap1 mutations remains poorly understood. To enable real-time visualization of NRF2 dynamics, we developed a dual fluorescent reporter system to independently monitor NRF2 protein stability and transcriptional activity at single-cell resolution. The first reporter (Neh2-YFP) fuses YFP to the NRF2 Neh2 degron domain, providing a readout of KEAP1-dependent NRF2 protein turnover. The second reporter (ARE-CFP) places CFP under control of antioxidant response elements (AREs), enabling measurement of NRF2-dependent transcriptional output.

Using confocal live-cell imaging in NMuMG mammary epithelial cells, we validated both reporters by demonstrating increased fluorescence after exposure to NRF2 activators (H_2O_2, TBHQ) and decreased signal with NRF2 inhibitors (ML385, luteolin). Building on this foundation, we will use the reporters to define how NRF2 activity fluctuates over short timescales and how these dynamics change during transitions from therapy-naïve to drug-tolerant, recurrent, or metastatic cell states. Because the two reporters disentangle protein stabilization from transcriptional competence, this system will also allow us to identify noncanonical mechanisms of NRF2 activation - such as altered kinase signaling or autophagy - specifically in breast cancer models lacking Nfe2l2/Keap1 mutations.

Together, this dual-reporter platform enables dynamic, single-cell characterization of NRF2 regulation and will provide new insight into how NRF2-driven stress tolerance and metabolic adaptation contribute to tumor persistence, recurrence, and metastatic progression.

: MicroRNAs as Cancer Biomarkers, Therapeutic Targets, and Modulators of Treatment Response
Poster Session

#2041 Short-term pre-operative caloric restriction downregulates miR-21 and modulates gut microbiome in breast cancer and prostate cancer patients.

Meera Gupta[1], Anuradha A. Shastri[1], Pramila Anne[1], Tiziana DeAngelis[1], Leonard G. Gomella[2], Adeseye Adekeye[1], Melissa Lazar[1], Nicole L. Simone[1]

[1]Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA,[2]Thomas Jefferson University, Philadelphia, PA

Purpose: Calorie restriction (CR) has been shown to improve oncological markers in numerous studies, the mechanism and extent to which it can modulate clinical outcomes remain of interest. In this study, we sought to determine the effect of a 2-5-week preoperative CR intervention on the oncogenic microRNA miR-21, as well as other clinical, microbiome and metabolic markers in patients with breast cancer and prostate cancer. We hypothesized that caloric restriction would lower miR-21-mediated inflammation, inducing a favorable shift in patient characteristics and enhancing anti-tumor responses.

Methods: Breast cancer and prostate cancer patients from a large academic medical center were recruited to participate in a 25% reduced calorie diet intervention up to 12 weeks before definitive surgery. Adherence was maintained via a diet journal, regular check-ins, as well as nutritional and behavioral counseling. Clinical labs, weight, body composition, biomarkers and microbiome samples were collected pre and post-intervention. Paired t-tests were used to identify significant clinical parameters. Microbiome data was analyzed with QIIME2 and microbiome pathway analysis was conducted with PiCrust2.

Results: From August 2016 to October 2018, 35 patients enrolled in the study and completed the pre-operative CR intervention, lasting an average of 21 days. The intervention resulted in significant weight loss, with an average of 7.8 pounds lost ($p<0.0001$). Patient fatigue was decreased, as measured by the Promis Fatigue scale ($p < 0.01$). Leptin ($n=23$) and IGFBP-3 ($n=25$) were both significantly decreased ($p<0.05$). MiR-21 expression was found to be significantly downregulated post-intervention ($p<0.05$). Microbiome analysis did not find any significant differences in alpha or beta diversity. Picrust2 analysis revealed 10 differentially expressed functional microbiome pathways, with the three greatest changes being decreased benzoyl-CoA degradation, decreased L-arabinose degradation IV, and decreased glycogen degradation. Serum biomarker microarray analysis revealed significantly post-intervention downregulation of Eotaxin 2 and IP 10 chemokines in breast cancer patients (FDR < 0.05), and significant upregulation of IGFBP-1 in prostate cancer patients (FDR < 0.05).

Conclusions: This study demonstrates that short term preoperative caloric restriction is feasible and elicits rapid biologic changes in breast and prostate cancer patients, including significant downregulation of the oncogenic miR-21 and modulation of inflammatory chemokines. Microbiome pathway and taxa shifts suggest coordinated host/microbiome adaptation during the intervention. These findings support CR as a low-risk short-term intervention that warrants further investigation to determine the potential impact on long-term cancer outcomes.

#2042 A mechanosensitive RNAi machinery regulates pro-tumorigenic transformation in the colon.

Carlos Gomez, Joyce Nair-Menon, Amanda Daulagala, Antonis Kourtidis

Medical University of South Carolina, Charleston, SC

Background: Up to 90% of all cancers are of epithelial origin, such as the cancers of the gastrointestinal tract. A hallmark of the epithelial tissue is that cells that comprise it form a barrier that depends on the integrity of the adherens junctions (AJs), an essential cell-cell adhesion complex. However, a common observation in cancer is that this barrier and the AJs are compromised, promoting cancer progression. We have particularly discovered mislocalization of the AJ and barrier component PLEKHA7 in colon cancer, resulting in pro-tumorigenic cell behavior, caused by dysregulation of a PLEKHA7-associated RNA interference (RNAi) machinery and oncogene upregulation. However, the reasons for this PLEKHA7-RNAi disruption in colon tumors are unclear. To investigate what causes this disruption, we will perturb the extracellular matrix (ECM), which is commonly found to increase in stiffness as cancer progresses, potentially promoting tumor behavior. Our hypothesis is that mechanical changes that occur during cancer progression cause disruption of the PLEKHA7-RNAi machinery.
Methods: To test this hypothesis, we have generated several substrates of polyacrylamide gels and functionalized them with collagen to simulate the ranges of elastic moduli seen in normal and diseased colonic tissues. We will be plating non-malignant colon Caco2 cells on these substrates to investigate how ECM stiffness impacts localization of PLEKHA7 and RNAi components at AJs, as examined by immunofluorescence and confocal microscopy.
Results and Conclusions: Currently, our results show that increasing ECM stiffness disrupts formation of this AJ complex, suggesting that the elastic modulus of the ECM indeed impacts PLEKHA7-RNAi function and epithelial integrity. We will be conducting further analyses to delineate the exact properties of the elastic moduli of the ECM that result in PLEKHA7-RNAi disruption and the extent that this ECM-PLEKHA7-RNAi crosstalk contributes to disease progression.

#2044 Single-cell spatial profiling microRNA in human colon cancer tissue using high-plex multiomic Spatial Molecular Imaging (SMI).

Rachel Liu, Joe Phan, Rustem Khafizov, Kimberly Young, Ashley Heck, Dwayne Dunaway, Sayani Bhattacharjee, Courtney Anderson, Mirko Corselli, Prajan Divakar, Margaret L. Hoang, Joseph M. Beechem

Research and Development, Bruker Spatial Biology, Seattle, WA

MicroRNAs (miRNAs) are small, conserved noncoding RNAs that play an important role in cancer mechanisms and translational research, acting as oncogenes (e.g., miR-21), tumor suppressors (e.g., miR-200 family), and immune modulators (e.g., miR-155). However, miRNAs and their spatial and temporal implications, until now, have not been spatially profiled on an “omics-scale,” as short sequence length complicates traditional in situ hybridization probe design. The CosMx® Spatial Molecular Imager (SMI) fills this gap by providing a multiomics platform that profiles over 800 miRNAs spatially in tandem with 64+ proteins and over 1,000 RNAs, allowing the collection of a rich dataset that enables precise cell typing, miRNA imaging, and observation of the tumor microenvironment. Detection is achieved through the attachment of barcode oligos to miRNA targets and rounds of readout reporter binding and fluorescence imaging of these barcodes. Although over 38,000 miRNA sequences are cataloged, only a subset is considered biologically or clinically relevant per the latest miRBase database release. The CosMx miRNA Expression Panel targets these most impactful 827 human miRNAs, including key molecules such as miR-21, miR-200 isoforms, and miR-155, among others.Using the CosMx SMI multiomics workflow, we spatially profiled sections of formalin-fixed paraffin-embedded (FFPE) colon adenocarcinoma miRNA at the highest plex ever achieved at subcellular resolution in combination with same-section protein or RNA data. Results showed distinct miRNA enrichment in tumor cells, revealed miRNA-mRNA interactions, and highlighted regulatory networks across tissue compartments. These results underscore the power of high-plex spatial miRNA imaging for translational and clinical research.

#2046 Streamlined workflow generates small RNA and RNA-seq libraries from the same sample for deeper insights into tumor and normal matched tissues.

Heather M. Raimer Young, Gautam Naishadham, Bradley W. Langhorst, Louise Williams

Applications and Product Development, New England Biolabs, Inc., Ipswich, MA

Small noncoding RNAs (sncRNAs) play fundamental roles in many biological processes including cancer development and drug resistance. Increasing evidence shows that sncRNA expression signatures can be used to discriminate between normal and cancer tissues, highlighting their potential as diagnostic and prognostic biomarkers of the disease. Differentially expressed sncRNAs can be investigated using small RNA next generation sequencing methods and can be used to infer downstream effects on the transcriptome. However, performing RNA-seq from the same samples is necessary to confidently determine expression of any given affected transcript and understand the overall transcription profile. Making both small RNA and standard RNA-seq libraries can be challenging when sample material is limiting. Workflows that enable multiple data types to be generated from a single sample are needed for comprehensive understanding of disease.

Here we demonstrate the use of the NEB Monarch RNA size fractionation workflow to allow a single sample to be used for both small RNA and ribosomal depleted RNA-seq library preps. The Monarch RNA cleanup columns were used to enrich small RNA (< 200 nucleotides) and recover large transcripts (> 200 nucleotides) from 6 different human tissues (brain, testis, placenta, bladder, ovary, and esophagus) as well as 5 sets of matched normal and tumor samples (breast, stomach, rectum, colon, and liver).

Small RNA libraries were prepared using either total RNA or enriched small RNA samples (from the Monarch RNA column) with the NEBNext® Low-bias Small RNA Library Prep Kit. Ribosomal depleted RNA-seq libraries were prepared from the large transcript fractions using the NEBNext UltraExpress® RNA Library Prep Kit downstream of NEBNext rRNA Depletion Kit v2. We correlated expression of individual sncRNAs between total RNA and enriched small RNA libraries across all six normal tissues. In matched tumor and normal samples, we evaluated the relationships between miRNAs and their targets within the differentially expressed transcripts from both small RNA and transcriptome datasets. Overall, generation of small RNA and RNA-seq libraries from the same starting material permits a better understanding of the biological regulation of transcriptomes in individual samples.

#2047 Overcoming drug resistance by novel gemcitabine-modified miR-15a in colorectal cancer.

Anushka Ojha, Amartya Pal, Max Chao, Ramana Davuluri, Jingfang Ju

Stony Brook University, Stony Brook, NY

Colorectal cancer (CRC) is the third most prevalent cancer globally. Despite therapeutic advances, chemoresistance remains a major challenge, with ~20-30% of advanced-stage CRC patients experiencing recurrence within the first five years of treatment. Growing evidence suggests that targeting DNA damage response proteins, such as ATR/ATM, WEE1, and CHK1, is critical for overcoming resistance. In this regard, microRNAs (miRNAs) offer great therapeutic potential, as they can simultaneously target multiple signaling pathways and their dysregulation is widely implicated in cancer. Notably, tumor-suppressor miRNA-15a (miR-15a) is frequently downregulated in CRC and has been associated with poor patient prognosis. While miR-15a restoration has shown great promise, effective miRNA delivery remains a significant challenge due to its instability. Various chemical modifications have been shown to greatly enhance the stability of miRNAs. One such modification, 5-FU modified miR-15a (5-FU-miR-15a) was demonstrated as a promising therapeutic in CRC by our lab. Building on this, we engineered a new gemcitabine-modified miR-15a (Gem-miR-15a), which integrates the tumor-suppressive properties of miR-15a with the chemotherapeutic ability of gemcitabine. Though not a standard therapy in CRC, gemcitabine is emerging as an alternative for advanced refractory and resistant cases. Thus, we hypothesized that Gem-miR-15a would have an enhanced therapeutic advantage in overcoming chemoresistance to standard drugs, such as 5-FU. In this study, we assessed the effects of Gem-miR-15a on cell viability, apoptosis, and cell cycle progression of various parental (HCT116, SW480, SW620, HT-29) and 5-FU resistant CRC cell lines. Gem-miR-15a drastically reduced cell viability in both parental (IC_{50}=1-10nM) and resistant cells (IC_{50}=4.08 nM) without any delivery vehicle, significantly induced apoptosis, and caused an S-phase cell cycle arrest. Gem-miR-15a demonstrated dramatically increased cytotoxicity, with an almost 1000-fold reduction in IC_{50} as compared to the standard drug, 5-FU. The effects were consistent in 3D spheroids (IC_{50}=9.76 nM) and patient-derived organoids (IC_{50}=6-14 nM), too. The modification retained the target specificity of the native miR-15a, and downregulated key oncogenes like WEE1, CHK1 and BMI1 which was confirmed by western blotting. Additionally, Gem-miR-15a demonstrated strong synergy with oxaliplatin (Synergy score: 11.03). Experiments were done in triplicate (n=3) and analyzed using Student's t-test ($p < 0.05$). Gem-miR-15a (4mg/kg) was also significantly able to reduce the tumor growth in *in vivo* metastatic mouse models, as compared to the mice treated with vehicle alone, with no visible toxicities. Hence, our findings establish Gem-miR-15a as a potent and multi-targeted therapeutic candidate capable of overcoming chemoresistance in CRC.

#2048 Exosomal micrornas as epigenetic biomarkers of disease progression in Hispanic men with metastatic castration-resistant prostate cancer.

Carmen M. Ortiz-Sanchez[1], Jarline Encarnacion[1], Stephanie Montalvo[2], Shakira Abad[3], Gabriela Castro[3], Lenin Godoy[1], Ralphdy Vergne[1], Jong Y. Park[4], Gilberto Ruiz-Deya[1]

[1]Ponce Health Sciences University, Ponce, Puerto Rico,[2]University of Puerto Rico at Mayaguez, Mayaguez, Puerto Rico,[3]Pontificia Universidad Catolica de Puerto Rico, Ponce, Puerto Rico,[4]Moffitt Cancer Center, Tampa, FL

Background: Metastatic castration-resistant prostate cancer (mCRPC) arises when localized prostate tumors become unresponsive to androgen deprivation therapy (ADT) and develop metastatic potential. Despite therapeutic advances, mCRPC remains incurable, with a median survival of only 9-13 months. Identifying epigenetic biomarkers, such as exosomal microRNAs (exo-miRNAs), that can aid in early detection and monitoring disease progression is therefore critical, particularly among underrepresented populations such as Hispanic men.

Methods: Matched plasma samples from Puerto Rican men with prostate cancer at localized and metastatic stages (n=11) were analyzed to identify exo-miRNAs associated with progression to mCRPC. Exosomes were isolated from plasma, total exo-miRNAs were extracted, and expression profiling was performed using the nCounter Human v3 miRNA Expression Assay (NanoString Technologies) at Moffitt Cancer Center. Data were normalized, and statistical significance was evaluated using two-sample t-test and the Welch's t-test. All analyses were performed in R (v4.5.1) using the tidyverse, readr, and ggplot2 packages.

Results: The initial expression matrix (M) contained 798 miRNAs after excluding controls and spike-ins. Homogeneity assessment yielded a refined matrix of 66 targets. Applying an SD=1 threshold identified 18 candidate miRNAs differentially expressed during disease progression. Among these, miR-302d-3p ($p=0.01$) and miR-23a-3p ($p=0.045$) were significantly altered between localized and metastatic disease. Six additional candidates (miR-1246, miR-16-5p, miR-199a-3p/miR-199b-3p, miR-2053) showed borderline significance ($p<0.05$), suggesting potential biological relevance. This study provides novel insight into the epigenetic landscape of prostate cancer progression among Hispanic men, highlighting circulating exo-miRNAs as minimally invasive biomarkers for disease monitoring. Given the limited availability of clinical specimens from this population, these findings are particularly significant. The identification of circulating exo-miRNA signatures offers a minimally invasive approach to monitor disease progression and could ultimately support the development of blood-based biomarkers for early detection and risk stratification in advanced prostate cancer.

Funding: Supported by the American Cancer Society Institutional Research Grant (ACS-IRG Subaward No. 60-21510-99-20), the Catalyzer Research Grant from the Puerto Rico Science, Technology & Research Trust (PRST), and the NIH/NCI U54 Partnership Grants (U54CA163071 & U54CA163068) between Ponce Health Sciences University and Moffitt Cancer Center.

#2049 miR-1260a promotes proliferation and migration in breast cancer.

Marina Bataller[1], Andrea Feliciano[1], Yilin Sun[2], Daniela Gala[1], Marc Biasini[1], Almudena Sanchez-Garcia[1], Cristina Mir[1], Josep Castellvi[3], Sergi Benavente[4], Yoelsis Garcia-Mayea[1], **Matilde Esther LLeonart Pajarin**[1]

[1]Otorhinolaryngology, Vall d'Hebron Research Institute (VHIR), Barcelona, Spain,[2]CNIC, Madrid, Spain,[3]Pathology, Vall d'Hebron Research Institute (VHIR), Barcelona, Spain,[4]Radiotherapy, Vall d'Hebron Research Institute (VHIR), Barcelona, Spain

Background: MicroRNAs (miRNAs) regulate cellular and pathological processes, including cancer. As previously described by our group, miR-1260a was upregulated in breast cancer tissue. The aim of this research was to characterize miR-1260a in the breast cancer model.

Methods: MiR-1260a levels were studied by RNA array and qRT-PCR in breast cancer patients. The role and mechanisms underlying miR-1260a-mediated breast cancer cell growth, invasion and target proteins were studied using proliferation assays, colony formation assays, western blot, RT-qPCR and immunohistochemistry.

Results: Here, we found that miR-1260a expression is higher in luminal B tumors, followed by triple-negative tumors, and luminal A tumors in a clinical database of 50 breast cancer patients. Moreover, miR-1260a expression correlates positively with cyclin D1 protein. On the other hand, miR-1260a overexpression promotes the proliferation of MCF7, MDA-MD-231, MDA-MB-468, and T47D cells. In addition, miR-1260a induces the invasion of MCF7 and MDA-MB-231 cells. Moreover, our results suggest that the oncogenic properties of miR-1260a are linked to GCDH and ERP29 inhibition, two tumor suppressor proteins downregulated in breast cancer.

Conclusion: These findings indicate that miR-1260a promotes the oncogenic properties of cancer cells and may be useful as a new potential therapeutic target in hormone-dependent (luminal A and B) and triple-negative breast cancer.

#2050 Adipocyte-conditioned medium enhances the proliferation, motility and invasion of prostate cancer cell lines: Involvement of the microRNAs.

Masatoshi Watanabe[1], Hitoshi Nakano[2], Yoshifumi Hirokawa[1], Kazutoshi Iijima[3], Yuhei NIshimura[2]

[1]Department of Oncologic Pathology, Mie University Graduate School of Medicine, Tsu, Japan,[2]Department of Integrative Pharmacology, Mie University Graduate School of Medicine, Tsu, Japan,[3]Faculty of Engineering, Yokohama National University, Yokohama, Japan

Adipocytes (e.g., periprostatic adipose tissues, bone marrow) are one of the critical components in the prostate cancer tumor microenvironment. It has been reported that adipocytes influence the behavior of prostate cancer cells through adipocytokines and exosomes. We have previously shown effects of conditioned medium (CM) from adipocytes in behaviors of DU145 prostate cancer cells, and analyzed the microRNA profile of DU145 cells cultured in CM by a microarray. In this study, two additional cell lines (LNCaP and PC-3)were added to analyze cell behaviors. CM enhanced the proliferation, motility and invasion of PC-3 cells as same as DU-145 while not enhanced these behaviors of LNCaP, suggesting that CM promote androgen-independent cancer cell behaviors. However, in the invasion assay under CM, DU145 and PC-3 cells showed different amoeboid-mesenchymal transition plasticity, suggesting that effects of CM involve different mechanisms depending on the cell line. In addition, we re-analyzed the microRNA profiles of DU145 and PC-3 cells, verified target scores using miRDB and Target Scan, assessed overall survival and disease-free survival using GEPIA and Human Protein Atlas to identify candidate target genes. We also confirmed the expression levels of these candidate target genes in DU145 and PC3 cells using the DepMap. These results suggest that CM may affect behaviors of prostate cancer cells through microRNA-5787 and its multiple target genes such as WWOX and FLNA.

#2051 Simultaneous quantification of microRNA155 and let-7a using digital PCR.

Yu Zhao, Lindsey Cambria

Roche Diagnostics, Wilmington, MA

MicroRNAs (miRNAs) are small, non-coding RNAs that regulate gene expression post transcriptionally. Detection of miRNAs remains technically challenging due to the short length and high sequence similarity among family members. Accurate and sensitive quantification methods are therefore desired for clinical research. Digital PCR (dPCR) provides absolute quantification without the need for standards, offering high sensitivity and tolerance to inhibitors. These features make dPCR a powerful tool for miRNA analysis. In this study, a single well multiplex assay for the simultaneous detection of miR155, let-7a, and U6 snRNA as an internal control was developed with an advanced TaqMan-like probe design. Target specific reverse primers were used for cDNA synthesis, with or without 10-12 nt artificial sequence at the 5' end, followed by using Roche Digital LightCycler® dPCR system with universal nanowell plates equipped with 28,000 partitions. Each target was amplified with four primers in optimized ratios. The TaqMan-like probe incorporated a target specific reverse primer extended with an additional 20-22 nt sequence labeled with a 5' fluorophore, paired with a complementary primer containing a 3' quencher to block extension. Synthetic mature miR155 and let-7a miRNAs, along with commercial cell line RNAs were used to test assay performance. Ten-fold serial dilutions of mature miRNAs demonstrated robust detection down to 4-6 copies per reaction in singleplex and multiplex for both targets. No cross reactivity or competitive inhibition was observed when one target was present at 1000-fold excess relative to the other through spiked samples. In control RNA from Raji cell line, the assay quantified let-7a at 165 ± 21 copies and miR155 at 1,185 ± 141 copies, while in universal human reference RNA with pooled cell lines, it measured let-7a at 120 ± 14 copies and miR155 at 33 ± 8 copies in 25 pg total RNA. Furthermore, the assay successfully discriminated let-7a from closely related family members let-7b (two nucleotides difference) and let-7c (single nucleotide difference). Intermediate fluorescence (rain) is one of the major challenges for accurate quantification by using dPCR. To achieve reliable quantification results in this study, assay required supplement with 20-37.5 mM dNTPs per reaction, as well as optimized thermocycling parameters. In addition, to address unexpected clusters, multiplexing required distinct TaqMan-like probe sequences for each target. Together, these findings demonstrate that advanced TaqMan-like multiplex dPCR assay provides sensitive, specific, and reliable quantification of clinically relevant miRNAs, with potential applications in biomarker discovery and cancer research.*Data on file at Roche Diagnostics, Wilmington, MA, USA

#2052 miR-342-5p: A promising tumor suppressor in diffuse pleural mesothelioma.

So-Hyun Yoon, Anand Singh, Nathanael Pruett, Vivek Singh, Smrity Sahu, Yelixza Avila, Chuong Hoang

NIH-NCI, Bethesda, MD

Diffuse pleural mesothelioma (DPM) is an incurable, aggressive neoplasm with limited therapies. Moving beyond conventional approaches, we posit that microRNAs (miRNA), short, non-coding RNA that coherently regulate gene expression, can uniquely disrupt the molecular networks involved in DPM. In this study, we identified miR-342-5p as a novel DPM-associated miRNA. We used a human miRNA mimic library to screen for miRNAs with antiproliferative effects on a panel of DPM cell lines. Among the most potent candidates was miR-342-5p. We profiled the downregulation of miR-342-5p in DPM patient specimens compared to normal pleura (Normal=22, Tumor=50). TCGA-MESO analysis revealed that miR-342-5p downregulation is significantly associated with poor survival outcomes. Our results demonstrated that the re-expression of miR-342-5p significantly impaired DPM cell viability, reduced 2D colony foci formation, and inhibited anchorage-independent cell growth in soft-agar and sphere assays. Additionally, Annexin-V assays showed a significant increase in early and late apoptotic cells in miR-342-5p transfected DPM cells compared to controls. Furthermore, we confirmed the induction of apoptosis in miR-342-5p-treated DPM cells through PARP cleavage and the activation of caspase-3/7. Importantly, no significant biological effects were observed when normal human mesothelial cells (NP1 line) were treated with miR-342-5p. Next, we performed a Biotin-miRNA (Bi-miR) pull-down assay, a direct binding assay in which a biotin-tagged miR-342-5p probe captures its associated mRNA transcripts in a pooled lysate. Then, RNA-seq analysis is conducted to identify direct target genes associated with apoptosis and cell death pathways in DPM. We identified the top transcripts targeted by miR-342-5p that are also involved in its tumor-suppressive activity in DPM. Overall, our findings highlight the tumor suppressive effects and therapeutic potential of miR-342-5p for DPM treatment.

#2053 Developing the miR-888 cluster members as an antimiRNA therapy for aggressive prostate cancer.

Alex Cain[1], Katherine Routon Stanton[1], Vishal Kasina[2], Raman Bahal[2], Aurora Esquela Kerscher[1]

[1]Biomedical and Translational Sciences, Macon and Joan Brock Virginia Health Sciences at Old Dominion University, Norfolk, VA,[2]Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT

Metastatic prostate cancer (PCa) represents an unmet treatment need, with a 5-year survival rate of only 30%. MicroRNAs (miRNAs) are small noncoding RNAs that hold therapeutic promise for PCa and act as important tumor suppressors and pro-oncogenic factors in the prostate. The Kerscher lab identified the miR-888 cluster as preferentially enriched in human metastatic PCa cell lines and prostatic fluids from patients with high-grade PCa compared to low-grade or non-cancer patients. We showed that cluster members promoted prostate growth and aggressiveness in vitro, particularly miR-888 and miR-891a, and these miRNAs accelerated tumor load in mice. Reciprocally, inactivation of miR-888 and miR-891a using antisense oligos reversed these effects, highlighting their potential as antimiR targets for PCa. AntimiRs are valuable tools for inhibiting miRNA function, but current antimiR therapies require high dosage and suffer from poor tissue specificity. To address these shortcomings, the Kerscher lab collaborated with Dr. Raman Bahal's group to test the efficacy of their acid-sensing peptide pHLIP (pH low insertion peptide) as a novel prostate tumor delivery reagent conjugated to peptide nucleic acids (PNAs) designed to inhibit miR-888 or miR-891a. We hypothesized that pHLIP-PNA-antimiRs against miR-888/-891a would allow efficient delivery to prostate tumors (with inherently acidic microenvironments) and inhibit progression to lethal disease. We also predicted more pronounced effects in castration-resistant PCa. Indeed, when endogenous miR-888/891a levels were analyzed by qRT-PCR across a panel of human PCa cell lines representing the spectrum of this disease, we noted that miR-888 & miR-891a expression was especially elevated in castration-resistant, neuroendocrine PCa lines. pHLIP-PNA-antimiR-888 and antimiR-891a reagents were further validated in vitro to reduce miRNA levels and suppress cancer phenotypes in PCa cell lines. For these experiments, PCa cells were treated with 4 uM pHLIP-PNA-antimiR or control reagents in pH 6.0 media for 3 hours, recovered for 24-48 hours, and harvested for qRT-PCR, WST-1 (proliferation), and soft agar (anchorage-independent growth) assays. As predicted, pHLIP-PNA-antimiR treatment reduced growth more effectively in metastatic PC3-ML than in indolent LNCaP cells. Ultimately, we sought to determine pHLIP-PNA-antimiR efficacy in a xenograft mouse model. We first validated that cy5-pHLIP alone efficiently targeted PC3-ML xenografts in mice, with low signal in kidney and liver. In a pilot efficacy study, we then injected PC3-ML cells into the flanks of mice. When tumor volume reached ~300 mm^3, animals were injected with pHLIP-PNA-antimiR-891a or -NC67 controls by tail vein on days 1, 4, 8, and 11. This preliminary study showed that antimiR-891a reduced tumor load. These novel pHLIP-PNA-antimiR reagents demonstrate clinical promise for late-stage PCa.

#2054 Melatonin and estradiol action on let-7 family members in triple-negative breast cancer cells.

Bruna Cristine De Almeida, Kelly Pedrozo Ferreira, Jose Maria Soares-Junior, **Katia Candido Carvalho**, Edmund Chada Baracat

Obstetrics and Gynecology, Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil

The widely studied tumor suppressor miRNAs of the let-7 family are involved in many cellular processes through the regulation of several signaling pathways. They shared identical seed sequences and have variable stem-loop regions. The let-7 family regulates crucial physiological functions in cells. However, low expression is frequently found, and it was associated with cell proliferation, migration, and metastasis in triple-negative breast cancer (BC). Although the MDA-MB231 BC cell line is triple-negative, it has been shown to express estrogen receptor beta. Let-7 has a regulatory relationship with estrogen, acting as a negative regulator of estrogen receptors. The recovery or restoration of let-7 expression seems to be a key point to prevent breast cancer growth and development. In this context, melatonin (Mel) has gained notoriety due to its versatile and essential mechanisms for antagonizing tumor features, which involve modulation of differential miRNA expression. Studies have demonstrated that Mel can alter the expression of some members of the let-7 family in some contexts. Objective: We aimed to demonstrate the effects of Mel and 17beta-estradiol (E2) treatments on the proliferation of triple-negative BC and assess the expression profile of six let-7 family members (let-7a/b/c/g/i/f). Methods: MDA-MB231 cells were treated with 3 mM Mel and 100 nM E2, and the two drugs were combined (ME2) and were replaced daily for up to 96h. Cell proliferation was evaluated in treated cells. RNAs were extracted, and reverse transcription was performed. RT-PCR was carried out for the detection of selected let-7 family members. Results: Our preliminary results showed a significant decrease in the proliferation assay in the cell line after Mel and ME2 treatments. Cells presented a lower rate of proliferation at 72h of Mel and ME2 treatments. Mel treatment leads to slightly and significantly increased expression of let-7c/g/f (Fold:1.939; 1.132; 1.624, respectively), and the let-7c/g also showed higher expression related to ME2. Cells treated with ME2 showed a significant increase of let-7b/i/f (Fold:1.112; 1.123; 1.506, respectively) compared to CC and E2. Let-7c (Fold: 0.879) presented a significant decrease compared to CC. Additionally, lower expression of let-7a/b/g/i (Fold: 0.707; 0.823; 0.662; 0.759, respectively) was observed in cells treated with E2. Conclusion: Our results indicate that Mel can minimize E2 effects and inhibit the proliferation of triple-negative BC cells through the regulation of specific miRNAs. It seems to recover the expression of tumor suppressor miRNAs of the let-7 family in triple-negative BC. Supported by: FAPESP 2025/08621-1, 2022/04174-2, and 2018/24224-9, and CNPq 444345/2024-8.

#2055 Isoform-aware miRNA network mapping in NSCLC via computational consensus targeting and functional clustering.

Shaopeng Gu[1], Junhao Liu[2], Shaohong Feng[3], Rosario Distefano[4], Sebastiano Di Bella[5], Francesco Orilio[5], Rosario Brancaccio[5], Giulia Romano[6], Eswar Shankar[7], Mario Acunzo[6], Federica Calore[8], Christian Rolfo[7], Qin Ma[1], Giovanni Nigita[7]

[1]Department of Biomedical Informatics, The Ohio State University Comprehensive Cancer Center, Columbus, OH,[2]College of Engineering, The Ohio State University, Columbus, OH,[3]Department of Biomedical Informatics, The Ohio State University, Columbus, OH,[4]The Ohio State University Comprehensive Cancer Center, Columbus, OH,[5]University of Palermo, Palermo, Italy,[6]LUM University, Casamassima, Italy,[7]Department of Internal Medicine, Division of Medical Oncology, The Ohio State University Comprehensive Cancer Center, Columbus, OH,[8]Department of Cancer Biology and Genetics, The Ohio State University, Columbus, OH

MicroRNA (miRNA) isoforms (isomiRs), generated by alternative processing, RNA editing, and tailing/trimming, broaden regulation and can differ from canonical miRNAs in targets and function. Yet most cancer genomics workflows still collapse reads to canonical miRNAs or ignore non-canonical variants, obscuring isoform-specific regulatory networks. This gap is especially relevant in NSCLC, where heterogeneity and unmet needs in biomarkers and targets are high. Building on our pan-cancer data showing that isomiR-aware profiling improves clinicopathologic classification, we assumed that systematic isoform-level analysis would uncover NSCLC-specific biological signatures and vulnerabilities missed by traditional miRNA analyses.

Data from TCGA LUAD and LUSC were processed with an isoform-aware pipeline. Differentially expressed isomiRs between tumors and matched normals were defined using |fold-change|>1.5 and FDR<0.05. Consensus targets were predicted across six algorithms, retaining interactions supported by ≥4 tools and downregulated in isomiR-high versus isomiR-low tumors. Isoform functions were compared across subtypes using Jaccard distances on pathway-level target matrices, hierarchical clustering, and pathway-frequency summaries across lung cancer-related pathways.

We identified ~1,300 deregulated isomiRs in LUAD and ~1,100 in LUSC. Pathway-based clustering grouped isomiRs into functional clusters that separated LUAD and LUSC. Clusters enriched for hallmark oncogenic signaling networks (e.g., PI3K-AKT, MAPK, p53, VEGF) contained ~14% shared isomiRs that converged on these pathways. miR-183-5p, which contributed the largest isoform repertoire, aligned with high cluster activity and PTEN/p53-AKT signaling. Oncogenic clusters were further shaped by miR-17-5p/miR-93-5p and context-dependent miR-130b-3p, whereas tumor-suppressive isomiRs (e.g., miR-128-3p) marked restraint of cell-cycle progression and invasion.

Isoform-aware miRNA analysis uncovers NSCLC regulatory networks beyond traditional views. Integrating consensus targeting with cohort-level expression and pathway-based clustering enables functional identification of isomiRs and prioritization of isoform-target pairs, including subtype-specific and shared oncogenic networks, as potential biomarkers and therapeutic targets. These results are still limited by current challenges in isomiR quantification, context-specific target prediction, cohort variability, and the need for functional validation.

#2056 Cross-species microRNA expression patterns identify potential therapeutic targets in osteosarcoma.

Sophia C. Fernandes[1], Emma N. Vanderboon[1], Alicia Viloria-Petit[2], R. Darren Wood[1], Geoffrey A. Wood[1]

[1]Pathobiology, University of Guelph, Guelph, ON, Canada,[2]Biomedical Sciences, University of Guelph, Guelph, ON, Canada

Osteosarcoma is the most common primary bone tumour in both humans and dogs. In both species, osteosarcoma displays a marked propensity for pulmonary metastasis, making canines a robust and clinically relevant translational model of the disease. With current standard-of-care treatment, the 5-year survival rate for humans with localized osteosarcoma is approximately 60-70%, but falls to around 20-30% for patients presenting with metastatic disease. In dogs, amputation followed by chemotherapy yields a median survival time of roughly 10-12 months, with fewer than 20% surviving beyond two years. Despite incremental improvements in supportive care, therapeutic strategies for osteosarcoma have remained largely unchanged for more than three decades in both species, highlighting the need for novel prognostic indicators and therapeutic targets. MicroRNAs (miRNAs) are small, non-coding RNAs that can function as tumour suppressors or oncogenes. They are expressed across diverse tissues and are known to exhibit dysregulation in cancer. In this study, 20 osteosarcoma cell lines (6 human and 14 canine), derived from both primary and metastatic tumours, were evaluated for key malignant behaviours using a series of in vitro functional assays. These included measurements of proliferation (doubling time), migration (scratch and transwell assays), anchorage-independent survival (anoikis assay), invasion (drop invasion assay), and colony formation (clonogenic assay). RNA was subsequently isolated from each cell line, and expression of 48 candidate miRNAs was quantified using real-time quantitative polymerase chain reaction (RT-qPCR). Each miRNA was correlated with measured behaviours using Pearson's r and false discovery rate (FDR) analysis. Ten miRNAs were significantly associated with at least one behaviour at $p < 0.05$ following FDR correction. Notably, miR-708-5p demonstrated significant correlations with multiple malignant phenotypes, including doubling time, migration, and colony formation. MiRNA expression profiles, therefore, revealed several candidates associated with malignant behaviour, suggesting that select miRNAs may contribute to disease progression and represent promising targets for future therapeutic development.

#2057 Subtype-dependent modulation of mir-655-3p by melatonin in breast cancer cell lines.

Kelly Pedrozo Ferreira[1], Bruna Cristine De Almeida[2], Edmund C. Baracat[1], **Katia C. Carvalho**[3]

[1]Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil,[2]Fundacao Faculdade de Medicina, Sao Paulo, Brazil,[3]Obstetrics and Gynecology, HCFMUSP, Sao Paulo, Brazil

Background: Breast cancer (BC) is a highly heterogeneous disease composed of distinct molecular subtypes that influence tumor behavior and therapeutic response. Melatonin (MEL) has been widely investigated for its oncostatic properties, partly mediated through the modulation of microRNA (miRNA) expression—key post-transcriptional regulators of genes involved in proliferation, invasion, and metastasis. Among these, miR-655-3p has been described as a potential tumor-suppressive miRNA associated with reduced aggressiveness in several cancer types. However, the effects of MEL on miR-655-3p expression across different BC subtypes remain poorly defined. Therefore, we aimed to evaluate the impact of MEL treatment on miR-655-3p expression in BC cell lines with distinct molecular profiles, including luminal A and triple-negative (TN) subtypes.
Methods: Human BC cell lines MCF-7 and T47D (luminal A; ER+/PR+) and MDA-MB-231 (TN) were cultured under standard conditions and treated with 3000 µM MEL or left untreated (control group — CC). Total RNA was extracted using the mirVana™ miRNA Isolation Kit. cDNA synthesis was performed with the High-Capacity cDNA Reverse Transcription Kit, and miR-655-3p expression was quantified by qRT-PCR using specific TaqMan® assays. Relative expression levels and normalization to endogenous controls were obtained using ExpressionSuite™ Software v1.3.
Results: MEL treatment resulted in a significant upregulation of miR-655-3p in MDA-MB-231 (TN) cells compared with untreated controls. In contrast, luminal A cell lines (MCF-7 and T47D) exhibited a significant decrease in miR-655-3p expression under the same MEL exposure conditions.
Conclusion: Melatonin differentially modulates miR-655-3p expression across BC molecular subtypes, increasing its expression in TN cells while reducing it in luminal A cells. These opposite expression patterns suggest that MEL's regulatory effects on miR-655-3p are subtype-dependent, potentially reflecting differences in signaling pathways associated with hormone receptor status. Together, these findings indicate that miR-655-3p may serve as a biomarker of subtype-specific responses to melatonin and a potential therapeutic target involved in the modulation of tumor aggressiveness. Further studies are warranted to identify its direct gene targets and elucidate the biological relevance of this regulation.

#2058 Melatonin modulates mir-340-5p expression in breast cancer molecular subtypes: Implications for subtype-specific regulation and therapeutic targeting.

Kelly Pedrozo Ferreira[1], Bruna Cristine De Almeida[2], **Katia C. Carvalho**[3]

[1]Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil,[2]Fundacao Faculdade de Medicina, Sao Paulo, Brazil,[3]Obstetrics and Gynecology, HCFMUSP, Sao Paolo, Brazil

Background: Breast cancer (BC) comprises highly heterogeneous subtypes with distinct molecular and clinical features. Triple-negative breast cancer (TNBC) is characterized by poor prognosis and limited therapeutic options, whereas luminal A tumors exhibit hormone receptor positivity and more favorable outcomes. Emerging evidence suggests that melatonin (MEL) exerts oncostatic effects through the modulation of gene expression, including microRNAs (miRNAs), which regulate key oncogenic pathways. Among these, miR-340-5p has been implicated in tumor suppression and in the regulation of epithelial-mesenchymal transition (EMT). However, its modulation by MEL across BC molecular subtypes remains poorly understood. Therefore, we investigated the differential expression of miR-340-5p in BC cell lines representing distinct molecular profiles (luminal A and TN) following melatonin treatment.
Methods: Human BC cell lines MCF-7 and T47D (luminal A) and MDA-MB-231 (TN) were cultured and either left untreated (control) or treated with 3000 μM MEL. Total RNA was extracted using the mirVana™ miRNA Isolation Kit. cDNA synthesis was performed with the High-Capacity cDNA Reverse Transcription Kit, and miR-340-5p expression was quantified by qRT-PCR using specific TaqMan® assays. Relative expression levels, endogenous control normalization, and data processing were performed using ExpressionSuite™ Software v1.3.
Results: MEL treatment resulted in an upregulation of miR-340-5p in MDA-MB-231 (TN) cells compared with untreated controls. Conversely, luminal A cell lines (MCF-7 and T47D) exhibited a reduction in miR-340-5p expression following MEL treatment relative to control cells.
Conclusion: Melatonin modulates miR-340-5p expression in a molecular subtype-dependent manner, increasing its expression in TN cells while reducing it in luminal A cells. This differential regulation highlights the potential of miR-340-5p as a biomarker for subtype-specific responses to melatonin and may contribute to distinguishing aggressive from hormone-responsive BC phenotypes. Additional studies are needed to identify downstream targets and elucidate the biological significance of this regulatory pathway.

#2059 Auro-Liposome miR-195 delivery system impedes ovarian cancer progression and enhances cisplatin-sensitivity.

Arpan Dey Bhowmik, Pallab Shaw, Prasanta Panja, Geeta Rao, Resham Bhattacharya, Priyabrata Mukherjee, Shailendra Kumar Dhar Dwivedi

Peggy and Charles Stephenson Cancer Center, University of Oklahoma Health Sciences Campus, Oklahoma City, OK

Background: Ovarian cancer (OvCa) accounts for the highest mortality rate among all gynecological malignancy. This is mainly due to late-stage detection, early metastasis and drug-resistance. While most patients initially respond to chemotherapy, Cancer Stem-like Cells (CSCs) facilitate chemoresistance and tumor relapse. WNT7A, a key activator of β-catenin signaling, is overexpressed in OvCa and promotes CSC characteristics, epithelial-mesenchymal transition (EMT), chemoresistance, whereas the tumor-suppressive miR-195 is downregulated. In this study, we investigated whether restoring miR-195 expression could inhibit cancer progression and improve drug-sensitivity by targeting WNT7A mediated β-catenin signaling.
Methods: CSCs were enriched using anchorage-independent spheroid culture conditions. miR-195 expression levels were assessed by qRT-PCR. Functional assays were performed to determine the effect of miR-195 on CSC markers, EMT, drug-sensitivity. A luciferase reporter assay was utilized to validate the direct miR-195 binding within the WNT7A 3'UTR. β-catenin activation and nuclear localization were analyzed by immunoblot, immunofluorescence. To mimic tumor microenvironment, multicellular aggregate model was generated using OvCa cell line (A2780-CP20), cancer-associated fibroblast (CAF19) and human microvascular endothelial cells (HMEC1) and for assessing AuLPs's potential as a miR-195 delivery system.
Results: Spheroid-derived CSCs displayed enhanced expression of stem cell markers NANOG, OCT4, cMYC, KLF4, accompanied by a significant reduction in miR-195 levels. Restoration of miR-195 expression inhibited spheroid growth, caused downregulation of stemness markers and enhanced cisplatin-sensitivity. miR-195 directly targeted WNT7A, leading to decreased nuclear localization of active β-catenin and inhibition of WNT/β-catenin signaling, EMT pathway. Furthermore, *in vivo* homing assay revealed that stable miR-195 re-expression significantly reduced A2780-CP20 adhesion to the mice omentum, highlighting its anti-metastatic role. Noticeably, our novel AuLPs system conferred superior intracellular delivery of miR-195 compared to commercial agents and more striking inhibition of oncogenic WNT7A/β-catenin pathway and profound anti-tumor effect against multicellular aggregate.
Conclusions: miR-195 suppress OvCa progression by targeting cancer stemness, EMT and enhance cisplatin-sensitivity via directly modulating WNT7A/β-catenin pathway and formulations of novel AuLPs delivery system offers a promising miRNA-based therapeutic strategy.

#2060 Targeting microRNA-mediated copper homeostasis dysregulation to enhance intratumoral susceptibility to oncolytic herpes simplex virus-1 in glioblastoma.

Tae Jin Lee[1], Min Hye Noh[1], Citu Citu[2], Alexandra A. Miller[1], Jiyeon Kim[1], Grace Nguyen[1], Minxin Huang[1], Amanda S. Kouaho[1], Stephanie M. Bean[1], Dohyoung Lee[1], Lily Nguyen[1], E. Antonio Chiocca[3], Zhongming Zhao[2], Ji Young Yoo[1]

[1]Department of Neurosurgery, UT Health Houston, Houston, TX,[2]Center for Precision Health, UT Health Houston, Houston, TX,[3]Department of Neurosurgery, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Glioblastoma (GBM) is a WHO grade IV astrocytoma characterized by diffuse infiltration, rapid proliferation, and resistance to conventional therapies, resulting in dismal patient outcomes. Oncolytic virotherapy, particularly utilizing genetically engineered oncolytic herpes simplex virus-1 (oHSV), has demonstrated tumor-selective cytolysis and immunogenic cell death. Despite promising preclinical data, clinical efficacy remains limited due to poorly defined intrinsic resistance mechanisms within the tumor microenvironment (TME) of GBM. Our study identified microRNA-155 (miR-155) as a critical modulator of oHSV therapeutic resistance. We found elevated miR-155 expression in GBM compared to low-grade gliomas, which correlates with a poor prognosis and reduced response to OV therapy. These findings were further supported by The Cancer Genome Atlas (TCGA) data. Ectopic overexpression of miR-155 significantly attenuated oHSV replication and cytopathic effects. Transcriptomic profiling and pathway enrichment analyses revealed that miR-155 upregulates metallothioneins *MT1E* and *MT1F*, key regulators of intracellular copper sequestration and antiviral defense. Mechanistically, miR-155 disrupts copper homeostasis via the MT1 axis, impairing viral replication and therapeutic efficacy. Functional ablation of miR-155 via CRISPR/Cas9-mediated knockout or Locked Nucleic Acid (LNA)-based inhibition restored copper homeostasis, oHSV replication kinetics, and enhanced oncolysis in vitro and in orthotopic GBM xenograft models, resulting in prolonged survival. These data suggest that the miR-155/MT1E-MT1F/copper signaling axis represents a novel barrier to oHSV therapy. This work elucidates a previously uncharacterized antiviral resistance pathway in GBM and validates miR-155 inhibition as a rational therapeutic strategy to potentiate oHSV efficacy. Our findings provide a mechanistic framework for overcoming innate resistance and advancing the clinical translation of virotherapy in neuro-oncology. This abstract was originally written by the authors and then edited and revised with generative artificial intelligence (AI).

#2061 MicroRNAs targeting tumor suppressor GRK2: Novel potential therapeutic strategies for restraining MALT1-dependent DLBCL.

Jing Cheng[1], Mei Smyers[2], Matt Trotta[2], Neil M. Carleton[3], Lisa M. Maurer[2], Uma R. Chandran[4], Min Xia[5], Ari M. Melnick[5], Peter C. Lucas[1], Linda M. McAllister-Lucas[6]

[1]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[2]Pediatrics, University of Pittsburgh, Pittsburgh, PA,[3]Pathology, University of Pittsburgh, Pittsburgh, PA,[4]Biomedical Informatics, University of Pittsburgh, Pittsburgh, PA,[5]Medicine, Weill Cornell Medical College, New York, NY,[6]Comprehensive Cancer Center, Mayo Clinic, Rochester, MN

Introduction/Objectives: The CARMA1-BCL10-MALT1 (CBM) signalosome plays crucial role in mediating antigen receptor-induced activation of NF-κB transcription factor and subsequent lymphocyte activation. The effector protein of the signalosome, MALT1, functions both as a scaffold to recruit downstream NF-κB signaling machinery, and as a protease to cleave and inactivate multiple substrates including negative regulators of NF-κB. Constitutive MALT1 activation, which can occur as a result of gain-of-function mutations of the B cell receptor, CARMA1, BCL10 or chromosomal translocation involving the *MALT1* gene, underlies the pathogenesis of multiple lymphoid malignancies including activated B-cell type-diffuse large B-cell lymphoma (ABC-DLBCL) and MALT lymphoma. We previously identified G-protein-coupled receptor kinase 2 (GRK2) as a tumor suppressor in MALT1-dependent lymphomas which binds MALT1 and inhibits MALT1 scaffolding and proteolytic activities. Accordingly, *GRK2* mRNA levels are markedly lower in a subset of DLBCL tumors compared to normal B cells and lower *GRK2* level in ABC-DLBCL is associated with reduced patient survival. In current study, we sought to investigate the mechanism of how GRK2 levels are regulated in ABC-DLBCL. **Methods/Results**: Using DICER1 depleted cells, we showed that globally impaired miRNA processing leads to increased GRK2 protein levels. We then conducted bioinformatic analyses of patient tumor samples and performed screening via microRNA Data Integration Portal to identify microRNAs that target GRK2 in ABC-DLBCL. Further GRK2 3'UTR reporter assay confirmed direct targeting of GRK2 by candidate miRNAs. ABC-DLBCL cell lines, OCI-LY3 and TMD8, which demonstrate reduced *GRK2* mRNA expression compared to primary B cells, show elevated expression of candidate GRK2-targeting microRNAs. Stable overexpression of miR-125a, 125b, or 148b in OCI-LY3 or TMD8 cells led to reduced GRK2 expression, enhanced MALT1 activity and increased cell proliferation. Conversely, in vitro inhibition of candidate miRNAs using anti-miRNA Locked Nucleic Acids (LNA) inhibitors led to enhanced GRK2 expression, reduced MALT1 activity and decreased cell proliferation. Importantly, treatment of mice with inhibitors of miR-125b and miR-148b abrogates the growth of ABC-DLBCL xenograft tumors in vivo. **Conclusion**: We have identified miRNAs that negatively regulate *GRK2* expression in ABC-DLBCL. These GRK2-targeting miRNAs serve a pro-tumorigenic role by promoting MALT1 oncoprotein's scaffold and protease activity. Furthermore, inhibitors of these miRNAs can enhance *GRK2* expression and thereby suppress MALT1 activity and MALT1-dependent tumor cell proliferation, both in vitro and in vivo. These studies suggest that microRNA inhibitors which enhance GRK2 expression could represent a novel approach for restraining MALT1-dependent lymphomagenesis.

