Results: Across two benchmark datasets, MTA-DTA consistently outperformed prior methods. On Davis, it achieved an MSE of 0.225, R^2 of 0.7155, and CI of 0.8796. On KIBA, it reached an MSE of 0.1612, R^2 of 0.7661, and CI of 0.8781, exceeding the performance of existing DTA models. In addition, qualitative analyses of the attention maps revealed that MTA captured biologically meaningful binding regions, highlighting continuous residue segments and sub-structural motifs rather than isolated token pairs. This indicates that the model effectively integrates both local chemical context and global interaction patterns, leading to improved accuracy and interpretability in drug-target affinity prediction.
Conclusion: In summary, the MTA-DTA model enhances conventional attention by extending it from single-token to multi-token interaction modeling, thereby bridging the gap between sequence-based learning and the true cooperative nature of molecular binding. By incorporating key-wise and head-mixing convolutions, the model gains the ability to represent local interaction motifs while maintaining global dependency awareness, resulting in more biologically realistic affinity predictions.

#0982 Pharmacophore profiling highlights diverging binding modes of nemtabrutinib and ibrutinib across tyrosine kinases.

Charly Empereur-mot[1], Giulio Sartori[2], Luca Pesce[1], Filippo Spriano[2], Chiara Tarantelli[2], Luciano Cascione[2], Alberto J. Arribas[3], Luca Aresu[4], Davide Rossi[2], Giovanna L.M. Damia[5], Massimo Broggini[5], Daniela Polino[1], Francesco Bertoni[2]

[1]Department of Innovative Technologies, University of Applied Sciences and Arts of Southern Switzerland, Lugano, Switzerland,[2]Institute of Oncology Research, Bellinzona, Switzerland,[3]Universita della Svizzera italiana, Lugano, Switzerland,[4]Department of Veterinary Science, Grugliasco (TO), Italy,[5]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy

Background. Commanding kinase selectivity remains a major bottleneck in the discovery of targeted anticancer drugs, with homologous ATP-binding pockets leading to off-target inhibition, toxicity, and reduced clinical effectiveness. Addressing these difficulties, we present a streamlined computational workflow allowing rationalizing selective compound activity by capturing subtle, transient structural differences across many homologous kinases. We demonstrate our approach by characterizing the diverging mechanisms of action of nemtabrutinib and ibrutinib in cell lines derived from two specific B-cell lymphoma subtypes (activated B-cell like [ABC] and germinal-center B-cell like [GCB] DLBCL), correlating *in vitro* anti-tumor activity with *in silico* selectivity scores computed across 20 tyrosine kinases.

Methods. To enable high-throughput, cost-efficient parallel processing of ATP-binding pocket variants, as a preliminary step we compiled a subset of metastable pocket conformations adopted by tyrosine kinases (DFG motif and associated dihedral) with and without generic compound binding (templating with AlphaFold2 and publicly available data). The structural alignment of this conformational dictionary and its processing via structure-based pharmacophore methods (CDP:Kit) produced rich maps of kinase pocket interactomes. Fitting compounds into these maps then enabled scoring matching pharmacophore features and computing a relative selectivity score between kinases for each compound (CDP:Kit and lightweight binding energy estimations) using BTK as baseline for confirmed targeting.

Results. We deciphered the synergistic interplay of 10 residue locations within the extended ATP-binding pocket, responsible for the selective binding of nemtabrutinib and ibrutinib across tyrosine kinases. As aligned to human BTK sequence and specifying potential for modified interactions, we highlight reference locations: Q412 (loop-mediated covalent binding, none), V416 (hydrophobic, H-bond), F442 and M449 (hydrophobic, sulfur-aromatic, cation-pi), L460 and I472 (hydrophobic, sulfur-aromatic, pi-stacking), T474 (hydrophobic, halogen-bond, H-bond, sulfur-aromatic, pi-stacking), C481 (covalent binding, H-bond, none), N484 (H-bond, none) and L542 (hydrophobic, sulfur-aromatic, none).

Conclusions. We demonstrate a general strategy for rational, structure-guided characterization of selective compound activity across conserved kinase families. Our approach enabled characterizing the diverging binding modes of nemtabrutinib and ibrutinib across 20 kinases, in agreement with anti-tumor activity data and expression levels in cell lines derived from two B-cell lymphoma subtypes. We identified FYN, FRK and MAST1 as likely targets of nemtabrutinib and not of Ibrutinib, responsible for GCB DLBCL non-proliferation.

#0983 Beyond the active site: Discovery of novel PYCR1 allosteric binding sites via structure-oriented fragment crystallographic screening.

Olha Tarkhanova[1], Kaylen R. Meeks[2], Juan Ji[3], Caitlin J. Mattingly[3], Jay C. Nix[4], Mykola Protopopov[1], John J. Tanner[3]

[1]Chemspace LLC, Charlotte, NC,[2]Brookhaven National Laboratory, Upton, NY,[3]University of Missouri, Columbia, MO,[4]Lawrence Berkeley National Laboratory, Berkeley, CA

Pyrroline-5-carboxylate reductase 1 (PYCR1), a member of the PYCR enzyme family, plays a pivotal role in the proline biosynthesis pathway. Enzymes involved in proline metabolism have been increasingly recognized as key regulators of cancer cell metabolic reprogramming, contributing to enhanced proliferation, survival, metastasis, and resistance to stress. Overexpression of PYCR1 has been consistently reported across multiple malignancies, including hepatocellular carcinoma, breast cancer, gastric cancer, bladder cancer, and lung cancer, as well as in fibrotic disorders. These observations highlight PYCR1 as an attractive therapeutic target for oncology drug discovery.

Despite its therapeutic potential, PYCR1 remains an understudied target, with limited data available on active small-molecule ligands and binding site characterization. Consequently, the discovery of novel chemical probes is critical both for validating PYCR1's role in disease pathology and for initiating structure-based drug design campaigns.

To this end, a fragment-based screening campaign was initiated using a focused subset of carboxylic acid-containing fragments from the Enamine fragment library. The subset was rationally designed through molecular docking of fragment-like, carboxylic acid-containing compounds from Enamine's in-stock collection, targeting the active site of PYCR1. A total of 37 fragments were selected and screened via X-ray crystallography. This screen yielded eight fragments with confirmed binding to the PYCR1 active site, as determined by co-crystal structures. Among these, three compounds demonstrated inhibitory activity in biochemical assays, with IC_{50} values ranging from 29 µM to 5.4 mM.

Encouraged by these results, a follow-up screen was conducted using 22 fragment-like compounds containing bioisosteres of the carboxylic acid functional group (e.g., tetrazoles, oxadiazoles) and sulfonic acid groups, to explore alternative chemical scaffolds. This second crystallographic screen identified one additional active-site binder. Importantly, at least two previously uncharacterized allosteric binding sites were discovered, both of which showed a measurable inhibitory effect on PYCR1 enzymatic activity. These findings open promising new avenues for the development of non-classical inhibitors targeting PYCR1.

#0984 MHC-associated peptide proteomics for immunogenicity risk assessment of immuno-oncology drug candidates.

Chloe Ackaert[1], Jana Schockaert[1], Aurelie Mazy[1], **Christoph Schifflers**[1], Martijn Vlaming[1], Elise Pepermans[2], Sofie Pattyn[1]

[1]IQVIA Laboratories, Gosselies, Belgium,[2]ImmuneSpec, Niel, Belgium

Traditional monoclonal antibodies and bispecifics have shown great promise for the treatment of various tumor entities. However, managing unwanted immunogenicity has become a challenge in the development of these promising therapeutics as there is a trend towards higher unwanted immune responses compared to classical monoclonal antibodies. Thorough assessment of their immunogenic potential is a crucial step in the development of safe biotherapeutics with high treatment efficacy. MHC-associated peptide proteomics (MAPPS Assay) enables the precise identification of all the regions of a protein that may evoke an immune response. High-sensitive MAPPS workflow in combination with high quality primary cells leads to higher numbers of identified self + non-self peptides and provides the analysis depth required for confident immunogenicity derisking and modulation. Here, we report the importance of peptides presented by HLA-DP and HLA-DQ (next to the standard HLA-DR presented peptides). Next, we also showed the first ever comparison of presented peptides by true immune cells: myeloid dendritic cells *versus* monocyte derived dendritic cells.

#0985 Anticancer efficacy of tricarbonylperrhenato(bathophen)rhenium(I) organometallic compound in pancreatic ductal adenocarcinoma.

Ishita Saha[1], Cecilia Parpinelli[2], Birsen Varisli[3], Santosh Mandal[3], **Santanu Bhattacharya**[1]

[1]Mayo Clinic Florida, Jacksonville, FL,[2]University of Central Florida, Orlando, FL,[3]Morgan State University, Baltimore, MD

Organometallic rhenium compounds have become powerful anticancer agents that show possibilities as a substitute for traditional platinum-based medications. While platinum-based chemotherapeutics like FOLFIRINOX and cisplatin are frequently used to treat pancreatic ductal adenocarcinoma (PDAC), they have a number of side effects, such as ototoxicity, neurotoxicity, nephrotoxicity, and peripheral neuropathy. Hepatotoxicity, cardiotoxicity, gastrointestinal toxicity, cytopenias, anaphylaxis, pain, alopecia, anorexia, cachexia, and asthenia are other commonly reported adverse effects.
However, ligands based on rhenium have been shown to preferentially cause cytotoxicity in cancer cells while avoiding harm to healthy cells. This suggests that rhenium could be a safer and more effective cancer treatment option. Different rhenium compounds with different ligands have been produced by Mandal et al. for a range of medicinal uses. In this work, we assessed the therapeutic potential of tricarbonylperrhenato(bathophen)rhenium(I) (PR-6) in PDAC. The cytotoxic effects and IC_{50} value of PR-6 were assessed in the metastatic pancreatic cancer cell line AsPC-1 using the MTS assay. The IC_{50} value for PR-6 in AsPC-1 cells was determined to be 5.85 µM. PR-6 treatment significantly inhibited cell growth, migration, and survival at the IC_{50} concentration, with a post-treatment survival rate of 2.3 ± 3.97%. Furthermore, PR-6 treatment led to the downregulation of phosphorylated MEK (pMEK) and phosphorylated P38 (pP38) protein expression, indicating its modulatory effect on the MAPK signaling pathway. According to our research, PR-6 has a great therapeutic promise for treating pancreatic cancer and efficiently alters the tumor microenvironment in PDAC cells.

#0986 Silyl ethers analogs of SN-38 with unique blue-fluorescent properties exhibit potent anti-cancer activity through topoisomerase I inhibition.

Sanika Vaidya[1], Ashley Mo[1], Alyssa Yee-Xin Chia[1], Katelyn Li[1], Shreya Somani[1], Isabella Lo[1], Lekhya Menta[1], Gary Johanning[2], Feng Wang-Johanning[2], **Edward Njoo**[1]

[1]Chemistry, Aspiring Scholars Directed Research Program (ASDRP), Fremont, CA,[2]SunnyBay Biotech, Fremont, CA

Topoisomerase I inhibitors, such as deruxtecan and irinotecan, represent an important class of cell cycle inhibitors in the treatment of cancers. Among these, silylated topoisomerase inhibitors, including DB-67 and karenitecin, have exhibited increased antiproliferative potency. In this study, we prepared and evaluated the biological activity of four synthetic SN-38 analogs bearing the tert-butyldimethyl, tert-butyldiphenyl, triisopropyl, and dimethylthexyl siloxy groups, blocking a key metabolic site and imbuing bright blue-fluorescent properties in such compounds. When evaluated against colorectal, TN breast cancer, and ovarian, non-small cell lung, and liver cancer models, we observed comparable or greater antiproliferative activity. Our dimethylthexyl siloxytecan demonstrated the greatest potency among the four analogs, with a 96 hour IC50 of 6 nM in HCT-116 cells. Correspondingly, analysis by flow cytometry indicates that the siloxytecans, compared to their parent compounds, display comparable apoptotic activity and increased cell cycle G2 arrest. Uniquely, we demonstrate that the enhanced fluorescence of these compounds enables real-time, quantitative visualization of the dynamics and selectivity of intracellular uptake through fluorescence microscopy without the need for extensive sample preparation or installation of auxiliary fluorophores, with the dimethylthexyl siloxytecan displaying the greatest rate of cellular uptake. Additionally, quantification of relaxed and nicked DNA levels via cell-free biochemical studies suggests that these siloxytecans largely exhibit increased topoisomerase inhibition from SN-38. Further computer modeling studies validated that differences in potency and permeability were not attributed to the siloxytecans' positioning within the Topoisomerase I-DNA binding pocket. This initial SAR is further supplemented by an evaluation of these compounds' DMPK properties and metabolic stability, with an assessment of different in-vivo delivery strategies. Moreover, direct tissue injection of the siloxytecans has demonstrated exceptional tissue retention and durability, establishing the dimethylthexyl siloxytecan as a preclinical lead for in vivo evaluation. Collectively, these studies demonstrate improved intracellular delivery of topoisomerase inhibitors with the introduction of silicon-containing motifs and highlight the utility of these compounds for enhanced anticancer activity with unique lipophilicity and fluorescent properties that enable quantitative tracking of compound distribution in cancer cells, which is currently being investigated for in vivo activity in triple negative breast cancer studies.

#0987 Optimization of bioinformatics parameters for DIA-based proteomics in targeted protein degradation.

Hui Zhou, Yi Liu, Aijuan Yu, Naizhong Zheng

DeepKinase Biotechnologies Ltd., Beijing, China

Targeted Protein Degradation (TPD) is a transformative strategy for targeting oncoproteins previously considered undruggable. A central challenge in translating TPD compounds into viable cancer therapeutics is the accurate delineation of on-target efficacy from off-target toxicities, which is critical for patient safety and therapeutic efficacy. Data-Independent Acquisition (DIA) mass spectrometry provides the profound sensitivity and comprehensive proteome coverage necessary for systematically mapping protein abundance changes induced by TPD compounds. However, the accurate assessment of on-target efficacy and off-target effects critically depends on the selection of appropriate bioinformatic parameters in DIA proteomics data analysis. To address this, we conducted a systematic evaluation of key bioinformatic parameters. Our findings identify Unique Peptide filtering and Imputation as the most influential factors in precisely defining both on-target efficacy and off-target effects. Specifically, applying a UniquePep threshold ≥2 effectively minimized off-target misidentification. For imputation methods: when data was completely missing in treatment groups, row_min imputation yielded non-significant p-values; when data was partially missing, min imputation resulted in high intra-group variance with non-significant p-values. Therefore, we recommend row_min_half as a general-purpose imputation approach. Furthermore, we investigated the impact of peptide-level bioinformatic parameters on on-target efficacy and off-target effects. Our analysis revealed that high-abundance outlier peptides in control groups, low peptide detection rates in samples, and the selection of specific peptides to represent protein abundance significantly influence result accuracy. These confounding factors can be mitigated by filtering high-abundance outlier peptides, improving peptide detection rates, and implementing appropriate peptide-level missing value imputation, thereby optimizing the reliability of TPD outcomes. This study provides a critical, optimized framework for DIA proteomics analysis specifically tailored to TPD research. By ensuring accurate assessment of degrader specificity, this pipeline will accelerate the prioritization of lead compounds and de-risk the development of safer, more effective targeted protein degraders for cancer therapy.

#0988 Synthesis, characterization, and biological evaluation of polyisoprenylated phosphonyl ester inhibitors on triple-negative breast cancer.

Joshua Kofi Ablordeppey, Kweku Ofosu-Asante, Amarender Burra, Jahnissi Odoom, Desmond Kwakye, Nazarius S. Lamango

Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL

Triple-negative breast cancer (TNBC) is an aggressive subtype lacking molecular targets and resistant to conventional therapy. Small GTPases such as RAS, RHO, and RAC regulate proliferation and cytoskeletal organization through prenylation and subsequent methylation-demethylation cycles. The methylation of prenylated cysteine residues by prenylated protein methyltransferase (PPMTase) and demethylation by polyisoprenylated methylated protein methyl esterase (PMPMEase) maintains GTPase turnover, activation and membrane localization. Overexpression of PMPMEase in cancers accelerates this cycle, disrupting the balance between methylated and demethylated states and sustaining aberrant MAPK and PI3K/AKT signaling that drives malignant growth. To selectively disrupt this process, polyisoprenylated phosphonyl ester inhibitors (PPEIs) were designed as irreversible, mechanism-based inhibitors that exploits PMPMEase's substrate recognition. Each PPEI incorporates a farnesyl tail that mimics the prenylated cysteine terminus of native substrates, promoting high-affinity binding and covalent modification of the catalytic serine. PPEIs were synthesized from farnesylated cysteine precursors and characterized by NMR and ion-trap mass spectrometry. Treatment of MDA-MB-231 and MDA-MB-468 cells with PPEIs produced dose-dependent reductions in viability and actin cytoskeletal integrity. NSL-AB-01 exhibited EC_{50} values of 4.1 µM (MDA-MB-231) and 3.3 µM (MDA-MB-468), while NSL-AJ-01 showed higher potency (3.2 µM and 2.7 µM, respectively). Actin-staining analysis revealed ~90% reduction in mean cell area, indicating impaired Rho-family GTPase signaling. Western blotting showed decreased p-AKT (-25% in MDA-MB-231; -50% in MDA-MB-468) and increased p-ERK (≈2.8-fold in MDA-MB-231; +70% in MDA-MB-468). To determine whether PPEI-induced cytotoxicity was associated with oxidative stress, intracellular ROS generation was quantified using DCFDA fluorescence. NSL-AJ-01 and NSL-AB-01 induced strong, concentration-dependent ROS production in TNBC cells. NSL-AJ-01 increased ROS levels approximately 25-fold in MDA-MB-231 and 24-fold in MDA-MB-468 at 3 µM ($p < 0.001$). NSL-AB-01 induced even greater oxidative responses, causing an approximately 32-fold increase of ROS in MDA-MB-231 and 30-fold increase in MDA-MB-468 at 3 µM ($p < 0.0001$). Together, these findings demonstrate that PPEIs induce oxidative damage to breast cancer cells, suppress pro-survival AKT signaling, and activate ERK-mediated stress pathways, driving cytoskeletal disassembly and reduced TNBC cell viability.

#0989 PTBP1-targeted siRNA reprograms cellular metabolism and induces apoptosis in human gastric cancer cells.

Hirokatsu Hayashi, Keita Matsumoto, Masashi Kuno, Masahiro Fukada, Ryuichi Asai, Yuta Sato, Itaru Yasufuku, Tajima Jesse Yu, Yoshihiro Tanaka, Manabu Futamura, Nobuhisa Matsuhashi

Gifu University, Gifu, Japan

Background: The prognosis of advanced gastric cancer remains poor despite recent therapeutic progress, underscoring the need for novel strategies. Cancer cells commonly rely on aerobic glycolysis (the Warburg effect). PTBP1 contributes to this metabolic phenotype by regulating the alternative splicing of the *PKM* gene, suppressing PKM1 and promoting the PKM2 isoform, which supports glycolytic metabolism. We hypothesized that PTBP1 inhibition would suppress tumor growth by shifting metabolic flux toward oxidative phosphorylation.
Methods: Thirteen chemically modified siR-PTBP1 derivatives were synthesized and tested in the gastric cancer cell line MKN1. Cell viability was measured by crystal violet staining. PTBP1 expression, PKM1/PKM2 isoform switching, ATP production, and apoptosis (cleaved PARP) were evaluated by Western blotting and ATP assay.
Results: Optimized siR-PTBP1 selectively reduced PTBP1 expression and increased the PKM1/PKM2 ratio, indicating metabolic reprogramming. ATP assay demonstrated that siR-PTBP1 treatment increased intracellular ATP production, supporting a metabolic shift from glycolysis toward oxidative phosphorylation. These metabolic changes were accompanied by elevated cleaved PARP levels, consistent with apoptosis induction. Consequently, siR-PTBP1 significantly inhibited MKN1 cell proliferation.
Conclusion: PTBP1 inhibition reprograms tumor metabolic pathways and triggers apoptosis in gastric cancer cells. siR-PTBP1 represents a promising metabolism-targeted nucleic acid therapeutic candidate, warranting further evaluation in in vivo xenograft models.

#0990 SR-B1 gene variants, inhibitors and the effect of glucose on IC50s in breast cancer.

Nandini Bhattacharya[1], Sree Aramgam[1], K. Sean Kimbro[2]

[1]Microbiology, Biochemistry, and Immunology, Morehouse School of Medicine, Atlanta, GA,[2]Morehouse School of Medicine, Atlanta, GA

Background: Ancestry-related genetic variations have been observed to influence the risk of certain cancers and diabetes through inherited genetic variations and their interaction with lifestyle and environment. Type 2 diabetes has been considered a risk factor for breast cancer, thus suggesting metabolism may drive cancer progression. The reverse cholesterol transporter and membrane receptor Scavenger receptor B1 (SR-B1), which is involved in insulin resistance and lipid metabolism, with its ancestry enriched variants, is evaluated in breast cancer as a novel target.
Methods: The triple negative breast cancer cell lines MDA.MB 231 and MDA.MB 468 were employed for this study. SNP genotyping to determine the genotype of each cell line was performed using the TaqMan SNP Genotyping assays for the SR-B1 missense SNP variant rs2293440. Cells were grown in media with varying glucose levels of 5.5 mM, 17.5 mM and 25 mM, representative of the blood glucose level indicator HbA1C. The cells were then treated with different concentrations of the SR-B1 inhibitor drug, Block lipid transport 1 (BLT-1), for total of 48 hours. After 48 hours, cell survivability assay was used to determine percent survival for each cell line under the conditions mentioned.
Results: The SNP genotyping results indicated that MDA.MB 231 contained the wild-type allele while MDA.MB 468 contained the variant allele. Results of the cell survivability assay showed that sensitivity of both the cell lines to BLT-1 was increased by 3-fold and 5-fold at 5.5 mM glucose concentration in media for MDA.MB 231 and 468 respectively, as was confirmed by the IC50 values. Both cell lines displayed resistance to BLT-1 at the higher media glucose concentrations of 17.5 and 25 mM with their IC50 values exhibiting up to a 5-fold increase. Further, MDA.MB 468 displayed almost 2-fold higher sensitivity to BLT-1 at both 5.5 mM and 17.5 mM media glucose concentration in comparison to MDA.MB 231.
Conclusions: These results indicate that there is a correlation between the blood glucose levels and the drug sensitivity or drug response in cancer. Further, our results suggest that the response to metabolism inhibitor drugs in cancer and glucose metabolism may also be impacted by the ancestry and genetic variation of an individual.

#0991 Synergistic effects of antineoplastic drugs and gap junction enhancer in heterogenous colorectal cancer.

Tomas Lugo[1], Annelise Nguyen[2]

[1]Texas Tech University, Lubbock, TX,[2]Texas Tech University, Amarillo, TX

Fibroblast tumor cell crosstalk, particularly through gap junction mediated signaling, is increasingly recognized as a modifier of colorectal cancer drug response. To test whether restoring gap junction function can enhance chemotherapy, we used co-culture spheroids composed of CCD-112 CoN fibroblasts and colorectal cancer cells (SW620, SW480, HT-29, or Caco-2) in a 1:1 ratio in 96-well plates. Doxorubicin, erlotinib, nilotinib, and cediranib were tested across multiple concentrations, alone and in combination with the gap junction enhancer, PQ, and drug interactions were quantified using the ZIP model, analytic tool and visualized using gigamap approach. For the combination treatment of doxorubicin and PQ, ZIP analysis revealed both antagonistic and synergistic regions. PQ alone and low concentrations of doxorubicin were predominantly antagonistic, with ZIP scores ranging from approximately 0.2 to −17.19. In contrast, high concentrations of both chemicals produced marked synergy, with a maximal ZIP score of 44.05 and an overall global ZIP synergy score of 4.53. On the 2D heatmap, this appears as largely additive to mild antagonistic effects at low to intermediate doses, with a distinct red hot spot of synergy in the upper-right corner (high [PQ]/high [Doxorubicin]). Consistently, the 3D surface plot shows a ridge of positive zip scores that increases with rising concentrations of both drugs. Together, these findings indicate that PQ enhances doxorubicin efficacy in a concentration dependent manner, with synergy restricted to a specific high-dose window rather than across all dose combinations. Similarly, the BCR-ABL targeted therapy nilotinib displayed a biphasic response in combination with PQ, characterized by two synergistic peaks at low and high concentrations separated by an antagonistic valley at intermediate doses. In conclusion, these results highlight both the synergistic and antagonistic properties of PQ with commonly used antineoplastic agents and support the approach of combinational treatment for colorectal cancer.

#0992 A novel targeted protein degradation platform based on internalization-enhancing peptide for lysosomal degradation of cell-surface proteins.

Dae Young Kim, Dahye Sim, Daeho Park, Yujin Park, Hee Young Kang, Hoil Choi

Peptron, Inc., Daeieon, Korea, Republic of

Targeted protein degradation (TPD) is an emerging therapeutic approach that enables the selective elimination of undesirable proteins with high specificity. Although TPD holds great promise for targeting traditionally undruggable proteins and overcoming resistance often seen with inhibition-based therapies, several challenges remain, including suboptimal pharmacokinetics, limited internalization, and the dependency on E3 ligases or lysosome-targeting receptors. Here, we present a novel TPD platform based on internalization-enhancing peptide (IEP). IEP binds tightly yet non-covalently to antibodies (Abs) without altering their structure and enhances Ab internalization. We hypothesized that IEP could promote lysosomal degradation of cell-surface proteins by facilitating internalization. To demonstrate its potential, Atezolizumab (ATZ), an FDA-approved monoclonal antibody targeting PD-L1, was used as a model. Since ATZ alone does not strongly induce PD-L1 internalization, it provides an ideal system to test IEP-mediated degradation. Indeed, PD-L1 protein levels were markedly reduced in MDA-MB-231 (TNBC) cells treated with ATZ-IEP (a non-covalent ATZ/IEP complex), whereas no reduction was observed with ATZ or IEP alone. The decrease in PD-L1 was blocked by BafA1, a lysosomal proteolysis inhibitor, but not by MG132, a proteasome inhibitor—indicating that ATZ-IEP mediates lysosomal, rather than proteasomal, degradation. To assess the generality of this effect, Durvalumab (DUR), another FDA-approved anti-PD-L1 antibody, and HCC827 (NSCLC) cells were tested. PD-L1 levels were reduced with DUR-IEP (a non-covalent DUR/IEP complex) to a similar extent as with ATZ-IEP, and ATZ-IEP also decreased PD-L1 expression in HCC827 cells, comparable to the effect observed in MDA-MB-231 cells. These results indicate that IEP functions broadly across different antibodies and tumor types. Intriguingly, using transgenic CHO cell lines with varying PD-L1 expression, we found that the extent of PD-L1 reduction increased as baseline PD-L1 expression decreased (~70 % in PD-L1^{Low} vs. ~20 % in PD-L1^{High}). This finding suggests that IEP may help overcome anti-PD-L1 resistance in tumors with low PD-L1 expression. In summary, ATZ-IEP mediates lysosomal degradation of PD-L1 and demonstrates broad applicability across antibodies and tumor types. Ongoing in vivo studies aim to confirm the efficacy of ATZ-IEP, further supporting the versatility of IEP as a novel TPD platform.

#0993 From phenotypic screening to mechanistic insight: Rational discovery of chemosensitizers for glioblastoma.

Lukas Gorecki, Lubica Muckova, Michaela Sadibolova, Ondrej Soukup

Biomedical Research Center, University Hospital Hradec Kralove, Hradec kralove, Czech Republic

Glioblastoma multiforme (GBM) represents the most aggressive form of primary brain tumor, characterized by rapid progression, therapeutic resistance, and near-universal recurrence. Despite multimodal treatment strategies—comprising maximal surgical resection followed by radiotherapy and temozolomide (TMZ)-based chemotherapy—median survival remains dismal, with most patients succumbing within one-year post-diagnosis. TMZ and ionizing radiation exert their cytotoxic effects primarily through the induction of DNA lesions, including single- and double-strand breaks. The cellular DNA damage response (DDR), encompassing a complex signaling network of kinases, repair enzymes, and checkpoint regulators, orchestrates the detection and repair of these lesions. Dysregulation or hyperactivation of DDR pathways—including those mediated by ATR/ATM signaling, PARP-dependent repair, and cell cycle checkpoints (e.g., WEE1, CDK1)—has been implicated in the pronounced therapeutic resistance of GBM. In this study, we pursued the rational design and synthesis of novel small molecules aimed at potentiating TMZ- and radiation-induced cytotoxicity in GBM. Over seventy compounds were generated across five focused series using structure-based design principles. Phenotypic screening was conducted in the TMZ-resistant T98G line and patient-derived GBM cultures to evaluate both intrinsic cytotoxicity and TMZ sensitization. Several lead candidates demonstrated superior chemosensitization efficacy compared to clinical DDR inhibitors. Interestingly, broad kinase profiling revealed an absence of canonical DDR kinase inhibition, indicating a potential non-classical mechanism of action. To delineate this mechanism, comprehensive quantitative proteomic analyses were performed, revealing modulation of pathways associated with DNA repair, stress response, and cell cycle control. The most promising candidates exhibited favorable pharmacokinetic and toxicological properties, along with effective blood-brain barrier penetration in vivo.

This work has been supported by the grant from the Ministry of Health of the Czech Republic (NW24J-03-00005); and by the Long-term development plan Military Faculty of Medicine, Healthcare Challenges of WMD II (DZRO-VLF22-ZHN II).

#0994 Selective oncolysis via oncomiR-driven DNA self assembly.

Akimitsu Okamoto[1], Kunihiko Morihiro[1], Makoto Yamamoto[2]

[1]University of Tokyo, Tokyo, Japan,[2]TKG Therapeutics, Inc., Tokyo, Japan

Introduction: Artificial nucleic acids attract significant attention as cancer immunotherapy materials because they can be recognized by various extracellular and intracellular nucleic acid sensors and stimulate innate immune responses. However, their low selectivity for cancer cells causes severe systemic immunotoxicity, hindering the realization of immune cancer therapy using artificial nucleic acid molecules. To address this challenge, we propose a hairpin DNA self-assembly technology that induces cytotoxicity through cancer-selective immune activation. Here, we discuss cancer growth suppression via DNA self-assembly triggered by overexpressed oncomiRs.

Experimental Design: Two hairpin DNA sequences were designed based on predictions of nucleic acid structural thermal stability (oHP-1 and oHP-2). This pair of hairpin DNAs (oHPs) triggered binding with one oncomiR, miR-21, forming a double-stranded DNA over 500 bp in length as a DNA aggregate. This structure is sufficiently large to induce innate immune activation. We examined the immune response induced by oHPs using cancer cells and tumor-bearing mice.

Results: DNA aggregates formed by oHPs bound to cGAS within cancer cells that abundantly express miR-21. Consequently, IFN-β was produced through the cGAS-STING pathway, resulting in selective cell killing. When oHPs were administered into tumors of cancer-bearing mice using an appropriate DDS, tumor growth was strongly suppressed. $CD8^+$ T cells and $CD4^+$ T cells were observed to accumulate at the periphery of the tumor tissue. While sufficient tumor growth suppression was observed with oHPs alone, higher efficacy was observed when combined with anti-PD-1 antibody.

Conclusions: This approach represents the first technology enabling selective tumor lysis derived from intracellular DNA self-assembly, providing a potent therapeutic modality for cancer treatment. The engineered oHPs assemble into long double-stranded DNA via cancer-associated miR-21, functioning as a selective immune amplifier and booster circuit for targeted tumor lysis. This design exhibits non-responsiveness in miR-21-deficient cells and immunodeficient cells, demonstrating significant potential as an efficient targeted cancer therapy.

#0996 Novel sulfonamide-aromatic amine hybrids: Synthesis, cytotoxic screening, and transcriptomic insights into anticancer activity.

Mohamed A. Eltokhy[1], Eman A. Fayed[2], Moustafa S. Abusaif[3], Ahmed Ragab[3], Yousry A. Ammar[3], Sahar Radwan[4], Sanjay K. Srivastava[1]

[1]Immunotherapeutics and Biotechnology, Texas Tech University Health Sciences Center, Abilene, TX,[2]Pharmaceutical Organic Chemistry, Al-Azhar University, Cairo, Egypt,[3]Chemistry, Al-Azhar University, Cairo, Egypt,[4]Microbiology and Immunology, Al-Azhar University, Cairo, Egypt

Cancer remains one of the causes of mortality worldwide and a major global health challenge. These challenges are attributed to factors such as medication resistance, tumor complexity, and heterogeneity. Targeted therapy with small molecules has emerged as a promising approach due to its ability to selectively inhibit cancer cell growth while minimizing off-target effects. In this study, a series of derivatives synthesized from 3-formyl-4-hydroxy benzene sulfonyl chloride (FHS) were evaluated for their cytotoxic effects on various cancer cells. The objective was to identify compounds with potent anticancer activity and favorable selectivity profiles for further development. The synthesis process began with FHS as the starting material, subjected to a series of chemical reactions to generate a library of compounds labeled C3 through C10. These compounds were characterized by using a combination of analytical techniques, including melting point determination, Proton Nuclear Magnetic Resonance (^{1}H NMR), Carbon-13 Nuclear Magnetic Resonance (^{13}C NMR), and Infrared (IR) spectroscopy to confirm their structural integrity. Cytotoxic effects were evaluated using Sulforhodamine B (SRB) assay for cytotoxicity was applied to an extensive panel of cancer cell lines, categorized into such as colorectal cancer (HT-29, MC38, CT26and COLO 205), hepatic (C3a and PLC/PRF), pancreatic (Suit-2, MiaPaca2, As-PC1 and Panc 02.03, CI66), breast (MDA-MB-468, MDA-MB-231, BT20, MCF7, 4T1, 4T1 paclitaxel resistant, JIMT-1, ZR-75-1, E0771, T47D, and HCC1806) and ovarian (OVCAR-5) cell lines. Normal breast epithelial cell line MCF10a was tested to analyze safety. Based on the SRB assay, 7 compounds exhibited variable but significant cytotoxicity in various cancer models. The most effective compound, C5, was chosen for further analysis to identify mechanism of its cytotoxic effect by transcriptomic analysis. The transcriptomic results showed ten genes with log2 fold change between control and treatment. These genes were related to DNA damage inducible transcript 4, FXYD domain containing ion transport regulator 4 and CHAC1 (glutathione-specific gamma-glutamylcyclotransferase 1). Further in vivo experiments and validation experiments are in progress to determine the most significant pathway for cytotoxicity.

#0997 Development of polyHis-targeting chimeras (HisTACs) for targeted protein degradation.

Annan Sun[1], Dong Zhu[2], Hui Chen[1], Monica Billitti[2], Lingtao Jin[3], Dongwen Lyu[2], Guangrong Zheng[1]

[1]Department of Medicinal Chemistry, University of Florida, Gainesville, FL,[2]Department of Cellular Biology and Anatomy, Augusta University, Augusta, GA,[3]Department of Molecular Medicine, University of Texas Health San Antonio, San Antonio, TX

Induced-proximity degraders hold great promise for oncology, yet their utility remains constrained by the need for high-affinity ligands for each protein of interest. Tag-based degrader systems provide ligand-independent surrogates but are limited by large tag size, risk of tag-driven ubiquitination, and difficulty of engineering substantial tags into endogenous genes. To address these challenges, we developed a polyhistidine-directed degrader platform (HisTAC) that uses Ni^{2+}-nitrilotriacetic acid (Ni^{2+}-NTA) to engage His-tagged proteins and recruit CRBN or VHL E3 ligases.Cellular uptake was first confirmed with a fluorescent His_6-CPP/Ni-NTA probe, which exhibited rapid entry and widespread intracellular distribution. We then generated a HeLa cell line with endogenously His_6-HiBiT-tagged BRD4 and screened a panel of Ni^{2+}-NTA-based degraders. Constructs containing two Ni^{2+}-NTA groups displayed the highest potency, yielding >50% BRD4 loss at micromolar levels. MG-132 co-treatment fully blocked BRD4 depletion, confirming proteasome dependence. Immunoblotting further revealed preferential degradation of BRD4 long isoform, with moderate reduction of the short isoform. VHL-recruiting HisTACs also induced potent, isoform-selective BRD4 degradation with sub-micromolar efficacy toward the long isoform.To test the generalizability of this platform, we engineered a polyHis-HiBiT-tagged PSPC1 cell line—an RNA-binding protein lacking tractable ligands. Both CRBN- and VHL-based HisTAC degraders induced rapid, dose-dependent PSPC1 degradation, demonstrating the applicability of Ni^{2+}-NTA-guided proximity to traditionally “undruggable” targets.
Together, these results establish HisTAC degraders as a versatile, ligand-independent strategy for probing challenging cancer targets and accelerating degrader discovery and mechanistic studies in cancer research.

#0998 The NVL inhibitor benzothiazepinone targets colorectal cancer by blocking ribosome biogenesis.

Ye Tao[1], Holly Guo[1], Min Fang[1], VIshal Khivansara[1], Shanhai Xie[1], Ashley Leach[1], Divya Reddy[1], Noelle S. Williams[2], Arin B. Aurora[1], Deepak Nijhawan[1], Jef K. De Brabander[1]

[1]Radiation Oncology, Section in Molecular Medicine, UT Southwestern Medical Center, Dallas, TX,[2]Dept. of Biochemistry, UT Southwestern Medical Center, Dallas, TX

The identification of new cancer-relevant protein targets is a major bottleneck in the discovery of small molecule therapies for the treatment of cancer. To meet this challenge, our team developed a platform that combines cell-based, high throughput phenotypic screens with forward genetics to identify new cancer targets and accompanying small molecule leads. By combining this approach with biochemical reconstitution and structural biology, we identified MM017 (benzothiazepinone scaffold) as a novel small molecule with anti-proliferative activity in colorectal cancer cells and its target nuclear valosin-containing protein-like (NVL), a hexameric AAA+ translocase required for large ribosomal subunit (60S) assembly. Simultaneously, an advanced medicinal chemistry campaign was launched to establish the SAR and to evaluate how continual modification balances the chemical-physical properties of candidate small molecules. Compounds that meet minimal criteria for in vitro ADME properties are progressed through the funnel and further evaluated through preclinical models to assess pharmacokinetics, toxicity, and efficacy.

#0999 N/C-terminus modification: enhanced TROP2-targeting cyclic peptide for PET imaging.

JONGMIN AN[1], Nisi Zhang[2], Marian Awadalla[1], SPENCER TUMBALE[3], Marina Raie[3], Basit Jan[3], Katherine W. Ferrara[4]

[1]Stanford University School of Medicine, Stanford, CA,[2]Stanford University School of Medicine, Palo Alto, CA,[3]Stanford University School of Medicine, Stanford, Palo Alto, CA,[4]Stanford University, Palo Alto, CA

Trophoblast cell surface antigen 2 (TROP2) has emerged as a compelling target in cancer therapy because it is highly overexpressed in many epithelial-derived malignancies while showing relatively low expression in normal tissues. To exploit this target, several modalities have been developed, including small molecules (e.g., Bruceine D) and antibody-based therapeutics (e.g., Sacituzumab govitecan). Despite these advances, challenges related to cost, specificity, and selectivity remain. In this flow, cyclic peptides have gained attention as attractive alternatives to conventional approaches due to their reduced conformational entropy and favorable biocompatibility.In this study, we report a chemically modified cyclic peptide designed for the visualization of TROP2 overexpression in cancer via PET/CT imaging. The peptide was modified at the N/C-terminus to promote π-π or cation-π interactions, thereby enhancing key biological properties such as binding affinity and stability. Each cyclic peptide was synthesized through Fmoc-based solid-phase peptide synthesis using HBTU/collidine-mediated amide coupling, and the final products were validated by mass spectrometry. The impact of the chemical modifications was assessed using circular dichroism (CD) spectroscopy, bio-layer interferometry (BLI), LogP analysis, and serum/glutathione stability assays. Radiolabeling with ^{68}Ga and ^{64}Cu demonstrated the preclinical capacity of this cyclic peptide. This strategy provides a versatile framework for the rational modification of cyclic peptides and supports the development of clinically relevant theragnostic agents.

#1000 Stereocontrolled synthesis and evaluation of functionalized lactams as potential anti-triple-negative breast cancer agents.

Leila Rahimian[1], Tolulope Omolekan[1], Ojasvi Dutta[1], Konstantin G. Kousoulas[1], Timothy K. Beng[2], Jean C. Chamcheu[3]

[1]Louisiana State University, Baton Rouge, LA,[2]Department of Chemistry, Central Washington University, Ellensburg, WA,[3]Department of Biological Sciences and Chemistry, Southern University and A&M College, Baton Rouge, LA

Triple-negative breast cancer (TNBC) is an aggressive subtype compromising ~ 10-15% of cases and defined by loss of ER, PR, and HER2, leading to limited therapies. Chemoresistance and tumor heterogeneity underscore the need for new small-molecule agents. Medicinal chemists note that stereocenters enhance drug potential; thus, chiral N-based cyclic compounds like lactams are valued. Here, we report the synthesis and anticancer evaluation of functionalized lactams bearing four contiguous stereocenters against TNBC models.A diversity-oriented synthesis strategy generated 40 structurally varied lactams. Compounds were screened for cytotoxicity against three TNBC (MDA-MB-231, BT-549, and 4T1) and one normal breast epithelial (MCF10A) cell lines using MTT assay. Clonogenic, wound-closure, ROS and Boyden chamber assays assessed growth and migration. Compounds with strong cancer-cell cytotoxicity and low MCF10A toxicity were selected for further analysis. Mechanistic data were obtained via immunoblotting and immunofluorescence for apoptosis markers. SwissADME was used for pharmacokinetic and drug-like predictions.Multiple lactams showed potent antiproliferative activity with sub-micromolar IC_{50} values, identifying W11, W12, and W23 as the most active, with IC_{50} values of (28.8, 40.8, and 28.4) μM in 4T1; (40.7, 38.7, and 21.6) μM in MDA-MB-231; and (22.2, 28.7, and 28.6) μM in BT-549. Lead compounds W11, W12, and W23 with cisplatin as control, significantly and dose-dependently reduced ROS, clonogenicity and migration, indicating anti-metastatic potential. W11 had the lowest EC_{50} (~23 μM), while W12, W23, and cisplatin showed EC_{50} values around 30-34 μM. These results indicate that the lead compounds reduce viability and impair TNBC cell motility. Mechanistic studies revealed robust activation of apoptosis pathways. SwissADME predicted high GI absorption, optimal lipophilicity (LogP<5), Lipinski compliance, and favorable biodegradability.This study identifies lactams W011, W012, and W023 as promising small-molecule candidates for TNBC. Their modulation of apoptotic and other pathways such as ROS-induction, along with favorable predicted pharmacokinetics, supports further preclinical optimization and development toward targeted TNBC therapy.

#1001 Targeting regulation of F-actin in cutaneous T-cell lymphoma: Synergistic inhibition of p38β with p38γ inhibitors.

Xu Hannah Zhang, Jack Hsiang, Markus Kalkum, Jun Wu, Steven T. Rosen

Beckman Research Institute of The City of Hope, Duarte, CA

Cutaneous T-cell lymphoma (CTCL) is an incurable T-cell malignancy characterized by dysregulated p38 MAPK signaling. Our recent studies identify p38β as an F-actin-binding kinase that regulates T-cell receptor (TCR) polarization and cytoskeletal organization. Loss or pharmacologic inhibition of p38β triggers compensatory activation of p38γ, promoting epithelial-to-mesenchymal transition (EMT) and potentially accelerating disease progression. To counter this effect, we evaluated a dual-targeting strategy combining the p38β inhibitor Nilotinib with p38γ inhibitors F7 (ATP-site) and CSH71 (ligand-binding-domain site). In Hut78 CTCL cells, combined F7 + CSH71 treatment significantly reduced cell viability with strong synergy (31.25 nM F7 + 1.25 μM CSH71; CI = 0.69). This dual inhibition markedly decreased F-actin polymerization, disrupted cellular polarization, and enhanced apoptosis compared with either single agent. Similarly, Nilotinib synergized with CSH71 in CTCL cells but not in healthy PBMCs, demonstrating tumor-selective cytotoxicity. Mechanistic analyses revealed that Nilotinib reduced γ-actin and ribosome-biogenesis-related proteins such as MDN1, as determined by LC-MS/MS, whereas CSH71 suppressed F-actin formation. These convergent effects destabilized the actin cytoskeleton and impaired TCR-dependent survival signaling. To extend these findings in vivo, ongoing studies using Hut78 xenograft mice are evaluating tumor reduction, apoptosis, survival benefit, and systemic safety following triple-drug combination (Nilotinib + F7 + CSH71). Collectively, these results support dual p38β/p38γ inhibition as a promising therapeutic approach for CTCL and other hematologic malignancies driven by cytoskeletal and stress-kinase dysregulation, while providing mechanistic insight into how targeted therapies remodel the F-actin network in vivo.

#1002 Parallel drug development strategies for fibrolamellar hepatocellular carcinoma and proteasome-dependent multiple myeloma.

Shalini Rawat, Najmeh Rahimi, Jared Alderman, Celeste Villasenor, Rodolfo Tello-Aburto, Barbara Lyons

Chemistry and Biochemistry, New Mexico State University, Las Cruces, New Mexico, NM

Fibrolamellar Hepatocellular carcinoma (FLC) is a rare liver cancer which occurs primarily in young adults and children under the age of 40. In FLC, a deletion of 400,000 base pairs occurs in one chromosome 19 copy, leading to the formation of a fusion protein comprised of a domain of the heat shock protein DNAJB1 and the catalytic subunit of Protein Kinase A (DNAJB1-PRKACA). Patients are typically asymptomatic at early stages, and 5-year survival remains below 50%. With surgery as the only partially effective treatment and no approved systemic therapies, there is a critical need for new therapeutics. The primary model compound of this project, Napabucasin, is a naphthoquinone natural product that has shown wide spectrum anti-cancer activities. Napabucasin was found to be a top hit in drug screening showing potency against FLC patient derived xenografts (PDX) models and direct-from-patient FLC tumor cells. Napabucasin is known to work in multiple signaling pathways including protein translation, the generation of reactive oxygen species, suppression of tumor cell stemness, and blocking tumor cell apoptotic escape. We anticipate the organic synthesis and development of optimized Napabucasin analogues, along with the evaluation of their cytotoxicity and proliferation effectiveness compared to the parent compound, Napabucasin, will result in compounds with improved bioavailability and efficacy, particularly in FLC model cell lines (Huh7-Chimera). In an additional approach to cancer drug development, we are evaluating the efficacy of promising next generation proteasome inhibitors. In eukaryotic cells, protein homeostasis is maintained through controlled synthesis and degradation, with the Ubiquitin Proteasome System (UPS) serving as the major pathway for regulated proteolysis. Cancer cells increase UPS activity to manage proteotoxic stress from rapid proliferation, leading to degradation of tumor-suppressive proteins and activation of oncogenic pathways. Targeted inhibition of UPS function causes accumulation of ubiquitinated proteins, G2/M arrest, and apoptosis, establishing the proteasome as a validated anticancer target. The 20S core of proteasome contains three catalytic β subunits (β1, β2, β5). Among all three, the chymotrypsin-like β5 activity remains the primary driver of cytotoxicity for clinically approved inhibitors such as bortezomib, carfilzomib; however, their therapeutic use is limited by toxicity. Peptidic β-lactones (the cystargolide family), are promising next-generation proteasome inhibitors. This project evaluates newly synthesized cystargolide analogs for cytotoxicity, bioavailability, and proteasome inhibition in RPMI-8226 myeloma cells. Using cell-based assays and IC_{50} determination, we aim to establish structure activity relationships and advance optimized β-lactone inhibitors with improved therapeutic potential.

#1003 Targeted co-delivery of gemcitabine and atRA via a GSH-responsive mutual prodrug enhances cytotoxicity through redox imbalance and Pin1 inhibition.

Nanhee Song[1], Ilseob Kim[1], Chnagjin Lim[1], Dongwon Lee[1], Sun Il Choi[2], Yun-Hee Kim[3]

[1]Jeonbuk National University, Jeonju-si, Korea, Republic of,[2]Research Institute of National Cancer Center, Goyang-si, Korea, Republic of,[3]National Cancer Center - Korea, Goyang-si, Korea, Republic of

Combination therapy offers strong potential to enhance anticancer efficacy, yet its success depends on the concurrent and targeted delivery of multiple agents. To address this challenge, we designed a self-assembling trimeric mutual prodrug, RqGem, which covalently links gemcitabine (GEM) and all-trans retinoic acid (atRA) through a glutathione (GSH)-depleting linker. This architecture enables excipients-free nanoassembly, achieving 100% drug loading and ensuring simultaneous delivery of both agents. RqGem nanoassemblies remained stable under physiological conditions and underwent esterase-mediated activation, releasing GEM and atRA along with a quinone methide intermediate that rapidly depletes intracellular GSH. This GSH depletion-driven redox modulation potentiated the cytotoxic mechanisms of both drugs by elevating oxidative stress and sensitizing cells to DNA damage and differentiation cues.The multiple and synergistic therapeutic actions of RqGem nanoassemblies were evaluated using cell culture and mouse models. RqGem nanoassemblies demonstrated significantly greater cytotoxicity, enhanced cellular uptake, and stronger apoptosis induction than the equivalent mixture of free GEM and atRA, reflecting robust synergy between atRA-mediated signaling modulation and GEM-induced DNA damage. The combined actions of self-assembly, 100% drug loading, concurrent drug release, and redox-dependent sensitization collectively contributed to the high potency of RqGem. Given that the role of atRA in targeting Pin1, a peptidyl-prolyl isomerase overexpressed in cancers and associated with poor prognosis, we further evaluated the impact of RqGem on Pin1 expression. Western blot analyses in AsPC-1 and CFPAC-1 pancreatic cancer cells showed marked Pin1 downregulation following RqGem treatment, supporting its dual mechanism of GEM delivery and atRA-mediated oncogenic pathway inhibition. Ongoing studies in orthotopic pancreatic tumor models aim to define the signaling pathways underlying RqGem-driven Pin1 suppression and its contribution to treatment synergy. Collectively, these findings establish RqGem as a rationally engineered, self-synergistic mutual prodrug that integrates drug self-delivery, controlled activation, and redox regulation to achieve potent and targeted anticancer activity. This platform holds strong translational promise for combination therapy in pancreatic cancer and beyond.