#2063 The impact of 4-thiouridine posttranscriptional modification on the oncosuppressive activity of bioengineered let-7e-5p in NSCLC cells.

Katherine K. Wang[1], Mei-Juan Tu[1], Yufan Zhou[1], Ziyuan Wang[2], Patrick A. Limbach[3], Hongxu Ding[2], Ai-Ming Yu[1]

[1]Department of Biochemistry and Molecular Medicine, UC Davis School of Medicine, Sacramento, CA,[2]Department of Pharmacy Practice and Science, Statistics and Data Science GIDP, University of Arizona, Tucson, AZ,[3]Department of Chemistry, Rieveschl Laboratories for Mass Spectrometry, University of Cincinnati, Cincinnati, OH

Current microRNA (miRNA) research and therapeutic development primarily rely on miRNA mimics chemically synthesized *in vitro*. While effective, miRNA mimics may not fully recapitulate the properties of natural miRNA agents synthesized *in vivo*. Our lab has developed a novel tRNA-fused pre-miRNA carrier-based RNA bioengineering platform technology, enabling consistent, high-yield, and large-scale production of biologic miRNAs (BioRNAs) through *in vivo* bacterial fermentation, which have shown strong potential in experimental therapeutics for non-small cell lung cancer (NSCLC). Among the tumor suppressive let-7-5p isoforms, BioRNA/let-7e-5p was identified as the most effective to suppress human NSCLC cell viability. Further, while we observed species-conserved posttranscriptional modifications, such as dihydrouridine (D) and 2′-*O*-methylguanosine (Gm) in the D-loop as well as 5-methyluridine (m^5U) and pseudouridine (Y) in the T-loop, liquid chromatography tandem mass spectrometry (LC-MS/MS) and nanopore-based direct RNA sequencing studies revealed the presence of a bacteria-specific 4-thiouridine (s^4U) modification at position 8 (s^4U8) of the human tRNA segment. To re-innovate our BioRNA technology and generate BioRNA/let-7e-5p molecules free of s^4U modification, we employed two strategies: (1) change of U8 through deletion or substitutions, and (2) expression of U8 BioRNAs in an *E. coli* strain deficient in s^4U synthesis. Both approaches proved successful, allowing us to produce milligrams of pure, ready-to-use BioRNA/let-7e-5p molecules per 200 mL bacterial culture, and LC-MS/MS and nanopore sequencing analyses confirmed the escape from s^4U modification. Surprisingly, comprehensive comparative studies showed minimal effects of the distal s^4U modification on the release of let-7e-5p from BioRNAs and consequently, downregulation of multiple targeted oncogenes in NSCLC cells. These findings will guide the development of BioRNA/let-7e-5p as potential therapeutics for NSCLC treatment.

#2064 miR-1293 suppresses diffuse pleural mesothelioma growth by targeting a novel S100A16-Hippo-EMT axis.

Vivek Singh[1], Anand Singh[1], Nathanael Pruett[2], So-Hyun Yoon[3], Smrity Sahu[2], Yelixza Avila[2], Chuong D. Hoang[4]

[1]Laboratory of Integrative Cancer Immunology (LICI), Center for Cancer Research, Bethesda, MD,[23]NIH-NCI, Bethesda, MD,[4]Assistant Professor, Dept. of Thoracic Surgery, National Cancer Institute, Bethesda, MD

Background: Diffuse pleural mesothelioma (DPM) features frequent NF2 loss, Hippo pathway disruption, and limited therapies. We identify miR-1293 as a tumor-suppressive miRNA that targets an S100A16-centered Hippo/EMT axis involving Hippo/YAP and epithelial-mesenchymal transition (EMT) in DPM. **Methods:** We performed a high-throughput human miRNA mimic screen across multiple DPM cell lines with proliferation assays to identify anti-tumor miRNAs. miR-1293 expression was measured by qRT-PCR in DPM tumors and normal pleura. Targets were mapped by biotin-miR-1293 pulldown plus RNA-seq and in silico prediction, then integrated with pathway and DepMap data to define an S100A16-Hippo/EMT module. Functional effects of miR-1293 re-expression were tested in NF2-wild-type and NF2/Hippo-deficient DPM lines and in MB52 xenografts using local hydrogel-based (SFH-miR-1293) delivery in subcutaneous and orthotopic pleural models. **Results:** The screen identified miR-1293 as a top antiproliferative miRNA, and miR-1293 was significantly underexpressed in DPM versus normal pleura. Re-expression in miR-1293-low DPM lines reduced proliferation, colony and soft-agar growth, with minimal impact on non-malignant mesothelial cells, and induced apoptosis and cell-cycle arrest. Target mapping yielded 345 genes enriched for Hippo signaling and EMT, with additional mTORC1, IL-2/STAT5, and hypoxia signatures, and a 19-gene core S100A16-Hippo-EMT module. Within this module, S100A16 was the most essential and strongest adverse prognostic gene, highly expressed in NF2/Hippo-deficient lines (H2052, MB52, MB24) with activated YAP/TAZ/TEAD and EMT-like features. miR-1293 re-expression preferentially impaired viability and clonogenicity in these NF2/Hippo-deficient cells, with coordinated suppression of S100A16, YAP/TAZ/TEAD, and EMT markers. In vivo, SFH-miR-1293 significantly reduced tumor burden, Ki-67, and bioluminescence, increased cleaved caspase-3, and prolonged survival in xenograft and orthotopic pleural models. **Conclusions:** miR-1293 is a tumor-suppressive miRNA in DPM that targets an S100A16-Hippo-EMT axis and shows preferential activity in NF2/Hippo-deficient mesothelioma. Local hydrogel-based delivery elicits strong antitumor effects in vivo, supporting miR-1293 as a therapeutic candidate for DPM and a rational partner for Hippo/YAP-directed and immunotherapy strategies.

#2065 Prognostic potential of microRNA-encoding gene signatures in gynecologic cancers.

Elizabeth Miller[1], Amber Hoskins[1], Natalie Gierat[2], Aneth Ochoa Negrete[2], **Riyaz Basha**[2]

[1]Texas College of Osteopathic Medicine, University of North Texas Health Science Center, Fort Worth, TX,[2]University of North Texas Health Science Center, Fort Worth, TX

Background/Significance: Effective early-stage biomarkers are needed for improving outcomes in gynecologic cancers. Micro RNAs (miRNAs) are small non-coding RNAs that function in post-transcriptional gene regulation and their dysfunction can play key role in cancer development and progression. Recently, the role of miRNAs is gaining attention as circulating biomarkers for various malignancies. However, there is a gap in studies involving gynecologic cancers with high-mortality rates such as ovarian serous cystadenocarcinoma (OV), uterine corpus endometrial carcinoma (UCEC), and uterine carcinosarcoma (UCS). The objectives of this study are to analyze the expression profiles of selected miRNA-coding genes such as hsa-mir-6511b-1, hsa-mir-6820, and hsa-mir-3198-2 in tumor specimens from patients with OV, UCEC, and UCS cancers using The Cancer Genome Atlas (TCGA) datasets. Additionally, we evaluated the prognostic significance of these miRNAs by correlating their expression levels with overall survival and clinical outcomes.

Methods: Data were obtained from TCGA, an online portal for analyzing tumor genes and survival curves. A comparison was made between the common miRNA-coding genes in OV vs UCS, OV vs UCEC, and UCS vs UCEC. Survival curves were obtained for OV (n=474) vs UCS (n=56). Clinical trials information was accessed through clinicaltrials.gov. Data was analyzed and the statistical significance was assessed by Student's t-test (comparisons between two-groups), or one-way ANOVA (for multiple-groups), and survival curves were analyzed using Kaplan-Meier method with log-rank test. A p-value of 0.05 or less was considered significant.

Results: Analyses revealed differences in patient survival based on the expression of the miRNA-coding genes of interest, hsa-mir-6511b-1, hsa-mir-6820, and hsa-mir-3198-2, in OV and UCS. High expression of hsa-mir-6511b-1 was associated with a shorter survival period in both OV (p=0.021) and UCS (p=0.035) patients. In contrast, high expression of hsa-mir-6820 showed opposite effects: it was linked to shorter survival in OV patients (p=0.024) but longer survival in UCS patients (p=0.028). High expression of hsa-mir-3198-2 was associated with longer survival in both OV (p=0.027) and UCS (p=0.046) patients. Data suggest that the role of miRNAs in these gynecologic cancers appears to be complex, showing both oncogenic and protective effects.

Conclusions: These preliminary findings emphasize that miRNAs behave in a context-dependent manner in gynecologic cancers. Importance of miRNAs should be further studied to validate their potential as biomarkers for early detection, prognosis, and treatment strategies. Our laboratory is conducting translational studies to precisely understand the role of miRNA-coding genes on drug resistance to address platinum-resistance in gynecologic cancer models.

#2066 Non-invasive screening of gynecologic tumors using miRNAs in urinary extracellular vesicles.

Hiroko Matsumiya[1], **Atsushi Satomura**[2], Hiroshi Asano[1], Hiroyuki Yamazaki[1], Ryutaro Yamamoto[1], Keiichiroh Akabane[1], Ryo Tamaki[1], Hiroyuki Kurosu[1], Kei Ihira[1], Daisuke Endo[1], Takashi Mitamura[1], Yosuke Konno[1], Takeshi Umazume[1], Motoki Mikami[3], Yuki Ichikawa[3], Hidemichi Watari[1]

[1]Hokkaido University Graduate School of Medicine, Hokkaido, Japan,[2]Craif USA, San Diego, CA,[3]Craif, Tokyo, Japan

Background:
Gynecologic malignancies constitute the second leading cause of cancer-related morbidity and mortality among women worldwide, following breast cancer. Despite the availability of effective screening programs, participation remains limited in several regions because of psychological reluctance toward pelvic examinations (e.g., approximately 40% in Japan) and constrained clinical resources. To address this issue, we explored a non-invasive screening strategy based on comprehensive microRNA (miRNA) profiling of urinary extracellular vesicles (uEVs).

Methods:
This study enrolled both pregnant and non-pregnant women with gynecologic diseases, along with healthy counterparts. In total, 456 urine samples were collected, from which uEVs were isolated and subjected to comprehensive miRNA profiling. A subset comprising 121 disease cases (84 malignant and 37 benign tumors) and 121 age-matched healthy non-pregnant controls was used to establish a diagnostic model. The dataset was randomly divided into training (N = 90) and holdout (N = 31) sets for performance evaluation. The resulting model was subsequently applied to pregnant women with gynecologic diseases and healthy pregnant women to assess its generalizability and diagnostic performance.

Results:
Differential expression analysis in the training set between disease cases and healthy controls identified 25 miRNAs with significant expression changes. A diagnostic model constructed using these differentially expressed miRNAs achieved an AUC of 0.907, with sensitivity and specificity of 0.867 and 0.856, respectively. When applied to the holdout set, the model maintained high performance (AUC = 0.937; sensitivity = 0.889; specificity = 0.944). Both malignant and benign tumors were detected with high scores in non-pregnant women, irrespective of cancer type or disease stage. Although healthy pregnant women, who were not included in model training, showed low predicted cancer probabilities, pregnant women with gynecologic diseases exhibited slightly reduced scores compared with their non-pregnant counterparts.

Conclusions:
Our results suggest that urinary uEV-miRNA profiling combined with machine learning enables accurate screening of gynecologic diseases. This non-invasive approach may complement general health checkups and enhance gynecologic screening rates, thereby contributing to earlier diagnosis and improved outcomes.

#2067 PiR-60643 is a novel inhibitor of fatty acid binding protein 5 (FABP5) in lung cancer cells.

Yousef G. Amaar, Mark E. Reeves

Loma Linda VA Medical Center, Loma Linda, CA

Introduction: It is important to discover and characterize new pathways and their associated gene networks in cancer cells to develop effective diagnostic and therapeutic tools. Our laboratory is focused on the impact of the RASSF1C-PIWIL1-piRNA pathway on non-small cell lung cancer (NSCLC) cell growth; and our studies have resulted in identifying specific PIWI-interacting RNAs (piRNAs) that appear to function both as oncogenes and tumor suppressors. Among the recent piRNAs identified, we found that piR-60643 targets fatty acid bind protein 5 (FABP5) in lung cancer and appears to function as a tumor suppressor.

Methods: In previously published work we reported on a global microarray screen which identified potential piRNA genes in non-small lung cancer cells over-expressing RASSF1C. We were able to detect several piRNAs that are modulated by RASSF1C. The expression of specific piRNAs that appear to be down or up-regulated by RASSF1C were confirmed by RT-PCR. We evaluated the impact of selected RASSF1C-target piRNAs on lung cancer cell proliferation and migration *in vitro*. We also have identified both host and target genes for specific piRNAs and have used piRNA mimics to down regulate target gene expression.

Results: We show that piR-60643 is down regulated by RASSF1C and seems to function as a tumor suppressor in non-small cell lung cancer cells. Consistent with this, treatment of lung cancer cells with piR-60643 mimics reduced cell proliferation and migration, supporting the idea that piR-60643 could be a new inhibitor of lung cancer cell growth and progression. To learn more about how piR-60643 may hinder lung cancer cell growth, we searched for genes that could be targeted by piR-60643. Interestingly, we identified FABP5 as a piR-60643-target gene. FABP5 is up regulated in lung tumor tissue and in tissues of other cancers and is associated with poor patient survival. FABP5 plays a key role in regulating lipid metabolism and fatty acid oxidation (FAO). FAO is critical to supply the high energy (ATP) demand of rapidly growing cancer cells and contributes to cell cycle progression, EMT, migration, and metastasis. We found that treatment of lung cancer cells with piR-60643 mimics resulted in down regulation of FABP5 expression both at the mRNA and protein levels, implying that piR-60643 could disrupt FAO-associated metabolic pathway(s) in lung cancer cells. Interestingly, we found that PIWIL1 overexpression up-regulates FABP5 expression in lung cancer cells, suggesting that the PIWIL-FABP5 gene axis may play a role in lipid metabolism/FAO. This novel finding has not been previously reported.

Conclusion: Targeting FABP5 by piR-60643 could prove a novel mechanism of inhibiting lipid metabolism/FAO and impeding tumor growth and progression. As such, piR-60643 could prove to be a useful diagnostic/therapeutic tool for lung cancer.

: Aging and Host Determinants of Tumor Progression: The Macroenvironmental Axis
Poster Session

#2071 Aging impairs NK-cell surveillance to promote metastatic outgrowth in breast cancer.

Pulkit Datt, Jhon Pasamonte, Kelly Coutant, Anastasiia Burtseva, Mitchell Fane

Cancer Signaling and Microenvironment Research Program, Fox Chase Cancer Center, Philadelphia, PA

Metastasis is the main driver of breast cancer mortality and is more common in older patients (55-85 years), yet most experimental work still relies on young (~8-week-old, equivalent to 20 human years) mice, which fail to capture the age-related dynamics of metastasis. Moreover, most studies focus exclusively on lung metastasis, even though breast cancer often spreads to the liver, which responds poorly to immune checkpoint inhibitors and other systemic therapies. Prior work shows that an aged lung microenvironment can promote breast cancer progression via stromal factors, but how aging reshapes immune surveillance, particularly natural killer (NK) cells, in lung and liver niches remains unclear. To address this, we developed syngeneic breast cancer metastasis models in young (8 weeks), middle-aged (12-16 months), and geriatric (22-26 months) C57BL/6 mice, generating primary tumors and lung or liver metastases. Strikingly, primary tumors progressed rapidly in geriatric mice and were associated with larger lung metastases, whereas young and middle-aged mice showed limited outgrowth. Tail-vein models recapitulated this whereby older mice had increased lung metastasis. Immune profiling of pre-metastatic lung revealed that NK cells were decreased in aged and geriatric mice relative to young mice. We then depleted NK cells in young mice to test their role in restraining outgrowth. NK-cell depletion significantly increased primary tumor size and lung metastatic burden, and surprisingly, in the tail-vein model, produced large liver metastases, a phenotype not seen in any age group with tail-vein injection. Pre-metastatic liver analysis confirmed reduced NK cells in middle-aged and geriatric mice. To assess their role, we used hydrodynamic tail-vein injection, which promotes colonization of the liver specifically. Interestingly, liver metastases peaked in middle-aged mice but were reduced in both young and geriatric mice, recapitulating human data where breast cancer incidence is low in young adults (<45 years), peaks between 65-75 years and then declines in women ≥80 years. Immune profiling showed overall NK cells in lung and liver were largely unchanged across ages in tumor-bearing mice; however, NK cells in middle-aged mice livers alone exhibited a dysfunctional phenotype, with increased expression of inhibitory receptors. Importantly, immunosuppressive PMN-MDSCs and regulatory T cells were elevated in middle-aged livers but remained low in young and geriatric mice. Together, these findings define an age- and organ-specific regulation of immune cells that drives metastatic outgrowth in middle-aged and geriatric lungs and enhances liver metastasis in middle-aged mice but, surprisingly, limits liver metastasis in geriatric mice. This work underscores the need for age-appropriate models and highlights NK cells as a key target to prevent metastatic outgrowth in older breast cancer patients.

#2072 Role of the aging on the γδ T-cells in metastatic cutaneous melanoma progression.

Kelly Coutant[1], Christopher Price[1], Jhon Pasamonte[2], Pulkit Datt[2], Mitchell Fane[1]

[1]Fox Chase Cancer Center, Philadelphia, PA,[2]Temple University, Philadelphia, PA

Melanoma incidence, metastasis, and mortality are significantly associated with age. Interestingly within the clinic, melanoma incidence is low in young adults, peaks between ages 65-79, and decreases thereafter (79+). This phenomenon has never been studied as pre-clinical studies predominantly focus on young (8-week-old) mouse models.

Syngeneic melanoma cells have been injected by IV (lung colonization) and hydrodynamic tail vein injection (liver colonization) into C57/Bl/6 young (8 weeks), aged (12 months) and geriatric (18-24 months) male mice. Spleen, lungs and liver have been collected to analyze metastasis and immune infiltration by flow cytometry. H&E and IHC staining have been performed to quantify the number of metastases and to determine different immune markers (e.g. CD45, CD8, CD4). Our data highlighted that middle aged mice had significantly increased γδ T cell infiltration in the metastatic lung and liver relative to young and geriatric mice, which had less metastasis. Based on this, we used a γδ T cell mouse model of depletion coupled with depletion antibodies against gamma delta in young and geriatric mice respectively. Finally, our preliminary data indicated that upon reactivation in middle-aged mice, melanoma cells secreted PROS1, which drives cancer proliferation. Its effects on the immune system within our model have not been studied. We overexpressed PROS1 in melanoma cells and injected them via IV and HDTV and analyzed metastasis and γδ T cell infiltration.

Our data shows that middle-aged mice have significantly increased lung and liver metastasis relative to young mice. Interestingly, geriatric mice have lower levels of metastasis, replicating what is seen in the clinic. Assessment of immune cell infiltration confirmed that γδ T-cells were significantly reduced in middle-aged mice relative to young and geriatric mice. We hypothesized that they may play an anti-tumor role in metastasis. To study this, we injected tumor cells as a primary tumor, IV, and HDTV into a transgenic γδ TCR diphtheria toxin depletion model and found that while the primary tumor grew slower, γδ depleted mice had increased lung and liver metastasis. Use of a γδ depletion antibody in geriatric mice replicated this phenotype. Finally, IV and HDTV injection of PROS1 overexpressing melanoma cells significantly increased lung and liver metastasis while subsequently decreasing δ T cells infiltration in young mice.

Age induced decrease of γδ T cell infiltration in middle-aged mice, induced largely by PROS1 secretion from melanoma cells, promotes aggressive metastases. Adoptive treatment with γδ T cells or use of a PROS1 inhibitor may be a viable therapeutic option for metastasis in elderly individuals.

#2073 In vivo single-cell CRISPR screens identify targets to restore T cell function in aged tumors.

Alex C. Y. Chen, Keely Ji, Cansu Yerinde, Daniela Martinez, Thomas J. LaSalle, Kazuhiro Taguchi, Marc A. Schwartz, Maria Zschummel, Thorsten R. Mempel, Nir Hacohen, Debattama R. Sen

MGH/Harvard Medical School, Boston, MA

Aging brings significant changes to the immune system, which slow down the immune response and make it less effective at detecting and fighting cancer. However, the mechanisms behind this are not fully understood. To address this open question, we focus on studying $CD8^+$ T cells, a type of immune cell that specifically recognizes and kills tumor cells, to understand how aging alters their antitumor function. Here, we demonstrated that the aged tumor microenvironment in older individuals has a stronger effect in weakening these T cells than the intrinsic aging impacts on these T cells. Even when young, healthy, naive T cells were transferred into older hosts, they quickly lost their ability to fight tumors, indicating that therapies relying on replenishing new T cells, such as adoptive T cell transfer therapy or CAR-T cell therapy, may not be effective if the aged environment drives them toward dysfunction. One strategy to further identify candidate genes associated with T cell dysfunction is to perform in vivo single-cell CRISPR screening. To achieve this, we designed a CRISPR library pool targeting genes encoding transcriptional regulators in $Cas9^+$ OT-1 $CD8^+$ T cells, with 6 sgRNAs targeting each gene to maximize statistical confidence. After transducing T cells with vectors containing the library pool and mAmetrine marker, these successfully transduced $mAmetrine^+$ naive T cells were sorted and transferred into aged mice one day before B16-OVA tumor inoculation. After 15 days, T cells were sorted from aged B16-OVA tumors and tumor-draining lymph nodes for Perturb-seq analysis. We found T cells lacking *Bcl6*, *Dusp4*, *Dusp5*, *Ets1*, *Ikzf2*, *Irf2bp2*, *Prdm1*, or *Zfp219* showed better T cell expansion and persistence in aged tumors and lymph nodes. Notably, Dusp5 acts as a negative feedback regulator of the ERK1/2 pathway. Dusp5 deletion promotes T cell proliferation and effector-like T cell differentiation, resulting in enhanced tumor control and survival benefit. Overall, our work fills a critical knowledge gap in the field of immune aging and cancer therapy, establishing Dusp5 as a novel and promising therapeutic target to restore T cell antitumor responses, particularly in older cancer patients.

#2074 Adenosine-driven inflammatory reprogramming of aged cancer-associated fibroblasts promotes immune suppression in pancreatic ductal adenocarcinoma.

Shuncang Zhu[1], Jinpeng Lu[1], Ziyi Tu[1], Hongyi Lin[2], Yinhao Chen[1], Yiting Chen[3], Haoxiang Zhang[4], Zuwei Wang[2], Shi Chen[2]

[1]Shengli Clinical Medical College of Fujian Medical University, Fuzhou, China,[2]Department of Hepatobiliary Pancreatic Surgery, Fuzhou University Affiliated Provincial Hospital, Fuzhou, China,[3]College of Biological Science and Engineering, Fuzhou University, Fuzhou, China,[4]University of Kentucky, Lexington, KY

Background: Aging exerts a profound influence on the tumor immune microenvironment of pancreatic ductal adenocarcinoma (PDAC). In elderly patients, PDAC is frequently characterized by pronounced stromal desmoplasia, enhanced immune evasion, and increased resistance to chemotherapy. The molecular underpinnings of these age-associated alterations remain largely undefined. Emerging evidence indicates that aging-related metabolic reprogramming can profoundly reshape the cellular and immunologic composition of the tumor microenvironment (TME). Yet, the mechanistic interplay between metabolic perturbations, stromal cell dynamics, and immune regulation in aged PDAC has not been fully elucidated.

Methods: Two PDAC clinical cohorts stratified by age and survival were analyzed using bulk and single-cell transcriptomics, and metabolomics. Nucleotide metabolism was assessed by targeted metabolomics. Functional studies included adenosine stimulation of aged and young cancer-associated fibroblasts (CAFs), B cell migration and co-culture assays, cytokine profiling, and orthotopic PDAC mouse models with adenosine receptor blockade. Multiplex immunohistochemistry (mIHC) was applied to spatially validate the proximity of $A2B^+CXCL13^+$ CAFs and $IL\text{-}10^+$ Bregs in aged human PDAC tissues.

Results: Aged PDAC exhibited increased regulatory B (Breg) cell abundance, which correlated with shorter overall survival. Multi-omic analyses identified age-related adenosine accumulation as the most dysregulated metabolite linked to both poor prognosis and Breg infiltration. Direct adenosine exposure failed to expand Bregs but reprogrammed aged CAFs toward a proinflammatory state. Aged CAFs expressed elevated adenosine receptor A2B and secreted the B cell chemoattractant CXCL13 upon adenosine stimulation. The adenosine-A2B-CXCL13 axis promoted $IL\text{-}10^+$ Breg recruitment, which suppressed $CD8^+$ T cell cytotoxicity and accelerated tumor growth. mIHC confirmed close spatial association between $CXCL13^+$ CAFs and Bregs within aged PDAC tissues. Pharmacologic inhibition of A2B signaling or CXCL13 neutralization reduced Breg infiltration, restored T cell activity, and prolonged survival in orthotopic aged PDAC models.

Conclusion: Age-associated adenosine accumulation reshapes the fibroblastic niche through A2B receptor-dependent inflammatory reprogramming, inducing CXCL13-mediated Breg recruitment and immune suppression. Targeting the adenosine-A2B-CXCL13 axis represents a promising strategy to restore anti-tumor immunity in elderly patients with PDAC.

#2075 Lactate-driven cholesterol reprogramming induces fibroblast senescence and immune suppression in aged pancreatic cancer.

Ziyi Tu[1], Jinpeng Lu[2], Shuncang Zhu[1], Hong-yi Lin[1], Yi-ting Chen[1], Yinhao Chen[1], Haoxiang Zhang[2], Zu-Wei Wang[1], Shi Chen[1]

[1]Shengli Clinical Medical College of Fujian Medical University, Fuzhou, China,[2]University of Kentucky, Lexington, KY

Background: Aging profoundly remodels the pancreatic tumor microenvironment (TME), where senescent cancer-associated fibroblasts (senCAFs) accumulate and promote tumor progression. However, the metabolic cues derived from aged tumor cells that induce fibroblast senescence and mediate immune suppression remain poorly understood.
Methods: Integrated analyses of murine and human single-cell RNA-sequencing datasets combined with multiplex immunofluorescence (mIF) revealed a marked enrichment of $p16^+$ senCAFs in aged pancreatic ductal adenocarcinoma (PDAC). Targeted metabolomics and isotope tracing identified lactate as a key metabolite driving fibroblast senescence. Lactyl-proteomics, ATAC-seq, CUT&Tag, and site-directed mutagenesis were used to define functional lactylation sites. Multiplex cytokine profiling identifies the secretome of senCAFs that modulates the immunosuppressive microenvironment.
Results: Aged PDAC exhibited a marked expansion of senCAFs, validated by scRNA-seq and mIF. Metabolomic and isotope-tracing analyses revealed that lactate secreted by aged tumor cells was preferentially imported by fibroblasts through upregulated MCT1 transporters, triggering metabolic and phenotypic senescence. Proteomic profiling identified enhanced histone A-protein lactylation (H3K18la) as a key senescence-associated modification strongly correlated with poor prognosis. Mutation of the lactylation site (K18R) restored fibroblast proliferative capacity and reduced SASP secretion. Mechanistically, histone lactylation reprogrammed cholesterol metabolism by transcriptionally activating SQLE (squalene epoxidase), a rate-limiting enzyme in cholesterol biosynthesis. Cholesterol accumulation further reinforced fibroblast senescence and sustained inflammatory SASP signaling, including IL-8, CXCL12, and TGF-β, establishing an immunosuppressive tumor microenvironment. Pharmacologic inhibition of SQLE or blockade of lactate import markedly decreased senCAF accumulation, restored $CD8^+$ T cell infiltration, and improved survival in aged PDAC models.
Conclusion: Aged PDAC cells metabolically reprogram fibroblasts via lactate-driven histone lactylation, reactivating cholesterol biosynthesis and maintaining senescence. This metabolic-epigenetic axis fuels immune suppression and tumor progression. Targeting the lactate-H3K18la-SQLE pathway offers a promising therapeutic strategy to reprogram the aged tumor stroma and enhance anti-tumor immunity in PDAC.

#2076 FGFR1 drives progression of ER+ breast cancer brain metastases in young and aged hosts.

Morgan S. Fox[1], Jenny A. Jaramillo-Gomez[1], R. Alejandro Marquez-Ortiz[1], Karen L. F. Alvarez-Eraso[1], Maria J. Contreras-Zarate[1], Trinh C. Pham[1], Elaina N. Barela[1], Stella Koliavas[1], Peter Kabos[2], Carol A. Sartorius[1], Elizabeth A. Wellberg[3], Diana M. Cittelly[1]

[1]Pathology, University of Colorado, Aurora, CO,[2]Medical Oncology, University of Colorado, Aurora, CO,[3]University of Oklahoma Health Sciences Center, Oklahoma City, OK

The purpose of these studies is to define mechanisms that drive estrogen receptor positive (ER+) breast cancer brain metastasis (BCBM) colonization and outgrowth. Most ER+ BCBMs arise in postmenopausal women due to prior endocrine therapies or age, yet most *in vivo* ER+ breast cancer (BC) models require estrogen (E2) supplementation and use young hosts. Thus, the mechanisms underlying metastatic progression in the aged/E2-depleted brain tumor microenvironment (TME) remain unknown. FGFR1-amplification (amp), an established driver of ER+ BC endocrine therapy resistance, was the only genomic alteration associated with increased late recurrence in post-menopausal women with ER+ BC on aromatase inhibitors, and FGFR aberrations are enriched in BCBM patients compared to non-BM metastatic BC. While FGFR1amp often causes auto-activation, TME-dependent FGFR1 activation has emerged as an important mechanism modulating its activity. Here, we tested the hypothesis that canonical and non-canonical activation of FGFR1 by astrocytes and neurons promotes FGFR1-dependent ER+ BCBM in E2-high young and E2-low aged hosts. Intracardiac injection of ER+ cells showed that FGFR1amp lines had higher BM incidence, and were E2-dependent in young but not aged hosts. FGFR1 knockdown (KD) did not alter proliferation but decreased BCBM in both E2-high/young and E2-low/aged mice. Spatial transcriptomics of the ER+ BCBMs TME showed that aging and E2-depletion reduced FGF2 expression and FGF/FGFR signaling in surrounding glial cells, suggesting that TME-driven FGFR1 activation may be distinct in young and aged hosts. In the normal brain, NCAM1, an adhesion molecule expressed on neurons and astrocytes, can activate FGFR1. We found that NCAM1 activated FGFR1 kinase activity and downstream signaling in ER+ BC cells, and induced differential expression of neuronal gene signatures including neural cell adhesion. FGFR1 KD reduced ER+ BC cell migration along neurites in co-culture with primary neurons and decreased synaptic puncta. NCAM1 KD in neuron-like SH-SY5Y cells also decreased ER+ cell migration, suggesting that FGFR1/NCAM1 facilitates ER+ BC interactions with neurons, contributing to early brain colonization. Activated FGFR1 was higher in young versus aged mice at early stages of colonization but absent in late-stage ER+ BCBMs, suggesting that paracrine FGFR1 activation and interactions with neurons and astrocytes are critical for early colonization. Consistently, an FDA-approved FGFR inhibitor blocked ER+ BCBM when administered at early stages of colonization in young mice but had no effect at late stages or in aged mice. Together, these studies suggest a novel mechanism whereby canonical and non-canonical activation of FGFR1 promote ER+ BCBM colonization in young and aged/E2-depleted hosts, and caution that FGFR1 inhibition may only be effective to prevent but not to treat BMs.

#2077 Remodeling the aged bone marrow niche: LRG1-mediated immunosuppression promotes prostate cancer metastasis.

Lele Xu[1], Yuanhao Song[2], Wenlin Zhao[2], Peter Ka Fung Chiu[1], Anthony Chi-Fai Ng[1], **Dinglan Wu**[1]

[1]SH Ho Urology Centre, Department of Surgery, The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]Shenzhen Hospital of Southern Medical University, Shenzhen, China

Prostate cancer (PCa) bone metastasis arises from intricate interactions between tumor cells and the bone marrow microenvironment. Chronic inflammation in the aging bone marrow is thought to foster an immunosuppressive niche that facilitates metastatic progression. Here, we identify Leucine-Rich Alpha-2-Glycoprotein 1 (LRG1) as a central mediator of this process. LRG1 protein is significantly elevated in the circulation of patients with metastatic castration-resistant prostate cancer (mCRPC), where its levels correlate with worse overall survival. In both human PCa tissues and our established RM1-BM3 mouse model of PCa bone metastasis, LRG1 expression is markedly upregulated. Functionally, LRG1 overexpression enhances tumor growth in bone and correlates with immunosuppressive bone microenvironment by accumulation of polymorphonuclear myeloid-derived suppressor cells (PMN-MDSCs). Mechanistically, MS and CO-IP assays reveal that LRG1 interacts directly with ITGA6 (CD49f) on prostate cancer cells to activate pro-metastatic pathways and with the inflammatory protein S100A9 to recruit and expand PMN-MDSCs. Furthermore, we show that interleukin-1 (IL-1) stimulates LRG1 expression in an androgen receptor (AR)-independent manner via NF-κB pathway activation. Collectively, we propose a model wherein IL-1 signaling in the aging bone marrow upregulates LRG1, which then acts dually: it promotes cancer cell aggressiveness via ITGA6 and fosters an immunosuppressive niche via S100A9-PMN-MDSC axis, thereby driving bone metastasis in CRPC. Our findings nominate LRG1 and its associated pathways as promising therapeutic targets for metastatic prostate cancer.

#2078 Aging promotes liver and lung melanoma metastasis via tissue-infiltrating Tregs.

Anastasiia Burtseva, Kelly Coutant, Jhon Pasamonte, Christopher Price, Mitchell Fane

Fox Chase Cancer Center, Philadelphia, PA

Metastasis is the leading cause of melanoma-related deaths, yet its age-related mechanisms remain poorly understood. This gap stems partly from reliance on young mouse models (~8 weeks old, equivalent to 20 human years) in most studies. Additionally, research has largely focused on lung metastasis, even though melanoma often spreads to other sites like the liver, which is notably more resistant to immune checkpoint inhibitors (ICIs).Using syngeneic melanoma cells, we optimized intravenous (IV) injections to model lung colonization and developed a novel liver colonization model using hydrodynamic tail vein injections. Tumor cells were injected into young (8 weeks) and aged (12-16 months) male C57BL/6 mice. Spleen, lungs, and liver were harvested to assess immune infiltration of lymphocyte and myeloid populations via flow cytometry. Hematoxylin and eosin (H&E) and immunohistochemistry (IHC) staining were used to quantify metastases and examine spatial immune cell locations. Upon observation that regulatory T cells (Tregs) increased consistently in aged mice in both lung and liver metastatic sites, we treated additional aged cohorts with either anti-mouse CD25 antibody, which we show decreased Tregs while not changing CD3+, CD4+ or CD8+ T cell infiltration, or an IgG control (200 µg/mouse, intraperitoneally) to evaluate the role of Tregs and in metastasis.Aging significantly increased melanoma colonization in both the lungs and liver compared to young mice. Analysis of common changes in the immune microenvironment of both the lung and the liver revealed elevated Treg infiltration in both metastatic sites of aged mice. Notably, Tregs were not elevated in the pre-metastatic niche, suggesting an age- and tumor-specific mechanism of immune suppression. Depletion of Tregs in aged mice using anti-CD25 antibody significantly reduced lung metastases compared to IgG controls. Moreover, depletion of Tregs decreased secretion of TGF-β and the number of myeloid cells in metastatic sites and increased the number of $NK1.1^+$ NK cells, $CD4^+$ and $CD8^+$ T cells.Our findings indicate that age-associated Treg infiltration promotes metastasis to the lung and liver, suggesting that targeting Tregs could offer a promising approach to mitigate age-related metastatic progression in melanoma.

#2079 Aging attenuates brain metastasis in lung cancer through the MT1G/NF-κB/SPARC signaling.

Abhishek Tyagi[1], Shih-Ying Wu[1], Jee Won Kim[1], Kerui Wu[2], Ravindra Deshpande[1], Kounosuke Watabe[3]

[1]Wake Forest University School of Medicine, Winston Salem, NC,[2]The Joint School of Nanoscience and Nanoengineering University of North Carolina, Greensboro, NC,[3]Associate Director for Basic Science, Wake Forest University Health Sciences, Winston-Salem, NC

Aging is a major risk factor for cancer, with incidence and mortality increasing significantly with age across most cancer types. With the global population aged over 60 projected to rise from 12-22 percent by 2050, understanding the relationship between aging and cancer is critically important. Aging and cancer share several hallmarks—including cumulative genetic damage, immune senescence, altered nutrient sensing, and chronic low-grade inflammation. This overlap implies that age-related biological changes may not only correlate with increased cancer incidence but also influence tumor progression and metastasis. Despite this preconceived notion, population-based epidemiological studies have revealed an inverse association between aging and brain metastasis incidence in lung cancer, with unclear molecular mechanism(s). Here, we show a significantly lower incidence of brain metastasis in aged lung cancer patients compared to younger patients or those with brain metastasis from other cancers, based on analysis of the SEER population-based cancer registry. Mechanistically, aging activates MT1G/NFκB signaling in reactive astrocytes within the brain, leading to increased secretion of SPARC from A1 type reactive astrocytes, which suppresses tumor growth by inhibiting ITGB1 signaling in tumor cells, thereby limiting brain colonization. Notably, therapeutic targeting of ITGB1 using liposome-encapsulated SPARC peptide effectively suppresses brain tumor growth and metastasis, supporting its tumor-suppressive role. These findings uncover an age-associated protective mechanism and provide a compelling rationale for developing targeted therapies to prevent or treat brain metastasis in younger lung cancer patients.

#2080 Aged-induced increases in IL-11 leads to immune escape and PD-1 resistance in melanoma through myeloid cell polarization.

Michael F. Emmons[1], Chao Zhang[1], ethan vallebuona[1], Richard L. Bennett[2], Manali Phadke[1], Jonathan D. Licht[2], Keiran Smalley[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]University of Florida, Gainesville, FL

Background: Stress-like states, associated with hypoxia, drug treatment and aging, can contribute to immune escape in cancer through mechanisms that remain poorly understood. IL-11 is a poorly studied cytokine whose expression increases with age. In previous work, we have identified histone deacetylase (HDAC)-8, as an epigenetic regulator whose expression increases in response to multiple stresses. Here, we identify HDAC8 as a regulator of IL-11 expression, leading to immune escape and immunotherapy resistance in melanoma. <
strong>Objectives: We investigated the role of IL-11 in modulating the immune microenvironment and its impact on melanoma progression and resistance to immunotherapy in young vs aged mice.
Methods: Intrinsically sensitive and resistant melanoma cells were assayed for cytokine secretion by cytokine arrays and ELISAs. Chromatin accessibility, histone modifications, and transcriptional changes of IL-11 were assessed in human melanoma cells overexpressing HDAC8 using ATAC-seq, ChIP-seq, and scRNA-seq. ELISA, immunohistochemistry (IHC), and flow assays were employed to evaluate IL-11 expression and its effects on myeloid-derived suppressor cells (MDSCs) and T cell interactions in young vs aged mice. Young (<3M) and old (>18M) mice were treated with an IL-11 blocking antibody and/or anti-PD-1 antibody to determine drug efficacy. TMAs and IHCS from patients were stained for IL-11.
Results: IL-11 expression was upregulated in melanoma cells in response to hypoxia as well as intrinsic and acquired targeted therapy treatment. Expression of IL-11 accelerated melanoma growth in vivo and led to increased accumulation of PMN-MDSCs and reduced CD8+ T cell infiltration. IL-11 expression reduced the efficacy of anti-PD-1 therapy in melanoma models, whereas IL-11 blockade enhanced anti-PD-1 responses. Old mice (>18M) had increased circulating levels of IL-11 levels compared to young mice (<3M), as well as increased IL-11 expression in the liver. Therapeutic blockade of IL-11 led to complete anti-tumor responses to anti-PD-1 in aged mice with melanomas. In melanoma patient samples, IL-11 expression was correlated with increased age, and was spatially expressed in areas of the tumor that had reduced CD8+ T cell infiltrate.
Conclusions: IL-11 promotes a "cold" immune microenvironment in aged mice by increasing accumulation of PMN-MDSCs and suppressing T cell recognition and infiltration. Blocking IL-11 in aged mice contributed to increased immunotherapy efficacy. Targeting IL-11 represents a promising therapeutic strategy to limit immune escape and boost responses to anti-PD-1 in melanoma, particularly in aged patients.

#2081 Age of host impact on epigenetics in tumors derived from early or late onset Hispanic colorectal cancer patients.

Lesly Torres-Gonzalez[1], Shivani Soni[1], Zeyi Yang[1], Ben Y. Tew[1], Jae H. Lo[1], Pooja Mittal[1], Unnati H. Shah[1], Michela Bartolini[1], Steve Soto Trujillo[1], Yitzher Goretsky[1], Sandra Algaze[1], Wu Zhang[1], David W. Craig[2], John D. Carpten[3], Salhia Bodour[1], Heinz-Josef Lenz[1]

[1]USC Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA,[2]City of Hope Comprehensive Cancer Center, Duarte, CA,[3]City of Hope, Duarte, CA

Introduction Over the past decade, the incidence of early-onset (EO) colorectal cancer (CRC) in adults under 50 has shown a significant increase compared to late-onset (LO) CRC rates, especially in the Hispanic/Latino (H&L) population. EO CRC exhibits unique molecular features compared to LO CRC, associating this distinct disease with a more aggressive presentation. Investigations on the effect of age within both the tumor and host environments could provide insight into key differences between EO and LO CRCs. This study, as part of Cancer Moonshot Program, explores how age of the host influences epigenetic changes in CRC tumors.
Methods CRC patient derived tumor samples from an EO 36 year old (young patient, YP) and a LO 66 year old (old patient, OP) H&L male were implanted into both young (2 months, YM) and old male NSG mice (13-14 months, OM) to establish four PDX models: YP in YM, OP in YM, YP in OM, and OP in OM. Tumor samples were collected at endpoint (15mm length or width). Tumors were processed for epigenomic analysis using the Illumina EPIC Array Epigenetics Kit. Methylation data was used to identify differentially methylated regions ($\Delta\beta>0.1$) in YP in OM compared to YP in YM and OP in YM compared to OP in OM. Identified regions were mapped to the nearest gene using the human genome (GRCh38 Genome Reference Consortium Human Reference 38) from UCSC. The differentially methylated genes ($\Delta\beta>0.2$) were input into Ingenuity Pathway Analysis to identify relevant biological pathways.
Results There were 8916 differentially methylated regions identified in YP in OM when compared to YP in YM. Of these regions, 5529 showed hypermethylation and 3387 showed hypomethylation. Regions were mapped to 5886 unique gene symbols, of which 1061 were hypermethylated and 999 were hypomethylated. YP in OM showed predicted activation of key genes, including TNF, WNT1, MYB, ERBB3, GLI3, EGR2, and EGR3, involved in the development and progression of gastrointestinal cancers. There were 28032 differentially methylated regions ($\Delta\beta>0.1$) identified in OP in YM when compared to OP in OM. If these regions, 17590 showed hypermethylation and 10442 showed hypomethylation. Regions were mapped to 11888 unique gene symbols, of which 4273 were hypermethylated and 2936 were hypomethylated. OP in YM showed predicted inhibition of key genes, including RELA, TNF, EGFR, YAP1, WNT3A, FGF2, IFNG, SP1, IGF1, ERBB2 and TEAD1, involved in cell transformation and tumor cell metastasis.
Conclusions Our current findings show differences in epigenetic DNA methylation patterns in EO and LO CRC PDX models. Differentially methylated region analysis in both EO and LO CRC suggests that an older host age may correlate with activation of cancer related genes while younger host age may inhibit similar pathways, regardless of tumor age. Further studies are warranted to understand the epigenetics modifications that influence the observed differences.

#2082 Multiplex immunofluorescence reveals compartment-specific immune cell correlations associated with age and immunotherapy response in ovarian carcinoma.

Kathy Kwock[1], Okan Gultekin[2], Hanim I. Ozkizilkaya[3], Lynda D. Roman[3], William Dean Wallace[3], Tirzah Petta[3], Joseph W. Carlson[4]

[1]University of Southern California, Los Angeles, CA,[2]Karolinska Institute, Stockholm, Sweden,[3]Keck School of Medicine of USC, Los Angeles, CA,[4]CIty of Hope, Duarte, CA

BackgroundOvarian carcinoma, an aggressive malignancy typically diagnosed at advanced stages, has shown limited response to immune checkpoint inhibitors. Increasing evidence suggests that age-related immune alterations and spatial heterogeneity within the tumor microenvironment influence immunotherapy outcomes. This study investigates whether immune cell organization across tissue compartments correlates with clinical response to immunotherapy.

MethodTwenty patients treated with immunotherapy were identified. FFPE tumor blocks were retrieved, and slides were stained using a multiplex immunofluorescence panel (DAPI, PD-L1, CD4, CD8, CD20, FoxP3, PanCK). Regions of interest were annotated by a pathologist and analyzed using supervised learning in inForm and PhenoChart. Immune cell phenotypes were quantified across tissue compartments, and correlation analyses were performed using RStudio, Excel, and GraphPad Prism.

ResultOlder patients demonstrated significantly improved immunotherapy outcomes, including longer progression-free survival and duration of effective immunotherapy, confirming an age-associated advantage in therapeutic response. Multiplex immunofluorescence revealed distinct immune correlation networks between responders and non-responders, driven by tissue compartmentalization. Among immunotherapy responders, stromal regions showed a positive correlation between $FoxP3^+$ and $PanCK^+$ tumor cells, whereas tumoral regions exhibited a negative correlation between $CD8^+$ cells and $PanCK^+$ cells. Whole-tissue analysis revealed a strong correlation between $FoxP3^+$ and $CD8^+$ cells in responders. In contrast, non-responders displayed a different pattern of immune cell organization, characterized by strong correlations between $CD4^+$ and $CD8^+$ T cells in the stroma and between $CD20^+$ B cells and $PanCK^+$ cells in the tumor compartment. Spatial proximity heatmaps demonstrated that responders had higher local clustering of $CD8^+$, $CD4^+$, and $CD20^+$ cells across multiple radii within both tumor and stromal regions, while non-responders exhibited limited spatial clustering consistent with “immunologically cold” tumors.

ConclusionThis study identifies distinct, compartment-specific immune cell relationships associated with immunotherapy response in ovarian carcinoma highlights age as a significant modifier of immune architecture. Responders, predominantly older patients, exhibited coordinated stromal $FoxP3^+$ interactions and tumoral $CD8^+$ engagement, whereas non-responders, predominantly younger patients, showed stromal $CD4^+$/$CD8^+$ clustering and tumoral $CD20^+$ associations characteristic of cold immune phenotypes. These findings suggest that immune cell correlations, rather than absolute densities, may serve as informative spatial biomarkers for predicting immunotherapy response.

#2083 Spatial profiling reveals distinct immune microenvironments in early vs late onset colorectal cancer.

Niti Jani[1], Michael Martinez[1], Christopher Flynn[1], Hatano Yuichiro[1], Zhongqiu Zhang[2], Daniel W. Rosenberg[3]

[1]University of Connecticut Health Center, Farmington, CT,[2]Waterbury Hospital, Waterbury, CT,[3]Professor of Med. & Co-Director, Colon Cancer Prev. Prog., University of Connecticut Health Center, Farmington, CT

Colorectal cancer (CRC) is the fourth most common cancer and the second leading cause of cancer related deaths in the United States. While CRC incidence increases with age, rates are rising among individuals younger than 50 years old (early-onset CRC; EOCRC). Most sporadic EOCRC tumors are microsatellite stable (MSS), and MSS tumors generally do not respond favorably to immunotherapy. The age-associated differences within the tumor microenvironment (TME) remain poorly understood. We hypothesize that EOCRC tumors have a more immunosuppressive microenvironment, which may influence treatment response. Methods: Tumor tissues were collected under an approved IRB protocol from Waterbury Hospital and UConn John Dempsey Hospital. Patients ≤50 years were classified as EOCRC (n = 8) and ≥60 years as late-onset (LOCRC; (n = 10). A total of eighteen regions of interest (ROIs) from tumor sections were selected by a pathologist. Imaging mass cytometry (IMC; 27-marker panel) was performed to spatially characterize the epithelial and immune cell populations. Images were processed to identify single cells, the data were adjusted to remove technical differences, and cells were grouped based on markers and visualized using MCD Viewer software. We also examined how different cell types were spatially arranged and interacted within the tissue. Statistical comparisons were performed using Welch's t-test and permutation-based tests. Results: Using IMC, a total of 142,992 single cells across 18 ROIs were analyzed. Unsupervised clustering identified 19 cell populations, including epithelial (40%), stromal (18%), $CD45^+$ lymphocytes (11%), myeloid subsets (11%), and rare intra-epithelial lymphocytes (<1%). Cluster identities were validated by marker expression and spatial localization. EOCRC tumors showed a significantly higher abundance of $FoxP3^+$ $CD4^+$ Tregs (P = 0.047), indicating an immunosuppressive TME. LOCRC samples trended toward higher intra-epithelial lymphocytes. Spatial analysis suggested a direct Treg-M2 macrophage interaction due to their colocalization, suggesting the possibility of suppressive niches forming within EOCRC. Immune-enriched stromal regions were slightly more abundant in EOCRC (20.3% of cells) than in LOCRC (16.5%). These regions were enriched with Tregs, CTLs, and M2 macrophages, with Treg infiltration being significantly higher in EOCRC (P = 0.032). These findings support a localized immunosuppressive phenotype. Conclusion: EOCRC tumors display a more immunosuppressive microenvironment, characterized by increased Treg infiltration and a higher M2 macrophage presence in immune cell-enriched regions. These findings suggest that age-related immune differences may exist within tumors of CRC patients. Ongoing validation by multiplexed immunohistology will strengthen these results and inform the development of age-tailored therapeutic strategies.

#2084 Angiotensin-II-induced chronic hypertension reprograms the antitumor-immune-response in pancreatic ductal adenocarcinoma.

Benjamin Wolf[1], Heena Kumra[1], Ryo Morisue[1], Karim El-marouk[1], Igor L. Gomes-Santos[1], Rieke Schleinhege[1], Tsion H. Tale[1], Marc Charabati[1], Sonu Subudhi[1], Dai Fukumura[1], Rakesh K. Jain[2]

[1]Massachusetts General Hospital, Boston, MA,[2]Harvard Medical School/Massachusetts General Hospital, Boston, MA

Introduction: Chronic arterial hypertension (CAH) is one of the most prevalent medical conditions worldwide and plays a causal role in cardiovascular diseases. Cancer patients with CAH have inferior outcomes compared to non-hypertensive cancer patients, especially in pancreatic ductal adenocarcinoma (PDAC). Furthermore, retrospective analyses have shown that antihypertensive therapy targeting angiotensin signaling is associated with improved oncological outcomes compared to other anti-hypertensive treatments in cancer patients. Methods and Results: To investigate this relationship, we employed a syngeneic, orthotopic PDAC model in mice with chronic hypertension induced by subcutaneously implanted osmotic minipumps delivering angiotensin II. Using highly multiplexed spectral flow cytometry, we found that chronic angiotensin II administration re-wires the anti-tumor immune response, leading to an increased presence of myeloid cells, particularly Ly6C+ monocytes, and CD206+ macrophages. Blockage of the angiotensin II receptor type I (AT1) with losartan leads to a marked decrease in tumor growth and a reduction in MDSCs. This effect was observed only with the synchronous administration of angiotensin II and losartan, not with losartan alone, and was consistent across different PDAC treatment regimens. In addition, we observed a trend toward improved tumor vessel perfusion in hypertensive mice treated with losartan, indicating vascular repair. Additional findings suggest that inhibition of the angiotensin II receptor type 2 (AT2) and the Mas receptor (which physiologically counterbalance AT1 signaling) abrogated the beneficial effect of AT1 blockade with losartan, suggesting a role for AT2 and the Mas receptor in shaping the immune microenvironment. Conclusion: Overall, our findings show that CAH reprograms the tumor microenvironment in PDAC and that inhibition of angiotensin signaling reverses these changes. This may indicate that inhibition of angiotensin signaling in cancer patients with CAH may exert its beneficial effect by reprogramming the anti-tumor immune response.

#2085 Novel obesity-associated adipokine modulates the malignant phenotype of endometrial cancer cells.

Chi Lam Au Yeung, Gaayathri Binoj, Qian Zhang, Yadira Pacheco, Samuel Mok

UT MD Anderson Cancer Center, Houston, TX

Endometrioid Endometrial Cancer (EEC) is the most common gynecologic malignancy in the United States. Around 60% of women with EEC are believed to be associated with being overweight or obese. This fraction of patients is likely to increase as the obesity epidemic continues in the United States. Omentin (ITLN1) is a novel adipokine that is expressed in mesothelial cells covering the omental adipose tissue. The serum omentin level is inversely correlated with Body Mass Index and it increases with weight loss. We demonstrated that serum omentin level is significantly lower in patients with EEC compared to healthy women. Besides, immunocompetent mice fed with high-fat diet demonstrated a significantly higher tumor burden and lower circulating omentin level than those fed with low-fat diet, suggesting that obesity suppresses circulating omentin level and promotes EEC progression. To determine the roles of omentin in EEC pathogenesis, both human and mouse EEC cell lines were treated with recombinant omentin to evaluate cell growth and cell motility. We found that EEC cells treated with recombinant omentin have a significantly lower cell proliferation rate compared to control cells treated with PBS. Omentin-treated EEC cells also resulted in a significantly reduced migration rate compared to control cells. Since omentin was previously reported to bind to alpha-v-beta-3 (αvβ3) integrin to exert biological functions, we treated the EEC cells with αvβ3 blocking antibody to see if the effects of omentin on cell growth and motility would be abrogated. We found that αvβ3 blocking antibody abrogated the suppressive effect of omentin on cell growth compared to normal mouse IgG control. Similarly, αvβ3 blocking antibody counteracted the effect of omentin on cell migration. These suggest that omentin binding to the αvβ3 integrin inhibited cell proliferation and motility. In addition, Western blot analysis showed that omentin downregulated key αvβ3 downstream signaling molecules, such as p-ERK and p-CREB. Addition of αvβ3 blocking antibody in omentin-treated cells reversed the suppressive effect of omentin on p-ERK, further suggesting that omentin/αvβ3 integrin axis may play an important role in mediating the tumor suppressive effect of omentin.In conclusion, the above findings suggest that omentin suppresses EEC cell growth and migration potentially through binding to αvβ3 integrin. Further study is needed to characterize the specific pathways involved in omentin-mediated suppression on EEC cells and to develop omentin as a low toxicity chemopreventive and therapeutic agent for EEC patients

#2087 Intermittent fasting remodels gut ecosystem to influence initiation and therapy responses in pancreatic cancer.

Le Li[1], Vidhi Chandra[2], Fuduan Peng[2], Luca S. Santovito[3], Olivereen Le Roux[2], Rian M. Howell[2], Thais Bartelli[2], Virginia Tahan[2], Erika Y. Faraoni[2], Seyda Baydogan[2], Haiyan D. Miller[4], Kejing Song[4], Vasanta Putluri[5], Badrajee Piyarathna[5], Abu Hena Kamal[5], Nagireddy Putluri[6], Joseph Petrosino[5], Arun Sreekumar[5], Jay Kolls[4], James R. White[7], Zheng Sun[5], Lora V. Hooper[8], Linghua Wang[2], Faraz Bishehsari[3], Florencia McAllister[2]

[1]Department of Genetics, UT MD Anderson Cancer Center, Houston, TX,[2]UT MD Anderson Cancer Center, Houston, TX,[3]UT Health Center Houston, Houston, TX,[4]Tulane University, New Orleans, LA,[5]Baylor College of Medicine, Houston, TX,[6]Baylor College of Medicine, Sugar Land, TX,[7]Resphera Biosciences, Baltimore, MD,[8]UT Southwestern, Dallas, TX

Pancreatic ductal adenocarcinoma (PDAC) has one of the lowest cancers related-survival rates with high resistance to therapies and no available preventive strategies. Even immunotherapy, which has transformed cancer treatment by providing survival benefits in many solid tumors, has shown limited efficacy in PDAC. Eating patterns can modulate the composition and metabolic activity of the gut microbiota, thereby affecting anti-tumor immune responses. Fasting, a common treatment for pancreatic inflammatory conditions, can affect the composition of gut microbiota, regulates immunity and host metabolic responses. Although fasting is known to offer therapeutic benefits in pancreatic disorders such as pancreatitis and diabetes, its potential role in the prevention or treatment of pancreatic cancer remains unclear. Intermittent fasting (IF) refers to dietary regimens that limit food intake to specific time windows while allowing ad libitum calorie consumption during those periods. Using multiple spontaneous genetically engineered premalignant and orthotopic murine cancer models, we show that IF delays pancreatic tumorigenesis and induces sensitivity to immunotherapy in PDAC. IF-mediated reversal of PD-1 blockade resistance is dependent on gut microbiota mediated $CD8^+$ T cells activation and migration. IF modulates the relative abundance of gut microbiota as well as the serum metabolite levels, which activates intratumoral dendritic cells (DCs). Timeseries single cell transcriptomic analysis revealed that IF remodels the circadian clock of $CD8^+$ T cells and promotes anti-tumor immune responses through shifting the oscillation of genes, including *Kat2b*, *E2f4*, *Carns1* and *Ccnc*. Integration of these gene-expression profiles enables stratification of survival among PDAC patients. Spatial analysis confirmed that long-term fasting was associated with increased the proportion of $CD8^+$ T cells which were in proximity to DCs compared to short-term fasting, suggesting clinical evidence supporting a role for fasting in the redistribution of immune cells within the tumor microenvironment of PDAC. Our findings demonstrate the efficacy of IF in PDAC prevention and reversal of therapy resistance by modulating the activation and egress of rhythmic $CD8^+$ T cells, ultimately affecting the pancreas tumor ecosystem.

#2088 Prostaglandin E_2 signaling promotes adverse survival outcome in B-cell acute lymphoblastic leukemia.

Michael Cohen[1], Nayaonika Vasishtha[1], Byourak Shabane[1], Jia Tan[1], Tyler Kuk[1], Neha Chandra[1], In Sook Ahn[1], Xia Yang[1], Etan Orgel[2], Steven D. Mittelman[1]

[1]UCLA - University of California Los Angeles, Los Angeles, CA,[2]Children's Hospital Los Angeles, Los Angeles, CA

Obesity increases risk and worsens treatment outcome of acute lymphoblastic leukemia (ALL). To explore how adipose tissue may contribute to these effects, we previously performed single cell RNA sequencing in obese mice to compare gene expression in ALL from adipose tissue to ALL from marrow. We identified 577 differentially expressed genes (DEGs) with a $\log_2$-fold threshold of ±0.25 and Bonferroni corrected p-values <0.05. Using *ex-vivo* coculture of ALL and human adipose explants, we confirmed that adipose tissue upregulates a top DEG, *TNFSF11*, in ALL cells via secretion of prostaglandin E2 (PGE_2). Additionally, we observed that PGE_2 conferred modest resistance *in vitro* to vincristine and daunorubicin chemotherapies. In the present study, we explored whether adipose tissue PGE_2 might contribute to poor ALL treatment outcome. We identified six additional genes in the top 50 DEGs that may be induced by PGE_2-cAMP signaling and confirmed that these genes were upregulated *in vitro* by 200 ng/mL PGE_2 in BV173 and RS4;11 ALL cell lines (Table)(N=6). To investigate the relevance of these genes to ALL survival, we analyzed data from the TARGET-ALL P2 clinical trial using the NCI GDC Data Portal. TARGET-ALL P2 included pediatric and young adult B-precursor ALL patients treated on Children's Oncology Group protocols, enriched for patients who experienced relapse within 4 years of diagnosis. Survival and RNAseq expression on diagnostic specimens were available for 466 subjects. Expression of these six genes, as well as *TNFSF11*, was associated with significantly worse survival, with hazard ratios ranging from 1.7 to 3.7 (Table). Overall, our data shows that adipose tissue PGE_2 can upregulate genes that are associated with a worse prognosis in ALL patients. Further work is needed to test whether adipose tissue PGE_2 is a contributing factor for worse ALL outcomes in obese patients.

Gene name	Symbol	Log_2 FC adipose vs. marrow (scRNAseq)	Fold change with PGE_2 (qPCR) BV173, RS4;11	p-value BV173, RS4;11	Hazard ratio	Log-rank p-value

#2089 Sex-specific IgA secretion in muscle-invasive bladder cancer: A preliminary study.

Yasmine Ilkhani[1], Sirine Bouabda-Barc[1], Rachel Chevalier[1], Orlando Yuan[1], Jose Joao Mansure[1], Madhuri Koti[2], Wassim Kassouf[3], **Eva Michaud**[3]

[1]Urologic Oncology Research Division, Cancer Research Program, Research Institute of the McGill University Health Center, Montreal, QC, Canada,[2]Department of Biomedical and Molecular Sciences, Queen's University, Kingston, ON, Canada,[3]Department of Surgery, Division of Surgery, Cancer Research Program, McGill University, Montreal, QC, Canada

Background: Males are 3 times more at risk to develop muscle-invasive bladder cancer (MIBC), yet females present with higher-grade disease, worse prognosis, and reduced response to available treatments. The biological basis of these sex differences remains elusive. Secretory IgA (SIgA), including SIgA1 and SIgA2, maintains mucosal homeostasis by binding commensal microbes. SIgA is secreted *via* pIgR-mediated transcytosis and microbe-bound SIgA2 can traffic back to the *lamina propria* by binding to Dectin-1 and Siglec-5 (reverse transcytosis). This is known in other mucosae but not the bladder. Urinary IgA is elevated in MIBC patients, yet existing studies suggest conflicting roles: IgA is linked to reduced immunosuppression and improved immunotherapy response, yet also to poor survival in cohorts largely dominated by male cases. This leaves sex-specific IgA biology uncharacterized in urinary immunity. *Hence, we hypothesize that bladder IgA secretion is distinct in males and females and may influence MIBC outcomes.*

Methods: Digital Spatial Profiling (GeoMx) was performed on pre-treatment MIBC tumors (n=171; 35F/136M). RNAscope pan-bacterial 16S and multiplex IHC (IgA1, IgA2, ER, AR) were applied to the same tissues. Urinary IgA1/IgA2 were quantified by ELISA (n=20F/20M). Wild-type (n=20F/20M), gonadectomized (n=15F/15M), and sex-reversed FCG mice (FCG, n=5-8 XX-F, XY-F, XY-M and XX-M) received 0.05% N-butyl-N-(4-hydroxybutyl)-nitrosamine (BBN) for 20 weeks. HBLAK cells were cultured on inserts for stratification± β-estradiol then exposed to commercial IgA (2h). Q-omics was used to query TCGA MIBC datasets.

Results: Female tumors were enriched for *IGHA1*, with increased urinary IgA2. In TCGA, high tumoral *IGHA2* correlated with improved survival in women only, particularly in tumors with low ESR1 expression. We also found increased *CLEC7A* (dectin-1) and *SIGLEC5* expression in tumors compared to matched normal area. Female mice displayed higher urinary and urothelial IgA, with ovariectomy modulating IgA only after tumor establishment. We found a staining gradient in the urothelium and IgA-positive vesicles, indicating active transport of complexed IgA. No differences in urinary IgA were observed between sex-reversed FCG and WT mice, supporting hormonal rather than autosomal control of IgA. HBLAK pIgR expression was downregulated by β-estradiol. In stratified cultures, IgA added to either side of culture inserts was detected on the opposite side, demonstrating both transcytosis and reverse transcytosis. Long-term exposure to β-estradiol led to significantly less transcytosis, but not reverse-transcytosis.

Impact: This is the first investigation of bladder IgA biology in MIBC; we show human and mice tumors are broadly poised for IgA secretion and retro-transport, modulated by female hormones. IgA may represent a novel sex-specific biomarker, its integration in a predictive response model is pending.

#2090 Modifiable lifestyle factors and immune gene expression in breast tumor and normal-adjacent tissue.

Kristen D. Brantley[1], Cheng Peng[2], Clara Bodelon[3], Deborah A. Tadesse[4], Peter Kraft[5], Rulla M. Tamimi[6]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Brigham and Women's Hospital, Boston, MA,[3]American Cancer Society, Atlanta, GA,[4]Trans-Divisional Research Program, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[5]National Cancer Institute, Rockville, MD,[6]Weill Cornell Medicine, New York, NY

Background: The tumor immune microenvironment may provide key information on breast cancer prognosis. Several modifiable risk factors influence the immune response, including weight, physical activity, and diet; however, whether these factors alter the breast tumor immune microenvironment remains unknown.

Methods: Participants enrolled in the Nurses' Health Studies diagnosed with invasive breast cancer and available tumor and/or normal adjacent tissue were included (N=945). Immune cell abundance was deconvoluted using CIBERSORTx. Gene expression signatures were derived for components of the immune profile such as immune checkpoint markers, co-regulatory signal and antigen presentation, and cytokine signaling. Participant weight, BMI, alcohol use, and smoking status were collected via bi-annual questionnaires. Overall diet was summarized by the alternative healthy eating index (AHEI) and the empirical dietary inflammatory pattern (EDIP), derived from food frequency questionnaires completed every 4 years. Linear regression was used to test the association between pre-diagnostic exposures (from questionnaires closest to diagnosis) and immune cell abundance and gene expression. Tumor and normal-adjacent tissue were analyzed separately. Models were adjusted for year and age of diagnosis, menopausal status, and estrogen-receptor (ER) status. Multiple testing of immune components was controlled via the false discovery rate. Models were also stratified by ER and menopausal status.

Results: Among 875 women with available tumor tissue, mean age at diagnosis was 59 years (SD=11.4). The majority (73%) were post-menopausal, had ER-positive tumors (77%), and were diagnosed at stage 1-2 (91%). In ER-positive tumor tissue of postmenopausal women, weight gain since age 18 was positively associated with interferon signaling, MHCII, and PD1 expression (all $p_{adj}<0.05$). Higher physical activity was associated with enriched CD8:CD68 ratio in this group. In ER-negative tumor tissue of pre- and postmenopausal women, consuming more drinks per week was associated with higher PDL1 and lower CSR expression. In normal-adjacent tissue, current smoking was associated with enriched cytokine signaling in premenopausal women and total pack-years was associated with higher B cell plasma in postmenopausal women. Higher EDIP was associated with heightened MHCII and IL12 expression in ER-negative tumor tissue while higher AHEI was associated with lower lymphocyte infiltration expression in normal adjacent tissue, regardless of menopausal status.

Conclusions: Weight gain, smoking, alcohol use, and diet (AHEI and EDIP) are associated with differences in the breast cancer immune microenvironment, with distinct associations by ER and menopausal status. Changes in lifestyle behaviors may influence the tumor immune response and impact patient prognosis, though further studies are needed.

#2091 Progesterone promotes immunosuppression in murine mammary tumors by modulating CD4 T cell viability and helper functions, promoting T cell apoptosis and a shift from inflammatory to anti-inflammatory cytokine profiles.

Amanda Glen Heard

Cancer Biology, Univerisity of Kansas Medical Center, Kansas City, KS

Breast Cancer is the most common cancer diagnosed in women in the US. Breast cancer results in the second greatest number of cancer deaths for women. Hormone receptor positive (HR+) breast cancers - cancers expressing the nuclear receptors for steroid hormones estrogen and progesterone, termed the estrogen receptor (ER) and progesterone receptor (PR) - make up the 70% of diagnosed breast cancers, making the HR+ subtype the largest contributor to breast cancer mortality despite a favorable prognosis compared to other breast cancer subtypes. Treatment consists of anti-endocrine therapies, targeting ER/estrogen signaling pathways. Most women respond well to these therapies, but for women who do not, there are few alternative options. It is accepted that lifetime exposure to estrogens increases the risk of developing of HR+ breast cancer, but both estrogen and progesterone are part of the normal menstrual cycle. Prior work from our lab has uncovered a novel immune-modulatory role for progesterone, pivotal to promoting the growth of PR-positive mammary tumors. Single cell RNA sequencing data from these PR+, progesterone treated tumors show a significant decrease in tumor-infiltrating T cells, specifically of the CD4+ helper T cell subset. Interestingly, *in vitro* progesterone treatment increases the percentage of CD4+ T cell undergoing apoptosis post T cell activation. Progesterone treatment also significantly decreases IFNγ production in CD4+ T cells, while increasing Th2 cytokine production. Our lab show that the culmination of these effects provides protection against T cell killing in a co-culture with mouse mammary tumor cells. Our lab has also found that mouse mammary tumor cells do not express select progesterone metabolism genes to efficiently metabolize progesterone, and that the human orthologs for these genes are also downregulated in human breast cancer. These results suggest that progesterone in the tumor microenvironment could modulate T cell functions, providing tumor cells with protection from immunosurveillance and contributing to HR+ breast cancer development. These data also argue for the use of anti-progestins to boost anti-tumor immune activity and synergize with current cancer immunotherapy regimens, providing an alternative option for women who have failed anti-estrogen therapies.

#2092 Single-cell RNA sequencing reveals ancestry-associated molecular and cellular immunosuppressive features in non-small cell lung cancer.

Liang Liu[1], **Pengbo Zhang**[2], Enzo Palma[1], Ashley Ballard[1], Lance Miller[1], Gregory Hawkins[3], Cristina M. Furdui[3], Edward Levine[4], Alberto de Hoyos[5], Wencheng Li[6], Fang-Chi Hsu[7], Ralph D'Agostino[7], David Foureau[8], Wei Zhang[1]

[1]Cancer Biology, Wake Forest University School of Medicine, Winston Salem, NC,[2]Atrium Wake Forest Baptist Comprehensive Cancer Center, Winston Salem, NC,[3]Biochemistry, Wake Forest University School of Medicine, Winston Salem, NC,[4]General Surgery, Wake Forest University School of Medicine, Winston Salem, NC,[5]Cardiothoracic Surgery, Wake Forest University School of Medicine, Winston Salem, NC,[6]Pathology, Wake Forest University School of Medicine, Winston Salem, NC,[7]Biostatistics and Data Science, Wake Forest University School of Medicine, Winston Salem, NC,[8]Cancer Medicine, Wake Forest University School of Medicine, Winston Salem, NC

Background: Racial disparities in non-small cell lung cancer (NSCLC) outcomes persist, with Black American (BA) patients having inferior survival compared to White American (WA) patients, even after adjusting for stage, treatment, and socioeconomic factors. We hypothesize that distinct molecular and cellular features in the tumor microenvironment (TME) contribute to ancestry-specific heterogeneity and these disparities.

Methods: We performed 10x scRNA-seq on treatment-naïve, early-stage NSCLC from 42 patients: 29 adenocarcinomas (15 WA, 14 BA) and 13 squamous (10 WA, 3 BA). Unsupervised clustering and annotation of 220,591 cells identified six major cell types: epithelial, endothelial, fibroblasts, myeloid, mast, and lymphocytes-each further subdivided into lineage-specific phenotypes. Analyses stratified by ancestry include: differential gene expression and cell abundance, gene set enrichment analysis, trajectory inference, and ligand-receptor analysis.

Results: Malignant epithelial cells showed significant pathway enrichment of OXPHOS, fatty acid metabolism, and G2/M checkpoint in BA tumors ($q \leq 0.01$) and TNF-α signaling via NF-κB, IFN-γ response, and heme metabolism in WA tumors ($q=0.004$, 0.008, and 0.02, respectively). Endothelial cells showed enrichment in IL-2/STAT5 signaling and fatty acid metabolism in BA tumors ($q=0.01$ and 0.03, respectively) and in proliferation pathways in WA tumors (Myc Targets V1, $q=0.005$).BA and WA tumors exhibited distinctive immunosuppressive features. BA tumors showed higher numbers of FAP- cancer associated fibroblasts (CAF; $q=0.07$) and M2 macrophages ($q=0.004$) but low effector CD8+ ($p=0.02$) and γδ T cells ($p=0.018$). BA tumor associated macrophages (TAM) showed preserved activation (CD40, CD80) but impaired antigen presentation (HLA-DM/DQ/DR, all $q<0.05$) and were enriched for hypoxia and TGF-β signaling gene signatures ($q<0.01$). In contrast, WA tumors contained more FAP+ CAFs and macrophages displayed M0/M1-like features with prominent antigen presentation and IFN-I/II responses ($q<0.01$). Also, BA tumors showed active innate immune networks, particularly SPP1-CD44 signaling ($p<0.001$), whereas WA tumors exhibited stronger adaptive stimulatory (MHCII-TCR) and inhibitory (CD86-CTLA4) signaling ($p<0.001$). Furthermore, $CD8^+$ T cells in BA tumors adopted an early exhaustion phenotype associated with TGF-β signaling ($q<0.01$), while in WA tumors they showed progressive exhaustion (high PDCD1, HAVCR2, LAG3) in an IFN-α/γ-driven environment ($q<1E-5$).

Conclusions: This first large-scale, ancestry-stratified scRNA-seq atlas of NSCLC reveals molecular mechanisms underlying distinctive immunosuppressive programs in BA and WA patients and highlights molecular and cellular TME features that may contribute to racial disparities in NSCLC.

#2093 Elucidating the mechanistic connection between the elevated occurrence of EGFR mutation in Hispanic/Latinx lung adenocarcinoma patients.

Jonathan Castillo[1], William D. Wallace[2], Leonidas Arvanitis[3], Dan Raz[4], Crystal N. Marconett[1]

[1]Department of Integrative Translational Sciences, City of Hope, Duarte, CA,[2]Department of Pathology, USC Keck School of Medicine, Los Angles, CA,[3]Department of Pathology, City of Hope, Duarte, CA,[4]Division of Thoracic Surgery, Department of Surgery, City of Hope, Duarte, CA

Hispanic/Latinx (H/L) patients with lung adenocarcinoma have higher rates of epidermal growth factor receptor (EGFR) mutation than those who identify as non-H/L White. Although the overall survival outcome of H/L patients is better than non-H/L White patients, the subset of H/L patients with EGFR mutations have poorer survival outcomes. Immunotherapy has improved survival outcomes for lung adenocarcinoma, but their role in EGFR-mutant lung adenocarcinoma has been underwhelming, as EGFR-mutant tumors are often associated with an immunosuppressive tumor microenvironment and non-response to immunotherapy. Understanding how EGFR mutations and race/ethnicity shape the tumor immune microenvironment is critical to close gaps in health disparities. To address this, we utilized spatial transcriptomics (Visium HD) on lung adenocarcinoma patients from H/L and non-H/L patients stratified by EGFR status and sex (n=4 per group, n=24 total) to characterize spatial patterns of immune infiltration, immune cell composition, and changes to signaling pathways within the tumor-immune microenvironment. To validate and extend these findings to a larger population, bulk RNA-seq data (n=237) from a diverse cohort will be used to quantify immune-cell composition via cell deconvolution (CIBERSORT). In addition, associations between EGFR mutational status, race/ethnicity, and clinical variables including survival, smoking history, and therapy response are also considered. We hypothesize that EGFR-mutant tumors in H/L patients display distinct spatially organized immune-suppressive, resulting in the observed poorer survival outcomes. Taken together, this work integrates spatial and bulk transcriptomic approaches with EMR chart records to uncover mechanistic, race/ethnicity-specific immune features associated with EGFR mutation prevalence in H/L lung adenocarcinoma patients, with the goal of bridging the gaps in health outcomes.

#2094 Investigating the influence of genetic background on TNBC-T cell interactions in TNBC organoids and co-cultures.

Batoul Farran[1], Moses Kamita[2], Shuk Mei Wong[1], Sylvester Antwi[1], Valerie Ofori Aboah[1], Harriet Larrious-Lartey[1], Jessica Jessica Bensenhaver[1], Ali Haythem[1], Walker Eleonor[1], Foster Amponsah[3], Josephine Nsafu.[3], Rose Dampson[3], Patrick Kafui Akapko[3], Evelyn Jiage[1]

[1]Henry Ford Health System, Detroit, MI,[2]Fox Chase Cancer Institute, Philadelphia, PA,[3]PMABC, Accra, Ghana

Triple negative breast cancer (TNBC) is an aggressive form of breast cancer (BC) characterized by early relapse and poor prognosis. The TNBC mortality burden is unequally distributed among populations of different genetic ancestry, with populations of African descent displaying higher incidence of TNBC with high mortality rates. The tumor microenvironment (TME) plays a key role in TNBC development. Interactions between different TME components, such as T cells, can modulate TNBC progression and resistance to therapies. Additionally, the TME can contribute to the disparities in outcomes observed between TNBC patients of EA versus African ancestry. However, the immunomodulatory mechanisms that mediate immune evasion in TNBC in women of African descent remain understudied. To investigate these mechanisms, we developed organoids from TNBC patients of African American and Ghanian ancestry. TNBC tumors from EA, AA and GH patients were implanted into immunosuppressed mice and PDX-derived organoids (PDXos) were established from these tissues. The expression of epithelial, mesenchymal, stromal and immune markers in PDXos and matching PDXs and primary tissues was assessed using multiplex IF and qRT-PCR. T cells were isolated from healthy control PBMCs and activated as per previously published protocols. 5 different TNBC organoids, including 1 EA, 2 AA and 2 GH PDxOs, were co-cultured with T cells, following which the responsiveness of organoids to T cells was assessed using flow cytometric analysis. Finally, immune-resistant organoids were co-cultured with T cells then sorted for downstream analysis. We have successfully established 8 TNBC organoids (PDxOs) from patients of different genetic ancestries, including 1 EA TNBCs, 3 GH TNBCs and 5 AA TNBCs. Multiplex IF and qRT-PCR analysis revealed that the obtained PDXos retained the epithelial (EpCAM) and mesenchymal (vimentin) signatures of their tissues of origin. Co-culture with T cells revealed that the organoids displayed differing patterns of immune responsiveness and exerted distinct effects on T cell exhaustion and activation. Flow cytometric analysis showed that epithelial TNBC organoids were more responsive to T cells whereas mesenchymal-like organoids were more immune resistant. qRT-PCR analysis of organoids grown in co-culture with T cells revealed that they had increased vimentin expression, suggesting a role for EMT in immune evasion in these organoids. These findings reveal that PDXos recapitulate the epithelial and mesenchymal patterns of their tissues of origin and represent a valuable platform for investigating ancestry-specific pathways of immune responsiveness and resistance in TNBC patients of African ancestry.

#2095 Smoking is associated with reduced tumor-infiltrating lymphocyte density in breast cancer.

Annelie Marika Augustinsson[1], Karolin Isaksson[2], Aniko Kovacs[3], **Helena Jernstrom**[4]

[1]Department of Clinical Sciences, Lund, Lund University, Lund, Sweden,[2]Clinical Sciences Lund and Surgery, Lund University and Skane University Hospital Kristianstad, Lund and Kristianstad, Sweden,[3]Clinical Pathology and Institute of Biomedicine, Sahlgrenska University Hospital and Sahlgrenska Academy Gothenburg University, Gothenburg, Sweden,[4]Clinical Sciences Lund, Lund University, Lund, Sweden

Purpose: Previous studies examining the relationship between smoking and stromal tumor-infiltrating lymphocytes (TILs) in breast cancer (BC) have reported conflicting findings, ranging from no significant association to evidence suggesting that smoking may modify the immune tumor microenvironment (TME) and potentially increase TIL density. This study aimed to clarify whether smoking is associated with TIL density in BC.

Methods: Within the prospective Melanoma in Southern Sweden (MISS) study, tissue micro arrays (TMAs) were available for 1,276 women diagnosed with a primary invasive BC between March 1, 1992, and October 31, 2013. The presence of TIL was successfully annotated in 1,173 (91.9%) tumors by a breast pathologist and classified into three categories based on the percentage of stained TILS as low (<10%), intermediate (10-49%), or high (≥50%). Associations between TIL categories and ever smoking at study inclusion between 1990-1993, age at BC diagnosis, tumor size, nodal status, histological grade, and triple-negative subtype were assessed using Pearson's Chi² test and multivariable linear regression. Two-tailed *p*-values <0.05 were considered statistically significant.

Results: Median age at BC diagnosis was 61 years (interquartile range 53-69 years). Of the TMAs with TILs scored, 839 (71.5%) were classified as low, 259 (22.1%) as intermediate, and 75 (6.4%) as high. Smoking was significantly associated with lower TIL density (p = 0.033, adjusted P_{trend} = 0.013). Age at BC diagnosis showed a borderline association with lower TIL density (adjusted P_{trend} = 0.060). Higher TIL density was associated with larger tumor size (p < 0.001, adjusted P_{trend} = 0.023), higher histological grade (p < 0.001, adjusted P_{trend} < 0.001), and triple-negative subtype (p < 0.001, adjusted P_{trend} < 0.001). Nodal positivity was highest in the intermediate group, with no linear association (p = 0.006, adjusted P_{trend} = 0.57).

Conclusions: In this large prospective cohort, smoking was independently associated with significantly lower TIL density in breast cancer, while associations between TILs and other clinicopathological factors were as expected. These findings suggest that smoking may negatively influence immune TME and shed new light on a mechanism through which smoking could modify response to breast cancer treatments. Further studies are warranted to explore the clinical impact of smoking on TILs in breast cancer.

#2096 Investigating the effect of SGLT2 inhibitor dapagliflozin on acute lymphoblastic leukemia in obese mice.

Jia Tan[1], Thomas Tran[1], Tyler Kuk[1], Houfu Leng[1], Michael Cohen[1], Etan Orgel[2], Steven D. Mittelman[1]

[1]UCLA - University of California Los Angeles, Los Angeles, CA,[2]Children's Hospital Los Angeles, Los Angeles, CA

Patients who are obese at diagnosis of acute lymphoblastic leukemia (ALL) have a 50% higher relapse rate. We showed that diet and exercise can improve ALL treatment outcome in mice and patients, but these interventions can be difficult due to financial and logistical barriers. Alternative interventions that induce weight-loss or metabolic changes could prove more accessible in real-world treatment. The SGLT2 inhibitor dapagliflozin (DAPA) is a diabetes medication that inhibits renal glucose reabsorption, lowers blood glucose, and induces modest weight loss. It has been shown to improve outcomes of heart failure and chronic kidney disease. In mice, SGLT2 inhibitors have been shown to slow tumor growth and synergize with chemotherapy in liver, colon, and breast cancer. However, no studies have tested SGLT2 inhibitors on ALL. We investigated whether SGLT2 inhibition might be an alternative to diet and exercise to improve ALL outcome. Human (BV173, RS4;11) and mouse (8093) ALL cell lines expressed *Sglt2* by qPCR (n=4). DAPA showed synergistic effects with chemotherapy vincristine (VCR) *in vitro* (Table). DAPA treatment (3 mg/kg/day in water, 28 days) in obese male C57Bl/6 mice induced glucose loss in urine (2 g/dL vs. undetectable, n=12) and decreased blood glucose (179±17 vs. 203±14 mg/dL, p=0.008, n=6). As monotherapy, DAPA slowed but did not halt ALL progression in a syngeneic ALL model (median survival: 18 vs. 21 days, p=0.027 log rank, n=6). Surprisingly, combining DAPA with VCR resulted in higher mortality than VCR alone (83 vs. 33% mortality, p=0.047 log rank, n=6). Developing medication-based alternatives to diet/exercise interventions is important to ensure all patients with ALL can benefit from metabolic-interventions. Our study shows that SGLT2 inhibition is effective in vitro, but in vivo data imply it may not be a viable option for improving ALL treatment outcome.

Table

Cell Line	Control (x10^6)	VCR (2-2.5 nM)	DAPA (10 μM)	VCR+DAPA	P value (VCR vs VCR + DAPA)
BV173	1.95±0.45	1.70±0.25	1.73±0.38	1.21±0.51	0.037

#2097 Fibroblast galectin-3 remodels the obese breast tumor microenvironment to promote cancer progression.

Ellen E. Bamberg[1], Kiran Vinod-Paul[1], Amy L. Pyo[1], Kirk C. Hansen[2], Carol A. Sartorius[3], Paul S. MacLean[4], Peter Kabos[1], Heather Brechbuhl[1]

[1]Medicine - Division of Medical Oncology, University of Colorado Anschutz Medical Campus, Aurora, CO,[2]Biochemistry and Molecular Genetics, University of Colorado Anschutz Medical Campus, Aurora, CO,[3]Pathology, University of Colorado Anschutz Medical Campus, Aurora, CO,[4]Medicine - Division of Endocrinology, Metabolism, and Diabetes, University of Colorado Anschutz Medical Campus, Aurora, CO

Background: Obesity, affecting 42.4% of U.S. adults, correlates with higher tumor grade, increased metastasis, and reduced survival in breast cancer (BC). Our prior work revealed obesity-induced secretion of collagen-crosslinking enzymes, basement membrane proteins, and the matricellular protein galectin-3 (LGALS3) in the breast. These extracellular matrix (ECM) changes were positively associated with the fibroblast population in obese breast tissue. Elevated LGALS3 expression predicts poorer overall survival in estrogen receptor-positive (ER+) BC. We *hypothesize* that obesity amplifies LGALS3 fibroblast signaling to disrupt ECM composition and organization, supporting BC progression.

Methods: Rag1-/- mice were fed a high-fat high-sugar (HFHS) or low-fat low-sugar (LFLS) diet for 16 weeks to establish obese and lean phenotypes. ER+ UCD65 BC cells were implanted bilaterally into the mammary fat pad alone or with $CD146^{neg}$ (HS5) fibroblasts, generating four groups: LFLS, HFHS, LFLS + $CD146^{neg}$, and HFHS + $CD146^{neg}$. All mice received 1 mg of estrogen at implantation and remained on their assigned diets for eight weeks. Tumors, plasma, lungs, and mammary fat pads were collected at endpoint for analyses. LGALS3 was knocked down in $CD146^{neg}$ fibroblasts and overexpressed in $CD146^{pos}$ (HS27) fibroblasts for in vitro studies. Conditioned media was generated under starvation conditions and concentrated 20x for western blotting.

Results: Obese mice implanted with $CD146^{neg}$ fibroblasts exhibited a 2.7-fold increase in tumor growth and 8.8-fold increase in metastasis compared with lean controls. $CD146^{neg}$ fibroblasts significantly enhanced angiogenesis in both lean and obese settings but did not affect lymphangiogenesis. Obesity significantly disrupted the collagen organization of the mammary fat pads. In obese mice, with $CD146^{neg}$ fibroblasts, increased collagen deposition, macrophage infiltration, and circulating levels of LGALS3. Genetic manipulation of LGALS3 showed that it specifically regulates collagen I secretion without altering intracellular levels. This loss of secretion triggered unfolded protein response activation and reduced TGF-β signaling, further supporting a secretion-focused mechanism. LGALS3 was diet-responsive, with time-restricted feeding and intermittent fasting lowering circulating levels by 2.1 and 2.7-fold, respectively.

Conclusions: Obesity synergizes with $CD146^{neg}$ fibroblasts to accelerate BC aggression through LGALS3-mediated ECM remodeling, supported by a novel post-transcriptional control of collagen secretion. LGALS3 can serve as a therapeutic target and is modifiable by dietary strategies to mitigate obesity-associated BC risks, potentially improving outcomes for millions of at-risk patients.

#2098 CNTF governs exercise-induced myofibroblast reversion in prostate cancer.

Pengju Gong[1], Yuan Liu[2], Leng Han[2], Liuqing Yang[1], Chunru Lin[1]

[1]Department of Molecular and Cellular Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Biostatistics and Health Data Science, Indiana University School of Medicine, Indianapolis, IN

Prostate cancer (PCa) remains a major cause of cancer-related morbidity and mortality in the United States, with more than 2.5 million new cases reported annually. Epidemiological studies suggest that physical exercise reduces PCa risk and progression, yet the underlying molecular and stromal mechanisms remain poorly defined. Here, we demonstrate that long-term and moderate exercise significantly suppresses primary tumor growth and metastatic spread in the Transgenic Adenocarcinoma of the Mouse Prostate (TRAMP) model. Single-cell RNA-seq and spatial analyses of the tumor microenvironment (TME) revealed an abundance of myofibroblast populations in PCa, a hallmark associated with tumor progression and immunosuppression. Exercise robustly reversed this myofibroblast transition, shifting fibroblasts toward a resting phenotype in the TRAMP model. Mechanistically, we identified ciliary neurotrophic factor (CNTF) as an exercise-induced cytokine that restrains myofibroblast transition and enhances $CD8^+$ T-cell infiltration within the TME. This CNTF-dependent remodeling of the TME emerged as a key determinant of the anti-tumor effects of exercise. Therapeutically, recombinant CNTF suppressed PCa tumor growth in vivo and demonstrated synergy with immune checkpoint blockade, suggesting that CNTF restoration provides a promising strategy to sensitize PCa to immunotherapy. Collectively, our findings reveal a previously unrecognized CNTF-mediated axis that links physical exercise to fibroblast plasticity and anti-tumor immunity in PCa. This work also provides critical insights into mitigating potential risk factors for PCa patient survival outcomes, offering an avenue for further studies that may serve as a foundation for future clinical considerations for patients with this cancer type.

#2099 Iron supplementation rescues anemia of chronic disease in pancreatic ductal adenocarcinoma.

Yichi (Tony) Zhang[1], Cindy Pyo[1], Anna Barbeau[1], Davey Feng[1], Amit Roopan[1], Matthew Vander Heiden[1], Kendra Libby[2], Alison Epstein Ringel[3]

[1]Koch Inst. for Integrative Cancer Research at MIT, Cambridge, MA,[2]Ragon Institute, Cambridge, MA,[3]Massachusetts Institute of Technology (MIT), Cambridge, MA

Pancreatic cancer is a devastating malignancy that is rising in incidence and has nearly universal poor outcomes. We find rates of iron deficiency are high in pancreatic cancer patients and track with the high prevalence of anemia in these patients. From an evolutionary perspective, anemia of chronic disease is a condition seen where our bodies respond to an inflammatory insult, such as an infection, by sequestering iron from circulation to store the iron in peripheral tissues, such as muscle, to make this iron unavailable for pathogens. Our recent preliminary data suggest pancreatic cancer may act as the inflammatory stimulus to cause iron dysregulation and anemia. Analysis of a large cohort of pancreatic cancer patients shows both iron and hemoglobin decrease early in pancreatic cancer patients, suggesting of dysregulated iron metabolism. When pancreatic cancer is modeled in mice, decreases in hemoglobin and iron are also observed, as are increases in circulating hepcidin. Interestingly, supplementing mice with pancreatic cancer with iron improves anemia. Mechanistically, we want to understand why mice with PDAC develop anemia and analyzed Ter119-expressing erythrocyte differentiation and maturation in the bone marrow. We found that there is no defect in erythroid maturation in PDAC mice therefore its unlikely that defective erythropoiesis is the cause for anemia in PDAC. We also profiled Ter119-expression on the surface of F4/80-positive macrophages as a measure of hemophagocytosis and found that there is decreased Ter119-positive macrophages in PDAC so hemophagocytosis in the bone marrow is not the caused of anemia in PDAC. We find that iron-sequestering proteins such as hepcidin are increased throughout PDAC progression and iron sequestration in tumors and we find iron sequestration by many different cell types and tissues during PDAC. Hepcidin is known to cause iron sequestration in macrophages, which are the largest source of iron recycling and supply for heme and hemoglobin synthesis in the body. Furthermore, we observed decreased macrophage numbers in the bone marrows of PDAC mice. Hence, we proposed that PDAC leads to reduced iron-recycling by macrophages and this causes anemia of chronic disease. Therefore, iron supplementation is sufficient to rescue anemia in PDAC.

: Characterization of Metastases by Imaging and Profiling
Poster Session

#2103 Genome-wide DNA methylation profiling uncovers epigenetic alterations in key oncogenic pathways and prognostic biomarkers of metastatic thyroid cancer.

Sara Alnassar, Jana Almusallam, Nada Almutairi, Najla Albader, Amal Qattan, **Yufei Shi**

King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

Background: Thyroid cancer is the most prevalent endocrine malignancy with its incidence rising worldwide. Distant metastases are the leading cause of patient morbidity and mortality. While aberrant DNA methylation is known to drive thyroid cancer progression, the methylation landscape of metastatic thyroid cancer cells remains poorly characterized. This study aims to investigate DNA methylation dynamics in metastatic cells and to identify aberrantly methylated genes with potential clinical significance.
Methods: Whole-genome bisulfite sequencing (WGBS) was performed on four paired primary and metastatic thyroid cancer cell lines, each derived from genetically engineered mouse models of PTC, FTC, PDTC, and ATC. GO and KEGG analyses were conducted to annotate the functions and pathways associated with differentially methylated regions (DMRs). The cBioPortal for Cancer Genomics was utilized to access the TCGA-ThCa database for biomarker screening and to construct a prognostic multi-gene signature.
Results: DNA hypomethylation was markedly increased in metastatic cells. Comparative methylome analysis identified more than 3,500 DMRs in each cancer pair. Among these, 133 hypomethylated and 20 hypermethylated regions were consistently detected across all metastatic cancer types, representing a set of common metastatic DMRs. Pathway enrichment analysis revealed that the hypomethylated genes were significantly overrepresented in several key signaling pathways implicated in cancer progression, including focal adhesion, ECM-receptor interaction, PI3K-Akt, Wnt, and MAPK pathways. Notably, these epigenetic alterations were positively correlated with the transcriptional upregulation of the corresponding genes as determined by RNA-Seq analysis. Several metastasis-driven genes were found to be hypomethylated, such as Col4a1, lamc1, Il6ra, Rptor, Tcf7l2, and Nfatc1, suggesting their potential as therapeutic targets. Furthermore, a five-gene hypomethylation signature comprising DEDD, TJAP1, CAVIN4, YWHAG, and FABP4 was identified, the overexpression of which was significantly associated with poor overall survival ($p < 10^{-10}$), poor disease-specific survival ($p < 10^{-10}$), and poor progression-free survival. Clinically, overexpression of these genes exhibited a statistically significant correlation with older age at diagnosis, higher aneuploidy and hypoxia scores, and advanced disease stage.
Conclusions: Metastatic thyroid cancer cells demonstrated significant global DNA hypomethylation, resulting in the transcriptional activation of numerous metastasis-driving genes. The hypomethylated gene signature may serve as a potential prognostic biomarker to stratify patients at elevated risk for distant metastasis and to guide individualized therapeutic strategies.

#2104 RNA editing based risk model to predict extrahepatic metastasis in colorectal cancer liver metastasis.

Eiki Miyake, Kunitoshi Shigeyasu, Toshiaki Takahashi, Kazuya Moriwake, Masashi Kayano, Yuhei Kondo, Yuya Sakurai, Shunsuke Nakamura, Masafumi Takahashi, Kaori Nitta, Kazuya Yasui, Tomokazu Fuji, Kosei Takagi, Hiroshi Tazawa, Toshiyoshi Fujiwara

Gastroenterological Surgery, Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan

Background: The management of colorectal cancer liver metastases (CRLM) remains an urgent challenge in metastatic colorectal cancer. The efficacy of liver transplantation for unresectable CRLM has recently introduced a new treatment option. However, extrahepatic metastasis (EHM), which is one of the key exclusion criteria for liver transplantation, is a poor prognostic factor in CRLM. Therefore, establishing a method to accurately detect EHM prior to treatment is needed. Existing imaging diagnostics have limitations in detecting small lesions, necessitating complementary biomarkers. Adenosine-to-inosine RNA editing, which is a post-transcriptional modification driven by adenosine deaminase acting on RNA (ADAR), promotes tumor malignancy and the acquisition of metastatic potential. We have previously reported that ADAR1 expression in liver metastases is a predictor of residual liver recurrence, but the significance of RNA editing in extrahepatic metastasis remains unclear. This study aimed to analyze RNA editing profiles in primary tumors and liver metastases to clarify the clinical significance of RNA editing in EHM.
Methods: We analyzed gene profiling datasets from normal tissue, primary tumor and liver metastasis in silico discovery from GEO (Gene Expression Omnibus) for both gene expression analysis and RNA editing analysis. For clinical validation, we analyzed 70 CRLM cases (39 EHM and 32 non-EHM).
Results: Public data analysis revealed significantly higher ADAR1 expression in primary tumors and liver metastases compared to normal colon tissue ($P = 0.03$, $P < 0.001$, respectively). RNA editing analysis identified numerous RNA editing events specific to both primary tumors and liver metastases, in addition to common editing events shared between the two sites. These findings suggest that the RNA editing program regulated by ADAR1 changes according to the metastatic site, implying involvement in organ specificity and multiorgan metastasis. In clinical validation, primary tumor ADAR1 expression was an independent predictor of EHM alongside sex (female) and poorly differentiated histology. Furthermore, a risk model that incorporated CEA and the presence of multiple CRLM in addition to the three independent predictors effectively predicted EHM (AUC = 0.78), suggesting clinical utility. Further characterization of site-specific RNA editing events may improve predictive performance.
Conclusion: ADAR1 expression is a promising biomarker for predicting EHM in patients with CRLM. Identification of EHM-specific RNA editing events may enable the development of non-invasive and highly accurate metastasis prediction models with clinical applicability.