[1]Bradford Hill Clinical Cancer Research Center, Santiago, Chile,[2]IRCCS Humanitas Research Hospital, Rozzano MI and Humanitas University, Pieve Emanuele MI, Italy,[3]Princess Margaret Cancer Centre and University of Toronto, Toronto, ON, Canada,[4]Ankara Yıldırım Beyazıt University and Ankara Bilkent City Hospital, Ankara, Turkey,[5]Medical University of Gdansk, Gdansk, Poland,[6]Associate Professor, Dept. of Hem./Onc., Samsung Medical Center, Sungkyunkwan University, School of Medicine, Seoul, Korea, Republic of,[7]START Madrid, Madrid, Spain,[8]Jusidman Cancer Center, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel,[9]Zhejiang Cancer Hospital, Hangzhou, China,[10]Hacettepe University Cancer Institute, Ankara, Turkey,[11]Shanghai Chest Hospital, Shanghai Jiao Tong University, School of Medicine, Shanghai, China,[12]Chris O'Brien Lifehouse Research Institute, Camperdown, Australia,[13]Hamilton Health Sciences-Juravinski Cancer Centre, Hamilton, ON, Canada,[14]Beijing Friendship Hospital, Capital Medical University, Beijing, China,[15]Merck & Co., Inc., Rahway, NJ,[16]Maria Sklodowska-Curie National Research Institute and Oncology Centre, Warsaw, Poland

Background: Preliminary data from the phase 1 KANDLELIT-001 trial (NCT05067283) showed a manageable safety profile and preliminary antitumor activity for MK-1084, a next-generation, selective KRAS G12C-GDP covalent inhibitor, in participants (pts) with previously treated, *KRAS* G12C-mutant solid tumors. Here, we examine the effect of MK-1084 monotherapy on KRAS G12C variant allele frequency (VAF) and maximum somatic allele frequency (MSAF) ctDNA levels in pts with advanced KRAS G12C-mutant solid tumors during the monotherapy dose escalation phase of KANDLELIT-001.
Methods: KANDLELIT-001 enrolled pts with any KRAS G12C-mutated advanced solid tumor to receive MK-1084 alone or in various combination therapies. Pts with any advanced solid tumor and ≥1 prior systemic therapy received MK-1084 monotherapy PO QD or BID in Arm 1 (total daily dose, 25-800 mg). Serial blood samples collected from pts enrolled in Arm 1 were evaluated for changes in ctDNA KRAS-G12C VAF and MSAF levels at baseline, and before beginning cycle 1 and cycle 3 using the Guardant Health OMNI panel. Differences in ctDNA levels were assessed using descriptive statistics.
Results: In Arm 1, 22 of 23 pts were evaluable for changes in ctDNA levels. Median KRAS G12C VAF and MSAF ctDNA levels decreased ≥90% each from 14% to 0.9% and from 25% to 2%, respectively, from cycle 1 (pre-dose, day 0) to cycle 3 (day 42 on treatment); 6 (26%) pts achieved complete clearance of KRAS G12C VAF ctDNA. Greater reductions in tumor size were observed in pts who achieved complete clearance of KRAS G12C ctDNA. Larger reductions in ctDNA levels were seen in pts with a complete or partial response (responders) vs those with no response. Co-occurring mutations in PI3KCA, KEAP1, and KRAS G12D, Q61H, and BRAF were detected at baseline.
Conclusions: In a cohort of 23 patients with KRAS G12C mutations receiving MK-1084 monotherapy, tumor response was associated with reductions in KRAS G12C VAF and MSAF ctDNA levels. This potentially reflects the molecular activity and therapeutic effect of MK-1084 in KRAS G12C-mutated tumors. The small sample size of this analysis limits interpretation of these findings.

#1009 Landscape of homozygous copy number (CN) losses with established and emerging clinical actionability across 430,467 pan-tumor tissue samples.

Timothy A. Yap[1], Jessica K. Lee[2], Xin Liu[2], Erica Gornstein[2], Amaya Gasco[2], Richard S. P. Huang[2], Alexa B. Schrock[2]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Foundation Medicine, Inc., Boston, MA

Background: Loss-of-function (LOF) alterations (alts) in *BRCA1/2* and *PTEN* are associated with approved therapies in multiple tumor types, *RB1* and *STK11* are established prognostic biomarkers, and LOF of a growing number of additional genes (e.g. *MTAP, NF1*) have emerging actionability and are under investigation in clinical trials. LOF alts include inactivating mutations, rearrangements, and homozygous CN losses, which can be analytically challenging to detect. With the growing clinical importance of CN losses, we assessed their prevalence in a cohort of pan-tumor samples submitted for tissue comprehensive genomic profiling (CGP).
Methods: 430,467 pan-tumor tissue samples underwent NGS-based CGP on FoundationOne®CDx. A genome-wide CN model for each sample was generated, segmented and combined with variant allele frequencies of heterozygous SNPs to estimate tumor purity (TP), ploidy and CN for each segment; the presence of homozygous CN losses was assessed for 310 genes.
Results: CN losses were detected in 31% of pan-tumor samples and were most prevalent in glioma (53%), pancreas (50%), and gallbladder (50%). The most prevalent pan-tumor homozygous losses were in *CDKN2A/*B (15/17%), *MTAP* (11%), *PTEN* (4.2%), *SMAD4* (2.2%), and *RB1* (1.5%). Disease-specific CN loss enrichments were observed, including *PTEN* in prostate (22%), *SMAD4* in GI tumors (12% pancreas, 8.2% gallbladder, 8% small intestine, 4.9% CRC), *RB1* in SCLC (12%), *STK11* in cervix (5.0%) and NSCLC (2.9%), *NF1* in ovarian (4.2%), and *KEAP1* in NSCLC (0.6%). HRD associated losses were also detected in *BRCA2* (2.8%, 0.5%, and 0.3%), *BRCA1* (0.06%, 0.3%, and 0.6%), and *PALB2* (0.02%, 0.03%, and 0.02%) in prostate, breast, and ovarian cancers, respectively. CN losses comprised >98% of LOF alts in *CDKN2B* and *MTAP*, and >20% of LOF alts in many genes including *CDKN2A*, *PTEN, RB1*, and *STK11*. 27% of samples harbored a CN loss associated with a clinical trial enrolling based on LOF alts (across 63 genes), and 22% harbored a CN loss (across 16 genes) associated with trials specifically requiring a CN loss or deletion vs. any LOF alt. The median TP of a sample with a CN loss detected was 50% (IQR 33-68%). The pan-tumor prevalence was 16% in samples with TP < 20% (n=65,881), increased to 34% in samples with 20-30% TP, and remained relatively stable at higher TPs: 36% at 30-40% TP and 33% at >40% TP.
Conclusions: CN losses were detected in >30% of pan-tumor tissue samples and included losses associated with approved or investigational therapies such as *BRCA1/2, PTEN, MTAP*, and *NF1*, and losses with prognostic implications such as *RB1* and *STK11*. Prevalence trended with increasing TP and reached the prevalence of the overall cohort in samples with TP ≥ 20%. CN losses are a diverse class of analytically challenging but increasingly clinically relevant biomarkers, and reliable detection of these events will be important for optimal therapy selection.

#1010 DNA-level complex fusions show high discordance with RNA expression: A validation study of 115 Chinese cases.

Xinyue Wang[1], Lu Zhang[2], Xinyan Li[1], He Jiang[1], Jiayi Zhao[1], Richeng Jiang[1]

[1]Center for Precision Cancer Medicine & Translational Research, National Clinical Research Center for Cancer, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China,[2]Center for Precision Cancer Medicine & Translational Research, Tianjin Cancer Hospital Airport Hospital, Tianjin, China

Background:
Gene fusions identified by DNA-based next-generation sequencing (DNA-NGS) play a crucial role in guiding targeted therapy for solid tumors. However, complex fusion structures may not always transcribe into functional chimeric RNAs or proteins, due to disrupted open reading frames, opposing transcriptional directions, or absence of promoter elements. Such discrepancies can lead to false-positive DNA-NGS findings and subsequent inappropriate treatment decisions.
Methods:
We analyzed 115 tumor samples from the Chinese population with DNA-NGS-identified complex fusions using simultaneous DNA and RNA-based NGS (DR-NGS) for validation. Seven samples with inadequate pathology quality control were excluded.
Results:
Lung cancer accounted for the majority of the 115 samples (89, 77.4%). Complex fusion patterns included 5′-5′ fusions, 3′-3′ fusions, primary/reciprocal fusions, non-canonical breakpoints or partners, co-occurrence of multiple fusion drivers, UTR-region fusions, and intergenic fusions. The involved genes were *ALK* (32), *ROS1* (10), *NTRK* (6), *EGFR* (9), RET (28), *HER2/3* (2), *MET* (4), *FGFR1-4* (15), *NRG1* (1), *BRAF* (4), and multiple co-existing fusion genes (3).
Among the 108 successfully tested cases, 45 showed no fusions by DR-NGS testing but revealed other driver mutations in 57.78% of cases, including *EGFR* (22, 48.89%), *FGFR2* (1), *BRAF* (1), and *KRAS* (2). In the remaining 63 cases, DR-NGS testing confirmed the presence of fusions, with only one case showing a co-existing *EGFR* mutation (1.59%, $p < 0.001$). Among these, 55 exhibited classic single fusions at the RNA level after transcriptional splicing, while 8 cases with rare fusion partners in DNA-level were validated as true partners by DR-NGS testing.
RNA fusion-positive and -negative groups showed male-to-female ratios of 21:42 and 23:22 ($p = 0.064$), and age distributions (≥65 vs. <65 years) of 9:54 and 20:25 ($p < 0.001$), respectively.
Conclusion:
This study reveals a substantial discordance between DNA-level complex fusions and their RNA expression. Nearly half of the DNA-identified complex fusions were not transcribed, with many instead harboring other driver mutations—most commonly EGFR. By contrast, RNA-verified fusions predominantly presented as classic single transcripts, with rare co-occurrence of other driver mutations. RNA fusion status was also significantly associated with patient age. These findings underscore the necessity of RNA-based confirmation for DNA-detected complex fusions, especially those coexisting with other driver gene mutations, to prevent false-positive interpretations and to optimize targeted therapy selection.

#1011 Correlation of mitophagy related genes expression and clinical outcome in metastatic colorectal cancer patients enrolled in CALGB (Alliance)/SWOG 80405.

Shivani Soni[1], Yan Yang[2], Michela Bartolini[1], Pooja Mittal[3], Fang-Shu Ou[4], Lesly Torres-Gonzalez[5], Unnati Hemant Shah[5], Jae Ho Lo[1], Steve Soto Trujillo[1], Yitzhar Goretsky[5], Wu Zhang[5], Alan P. Venook[6], Sandra Algaze[1], Joshua Millstein[7], Heinz-Josef Lenz[5]

[1]Medical Oncology, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Population and Public Health, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[3]Keck School of Medicine of USC, Los Angeles, CA,[4]Alliance Statistics and Data Management Center, Mayo Clinic, Rochester, MN,[5]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[6]University of California, San Francisco, CA,[7]Population and Public Health Sciences, USC Norris Comprehensive Cancer Center, Los Angeles, CA

Background. Mitophagy plays a crucial role in removing dysfunctional mitochondria to maintain cellular homeostasis but also has been implicated in cancer tumorigenesis. Previously, we showed that genetic variation in mitophagy pathway genes holds a predictive value in metastatic CRC (mCRC) patients (pts) treated with bevacizumab-based chemotherapy. In this study, we analyzed the correlation between tumor expression profiles of genes associated with PINK1/Parkin and BNIP3/NIX/FUNDC1 mitophagy pathways with clinical outcome in a large phase III randomized clinical trial CALGB SWOG 80405.

Method. We analyzed 433 pts with mCRC treated with first-line chemotherapy in combination with the targeted agents bevacizumab (Bev, $n = 226$) or cetuximab (Cet, $n = 207$). Tumor RNA isolated from FFPE samples was sequenced using the HiSeq 2500 platform (Illumina). Median Overall survival (mOS) and median progression-free survival (mPFS) were compared across pts groups divided into high, medium, and low tertiles based on mitophagy-related gene (*BNIP3*, *BNIP3L*, *PINK1*, *PRKN*) expression levels. Likelihood ratio tests, hazard ratios (HRs), and 95% confidence intervals (CIs) were calculated using multivariable Cox proportional hazards models, adjusting for age, sex, ECOG performance status, tumor location, number of metastatic sites, *KRAS* status, Consensus Molecular Subtypes, and treatment arm.

Results: Overall, *BNIP3L* demonstrated significant prognostic value for both PFS and OS after adjustment for multiple testing (false discovery rate [FDR] < 0.05). Tumors with low *BNIP3L* expression showed longer PFS and OS compared to those with medium or high expression levels (mPFS 14.8 vs. 10.0 vs. 9.2 months, HR 1.16, 95% CI 1.04 - 1.29$p = 0.0182$; mOS: 37.4 vs. 30.2 vs. 24.4 months, HR 1.22, 95% CI 1.09 - 1.38, $p = 0.0036$), independent of treatment. In pts treated with Cet, high *PRKN* expression was associated with improved PFS and OS (mPFS: 8.9 vs. 10.3 vs. 14.6 months, HR 0.79; 95% CI 0.69 - 0.91, $p = 7.3e-05$; mOS: 21.2 vs. 27.7 vs. 41.1 months, HR 0.87; 95% CI 0.75 - 1.01, $p = 0.00084$), whereas low *PINK1* expression was significantly associated with longer OS (mOS: 24.9 vs. 30.9 vs. 39.2 months, HR 1.23; 95% CI 1.04 -1.46, $p = 0.013$). No significant associations were observed in Bev-treated patients for *PRKN* or *PINK1*. No significant results were found for *BNIP3* expression analysis.

Conclusion. Mitophagy is a crucial player in CRC biology due to its tumor-intrinsic (mitochondrial bioenergetics) and microenvironment (interacts with immune components) effects. Our study highlights the prognostic value of *BNIP3L* and predictive potential of *PINK1* and *PRKN*, suggesting a potential combinatorial therapeutic approach using mitochondrial targeting drugs and targeted agents e.g Cet, which warrants further investigation.

Support: Genentech; Clinicaltrials.gov Identifier: NCT00265850

#1012 Multi-omic method to detect MTAP homozygous deletions enables high sensitivity detection from blood samples.

Geethika Yalamanchili, Sean Gordon, Evan Warner, Shile Zhang, Keelia Clemens, Matthew Ellis, Vishnu Ramani, Marisa Juntilla, Martina Lefterova, Justin Odegaard, Darya Chudova

Guardant Health, Palo Alto, CA

Introduction: The methylthioadenosine phosphorylase (*MTAP*) gene encodes a tumor suppressor and component of the methionine salvage pathway. *MTAP* homozygous deletion (HomDel) can induce synthetic lethality when either PRMT5, MAT2A, or both are inhibited. Successful detection of *MTAP* HomDel can, therefore, offer novel options for targeted therapy. Unfortunately, tumor tissue is often unavailable for genomic profiling and detection of *MTAP* HomDel. While cfDNA testing is available for CGP, detection of *MTAP* HomDel in plasma cfDNA is challenging, as detection by conventional coverage-based methods is masked by non-tumor DNA coverage, especially in low-tumor fraction samples, thus limiting sensitivity in these settings.

Methods: We developed a multi-omic approach that integrates genomic and tumor-specific methylation features to enhance detection sensitivity for *MTAP* HomDel in circulating tumor DNA (ctDNA). Tumor-specific methylation features were identified by analyzing methylation profiles from 100,089 plasma samples spanning diverse solid tumor types and used to train a classifier optimized to detect *MTAP* HomDel using the Guardant360 Liquid test. The resulting tumor-specific methylation classifier was then combined with genomic copy-number calling to maximize sensitivity and specificity for *MTAP* HomDel detection in plasma. Analytical accuracy was assessed in 87 matched cfDNA and tissue samples (NSCLC = 40%, pancreatic = 9%, melanoma = 9%, breast = 7%, other = 35%) from patients with advanced cancer. *MTAP* HomDel and single copy number loss were treated as distinct categories. Consecutive samples tested in routine clinical care were used to determine detection rates. Limit of blank (LoB) specificity was established using 120 cancer-free donor cfDNA samples (30 ng input), and the 95% Limit of Detection (LoD) was determined via *in silico* dilutions of 50 high confidence *MTAP* HomDel samples.

Results: Our multi-omic methodology achieved a positive predictive value (PPV) of 100% and negative percent agreement (NPA) of 100% above LoD (90.9% and 96.6% overall) against a tissue-based reference. No false positives were observed among 120 cancer-free donors. Assessment of cfDNA samples from patients with advanced cancer demonstrated that multi-omic *MTAP* HomDel detection was over 2.4 fold as sensitive as genomic-only methods.

Conclusion: Augmenting genomic information with tumor-specific methylation significantly enhances the detection of *MTAP* HomDel in plasma cfDNA, especially in low-tumor-fraction samples. Future work may leverage similar methylation coverage on the Guardant360 Tissue test to enhance *MTAP* HomDel detection in low input and low tumor purity tissue samples. This approach has potential to not only improve patient access to PRMT5- and MAT2A-targeted therapies but also to other therapies that are guided by gene deletions.

#1013 Immune microenvironment driven immunotherapy resistance in 11q13-amplified hepatocellular carcinoma.

Weiping Zhu

Fudan University Shanghai Cancer Center, Shanghai, China

Background: Immune checkpoint inhibitors (ICIs) have provided new therapeutic opportunities for patients with liver hepatocellular carcinoma (LIHC); however, only a subset of patients achieve meaningful benefit. Previous studies have suggested that co-amplification of the chromosome 11q13 region—which includes CCND1, FGF3, FGF4, and FGF19—is associated with poor immunotherapy response and unfavorable prognosis. Nonetheless, whether the immune microenvironment contributes to ICI resistance in 11q13-amplified LIHC remains unclear. This study aimed to elucidate the genomic and immunologic correlates of 11q13 amplification in LIHC.

Methods: Tumor samples from 890 LIHC patients were analyzed using a 733-gene next-generation sequencing (NGS) panel to characterize genomic alterations, including DNA damage repair (DDR) pathway genes, tumor mutation burden (TMB), and intratumor heterogeneity (ITH). Multiplex immunofluorescence (mIF) was performed to evaluate the immune microenvironment, focusing on stromal and intratumoral immune cell populations. Comparative analyses were conducted between patients with and without 11q13 amplification to determine differences in genomic alterations and immune cell infiltration patterns.

Results: Among the 890 LIHC patients, 8.9% (79/890) harbored chromosome 11q13 amplification. Genomic profiling revealed no significant differences in DDR pathway mutations, TMB, or ITH between 11q13-amplified and non-amplified patients, suggesting that 11q13-associated immunotherapy resistance is unlikely to stem from genomic instability. In contrast, immune microenvironment analysis revealed substantial alterations associated with 11q13 amplification: patients with amplification demonstrated increased stromal $CD8^+$ T-cell positivity (P=0.04), as well as significantly elevated intratumoral infiltration of $CD68^+CD163^+$ M2-TAMs (higher density, P=0.03; higher positivity, P=0.03) and increased positivity of $CD68^+HLA\text{-}DR^+$ M1-TAMs (P=0.03). These findings indicate that 11q13-amplified tumors may harbor a more complex immunosuppressive and inflammatory microenvironment, potentially contributing to ICI resistance.

Conclusion: Chromosome 11q13 amplification in LIHC is not associated with distinct genomic instability features but is strongly correlated with alterations in the tumor immune microenvironment, including increased $CD8^+$ T-cell presence and enrichment of both M1 and M2 tumor-associated macrophages. These results suggest that immune microenvironment dysregulation, rather than genomic variation, may underlie immunotherapy resistance in 11q13-amplified LIHC, underscoring the need for tailored immunotherapeutic strategies for this molecularly defined subgroup.

#1014 Multimodal AI predicts immune checkpoint inhibitor response from clinically available inputs and whole-slide images with explainable tumor biology and combination therapy insights.

Felicia Kuperwaser, Sunil Kumar, Sepideh Foroutan, Dillon Tracy, Kevin Freisen, Taylor Wood, Zong Miao, Nathaniel Tann, Fahad Khan, Jean Michel Rouly, Anshu Jain, Jeff Sherman, Emily Vucic, **Maayan Baron**

Zephyr AI, McLean, VA

Background: Immune checkpoint inhibitors (ICIs) provide durable benefit for a subset of patients, yet most do not respond and current biomarkers (PD-L1, TMB, MSI) have limited predictive value. We developed AIM-io, a multimodal, biologically interpretable AI model that predicts ICI response using routine clinical inputs including liquid biopsy, tissue NGS and, for proof-of-concept, whole-slide images (WSI) processed with publicly available research-only foundation-model embeddings. AIM-io integrates reconstructed gene-expression and TME programs with predicted small-molecule sensitivities, enabling biological interpretation of each prediction.
Methods: A pan-cancer real-world cohort (~3,000 patients, 13 tumor types) treated with anti-PD-(L)1 or anti-CTLA-4 therapy was assembled with linked rwOS/rwPFS. Inputs included liquid-biopsy, tissue NGS, or WSIs encoded embeddings (e.g., GigaPath, UNI). AIM-io incorporated clinical variables, genomic alterations from commercial LDTs, reconstructed expression/TME signatures (AIM-Ex), ICI drug/target embeddings, and AIM-Bx-derived small-molecule sensitivity profiles (~100 agents). Performance was assessed using C-index, hazard ratios, KM stratification, and comparisons to available biomarkers.
Results: AIM-io showed robust cross-modality performance. In held-out LDT data, AIM-io significantly separated responders vs. non-responders ($p < 10^{-7}$, HR = 0.23, 95% CI 0.14-0.41), outperforming PD-L1 ($p = 0.26$, HR = 0.77, 95% CI 0.48-1.22) and TMB ($p < 10^{-3}$, HR = 0.39, 95% CI 0.24-0.65). Using liquid-biopsy DNA, AIM-io significantly stratified outcomes ($p < 0.05$, HR = 0.63, 95% CI 0.39-1.01). Results were consistent across cancer types and NGS platforms. With WSI-only inputs, AIM-io achieved significant outcome separation (HR = 0.46, $p < 0.05$; 95% CI 0.22-0.97) and outperformed models using WSI embeddings alone (HR = 0.62, $p = 0.12$), demonstrating feasibility in settings lacking molecular assays. Predicted responders showed enrichment for reconstructed TME programs (e.g., lymphocyte infiltration), whereas non-responders showed immunosuppressive signatures (e.g., TGF-β, wound healing). Small-molecule sensitivity predictions differed, with responders showing greater predicted PARPi sensitivity and non-responders enriched for VEGFi sensitivity.
Conclusions: AIM-io provides an explainable multimodal framework for ICI-response prediction using diverse, clinically accessible inputs—including liquid biopsy DNA and WSI embeddings. By integrating reconstructed expression, TME biology, and predicted therapeutic vulnerabilities, AIM-io offers an assay-agnostic approach for retrospective evaluation of immunotherapy response and hypothesis generation for rational combinations. Prospective validation is warranted.

#1015 Quantitative c-MET immunohistochemistry reveals prognostic subgroups in papillary renal cell carcinoma.

Yong Il Lee[1], Jamin Park[1], Sun Young Yoon[1], Yong Mee Cho[1], Inkeun Park[2], **Bokyung Ahn**[1]

[1]Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Background: MET is a key driver gene in papillary renal cell carcinoma (PRCC), yet the prognostic significance of c-MET immunohistochemical (IHC) expression remains unclear. Previous studies have been limited by heterogeneous cohorts containing mixed renal tumor entities and by subjective variability inherent to manual IHC assessment. As c-MET targeted antibody-drug conjugates (e.g., Telisotuzumab vedotin) show therapeutic promise in several cancers, we aimed to quantitatively evaluate c-MET expression in a strictly defined PRCC cohort and to clarify its prognostic value using an image analysis platform.
Methods: A total of 505 surgically resected PRCC cases (1989-2023, Asan Medical Center) were reclassified according to the 2022 WHO system after excluding non-PRCC entities using a 19-marker IHC panel. c-MET IHC (SP44, Ventana) was performed in the final 415 PRCC cases and scored both manually (H-score) and by HALO image analysis. Expression levels were dichotomized into high and low by the median value. Statistical analyses included Spearman correlation, and survival analyses for 5-year recurrence-free (RFS) and disease-specific survival (DSS).
Results: HALO-based c-MET quantification showed a strong correlation with manual scoring ($R = 0.88$, $P < 0.001$), supporting the validity of automated evaluation. HALO scoring demonstrated significantly higher c-MET expression in type 1 compared to type 2 PRCC (median 64.03 vs. 33.26, $P < 0.001$). Type 2 PRCC exhibited worse RFS and DSS than type 1 (both $P < 0.001$). In subgroup analyses, type 2 PRCC with low c-MET expression had significantly poorer DSS than type 1 PRCC with either low ($P = 0.022$) or high ($P = 0.029$) expression, however type 2 PRCC with low c-MET expression did not show statistical significance compared to type 1 PRCC. For RFS, type 2 PRCC showed consistently worse outcomes than type 1 PRCC regardless of c-MET level. However, c-MET expression was not an independent prognostic factor in univariate or multivariate Cox models.
Conclusions: This study's strength lies in its large, rigorously reclassified PRCC cohort and the combined use of manual and automated scoring methods. Importantly, automated HALO scoring provided an objective, reproducible measure of c-MET expression while maintaining excellent concordance with manual evaluation, supporting its utility in standardizing biomarker assessment. Although PRCC subtyping is no longer recommended in the current WHO classification, we found that low c-MET expression strongly correlated with type 2 morphology and poorer DSS, reflecting the fundamentally different underlying molecular pathways between type-specific phenotypes. Also, since type 2 PRCC with high c-MET expression showed survival patterns similar to type 1, quantitative assessment of c-MET expression may refine risk stratification in PRCC and furhter guide patient selection for emerging MET-targeted therapies.

#1016 PHIT score integrates tumor biology to predict PDAC prognosis and therapy response.

Derek Erstad[1], Alejandro Zulbaran y Rojas[1], Christy Chai[1], Eugene Choi[1], George Van Buren[1], E. Ramsay Camp[1], William E. Fisher[1], Natalie Vokes[2]

[1]Baylor College of Medicine, Houston, TX,[2]University of Texas MD Anderson Cancer Center, Houston, TX

Background: Pancreatic ductal adenocarcinoma (PDAC) exhibits wide variation in tumor plasticity (P), heterogeneity (H), immune suppression (I), and treatment resistance (T). Existing clinical and molecular classifiers capture only part of this biology. We developed PHIT, a 12-gene transcriptomic score integrating these four axes, and evaluated its prognostic and therapeutic relevance across resected and metastatic PDAC.

Methods: RNA-seq from TCGA, PACA-CA/ICGC, and CPTAC (n=419) was batch-corrected and analyzed with weighted Cox models to generate gene-level survival coefficients. These were integrated with chemotherapy-response metrics from the metastatic COMPASS cohort (n=188; continuous tumor-volume change and PR/SD/PD categories across all patients and within FOLFIRINOX and gemcitabine/nab-paclitaxel subgroups) to build a joint survival-chemo composite. Bootstrap selection yielded a 12-gene PHIT signature. PHIT scores were computed using training-cohort means/SDs and Cox logHR weights. Prognostic performance was tested using Kaplan-Meier, Cox models, and c-index. Validation included PACA-AU, Chen, Nones, and Moffitt cohorts (n=339). Hallmark analyses compared PHIT-high vs PHIT-low tumors within molecular subtypes.

Results: PHIT significantly stratified overall survival (OS) in the 419-patient training cohort (median 32.7 vs 10.4 months for PHIT Q1 vs Q4; HR 3.49, $p=7\times10^{-14}$), improved a tumor grade/stage model (c-index 0.590→0.685), and remained independently prognostic after adjustment for Moffitt, Collisson, and Bailey molecular subtypes (HR 2.36, $p<0.001$). In COMPASS, PHIT correlated with chemotherapy resistance (tumor-volume change $r=0.40$ overall; 0.45 FOLFIRINOX; 0.34 GA) and stratified metastatic OS (12.6 vs 5.6 months; HR 2.92, $p=1.4\times10^{-5}$). In validation cohorts, PHIT consistently separated risk: PACA-AU (50.4 vs 10.9 months; HR 4.90, $p=0.008$), Chen (31.5 vs 15.6; HR 3.09, $p=0.01$), Nones (24.5 vs 15.1; HR 3.47, $p=0.01$), and combined arrays (30.1 vs 15.1; HR 2.45, $p=6.45\times10^{-5}$). Mechanistically, PHIT-high Classical tumors showed selective enrichment of EMT, ECM remodeling, and inflammatory NF-κB pathways, whereas PHIT-high Basal-like tumors showed glycolytic and metabolic plasticity with hypoxia, mTORC1, and proliferative G2M/E2F programs. These subtype-specific patterns were reproducible across Collisson and Bailey frameworks.

Conclusions: PHIT is a concise transcriptomic score that integrates four dimensions of aggressive PDAC biology. It predicts survival across seven cohorts (n=946), correlates with chemotherapy response, and reveals distinct EMT- and glycolysis-associated high-PHIT phenotypes, supporting its utility for biological risk stratification and treatment selection.

#1017 STAT5A promoter hypermethylation as a biomarker of immune checkpoint inhibitor response in squamous cell carcinoma in cfDNA liquid biopsies.

Janice Patterson, Brooke Overstreet, Jiemin Liao

Guardant Health, Palo Alto, CA

Background: STAT5A is a downstream transcription factor in the JAK-STAT pathway that regulates immune- and tumor-related gene expression. Hypermethylation of the STAT5A promoter is linked to immune cell depletion and reduced antitumor immune activity in head and neck squamous cell carcinoma (HNSCC) and lung squamous cell carcinoma (LSCC) (Liang et al. 2023). We hypothesized that STAT5A promoter hypermethylation (PM) detectable in cfDNA is a predictive biomarker of immune checkpoint inhibitor (ICPI) response in squamous cell carcinomas (SCC).
Methods: Guardant360 Liquid (Guardant Health, Palo Alto, CA) was used to detect hypermethylated STAT5A promoter region, defined initially as 5kb upstream from the transcription start sites (TSS). Correlation between methylation and expression for PM regions was determined using The Cancer Genome Atlas (TCGA) data to identify loci where PM was associated with transcriptional silencing. Candidate loci were evaluated in a large cohort of cancer-free samples (n=32k) to ensure analytical specificity. PM status is distinguished relative to constitutively hypermethylated control regions, measuring methylation level relative to total cfDNA. Clinical outcomes analyses used the GuardantINFORM real-world clinico-genomics database.
Results: STAT5A PM prevalence as measured by Guardant360 Liquid was concordant with published datasets across tumor types. The assay demonstrated high analytical specificity (negative percent agreement > 98%). STAT5A PM was associated with a shorter time to next treatment (TTNT) among ICPI-treated patients with SCC (n=815, 91% LSCC, 9% HNSCC, unadjusted log-rank p=0.01). Median TTNT for STAT5A PM+ patients (n=16) was 8.6 mo (95% CI, 4.6-10.4) versus 30.7 mo (95% CI, 25.6-38.1) for PM- patients (n=799). In a multivariable Cox proportional hazards model, adjusting for clinical covariates (age, gender, and line of therapy), PM+ remained independently associated with shorter TTNT (HR=2.10; p=0.03). When analyzed by cancer type, the association between STAT5A PM and TTNT was primarily driven by LSCC (HR=2.33; p=0.01). The limited number of PM+ HNSCC cases (n=3) precluded statistical significance in that subgroup.
Conclusion: Non-invasive detection of STAT5A PM using Guardant360 Liquid is inversely correlated with real-world ICPI benefit in patients with LSCC, adding to a growing list of biomarkers demonstrated to have predictive significance in ICPI and broadening the role of methylation-based profiling in precision oncology.

#1018 Longitudinal peripheral blood TCR tracking predicts response to immune checkpoint inhibitors.

Dingyuan Wang[1], Kaiyan Xu[2], Parker J. Li[3], David J. H. Shih[3], Matthew K. L. Chiu[1], Jason W. H. Wong[3], Wei Dai[1], Aya El Helali[1]

[1]Department of Clinical Oncology, School of Clinical Medicine, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong,[2]Centre for Oncology and Immunology, Hong Kong Science Park, Hong Kong, Hong Kong,[3]School of Biomedical Science, The University of Hong Kong, Hong Kong, Hong Kong

Background: While immune checkpoint inhibitor (ICI) therapy has revolutionized oncology, reliable biomarkers to predict clinical response are critically needed. Static, single-time-point analysis of the T-cell receptor (TCR) repertoire has proven inadequate. We hypothesized that the longitudinal tracking of TCR clonal dynamics would provide a more powerful and predictive biomarker of clinical outcome.

Methods: To test this hypothesis, we employed a two-stage strategy. First, we performed an exploratory analysis on the public longitudinal TCR-seq dataset GSE212217 to investigate whether dynamic changes in TCR clones could distinguish responders from non-responders. Based on the observed temporal expansion patterns, we developed a novel classification model that categorizes TCR clones algorithmically by quantifying the direction and magnitude of change in their relative abundance over time. Clones are assigned to distinct behavioral types, Response, Super-response, Transient, and Quiescent, based on specific, quantitative criteria applied to their longitudinal trajectories. Second, we validated this model in an independent, prospective pilot cohort of advanced melanoma patients using TCR sequencing from serial blood samples.

Results: Analysis of the public dataset confirmed that baseline TCR diversity metrics were unable to differentiate between clinical responders and non-responders. In contrast, our longitudinal model identified distinct clonal expansion trajectories. This novel response score was significantly elevated in responders compared to non-responders in the discovery cohort (Wilcoxon test, $P = 0.011$). Critically, patients with a high score exhibited a marked survival advantage (Log-rank $P = 0.040$), confirming the clinical prognostic value of our dynamic metric. Validation in our independent melanoma cohort confirmed the clinical utility of our model. Strikingly, the patient with disease progression exhibited a low proportion of active, expanding clones (5.5%), whereas the patient achieving a deep clinical response demonstrated a markedly higher proportion of active, expanding clones (10.5%).

Conclusion: We have developed and validated a novel biomarker based on the dynamic expansion of T-cell clones that effectively predicts ICI response and survival. This work definitively moves beyond the limitations of static TCR metrics, establishing longitudinal clonal tracking as a crucial strategy for liquid biopsy. This approach provides a critical tool for real-time response monitoring and precision stratification of cancer immunotherapy.

#1020 Characterization of functional estrogen receptor (ER) dependence via comprehensive epigenomic liquid biopsy stratifies endocrine therapy (ET) responders with metastatic breast cancer (MBC).

Stefania Morganti[1], Jonathan Beagan[2], Ningxuan (Shirley) Zhou[1], Khoi Nguyen[2], Kalie Smith[1], Ashka Patel[1], Catherine Stever[1], Katheryn Santos[1], Molly Skeffington[1], Olivia D'Amico[1], Travis Clark[2], Justin Finkle[2], Anthony D'Ippolito[2], Mike Zhong[2], Jamey Guess[2], Kristian Cibulskis[2], Aparna Gorthi[2], Tyrone Tamakloe[2], Charlene O'Brien[2], Baovy Tran[2], Mary McGillicuddy[2], Nabihah Tayob[1], Sara M. Tolaney[1], Nancy U. Lin[1], Hillary Heiling[1], Corrie A. Painter[2], Matthew L. Eaton[2], J. Carl Barrett[2], Heather A. Parsons[3]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Precede Biosciences, Boston, MA,[3]Fred Hutch Cancer Center, Seattle, WA

Background: Endocrine therapy (ET) is standard of care for ER+ MBC, but virtually all patients (pts) develop ET resistance over their disease course. Biomarkers predictive of loss of ER dependence to guide therapy (tx) are lacking.
Methods: We identified 122 pts with ER+/HER2- MBC enrolled in the EMBRACE study at Dana Farber Cancer Institute who received 1-2 lines (L) of ET and had a blood drawn within +/- 30 days of switch from 1L to 2L (n=77) or from 2L to 3L (n=53). Using 1mL plasma, we profiled genome-wide enhancers, promoters and DNA hypermethylation to infer pathway activation and gene expression levels. Samples that did not meet quality thresholds (n=16) or had tumor fraction <0.5% (n=48) were excluded. We applied the Precede ER dependence index (PERDI) that quantifies relative activities of ER-driven vs estrogen-starvation-induced enhancers and classified samples as PERDI-high or -low using a predefined threshold. We investigated the association between PERDI and time-to-next-treatment (TTNT). A conditional landmark approach defined TTNT beginning from 30 days after the start of tx of interest (ET or non-ET) until the start of the next tx line, considering only tx switch for tumor progression as events. Time-dependent ROC curves were used in the prespecified primary analysis investigating the association between PERDI and early progression on ET. Kaplan Meier methods and Cox proportional hazard models were used in additional analyses.
Results: A total of 71 pts (79 samples) were included: 57 pts had draws collected before ET (40 switch from 1L to 2L ET, 17 from 2L to 3L ET); 22 pts had samples collected from 2L ET to 3L non-ET. Most common next-line ET regimens were SERD (n=17), SERD + CDK4/6 inhibitors (i) (n=14), aromatase inhibitors (AI) + mTORi (n=9), SERD + other targeted therapy (n=6). Among 57 pts starting next-line ET, PERDI was associated with landmark TTNT (median TTNT 2.4 months (mo) with low vs 4.1 mo with high PERDI, HR 2.65, 95% confidence interval [CI] 1.24-5.66, p=0.012). However, PERDI did not reliably identify early progressors to next-line ET (time-dependent AUC at 2 mo c = 0.51). Among 22 pts who switched from ET to non-ET (primarily chemotherapy), PERDI was not associated with TTNT (HR 0.66, 95% CI 0.23-1.85, p=0.426), suggesting a potential predictive role specifically for ET. Among pts with high PERDI but poor response to next-line ET, preliminary analyses identified 6 outliers for activity of known resistance pathways (e.g. *FGFR1*, *ERBB2*).
Conclusions: We observed a significant association between PERDI and benefit from ET. Our exploratory analysis integrating resistance pathways beyond ER further identified pts with high PERDI but ET resistance. Upon further clinical validation, this blood based comprehensive epigenomic assay could become a valuable tool to guide tx for pts with ER+/HER2- MBC.

#1021 Detection of rare genomic fusions revealed through comprehensive genomic profiling of atypical tumors.

Jennifer B. Jackson[1], Stanislav Fridland[2], Behtash G. Nezami[2], Gunja Pathak[1], Jennifer Dickey[1], Lawrence Jennings[2]

[1]Labcorp, Baltimore, MD,[2]Department of Pathology, Northwestern University Feinberg School of Medicine, Chicago, IL

Next-generation sequencing (NGS) of tumor tissue is the gold standard for genomic profiling of most solid cancer types, facilitating the identification of treatment options and patient management strategies by uncovering clinically actionable variants that can be targeted with biomarker-specific FDA-approved drugs. Validation of NGS assays requires large numbers of patient samples to evaluate the performance of each variant class, including single nucleotide variants, insertions and deletions, structural variants like copy number amplifications and translocations, as well as genomic signatures (microsatellite instability and tumor mutation burden). Sourcing clinical samples, however, is often a challenge due to limited number of patient samples available and more so by the biological prevalence of rare biomarkers, such as *NTRK3* and *RET* fusions. An often-overlooked source of patient samples is those where genomic profiling is not regularly employed due to the early stage of the cancer that can be treated with curative surgical resection rather than requiring targeted precision oncology drugs. Furthermore, uncommon tumor types rarely receive comprehensive genomic profiling as it is not considered standard of care or medically necessary and therefore are not well-characterized for genomic alterations. Using the PGDx elio™ tissue complete, a 505-gene FDA-cleared NGS solid tumor profiling assay, several tumor types not traditionally profiled were assessed under investigator-initiated studies and were unexpectedly found to have an enrichment of *NTRK3* and *RET* fusions. *NTRK3* fusions, occurring in less than 1% of most adult cancers, were observed at a higher-than-expected frequency in atypical Spitz tumor, an uncommon melanocytic skin lesion normally treated through surgical resection. Other tumor types positive for this fusion were ganglioglioma and secretory carcinoma. *RET* fusions, with prevalence highest in papillary thyroid carcinoma at 2-5%, were also identified in atypical Spitz tumor, glioblastoma, and lung adenocarcinoma. To confirm these findings, samples were also run on a validated, modified Archer FusionPlex® solid tumor RNA-based panel targeting 142 genes. Of the 13 *NTRK3* and 10 *RET* fusions detected by the PGDx elio tissue complete, all fusions were confirmed by the RNA-based fusion panel. These findings demonstrate the performance of PGDx elio tissue complete for rare fusion detection and also identify a unique source for these variants that are critical to biomarker validation. Additional work is warranted to establish the prevalence of these rare, targetable fusions in these tumor types which may represent a potential opportunity for targeted therapy.

#1022 NFKBIA amplification attenuates B2M expression in NKX2.1-amplified lung adenocarcinoma, indicating immune evasion potential.

Ka Yee Li, Anthony J. Iafrate

Molecular Pathology, Massachusetts General Hospital, Boston, MA

Introduction: Lung adenocarcinoma (LUAD) is the predominant subtype of non-small cell lung cancer, accounting for approximately 40% of cases. With growing insights into tumor immunology and the advancement of immunotherapy, LUAD has shown remarkable therapeutic benefits in clinical trials. *NKX2.1* is located in the 14q13.3 amplification interval and is the most frequently amplified genes in LUAD. *NFKBIA*, also resides in this region, is frequently co-amplified with *NKX2.1*. *NFKBIA* encodes IκBα, an inhibitor of NF-κB transcription factors that prevents their activation. A major challenge in lung cancer immunotherapy is the loss of major histocompatibility complex (MHC) class I expression. β2-microglobulin (B2M) is an essential subunit of MHC class I molecules and is crucial for presenting tumor antigens to T cells. Loss of B2M expression contributes to immune evasion and is regulated by the NF-κB signaling pathway. We hypothesize that NFKBIA amplification suppresses B2M, impairing immune responses and reducing immunotherapy efficacy. This study investigates whether reducing *NFKBIA* can restore B2M and enhance immunotherapy in *NKX2.1* amplified LUAD.

Methods: Multiple LUAD cell lines were treated with TNF-α to activate NF-κB. Stable cell lines with CRISPR-mediated NFKBIA knockout or overexpression were generated to assess effects on NF-κB activity and B2M expression.

Results: Western blot analysis revealed that cell lines with high IκBα expression showed low B2M expression, suggesting that elevated IκBα inhibits NF-κB activation and reduces transcription of its target genes. TNF-α treatment significantly increased B2M expression within 12 h, with variable duration across cell lines. H3122 and HCC827 maintained elevated B2M levels for more than 5 days, while H23 and H661 showed transient induction returning to baseline within 3 days. These differences may serve as potential biomarkers predicting immunotherapy response. H3122 and H23 cells with *NFKBIA* knockout exhibited increased baseline B2M levels and enhanced induction after TNF-α treatment. Conversely, MGH006 and H2228 cells with NFKBIA overexpression showed reduced baseline B2M and diminished induction following TNF-α stimulation. Further studies on NFKBIA's role in NF-κB signaling and validation using clinical LUAD samples are ongoing.

Conclusion: TNF-α-mediated NF-κB activation enhances B2M expression in LUAD, with duration varying by cell line. *NFKBIA* knockout increases, and overexpression decreases, B2M and NF-κB activation. *NFKBIA* may serve as a prognostic biomarker and therapeutic target to improve immunotherapy efficacy.

#1023 Ki67-kinetics and tumor biology shifts during neoadjuvant letrozole and ribociclib in ER-pos./HER2-neg. breast cancer: Insights from the NEOLETRIB-trial.

Background:
Cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitors have recently transformed the treatment algorithms for hormone receptor-positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) breast cancer. This has led to approval in combination with antihormonal therapies for first- and second-line therapy in the metastatic setting as well as in the adjuvant setting. The NEOLETRIB trial investigated the combination of the CDK4/6 inhibitor ribociclib with the aromatase inhibitor letrozole as neoadjuvant therapy in patients will locally advanced HR+/HER2- breast cancer characterized by cT3-cT4 tumors and/or cN2-3 lymph node involvement. This analysis focused on a comprehensive exploration of Ki67 kinetics and biology shifts to improve patient selection.
Patients and Methods:
NEOLETRIB was a single-arm, multicenter, open-label, phase II neoadjuvant trial enrolling 85 patients who received six cycles of ribociclib (starting dose: 600 mg once daily, 21 days on / 7 days off) combined with continuous letrozole prior to surgery. Ki67 was evaluated on tumor-biopsies obtained at baseline, day 21 of cycles 1 and 6, and at surgery. Thirty one patients from the Akershus cohort were randomly selected for additional Prosigna® testing in order to assess molecular subtype shifts between baseline and surgery.
Results:
Of 85 patients enrolled in this trial, 4 withdrew consent or were excluded due to screening failure. Complete tumor biopsy sets at all four time points were available from 71 patients. Patients were grouped in mutually exclusive groups based on Ki-67 profiles: Group 1 (Ki67 <20% at any timepoint) included 43 patients; Group 2 (Ki67 ≥20% at baseline and <20% later) included 21 patients. Four patients maintained Ki67 ≥20% at both baseline and surgery (Group 3) and 3 patients experienced Ki67 ≥30% at both baseline and surgery (Group 4). A total of 8 patients had Ki67 ≥50% at any given timepoint (Group 5).
Among 31 patients analyzed by Prosigna, 9 were classified as Luminal B at baseline, out of whom 8 converted to Luminal A after treatment. Three patients were classified as HER2-enriched at both time points despite having HER2 negative disease by immunohistochemistry routine staining. All three belonged to the high-proliferation (Ki67 >50%) subgroup 5.
Conclusions:
Neoadjuvant treatment with ribociclib in combination with letrozole appears to induce antiproliferative effects and a shift of molecular subtype from Luminal B to Luminal A in the majority of HR-positive, HER2-negative breast cancer patients in this trial. Improved understanding of the Ki67 dynamics and Prosigna-signatures may help identify subgroups of patients who may benefit from neoadjuvant letrozole/ribociclib combination and may potentially inform postneoadjuvant treatment decisions in the long run.

#1024 CIN signatures as biomarkers of drug sensitivity: Real-world evidence from DNA targeted sequencing data.

David Gomez-Sanchez[1], Adam Price[1], Max Schmidt[1], Sharafudeen Abubakar[1], Farheen Shah[1], Christina Lee[1], Chin-Tung Chen[1], Barbara Hernando[2], Daniel Muldoon[1], Areej Alsaafin[1], Evan Seffar[1], George Li[1], Subhiksha Nandakumar[1], Wassim Abida[1], Stephen Graves[1], Mackenzie Sullivan[1], Rachel N. Grisham[1], Britta Weigelt[1], Luc GT Morris[1], Nadeem Riaz[1], Pedram Razavi[1], Allison L. Richards[1], Mark Donoghue[1], Walid Khaled Chatila[1], Chaitanya Bandlamudi[1], Nikolaus Schultz[1], Michael F. Berger[1], Sohrab Shah[1], Geoff Macintyre[2], Julio Garcia-Aguilar[1], Francisco Sanchez-Vega[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Spanish National Cancer Research Ctr. (CNIO), Madrid, Spain

Chromosomal instability (CIN) signatures are DNA copy number-based genomic biomarkers with emerging evidence for predicting treatment sensitivity across multiple drugs and cancer types. Modern computational approaches enable the quantification of CIN signatures from clinically validated targeted DNA sequencing panels such as MSK-IMPACT.

In this study, we derived copy number profiles from 63,630 tumor-normal MSK-IMPACT pairs using FACETS and computed pan-cancer CIN signatures across 73 cancer types. Analyses were restricted to pre-treatment samples, and CIN signature exposures were used to build three therapy-specific biomarkers: (i) a new biomarker of sensitivity for PARP inhibitors (PARPi) trained on progression-free survival (PFS) data from BRCA wild-type (BRCAwt) high-grade serous ovarian cancer (HGSOC) (ii) a new biomarker of sensitivity to platinum-based chemotherapies trained on disease-free survival (DFS) data from locally advanced rectal cancer (LARC) and (iii) an existing biomarker for resistance to anthracycline-based chemotherapies, now derived from targeted sequencing data for the first time. Each biomarker was validated in at least one independent MSK-IMPACT cohort of a different cancer type, using PFS calculated from treatment initiation and assessed at 12 months.

The PARPi biomarker performed similarly to the Myriad MyChoice Genomic Instability Score (GIS) in identifying BRCAwt HGSOC patients with longer PFS after treatment (CIN signatures: n=84, HR=0.38, p=0.005; GIS: n=84, HR=0.41, p=0.004) and fully identified responders in an independent BRCAwt prostate adenocarcinoma (PRAD) cohort (Sensitivity 100%, Specificity 60%, AUC=0.73). The platinum biomarker predicted longer PFS in primary head and neck squamous cell carcinoma (HNSCC) (n=82, HR=0.43, p=0.007). The anthracycline biomarker predicted shorter PFS in hormone-receptor positive HER2 negative (HR+/HER2-) breast cancer - both primary (n=191, HR=1.72, p=0.015) and metastatic (n=216, HR=1.72, p=0.003) - and in primary soft-tissue sarcoma (n=251, HR = 1.81, p=0.006).