#2105 Transcriptomic insights into MAO B inhibition and bevacizumab synergy in colorectal cancer model.

Unnati Hemant Shah[1], Shivani Soni[1], Pooja Mittal[1], Lesly Torres-Gonzalez[1], Michela Bartolini[1], Steve Soto Trujillo[1], Yitzhar Goretsky[1], Francesca Battaglin[1], Goar Smbatyan[1], Yan Yang[2], Joshua Millstein[2], Karam Ashouri[1], Sandra Algaze[1], Wu Zhang[1], Jean Chen Shih[3], Heinz-Josef Lenz[1]

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, CA,[3]Department of Pharmacology and Pharmaceutical Sciences,, Afred E. Mann School of Pharmacy and Pharmaceutical Sciences, Los Angeles, CA

Background: Monoamine oxidase B (MAO B) plays a critical role in colorectal cancer (CRC) by influencing oxidative stress, angiogenesis, and therapy resistance. Building on preclinical evidence of MAO B inhibition in CRC, this study aimed to characterize transcriptomic alterations following treatment with MAO B inhibitors—Deprenyl, Rasagiline, and Safinamide alone and in combination with the anti-angiogenic agent Bevacizumab (Bev), to elucidate potential mechanisms underlying their antitumor synergy.
Methods: RNA sequencing was performed on HT29 CRC xenograft model tumor samples treated with MAO B inhibitors as single agents and in combination with Bev. Differential gene expression (DEG) analysis ($|\log2FC| > 2$; adjusted $p < 0.05$) identified distinct gene signatures across treatment groups. DEGs were clustered using Gene Ontology (GO), and enrichment was assessed using Fisher's exact test. Canonical pathway analysis was performed to characterize major signaling changes. To assess clinical relevance, DEGs were evaluated for correlation with MAO B expression in TCGA CRC datasets.
Results: Distinct and overlapping transcriptional signatures were observed across treatment groups. Tumor-suppressive genes: *VSIG1, GLIPR1, GUCY2C, SMPD3, CDX1, CDX2*, and *GJA1* were strongly upregulated with MAO B inhibitor treatment, indicating enhanced apoptotic and anti-angiogenic signaling. Oncogenic drivers: *MAGEA12, SOX5, OXCT1, VCAM1*, and *TNC* were significantly downregulated, in combination therapy groups, suggesting suppression of epithelial mesenchymal transition and metastatic potential. Long non-coding RNA (lnc) *TPTEP1* and anti-inflammatory mediator *LYPD8* were upregulated in Rasagiline-treated tumors, while oncogenic lncRNA *XIST* was downregulated in Safinamide-treated samples. When compared with TCGA CRC datasets, these treatment-responsive genes showed significant correlation with MAO B expression. Upregulated genes: *GUCY2C, CDX1, BTNL3,* and *SMPD3* showed negative correlation with MAO B, whereas downregulated genes including *SOX5, OCT1, VCAM1*, and *TNC* exhibited a positive correlation, further supporting the clinical relevance of MAO B associated gene expression patterns. GO analysis showed enrichment of oxidation reduction and neural signaling pathways in the Deprenyl group, whereas Bev combinations were associated with inhibited Wnt signaling and activation of the CDX pathway which is associated with the upregulation of CDX1/2 gene that plays a crucial role in the development and maintenance of the intestinal epithelium.
Conclusion: MAO B inhibition modulates key oncogenic, apoptotic, and angiogenic pathways in CRC tumors. Combination treatment with Bev amplifies tumor-suppressive gene expression and attenuates pro-angiogenic signaling, highlighting the therapeutic potential of MAO B inhibitors as complementary agents in CRC treatment strategies.

#2106 High-throughput and accurate intrasplenic injection in mice for metastatic cancer modeling using a robotic injection device.

Alexis Stanley, James Tseng, Ryan Gessner, **Tomasz J. Czernuszewicz**, Jeffrey D. Peterson

Revvity, Waltham, MA

Intrasplenic injections represent a critical technique for establishing metastatic cancer models, particularly for hepatic metastases from colorectal, pancreatic, and gastric cancers. However, traditional intrasplenic injection methods have distinct challenges: blind percutaneous approaches suffer from targeting inaccuracy and variable outcomes, while surgical methods, though more precise, significantly increase procedural complexity and limit experimental throughput. Ultrasound-guided percutaneous injection combines the reproducibility of surgical visualization with the efficiency of minimally invasive delivery. To this end, we have developed a standardized protocol using the Revvity VivoJect (VJ) instrument to enable precise, high-throughput intrasplenic cell delivery in mice. The VJ platform combines real-time ultrasound imaging with motor-controlled needle positioning for accurate target identification and injection. To demonstrate feasibility of spleen injection with VJ, a pilot study was conducted comparing percutaneous (N=7) and surgical (N=5) spleen injections in nude mice. For the percutaneous group, mice were sedated with isoflurane, positioned in right lateral recumbency, coupled to the VJ transducer with ultrasound gel, and injected using ultrasound guidance to identify the spleen. Mice received 50 µL injections of HT-29-RedF-Luc human colorectal adenocarcinoma cells (1×10^6 cells) mixed with IVISense 750 fluorescent tracer. The FLI tracer was used for ex vivo confirmation of injection delivery, while Luc-tagged cells were used for in-vivo tracking of metastasis. For traditional surgical group, anesthetized mice underwent mini-laparotomy to expose the spleen for direct injection of the same cancer cell suspension, followed by surgical staple closure and standard post-operative monitoring. Injection accuracy was confirmed through immediate ex vivo fluorescent imaging (FLI) in a small subset of mice (N=2) and subsequent bioluminescence (BLI) monitoring. VJ achieved 100% successful percutaneous intrasplenic delivery across all test animals, as confirmed by FLI tracer localization and absence of peritoneal spillage. Day 4 in vivo BLI demonstrated successful establishment of hepatic metastases in all injected mice, with consistent tumor burden distribution to the surgical group. VJ reduced procedure time to under 5 minutes per animal with immediate animal recovery and no adverse effects. These results suggest VJ can transform intrasplenic injection from a technically challenging, low-throughput invasive surgical procedure into a reproducible, high-efficiency method suitable for large-scale metastasis studies. This advancement enables more robust preclinical evaluation of anti-metastatic therapies and biomarker validation in clinically relevant models of hepatic metastasis from gastrointestinal cancers.

#2107 Genomic landscape of melanoma brain metastases: Real-world analysis and comparison with public melanoma cohorts.

Dina Elantably[1], **Joseph B. Parker**[1], Jakob Hamilton[1], Ahmed Abdelhakeem[1], Oluwatayo Adeoye[1], Saivaishnavi Kamatham[1], Winston Tan[1], Arkadiusz Z. Dudek[2], Anastasios Dimou[2], Matthew S. Block[2], Robert McWilliams[2], Svetomir Markovic[2], Mahesh Seetharam[3], Roxana Dronca[1], Ruqin Chen[1]

[1]Mayo Clinic Comprehensive Cancer Center, Jacksonville, FL,[2]Mayo Clinic Comprehensive Cancer Center, Rochester, MN,[3]Mayo Clinic Comprehensive Cancer Center, Phoenix, AZ

Background: Melanoma brain metastases (MBM) represent a biologically distinct and clinically aggressive subset of melanoma. Comprehensive molecular characterization focused on intracranial disease remains limited. We aimed to define the genomic landscape of MBM and compare these findings with public melanoma datasets.
Methods: We retrospectively identified 166 patients with histologically confirmed MBM across Mayo Clinic tri-sites (2011-2025). Molecular testing was performed in 123 patients (74.1%). Comprehensive next-generation sequencing (NGS; ≥300-gene platforms including Tempus, FoundationOne, Caris, NeoGenomics, and MayoComplete Solid Tumor Panel) was available in 41 patients (24.7%). Intermediate-depth profiling using the MayoComplete Melanoma Panel (17 genes) was performed in 21 patients (12.7%), and a targeted 5-gene melanoma driver panel (BRAF, NRAS, KIT, GNAQ, GNA11) in 52 patients (31.3%). cfDNA-based NGS was available in 12 patients (7.2%). Genomic alterations were summarized and benchmarked against TCGA-SKCM and MSK-IMPACT datasets via cBioPortal. We considered assay heterogeneity, as Mayo panels varied in sequencing depth and CNV coverage, and hybrid-capture platforms often under-detect TERT promoter hotspots.
Results: Patients had a median age of 67 years, and 63% were male. BRAF mutations occurred in 48.8% (BRAF V600E/K 41.6%; non-V600 7.2%). Additional MAPK alterations included NRAS (17.5%), KIT (5.4%), GNAQ (1.2%), and GNA11 (0.6%). In the comprehensive NGS subset, tumor-suppressor alterations included CDKN2A (17.5%), PTEN (7.8%), NF1 (9.0%), TP53 (8.4%), and TERT promoter mutations (22.9%). Median TMB was 11.55 mut/Mb (IQR 5.0-25.5). Co-alterations included BRAF+CDKN2A (7.2%), BRAF+PTEN (4.2%), NRAS+CDKN2A (4.2%), NRAS+PTEN (1.2%), and CDKN2A+PTEN (3.6%); overall, 18.1% harbored MAPK driver + tumor-suppressor co-alterations. Compared with TCGA and MSK cohorts, MBM showed similar MAPK driver frequencies but fewer MAPK + tumor-suppressor co-alterations and lower CDKN2A, PTEN, and TP53 disruption, alongside a more prevalent of TERT promoter mutations (22.9% vs 7% and 2.1%), which may partly reflect coverage differences.
Conclusion:MBM exhibit a distinct genomic profile characterized by reduced tumor-suppressor loss, fewer MAPK-tumor-suppressor co-alterations, and higher prevalence of TERT promoter mutations. While assay heterogeneity limits direct cross-cohort comparisons, these patterns suggest potentially distinct biological features of intracranial melanoma and underscore the need for harmonized, MBM-specific molecular studies to guide therapeutic development.

#2108 Proteomic insights into metastatic small cell lung cancer using patient derived xenograft models.

Sara Surguta[1], Laura Svajda[2], Zsolt Megyesfalvi[3], Bence Ferencz[3], Ildiko Kovacs[3], Vivien Teglas[3], Lilla Horvath[3], Szilvia Torok[3], Balazs Dome[3], Melinda Rezeli[4], Jozsef Tovari[1]

[1]National Institute of Oncology, Budapest, Hungary,[2]KINETO Lab Ltd., Budapest, Hungary,[3]National Koranyi Institute of Pulmonology, Budapest, Hungary,[4]BioMS Swedish National Infrastructure for Biological Mass Spectrometry, Lund, Sweden

Small cell lung cancer (SCLC) is one of the most aggressive solid malignancies with limited treatment options. Access to clinically relevant SCLC tissue is restricted because surgical resection is rare in metastatic disease, making this cancer type difficult to study. Through our multicenter rapid research autopsy (RRA) program, however, we are able to collect not only primary tumors but also multiple metastatic lesions, providing a unique and rare collection of SCLC specimens. In this program, rapid autopsies are performed within four hours after death to ensure optimal tissue quality for downstream analyses. In the current project, we analyzed samples from seven patients with histologically confirmed SCLC, including clinical and metastatic lesions, as well as their corresponding patient-derived tumor xenografts (PDTXs) serially passaged through three generations. To assess whether the original tissue architecture and intratumoral heterogeneity are preserved across PDTX generations, we performed immunohistochemical and proteomic analyses, comparing molecular profiles between the original tumors and their corresponding PDTX models. A subset of SCLC clinical specimens, including matched PDTX-clinical pairs, confirmed that the histologic landscape of the tumors of origin is preserved in the derivative PDTX models. Samples were grouped by patient and anatomical site, and pairwise Pearson correlations of global protein abundance profiles were computed within each group. The mean within-lineage correlation was high (typically >0.8), and correlation heatmaps showed tight clustering across PDTX generations from the same lineage. Across all patients, the only pathways consistently and significantly downregulated in PDTX models compared with the original tumors were the ECM-receptor interaction and Complement and Coagulation Cascade pathways. When analyzing metastatic PDTX samples, we compared liver and lymph node metastases with their corresponding primary patient tumors across PDTX generations. In lymph node metastases, proteins involved in ECM-receptor interaction and EMT pathways were upregulated. In contrast, liver metastases showed upregulation of fatty acid metabolism and peroxisome proliferator-activated receptor signaling pathways, with downregulation of EMT, ECM-receptor interaction, E2F targets, and G2M checkpoint. These findings demonstrate that the proteomic identity of SCLC tumors is largely preserved during serial passaging in PDTX models, while site-specific adaptations emerge in distinct metastatic microenvironments.

#2109 Analysis of collagen architecture in brain metastasis and paired primary tumors in Non-small cell lung cancer supports the recruitment of fibroblasts originating outside the brain.

Jordi Alcaraz[1], Alejandro Bernardo Suarez[1], Gabriela Caballero[2], Patricia Fernandez-Nogueira[1], Marc Rico-Pasto[1], Victoria Batto[1], Iban Aldecoa Ansorregui[2]

[1]Universitat de Barcelona, Barcelona, Spain,[2]Clinic Barcelona, Barcelona, Spain

Lung adenocarcinoma (LUAD) is the most common subtype of non-small cell lung cancer (NSCLC) and frequently metastasizes to the brain. Lung brain metastases arise in a microenvironment that is structurally and mechanically distinct from the collagen-rich, highly desmoplastic stroma of primary LUAD tumors, which is driven by the chronic activation of cancer-associated fibroblasts (CAFs). In contrast, the normal brain lacks fibroblasts and is virtually devoid of fibrillar collagens. Although recent work suggests that disseminated tumor cells may co-travel with fibroblasts to recreate a primary tumor-like stroma at metastatic sites, the extent to which LUAD brain metastases recapitulate the fibrotic landscape of the primary tumor remains poorly defined. We retrospectively analyzed collagen architecture and common markers of immunosuppressive CAF phenotypes in LUAD patient samples, including primary tumors, paired brain metastases (n=17), and normal brain tissue from epilepsy patients (n=5). Collagen organization was assessed by picrosirius red staining, polarized light microscopy, and quantitative extraction of collagen fiber descriptors using CT-FIRE (Almici et al., Mod Pathol 2023). As expected, collagen fibers were virtually absent in normal brain. In contrast, LUAD brain metastases displayed prominent fibrillar collagen deposition. However, collagen architecture differed substantially from that of primary tumors, with brain metastases exhibiting fewer, shorter, and less aligned fibers. To explore whether EMT contributes to collagen production, LUAD cells and normal pulmonary fibroblasts were stimulated with TGF-β1. Although TGF-β1 increased vimentin and fibrillar collagens in cancer cells, their levels remained substantially lower than in activated fibroblasts. Consistently, brain metastases contained numerous elongated, fibroblast-like stromal cells expressing α-SMA but not markers of activated astrocytes and pericytes, supporting a fibroblast origin. Our findings demonstrate for the first time that LUAD brain metastases develop a fibrotic stroma characterized by de novo collagen deposition driven by fibroblast-lineage cells originating outside the brain, rather than by cancer cells undergoing EMT. These results indicate that collagen-rich fibrosis is a defining feature of the LUAD metastatic niche in the brain and may influence immune cell localization, tumor progression, and therapeutic response. Ongoing studies are examining CAF heterogeneity and functional differences between primary tumors and brain metastases.

#2110 Characterizing drivers of invasiveness in basal-like triple negative breast cancer.

Perrin Black[1], Destiny Ball[1], Antonisha McIntosh[1], Alayjha Edwards[1], Sewedo Ajisegiri[1], Nobelle I. Sakwe[1], Ngoc Vuong[1], Olga Korolkova[2], Qingguo Wang[2], Amos M. Sakwe[3]

[1]Biomedical Sciences, Meharry Medical College, Nashville, TN,[2]Meharry Medical College, Nashville, TN,[3]Assistant Professor, Cancer Biology, Meharry Medical College, Nashville, TN

PURPOSE: Triple-negative breast cancer (TNBC) is characterized by aggressive tumor growth, resistance to treatment, higher likelihood of relapse, and overall worse prognosis when compared to other breast cancer subtypes. The TNBC tumor microenvironment is molecularly heterogeneous, containing various numbers of rapidly growing basal-like (BSL), and invasive mesenchymal-like (MSL) stromal and TNBC cells. Annexin A6 (AnxA6) is a multifunctional calcium-dependent scaffolding protein that is highly expressed in MSL TNBC cells but expressed at low levels in BSL TNBC, and is implicated in cell proliferation, motility, and drug resistance. It is currently unclear how altered AnxA6 levels influence the invasiveness of MSL and BSL TNBC cells. We hypothesize that altered expression of AnxA6 differentially contributes to the invasiveness of BSL and MSL TNBC subgroups.
METHODS: Short hairpin RNAs were used to downregulate AnxA6 in parental (PAR) subpopulations of model MSL (BT-549) and BSL (MDA-468) TNBC cell lines. The invasive subpopulations (INV) of these cell lines with or without AnxA6 downregulation were isolated from control and AnxA6 downregulated cells by sequential invasion assays in Boyden chambers. The parental and invasive subpopulations were then assessed for markers of invasiveness, cancer stem cell (CSC) expression, drug sensitivity, oncoprotein expression, and differential gene expression.
RESULTS: Invasiveness increased AnxA6-dependently in BSL TNBC INV subpopulations compared to the PAR population. Sensitivity to doxorubicin was decreased in the INV subpopulations of both MSL and BSL TNBC. Flow cytometry revealed an increase in CD49f+/EpCAM+ CSC expression among BSL TNBC INV subpopulations. Carbonic anhydrase IX (CA9) was found upregulated only in the INV subpopulations of BSL TNBC, and that downregulation of CA9 results in decreased invasiveness and viability within BSL TNBC INV subpopulations. RNA sequencing and RT-qPCR validation has revealed an upregulation of *EDN2* and *PDXN* among INV BSL TNBC subpopulations, while *BIRC3* and *PARP9* were found to be upregulated in MSL TNBC INV subpopulations.
CONCLUSION: Our data suggest that the invasive subpopulations of both TNBC subgroups differentially modify key oncogenes with respect to their parental controls. Altered AnxA6 expression is associated with differential invasive potential and sensitivity to chemotherapy for MSL versus BSL TNBC cells. Sequential invasion assays have successfully isolated invasive subpopulations that upregulate TNBC subgroup-dependent biomarkers. Targeting the upregulated genes and proteins identified in this study may yield promising results in the future for treating TNBC metastatic disease.

#2111 Mapping immuno-vascular signatures to characterize blood brain barrier disruption and tumor colonization in triple negative breast cancer brain metastasis..

Shruti Rodrigues[1], Maria Jose Godoy Calderon[2], Manali Patwardhan[2], VK Gadi[3]

[1]College of Medicine, University of Illinois at Chicago, Chicago, IL,[2]Medicine, University of Illinois at Chicago, Chicago, IL,[3]Hematology/Oncology, University of Illinois at Chicago, Chicago, IL

Introduction: The incidence of brain metastases in breast cancer patients is rising, with brain metastases affecting 25-40% of women with triple-negative breast cancer (TNBC), with a median survival of under six months. Disruption of the blood-brain barrier (BBB) leads to the formation of a blood-tumor barrier (BTB), which is a critical event in brain colonization. We hypothesize that metastatic tumor cells disrupt neurovascular integrity via specific molecular mechanisms, thereby enabling BTB formation. Elucidating the molecular mechanisms and key players underlying TNBC brain tropism—focusing on BBB disruption and immune evasion— will help identify and manipulate key players in this metastatic process, offering potential for preventing or reversing colonization.

Methods: We performed bulk RNA sequencing to compare brain-tropic 4T1-Br5 cells with parental 4T1 cells and characterized the transcriptional programs supporting brain adaptation. We also established a dual-phased *in vivo* injection model (orthotopic mammary fat pad injection (MFP) followed by intracardiac injection (IC) 7 days later) to obtain BrM tissue for spatial analysis.

Results: For the *in vivo* study, 10 mice got hybrid injections of 4T1-Br5 cells; however, only 5 mice survived to the endpoint. Robust, histologically confirmed brain metastases were detected in 1 of 5 mice (20%). This rate aligns with literature reports and also highlights modeling challenges in immunocompetent settings. RNA-seq showed upregulation of cell cycle drivers (MYC,E2F) and DNA repair pathways, indicating rapid proliferation and genomic resilience. altered BRCA1/TP53 balanced instability with survival often observed with aggressive metastasis. Adaptive pathways for brain colonization, including neuronal signaling (via NGFR-BDNF), cytoskeletal remodeling, and ESR1 activation, exhibited distinct upregulation. Immune-evasive signatures were characterized by the reduced expression of IL-1β, IFN-γ, as well as impaired antigen presentation (MHC I/II), and the activation of CCL5 and the complement cascade. As expected with brain vasculature remodeling, angiogenesis/vascular markers, such as VEGF, HCN, and BGN, were upregulated, while THBS2 and NOTCH signaling were downregulated.

Conclusion: Overall, the brain-tropic 4T1-Br5 cells exhibit a coordinated reprogramming of proliferation, immune evasion, angiogenesis, epigenetic plasticity, and neuronal mimicry pathways, collectively empowering them cells to overcome the unique barriers of the brain, thus supporting their metastatic growth. This establishes a strong scientific foundation for identifying actionable targets for therapeutics. I*n vivo* model dose optimization will yield more consistent brain metastases, enabling a comparative spatial analysis of mouse tissue with patient-derived tissue samples.

#2112 Image activated cell sorting reveals distinct morpholomic manifolds in breast cancer cell lines.

Andres Jose Nevarez[1], Lan Zheng[2], Songyun Li[2], Nicholas E. Navin[1]

[1]Systems Biology, UT MD Anderson Cancer Center, Houston, TX,[2]Graduate School of Biomedical Sciences , UT MD Anderson Cancer Center, Houston, TX

Background: Breast cancer progression is driven by genomic alterations that fundamentally reshape cellular architecture. However, the specific mapping between genomic drivers and the resulting quantitative morphological phenotype—the "morpholome"—remains poorly understood. We hypothesize that distinct breast cancer subtypes occupy unique, stable morphological "attractor states" defined by high-dimensional features invisible to standard microscopy, and that this morpholome is a direct, quantifiable readout of underlying genomic identity.

Methods: To decode these morpholomic states, we established a multimodal, high-throughput imaging pipeline applied to a controlled model system of three genetically distinct breast cancer cell lines: MCF10A (normal-like), SKBR3 (HER2+), and MDA-MB-231 (TNBC). We generated a massive dataset of single-cell images using two complementary platforms: (1) DeepCell for high-resolution, label-free brightfield structural analysis, and (2) BD FACSDiscover S8 for multi-channel, image-based flow cytometry to capture molecularly-defined morphological features. We then extracted deep, self-supervised (DINOv3) features from >150,000 single cells to construct a high-dimensional morpholomic atlas.

Results: Our analysis revealed that genomic identity dictates a robust and quantifiable morphological manifold. (1) **Distinct Attractor States:** In latent space analysis (PHATE), each cell line occupied a distinct, non-overlapping morphological manifold, confirming that the "morpholome" faithfully captures subtype-specific genomic differences without the need for molecular labels. (2) **Robust Biological Signal:** This morphological separation was highly robust, with independent biological replicates of the metastatic MDA-MB-231 line showing near-perfect overlap in feature space (e.g., Area, Intensity SD, Elongation), demonstrating that these are stable biological properties rather than technical artifacts. (3) **Intra-line Heterogeneity:** Crucially, we resolved distinct morphological sub-clusters within the clonally derived MDA-MB-231 population, suggesting that even isogenic cancer populations fluctuate between distinct morphological states that may correspond to functional plasticity.

Conclusions (Future Directions): These findings establish the single-cell morpholome as a powerful, high-dimensional biomarker of breast cancer cell state. Having validated that genomic subtypes drive distinct morphological manifolds in cell lines, we are now applying this framework to patient samples. Our next steps will utilize this approach to identify the specific "morpho-genomic metaprograms" that drive metastasis, using generative AI to causally link these subtle morphological shifts to their genomic drivers in primary tumors.

#2113 Optical imaging and digital pathology evaluation increases the translational value and robustness of patient-derived metastatic breast cancer models.

Philipp Meyer[1], Laura Neagu-Lund[2], Eva Oswald[1], Aleksandra Zuraw[3], Loreen Weichert[1], Michael Staup[4], **Julia B. Schueler**[1]

[1]Charles River Laboratories, Freiburg, Germany,[2]Charles River Laboratories, Laval, QC, Canada,[3]Charles River Laboratories, Reno, NV,[4]Charles River Laboratories, Wilmington, MA

Breast cancer remains the most prevalent malignancy among women and a leading cause of cancer-related death, primarily due to metastatic progression. Reliable preclinical models that recapitulate the metastatic cascade are essential for understanding disease mechanisms and evaluating novel therapies. Traditional methods, while informative, often lack the sensitivity and dynamic resolution needed to track metastatic spread *in vivo*. This study demonstrates the utility of integrating *in vivo optical* digital image analysis with *histopathological* digital image analysis to enhance the detection, characterization, and translational relevance of patient-derived xenograft (PDX) models of metastatic breast cancer. The metastatic potential of three breast cancer models first was classified *in-vitro* using two assays: 2D scratch wound and 3D spheroid invasion. Next, five PDX models, composed of two Her2+(1162, 1322) and three triple negative models (401, 857, 1387), were developed and evaluated for spontaneous *in-vivo* metastasis in mice. The breast cancer cell line MDAMB231 served as positive control. To enable in vivo tracking, tumor cells were infected with a fluorescent reporter or a bioluminescent reporter (luciferase) and visualized using optical imaging systems (IVIS Lumina S5 and Licor Pearl). In the in-vitro assays, MDAMB231, MCF-7, and 401 (triple negative PDX) were classified as high, low, and non-metastatic respectively. In the in-vivo lung metastasis assay, two triple negative models (401, 1387) and one HER2+ model (1387) were classified as low-metastatic. The other triple negative model (1162) and HER2+ model (1162) displayed no metastases at all. Unfortunately, it was not possible to create a PDX with a reporter that was stably expressed because the reporters reduced with passages over time. However, these results demonstrate that transient transfection is a promising tool to follow tumor growth in vivo. Finally, the organs were harvested, and metastases were evaluated via histology (H&E) and human-specific immunohistochemistry (IHC, hLaminB1). The hLaminB1+ metastasis were quantified by digital image analysis (DIA) using the Visiopharm software. MDAMB231 metastasized mainly to the lung and to a lower extend to the liver and the brain. Its metastatic level was much higher than all the PDXs, reflecting the aggressive growth of the cell line. The DIA provided a robust interpretation of the PDX models, illustrating that this integrated workflow supports the selection and quantification of metastatic models, with applications in therapeutic testing and mechanistic studies.

#2114 Murinemodels of bone and brain metastasis for preclinical cancer research.

Hongyan Sun, Fang Zhu, Yan Wang, Yuan Fang, Yuqing Han, Jianming Xu, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

Tumor metastasis remains a daunting challenge in cancer treatment and is a major driver of poor prognosis and therapy resistance. Despite remarkable advances in oncology, effective therapies for metastatic disease remain scarce—highlighting an urgent need for clinically relevant preclinical models to dissect metastasis mechanisms and validate anti-metastatic strategies. To bridge this gap, we developed robust mouse models of bone and brain metastasis that faithfully recapitulate clinical metastatic progression. For the bone metastasis model, MDA-MB-231-Luc human breast cancer cells were injected into the left ventricle of immunodeficient mice via ultrasound-guided intracardiac injection. Through in vivo selection, we derived a subclone with enhanced metastatic potential that preferentially colonizes the spine and lower limb bones. This model recapitulates key clinical hallmarks of bone metastasis—including tumor-mediated bone destruction and osteolytic lesions—with tumor colonization confirmed via bioluminescence imaging (BLI). For the brain metastasis model, LLC1-Luc lung cancer cells were injected into the common carotid artery to enable direct dissemination to the brain. Bioluminescence imaging demonstrated progressive tumor colonization over time, and this model provides a valuable platform to dissect brain metastasis mechanisms and test novel therapeutic strategies targeting central nervous system (CNS) metastases. Collectively, these models offer clinically relevant platforms to investigate metastasis mechanisms, identify therapeutic targets, and discover novel biomarkers. Furthermore, we generated a panel of luciferase-labeled cancer cell lines to facilitate advanced metastasis research. Our preclinical models accurately recapitulate the metastatic cascade, serving as a translational bridge for drug discovery, therapeutic validation, and biomarker development—ultimately accelerating the translation of next-generation cancer therapeutics into the clinic.

#2115 Development of the cf-MMSP assay for enhanced detection of methylated cfDNA in breast cancer by liquid biopsy.

Liqun Zhang, Wenfei Xia, Mary Jo Fackler, Gang Yu, Madison Pleas, Leslie Cope, Saraswati V. Sukumar

Johns Hopkins University School of Medicine, Baltimore, MD

Background: While mammography remains a standard screening tool for breast cancer, its high false positive rate and invasiveness of subsequent biopsies highlight the need for improved technologies. Liquid biopsy, leveraging circulating cell-free DNA (cfDNA), offers a noninvasive alternative, yet the low levels of cfDNA in blood demand highly sensitive detection techniques. In this study, we sought to improve our two-step lab assay, cMethDNA (1), by testing three commercial DNA isolation kits, and through innovative use of primer combinations to specifically enrich for methylated cfDNA in blood.
Methods: Circulating cfDNA was isolated using three kits: QIAamp MinElute Virus Spin Kit (Virus kit), QIAamp MinElute ccfDNA Mini Kit (ccfDNA kit), and MAGicBead cfDNA Isolation Kit. A 9-gene panel consisting of AKR1B1, COL6A2, HIST1H3C, HOXB4, RASGRF2, RASSF1A, TM6SF1, TMEFF2, and ZNF671 (2) was amplified using bisulfite-converted DNA and optimized primer combinations in a cell free, multiplexed, methylation-specific PCR (cf-MMSP) assay. Technical validation of the assay was performed with normal plasma spiked with 12.5-50 copies of fully methylated human genomic DNA and 10 copies of STDHOXB4 plasmid. We quantified relative methylation levels for each gene, and cumulative methylation (CM) of all 9 markers in each sample. The cf-MMSP assay was validated in a pilot study of plasma samples from 21 stage IV breast cancer patients and 20 healthy controls or women with benign disease.
Results: The Virus Spin kit outperformed the MAGicBead and ccfDNA kits in cfDNA recovery, showing a significant improvement in the detection of STDHOXB4 reference DNA ($p < 0.0001$ vs. MAGicBead). Using a combination of a methylation-agnostic (ExtF) and a methylation sequence-specific primer (IntMR) set in the first multiplex PCR step significantly reduced Ct values of target genes (median 17.9 vs. 19.8, $p = 0.0001$) and STDHOXB4 (median 16.8 vs. 18.8, $p < 0.0001$), enhancing detection sensitivity by at least 4-fold compared to cMethDNA. In clinical samples, the cf-MMSP assay distinguished stage IV breast cancer patients from controls with 86% sensitivity (95% CI = 65.4-95.0) and 90% specificity (95% CI = 69.9-98.2), achieving an area under the curve (AUC) of 0.8929 ($p < 0.0001$).
Conclusions: The cf-MMSP assay, which included the use of the Virus kit for cfDNA isolation, choice of primers that selectively amplified methylated products, and a single STDHOXB4 standard, significantly reduced assay cost and time and enhanced its sensitivity for detecting methylated cfDNA in plasma from breast cancer patients.

#2116 Genomic landscape of 1007 pan-cancer brain metastases.

Ramzi Homsi[1], Henry Walch[1], Roshal Patel[1], Anna Skakodub[1], Emily Miao[1], James Lee[1], Chengcheng Gui[1], Mitchell Parker[1], Zachariya Yazdani[1], Michel A. Padilla Mazzeo[1], Claire Cooper[1], Kyle Sporn[1], Brandon Imber[1], Yao Yu[1], Jessica Wilcox[1], Nelson Moss[1], Ahmet Turan Ilica[2], Rabih Bou-Nassif[1], Joseph Stember[1], Christopher Jackson[1], Connor Kinslow[1], Gustav Cederquist[1], Caleb Lareau[1], Helena A. Yu[1], Soo Ryum Yang[1], Pedram Razavi[1], Joseph Chan[1], Kenny Kwok Hei Yu[1], Walid Khaled Chatila[1], Nikolaus Schultz[1], Luke R. G. Pike[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]University of Miami, Miami, FL

Background: The pan-cancer genomic landscape of brain metastases (BM) has not been well-characterized. Herein, we evaluate genomically profiled BM tumor samples and additional sequenced tumor samples from other sites to further understand disease evolution.

Methods: We analyzed BM specimens from 1007 patients who underwent craniotomy between 2014 and 2024. Targeted sequencing was performed with MSK-IMPACT, a next-generation sequencing assay which detects genomic alterations in up to 505 genes. The FACETS algorithm was used to estimate tumor purity, fraction of genome altered (FGA) and whole-genome duplication (WGD) status. We analyzed matched sample pairs from patients who had additional sequenced tumor samples resulting in 227 primary-BM (P-BM) pairs, 189 extracranial metastasis-BM (ECM-BM) pairs and 60 BM-BM pairs. One pair per patient was selected for each category based on maximum purity. For paired comparisons, the Wilcoxon signed-rank test was used to compare continuous features and McNemar's test was used to compare WGD, with Benjamini-Hochberg p-value adjustment. The Jaccard index was computed to assess mutational concordance between pairs. Private mutation analysis was limited to genes with driver mutations in >5 pairs in each P-BM/ECM-BM group.

Results: Median intracranial progression-free survival (iPFS) and overall survival (OS) from craniotomy were 11.3 and 25 months, respectively. The most frequent histologies in the cohort were non-small cell lung cancer (NSCLC; n = 360), breast (n = 181), and melanoma (n = 128). The genes with the highest proportion of oncogenic alterations were *TP53* (62.0%), *CDKN2A* (25.0%), *TERT* (23.4%), *KRAS* (19.7%), and *ERBB2* (12.3%). At least one structural variant or mutation was shared by 88.1% of P-BM pairs, 90.0% of ECM-BM pairs and 98.3% of BM-BM pairs. The mean number of shared driver mutations was 2.48 for P-BM pairs, 2.43 for ECM-BM pairs and 4.02 for BM-BM pairs. In a pan-cancer paired analysis, FGA, WGD and tumor purity were higher in BM in P-BM pairs ($q < 0.01$ for all) and in ECM-BM pairs ($q < 0.01$ for all). FGA and purity were higher in BM for P-BM pairs in upper gastrointestinal (GI) and NSCLC ($q < 0.01$), and in ECM-BM pairs for NSCLC ($q < 0.01$). By histology, in P-BM pairs, lower GI (n = 22) had the highest mean Jaccard index (J = 0.71) and prostate cancer (n = 10) had the lowest (J = 0.33), while in ECM-BM pairs melanoma (n = 23) had the highest (J = 0.77) and sarcoma (n = 9) had the lowest (J = 0.36). *TP53* was the most commonly mutated gene in both P-BM (n pairs = 147, shared proportion = 0.816) and ECM-BM pairs (n pairs = 111, shared proportion = 0.869). Mutations in *NFE2L2* and *KMT2B* were most commonly private to the BM in P-BM pairs (4/6 and 5/8 pairs with driver mutations private to BM, respectively), while *NF1* mutations were most often BM-private in ECM-BM pairs (4/7).

Conclusion: There is a high degree of concordance in alterations between P-BM and ECM-BM pairs. Alterations more commonly private to BM warrant further investigation.

#2117 Single cell chromatin accessibility profiling of human metastatic tumor cells.

Valentina Opazo-Mellado[1], Maria Jose Oviedo[1], Diego Figueroa[1], Carlos Perez[1], Laura Hernandez[1], Joanna Phillips[2], Jeroen Roose[3], **Hugo Gonzalez**[4]

[1]Tumor Microenvironment and Metastasis Laboratory, Centro Basal Ciencia & Vida, Fundacion Ciencia y Vida., Santiago, Chile,[2]Department of Neurological Surgery, University of California San Francisco, San Francisco, CA,[3]Department of Anatomy, University of California San Francisco, USA., San Francisco, CA,[4]Tumor Microenvironment and Metastasis Laboratory, Centro Basal Ciencia & Vida, Fundacion Ciencia y Vida; Universidad San Sebastian., Santiago, Chile

Metastasis is responsible for the vast majority of cancer deaths, yet the regulatory programs that enable metastatic tumor cells (MTCs) to survive, adapt, and expand in distant organs remain incompletely understood. Brain metastasis (BrM) is particularly lethal, marked by limited therapeutic options and profound resistance to existing treatments. Although chromatin accessibility orchestrates transcriptional states and cellular plasticity, its contribution to metastatic colonization has been largely unexplored.Here, we present the most comprehensive single-cell chromatin accessibility atlas of human BrM MTCs to date, spanning 15 metastases originating from diverse primary carcinomas. Following immune-cell depletion, nuclei were profiled using 10x Genomics single-cell ATAC-seq and analyzed with Cell Ranger ATAC, Signac, and Seurat, integrating inferred gene expression from published BrM datasets. We reconstructed gene regulatory networks (GRNs) with Pando to connect transcription factor activity, DNA accessibility, and downstream gene regulation.Across 49,907 high-quality single cells and 147,139 shared accessible peaks, we uncovered three dominant regulomes: two aligned with known inflammatory and proliferative programs, and a third non-proliferative, developmentally biased state not previously characterized in BrM or any other distant metastasis. We performed mechanistic validation of key markers from these modules, complemented by protein-level validation in human specimens. We also identified 22,242 conserved cis-regulatory elements (CREs), with 91% mapping to known human enhancers—yet with previously unknown implications for metastatic fitness. Notably, we discovered abundant CREs located in non-coding regions linked to developmental and mesodermal transcription factors, highlighting a core regulatory architecture underlying metastatic adaptation. This work provides an expansive reference map of the cis-regulatory landscape of human BrM and reveals previously unappreciated developmental regulatory circuits in MTCs, offering new avenues for therapeutic targeting in metastatic cancer.

#2118 Cell surface anchored ratiometric probes for heparan sulfate enable live cell bioimaging and suppression of cancer cell migraion.

Minwoo Jeong[1], Hyun Jung Hwang[2], Donghee Kang[2], Min-Ji kim[2], Lee Keun-Hyung[2], Jae-Seon Lee[1]

[1]Program in Biomedical Science and Engineering, Inha University, Incheon, Korea, Republic of,[2]Research Center for Controlling Intercellular Communication, Inha University, Incheon, Korea, Republic of

Heparan sulfate (HS) proteoglycans are essential molecular components of the cell surface glycocalyx that play critical roles in tumor growth, cell migration, and cancer invasion. Despite their biological significance, the development of fluorescent probes capable of selectively and quantitatively visualizing HS in live cells has been highly challenging due to poor water solubility, limited cell-surface retention, and insufficient molecular selectivity. Here, we synthesized a rationally designed peptide-based fluorescent probe (probe 2) that selectively binds to HS on live cell membranes. This probe exhibits prolonged membrane localization and produces a distinct ratiometric fluorescence response. Under physiological conditions, probe 2 achieves stable anchoring on the cell surface and enables quantitative detection of HS through red-shifted emissions upon aggregation. Importantly, this probe allows real-time visualization of HS downregulation in live cells following siRNA-mediated gene silencing or chemical inhibition of HS biosynthesis. Moreover, probe 2 significantly inhibited cell migration and wound healing in vitro, suggesting that HS modulation by the probe may influence tumor-associated cellular behaviors. Collectively, this study introduces a new class of membrane-anchored fluorescent probes that enable dynamic and quantitative imaging of HS in live cells. These findings suggest that probe 2 is both a diagnostic imaging tool for heparan sulfate and a molecular modulator of HS-related cancer biology, with potential implications for cancer research and therapeutic development.

#2119 Spatial gene expression profile of primary tumor is associated with the release of aggressive CTCs from the invasive front, leading to early recurrence in OSCC.

Geeta S. Boora[1], Anshika Chauhan[1], Suvradeep Mitra[2], Arindam Maitra[3], Sushmita Ghoshal[4], Arnab Pal[1]

[1]Biochemistry, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India, Chandigarh, India,[2]Histopathology, Postgraduate Institute of Medical Education & Research, Chandigarh, India,[3]BRIC-NIBMG, Kalyani, India,[4]Radiotherapy, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India

Background Oral squamous cell carcinoma (OSCC) exhibits high incidences of relapse and treatment failure. To understand the molecular mechanisms driving these poor outcomes, we explored the spatial and temporal heterogeneity of primary tumors and their circulating tumor cells (CTCs) using whole transcriptome analysis.

Methods Bulk RNAseq was performed on three tumor regions (T1-invasive front, T2, T3) and the tumor-free margin (TFM) from early (EarlyR) and no recurrence till 2 years (NoR) patients (N=5 per group). Ultra-low cell RNAseq of CTCs was performed at diagnosis and at post-therapy/recurrence. Differential gene expression analysis and pathway enrichment using fgsea and clusterProfiler, with the Hallmark and Reactome databases, were performed to identify biologically relevant genes/pathways.

Results Spatially distant tumor regions of EarlyR patients were highly diversified from their adjacent free margin in comparison to the NoR group, as indicated by a significantly high number of DEGs - T1 vs TFM (EarlyR-2969, NoR-23), T2 vs TFM (EarlyR-4220 vs NoR-50), and T3 vs TFM (EarlyR-3883 vs NoR-1239). We ruled out that these increases in DEGs were not due to differences in TFMs of the EarlyR and NoR groups (DEGs-17). The pathway analysis revealed enrichment of metastasis-related pathways, including EMT, TNFA signalling via NFκB, and ECM remodelling, in the T1-invasive front of the EarlyR tumor, while the other regions(T2/T3) showed enrichment of proliferation-related pathways, indicating that the invasive front -T1 might be the source of release of aggressive CTCs. We identified SERPINE1, BMP2, CXCL10, CXCL11, ICAM1, IFIH1, IFIT2, IL15, IL15RA, IRF1, JUNB, TGFB1, and TNC as hub genes across multiple pathways enriched in T1, which may contribute to the aggressiveness of this tumor region. Among these genes, IFIT2, IRF1, and JUNB were also upregulated in baseline CTCs of the EarlyR group, indicating the importance of tracking these genes as markers of aggressive CTCs. The PCA analysis of CTC data revealed that, although baseline CTCs are transcriptomically similar between the EarlyR and NoR groups, the post-therapy CTCs are more evolved in the EarlyR group than in the NoR group. We also identified a key molecular marker, FNBP1L, overexpressed in the tumor invasive front (T1) of EarlyR and in their CTCs at pretherapy and posttherapy. However, FNBP1L was downregulated in other regions of the primary tumor (T2/T3), suggesting that aggressive CTCs originate primarily from the invasive front, and FNBP1L (implicated in cytoskeletal reorganisation) might be a key player driving early recurrence and metastasis.

Conclusion OSCC tumors from EarlyR patients undergo extensive spatial and temporal transcriptomic evolution, and the invasive front is plausibly involved in the release of aggressive CTCs marked by expression of IFIT2, IRF1, JUNB, and FNBP1L.

#2120 Spatially resolved transcriptomic analysis revealed the molecular characteristics of the worst pattern of invasion in oral squamous cell carcinomas.

Seungeun Lee[1], Yeonbi Han[2], Dohoon Kim[3], Sumin Lee[3], Amos Chungwon Lee[3], Wonjae Cha[4], Jin-Ku Lee[5]

[1]Biomedical Sciences, Seoul National University, Seoul, Korea, Republic of,[2]Seoul National University Bundang Hospital, Gyeonggi-do, Korea, Republic of,[3]Meteor Biotech, Seoul, Korea, Republic of,[4]Otorhinolaryngology-Head & Neck Surgery, Seoul National University Bundang Hospital, Seoul, Korea, Republic of,[5]Department of Anatomy and Cell Biology, Department of Biomedical Sciences, Seoul National University, Seoul, Korea, Republic of

Worst pattern of invasion (WPOI), defined by the presence of dispersed satellite nodules ≥1 mm from the primary tumor, is strongly associated with LNM; however, the molecular features that functionally link invasive histopathology to metastasis are not fully characterized. We aimed to elucidate the relationship between histopathology invasion pattern and metastatic progression at the molecular level, and to determine whether invasion patterns share early metastatic features. Accordingly, we performed full-length single-cell mRNA sequencing using Spatially resolved Laser Activated Cell Sorting (SLACS), which isolates regions of histologically interest from Hematoxylin and Eosin (H&E) stained tissue slides and obtains transcriptomic and genomic while preserving pathological context. A total of 849 spatially annotated regions of interest (5-10 cells/ROI) were captured from matched tumor, WPOI, tumor-stromal interface, and lymph node metastasis sites from five OSCC patients. Integration of single-cell transcriptomic and genomic features revealed heterogeneous tumor characteristics associated with distinct pathological patterns. We identified a WPOI-associated malignant subpopulation (Cluster 2) characterized by upregulation of IQCE and SMPD2 and an elevated partial epithelial-to-mesenchymal transition (p-EMT) phenotype, indicative of invasive plasticity. In contrast, LNM-enriched populations exhibited re-acquisition of epithelial differentiation programs, including increased expression of CRNN and SPRR3, suggesting epithelial resurging following metastatic colonization. These findings support a dynamic invasion-metastasis continuum in OSCC, especially WPOI represents an intermediate state enabling metastasis in molecular level. We are ongoing reconstruct the evolutionary trajectories. A molecular understanding of pathological invasion patterns such as WPOI may inform precision stratification and guide personalized surgical and adjuvant strategies for OSCC patients.

#2122 Integrative transcriptomic analysis identifies malaria-associated signaling pathways and repurposable drug candidates for ovarian cancer metastasis.

Dr. Muhibullah Ghafoorzai[1], Arsalan Riaz[2], Dr. Faisal F. Khan[1]

[1]Precision Medicine Lab, Peshawar, Pakistan,[2]Centre for Genomics Sciences, Rehman Medical Institute, Peshawar, Pakistan

Ovarian cancer metastasis remains a leading cause of cancer-related mortality and presents major challenges for effective therapy. This study aimed to identify pivotal genes, proteins, and pathways involved in ovarian cancer metastasis and to explore already approved drugs with potential to inhibit these metastatic mechanisms through a drug repurposing framework. A comparative in silico analysis was conducted using transcriptomic data from matched primary and metastatic ovarian tumors. In Phase 1, gene expression profiles from three microarray and four RNA-sequencing datasets were analyzed using R (v4.3.1) to identify differentially expressed genes (DEGs). In Phase 2, pathway enrichment and protein–protein interaction analyses were performed to pinpoint key signaling networks, followed by systematic drug repurposing using dgiDB and PanDrug databases. Top significant 100 DEGs were identified among 27,985 transcripts from the microarray datasets, while RNA-sequencing analysis revealed DEGs from 25,551 transcripts. KEGG pathway analysis highlighted ten major pathways, of which three, malaria, TGF-β, and PPAR signaling, were common to both datasets and significantly associated with metastatic transformation. Gene literature mining identified eight genes (THBS1, VCAM1, ADIPOQ, LPL, ACKR1, CD36, FABP4, HBA1) overlapping malaria-associated and metastasis gene sets. Network analysis using the STRING database showed strong interactions among 14 of 17 key genes, with VCAM1 emerging as a central hub protein linked to adhesion and immune-related pathways. Subsequent drug–gene interaction screening identified 37 potential repurposed drug candidates, with highest-priority agents including chloroquine (ACKR1, interaction score 0.711), fenofibrate and pioglitazone (ADIPOQ/LPL, 0.622), pirfenidone (THBS1, 0.702), and bevacizumab (THBS1/VCAM1, 0.908), all approved drugs with established clinical safety profiles.These findings emphasize the convergence of TGF-β, PPAR, and malaria-associated signaling in ovarian cancer metastasis, suggesting that repurposed drugs targeting these pathways, particularly chloroquine and PPAR agonists, may have therapeutic potential in this context. The computational identification of bevacizumab, an agent already approved for ovarian cancer, corroborates the approach. Future work will focus on in vitro validation of prioritized drug candidates, including chloroquine, PPAR agonists, and pirfenidone, against ovarian cancer cell lines to substantiate the in silico predictions and support the development of new treatment strategies derived from existing pharmacologic agents with reduced development timelines.

#2123 A high resolution spatial transcriptomic atlas of the bone marrow microenvironment pre and post prostate cancer seeding.

Haley du Bois[1], Alberto Chaves[2], Mostafa Nasr[2], Tao Li[3], Karl Nyman[2], Ryan Bishop[3], Conor C. Lynch[3]

[1]Tumor Microenvironment & Metastasis, Moffitt Cancer Center, Tampa, FL,[2]University of South Florida, Tampa, FL,[3]Moffitt Cancer Center, Tampa, FL

Prostate cancer is the second leading cause of cancer-related death in men, and nearly 80% of patients develop skeletal metastases. However, how primary prostate tumors sculpt the bone microenvironment prior to or during the earliest stages of metastatic spread remains poorly understood. To fill this gap, we generated a spatiotemporal map of tumor-induced changes in the bone marrow using an immunocompetent syngeneic mouse model of prostate cancer (RM1; C57BL/6).Using whole-genome Visium HD spatial transcriptomics, we profiled bone microenvironments from (1) tumor-naïve mice, (2) mice bearing primary prostate tumors but lacking bone metastases (pre-metastatic), and (3) early metastatic mice following intra-arterial delivery of RM1 cells. We interrogated these datasets using a comprehensive bioinformatic workflow (Seurat, GPTcelltype, Banksy, STenrich, Monocle, and CellChat) to resolve coordinated stromal and immune remodeling as disease progresses. We discovered that primary prostate tumors initiate *mixed bone-remodeling programs* characterized by sustained osteoclast activation and a progressive collapse of osteoblast differentiation. Consistent with this, microCT imaging revealed measurable bone loss in pre-metastatic mice, which intensified upon metastatic colonization. Within the immune compartment, we found a concomitant disruption of plasma cells, possibly driven by the loss of osteoblasts which are key niche cells required for normal plasma cell recruitment and survival. Unexpectedly, despite inoculation with a genetically homogeneous RM1 line, we observed that early metastatic lesions diverged into two transcriptionally distinct tumor populations occupying separate spatial neighborhoods. The proximal, trabecular-associated lesion is embedded in a stromal-rich niche and shows upregulation of hypoxia- and oxidative stress-related programs. In contrast, the distal lesion in a more immune-dense region exhibits heightened interferon signaling. These findings demonstrate that *local bone microenvironments impose divergent selective pressures on metastatic tumors*, shaping their phenotypic evolution. Together, our work provides a high-resolution spatiotemporal atlas of prostate cancer progression to bone, illuminating early stromal and immune perturbations that may prime the bone for metastatic takeover. This dataset serves as a platform for hypothesis generation and identifies potentially targetable microenvironmental mechanisms for preventing or treating bone metastatic prostate cancer.

#2124 Patient-derived CSF and ascites organoids reveal divergent metastatic mechanisms in advanced gastric cancer.

Byeong Gyu Yoon, Chan Hee Park, Woo Sun Kwon, Tae Soo Kim, Sun Young Rha

Yonsei University College of Medicine, Seoul, Korea, Republic of

Gastric cancer most frequently metastasizes to the peritoneum (PM), whereas leptomeningeal metastasis (LM) is extremely rare but highly lethal. Although LM shows markedly worse outcomes than PM, the mechanisms driving LM remain poorly understood due to the absence of appropriate experimental models. To address this limitation, we established organoid models derived from PM and LM from the same patient and compared their morphological and genomic characteristics. Organoids were generated from ascites and Cerebrospinal fluid obtained from a 50-years old female patient with stage IV diffuse-type gastric cancer, with passage 5 defined as the establishment point. Organoid cultures were initiated under optimized 3D conditions and maintained through multiple passages to ensure stability and expansion. Morphological and phenotypic features were characterized using 3D bright-field imaging, scanning electron microscopy (SEM), and hematoxylin and eosin (H&E) staining. For molecular characterization, targeted panel sequencing and whole-genome sequencing were performed. Copy number variations of selected genes were validated by qPCR. The ascites-derived organoids (AS2 and AS4) required approximately 34-39 days to reach establishment, while the Cerebrospinal fluid-derived organoid (CSFO) required about 39 days. At morphological characterization, AS2 formed a lumen structure and displayed pronounced pseudopodia with elongated cellular shape, indicative of stronger cell-cell interactions. In contrast, CSFO and AS4 exhibited rounder cellular shapes with grape-like clustered architectures and weaker intercellular adhesion. Despite the different metastatic microenvironments, 136 mutations common among all organoids, 20 mutations were CSFO-specific, 19 mutations were AS2-specific, and 28 mutations were AS4-specific. Subsequently, we conducted Gene Ontology analysis. CSFOs were enriched for mutations associated with vascular morphogenesis. In contrast, ASOs harbored mutations related to epithelial proliferation and organ development. Patient-derived peritoneal tissues exhibited mutations predominantly in immune-regulatory pathways, including MHC class I/II-mediated antigen presentation. Notably, MET amplification and CDKN2A deletion were consistently detected in all organoid models but not in the original patient tissues, highlighting culture-associated genomic selection. MAP2K4 deletion was observed in CSFOs and GO15-5, while MYCN and ADGRA2 amplification were detected only in GO15-5, suggesting additional clonal evolution during extended in vitro passage, and genomic variants were validated using qPCR. Overall, this study demonstrates the feasibility of using patient-derived organoids to model atypical metastatic routes of gastric cancer and provides novel insights into the biology of LM through integrative morphological and genomic analyses.

#2125 Patient-derived orthotopic xenograft models recapitulate the peritoneal dissemination of pancreatic cancer and delineate its transcriptomic, regulatory, and spatial programs.

Takaaki Furukawa[1], Kohei Kumegawa[1], manabu takamatsu[2], Kenichi Miyata[1], Sumito Saeki[1], Chikako Shibata[1], Takafumi Mie[3], Takeshi Okamoto[3], Tsuyoshi Takeda[3], Takashi Sasaki[3], Masato Ozaka[3], Miwa Tanaka[1], Shunji Takahashi[4], Tetsuo Noda[5], Yao Ryoji[6], Naoki Sasahira[3], Reo Maruyama[1]

[1]Division of Cancer Epigenomics, Cancer Institute, Japanese Foundation for Cancer Research, Tokyo, Japan,[2]Division of Pathology, Cancer Institute, Japanese Foundation for Cancer Research, Tokyo, Japan,[3]Division of Hepato-Biliary-Pancreatic Medicine, Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan,[4]The Cancer Institute Hospital of JFCR, Tokyo, Japan,[5]Director, Japanese Fndn. for Cancer Res. Cancer Institute, Tokyo, Japan,[6]The JFCR Cancer Institute, Tokyo, Japan

BACKGROUND: The mechanisms of peritoneal dissemination in pancreatic ductal adenocarcinoma (PDAC) remain unclear partly owing to the lack of patient-derived models that recapitulate this process. This study aimed to establish an orthotopic model of PDAC peritoneal dissemination and to uncover the transcriptional and regulatory programs underlying this process.
METHODS: Organoids were established from primary pancreatic tumors and malignant effusions of patients with PDAC and orthotopically transplanted into the pancreas of immunodeficient mice to generate patient–derived orthotopic xenograft (PDOX) models. Subsequently, the organoids were rederived from pancreatic and peritoneal lesions of a representative model (PDOX12) and orthotopically reimplanted to assess the dissemination capacity. Single-nucleus RNA sequencing (snRNA-seq), single-cell ATAC sequencing (scATAC-seq) and spatial transcriptomic analysis were performed to analyze the tumors from these models.
RESULTS: The organoids that were derived from malignant effusions reproducibly generated peritoneal metastases after orthotopic implantation. To dissect this process more precisely, we focused on one representative model (PDOX12) and rederived organoids from its pancreatic and peritoneal lesions (PDXO12P and PDXO12A, respectively). These organoids generated matched PDOX models that differed only in dissemination potential when reimplanted orthotopically. The results of snRNA-seq revealed a distinct subpopulation enriched in the high-dissemination model, suggesting a dissemination-primed state. Integration with scATAC-seq identified potential upstream regulators of the gene programs in the subpopulation. Furthermore, the cellular plasticity was revealed by the PDOX system. In vitro, PDXO12P and PDXO12A organoids exhibited nearly indistinguishable transcriptional and proliferative profiles. However, their latent differences were unmasked when placed in vivo: PDXO12A demonstrated stronger peritoneal dissemination, accompanied by the clear transcriptional divergence. We hypothesized that these differences were unveiled by the influence of the tumor microenvironment (TME) and performed spatial transcriptomic analysis to profile the TME in the high-dissemination model and comprehensively characterize the transcriptional features of fibroblasts.
CONCLUSIONS: We established PDOX models that isolate the peritoneal dissemination phenotype and reveal the transcriptional and regulatory programs driving this process.

#2129 Pharmacodynamics of Akt drugs revealed by a kinase-modulatedbioluminescent indicator withBBB-permeable substrate.

Yan Wu[1], Chenzhou Hao[1], **Chao Gao**[2], Matt Hageman[2], Sungmoo Lee[1], Thomas A. Kirkland[3], Nathanael S. Gray[1], Yichi Su[4], Michael Z. Lin[1]

[1]Stanford University, Stanford, CA,[2]Promega Corporation, San Luis Obispo, CA,[3]Head of ATG Chemistry Research, Promega Corp., Madison, WI,[4]Department of Nuclear Medicine, Fudan University, Shanghai, China

Noninvasive imaging tools that enable real-time visualization of biological events in living subjects are highly valuable in biomedical research. Bioluminescence imaging (BLI), with its high sensitivity and low background, provides an ideal platform for developing molecular sensors to monitor intracellular signaling *in vivo*. Here, we report the development of a kinase-modulated bioluminescent indicator (KiMBI) for rapid, noninvasive pharmacodynamic (PD) assessment of Akt-targeted therapeutics, substantially reducing compound use and animal requirements. This ATP-independent reporter, based on NanoLuc luciferase, produces light upon administration of the brain-penetrant substrate cephalofurimazine (CFz9). Using KiMBI, we performed a structure-PD relationship analysis of the brain-active Akt inhibitor ipatasertib by designing and characterizing two novel analogs. One analog, ML-B01, exhibited robust Akt inhibition in both brain and peripheral tissues. Remarkably, capivasertib, ipatasertib, and ML-B01 all demonstrated prolonged PD effects that outlasted their pharmacokinetic (PK) profiles. Furthermore, KiMBI imaging revealed that the PD effect of an Akt-targeted proteolysis-targeting chimera (PROTAC) degrader persisted for more than three days following a single dose. Together, these results establish bioluminescence imaging with the Akt KiMBI as a sensitive and efficient method for real-time, longitudinal visualization of Akt inhibitor and degrader activity in vivo. This platform offers a powerful approach for early-stage drug optimization and for elucidating the pharmacodynamics of kinase-targeted therapies in live animals.

#2130 High-throughput imaging approaches to characterize CAR T therapies for solid tumor microenvironments.

Ernest Heimsath, Paul Held, Peter Brescia, Joe Clayton

Agilent Technologies, Inc., Winooski, VT

CAR T therapies have revolutionized hematologic cancer treatment but face significant barriers in solid tumors, primarily due to the tumor microenvironment. Dense extracellular matrix (ECM) regions impede lymphocyte migration and infiltration, reducing therapeutic efficacy. To model these clinical challenges, we developed a high-throughput imaging assay to evaluate CAR T cytotoxicity in three-dimensional (3D) ECM-embedded tumor spheroids.

The epithelial cell adhesion molecule (EpCAM), typically overexpressed in epithelial cancers, provides a clinically relevant target for CAR T therapy. EpCAM-targeted CAR T cells were tested against T-47D spheroids embedded in ECM to mimic solid tumor architecture. Our imaging-based approach revealed dose-dependent cytotoxicity and deep infiltration of spheroids by CAR T cells, despite delayed cytopathic responses compared to suspension cultures. Furthermore, this cytotoxicity is distinct to EpCAM-engineered CAR T cells when compared to nonengineered T lymphocytes. Importantly, elevated IC_{50} values under embedded conditions underscore the impact of ECM on therapeutic kinetics. These results offer actionable insights for optimizing CAR T design and dosing strategies to overcome microenvironmental barriers. By quantifying migration, infiltration, and killing in physiologically relevant models, this work supports translational efforts to improve CAR T efficacy in solid tumors and informs clinical development pathways for next-generation immunotherapies.

#2131 Hyperpolarized carbon-13 MRI for early treatment response assessment in pancreatic ductal adenocarcinoma patients.

Minjie Zhu[1], Hsin-yu Chen[1], Tanner Nickles[1], Robert Bok[1], Andrew H. Ko[2], Zhen Wang[1], Jeremy W. Gordon[1]

[1]Radiology and Biomedical Imaging, UCSF School of Medicine, San Francisco, CA,[2]UCSF School of Medicine, San Francisco, CA

Current methods for monitoring treatment response in pancreatic ductal adenocarcinoma (PDA), primarily relying tumor size measurement using response evaluation criteria in solid tumors (RECIST), are often delayed and limited by the infiltrative nature of the disease. Timely, non-invasive assessment is crucial for adapting therapies for non-responders. PDA tumor cells are characterized by significant metabolic reprogramming, driven by KRAS oncogene mutations, which enhance glycolysis and lactate production while downregulating alanine aminotransferase, which mediates pyruvate to alanine conversion. Hyperpolarized (HP) carbon-13 (^{13}C) magnetic resonance imaging (MRI) offers a non-invasive solution to interrogate these metabolic changes. Utilizing dynamic nuclear polarization, this technique provides unprecedented sensitivity(> 10,000-fold signal increase) and chemical specificity for rapid and pathway-specific investigation of dynamic metabolic processes that were previously inaccessible by ^{1}H MRI or CT. Pre-clinical studies have shown HP ^{13}C MRI using [1-^{13}C]pyruvate as substrate can detect and monitor PDA precursor lesion progression, with an increase in the lactate-to-pyruvate ratio and decrease in the alanine-to-pyruvate ratio observed in the affected mice pancreas. Initial clinical studies have further demonstrated the feasibility and safety of HP ^{13}C MRI for quantifying metabolism in PDA patients. In this ongoing study, five PDA patients underwent multiparametric ^{1}H MRI and HP ^{13}C MRI both pre- and at 4&8 weeks post-treatment. ^{13}C pyruvate, lactate, alanine signal intensities and their respective ratios in the primary tumor and normal pancreas were assessed. All five patients exhibited elevated pre-treatment primary tumor lactate-to-pyruvate ratios. A significant decrease (approximately 25%) in the primary tumor lactate-to-pyruvate ratio post-treatment correlated with partial response by RECIST in four patients, while one patient with stable disease showed minimal change (<5%). Reduced alanine-to-pyruvate ratios were observed in pre-treatment tumors for two patients, though their relationship to treatment response could not be fully quantified. No significant changes in tumor ADC from diffusion-weighted ^{1}H MRI were observed pre- and post-treatment, suggesting that metabolic alterations detectable by HP ^{13}C MRI precede significant changes in cellularity at this early time point. These initial findings indicate that HP ^{13}C MRI can detect early metabolic changes in PDA tumors in response to therapy, holding significant potential for providing timely treatment response information, facilitating adaptive treatment strategies, and improving patient outcomes in PDA.

#2132 Near-Infrared Claudin-1 antibody enables accurate detection of primary and metastatic colorectal tumors in mice.

Javier Bravo[1], Shanglei Liu[1], Siamak Amirfakhri[1], Blackberrie Eddins[1], Keita Kobayashi[1], Jasmin Zaker[1], Robert Hoffman[1], Sumbal Talib[2], Aaron M. Mohs[3], Punita Dhawan[4], Michael Bouvet[1]

[1]UC San Diego Health, San Diego, CA,[2]University of Nebraska Medical Center, Omaha, NE,[3]Pharmaceutical Sciences, University of Nebraska Medical Center, Omaha, NE,[4]University of Kansas Medical Center, Kansas City, KS

Background: Claudin-1, a tight-junction protein frequently overexpressed in colorectal cancer (CRC), is an attractive target for antibody-mediated near-infrared (NIR) fluorescence imaging. This study evaluates an anti-Claudin-1 antibody conjugated to IRDye800CW for detecting and validating colorectal tumors using bioluminescence correlation in orthotopic and metastatic mouse models.

Methods: Luciferase-expressing LS174T human colon cancer cells were implanted into athymic nude mice to establish orthotopic (n = 10) and hepatic (n = 9) tumor models. Mice received 50 µg of Claudin-1-IRDye800CW intravenously 48 hours before imaging. In vivo imaging was performed using both the Pearl Trilogy Small Animal Imaging System and the Arthrex Synergy Vision System equipped for 800 nm fluorescence. Mean fluorescence intensity (mFI) was used to calculate tumor-to-background (TBR) and tumor-to-liver (TLR) ratios. Co-registration with luciferase bioluminescence was used to confirm probe specificity, and ex vivo imaging validated biodistribution.

Results: In the orthotopic model, Claudin-1-IRDye800CW achieved a mean TBR of 3.92, clearly delineating tumor margins, while sub-millimeter peritoneal metastases (< 1 mm) produced a mean TBR of 2.9. In the hepatic model, the mean TLR was 3.42, confirming selective tumor contrast over surrounding tissue. Ex vivo analysis further increased contrast (TBR = 16.4; TLR = 4.78). Fluorescent signals consistently co-localized with luciferase activity, confirming targeting specificity. Both imaging systems demonstrated high-resolution detection, and the Arthrex clinical laparoscope enabled real-time intraoperative visualization under clinically relevant conditions.

Conclusion: The anti-Claudin-1-IRDye800CW conjugate selectively and accurately identifies both primary and metastatic colorectal tumors in vivo. Strong tumor contrast and spatial concordance with bioluminescence validate its specificity, while compatibility with a clinical laparoscopic platform underscores the translational promise of Claudin-1-targeted NIR fluorescence imaging for colorectal cancer detection and fluorescence-guided surgery.

#2133 Fibronectin extra-domain B-recognizing gold nanoparticles as an innovative tool for neuroblastoma targeting.

Chiara Barisione[1], Silvia Ortona[2], Veronica Bensa[3], Caterina Ivaldo[1], Eleonora Ciampi[3], Simonetta Astigiano[4], Michele Cilli[4], Luciano Zardi[1], Mirco Ponzoni[3], Domenico Palombo[5], Giovanni Pratesi[6], Pier Francesco Ferrari[7], **Fabio Pastorino**[3]

Background/Objectives: Neuroblastoma (NB) is the most common extracranial solid tumor in children and accounts for 12-15% of pediatric cancer-related deaths. Current multimodal therapies still lack of specific cellular targets, causing systemic toxicity and drug resistance. The development of innovative tumor-targeted nanoformulations might represent a promising approach to enhance NB diagnosis and antitumor efficacy, while decreasing off targets side effects. Fibronectin extra-domain B (FN-EDB) is upregulated in the tumor microenvironment.
Methods: Here, FN-EDB expression was evaluated by immunohistochemical (IHC) staining in several animal models of NB. A gold nanoparticle, decorated with an antibody (Ab) recognizing FN-EDB (L19-AuNP) was developed by the company Nano Flow and its tumor binding was tested by ELISA *in vitro* and in Patient-Derived Xenografts (PDX) models of NB by photoacoustic imaging *in vivo*.
Results: All models of NB used expressed FN-EDB, at the tumor cell, stroma and tumor vasculature levels. Compared to the non-targeted (no L19 Ab) Au-NP (size: 35.59 ± 2.54 nm; PDI: 0.47 ± 0.08; zeta potential: -51.18 ± 0.84), L19-AuNP was found to be stable (size: 108.70 ± 1.37 nm; PDI: 0.29 ± 0.07; zeta potential: -28.34 ± 0.48) and able to specifically bind to FN-EDB *in vitro*. *In vivo*, L19-AuNP specifically homed into PDX of NB, accumulating more in the tumor expressing higher levels of FN-EDB.
Conclusions: In this preliminary study, L19-AuNP was shown to be a novel diagnostic tool specific for binding NB expressing FN-EDB, paving the way for the development of theranostic nanoformulations co-encapsulating gold moiety and standard-of-care for NB.

#2134 Targeting primary gastric tumors and peritoneal metastases in cell-derived xenograft mouse models using an anti-mucin-4-antibody conjugated near infrared fluorophore.

Blackberrie Eddins[1], Sunidhi Jaiswal[1], Abhijit Aithal[2], Siamak Amirfakhri[1], Javier Bravo[1], Jasmin Zaker[3], Sumbal Talib[4], Kavita Bantwal Mallya[2], Aaron M. Mohs[4], Maneesh Jain[2], Robert M. Hoffman[5], Surinder K. Batra[2], Michael Bouvet[1]

[1]Department of Surgery, University of California San Diego, La Jolla, CA,[2]Department of Biochemistry and Molecular Biology, University of Nebraska Medical Center, Omaha, NE,[3]VA San Diego Healthcare System, La Jolla, CA,[4]Department of Pharmaceutical Sciences, University of Nebraska Medical Center, Omaha, NE,[5]President, AntiCancer, Inc., San Diego, CA

Introduction: The purpose of the present study is to validate the use of an anti-MUC4 antibody conjugated near infrared dye to target primary and metastatic gastric cancers in nude mouse models.

Methods: Subcutaneous models were created in nude mice by injecting 10^6 cells of human gastric cancer cell lines SNU-16 or NCI-N87 into their flanks. These tumors were excised after 2 months and 1 mm^3 fragments were implanted into the stomachs of nude mice to establish orthotopic gastric cancer models of SNU-16 and NCI-N87. Experimental metastasis models were established by injecting 10^6 SNU-16 or 10^6 NCI-N87 cells intraperitoneally in nude mice. 2-3 months after tumor implantation mice were injected via tail vein with a mucin4 antibody conjugated to a near infrared fluorescent dye IRDye800CW (MUC4-IRDye800CW). Mice were sacrificed 72 hours after tail vein injection of 50 µg MUC4-IRDye800CW and imaged with the LI-COR Pearl Imaging System and a Stryker laparoscope. The tumor-to-background ratios (TBR) were calculated by dividing the mean fluorescence intensity of the tumors by that of the surrounding stomach. Histopathological analysis was performed on tumors with immunohistochemical (IHC) staining with anti-mucin-4 and anti-immunoglobulin G (IgG) as a negative control.

Results: 20 total mice were imaged, including 14 primary gastric cancer models and 4 intraperitoneal metastatic gastric cancer models. Primary gastric SNU-16 tumors (n = 6) had a mean TBR of 1.99 (SE ± 0.58), and primary gastric NCI-N87 tumors (n = 8) had a mean TBR of 2.81 (SE ± 1.04). Metastatic SNU-16 tumors (n = 3) had a mean TBR of 3.7 (SE ± 0.75), and metastatic NCI-N87 tumors (n = 3) had a mean TBR of 3.91 (SE ± 0.98). Tumor borders were clearly visualized with both Pearl and the Stryker laparoscope fluorescence imaging systems. Representative tumors stained with anti-mucin-4 stained brown while those stained with anti-IgG did not.

Conclusions: Anti-MUC4-IRDye800CW can be used to accurately localize both primary and metastatic gastric cancer models in nude mice with fluorescence imaging and is promising for identifying both primary tumor margins and intraperitoneal metastasis intra-operatively.

#2135 Optimized iron-carbon nanoparticles demonstrate superior; in vivo antitumor efficacy in magnetic hyperthermia treatment.

Mariam Elabbasi[1], Sofia Cooper[1], Ahmed El Gendy[2]

[1]Environmental Sciences and Engineering, The University of Texas at El Paso, El Paso, TX,[2]The University of Texas at El Paso, El Paso, TX

This study aims to develop and evaluate iron-carbon (Fe/C) nanoparticles synthesized for magnetic hyperthermia-based cancer therapy, as a continuation of our previously published in vitro work on the same cell lines. The Fe/C nanoparticles were prepared using a co-precipitation method with optimized precursor ratios to enhance magnetic performance. Structural and magnetic characterization revealed improved properties, with a saturation magnetization of 148.6 emu/g. In vitro cytotoxicity assays in MCF-7 breast cancer cells showed significant cell death at lower nanoparticle doses, confirming effective hyperthermic activity. In vivo experiments were performed using DU145 prostate and MCF-7 breast cancer xenograft models, where intratumoral injections of SPINs at 50 µg/mL and 100 µg/mL were followed by alternating magnetic field exposure. The 50 µg/mL dose led to gradual tumor reduction, while the 100 µg/mL dose induced rapid and uniform shrinkage, with near-complete regression in several cases. Thermal imaging verified temperature increase within the tumors. These findings indicate that Fe/C SPINs are promising agents for targeted and minimally invasive magnetic hyperthermia monotherapy in cancer treatment.

#2136 Optimizing an S100A9 probe to enhance CD147 targeting for image guided surgery of pancreatic ductal adenocarcinoma.

Barish H. Edil, Rohit Singh, Ryan C. Bynum, Karl N. Thomas, Lacey R. McNally

Surgery, University of Oklahoma Health Science, Oklahoma City, OK

Background: Pancreatic ductal adenocarcinoma, PDAC, remains of the deadliest cancers with the 5-year survival rate being 10-15%. Surgery is one of the only curable treatments for PDAC with up to 70% of patients that are candidates for surgery having positive margins; it is critical to have accurate imaging of PDAC which can contribute to patient stratification. S100A9 is a calcium binding ligand that binds to CD147, also designated as extracellular matrix metalloproteinase inducer (EMMPRIN), a membrane-bound glycoprotein. To better visualize PDAC cells, an S100A9 derivative Near-infrared fluorescent probe was created to have increased binding to CD147 while minimizing off-target accumulation.
Methods: The pancreatic adenocarcinoma cancer cell lines, MiaPaca2, Panc1, Suit2, S2VP10 and S2013 were assessed for CD147 levels using western blot. The 114 amino acid S100A9 was synthesized using microwave chemistry and lyophilized. Hilyte 750 succinimidyl ester and Hilyte 750 amine reactive dyes were independently conjugated to the S100A9 peptide to determine the ideal orientation. Spectroscopy confirmed the conjugation of the probes. NIR imaging determined 750-S100A9 probes binding to S2VP10 cells. S100A9 peptide length was reduced to 89 or 80 amino acids and conjugated to HiLyte Fluor 750 acid SE dye on the C-Terminal end. Conjugation was tested with spectroscopy and the full length and cut down probes binding to S2VP10L were tested with NIR imaging.
Results: The western blot demonstrated that MiaPaca2, Panc1 and S2013 were highly positive for CD147 while Suit2 and S2VP10 were less positive. Successful conjugation of peptides to the reactive dyes resulted in an OD of 0.1 each. 750 dye conjugated to the C-terminal of the S100A9 probe determined stronger binding to S2VP10 at 279,600 a.u. at 500 nM compared to 4,055 a.u. of N-terminal 750-S100A9 ($p< 0.05$). The 89 amino acid probe resulted in the highest expression at 291,760 a.u. compared to the full-length at 46,580 a.u. and the S100A9-750 80 amino acid probe at 115,200 a.u. when assessed with binding to S2013Q ($p< 0.05$).
Conclusion: CD147 is a suitable target for PDAC using an S100A9 ligand conjugated near infrared fluorescent dye. In addition, S100A9 cut down to 89 amino acids on the C-Terminal with the HiLyte Fluor 750 acid SE dye determines to be a strong target for PDAC. The findings suggest that off-target accumulation of S100A9 could be minimized with the use of the smaller probe. The results also suggest that the S100A9 probes can improve detection and treatment of PDAC specificity with contrast agents or nanoparticles.

#2137 *In vivo* short-wave infrared imaging for liquid tumor and immuno-oncology models.

Tiffany W. Leong[1], Pavel Abdulkin[2], Ameena A. Moghe[1], Vidya Ganapathy[3], Mark C. Pierce[4], Mark Ravera[1]

[1]Nanoink Imaging Inc., Bernardsville, NJ,[2]SMALL Bio GmbH, Zug, Switzerland,[3]Rider University, Lawrenceville, NJ,[4]Biomedical Engineering, Rutgers University, Piscataway, NJ

In vivo imaging challenges in cancer drug discovery include imaging liquid tumors and tracking immune cell activity after checkpoint immunotherapy for solid tumors. Current methods for real-time *in vivo* imaging of tumor models include bioluminescence imaging (BLI), which involves using genetically modified cell lines that can confound study data due to potential changes in the cell lines' biology. This risk of potentially aberrant data is especially a concern with patient-derived xenograft (PDX) models. Our earlier work utilized targeted albumin-coated nanoparticles encapsulating rare earth-containing cores to image tumors in *in vivo* models of solid tumors and to image T cells in the tumor microenvironment. These biocompatible nanoparticles enable imaging without the need for genetic modification by emitting short-wave infrared (SWIR) light after excitation by a 980 nm light source. SWIR light travels through blood and tissue more efficiently than does visible bioluminescent light, providing deeper tissue illumination and sharper images. By functionalizing this technology with targeting antibodies, we were able to not only specifically image a range of solid tumors but also visualize CD8+ T cell activity around tumor sites. More recently, we have shown that our nanoparticles can be used to image and track an increase in liquid tumor burden within bone marrow and spleen over a three-week period in a lymphoma model. Briefly, U937 cells (50,000 per mouse) were injected i.v. into NSG mice on Day 0. Nanoparticles targeted to CD45 were injected on Days 10, 16, and 21, and the animals were imaged four hours post-injection using a SWIR-based imaging system. Tumor burdens were confirmed using flow cytometry. Since this initial lymphoma imaging study, we have improved our nanoparticle formulation by encapsulating the rare earth cores with a combination of biocompatible lipids and polymers, and by switching from a batch synthesis process to a microfluidics-based fabrication process. This microfluidics-based approach enables scalability and a high degree of batch-to-batch reproducibility. We tested these next-generation nanoparticles *in vivo* and showed that they are ≥5-fold brighter than our original albumin formulation, providing researchers with a highly sensitive imaging modality to interrogate the tumor microenvironment and to visualize liquid tumors in real time, all without the risks inherent in genetic modification of the tumors and immune cells being studied.

#2138 Development of a bioluminescence imaging-guided CTC liquid biopsy procedure to identify the optimal time window for achieving superior photothermal therapy efficacy.

Abhijit De, Chetna Patnaik

Molecular Functional Imaging Laboratory, ACTREC, Tata Memorial Centre, Navi Mumbai, India

Global cancer burden represents one of the most significant challenges in public health. Notable concern for the mainframe therapeutic procedures is the high incidence of relapsed disease among majority patients availing those. This problem is frequently attributed to the evolving state of cancer cell dissemination, where circulating tumor cells (CTCs) begin to appear in the blood circulation. However, due to CTC enrichment requirement, high-volume blood withdrawal repeatedly during initial or follow up diagnosis, raises an ethical concern, and therefore CTC determination not integral in practice. Given the sparse nature of CTC applications in preclinical experiments using mouse model, where the total blood volume is limited to only 1.5 ml/mouse, in this study we challenged this dogma, and established a luminescence-based CTC detection method using preclinical mouse tumor models. The optimized liquid biopsy process using bioluminescence imaging-guidance allowed detection of up to two cells from as low as 100µl blood volumes, allowing us to follow the CTC surge dynamics from a very low blood volume. We examined both CTC dynamics and metastatic potential in mice bearing highly aggressive 4T1-FLuc2 and a relatively indolent ZR-75-1-Nanoluc orthotopic breast cancer models. To test the case, we further used our well-standardized photothermal therapy (PTT) procedure using gold-coated solid lipid nanomaterial (Au-SLN) and demonstrate that when PTT is performed in a temporally optimized window, the therapy application does not induce a detectable CTC flux ($p < 0.05$), nor distant spread of malignant tumors in the vital organs, both in highly aggressive and less aggressive breast cancer models. Imaging signal from CTC was confirmed further by molecular biomarker and transcriptomic characterization, revealing a close association of EpCAM positive CTCs with tumor aggressiveness and their metastatic propensity. These effects essentially improve mice longevity and relapse-free survival of the mice. Our findings highlight that Au-SLN mediated PTT could provide a relapse-free efficacious treatment, when performed before viable CTCs are released and underscore the importance of integrating a sensitive liquid biopsy method for monitoring metastatic risk and chance of disease relapse.

#2139 [^{18}F]-FMISO-PET imaging to characterize the impact of obesity on the hypoxic tumor microenvironment during immunotherapy.

Corinne Crawford[1], Shannon Elizabeth Lynch[2], Jonathan Moye[2], Chloe T. DeMellier[2], Patrick N. Song[2], Kelsey M. O'Brien[2], Benjamin P. Lee[2], Benjamin Larimer[2], Anna G. Sorace[2]

[1]Department of Biomedical Engineering, University of Alabama at Birmingham, Birmingham, AL,[2]Department of Radiology, University of Alabama at Birmingham, Birmingham, AL

Introduction: 40% of patients with triple-negative breast cancer (TNBC) also have obesity (BMI>30 kg/m^2). Clinical studies have demonstrated that obesity worsens cancer outcomes, urging investigation of novel therapeutic targets within the obese tumor microenvironment (TME). Preclinical studies have shown that obesity increases tumor hypoxia, diminishing immunotherapy (IMT) response via reduced IMT distribution and pro-tumoral immune shifts. [^{18}F]-fluoromisonidazole (FMISO) positron emission tomography (PET) can non-invasively quantify hypoxia, allowing for patient stratification by hypoxia levels to predict IMT response and inform the use of secondary hypoxia-activated prodrugs, like evofosfamide (EVO).

Methods: C57/Bl6J mice were fed a high-fat diet (HFD, n=68) or low-fat diet (LFD, n=19) for 13 weeks prior to E0771 implantation in the 3rd mammary fat pad on day -12. To explore the impact of obesity on baseline tumor hypoxia, a cohort of LFD and HFD were imaged with [^{18}F]-FMISO PET. A second HFD cohort was split into controls (saline, n=19) or IMT (anti-CTLA-4 and anti-PD-1 every 3 days, n=49). Mice were imaged with [^{18}F]-FMISO PET on days 0, 5, and 12, and signal was quantified via standard uptake value (SUV) metrics. On day 6, IMT mice were randomized to continue with IMT (n=30) or also receive EVO (n=19). Based on ROC analysis, a threshold of day 5 tumor to background ratio (TBR) of the muscle of 1.3 was used to categorize tumors as hypoxic/normoxic. A correlation evaluated the predictive ability of day 5 TBR on long-term response (defined by RECIST criteria). A subset of treatment groups was euthanized at imaging timepoints for flow cytometry of immune populations. A two-way ANOVA was used for statistical analysis.

Results: HFD mice demonstrated significantly increased tumor hypoxia (SUV_{mean}) compared to LFD mice on day 0 ($p<0.0001$) without tumor volume differences. In HFD, IMT resulted in a 25% response rate by day 21. Day 5 TBR was inversely correlated with long term survival for IMT-treated mice ($p=0.003$, $r^2=0.5$). When stratifying tumors as normoxic or hypoxic, adding EVO to IMT demonstrated a 21% reduction of tumor hypoxia (SUV_{max}) within hypoxic tumors compared to IMT alone ($p=0.008$). Interestingly, combination therapy led to a 330% and 173% increase in M2-like macrophages ($p=0.06$) and regulatory T cells ($p=0.06$) compared to IMT alone and did not reveal improvements in long-term tumor volume.

Conclusions: Our study supports ongoing literature demonstrating increased hypoxia in tumors in a HFD environment and that [^{18}F]-FMISO stratification predicted response to immunotherapy in a TNBC model. Previous studies showed that lean tumor models have additive response when adding EVO to IMT in hypoxic tumors; however, our study demonstrated that EVO reduces hypoxia in hypoxic, obese tumors, but this did not salvage IMT response, likely due to increased tumorigenic immune changes.

#2140 Diet composition - A critical variable in fluorescence imaging for preclinical cancer research.

STEVEN YEUNG[1], Phuong Dang[2], Jeffrey D. Peterson[3], Sridhar Radhakrishnan[1]

[1]Research Diets, Inc., New Brunswick, NJ,[2]The Jackson Laboratory, Bar Harbor, ME,[3]Revvity, Durham, NC

Background: Fluorescence based imaging is a cornerstone of preclinical cancer research, enabling noninvasive, real time assessment of tumor growth, metastasis, and therapeutic response. However, dietary ingredients can impact image quality and data integrity. Grain-based chow diets contain nonnutritive components such as phytochemicals and potential toxins including endotoxins, mycotoxins, and heavy metals, that vary by batch and influence animal phenotype, metabolism, and imaging outcomes. Dyes (FD&C Blue #1, Yellow #5, Red #40) commonly added to diets for visual differentiation may introduce background fluorescence, while alfalfa and other chlorophyll-rich dietary ingredients fluoresce strongly in the red and near infrared (NIR) range, overlapping with wavelengths used by many NIR fluorescent cancer imaging probes. The effect of different dietary ingredients on fluorescence imaging quality was evaluated in this study.

Methods: Direct fluorescence imaging measurements of diet pellets were acquired on the IVIS™ Spectrum 2 using excitation wavelengths from 640 to 750 nm. For *in vivo* studies, 8 wk old male C57BL/6J and NU/J mice were initially fed alfalfa containing chow for a week, then transitioned to either purified diets (with or without dyes) or chows (with or without alfalfa) for two weeks. Multiple excitation wavelengths were used with appropriate excitation/emission filter sets to capture the range of diet- and dye-related signal from 500-750 nm with most analysis focused on the 640-750 nm range. Datasets were analyzed using Living Image™ 4.8.3 system software to quantify gastrointestinal fluorescence, using spectral unmixing algorithms to separate the signal from chlorophyll/dye and a relevant NIR fluorescent probe.

Results: *In vitro*, both alfalfa (640 nm and 675 nm) and incorporated dyes (640 nm) contributed to strong fluorescence signal. However, only the alfalfa containing diets produced strong background signal at 640 and 675 nm *in vivo*, sufficient to obscure tumor and inflammation probe signals. Alfalfa free and purified diets, with or without added dyes, cleared the background chlorophyll signal within 1-2 weeks, improving signal to noise ratios and image clarity. Data were similar in both NU/J and C57BL/6J strains.

Conclusions: Diet composition strongly influences fluorescence imaging. Alfalfa derived chlorophyll in chows introduces substantial NIR autofluorescence, which is minimized in alfalfa-free diets. Although dyes in purified diets fluoresce strongly *in vitro*, they likely degrade upon consumption contributing to minimal in vivo signal. Standardizing diet offers a simple, cost effective approach to improve image quality, reproducibility, and translational relevance in preclinical cancer imaging.

#2141 Progression of blood brain barrier leakage in orthotopic glioma SRG rat model using contrast enhanced MRI.

Tuulia Huhtala, Jussi Rytkonen, Riikka Immonen, Ayhan Korkmaz, Torsten Giesemann, Julia B. Schueler

Charles River Laboratories, Inc., Kuopio, Finland

Gliomas are the most common type of primary brain tumors. Innovative therapies are vital to improve treatment outcomes but to be efficient, trafficking across the blood brain barrier (BBB) is required. For this advent, animal models provide important information prior to clinical studies. Among the different in vivo models, orthotopic models mimic the biological environment. In addition to traditional mouse models, novel immunocompromised rat models offer new approach to preclinical efficacy testing facilitating PK/PD studies for IND enabling studies. SRG rats enable high engraftment rates and rapid growth of a variety of human tissues and tumors. Severe immunodeficiency ensures high engraftment rates and larger organism size allows larger sample collection e.g. for blood biomarker analysis. Especially in the brain tumor research, imaging has a central role in clinical diagnosis and as a prognostic factor to monitor therapy response. It enables longitudinal monitoring in a fully translational manner. Magnetic resonance imaging (MRI) offers unprecedented soft tissue contrast, high spatial resolution and non-invasive nature renders MRI in rodents a perfect tool for preclinical work in oncological applications. In addition to monitor tumor growth, cerebral blood flow (CBF) and leakage of BBB can be measured with a contrast agent. Perfusion indicates angiogenesis in tumor, one hallmark of most malignant gliomas as well the leakage status of glioma is critical to understand for possible therapeutic intervention. The purpose of this work was to establish orthotopic glioma model in SRG rats using U87MG cells. Development of brain pathologies were longitudinally monitored in vivo using MRI. Key readouts were anatomical visualization of abnormalities, tumor volumetry, vascularization in tumor, CBF and development of BBB leakage. Differences in CBF represents mass effect from brain tumors impairing blood flow in the surrounding brain parenchyma. As a conclusion, translational in vivo imaging techniques were applied to study orthotopic tumor progression. These readouts provide a powerful and translational research tool together with oncological disease animal models with detailed understanding about disease progression and improved treatment intervention design.

#2142 MRI radiomic features to differentiate aggressive and indolent renal tumors.

Huan Lu, Salim Rukhsar, Xueqing Yin, Garima Suman, Ashish Khandelwal, Ananth J. Madhuranthakam, Durga Udayakumar

Mayo Clinic, Rochester, MN

Renal tumors are highly heterogeneous, ranging from benign lesions and indolent renal cell carcinoma (RCC) to highly aggressive phenotypes. Accurately determining tumor aggressiveness before treatment remains a major clinical challenge. Conventional MR imaging lacks sensitivity to microarchitectural differences underlying tumor biology, and biopsy is limited by sampling error and tumor heterogeneity. Radiomics offers a noninvasive approach to extract high dimensional features that may capture biologically relevant patterns. In this IRB-approved retrospective study, we evaluated MR-based radiomics combined with machine learning (ML) to differentiate indolent from aggressive tumors. Pre-operative clinically acquired MR images obtained from eighty-two RCC patients (aggressive, n = 56; indolent, n = 26) who underwent nephrectomy were included for the analysis. Regions of interest (ROIs) of the entire tumor were manually drawn using 3D Slicer on the morphological T2-weighted images and four phases (pre-contrast [PRE], corticomedullary [CM], nephrographic [NG], and delayed [DEL]) from the contrast-enhanced MR images, normalized, and used for radiomic feature extraction (PyRadiomics, v3.1.0). Independently, tumors were grouped into aggressive and indolent phenotypes based on the established histological classification of Mayo Clinic. Statistical analysis used two-sided t-test. Features selected based on mutual information were used for ML classification (Random Under-Sampling Boosting (RUSBoost)) and performance assessed using accuracy, sensitivity, precision, specificity, F1-score, and area under the curve (AUC). Of 107 radiomics features extracted, the following numbers showed statistically significant differences between aggressive and indolent tumors ($p < 0.05$): CM phase (n = 19), NG phase (n = 24), DEL phase (n = 22), and T2-weighted images (n = 29). Several features consistently differed among contrast-enhanced images and included first-order (length, surface area, volume), GLCM (correlation, IDM, IMC1, IMC2), GLDM (dependence entropy, dependence non-uniformity, dependence variance), GLRLM (gray-level non-uniformity, run entropy, run-length non-uniformity), GLSZM (high gray-level emphasis, zone entropy), and NGTDM (coarseness). Using the 15 features with highest mutual information across 50 patients (aggressive, n = 31; indolent, n = 19), a five-fold cross-validation RUSBoost classifier achieved accuracy 0.81, sensitivity 0.84, precision 0.87, specificity 0.77, F1-score 0.85, and AUC 0.80 for identifying the aggressive phenotype. MRI radiomics features show potential to differentiate aggressive from indolent renal tumors. ML-based classification using these features demonstrates promising accuracy. Further optimization and validation in larger cohorts, may help guide individualized care, including consideration of active surveillance for indolent renal tumors.

#2143 From local growth to distant metastasis: A versatile in vivo imaging platform for modeling cancer progression.

Na Li, Hao Huang, Xinyu Zhong, Xuyang Duan, Xing Lan, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., LTD, Beijing, China

Background: A comprehensive understanding of cancer progression requires experimental models capable of dynamically capturing both localized tumor growth and the multi-step process of systemic dissemination. Conventional models often recapitulate isolated aspects of this cascade, thereby limiting their translational relevance.
Objective: To establish and validate an integrated in vivo platform that utilizes luciferase-based imaging to quantitatively model distinct stages of cancer progression—from primary engraftment to organotropic dissemination.
Methods: We engineered a series of site-specific cancer models in immunodeficient mice, with disease progression continuously monitored by bioluminescent imaging (BLI). These included: 1. Intracardiac injection of MDA-MB-231-Luc2 cells to model disseminated metastatic seeding. 2. Intratibial and intracranial inoculation to evaluate site-specific growth of breast cancer cells in bone and brain microenvironments. 3. Intravenous injection of Ba/F3 and lymphoma cells to simulate hematogenous dissemination. 4. A systematic analysis of intracranial engraftment topography, where A375-GFP-Luc cells were inoculated at stereotactic coordinates 0.5 mm anterior, 1.5 mm anterior, and 0.5 mm posterior to the bregma.
Results: The platform robustly recapitulated diverse disease phenotypes. Intracardiac injection resulted in widespread bioluminescent signals indicative of metastatic colonization. Orthotopic tibial and intracranial inoculations led to progressive, quantifiable local tumor growth. Intravenous injection of hematopoietic cells produced a systemic pattern of leukemic proliferation. Importantly, the intracranial implantation site emerged as a key determinant of disease progression: injections posterior to the bregma were associated with a significantly greater propensity for metastatic dissemination compared to anterior sites.
Conclusion: We present a validated and versatile in vivo platform that enables the spatiotemporal quantification of tumor dynamics across multiple disease contexts. This integrated system provides a powerful tool for investigating organ-specific tumor biology and evaluating therapeutic efficacy against both primary and metastatic disease.

#2144 Sodium nitrite alters perfusion and hypoxia in preclinical models of breast cancer.

Kelsey M. O'Brien[1], Patrick N. Song[2], Katrina Ricart[3], Seth N. Lee[2], Chloe T. DeMellier[2], Zora Paschel[4], Urvi Rawal[4], Hailey Houson[2], Suzanne E. Lapi[2], Rakesh P. Patel[3], Anna G. Sorace[2]

[1]Graduate Biomedical Sciences, University of Alabama at Birmingham, Birmingham, AL,[2]Radiology, University of Alabama at Birmingham, Birmingham, AL,[3]Molecular and Cellular Pathology, University of Alabama at Birmingham, Birmingham, AL,[4]Biomedical Engineering, University of Alabama at Birmingham, Birmingham, AL

Breast cancer is known to have high levels of hypoxia, leading to poor prognosis and reduced treatment response. Sodium nitrite is an exogenous agent that has been shown to decrease hypoxia in ischemic limb injury and is being explored to improve hypoxia in the tumor microenvironment. The goal of this study is to use non-invasive imaging to characterize changes in perfusion, hypoxia, and drug delivery in vivo following exposure to sodium nitrite.

Mouse models of breast cancer (BT474 human and 4T1 syngeneic cell lines) were treated with saline or sodium nitrite (165μg/kg IP) twice daily. Dynamic contrast-enhanced (DCE) MRI was used to monitor changes 20 minutes after the administration of a single dose of sodium nitrite. [^{18}F]-fluoromisonidazole ([^{18}F]FMISO) positron emission tomography (PET) enabled visualization and quantification of hypoxia within both models, with the BT474 model receiving one week of treatment and the 4T1 model receiving three doses of treatment before imaging. Sodium nitrite-induced changes to drug delivery were measured via dynamic [^{89}Zr]Zr-atezolizumab PET in the 4T1 model, which informed on delivery alterations and the 24-hour retention of an antibody drug delivery. Mice were given sodium nitrite 24 hours, 12 hours, and 20 minutes prior to scan. Modeling of dynamic PET was performed with a two-tissue compartment model to extract biological metrics of perfusion (*K1*) and retention (*k3*). For all molecular studies, tracer uptake was quantified using the mean and distribution of the standardized uptake value (SUV) in the tumor. The Wilcoxon rank sum test was used to assess differences in K^{trans} extracted from Kety-Tofts analysis of DCE-MRI data. One-way and two-way ANOVAs were used to determine the effects of treatment. Independent t-tests were used to examine differences between treatment groups.

Mice treated with sodium nitrite showed increased perfusion (K^{trans} from DCE-MRI) compared to those treated with saline (p=0.03). In both models, hypoxia was shown to be significantly reduced with the introduction of sodium nitrate compared to controls, with a decrease observed after 10 doses in BT-474 (p=0.01) and after two doses in 4T1 (p=0.02). Compartmental modeling showed that adding sodium nitrite increased the rate of delivery of the tracer (*K1*) compared to control (p=0.02) and improved retention (*k3*) at 24 hours (p=0.015).

Non-invasive imaging revealed tumor microenvironment alterations in perfusion and oxygenation following sodium nitrite in two breast cancer models. Further, sodium nitrite was able to increase delivery of an antibody PET tracer, serving as a measure of antibody therapy delivery. As perfusion and hypoxia are key drivers in response to therapy, the addition of sodium nitrite can modulate hypoxia, perfusion, and drug delivery in solid tumors and could potentially offer new therapeutic insights for optimizing treatment in breast cancer.

#2145 Biophysical enhancement of radiation-activated photodynamic therapy (radioPDT) and translational brain tumor models.

Manjusha Muralidharan[1], Deepak Dinakaran[2]

[1]Biological Sciences, Sunnybrook Health Sciences Centre, Toronto, ON, Canada,[2]University of Toronto, Toronto, ON, Canada

Background: Radiation-activated photodynamic therapy (radioPDT) uses X-ray-excited nanoscintillators to activate photosensitizers deep within tissues, generating cytotoxic reactive oxygen species without requiring receptor expression. This biophysical strategy is well suited for heterogeneous tumors such as glioblastoma (GBM), where receptor-targeted approaches often fail. A major translational barrier is the blood-brain barrier (BBB), which restricts nanoparticle entry. Physical modulation via focused ultrasound (FUS) and microbubble cavitation can enhance nanoparticle delivery and potentially improve radioPDT efficacy. To evaluate this approach, we established a multi-model pipeline incorporating flank xenografts, intracranial GBM models, and the chick CAM system, allowing visualization of nanoparticle transport, vascular effects, and treatment response.