These results highlight the feasibility and clinical potential of CIN signatures at a pan-cancer level, illustrating how the frequently overlooked complexity of genome-wide copy number alterations contained in routine targeted panels can be transformed into interpretable biomarkers to guide therapy selection. This proof-of-concept establishes that CIN signatures can be extracted from regulatory-approved assays such as MSK-IMPACT, although further validation is needed to facilitate clinical adoption.

#1025 Monitoring PD-L1 in tumor macrophage fusion cells in blood correlates to PD-L1 checkpoint inhibitor responses in metastatic breast cancer.

Sonia Muthuraj[1], Massimo Cristofanilli[2], Carolina Reduzzi[2], Giuseppe Del Priore[3], William V. Williams[3], Cha-Mei Tang[4], Daniel L. Adams[5]

[1]Rutgers University, New Brunswick, NJ,[2]Weill Cornell Medicine, New York, NY,[3]BriaCell Therapeutics, Philadelphia, PA,[4]Creatv MicroTech, Inc., Rockville, MD,[5]Creatv MicroTech, South Brunswick, NJ

In metastatic breast cancer (mBC), anti-PD-L1/PD-1 immune checkpoint inhibitors (ICIs), e.g. pembrolizumab, are approved in a subpopulation of mBC patients (pts) with a PD-L1 combined positive score (CPS) ≥10, median progression-free survival (mPFS) of 9.7 months and median overall survival (mOS) of >24 months. However, 62% of pts have CPS <10, and may also benefit from ICIs (i.e. ≥1 CPS have mPFS=7.6 months vs 5.6 for chemotherapy). One hypothesis to why low PD-L1 pts respond to ICIs is dynamic PD-L1 upregulation after starting a new therapy, requiring a biomarker to monitor PD-L1 and subsequent ICI benefit. Recent studies have identified PD-L1 expressing myeloid cells that disseminate into the blood from primary tumors, tumor-macrophage fusion cells (TMFCs), which may predict ICI response. However, dynamic changes in TMFC PD-L1 during ICI and their relationship to patient response is unknown. In this study, we monitored PD-L1 expression in TMFCs during ICI treatment, compared to tumor CPS, in mBC pts to evaluate PFS & OS at 24 months. We conducted a prospective pilot study of n=43 pts with pathologically confirmed mBC prior to receiving anti-PD-L1 ICIs. CellSieve microfilters isolated TMFCs from 7.5ml peripheral blood samples at 4 time points, prior to start of PD-L1 ICI (T0) and at monthly timepoints (T1-T3) for 4 months after ICI induction. TMFCs were identified by enlarged cell size (>30 μm) and polyploid nucleus. Average PD-L1 expressions in TMFCs were categorized as negative/low or high. Pearson's correlation compared average TMFC PD-L1 to CPS PD-L1 from tissue. TMFC PD-L1 expression and CPS were compared to pts' PFS and OS by Cox proportional univariate/multivariate analysis at 24 months. 95.3% (n=41/43) of pts provided a T0 sample. 90.7% (n=39/43) of pts provided a T1 sample (~28 days after ICI). 67.4% (n=29/43) of pts provided a T2 sample (~71 days), and 41.9% (n=18/43) of pts provided a T3 sample (~117 days). mPFS of pts with CPS ≥10, 1-10, <1 was 8.5, 7.0, 2.0 months, respectively (≥10 CPS vs <10 CPS HR=1.5, p=0.9180), and mOS was 12.1, 9.0, 18.9 months (≥10 CPS vs <10 CPS HR=0.6, p=0.9981). No correlations were identified between CPS and T0 TMFC PD-L1 (p=0.6109). Further, pts with high TMFC PD-L1 at T2 (HR=3.1, p=0.0475) had significantly better PFS, while T1 (HR=1.8, p=0.1843) and T3 (HR=4.0, p=0.0686) trended toward better PFS, but not for OS. Pts with high TMFC PD-L1 at any time point had significantly improved PFS (HR=2.8, 95% CI=1.4-5.5, p=0.0052), but not OS, compared to pts with consistently low TMFC PD-L1. In this pilot study, tumor PD-L1 CPS was not found to be correlated with clinical outcomes. However, high TMFC PD-L1 expression at any timepoint correlated with improved PFS, suggesting that monitoring PD-L1 in TMFCs may serve as a real-time biomarker to better indicate ICI response. Further studies into the role of TMFC PD-L1 in predicting therapeutic response are ongoing.

#1026 The copy number amplification of MYCL indicated activation of angiogenesis in small cell lung cancer.

Zihang Yuan, Jingwei Zhang, Yan Ju, Xingyuan Wu, Mantang Qiu, Xiao Li

Department of Thoracic Surgery, Peking University People's Hospital, Beijing, China

Background: Amplification of MYC family genes (MYC/MYCN/MYCL), a common phenomenon in small cell lung cancer (SCLC), has been widely reported to promote tumor angiogenesis. However, previous studies mainly focused on MYC and MYCN, while the role of MYCL amplification remains largely unexplored due to relatively low frequency. Here we aim to characterize the distribution of MYCL amplification in SCLC and elucidate the potential mechanism related to angiogenesis.
Methods: A total of 135 surgically resected SCLC patients with stage IA to IIIB were recruited from Peking University People's Hospital. A triple-color MYC-paralogs FISH probe was used to assess amplification patterns of MYC family genes. The amplification status were defined in the samples with ≥ 4 signals of each MYC-paralogs per cell in average. Immunohistochemistry (IHC, CD31/PAS) and multiplex IHC (mIHC, CD31/CD3/CD68/CD11b/PanCK/Ki67) were performed on tissue microarrays (TMA, n = 96) to quantify microvessel density (MVD) and endothelial cell proportion. Paired whole genome sequencing (WGS) and single-cell RNA sequencing (scRNA-seq) of SCLC patients (n = 20) were performed to define MYCL amplification status and cell proportion for functional analysis.
Results: Among the 135 SCLC samples, a total of 9 samples were identified as MYCL-amplified samples (6.7%). A higher proportion of endothelial cells in MYCL-amplified samples (n = 7) were observed compared to non-amplified samples (n = 89, Mann-Whitney U test, $p = 9.5\times10^{-3}$), as well as higher MVD in MYCL-amplified SCLC ($p = 5.7\times10^{-3}$). To further explore potential mechanism, we performed scRNA-seq in MYCL-amplified (n = 6) and non-amplified (n = 14) SCLC samples based on WGS results. A total of 199,644 cells were clustered and annotated into 28 cell subtypes, and elevated vascular endothelial cell proportion were further confirmed in MYCL-amplified samples. Additionally, MYCL-amplified samples exhibited the activation of cell adhesion, endothelial cell migration and angiogenesis pathways, indicating the highly activated vasculature morphogenesis process associated with MYCL amplification. Meanwhile, we also found higher hypoxia signature scores in MYCL-amplified samples using AddModuleScore, as well as enhanced VEGF signaling-mediated communication from MYCL+ tumor cells to endothelial cells by CellChat, indicating that MYCL+ tumor cells may drive angiogenesis through the activated VEGF pathway in hypoxic tumor microenvironment.
Conclusions: The amplification of MYCL exhibited higher endothelial proportion and elevated vascular density, potentially through activated interaction between hypoxic tumor and VEGF-induced angiogenesis, which may serve as potential biomarkers for anti-angiogenic therapy in SCLC.

#1027 A robust predictive marker of clinical outcomes to immune-checkpoint inhibition in advanced squamous head-and-neck cancer calculated from histopathological slides.

Yaron Kinar[1], Tien-Hua Chen[2], **Gal Dinstag**[3], Ranit Aharonov[1], Tuvik Beker[3], Johnathan Arnon[4], Anna Elia[4], Aron Popovtzer[5], Changsu Lawrence Park[6], Carlos Diego H. Lopes[6], Muh-Hwa Yang[2]

[1]Pangea Biomed, Tel Aviv, Israel,[2]Taipei Veterans General Hospital, Taipei City, Taiwan,[3]Pangea Biomed, TEL AVIV-JAFFA, Israel,[4]Hadassah-Hebrew University Medical Center, Jerusalem, Israel,[5]Sharett Institute of Oncology, Jerusalem, Israel,[6]Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Immune checkpoint inhibitors, namely programmed death-1 (PD-1) inhibitors, prolong survival in advanced head and neck squamous cell carcinoma (HNSCC). The combined positive score (CPS) guides treatment selection but has limited predictive value, underscoring the need for development of accurate and practical biomarkers in this space. ENLIGHT-DP predicts clinical outcomes to targeted and immune therapies directly from hematoxylin and eosin (H&E) slide scans. We previously showed that ENLIGHT-DP is predictive of outcomes in HNSCC treated with PD-1 inhibitors and in other indications. Here, we train and test an ENLIGHT-DP biomarker on a cohort of HNSCC cases using cross-validation (CV), and further validate it on two independent cohorts.
Methods: We obtained high resolution scans of pre-treatment tumor H&E slides of 89 advanced HNSCC patients from National Yang Ming Chiao Tung University (NYCU) treated with first-line PD-1 inhibitors +/- chemotherapy. Response (RECIST v1.1) was available for all cases, and long-term follow up for 65 of them. Using this dataset, we trained a model to predict response, in leave-4-out-CV. The model consists of (1) splitting the slides into tiles of 256x256 pixels, (2) extracting tile features using a deep learning model, (3) predicting tile states using a multi-layered perceptron, (4) pooling the tile states into a whole slide state using attention-based multiple instance learning, and (5) Predicting the response from the pooled state using a linear layer. We report the CV results on this dataset, as well as the performance of the same model on two previously reported cohorts from Hadassah Medical Center (Hadassah, n=25, Oral Oncology 2025) and Princess Margaret Cancer Centre (BIO2, n=14, JITC 2019, ASCO 2025).
Results: The model is predictive of ORR in the NYCU cohort with ROC AUC of 0.67 and was able to stratify progression free survival (PFS, HR: 0.943, p=0.017). Applying the model to the Hadassah cohort resulted in ROC AUC of 0.76, and stratification of PFS (HR: 0.89, p=0.023), while CPS, which was available for that cohort, exhibited no predictive power (AUC=0.47, insignificant PFS association). Applying the model to the BIO2 cohort also resulted in ROC AUC of 0.76 and showed an insignificant trend for PFS prediction. CPS exhibited a much weaker effect for response prediction, with an AUC of 0.56, and insignificant association with PFS.
Conclusion: The ENLIGHT-DP IO biomarker predicts response to immunotherapy directly from whole H&E slide image scans and demonstrates high predictive power for ORR to PD-1 inhibitors +/- chemo in HNSCC. Although the model was trained on a relatively small cohort and using only response labels, it achieves significant results in terms of both response and PFS and generalizes well to two independent cohorts, on which it outperforms the commonly used PD-L1 IHC marker.

#1028 A tumor-agnostic YAP/TAZ score predicts TEAD inhibitor sensitivity independent of Hippo alterations.

YAP and TAZ are Hippo pathway effectors that bind TEAD transcription factors to drive oncogenic programs. First-in-human trials of TEAD inhibitors (TEADis) showed activity and tolerability in pretreated mesothelioma patients, yet current trials focus on mesotheliomas and rare Hippo-altered tumors, despite the broad oncogenic role of YAP/TAZ in various solid cancers. Whether YAP/TAZ target gene signatures can identify tumors with high YAP/TAZ activity and potential TEADi sensitivity beyond these indications remains unclear.

We profiled YAP/TAZ activity using a 22-gene signature across 2390 advanced pediatric and 3746 advanced rare cancers or cancers from young adults (<51y) from the INFORM and DKFZ/NCT/DKTK MASTER (MASTER) trials. Benchmarking against mesothelioma

and YAP fusion-driven ependymoma revealed subsets of cancers across entity baskets with equal or higher YAP/TAZ activity independent of Hippo alterations.
To dissect tumor-intrinsic versus stromal contributions, we performed spatial transcriptomics on MASTER samples using microarrays and the Xenium platform (n=106 cores from 89 tumors representing >70 histological subtypes). Tumor-cell YAP/TAZ scores correlated strongly with bulk scores (r=0.61), whereas fibroblast (r=0.23) and immune-cell (r=0.35) correlations were weak, indicating that bulk scores largely reflect tumor-cell activity.
We highlight a MASTER patient with MET-amplified carcinoma in whom progression on the MET inhibitor capmatinib coincided with a marked YAP/TAZ-score increase. In MET-amplified HS746T gastric cancer cells, genetic YAP/TAZ activation reduced capmatinib sensitivity, partially reversed by TEAD inhibition, supporting an unrecognized YAP/TAZ-linked resistance mechanism.
To evaluate predictive capacity of the YAP/TAZ signature, 23 cancer cell lines and 30 patient-derived spheroid cultures (PDSCs) were treated with IAG933 (Ω-loop-binding TEADi) or VT107 (TEAD autopalmitoylation inhibitor). Across compounds and models, expression of genes most strongly associated with TEADi response were enriched for YAP/TAZ targets, enabling refinement of a TEADi response signature. This refined signature correlated with area-under-the-drug-response-curve (AUC) values (IAG933: Pearson r=0.81 for cell lines, r=0.60 for PDSCs; VT107: r=0.46 and r=0.45).
Notably, the refined signature derived from INFORM/MASTER tumors predicted TEADi response in matched PDSCs (n=13; r=0.70 for IAG933, r=0.72 for VT107), with IC50 values as low as 30 nM. Sensitive PDSCs included atypical rhabdoid tumor, colorectal, and pancreatic carcinoma - all lacking Hippo alterations and representing entities not typically considered YAP/TAZ-driven.
In summary, these data provide a strong rationale for a transcription-based stratified clinical trial evaluating TEAD inhibition across pediatric and adult advanced cancers irrespective of Hippo alterations.

#1033 Leronlimab induces PD-L1 expression and is associated with long-term survival with an ICI in PD-L1 low metastatic TNBC.

Richard G. Pestell[1], Ritika Harish[1], Zhiping Li[1], Danni Li[1], Xuanmao Jiao[1], Hallgeir Rui[2], Massimo Cristofanilli[3], Daniel L. Adams[4], Neil E. Buss[5], Jonah B. Sacha[6], Jacob P. Lalezari[7]

[1]Pennsylvania Cancer and Regenerative Medicine Research Center, Baruch S. Blumberg Institute, Wynnewood, PA,[2]Thomas Jefferson University, Philadelphia, PA,[3]Cornell University, New York, NY,[4]Creatv MicroTech, Inc., Monmouth Junction, NJ,[5]Nucleus Global, Buren, Switzerland,[6]Vaccine and Gene Therapy Institute, Oregon Health and Science University, Portland, OR,[7]CytoDyn Inc, Vancouver, WA

Introduction. Patients with metastatic triple-negative breast cancer (mTNBC) have poor survival but may be eligible for immune check point inhibitor (ICIs). CCR5 is overexpressed in ~95% of TNBC. Data suggest that combining the CCR5 inhibitor leronlimab with an ICI may improve survival in mTNBC.
Methods. Analysis of patient gene expression, tumor histology, cancer-associated macrophage-like cells/circulating tumor cells (CAML/CTC) from clinical studies and tissue cultures of TNBC were conducted.
Findings. In breast cancer cohorts (N=1,096) CCR5 expression correlated with gene signatures of T cell immune exhaustion. Across public TNBC cohorts (N=73; after deduplication), CCR5 expression correlated with both GSEA and gene signatures of T cell infiltration and T cell immune exhaustion. TNBC subtype analysis showed CCR5 enrichment in epithelial cells of MLIA (Mesenchymal-like Immune-Altered, Jézéquel subtype) and IM (immune modulatory, Lehmann subtype). TNBC Subtype analyses showed higher CCR5-related signals in tumors classified as MLIA and IM subtypes. In cultured MDA-MB-231 TNBC cells, CCR5 expression suppressed glycosylated PDL1; CCR5 inhibition increased the abundance of PDL1 (18 kDa, 35 kDa, and glycosylated 55 kDa forms). To understand the mechanisms by which CCR5 may promote immune exhaustion, we investigated a heterotypic signal between TNBC cultured cells and the tumor microenvironment (TME) using a proteomic approach. CCR5 activity induced sB7-H3 (CD276), sTyro3 and the Tyro3 ligand Pros1. Both CD276 and Tyro3 are associated with ICI resistance; and abundance of both were attenuated by CCR5 blockade with leronlimab.
In Vivo. Leronlimab induced PD-1 expression in $CD8^+$ T cells in lymph node of rhesus macaques and had variable modulation on expression of several T cell exhaustion markers. In a retrospective analysis of data pooled from 28 patients with mTNBC leronlimab induced PD-L1 in CTC/CAMLs. Leronlimab was generally well tolerated. Higher leronlimab dose (550-700 mg once weekly), induction of PD-L1, and the formation of CCR5 dots in CTC/CAMLs, and treatment with leronlimab in combination, or subsequently, with an ICI were associated with improved survival. The median age of the 28 patients was 48.5 years (range 32-83), patients had a median of 2 prior lines of therapy in the metastatic setting (range 0-5), 18 patients had visceral metastases (64%), of which 8 had brain metastases, and 10 had non-visceral metastases, 17.9% of heavily pretreated mTNBC patients are currently alive after median >60 months of follow-up.
Conclusions. Leronlimab is well tolerated, inducing PDL1 expression on CTC/CAMLs, which may prime tumors for PDL1 blockade. CCR5 may promote ICI resistance in TNBC by upregulating immune checkpoints (sB7-H3) and sTyro3. Overall, 17.9% (5/28) of patients with mTNBC treated with leronlimab are currently alive after a median of >60 months follow-up.

#1034 Transcriptomic and genomic signatures associated with response or resistance to immunotherapy(IO) in locally advanced/metastatic (LA/M) head and neck squamous cell carcinoma (HNSCC) patients.

Elodie Girard[1], Sonia Canjura-Rodriguez[2], Bastien Cabarrou[3], Constance Lamy[1], Anne Schnitzler[1], Frederique Penault-Llorca[4], Emmanuel Bouilhol[5], Roger Sun[6], Eric Deutsch[7], Francois Legrand[8], Severine Tabone-Eglinger[9], Valery Attignon[2], Caroline Even[10], **Christophe Le Tourneau**[1], Ellen Van Obberghen-Schilling[5], Marta Jimenez[11], Nicolas Servant[1], Thomas Filleron[3], Edith Borcoman[1], Pierre Saintigny[12], Ivan Bieche[13]

[1]Institut Curie, Paris, France,[2]Centre Leon Berard, Lyon, France,[3]Oncopole Claudius Regaud - IUCT-O, Toulouse, France,[4]Centre Jean Perrin, Clermont Ferrand, France,[5]Institut de Biologie Valrose, Nice, France,[6]Radiotherapy, Institute Gustave Roussy, Villejuif, France,[7]Full Professor, Dept. of Radiation Onc., Institute Gustave Roussy, Villejuif, France,[8]R&D, Unicancer, Paris, France,[9]Cancer Research Center of Lyon, Lyon, France,[10]Gustave Roussy, Villejuif, France,[11]Unicancer, Paris, France,[12]Ctr. Leon Berard, Lyon, France,[13]Genetics Department, Inst. Curie, Paris, France

Background: IO efficacy in LA/M HNSCC patients is limited. Identifying biomarkers of resistance and response is crucial to better stratify patients. We characterized the genomic and transcriptomic landscape of IO-naive HNSCC patients to identify specific genomic and transcriptomic signatures of response to IO.
Methods: We analyzed baseline FFPE samples of 176 LA/M HNSCC patients treated with IO from CHECK'UP (NCT03412058) and TOPNIVO (NCT03226756) trials, for whom baseline RNAseq data were available. A penalized Cox model with Elastic Net procedure was used to identify gene signatures associated with PFS and OS. Using a resampling procedure, a bootstrap selection stability (BSS) index was computed for each gene and only those with a BSS > 30% were included in the final model to determine a score for both PFS and OS. In addition, 149 paired tumor and germline DNA were sequenced using whole exome. For biostatistics analysis using genomic alterations, only variants (SNVs, Indels, CNVs) in oncogenes, tumor suppressor genes with a variant allele frequency (VAF) of at least 10% and altered signaling pathways were considered.
Results: The cohort (median age 62.5 yo) included a majority of oropharynx (39.8%) and oral cavity (29.8%) tumors, 77.8% males, 62.3% with alcohol and 81.7% with tobacco use history and 60.0% of them were metastatic. Objective response rate was 17.4%, median PFS and OS were 1.9 months (mo) (95%CI=[1.8-2.5]) and 8.1 mo (95%CI=[6.1-9.7]), respectively (median follow-up of 33.3 mo, 95%CI=[28.7-36.5]). The most frequent genomic alterations affected *CCND1*, *CDKN2A*, *FAT1*, *TERT*, *TP53* genes and a gain of 3q26-q28. In univariable analyses, the presence of *TERT* or *FAT1* alteration were significantly associated with worse PFS. After adjustment for clinical variable, the presence of *FAT1* alteration and the upregulation of Hippo signalling pathway remained associated with worse PFS. The presence of *TERT* mutation was also associated with worse OS whereas the PI3K/AKT/mTOR pathway was associated with
improved OS in univariable and multivariable analysis, respectively. Among the 500 most differentially expressed transcripts, 21- and 18-gene expression signatures were selected to assess their association with PFS and OS, respectively. C-Index was 0.72 and 0.71 (0.58 and 0.57 after internal bootstrap validation) for PFS and OS, respectively. Scores were dichotomized using time-dependent ROC Curve (Low vs High) and HR adjusted for clinical factors were 3.62 (95%CI = [2.42; 5.43]) and 3.86 (95%CI = [2.52; 5.91]; p<0.0001) for PFS and OS, respectively.
Conclusions: We identified robust transcriptomic signatures and genomic alterations strongly associated with IO resistance, offering potential biomarkers for patient stratification. *TERT* or *FAT1* alteration were associated with worse prognosis.

#1035 Ultrasensitive cfDNA fragmentomics assay for early treatment response assessment in solid tumors.

Atul Bharde[1], Kiran Kirdat[1], Amol Chaudhari[1], Ajay Pandita[2], Gowhar Shafi[3], Mohan Uttarwar[2], Sudhir K. Sinha[4], Hiromi Brown[4], Bill Haack[5]

[1]1Cell.Ai, Pune, India,[2]1Cell.Ai, Foster City, CA,[3]1Cell.Ai, Mumbai, India,[4]InnoGenomics Technologies, New Orleans, LA,[5]Cadex genomics, New Orleans, LA

Introduction: Early identification of treatment response remains a major clinical challenge, as imaging lacks the spatial and temporal resolution required to measure the therapy response. Liquid biopsy (Lbx)-based fragmentomics offer a minimally invasive, tumor-agnostic approach to capture dynamic changes in tumor burden and can serve as an early surrogate marker for response. Here, we present the analytical validation of OncoAlibrex, a highly sensitive, NGS independent cfDNA fragmentomics assay for therapy response monitoring (TRM), and demonstrate its clinical utility in patient samples.

Methods: Analytical validation was conducted to evaluate various assay parameter using cfDNA extracted from healthy plasma and cancer patient samples (n =140). cfDNA fragments were quantified using multiplexed qPCR on ABI 7500 thermal cycler. Primers and probes were designed based on high copy number Alu and SVA retrotransposon represented across the genome. cfDNA fragment distributions at >80 bp, >105 bp, and >265 bp to detect tumor relevant shifts linking to tumor burden was detected using fragment-specific primer pairs. Therapy response was predicted using an integrated algorithm developed to interpret cfDNA fragments distribution.

Results: Standard cfDNA samples, and cfDNA isolated from healthy volunteers (n = 10) and cancer patients, were analyzed in triplicate across multiple days, operators, and reagent lots. Intra-assay variability was ≤1 % for ct value and ≤13 % for the ratiometric quantity, while inter-assay precision showed <2.0% ct variability. Excellent linearity ($R^2 \geq 0.99$) and qPCR efficiencies (>98%) were demonstrated across 0.6 pg to 20 ng/µL of ccfDNA. Analytical sensitivity parameters per CLSI were: limit of blank = 0. 37 pg/µL (>80 bp, ctDNA specific), 0. 01 pg/µL (>105 bp, ctDNA specific), 0.021 pg/µL (>265 bp, non-tumor specific); limit of detection = 0. 85 pg/µL (>80 bp), 0.17 pg/µL (>105 bp), and 0.074 pg/µL (>265 bp). Fragmentation pattern of patient-derived ccfDNA was enriched with shorter fragments (80-105 bp) compared to healthy individuals. The cfDNA specific fragmentation pattern of cancer patients showed high progression score with 100 % specificity to indicate therapy non-response.

Conclusions: OncoAlibrex assay detected tumor-specific cfDNA fragmentation pattern indicative of therapy resistance with very high sensitivity, specificity, and accuracy. This assay can be used for TRM during the early phase of the treatment and MRD detection post-treatment independent of the sequencing-based Lbx assays.

#1036 An integrated clinicopathologic and genomic analysis of *PPP2R1A* alterations reveals distinct patterns in uterine and ovarian cancers.

Kai Wang, Bo Yang, Chengyi Wang, Yannan Zhu, Jinmei Wang, Kunxu Xu, Zanmei Xu

OrigiMed, Shanghai, China

Purpose: *PPP2R1A* (encoding the PP2A Aα subunit) mutations are increasingly associated with immune checkpoint blockade (ICB) response in gynecologic cancers. However, their distinct patterns across histologies remain unclear. We bridged this gap via a comprehensive clinicogenomic analysis of *PPP2R1A*-mutant tumors.

Methods: We retrospectively profiled 159 Chinese patients with *PPP2R1A*-mutant gynecologic cancers using next-generation sequencing (NGS) in a CAP/CLIA-certified laboratory. Variant classes interrogated included single nucleotide variants (SNVs), indels, copy number alterations, and fusions. Tumors were categorized by primary site (uterine vs. ovarian) and histology. We assessed features including co-mutation patterns, pathways, tumor mutational burden (TMB), and PD-L1 expression.

Results: We identified 182 *PPP2R1A* genomic alterations across 159 patients (SNVs/indels 95.1%; amplifications 3.8%; rearrangements 1.1%). Uterine primaries predominated (109/159, 68.6%), most commonly with endometrioid histology (48.1%). Three hotspot SNVs (R183W, P179R, and S256F) accounted for 39% of all alterations. R183W was significantly enriched in ovarian clear cell carcinoma (OCCC) compared with endometrioid carcinoma (42.1% vs 20.0%; $P<0.05$). Overall PD-L1 positivity (CPS ≥1) was 66.4% (73/110) and was strongly associated with TMB-H in uterine tumors. Notably, 11.9% of patients (19/159) carried ≥2 *PPP2R1A* alterations (“multi-hit”). These multi-hit cases were almost exclusively uterine endometrioid cancers, demonstrated 81.2% dual positivity (TMB-H and PD-L1+). Mean TMB was markedly higher in uterine versus ovarian tumors (118.7 vs 14.9; $P<0.001$). *POLE* co-mutations (25.8%) are all TMB-H, and consistently conferred hypermutation. Frequent *PPP2R1A* co-mutations included *TP53* (61.6%), *PIK3CA* (57.9%), *ARID1A* (49.1%), and *PTEN* (44.7%). *PTEN* co-mutation was strongly enriched in uterine tumors (60.6% vs 9.8%; $P<0.001$).

Conclusions: *PPP2R1A* alterations show distinct clinicogenomic patterns that vary by primary site and histology. Uterine *PPP2R1A*-mutant tumors differ clearly from ovarian tumors, with higher TMB and frequent *PTEN* co-mutations. In contrast, ovarian tumors, especially OCCC, tend to have low TMB and rarely show combined TMB-H/PD-L1 positivity, suggesting different underlying biological pathways. For the first time to our knowledge, we also identified a “multi-hit” *PPP2R1A* subgroup (11.9%), observed almost exclusively in uterine cancers that were enriched for TMB-H/PD-L1 positivity and diagnosed at early stage. These findings reinforce that *PPP2R1A* alterations are highly context-dependent and support the need for integrated clinicogenomic assessment when selecting patients for future immunotherapy and ICB trials.

#1037 Single cell and spatially resolved determinants of the clinical outcome of patients (pts) treated with locally advanced/metastatic head and neck squamous cell carcinoma (LA/M SCCHN) treated with immunotherapy (IO).

Mehdi Lamkhioued[1], Thimothee Casini[1], Elodie Girard[2], Karene Mahtouk[1], Sonia Canjura-Rodriguez[1], Valery Attignon[1], Bastien Cabarrou[3], Constance Lamy[2], Anne Schnitzler[2], Frederique Penault-Llorca[1], Caroline Even[4], Christophe Le Tourneau[4], Ellen Van Obberghen-Schilling[5], Nicolas Servant[2], Fayette Jerome[1], Nathalie Bendriss-Vermare[1], Ivan Bieche[6], Pierre Saintigny[1]

[1]Ctr. Leon Berard, Lyon, France,[2]Inst. Curie, Paris, France,[3]IUCT Oncopole, Toulouse, France,[4]Gustave Roussy, Paris, France,[5]Universite cote d'Azur, Nice, France,[6]Genetics Department, Inst. Curie, Paris, France

Background: We developed a composite Gene Expression Signature (cGES) comprising 22 protective (P) and 19 adverse (A) genes, agnostic of the tumor type, stratifying IO-treated pts in 3 risk groups : low (L-), intermediate (I-) and high-risk (H-) (abstract#6360 AACR2025). Herein, we validate its predictive value for progression free (PFS) and overall survival (OS) in a prospective cohort and uncover the single-cell and spatial determinants underlying clinical outcomes.
Methods: (1) The cGES was computed in 170 pts with LA/M SCCHN from 2 trials (NCT03226756; NCT03412058). (2) Next, we built a scRNAseq SCCHN atlas (scAt) of 219,138 cells from 77 independant pts including 19 and 21 pts classified as H-risk and L-risk respectively, and studied the distribution and functional states of cell populations between the 2 groups of pts. Cell-type-specific enrichments of A & P genes werequantified and intercellular communication networks were inferred to identify ligand-receptor (L-R) interactions. (3) Deconvoluted Visium data from 12 of the 77 SCCHN including 3 H-risk and 3 L-risk pts were used to map the spatial organization of cGES and to localize specific L-R interactions.
Results: (1) Multivariate analysis adjusted for ECOG, age, gender, and alcohol/tobacco use showed that I- and L-risk pts had significantly better outcomes. For PFS, hazard ratios were 0.64 ($p=0.04$) and 0.51 ($p=0.005$), and for OS 0.81 ($p>0.05$) and 0.54 ($p=0.015$), respectively. (2) Analysis of the scAt revealed that A genes from cGES were mainly expressed by epithelial and stromal cells. Conversely, P genes were mainly expressed by immune cells. H-risk tumors exhibited an altered communication landscape marked by strengthened epithelial junctions, developmental signaling, and universally increased EGFR L-R activity, whereas L-risk tumors showed an immune-enriched network dominated by extracellular remodeling, adaptive immune activation and immune cell recruitment. (3) Visium deconvolution identified 5 major cell-composition clusters (C), with epithelial-enriched C2 showing the highest A genes expression, while T cell-enriched C4/C5 displayed the strongest P genes expression. H-risk tumors exhibited prominent EGFR ligand expression, consistent with the results from the scAt data. In contrast, L-risk tumors displayed increased antigen-presentation, T-cell chemotaxis, and complement signaling.
Conclusion: cGES reliably stratified prognosis and reflects tumor ecosystem biology. H-risk tumors were dominated by epithelial-driven, EGFR-centered signaling, whereas L-risk tumors showed coordinated inflammatory T-cell-oriented programs. These findings suggest cGES as a prognostic and mechanistic biomarker, and provides a rational for EGFR-IO combination strategies to improve outcomes in LA/M SCCHN.

#1038 Integrating genomics and real-world data to predict fam-trastuzumab deruxtecan response in metastatic breast cancer across HER2 subtypes.

Abraham Apfel[1], Alka A. Potdar[1], Yuanqing Ye[1], Viswanath Devanarayan[1], Evvie Jagoda[2], Shelley MacNeil[2], Yan Zhang[1], Pallavi Sachdev[1]

[1]Eisai Inc., Nutley, NJ,[2]Tempus, Chicago, IL

Background: Metastatic breast cancer (MBC) is a major clinical challenge. Fam-trastuzumab deruxtecan-nxki (T-DXd), an antibody-drug conjugate targeting HER2, has shown efficacy across HER2+ and HER2-low subtypes. However, predictive biomarkers beyond HER2 status are underexplored in real-world settings. We leveraged real-world data from the Tempus database[1] to evaluate associations between somatic mutations and clinical outcomes in a clinically annotated cohort of patients with MBC treated with T-DXd, aiming to identify genomic correlates of response and survival to inform patient selection and therapeutic strategies.

Methods: We analyzed 124 patients with MBC with baseline tumor-normal matched sequencing data (Tempus xT [2]). Endpoints included real-world best overall response (rwBOR), progression-free survival (rwPFS), time to next treatment (rwTTNT), and overall survival (rwOS). Patients were classified as responders (CR/PR) or nonresponders (SD/PD) based on curated rwBOR. Oncoplots identified frequently mutated genes by rwBOR and HER2 status. Logistic regression assessed rwBOR (nonresponder as reference); Cox proportional hazard models evaluated rwPFS, rwTTNT, and rwOS, adjusting for age at T-DXd initiation, ER/PR status, care plan, sampling time, and tissue location. Models were run for all variants and for pathogenic-only subsets, stratified by HER2 status. Genes with >4% mutation frequency were included (50-60 genes for all-variant models; 11-13 genes for pathogenic-only models).

Results: The most frequently mutated genes were *TP53* (48%), *PIK3CA* (31%), and *GATA3* (17%). In all-variant models, *DYNC2H1* was associated with worse rwBOR (HER2+: P= 0.006; HER2-low: P=0.049), rwOS (HER2-low: P=0.014), and rwTTNT (HER2-low: P=0.004). *PIK3CA* mutations correlated with improved rwBOR (HER2+: P=0.016), rwPFS (all: P=0.01; HER2-low: P=0.007), and rwOS (HER2-low: P=0.002). Additional genes with consistent associations included *SPEN*, *POLQ*, *MED12*, *MAP2K4*, *ARID1B*, *SYNE1*, *KMT2C*, and *RB1*. Pathogenic-only analyses confirmed *PIK3CA* as a key predictor across multiple endpoints. While most models yielded FDR-adjusted P values >0.2, we prioritized genes with nominal P<0.1 and consistent prognostic direction across endpoints as indicative of potential signal.

Conclusions: Mutations such as *PIK3CA* were consistently correlated with improved outcome across HER2 subtypes, suggesting potential as predictive/prognostic biomarkers. Conversely, *DYNC2H1* mutations correlated with poorer outcomes, particularly in HER2-low patients, implicating potential resistance mechanisms. These findings support integrating genomic data into real-world evidence frameworks to enhance patient stratification, personalize treatment, and guide biomarker-driven clinical trials in MBC.

#1040 Blinded clinical validation of LiquidTME, a cell-free DNA assay for predicting response to immunotherapy by noninvasively profiling the tumor microenvironment.

Aadel A. Chaudhuri[1], David Y. Chen[2], Tucker Hansen[2], Mirna Jarosz[3], Vincent A. Miller[3], Aaron M. Newman[4]

[1]Mayo Clinic, Rochester, MN,[2]Washington University in St. Louis, St. Louis, MO,[3]LiquidCell Dx, San Carlos, CA,[4]Stanford University, Stanford, CA

Background: Combination immune checkpoint inhibitor (ICI) therapy represents a standard-of-care for patients with metastatic melanoma. However, >40% of patients do not respond to treatment and severe immune-related toxicity affects up to 60% of patients. Accordingly, we need more precise ways to select patients for combination ICIs. To address this, we developed LiquidTME, a liquid biopsy method based on Spatial EcoTyper (*Cancer Res* (2025) 85 (8_Supplement_1): 153) that leverages a deep learning approach to noninvasively assess the tumor microenvironment from cell-free DNA (cfDNA) methylation data. LiquidTME was previously trained to predict ICI response using 78 patients with advanced melanoma treated at Yale University. Here we performed a blinded validation of LiquidTME in coordination with clinicians at Washington University (WashU).

Methods: The WashU cohort consisted of pre-ICI plasma from 34 patients with advanced melanoma, each treated with ipilimumab and nivolumab (n=27) or relatlimab and nivolumab (n=7). ICI response was classified as durable clinical benefit (DCB) or no durable benefit (NDB) by a board-certified oncologist. Tumor mutational burden (TMB) was determined for 27 patients using commercial CLIA assays and analyzed as nonsynonymous mutations (mt) per megabase (Mb), using the FDA-approved 10 mt/Mb cutpoint for TMB-high and -low groups.

The WashU cohort was sent to a scientific team that was blinded to all clinical and TMB data. Cell-free DNA was extracted from 2 mL plasma per patient and subjected to enzymatic methyl-seq (EM-seq) at a median depth of 15x. LiquidTME was performed on the resulting profiles, yielding a binary response prediction and a continuous response score for each sample. Test results were locked down and returned. Both assays were compared by AUC and two-sided Wilcoxon rank-sum tests for response classification, and Kaplan-Meier analysis for progression-free survival (PFS).

Results: Median follow-up time of the cohort was 21.6 months. LiquidTME performed on cycle 1 day 1 pre-ICI plasma significantly stratified PFS with a hazard ratio (HR) of 0.27 ($P = 0.005$), with LiquidTME(+) patients achieving a median PFS of 1.7 years longer than LiquidTME(-) patients. LiquidTME distinguished DCB from NDB with an AUC of 0.77 ($P = 0.007$). Similar performance was seen across distinct combination ICI regimens. In patients with TMB data, LiquidTME maintained whole-cohort performance with a PFS HR of 0.30 ($P < 0.03$; AUC = 0.77). In contrast, TMB high vs. low subsets failed to stratify PFS (HR = 0.49; $P = 0.17$) or response (AUC = 0.53; $P = 0.8$).

Conclusion: LiquidTME identified durable responders to combination ICI from pretreatment plasma in this blinded validation cohort of melanoma patients. Given its favorable performance, LiquidTME shows promise as a clinical tool to guide personalized immunotherapy decision-making.

#1041 Extracellular vesicle-associated noncanonical ORFs as biomarkers of surgical outcome and chemoresistance in ovarian cancer.

Tatiana V. Karpinets[1], Xiaogang Wu[1], Sara Corvigno[2], Amma Asare[2], Joseph Celestino[2], Jeffry J. Cutrera[2], Pamela T. Soliman[2], Shannon N. Westin[2], Amir A. Jazaeri[2], P. Andrew Futreal[1], Anil K. Sood[2], **Sanghoon Lee**[2]

[1]Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX,[2]Gynecologic Oncology and Reproductive Medicine, UT MD Anderson Cancer Center, Houston, TX

Background: High-grade serous ovarian cancer (HGSOC) is the deadliest gynecologic malignancy, with recurrence and chemoresistance driving poor survival outcomes. Beyond canonical resistance mechanisms, large portions of the genome encode non-canonical open reading frames (ncORFs) that produce short, intrinsically disordered proteins/peptides (ncPRs), largely undetectable by standard proteomics (“dark proteome”). Emerging evidence implicates ncPRs in tumor plasticity, stress adaptation, intercellular communication, and drug resistance. Their role in HGSOC chemoresistance and packaging into extracellular vesicles (EVs) remain unexplored.

Methods: We analyzed RNA-seq datasets from primary tumors of 30 patients and matched EV RNA-seq from 28 patients. Cohorts included patients with complete gross resection (CGR, n = 10) and neoadjuvant chemotherapy (NACT) with excellent (NACT-ER, n = 9) or poor response (NACT-PR, n = 9). ncORF abundances were quantified using a non-canonical ORF database and associations with clinical outcomes were assessed.

Results: Primary tumors and EVs showed distinct ncORF biotype distributions. exhibited a 17% decrease in coding and 10% decrease in intronic ncORFs ($p < 0.0001$), with 64% and 53% increases in pseudogene- and ncRNA-derived ncORFs and 3′UTR-derived ncORFs, respectively ($p < 0.0001$). Although fewer in number, pseudogene-derived ncORFs showed higher mean abundance than coding-derived ncORFs in EVs. Their abundance patterns trended toward discriminating CGR versus NACT patients (Fishers’ exact test $p = 0.004$) and NACT-ER vs NACT-PR ($P = 0.08$).

Conclusions: ncORFs, particularly pseudogene and ncRNA-derived, are selectively enriched in EVs from HGSOC patients, suggesting roles in intercellular communication and therapy response. These findings highlight EV-associated ncORFs as potential biomarkers and therapeutic targets in ovarian cancer.

#1042 Clinical and immune correlates of response to neoadjuvant chemoimmunotherapy in dMMR/MSI-H gastric cancer.

Pengfei Yu[1], Xingmao Huang[2], Xiangliu Chen[1], Hang Chen[1], Song Wang[3], Di Wang[3], Junrong Yan[3], Jiahui Chen[1], Qing Wei[1], Zequan Wu[1], Shengxin Fang[1], Han Chen[1], Hongtao Wang[1], Chengkang Zhu[1], Ling Huang[1], Yian Du[1], Hua Bao[3], **Haimeng Tang**[3], Xue Wu[3], Xiangdong Cheng[1]

[1]Zhejiang Cancer Hospital, Hangzhou, China,[2]The First Affiliated Hospital of Ningbo University, Ningbo, China,[3]Nanjing Geneseeq Technology Inc., Nanjing, China

Background: Neoadjuvant chemoimmunotherapy (NCIT) has shown promising efficacy in resectable deficient DNA mismatch repair/microsatellite instability-high (dMMR/MSI-H) gastric or gastroesophageal junction adenocarcinoma (GAC/GEJAC), yet predictive biomarkers of response remain unclear.
Methods: We analyzed 22 patients with resectable dMMR/MSI-H GAC/GEJAC treated with perioperative sintilimab plus oxaliplatin and S-1 (SOX). Clinical response, pathological regression, genomic alterations, and tumor microenvironment (TME) features were characterized by imaging, histopathology, multi-omics profiling, and multiplex immunohistochemistry. Patients were classified as responders or non-responders based on radiological and pathological evaluations.
Results: Radiological partial response was achieved in 10 of 22 patients (45.5%). Seventeen underwent R0 resection, with Becker tumor regression grades 1a, 1b, and 2 in 10, 1, and 6 cases, yielding a pathological complete response rate of 58.8%. Two-year event-free and overall survival were 81.8% and 80.7%. Non-responders exhibited poorer survival and greater baseline intratumor heterogeneity, with enriched mutations in *NF1*, *KDR*, *CDKN2A*, and *PLK1*. Transcriptomic profiling revealed upregulation of *GYLTL1B*, *PHLDA1*, *IGFN1*, and *SH2D5* in responders, alongside activation of proliferative (E2F, MYC targets) and immune-stimulatory (TNFA-NFKB, interferon) pathways. In contrast, non-responders lacked these signatures and showed immunosuppressive TME features, including elevated methylated tumor-infiltrating lymphocytes, Th17 signature expression, and M1 macrophage infiltration. Post-treatment analysis indicated favorable immune remodeling in responders, marked by increased dendritic and NK cells and decreased M1 macrophages, while non-responders maintained an M1-dominant state. Predictive biomarkers such as *CDKN2A* mutation, Fanconi anemia pathway alteration, and specific transcriptomic signatures correlated with both response and prognosis.
Conclusions: NCIT yielded high pathological response and survival rates in dMMR/MSI-H GAC/GEJAC. Integrated molecular and immune profiling identified genomic and transcriptomic determinants of response, supporting biomarker-guided therapeutic strategies in this molecularly defined cohort.

#1043 MUC5AC expression defines an immune-inflamed but functionally restrained tumor microenvironment in pancreatic ductal adenocarcinoma.

Ashish Manne[1], Wancai Yang[1], Yongchen Guo[1], Vaibhav Sahai[2], Prachi Bajpai[3], Yonghua Bao[1], M Khalid Khan Niazi[1], Alejandro Leyva[1], Upender Manne[3]

[1]The Ohio State University, Columbus, OH,[2]Fellow, Univ. of Michigan, Ann Arbor, MI,[3]University of Alabama at Birmingham, Birmingham, AL

Pancreatic ductal adenocarcinoma (PDAC) is highly resistant to immune checkpoint inhibitors (ICIs), largely due to an immune-excluded and stromal-dense microenvironment. MUC5AC, a gel-forming mucin aberrantly expressed in PDAC, is implicated in tumor progression and immune evasion. To define its role in shaping the tumor immune landscape, we investigated transcriptomic pathway, and immune infiltration features of MUC5AC-high versus MUC5AC-low PDACs. Transcriptomic data from TCGA, ICGC, and GEO PDAC cohorts (N=1047) were analyzed. Differential expression and pathway enrichment were assessed using Gene Ontology and KEGG. To ensure cross-platform robustness, immune cell infiltration was inferred using multiple transcriptomic deconvolution algorithms, including CIBERSORT, CIBERSORT-Abs, EPIC, MCPcounter, quanTIseq, xCell, ESTIMATE, and TIMER. Expression of immunomodulator and immune inhibitory genes was correlated with MUC5AC levels using median cut-offs, with cross-cohort validation. MUC5AC-high tumors showed enrichment of lipid and glycan metabolism, glycosyltransferase activity, extracellular vesicle secretion, and cytoskeletal/adhesion pathways, consistent with metabolic rewiring and stromal remodeling. Although KEGG immune pathways (T cell receptor, B cell receptor, NK cytotoxicity, chemokine signaling) were transcriptionally activated, functional signature evidence indicated immune suppression. Immune infiltration analysis revealed that MUC5AC-high tumors had significant associations ($p<0.05$) with higher Tregs, resting memory $CD4^+$ T cells, M0 macrophages, resting natural killer (NK) cells, memory B cells, plasma cells, and resting dendritic cells, and lower $CD8^+$ T cells, activated NK cells, follicular helper T cells, activated memory $CD4^+$ T cells, M1 macrophages, naïve B cells, γδ T cells, and M2 macrophages . Importantly, immunomodulator profiling demonstrated significant differences ($p<0.05$) in inhibitory molecules, with positive associations with PD-L1, LGALS9, IL10/IL10RB, TGFB1/TGFBR1, and IDO1, and negative associations with PD-1, PD-L2, CTLA4, LAG3, and TIM-3.Thus, MUC5AC-high PDAC exhibits an “immune-inflamed but functionally restrained” phenotype, characterized by immune signaling engagement but dominance of stromal, metabolic, and ligand-driven suppressive programs. MUC5AC may serve as a biomarker of immune exclusion, guiding patient stratification for ICI-based therapies.

#1044 Class II HLA supertype diversity predicts poor outcomes with immune checkpoint inhibitors in a pan-cancer cohort.

Luke Xiyu Zhao[1], Franshisca Hayek[2], Howard Liu Li[2], Mark Yarchoan[2], Mari Nakazawa[2]

[1]The Johns Hopkins Hospital, Baltimore, MD,[2]Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Background: HLA diversity shapes the T-cell repertoire and antigen presentation, with potential effects on immune checkpoint inhibitor (ICI) outcomes. Several diversity metrics have been proposed, including zygosity, HLA evolutionary divergence (HED), and HLA supertype diversity (functional peptide-binding groups). Their relative value in pan-cancer cohorts remains unclear.
Methods: We examined the relationship between HLA diversity and clinical outcomes in a pan-tumor cohort of 140 patients treated with ICIs at Johns Hopkins. DNA was extracted from peripheral blood mononuclear cells and genotyped using the Illumina Infinium Global Screening Array v3.0. Class I and Class II HLA alleles were imputed from SNP genotype data using standard reference panels, and from these we derived Class I and Class II zygosity, HLA epitope diversity (Grantham distance matrix-based HED), and Class I and Class II supertype diversity (9 Class I and 7 Class II functional groups from IMGT/HLA). High versus low diversity was defined by cohort median splits. Treatment response was defined as complete or partial response. Multivariate logistic regression adjusted for age, gender, race, BMI, cancer type, MSI/TMB status, line of therapy, therapy class, and all HLA diversity metrics simultaneously.
Results: In the fully adjusted model, only Class II supertype diversity remained significant. Patients with at least four distinct supertypes had lower response rates than those with fewer than four (23.2% vs 36.9%, OR 0.199 [0.060-0.608], p=0.006). The effect was unchanged in models without cancer type terms (OR 0.199, p=0.005) and in models conditioning on DR4 and DPmain (OR 0.235, p=0.019). Spline analyses supported the four-supertype cutoff (LR test p=0.274), and no interactions were observed with line of therapy, MSI/TMB, or treatment class. Cox models showed worse OS (HR 1.834 [1.017-3.304], p=0.044) and PFS (HR 1.981 [1.067-3.678], p=0.030), with similar HR in cancer type-stratified and DR4 or DPmain-conditioned analyses. Individual Class II supertypes were consistent with the composite index: DR4 carriers had worse OS (HR 2.062, p=0.007) and PFS (HR 1.872, p=0.025), and DPmain carriers had worse OS (HR 1.524, p=0.043). Alternative constructs including Class I/II zygosity and HED were less informative or nonsignificant.
Conclusions: Class II HLA diversity emerged as an unexpected negative predictor of response and survival with ICI therapy. These findings differ from results reported in other ICI-treated cohorts. Although increased HLA diversity can broaden antigen recognition in some settings, prior studies also show that greater Class II diversity can increase thymic deletion of self-reactive T cells. This process reduces the breadth of the peripheral T-cell repertoire and limits tumor neoantigen recognition, providing a biologically plausible explanation for the pattern observed here.