Methods: SCID mice bearing PC3 flank tumors received control, radiation, FUS, NP+RAD, NP+FUS+RAD, or NP+microbubbles+FUS+RAD. Tumors were analyzed using multiplex immunofluorescence for proliferation/apoptosis (Ki67, cleaved Caspase-3), DNA damage (γ-H2AX, 53BP1), oxidative injury (4-HNE, TUNEL), vascular structure (CD31, NG2), hypoxia (CA9, HIF-1α), and inflammation (CD45, Iba1). For translational studies, U87 and U251 GBM cells expressing LUC-GFP were validated and used to generate intracranial xenografts for bioluminescence imaging and a CAM model enabling rapid assessment of nanoparticle behavior and radioPDT effects.

Results: radioPDT alone disrupted endothelial cells, while radioPDT combined with microbubble-enhanced FUS produced both endothelial and pericyte disruption, suggesting potential for BBB modulation. Multiplex tumor analysis is ongoing. LUC-GFP GBM models have been established, and intracranial and CAM tumors provide complementary systems to study FUS-mediated BBB opening and nanoparticle delivery during radioPDT.

Conclusions: radioPDT may amplify ultrasound-mediated vascular modulation without requiring receptor-specific targeting. The integrated PC3, intracranial GBM, and CAM platforms establish a translational pathway to evaluate BBB-penetrant, physics-based radioPDT. These studies are designed to define how physical forces—rather than receptor-mediated uptake—shape nanoparticle distribution, vascular response, DNA damage, oxidative injury, and overall radioPDT potency.

#2146 Innovative preclinical platform to highlight the impact of macro and microenvironment on pancreatic cancer development and therapy response.

Isabella Manni[1], Francesca Romana Auciello[1], Giulia Cristinziano[1], Clizia Maccaroni[1], Elena di Gennaro[2], Maria Serena Roca[2], **Giulia Piaggio**[1]

[1]IRCCS Regina Elena National Cancer Institute, Rome, Italy,[2]Inst. Nazionale Tumori IRCCS - Found. Pascale, Napoli, Italy

The poor outcome of pancreatic adenocarcinoma (PDAC) is due to the lack of early biomarkers and therapeutic options. The impact of the systemic temporal and spatial activation response, defined as macroenvironment, on PDAC is not fully understood. Key questions remain about the timing and occurrence of early systemic responses. This knowledge gap is primarily due to the absence of human and animal models that can intercept early tumor-related systemic perturbation before tumor uptake. We have developed the MITO-Luc reporter mouse model to measure physiological and/or aberrant proliferation in any body district by non-invasive bioluminescence imaging. To design new therapeutic protocols< with precise timing, targeting systemic aberrant proliferation before tumor appearance, we crossed MITO-Luc mouse with PDAC models carrying oncogenic Kras alone (KC) or with mutant p53 (KPC) in pancreatic cells. This mice model allows for the non-invasive tracking of early and late stages of PDAC development in live animals. Taking advantage of this model, we have been able to intercept early systemic events in the hematopoietic organs occurring significantly before the appearance of pre-cancerous lesions and/or a palpable tumor. We also have results regarding the molecular and cellular critical players involved in the early steps of PDAC development. To generate a preclinical platforms to explore the efficacy of new combination therapies, targeting both PDAC cells and microenvironment, we inoculated cell lines with different ability to recruit microenvironment derived from KC and KPC mouse models into MITO-Luc mice. We found a different immune cells and CAFs recruitment in tumors that recruit lower or higher number of proliferating endogenous cells. Furthermore, taking advantage of tumor slice cultures reflecting the state of tumor behavior and heterogeneity, we highlighted a simple approach to study cancers with intact microenvironment. We observed that, upon 72 hours of culture, PDAC, stromal and immunological cells are present and still alive.

Poster Session

#2150 *Drosophila*-based screening identifies ferroptosis induction via NAD-GPx4 axis inhibition as a therapeutic strategy for PDAC.

Masahiro Sonoshita

Institute for Genetic Medicine, Hokkaido University, Sapporo, Japan

Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies, and substantial progress has been made using mammalian models to elucidate its pathogenic mechanisms. To enable systematic discovery of actionable vulnerabilities, we generated a Drosophila PDAC model library that recapitulates key genetic alterations observed in human disease. Among these models, the *"4-hit"* flies—harboring alterations in *KRAS*, *TP53*, *CDKN2A*, and *SMAD4*, a genotype associated with the poorest clinical prognosis—exhibited robust tumorigenic manifestations, including epithelial transformation and impaired organismal viability. A genetic screen using this high-fidelity model uncovered a critical role for the nicotinamide adenine dinucleotide (NAD) biosynthesis pathway in promoting PDAC progression. Within this pathway, we identified glutathione peroxidase 4 (GPx4) as a key effector that mitigates reactive oxygen species (ROS)-mediated cytotoxicity. Combined inhibition of GPx4 and MEK using ML210 and trametinib, respectively, markedly ameliorated lethality and tumor-like phenotypes in the *4-hit* flies. Importantly, this combinatorial treatment synergistically suppressed proliferation of human PDAC cells and their corresponding xenografts, primarily by inducing ROS accumulation and triggering ferroptotic cell death.Collectively, these findings reveal a conserved dependency of PDAC on the NAD-GPx4 redox axis and demonstrate that therapeutic induction of ferroptosis represents a promising strategy to target genetically refractory PDAC.

#2151 Understanding the mechanisms by which environmental arsenic elevates the risk of urothelial bladder cancer.

Yuyang Huang[1], Britton C. Goodale[1], Jordan E. Magurk[1], Xiaoying Liu[2], Yang Zheng[1], Stephen A. Watts[3], Steven D. Leach[1]

[1]Department of Molecular and Systems Biology, Geisel School of Medicine at Dartmouth, Hanover, NH,[2]Department of Pathology and Laboratory Medicine, Dartmouth Hitchcock Medical Center, Lebanon, NH,[3]Department of Biology, The University of Alabama at Birmingham, Birmingham, AL

Arsenic (As) in drinking water is associated with increased risk of multiple malignancies, particularly urothelial bladder cancer (UBC), yet the underlying mechanisms remain poorly understood. We previously demonstrated that zebrafish possess a contractile urinary bladder with a specialized urothelium closely resembling the human bladder structurally and functionally. We and others have further shown that zebrafish As metabolism parallels that of humans and that zebrafish express the key As metabolism genes AS3MT and MTHFR. AS3MT is essential for methylating inorganic As into less toxic metabolites, while MTHFR is required for generating the universal methyl donor SAM; hypoactive SNPs in both genes are associated with increased UBC risk. Using both adult zebrafish and human cell lines, we aim to investigate how As impacts the bladder urothelium and elevates UBC risk. In a 28-day study, adult zebrafish exposed to 500 ppb As (III) exhibited histological evidence of As-induced hyperplasia and urothelial thickening. Bulk RNA-seq of As-exposed zebrafish bladders revealed upregulation of cancer-related pathways including MYC, mTOR, and unfolded protein response. Single cell RNA-seq further identified female-specific urothelial and non-urothelial clusters and revealed distinct clusters altered by As that differed between sexes, suggesting a potential link to the known sex bias in UBC. In both female and male urothelial clusters, As induced a shift of cells from a UPK+ phenotype to a less-differentiated UPK- phenotype. Loss of both luminal and basal markers including UPK3B, KRT5, and KRT15 was observed, while lineage-regulating factors like FOXA1 are retained. Induction of the AP-1 transcriptional complex, implicated in promoting tumor growth and invasion, was also observed. To validate, we employed the spontaneously immortalized human urothelial cell line HBLAK. While HBLAK cells are homogeneously basal, they can be induced with EGFR inhibition and PPARγ activation to express luminal markers, providing a platform to study urothelial differentiation. Upon induction, As-exposed HBLAK cells exhibited a dose-dependent decrease in both basal (KRT14) and luminal (UPK2) markers while retaining FOXA1 expression, accompanied by upregulated AP-1 components, consistent with zebrafish *in vivo* findings. As also induced global loss of histone and DNA methylation, with reduced SAM levels. We will employ newly generated AS3MT and MTHFR knockout zebrafish lines and human urothelial cell lines to understand As-induced epigenetic dysregulation and its link to disrupted differentiation. Our findings establish zebrafish as a powerful model for studying As-induced changes in urothelial differentiation and suggest that As induces urothelial cell dedifferentiation in both zebrafish and human models, which may lead to the early emergence of tumor-initiating cells during tumorigenesis.

#2153 The Miniature Oncopig® cancer model as an innovative large animal platform for preclinical pharmaceutical evaluation.

Taeyoung Shin[1], Jennifer J. Meudt[1], C. Dustin Rubinstein[1], Brent Lehman[1], **Lobna Elkhadragy**[2], Matthew M. Niemeyer[1], Jamie Reichert[1], Kathryn M. Nelson[1], Jennifer Frank[1], Ashley Nelson[1], Paige Munns[1], Devon Klipsic[1], Eric Schmuck[1], Mahmoud Khalafalla[3], Navin Viswakarma[3], Jessicca Rege[3], Ali Pirasteh[1], Lawrence B. Schook[3], Tanja Dominko[1], Dhanansayan Shanmuganayagam[1], Kyle M. Schachtschneider[3]

[1]University of Wisconsin-Madison, Madison, WI,[2]University of Illinois at Chicago, Chicago, IL,[3]Sus Clinicals, Inc., Chicago, IL

Background: Advances in cancer care rely on human-like preclinical animal models to evaluate safety, metabolism, pharmacokinetics, and efficacy of novel therapeutics in a translational manner. We previously developed the transgenic Oncopig®, a genotypically, anatomically, metabolically, and physiologically relevant large animal model that develops inducible tumors on demand. While the Oncopig® platform is ideal for short-term device-based therapeutic and diagnostic studies, its rapid growth and large size limits use for pharmaceutical and long-term efficacy studies. To overcome this limitation, we used the Wisconsin Miniature Swine™ (WMS™) to develop a miniature version of the Oncopig® (WMS™-Oncopig®). The WMS™-Oncopig® is a valuable model for preclinical drug studies due to its reduced size in addition to predisposition to obesity, metabolic disorders, and other clinically relevant cancer comorbidities.

Methods: The WMS™-Oncopig® transgene cassette was designed to harbor Cre recombinase-inducible *KRAS*^{G12D} and *TP53*^{R167H} driver mutations. The cassette also includes a mScarlet fluorescence gene flanked by LoxP sites, serving as a negative marker of Cre-induced recombination and driver mutation expression. Using CRISPR/Cas9 technology, the transgene cassette was inserted into the Rosa26 locus of WMS™ fibroblasts. After validation, the modified fibroblasts were used for reproductive cloning of WMS™-Oncopigs® by somatic cell nuclear transfer. Tumor induction studies were conducted on WMS™ -Oncopig® clones (n=2) with established Oncopig® liver tumor induction protocols, while the remaining clones were used for breeding.

Results: WMS™-Oncopig® fibroblasts were selected based on fluorescent imaging (mScarlet) and sequencing. Transgene cassette functionality was confirmed based on *KRAS*^{G12D} and *TP53*^{R167H} expression, increased proliferation, and loss of red fluorescence following nucleofection with a Cre recombinase-expressing plasmid. WMS™-Oncopigs® formed liver tumors within 2 weeks of induction using established Oncopig® tumor induction protocols. Finally, cells isolated from 3 of 5 fetuses generated by breeding WMS™-Oncopig® clones to wild-type WMS™ displayed red fluorescence, with genomic PCR confirming germline transmission of the transgene cassette.

Conclusions: The WMS™-Oncopig® model enables on-demand tumor induction in a clinically relevant pig breed with reduced size and growth compared to the current Oncopig® model. This, combined with predisposition to obesity and other clinically relevant cancer comorbidities supports the translational relevance of the WMS™-Oncopig® for preclinical oncologic drug metabolism, pharmacokinetic, safety, and efficacy studies. The WMS™-Oncopig® thus fulfills the current unmet need for translationally relevant models for preclinical investigation of novel cancer therapeutics.

#2154 Modeling olaparib resistance in prostate cancer PDXs to elucidate PARP inhibitor escape mechanisms.

Nadege BIDAN[1], Claire BERAUD[1], Emilie INDERSIE[2], Marie TAVERNIER[2], Clementine KRUCKER[3], Eric POTIRON[4], Philippe LLUEL[1], Olivier DEAS[2]

[1]Urosphere, Toulouse, France,[2]XenTech, Evry-Courcouronnes, France,[3]Department of Pathology, Institut Curie, Paris, France,[4]Department of Urology, Clinique Urologique, Nantes, France

Patient-derived xenografts (PDXs) are essential preclinical tools for modeling prostate cancer (PCa) biology and assessing therapeutic responses. Over the past years, we have established and comprehensively characterized a panel of 15 prostate cancer PDX models that recapitulate the histological and molecular heterogeneity of human disease. While PARP inhibitors such as olaparib provide clinical benefit to patients harboring BRCA1/2 mutations or homologous recombination deficiency (HRD), resistance inevitably emerges and remains a major clinical challenge. Here, we present insights that pave the way for characterizing mechanisms of PARP inhibitor resistance and identifying strategies to circumvent PARPi escape using our panel of PCa PDX models. Therapeutic responses to olaparib were evaluated across the biobank, alongside assessment of homologous recombination repair (HRR) status. Most PDX models displayed intrinsic resistance, whereas three showed marked sensitivity. Notably, a neuroendocrine prostate cancer (NEPC) PDX harboring DNA damage-repair alterations exhibited pronounced olaparib sensitivity, providing the first preclinical evidence supporting PARP inhibitor activity in a neuroendocrine context. These three sensitive models were then exposed to chronic treatment until tumor recurrence, generating acquired olaparib-resistant derivatives. Resistant PDXs were compared with their isogenic sensitive counterparts through histopathological analysis and transcriptomic and genomic profiling, with a focus on DNA repair and compensatory pathways. Multi-omic analyses indicate involvement of mechanisms such as partial restoration of homologous recombination and activation of alternative DNA repair pathways. Overall, this unique PCa PDX panel, together with the newly generated olaparib-resistant derivatives, constitutes a valuable preclinical resource for deciphering PARP inhibitor resistance mechanisms and informing the development of next-generation therapeutic combinations for prostate cancer.

#2156 Syngeneic mouse models of prostate cancer driver mutations.

Jean C. Tien[1], Yunhui Cheng[1], Fan Yang[1], Christina E. Wheeler[1], Abigail J. Todd[1], Somnath Mahapartra[1], Shuqin Li[1], Jie Luo[1], Rahul Mannan[1], Arul M. Chinnaiyan[2]

[1]Pathology, University of Michigan, Ann Arbor, MI,[2]University of Michigan, Ann Arbor, MI

Immunotherapy, such as immune checkpoint blockade, has emerged as a highly successful treatment for cancers including melanoma. While prostate cancer has been termed a “cold malignancy”, generation of models that effectively recapitulate the tumor immune environment offers an avenue by which immunotherapeutic approaches with potential clinical viability can be developed. Syngeneic mouse systems—in which implanted tumor tissue is genetically similar to that of a host animal—represent one such model. At present, syngeneic mouse models of prostate cancer—Myc-CaP, TRAMP-C2, RM1 and PPSM (*Pten*-/-; *P53*-/-; *Smad4*-/-)—do not encompass most driver mutations implicated in tumorigenesis. We therefore sought to broaden the suite of available syngeneic systems, by generating mice harboring tumors with the following mutations: *Cdk12* inactivation, *ERG* overexpression, *Myc* overexpression, *SPOP* mutation, *FOXA1* mutation, *BRAF* fusion, *Brca2* mutation, and MMR deficiency. In producing these lines, we applied a variety of molecular approaches, subjecting prostate tumor cells from pre-existing genetically modified mouse models (GEMMs e.g. *p53* knockout) to *in vitro* overexpression of fusion oncogenes (e.g. *ACPP-FGFR2*) or CRISPR-based knockout of tumor suppressor genes (e.g. *Msh2*). Growth of the resultant tumor lines in immunocompetent mice provided a platform for novel therapeutic testing. For instance, we generated organoids from *Rosa26*^{ERG}*;Pten* mice, then subcutaneously implanted them in C57Bl/6 hosts. Upon histological examination, resultant tumors exhibited classical adenocarcinoma histology strongly immunopositive for ERG. While tumors were essentially non-responsive to classical immune checkpoint blockade (anti-PD1), they exhibited reduced growth upon treatment with CBPD-409, a degrader of the key prostate cancer transcriptional coactivator CBP/p300. Strikingly, combination therapy with the aforementioned agents yielded overt tumor regression and marked tumor lymphocytic response encompassing CD4, CD8 and NK cells. This proof of concept experiment highlights the utility of our syngeneic models for *in vivo* combinatorial pharmacologic testing aimed at generating novel immunotherapy vulnerabilities.

#2157 Feasibility and challenges of developing PDX models of neuroendocrine cancers.

Caleb A. Morgan[1], Alexandria A. Peterson[1], Carlos H.F. Chan[2], Andrew M. Bellizzi[1], James R. Howe[3], **Po H. Ear**[1]

[1]University of Iowa, Iowa City, IA,[2]Carver College of Medicine, University of Iowa, Iowa City, IA,[3]Univ. of Iowa Hospitals and Clinics, Iowa City, IA

Neuroendocrine neoplasms (NENs) are a family of heterogenous cancers with neuronal and hormone-secreting features. NENs are subdivided into slow growing well-differentiated neuroendocrine tumors (NETs) and rapidly growing poorly differentiated neuroendocrine carcinomas (NECs). The incidence and prevalence of NENs have been steadily rising over the last twenty years. Yet, few effective therapeutic options are available for curing these complex diseases. The main bottleneck has been linked to the lack of preclinical NEN models for therapy testing. Recent advances in NET patient-derived organoid or spheroid models have significantly improved and contributed to accelerating the drug discovery pipeline. In addition, efforts in developing patient-derived xenograft (PDX) models of NECs have also been successfully reported by several research groups. However, efforts to develop PDX models of NETs remained largely unsuccessful. Our group aimed to prioritize the development of novel NET PDX models. We performed subcutaneous implantation of tumor cells isolated from 50 patient tumor samples from small bowel and pancreatic NETs (sbNETs and pNETs) in NOD scid IL2R gamma null (NSG) mice. Nine engraftments produced detectable tumors within 3-6 months. Of these, 2 sets of mice harbored spontaneously developed mouse tumors with no neuroendocrine feature, and 7 sets of mice harbored human tumor samples confirmed by short tandem repeat analyses to match with the original patient NET samples. Six of the 7 PDX tumors measured less than 5 mm in diameter at 4-6 months post-tumor cell implantation. Although these tumors were small, they recapitulated NET features and expressed NET markers such as synaptophysin (SYP), chromogranin A (CgA), or somatostatin receptor 2 (SSTR2), and have Ki67 staining in less than 25% of the tumor cells. One pNET PDX model yielded large tumors measuring over 10 mm in diameter at 3 months post-tumor cell implantation. Interestingly, these large tumors stained negative for SYP, CgA, or SSTR2, and displayed elevated Ki67 levels (over 35%). Analyses of the mutational landscape of these PDX models are underway and will reveal insights into key genetic regulators that hinder the development of NET PDX models. Overall, these findings highlight both the feasibility and challenges of developing NET PDX.

#2159 Establishment of new preclinical tumor models for pancreatic neuroendocrine carcinoma.

Takuto Yasuda[1], Ryota Tanaka[1], Daisuke Inoue[1], Koichi Nakanishi[1], Kosuke Hatta[1], Shigeaki Kurihara[1], Jun Tauchi[1], Sadaaki Nishimura[1], Masahiko Kinoshita[1], Kohei Nishio[1], Hiroji Shinkawa[1], Ken Kageyama[2], Akira Yamamoto[2], Takeaki Ishizawa[1]

[1]Hepatobiliary-Pancreatic Surgery, Osaka Metropolitan University, Osaka, Japan,[2]Diagnostic and Interventional Radiology, Osaka Metropolitan University, Osaka, Japan

Introduction: Pancreatic neuroendocrine carcinoma (PanNEC) is an extremely aggressive and rare malignancy with a poor prognosis. Owing to its rarity, therapeutic development has been significantly delayed, highlighting the urgent need for novel treatment strategies. Although preclinical models such as cell lines and patient-derived xenograft (PDX) models are essential tools for drug discovery, only one PanNEC cell line has been reported to date. In this study, we successfully established novel PanNEC cell lines and multiple PDX models and aimed to clarify their biological features and drug responses.

Experimental procedures: Tumor tissue obtained from a PanNEC patient was sutured onto the pancreatic tail of severe combined immunodeficient (SCID) rats to generate orthotopic pancreatic PDX models. In addition to orthotopic models, subcutaneous models and peritoneal dissemination models were created. Tumor tissue and malignant ascites obtained from orthotopic PDX models were subjected to primary culture, leading to the establishment of two novel PanNEC cell lines. Drug sensitivities to etoposide, irinotecan, cisplatin, and carboplatin were assessed using the CCK-8 assay. Furthermore, cell line-derived xenograft (CDX) subcutaneous models were generated to validate in vivo tumorigenicity.

Summary of the data: The engraftment rate of the orthotopic pancreatic PDX was 100% (2/2), with engraftment requiring approximately two months. Both tumor-derived and ascites-derived cell lines exhibited semi-adherent morphology. Tumor-derived cells showed planar adherent proliferation, whereas ascites-derived cells demonstrated three-dimensional spheroid-forming growth. The doubling times were 2.7 and 2.5 days, indicating strong proliferative capacity. Immunohistochemistry showed consistent expression of markers such as synaptophysin and chromogranin A across the primary tumor, PDX models, CDX models and the established cell lines. CCK-8 assays revealed growth-inhibitory effects for all four drugs without notable resistance, and the combination of etoposide and cisplatin demonstrated a synergistic effect.

Conclusion: We successfully established novel PanNEC cell lines and multiple PDX models, including orthotopic, subcutaneous, and peritoneal dissemination models, as well as CDX models. These rare models provide a valuable platform for future preclinical studies and may facilitate the development of new therapeutic strategies for PanNEC.

#2161 Paired PDX-PDXO models serve an integrated preclinical platform for high-throughput payload screening and ADC drug development.

Jinxi Wang, Leilei Chen, Qingzhi Liu, Jiawen Gao, Jun Zhou, Wubin Qian, Likun Zhang, Ludovic Bourre, Jessie Jingjing Wang

Crown Bioscience, Inc., San Diego, CA

Introduction Antibody-drug conjugates (ADCs) offer an effective and targeted strategy to kill tumor cells by delivering potent cytotoxic payloads directly to tumor cells. However, payload activity can lead to the emergence of resistance through ADC mechanisms such as altered metabolism, efflux pumps, or impaired intracellular activation. Here, we describe an integrated strategy using patient-derived xenograft (PDX) models and paired PDX-derived organoids (PDXOs) for high-throughput payload screening to guide the selection of optimal ADCs and the preclinical validation.

Methods PDX models were successfully established from a metastatic triple-negative breast cancer patient who showed resistance to Sacituzumab Govitecan (Trodelvy®), an ADC incorporating a topoisomerase I (TOP1) inhibitor payload (SN-38). The phenotypic and biomolecular characteristics of these models were thoroughly validated via RNA sequencing and whole-exome sequencing (WES). PDX-derived organoid (PDXO) model was developed from fresh PDX tumor tissue. *In vivo* efficacy was evaluated by tumor growth inhibition (TGI) ratio of each treatment group was calculated by formula: 1-Delta (Treatment group)/ Delta (Vehicle group). *In vitro* response to different payload of organoids were tested using CellTiter-Glo (CTG) assay and assessed by IC50 values.

Results Biomarker analysis showed the PDXO models faithfully recapitulated key features of the corresponding PDX tumors, including high TROP2 expression and reduced sensitivity to Trodelvy. High-throughput *in vitro* cytotoxicity screening of various ADC payloads revealed a distinct sensitivity profile in these PDXOs: they were insensitive to TOP1 inhibitor payloads (SN-38: IC50>0.008 and DXD: IC50>0.007) but exhibited sensitivity to the tubulin-targeting agent monomethyl auristatin E (MMAE: IC50≤0.0004). Subsequent *in vivo* efficacy studies of the PDX models with ADCs with different payloads shown consistent sensitivity with the PDXO screening results. The PDX models showed less sensitivity to Trodelv Dato-Dxd and SKB264 which carry TOP1 inhibitor payloads (TGIs rang 24%-57%) but were more sensitive to Dato-MMAE, which showed obvious tumor regression with a TGI of more than 90%, thereby showing correlation with the *in vitro* predictions.

Conclusion This study validates an efficient and integrated preclinical platform for early-stage ADC development. The combined PDX/PDXO approach significantly streamlines the ADC discovery process by enabling high-throughput payload screening, helping prioritize the most promising ADC candidates before advancing to more resource-intensive *in vivo* studies. This streamlined strategy accelerates data-driven decision-making for developing more effective, patient-tailored ADC therapies and for overcoming clinical resistance mechanisms.

#2162 GliomaPDOX - A direct brain-to-brain glioma xenograft library for drug discovery and development.

Elizabeth G. Fernandez[1], Christopher Tse[1], Jennifer Salinas[1], Nicholas Bayley[1], Lisa H. Ta[1], Laura Gosa[1], Henan Zhu[1], Michael Vigman[1], Francesco Sanvito[1], Benjamin M. Ellingson[2], Linda M. Liau[3], Timothy Cloughsey[1], Thomas G. Graeber[1], Nathanson David[1]

[1]University of California, Los Angeles, Los Angeles, CA,[2]Assistant Professor of Radiology; Dept. of Radiological Sciences, University of California, Los Angeles, Los Angeles, CA,[3]UCLA David Geffen School of Medicine, Los Angeles, CA

Cancer drug discovery and development rely on preclinical models that accurately reflect the molecular and functional characteristics of human tumors, while accounting for *in vivo* factors that influence drug efficacy, such as pharmacokinetics, metabolism and toxicity. Malignant gliomas are highly aggressive brain tumors that develop within the brain parenchyma, where their heterogeneous cellular composition engage in complex interactions with highly specialized brain cells, and a blood brain barrier that restricts drug penetration. When removed from this native environment, such as in culture or heterotopic *in vivo* environments (e.g., flank), gliomas either lose their molecular diversity or fail to grow altogether. Therefore, there is a critical need for physiologically relevant models that capture both the intra and inter-tumor diversity of glioma, as well as the organismal context required for drug development. Here, we present GliomaPDOX - a direct brain to brain glioma orthotopic xenograft biobank, consisting of more than 200 unique models that faithfully recapitulate the key molecular, histopathological, and proliferative features of their parental tumors. By incorporating a non-invasive, secreted reporter system to monitor tumor burden in real time—including drug-induced changes in intracranial tumor growth—we demonstrate the utility of GliomaPDOX for therapeutic evaluation. Together, this robust platform provides a physiologically relevant system to accelerate drug discovery and development for glioma.

#2163 Triple-negative breast cancer PDX models with acquired resistance to Enhertu®: A preclinical platform to uncover mechanisms of escape.

Emilie INDERSIE, Benjamin GUERRIN, Eugenie DELHORBE, Eva CYPRIEN, Elena DARBINEAN, Delphine NICOLLE, Marie TAVERNIER, **Olivier DEAS**

R&D, XenTech, Evry-Courcouronnes, France

Triple-negative breast cancer (TNBC) remains an aggressive and heterogeneous subtype with a poor prognosis. Although the antibody-drug conjugate Enhertu® (trastuzumab deruxtecan, T-DXd) has shown clinical activity in a subset of TNBCs with low HER2 expression, the rapid emergence of resistance limits its long-term efficacy. Robust preclinical models are therefore essential to investigate resistance mechanisms and evaluate novel therapeutic combinations. Within our panel of 40 TNBC patient-derived xenografts (PDXs), 14 were exposed *in vivo* to Enhertu®, of which 11 were sensitive. Among these, some PDX models were treated until the development of acquired resistance. To date, we have established five resistant derivatives from three initially sensitive models through continuous T-DXd exposure. Transcriptomic profiling was performed by RNA sequencing (HTSeq), followed by DESeq-based normalization and differential expression analysis. Functional enrichment analyses focused on predefined pathways related to endocytosis, receptor recycling, lysosomal trafficking, drug efflux, and DNA repair. Differential expression analysis revealed hundreds of significantly modulated genes. HER2 expression was assessed by immunohistochemistry, and RNA-Seq expression levels and mutational status of lysosomal cathepsins (CTSD, CTSB, CTSL) were examined in detail, given their potential involvement in the observed resistance mechanisms. In addition, resistant models were tested with HER2-targeting agents and a topoisomerase I inhibitor to evaluate the respective contributions of the two pharmacological targets of Enhertu® in the resistance mechanisms. Overall, resistance to Enhertu® in TNBC PDX models involves multifactorial adaptations, including signaling pathway reprogramming, altered drug efflux, and modulation of DNA repair. This collection of resistant models represents a valuable preclinical resource to investigate resistance mechanisms and to support the development of novel therapeutic strategies.

#2164 Breast cancer PDX models with acquired resistance to olaparib: A preclinical platform to uncover mechanisms of PARP inhibitor escape.

Emilie INDERSIE, Benjamin GUERRIN, Eugenie DELHORBE, Eva CYPRIEN, Elena DARBINEAN, Delphine NICOLLE, Marie TAVERNIER, **Olivier DEAS**

XenTech, Evry-Courcouronnes, France

PARP inhibitors (PARPi), such as olaparib, have significantly improved the prognosis of breast cancer patients harboring BRCA1/2 mutations or with homologous recombination deficiency (HRD). However, the emergence of acquired resistance remains a major clinical obstacle. Robust preclinical models are therefore essential to elucidate the mechanisms of resistance and evaluate new therapeutic strategies. Within our cohort of 55 patient-derived breast cancer (PDX) xenografts, 51 were exposed *in vivo* to olaparib, of which 19 showed sensitivity. Several HRD models were then chronically treated with olaparib until tumor recurrence, indicating acquired resistance. Resistant tumors and their parental sensitive counterparts were comprehensively compared using histopathological, transcriptomic (RNA-seq), and genomic (whole-exome sequencing) analyses. To date, we have established a panel of nine olaparib-resistant derivatives from six initially sensitive PDX models through continuous *in vivo* exposure. These resistant models exhibit heterogeneous resistance mechanisms, including BRCA1 mutation reversion, partial restoration of homologous recombination, and overexpression of DNA repair pathways. Overall, this panel of olaparib-resistant PDX breast cancer models represents a valuable preclinical resource to investigate PARPi resistance mechanisms and to guide the development of second-line combination therapies for HRD breast cancer.

#2165 An integrated preclinical platform for comprehensive evaluation of T-Cell engagers.

Hongyan Sun, Xinjie Lian, Shiying Guo, Yujing Zhang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

T-cell engagers (TCEs) are bispecific antibodies designed to bind both CD3 on T cells and a tumor-associated antigen (TAA) on cancer cells, representing a promising class of immunotherapies. Given their complex mechanisms of action, physiologically relevant preclinical models are essential for accurately evaluating the efficacy and safety profiles of TCE candidates. We developed a panel of medium- to high-throughput in vitro assays to screen TCEs based on target binding, T-cell activation, and tumor cell killing capabilities. Lead candidates were further assessed using in vivo efficacy studies in both xenograft and syngeneic models. In xenograft studies, we utilized NCG mice and NCG-MHC-dKO mice—the latter generated by deleting murine MHC class I and II genes in the NCG background—to reduce graft-versus-host disease (GvHD) after human PBMC engraftment and extend the experimental observation period. AMG509 (targeting STEAP1), AMG757 (targeting DLL3), and IBI-389 (targeting CLDN18.2) were evaluated in models of prostate cancer, small-cell lung cancer, and patient-derived xenografts (PDX), respectively. For syngeneic studies, we used BALB/c-hCD3EDG mice, in which endogenous Cd3e, Cd3d, and Cd3g genes were replaced with human versions. These mice were engrafted with A20-hCD20 lymphoma cells to test a CD3/CD20 bispecific antibody.

Both AMG509 and AMG757 significantly suppressed tumor growth in PBMC-humanized NCG and NCG-MHC-dKO models, with no major adverse effects on animal health. The efficacy of AMG509 varied across prostate cancer cell lines with different levels of STEAP1 expression. In NCI-H69 tumor-bearing mice treated with AMG757, the degree of tumor response correlated with the extent of human immune cell reconstitution observed three weeks post-treatment. IBI-389 exhibited marked tumor growth inhibition in two gastric cancer PDX models and one pancreatic cancer PDX model. In the BALB/c-hCD3EDG syngeneic model, administration of the CD3/CD20 bispecific antibody led to 81.5% tumor growth inhibition after 18 days.

GemPharmatech's integrated strategy—combining in vitro screening with a range of in vivo models such as NCG, NCG-MHC-dKO, and CD3-humanized mice—enables rapid, scalable, and translationally relevant assessment of T-cell engager candidates. This comprehensive platform supports robust and efficient immuno-oncology drug discovery and development.

#2166 Robust *in vivo* CAR-T efficacy evaluation in a PBMC-reconstituted NCG-MHC-dKO model with delayed GVHD.

Hongyan Sun, Xiaoliu Yang, Shiying Guo, Yujing Zhang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

Background: Humanized mouse models are critical for evaluating in vivo CAR-T therapies, but their utility is limited by rapid onset Graft-versus-Host Disease (GVHD). We employed a novel NCG-MHC-dKO model to mitigate GVHD, enabling prolonged assessment of anti-tumor efficacy for different in vivo CAR-T modalities. **Methods:** The NCG-MHC-dKO model was reconstituted with human PBMCs, confirming delayed GVHD. Mice bearing Nalm-6 tumors were treated with a single dose of either a lentiviral vector or an LNP formulation delivering a CD19-targeting CAR. Tumor growth was monitored via bioluminescence imaging. **Results:** The PBMC-NCG-MHC-dKO model demonstrated a significantly extended observation window due to postponed GVHD. In this model, both lentiviral and LNP-based in vivo CAR-T therapies potently suppressed Nalm-6 tumor growth. Functional CAR-T cells generated in vivo were detected and expanded in treated mice. **Conclusion:** The PBMC-reconstituted NCG-MHC-dKO model provides a robust and durable platform for in vivo CAR-T evaluation by overcoming early GVHD. We successfully validated its utility for both lentiviral and LNP delivery platforms, demonstrating significant and comparable anti-tumor efficacy.

#2167 A novel humanized mouse model for preclinical assessment of anti-CD47 and anti-SIRPAtherapeutics.

Hongyan Sun, Shaotong Ma, Yujing Zhang, Huixin Yang, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

Background: CD47, a ubiquitously expressed "don't eat me" molecular signal, mediates the evasion of tumor cells from phagocytic clearance through specific interaction with signal regulatory protein alpha (SIRPA) expressed on the surface of macrophages and dendritic cells. Therapeutic agents targeting the CD47-SIRPA pathway promote tumor cell eradication through two well-characterized mechanisms: 1. Blocking antibodies, including monoclonal and bispecific antibodies, interfere with the CD47-SIRPA interaction to enhance macrophage-driven phagocytosis of tumor cells; 2. The Fc domain mediates antibody-dependent cellular cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC). These biological processes further strengthen dendritic cell-mediated antigen presentation and initiate anti-tumor adaptive immune responses, which collectively establishes the CD47-SIRPA axis as a high-priority target in immuno-oncology.
Methods: To support the translational assessment of CD47-targeted therapies, GemPharmatech developed a BALB/c-derived double humanized hCD47/hSIRPα knock-in mouse model, in which the extracellular domains of human CD47 and SIRPA were expressed. Successful model construction was verified by detecting the protein expression levels of hCD47 and hSIRPA in BALB/c-hCD47/hSIRPA mice. This model was used to evaluate the anti-tumor efficacy of the anti-hCD47 antibody Magrolimab (5F9) using a CT26-hCD47 colorectal tumor model—established by engrafting CT26 overexpressing human CD47 into BALB/c-hCD47/hSIRPA mice. Given the well-documented toxicity of CD47 blockade, anti-SIRPA antibodies were also tested to explore an alternative targeting strategy. Additionally, the anti-tumor efficacy of the hSIRPA × hClaudin18.2 bispecific antibody (BsAb) was evaluated in BALB/c-hCD47/hSIRPA mice bearing the EMT6-hCD47-hClaudin18.2 triple-negative breast tumor model, where EMT6 cells overexpress both human CD47 and human Claudin18.2.
Results: Expression of hCD47 and hSIRPA in BALB/c-hCD47/hSIRPA mice was successfully verified. Administration of the anti-hCD47 antibody induced dose-dependent tumor regression in the established colorectal tumor model. Notably, the hSIRPA×hClaudin18.2 bispecific antibody (BsAb) exerted a significant anti-tumor effect in BALB/c-hCD47/hSIRPA knock-in mice implanted with EMT6-hCD47-hClaudin18.2 tumor cells.
Conclusions: The BALB/c-hCD47/hSIRPA mouse model serves as a clinically relevant tool for evaluating therapeutics targeting the CD47-SIRPA pathway within an immuocompetent model. Notably, it addresses key limitations of traditional immunocompromised murine models while providing critical insights into the mechanisms underlying CD47 pathway-mediated tumor clearance, toxicity management, and immune activation.

#2168 Human IgG1-expressing mouse models for tolerance induction and reliable assessment of IgG1-based therapeutic antibodies.

Angela Pappalardo, Gaelle H. Martin, Patricia Isnard-Petit, **Fabiane Sonego**, Kader Thiam

genOway, Lyon, France

Mouse models expressing human targets offer strong translational relevance for evaluating human antibody-based therapies in IO. However, when treated with human antibodies, these models frequently develop anti-drug antibodies (ADA), which can compromise the interpretation of preclinical data. ADA formation may alter pharmacokinetics, reduce therapeutic efficacy, and introduce immune-related artifacts that do not reflect human responses. This immune recognition limits the duration and reliability of treatment studies, especially for repeated dosing or long-term efficacy assessments. Therefore, careful selection and engineering of preclinical models that minimize ADA formation are essential to accurately predict clinical performance and support the development of safe and effective biologics. We generated a model expressing humanized IgG1, the most used isotype in clinical development, which was designed to induce tolerance to human IgG1-based therapies. Herein, we describe the investigation of the tolerance induced by the expression of hIgG1 in a mouse model humanized for serum albumin, FcRn, which was developed to investigate PK profile of antibodies in a context of tolerance to hIgG1. Both hSA and FcRn have already been shown to be expressed and enable half-life extension of compounds with enhanced binding to hFcRn and hSA in genO-hSA/hFcRn mice (Viuff *et al.*, 2016). Humanization has been confirmed by the detection of circulating human IgG1 levels in mice. Other immunoglobulins are also present in their serum, with only minor differences relative to WT mice, and suggesting no impairment on class switch. To test the tolerance to hIgG1, mice received a weekly injection of Teropavimab (anti-gp120- hIgG1κ) for 7 weeks. Blood was collected 2 hours after each injection for quantification of circulating Teropavimab. Expression of hIgG1 in mice leads to better tolerance to multiple cycles of Teropavimab compared to WT and genO-hSA/hFcRn mice. Indeed, one week after the last injection (day 49), Teropavimab is not detected in genO-hSA/hFcRn mice, whereas is detected in 2/5 WT mice, and in 5/5 mice expressing hIgG1 mice. Taken together, these results indicate that constitutive expression of hIgG1 promotes immunological tolerance to repeated administrations of therapeutic hIgG1 in murine models. Moreover, hIgG1 expression has been integrated into advanced mouse models such as genO-PanhCD3 and genO-FcγR to enable tolerance induction in experimental systems designed for the evaluation of T-cell engagers and Fc-mediated effector functions, respectively. In addition, an hIgG1-expressing variant of genO-TFRC model is available to support the characterization of hIgG1-based antibodies engineered for TFRC-mediated transcytosis, facilitating targeted delivery of therapeutic antibodies across the blood-brain barrier.

#2170 Patient-derived orthotopic xenograft models predict chemotherapeutic response in pancreatic ductal adenocarcinoma: an emerging platform for translational research.

Xin Zhang[1], Nathan Bolton[2], Alicia Ray[1], Grace Maresh[1], Rachel Graham[3], Li Li[1]

[1]Institute of Translational Research, Ochsner Health System, New Orleans, LA,[2]Department of Surgical Oncology, Ochsner Health System, New Orleans, LA,[3]Multi-specialty Clinical Research, Ochsner Health System, New Orleans, LA

Background: Pancreatic Ductal Adenocarcinoma (PDAC) is the third leading cause of cancer death. Current chemotherapy options are centered on a gemcitabine as backbone. However, the chemotherapy responsive rate and prognosis are still very poor with a five-year survival rate of 13%. Animal models mimicking tumor microenvironment have been used for pre-clinical and therapeutic studies, but the subcutaneous xenograft model does not replicate the clinical location and human PDAC chemotherapy responses. In this study, we used patient-derived orthotopic xenograft (PDOX) mouse models, with tumors localized to the pancreases, that mimic the natural tumor microenvironment, to test the efficacy of chemotherapeutic gemcitabine on PDAC progression and compare to their clinical response.
Methods: Totally 71 PDAC patients were consented and their tumor/blood specimens were collected after reviewed by pathologists. Tumor cells from one representative partial/moderate chemo-responding PDAC patients (PaCa23) and one representative poor chemo-responding PDAC patient (PaCa54), were expanded, isolated and intra-pancreas injected to NOD/SCID mice. Gemcitabine (100 mg/kg) was administered weekly by intravenous infusion for 4 weeks. Tumor volumes and mouse body weights were monitored weekly. After mice were euthanized, tumors were collected for tumor weight measurement. Hematoxylin & Eosin staining and OpalTM 4-color immunofluorescence staining were performed for tumor cell profile and tumor microenvironment study.
Results: Our PDOX model in both PaCa23 and PaCa54 retains the principal histologic characteristics of their donor tumor with similar infiltration patterns of stromal cells and remains stable across passages. No significant body weight loss was observed in the gemcitabine group. PaCa23 tumor responded to gemcitabine with significantly decreased tumor volume and tumor weight compared to control group ($p=0.007$ and $p=0.01$, respectively). PaCa54 tumor poorly responded to gemcitabine without significant tumor weight decrease compared to controls ($p>0.05$).
Conclusion: Our PDOX mouse model successfully recapitulates key histopathological and microenvironmental features of human PDAC and reflects patient-specific responses to gemcitabine treatment. The differential tumor response observed in PaCa23 and PaCa54 models mirrors their respective clinical outcomes, underscoring the predictive value of this platform. This orthotopic model holds significant promise as a preclinical tool for evaluating chemotherapeutic efficacy, guiding personalized therapy strategies, and studying tumor biology within a clinically relevant microenvironment.

#2171 Maintaining blood-brain barrier integrity in translational brain tumor models.

T. Liz Bailey, Melissa Tran, Cheryl Davis, Ben Hoerner, Victoria Caruso, Kathleen Hutchinson, Helen Ketteringham, Corrine Silvio, Shannan Paul, Chris Holding, Aliccia Koznecki, Dawn Lusk, Shorena Nadaraia-Hoke

Reaction Biology Corp, Malvern, PA

Brain metastases remain exceptionally challenging to treat, in part because many candidate therapies fail to demonstrate the clinical benefit observed in preclinical studies. A major contributor to this gap is the limited ability of traditional animal models to accurately replicate the functional blood–brain barrier (BBB). Conventional intracranial orthotopic tumor models are commonly used but inherently compromise BBB integrity, reducing their utility for evaluating drug penetration and therapeutic performance. Other implantation routes, such as intravenous or intracardiac delivery, better preserve the BBB but often produce extensive extra-cranial metastases, shortening study duration and diminishing relevance for brain-specific disease.

To overcome these limitations, we established an intra-carotid tumor cell delivery method that selectively seeds the brain while minimizing systemic spread. This technique enables localized tumor growth in disease relevant brain regions without disrupting BBB architecture. Tumor progression and spatial distribution were followed longitudinally using magnetic resonance imaging (MRI) together with bioluminescence imaging (BLI). These modalities consistently demonstrated reliable brain colonization and supported high-resolution tracking of tumor growth dynamics.

Our intra-carotid model provides a more physiologically faithful system for studying metastatic brain disease. By retaining BBB functionality and supporting reproducible, long-term monitoring, this platform offers a powerful tool for assessing BBB-permeant therapeutics and may enhance the translational value of preclinical studies in for brain targeted therapies, particularly in the context of metastatic disease.

#2172 Differential expression of the Kv3.4 channel in *in vitro* and *in vivo* models of cervical cancer: Potential clinical implications.

Ana Alejandra Ramirez[1], Andrea Jazmin Chiliquinga[2], Ingrid Ogonaga-Borja[2], Brenda Acosta[2], Patricio Gariglio[3], Rodolfo Ocadiz-Delgado[3], Jaime de la Garza[4], Elisabeth Hernandez-Gallegos[5], Maria de Guadalupe Chavez-Lopez[5], J. Martha Noyola[5], Javier Camacho[5]

[1]Faculty of Chemical Sciences and Engineering, Autonomous University of Baja California, Tijuana, B.C., Mexico,[2]Technical University of the North, Ibarra, Ecuador,[3]Department of Genetics and Molecular Biology, Center for Research and Advanced Studies of the National Polytechnic Institute, Mexico City, Mexico,[4]National Institute of Cancerology, Mexico City, Mexico,[5]Department of Pharmacology, Center for Research and Advanced Studies of the National Polytechnic Institute, Mexico City, Mexico

Introduction: Cervical cancer remains a major global health concern, and current diagnostic methods have significant limitations, highlighting the need for improved molecular biomarkers. Its progression is primarily linked to HPV infection, estrogen exposure, and ion channel deregulation. Ion channels such as Kv3.4 have gained relevance due to their involvement in carcinogenesis. This study examines the gene and protein expression of the Kv3.4 (KCNC4) channel in cervical cancer models and evaluates the effects of its pharmacological blockade as a potential diagnostic and therapeutic strategy.
Experimental procedure: KCNC4 gene expression was study in HeLa and SiHa cells by qRT-PCR, while Kv3.4 protein was evaluated by immunocytochemistry in HeLa, SiHa, normal keratinocytes (KN) and keratinocytes with HPV16 E6/E7 oncogenes (KT E6E7). The effect of Kv3.4 functional inhibition was assessed by metabolic activity assays following treatment with the Kv channel blocker BDS-I. In vivo model from four mouse groups: transgenic K14E7 mice treated with 17β-estradiol (K14E7+E2), untreated K14E7 mice, non-transgenic FvB mice treated with 17β-estradiol (FvB+E2), and untreated FvB controls, were examined by immunohistochemistry to determine the impact of HPV oncogenes and estrogen exposure on Kv3.4 regulation in cervical epithelium.
Results: Gene expression analysis showed a significantly higher KCNC4 expression in HeLa cells compared with SiHa cells, consistent with their differing HPV copy numbers. Immunocytochemistry confirmed Kv3.4 protein expression in HeLa, SiHa, and KT E6E7 cells, but not in KN cells. BDS-I treatment significantly reduced metabolic activity only in KT E6E7 cells, with no effect in KN cells. In mouse cervical tissues, Kv3.4 expression was strongest in FvB+E2 mice, followed by K14E7 and untreated FvB at 4 months. At 7 months, expression remained highest in FvB+E2, then K14E7+E2, K14E7, and FvB, indicating that estrogen exposure and HPV oncogenes enhance Kv3.4 expression in vivo.
Conclusion. Our findings show that the Kv3.4 channel is linked to HPV-related cervical carcinogenesis. Kv3.4 protein was detected in HeLa, SiHa, KT E6E7, and in cervical tissues from FvB+E2, K14E7+E2, and K14E7 mice, indicating that estrogen and HPV oncogenes upregulate the channel in vivo. Notably, Kv3.4 blockade selectively reduced proliferation in KT E6E7 cells, suggesting a greater dependence of HPV-transfected keratinocytes on this channel. Overall, these results support Kv3.4 as a potential biomarker and therapeutic target in early HPV-mediated cervical cancer. Partially supported by Conacyt grant A1-S-9783 to JdlG.

#2173 Development of novel syngeneic mouse models of mHSPC and mCRPC for evaluation of radiopharmaceuticals on the immune tumor microenvironment (TME).

Brian Ragaishis[1], Andrei Molotkov[2], Shruti Bansal[1], Krishan Saini[1], Meirdan Palihati[1], Chelsea Rahiman[2], Courtney Buress[1], Jasleen Kaur Virk[1], Mikhail Doubrovin[2], Catherine Spina[2]

[1]Radiation Oncology, Columbia University Irving Medical Center, New York, NY,[2]Columbia University Irving Medical Center, New York, NY

Introduction Radiopharmaceutical therapy (RPT) offers a safe and effective treatment for metastatic castrate resistant prostate cancer (mCRPC), however little is known about the differential impact of α- and β-emitters at the single cell level and on the immune tumor microenvironment (TME). This investigation aims to design novel mHSPC and mCRPC syngeneic mouse models to compare the therapeutic efficacy of α- and β-emitting RPTs and understand how different RPTs influence immune cell dynamics within the TME.