#1045 A novel epithelial tumor signature predicts survival and response to PD-1 blockade in non-small cell lung cancer.

Muaath Alsufi[1], Jehad Yasin[1], Muthafar Alsufi[1], Osama Younis[1], Amro Assayed[2], Fawzi Abu Rous[3]

[1]Faculty of Medicine, University of Jordan, Amman, Jordan,[2]University of Central Florida, Orlando, FL,[3]Henry Ford Health System, Detroit, MI

Introduction: Immune checkpoint inhibitors (ICIs) are the standard of care for NSCLC lacking driver alterations, yet many patients do not derive clinical benefit. Current biomarkers, such as PD-L1, are imperfect in predicting response. Identifying tumor epithelial gene markers linked to immunotherapy response could improve prediction of patient outcomes.
Methods: A single-cell RNA (scRNA) dataset (GSE205335, n=12,975 cells) of NSCLC patients treated with anti-PD1 therapy was analysed to identify DEGs between responders (CR/PR) and non-responders (SD/PD). A bulk RNA-seq cohort (SU2C-MARK, n=142) was used to build a prognostic model. Genes associated with overall survival (OS) were identified using univariate Cox regression, followed by Least Absolute Shrinkage and Selection Operator (LASSO) and a multivariate Cox model to identify independent predictors of survival. A signature-based risk score was calculated, stratifying patients into High and Low-Risk groups based on median risk score. Associations with response and survival were assessed using Wilcoxon, Kaplan-Meier, and log-rank tests. Multivariate Cox analysis was performed to adjust for clinical covariates. The signature was validated using combined, batch-corrected datasets (GSE13522, GSE126044, GSE190265, GSE274975; n=129). xCELL was used to perform computational immune deconvolution.
Results: scRNA-seq analysis revealed 816 epithelial genes linked to treatment response. Univariate Cox regression of the bulk RNA-seq cohort identified 36 OS-associated genes, which were reduced to 17 genes by LASSO-Cox. Multivariate Cox regression resulted in a 4-gene signature of independent predictors of survival: CXCL8 (HR: 1.27, p=0.008), C11orf58 (HR: 0.59, p=0.010), SERF2 (HR: 2.11, p=0.015), and MT-CO1 (HR: 1.27, p=0.045). The 4-gene risk score was used to split patients into High (n=71) and Low (n=71) risk groups. High-Risk patients exhibited shorter OS and PFS (HR=3.49, $p = 4\times10^{-7}$; HR=2.029, p = 0.0007), and non-responders were associated with higher risk scores (p=0.0175). The 4-gene risk score was an independent predictor of OS (HR=2.785, p=0.0082) and PFS (HR=1.650, p=0.028) after adjusting for age, sex, stage, smoking, and PD-L1 TPS. TME deconvolution revealed that the High-Risk group featured higher Macrophages (M0, M1) and Neutrophils, while the Low-Risk group featured higher CD4+ T-cells and naive B-cells. In the combined validation dataset (n=129), the High-Risk group experienced worse PFS compared to the Low-Risk group (HR=1.58, p=0.036).
Conclusion: We present a novel signature of 4 tumor-intrinsic epithelial genes (CXCL8, C11orf58, SERF2, MT-CO1) that predict response and survival in NSCLC patients treated with anti-PD-1 therapy. The link between these genes and the immune microenvironment highlights a key tumor-TME axis, and represents promising potential for translational biomarker studies.

#1046 Leveraging transcriptomic profiles and deep learning to detect homologous recombination deficiency in breast cancer with softHRD.

Yashwin Madakamutil, Leo Joseph, Daniyal Rahman, Ammal Abbasi, Ludmil Alexandrov

Bioengineering, UCSD Medical Ctr., San Diego, CA

The homologous recombination (HR) pathway is the canonical repair mechanism by which cells repair DNA double-strand breaks. Defects in this pathway, known as homologous recombination deficiency (HRD), can lead to genomic instability and are observed in approximately 13% of breast cancers. HRD is often driven by somatic or germline mutations in *BRCA1/2*, which render tumors sensitive to PARP inhibitors and platinum-based therapies through synthetic lethality. However, many HRD-positive cancers lack *BRCA1/2* mutations, underscoring the need for more reliable approaches to identify tumors likely to benefit from these treatments. To address this, we developed softHRD, a transcriptomics-based framework for detecting HRD in breast cancer. softHRD was trained on RNA-seq profiles from 857 breast cancer patients in The Cancer Genome Atlas (TCGA), filtered for protein-coding genes. A variational autoencoder was first used to reconstruct these transcriptomic profiles, generating latent representations that capture the underlying structure of gene expression patterns. A sparse autoencoder was then applied to these latent features to derive mechanistically interpretable components and identify an HRD-associated gene set. These genes were subsequently leveraged to train a downstream Elastic Net regression model, yielding a robust 111-gene transcriptional signature indicative of HRD. We validated softHRD in 80 breast cancer patients from the I-SPY 2 clinical trial treated with neoadjuvant chemotherapy and olaparib. The model identified a statistically significant difference in pathologic complete response between HRD-predicted and HR-proficient tumors ($p = 0.00676$). Unlike whole-genome sequencing, which provides a static view of mutational alterations, transcriptomic profiling captures the dynamic state of gene expression, revealing biological changes that genomic methods may overlook. softHRD demonstrated robust performance across all PAM50 breast cancer subtypes, highlighting its generalizability. With the growing integration of transcriptomics into clinical research and diagnostics, softHRD represents a scalable and adaptable framework for accurate, efficient HRD characterization, with potential applications across multiple cancer types.

#1047 MORPHEUS-lung: Biomarkers and clinical response to atezolizumab + bevacizumab + stereotactic body radiotherapy in patients with metastatic non-small cell lung cancer.

Byoung Chul Cho[1], Sun Min Lim[2], Sang Hoon Lee[3], **Dong Kwon Kim**[3], Nuria Pardo[4], Hen Prizant[5], Yaacov R. Lawrence[6], Nedal Al-Sakaff[7], Hans-Joachim Helms[7], Gayevskiy Velimir[8], Barzin Nabet[8], Jan Pintoffl[7], Francois Ghiringhelli[9]

[1]Yonsei University College of Medicine, Seoul,[2]Department of Internal Medicine and Yonsei Cancer Center, Division of Medical Oncology, Seoul, Korea, Republic of,[3]Severance Biomedical Science Institute, Seoul, Korea, Republic of,[4]Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain,[5]Genentech, Inc., South San Francisco, CA,[6]Sheba Medical Center, Jerusalem, Israel,[7]F. Hoffmann-La Roche Ltd, Basel, Switzerland,[8]Genentech, South San Francisco, CA,[9]Department of Medical Oncology, Centre le Cancer G.-F. Leclerc, INSERM, Dijon, France

Purpose: Results from the MORPHEUS-Lung (NCT03337698) study suggest that atezolizumab+bevacizumab+stereotactic body radiotherapy (SBRT) was associated with numerically improved efficacy outcomes vs docetaxel (control) in immune checkpoint inhibitor-exposed patients with metastatic non-small cell lung cancer. We report exploratory analyses to identify potential biomarkers associated with this clinical response.
Experimental Design: Tumor samples were analyzed for differential gene expression and pathway/immune subset gene signatures by single cell RNA-sequencing and further validated with bulk RNA-sequencing.
Results: A total of 58 patients were included in the biomarker-evaluable population (atezolizumab + bevacizumab + SBRT (Atezo+Bev+Radio), n = 26; docetaxel control, n = 32). In the discovery analysis comparing patients with clinical benefit (CB) versus non-clinical benefit (non-CB) at baseline, tumor-resident memory $CD8^+$ T cells (CD8 T_{RM}) were significantly enriched in the CB group (P = 0.027) accompanied by an increased T-cell receptor clonality, indicating clonal expansion of tumor-reactive T cells (Gini index P = 0.018). PDCD1, the target molecule of immune checkpoint therapy, was highly expressed in CD8 T_{EX}, supporting their responsiveness to atezolizumab treatment. Furthermore, the CB group showed increased abundance of $CXCL10^+$ and $FOLR2^+$ macrophages, suggesting enhanced myeloid-T cell crosstalk. CD8 T_{RM} with high tumor-recognition potential exhibited strengthened antitumor activity through CXCL-mediated interactions with $CXCL10^+$ macrophages, which expressed PD-L1 at the highest level. Following Atezo+Bev+Radio treatment, CD8 T_{RM}—identified as predictive biomarkers—maintained a persistent tumor-reactive state, whereas CD8 TEMRA cells showed increased cytotoxic function likely driven by radiation exposure. Atezo+Bev+Radio treatment also induced a marked increase in $FOLR2^+$ and $FABP4^+$ macrophages in the post-treatment group. $FOLR2^+$ macrophages interacted with CD8 T cells expressing ICOS via the ICOS-ICOSL signaling pathway, promoting T cell-mediated antitumor immunity. In contrast, $FABP4^+$ macrophages engaged Treg cells expressing TIGIT through the PVR-TIGIT signaling axis, thereby contributing to immune suppression. Integration of the data revealed T cell- and macrophage-related gene signatures validated in an independent cohort, correlating with survival benefit after atezolizumab + bevacizumab + SBRT treatment.
Conclusions: These results suggest that activation of T cells and macrophages are associated with a favorable clinical response Atezo+Bev+Radio. Moreover, CD8 T_{RM}, CD8 T_{EX}, and $CXCL10^+$ macrophages may serve as potential biomarkers of response to Atezo+Bev+Radio treatment and potentially aid in tailored, precision medicine for individual patients.

#1048 Smad deficiency impacts chemotherapeutic responses through alterations in immuno-stromal microenvironment of pancreatic adenocarcinoma.

Chih Chieh Yen[1], Ying Jui Chao[2], Ping Jui Su[2], Ting Kai Liao[2], Wei Hsun Lu[2], Zhe Wei Hsu[3], Chien Jui Huang[4], I Ting Liu[1], Wen Yen Huang[5], Yan Shen Shan[2], Chia Jui Yen[1]

[1]Department of Oncology, National Cheng Kung University Hospital, Tainan, Taiwan,[2]Department of Surgery, National Cheng Kung University Hospital, Tainan, Taiwan,[3]Department of Pathology, National Cheng Kung University Hospital, Tainan, Taiwan,[4]Division of Gastroenterology and Hepatology, Department of Internal Medicine, National Cheng Kung University Hospital, Tainan, Taiwan,[5]Institute of Clinical Medicine, National Cheng Kung University, Tainan, Taiwan

Background: Pancreatic adenocarcinoma (PDAC) is a devastating cancer with a dismal prognosis. Preoperative chemotherapy (PreOP_CT) has reshaped the treatment paradigm. However, factors influencing therapeutic responses and immune/stromal alterations have not been established. Smad family exerts pivotal biological actions through transforming growth factor-β (TGFβ) axis and affects tumor microenvironment (TME), yet the correlation with therapeutic responses has not been fully explored.
Methods: We explored a prospective cohort of patients with resectable PDAC who received PreOP_CT. Genomic aberrations of the Smad family in the TGFβ axis were assessed and compared for clinical outcomes. Single-cell RNA sequencing delineated the immuno-stromal alterations in Smad-deficient vs. -proficient tumors.
Results: Fifteen of 106 patients had Smad-deficient tumors and showed reduced tumor regression, higher metastatic progression and adverse survival as compared with -proficient ones. *SMAD4* or *TGFBR2/3* mutations were observed in Smad-deficient tumors. Smad deficiency correlated with different enrichments of tumor-infiltrating immune cells (TIMCs) and cancer-associated fibroblasts (CAFs). Collectively, inflammatory and antigen-presenting CAFs were distinctive in the deficient tumors and presented with immune evasive actions.
Conclusion: Smad deficiency influences therapeutic and surgical outcomes in PreOP_CT-treated PDAC. The Smad family potentially affects TIMCs and CAFs, potentiating an immune evasive and profibrotic TME. The results provide insight into a putative biomarker for PreOP therapies in PDAC.

#1049 DNA repair phenotypes inform carboplatin and PARP inhibitor response.

Ionut-Gabriel Funingana[1], John Ambrose[2], Luca Porcu[1], Philip Smith[1], Bradley Thomas[1], Ines Prata Machado[3], Patrick Tarpey[4], Mireia Crispin-Ortuzar[3], Marc Tischkowitz[5], Florian M. Markowetz[1], Alona Sosinsky[2], James D. Brenton[1]

[1]CRUK Cambridge Institute, University of Cambridge, Cambridge, United Kingdom,[2]Bioinformatics Department, Genomics England, London, United Kingdom,[3]Early Cancer Institute, University of Cambridge, Cambridge, United Kingdom,[4]East Genomic Laboratory Hub, Cambridge, United Kingdom,[5]Department of Genomic Medicine, University of Cambridge, Cambridge, United Kingdom

High-grade ovarian carcinoma (HGOC) is characterized by multilayered genomic complexity driven by early disruption of the p53 pathway which enables diverse mutational processes and chromosomal instability (CIN). The molecular consequences of defective DNA repair and replication have been used to derive mutational signatures to predict mutational processes operative in each HGOC. Clinical testing for homologous recombination deficiency (HRD) signatures does not reliably guide the use of platinum-based therapy or poly(ADP-ribose) polymerase inhibitors (PARPi) for women with HGOC. Previous studies have shown that multiple HRD signatures are operative at the single-base substitution, indel, and structural variant levels in the same tumors. However, separate signatures do not capture the continuum of erroneous repair programs active in *BRCA1*- and *BRCA2*-deficient tumors. Here, we propose a new integrative mathematical approach to recover all naturally occurring genomic features associated with operational DNA repair pathways. We established a national healthcare outcome study of 466 HGOC patients, integrating tumor-normal deep whole-genome sequencing (WGS) with real-world treatment and outcomes. We demonstrated that seven integrative genomic features (IGFs) capture the mutational programs operative in HGOC tumors. We validated the clinical relevance of these IGFs using causal-inference methods. IGF2 captured microhomology-flanked deletions, templated insertions (TINs), and interstitial deletions. IGF5 captured 1 kilobase (kb) to multi-megabase (Mb) tandem duplications (TDs) and blunt deletions. IGF8 was rich in inversions and multi-Mb TDs, whereas IGF10 linked CpG transversions with TINs. IGF2 reflects polymerase theta-mediated end joining, associated with *BRCA2* inactivation, favorable prognosis after first-line platinum, and reduced benefit from maintenance PARP inhibitors. IGF5, marked by tandem duplications and non-homologous end joining, is enriched in *BRCA1*-inactivated tumors and predicts earlier relapse but increased benefit from maintenance PARPi. In Cox models (per 1 standard deviation unit), IGF2 improved overall survival (OS) (HR 0.81, 95% CI 0.71-0.92) and IGF8 was adverse (HR 1.25, 1.08-1.46), and IGF10 predicted benefit at second-line relapse when half of patients received maintenance PARPi (progression-free survival HR 0.75, 0.62-0.89). IGF2 modified second-line PARPi benefit (IGF2-binary x PAPRi interaction P=0.042), with benefit confined to IGF2-low. This WGS-based taxonomy reframes HRD as a continuum of DNA double-strand break repair choices. The mechanism-specific, WGS-derived phenotypes can be replicated in clinical practice, providing a basis for biomarker-stratified trials of PARP inhibitors and emerging polymerase theta (POLQ) inhibitors in ovarian cancer and in other tumors with DNA-repair defects.

#1050 Assessment of spectral overlap and crosstalk in multiplex digital PCR for effective monitoring of next-generation CAR T-cells in cancer clinical trials.

Sarah Johnson, Yogita Raj, Nathan Riccitelli

Navigate BioPharma Services, Inc., Carlsbad, CA

Introduction: As new chimeric antigen receptor (CAR) T cells emerge as secondary therapies in patients already treated with an approved CAR, clinical trial investigation of next generation constructs requires monitoring for the presence of residual first generation CAR-T therapies, often from limited patient samples. Multiplex digital PCR (dPCR) enabling absolute quantification without standard curves and supporting detection of as few as 10 copies, is an ideal approach to monitor multiple approved CAR-Ts in a limited clinical trial specimen (Morley, 2014; QIAGEN, n.d.). While multiplexing improves efficiency, it introduces challenges such as spectral overlap, potentially causing crosstalk and misinterpretation. Herein, we investigate how bleed-through affects signal interpretation in multiplex dPCR and evaluate the effectiveness of threshold adjustments and software updates in mitigating crosstalk and preserving monitoring accuracy of multiple CAR-Ts on the QIAcuity platform.

Method: A multiplexed dPCR assay targeting three CAR domains, a viral safety marker, and one reference gene was tested using probes labeled with FAM, TxRED, VIC, TAMRA, and Cy5 across five optical channels. Two formats were run on QIAcuity: singleplex reactions to confirm specificity and baseline crosstalk, and multiplexed reactions to assess cumulative interference. Analysis was performed using Software Suite (SS) versions 2.5 and 3.1. Fluorescence plots assessed signal clarity, crosstalk, and the impact of optical and threshold settings on droplet classification and quantification.

Result : Singleplex reactions showed no bleed-through in FAM, VIC, TAMRA, or Cy5 channels. TxRed bled into Cy5. TxRED bled into Cy5, and TAMRA into VIC, confirmed by 2D plots showing double-positive patterns and unexpected VIC-positive droplets in TAMRA-only samples. VIC-to-TAMRA crosstalk was concentration-dependent, decreasing at lower input levels, while TxRED-to-Cy5 remained constant. Signal clarity for TAMRA improved with optical or threshold adjustments. Despite visible bleed-through, multiplex quantification remained accurate. Cy5-labed targets were correctly identified, with software ignoring TxRED bleed-through. No differences in crosstalk or quantification accuracy were observed between SS versions 2.5 and 3.1, confirming consistency across updates.

Conclusion: Spectral bleed-through, especially from TxRED into Cy5, was a key source of signal misclassification. Manual thresholding and optical adjustments in both software versions effectively reduced crosstalk and improved quantification of all CAR domains. These findings highlight the importance of optimized assay design and analysis tools for reliable quantification of residual CAR-T therapies, which are critical for safe advancement of next generation CAR-T therapies.

#1051 CXCR4/LITAF as predictive biomarkers for nimotuzumab plus AG therapy in pancreatic cancer with liver metastasis: Integrative single-cell and spatial analysis.

Linze Xu[1], Yang Liu[1], Linlin Fu[2], Dandan Wu[1], Jin Zhang[1], Hao Wang[1], Huikai Li[2], Jihui Hao[3]

[1]Department of Hepatobiliary Cancer, Liver Cancer Center, Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, TianJin, China,[2]Department of Hepatobiliary and Pancreatic Oncology, Tianjin Cancer Hospital Airport Hospital, TianJin, China,[3]The Pancreas Center, Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Tianjin Key Laboratory of Digestive Cancer, Tianjin's Clinical Research Center for Cancer, Tianjin, China

Background: Pancreatic cancer with liver metastasis (PCLM) accounts for most advanced pancreatic cancer cases and carries poor prognosis. While Gemcitabine plus Nab-paclitaxel (AG) remains the NCCN-recommended regimen for fit patients, outcomes remain suboptimal. Previous studies suggested that adding Nimotuzumab may improve conversion to resection, but the molecular determinants of response are unclear (2025 AACR# CT167, NCT06405685) . This study integrates clinical and correlative analyses to identify predictive biomarkers for Nimotuzumab + AG therapy.
Methods: Treatment-naïve PCLM patients received Nimotuzumab (400 mg iv, qw) plus AG (Gemcitabine 1000 mg/m² and Nab-paclitaxel 125 mg/m², d1, d8, q3w). Primary endpoints were objective response rate (ORR) and disease control rate (DCR); secondary endpoints included conversion and R0 resection rates. In parallel, single-cell RNA-seq data from paired primary and metastatic lesions (GEO) were analyzed to identify PCLM-specific subpopulations via hdWGCNA and machine-learning algorithms (SVM, LASSO, random forest). For clinical validation, immunofluorescence staining of CXCR4 and LITAF was performed on PCLM tumor tissues. Spatial quantification was performed using an automated CK-pan-guided epithelial segmentation. Intensities were normalized and a hotspot-weighted aggregation produced a combined CXCR4/LITAF score per patient, reflecting co-activation.
Results: Among 23 evaluable PCLM patients, the ORR was 17.4%, DCR 78.3%, and 43.5% achieved conversion surgery, consistent with previous findings. Single-cell analysis identified 22 cell clusters, including a distinct PCLM-specific subpopulation enriched in hepatic metastases. CXCR4 and LITAF emerged as central hub genes positively correlated with the abundance of these metastatic-specific cells and with poorer clinical outcomes. Imaging-based spatial quantification showed that patients with higher CXCR4/LITAF combined scores exhibited significantly worse treatment responses (progressive disease, PD). The automated pipeline—from epithelial segmentation (CK-pan-guided) to combined molecular scoring—achieved robust reproducibility across samples and accurately stratified responders versus non-responders. Preliminary analyses suggest that KRAS-mutant tumors may exhibit enhanced CXCR4/LITAF co-activation, contributing to therapeutic heterogeneity.
Conclusions: Nimotuzumab plus AG demonstrates favorable disease control and conversion potential in PCLM. Integrative single-cell and spatial analyses identify CXCR4 and LITAF as candidate biomarkers linked to treatment response. The CXCR4/LITAF combined spatial score offers a quantitative imaging tool for predicting response to Nimotuzumab + AG in metastatic pancreatic cancer.

#1052 Real-world treatment patterns and outcomes reveal distinct clinical trajectories of patients with Cyclin E1-positive ovarian cancer.

Jinkil Jeong[1], Mona Abed[1], Catherine Lee[1], Heekyung Chung[1], Alexandra Levy[1], Nandini Molden[1], Divya Rajendran[1], Joyce F. Liu[2], Leslie M. Randall[3], Fiona Simpkins[4], Funda Meric-Bernstam[5], Danielle D. Jandial[1], Doris Kim[1], Olivier Harismendy[1]

[1]Zentalis Pharmaceuticals, San Diego, CA,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Inova Health, Fairfax, VA,[4]University of Pennsylvania, Philadelphia, PA,[5]University of Texas MD Anderson Cancer Center, Houston, TX

Background: The success of novel therapies as they progress in later phases of clinical development requires accurate benchmarking of the benefit provided by the standard of care (SOC) at the time of clinical study completion. Information collected from published investigational studies or retrospective registries can be outdated or may not reflect the most current SOC. Furthermore, the development of novel agents, especially for patients on later lines of treatment, may be restricted to select populations, not previously characterized in the literature, perhaps defined by criteria such as a novel biomarker (e.g. Cyclin E1 positive tumors) or narrow indication sub-types (e.g., platinum resistant ovarian cancer with less than N prior therapy lines). Here, we demonstrate how the analysis of Real-World Data (RWD), as well as screening data — collected in the context of recent early phase clinical studies — is guiding development of the WEE1 inhibitor azenosertib in Cyclin E1 positive high grade serous ovarian cancer (HGSOC). Methods: The records of medications and lines of therapy were curated from Tempus Lens (TLOv) or Zentalis Retrospective Study of Early Treatment (ReSET) cohorts. Outcomes such as best response, progression free survival and treatment free survival were evaluated for patient subsets defined by treatment history or Cyclin E1 expression status from RNA sequencing (for TLOv) or protein immunohistochemistry (IHC for ReSET) after benchmarking RNA-based classification using independent HGSOC tissues (N=92). Results: Compared to IHC, RNA-based Cyclin E1 classification was > 70% accurate, with higher rates of False Negative than False Positives, providing an acceptable surrogate to stratify patients in the TLOv cohort. The treatment regimens used in early lines were consistent between TLOv and ReSET cohorts and reflected current SOC, including partial use of PARPi in 1L maintenance and a preference for doxorubicin-based regimens in 2L for platinum-resistant patients. The data confirmed previous observations that BRCA-mutated patients had better prognosis, likely due to PARPi treatment eligibility after 1L. Patients with Cyclin E1 positive tumors were observed in both platinum-resistant and platinum-sensitive settings, with a higher prevalence in platinum-resistant setting. Patients with Cyclin E1 positive tumors had worse outcomes in 1L, or with selected treatment regimens in subsequent lines, highlighting their consistent unmet need throughout the entire treatment journey. Conclusions: RWD represents a reliable and up-to-date source of treatment and outcomes information for HGSOC patients. Clean identification of lines and intent of treatment as well as availability of direct or surrogate Cyclin E1 expression status were key to highlighting the unmet need of patients with Cyclin E1 positive tumors, informing azenosertib’s development.

#1053 Single-cell immune profiling reveals biomarkers of pembrolizumab response in early triple-negative breast cancer.

Inaki Comino-Mendez[1], Maria Rosario Chica-Parrado[1], Maria Elena Quiros-Ortega[1], Ana Godoy-Ortiz[1], Maria Emilia Dominguez-Recio[1], Esperanza Lopez-Lopez[1], Maria Victori Ortega-Jimenez[2], Martina Alvarez[1], Javier Pascual[1], Enrique de Alava[3], Emilio Alba[1]

[1]Institute of Biomedical Research of Malaga (IBIMA), Malaga, Spain,[2]Hospital Universitario Virgen de la Victoria, Malaga, Spain,[3]Department of Normal and Pathological Cytology and Histology, Institute of Biomedicine of Sevilla (IBiS), Sevilla, Spain

Background: Triple-negative breast cancer (TNBC) is an aggressive subtype representing 15-20% of all breast cancers, characterized by early recurrence and lack of targeted therapies. The addition of pembrolizumab to standard neoadjuvant chemotherapy significantly improves outcomes; however, clinical benefit remains heterogeneous and predictive biomarkers of response or resistance are still lacking.
Objectives: To characterize peripheral immune cell states associated with response and resistance to pembrolizumab-based neoadjuvant therapy in early TNBC.
Methods: Patients with early TNBC treated with neoadjuvant pembrolizumab plus chemotherapy were included. Serial blood samples were obtained at baseline, during treatment, before surgery, and one month after surgery. Peripheral blood mononuclear cells (PBMCs) were analyzed by single-cell RNA sequencing and paired TCR/BCR sequencing using the 10x Chromium platform. Cellular composition, transcriptional states, checkpoint expression, and clonal architecture were compared between responders, defined as patients with Residual Cancer Burden (RCB 0) and non-responders (RCB I-III).
Results: Single-cell analysis revealed distinct systemic immune profiles between responders and non-responders at baseline. Responders displayed an immune-prepared state characterized by enriched cytotoxic NK cells and effector T cells, together with reduced naïve CD4+ T cells and regulatory T cells. In contrast, non-responders showed dominance of naïve and suppressive populations. At the transcriptional level, CD4+ T cells from responders exhibited lower basal activation (↓AP-1, ↓TNF) but higher antigen presentation and proliferation signatures. NK and monocyte compartments were more inflammatory and metabolically active, while B cells showed increased antigen-presenting capacity (↑MHC-II, ↑CD86). Checkpoint expression analysis revealed higher mean and frequency of *TIGIT*, *TIM3*, and *PD-1* across multiple immune lineages in responders. TCR-seq data showed oligoclonal expansions in responders, contrasting with the polyclonal, unexpanded repertoires of non-responders.
Conclusions: Peripheral immune profiling reveals distinct systemic immune programs associated with response and resistance to pembrolizumab in early TNBC. Responders display features of antigen-experienced, cytotoxic, and clonally expanded immune populations, whereas resistant cases show quiescent and regulatory-dominant profiles. These findings highlight the potential of immune-based liquid biopsy as a minimally invasive tool to identify predictive biomarkers of immunotherapy efficacy and resistance in breast cancer.

#1054 Plasma metabolomic profiling predicts response to neoadjuvant immunochemotherapy in locally advanced NSCLC.

Yan Wang[1], Hui Yang Shi[1], Haonan Gu[2], Wenxin Jiang[1], Linyan Tian[1], Fang Wei[1], Danru Zheng[1], Haiyan Xu[3], Ting Xiao[2]

[1]Department of Medical Oncology, National Cancer Center/ National Clinical Research Center for Cancer/ Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[2]State Key Laboratory of Molecular Oncology, Department of Etiology and Carcinogenesis, National Cancer Center/ National Clinical Research Center for Cancer/ Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[3]Department of Comprehensive Oncology, National Cancer Center/ National Clinical Research Center for Cancer/ Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: While immune checkpoint inhibitors (ICIs) have demonstrated significant benefit in non-small cell lung cancer (NSCLC), the efficacy varies substantially among individuals. Established biomarkers like PD-L1 expression and tumor mutational burden (TMB) offer limited predictive value, underscoring the critical unmet need for more reliable predictive biomarkers. To address this, our study aimed to discover predictive plasma metabolomic biomarkers for treatment response to neoadjuvant immunochemotherapy in patients with locally advanced NSCLC.

Methods: Between November 2023 and July 2025, 71 patients with locally advanced NSCLC receiving neoadjuvant immunochemotherapy were prospectively enrolled. According to best overall response (BOR), patients were classified into the good response (GR) group (n=38, partial response) and the limited response (LR) group (n=33, stable or progressive disease). Plasma sampling included 71 baseline samples, 50 samples after cycle one and 39 samples after cycle two. The association between clinicopathological features and clinical response was assessed using multivariate logistic analysis. Untargeted metabolomic profiling of all plasma samples was conducted using liquid chromatography-tandem mass spectrometry (LC-MS/MS) to identify predictive metabolic biomarkers.

Results: After neoadjuvant therapy, surgical resection in 22 patients revealed a pathological complete response (pCR) rate of 36.4% (8/22). Multivariate analysis identified squamous cell carcinoma histology and tumor cell PD-L1 expression >50% as predictors of good response to neoadjuvant immunochemotherapy. Plasma metabolomic profiling detected 3,756 metabolites. The GR group exhibited significantly higher levels of glycerol ester of acylcarnitine and hydroxypropionylcarnitine, whereas the LR group was enriched in glycocholic acid, phosphatidylcholine and taurocholic acid. KEGG pathway analysis indicated that the differential metabolites were involved in primary bile acid biosynthesis and cholesterol metabolism. Using machine learning, we integrated the baseline, post-cycle one and post-cycle two plasma metabolomic profiles to develop a 15-signature GLMNet model for pCR prediction, which achieved an area under curve (AUC) of 0.906.

Conclusion: Dynamic plasma metabolomic signatures are promising non-invasive biomarkers for predicting outcomes to neoadjuvant immunochemotherapy in NSCLC. These findings provide a rationale for leveraging metabolomics to stratify patients and optimize personalized treatment strategies.

#1055 Assessing biomarker reproducibility for glioblastoma patient response stratification.

Christopher M. Jannotta[1], **C. Zoe Linke**[1], Charles A. Whittaker[2], Vikas Patil[3], Accelerating GBM Therapies TeamLab, Farshad Nassiri[4], Gelareh Zadeh[5], E. Antonio Chiocca[1], Alexander L. Ling[1]

[1]Department of Neurosurgery, Brigham and Women's Hospital, Boston, MA,[2]Bioinformatics & Computing Core Facility, Massachusetts Institute of Technology, Cambridge, MA,[3]Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada,[4]Division of Neurosurgery, University Health Network, Toronto, ON, Canada,[5]Department of Neurosurgery, Mayo Clinic, Rochester, MN

Purpose: Glioblastoma (GBM) is the most common and aggressive primary malignant brain tumor, with a median survival of only 15 months. Effective therapeutic advances remain limited, with few clinical trial patients exhibiting robust responses to experimental therapies. This has led to efforts to identify molecular biomarker signatures capable of stratifying patient responses either prognostically (pre-treatment) or diagnostically (post-treatment). This study aims to assess the robustness and reproducibility of published transcriptional GBM biomarker signatures for predicting clinical outcomes in GBM trials.

Methods: We analyzed published RNA-seq data from 4 clinical trials involving oncolytic virotherapy and immune checkpoint inhibitors, as well as multiple cohorts of patients treated via the Stupp protocol. The performance of reported immune gene signatures was evaluated across all datasets using both grouped and continuous survival modeling. Intra-patient signature variation between different biopsy sites and timepoints was assessed using longitudinal, multi-site sampling collected by the Break Through Cancer Accelerating GBM Therapies TeamLab. LASSO, multivariate Cox regression, and risk scoring with FDR adjustment were used to identify novel signatures with cross-cohort utility.

Key Findings: No single published signature consistently predicted survival across all analyzed trials. A post-treatment ssGSEA antitumor cytokine signature that was associated with survival in the CAN-3110 OV trial ($R = 0.74$, $p < 0.01$) was also significantly associated with improved survival in an adjuvant anti-PD1 trial ($R = 0.75$, $p = 0.03$) and neoadjuvant anti-PD1 trial ($R = 0.30$, $p = 0.05$), but not in standard-of-care controls. PAM clustering of MCP immune signatures, as reported for the DNX-2401 OV+Anti-PD1 trial, also stratified post-treatment survival in the CAN-3110 OV trial ($p < 0.01$), with the coldest TME subtype consistently predicting worse survival. However, the prognostic value of the most immune enriched TME subtype was inconsistent and did not extend to the Anti-PD1 trials. Furthermore, multi-site, longitudinal biopsy samples revealed marked heterogeneity in biomarker signatures between biopsies from individual patients, even when assessed at the same timepoint. We've identified several candidate transcriptomic signatures that show promise for generalizable prognostic value in GBM patient cohorts and are characterizing their spatiotemporal variability.

Conclusions: While no individual immune signature is universally predictive in GBM immunotherapy, certain post-treatment cytokine signatures and TME stratifications are significant in multiple immunotherapy contexts, though not in standard-of-care patient cohorts. Marked spatiotemporal heterogeneity in these signatures underscores the need for composite prognostic markers resilient to sampling variance.

#1056 Integrative multi-omics characterization and AI-driven biomarker discovery for NSCLC stage III outcomes.

Katherina C. Chua, Yun-Ching Chen, Ariel Chen, Stewart Bates, Mehdi Pirooznia, Assieh Saadatpour

Johnson & Johnson, New Brunswick, NJ

Background: The PACIFIC trial established consolidation durvalumab as standard of care for unresectable stage III non-small cell lung cancer (NSCLC) following concurrent chemoradiotherapy (CRT). Real-world studies such as PACIFIC-R confirmed these benefits; however, comprehensive characterization of molecular features in this setting remains limited. Advances in AI enable integration of heterogeneous genomic and transcriptomic data, opening new opportunities for biomarker discovery. Our study applies a multimodal AI framework combining contrastive learning and foundational-model representations to identify distinct molecular features associated with survival outcomes from pre-treatment tumor data.

Methods: Stage III NSCLC *EGFR*/*ALK*-negative patients with unresectable disease who received CRT with subsequent durvalumab (CRT+D, N=281) or CRT alone (N=72) were identified from the Tempus AI multimodal real-world database. Molecular characterization included assessment of radiation and immunotherapy (IO)-related biomarkers to evaluate the impact on real-world progression-free survival (rwPFS). To identify potential DNA and RNA biomarkers, a multimodal AI framework was developed via integration of two recently published models: 1) COMPASS, a foundation model encoding RNA profiles into 43 interpretable immune-related concept scores, and 2) Predictive Biomarker Mapping Framework, a deep learning model mapping molecular features to treatment outcomes in CRT+D when compared to CRT-alone.

Results: In the CRT+D group, patients with high levels of biomarkers linked to IO response, such as PD-L1 ≥50% (p-value = 0.01) and a high tumor mutational burden (p-value = 0.02), showed improved survival rates. Patients exhibiting low *STK11* gene expression signature had shortened rwPFS (p-value=0.03). Tumors classified as radioresistant using the radiosensitivity index also showed diminished rwPFS benefit (p-value=0.02). Our multimodal AI framework revealed additional markers associated with improved rwPFS to CRT+D therapy, including tumors with adenocarcinoma histology, mutations in *LRP1B*, *NF1*, *KRAS*, and *CDKN2A*, and enrichment in expression of immune activation pathways (cytotoxic T-cell, IFN-γ, tertiary lymphoid structure, and immune-checkpoint signatures). In contrast, tumors with mutations in *TP53*, *RB1*, *NOTCH1*, *CUX1*, and *STK11* as well as those with elevated expression of regulatory and stromal signals (Tregs, exhaustion, stroma) were linked to worsened outcomes in patients treated with CRT+D. Cross-validation confirmed model reproducibility and feature stability.

Conclusions: Our study demonstrates the utility of a multi-omics approach to characterize molecular landscape of tumors treated with consolidation durvalumab and to drive biomarker discovery using an AI-driven, foundational-model-based framework.

#0070 SPOT-Met: Spatially decoding organotropism and immunotherapy response in colorectal cancer from 1,000 multi-omic tumors.

Jiwoon Park[1], Ryan Shultzaberger[2], Braulio Banuelos[2], McKenzie Pavlich[2], Sabrina Shore[2], Daan Witters[2], Kyung-A Kim[3], Taeyul K. Kim[3], Minsun Jung[3], Han Sang Kim[1], Christopher E. Mason[1]

[1]Weill Cornell Medicine, New York, NY,[2]Singular Genomics, San Diego, CA,[3]Yonsei University, Seoul, Korea, Republic of

Metastasis accounts for over 90% of mortality in colorectal cancer (CRC), yet predicting whether, when, and where it will occur remains a major clinical challenge. Existing tools, including TNM staging, ctDNA, and mutational profiling, cannot anticipate metastatic tropism or guide site-specific surveillance and therapy decisions. Consequently, many patients with stage II-III CRC receive suboptimal postoperative treatment. To address this gap, we established SPOT-Met (Spatial Predictors Of Tropism and Metastasis), a foundation-scale initiative that integrates subcellular-resolution spatial multi-omics with AI-driven modeling to infer the molecular and architectural rules governing organ-specific metastasis. We spatially profiled 1,000 CRC primary tumors and ~100 matched metastatic and adjacent normal tissues using the Singular Genomics G4X platform, generating >300 million same-sample transcriptomic, proteomic, and morphologic cell profiles at submicron resolution. Each case is linked to bulk RNA-seq, qPCR-based mutational data, and detailed clinical metadata encompassing metastasis site, timing, therapy response, and survival. SPOT-Met also incorporates a focused cohort of patients treated with pembrolizumab, enabling the spatial dissection of immunotherapy responses. Comparative analyses of responders and non-responders are underway, revealing emerging spatial differences in immune and stromal architecture. Preliminary data suggest that immune organization and cell-cell topology, rather than total immune content, may distinguish therapeutic outcomes, highlighting the potential of spatial context as a predictive biomarker beyond PD-L1 expression or tumor mutational burden. Early findings further indicate that liver-tropic tumors preferentially form perivascular stromal hubs enriched for metabolic and extracellular matrix signatures, whereas non-metastatic tumors retain compact, immune-regulated crypt structures. Integrating these spatial and molecular features enhances the retrospective classification of metastatic organotropism compared to histopathology alone. SPOT-Met is being developed as a biopsy-compatible diagnostic assay to predict metastatic potential and organotropism at the time of diagnosis, aiming to double current prognostic precision for stage II-III CRC. By uniting spatial multi-omics and AI at unprecedented scale, SPOT-Met transitions metastasis research from retrospective observation to prospective prediction, advancing precision oncology and immunotherapy stratification.

#0071 Bridging histopathology and spatial transcriptomics for comprehensive tumor microenvironment profiling.

Xiaohan Xing, Lei Xing

Stanford University, Palo Alto, CA

Purpose: The tumor microenvironment (TME) critically influences cancer progression, treatment response, and patient outcomes. Histopathology reflects morphological features of TME states but lacks molecular specificity, whereas spatial transcriptomics (ST) provides spatial gene expression yet is costly and impractical for large-scale use. To bridge this gap, we develop a multimodal AI framework that transfers spatial molecular information from ST into histopathology-derived representations, enabling reconstruction of molecular programs, TME phenotypes, and spatial biology directly from routine H&E slides. This sequencing-free approach supports biomarker discovery and advances precision oncology through scalable molecular profiling.

Methods: We introduce a multi-scale multimodal learning strategy that aligns two large-scale foundation models: UNI (trained on 100,000 pathology slides) [1] and Visiumformer (trained on 3.94 million ST profiles) [2]. Rather than training a unified model from scratch, we integrate the two modalities through multi-scale contrastive alignment. We curated 355 samples from the HEST-1K dataset [3], comprising 801,157 paired H&E patches and ST spots across 16 tissue types. At the patch level, we enforce consistency between paired histology and ST embeddings. At the region level—where each region is defined as a cluster of nine neighboring patches—we further constrain cross-modal agreement. To maintain hierarchical coherence, we additionally encourage alignment between each patch and its corresponding parent region. This multi-scale contrastive alignment effectively transfers spatial molecular knowledge from ST into histopathology-based representations, enhancing various downstream tasks.

Results: We evaluated our framework on two downstream tasks. (1) Gene expression status prediction: On the BCNB dataset (n=1,058 WSIs), our model improved ER/PR/HER2 prediction over pretrained UNI. ER AUC/BACC increased from 0.882/0.780 to 0.891/0.771; PR from 0.792/0.712 to 0.812/0.715; and HER2 from 0.662/0.602 to 0.696/0.634. (2) Spatial spot classification: On the DLPFC dataset (n=12 WSIs), linear probing achieved 71.75% balanced accuracy and 78.15% weighted F1, compared with 55.19% and 63.61% for UNI—improvements of 16.56% and 14.54%.

Conclusions: Our multi-scale contrastive alignment framework transfers spatial molecular signals from ST into histopathology-derived representations, improving gene expression prediction, mutation inference, and spatial TME characterization. By enabling sequencing-free reconstruction of molecular and microenvironmental features, this approach offers a scalable solution for large-cohort cancer profiling and may facilitate biomarker discovery, patient stratification, and biologically informed precision oncology.

#0072 Unbiased AI detection of tertiary lymphoid structures from H&E whole-slide images using mRNA-derived labels predicts survival in NSCLC.

Anthony J. Wong[1], **Jessica Kim**[2], Shinkyo Yoon[3], Young Kwang Chae[1]

[1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Northwestern University, Evanston, IL,[3]Department of Oncology, Asan Medical Center, College of Medicine, University of Ulsan, Seoul, Korea, Republic of

Tertiary lymphoid structures (TLS) are recognized prognostic markers in non-small cell lung cancer (NSCLC), yet manual detection from H&E whole-slide images (WSI) remains subjective and labor-intensive, limiting clinical adoption.
We conducted an integrative analysis combining transcriptomic and histopathologic approaches. TCGA NSCLC mRNA expression data (n = 922) were analyzed using xCell to compute enrichment scores for B cells, T cells (CD4+ and CD8+), and dendritic cells. TLS enrichment score was calculated by averaging z-standardized xCell aggregate enrichment scores for B cells, T cells, and dendritic cells. Samples in the upper quartile were labeled 'TLS enriched' and those in the lower quartile were labeled 'TLS non-enriched.' These quartile-derived labels were then used to train a machine learning model for TLS detection from TCGA H&E whole-slide images using Imagene's OI Suite platform with a 3:1 train-test split. Univariable and multivariable cox proportional hazards regression analysis evaluated whether AI-predicted TLS enrichment independently predicted overall survival (OS).
The AI model demonstrated robust performance for TLS detection, achieving an AUC of 0.84 in the training set and a test AUC of 0.92. Kaplan-Meier analysis showed that patients in the AI-predicted TLS-enriched group (n = 366, 366/922=39.7%) demonstrated improved OS compared with the AI-predicted TLS-non-enriched group (n = 556, 556/922=60.3%; HR 0.76; 95% CI 0.61-0.94; log-rank p = 0.014). Adjusting for age, sex, and histology, AI-predicted TLS enrichment remained independently associated with favorable OS (HR 0.77; 95% CI, 0.61-0.97; p = 0.025). Among the covariates, older age (greater than the cohort median) was associated with worse survival (HR 1.25; 95% CI, 1.01-1.55; p = 0.039), while sex and histologic subtype (LUSC vs LUAD) were not significant predictors (HR 1.12; 95% CI, 0.89-1.41; p = 0.337 and HR 0.99; 95% CI, 0.79-1.25; p = 0.957, respectively). These findings indicate that the model's TLS-enrichment prediction captures clinically meaningful tumor microenvironment features that stratify OS beyond standard clinicopathologic factors.
AI-assisted H&E WSI analysis helps identify TLS enrichment as a potential independent predictor of overall survival in NSCLC. This unbiased computational approach provides a reproducible and objective methodology for TLS assessment and survival prediction in a resource-limited context using H&E WSI only, and may support downstream treatment selection in the context of precision immunotherapy.

#0073 Accurate prediction of microsatellite instability-high gastric cancer from H&E-stained whole slide images.

Shima Nofallah[1], Jake Conway[1], Jacqueline Brosnan-Cashman[2], Syed Ashar Javed[1], Bahar Rahsepar[2]

[1]PathAI, Boston, MA,[2]PathAI, Inc., Boston, MA

Background: While prognosis is poor for patients with gastric cancer (GC), those with microsatellite instability-high disease (MSI-H) respond well to checkpoint inhibition. Next-generation sequencing approaches for MSI-H detection are complicated by cost, turnaround time, and accessibility. Artificial intelligence (AI)-powered pathology has the potential to improve MSI-H detection.
Methods: Hematoxylin and eosin (H&E)-stained GC whole slide images (WSIs; N=316) from TCGA were used, and ground truth MSI-H status was determined as described [1]. A model, utilizing an additive multiple instance learning (aMIL) framework [2] and embeddings from PLUTO v3.1* [3] (PathAI, Boston, MA), a pathology foundation model, was trained to predict slide-level MSI-H status using 5-fold cross-validation. Model predictions were compared to ground truth labels using area under the receiver operating curve (AUROC) analysis.
Results: Model performance results are summarized in Table 1. The aMIL model achieved a mean AUROC of 0.86 (range: 0.81-0.89). These model predictions were highly accurate and consistent across folds, suggesting that the model is highly robust for predicting MSI-H status.
Conclusions: Here, we describe an AI pathology model that consistently and accurately identifies MSI-H GC from H&E-stained WSIs. The application of such models to routine GC biopsies has the potential to streamline the detection of MSI-H and other molecular biomarkers. Future studies will assess histologic features associated with model attention and extend this work to other MSI-H cancer types, including colorectal and endometrial cancer.

#0074 Improving histopathological diagnostic turnaround time through the GLORIA Telepathology Network in complex oncological cases.

Rafael Parra-Medina[1], Andres Mosquera-Zamudio[1], Rita Paez[2], Manuel Lopez[3], Maria Alejandra Espinosa[4], Yeison Carlosama Rosero[5], Yesid Poveda[6], Katherine Redondo-De Oro[7], Marcela Gomez-Suarez[8]

[1]Research Institute, FUCS, Bogota, Colombia,[2]Laboratorio Rita Paez, Armenia, Colombia,[3]Research Institute, Laboratorio Lopez Correa, Pereira, Colombia,[4]Laboratorio de Patologia, Clinica IMAT Oncomedica Auna S.A.S., Monteria, Colombia,[5]Laboratorio de patologia, Patologos asociados, Bogota, Colombia,[6]Laboratorio de patologia, Medical Duarte, Cucuta, Colombia,[7]Laboratorio de Patologia, CENDIPAT, Cartagena, Colombia,[8]Research Institute, FUCS, FUCS, Colombia

Introduction: In Latin American countries, disparities in access to timely and accurate oncological diagnoses contribute to differences in survival outcomes between urban and rural populations. Colombia exemplifies this situation, with only 0.88 pathologists per 100,000 inhabitants and a very limited number of oncopathologists, most of whom are concentrated in major cities.The GLORIA Telepathology Network was developed to address these inequities by implementing a digital diagnostic platform that connects peripheral hospitals with expert centers. Through whole-slide imaging (WSI) and real-time remote consultations, GLORIA enhances diagnostic accuracy, reduces turnaround time for histopathological reports, and supports clinical decision-making in oncological care across the country. The aim of this study is to describe the most frequently consulted tumor types and to evaluate the diagnostic turnaround times since the implementation of Telepathology Network.

Methdology: Six WSI scanners (Roche DP200) were installed in different regions of Colombia (Armenia, Pereira, Pasto, Cartagena, Cúcuta, and Montería) to enable the digitalization of oncological cases that present diagnostic challenges. These digital slides are remotely reviewed and discussed with specialized oncopathologists

Results: During the first 10 months of implementation, including the progressive integration of the digitalization centers, a total of 363 oncological cases were interconsulted. The most frequently interconsulted tumor types were: Skin tumors (14.0%), Gynecologic tumors (10.7%), Breast tumors (9.6%) and Soft tissue tumors (9.4%). The average diagnostic turnaround time (from case upload to expert report) was 18 hours.

Discussion: This reduction in turnaround time reflects a substantial improvement compared to traditional consultation methods (20 days). The implementation of the GLORIA Telepathology Network demonstrates the critical role of telepathology in reducing diagnostic delays, particularly in regions lacking access to oncopathologists. By enabling rapid expert review and fostering nationwide collaboration, GLORIA contributes to more equitable and timely oncological care across Colombia.

#0075 From single H&E to virtual immunohistochemical biomarker staining in the lung tumor microenvironment.