Methods We developed two novel murine PC cell lines that over express FOLH1/PSMA, MyC-CaP^{PSMA+} and MyC-CaP$^{HER2+PSMA+}$ (HER2 serving as a tumor antigen to quantify anti-tumor immune responses). Cell lines were developed by lentiviral transduction using EGFP+ as a positive selection marker. Transduction stability was confirmed by EGFP positivity by flow cytometry. We characterized expression of FOLH1 (the gene encoding PSMA) and PSMA by qPCR and western blot (WB), respectively, and quantified uptake of 68Ga-PSMA-11 in vitro. In immunocompetent FVB/NJ mice, MyC-CaP and MyC-CaP^{PSMA+} growth kinetics were evaluated and tumor PSMA expression was quantified by qPCR and WB. In vivo, we conducted biodistribution studies with 177Lu-PSMA-617 in mice bearing bilateral subcutaneous MyC-CaP and MyC-CaP^{PSMA+} tumors. After delivery of 3-5MBq, tumor and normal tissues were collected at 4 timepoints post-treatment (1h, 24h, 72h, 168h) and activity in the tumor and normal tissues was estimated using a HIDEX gamma-counter. Tumor and tissue percent injected dose per gram (%ID/g) was calculated. Mice bearing single flank 200mm^3 MyC-CaP^{PSMA+} tumors were chemically castrated with degarelix (25mg/kg body weight) to generate a mCRPC model.

Results MyC-CaP^{PSMA+} and MyC-CaP$^{HER2+PSMA+}$ showed a 10x increase in FOLH1 gene and protein expression compared to parent MyC-CaP and MyC-CaP^{HER2+}. In our in vitro uptake assay, we demonstrated a 30-50x increase in 68Ga-PSMA-11 uptake by transduced cell lines. In vivo, MyC-CaP^{PSMA+} tumors showed 1000x increase in expression of FOLH1 compared to parent MyC-CaP tumors. However, compared to in vitro, FOLH1 expression decreased by 10-fold in 33-day old tumors, likely due to immunoediting. Biodistribution studies demonstrated tumor MyC-CaP^{PSMA+} %ID/g was 33x higher compared to MyC-CaP tumors, with a Tumor/Kidney absorption ratio of 0.39, on par with other well-characterized models of mHSPC. 100% of MyC-CaP^{PSMA+} tumors treated with degarelix regressed for 20 days before rebounding.

Conclusion Here we reveal translationally relevant models of mHSPC and mCRPC for mechanistic investigations of α- and β-emitting RPTs. Leveraging these tools, we aim to study DNA damage and immune responses to generate foundational data to guide the development of combination therapies to improve outcomes of RPT for patients with mHSPC and mCRPC.

#2174 A comprehensive CRISPR/Cas9-based RAS knock-in cell line platform (50+ models) for assessing efficacy of KRAS-targeted inhibitors in RAS-mutant malignancies..

Lin Zhou, Guoqian Wang, Tingduo Lv, Zidan Su, Yue Huang, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., LTD, Beijing, China

The rat sarcoma gene (RAS) was the first discovered human proto-oncogene. Its product, the RAS protein, is a small guanine nucleotide-binding protein with intrinsic guanosine triphosphatase (GTPase) activity. Currently, three subtypes are known in the RAS family: KRAS, NRAS, and HRAS.RAS is a key mediator of the MAPK pathway. Activated RAS proteins bind GTP, while inactivated RAS proteins bind GDP; thus, the function of RAS proteins primarily depends on their GTP/GDP ratio. Missense mutations in the RAS protein alter the GDP/GTP homeostasis and lead to sustained activation of signaling pathways by reducing GTP hydrolysis (G12, Q61), increasing GTP loading rates (G13, K117), or affecting nucleotide exchange (A146). This uncontrolled signaling promotes unregulated cell proliferation and ultimately leads to carcinogenesis. RAS mutations occur most frequently in the KRAS subtype (>80%), followed by NRAS and HRAS. Notably, KRAS mutations are found in 97.7% of pancreatic ductal adenocarcinomas. In colorectal adenocarcinoma, multiple myeloma, lung adenocarcinoma, and cutaneous melanoma, the overall prevalence of RAS mutations is 52.2%, 42.6%, 32.2%, and 29.4%, respectively.For decades, RAS was notoriously considered an "undruggable" target, posing significant challenges for drug development. The approval of AMG510 (sotorasib) broke this barrier, proving that direct targeting of RAS is achievable. Since then, the field of RAS-targeted therapy has advanced remarkably, moving the "undruggable" label into the past. With deepening understanding, targeting RAS is poised to drive the next wave of breakthroughs in cancer treatment.Using CRISPR/Cas9 technology, we have developed over 50 knock-in cell line models with KRAS and NRAS mutations for evaluating KRAS-targeted inhibitors. These include common mutations such as G12C, G12D, and G12V, as well as various double and triple mutation combinations. This Ras knock-in mutant cell line platform stands as a powerful tool for developing and evaluating the next generation of RAS inhibitors.

#2175 Towards ethical and robust drug development: comprehensive validation of an animal-free matrix for in vivo tumor models.

Julia B. Schueler[1], Kanstantsin Lashuk[1], Philipp Meyer[1], Alejandra Ferrer Diaz[2], Eva Oswald[1], Kalhara Menikdiwela[2], JOHN HUANG[2]

[1]Charles River Laboratories, Freiburg, Germany,[2]theWell Bioscience, Monmouth Junction,, NJ

The 3R principles are embedded in regulatory frameworks and industry standards. However, drug development pipelines are highly standardized and validated over decades. Introducing new and adapting existing models requires extensive validation. The need to compare data before and after these adaptions can lead to inconsistencies and complicating interpretation. The aim of the current project is to introduce an animal-free matrix, VitroGel® (TheWell Bioscience), in our experimental pipeline, focusing on subcutaneously implanted human and murine cancer cell lines into mice. Of the 250 human and 38 murine cell line-derived models in our panel, 92 require the use of a matrix for optimal growth. To introduce the new matrix in a comprehensive way, we implemented a two-step process. At first, we validated the technical feasibility and the influence of the new matrix in two models, which are known to have low take rates and show experiment-limiting characteristics such as the onset of ulceration. The ovarian cancer cell line SKOV-3 and the breast cancer cell line MDA-MB-468 were implanted with two different cell numbers and three different matrices into NSG mice. Tumor volume was followed twice weekly, and in the case of SKOV-3, the time and degree of ulceration were plotted as well. In this experiment, we could show that SKOV-3 tumor growth and ulceration rate are independent of the matrix. For MDA-MB-468, the synthetic hydrogel induced faster tumor growth in the group receiving the higher cell numbers and vice versa. The histological examination of the tumors did not show any differences. Based on those results, we decided to fully implement the VitroGel hydrogel across all models. For each cell line, we injected 5 animals using hydrogel and 5 animals using Matrigel. Again, tumor volume was monitored by twice-weekly caliper measurements. To better understand the influence of the matrices in relation to other biological and technical parameters that influence tumor growth, we compared the actual wet lab data with our database of control groups, which is annotated for cell line passage, mouse strain, and control vehicle (Clark et al, Cancer research. 2023;83(7_Supplement):4676-4676). By feeding these data into the database, we were able to quantify the biological variability and determine whether the matrix had an influence on tumor growth beyond or within the range of the biological variability of the specific model. So far, we have tested 32 of 92 lines and have not observed significant differences driven by the choice of matrix. With this combination of wet lab experiments and in silico analysis, we can refine our in vivo experiments while minimizing the use of additional animals. Furthermore, this workflow ensures the consistency of data output from those experiments and enables the comparison of data before and after the implementation of the animal-free hydrogel.

#2176 Mutating E-cadherin in rats to model invasive lobular breast cancer.

Yuxiang Lin, Luyu Jia, Derrick Manosh Thomas, Wen Bu, Carolina Gutierrez, Yi Li

Baylor College of Medicine, Houston, TX

Background: Invasive lobular carcinoma (ILC) is the most common special histologic subtype of breast cancer, accounting for 8-14% of cases. Nearly 95% of ILCs are estrogen receptor positive (ER+) and managed with endocrine therapy. However, optimal rodent models are limited for studying ILC evolution and therapeutic vulnerabilities. Although mouse ILC models have been generated by mutating CDH1 (which encodes E-cadherin), a hallmark of ILC, but these tumors rarely show estrogen dependence. Rats, which have mammary biology more similar to humans, can easily generate ER+ and estrogen-dependent tumors. Our lab has successfully established ER+, estrogen-dependent ductal tumors in rats using intraductal CRISPR/Cas9 editing. Here, we aim to develop a rat model of ILC by targeting CDH1 and PIK3CA, the most frequently mutated driver in human breast cancer.
Methods: AAV-sgRNA constructs targeting CDH1 and activating PIK3CA^{H1047R} were delivered intraductally to induce somatic CDH1 loss and PIK3CA activation in rat mammary epithelial cells and drive tumor formation.
Results: AAV targeting CDH1 (AAV-C) efficiently induced knockout in Cas9-expressing rat primary cells in vitro, and deep sequencing confirmed high editing rates. Intraductal delivery of AAV inducing CDH1 loss and PIK3CA^{H1047R} activation (AAV-rPC) generated tumors with a latency of 2-3 months, significantly shorter than tumors induced by AAV-PIK3CA^{H1047R} alone (AAV-rP, ~4 months). Importantly, AAV-C alone did not induce tumors in the rat mammary gland, and AAV-rP did not generate lobular lesions. Somatic CDH1 knockout combined with PIK3CA^{H1047R} activation efficiently induced widespread LCIS and ILC. Mammary tumors induced by AAV-rPC were characterized by high ER and progesterone receptor (PR) expression with moderate Ki67 and were hormone-dependent. Ongoing studies are profiling tumor transcriptomes and immune features and comparing them with human ILCs.
Conclusion: CRISPR/Cas9-mediated targeting of CDH1 and PIK3CA in rats produces a clinically relevant ER+ ILC model.

#2177 Characterization of a panel of PDX models derived from PARP inhibitors pretreated breast and ovarian cancer patients for therapeutic evaluation.

Qingzhi Liu, Jinxi Wang, Leilei Chen, Wubin Qian, Likun Zhang, Ludovic Bourre, Jessie Jingjing Wang

Crown Bioscience, Inc., San Diego, CA

Introduction: Poly (ADP-ribose) polymerase (PARP) inhibitors benefit patients with homologous recombination-deficient cancers, especially BRCA-mutated, but resistance frequently emerges through multiple adaptive mechanisms, limiting long-term efficacy. To better recapitulate clinical resistance and advance precision therapy development, we established a panel of patient-derived xenograft (PDX) models from PARP inhibitors pretreated breast and ovarian cancers, providing a translational platform to investigate resistance mechanisms and assess novel treatment strategies.

Methods: Ten PDX models from patients pretreated with PARP inhibitors (Olaparib, Niraparib ± Bevacizumab), and Talazoparib + Avelumab) were established subcutaneously in immunodeficient mice (NOD.SCID, BALB/c nude, NSG-like) and characterized by histology and RNA sequencing. Homologous recombination-related alterations (BRCA1/BRCA2 mutations, PALB2 deletions) were present in some patients, and all had disease progression after PARP inhibitor therapy. For *in vivo* efficacy studies, three breast cancer PDX models were treated with Olaparib (100 mg/kg, p.o., QD) for 3-5 weeks following clinical schedule. Tumor growth inhibition (TGI) was calculated as [1 - (mean treated tumor volume / mean control tumor volume)] * 100%. Homologous recombination deficiency (HRD) scores from whole exome sequencing via scarHRD and PureCN used a cutoff of 38; high HRD scores (≥38) correlated with PARP inhibitors sensitivity.

Results: A panel of PAPR inhibitor clinical pretreated PDX models, including three breast cancer (BR9671, BR9679, BR9815) and seven ovarian cancer (OV9576, OV9670, OV9692, OV9563, OV9568, OV9803, OV9805), were established with comparable genomic profiles to the clinic. To evaluate the PARP inhibitor efficacy *in vivo*, BR9671, BR9679 and BR9815 derived from the same Olaparib-treated BRCA1 mutated patient were re-challenged with Olaparib. Tumor progression was observed in all three PDX models (TGI: BR9671=29.68%, BR9679=-9.30 %, BR9815=13.77%) despite high HRD scores (58, 59, and 64, respectively), indicating pronounced genomic instability. Besides, each model carried the MDM4-S367L mutation and had high MDM4 (BR9671: 3.654, BR9679: 3.755, BR9815: 4.539) and MDM2 (BR9671: 6.028, BR9679: 6.118, BR9815: 6.524) expression. As MDM2/MDM4 are known p53 suppressors, these findings suggest impaired p53 function may contribute to PARP inhibitor resistance; but further investigation is required.

Conclusion: By developing this panel of clinically PARP inhibitor pretreated PDX models, we established a translational platform that reflects clinical disease progression. These models enable investigation of resistance mechanisms and evaluation of next-generation therapies and combinations, supporting preclinical decision-making.

#2178 Integrating patient-derived tumor models into translational oncology and drug discovery.

Umar Khalid, Thomas Quinn, **Cong Fu**, Lucia Arabit Loosbrock, Anand Panigrahy, Aniket Shetty, Keith Ligon, Sonam Bhatia

Dana-Farber Cancer Institute, Boston, MA

Patient-derived tumor models provide powerful tools to investigate cancer biology and therapeutic responses in clinically relevant contexts. The Center for Patient-Derived Models (CPDM) at the Dana-Farber Cancer Institute is a collaborative research hub specializing in the generation, characterization, and application of patient-derived xenografts (PDX), patient-derived cell lines (PDCLs), and organoid/spheroid cultures to accelerate translational oncology. CPDM partners with both academic and industry researchers to enable data-driven drug discovery, preclinical validation, and functional precision medicine. The center maintains an extensive repository of patient-derived models spanning brain tumors, hematologic malignancies, and a broad range of solid tumors, each annotated with corresponding clinical and genomic data. These models are available to collaborators worldwide to advance translational and precision oncology research. To support precision oncology and preclinical research, CPDM has established automated imaging pipelines and standardized quantitative assays for real-time monitoring of growth and drug response in both 2D and 3D culture systems. In addition, the center's Functional Precision Medicine (FPM) platform integrates live-cell imaging and patient-specific drug screening to inform therapeutic selection and improve translational predictive accuracy. Together, these efforts position CPDM as a translational bridge between preclinical modeling and clinical application, facilitating data-driven collaborations that advance personalized cancer treatment.

#2876 Influence of transgenic MUC13 expression on gut microbiota and chemokine profile.

Swati Dhasmana, Anupam Dhasmana, Shweta Singh, Iris A. Perez, Shabnam Malik, Bilal B. Hafeez, Sheema Khan, Murali M. Yallapu, Subhash C. Chauhan

University of Texas Rio Grande Valley, McAllen, TX

Background: MUC13 is an important oncoprotein that is often overexpressed in cancers, including colorectal cancer, and is linked to worse outcomes, although its exact role is not fully understood. Using a MUC13 transgenic mouse model, we examined how MUC13 overexpression affects gut microbiome and cytokines that can influence cancer risk and treatment responses.
Methods: Fecal specimens were collected from MUC13-overexpressing transgenic mice (MUC13Tg) and wild-type mice. To assess the fecal bacterial communities, we performed DNA extraction followed by 16S rRNA metagenomic sequencing on the Illumina MiSeq platform. Additionally, colon tissues from MUC13Tg and wild-type mice were assessed by IHC to confirm the overexpression of MUC13. Furthermore, chemokine profiling analyses were performed using chemokines arrays in serum samples of MUC13-overexpressing mice and wild-type mice, respectively.
Results: IHC confirmed elevated MUC13 expression in the colon of transgenic mice, leading us to investigate associated changes in the gut and immune environment. 16S rRNA sequencing showed clear shifts in the gut microbiota, with increases in Alistipes, Clostridium_XIVa, Oscillibacter, and TM7 (25→35%, 1.6→11.6%, 8.3→16.6%, 2.5→6.6%) and decreases in Parabacteroides and Akkermansia (31.6→11.6%, 15→3.3%) compared with wild-type mice. These microbial alterations were accompanied by cytokine changes, including elevated EGF, FGF21, CD93, and Leptin, as well as reduced levels of cytokines such as Angiopoietin-1, CD14, HGF, and CCL17. Together, these results demonstrate that MUC13 overexpression not only shifts gut microbial composition but also modifies systemic inflammatory signaling.
Conclusion: This study suggests that MUC13 overexpression markedly alters the gut microbiome and cytokine expression profile in mice. The increased Firmicutes/Bacteroidetes ratio, enrichment of pro-inflammatory species, and repression of beneficial bacteria collectively indicate a shift toward gut dysbiosis and a pro-tumorigenic environment. These findings suggest that MUC13 plays a key role in shaping the gut microbial landscape and influencing immune modulation, both of which are important drivers of cancer development.

#2182 Upregulation of mitochondrial sirtuins in prostate cancer stem-like cells.

Shiv Verma[1], Leah Tharian[2], Jason A. Mears[3], **Sanjay Gupta**[4]

[1]Urology, Case Western Reserve University, Cleveland, OH,[2]Case Western Reserve University, Cleveland, OH,[3]Pharmacology, Case Western Reserve University, Cleveland, OH,[4]Case Western Reserve University School of Medicine, Cleveland, OH

Bone metastasis represents one of the most aggressive and painful late-stage manifestations of prostate cancer. Current treatments, primarily docetaxel-based chemotherapy with or without radiation, provide only temporary benefit, as relapses driven by therapy-resistant cancer stem-like cells (CSCs) are common. These CSCs are maintained by active gene networks that promote self-renewal through symmetrical division while retaining the ability for asymmetrical division and differentiation. However, the molecular mechanisms that govern CSC differentiation and therapy resistance remain poorly understood. To elucidate transcriptomic signatures associated with CSC differentiation, we profiled gene expression in androgen-repressive human prostate cancer C4-2B cells. CSC-enriched and non-CSC fractions were isolated using magnetic bead separation with CD133 antibody, followed by fluorescence-activated cell sorting and ALDH1 assay to identify the $CD133^{+}/ALDH1^{high}$ and $CD133^{-}/ALDH1^{low}$ populations. RNA sequencing revealed 33,676 expressed genes, of which 615 were significantly differentially expressed ($p < 0.05$). After false discovery rate correction, 56 genes remained significant ($q < 0.05$). Pathway analysis using QIAGEN Ingenuity Pathway identified activation of the sirtuin signaling pathway as a key feature in the CSC fraction, alongside enrichment of oxidative phosphorylation (OXPHOS), mitochondrial dysfunction, B cell receptor, CXCR4, Th2, IL17A, and TNFR2 signaling pathways. Transcript profiling of the sirtuin gene family (SIRT1-SIRT7) revealed marked upregulation of mitochondrial sirtuins: SIRT3, SIRT4, and SIRT5 in the $CD133^{+}/ALDH1^{high}$ population, consistent with enhanced OXPHOS activity relative to the $CD133^{-}/ALDH1^{low}$ cells. Network analysis further demonstrated that the SIRT3-SIRT4-SIRT5 interactome integrates into the NAD^{+} metabolic framework, connecting key enzymes involved in NAD^{+} synthesis and utilization, including NADSYN1, NMNAT1/2, NADK2, BST1, NNMT, and ENPP3. Notably, SIRT3 emerged as the central regulatory hub, coordinating interactions with SIRT4 and SIRT5 to sustain oxidative metabolism and suppress reactive oxygen species accumulation. This coordination promotes metabolic flexibility, redox balance, and resistance to differentiation cues which are hallmarks of CSC persistence and therapeutic resistance. Collectively, these findings identify mitochondrial sirtuins, particularly SIRT3, as key regulators of metabolic reprogramming and redox homeostasis in castration-resistant CSCs. Targeting mitochondrial sirtuin signaling, alone or with chemotherapy, represents a promising strategy to eliminate CSCs and prevent prostate cancer progression and bone metastasis.

#2183 FABP4 functions as a novel cancer stem cell marker in triple-negative breast cancer.

Huiyi Feng[1], Jinquan Xia[2], Fuhua Zhong[2], Yinghuan Cen[1], Lu Jiang[2], Pan Zhao[2], Lin Gao[2], Chang Zou[2]

[1]Shenzhen Hospital, Shenzhen Hospital of Southern Medical University, Shenzhen, China,[2]Shenzhen People's Hospital, Shenzhen, China

Anthracycline-paclitaxel (A/P)-based chemotherapy remains a cornerstone of triple-negative breast cancer (TNBC). However, chemo-resistance continues to compromise durable clinical benefit. Cancer stem cells (CSCs) are major contributors to tumor heterogeneity and therapeutic resistance. Identifying novel CSC-associated genes may provide new strategies for overcoming drug resistance in TNBC. Single-cell RNA sequencing on five paired TNBC tumors and adjacent normal tissues. FABP4 exhibited the strongest enrichment within the CSC-like population compared with luminal and basal epithelial cells. Spatial transcriptomics further confirmed the expression of FABP4 within CSC-enriched cell clusters. Integrated transcriptome profiling demonstrated significant upregulation of FABP4 in paclitaxel-resistant 4T1 cells, which was further validated in resistant and sphere-forming TNBC models across both 4T1 and MDA-MB-231 cells. Knockdown of FABP4 by siRNA markedly reduced spheroids-forming capacity of these breast cancer cells, supporting its functional role in maintaining the stemness in TNBC. Moreover, FABP4 was identified highly expressed and accompanied by CSC markers in TNBC clinical tissue by immunofluorescence, indicating its spatial and biological association with the CSC niche. Further studies are warranted to elucidate the mechanistic pathways through which FABP4 contributes to chemo-resistance and CSC stemness maintenance.

#2184 Defining cancer initiating cells and their vulnerabilities in renal cell carcinoma.

Zohreh Mehrjoo[1], Hellen Kuasne[2], Ariel M. Aguirre[1], Ozge Saatci[3], Ali Shahini[1], Matthew G. Annis[2], Anne-Marie N. Fortier[2], Tianyuan Lu[1], Larisa M. Soto[1], Hong Zhao[2], Dongmei Zuo[2], Virginie Pilon[2], Matthew Dankner[2], Tamiko Nishimura[1], Kevin Petrecca[4], Jonathan D. Spicer[5], Peter Siegel[2], Simon Tanguay[6], Hamed S. Najafabadi[1], Sahin Ozgur[3], Morag Park[2], Yasser Riazalhosseini[1]

[1]Department of Human Genetics, McGill University, Victor Dahdaleh Institute of Genomic Medicine at McGill University, Montreal, QC, Canada,[2]Rosalind and Morris Goodman Cancer Research Institute, McGill University, Montreal, QC, Canada,[3]Department of Biochemistry and Molecular Biology, Hollings Cancer Center, Medical University of South Carolina, Charleston, SC,[4]Montreal Neurological Institute and Hospital, Department of Neurology and Neurosurgery, McGill University, Montreal, QC, Canada,[5]Cancer Research Program, Research Institute of the McGill University Health Centre, Montreal, QC, Canada,[6]Department of Surgery, Division of Urology, McGill University Health Center, McGill University, Montreal, QC, Canada

Tumor initiating cells (TICs) drive tumor initiation, growth, therapy resistance, and metastasis, yet their molecular characteristics remain poorly defined in clear cell renal cell carcinoma (ccRCC). ccRCC is the most common form of kidney cancer, leading to 179,000 cancer-related deaths annually. We aim to identify ccRCC-TICs and their essential genes using a cell marker-agnostic strategy.We performed scRNA-seq on five ccRCC patient-derived xenograft (PDX) models and applied RNA velocity and CytoTRACE analyses to identify malignant cells that are origin for other cancer cells in each tumor. We identified a minor cell population (less than 15% of cells) as the origin of other tumor cells, representing putative CICs. Pathway and network analyses on the genes that were specifically up-regulated in the origin cells, suggested that a core network of proteins, regulated by PLK1-FOXM1 axis, conventionally known to regulate mitosis, are highly active in TICs and may be essential for their function.We validated the role if these proteins in tumor initiation in PDX and 3D patient-derived models of ccRCC, through functional experiments. These proteins were expressed in spheroids established following a TIC enrichment protocol. Spheroid cells exhibited higher tumorigenicity and colony formation ability compared to parental tumor cells, as confirmed by in-vivo injection in nude mice and in-vitro colony formation assays. Successive in vivo passaging confirmed the self-renewal capacity of spheroid-derived tumors. Pharmacological blockade of PLK1 with Volasertib elicited dose-dependent inhibitory effect on spheroid and colony formation, with in-vivo validation showing that blocking PLK1 significantly delayed tumor growth and more efficiently prevented tumor formation in nude mice. Cultivation of tumor cells isolated from treated PDX demonstrated loss of self-renewal and tumor-propagating capacity in these cells. Notably, RCC-TICs remained vulnerable to PLK1 inhibition despite bypassing mitotic arrest using TCMps1-12, revealing that PLK1 elicit its TIC-related functions independently from its canonical G2/M regulatory roles. RNA-seq analysis of treated models identified pathways in adhesion, cytokine signaling, immune evasion, and developmental self-renewal circuits, as potential processes mediating PLK1 roles in RCC stemness.Overall, we identified and validated essential proteins in RCC-TICs using single-cell transcriptome data, RCC spheroids, and PDX models. Targeting PLK1 disrupts the fundamental self-renewal and tumor-initiating capacities of ccRCC, offering a promising avenue for therapeutic intervention through PLK1 inhibition. Furthermore, our data uncover novel and non-canonical functions for PLK1, which upon further characterization may open new ways for combinational therapeutic strategies involving PLK1 and its effectors with standard of care in advanced ccRCC.

#2185 Trem1 sustains liver cancer stemness in hepatocellular carcinoma.

Ashwin Ajith[1], Arsha Sreekumar[1], Kanza Mamouni[2], Anatolij Horuzsko[2]

[1]Augusta University, Augusta, GA,[2]Augusta University, August, GA

Hepatocellular carcinoma (HCC) is the most common primary liver malignancy and a leading cause of cancer-related mortality worldwide. Although the Triggering Receptor Expressed on Myeloid Cells 1 (TREM1) is well known for shaping tumor-infiltrating myeloid populations and promoting an immunosuppressive tumor microenvironment, its tumor-intrinsic function remains poorly defined. Here, we identify a previously unknown function of TREM1 in sustaining the stem-like properties of liver cancer stem-like cells (LCSLCs). Flow cytometric analyses revealed high TREM1 expression within the $CD133^{+}EpCAM^{+}$ LCSLC population. CRISPR-Cas9-mediated knockout of TREM1 in HCC cell lines markedly impaired proliferation and migration while enhancing apoptosis. Specifically, in LCSLCs TREM1 deficiency reduced clonogenic growth and spheroid formation, indicating loss of self-renewal and stemness. Consistently, cell line-derived xenografts generated from TREM1-deficient LCSLCs exhibited substantially diminished tumorigenicity in vivo. Transcriptomic profiling of FACS purified LCSLCs demonstrated that TREM1 loss disrupted various nuclear and extracellular signaling programs associated with oncogenic and stemness pathways. Moreover, pharmacologic inhibition of TREM1 using the small-molecule antagonist VJDT phenocopied the tumor-suppressive effects observed in genetic knockout models. Collectively, these findings establish TREM1 as a critical intrinsic regulator of LCSLC survival and tumorigenic potential, independent of its immunomodulatory activity in the tumor microenvironment. Therapeutically, targeting TREM1 may offer a dual-action approach to simultaneously suppress cancer stem-like cell function and attenuate cancer progression in HCC.

#2186 Galangin effectively inhibits the proliferation and stemness characteristics of liver cancer stem cells by knocking down the expression of TINCR..

Amira S. Fyala[1], Mohamed M. H Elkewedi[2], Ahmed S. Sultan[3]

[1]Biochemistry Department, Faculty of Science, Alexandria University, Alexandria, Egypt,[2]Biochemistry Department, Faculty of Pharmacy, Alexandria University, Alexandria, Egypt,[3]Oncology Department, Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC

Hepatocellular carcinoma (HCC) is a leading cause of cancer-related deaths worldwide. Liver cancer stem cells (LCSCs) are thought to play a crucial role in its pathology, but their mechanisms in HCC remain poorly understood. TINCR (terminal differentiation-induced long non-coding RNA) influences cancer cell behavior in various malignancies, including HCC. Recent research has highlighted the potential of natural anticancer agents, particularly Galangin (GLN). This compound is recognized for its antibacterial, antifungal, and antiviral properties, and it may also contribute to managing conditions like hypertension, diabetes, and cancer prevention. However, the specific effects of GLN on HCC are still not fully understood. The present study aims to explore the molecular mechanism and anticancer properties of GLN on TINCR expression, which may influence the stemness characteristics of liver cancer stem cells (LCSCs). Our findings demonstrate that TINCR is highly expressed in LCSCs, suggesting that it is essential for maintaining the stemness properties and tumorigenesis of these cells. In the Wst-1 assay, GLN treatment exhibited a dose-dependent inhibitory effect on proliferation and induced significant morphological changes in LCSCs, indicative of apoptosis induction after 24 h of treatment. Furthermore, the expression of TINCR was significantly inhibited after 24 h of GLN treatment compared to the control. Western blot analysis and qRT-PCR were conducted to assess oncogenic signaling pathways, including β-catenin, mTOR, and STAT3, along with downstream targets. Our results indicated a significant reduction in cell viability and oncogenic signals, as well as in LCSC stemness markers, following GLN treatment combined with TINCR knockdown, suggesting that inhibiting TINCR expression alongside GLN treatment effectively disrupts oncogenic signals and inhibits LCSC stemness characteristics. In addition, TINCR knockdown significantly enhanced the antiproliferative effects and sensitivity to Doxorubicin. Our data introduce GLN as a promising, natural, and non-toxic anticancer compound, demonstrating its therapeutic potential for treating HCC by regulating the expression pattern of TINCR.

#2187 Direct regulation of the cancer stemness by eIF4A1 in triple-negative breast cancer.

Azeezat Oluwatobiloba Osikoya, Shobhit Srivastava, David Terrero, Dayanidhi Raman

Cell and Cancer Biology, College of Medicine & Life Sciences, University of Toledo-Health Science Campus, Toledo, OH

Triple-negative breast cancer (TNBC) is very aggressive with relapses after chemotherapy and high mortality due to metastases. Though there is an initial response to neoadjuvant chemotherapy (NACT) it frequently recurs leading to chemoresistance. Prior evidence points to a small population of chemoresistant tumor-initiating cells termed breast cancer stem-like cells (BCSCs). These cells exhibit intrinsic drug resistance and self-renewal capacity driven by pluripotency transcription factors (PTFs) such as SOX2, OCT4, NANOG, and KLF4. BCSCs survive following NACT, resulting in minimal residual disease (MRD), a clinically significant state of tumor persistence that seeds relapse, aggressive regrowth and metastasis. Our prior studies identified eukaryotic translation initiation factor 4A1 (eIF4A1) as an important regulator of cancer stemness in TNBC. Here, we investigate the mechanistic basis by which eIF4A1 helicase activity regulates cancer stemness that promotes MRD. To establish clinical relevance, we analyzed human TNBC biospecimens and matched adjacent normal tissues for PTFs expression. To demonstrate a causative role for eIF4A1 in sustaining cancer stemness *in vitro*, eIF4A1-knockout (KO) TNBC cells generated by CRISPR/Cas9 were rescued by ectopic expression of wild type (WT)-eIF4A1 and its helicase-defective mutants. Expression of PTFs was assessed by immunoblotting and qPCR, while measures of cancer stemness were evaluated by ALDH activity, tumorsphere formation, anchorage-independent growth, and 3D growth assays. To directly determine translational regulation of PTFs by eIF4A1, we employed a luciferase reporter system to measure eIF4A1-dependent translation through mutational analysis of 5′ untranslated regions (UTRs) of SOX2, OCT4, NANOG and KLF4 mRNAs. A significantly higher eIF4A1 and PTF protein levels were observed in TNBC but lower in adjacent normal area. Consistent with this, ectopic WT-eIF4A1 in the eIF4A1-KO background robustly significantly rescued PTF expression, tumorsphere formation efficiency, 3D-colony growth on Matrigel, and anchorage-independent growth. The helicase-defective mutants failed to restore PTF levels and stemness traits. Furthermore, total ALDH activity and expression of some ALDH isoforms followed a similar trend. Cloning of WT or mutant 5′-UTRs of PTFs and analysis of reporter luciferase activity confirmed that eIF4A1 can directly regulate the translation of PTF mRNAs and hence the PTF-driven cancer stemness program. Our findings demonstrate for the first time that eIF4A1 helicase activity directly governs a cancer stemness program in TNBC by promoting translation of PTF mRNAs harboring structured 5′ UTRs. Ongoing studies are assessing tumor initiation frequency *in vivo*. Thus, targeting the helicase activity of eIF4A1 may suppress cancer stemness, restore sensitivity to therapy, reduce relapses and improve longevity in TNBC.

#2188 Integrative transcriptomic profiling and flow cytometry analysis of AML PDX models identify purine-pyrimidine metabolic dependency shared in LSCs and blasts.

Kangsan Kim[1], Haiming Xu[1], Geoff Nelson[2], Tim Nieuwenhuis[2], Huiyun Liu[1], Justine Roderick-Richardson[1], Jessie Hao-ru Hsu[1], Brandon Willis[1], Lisa Drew[1], Omid Tavana[1]

[1]Hematology R&D, AstraZeneca, Waltham, MA,[2]Oncology Data Science & AI, AstraZeneca, Waltham, MA

Acute myeloid leukemia (AML) comprises a heterogeneous population in which leukemic stem cells (LSCs) can drive initiation, persistence, and relapse. While current standard of care effectively reduces disease burden, 30-80% relapse rates emphasize the need of investigating LSC as a potential driver of relapse. To better understand biology of LSC, we performed RNA-seq and flow cytometry analysis in AML patient-derived xenograft (PDX) models with defined LSC, progenitor, and blast compartments. Ex vivo culture conditions were optimized for AML PDXs to preserve subpopulation heterogeneity in vitro by supplementing cytokines. For RNA-seq, CD34/CD38 markers-based sorting isolated LSCs, progenitors, and blasts; differential expression analyses identified LSC-specific genes and shared vulnerabilities that could enable dual targeting of LSCs and blasts. For immunophenotyping, we developed a 20-color flow cytometry panel incorporating LSC, differentiation, and classic AML surface markers to quantify expression patterns across compartments. RNA-seq of sorted LSCs and blasts demonstrated differential expression between LSCs and blasts with a clear upregulation in the LSC17 score, consistent with previous results and confirming our data purity/quality. Flow cytometry panel also displayed differential surface marker expression across LSCs and blasts. Focusing on LSC-enriched biology first, we identified around 160 genes consistently upregulated in LSCs across 2 independent AML PDX models. These LSC-elevated targets showed limited dependency in DepMap (which have AML cell lines that represent blast), suggesting these genes may exert functional effects only in LSC, and not in blasts. To identify targets showing a dependency in all subsets, we implemented a blast-centric filter. We first selected AML dependency genes from DepMap and then intersected this set with genes highly expressed in both LSCs and blasts. This approach yielded 16 candidate genes with dual relevance. Functional annotation indicated that half of these genes map to purine/pyrimidine biosynthetic pathways, pointing to a metabolic vulnerability and supporting a potential dual-targeting strategy to impact both the LSC and blast population. Integrated transcriptomic profiling and flow cytometry analysis exhibit LSC-restricted programs while uncovering shared metabolic dependencies across LSCs and blasts. By combining expression with AML dependency data, we prioritized 16 dual-compartment candidates, where about half align to purine/pyrimidine biosynthesis nominating nucleotide metabolism as a potential axis for dual targeting. Together elevated LSC17 scores that confirm dataset quality, these findings provide a roadmap for target selection, patient stratification, and rational combinations aimed at durable remission and reduced relapse in AML.

#2189 Metabolic control of pancreatic cancer stemness through PDK3 dependent SOX2 lactylation.

Neelanjana Gayen, Nivedeta Krishna Kumar, Ayoola O. Ogunleye, Palanisamy Nallasamy, Venkatesh Varadharaj, Saravanakumar Marimuthu, Surinder K. Batra, Moorthy P. Ponnusamy

University of Nebraska Medical Center, Omaha, NE

Cancer stem cells (CSCs) pose a critical challenge in Pancreatic cancer (PC) management because of their unique ability to survive treatment and drive tumor relapses. CSCs exhibit metabolic flexibility to adapt to stress by switching between glycolysis and oxidative phosphorylation. Pyruvate dehydrogenase kinase 3 (PDK3) governs this transition by phosphorylating and inactivating the pyruvate dehydrogenase complex (PDHA), thereby promoting a glycolytic phenotype. Understanding the metabolic reprogramming that sustains cancer stem cells may reveal strategies to disrupt their survival and propagation. In this study, RNA sequencing of spheroid-based PCSC model followed by unbiased *in-silico* analysis identified 14 upregulated metabolic regulatory genes, with *PDK3* emerging as the top candidate. PDK3 expression was elevated in CSC subtype population, pancreatic tumor tissues from patients and Kras; PdxCre (KC) mouse models, but minimal in normal pancreatic tissues. Dual-IHC staining demonstrated co-expression of PDK3 with the stemness marker *CD44* in human pancreatic tumor tissues, highlighting its association with CSC phenotypes. Stable lentiviral-mediated shRNA knockdown (KD) or pharmacologic inhibition with artesunate (a PDK3 targeting compound identified in this study) significantly reduced stemness markers (CD44, SOX2, and CD133), glycolytic genes (GLUT1 and LDHA), and phosphorylated PDHA levels. Functionally, PDK3 depletion decreased the side-population fraction, impaired sphere-formation, and colony-forming capacities, suggesting suppressed sustenance and self-renewal properties. Metabolomic profiling by LC-MS revealed lactic acid as one of the most enriched metabolites in scramble PC cells compared to PDK3 KD cells. Consistently, metabolomic analysis revealed a significant reduction in lactic acid release and glucose uptake upon PDK3 KD. Seahorse analysis further demonstrated that PDK3 depletion lowered ECAR and elevated OCR, indicating a metabolic shift from glycolysis toward oxidative phosphorylation. Interestingly, elevated lysine lactylation and SOX2 expression were observed in control and lactate-treated PC cells, whereas both were markedly reduced upon glycolysis inhibition and PDK3 KD, indicating a strong dependence on PDK3-mediated metabolic activity. Mechanistically, immunoprecipitation and immunofluorescence revealed that PDK3 promotes lactate-dependent lysine lactylation of SOX2, enhancing its stability and stemness activity. Orthotopic implantation of PDK3 KD human PC cells resulted in significantly reduced tumor growth *in vivo*, underscoring PDK3's pivotal role in driving CSC-mediated tumor progression. In conclusion, our findings establish PDK3 as a central metabolic regulator of PCSC maintenance and tumor progression, offering new opportunities to develop therapies that disrupt lactate-fueled stemness in pancreatic cancer.

#2190 Trib3 identified as a key therapeutic target for pancreatic cancer stem cells.

Nirjhar M. Aloy[1], Kyle McAndrews[2], Adam Zulli[1], Kathryn Baldwin[1], Kristine Von Maltzan[1], Sarah Thayer[1]

[1]Surgery, LSU Health Shreveport (LSUHS), Shreveport, LA,[2]University of Nebraska Medical Center, Omaha, NE

Background: Pancreatic ductal adenocarcinoma (PDAC) is among the most lethal cancers, exhibiting early dissemination and chemoresistance. These features are attributed to a specialized subpopulation of cancer stem cells (CSCs). Our lab has defined the cell of origin for PDAC within the pancreatic duct gland (PDG) stem cell compartment, a region crucial for epithelial renewal. Creation and maintenance of the CSC pool is hypothesized to underlie aggressive tumor biology, but transcriptional networks in this compartment remain poorly characterized.
Objective: To define molecular pathways unique to pancreatic cancer stem cells (CSCs) that can be exploited as targeted therapies to eradicate CSCs while sparing normal pancreatic stem cells.
Methods: Genetically engineered mouse models and single-cell RNA sequencing were used to trace and compare CSC-enriched (TTKS) and normal (TT) PDG organoids. Key findings were validated in other mouse and human PDAC models.
Results: Single-cell analysis revealed broad upregulation of stem cell and CSC markers (Mthfd2, Slc7a5, Gadd45a), supporting conserved stem-like signatures in CSCs. Twelve genes were uniquely upregulated in PDAC CSCs, revealing new CSC-selective pathways. Trib3 was most strongly and widely upregulated among these, with multiple downstream regulators (β-catenin, FOXO1, ATF4) also enriched, indicating robust Trib3-driven network activation.
Conclusion: Identification of a discrete PDG stem cell origin for PDAC enables detailed interrogation of CSC biology. Our model demonstrates that PDAC CSCs activate unique survival and adaptation pathways, with Trib3 emerging as a central regulator. Collectively, this provides new mechanistic insight and positions Trib3 as a compelling CSC-targeted therapeutic candidate. Work is going on to understand the biological role of Trib3 in progression of CSCs in PDAC.

#2191 NQO1 inhibits FBXL14-dependent SNAIL degradation to promote EMT-mediated stemness in colorectal cancer cells.

Ha Gyeong Kim, Yunmi Cho, Eun-Taex Oh

Department of Biomedical Sciences, Inha University College of Medicine, Incheon, Korea, Republic of

Overexpression of NAD(P)H:quinone oxidoreductase 1 (NQO1) is associated with poor prognosis in various human cancers. In colorectal cancer (CRC), NQO1 overexpression is frequently associated with tumor progression and the formation of cancer stem cells (CSCs), which can drive therapy resistance, recurrence, and metastasis via their self-renewal and differentiation capacities. However, the precise mechanisms by which NQO1 regulates CSC traits remain poorly understood. Here, we investigated the functions of NQO1 in modulating CSC properties in human CRC cells. Knockdown of NQO1 in CRC cell lines markedly reduced colonosphere formation and downregulated the key stemness-related marker genes, *Nanog*, *Oct4*, and *Sox2*. Conversely, restoration of NQO1 expression in NQO1-knockdown cell lines rescued colonosphere-formation and restored the levels of these CSC marker genes. Further investigation revealed the modulation of NQO1 changed the expression and stability of Snail, a key transcription factor involved in CSC maintenance. Suppression of NQO1 downregulated Snail and its targeted CSC marker genes. NQO1 was found to directly bind the nuclear export signal (NES) domain of Snail to prevent its interaction with the E3 ubiquitin ligase FBXL14, which targets Snail for proteasomal degradation. This protective interaction stabilized Snail and enhanced its downstream stemness-related transcriptional activity. In line with these results, NQO1 knockdown enhanced the sensitivity of CRC cells to 5-FU and ionizing radiation. Importantly, Snail overexpression partially restored the resistance to these treatments in NQO1-suppressed cells, suggesting that NQO1 promotes therapy resistance by stabilizing Snail. Analysis of clinical CRC datasets demonstrated that there is a strong positive correlation between NQO1 and Snail-targeted CSC marker gene expression, and this was further correlated with poor prognosis in CRC patients. Our findings collectively suggest that NQO1 promotes CRC stemness and poor patient prognosis by stabilizing Snail. Targeting NQO1 may therefore represent a promising therapeutic strategy to eliminate CSCs and improve treatment outcomes in CRC.

#2192 SLFN5 mediates liquid-to-solid phase transition of NOTCH1 to suppress stemness and radioresistance of non-small cell lung cancer.

Mi Tang, Lu Zhang, Jiaxin Zhao, Hongji Dai, Zhiyong Yuan, Zeyun Mi, **Zhiqiang Wu**

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Radiotherapy remains one of the principal therapeutic modalities for non-small cell lung cancer (NSCLC), yet its therapeutic efficacy is frequently compromised by tumor recurrence, metastasis, and the development of radioresistance. Accumulating evidence identifies cancer stem cells (CSCs) as a critical driver of radioresistance. Therefore, elucidating the underlying molecular mechanisms and developing therapeutic targets to enhance radiosensitivity are of critical importance.
Methods: To identify key mediators of adaptive radioresistance in NSCLC, we established radioresistant NSCLC cell lines through repeated cycles of irradiation and subsequently performed RNA-seq analysis comparing them with their parental counterparts. The effects of SLFN5 on radiosensitivity were evaluated by flow cytometry and colony formation assays, and further validated in vivo using a nude mouse xenograft tumor model. Cancer stem-like properties were assessed by RT-PCR, Western blot, flow cytometry, sphere formation assay, and in vivo limiting dilution tumorigenesis assays. Subsequently, we employed mass spectrometry, co-immunoprecipitation, and proximity ligation assay to identify the interaction between SLFN5 and NOTCH1. Furthermore, phase separation assay, fluorescence recovery after photobleaching, CUT&Tag-seq, and ATAC-seq were used to investigate the role of NOTCH1 phase separation in promoting stemness and radioresistance, and the regulatory effect of SLFN5 on this process. Finally, the methylation status of the SLFN5 promoter was analyzed using bisulfite sequencing PCR.
Results: Our results demonstrate that SLFN5 was significantly downregulated in radioresistant NSCLC cell lines. Overexpressing SLFN5 effectively suppressed cancer stemness and epithelial-mesenchymal transition, thereby enhancing radiosensitivity both in vitro and in vivo. Conversely, knockdown of SLFN5 had significantly opposite effects. Mechanistically, liquid-liquid phase separation property is critical for NOTCH1 mediated stemness and radioresistance. Notably, SLFN5 interacts with NOTCH1 and induces the liquid-to-solid phase transition of NOTCH1, thereby impairing NOTCH1 signaling and the subsequent stemness and radioresistance. Finally, we identified DNMT3A and DNMT3B as the epigenetic regulators responsible for promoter hypermethylation and consequent silencing of SLFN5.
Conclusion: Our study reveals that DNA methylation downregulated SLFN5 resulting in radioresistance of NSCLC via liberating NOTCH1 from gel-like phase to liquid droplet to potentiating stemness of cancer cells. This research provides a potential therapeutic strategy to overcome radioresistance in NSCLC.

#2193 UPP1 promotes cisplatin-induced cancer stem cell enrichment in ovarian cancer via metabolic reprogramming.

Jessica J. Miao[1], Linzhou Wang[1], Ananya Banerjee[1], Na Li[1], Yajing Yang[1], Aidan Li[1], Kevin Wang[2], Patrick Stevens[2], Xiaoli Zhang[3], Qi-En Wang[1]

[1]Department of Radiation Oncology, Comprehensive Cancer Center, The Ohio State University, Columbus, OH,[2]Department of Bioinformatics, College of Medicine, The Ohio State University, Columbus, OH,[3]Biostatistics Core, College of Nursing, University of South Florida, Tampa, FL

Epithelial ovarian cancer (EOC) remains one of the leading causes of cancer-related mortality in women, largely due to late-stage diagnosis, recurrence, and resistance to chemotherapy. Growing evidence suggests that cancer stem cells (CSCs), a subpopulation of cancer cells that exhibit enhanced tumorigenicity and chemoresistance, are major drivers of these challenges. However, it remains unclear how CSCs maintain their stemness properties and survive chemotherapy. To gain deeper insights into the heterogeneity of ovarian cancer cells in response to cisplatin treatment, single-cell RNA sequencing (scRNA-seq) was conducted on spheroid-cultured ovarian cancer cells exposed to cisplatin. Following a two-week treatment period and a subsequent two-week recovery phase, several distinct clusters of cisplatin-surviving ovarian cancer cells were identified, exhibiting enhanced growth advantages. Analysis of the gene expression profiles of the cell clusters revealed that Uridine Phosphorylase 1 (UPP1) is highly expressed in clusters that survived cisplatin treatment compared to those eliminated by cisplatin. Given that cisplatin enriches CSCs and upregulates UPP1 expression, we sought to determine if UPP1 is linked to CSC properties. Our studies demonstrated that downregulation of UPP1 in CSCs impairs their self-renewal capability and their tumorigenic potential, establishing a causal relationship between UPP1 and the maintenance of CSC fitness and stemness in ovarian cancer. Further untargeted metabolomics analysis by LC-MS/MS indicated that UPP1 knockdown impacts several potential metabolic pathways, such as the “Superpathway of glycolysis, pyruvate dehydrogenase, TCA, and glyoxylate bypass” and “Superpathway of pentose and pentitol degradation”. This implies that UPP1 may bolster the stemness of ovarian cancer cells by reprogramming their metabolism, especially under cisplatin-induced stress. In summary, our findings reveal a novel mechanism through which cisplatin treatment enhances the stemness of ovarian cancer cells and promotes the expansion of the CSC population. Targeting UPP1 or UPP1-mediated metabolic reprogramming may represent a promising therapeutic strategy to improve ovarian cancer outcomes and reduce tumor recurrence after conventional platinum-based chemotherapy.

#2194 A PLK1-OCT4 regulatory axis controls lineage plasticity and neuroendocrine differentiation in prostate cancer.