Kenneth To[1], Christopher Jackson[1], Louis Vaickus[2], Lawrence Schobs[1], Rohan Kamra Lyons[1], Rafay Azhar[1]

[1]ViewsML, Vancouver, BC, Canada,[2]Darthmouth-Hitchcock Medical Center, Lebanon, NH

Profiling the tumor microenvironment (TME) is fundamental to understanding immune, stromal, and tumor interactions influencing cancer diagnosis, progression, and therapeutic response. Physical immunohistochemistry (IHC) remains essential but is limited by reagent dependency, labor-intensive workflows, and tissue exhaustion. This study aimed to develop and validate a virtual IHC platform to reproduce biomarker staining directly from hematoxylin and eosin (H&E) slides, enabling high-fidelity TME characterization while conserving tissue. Using the ViewsML deep learning platform, a virtual TME panel was trained to predict five key biomarkers: CD31 (endothelial/vasculature), CD45 (pan-leukocyte), CD68 (macrophage), smooth muscle actin/SMA (activated fibroblasts and pericytes), and cytokeratin AE1/3 (tumor epithelium). 316 digitized lung cancer biopsy slides (Aperio GT450) encompassing over 150 million annotated cells were used. Data were split into training (70%), validation (15%), and test (15%) sets. Neural networks were optimized for biomarker-specific predictions, and model performance was evaluated using ROC AUC metrics and blinded pathologist review. Virtual biomarkers showed strong concordance with physical IHC, achieving AUCs of CD31=0.91, CD45=0.90, CD68=0.93, SMA=0.91, and CK AE1/3=0.90. Pearson's correlations were 0.73, 0.72, 0.76, 0.73, and 0.76 ($p<0.0001$). Virtual stains preserved spatial and morphological features, including CD31-positive vascular frameworks at tumor-stroma boundaries, CD45-positive immune infiltration, CD68-positive macrophage aggregates, SMA-positive stromal reaction patterns, and CK-positive tumor epithelium. Quantitative per-cell biomarker expression enabled automated precise cell fraction, cell ratio, spatial proximity, and immune and macrophage clustering analysis. These findings demonstrate that ViewsML's virtual IHC technology can reproduce physical staining from standard H&E slides, offering a scalable solution for digital TME profiling and conserving tissue. This approach supports translational research, virtual biomarker screening in drug development, and clinical application by enabling immune versus stroma-dominant tumor stratification to guide immunotherapy. Future work will extend this platform to more tumor types and incorporate multiplex virtual staining for broader digital pathology integration.

#0076 IHCExplore: An AI-driven computational pathology platform for accurate and scalable immunohistochemistry scoring.

Kelsey Luu[1], Ciyue Shen[2], Chintan Shah[3], John Shamshoian[3], Blake Martin[1], Daniel Shenker[1], Jackson nyman[1], Nhat Le[1], Zahil Shanis[1], Syed Ashar Javed[3], Matthew Bronnimann[3], Robert Egger[4], Harsha Pokolla[1], Andrew H. Beck[5], Benjamin Glass[2], Jennifer Hipp[3], Ryan Leung[6], Jacqueline Brosnan-Cashman[1], Santhosh Balasubramanian[1], Bahar Rahsepar[1], Emma Krause[7]

[1]PathAI, Inc., Boston, MA,[2]PathAI, Boston, MA,[34]PathAI, Inc.,[5]PathAI, Inc., Cambridge, MA,[6]Pathai, Boston, MA,[7]PathAI, boston, MA

Precise scoring of biomarker expression using immunohistochemistry (IHC) influences the success of precision therapeutics in oncology, such as antibody-drug conjugates (ADCs). However, manual IHC scoring by pathologists is limited by inter- and intra-pathologist variability, poor scalability, and limitations in visually accessible (e.g., spatial) information.

IHCExplore* is an artificial intelligence (AI)-enabled tool that provides comprehensive and reproducible characterization of protein expression from an IHC specimen. IHCExplore leverages PLUTO, a pathology foundation model,1 and was trained on a dataset of 24,390 whole slide images (WSIs) from 123 distinct staining assays. The model identifies cell types (cancer cells and lymphocytes) and segments tissue regions into cancer epithelium, cancer-associated stroma, and necrosis. It further segments the nucleus, cytoplasm, and membrane of individual cells to quantify protein expression at subcellular resolution.

Model-derived features quantify expression at the slide-level and classify cancer cells into unstained, low-, medium-, and high-intensity categories. Spatial features describe the distribution of these cells within the tumor microenvironment. Additional quantitative readouts include continuous H-score, membrane: cytoplasm intensity ratio, expression heterogeneity score, and spatial proximity score (to assess bystander activity).As a proof of concept, IHCExplore features were used to calculate PD-L1 tumor proportion score (TPSIHCExplore) as follows: total cancer cells with membrane staining above a threshold/total cancer cells. In a cohort of non-small cell lung cancer WSIs (N=597) stained with multiple PD-L1 clones (SP263, SP142, 28-8, 22C3), TPSIHCExplore was compared to manual consensus TPS from N=5 pathologists using intraclass correlation coefficient (ICC). After adjusting the staining threshold from a preset cutoff (4) to a calibrated cutoff (7), the ICC of TPSIHCExplore compared to consensus increased from 0.73 to 0.91, a value on par with the ICC of the average annotator compared to consensus (0.90). Therefore, outputs from routine IHCExplore deployments can recapitulate existing biomarker scoring with simple threshold optimization.Thus, IHCExplore is a scalable and accurate AI-driven solution for IHC scoring. The model's ability to generalize across tumor types and staining modalities, along with its fine-grained cell compartment segmentation, positions it as a powerful tool for biomarker discovery, assay optimization, and potential deployment as a companion diagnostic or scoring-assist system for precision oncology.

*IHCExplore is For Research Use Only. Not for use in diagnostic procedures.

#0077 AI-driven 3D spatial transcriptomics for 3D tumor microenvironment mapping in prostate adenocarcinoma.

Cristina Almagro-Perez[1], Andrew Song[1], Luca Weishaupt[1], Ahrong Kim[2], Guillaume Jaume[1], Konstantin Hemker[1], Drew F.K. Williamson[3], Stephanie Pei Tung Yiu[4], Qinghua Han[5], Renao Yan[5], Elena Baraznenok[5], Long Phi Le[1], Alexander S. Baras[6], Ali Bashashati[7], Sizun Jiang[4], Jonathan T.C. Liu[5], Faisal Mahmood[4]

[1]Brigham and Women's Hospital, Boston, MA,[2]Pusan National University, Busan, Korea, Republic of,[3]Emory University, Atlanta, GA,[4]Harvard Medical School, Boston, MA,[5]Stanford University, Palo Alto, CA,[6]Johns Hopkins Medicine, Baltimore, MD,[7]University of British Columbia, Vancouver, BC, Canada

Prostate adenocarcinoma (PRAD) is a multifocal and highly heterogeneous malignancy, marked by the coexistence of multiple Gleason grade glands within the same tumor microenvironment (TME). Spatial Transcriptomics (ST) has recently emerged as a powerful technology for characterizing the TME, yet its application is largely limited to two-dimensional (2D) histological sections, which typically capture less than 0.1% of the three-dimensional (3D) tumor context available upon resection. While promising, recently proposed in-situ approaches for 3D ST remain confined to reduced patient cohorts due to lengthy processing times and substantial costs.

To enable scalable 3D morphomolecular analysis of PRAD TME, we devise an AI framework that obtains 3D spatial molecular maps in a cost-effective and efficient manner. Our framework, VORTEX (Volumetrically Resolved Transcriptomics EXpression), leverages 3D high-resolution tissue morphology from 3D pathology imaging modalities, and minimal 2D ST to predict 3D ST. By pretraining on diverse 3D morphology-transcriptomic pairs from heterogeneous tissue samples and then fine-tuning on minimal 2D ST data from a specific volume of interest, VORTEX captures both generic tissue-related and sample-specific morphological correlates of gene expression. Our framework leverages pathology and single-cell foundation models, and integrates a cross-modal registration pipeline for accurate learning of morphomolecular links.

To evaluate our approach, we apply VORTEX to a cohort of 23 3D pathology volumetric images of PRAD specimens across 17 patients, acquired with micro computed tomography (microCT, 11 volumes) and open-top light-sheet microscopy (OTLS, 12 volumes). We additionally collect 88 sections of Visium ST across these samples and public cohorts, resulting in 243,682 spots with corresponding morphology. We demonstrate that VORTEX accurately predicts 3D ST and we identify two major trends: incorporating 3D morphology enhances the ability to learn morphomolecular links compared to 2D morphology alone, and including 2D ST data from the volume of interest further improves the performance by accounting for inter-patient heterogeneity. We observe that VORTEX captures intra-tumoral and inter-tumoral heterogeneity, with genes such as AZGP1 or GLO1 showing different expression profiles across patients and Gleason Grades. Furthermore, by analyzing 3D ST from multiple genes through Hallmark's pathways, we identify hidden structures in 2D views, including the 3D invasive tumor front.

In summary, VORTEX, by leveraging AI, 3D tissue morphology and 2D ST, generates 3D spatial molecular maps in a reliable, efficient and scalable manner. The combined morphomolecular analysis of the 3D tumor context can provide a novel perspective of the TME for improved characterization of PRAD heterogeneity.

#0078 OncoPredikt: A deep-learning framework for tumor detection and biomarker quantification in breast cancer IHC whole-slide images.

Gowhar Shafi[1], PM Shivamurthy[1], Aditya Satpute[1], Hrishita Kothavade[1], Aarthi Ramesh[2], Mohan Uttarwar[3], Nandini Ramchandani[1]

[1]OneCell Diagnostics India Private Limited, Pune, India,[2]1Cell.Ai, Mumbai, India,[3]1Cell.Ai, Foster city, CA

Background: Biomarker quantification in breast cancer remains challenging despite standardized protocols. Manual pathologist assessment introduces variability and misses subtle HER2 patterns, with inter-pathologist concordance for HER2 0 vs. 1+ distinction at only 26%. Second-generation antibody-drug conjugates now target HER2-low and HER2-ultralow tumors, but traditional visual assessment fails to reliably identify patients with barely detectable HER2 (faint staining in ≤10% of cells). We present an AI-driven approach for objective tumor detection and automated biomarker quantification of ER, PR, HER2 and Ki67 in Breast Cancer.
Methods: AI-based OncoPredikt model was designed and trained on H&E images (130 training, 53 validations from TCGA/in-house cohorts), tested on IHC WSIs for cross-stain generalization for automated Tumor detection. Further, automated biomarker quantification was performed within the detected tumor regions. The workflows were all validated against pathologist annotations.
Results: Tumor masks achieved Dice Similarity Coefficient >0.8 on H&E and better results with IHC WSIs. The ER/PR prediction using our AI-based approach shows a weak positive for a negative sample. For 2 pathologist-analyzed IHC 0 (Neg) HER2 samples tested through the AI-based approach yielded Ultra-Low (0+) and (1+) predictions indicating subtle positivity. The algorithm demonstrated promising performance in discriminating 0+ ultra-low (faint staining ≤10% cells) from 0 (no staining), addressing the critical diagnostic gap where HER2-ultralow patients were previously inaccessible for ADC selection. Automated assessments showed strong concordance with pathologist scoring across ER/PR Allred classification and Ki67 proliferation indices.
Conclusion: The HER2 ultra-low detection capability directly addresses a recognized bottleneck: visual inspection of faint, incomplete membrane staining in <10% of cells fall below reliable human detection, yet clinical trials confirm ADC efficacy in HER2-low/ultralow disease. The 26% inter-pathologist concordance for 0 vs. 1+ distinction underscores the clinical value of objective quantification. The shift from manual annotation to algorithm-derived tumor masks eliminates observer variability and saves the time of pathologists with heavy workload and reduces subjectivity in reporting. Thus, AI-driven tumor detection coupled with objective biomarker quantification constitutes a meaningful advancement for precision oncology in breast cancer, enabling identification of biomarkers previously invisible to standard pathology assessment. Further validation on large sample sets is still warranted.

#0079 From pixels to spatial microenvironments: AI-powered CAF-Epi niche prediction on H&E slides.

Zhixuan You[1], Qiankun Li[2], Jiaying Zhu[3], Guoyu Cheng[1], Yanrong Shen[1], Jiang Chang[2], Chen Wu[1]

[1]Department of Etiology and Carcinogenesis, National Cancer Center/National Clinical Research Center/Cancer Hospital, Chinese Academy of Medical Sciences (CAMS) and Peking Union Medical College (PUMC), Beijing, China,[2]Huazhong University of Science and Technology, Wuhan, China,[3]College of Computing and Data Science, Nanyang Technological University, Singapore, Singapore

Routine H&E slides remain the most accessible and rapid diagnostic material in clinical practice, particularly for gastrointestinal cancers. However, although H&E effectively distinguishes cancer from non-cancer, it provides insufficient information to predict treatment response. Spatial niches can be conceptualized as multicellular microanatomical units—defined by characteristic patterns of cellular adjacency, interaction and coordinated signaling. Using spatial transcriptomics across multistage esophageal squamous cell carcinoma (ESCC), we identified a CAF-epithelial (CAF-Epi) niche in which cancer-associated fibroblasts and epithelial cells cooperatively shield tumor cells from immune surveillance. In a neoadjuvant immunotherapy cohort, we found CAF-Epi score derived from this niche robustly discriminated responders from non-responders and stratified long-term survival, indicating that this functional niche, rather than subtle changes in cell proportions or morphology, more directly governs treatment outcome. To enable scalable CAF-Epi assessment on routine histopathology, we developed SHEEN-CAF (Spatial H&E-based CAF-Epi niche model), a deep-learning model that identifies ST-defined CAF-Epi niches directly from H&E slides. We assembled a paired H&E-ST atlas of 198 multistage ESCC specimens, totaling 9.6 million cell annotations and 275,753 CAF-Epi-labeled FOVs. SHEEN-CAF learns multi-scale morphological representations and reconstructs whole-slide CAF-Epi distributions. In the test set, it achieved an AUC of 0.91 with cross-center accuracies of 87-94%. In an independent external validation cohort with paired H&E and multiplex immunofluorescence, SHEEN-CAF-derived CAF-Epi scores correlated with immunofluorescence-defined CAF-Epi signals ($r = 0.81$, $P < 0.01$) and discriminated high- versus low-CAF-Epi burden lesions (AUC = 0.89). In an ESCC cohort treated with immune checkpoint blockade, non-responders exhibited significantly higher CAF-Epi scores than responders ($P < 0.05$), linking CAF-Epi burden on routine H&E to immunotherapy resistance. In summary, SHEEN-CAF converts CAF-Epi niche burden—previously measurable only with advanced spatial-omics—into an automated, quantitative biomarker derived solely from routine diagnostic H&E slides. By requiring no additional tissue or sequencing, it provides an efficient and scalable measure of the spatial microenvironment, with potential to refine immunotherapy response assessment and risk stratification in ESCC.

#0080 Quantitative assessment of tumor-infiltrating lymphocytes using AI in non-small cell lung cancer and association with immunotherapy response.

Mona Tuysserkani[1], Siraj Ali[2], Yoojoo Lim[2], Ken Nesmith[2], Sanghoon Song[2], Sanja Dacic[1], David Rimm[1]

[1]Pathology, Yale School of Medicine, New Haven, CT,[2]Lunit, Seoul, Korea, Republic of

Tumor-infiltrating lymphocytes (TILs) have been associated with treatment outcomes in non-small cell lung cancer (NSCLC), but challenges in visual and digital assessment have limited their clinical use. In this study, we used a quantitative AI-based approach on digitized H&E-stained sections to quantify intratumoral (iTIL) and stromal (sTIL) TILs and to evaluate optimal digital cutoff points associated with clinical outcomes across NSCLC cohorts treated with non-neoadjuvant and neoadjuvant immunotherapy. Two independently collected, annotated retrospective NSCLC cohorts from surgical resections treated with immune checkpoint inhibitors (ICIs) were included: the Yale 471 cohort (training set, n=42) and the Yale 592 cohort (validation set, n=41). Quantification of iTIL and sTIL was performed on whole-tissue H&E sections using the SCOPE IO™ platform developed by Lunit. A cutoff associated with clinical outcome was identified in the training cohort and applied to the validation cohort to assess associations with progression-free survival (PFS) and overall survival (OS). The two cohorts were then combined into a larger non-neoadjuvant training set (n=83). An optimal cutoff point was applied to the neoadjuvant validation set collected from pretreatment transbronchial and needle-core biopsies of patients with surgical resection after neoadjuvant therapy (n=76). This neoadjuvant cohort provided a clinically enriched population for assessing associations with PFS and OS. In the Yale 471 training cohort, higher sTIL scores were significantly associated with longer progression-free survival (PFS) at an optimal cutoff point of 2.4% (HR = 2.7). This cutoff remained significant in Yale 592 (HR = 5.8; $P < 0.0001$). No significance was found when assessing iTIL in this manner. In the non-neoadjuvant training set, higher iTIL scores were linked to longer PFS with an optimal cutoff point of 0.28%, dividing patients into equal groups (HR = 0.36). The neoadjuvant cohort showed significance (HR = 0.28; $P = 0.0045$). Higher sTIL scores were also associated with improved PFS in the non-neoadjuvant training cohort using the same 2.4% cutoff point, splitting patients into 70% high and 30% low groups (HR = 0.21). The neoadjuvant validation set showed significance (HR = 0.34; $P = 0.0066$). Although higher iTIL and sTIL values showed consistent trends for overall survival (OS) in the training sets, these associations did not reach statistical significance. Quantitative assessment of tumor-infiltrating lymphocytes (TILs) may provide an objective biomarker for immunotherapy response in NSCLC, particularly for intratumoral TILs (iTIL), which are not assessable by pathologists. Future work is planned to include additional analyses of neoadjuvant and prospective NSCLC cohorts to further validate associations between TIL assessment and clinical outcomes.

#0081 Clinical-grade quality control and stain harmonization enhancement in whole-slide images of lung cancer using deep learning.

Meghdad Sabouri Rad[1], Mohammad Mehdi Hosseini[1], Rakesh Choudhary[1], Harmen Siezen[2], Saverio J. Carello[1], Ola El-Zammar[1], Michel R. Nasr[1], **Bardia Rodd**[1]

[1]SUNY Upstate Medical University, Syracuse, NY,[2]University of Maryland at College Park, College Park, MD

Background: Deep learning models trained on hematoxylin-eosin (H&E) whole-slide images (WSIs) increasingly support prognostic and therapeutic-response biomarkers in lung cancer. However, their reliability is often compromised by image blur, scanner and pen artifacts, and inter-slide stain variability that obscure tissue morphology and introduce spurious predictive signals. To mitigate these issues, we developed a comprehensive, quantitative WSI quality-control (QC) and stain-harmonization pipeline tailored to single-pattern lung adenocarcinoma and assessed its downstream impact on clinical outcome prediction.
Methods: We analyzed 143 H&E WSIs (20×, 0.5 µm/pixel) from a Dartmouth lung adenocarcinoma cohort. QC incorporated multiple slide-level metrics, including tissue masks excluding artifacts, quantification of local blur using variance of the Laplacian across ≤600 tissue-centered crops, thumbnail-derived brightness statistics, and hematoxylin optical-density medians. Slides were retained only if they satisfied strict thresholds: tissue coverage ≥40%, artifact fraction ≤1%, blurry-tissue fraction ≤5%, brightness 140-210, and hematoxylin median 0.10-0.35. Among QC-cleared slides, an automated procedure selected a cohort-representative reference slide based on proximity to median brightness and hematoxylin metrics; its Macenko stain vectors and 99th-percentile concentration parameters were used for harmonization. All accepted WSIs were normalized to this reference. From normalized slides, 256×256 tiles (stride 256) with tissue fraction ≥70% and artifact fraction ≤2% were extracted to train a slide-level binary outcome model.
Results: Of 143 WSIs, 140 (97.9%) passed QC; three were excluded. Retained slides had a median resolution of 33,792 × 46,080 pixels. From 128 QC-passing cases, we obtained 215,220 analysis-ready tiles (median 1,590 per slide). By comparison, a simpler Otsu-based pipeline produced 249,073 tiles; thus, QC-aware masking removed 13.6% of candidates—primarily low-tissue or artifact-laden regions—without diminishing tumor or stromal coverage. Stain-normalized previews demonstrated highly consistent H&E appearance. Classifier performance improved from 90.63% ± 9.36 without QC/harmonization to 95.32% ± 4.05 following implementation.
Conclusions: This standardized QC and stain-harmonization framework effectively excludes low-quality slides and artifact-heavy regions while substantially improving the stability and accuracy of deep learning-based clinical outcome prediction in lung adenocarcinoma. By reducing technical confounders and enforcing stain consistency, the workflow enhances the robustness, reproducibility, and translational readiness of WSI-derived biomarkers and supports multi-institutional harmonization efforts in computational pathology.

#0082 Artificial intelligence derived spatial transcriptomic signatures from H&E slides predict survival in primary melanoma.

Amritpal Singh[1], Merin George[2], Tilak Pathak[1], Ujjwal Baid[1], Douglas Parker[3], Michael C. Lowe[4], Anant Madabhushi[1], **Bhakti Baheti**[1]

[1]Department of Biomedical Engineering, Emory University, Atlanta, GA,[2]Mercer University School of Medicine, Macon, GA,[3]Department of Pathology and Laboratory Medicine, Emory University, Atlanta, GA,[4]Department of Surgery, Emory University, Atlanta, GA

Introduction: Melanoma exhibits pronounced spatial and molecular heterogeneity, which drives tumor progression and clinical outcomes. While spatial transcriptomics (ST) assays can capture this complexity, their high cost and limited tissue availability hinder widespread use. Recent advances in computational pathology enable prediction of spatial gene expression directly from routine Hematoxylin and Eosin (H&E) whole slide images (WSIs), providing a scalable virtual alternative for true spatial profiling. This work investigates whether artificial intelligence (AI) derived ST features extracted from TCGA-SKCM H&E slides can serve as prognostic biomarkers of overall survival (OS) in primary melanoma.

Methods: We analyzed formalin-fixed paraffin-embedded H&E WSI of primary melanoma from TCGA-SKCM with available survival data (N=292 patients). Dataset was randomly split in a 30:70 ratio to generate training (N=87) and testing (N=205) cohorts. WSI were divided into patches of 290x290 pixels, and spatial expression of 5000 genes was predicted using the pretrained DeepSpot model. Downstream analyses were limited to 18 melanoma-relevant genes shortlisted from prior literature. AI predicted spatial gene expression values of these genes were summarized into per-spot and per-gene descriptors, producing 269 quantitative features encompassing statistical metrics, spatial autocorrelation indices, and Ripley's K derived spatial clustering measures. After removing highly correlated and low-variance features, bootstrapped LASSO regression was used to select the top 5 survival-informative features. A Cox proportional hazards model was used to create an integrated AI signature. Model performance for 10-year OS was evaluated using hazard ratios (HR), concordance indices, log-rank tests, and Kaplan Meier analyses on training and holdout testing cohorts.

Results: Survival times were right-censored at 10 years, resulting in 116 observed deaths and 176 censored patients. AI derived ST signature consisted of spatial features for KRT6B, UBE2L6, and PFKFB3 genes, along with average gene expression, and significantly stratified patients by OS. In the training set, the high-risk group had significantly poorer survival (HR = 3.39; 95% CI: 1.67-6.88; $p < 0.001$, C-index = 0.654). Independent validation in the testing cohort confirmed prognostic utility (HR = 2.17; 95% CI: 1.37-3.44; $p = 0.001$; C-index = 0.615), demonstrating generalizability.

Conclusion: AI inferred ST features derived from standard H&E slides capture biologically meaningful patterns associated with outcomes in primary melanoma. This virtual-omics pipeline provides a scalable and non-destructive approach for prognostication and may complement or substitute traditional molecular assays in settings where ST is not feasible.

#0083 AI-powered analysis of pancreatic ductal adenocarcinoma tissues to study the tumor immune ecosystem and identify novel classifiers.

Rebecca Polidori[1], Marika Viatore[1], Anna Rita Putignano[2], Greta Donisi[2], Capretti Giovanni[2], Arturo Bonometti[2], Silvia Uccella[2], Silvia Bozzarelli[2], Jakob Nikolas Kather[3], Massimo Locati[1], Federica Marchesi[1]

[1]University of Milan, Milan, Italy,[2]IRCCS Humanitas Research Hospital, Rozzano, Italy,[3]Technische Universitat Dresden, Dresden, Germany

Background: Digital pathology and artificial intelligence (AI) are emerging as powerful tools in immuno-oncology, enabling enhanced diagnostic and prognostic workflows. The current trend regards the application of AI on histopathological images to extract relevant features beyond human visual perception. Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest cancers worldwide, for which lack of efficient biomarkers to stratify patients and grade the response to therapy may play a significant impact. *Aim*: This project presents a computational pipeline integrating machine and deep learning approaches to characterize the PDAC tumor immune ecosystem and extract features with potential clinical relevance.

Methods: Whole-slide images from 53 PDAC patients, including those treated and untreated with neoadjuvant chemotherapy (NAT), were analyzed. Slides were stained with H&E, picrosirius red to detect fibrosis, and a CD68 antibody to detect macrophages. On H&E slides, a deep learning tissue classifier pretrained on colorectal cancer quantified Tumor and Stroma areas and their Spatial Entropy. QuPath-based pixel classifiers segmented CD68+ regions to compute macrophage abundance and spatial aggregation measured by the Morisita Index, and quantified picrosirius red+ areas to assess fibrosis and collagen maturity. Tissue and immune metrics were correlated, and slide-level embeddings extracted with the foundation model CTransPath were projected onto UMAP to explore clustering patterns.

Results: The deep learning tissue classifier achieved a global F1-score of 0.79 on PDAC slides. High macrophage abundance and Stroma Entropy were associated with worse overall survival. Integrating immune with tumor or stromal features improved patient stratification. NAT-treated patients showed increased fibrosis and reduced macrophage infiltration, with Stroma Entropy being predictive only in this group. Moreover, CTransPath-derived embeddings of CD68 and picrosirius red-stained slides clustered according to NAT regimen.

Conclusions: This AI-driven pipeline enables quantitative spatial profiling of the PDAC immune microenvironment, revealing interpretable features with prognostic and predictive value. Our findings highlight the potential of computational pathology to derive clinically meaningful biomarkers and support therapy response evaluation.

#0084 Deep-learning prediction of progression-free survival to EGFR inhibitors from H&E tissue slides in advanced *EGFR*-mutated non-small cell lung cancer.

Lodovica Zullo[1], Elin Samuelsson[2], Fabrizio Citarella[3], Mina Farag[2], Francesco Cortiula[4], Andrea De Giglio[5], Frank Aboubakar[6], Katharina von Loga[2], Etienne Hatton[2], Lorenzo Nibid[3], Giovanna De Maglio[4], Francesca Ambrosi[7], Beatrice Ramella Pollone[8], Melanie Janson[9], Alessandro Russo[10], Andrew Whittum[1], Ingrid Garberis[1], Victor Aubert[2], Hortense Deslandes[2], David Planchard[1], Fabrice Andre[1], Cecile Badoual[1], Benjamin Besse[1], Maria Rosa Ghigna[1], Mihaela Aldea[1]

[1]Gustave Roussy, Villejuif, France,[2]Owkin France, Paris, France,[3]Campus Bio-Medico, Rome, Italy,[4]University Hospital of Udine, Udine, Italy,[5]University of Bologna, Bologna, Italy,[6]Cliniques Universitaires Saint-Luc, Bruxelles, Belgium,[7]Maggiore Hospital-AUSL Bologna, Bologna, Italy,[8]IRCCS Ospedale Policlinico San Martino, Genova, Italy,[9]Francois BACLESSE, Comprehensive Cancer Center, Caen, France,[10]Ospedale Papardo, Messina, Italy

Background: Third-generation tyrosine kinase inhibitors (TKIs) like osimertinib are standard for untreated advanced non-small cell lung cancer (aNSCLC) with common *EGFR* mutations (exon 19 deletion/L858R). Combination with chemotherapy, bispecific antibodies or anti-angiogenic agents prolong survival but raises toxicity. No biomarker identifies patients benefiting from combinations versus osimertinib alone, yet.

Methods: We trained a multiple-instance model to predict progression-free survival (PFS) to first line EGFR-TKIs from hematoxylin-eosin (H&E) tissue slides, adjusting to the TKI type. Diagnostic slides from primary tumors of aNSCLC with common *EGFR* mutations were digitized at 20× at three independent institutions, and retrospectively included with clinical data. Performance was evaluated with C-index for continuous PFS and AUC for 1-year PFS, using bootstrapping.

Results: In total, 141 patients were included (n=73 osimertinib; n=68 erlotinib/gefitinib). We trained on Gustave Roussy (GR, France) and inferred on Campus Bio-Medico (CBM, Italy) and University Hospital of Udine (U, Italy). Patients were mostly female (65%, 62%, 72%), with no smoking habit (63%, 59%, 55%), had adenocarcinoma (92%, 94%, 100%) and exon 19 deletions (56%, 56%, 55%) across GR, CBM, U cohorts. Median (IQR) age was 65 (56-74), 71 (62-78), 68 (63-73) years in GR, CBM, U, respectively. Median true PFS and model performances are presented in the table.

Conclusion: This is the first study to predict PFS to EGFR-TKIs from H&E slides. Despite limited sample size, these findings support further investigation of digital pathology for PFS prediction in *EGFR*-mutated NSCLC. Results on additional cohorts, combination of the model with clinical variables, and interpretability will be presented at the congress.

Model's performance across cohorts

Cohort	Subset	#Patients	True PFS median (95%CI)	C-index continous PFS Mean (95%CI)	AUC 1-year PFS Mean (95%CI)
	All TKIs	78	11.9 (9.5, 15.4)	NA-Training cohort	NA-Training cohort
GR	Osimertinib	42	12.6 (9.8, 16.9)	NA-Training cohort	NA-Training cohort
	Erlotinib/gefitinib	36	9.9 (7.0, 15.4)	NA-Training cohort	NA-Training cohort
	All TKIs	34	9.5 (6.4, 16.3)	0.63 (0.53, 0.73)	0.73 (0.57, 0.86)
CBM	Osimertinib	16	13.6 (5.5, 23.3)	0.63 (0.49, 0.77)	0.62 (0.40, 0.86)
	Erlotinib/gefitinib	18	7.4 (2.1, 9.5)	0.59 (0.44, 0.74)	0.77 (0.57, 0.94)
	All TKIs	29	13.0 (9.4, 17.9)	0.78 (0.70, 0.84)	0.83 (0.69, 0.95)
U	Osimertinib	15	23.0 (6.7, 50.1)	0.84 (0.70, 0.94)	0.90 (0.72, 1.00)
	Erlotinib/gefitinib	14	12.7 (8.0, 17.5)	0.74 (0.61, 0.85)	0.73 (0.46, 0.93)

#0085 Path2Marker: Cell-level prediction of multiplex protein expression from routine H&E slides.

Amos Stemmer[1], Tiangen Chang[1], Thomas Cantore[1], Saugato Rahman Dhruba[1], Sumona Biswas[1], Sumeet Patiyal[1], Eldad David Shulman[1], Emma M. Campagnolo[2], Aagam Shah[3], Simon Knott[3], Chi-Ping Day[2], Danh-Tai Hoang[1], Eytan Ruppin[3]

[1]National Cancer Institute - Cancer Data Science Laboratory (CDSL), Bethesda, MD,[2]National Cancer Institute - Cancer Data Science Laboratory (CDSL), Bathesda, MD,[3]Cedars-Sinai Medical Center, Los Angeles, CA

Background: High-plex spatial proteomics platforms (e.g., PhenoCycler) have transformed our ability to map the tumor microenvironment (TME) at single-cell resolution, but their cost constrains cohort sizes for biomarker discovery and validation. Recently, ROSIE (Wu et al., Nat Commun 2025) aimed to tackle this problem by predicting protein markers directly from H&E stained slides. However, the number of robustly predicted markers obtained by it has been fairly limited, with only 5 markers reaching a Pearson r correlation of above 0.4 between measured and predicted marker intensity. Here, we present Path2Marker, a cell-level deep learning framework that substantially expands the panel of robustly predicted protein markers in multiple tumor types.**Methods:** We analyzed three new cancer-specific PhenoCycler (CODEX) cohorts with paired H&E and multiplex immunofluorescence, including lung cancer (88 samples, 660791 cells), colorectal cancer (106 samples, 624919 cells) and breast cancer (115 samples, 901684 cells), each stained with a 55 proteomic marker panel. For each disease, we trained a cancer-specific model to predict per-cell marker intensities from the H&E slides, and additionally evaluated an ensemble model that averages predictions from all three cancer-specific models. Model performance was evaluated on 60 held-out samples (all three diseases; 396,995 cells), using Pearson correlation between the measured and predicted marker intensities.**Results**: We robustly predict (Pearson r > 0.4 for measured vs. predicted intensity) 23, 26, and 44 markers in the breast, lung and colorectal cohorts, respectively, markedly outperforming the published state of the art. When benchmarked on the same samples, ROSIE achieved fewer robustly predicted markers, with only 3 markers in colon, 2 in lung and 0 in breast. The ensemble model significantly improved mean marker-level correlation in lung and was comparable to the indication-specific models in breast and colorectal cancer. Top-performing markers included EpCAM in colon (r=0.79), PanCK in lung (r=0.73), and PanCK in breast (r=0.64). Notably, they include not only lineage markers (e.g., PanCK, CD3e) but also functional markers (e.g., PD-L1, Ki-67), enabling downstream cell-state and cell-type annotation, laying the basis for robust annotation of 25, 16, and 17 different cell-types in colon, lung, and breast, respectively.**Conclusion**: Path2Marker enables robust prediction of more than 20 multiplex protein markers at single-cell, spatial resolution directly from standard H&E slides across three major solid tumors. It markedly improves upon the predictive accuracy of extant tools, opening up the possibility of fast and low-cost annotation of large cancer patients cohorts directly from the histopathology slides.

#0087 *Path2Prot* offers a new way for breast tumor subtyping and treatment response prediction from AI-inferred proteomic biomarkers.

Saugato Rahman Dhruba[1], Danh-Tai Hoang[1], Sumit Mukherjee[1], Amos Stemmer[1], Eldad Shulman[1], Ranjan Kumar Barman[2], Sanna Madan[2], Sanju Sinha[3], Kenneth D. Aldape[4], Eytan Ruppin[5]

[1]National Cancer Institute - Cancer Data Science Laboratory (CDSL), Bethesda, MD,[2]National Cancer Institute - Cancer Data Science Laboratory (CDSL), Rockville, MD,[3]Sanford Bernham Prebys, La Jolla, CA,[4]Professor, Dept. of Pathology, Chair, NCI-CCR, Bethesda, MD,[5]Cedars-Sinai Medical Center, Los Angeles, CA

Background: The advent of AI is revolutionizing precision medicine, including digital pathology where large foundation models (FMs) are applied to readily extract genomic/transcriptomic patterns from tumor whole-slide histopathology images (WSIs). In contrast, fewer studies have attempted to derive direct functional insights *via* proteomics from tumor morphology in WSIs, partly due to data scarcity. Henceforth, we propose a weakly-supervised deep learning model called *Path2Prot* to infer the relative abundance of 413 clinically relevant proteomic biomarkers in breast cancer (BC) from tumor H&E slide images. We show the clinical utility of such models in tumor subtyping and treatment response prediction by leveraging the inferred proteomic markers.

Methods: *Path2Prot* is composed of two stages: *First*, each WSI is preprocessed *via* a standard pipeline to a set of 512 x 512 tile images at 20x magnification, which are fed to a transformer-based FM to extract morphological features; *Next*, using these features with matched patient-level proteomics, a multilayer perceptron is trained to infer the proteomic marker levels. To train, we used 2,074 WSIs from 841 TCGA-BRCA patients and the matched reverse-phase protein array (RPPA) data for 413 proteins (total + post-translationally modified). We leveraged both WSI types available *via* building three distinct models: *FFPE model*, trained on 893 formalin-fixed paraffin embedded WSIs (used for diagnosis); *FF model*, trained on 1,181 fresh-frozen WSIs (better RNA quality); and *Combo model*, combining the predictions of both models.

Results: We assessed model performance with Pearson correlation (R) between inferred and measured proteomics, where proteins with $R \geq 0.4$ are referred as the *well-predicted proteins* (WPPs). The Combo model performed the best with 23.7% WPPs (mean R = 0.31) in cross-validation and successfully generalized to cross-platform mass spectrometry proteomics in external validation with CPTAC-BRCA with 27.1% WPPs (mean R = 0.28; Overlap-in-WPPs = 71.8%). We further dichotomized the inferred HER2 and ER levels to identify their immunohistochemistry status and assigned patient tumors to clinically actionable subtypes (HER2+, ER+ & TNBC) across TCGA-BRCA (n = 733), CPTAC-BRCA (n = 89), TransNEO (n = 160) and IMPRESS (n = 126). This task can be done fairly well, yielding area under the curve (AUC) values of HER2+ = 0.69-0.72, ER+ = 0.72-0.77 and TNBC = 0.83-0.88. Finally, the inferred protein targets successfully estimated anti-HER2 response in TransNEO (n = 60, AUC = 0.71) and CSHS-BRCA (n = 20, AUC = 1.0) cohorts, and anti-PD1 response in CSHS-BRCA (n = 16, AUC = 0.78).

Conclusion: Our analysis reveals a clinically important subset of proteins in breast cancer can be robustly predicted from routine WSIs for clinical application. One may expect to significantly improve upon these results with the advent of larger proteomics datasets.

#0088 Multiscale characterization of early morphologic radiation response in rectal cancer via digital pathology.

Sriya Veerapaneni[1], Paul Acosta[2], Bassel Dawod[3], Sebastian Diegeler[4], Mengxi Yu[1], Eslam Elghonaimy[3], Megan Wachsmann[5], Purva Gopal[5], Todd Aguilera[3], Satwik Rajaram[1]

[1]Lyda Hill Department of Bioinformatics, The University of Texas Southwestern Medical Center, Dallas, TX,[2]The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Radiation Oncology, The University of Texas Southwestern Medical Center, Dallas, TX,[4]University of Cambridge, Cambridge, United Kingdom,[5]Department of Pathology, The University of Texas Southwestern Medical Center, Dallas, TX

With effective neoadjuvant chemotherapy and radiotherapy (RT), some patients with locoregional rectal cancer may avoid surgery. However, patient responses are highly heterogeneous and poorly understood. Although morphological assessment remains the clinical gold standard, it is often dominated by tumor abundance, potentially overlooking complex biological adaptations to treatment. To address this, we sought to gain insights through a multiscale characterization of early histologic changes following RT. We leveraged matched pre- and post-RT histology slides from the INNATE trial dataset, using adjacent tissue as a control, to develop a dual-pipeline framework: (1) C-MorphQuant, for analysis of predefined classical features such as tissue composition, spatial organization, and nuclear morphology based on a finetuned cell classifier and a trained region classifier; and (2) DL-RadScore, a novel deep learning metric that learns de novo morphological features by distinguishing irradiated from non-irradiated tissue. Our C-MorphQuant analysis revealed: (1) compositionally, a clear reduction in tumor and normal epithelium with a commensurate increase in stroma; (2) spatially, the disruption of glands into fragmented small clusters (<30 nuclei); and (3) nuclearly, alterations in size and shape that were evident but patient-specific. Notably, while the overall radiation impact was generally stronger in tumor, C-MorphQuant phenotypes were more heterogeneous than the stereotypical adaptations observed in adjacent normal tissue. The DL-RadScore accurately distinguished unseen pre- and post-radiation samples. We established biological relevance by comparing with tumor epithelial Ki67 proliferation and found strong negative correlations at both the patient ($r = -0.59$, $p = 2.08*10^{-2}$) and intra-slide ($r = -0.43$, $p = 2.17*10^{-78}$) levels. While DL-RadScore maintained strong concordance with C-MorphQuant composition metrics, it outperformed measures of tumor cellularity in capturing proliferative status. Most intriguingly, our results demonstrated that rather than a gradual accumulation of morphological changes, some tumors appeared to initially "shrug off" early radiation doses, preserving a pre-treatment-like morphology, yet ultimately collapsed by the time of surgery. In summary, this study underscores the value of characterizing treatment-induced phenotypes beyond mere tumor cell abundance and highlights the complex non-linear spatiotemporal dynamics in which early morphological persistence does not preclude long-term cure.

#0089 TissueTrek: An interactive multimodal web-based platform for exploring spatial morphology-molecular relationships in cancer.

Vibha R. Rao[1], Marvin Escobar Barajas[2], Candice C. Black[1], Madhumala K. Sadanandappa[1], Scott M. Palisoul[1], Adrienne A. Workman[1], Todd A. MacKenzie[2], Louis J. Vaickus[1], Mary D. Chamberlin[1], George J. Zanazzi[1], **Shrey S. Sukhadia**[1]

[1]Pathology and Laboratory Medicine, Dartmouth Health, Lebanon, NH,[2]Dartmouth College, Hanover, NH

Background: The spatial organization of epithelial, stromal, and immune compartments plays a fundamental role in shaping tumor behavior, yet researchers and clinicians lack accessible tools to concurrently explore morphology, pathomic features, and spatial molecular measurements. Existing methods typically examine a single modality at a time, require specialized expertise, or offer limited interpretability. To address this gap, we developed TissueTrek, an interactive web-based platform that integrates H&E morphology, quantitative pathomics, spatial gene and protein expression, and explainable Machine Learning(ML) outputs into a unified environment that can be easily used by researchers, clinicians, trainees, and patients alike.

Methods: The platform was built using a GeoMx DSP cohort of 57 FFPE triple-negative breast cancer (TNBC) tissue cores. Board-certified pathologists annotated tumor regions of interest (ROIs). Three ROI-matched modalities were extracted: 77 pathomic features from H&E images, 91 spatially profiled and biologically relevant genes, and 570 spatially profiled proteins. The results from several ML pipelines developed upstream were incorporated to aid interpretability. Several web-based technologies enabled dynamic linking of ROIs with their molecular, pathomic, and model-derived representations for real-time exploration.

Results: TissueTrek provides the first ROI-resolved interface enabling simultaneous visualization of (i) spatially measured gene and protein expression, (ii) quantitative pathomic features, and (iii) interpretable deep-learning and pathomics-ML outputs within the same tissue context. Users can interactively conduct exploration of results through multiple features to decipher the biology underlying the tissue ROIs. The Model Output panel displays interpretable maps of these ROIs, enabling the study of spatial morphology-molecular relationships in TNBC that are otherwise difficult to discern.

Conclusions: TissueTrek represents a first-of-its-kind, fully interpretable spatial pathology interface that unifies morphologic, molecular, and deep-learning-derived insights into the same ROI-resolved environment. Although demonstrated in TNBC, the framework is generalizable and is capable of seamlessly incorporating additional biomarkers, diseases, or spatial-omics technologies, making it widely accessible, from expert computational scientists to clinicians, trainees, and patients seeking to understand their tissue biology. By enabling broad, user-friendly access to multimodal spatial biology, the platform advances computational pathology toward more transparent, clinically translatable, and educationally usable digital tissue ecosystem. This platform will be updated with the data and results constantly to serve the community better.

#0090 Histologic stratification of hepatocellular carcinoma using deep learning informed by spatial transcriptomics.

Tyler M. Yasaka[1], Chang Kyung (Joanna) Kim[1], Po-Yuan Chen[1], Rebekah E. Dadey[1], Riyue Bao[1], Satdarshan Pal S. Monga[2], Yu-Chiao Chiu[3]

[1]University of Pittsburgh, Pittsburgh, PA,[2]Associate Professor of Pathology & Med., University of Pittsburgh, Pittsburgh, PA,[3]UPMC Hillman Cancer Center, Pittsburgh, PA

Introduction: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality. Although multiple classification systems have been developed, their clinical utility remains limited. With the increasing use of tissue biopsies in targeted therapy trials, there is an opportunity to advance both molecular and histologic approaches for HCC stratification.
Methods: Publicly available spatial transcriptomics data with paired hematoxylin and eosin (H&E) images from 10 HCC slides were used to train deep learning models to predict Hoshida subtype (S1, S2, S3) signatures within spatial transcriptomics spots from corresponding H&E tiles. Models were evaluated using an 80/20 training/test split and subsequently applied to H&E whole-slide images from The Cancer Genome Atlas (TCGA; n=340) as well as an in-house validation cohort (n=48). Tile-level predictions were aggregated to generate patient-level histologic scores, which were then clustered into three subclasses (A, B, and C), which were then assessed for unique clinical and molecular characteristics.
Results: Models achieved holdout AUROCs of 0.93 (S1), 0.92 (S2), and 0.94 (S3). In TCGA, subclasses predicted overall survival (A vs B, $p<0.0001$; A vs C, $p<0.0001$), disease-free interval (A vs B, $p<0.001$; A vs C, $p<0.0001$), and progression-free interval (A vs B, $p<0.01$; A vs C, $p<0.0001$). Histologic subtypes were independently prognostic when considered alongside clinical variables via stepwise Cox proportional hazards (A vs B, $p=0.008$; A vs C, $p=0.001$). Each cluster associated with distinct clinical features (e.g. cluster A with early pathologic stage and HBV etiology, and cluster B with late stage), mutations, and enriched pathways (cluster A with metabolic pathways, cluster B with cell cycle pathways, and cluster C with immune pathways). Cluster C was also enriched for a signature of anti-PD-1 response in HCC ($p<1x10-10$). In the validation cohort, overall survival trends were maintained (A vs B, $p=0.121$, A vs C, $p=0.005$).
Conclusions: Using a deep learning model which predicts spatial subtype signatures from H&E whole slide images, we developed a histology-based stratification with improved prognostic power compared to existing HCC subtypes. The associated clinical and molecular features suggest that these subtypes exhibit not only distinct phenotypes (metabolic, proliferative, and immune) but also potentially pathogenesis, supporting the potential of H&E to guide patient stratification in clinical trials and inform personalized therapeutic strategies.

#1061 Tumor-informed circulating tumor DNA identifies high-grade serous ovarian cancer patients at highest risk for recurrence despite optimal first-line treatment with primary macroscopic complete resection.

Magdalena Postl[1], Christina Victoria Tauber[2], Valentina Glueck[3], Mira Maria Gliga[2], Nuria Segui[4], Karen Howarth[4], Miguel Alcaide[4], Lucia Oton[4], Gerda Hofstetter[5], Isabelle Maurer[2], Alexander Burges[2], Sven Mahner[2], Mirjana Kessler[2], Melina Danisch[1], Stephan Polterauer[1], Nicole Concin[1], Christoph Grimm[1], Fabian Trillsch[2]

[1]Department of Obstetrics and Gynecology, Gynecologic Cancer Unit, Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria,[2]Department of Obstetrics and Gynecology and Comprehensive Cancer Center Munich, LMU University Hospital, LMU Munich, Munich, Germany,[3]Department of Obstetrics and Gynecology, Klinikum Starnberg, Starnberg, Germany,[4]SAGA Dx, Morrisville, NC,[5]Department of Pathology, Medical University of Vienna, Vienna, Austria

Background: Complete macroscopic tumor resection estimation as visualized by the surgeon is the foremost prognostic factor in high-grade serous ovarian cancer (HGSOC). Objective measures of postoperative molecular residual disease (MRD) are lacking, including serologic and radiologic evaluation. Tumor-informed circulating tumor DNA (ctDNA) has shown promise as a new approach to identify patients at higher risk for relapse.
Methods: This prospective bicentric study included advanced HGSOC patients (pts) undergoing primary debulking surgery (PDS), six cycles of chemotherapy and maintenance therapy (07/2021 - 09/2024). Whole-genome sequencing of tumor tissue identified structural variants, used to design personalized multiplex dPCR assays to detect MRD. Plasma samples were collected: perioperatively (preop, postop day[d]2 and d10), during chemotherapy (C1, C3, C6) and every 3 months (mo) until progression or 24 mo of follow up (FU). CA-125 was analyzed accordingly (cutoff 35 kU/L). Statistics included chi-square and log-rank tests, multivariate Cox model and Kaplan-Meier estimates for progression-free survival (PFS).
Results: 33/84 pts (39%) experienced relapse with a median PFS of 12.0 mo during a median FU time of 15.4 mo. ctDNA was detected in 77/82 pts (94%) at baseline and in 63/74 pts (85%) postoperatively. At postop d10, pts with complete tumor resection had significantly lower ctDNA levels than pts with postop residual disease (p=0.0018). Median ctDNA level decreased by 94% between preop and postop d10 in pts with complete tumor resection (p=0.0247), but not in pts with postop tumor residuals (p=0.891). Within the pt subgroup with complete tumor resection, ctDNA clearance at C1 (20%) and C6 (70%) was associated with significantly lower recurrence risk compared to persistent ctDNA levels (C1: 80%, C6: 30%) with a stronger association at C6 (C1: HR=3.39, p=0.0470, C6: HR= 52.21, p<0.0001). Median time to recurrence in the C6 ctDNA positive group was 10.7 mo compared to 21.3 mo in the ctDNA negative group. This effect was not observed at postop d10 (p=0.273) or for pts with residual tumor. ctDNA outperformed CA-125 for prognosis, as CA-125 levels at C1 or C6 failed to predict recurrence (C1: p=0.189; C6: p=0.165). In a multivariate analysis, ctDNA persistence at C6 (HR=14.58, p<0.0001) and postoperative residual tumor were confirmed as independent prognostic markers.
Conclusion: Tumor-informed ctDNA analysis can further accurately stratify HGSOC pts at high risk of recurrence despite primary surgery with complete macroscopic resection. ctDNA assessment at C6 may provide an opportunity window for risk-stratified treatment adjustments directly after chemotherapy, enabling new personalized maintenance strategies.

#1062 Longitudinal monitoring of circulating tumor cells (CTC) reveals dynamic CTC behaviors associated with disease progression and survival in ALK-positive NSCLC.

Yuru Chen[1], Shamileh Fouladdel[1], Leah Kidder[1], Yuehang Tang[1], Harrison Ball[1], Habib Serhan[1], Zhaoping Qin[1], Albert Liu[1], Xu Cheng[1], Liwei Bao[1], Varun Kathawate[1], Larua Goo[1], Mary Horn[1], Stacy Fry[1], Aaron N. Hata[2], Justin Gainor[3], Jessica J. Lin[4], Stuart Hinton[5], Chao H. Huang[6], Nathan Merrill[1], Aaron M. Udager[1], Peter J. Ulintz[1], Angel Qin[1], Sofia Merajver[1], Sunitha Nagrath[1]

[1]University of Michigan, Ann Arbor, MI,[2]Massachusetts General Hospital, Charlestown, MA,[3]Harvard Medical School, Boston, MA,[4]Mass General Brigham Cancer Institute, Boston, MA,[5]Hematology Oncology, University of Kansas Hospital Authority, Kansas City, KS,[6]Internal Medicine / Division Hem & Oncology, University of Kansas Medical Center, Westwood, KS

Introduction: Heterogeneous mutation profiles are common in anaplastic lymphoma kinase-positive non-small cell lung cancer (ALK+ NSCLC), especially upon progression, supporting that robust longitudinal monitoring to detect these changes early can play a role in disease management. Circulating tumor cells (CTCs) provide a minimally invasive modality for real-time monitoring. We longitudinally analyze CTC counts and sc-transcriptomes to assess their reflection of clinical responses and correlation with progression risk in ALK+ patients.

Methods: Following informed consent, we collected 61 samples from 12 ALK patients (2-10 timepoints/patient; 11 Stage IV, 1 Stage III). Serial peripheral blood samples were processed using the in house developed microfluidic Labyrinth device for CTC enrichment. CTC subgroups were identified by immunofluorescence staining for Cytokeratin (CK), EpCAM, and Vimentin. At each sampling point, clinical response was assessed by a treating physician. Sc-RNA sequencing was performed on enriched CTCs, characterizing differentially expressed gene (DEG), survival, trajectory states, immune interactions, and inferred CNV profiles.

Results: Patients receiving a single TKI treatment (Alectinib) with clinically stable disease showed decreasing CTC burden. Patients with prior exposure to multiple TKIs and progressive disease showed fluctuating dynamics. Kaplan-Meier analysis showed a decrease in total CTCs (77%, p=0.016) and a decrease in CK+ CTCs (6.05%, p=0.049) significantly correlated with lower progression risk. scRNA-seq on three Stage IV patient's CTC collected at multiple time points revealed dynamic immune populations changed between the visits. DEGs in CTC compared to the rest of immune cells in all 3 visits displayed EMT-associated upregulation (TUBB1, PPBP, ITGA2B); and downregulation of GATA2, consistent with its reported reduction in lung cancer. A composite of 45 consistently downregulated genes was correlated with reduced survival, using a TCGA cohort (n=500; p=0.039). Notably, downregulated genes obtained after the patient started progressing showed increasingly more significant associations with poor survival (p=0.21, p=0.019, p=0.0067). Trajectory analysis identified two CTC clusters, with later visits mapping to higher pseudotime states. CNV analysis revealed a CDK4 copy-gain specifically at progression. Intercellular communication analysis showed decreased CTC-B-cell and increased CTC-monocyte interactions at progression, which may suggest reduced anti-tumor surveillance and enhanced myeloid support.

Conclusion: Longitudinal monitoring integrating CTC burden and scRNA analysis provides insights into tumor evolution and immune interactions in ALK+ NSCLC, potentially signaling imminent progression and may help guide personalized treatment strategies.

#1063 Serum neuron-specific enolase (NSE) as a biomarker of central nervous system (CNS) metastases: Updated results from the BrainStorm program (Oncodistinct 006).

Background: Serum NSE, a marker of neuronal injury, may serve as a non-invasive indicator of early CNS involvement in solid tumors. Here, we explore the role of NSE for predicting development of CNS metastases.
Methods: The BrainStorm program, is an ongoing international, multicenter prospective initiative, allowing the constitution of a large clinicopathological database and biobank to study CNS metastases. The program is recruiting patients (pts) with newly diagnosed non-CNS metastatic solid tumors at high risk of (Part A) or with CNS metastases (Part B and C). All pts undergo serologic NSE testing at baseline and at regular intervals pre- and post-CNS metastases. Main objective of the present analysis was to assess the role of baseline NSE as a predictive biomarker of CSN development from pts tested in Part A vs B, using Mann-Whitney test for group comparisons and logistic regression models to estimate OR.
Results: 124 pts with available NSE results were included in the program from Nov/2020 to Jun/2025 (Part A, n=73; Part B, n=51) - Table 1. NSE levels were significatively higher in Part B than Part A (median 15.0 (IQR 12.8-24.3) vs 13.6 (IQR 11.4-16.4) ng/mL; p=0.017). In Part A, baseline NSE, as a continuous variable, was significantly associated with CNS metastases development (OR per ng/mL increase 1.12; 95% CI 1.02-1.22). Using the upper limit of normal as a categorical cut-off, baseline NSE showed a trend toward higher odds of CNS metastases (OR 2.84; 95%CI 0.60-13.39; 8 CNS events).
Conclusions: These findings support a potential role for NSE as a non-invasive predictive biomarkers for the development of CNS metastases although confirmation in the fully accrued BrainStorm program is required.

Table 1 - Baseline characteristics

	Part A (N=73)	**Part B** (N=51)
Age in years, median (IQR)	58 (48-66)	62 (56-68)
Female, n (%)	65 (89)	40 (78)
ECOG-PS, n (%)		
0	40 (55)	10 (20)

Other	-	5 (10)
No. metastatic sites, median (IQR)	2 (1-2)	2 (1-3)
Months from non-CNS metastases to NSE, median (IQR)	206 (76-495)	178 (26-972)
Weeks from CNS metastases to NSE, median (IQR)	-	15 (10-26)
Baseline serum NSE in ng/mL, median (IQR)	13.6 (11.4-16.4)	15.0 (12.8-24.3)

#1064 Novel approach of single-cell RNAseq analysis to assess cancer cells in prostate core biopsy specimens.

Dai Takamatsu[1], Kelly K. Chong[1], Gianna Jimenez[2], David Krasne[3], Jennifer A. Linehan[2], Timothy G. Wilson[2], Dave S. B. Hoon[1]

[1]Translational Molecular Medicine, Providence St. John's Cancer Institute, Providence Health System (PHS), Santa Monica, CA,[2]Urology and Urologic Oncology, Providence St. John's Health Center (PSJHC), PHS, Santa Monica, CA,[3]Surgical Pathology, PSJHC, PHS, Santa Monica, CA

Background: The core biopsy of prostate for detection of prostate cancer (PCa) remain heavily reliant on histopathology, varying by both surgeon and pathologist but carries the risk of misdiagnosis. This can result in missed opportunities for timely intervention or unnecessary treatment strategies. Our study leverages single-cell RNA (scRNA) seq analysis to enhance diagnostic accuracy, aiming to identify PCa cells by a novel precision oncology approach at the cellular and molecular level. **Methods**: We investigated 23 biopsy cases from patients with potential PCa. Core fine needle biopsies were performed on patients undergoing MRI-fusion image-guided prostate biopsy prior to decision to perform robotic-assisted radical prostatectomy if biopsy is diagnosed PCa positive. We used the pico-well-based HIVE™ (HoneyComb Biotech, MA) to isolate barcoded sc from the cell suspension of prostate tissue biopsy. This method allows specific physical single-cell analysis followed by in-depth scRNAseq. Each sample underwent traditional pathology diagnosis at post biopsy and prostatectomy. Initially, cell type markers were used to classify each clusters cell type from the scRNA seq data. For known PCa gene markers, we assessed KLK3, FOLH1, PCA3, KRT34, AMACR, and TP63. To improve the accuracy of the subset identified as PCa cells, Single Cell Variational Aneuploidy analysis (SCEVAN) classification was used to categorize subsets of cells based on calculated aneuploidy level. This algorithm accurately performs a variational deconvolution to unravel the clonal substructure of tumors using the scRNAseq data. It employs a multichannel segmentation approach based on the premise that cells within a particular copy number clone have similar breakpoints. **Results**: Our study included 23 patients categorized into 5 benign cases versus specific PCa Gleason grades: 4 GG1, 5 GG2, 3 GG3, 3 GG4, and 3 GG5 based on standard histopathology. The subsets of tumors classified using 2 approaches; deconvolution with cell mRNA markers and deconvolution of marker expression profiles with SCEVAN classification, were consistent. These tumor subsets analysis by the 2 analytic approaches identified PCa cells. Notably, in cases initially diagnosed as benign, scRNAseq data showed variability; some cases were benign with no detectable PCa cells, while others displayed PCa cells through SCEVAN classification, highlighting the potential of the approach uncovering hidden molecular malignant profiles. **Conclusion**: Our study demonstrates the efficiency of scRNAseq data in detecting PCa cells, which can improve and further validate conventional histopathology diagnosis. This novel approach allows one to uncover occult PCa cells by molecular profiling, enhancing diagnostic status prior to therapy, and potentially triaging patients for surgery, radiation, or observation.

#1065 Mitosis in circulating tumor cells correlates with highly aggressive disease in metastatic breast cancer.

Alexis B. Duffy[1], Massimo Cristofanilli[2], Carolina Reduzzi[2], WIliam V. Williams[3], Giuseppe Del Priore[3], Saranya Chumsri[4], Cha-Mei Tang[5], Toshiaki Iwase[6], Naoto Ueno[6], Daniel L. Adams[1]

[1]Creatv MicroTech, Inc., Monmouth Junction, NJ,[2]Weill Cornell Medicine, New York, NY,[3]Briacell Therapeutics Corp., Philadelphia, PA,[4]Mayo Cancer Clinic, Jacksonville, FL,[5]Creatv MicroTech, Inc., Rockville, MD,[6]University of Hawai'i Cancer Center, Honolulu, HI

Background: Circulating tumor cells (CTCs) are a well-known non-invasive blood biomarker which can stratify metastatic breast cancer (mBC) patients, especially those with highly aggressive subtypes. Initial pilot studies have characterized a distinct subtype of CTCs undergoing mitosis, whose presence correlates with worse survival outcomes than CTCs alone. However, their prognostic value and their influence in different therapeutic regimes remains unknown. In a multi-institutional prospective study, we isolated CTCs from n=138 mBC patients to categorize mitotic CTCs, evaluate their association with progression-free survival (PFS) & overall survival (OS) over 2 years, and how their response rates effect different therapeutic strategies.

Methods: Peripheral blood samples (7.5ml) were collected from n=138 mBC patients progressing on systemic therapies but prior to new systemic therapies (i.e. chemotherapy n=48, hormone therapy n=17, immunotherapy n=64, targeted therapy n=22). CellSieve microfilters isolated CTCs via size exclusion and cells fluorescently stained for CD45, Cytokeratin, and DAPI. CTCs were imaged, enumerated, and subtyped based on the presence of ≥1 mitotic CTC, using previously established visual indicators. PFS and OS were assessed over 2 years by censored univariate and multivariate analyses. Therapy efficacy was assessed by comparing median PFS (mPFS) and median OS (mOS) in the therapy categories.

Results:

CTC Type	Treatment	mPFS (months)	mOS (months)
No CTCs (n=77/138)	All Pts (n=77)	5.0	16.6
	Chemotherapy (n=23)	4.0	9.2
	Hormone Therapy (n=9)	>24.0	>24.0
	Immunotherapy (n=39)	4.3	13.1
	Targeted Therapy (n=11)	13.1	>24.0
Non-mitotic CTCs (n=30/138)	All Pts (n=30)	4.0	14.2
	Chemotherapy (n=9)	3.1	13.0
	Hormone Therapy (n=4)	6.7	>24.0
	Immunotherapy (n=14)	3.3	7.4
	Targeted Therapy (n=5)	14.1	20.0
Mitotic CTCs (n=31/138)	All Pts (n=31)	2.4	4.1
	Chemotherapy (n=12)	2.4	4.3
	Hormone Therapy (n=4)	1.3	7.1
	Immunotherapy (n=11)	2.0	4.7
	Targeted Therapy (n=6)	3.5	18.6

Conclusion: In this study, patients with CTCs had poorer outcomes than patients with no CTCs, while patients with mitotic CTCs had the worst outcomes. Further, patients with no CTCs or non-mitotic CTCs showed similar PFS & OS in some treatment types, while patients with no CTCs treated with hormone therapy had better PFS and patients with mitotic CTCs had better OS if treated with targeted therapy. This study highlights the need for larger more comprehensive studies to expand on these prognostic findings and correlations to therapy types.

#1066 Early detection of prostate carcinoma using trajectories of circulating epithelial tumor cell (CETCs/CTCs) numbers.

Dorothea Schott[1], Monika Pizon[2], Joachim Fluhrer[1], Ulrich Pachmann[1], Katharina Pachmann[3], Peter Eng[4]

[1]Laboratory Dr. Pachmann, Bayreuth, Germany,[2]Simfo GmbH, Bayreuth, Germany,[3]Pachmann (Individual), Bayreuth, Germany,[4]Eng Medical Centre, Melbourne, Australia

Background: Prostate cancer is a leading cause of mortality in elderly men, underscoring the need for early and effective detection strategies. PSA-based screening remains controversial due to uncertain benefits in reducing mortality and associated risks, such as invasiveness, comorbidities, and overdiagnosis. Overdiagnosis can lead to unnecessary treatments and complications for indolent disease. In clinical practice, patients often retain limited information after consultations, and inconsistent risk communication by physicians can hinder informed shared decision-making. Therefore, a minimally invasive screening approach using serial circulating epithelial tumor cells (CETCs/CTCs) in patients at increased risk of prostate cancer may enhance informed decision-making.
Methods: CETCs/CTCs were quantified in peripheral blood from men aged 50-85 years in a screening cohort (n=35) and in patients undergoing PSMA-PET for suspected prostate cancer (n=49). PSA levels were measured at the time of PSMA-PET, and serial CETC/CTC counts were correlated with PSMA-PET findings.
Results: Serum PSA levels did not differ significantly between patients with positive (n=27) and negative (n=24) PSMA-PET scans ($p=0.94$). However, CETC/CTC counts were significantly higher in PSMA-PET-positive patients compared to those in the screening cohort ($p<0.001$). ROC analysis identified an optimal threshold of 450 CETCs/CTCs per mL blood, with a specificity of 0.7 and a sensitivity of 0.6. Serial monitoring revealed distinct trajectories: increasing CETC/CTC counts were observed in 11 of 13 (90%) patients who later developed PSMA-PET-positive findings, while only 2 of 21 (8%) patients with decreasing CETC/CTC counts were PSMA-PET positive. Kaplan-Meier analysis demonstrated a highly significant difference in PSMA-PET-free survival between the two groups ($p<0.001$; hazard ratio 9.48).
Conclusions: Serial monitoring of CETCs/CTCs provides dynamic, non-invasive insights into prostate cancer activity. Rising CETC/CTC counts were strongly associated with PSMA-PET positivity, suggesting their potential as early biomarkers for prostate cancer progression and treatment monitoring.

#1067 Whole genome sequencing of multiple myeloma genomes with a novel clinical assay enables identification of genetic alterations underlying immunotherapy resistance.

Bruno Paiva[1], Peter Voorhees[2], Patricia T. Greipp[3], Danielle Sookiasian[4], Julian Hess[4], Marisa DeMeo[4], Vicki Pounder[4], Sarah Calkins[4], Reid Meyer[3], Linda B. Baughn[3], Christine-Ivy Liacos[5], Meletios-Athanasios Dimopoulos[5], Alexandra Papadimou[5], Taouxi Konstantina[5], Efstathios Kastritis[5], Jesus Berdeja[6], Daniel Auclair[4], Valentina Nardi[4], Thomas Mullen[4], Francois Aguet[4], Shaji Kunnathu Kumar[3]

[1]Univ. de Navarra, Pamplona, Spain,[2]Levine Cancer Institute, Atrium Health Wake Forest University School of Medicine, Charlotte, NC,[3]Mayo Clinic, Rochester, MN,[4]Predicta Biosciences, Cambridge, MA,[5]National and Kapodistrian University of Athens School of Medicine, Athens, Greece,[6]Greco-Hainsworth Centers for Research at Tennessee Oncology, Nashville, TN

The detection of genetic abnormalities is required during diagnostic workup and for potential individualization of therapy selection in multiple myeloma (MM) and its precursor conditions. At present, this relies on invasive bone marrow (BM) biopsies, severely limiting early detection, frequent longitudinal monitoring, and the precise selection of therapy. The current standard for detecting genetic alterations in MM is fluorescence in situ hybridization (FISH), which cannot detect point mutations and other clinically relevant alterations. Consequently, the IMS-IMWG guidelines were recently updated to require next-generation sequencing for the classification of high-risk MM. To address these needs, we recently launched GenoPredicta, a CLIA-approved LDT that enables routine monitoring, informing diagnosis, and treatment selection by comprehensively characterizing MM genomes with whole genome sequencing (WGS) from as few as 50 circulating tumor cells (CTCs) isolated from peripheral blood (PB) or tumor cells from BM. Briefly, tumor cells are isolated from samples using fluorescence-activated cell sorting and subjected to WGS, from which copy number alterations, structural variants, and short variants (SNVs/indels) are identified using a fully automated pipeline generating physician-ready clinical reports from raw sequencing data in ~6h. Analytical validation of GenoPredicta showed complete concordance with FISH results.
Identifying alterations in therapeutic targets (e.g., BCMA, GPRC5D) for guiding MM immunotherapies is becoming increasingly important. Here, we describe GenoPredicta results from relapsed/refractory MM patients, highlighting resistance-conferring alterations that can only be detected by WGS, such as deletions in the kilo- to megabase scales that are observed in conjunction with SNVs and indels, leading to biallelic loss/inactivation of the gene, including at subclonal levels. In addition to biallelic loss of BCMA and GPRC5D in response to CAR T or T cell engager therapies, we observed similar resistance mechanisms for targets of immunomodulatory drugs, e.g., CRBN. The observation of these resistance mechanisms was consistent with patients' clinical histories.
In summary, we demonstrate that low input WGS-based characterization of MM from BM or CTCs is a viable replacement for FISH for clinical diagnosis and monitoring, with CTC-based measurements enabling comprehensive profiling of the MM genome. Crucially, this includes genetic alterations that confer resistance to therapy, allowing for both early detection of such alterations and more precise selection and guidance of therapy. The dramatically improved variant calling ability from WGS, especially in low-input CTC applications, extends to other malignancies and will gain wider adoption as sequencing costs continue to decrease.

#1068 Combining circulating tumor cells and cancer associated macrophage-like cells enhances risk stratification models in pan-cancer metastatic disease.

Daniel L. Adams[1], Steven H. Lin[2], Massimo Cristofanilli[3], Carolina Reduzzi[4], Saranya Chumsri[5], Martin J. Edelman[6], Susan Tsai[7], Raymond C. Bergan[8], Mohammed Aldakkak[9], Thai H. Ho[10], Cha-Mei Tang[11]

[1]R&D, Creatv Microtech, Inc, Monmouth Junction, NJ,[2]Asst. Professor, Dept. of Radiation Onc., UT MD Anderson Cancer Center, Houston, TX,[3]Weill Cornell University, New York, NY,[4]Weill Cornell Medicine, New York, NY,[5]Mayo Clinic Florida, Jacksonville, FL,[6]Fox Chase Cancer Center, Philadelphia, PA,[7]Ohio State University, Columbus, OH,[8]Stony Brook University, Stony Brook, NY,[9]The Medical College of Wisconsin, Milwaukee, WI,[10]Medical University of South Carolina, Charleston, SC,[11]Creatv MicroTech, Inc., Rockville, MD

Background: In metastatic cancer, Circulating Tumor cells (CTCs) are established prognostic indictors of patients (pts) less likely to respond to new lines of systemic therapy, with poor clinical outcomes, such as shorter progression free survival (PFS) and overall survival (OS). However, CTCs are typically found in specific malignancies (breast, prostate & colon), often in <20% of pts with metastatic disease, and pts without CTCs may also rapidly progress. Recently, an inflammatory pro-tumorigenic macrophage emanating from tumor stroma (i.e. Cancer associated macrophage-like cell [CAML]) was found in >90% of metastatic cancer pts, and whose phagocytic engorgement appears to correlate with poor outcomes, independent of CTCs. As CTCs and CAMLs are isolated in conjunction from a single blood sample, and both are prognostic for outcomes, we evaluated their utilization prior to induction of new systemic therapy in 6 types of metastatic cancer to model pt risk stratification based on 2 year outcomes.
Methods: A prospective 2 year blind multi-institutional study was undertaken to model CTCs and CAMLs in prognosticating outcomes prior to induction of a new line of systemic therapy (n=233) in metastatic: Breast (n=60), Prostate (n=40), Pancreas (n=25), Colon (n=28), Renal Cell Carcinoma (RCC) (n=39), and Lung (n=40). Blood was filtered by CellSieve^{TM} filters with subtypes of CTCs & hyper-enlarged CAMLs (≥100µm) enumerated. A machine learning algorithm was trained on this initial data set to develop predictive models which could stratify pt populations by risk for likelihood of PFS & OS over 2 years, including known clinical variables.
Results: CTCs were absent in 80% (n=185/233) of pts, and their absence was prognostic for better PFS (HR=1.6, p=0.046), but not OS (HR=1.3, p=0.2045). In parallel, enlarged CAMLs (≥100µm) were found in 28% (n=51/185) of pts without CTCs, and were also prognostic for worse PFS (HR=2.0, p=0.0082) and OS (HR=1.9, p=0.0412). Specifically, CTCs were found in 55% (n=33) breast, 20% (n=8) prostate, 12% (n=3) pancreas, 11% (n=3) colon, 0% (n=0) RCC, and 0% (n=0) lung pts. Enlarged CAMLs were found in 45% (n=27) breast, 20% (n=8) prostate, 44% (n=11) pancreas, 44% (n=17) colon, 18% (n=7) RCC and 20% (n=8) lung pts. Overall, models indicated that ≥1 CTC (n=47) had mPFS=3.9 & mOS=14.9, while pts with 0 CTCs and ≥100µm CAMLs (n=51) had a mPFS=6.9 & mOS=13.8, and pts with 0 CTCs and <100µm CAMLs (n=134) had a mPFS=10.7 & mOS>24 months.
Conclusions: These initial models confirm that both CTCs and enlarged CAMLs are prognostic indicators of worse PFS & OS. The simultaneous quantification both CTCs and CAMLs allows for more accurate pan-cancer risk stratification in an array of cancer pt populations. Additional clinical variables incorporated into the models may allow better risk subtyping and possibly forecast optimal treatment regimens.

#1069 Clinical significance of viable circulating tumor cells (v-CTCs) and PD-L1 expression in pancreatic cancer patients using a novel oncolytic virus system.

Masahiro Tanemura[1], Hisataka Ogawa[1], Yoshiaki Ohmura[1], Tadafumi Asaoka[2], Yasuo Urata[3], Daisaku Yamada[4], Hirofumi Akita[4], Hidetoshi Eguchi[4]

[1]Department of Surgery, Rinku General Medical Center, Izumisano, Japan,[2]Department of Surgery, Osaka Police Hospital, Osaka, Japan,[3]Oncolys BioPharma Inc., Tokyo, Japan,[4]Department of Gastroenterological Surgery, University of Osaka Graduate School of Medicine, Osaka, Japan

Background: Detecting circulating tumor cells (CTCs) as a peripheral blood liquid biopsy is a promising approach. We previously succeeded in visualizing viable-CTCs (v-CTCs) with high biological activity from the peripheral blood of resectable and borderline resectable pancreatic cancer (PC) patients using a novel telomerase-specific oncolytic virus (TelomeScan F35). This study aimed to analyze the clinical significance of v-CTC detection and the expression of PD-L1 on v-CTCs in PC patients to explore potential therapeutic selection strategies.
Methods: Thirty-nine PC patients were analyzed. CTCs were analyzed at pre-/post-operative time points in the Upfront Surgery (S) group, and at pre-NACRT, post-NACRT, and post-operative time points in the Neoadjuvant Chemoradiotherapy (NACRT) group (RT + GEM + S-1). PD-L1 expression was also assessed in v-CTCs, primary tumors and metastatic lymphnodes.
Results: [S Group] (n=24; M/F=12/12; median age 73). All patients underwent curative resection. Six patients were consistently v-CTC negative (pre- and post-op); five of these patients remained disease-free, with only one case of peritoneal recurrence. In contrast, 18 patients were v-CTC positive at either or both time points; 13 of these developed early distant metastatic recurrence post-surgery. [NACRT Group] (n=15; M/F=4/11; median age 67). All patients underwent curative resection. Five patients were consistently v-CTC negative at all three time points and all remain disease-free. In six patients who were v-CTC positive pre-NACRT, the v-CTC count significantly increased post-NACRT in five cases, and three of them developed early liver metastasis, suggesting that RT might induce v-CTC intravasation/dissemination. [PD-L1 Expression] PD-L1 analysis was performed on 18 patients in the S group and 3 in the NACRT group. In primary tumors of the S group, PD-L1 expression was observed in 0%/10%/20%/40% of tumor cells in 6/6/4/2 cases, respectively. The expression rate on v-CTCs was 97% pre-operation and 81% post-operation. Among 12 patients with lymph node metastasis, PD-L1 expression was positive in only 4 cases (33%). In the NACRT group, primary tumors were all PD-L1 negative. The expression rate on v-CTCs was 50% pre-NACRT, 96% post-NACRT, and 50% post-operation. Two cases showed lymph node metastasis, both PD-L1 negative.
Conclusion: The presence of v-CTC dissemination suggests a risk of metastasis development following NACRT, advocating for upfront surgery or neoadjuvant chemotherapy (NAC) without RT in v-CTC positive patients. Given the high rate of PD-L1 expression on v-CTCs, immune checkpoint inhibitors are expected to be effective for targeting v-CTCs and controlling distant metastasis. Detection of v-CTC dissemination may be utilized for therapeutic selection in PC patients.

#1070 Molecular profiling of diffuse gliomas via liquid biopsy: Insights from circulating tumor cells and ctDNA analysis.

Josef Srovnal[1], Pavel Stejskal[1], Ondrej Kalita[2], Marek Slachta[2], Lumir Hrabalek[2], Alona Rehulkova[1], Monika Vidlarova[1], Marian Hajduch[1]

[1]Institute of Molecular and Translational Medicine, Palacky Univ. Faculty of Medicine, Olomouc, Czech Republic,[2]Department of Neurosurgery, University Hospital Olomouc, Olomouc, Czech Republic

Introduction: Diffuse gliomas are the aggressive primary brain tumor, characterized by poor prognosis and pronounced molecular heterogeneity. Although systemic spread is uncommon due to the blood-brain barrier, tumor cells and nucleic acids can still reach the peripheral circulation. Liquid biopsy, including circulating tumor cells (CTCs) and circulating tumor DNA (ctDNA), provides a minimally invasive approach for tumor characterization and monitoring in diffuse gliomas.
Methods: After validating our CTC detection workflow using spiking experiments with the U87-MG cell line, we analyzed peripheral blood samples from patients undergoing curative resection for diffuse gliomas. Samples were collected prior to surgery in Cell-Free DNA BCT® tubes (Streck, Inc.). CTCs were identified using the CytoTrack CT11™ (2/C) semi-automated immunofluorescence microscopy platform, with immunostaining for GFAP, vimentin, and CD45, and DAPI nuclear counterstaining. For ctDNA analysis, cfDNA was isolated from 2 ml of plasma using the QIAamp Circulating Nucleic Acid Kit (Qiagen), and the IDH1 R132H mutation was assessed by digital droplet PCR (Bio-Rad Laboratories, Inc.).
Results: CTCs were detected in 29.1% of 110 blood samples collected from patients at the time of their first surgery. Among 19 samples from relapsing patients, CTC positivity increased to 54.5%. Kaplan-Meier survival analysis in a cohort of 67 patients with IDH wildtype glioblastoma and at least two years of follow-up revealed no significant association between CTC status and overall survival.Analysis of cfDNA identified IDH1 R132H mutations in 14% of patients with diffuse gliomas, including cases with both tumor-informed positive and negative status.
Conclusion: Our results demonstrate that both CTCs and ctDNA can be reliably detected in patients with diffuse gliomas, underscoring the potential of liquid biopsy to complement traditional tissue-based diagnostics. Detection of IDH1 R132H mutations in plasma— even in tumor-informed negative cases—may indicate intratumoral heterogeneity, compartmentalized tumor biology, or sampling limitations. The lack of survival association may reflect the overall short life expectancy in GBM and/or restricted tumor proliferation outside the CNS. Patient recruitment and data collection remain ongoing. Acknowledgment: This study was supported by European Union - Next Generation EU (LX22NPO5102), Palacky University Olomouc (IGA LF 2025_006), and SALVAGE - CZ.02.01.01/00/22_008/0004644.

#1071 Delta-like ligand 3 (DLL3)-based enrichment enables sensitive and specific detection of circulating tumor cells during immunotherapy in small-cell lung cancer.

Hyung-Joo Oh[1], Hyun-Ju Cho[1], Seung-Hee Song[1], Yoo-Duk Choi[2], Woo-Jae Son[3], Jin-Han Bae[3], In-Jae Oh[1], Young-Chul Kim[1], Hae Ung Lee[3], Cheol-Kyu Park[1]

[1]Internal Medicine, Chonnam National University Medical School and Hwasun Hospital, Hwasun, Jeollanam-do, Korea, Republic of,[2]Pathology, Chonnam National University Medical School, Gwangju, Korea, Republic of,[3]CTCELLS, Inc., Seoul, Korea, Republic of

Background: Delta-like Ligand 3 (DLL3), a Notch receptor ligand, is highly expressed in small cell lung cancer (SCLC) and has emerged as a promising therapeutic target. Circulating tumor cells (CTCs), abundant in SCLC, interact with diverse immune cell populations in peripheral blood. This study investigates the potential of DLL3 as a biomarker to enhance CTC detection and monitor immunotherapy response in SCLC.

Methods: We enrolled 17 patients with extensive-stage (ES) SCLC and 5 with stage IV non-small cell lung cancer (NSCLC; as controls), all scheduled for an immune checkpoint inhibitor or a bispecific T-cell engager. Whole blood (6 mL) was collected before and during treatment. CTCs were enriched using CTCeptor^{TM}, a fully automated, negative depletion-based continuous centrifugal microfluidic system, and classified into three phenotypes: pan-cytokeratin (CK)$^+$/DLL3$^-$/CD45$^-$, CK$^-$/DLL3$^+$/CD45$^-$, or CK$^+$/DLL3$^+$/CD45$^-$. Baseline tumor samples were analyzed by immunohistochemistry for SCLC molecular subtypes and DLL3.

Results: DLL3$^+$/CD45$^-$ CTCs were detected in all ES-SCLC patients (100%) prior to treatment with atezolizumab plus chemotherapy or tarlatamab, with a median count of 23 (range 7-121) and a median size of 9.71 μm (7.33-12.18). In contrast, no DLL3$^+$/CD45$^-$ CTCs were detected in NSCLC patients, where only CK$^+$/DLL3$^-$/CD45$^-$ CTCs were observed (1-4 cells). Among ES-SCLC patients, CK$^-$/DLL3$^+$/CD45$^-$ cells were the predominant subtype (63.3%, 522/825), while CK$^+$/DLL3$^+$/CD45$^-$ CTCs accounted for 27.7% (228/825) of all detected CTCs, representing additional CTCs not captured by CK-based detection alone. ASCL1 was the most prevalent molecular subtype (12/17), with DLL3 exhibiting the highest H-score (median, 185; range, 20-300). Notably, no correlation was observed between the number or proportion of DLL3$^+$CTC and the DLL3 H-score (r = -0.163, p = 0.578), while DLL3$^+$CTCs remained prevalent in NERUDO1 and POU2F3 subtypes. Furthermore, both total and DLL3$^+$CTC counts markedly decreased within 2 cycles of atezolizumab chemotherapy or 1 week after tarlatamab treatment.

Conclusion: DLL3$^+$CTCs can be efficiently and specifically detected in ES-SCLC patients using CTCeptor^{TM}, serving as a complementary marker to CK for CTC identification. DLL3 appears more frequently in CTCs than in tumor tissue. These findings support DLL3 as a potential biomarker for CTC-based monitoring in ES-SCLC and warrant further validation in larger cohorts, including analyses of immunologic features.

#1072 Parallel microfluidic platform enables efficient label-free capture of p16+ circulating tumor cells in oropharyngeal cancer.

Chameera E. Weeramange[1], Jian Zhou[2], Sreedevi Damodaran[1], Chiara F. Ghera[3], Lizbeth Kenny[4], Brett Hughes[4], Sarju Vasani[5], Omar Breik[6], Rahul Ladwa[7], **Ian Papautsky**[3], Chamindie Punyadeera[1]

Circulating tumor cells (CTCs) are clinically significant biomarkers for cancer detection and monitoring due to their role in metastasis. However, their extreme rarity in peripheral blood and phenotypic heterogeneity, particularly following epithelial-to-mesenchymal transition (EMT), pose challenges for reliable isolation. Conventional epitope-dependent capture methods often fail to detect mesenchymal-like CTCs. Label-free microfluidic platforms offer a promising alternative by exploiting biophysical properties such as size and deformability. Building on our prior work, we developed a high-throughput multi-flow microfluidic (MFM) device to isolate diverse CTCs from clinically relevant blood volumes, with a focus on oropharyngeal cancer (OPC), where CTCs exhibit favorable size characteristics for inertial separation. A parallel microfluidic device comprising six inertial separation channels was fabricated using dry film photolithography and PDMS molding. Two versions were constructed: Chip A (20 mm in length) and Chip B (25 mm in length), both with a 150 µm x 50 µm cross-section. Device performance was evaluated using fluorescent microparticles (10.3, 15.5, and 18.7 µm) and head and neck cancer cell lines CAL27, SCC9, and HPV16-positive SCC2. Samples were processed at 600 µL/min with a buffer flow of 1.2 mL/min. Cell recovery and purity were assessed by high-content imaging and immunofluorescence. SCC2 DNA enrichment was quantified by qPCR. Clinical validation involved 20 p16+ oropharyngeal cancer patients. The MFM device achieved a 5-fold increase in throughput compared to the earlier single-channel design, while maintaining high separation efficiency. Chip A (~14 µm cutoff) recovered 90-94% of CAL27 and SCC9 cells with <17% WBC contamination. Chip B (~12 µm cutoff) improved recovery to 92%-97%, but with slightly higher WBC carryover. PCR analysis of HPV16-positive SCC2 cells confirmed >35-fold enrichment of tumor DNA in the CTC fraction. In clinical samples, CTCs were detected in 60% of OPC patients, including epithelial, mesenchymal-like, and dual CK/CSV-positive phenotypes. Notably, dual CK/CSV-positive CTCs, indicative of partial EMT, were observed in 25% of patients. p16 expression was observed in CTCs from 4 of 14 patients, suggesting potential concordance with tumor HPV status. The device preserved cell integrity, enabling downstream molecular analysis. The parallel MFM platform enables robust, label-free isolation of phenotypically diverse CTCs from clinically relevant blood volumes. Its ability to detect EMT-associated phenotypes and HPV16/p16 expression supports its utility in head and neck oncology. Compatibility with molecular workflows such as qPCR and successful clinical validation in OPC patients highlight its translational potential for liquid biopsy applications, including disease monitoring and precision oncology.

#1073 Monitoring androgen receptor and neuroendocrine marker expression dynamics in CTCs in patients with mCRPC.

Nobuaki Matsubara[1], Kentaro Shirai[2], Hiroyuki Obinata[2], Hiromichi Nakajima[1], Chikako Funasaka[1], Chihiro Kondoh[1], Kana Kawasaki[2], Eri Katsumata[2], Taiga Ajiri[2], Maharjan Bishnu[2], Fumie Kato[2], Masatoshi Yanagida[2], Reiko Watanabe[1], Toru Mukohara[1]

Androgen receptor (AR) remains important treatment target for prostate cancer and androgen receptor signaling inhibitor (ARSI), such as abiraterone acetate (AA) or enzalutamide have already been widely used in daily practice. However, approximately 30% of patients show primary refractory and almost all patients eventually resist ARSI within several years. One of the resistant mechanisms is *AR* amplification and/or mutation which is detected by ctDNA after ARSI treatment. Another one is phenotypic transformation from adenocarcinoma to neuroendocrine prostate cancer (NEPC) by treatment pressure with ARSI. This study investigated dynamic changes of AR and neuroendocrine markers expression during abiraterone treatment by longitudinal Circulating Tumor Cells (CTCs) collection. We have developed a method using molecular imaging flow cytometry to detect CTCs and their AR and Synaptophysin (SYP) expression. For CTC enrichment from whole blood, cell size-based approach using microfluidics technology was adapted. Our focus was on AR nuclear localization status of CTCs in patients with metastatic castration resistant prostate cancer (mCRPC). To validate the analytical performance of our method, the AR and SYP expression of detected CTCs was compared with the pathological results of tissue biopsy obtained within 28 days before or after blood sampling. One or more CTCs were detected in 89.4% (17/19) of patients, and 13 of 17 patients had available pathological results. The sensitivity and specificity of CTC detection for the pathological results were 67% and 100% in AR, and 75% and 89% in SYP, respectively. Additionally, SYP showed relatively high positive predictive value of 75% and negative predictive value of 89%. Furthermore, we have studied the change in AR nuclear localization of AR-positive CTCs before and one month after the start of AA treatment. The degree of AR nuclear localization of each CTC was quantified by calculating the similarity between the nucleus staining and AR immunofluorescent image. Our results demonstrated the tendency with lower degree of AR nuclear localization in patients who responded to AA. In the AA-treated cohort, PSA responders showed a decrease in AR nuclear localization in average and non-responders did not (AR nuclear localization positive rate one month after treatment (0% vs 33.0%, p=0.206, Fisher’s exact tests). In contrast, in the control cohort (non-AA-treated group), AR nuclear localization scores remained unchanged or increased in both PSA responders and non-responders (33.0% vs 33.3%, p=1.0). Our observations suggest that CTC SYP may guide indication for tissue re-biopsy to detect NEPC and the AR nuclear localization in CTCs may serve as a pharmacodynamic marker of AA for mCRPC. It represents an important finding for clinical applications such as predicting treatment efficacy, monitoring treatment and selection for anti-prostate cancer drug.

#1074 Pre-treatment circulating tumor cells are a significant predictor of progression in patients with metastatic breast cancer undergoing abemaciclib therapy.

Qiang Zhang[1], Justin Zhang[2], Andrew A. Davis[3], Natalie Heater[4], Diana Jaber[5], Paolo D'Amico[6], Jianhua Jiao[7], Weijun Qin[8], Pan Du[9], Shading Jia[9], Akhil Chawla[10], Janice Lu[11], Lisa Flaum[4], William J. Gradishar[1]

Lurie Cancer Center, Northwestern University - Evanston, Chicago, IL,[2]Department of Surgery, Division of Surgical Oncology, Northwestern University and Whitney High School, Chicago, IL,[3]Washington University School of Medicine in St. Louis, St. Louis, MO,[4]Department of Medicine, Division of Hematology and Oncology, Robert H. Lurie Cancer Center, Northwestern University, Chicago, IL,[5]Department of Medicine, Division of Hematology and Oncology, Northwestern University, Chicago, IL,[6]Northwestern University, Chicago, IL,[7]Fourth Military Medical University, Xi'an, China,[8]Department of Urology, Fourth Military Medical University, Xi'an, China,[9]Predicine Inc, San Francisco, CA,[10]Department of Surgery, Division of Surgical Oncology, Northwestern University, Chicago, IL,[11]Department of Medicine, Division of Hematology and Oncology, Stanford University, Stanford, CA

Background: Abemaciclib, a CDK4/6 inhibitor widely used in the treatment of metastatic breast cancer (MBC), has significantly improved progression-free survival. However, despite these therapeutic benefits, a substantial proportion of patients still experience recurrence. This ongoing clinical challenge highlights the urgent need for reliable biomarkers that can identify high-risk individuals *before* treatment initiation which remains insufficiently explored. Our previous work showed that monitoring circulating tumor cells (CTCs) and ctDNA mutations can serve as a predictive tool for poor prognosis in MBC (ASCO 2025 #1042; AACR 2025 #3613; CCR 2024). Here, we report new findings demonstrating that baseline CTC levels provide important predictive value for identifying recurrence risk in patients receiving abemaciclib.

Methods: A total of 66 $ER^{+}/HER2^{-}$ MBC patients were enrolled, and due to treatment discontinuation and re-initiation among some individuals, 76 courses of abemaciclib therapy were administered at Northwestern Memorial Hospital (2016-2024, IRB: NU16B06). The median follow-up period was 36.3 months. Blood samples (7.5 mL) were collected from patients prior to initiating abemaciclib therapy. CTC enumeration (classified as CK+/DAPI+/CD45–) was performed in FDA-approved CELLTRACKS System. Statistical analyses were conducted using causal inference with ensemble learning approaches.

Results: Of the 76 treatment courses, 28 patients had CTC counts ≥5, while 48 patients had CTC counts <5. All patients were categorized into two cohorts based on progression after abemaciclib treatment. First analysis (cut-off: 6 months): Cohort 1 (early progression <6 months): 29 patients (range: 0.5-5.5 months; median: 2.75 months); Cohort 2 (late progression ≥6 months): 36 patients (range: 6.5-45 months; median: 17.5 months), plus 11 patients with no progression at the end of the study (follow-up: >12 to >70 months). The mean CTC count in Cohort 1 was 9.2, significantly higher than 6.1 in Cohort 2 ($P < 0.01$). Second analysis (cut-off: 12 months): Cohort 1 (early progression <12 months): 41 patients (range: 0.5-11 months; median: 3.75 months). Cohort 2 (late progression ≥12 months): 24 patients, plus the same 11 patients with no progress. The mean CTC count in Cohort 1 was 11.2, significantly higher than 2.8 in Cohort 2 ($P < 0.01$). There was no significant difference in CTC levels between the late-progression group (mean 2.3) and the no-progression group (mean 3.1).

Conclusions: These findings demonstrate, for the first time, that pre-treatment CTC levels serve as a strong predictor of progress following abemaciclib therapy. Early identification of elevated CTCs in patients with MBC may therefore be critical for optimizing CDK4/6 inhibitor treatment strategies and identifying patients who may benefit from alternative therapeutic approaches.

#1075 Comparison of tissue and liquid biopsy CGP in advanced solid tumors: Insights from a community cancer center.

Padmapriya Swaminathan[1], McKenna Perrin[1], Crystal Hattum[1], Stephanie B. Hastings[2], Shakeel Mir[3], Zachary Wallen[2], Lucia Speroni[3], Michelle F. Green[2], Emily Teslow[3], Heidi Ko[2], Rebecca A. Previs[2], Kalpesh Patel[2], Shakti Ramkissoon[2], David Starks[1], Benjamin Solomon[1], William Spanos[1], Tobias Meissner[1], Rachel Elsey[1]

[1]Avera Cancer Institute, Sioux Falls, SD,[2]Labcorp, Durham, NC,[3]Tempus AI, Chicago, IL

Introduction: Next-generation sequencing (NGS) tumor profiling is a mainstay for guiding therapy in oncology. Circulating tumor DNA (ctDNA) testing offers an additional, minimally invasive approach of detecting actionable alterations. We evaluated the concordance between solid tissue and liquid biopsy comprehensive genomic profiling (CGP) results in a largely rural cohort within the Great Plains.
Methods: Participants were enrolled in the Avera Cancer Sequencing and Analytics Protocol (ASAP; NCT05142033). Inclusion required an advanced unresectable or metastatic solid tumor and concurrent tumor and liquid biopsy CGP collected within 90 days. Concordance was calculated based on reported alterations after excluding those not covered by both panels (liquid biopsy panel: Tempus xF+; solid tissue panel: Labcorp OmniSeq INSIGHT®; analyzed alterations: 388 SNV, 7 CNV, 10 Fusions) and variants of unknown significance (VUS).
Results: Eighty-six patients met criteria (mean age +/- SD: 65 +/-10y; 52% female). Seventeen tumor types were represented; lung cancer (26%) and head-and-neck cancer (16%) were most frequent, and 20% had ≥ 2 cancer diagnoses. Patient-level full concordance, defined as identical sets of biologically relevant identified in both tissue and liquid biopsy, was 59%. Variant-level concordance across all alteration types was 31% (CNV [n=23]: 22%, Fusion [n=6]: 50%, SNV [n=365]: 30%). Among unique variants, most SNVs (54%) and CNVs (89%) were detected only in tissue. After filtering 17 genes related to clonal hematopoiesis (CH) from liquid biopsy, variant-level concordance across all alteration types was 35% (CNV [n=23]: 22%, fusion [n=6]: 50%, SNV [n=296]: 38%). OncoKB levels of therapeutic evidence (1-4 and R1-2) were applied to the variants and tumor types in which they were identified. Of the 112 variants with an annotated level of evidence in the data set, 42 were concordant variants, 45 unique to tissue, and 25 to liquid biopsy. MSI status was 100% concordant (2 MSI-high / 84 MSI-stable). High tumor mutational burden (TMB-H) showed 90% concordance (72/80 concordant, 8/80 discordant, 6 non-evaluable). Additional analyses will assess concordance by tumor type, tissue sampled, metastatic sites, treatment, time between liquid and tissue sample collection, and time from diagnosis to sample collection.
Conclusions: Tissue and liquid biopsy CGP each provide complementary, actionable information for therapy selection. Forty percent of patients had unique findings in liquid or tissue-based testing. These results support the value of a comprehensive CGP strategy in advanced solid tumors.

#1076 Cancer-neuron interaction initiates neural mimicry and brain colonization in EGFR-mutant NSCLC.

Sam Song[1], Tomohiro Takehara[2], Yan Yang[1], Monique B. Nilsson[1], Alissa Poteete[2], Sherise Desiree Ferguson[1], Xiuning Le[1], John V. Heymach[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]MD Anderson Cancer Center, Houston, TX

Brain metastasis is a major clinical challenge for patients with non-small cell lung cancer (NSCLC), and NSCLC patients with tumors harboring EGFR mutations have an increased risk of central nervous system (CNS) involvement, with up to 50-60% of patients developing CNS metastasis. The process of metastasizing to the brain is a complex multistep process in which tumor cells must cross the blood-brain barrier and adapt to the unique CNS environment. Recent studies in small cell lung cancer (SCLC) suggested that lung cancer cells residing in the brain acquired neural-like transcriptomic programs as compared to primary tumors in the lung. Given that EGFR mutant NSCLC tumor cells can exhibit lineage plasticity through processes including epithelial to mesenchymal transition (EMT) and SCLC or neuroendocrine transformation as part of acquired therapeutic resistance to EGFR inhibitors, we hypothesized that EGFR mutant NSCLC cells may interact with neuronal cells to facilitate CNS metastasis and lineage change. Here, we used in vitro and in vivo models to evaluate the impact of neuronal interaction on EGFR mutant NSCLC cells. We isolated primary murine neurons and co-cultured them with HCC827, HCC4006, and H1975 EGFR mutant NSCLC cells. After two days, immunofluorescent staining for neuronal markers, NeuN and MAP2, showed that EGFR mutant tumor cells co-cultured with neurons upregulated expression of these neuronal markers whereas tumor cells grown alone did not. Our in vivo models of EGFR mutant NSCLC brain tumors supported the enrichment of neuronal, synaptic, and axonal genes in cancer cells exposed to neuronal interaction. Moreover, we performed spatial transcriptomic analysis of human EGFR mutant NSCLC brain tumors paired with primary lung tumors to evaluate alteration of tumor microenvironment (TME) compartments associated with brain metastasis. Together, we propose neural mimicry as a potential mechanism exploited by EGFR-mutant NSCLC cells growing in the brain microenvironment. Our study further sheds light on novel targets for disrupting cancer-neuron interaction to inhibit the growth of brain metastasis in EGFR mutant NSCLC.

#1077 Discordance in molecular classification of primary and metastatic endometrial cancer: Implications for precision treatment.

Mari Kylleso Halle[1], Janka Babickova[1], Hege Fredriksen Berg[1], Erling Andre Hoivik[2], Rose M. Gold[1], Kadri Madissoo[1], Marta Hjelmeland[1], Hilde Eide Lien[1], Jone Trovik[3], Ingfrid S. Haldorsen[4], Kathrine Woie[5], Gema Moreno-Bueno[6], Rameen Beroukhim[7], Camilla Krakstad[1]

[1]Department of Clinical Science, Centre for Cancer Biomarkers, University of Bergen, Bergen, Norway,[2]Gynecology & Obstretics, Haukeland University Hospital, Bergen, Norway,[3]Department of Obstetrics and Gynecology, Haukeland University Hospital, Bergen, Norway,[4]Department of Radiology, Haukeland University Hospital, Bergen, Norway,[5]Department of Obstetrics and Gynecology, Haukeland Univesity Hospital, Bergen, Norway,[6]Biochemistry Department, Universidad Autonoma de Madrid, Madrid, Spain,[7]Department of Cancer Biology and Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: Endometrial cancer is the most prevalent gynecological cancer in high-income countries, and the incidence rate is increasing. Molecular classification with *POLE* sequencing and immunohistochemistry (IHC) for mismatch-repair (MMR) proteins and p53, refines prognostic accuracy when integrated with existing risk models. This study investigates whether molecular classification derived from primary tumor biopsies (PBs) is retained in matched metastatic biopsies (MBs), as reclassification may influence treatment strategies for advanced and recurrent disease.