Mohammad Esfini Farahani, Yanquan Zhang, Meng Wu, Ruixin Wang, Fatemeh Seilani, Xinyi Wang, Xiaoqi Liu

University of Kentucky, Collage of Medicine, Lexington, KY

Prostate cancer remains the most frequently diagnosed malignancy and a major cause of cancer-related death among men in the United States. A particularly aggressive subtype, neuroendocrine prostate cancer (NEPC), often emerges as a treatment-induced state in patients receiving prolonged second-generation anti-androgen therapies. NEPC tumors progress rapidly, respond poorly to conventional treatments, and are associated with markedly worse outcomes. This therapy-driven lineage switch highlights the need to define the molecular mechanisms governing neuroendocrine transformation and identify actionable vulnerabilities. PLK1 (Polo-like kinase 1) is a key regulator of mitosis and has been increasingly linked to prostate cancer progression. Our work identifies OCT4, a core pluripotency transcription factor, as a novel PLK1 substrate. We demonstrate that PLK1 phosphorylates OCT4 and promotes its degradation. In CRPC cells, short-term enzalutamide treatment elevates both stemness and neuroendocrine markers; however, with prolonged exposure, stemness features decline while neuroendocrine markers remain elevated, suggesting a transition from a transient stem-like state to a stable NEPC phenotype. We observed a similar plasticity pattern in 16D cells treated with enzalutamide, and in a DOX-inducible LNCaP Rb/p53 knockdown model, where DOX induction likewise promoted a shift toward neuroendocrine features. In N2P1 as a NEPC cells, knockdown or degradation of OCT4 further increased MYC and neuroendocrine markers, emphasizing OCT4's role in lineage balance and tumor plasticity. RNA-sequencing of N2P1 cells revealed significant elevation of MYC and BRD2, a BET-family chromatin regulator associated with MYC transcriptional control. Increased BRD2 expression, combined with enhanced MYC signaling, prompted us to investigate whether dual inhibition of PLK1 and BET proteins could more effectively suppress NEPC growth. To test this, we performed in vivo xenograft studies using pre-castrated NSG mice bearing N2P1 tumors and treated animals with vehicle, the PLK1 inhibitor Onvansertib, the BET inhibitor AZD5153, or the combination. Both single agents reduced tumor growth, but the combination therapy produced the most robust and sustained suppression, suggesting a synergistic effect and supporting co-targeting of PLK1 signaling and BET-driven chromatin regulation. Collectively, our findings reveal a critical role for the PLK1-OCT4 axis in prostate cancer plasticity and neuroendocrine differentiation. These results support a therapeutic strategy that simultaneously inhibits PLK1 and BET proteins as a promising approach to slow NEPC progression and improve patient outcomes.

#2195 The morphological discovery of the natural killer cells and enhancement of their activity using micellized nutraceuticals.

Jerry T. Thornthwaite[1], Olufemi Emmanuel Akanni[2], Daniel Strasser[3], Kyle A. Thornthwaite[1]

[1]Immunogenicity- Oncology, Cancer Research Institute of West TN, Henderson, TN,[2]Osun State University, Osogbo, Nigeria,[3]Immunogenicity- Oncology, miVital AG, St. Gallen, Switzerland

We observed that sheep erythrocytes and, later, Cancer Stem Cells (CSCs) are spontaneously destroyed by circulating lymphocytes without prior immunization. These lymphocytes, subsequently referred to as Natural Killer Cells (NKC), are the first line of defense in the blood against viruses and cancer stem cells. Much of our research has used nutraceuticals to enhance NKC activity against cancer cells. Our initial discovery of the NKC occurred while carefully observing non-immunized mouse lymphocytes centrifuged onto a lawn of sheep Red Blood Cells (SRBC) on a microscope slide. These “killer” lymphocytes would completely destroy the surrounding foreign erythrocytes on contact within a 15-minute incubation at 37 °C, forming clear plaques in a lawn of SRBC. We were able to purify these killer cells at least fivefold using continuous isotonic bovine serum albumin gradients (density = 1.0498) of normal mouse spleen cells. After glutaraldehyde fixation and Giemsa staining, Nomarski microscopy showed that the killer cells were small to medium lymphocytes. Scanning electron microscopy revealed a rough surface for these cells. Subsequently, a lawn of K562 leukemic stem cells was used as a target for the lymphocytes. We observed binding to the cancer cells, followed by the destruction of their cell membranes, as shown by Nomarski microscopy. The “blebbing” destruction of the K562 membranes is visualized in the transmission and scanning electron microscopy images. Interestingly, the NKCs exhibit pseudopodia membranes that resemble fangs, allowing them to deposit their venom into the cancer cell. Additionally, one can observe the rough endoplasmic reticulum aligning itself on the side where destruction occurs, indicating the production of cytolytic proteins. We have devoted significant research to identifying nutraceuticals that enhance NKCs and overall immunity, with an emphasis on increasing bioavailability through micellized formulations, which will be presented.https://youtu.be/HNP1EAYLhOs?si=QmsD3xDo5C9FrRZw

#2196 Matrix softness and fluid shear forceact through TRPV4 to promote ovarian cancer stemness, tumorigenicity and metastasis.

Zhenchuan LEI

The Chinese University of Hong Kong, Hong Kong, Hong Kong

Matrix stiffness and fluid shear force are key mechanical cues in ovarian cancer microenvironment that can impact cancer stemness, tumorigenicity and metastasis. However, the molecular identity of mechanosensors and/or mechanosensitive mediators that can be respond to matrix stiffness and fluid shear force in ovarian tumor microenvironment is unclear. TRPV4 is a mechanosensitive Ca^{2+}-permeable channel expressed in ovarian cancer cells. In the present study, we used 3D fibrin gel to enrich ovarian cancer stem cell (OCSC)-like cells. We found that matrix softness can increase the expression level of TRPV4 in OCSC-like cells. The activity of TRPV4 subsequently stimulates the growth of OCSC-like cells in tumor spheroids and increases the expression of OCSC markers in vitro, and promotes the growth of tumor xenografts in NOD/SCID mice in vivo. Atomic force microscope measurement of patients' samples and spatial transcriptome analysis of ovarian tumor database demonstrated that softer tumor regions have lower TRPV4 expression. Light-induced photolysis of 3D CarHc hydrogel, which rapidly dissipates the gel stiffness, elicited a TRPV4-mediated Ca^{2+} transient in the gel-encapsulated OCSC-like cells. Furthermore, we found that TRPV4 activity has positive feedback regulation on its own expression and that matrix softness may act through integrin β3 to stimulate TRPV4 activity. In another series of experiments, fluid shear force was found to directly stimulates the activity of TRPV4 channels, consequently elevating the expression level of OCSC markers, and promoting transwell migration of OCSC-like cells in vitro and peritoneal tumor metastasis in vivo. Taken together, the present study provides strong evidence that soft matrix and fluid shear act though mechanosensitive TRPV4 channels to promote ovarian cancer stemness, consequently aggravating ovarian cancer malignancy.

#2197 Mechanistic basis of panobinostat, venetoclax, and anti-CD40 combination therapy in the immune elimination of cancer stem cells.

Yishu Xu[1], Juraj Jakubik[2], Leoni Moldaner[1], Gautami Atul Gaidhani[1], Zuzana Tatarova[1]

[1]DKFZ German Cancer Research Center, Heidelberg, Germany,[2]Georg-Speyer-Haus, Frankfurt, Germany

Resistance in breast cancer treatment drives the search for new therapies. Cancer stem cells (CSCs) contribute to metastasis, recurrence, and therapy resistance. Our data suggest that combining panobinostat, venetoclax, and anti-CD40 (aCD40) immunotherapy effectively eliminates CSCs through immune modulation. This triple combination showed superior outcomes in three breast cancer mouse models, though its precise mechanism remains unclear. To dissect these mechansims, we use a multiplex implantable microdevice assay (MIMA) for precise drug delivery, cyclic immunofluorescence for tumor microenvironment characterization, and computational analyses to investigate treatment response and resistance. Single-cell RNA sequencing and multiplex tissue imaging map drug-induced cellular changes. Our results demonstrate that the panobinostat and venetoclax combination (PV) increase intratumoral immune infiltration, recruiting neutrophils, macrophages, and dendritic cells (DCs). Spatial analysis reveals APOE+ myeloid cells accumulating in PV-treated regions. Systemic PVaCD40 treatment enhances tumor killing, reduces CSCs, and improves antigen presentation by activating DCs and macrophages. Mechanistically, macrophages upregulate interferon-induced genes, boosting antigen presentation, while DCs regulate T cell migration and also increase antigen presentation. Interactions between CSCs and DCs/macrophages are elevated, and ligand-receptor analyses indicate that Mif-Cd74 and App-Cd74 signaling mediate CSC-immune cell communication. Collectively, these results provide a mechanistic framework for how Panobinostat-Venetoclax-Anti-CD40 triple combination therapy remodels the tumor microenvironment to eliminate breast CSCs and potentiate antitumor immunity.

#2198 Targeting Bmi-1 suppresses cancer stemness and tumor growth in mucoepidermoid carcinoma.

Satoshi Yamada, Kristy Warner, Jaqueline Vaz Vanini, Zhaocheng Zhang, Ririko Tsuboi, Jacques Eduardo Nor

Department of Cariology, Restorative Sciences, Endodontics, University of Michigan School of Dentistry, Ann Arbor, MI

Salivary gland carcinomas display considerable histopathological diversity and mucoepidermoid carcinoma (MEC) is recognized as the most frequent malignant subtype. However, chemotherapy provides limited benefit in MEC, highlighting the need for novel therapeutic approaches. Recent studies have highlighted the impact of cancer stemness in treatment resistance and tumor progression. Bmi-1 is a polycomb group protein and master regulator of stemness in head and neck cancers and therefore is a potential therapeutic target. This study aimed to evaluate the impact of therapeutic Bmi-1 in salivary gland MEC. Three MEC cell lines (UM-HMC-1, UM-HMC-3A, UM-HMC-3B) were treated with the Bmi-1 inhibitor PTC596 (Unesbulin), currently under clinical evaluation for solid tumors. Western blotting, flow cytometry, and sphere formation assays were performed. For Western blotting and flow cytometry, PTC596 was administered at 0-500 nM for 24-72 hours. Sphere assays in ultra-low attachment plates were performed with 0-100 nM for 10 days. Xenograft models were generated by implanting cell-seeded scaffolds of UM-HMC-3A and UM-HMC-3B into immunodeficient mice. When tumors reached 200 mm^3, mice were randomized to receive vehicle, 5 mg/kg or 10 mg/kg PTC596 every three days for 30 days. Tumor volume and body weight were recorded throughout treatment. We observed dose- and time-dependent inhibition of Bmi-1 protein expression in all MEC cell lines following PTC596 exposure. Flow cytometry revealed marked reductions in the fraction of $ALDH^{high}CD44^{high}$ cells, indicating effective targeting of cancer stem cells. Sphere formation assays further confirmed a significant dose-dependent decrease in sphere-forming capacity. *In vivo*, PTC596 induced rapid tumor regression, with tumors shrinking and remaining stably suppressed thereafter. Both 5 mg/kg and 10 mg/kg PTC596 regimens produced comparable antitumor effects. Importantly, mice maintained or gained body weight, and no overt treatment-associated toxicity was observed. Notably, PTC596 ablated cancer stem cells ($ALDH^{high}CD44^{high}$) and produced antitumor responses in preclinical salivary gland MEC models. Collectively, these findings provide compelling preclinical evidence that Bmi-1 represents a promising and clinically relevant therapeutic target for salivary gland mucoepidermoid carcinoma, supporting further translational and clinical investigation.

#2199 Dissecting ROBO4 function in regulating breast cancer cell plasticity.

Isobel J. Fetter[1], Veronica Haro Acosta[1], Paloma Medina[2], Shaheen S. Sikandar[1]

[1]Molecular, Cell, and Developmental Biology, UC Santa Cruz, Santa Cruz, CA,[2]Biomolecular Engineering, UC Santa Cruz, Santa Cruz, CA

Breast cancer is the most common cancer in women and the second-leading cause of cancer-related deaths in women. Breast cancer tumors are highly heterogeneous, with small populations of stem-like tumor-initiating cells that exhibit high cellular plasticity and often display both epithelial and mesenchymal characteristics (hybrid). These plastic stem-like cells contribute to tumorigenesis, so identifying and targeting these populations can lead to improved patient survival. ROBO1-4 proteins are transmembrane receptors that, with their SLIT1-3 ligands, regulate axon guidance, cell adhesion, mammary gland development, and angiogenesis. This signaling pathway is tightly regulated and has a wide variety of roles in normal development, but cancer is defined as abnormal development and frequently has alterations in signaling pathways. SLIT-ROBO signaling has been implicated in cell adhesion regulation in breast, lung, and colorectal cancer, but there is conflicting evidence on whether it is tumor-promoting or tumor-suppressive. Previous studies have shown that ROBO4 expression in endothelial cells suppresses breast cancer growth; however, ROBO4 has not been investigated in tumor epithelial cells. We have found that ROBO4 is expressed in epithelial breast cancer cells, and a high ROBO4+ epithelial fraction in basal-like tumor cells predicts worse survival in patients. ROBO4 knockdown in breast cancer cells reduces colony formation and proliferation, and increases apoptosis. Using patient-derived xenografts (PDXs) *in vivo,* constitutive ROBO4 knockdown reduced tumorigenesis, and inducible knockdown halted further tumor growth in pre-established tumors. Transcriptomic and proteomic analyses reveal enrichment of cancer stem cell and plasticity markers in control cells compared to ROBO4 knockdown, including *ALDH3A1, MSI2*, *CD44,* and *S100A4.* Flow cytometry analysis of tumor cells shows that knocking down ROBO4 reduces hybrid cells as measured by co-expression of CD44 (mesenchymal cells) and CD104 (epithelial cells). Preliminary results from ROBO4 overexpression tumors show an increase in hybrid $CD44^{+}/CD104^{+}$ cells, suggesting that ROBO4 maintains stem and hybrid populations in breast cancer. Gene Set Enrichment Analysis (GSEA) suggests Rho GTPase, Wnt/β-catenin, and Notch signaling are downregulated in *ROBO4* knockdown cells. These findings reveal a novel role for ROBO4 in maintaining stem-like and hybrid cell populations in breast cancer, with ROBO4's location on the cell surface providing an attractive target for potential therapeutic applications.

#2200 The mesenchymal state drives stemness and limits differentiation in glioblastoma.

Emanuele Filiberto Rosatti, Denise Sighel, Anna Veronese, Toma Tebaldi, Alessandro Quattrone

Department of Cellular, Computational and Integrative Biology, University of Trento, Trento, Italy

Glioblastoma is a highly heterogeneous and lethal brain cancer with limited therapeutic options. Recent single-cell omics studies have emphasized the importance of the proneural-mesenchymal axis and strengthened the link between glioblastoma and neurodevelopment, yet the identity and regulatory drivers of glioblastoma stem cells remain poorly defined. In this work, we combined published single-cell datasets with in vitro models to investigate glioblastoma stemness and the tumor's response to differentiation cues. Through integrative analysis of single-cell RNA sequencing and single-nucleus ATAC sequencing, we refined the landscape of glioblastoma cellular states. Comparison with human subventricular zone profiles reveals a striking similarity between a mesenchymal-like subpopulation and adult radial glia. We further established a comprehensive differentiation assay incorporating phenotypic, transcriptomic, and proteomic readouts. Using this system, we show that glioblastoma cells exhibit heterogeneous responses to differentiation signals and that mesenchymal-like cells, in particular, display pronounced resistance to lineage commitment. Together, these findings highlight the mesenchymal state as a key barrier to differentiation in glioblastoma and lay the groundwork for targeting its underlying drivers to restore differentiation capacity and potentially improve therapeutic outcomes.

#2201 Multidimensional transcriptomic alas of recurrent uterine leiomyosarcomas uncovers stem-like hormonal cells with high drug sensitivity and improved patient outcomes.

Maria Moozhiyil Korah[1], James P. Agolia[1], Biren Reddy[1], Renceh A. B. Flojo[1], Amanda Goncalves[1], Lilin Wang[2], Rosyli F. Reveron-Thornton[1], Chuner Guo[1], Beatrice Sun[1], Amanda R. Kirane[1], George Poultsides[1], Deshka Foster[1], R. Stephanie Huang[3], Gregory W. Charville[1], Michael T. Longaker[1], Daniel Delitto[1]

[1]Stanford University, Stanford, CA,[2]University of Minnesota, Minneapolis, MN,[3]Asst. Professor, Dept. of Medicine, University of Minnesota, Minneapolis, MN

INTRODUCTION: Uterine leiomyosarcomas (ULMS) are rare, aggressive tumors with profound genomic heterogeneity, which has precluded the identification of effective targeted therapies. The overall purpose of this study was to investigate the transcriptomic and spatial landscape of ULMS to identify new therapeutic avenues.

METHODS: We performed single-cell RNA sequencing (scRNA-seq) on fresh ULMS tumors using the 10X Genomics platform and spatial transcriptomics on FFPE sections using the Singular G4X platform. Resulting cells were integrated with scVI or resolVI and annotated using canonical markers. Tumor signatures were correlated with patient outcomes using bulk RNA sequencing data and novel drugs predictions for each tumor cell subtype were computed using the scIDUC algorithm.

RESULTS: ScRNA-seq was performed on 15 recurrent, metastatic ULMS tumors from 13 patients at the time of debulking surgery, which yielded 204,250 high quality cells. Spatial transcriptomics was performed on 29 sections from 10 patients, which yielded 2.3 million spatially resolved cells. Both assays revealed heterogenous tumor microenvironments comprised of several types of cells, including myeloid cells, lymphoid cells, endothelial cells, and tumor cells. Among the tumor cells, three prevalent subtypes emerged: 1) interferon-signaling cells that were distributed throughout sections, 2) mesenchyme-like cells arranged in nest-like configurations and around blood vessels, 3) ischemic cells with a high ribosomal signature organized around necrotic penumbras. Additionally, dedifferentiated stem-like cells with high expression of *ESR1*, *PGR*, and *AR*, along with Wnt signaling pathway markers, were scattered throughout tumor sections. These hormonal cells clustered into two subtypes on scRNA-seq: 1) those with high ESR1 and low AR/PGR and 2) those with low ESR1 and higher AR/PGR expression. These cells were the most sensitive to all interrogated drugs, including current first-line therapies gemcitabine, docetaxel, and doxorubicin. All other tumor subtypes were highly resistant to most drugs, though several alternative drug candidates uniquely targeting each tumor subtype were identified. Furthermore, by correlating with bulk RNA sequencing, each tumor subtype was shown to be associated with unique patient outcomes. AR and PGR hormone receptor-expressing cells correlated with improved patient survival, whereas ischemic cells correlated with the worst survival outcomes.

CONCLUSIONS: We present a comprehensive atlas of ULMS, identifying several transcriptomic subtypes of tumor cells, including dedifferentiated stem-like hormonal cells that correlate with better drug sensitivity and improved patient outcomes. Findings from this study may further facilitate patient prognostication and guide targeted therapeutic management.

#2202 APOBEC3C rewires RNA splicing and self-renewal in hematopoietic stem and progenitor cells.

Inge van der Werf[1], Jane Isquith[1], Emma Klacking[1], Jessica Pham[1], Wenxue Ma[1], Shuvro P. Nandi[2], Rongjie Wu[2], Claire Engstrom[1], Neha Katragadda[1], Anna A. Khachatrian[3], Thomas Whisenant[2], Ludmil Alexandrov[2], Catriona Jamieson[1]

[1]Sanford Stem Cell Institute, UC San Diego, La Jolla, CA,[2]UC San Diego, La Jolla, CA,[3]Scripps Health, La Jolla, CA

Introduction Inflammatory cytokine-responsive APOBEC3 cytosine deaminases promote antiviral defense through DNA and RNA editing and, when deregulated, drive somatic mutations and cancer progression. While APOBEC3A and APOBEC3B are well studied, the role of APOBEC3C remains less defined. However, our recent whole genome and whole transcriptome analyses of myeloproliferative neoplasm (MPN) derived hematopoietic stem and progenitor cells (HSPCs) revealed that APOBEC3C is highly expressed in this context, suggesting a context-specific function in hematopoiesis. This observation prompted us to investigate the effects of APOBEC3C, alongside other APOBEC family members, on HSPC biology, with an emphasis on their roles as drivers of clonal hematopoiesis (CH) and myeloid disorders in the context of aging and inflammation.

Methods We collected healthy cord blood (CB) and aged bone marrow (ABM), and lentivirally transduced immunomagnetic bead-selected $CD34^+$ cells with APOBEC3B, C, D, F, or G, or pCDH lentiviral backbone controls. Subsequently, we performed whole genome and transcriptome analyses and assessed C-to-T DNA mutations, C-to-U RNA edits and differential gene expression. As widespread changes in RNA splicing where observed as well as widespread changes in expression of genes implicated in CH upon lentiviral transduction of APOBEC3C, we also performed dual fluorescent splicing reporter assays, survival and self-renewal assays, and in vivo engraftment studies, respectively.

Results We discovered that APOBEC3C and 3F, induce more DNA mutations, whereas APOBEC3B, 3C and 3G disrupt RNA splicing. We observed differential expression of genes crucial for hematopoiesis, such as ZRSR2, U2AF1, and SRSF2, as well as differential exon usage and enrichment of the spliceosome pathway. Additionally, we demonstrated that APOBEC3C induced substantially greater transcriptomic effects in ABM HSPCs compared to CB HSPCs. We observed a 10-fold increase in differential gene expression, including alterations in ribosomal genes (RPS19 and RPL5), alongside splicing factors (U2AF1, ZRSR2, and SF3B2) implicated in CH, MPN, and myelodysplastic syndrome (MDS) pathogenesis. Moreover, in ABM HSPCs, APOBEC3C was found to affect CH-associated transcripts, including DNMT3A, enhance ADAR1-mediated RNA editing, and increase self-renewal capacity. Consistent with these findings, APOBEC3C is elevated in $JAK2^+$ MPN HSPCs, while its knockdown reduced $JAK2^+$ MPN $CD34^+$ self-renewal and ADAR1 reporter activity.

Conclusion In conclusion, these findings demonstrate that APOBEC3C modulates RNA splicing and C-to-U RNA editing in CB derived HSPCs, with more pronounced effects in ABM derived HSPCs. In ABM, this also includes increased ADAR1p150 expression and elevated A-to-I editing, which combined with increased HSPC expansion, may contribute to the pathogenesis and progression of myeloid disorders.

#2203 PSMD2 Suppression Disrupts Autophagy Turnover and Creates an Autophagy-Dependent Vulnerability in ER+ Breast Cancer.

Yejoo Lee[1], Ju Hee Kim[2], So-Youn Jung[3], Wonshik Han[4]

[1]Integrated Major in Innovative Medical Science, Seoul National University Graduate School, Seoul, Korea, Republic of,[2]Center for Medical Innovation, Seoul National University Hospital, Seoul, Korea, Republic of,[3]National Cancer Center - Korea, Goyang-si, Korea, Republic of,[4]Seoul National Univ. College of Medicine, Seoul, Korea, Republic of

Background: The ubiquitin-proteasome system (UPS) and autophagy cooperate to maintain protein homeostasis, yet how these pathways interact to regulate breast cancer stem cells (BCSCs) remains unclear. PSMD2, a 19S regulatory subunit of the proteasome, has been linked to poor outcomes in several cancers, but its role within the autophagy-proteostasis network in ER$^+$ breast cancer has not been defined. Here, we examined how PSMD2 influences CSC maintenance and drug response through UPS-autophagy crosstalk and explored how its suppression alters autophagy regulation and CSC vulnerability in ER$^+$ breast cancer.
Methods: Stable PSMD2 knockdown (ShPSMD2) lines were generated in ER$^+$ breast cancer cells (MCF-7, ZR-75-1). Autophagy was modulated using hydroxychloroquine (HCQ). Western blotting assessed CSC-related markers (SOX2, OCT4, NANOG), EMT markers (E-cadherin, N-cadherin, Vimentin), and autophagy proteins (LC3B-II, p62, p-mTOR). Functional assays, including MTT viability, colony formation, migration, and invasion, were performed to evaluate PSMD2-dependent phenotypes. Mammosphere and viability assays assessed CSC formation and HCQ sensitivity. Tumor growth and metastasis were tested using mammary fat-pad and tail-vein xenografts in NSG mice.
Results: PSMD2 depletion reduced CSC frequency, mammosphere formation, and colony formation, with decreased stemness markers (SOX2, OCT4, NANOG) and reversal of EMT features, shown by lower N-cadherin, Vimentin, and Snail. Loss of PSMD2 resulted in LC3B-II and p62 accumulation with mTOR suppression, indicating impaired autophagy turnover and disrupted proteostasis. PSMD2-deficient cells displayed reduced migration and invasion and were more sensitive to HCQ-induced cytotoxicity. HCQ treatment further lowered PSMD2 protein levels in a dose-dependent manner, implying feedback destabilization of the proteasome under lysosomal stress. This correlated with loss of $CD44^+/CD24^-$ CSC-like populations and reduced sphere-forming ability. In xenografts, PSMD2 knockdown suppressed tumor growth and lung, liver metastasis, suggesting that PSMD2 is a critical node linking proteostasis to metastatic progression.
Conclusions: PSMD2 depletion disturbs UPS-autophagy coordination, leading to loss of proteostasis and CSC depletion in ER$^+$ breast cancer. This insight reveals PSMD2 as a key regulator of proteolytic balance and a potential target for autophagy-based therapeutic strategies.

#2204 ID proteins regulate IL-6 expression and cancer stem-like cell features following chemotherapy in ovarian cancer.

Megan A. Keene[1], Mikella Robinson[2], Darren Lighter[3], Carrie D. House[2]

[1]Cell and Molecular Biology, San Diego State University / University of California San Diego, San Diego, CA,[2]San Diego State University, San Diego, CA,[3]Cell and Molecular Biology, San Diego State University, San Diego, CA

Ovarian cancer (OC) remains the most lethal gynecological cancer. Discreet OC symptoms lead to late stage diagnosis, limiting treatment options. Most patients are initially responsive to chemotherapy, but over 80% of advanced cases relapse with treatment-resistant disease within 2 years. Cancer recurrence has been attributed to a small subpopulation of cancer stem-like cells (CSCs) that possess the ability to resist chemotherapy, self-renew, and asymmetrically divide. ID1-4 proteins, also known as inhibitors of differentiation, regulate cell fate and differentiation in normal stem and progenitor cells. In gliomas, ID1-4 proteins have been identified as master transcriptional regulators of CSC identity, signaling to downstream pathways important for self-renewal, tumor initiation, and survival; however, their role in OC CSCs and recurrence is unclear. Recently, we found that ID1-3 gene expression significantly increased following chemotherapy treatment in OC clinical samples and cell lines, and higher gene expression of ID1 and ID3 was associated with worse clinical outcomes. We hypothesize that ID proteins are required for OC CSC survival, self-renewal, and tumor recurrence following chemotherapy. In a subcutaneous xenograft mouse model, we found that cancer cell ID2 and ID4 protein expression significantly increased within 3 days following carboplatin treatment compared to vehicle groups, but this trend waned at later time points. Furthermore, we saw ID1-4 gene expression significantly increased stepwise following one and two cycles of chemotherapy in OVCAR8, OVCAR4, OVCAR5, and OV90 OC cell lines. Using a pan-ID inhibitor, AGX51, we have significantly knocked down ID expression in the four OC cell lines, and quantified CSC presence and function. Our data shows ID inhibition in OC cell lines reduces chemotherapy-dependent increases in CSC marker expression by flow cytometry (ALDH), spheroid formation, and gene expression of SOX2 and IL-6. Future studies will utilize siRNA silencing to elucidate the ID-dependent mechanisms of chemotherapy-induced SOX2 and IL-6 expression and how this contributes to OC survival. These studies highlight a novel target important in CSC maintenance that contributes to tumor progression and relapse. Understanding these mechanisms will enable development of therapies to overcome chemotherapy resistance and relapse, ultimately improving clinical outcomes.

#2205 Isoform-level transcriptome analysis for enriched cancer stem cells from patient-derived ovarian cancer cell lines.

Rachel S. Perkins[1], Jisun Kang[1], Matthew S. Jung[1], Sue Chin Lee[2], Wenjing Zhang[1], Won-Young Choi[1]

[1]Department of Pathology, University of Tennessee Health Science Center, Memphis, TN,[2]Department of Physiology, University of Tennessee Health Science Center, Memphis, TN

Background: In high-grade serous ovarian cancer (HGSOC), the abilities of tumor cells to resist cytotoxic treatment and relapse are largely driven by ovarian cancer stem cells (CSCs). CSCs are a population of cells within a tumor that maintain stem-like qualities, such as self-renewal and asymmetric division, but also have the capacity to produce metastasis and drive drug resistance. Despite extensive research over the past two decades, no specific CSC target has been identified in ovarian cancer, and no drug has proven effective in neutralizing the CSC population. Therefore, identifying the molecular mechanisms underlying CSC development in HGSOC is urgently needed, as eradicating CSCs represents one of the most formidable challenges in oncology, yet also offers one of the most transformative opportunities to alter the course of cancer therapies. Based on the emerging evidence of linking differential isoform usage to the regulatory mechanisms of developmental process, we hypothesize that CSCs exploit isoform diversity to sustain stemness, drive therapy resistance, and shape prognosis while gene-level programs shape general differentiation status.
Methods: We employed CSC-enriched sphere culture system to emphasize the features of CSC population from 3 patient derived high grade serous ovarian carcinomas (PD-HGSOC) with different metastatic abilities and tumor aggressiveness. For these cell lines, we generated RNA-seq data for genome-wide transcriptome profiling to investigate stemness and differentiation status comparing standard culture condition and CSC-enriched spheres. In this study, we analyzed RNA-seq data in gene-level as well as in isoform-level with the most up-to-date transcript annotation to identify patient-specific CSC features and define the mechanism of cancer related stemness and plasticity.
Results: We analyzed gene-level transcriptome profiles focusing on stemness signatures in PD-HGSOC and CSC-enriched spheres. We observed that CSCs exhibited markedly higher stemness characteristics and identified differentially expressed gene sets across PD-HGSOCs. We noted that each cell line had a distinct subset of genes regulating stemness which suggested multiple mechanisms of CSC development and maintenance. In result of isoform-level analysis, we found that a large proportion of gene-level expression changes were driven by the differential expression of a single predominant isoform. Importantly, our isoform-level analysis enabled the identification of differential isoform usage that would not be detected at the gene level expression analysis, as changes in isoform composition can occur while total gene expression remain unchanged. These results are instrumental for foundational understanding of CSC plasticity and for next generation drug design, increasing target specificity and reducing adverse effects.

#2206 Uncovering a pancreatic ductal adenocarcinoma sub-population with stemness and unique therapeutic response.

SHIFA KHAN, Wen-Cheng Chung, Charles D. Moore, Keli Xu

University of Mississippi Medical Center, Jackson, MS

Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies, primarily due to its detection at advanced stages, with therapy resistance being the second major cause, leading to limited treatment options. It is well established that pancreatic differentiation is controlled by Notch during organogenesis, and its reactivation is seen in pancreatic tumorigenesis. The regulation of Notch signaling and its relationship with pancreatic exocrine and endocrine cells in pancreatic cancer is still unclear. Therefore, this study was designed to investigate the role of Notch in PDAC initiation and progression with respect to different cells of origin, along with a significant focus on understanding the potential of these cells to behave like cancer stem cells. The two different types of PDAC cells, derived from primary mouse tumors with Kras mutation and p53 deletion, were tested for their sensitivity to various pharmacological inhibitors. These cells originated from Lunatic Fringe (Lfng)-expressing centroacinar cells (CAC) and Mist1-expressing acinar cells. The subsets of $Lfng^+$ tumor cells in these two types of PDAC were sorted for the tests in comparison with their $Lfng^-$ counterparts. The protein expression of Notch receptors was analyzed along with their downstream targets. The cells isolated from mice harboring PanIN lesions (not yet developed into PDAC) were examined for their organoid-forming capability to trace which lineage of PDAC cells carries the stem-like properties. Finally, the organoids were analyzed for various markers of pancreatic progenitors and stem-like characteristics to gain insight into the subset of pancreatic cells involved in the initiation of PDAC. It was found that the PDAC cells derived CAC population has an inherent property of behaving as cancer stem-like cells. These cells were highly resistant to the inhibitory effects of the chemotherapy drug gemcitabine compared to acinar-derived PDAC cells. However, they were uniquely sensitive to a gamma-secretase inhibitor, which blocks Notch activation. High expression of Notch3 and Hes1 was predominantly found in the CAC-derived PDAC cells, along with the high efficiency in forming 3D organoids, even at the early stage of tumor initiation. The organoids were found to co-express ductal (CK19) and acinar (Amylase) cell markers, containing cells expressing the pancreatic progenitor marker (Pdx1), stem cell marker (Aldh1a1), and Vimentin-expressing cells, which represent a more aggressive and metastatic subpopulation. These findings hold significant potential in unraveling treatment options and screening patients based on the subtype of the PDAC population. The full potential of GSI needs to be explored for its use as a treatment option alongside other available chemotherapy drugs. Targeting Lfng-dependent Notch signaling may offer an option for treating patients with CAC-derived PDAC.

#2207 The impact of tumor treating fields (TTFields) on the transcriptome and the secretome of cancer stem-like cells isolated from the sub-ventricular zone of glioblastoma patients.

Rachel B. Sidebottom[1], Antonia E. Sajche Sapon[1], Yamhilette Licon-Munoz[1], Christian A. Bowers[2], **Sara G.m. Piccirillo**[1]

[1]Cell Biology and Physiology, University of New Mexico Health Sciences Center, Albuquerque, NM,[2]Neurosurgery, University of New Mexico Health Sciences Center, Albuquerque, NM

Glioblastoma (GBM) is the most aggressive brain tumor in adults that almost inevitably recurs despite radical treatments. Recurrence is driven by residual disease, which is extremely difficult to identify and target. We were the first to identify and characterize specific anatomic/functional areas of residual disease in GBM patients, including the sub-ventricular zone (SVZ), the most well-characterized neurogenic area in the mammalian brain. Specifically, we showed that the SVZ is a reservoir of cancer stem-like cells (CSCs) seeding recurrence. Thus, the SVZ holds the key to identifying novel therapeutic targets for GBM patients. We previously evaluated the impact of Tumor Treating Fields (TTFields) - electric fields exerting physical forces on tumor cells - on the morphology and proliferation of CSCs isolated from the SVZ of GBM patients. We observed that the proliferation of CSCs resistant to Temozolomide and ionizing radiation is significantly inhibited by TTFields when cells are exposed for 48 hours to the optimized frequency for GBM (200 kHz). Moreover, we observed that this antiproliferative effect of TTFields is maintained among patients. In our recent work, we examined the impact of TTFields on the transcriptome and secretome of CSCs isolated from the SVZ of GBM patients using single-cell transcriptomics and functional phenotyping. First, we isolated and characterized 10 CSCs. These cells were maintained in conditions that preserve the molecular profile of the original patient tumor, thus representing *bona fide* models to study the impact of TTFields on GBM residual disease. Second, we used the 10x Genomics platform and the Bruker single-cell proteomic barcoding solution to perform single-cell transcriptomics and functional phenotyping. Our results indicate changes in the transcriptomic profile of CSCs after TTFields compared with matched untreated cells. Specifically, TTFields altered the expression of genes related to cell cycle and GBM cell states. Moreover, functional phenotyping analysis of the innate immune cytokine secretome revealed that CSCs treated with TTFields secrete less VEGF and more soluble CD137 (sCD137) than untreated cells. CD137 is a member of the TNF family contributing to the activation of cytotoxic responses in T cells, while sCD137 exhibits immunoinhibitory functions. Clinical trials involving agonistic anti-CD137 antibodies(Abs) that also counteract sCD137-mediated immunoinhibition are currently underway in patients with advanced tumors. Combined with TTFields, these Abs offer a novel therapeutic opportunity for the treatment of GBM. Collectively, our results point to the effectiveness of TTFields in GBM and identify a novel therapeutic target in GBM residual disease.

#2208 MAP2-mediated integrin dysregulation reprograms cancer cell plasticity to drive liver cancer cell transition to a mesenchymal and stemness state in hepatocellular carcinoma.

Ut Kei Lou[1], Tin-Lok Wong[1], Huajian Yu[1], Ki-Fong Man[1], Ka-Hei Lam[1], Jia Jian Loh[1], Lei Zhou[2], Yuan Gao[3], Cheng-Han Yu[1], **Stephanie Ma**[1]

[1]School of Biomedical Sciences, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong,[2]Precision Medicine Institute, The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China,[3]State Key Laboratory of Cancer Biology, Biotechnology Centre, School of Pharmacy, Fourth Military Medical University, Xi'an, China

Targeting tumor cell plasticity is central to overcome drug resistance and metastasis, two major obstacles in eradicating cancer. Through lineage-tracing and lineage-ablation studies, our team has previously shown hepatocellular carcinoma (HCC) cells marked by prominin-1 (CD133) to represent a functional subset displaying dedifferentiated status with stemness traits, yet there are limited therapies effective for eradicating such resilient cell populations. To address this unmet clinical need, we explore the therapeutic potential of repurposing an existing drug estramustine phosphate (EMP) for targeting HCC plasticity through inhibiting microtubule associated protein 2 (MAP2), a gene uniquely enriched in CD133+ 'HCC' stemness subset but not in CD133+ 'normal' regenerative cells. MAP2 is transcriptionally activated by p300-driven histone 3 lysine 27 acetylation, and its upregulation is associated with aggressive clinical features. Functional characterization demonstrates that MAP2 confers tumor-initiating and migratory abilities to HCC cells both in vitro and in vivo, and enables cells to resist cell apoptosis upon sorafenib treatment. Comparative transcriptome profiling and pathway analysis by Gene Set Enrichment Analysis and Gene Ontology identifies a pan-deficiency of integrin α expressions and depletion of integrin-directed adhesion pathways upon MAP2 overexpression. Mechanistically, MAP2 sustains tumor plasticity and transition to a mesenchymal phenotype through inducing filamentous actin polymerization and activation of yes-associated protein (YAP), which subsequently disrupts integrin-mediated cell adhesion behaviors on type I collagen. Of note, pharmacological inhibition of MAP2 effectively sensitizes HCC to targeted therapy sorafenib in HCC cells lines, patients-derived organoids and immunocompetent HCC mice model. Collectively, our research offers a promising opportunity for drug repurposing using EMP in combination with sorafenib to target HCC at its stemness roots.

#2209 RelB drives integrin-mediated stress tolerance and relapse in high-grade serous ovarian cancer.

Omar Lujano Olazaba[1], Mikella Robinson[1], Greg J. Jordan[1], Sofia Howe[1], Cassidy Lucht[1], Anna Platen[1], Dishant Vandra[1], Mena Shammas[1], Katelyn Shelby[2], Ingrid Niesman[1], Christina M. Annunziata[3], **Carrie Danielle House**[1]

[1]San Diego State University, San Diego, CA,[2]BioLegend, San Diego, CA,[3]American Cancer Society, McLean, VA

High-grade serous ovarian cancer (HGSOC) initially responds to chemotherapy but frequently relapses with chemoresistant disease, potentially driven by cancer stem-like cells (CSCs), a minority tumor cell population with enhanced chemoresistance and tumor-initiation capacity that persists following treatment. We previously demonstrated that NF-κB signaling is upregulated in HGSOC and promotes stemness features in ovarian cancer cells including drug resistance, asymmetric division, tumor-initiation capacity, and epithelial to mesenchymal transition (EMT). Here, we investigated potential mechanisms by which this signaling cascade supports stress tolerance and tumor regrowth following chemotherapy to identify new therapeutic targets to prevent relapse. We found that NF-κB transcription factors RelA and RelB commonly regulate extracellular matrix organization genes but differentially regulate specific integrin subunits, including *ITGAV* (αV) by RelA and *ITGB3* (β3) by RelB. Given the clinical feasibility of targeting integrins we investigated αVβ3 in ovarian CSCs. We show that $\alpha V\beta 3^{+}$ cells have significantly enhanced tumor-initiation capacity relative to $\alpha V\beta 3^{-}$ cells and αVβ3 and αVβ5 are enriched on ovarian CSCs following standard of care chemotherapy. We developed a relapse model that demonstrates αVβ3 expression on ~90% of cells derived from re-established tumors and $\alpha V\beta 3^{+}$ cells exhibit preferential growth on mesentery, which is mediated by RelB. Importantly, knockdown of RelB combined with inhibition of αVβ3 and αVβ5 eradicated stress-tolerant cells, reduced overall tumor burden, and significantly prolonged survival following chemotherapy. Studies are underway to elucidate stromal responses to cytotoxic chemotherapy in peritoneal tissues that generate a modulated matrisome characterized by increased vitronectin and fibronectin. These tissues, which include the mesentery, may be susceptible to colonization of stress tolerant cells expressing αVβ3 and αVβ5 following chemotherapy and thus may play a significant role in relapse. Crucially, this work proposes integrins as promising therapeutic targets for HGSOC and indicates distinct roles for NF-kB transcription factors in regulating integrin expression and metastatic growth in this disease.

#2210 Ouabain exerts both anti-tumor and senolytic effects in brain cancer stem and tumor cells.

Alaa Daoud Sarsour[1], Gila Kazimirsky[1], Moran Dvela-Levitt[1], Chaya Brodie[1], Heidrun Weidemann[2], Iris Frid[3]

[1]The Mina and Everard Goodman Faculty of Life Sciences, Bar-Ilan University, Ramat Gan, Israel,[2]Internal Medicine,, Saint Georg Clinics, Eisenach, Germany,[3]Pediatric Hematology Oncology Unit, Shaare Zedek Hospital, Jerusalem, Israel

Glioblastoma (GBM) and diffuse intrinsic pontine glioma (DIPG) are highly aggressive brain tumors with dismal prognoses. These tumors contain therapy-resistant cancer stem cells (CSCs) that drive tumor progression and relapse. Standard treatments such as radiation and temozolomide (TMZ) induce senescence in a subset of tumor cells, generating a persistent, treatment-refractory population. Senolytic agents that selectively eliminate senescent cells may overcome this resistance. Here, we investigated the anti-tumor and senolytic effects of the cardiac glycoside ouabain in glioblastoma stem cells (GSCs), DIPG stem cells, and glioma cell lines. Neurosphere formation and transwell assays were used to assess self-renewal and migration, and senolytic activity was examined in TMZ-treated cells using β-galactosidase staining. RT-PCR quantified stemness-associated gene expression.Ouabain inhibited the self-renewal of GSCs and DIPG stem cells in a dose-dependent manner and reduced their migratory capacity. TMZ pre-treatment sensitized GSCs to ouabain, resulting in a more pronounced suppression of neurosphere formation and an enhanced inhibition of migration. Ouabain decreased the expression of stemness and EMT-related genes, including SOX2, YKL-40, OCT4, and NANOG.In addition, ouabain selectively eliminated TMZ-induced senescent cells in both glioma cell lines and differentiating GSCs. Together, these findings demonstrate that ouabain exerts dual anti-tumor and senolytic effects in GBM and DIPG cells by suppressing CSC stemness, migration, and eliminating senescent, stem-like populations. These combined effects highlight ouabain as a potential therapeutic strategy for targeting treatment-resistant cells in malignant gliomas.

#2211 STAT1 and STAT3 cooperatively control cancer stem cell (CSC) fate and IFNγ-dependent CSC maintenance.

Sophia Hidalgo[1], Anushka Poola[1], Yipeng Zhang[1], Rachel Zhou[1], Kourosh Kouhmareh[2], Jack D. Bui[1], **Magalie Dosset**[1]

[1]Department of Pathology, UC San Diego, La Jolla, CA,[2]UC San Diego School of Medicine, La Jolla, CA

Background: Cancer stem cells (CSCs) are a rare tumor cell subset with self-renewal and differentiation capacity that drives tumor initiation, heterogeneity, metastasis, and therapy resistance. Interferon-γ (IFNγ) has been implicated in regulating CSC fate, but its effects are highly context dependent. How the intrinsic balance between opposing IFNγ pathway effectors such as STAT1 and STAT3 shapes CSC properties remains poorly understood.
Methods: Breast (4T1, PY230) and sarcoma (F244, F236, H74) cell lines were exposed to high acute or persistent IFNγ stimulation. STAT1/STAT3 were deleted via CRISPR-Cas9. Retroviral transfection was used to restore STAT1 in STAT1-deficient H74 sarcoma cells. CSC induction was monitored using molecular and sphere formation assays for in vitro and in vivo experiments. Bioinformatic analyses include single-cell and bulk-RNA sequencing from public databases of human breast cancer.
Results: In this study, we found that cancer cell lines with higher expression of stem-cell-associated markers at baseline tend to have a lower STAT1/ STAT3 ratio and/or constitutive STAT3 activation. Exposure to acute high dose of IFNγ or persistent exposure to IFNγ led a progressive increase of CSC-associated genes (e.g. *Zeb1, Bst2, Tert*). STAT1 depletion favored CSC induction, while STAT3 loss led to increased cell death both with or without IFNγ stimulation. Interestingly, combined STAT1/STAT3 depletion markedly increased sphere size independently of IFNγ treatment, indicating that those two transcription factors may cooperate to restrain CSC proliferation. In vivo, STAT1-deficient H74 sarcoma cell line exhibited accelerated tumor progression and CSC induction in an IFNγ-dependent manner. By contrast, restoration of STAT1 completely abrogated H74 tumor growth in immunocompetent but not immunodeficient mice, confirming that STAT1 limits CSC induction by sensitizing tumor cells to immune-mediated cytotoxicity. Finally, single-cell RNAseq of human breast cancer cells revealed an inverse correlation between STAT1 and STAT3 expressions. STAT1-negative tumor cells with high IFNγ score were enriched in EMT- and apoptosis-related programs. Consistently, $IFN\gamma^{hi}/STAT3^{hi}$ breast tumors exhibited a stronger EMT signature and were associated with poorer clinical outcomes compared with $IFN\gamma^{hi}/STAT3^{lo}$ tumors.
Conclusions: Modulating the STAT1/STAT3 balance can suppress CSC expansion and preserve tumor cell vulnerability to immune-mediated killing. STAT1-sufficient tumors respond to IFNγ typically by increasing immunogenicity and limiting CSC potential, whereas STAT1-deficient tumors respond to IFNγ by increasing CSC properties. These results suggest that STAT1 serves as a toggle for anti- and pro-tumor effects of IFNγ.

: Tertiary Lymphoid Structures in Cancer
Poster Session

#2215 Tertiary lymphoid structure score associates with unique immune profile and therapeutic response in triple negative breast cancer.

Kei Kawashima[1], Akimitsu Yamada[2], Itaru Endo[2], Kazuaki Takabe[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Yokohama City University, Yokohama, Japan

Background: Tertiary lymphoid structures (TLSs) are aggregates of immune cells that resemble secondary lymphoid organs in both morphology and function, and are frequently observed within the tumor microenvironment (TME) of solid cancers including breast cancer. TLS have emerged as a predicter of anti-tumor immune activation and improved responses to immune checkpoint inhibitors (ICIs). However, TLS evaluation typically relies on histology that limits its generalizability. We hypothesize that TLS score is associated with distinct immune profiles and therapeutic response in triple negative breast cancer.
Methods: Clinical and transcriptomic data from 12 independent TNBC cohorts (TCGA(n=170), METABRIC(n=335), SCAN-B(n=174), GSE194040(n=363), GSE25066(n=133), GSE163882(n=90), GSE123845(n=86), GSE20271(n=63), GSE50948(n=17), GSE230881(n=49), GSE41998(n=151), GSE176078(n=10)) were analyzed using established 12-gene TLS signature score. The patients in each cohort were divided into TLS-high and low groups by median cutoff. For validation of the TLS score, we utilized pathological and spatial transcriptomic data from GSE17703(n=30) and EGAC50000000323(n=96). Associations between the TLS score and clinicopathologic features, genomic features and therapeutic outcomes were assessed.
Results: The TLS score was significantly higher in tumors with histologically confirmed TLSs. Spatial transcriptomic analysis revealed that high TLS scores colocalized with histologically confirmed TLSs, suggesting that the TLS score reliably reflects the presence of TLS. High-TLS score tumor had higher histological grade and lymph node involvement, and associates with significant enrichment of Hallmark cell proliferation-related pathways. Immune-related pathways were also significantly enriched in the TLS-high group, which exhibited significantly greater infiltration of CD8+ T cells, B cells, regulatory T cells, macrophage M1, and dendric cells. Among immune cells, macrophages displayed particularly elevated TLS scores, and TLS-high immune cells showed stronger intercellular communication. TLS scores were not associated with HRD or mutation burden, however, TLS-high tumors showed higher intratumoral genomic heterogeneity, suggesting that they are genomically stable yet immunologically inflamed and likely to be aggressive. Across 8 independent neoadjuvant chemotherapy cohorts, TLS scores were significantly higher in patients who achieved pathological complete response, with the largest effect observed in the ICI-treated cohort. Despite their association with features of aggressive biology, TLS-high tumors demonstrated more favorable clinical outcomes.
Conclusions: TLS-high TNBC were highly proliferative but immunologically active, and the TLS score was strongly associated with better treatment response and improved prognosis.

#2216 Spatial multi-omics reveals functional diversity of tertiary lymphoid structures in brain metastases.

Sadaf Shabbir Mughal[1], Jennifer H. Lun[2], Karina Martinez[1], Jadranka Macas[2], Jonathan Schupp[2], Tatjana Starzetz[2], Stefanos Voglis[3], Benedikt Brors[1], Karl H. Plate[2], Yvonne Reiss[2]