Material and methods: We analyzed 155 patients with matched PBs and MBs. *POLE* mutations were identified via Sanger sequencing of exons 9, 11, 13, and 14. IHC was used to assess expression of MSH2, MSH6, PMS2, MLH1, and p53. For 75 patients, whole-exome sequencing (WES) data provided mutational profiles for *POLE* and *TP53* in both PBs and MBs. Molecular classification was assigned using the ProMisE algorithm to separately classify PBs and MBs in four molecular groups.

Results: Molecular classification was discordant between PBs and MBs in 19% of cases. The most frequent discrepancy involved MMR status, with 10% (n = 16) showing MMR proficiency in PBs and deficiency in MBs. For p53, 9% (n = 20) had aberrant expression in PBs but wildtype in MBs. Notably, inter-MB heterogeneity was observed in both IHC-detected p53 expression and WES-derived *TP53* mutations. All *POLE* mutations were conserved across PB-MB pairs. Molecular classification based on MBs was significantly associated with prognosis ($p = 0.01$), whereas classification from PBs was not ($p = 0.31$).

Conclusions: This comprehensive molecular profiling reveals substantial shifts in molecular classification between primary and metastatic lesions, particularly in MMR and p53 status. These changes have prognostic implications and underscore the importance of reassessing molecular features in metastatic biopsies to guide precision treatment strategies for advanced endometrial cancer.

#1078 From protocol to practice: The gap in obtaining progression disease biopsies across 182 oncology trials.

Anjali Vinocha, Kanwal Pratap Singh Raghav, David S. Hong, Christine Parseghian, Joshua P. Hein, Jyotsna Pera, Funda Meric-Bernstam, Scott Kopetz, Alda L. Tam, Michael J. Overman

UT MD Anderson Cancer Center, Houston, TX

Background: Post-progression (PD) biopsies provide critical insights into treatment resistance and tumor evolution. Despite their growing inclusion in clinical trial designs, the extent to which PD biopsies are successfully obtained and the factors that influence said acquisition are unknown.
Methods: Protocols from consecutive oncology clinical trials that integrated at least one research biopsy [at either pre-treatment, on-treatment and/or post-progression timepoint(s)] from 1/2021 to 12/2022 were reviewed and categorized according to tumor type, trial phase, study type, planned biopsy timepoints, mandatory/optional biopsy status, biopsy rationale and endpoint inclusion. All enrolled patients at the University of Texas MD Anderson Cancer Center were reviewed for research biopsy execution. Statistical associations were tested using Fisher's exact or chi-square analyses, with $p<0.05$ considered significant.
Results: A total of 182 clinical trial protocols were analyzed, of which 119 (65%) included a PD research biopsy. Of these 119 protocols, 81% involved solid tumors, 87% were multicenter, 59% were phase 1 trials, 27% specified PD biopsy as mandatory, and 7% included use of PD biopsy as a study endpoint. Incorporating a PD biopsy in a protocol was significantly associated with cancer type (hematologic (81%) vs solid tumors (19%), $p = 0.042$) and study type (multicenter (87%) vs. single center (13%), $p = 0.003$). In these 119 protocols a total of 797 patients were enrolled at MDACC (median 3, range 0-66), of whom 465 (58%) were treated (median 2, range 0-25). At least one research biopsy [screening (n=263), on-treatment (n=126), or PD (n=48)] was performed in 74 trials (62%), with a median of 2 biopsies per trial (range 1-46). PD biopsies were obtained in 24 of 119 protocols (20%) with a median of 1 PD biopsy per trial (range 1-12). Phase 1 trial type was the only protocol factor significantly associated with obtaining any research biopsy ($p = 0.01$). No protocol factors were statistically associated with a patient undergoing a PD biopsy. Among protocols where PD biopsy was mandated, 9/32 (28%) executed a PD biopsy versus 15/87 (17%) in optional protocols ($p = 0.204$). Similarly, 3/8 (38%) of protocols listing PD biopsy as a study endpoint
executed a PD biopsy versus 21/111 (19%) of those without endpoint incorporation ($p = 0.201$).
Conclusions: Despite widespread protocol inclusion, PD biopsies were successfully obtained in only one-fifth of eligible trials, underscoring the gap between design intent and clinical feasibility, which limits the ability to study mechanisms of resistance and tumor evolution. These findings highlight the need for pragmatic trial designs (PD biopsies at time of tumor marker rise or increasing RECIST percentage) and institutional infrastructure that support consistent tissue collection at progression.

#1079 Over expressing PD-L1 circulating tumor cells with clusters in prostate cancer patients.

Jayant Khandare[1], Bharat Bhosale[2], Gourishankar Aland[3], Sreeja Jayant[3], Amrut Ashturkar[3], Vikas Jadhav[3], Ashish Joshi[4], Sourav Mishra[5], Pradip Kendre[6], Aravindan Vasudevan[3], Vashishth Maniar[7], Jagdeesh Kulkarni[8]

[1]Research, Actorius Innovations and Research, Pune, India,[2]Research, Bombay Hospital, Mumbai, India,[3]Actorius, Pune, India,[4]Mumbai Oncocare Center, Mumabi, India,[5]Research, AIIMS Bhubaneswar, Bhubaneswar, India,[6]Oncology, Mumbai Oncocare Centre, Mumbai, India,[7]Medical Oncology, Mumbai Oncocare Center, Mumbai, India,[8]Surgery, Bombay Hospital, Mumbai, India

Background:
Prostate cancer (PC) detection remains challenging due to the limited specificity and sensitivity of current screening methods, including PSA testing. However doesn't distinguish aggressiveness from indolent disease, leading to overdiagnosis and overtreatment. Circulating Tumor Cells (CTCs), however, offer greater clinical value as they provide real-time insights into tumor biology, disease progression, and treatment response. Unlike PSA, CTCs represents a dynamic biomarker implicating minimal cellular residual disease (MCRD) systemically, helpful for monitoring and guiding the personalized prostate cancer management. In addition, the over-expression of PD-L1 on CTCs provides insights into immune evasion mechanisms and may have predictive and prognostic value in PC. We report CTC capture, having PD-L1 positivity and clusters, in PC patients.
Methods:
Retrospectively, 239 prostate cancer patients were analysed for presence of CTC-PD-L1 and CTC clusters, including 216 (90.4%) baseline and 23 (9.6%) follow-up samples. CTCs were isolated using the CDSCO-approved (India) *OncoDiscover Test* employing anti EpCAM antibody-based immunomagnetic enrichment / 1.5 ml of blood. CTCs were identified as $CK18^{+}/DAPI^{+}/CD45^{-}$, PD-L1 $expression^{+}$ cells with distinct morphology. Automated fluorescence imaging quantified signal intensities to correlate with clinicopathological parameters. Patients were stratified for age, and quantitative analysis of CTC positivity, PD-L1 expression, and cluster frequency was performed.
Results:
CTCs were detected in 173 (72.4%) patients, while 66 (27.6%) were negative. Amongst 157 evaluable samples for PD-L1, 131 (54.8%) were PD-L1 positive and 26 (10.9%) were negative. CTC clusters were observed in 19 (11%) patients, while 154 patients (89%) had only single CTCs. At baseline, CTCs were detectable in 70.4% of patients, increased to 91.3% at follow-up patients. While, CTC-PD-L1 positivity was observed in 52.3% patients at baseline and 85.7% in follow-up. Additionally, PD-L1-positive CTC clusters increased from 10.5% at baseline to 13.1% at follow-up. The predominant age groups were 61-70 years (39.0%) and 71-80 years (39.9%), together comprising nearly 80% of the cohort. The mean distribution of CTC counts per patient were 1.14, 0.95 for CTCs with PD-L1, and 0.12 for CTC clusters.
Conclusion:
A high prevalence of CTCs and PD-L1 expression was observed among prostate cancer patients, particularly in older age groups. The detection of PD-L1 +ve CTCs highlights the presence of confirmative MCRD, and presence of disease in circulation. The relatively low incidence of CTC clusters suggests limited collective migration, although their presence may signify more aggressive disease phenotypes.

#1080 Development of a murine leptomeningeal disease model for a point-of-care cerebrospinal fluid liquid biopsy assay.

Eileen Shiuan[1], Jorge Salcedo-Sifuentes[2], Leilani Pradis[2], Trinh Phan[2], Sonia Su[3], Martin Shum[3], Daniel T. Kamei[3], Won Kim[2], Robert M. Prins[2]

[1]Hematology/Oncology, UCLA Health, Los Angeles, CA,[2]Neurosurgery, UCLA Health, Los Angeles, CA,[3]Bioengineering, UCLA Samueli School of Engineering, Los Angeles, CA

Background: Leptomeningeal disease (LMD), the metastatic dissemination of cancer cells to the leptomeninges and cerebrospinal fluid (CSF), is a devastating complication of cancer. LMD occurs most commonly in advanced melanoma, lung, and breast cancers, and typically portends a poor prognosis that is accompanied by rapid neurological decline. Diagnosis and disease monitoring has been historically challenging. Prior work by our colleagues has led to the development of a barcode-style rapid, semi-quantitative lateral flow assay (LFA) able to detect MCF-7 breast cancer cells in artificial CSF using an epithelial marker. Here, we present murine models of LMD developed to further refine the assay and test its detection limit in an *in vivo* setting.

Methods: Two brain-tropic murine cancer lines previously generated by serial *in vivo* intracarotid injections, B16-BrM melanoma and LLC-LeptoM lung carcinoma, were engineered to stably express mCherry and secreted Gaussia luciferase (sGluc) via lentiviral transduction. Pure populations were isolated by fluorescence-activated cell sorting, and bioluminescence signal was evaluated *in vitro* using cultured supernatant at various cell concentrations. For *in vivo* studies, 1000 parental or mCherry-sGluc cells were stereotaxically injected into the right lateral ventricle of syngeneic C57BL/6 mice at 8-10 weeks of age. CSF was collected terminally via cisterna magna puncture on days 1, 5, 9, and 13 post-implantation. Tumor burden was assessed using bioluminescence and flow cytometry on CSF. Murine brains were collected and processed for histological analyses.

Results: Bioluminescence signal was detectable in cultured supernatant from both B16-BrM and LLC-LeptoM cells, even in concentrations less than 10 cells per ml. When adopted into the *in vivo* LMD model, mice began to display clinical decline starting around day 12 post-implantation. Histological analysis demonstrated tumor cell clusters sequestered in the ventricular space. Bioluminescence signal was detectable from just 1 ul of mouse CSF in animals injected with mCherry-sGluc cells, compared to those injected with parental cells or with no injection. On day 13 post-implantation, bioluminescence signal was saturated in about half of the experimental cohort. In most cases, bioluminescence was detected in CSF even when mCherry+ cells were not detected on flow cytometry.

Conclusion: We have established a murine LMD model that allows for highly sensitive detection of tumor burden via liquid biopsy of CSF. Further studies evaluating tumor burden kinetics and the performance of the point-of-care LFA on mouse and human CSF are ongoing. The success of this work may revolutionize the diagnosis and management of LMD.

#1081 Development and validation of a standardized CELLSEARCH® assay for real-time monitoring of prostate-specific membrane antigen (PSMA) expression on circulating tumor cells.

Steven M. Jones, Thai Bui, Damodara Gullipalli, Shemeeakah Powell, Margaret LaCava, **Zoltan Simandi**

Menarini Silicon Biosystems, Huntingdon Valley, PA, PA

BACKGROUND:
Prostate-Specific Membrane Antigen (PSMA) is a critical biomarker whose dynamic expression dictates the clinical utility of emerging PSMA-targeted radioligand therapies. A major clinical challenge remains the lack of a standardized, highly sensitive, and minimally invasive method for PSMA expression monitoring. We addressed this by developing and validating a novel PSMA-specific assay integrated into the CELLSEARCH® platform, the only FDA-cleared system for CTC enumeration.
METHODS:
The PSMA assay utilizes the CELLSEARCH® platform's immunomagnetic enrichment of EpCAM+ CTCs, followed by staining with fluorescently labeled anti-cytokeratin, anti-CD45, DAPI, and a high-affinity anti-PSMA antibody. Analytical validation was conducted using PSMA-positive (LNCaP, 22Rv1) and PSMA-negative (PC-3.9) cell lines spiked into healthy donor blood, assessing assay sensitivity, specificity, and recovery over a 96-hour sample preservation time in CellSave™ tubes. Captured CTCs are suitable for both platform imaging and subsequent molecular analysis.
RESULTS:
The customized PSMA assay demonstrated exceptional analytical performance, meeting all pre-defined criteria. The linear relationship between spiked and recovered PSMA-positive LNCaP cells was robust, achieving R^2 values >0.999 across all tested donors. High accuracy was confirmed by mean percent recovery for PSMA-positive cells, which ranged from 83.3% to 93.3% for spike levels of 10 to 1000 cells. Assay precision was also confirmed, with a Coefficient of Variation (CV) of 6.97% at the 10-cell spike level. In a preliminary clinical cohort (N=20) of PCa patients, the assay successfully detected PSMA+ CTCs. Enriched patient samples were then subjected to orthogonal flow cytometry analysis and cell sorting to provide independent confirmation of PSMA protein expression. Downstream molecular analysis of the sorted cells confirmed the presence of PCa-specific genomic alterations, providing molecular verification of the PSMA-positive CTC population.
CONCLUSIONS:
This novel, fully validated PSMA CTC assay provides a highly specific, and standardized liquid biopsy tool for PSMA detection. Its robust analytical performance establishes the utility of the platform in monitoring PSMA expression dynamics to inform therapeutic decisions in metastatic prostate cancer patients.

#1082 Development of a novel CDH17 CTC assay to monitor colorectal patient blood and cerebrospinal fluid.

Jennifer C. Chow[1], Casey E. Helmicki[1], Rachel Ponting[1], Arturo B. Ramirez[1], **Pashtoon Murtaza Kasi**[2]

[1]RareCyte, Inc., Seattle, WA,[2]City of Hope Comprehensive Cancer Ctr., Duarte, CA

CDH17 is a cell adhesion molecule typically expressed in intestinal epithelial cells and pancreatic ducts. CDH17 overexpression is linked to tumor progression, metastasis and poorer prognosis and is being investigated as a target of CAR-T therapies currently in clinical development. Circulating tumor cells (CTCs) are intact cells shed from the tumor into blood or other biological fluids and can serve as a liquid biopsy for dynamic assessment of tumor protein expression. In this study we developed and validated an immunofluorescent assay to measure CDH17 expression in CTCs, and enable longitudinal monitoring of tumor CDH17 expression in patient blood and cerebrospinal fluid (CSF) samples. To optimize the CDH17 CTC assay, multiple clones were screened using positive and negative cell lines spiked into healthy donor blood. Clone E5J8Z (Cell Signaling Technologies) applied using the Leica BOND RX autostainer, provided the highest signal-to-background (S:B) ratio between positive negative cell lines. Final assay had S:B of 138 and 99.9% accuracy in distinguishing positive from negative cells.The verified assay was applied to 4 longitudinal blood and CSF samples collected from a stage IV colorectal cancer patient with brain metastasis undergoing CAR-T therapy targeting CDH17 (see table). CDH17(+) CTCs were detected in both blood and CSF, with higher CTC numbers and CDH17 expression observed in CSF samples compared to blood from the same timepoint. CTC numbers and CDH17 expression in blood and CSF decreased upon anti-CDH17 CAR-T therapy and reached undetectable levels in later samples.

This study demonstrates the feasiblity and robust performance of the CDH17 CTC assay in blood and CSF of a CRC patient. Changes in CTC number and CDH17 expression can be harbingers of response to therapy and offer a minimally invasive method to longitudinally monitor biomarker expression. This approach may offer predictive and prognostic insights for patients on CDH17-targeted therapies.

Longitudinal CTC and CDH17 monitoring

#1083 Kras activity-linked glycolysis and immunosuppression in metastatic pancreatic cancer.

Shuichi Mitsunaga[1], Mari Masuda[2], Kota Kato[1], Hidetaka Suzuki[1], Mitsuhito Sasaki[3], Hiroki Yoshimatsu[4], Yoichi Kamei[4], Masafumi Ikeda[3]

[1]Division of Biomarker Discovery, National Cancer Center, Exploratory Oncology Research & Clinical Trial Center, Kashiwa, Japan,[2]Staff Scientist, National Cancer Ctr. Research Inst., Tokyo, Japan,[3]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan,[4]Pfizer R&D Japan G.K., Tokyo, Japan

Background: KRAS mutations act as a driver of pancreatic ductal adenocarcinoma (PDAC), involving ERK-dependent gene transcription. Inhibition of mutated KRAS activity suppresses glycolysis and reshapes the poor immune profile in murine PDAC. Identification of these relationships in human PDAC is useful for realizing pivotal drivers of metabolic and immune dependency. Recently identified PDAC siKRAS KRASi iKras gene sets enable the creation of a precise KRAS signature score for KRAS activity. Using liver metastasis (LM)-derived transcriptome data, we evaluated the effect of KRAS signature score on clinical outcomes and the molecular features of metastatic PDAC.
Methods: Comprehensive mRNA expression on cDNA microarray and 435 protein expressions on reverse-phased protein array (RPPA) were measured using needle-biopsied samples from treatment-naïve LM of PDAC. KRAS signature score was calculated in each sample. A KRAS-related gene module was determined based on the relationship between KRAS signature score and module eigengene from weighted co-expression network analysis. Hierarchical clustering of RPPA data generated KRAS-related subtypes, in which a KRAS-related protein was selected from the molecule encoded by the genes of KRAS-related gene modules.
Results: KRAS signature score in LMs was calculated in 77 patients (Male: 65%; median age: 66 years). Patients with high KRAS signature score tumors (n=38) showed poor overall survival as compared to those with low KRAS signature score tumors (n=39; hazard ratio: 1.895 [95% confidential interval: 1.123 to 3.198]). KRAS mutated LMs (90.9%) were related to high KRAS signature scores (P=0.004). *DUSP4* mRNA expression, an ERK-dependent negative feedback gene for ERK dephosphorylation, increased in tumors with high KRAS signature scores (P=0.017) and with KRAS mutation (P<0.001). Thirty-seven proteins were identified as KRAS-related UP proteins, including those involved in the glycolysis pathway and a lactate transporter, MCT4. The gene up-regulation of glycolysis and lactate-efflux pathway was found in *HK2* (P=0.132), *Eno1, 2* (P<0.001, P=0.016), *PKM* (P<0.001), *LDHA* (P<0.001), and *MCT4* (P<0.001). ZAP-70, a cytosolic tyrosine kinase essential for T cell receptor signaling, was present in nine KRAS-related DOWN proteins. The gene down-regulation of the immune profile was found in *CD4* (P<0.001), *CD8A* (P<0.001), *CD8B* (P=0.013), and *ZAP-70* (P<0.001).
Conclusion: KRAS up-regulated tumors showed elevation of glycolytic molecules and immunosuppression in LM of pancreatic cancer. KRAS activity might drive metabolic and immunological aggravation, leading to a poor prognosis.

#1084 Serum proteomic profiling reveals metastasis-associated molecular signatures and early systemic remodeling in triple-negative breast cancer.

Jina Kim[1], Hyoyoung Kim[1], Sunao Tanaka[1], Takeo Fujii[2], Sungyong You[1], **Hideki Furuya**[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]National Cancer Institute, Bethesda, MD

Background and Objectives: Triple-negative breast cancer (TNBC) is an aggressive subtype with high risk of distant metastasis and limited biomarkers for early detection of recurrence. Clinical surveillance relies on imaging, which often identifies metastasis only after systemic progression. This study evaluated whether serum proteomic profiling can identify molecular changes associated with metastatic transition in TNBC. **Methods:** Serum samples were collected from 29 patients with TNBC and 10 healthy donors. Among TNBC cases, 12 and 9 samples were obtained at the time of initial diagnosis from patients who never developed distant recurrence (NR-DIG) and those who developed distant recurrence (DR-DIG), respectively. Eight samples were collected at recurrence (DR-REC). All samples were analyzed using the SomaScan® 11K proteomic platform. Differential protein expression ($|\log_2[\text{Fold Change}]| > 0.35$, False Discovery Rate (FDR) < 0.10), pathway enrichment, and immune deconvolution analyses were performed. **Results:** Comparison between DR-REC and DR-DIG identified 299 differentially expressed proteins (DEPs; 260 upregulated, 39 downregulated). Inflammation, coagulation, angiogenesis, and extracellular matrix remodeling were significantly enriched by the DEPs. Unsupervised hierarchical clustering distinguished DR-REC from DR-DIG, and one serum sample clinically classified as DR-DIG clustered with DR-REC, suggesting that metastasis-associated proteomic changes may precede clinical detection. Immune deconvolution revealed increased monocyte and neutrophil signatures in DR-REC compared with NR-DIG and DR-DIG, indicating systemic immune remodeling during metastatic progression. **Conclusions:** Serum proteomic profiling can detect molecular alterations associated with metastatic transition in TNBC, even before radiographic evidence of recurrence. These findings support the feasibility of a proteomics-based liquid biopsy as a minimally invasive approach for early detection and monitoring of metastatic progression in TNBC.

#1085 PHF8 is a major upstream regulator of RIPK2 in prostate cancer cells.

Jaceline Pires Sanches, Ahmed Elgehama, Lili Guerra, Wei Yang

Stony Brook University, Stony Brook, NY

Background: Despite significant progress, prostate cancer (PC) remains a leading cause of cancer-related death in men, underscoring the urgent need for new therapeutic strategies. Our previous study demonstrated that RIPK2 is overexpressed in advanced PC and promotes disease progression and metastasis by activating a noncanonical RIPK2/MKK7/c-Myc signaling pathway (*Nature Communications*, 2022). However, beyond gene amplification, the mechanisms underlying RIPK2 upregulation in PC cells remain elusive. The present study aims to identify the key transcription factor regulating RIPK2 expression in PC cells.
Methods: PC 22Rv1 and PC3 cells were treated with three NF-κB modulators, and RIPK2 and NF-κB target gene expression was measured by RT-qPCR. Candidate RIPK2 transcription factors were identified by integrating CHEA, ENCODE, JASPAR, and EoRothEA databases, and ranked using PCTA and TCGA correlations plus ENCODE ChIP-Seq data. PHF8 expression and its correlation with RIPK2 were assessed by RT-qPCR and western blotting in eight prostate cell lines. PHF8 was knocked out in two PHF8-high lines (22Rv1, PC3) via CRISPR/Cas9, and re-expressed using lentiviral wild-type (WT), demethylase-inactive (H283A. A dual-luciferase reporter assay was performed to evaluate the effect of PHF8 and its enzymatic activity on *RIPK2* promoter activity. A multiplexed fluorescence immunohistochemistry assay was developed to assess the correlation between PHF8 and RIPK2 in tumor cells within clinical tissue specimens.
Results: NF-κB decreased RIPK2 mRNA levels, indicating that NF-κB acts as a transcriptional repressor rather than a transcriptional activator of RIPK2 in PC cells. Integrative analysis identified 156 candidate RIPK2 transcription factors, with seven consistently correlated with RIPK2 mRNA (average rho > 0.25) in both PCTA and TCGA cohorts. Among these, PHF8 showed strong RIPK2 promoter binding in ENCODE ChIP-Seq data. Western blotting confirmed a strong PHF8-RIPK2 protein correlation across eight PC cell lines, with PHF8 most abundant in 22Rv1 and PC3. Genetic or pharmacologic PHF8 inhibition in these cells markedly reduced RIPK2 pre-mRNA, mRNA, and protein levels, whereas PHF8 overexpression in RWPE-2 and LNCaP increased RIPK2 in an enzymatic activity- and dose-dependent manner. In clinical tissue specimens, PHF8 and RIPK2 protein levels were significantly correlated in prostate tumor cells.
Conclusion: Our findings identify PHF8, rather than NF-κB, as a major transcriptional regulator of RIPK2 in PC cells and demonstrate that PHF8's demethylase activity is essential for its transcriptional regulation of RIPK2.

#1086 HER2 expression in circulating tumor cells as a minimally invasive biomarker of therapeutic response to trastuzumab deruxutecan in breast cancer.

Toru Mukohara[1], Nobuaki Matsubara[1], Yusuke Takahashi[2], Kentaro Shirai[2], Hiromichi Nakajima[1], Chikako Funasaka[1], Chihiro Kondoh[1], Kana Kawasaki[2], Maharjan Bishnu Devi[2], Fumie Kato[2], Hiroyuki Obinata[2], Taiga Ajiri[2], Masatoshi Yanagida[2], Reiko Watanabe[3]

[1]Department of Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan,[2]Central Research Laboratories, Sysmex Corporation, Kobe, Japan,[3]Department of Pathology and Clinical Laboratories, National Cancer Center Hospital East, Kashiwa, Japan

Over the last decade, a variety of antibody-drug conjugates (ADCs) have entered clinical practice. The antitumor activity of some ADCs is correlated with the level of target proteins. Trastuzumab deruxutecan (T-DXd), an anti-HER2 ADC, is presently indicated for breast cancer with a wide range of HER2 expression, from ultralow to overexpresssion. However, evaluation of HER2 status in a tumor poses significant clinical challenges. First, although HER2 expression levels have been shown to change during treatment, it is not always feasible to obtain tumor samples immediately before administration of T-DXd. Second, heterogeneity of HER2 has been reported in breast cancer, both between and within tumors. Therefore, there is a need for a noninvasive method that can evaluate HER2 expression across the entire tumor, thereby ensuring that T-DXd is delivered to patients most likely to benefit from this agent. Circulating tumor cells (CTCs) can be measured by blood sampling, providing a minimally invasive approach that allows molecular information to be obtained in a timely manner and is valuable for guiding therapeutic decisions. Single-cell analysis allows for precise detection of tumor heterogeneity, offering insights into the diverse characteristics of cancer cells. We have developed a method for detecting CTCs and evaluating their HER2 expression by combining size-based CTC isolation with molecular imaging flow cytometry. In this study, we compared HER2 expression in CTCs from whole blood samples drawn from 17 patients with breast cancer who had pathological results available from biopsy tissue specimens collected within 28 days before or after blood sampling. CTC-based evaluation of HER2 expression in tissue demonstrated a sensitivity of 71% and a specificity of 33%. The positive predictive value was 83%. We also evaluated the relationship between HER2 expression in CTCs and the therapeutic effect of T-DXd in a separate cohort. CTC measurements were performed up to three times, namely, before T-DXd, one month after initiation of T-DXd, and at the time of disease progression whilst receiving T-DXd. One month after initiation of T-DXd, the number of HER2-expressing CTCs decreased in all five patients who achieved stable disease or a partial response and increased in four of five patients with progressive disease. These findings suggest that HER2 expression in CTCs may reflect that in tumors. This CTC detection method may help to address the challenges faced during treatment, such as intratumoral molecular heterogeneity and dynamic changes in molecular expression. Ultimately, this detection method could replace tissue biopsies and improve the outcomes of cancer therapy.

#1087 Patient-derived breast and melanoma circulating tumor cell (CTC) *in vitro* models as encouraging new tools for cancer research.

Paul Lovell, Karlie Wysong, Fafali Deegbe, **Fang Tian**

American Type Culture Collection (ATCC), Manassas, VA

Circulating Tumor Cells (CTCs) have emerged as powerful tools for understanding the mechanisms behind cancer biology, particularly in context of metastatic disease. Although rare, CTCs are increasingly recognized for their potential in the early diagnosis, monitoring, and progression of tumors. These cells can detach from a primary cancer tumor and enter the bloodstream, facilitating metastasis at distant tissue sites. As research into CTCs advances, new opportunities will continue to emerge to better manage therapeutic targets, especially for metastatic disease. Despite progress in CTC isolation techniques, detecting CTCs remains challenging due to their rarity in the bloodstream. Furthermore, long-term and scalable in vitro culture of CTCs has not been previously achieved. As a result, there is a significant lack of widely available CTC models for studying cancer biology, metastatic progression and development of new treatment strategies. ATCC is actively collaborating with various institutions to make CTCs widely available for cancer research, focusing on the development of standardized expansion and characterization protocols for CTCs isolated from clinical patient samples. In this study, we present the successful propagation and characterization of six well-established breast and melanoma CTC models originating from metastatic breast and melanoma disease: Brx50 (ATCC® CRL-3648™), Brx61 (ATCC® CRL-3649™), Brx142 (ATCC® CRL-3650™), MEL167 (ATCC® CRL-3651™), MEL182 (ATCC® CRL-3652™) and PEM78 (ATCC® CRL-3653™). We evaluated the genomic, proteomic, and functional characteristics of both the breast cancer and melanoma CTC models. Genetic profiling via sequencing revealed key oncogenic drivers potentially linked to metastatic behavior. Gene expression profiles were compared with commonly used breast and melanoma cell lines to highlight distinct molecular signatures. Immunofluorescence staining was performed to assess the distinct presence of breast cancer or melanoma molecular biomarker panels. Drug response assays were conducted to evaluate the sensitivity of the breast models to estrogen receptor (ER) inhibitors and melanoma models to BRAF inhibitors. Additionally, drug response profiles of the breast CTC models were compared to those of commonly used triple-positive and triple-negative breast cancer cell lines, while melanoma CTC models were compared to the A375 melanoma cell line and CRISPR-engineered drug-resistant variants. In conclusion, metastatic disease remains difficult to treat due to reduced therapeutic response rates and increased disease relapse potential. The six new widely available CTC lines—Brx50, Brx61, Brx142, MEL167, MEL182 and PEM78—represent robust and versatile models for investigating the role of CTCs in pre-clinical diagnostics, disease monitoring, and the progression of metastatic breast cancer and melanoma.

#1092 Multi-analyte blood-based screening early detection of HPV-associated oropharyngeal and anal cancer within the PLCO cohort.

Krystle A. Kuhs[1], Hilary Robbins[2], Li Chen[3], Xiaoshuang Feng[4], Yana Al-Inaya[5], Gjystina Lumaj[6], Samuli Eldorfs[5], Qin Wang[5], Tim Waterboer[7], Dipon Das[5], **Daniel Faden**[8]

[1]Department of Epidemiology and Environmental Health, University of Kentucky, Lexington, KY,[2]International Agency for Research on Cancer, World Health Organization, Lyon, France,[3]University of Kentucky, Lexington, KY,[4]World Health Organization,[5]Otolaryngology-Head and Neck Surgery, Massachusetts Eye and Ear, Boston, MA,[6]Massachusetts Eye and Ear, Otolaryngology-Head and Neck Surgery, MA,[7]DFKZ-German Cancer Research Center, Heidelberg, Germany,[8]Mass General Brigham, Boston, MA

Background: Despite rising incidence, there are no early detection methods for HPV+ oropharyngeal (HPV+OPC) and anal (HPV+AC) cancers. HPV16 E6 antibody (E6 Ab) positivity is a promising early biomarker, appearing in most patients at diagnosis and years before symptoms, but the long interval between seroconversion and cancer limits clinical utility. Additional tumor-indicative biomarkers are needed. Circulating tumor HPV DNA (ctHPVDNA) is highly sensitive and specific for detecting HPV+ cancers at diagnosis. Ultrasensitive HPV whole genome sequencing (WGS) assays such as HPV-DeepSeek have shown strong performance for HPV+OPC early detection in a single institution cohort.
Methods: ctHPVDNA testing was performed on serial pre-diagnostic plasma samples from 73 OPC and 19 AC cases and 183 matched PLCO controls with available E6 Ab results. Samples were blinded, underwent cfDNA extraction, and were analyzed using HPV-DeepSeek as previously described.
Results: ctHPVDNA detection was strongly associated with future OPC and AC development (OR 20.52 [95% CI 4.80-87.59], P<0.0001; OR 33.63 [95% CI 7.05-Infinity], P<0.0001). Among E6 Ab positive cases (N=31, surrogate marker to HPV+), ctHPVDNA sensitivity was 61.3% (95% CI 42.2-78.2) for OPC and 71.4% (95% CI 29-96.3) for AC. Sensitivity was highest near diagnosis (100% for OPC within 2 years; 100% for AC within 5 years) and declined with longer lead time. ctHPVDNA read counts increased as the lead time to diagnosis decreased. Eighteen OPC and nine AC cases positive for ctHPVDNA had serial samples. 10 OPC (56%) were positive in all serial samples (median time between first positive ctHPVDNA test to diagnosis: 3.5 years) and 8 (44%) converted from ctHPVDNA negative to positive over follow-up (median time from conversion to diagnosis: 4.7 years, range 0.6 to 8.9 years). 2 AC (22%) were positive in all serial samples (median time between first positive ctHPVDNA test to diagnosis: 6.6 years) and 6 (67%) converted from ctHPVDNA negative to positive over follow-up (median time from conversion to diagnosis: 2.4 years, range 1.2 to 15.4 years).
Conclusions: ctHPVDNA, measured using an ultrasensitive WGS assay, HPV-DeepSeek, was strongly associated with future HPV cancer risk. Among E6 Ab positive cases, ctHPVDNA achieved 100% sensitivity in the years immediately preceding diagnosis in both OPC and AC. Serial sampling showed increasing detection rates and read counts as diagnosis neared, supporting ctHPVDNA as a time-dependent marker of emerging disease. Combining E6 Ab testing with ultrasensitive ctHPVDNA detection provides complementary information for blood-based early detection of HPV+ cancers which should be tested in prospective early detection trials.

#1093 Validation of a blood test for multi-cancer risk stratification in a lung cancer screening cohort.

Ehsan Irajizad[1], Johannes Fahrmann[2], Hamid Rudsari[1], Jody V. Vykoukal[2], Iakovos Toumazis[2], Sara Khoramisarvestani[1], Sara Ansari[3], Jane Yang[3], Nicole M. Kettner[2], Jennifer B. Dennison[4], Edwin Justin Ostrin[5], Samir M. Hanash[5]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]University of Texas MD Anderson Cancer Center, Houston, TX,[3]Quest Diagnostics, San Juan, CA,[4]Postdoctoral Fellow, UT MD Anderson Cancer Center, Houston, TX,[5]UT MD Anderson Cancer Center, Houston, TX

Purpose: We report a blinded validation study of a ten-protein marker blood test for assessing risk of developing or harboring nine common cancers in a prospective lung cancer screening cohort. **Patients and Methods:** The foundation of the multi-cancer risk stratification test (MCaST), test is a 4-marker protein panel consisting of ProSFTPB, CEA, CA125, and CYFRA-21 which has been extensively validated for risk of lung cancer and which has been expanded to include six additional markers to encompass, in addition to lung cancer, prostate, colorectal, breast, ovarian, pancreatic, liver, esophageal, and stomach cancers. Blinded validation samples consisted of 1,235 plasmas collected prior to diagnosis from 171 cancer cases and 526 randomly selected non-case controls. Fixed individualized combination rules as well as cancer-specific risk thresholds predefined based on established clinical guidelines were applied. **Results:** At the subject level, the MCaST tested positive for imminent risk of lung cancer in 65 of 73 lung cancer cases, including 45 of 51 early-stage cases, with a median time of 12.7 months (interquartile range [IQR]: 1.7 - 27.8 months) between the first positive MCaST and diagnosis of lung cancer. The positive rate of MCaST for other cancers was 88.9% for prostate, 63.6% for invasive breast, 85.7% for CRC, 50% for ovarian, 50% for pancreatic, and 67% for esophagus plus stomach cancers with a median (IQR) time of 20.7 months (10.2 - 42.8 months) from the first positive MCaST to a clinical diagnosis across the cancer types. Overall accuracy for tissue-of-origin (TOO) signal was 94.6%, and as high as 98.1% for lung cancer. **Conclusion:** MCaST has utility for assessing cancer risk for common and lethal solid cancers in this smoker population.

#1094 Circulating tumor DNA (ctDNA) for molecular residual disease (MRD) detection and recurrence monitoring in hepatocellular carcinoma (HCC); COSMOS-HCC01.

Background:
Surgery and ablation can be curative for early-stage HCC, but up to 70% recur or develop new primary HCC. ctDNA-based MRD assessment may improve risk assessment and identify recurrence earlier than current tools. Because HCC is often diagnosed radiologically and ablation yields no tissue, tumor-informed assays may be infeasible and unable to detect new primaries.
Methods:
Patients with completely resected or ablated stage I-III HCC were prospectively enrolled across 13 Japanese sites (Mar 2021-May 2022). Plasma was collected pre- and 4 weeks post-procedure and every 3-6 months with standard imaging and biomarker assessment. ctDNA was analyzed retrospectively using a tissue-free epigenomic assay (Guardant Reveal) evaluating ~20,000 differentially methylated/control regions. Samples are classified as ctDNA detected/not detected based on a pre-defined threshold. Associations between ctDNA status and recurrence were analyzed.
Results:
Among 95 patients eligible for this interim analysis, (87% resected, 57% stage I, median age 74), 610/611 samples were successfully analyzed. At 36.9 months median follow-up, 42 recurred. Pre-procedure ctDNA was detected in 75% (70/94) and correlated with shorter time to recurrence (HR 4.4; 95% CI 1.7-14.6; $p < 0.001$). Post-surgery ctDNA detection at 4 weeks also correlated (HR 3.8; 95% CI 1.7-7.8; $p = 0.002$) and was the only variable that remained statistically associated with recurrence on multivariate analysis at this timepoint. Surveillance ctDNA sensitivity was 60% (25/42), specificity was 98% (52/53), and median lead time was 63 days. ctDNA outperformed other biomarkers evaluated in this cohort (Table 1).
Conclusions:
Epigenomic ctDNA analysis enabled tissue-free MRD detection with high accuracy and superior performance vs conventional biomarkers, supporting its use for individualized recurrence risk assessment and surveillance.

Table 1. Performance of biomarkers (ever/never detected) to predict HCC recurrence during post-treat

	ctDNA	AFP (>10ng/mL)	AFP-L3 (>9.9%)	PIVKA-II (>39mAU/mL)
Sensitivity (positive/recurrence)	60% (25/42)	33% (14/42)	54% (13/24)	44% (18/41)
Specificity (negative/no recurrence)	98% (52/53)	87% (46/53)	68% (15/22)	87% (45/52)
Median lead time	63 days	55 days	12 days	32 days
HR (95% CI)	10.1 (5.3-20.3), P < 0.001	2.2 (1.1-4.1), P = 0.024	1.7 (0.7-3.9), P = 0.213	3.6 (1.9-6.7), P < 0.001

#1095 ARID1A protein expression enhances risk stratification in colorectal polyp surveillance.

Aula Ammar[1], Amna Matly[1], Kimiya Kabiri Arani[1], Scott Murray[1], Mayuri Hendricks[1], Alexander Winton[1], Natalie Fisher[2], Gerard Lynch[1], Mark Johnstone[1], Colin Steele[1], Noori Maka[3], Jennifer Hay[4], Philip Dunne[2], Stephen McSorley[1], **Joanne Edwards**[1]

[1]University of Glasgow, Glasgow, United Kingdom,[2]Queen's University Blefast, Glasgow, United Kingdom,[3]NHS Greater Glasgow & Clyde, Glasgow, United Kingdom,[4]Francis Crick Institute, London, United Kingdom

Background: Polyps detected during bowel cancer screening indicate an increased risk of developing metachronous colorectal lesions. Current British Society of Gastroenterology (BSG 2020) surveillance guidelines use polyp size, number, histology, and dysplasia grade to assess this risk but do not include molecular markers limiting accurate risk stratification. To address this gap, we investigated ARID1A expression as a potential predictive biomarker for metachronous colorectal lesions.
Methods: A total of n=1184 archival colorectal polyp samples assembled into tissue microarrays (TMAs) were stained for ARID1A protein expression using immunohistochemistry (IHC) and epithelial ARID1A histoscores were assessed using Qupath. Data were divided into training (n=819) and test (n=365) datasets. Molecular profiling included somatic mutation sequencing (n=623) and bulk RNA Temp-O-seq comparing low vs high ARID1A expression (n=117 for each group). Pathway analyses incorporated Hallmark gene sets using GSEA and ssGSEA as well as Reactome pathway enrichment and Dorothea transcription factor activity scoring.
Results: High ARID1A expression was identified as a predictor of metachronous disease independent of number of polyps, location of index polyp, dysplasia grade and sex (training HR=1.372, p=0.014; test HR=1.893, p=0.003). ARID1A predictive value was particularly strongest in patients with 1-4 polyps and in left-sided lesion and the rectum. ARID1A was among the most frequently mutated genes in precancerous polyps. ARID1A protein expression was decreased in presence of *ARID1A* and *KMT2D* mutations ($p<0.001$ and $p=0.021$, respectively). The most common type of base alteration in *ARID1A* mutations was C>T (47.96%) followed by G>A (16.33%). Truncation mutations accounted for 48% of ARID1A gene mutations and significantly correlated with reduced protein expression ($p<0.001$). Transcriptomic analysis showed a significant enrichment of proliferative Myc-targets_V2 pathway in ARID1A-high polyps, whereas inflammatory and differentiation pathways were enriched in ARID1A-low polyps. Transcription factor activity suggested a shift toward regenerative stem-cell signatures in ARID1A-high lesions, whereas ARID1A-low lesions showed TFs linked to suppression of transcription.
Conclusion: ARID1A expression is a promising molecular biomarker that improves prediction of metachronous colorectal lesions beyond current guideline criteria, particularly among patients currently classified as low risk. The associated biological programs highlight increased proliferation and activation of regenerative stem-cell pathways in ARID1A-high polyp, supporting ARID1A's potential utility in personalised surveillance strategies.

#1096 OncoSeek 2.0: An advanced multi-cancer blood test enhancing early detection and aiding cancer diagnosis.

Mao Mao[1], Yong Shen[2], Shiyong Li[1], Wei Wu[1], Yinyin Chang[3], PingPing Xing[3], Chenyu Ding[3], Dandan Zhu[3], Qingxia Xu[2], Wei Cui[2]

[1]SeekIn, Shenzhen, Guangdong, China,[2]The Affiliated Cancer Hospital of Zhengzhou University and Henan Cancer Hospital, Zhengzhou, Henan, China,[3]Shenyou Bio, Zhengzhou, Henan, China

Background: Early cancer detection and timely diagnosis are critical for improving patient outcomes and reducing healthcare costs. OncoSeek is an AI-driven, low-cost multi-cancer early detection (MCED) assay integrating seven protein tumor markers (PTMs) with clinical data, previously demonstrating 58.4% sensitivity, 92.0% specificity, and 70.6% tissue-of-origin accuracy in over 15,000 participants. Here, we present OncoSeek 2.0, an upgraded version that incorporates three additional PTMs to enhance the detection of prostate, lung, and squamous cell carcinomas, and evaluate its performance in validation cohorts and its expanded use for assisting cancer diagnosis in patients with tissue masses.

Methods: OncoSeek 2.0 retained the original machine learning framework with expanded biomarker inputs. MCED performance was assessed in a retrospective cohort including 722 cancer and 355 non-cancer subjects. To further evaluate clinical utility, a prospective cohort of 732 patients with tissue masses, clinically deemed likely malignant and scheduled for surgery, was analyzed to assess the assay's effectiveness in aiding cancer diagnosis.

Results: Compared with OncoSeek 1.0, OncoSeek 2.0 achieved a higher AUC (0.934 vs. 0.888) and improved sensitivity from 70.4% to 83.5% at 90.1% specificity across 15 prespecified cancer types collectively accounting for 76.5% of global cancer mortality. Sensitivity gains were notable in lung (79.9% → 89.6%), prostate (58.8% → 94.1%), cervical (44.4% → 72.2%), and esophageal (41.6% → 64.4%) cancers. In the prospective tissue-mass cohort, OncoSeek 2.0 correctly identified 573 of 682 confirmed cancers (84.0% sensitivity). Across the same 15 cancer types, sensitivities exceeded 80% in 12, with slightly lower values observed in ovary (76.9%), breast (72.3%), and lymphoma (63.6%). Among the remaining 50 patients with pathologically confirmed benign lesions, 28 (56.0%) were correctly classified as non-cancer, potentially sparing them from unnecessary surgical procedures.

Conclusion: OncoSeek 2.0 significantly improves sensitivity while maintaining high specificity and affordability (~$30 reagent cost per test). The upgraded assay strengthens its utility for multi-cancer early detection and demonstrates validated diagnostic value in clinically suspected cancer cases. Its ability to correctly identify 84% of confirmed cancer cases in a tissue-mass cohort demonstrates meaningful diagnostic support to help prioritize patients needing confirmatory procedures. These findings position OncoSeek 2.0 as a practical and scalable solution for both population-level cancer early detection and real-world diagnostic support, particularly for cancers without USPSTF-recommended screening modalities or established non-invasive diagnostic pathways, where surgical procedures are commonly needed for definitive diagnosis.

#1097 Performance of a blood-based screening test for the early detection of advanced precancerous lesions.

Prashanthi Natarajan, Preethi Srinivasan, Hsiao-Yun Huang, Alan Selewa, Rebecca Panitch, Caitlin Guccione, Fatemeh Almodaresi, Jayashree Joshi, Su Maw, Misagh Kordi, Yunshu Song, Yu Lin, Osama Khan, Breeana L. Mitchell, Adham Jurdi, Minetta C. Liu, Johannes G. Reiter, Trupti Kawli, Matthew Rabinowitz, Alexey Aleshin

Natera, Inc., Austin, TX

Current colorectal cancer (CRC) screening methodologies, such as colonoscopy and stool-based tests, have shown substantial efficacy but are often constrained by low patient compliance. A minimally-invasive blood-based test can enhance screening adherence. Previous studies evaluating the performance of our blood-based CRC screening test demonstrated high sensitivity and specificity; however these studies did not include precursor or early cancer lesions, the identification of which is critical for cancer prevention. Here, we evaluate the performance of a blood-based early cancer detection (ECD) screening test for advanced colorectal neoplasia (ACN) with a focus on advanced precancerous lesion (APL) performance in an average-risk population. A targeted panel for CRC screening composed of differentially methylated genomic regions was developed, and a machine-learning model was trained to classify patient samples into cancer-free and ACN based on observed differential methylation patterns in circulating cell-free DNA. This ECD screening blood test was applied to plasma samples from 92 sequentially collected subjects with APL and a representative cohort of 366 healthy individuals. These participants were drawn from the first 1400 cases of the ongoing, prospective, PROCEED-CRC clinical study (NCT06620627), designed for the collection of clinically annotated biospecimens from participants ≥40 years old who underwent asymptomatic colonoscopy screening. Performance of the blood-based ECD test was assessed based on its sensitivity to detect APL and specificity across different APL types and age groups. Based on colonoscopy findings from the 458 PROCEED-CRC study participants included in the study (median age: 57 years, range: 43-75 years), 79.9% (n=366) were cancer-free and 20.1% (n=92) had APL. Among those with APL, 6.5% (n=6) had polyps with high-grade dysplasia. Mean sensitivity across all subtypes of APL was 22.5% (CI: 15.4%-32.4%). Median size of APL lesions was 12 mm and 99% of APL were <30mm in size. Sensitivity of APL at 5-9 mm was 20% and sensitivity increased with increasing size. Overall specificity was 91.5% (CI: 88.2%-94%). We did not observe deterioration of specificity with increasing age (p-value n.s., $p > 0.05$). APL detection is critical for intercepting CRC before it develops. The performance reported here highlights the strong potential of minimally invasive, blood-based early detection assays in identifying ACNs, including APLs, with robust performance across the screening participant ages. Notably, most APLs included in this study were <30 mm, representing a challenging set of lesion sizes to detect. Detection of CRC and APL will be further evaluated in the ongoing FIND clinical study (NCT07046585).

#1098 Discrete precancer subtypes and biomarkers of cancer progression identified with spatiotemporal analysis of CDH1-driven diffuse gastric cancer.

Jeremy L. Davis[1], Amber Famiglietti[2], Yunhe Liu[3], Rachael Belcher[1], Sun A Kim[4], Baktiar O. Karim[5], Donna Butcher[5], Linghua Wang[3]

[1]University of Maryland School of Medicine, Baltimore, MD,[2]Department of Surgery, Georgetown University, Washington, DC,[3]UT MD Anderson Cancer Center, Houston, TX,[4]Laboratory of Pathology, National Cancer Institute, Baltimore, MD,[5]Frederick National Laboratory for Cancer Research, Frederick, MD

Introduction: Diffuse gastric cancer (DGC) is a sub-type of gastric adenocarcinoma for which early detection is uncommon. Early-stage gastric signet ring cell (SRC) lesions are ubiquitous in patients with germline CDH1 variants. Though SRC lesions appear to be non-obligate precursors of DGC, the drivers of SRC progression to DGC remain unknown. We sought to derive transcriptomic gene signatures associated with gastric SRC and advanced DGC.

Methods: We employed a single-cell spatial transcriptomic analysis (10X Genomics Xenium) of both early SRC (pT1a) and advanced DGC (≥T2) from 18 patients with germline *CDH1* variants. Spatially resolved analyses were conducted on 42 fields of view derived from gastric biopsies and total gastrectomy specimens that were analyzed according to depth of cancer cell invasion. Biomarkers of SRC precancer progression were identified within discrete epithelial cell subpopulations according to differentially expressed gene profiles. Immunohistochemistry was performed to correlate protein expression with mRNA markers of interest.

Results: Advanced DGC exhibited three distinct transcriptomic clusters based on depth of tumor invasion into the mucosa, submucosa and muscularis propria layers and clustered distinctly from early SRC precursor lesions. SRC phenotype varied based on depth of invasion of the gastric mucosa; SRC1 (superficial) and SRC2 (deep). Multi-modal segmentation of SRC1 and SRC2 subtypes within the SRC precancer cluster demonstrated distinct, spatially resolved transcriptomic profiles. Pathway analysis showed potential functional divergence between SRC1 and SRC2, such that SRC2 possessed a migratory and proliferative phenotype whereas SRC1 displayed loss of cell adhesion and epithelial architecture. We observed three differentially expressed genes with increased expression according to depth of tumor invasion: clusterin (CLU*)*, eukaryotic translation initiation factor 3 (EIF3E), and annexin A2 (ANXA2). CLU, a known regulator of epithelial-to-mesenchymal transition and apoptosis, was over-expressed both in advanced SRC lesions ($p<0.05$) compared to early SRC lesions and within SRC lesions compared to gastric epithelium ($p=0.03$). Clusterin protein expression was quantitatively greater in SRC lesions compared to unaffected gastric epithelium, with more intense staining associated with depth of tumor cell invasion in advanced DGC.

Conclusions: Signet ring cell precancers that originate due to *CDH1* loss-of-function mutations have discrete subtypes based on cell phenotype, depth of mucosal invasion, and spatial transcriptomic profile. Clusterin appears to be a biomarker of early SRC lesions and correlates with depth of gastric cancer invasion. These results may support novel strategies for cancer interception and increase our knowledge of diffuse gastric precancers.

#1099 The RNA editing enzyme ADAR1 is involved in carcinogenesis associated with intraductal papillary mucinous neoplasm.

Masashi Kayano, Kunitoshi Shigeyasu, Kazuya Moriwake, Toshiaki Takahashi, Eiki Miyake, Yuhei Kondo, Yuya Sakurai, Shunsuke Nakamura, Masafumi Takahashi, Kaori Nitta, Kazuya Yasui, Tomokazu Fuji, Kosei Takagi, Hiroshi Tazawa, Toshiyoshi Fujiwara

Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama, Japan

Background: Intraductal papillary mucinous neoplasm (IPMN) is a mucin-producing subtype of the pancreatic cyst lesions arising from the pancreatic duct system. IPMN is a potential precursor of pancreatic cancer and surgical decision-making is guided by “high-risk stigmata” and “worrisome features” according to international evidence-based Kyoto guidelines for the management of IPMN. However, these criteria can be insufficient for the prediction of invasive intraductal papillary mucinous carcinoma (IPMC). Adenosine-to-inosine (A-to-I) RNA editing, which is regulated by adenosine deaminase acting on RNA (ADAR) was reported to induce the posttranscriptional modification of oncogenes. However, the significance of RNA editing in IPMN remains unclear. We investigated whether ADAR1 expression increases with pathological progression in IPMN and whether higher expression is associated with adverse clinical outcomes.
Methods: We analyzed gene profiling dataset from IPMN tissue samples in silico discovery from GEO (Gene Expression Omnibus). AS a clinical validation analysis, we analyzed 102 IPMN patients who received surgical resection in our institution. Functional analysis was evaluated in ASAN-PaCa cell lines using small interfering RNA (siRNA) transfection.
Results: The mRNA expression data were obtained from a publicly available GEO dataset, comprising samples from 7 normal main pancreatic ducts, 6 low-grade intraductal papillary mucinous neoplasms (LGD-IPMNs), 7 high-grade IPMNs (HGD-IPMNs), and 3 invasive intraductal papillary mucinous carcinomas (IPMCs). Compared to normal epithelial cells, the expression of ADAR1 were elevated in LGD-IPMNs, HGD-IPMNs, and invasive IPMC samples ($p=0.0383$, 0.0383, and 0.0227, respectively). Among the participants in our hospital, 44 had LGD-IPMNs, 29 had HGD-IPMNs, and 29 had invasive IPMC. ADAR1 expression was significantly higher in the HGD-IPMNs and invasive IPMCs than in the LGD-IPMNs ($p<0.01$ for both). We observed a shorter OS and DFS in the high ADAR1 group (OS: $p = 0.0279$, DFS: $p = 0.0163$). In univariate Cox regression, high ADAR1 expression was significantly associated with shorter OS and DFS (OS HR=2.63, $p=0.034$; DFS HR=2.83, $p=0.021$). In multivariate analysis, ADAR1 remained an independent prognostic factor for both OS and DFS (OS HR=2.45, $p=0.042$; DFS HR=2.66, $p=0.033$). In comparison with control cells, ADAR1 knockdown cells exhibited significantly reduced proliferative activity ($p<0.01$) and decreased invasion potential, indicating that ADAR1 contributes to both cell growth and invasiveness in vitro.
Conclusion: IPMC showed frequent ADAR1 overexpression, and higher ADAR1 expression was associated with poorer prognosis. These findings suggest that elevated ADAR1 expression may be involved in IPMN carcinogenesis and could potentially serve as a biomarker for clinical application.

#1100 Epigenetic profiling identifies markers of aggressive cancer subtype using a targeted methylation-based multi-cancer early detection (MCED) blood test.

Kezhong Chen[1], Jian Huang[2], Dahong Zhang[3], Shu Wang[4], Hongxu Liu[5], Wenzhao Zhong[6], Xiangnan Li[7], Qiang Zhang[5], Zhigao Li[8], Jiaqi Liu[9], Ziqing Tian[10], Fei Zhou[11], Gongsheng Jin[12], Xudong Xiang[13], Zhigang Li[14], Hui Xie[15], Ya Wei[16], Guochun Zhang[17], Guolin Ye[18], Ming Cai[19], Junfeng Wang[8], Yan Zhang[20], Chao Cheng[21], Hefei Li[22], Desong Yang[23], Jianhong Lian[24], Sheng Huang[25], Tao Xu[26], Zengjun Wang[27], Xi Guo[28], Zhuowei Liu[29], Minfeng Chen[30], Yang Wang[31], **Yue An**[31], Yanzhan Yang[31], Min Li[31], Jing Liu[31], Baoliang Zhu[31], Yonghui Li[31], Xiaohui Wu[31], Fan Yang[1], Jun Wang[1]

Ltd., Shanghai, China

Background: Previous MCED studies have shown differences in detection performance across different aggressiveness cancer subtypes. However, the methylation profiles and ctDNA shedding patterns across different aggressiveness subtypes have not been analyzed. We systematically compared cell-free DNA (cfDNA) tumor fraction and methylation profiles across aggressiveness subtypes in three cancers to identify epigenetic biomarkers that differentiate tumor aggressiveness.
Methods: Blood samples from a case-control study (NCT06217900) including 757 cancer cases were analyzed using a targeted methylation-based MCED test. We compared cfDNA tumor fraction and methylation profiles between aggressiveness subtypes, stage-matched small cell lung cancer (SCLC) (n=137) versus (vs) non-small cell lung cancer (NSCLC) (n=137), stage I invasive lung adenocarcinoma (IAC) (n=81) vs minimally invasive adenocarcinoma (MIA) (n=81), triple-negative breast cancer (TNBC) (n=151) vs non-TNBC (n=151), and intermediate/high-grade prostate cancer (Gleason Grade Group[GG] 2-5)(n=14) vs low-grade prostate cancer(GG1)(n=6). Tumor fraction was estimated using zero-inflated Negative Binomial model based on the distribution of methylation signals, and methylation profiles were assessed by calculating methylated/unmethylated (M/U) ratios between different aggressiveness subtypes. Marker comparisons were conducted using the Mann-Whitney U test with multiple testing corrections.
Results: The sensitivity is higher in more aggressive subtypes (lung cancer 93.73% vs SCLC 99.27%; breast cancer 70.76% vs TNBC 81.46%; prostate cancer 40% vs intermediate and high-grad prostate cancer 42.86%). In lung cancer, SCLC exhibited a significantly higher cfDNA tumor fraction than NSCLC (Wilcoxon $p = 2.24\times10^{-24}$), with 41,136 markers (79.18% hypomethylated) showing elevated M/U ratios. In stage I lung adenocarcinoma, IAC demonstrated a higher cfDNA tumor fraction (Wilcoxon $p = 2.55\times10^{-6}$) and systematic methylation differences compared to MIA. In breast cancer, TNBC had a significantly higher cfDNA tumor fraction than non-TNBC (Wilcoxon $p = 2.55\times10^{-6}$), with 25,717 markers (80.32% hypomethylated) displaying increased M/U ratios. Among prostate cancers of the same stage, GG2-5 cases exhibited higher cfDNA tumor fraction (Wilcoxon $p = 0.038$) and systematic methylation alterations compared to GG1.
Conclusion: Aggressive tumor subtypes consistently display elevated cfDNA tumor fraction and characteristic methylation profiles marked by increased M/U ratios. These findings suggest cfDNA methylation patterns are promising epigenetic biomarkers for distinguishing tumor aggressiveness, potentially improving cancer screening precision and reducing overdiagnosis.

#1101 A novel method for tumor fraction estimation using methylation sequencing data.

Daokun Sun, Yu Sun, Alex Robertson, Lee A. Albacker, Chang Xu

Computational Biology, Foundation Medicine, Cambridge, MA

Introduction: Accurate estimation of tumor fraction in cell-free DNA (cfDNA) is critical for molecular residual disease monitoring and early cancer detection. Current approaches, such as maximum somatic allele frequency, i.e., MSAF, rely on the presence of detectable somatic mutations, limiting their sensitivity in samples with low tumor burden or shallow sequencing depth. Moreover, these approaches are susceptible to bias from clonal hematopoiesis and uneven mutation distribution, which can compromise the accuracy of tumor fraction (TF) estimation. DNA methylation signatures offer a promising avenue due to their abundance, consistency, and robustness. However, current methods to harness this information for tumor fraction estimation remain suboptimal.

Methods: We developed a new and tumor-naive computational framework that leverages DNA methylation signatures to quantify tumor-derived DNA with markedly high analytical sensitivity. The approach integrates pre-selected methylation markers and weighted linear regression to quantify tumor-derived DNA to a minimal detection threshold. Our machine learning-based method combines tumor- and normal-specific prior methylation frequencies and target coverage information to achieve a more reproducible and reliable estimation of tumor fraction. The method was developed using in-house clinical samples, and its performance was benchmarked against mutation-based ctDNA tumor fraction from FoundationOne Liquid CDx (F1LCDx). Besides, *in silico* and *in vitro* dilutions were used to assess accuracy and sensitivity at low tumor fractions.

Results: Our method demonstrated a limit of detection reaching the 0.01% TF, with strong accuracy maintained down to 0.1% in both *in vitro* and *in silico* dilution series. *In vitro* dilution experiments demonstrated a Spearman correlation of 0.86 and a Pearson correlation of 0.88 on $\log_{10}$-transformed data, with median fold changes of 0.84 at 0.1% TF and 3.76 at 0.01% TF. Performance was further supported by *in silico* dilution analyses, yielding a Spearman correlation of 0.98 and Pearson correlation of 0.97 on $\log_{10}$-transformed data. Additionally, when benchmarked against ctDNA TF estimates from F1LCDx, our method achieved a Spearman correlation of 0.88, a Pearson correlation of 0.90, and a median fold change of 0.91.

Conclusions: We present a novel methylation-based approach for TF estimation in cfDNA. This approach enables highly sensitive and accurate TF estimation, particularly at low TFs, highlighting its potential utility in molecular residual disease detection, early cancer detection or treatment response monitoring. This approach offers a powerful tool for advancing liquid biopsy applications in cancer diagnostics and clinical management, with validation in larger cohorts ongoing.

#1102 Uncovering early transcriptional alterations in lung cancer: Preliminary insights from the Boston Lung Trans-omics (BOLT) Initiative.

Yu Chen Zhao[1], Li Su[2], Lorelei A. Mucci[1], Timothy R. Rebbeck[3], Yi Li[4], David C. Christiani[5]

[1]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA,[2]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA,[3]Division of Population Sciences, Dana-Farber Cancer Institute, Boston, MA,[4]Department of Biostatistics, University of Michigan Medical School, Ann Arbor, MI,[5]Department of Medicine, Harvard Medical School, Boston, MA

Lung cancer's high mortality is driven by advanced-stage diagnoses and high recurrence rates. Existing genomic markers lack sensitivity for early detection and predicting recurrence, presenting ongoing clinical challenges. We introduce the Boston Lung Trans-omics (BOLT) Initiative, an early-stage sub-cohort of the Boston Lung Cancer Study with 1446 paired tumor/adjacent-normal bulk RNA-sequenced tissues from 723 NSCLC patients. We performed paired differential gene expression analysis between tumor and adjacent normal tissues using limma-voom, adjusting for batch effects and patient ID to account for inter-individual confounding. Statistically significant differentially expressed genes were defined as genes with FDR-adjusted $p<0.05$ and log2 change $|LFC|>2$. To emphasize biological relevance and minimize false positives, we performed pathway enrichment analysis with the Gene-set Enrichment Analysis software using curated pathway data retrieved from the Molecular Signature Database, Broad Institute. We then applied weighted gene co-expression network analysis (WGCNA) to the top 5000 most variable genes across all samples to identify gene modules and assessed module-trait associations. We identified 738 significant DEGs in the paired tumor/normal comparison. Among these, 387 (52%) were upregulated in tumor compared to normal lung tissues. *AGER* of the receptor for advanced glycation end-products (RAGE) pathway was the top downregulated gene in tumor compared to adjacent normal tissues ($FDR=3.3*10^{-156}$; LFC=-4.4) while *SPP1* of the PI3K/mTORC1 signaling and glycolysis pathways was the top upregulated gene in tumor compare to normal lung tissues ($FDR=3.6*10^{-134}$; LFC=4.8). Pathway enrichment analysis revealed that genes upregulated in tumors compared to normal tissues were most strongly associated with MYC target activation, MTORC1 signaling, glycolysis, and inflammatory responses. Modules defined by WGCNA recapitulated tumor/normal distinctions, suggesting system-level gene programs underlying early tumorigenesis.These preliminary insights from BOLT reveal consistent early transcriptional differences between NSCLC tumors and adjacent normal tissues characterized by upregulation of both novel and known oncogenic pathways and immune/inflammatory responses. Co-expression networks support the tumor/normal status as the principal driver of gene modules at early stages of NSCLC. Modeling time to recurrence remains a critical yet understudied area in lung cancer research. We will develop and validate predictive gene expression signatures and co-expression networks in BOLT to stratify early-stage NSCLC patients by recurrence risk and anticipated time to recurrence following primary treatment or neoadjuvant therapies.

#1103 The genomic landscape of melanoma-prone skin.

Katie Lee[1], Yung-Ching Kao[1], Darren Smit[1], Marietta K. Saldias Montivero[2], Joshua Jay Levy[3], Brock C. Christensen[2], Quan Nguyen[4], H. Peter Soyer[1], **Mitchell S. Stark**[1]

[1]Frazer Institute, University of Queensland, Brisbane, Australia,[2]Dartmouth Geisel School of Medicine, Lebanon, NH,[3]Cedars-Sinai Medical Center, Los Angeles, CA,[4]QIMR Berghofer Medical Research Institute, Herston, Australia

Normal skin carries a high burden of somatic mutations, yet this does not explain where a melanoma will form. From 3D total body photography studies of high-risk individuals, we have observed a trend toward melanoma excisions clustered in regions on the back. This posed the question - are these melanoma-prone skin regions? The PhotoMelanoma Study aimed to determine the genomic architecture of the microenvironment that favours melanoma formation. We assessed photodamaged skin adjacent to an invasive melanoma excision, photodamaged skin 5cm away, and photoprotected skin from the same individual. To address this, we invited 19 study participants from our high-risk melanoma cohort (n=300+) to donate three biopsies for genomic analysis. Firstly, we derived a single-cell whole transcriptome library to determine cell types present at each biopsy site. Next, each biopsy was evaluated for hotspot mutations via the ultra-sensitive droplet digital PCR system; somatic mutation burden, mutation signature, and copy number aberrations via deep panel sequencing of 300+ cancer-related genes (PanelSeq), and global methylation profiling of 900K loci. In brief - as expected, PanelSeq showed UV-related mutation signatures (SBS7) with levels similar the across sun-exposed sites, whereas signature SBS2 (APOBEC activity) was enriched (67%) at the scar-adjacent site, with the number of mutations associated with SBS2 reaching significance (Wilcoxon matched-pair; p=0.015). *BRAF* V600E mutations were significantly enriched near prior melanoma and were present in all sites including sun-protected. Global DNA methylation profiling identified 2000+ loci differentially methylated between photodamaged and photoprotected sites, including HOX family members, and 70 loci were differentially methyated between prior melanoma vs 5cm away, indicating that even with the same level of UV damage, skin sites may be more melanoma-prone. These data are part of a comprehensive genomic and transcriptomic profile to characterise melanocytes, naevi, and the microenvironment to identify the molecular triggers for melanoma formation. In sum, we have uncovered enrichment of somatic events at melanoma excision sites that may provide the soil for de novo melanoma development.

#1104 Detection of bladder cancer via urinary DNA mutation and methylation using modified qPCR.

Di Jin[1], **Roy Tan**[2], Ruiyun Zhang[1], Haige Chen[1]

[1]Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China,[2]Biovuetech Co Ltd, Shanghai, China

Background: Cystoscopy is the gold standard for diagnosing and monitoring bladder cancer (BC), but it is invasive and painful. Previous studies on urine biopsy have shown that urinary DNA mutation and methylation markers are promising auxiliary diagnostic methods; however, current PCR-based methods for detecting gene mutations or methylations are not accurate enough. This shortcoming highlights the urgent need for a more precise DNA marker detection technology and an auxiliary diagnostic method for bladder cancer.
Methods: We developed MTPD-PCR, a highly specific PCR-based detection method that uses dideoxyribonucleic acid (ddNA)-blocking PCR primers and pyrophosphorolysis-activated polymerization to prevent artificially erroneous amplification products that may be introduced by conventional PCR primers, achieving stable detection of mutations with an abundance of 0.01%. We used this method to integrate bladder cancer DNA mutation and methylation biomarkers for non-invasive detection of bladder cancer in urine samples. We conducted a prospective study in a two-center cohort from two tertiary hospitals in China, including 302 patients with histologically confirmed bladder cancer and 200 non-bladder cancer controls. Using cystoscopy combined with histopathological examination as the reference standard, diagnostic accuracy parameters (sensitivity, specificity, and accuracy) were calculated.
Results: The study cohort included 302 patients with bladder cancer, of which 114 (37.8%) were low-grade, 175 (58.0%) were high-grade, and 13 (4.2%) were ungraded. Evaluation of 489 analyzable samples showed an overall sensitivity of 85.9%, a specificity of 95.8% (100% in the healthy control group), and a diagnostic accuracy of 89.8%. The positive predictive value and negative predictive value were 97.0% and 81.3%, respectively. For different non-bladder cancer controls, the sensitivity was 85.95%, and the specificity ranged from 90% to 100%. Clinically significant, the method achieved a sensitivity of 70.3% in 91 early-stage tumors and maintained a sensitivity of 81.7% in a validation set of 191 T1/Tis/Ta stage tumors, indicating good performance across different disease stages.
Conclusion: This method demonstrated good performance in a cohort of 489 patients, exhibiting high sensitivity and accuracy. This non-invasive molecular detection method can detect bladder cancer at an early stage and serve as a treatment reference, especially suitable for cases with low DNA content, potentially reducing the burden of cystoscopy and avoiding unnecessary secondary transurethral resection of bladder tumors.

#1105 Nestin expression is prevalent but highly variable in human cancer: A tissue microarray study involving 5,917 cancers from 107 tumor entities.

Clara von Bargen[1], Muriel Torzewski[1], Fiete Gehrisch[1], Anne Menz[1], Florian Lutz[1], Viktoria Chirico[1], Florian Viehweger[1], David Dum[1], Ria Schlichter[1], Andrea Hinsch[1], Christoph Fraune[1], Chrisitan Bernreuther[1], Seyma Buyucek[1], Martina Kluth[1], Claudia Hube-Magg[1], Georgia Makrypidi-Fraune[1], Nina Schraps[1], Katharina Moller[1], Andreas M Luebke[1], Patrick Lekok[1], Guido Sauter[1], Maximilian Lennartz[1], Till Clauditz[1], Andreas H Marx[2], Ronald Simon[1], Eike Burandt[1], Natalia Gorbokon[1], Maria Chrisitna Tsourlakis[1], Sarah Minner[1], Till Krech[1], Morton Freytag[1], Viktor Reiswich[1], Stefan Steurer[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Academic Hospital Fuerth, Furth, Germany

Nestin (neuroepithelial stem cell protein) is a class VI intermediate filament protein which is transiently expressed in subsets of precursor cells of the peripheral and the central nervous system, muscle cells and other tissues during development. Upon differentiation, nestin expression becomes replaced by tissue-specific intermediate filament but it can be reinduced in the adult during pathological situations. In cancer, nestin was shown to promote tumor cell proliferation, migration, invasion, and angiogenesis. To determine the prevalence of nestin in cancer, nestin expression was analyzed by immunohistochemistry on tissue microarrays containing 5,917 samples from 107 different tumor types. Nestin positivity occurred in 749 (15.7%) of the 4,775 analyzable tumors, and was considered weak in 8.7%, moderate in 4.3%, and strong in 2.7% of cases. Of 107 tumor entities, 70 (65.4%) showed nestin expression in at least one case, and 22 (20.6%) included at least one case with strong nestin positivity. Highest rates tumors with nestin positivity occurred in pleomorphic adenoma of the parotid gland (100%), gastrointestinal stromal tumor (GIST; 93.8%), metastatic malignant melanoma (75.0%), pheochromocytoma (69.8%), leiomyosarcoma (47.4%), cholangiocarcinoma (40.6%), leiomyoma(40.0%), yolk sac tumor (34.1%), squamous cell carcinoma of the vagina (31.0%), the pharynx (27.3%), vulva (25.6%), anal canal (25.5%), oral cavity (24.7%), penis (19.4%), skin (14.7%), larynx (14.5%), cervix (10.8%), esophagus (9.5%), and the urinary bladder (9.5%), serous carcinoma of the ovary (26.7%), embryonal carcinoma of the testis (26.3%), adenocarcinoma of the cervix (26.1%), endometrioid endometrial carcinoma (22.1%), carcinosarcoma of the uterus(20.8%), pancreatic neuroendocrine tumor (20.7%), muscle-invasive urothelial carcinoma (18.3%), prostatic adenocarcinoma (17.2%), gastric adenocarcinoma of the intestinal type (16.2%), adenocarcinoma of the esophagus(15.1%), urothelial carcinoma of the kidney pelvis (14.3%), and in mucinous carcinoma of the ovary (14.3%). The largest cohort of tumors from one entity included 1,186 evaluable invasive breast cancers of no special type (NST). In these tumors, nestin staining was negative in 94.1%, weak in 3.9%, moderate in 1.3%, and strong in 0.8% of cases. A comparison with tumor phenotype revealed that detectable nestin expression was associated with advanced pT stage ($p=0.0103$), high grade of malignancy ($p<0.0001$), absence of estrogen ($p=0.0054$) and progesterone ($p=0.0051$) receptor expression as well as with “triple negativity” ($p=0.0028$). The data from this study provide an overview of nestin expression in human cancer and demonstrate that increased nestin levels can occur in many different tumor entities. At least in breast cancer NST, nestin positivity goes along with increased cancer aggressiveness.

#1106 Rapid identification of comprehensive multi-omic protein and RNA biomarkers on a single FFPE tissue section using a novel integrated nCounter® workflow.

Lakshmi Chandramohan[1], Kirsteen Maclean[1], Quratul Ain[1], Brigitte Lovell[1], Lisa Duncan[1], Sergio Hernandez[1], Christina Bailey[2], Michael Bailey[2], Patrick Danaher[2], Wei Yang[2], Shanshen He[2], Joseph M. Beechem[2]

[1]NeoGenomics, Fort Myers, FL,[2]Bruker Spatial Biology, Bothell, WA

Background: Biomarker detection approaches capable of rapid identification and quantification of both transcriptomic and proteomic datasets from the same tissue section have become increasingly valuable for investigating the highly complex biology of tumors. Unfortunately, today, the main challenges of true multi-omic analysis of protein and RNA on e.g. FFPE slides are the degradation and cross-linking of molecules from formalin fixation and storage, leading to variable and low-quality nucleic acids and proteins. This degradation, combined with inherent sample heterogeneity, makes it difficult to extract high yields of molecules and requires sophisticated bioinformatic methods to integrate resulting complex and often noisy multi-omics data. To address this need, we have developed and validated a novel workflow using the nCounter® Analysis System that enables simultaneous quantification of mRNA and protein targets from the same slide. This 'multiomics made simple' approach is uniquely enabled by Bruker Spatial Biology's streamlined workflow and direct hybridization chemistry, now accessible and validated through NeoGenomics.
Methods: The core innovation of this workflow lies in its ability to measure both mRNA and protein signal from a single FFPE slide as part of a simple 3-step protocol. Specifically, the assay leverages the harmonization of traditional nCounter mRNA Panels such as the PanCancer IO 360™ panel that measures up to 800 gene expression targets alongside newly designed and optimized Protein Panels capable of analyzing up to 800 proteins within a unified protocol. To validate performance specifications, NeoGenomics, a leading clinical research organization, evaluated this multi-omics application across diverse FFPE sample types, including breast, lung, colorectal, bladder, and urothelial tumors.
Results: Across all tissue types, the streamlined assay demonstrated high specificity, strong correlation between replicate runs, and excellent dynamic range for both mRNA and protein analytes. These results confirm the platform's utility across a wide range of tumor biology contexts and support its adoption for biomarker discovery, target validation, and mechanism-of-action studies. By delivering combined mRNA and protein profiling from a single tissue section, the nCounter platform enables rapid identification of tumor-specific signatures, strengthening biological interpretation and simplifying translational workflow complexity.
Conclusions: This newly validated application, now available through NeoGenomics, empowers research teams to unlock the synergistic power of true tissue multiomics through a simple, scalable, and reproducible workflow—making same-slide mRNA+Protein analysis from FFPE tissue a practical reality for pharma and translational research.

#1107 Development and performance of a multiomics lung cancer screening blood test.

Ofer Shapira, Alexander F. Lovejoy, Alvaro Gonzalez, Urvee Desai, Thomas Royce, Gurnit Atwal, Ian Bast, Eric Beraut, Alexandra Buckley, Austin Cauwels, Peter Combs, Nicholas Eisele, G Parker Flowers, Lourdes Gomez, Rebecca Gupte, Johnnie Hahm, Teng-Kuei Hsu, Saiful Islam, Poorval Joshi, Amanda Kahn-Kirby, Phuong Thuy Menchavez, Erene Mina, Jinesh Niroula, Cameron Pospisil, Sodany Son, Rashmi Sriram, Peter Ulz, Russell Williams, Rui Yang, Wilson Zhang, Marian Navratil, C Jimmy Lin, Tanya Moreno, Richard Bourgon

Freenome Holdings, Inc., South San Francisco, CA

Lung cancer is the leading cause of cancer death in the US. Early detection is crucial for improving survival rates, yet only 18% of eligible high-risk adults (aged 50-80 with ≥20 pack-years of cigarette smoking history) are up to date with recommended annual low-dose computed tomography screening. Non-invasive blood tests could increase screening participation. Here, we evaluate a multiomics approach for lung cancer detection in patients in the intended use population (IUP). Our test uses base-resolution methylation sequencing of circulating cell-free DNA (cfDNA), as previously described, and plasma protein immunoassays. An artificial intelligence/machine learning classifier was trained on tissue (n = 136) and plasma (n = 6,716) samples. Accuracy was evaluated in a cohort of 673 plasma samples, including lung cancer cases (n = 363) and cancer-negative controls (n = 310) from the IUP. This cohort encompassed all cancer stages and three major subtypes — adenocarcinoma, squamous cell carcinoma and small-cell lung cancer (SCLC) — and its age and pack-year smoking history distributions reflected the IUP. Two specificities were considered: 50% (prioritizing sensitivity) and 75% (prioritizing specificity). Reported sensitivities were adjusted for stage and subtype to address differences between the evaluation cohort and literature-reported distributions for the IUP. (Adenocarcinoma and squamous data were weighted per stage and subtype; due to small sample size, SCLC data were weighted only per subtype.) 95% confidence intervals (CIs) were computed via Wilson's method. The multiomics test had an IUP-adjusted sensitivity of 90.7% (CI: 86.8 - 93.7%) at 50% specificity and 80.4% (75.4 - 84.7%) at 75% specificity. Results for a methylation-only test were 85.8% (81.3 - 89.5%) and 78.2% (73.1 - 82.8%), respectively. The multiomics test showed higher sensitivity at both specificities but the differences were not statistically significant. At 50% specificity, the multiomics test had adjusted sensitivity for stages I through IV of 77.7% (73.3 - 89.0%), 95.2% (85.0 - 98.1%), 98.8% (93.6 - 99.7%) and 97.1% (90.7 - 98.9%), respectively. Corresponding results at 75% specificity were 63.5% (51.9 - 71.6%), 89.8% (76.6 - 94.1%), 90.9% (85.0 - 96.3%) and 95.9% (89.8 - 98.6%). At 50% specificity, the multiomics test's adjusted sensitivity for adenocarcinoma and squamous cell carcinoma was 88.7% (81.4 - 92.0%) and 91.1% (84.3 - 96.1%), respectively; nominal sensitivity for SCLC was 97.1% (85.1 - 99.5%). Corresponding results at 75% specificity were 73.0% (63.1 - 77.6%), 88.6% (81.6 - 94.6%) and 91.2% (77.0 - 97.0%). Our multiomics platform demonstrated promising initial performance for blood-based lung cancer detection. The complementary nature of cfDNA methylation and plasma protein may enhance performance relative to a methylation-only approach, and this will be further assessed in a future study with a previously unseen evaluation cohort.

#1108 Performance of an optimized methylation-protein multi-cancer early detection (MCED) test classifier.

Vladimir G. Gainullin[1], Melissa Gray[1], Madhav Kumar[1], Stephen Luebker[1], Amy Lehman[1], Darl D. Flake[1], Avinash Shanmugam[1], Kevin Cortes[1], Emily Chang[1], Philip J. Uren[2], Amin Mazloom[2], Jorge Garces[1], Gerard A. Silvestri[3], David W. Chesla[4], Robert W. Given[5], Tomasz M. Beer[1], **Frank Diehl**[2]

[1]Exact Sciences Corp., Madison, WI,[2]Exact Sciences Corp., La Jolla, CA,[3]Medical University of South Carolina, Charleston, SC,[4]Corewell Health, Grand Rapids, MI,[5]Urology of Virginia, Virginia Beach, VA

Background: Multi-cancer early detection (MCED) tests can detect several cancer types and stages. We previously developed a methylation and protein (MP V1) MCED classifier with a target specificity of ≥98.0% (Gainullin, medRxiv, 2025.08.24.25334244). Herein, we describe a refined MP V2 classifier that was identified based on the evaluation of classifier model architectures that improved performance.

Methods: Compared to MP V1, the MP V2 classifier was trained to achieve increased early-stage sensitivity at a case-control target specificity of ≥97.0%. MP V2 classifier architecture was developed using a training set (654 cancer; 2,373 non-cancer) partitioned into 5-fold cross validation and mini-holdout sets. Locked candidate models were compared using an independent mini-holdout test set (110 cancer; 509 non-cancer). MP V1 and MP V2 classifier performance were compared using a previously described test set (729 cancer; 2,434 non-cancer), and MP V2 performance was also evaluated in an independent clinical validation test set (324 cancer; 800 non-cancer) that was designed to more closely mimic the intended use population.

Results: Compared to MP V1, MP V2 (specificity of 97.4%) demonstrated a 7.3% increase in overall sensitivity, with sensitivity increases of 7.6%, 9.2%, 8.3%, 8.0%, 3.8%, and 13.3% for stages I, II, stages I/II, III, IV, and unknown, respectively, in the test set (Table 1). In the independent validation set, MP V2 (specificity 97.4%; 95% CI: 96.0-98.3%) overall sensitivity was 41.4%, with sensitivities of 16.0%, 31.3%, 22.8%, 52.9%, and 83.1% for stages I, II, stages I/II, III and IV, respectively. Excluding breast and prostate cancers, MP V2 overall sensitivity was 55.6%, with sensitivities of 26.8%, 42.9%, 34.8%, 63.6%, and 89.3% for stages I, II, stages I/II, III, and IV, respectively, in the validation set.

Conclusion: In a case-control setting, the MP V2 classifier offered improved sensitivity for early-stage cancers at a lower specificity target.

Table 1. MP V1 and MP V2 classifier performance in the test set. a breast and prostate excluded.

	MP V1 Classifier Performance (95% CI)	**MP V2 Classifier Performance (95% CI)**
Measured Specificity (N=2,434)	98.5% (97.9-98.9)	97.4% (96.7-97.9)
Overall Sensitivity, all cancers (N=729)	50.9% (47.3-54.5)	57.8% (54.1-61.3)
Stage I (n=182)	15.4% (10.9-21.3)	21.4% (16.1-27.9)
Stage II (n=163)	38.0% (30.9-45.7)	46.0% (38.5-53.7)
Stage III (n=180)	67.8% (60.6-74.2)	76.1% (69.4-81.8)
Stage IV (n=172)	85.5% (79.4-90.0)	89.5% (84.1-93.3)
Unknown Stage (n=32)	37.5% (22.9-54.7)	50.0% (33.6-66.4)
Stages I/II (n=345)	26.1% (21.7-31.0)	33.0% (28.3-38.2)
Overall Sensitivity, (N=590)[a]	56.8% (52.8-60.7)	64.1% (60.1-67.8)
Stage I (n=145)	17.2% (12.0-24.2)	24.8% (18.5-32.4)
Stage II (n=109)	48.6% (39.4-57.9)	57.8% (48.4-66.6)
Stage III (n=151)	73.5% (66.0-79.9)	81.5% (74.5-86.8)
Stage IV (n=155)	86.5% (80.2-91.0)	90.3% (84.6-94.0)
Unknown Stage (n=30)	40.0% (24.6-57.7)	53.3% (36.1-69.8)
Stages I/II (n=254)	30.7% (25.4-36.6)	39.0% (33.2-45.1)

#1109 The complementary contributions of methylation and protein biomarker classes in a multi-cancer early detection (MCED) test.

Vladimir G. Gainullin[1], Melissa Gray[1], Madhav Kumar[1], Stephen Luebker[1], Avinash Shanmugam[1], Kevin Cortes[1], Emily Chang[1], Philip J. Uren[2], Amin Mazloom[2], Jorge Garces[1], Tomasz M. Beer[1], **Frank Diehl**[2]

[1]Exact Sciences Corp., Madison, WI,[2]Exact Sciences Corp., La Jolla, CA

Background: Cancer is a complex disease driven by a multitude of molecular alterations. Multi-cancer early detection (MCED) tests rely on highly sensitive technologies to measure these diverse tumor-associated biomarker classes in blood. A multi-biomarker MCED testing approach may have the potential to detect more cancers than a single biomarker approach, as release of biomarkers into the circulation is driven by different mechanisms. We previously developed a multi-biomarker class (methylation and protein; MP V1) MCED classifier (Gainullin, medRxiv, 2025.08.24.25334244). Herein, we describe the contributions attributable to protein (P) and methylation (M) using a newly developed (MP V2) classifier.

Methods: A prospectively collected case-control study (N=3,163; 729 cancers, 2,434 non-cancers) was used to develop a refined MP V2 classifier. MP V2 was trained to achieve robust early-stage sensitivity at a target specificity of ≥97.0%. M and P classifiers were trained individually; results were combined using a logical OR overarching classifier to generate the final call. MP V2 calls were deemed positive when either the M or P assay provided a positive call. We assessed the percentage of MP V2 positive calls due to P-only, M-only, and M+P (logical AND) positive calls.

Results: Of the 378/590 positive MP V2 calls in the intended use (breast and prostate cancers excluded) cohort, M+P-positive calls were observed in 45.5%, P-only in 7.4%, and M-only in 47.1%. A P-only positive call was observed in 13.9%, 9.5%, 11.1%,6.5%, 5.7%, and 6.3% of stage I (N=36), II (N=63), stages I and II combined (N=99), III (N=123), IV (N=140), and unknown stage (N=16) MP V2 positive calls, respectively. An M-only positive call was observed in 63.9%, 65.1%, 64.6%, 52.0%, 28.6%, and 62.5% of stage I, II, stages I and II combined, III, IV, and unknown stage MP V2 positive calls, respectively. An M+P positive call was observed in 22.2%, 25.4%, 24.2%, 41.5%, 65.7%, and 31.1% of stage I, II, stages I and II combined, III, IV, and unknown stage MP V2 positive calls, respectively. Of the 64/2,434 (2.6%) false positive calls, none were positive for M+P; all false positives were a result of P-only or M-only positive calls.

Conclusions: M and P biomarker classes provide independent contributions for MP V2 classifier positive calls, especially in early-stage (I and II) cases, demonstrating the potential value of adding proteins to methylation analysis in MCED testing. Prospective, real-world evaluation of the MP V2 classifier is currently underway.

#1110 Promote biomarker identification for early detection of head and neck cancers through AHEAD and EDRN programs under the leadership and collaboration between NIDCR and NCI.

Zhong Chen[1], Wendy Wang[2], Guillermo Marquez[2], Jason Wan[3], Sudhir Srivastava[2]

[1]Oral Mucosa & Cancer Biology Program, Chronic Dental, Oral and Craniofacial Conditions Branch, National Institute of Dental & Craniofacial Research, National Institutes of Health, Bethesda, MD,[2]Cancer Biomarkers Branch, Division of Cancer Prevention, National Cancer Institute, National Institutes of Health, Bethesda, MD,[3]Odontogenic Diseases Program, Chronic Dental, Oral and Craniofacial Conditions Branch, National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD

The Oral Mucosa & Cancer Biology Program at National Institute of Dental and Craniofacial Research (NIDCR) supports research activities that improve early detection and treatment of cancers of the oral cavity, pharynx, and salivary glands. National Cancer Institute (NCI)'s Early Detection Research Network (EDRN) supports discovery, development, and validation of biomarkers and imaging methods for early detection and risk assessment of cancer, translating these discoveries into clinical tests. NIDCR and NCI have a long-standing collaborative relationship and jointly launched the AHEAD Program (Advancing Head and Neck Cancer Early Detection) in 2023. The AHEAD program co-funds seven research projects aimed at discovering and developing molecular signatures of early detection and diagnosis of HPV positive and negative head and neck cancer (HNC). The AHEAD leadership team and investigators actively participated in the EDRN Lung and Upper Aerodigestive Cancers Collaborative Group and have shared their work widely through national and international conference presentations and publications in high-impact journals. AHEAD investigators have also organized and led symposia and workshops at major scientific meetings to raise awareness of early detection and diagnosis of HNC. Ongoing AHEAD activities include identifying and validating biomarkers for early detection, creating a virtual tumor bank of oral potentially malignant disorders, conducting spatial transcriptomics analyses to identify high priority biomarkers, and publishing papers to describe AHEAD activities and progress. At the 2026 AACR Annual Meeting, NIDCR and NCI program directors will present an overview of the AHEAD program, highlighting collaborative efforts and funding opportunities between the two institutes, with an emphasis on early cancer detection and biomarker discovery and validation. This collaboration between NIDCR and NCI provides a unique and powerful platform to advance basic, translational, and clinical research aimed at improving early detection of head and neck cancer and ultimately benefiting patients.

#1111 Promoting awareness and enhancing access to low-dose computed tomography screening for early detection of lung cancer in underrepresented minority communities in Northern Illinois.

Subaranjana Saravanaguru Vasanthi[1], Georgia Kapetaneas[2], Rose Bahari[2], Shylendra B Sreenivasappa[3], Nameer Mardini[4], Sandra Martell[5], Joseph Ross[6], Yamile Molina[7], Neelu Puri[1]

[1]Department of Biomedical Sciences, University of Illinois College of Medicine (Rockford), Rockford, IL,[2]College of Medicine, University of Illinois College of Medicine (Rockford), Rockford, IL,[3]Department of Hematology Oncology, OSF Saint Anthony Medical Center, Rockford, IL,[4]Department of Oncology, UW Health Swedish American Carbone Cancer Center, Rockford, IL,[5]Public Health Administrator, Winnebago County Health Department, Rockford, IL,[6]Clinical Family and Community Medicine, University of Illinois College of Medicine (Rockford), Rockford, IL,[7]Associate Director, Community Outreach and Engagement, University of Illinois College of Medicine (Rockford), Rockford, IL

Background: Lung cancer remains one of the leading causes of cancer-related deaths in the United States, posing a persistent and inequitable public health challenge. In 2025, an estimated 226,650 new cases and 124,730 deaths are expected, disproportionately affecting racially and ethnically underrepresented minority communities. It's high mortality rate is partially due to the fact that ~75% of new cases are diagnosed in late stages. As of 2022, the age-adjusted mortality rates of Winnebago County and Ogle County are 22% and 30% higher than the national rate respectively. In the National Lung Screening trial (NLST), 90.9% of participants were white, 4.5% were African American, and 1.8% were Hispanic, highlighting the need for more widespread implementation of early-stage lung cancer screening. Low dose computed tomography (LDCT) is a valuable screening tool that utilizes ~90% less ionizing radiation than conventional chest CT scans.
Hypothesis/Aims: Increased awareness of LDCT in clinical and community settings will lead to higher rates of lung cancer detection at early-stages, reduce mortality and improve prognosis.
Study Design: We implemented a multifaceted approach to promote Low-Dose Computed Tomography (LDCT) screenings in four Illinois counties - Winnebago, Boone, Ogle, and Stephenson. We conducted community outreach through booths at minority-centered events, educating community members and physicians on the US Preventive Services Task Force (USPSTF) and ACS set LDCT guidelines. Participant ethnicity and their zip codes were recorded. To evaluate the impact of our efforts, hospital data from June 2015 to December 2025 were analyzed for LDCT screenings and lung cancer cases.
Results: From June 2015 to April 2026, 28 seminars and 76 public awareness booths targeting 3,055 people, with an estimated 335 physicians and 2,720 smokers were conducted to promote LDCT screening. Our outreach work reached 21.5% of Hispanics and 36.5% of African Americans out of 13,997 total LDCT screenings. There were 13,997 total LDCT screenings conducted, detecting 181 lung cancer cases, with 110 cases being diagnosed at early stages in our partnered local hospitals. Among all individuals who underwent LDCT screenings, ~86% were White, 8% were African American, 2% were Hispanic, and 1% were Asian and the rest 3% were other populations.
Conclusion: Rural and minority communities remain underrepresented in LDCT screenings for lung cancer. Thus, continued efforts to promote lung cancer screening and awareness in rural and minority communities may increase the rate of early detection of lung cancer among smokers, which is the primary goal of our study.

#1112 Circulating early myeloid-derived suppressor cells as indicators of tumor-driven myelopoiesis and disease progression in lung cancer.

Anna Zanichelli, Orazio Fortunato, Mara Lecchi, Paolo Verderio, Luigi Rolli, Ugo Pastorino, Gabriella Sozzi, Claudia Chiodoni, Sabina Sangaletti

Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Lung cancer (LC) remains the leading cause of cancer-related mortality worldwide. Despite major therapeutic advances, LC patients still experience poor prognosis. Increasing evidence indicates that tumor-driven hematopoietic remodeling and systemic inflammation actively sustain immune suppression and disease progression. The expansion of immature myeloid populations, particularly myeloid-derived suppressor cells (MDSCs), represents a hallmark of tumor-induced emergency myelopoiesis. However, the composition and developmental hierarchy of circulating MDSC subsets remain unclear. Here, we identify a previously unrecognized subset of circulating early MDSCs (eMDSCs) that mirrors tumor-driven myelopoietic activation and lung cancer progression.
Methods: In a prospective discovery cohort including LC patients (n=63) and heavy smokers without cancer (HS, n=52), circulating myeloid subsets were characterized from fresh peripheral blood. Multiparametric flow cytometry enabled comprehensive profiling of peripheral blood mononuclear cells (PBMCs). eMDSCs were defined as $CD11b^{+}CD33^{+}CD15^{-}$ within the $Lineage^{-}HLA\text{-}DR^{-}$ compartment. A retrospective validation cohort (LC, n=58; HS, n=58), matched for sex, age, and smoking status, confirmed the findings and explored associations with tumor stage and COPD-related inflammation. FACS-sorted eMDSCs from representative LC and HS samples underwent qPCR analysis for PD-L1 and ARG1 expression. Statistical analyses were performed using the Kruskal-Wallis (KW) and Wilcoxon (WILC) tests.
Results: In both discovery and validation cohorts (total n=231), LC patients displayed an increased enrichment of circulating $CD11b^{+}$ myeloid populations (WILC test p-value: non-significant p=0.052, p=0.001), particularly $Lin^{-}HLA\text{-}DR^{-}CD33^{+}CD11b^{+}$ MDSCs (WILC test p-value: p<0.0001, p=0.009). Within this population, a distinct immature subset of $CD15^{-}$ early MDSCs was identified (WILC test p-value: p<0.0001, p=0.014) and found to be specifically increased in stage II-III LC, but not further expanded at stage IV (KW test p-value: p=0.015). No association emerged between eMDSC levels and COPD-related inflammation, supporting a tumor-specific expansion. Moreover, NK cell frequencies increased in parallel with eMDSCs, suggesting a functional interplay, as eMDSCs may suppress NK activity (KW test p-value: p=0.002). Consistently, qPCR analysis revealed higher PD-L1 and ARG1 expression in LC-derived eMDSCs compared with HS, indicating their immunoregulatory polarization.
Conclusion: Our findings identify circulating early MDSCs as a hallmark of lung cancer-associated emergency myelopoiesis. Their selective expansion in stage II-III disease supports their potential as circulating biomarkers to identify and monitor tumor-driven myelopoietic activation and lung cancer progression.

#1113 Clinical validation of a targeted multi-cancer early detection (MCED) test using cfDNA mutation and integrated genomic signatures analysis.

Chee-Onn Leong[1], Boon Shing Tan[1], Hiu Ching Toh[1], Ee Mun Loo[1], Anand Mohan[1], Teryna Thu[1], Zhi Win Ng[2], Xin Yi Chew[1], Chin King Looi[2], Felicia Fei Lei Chung[3], Chun Wai Mai[2]

[1]AGTC Genomics, Kuala Lumpur, Malaysia,[2]International Medical University, Kuala Lumpur, Malaysia,[3]Sunway University, Kuala Lumpur, Malaysia

Early cancer detection significantly improves survival, particularly for high-burden cancers across Asia that are often diagnosed late. Plasma-derived cell-free DNA (cfDNA) is a promising non-invasive biomarker for identifying cancer earlier than conventional methods. This study evaluated the performance of a targeted multi-cancer early detection (MCED) test that analyzes tumour-associated mutations in cfDNA to detect 20 cancer types commonly seen in Asian populations. In this retrospective, multicentre validation study, participants aged ≥20 years with either confirmed cancer or cancer-free status were recruited. Plasma cfDNA was sequenced using a targeted panel constructed from large genomic datasets. Machine learning models were trained and validated in a blinded manner to assess diagnostic performance. Among 2342 cancer cases and 1646 controls, the MCED test achieved a sensitivity of 83.1% (95% CI: 81.5-84.6%) and specificity of 95.4% (95% CI: 94.4-96.4%), with a false-positive rate of 4.6%. Performance surpassed that of traditional biomarkers such as CEA. Notably, high sensitivity was observed in cancers of major concern in Asia—liver, gastric, pancreatic, bile duct, and nasopharyngeal cancers—with early-stage detection ranging from 75.0-91.3% and late-stage detection from 95.5-100%. These findings support the potential of cfDNA-based MCED testing as a non-invasive, complementary screening approach for populations in Asia. Its strong performance across multiple high-mortality cancers underscores its value for early detection, risk stratification, and integration into regional cancer control strategies.

#1114 Informatics-Driven Integration of OpenMRS and iBreastCheck to Strengthen Community-Based Cancer Screening in Ethiopia.

Tsedey Michele Tsegaye, Mukesh kumar Patel, Tulay Soylu

Collage of public health, Temple University, Philadelphia, PA

Background: Ethiopia faces a rising and disproportionate cancer burden, particularly among women, with breast, cervical, and colorectal cancers representing majority of cases. Limited healthcare infrastructure, fragmented data systems, and late-stage detection contribute to high mortality rates, especially in rural areas where access to oncology services is constrained. These systemic gaps highlight the urgent need for integrated, scalable, and data-driven solutions to improve early detection, care coordination, and health information management across all levels of the healthcare system. Objective: This study aims to design and propose an informatics-enhanced model that will integrate a customized OpenMRS electronic medical record platform with the mHealth application iBreastCheck to strengthen cancer screening, data interoperability, and referral pathways in Ethiopia. The model will be tailored to leverage existing community health structures specifically Health Extension Workers (HEWs) and designed to function in low-connectivity settings, with the goal of improving early cancer detection and standardizing oncology data capture. Methods: A multi-phase implementation approach will be employed, beginning with stakeholder interviews and training of HEWs on iBreastCheck for community-based breast cancer education and risk assessment. In parallel, OpenMRS will be customized and deployed with oncology-specific modules to support interoperability, using HL7 and XML standards for data exchange, and configured for offline functionality. The system design will emphasize open-source technologies, SQL-based data querying, and integration with national digital health infrastructure, supported by partnerships with the Ethiopian Ministry of Health, WHO, and NGOs. Results: The integrated OpenMRS and iBreastCheck model is projected to enhance cancer data completeness, improve screening participation through community health workers, and reduce diagnostic delays. By enabling standardized digital workflows and facilitating communication between community and clinical levels, the system will support more timely referrals and consistent protocol adherence. The use of offline-capable, interoperable tools will ensure functionality even in settings with limited internet connectivity, broadening accessibility across rural and underserved regions. Conclusion: The combination of OpenMRS and mHealth technologies offers a feasible and Scalable, model for improving cancer screening and care coordination in low-resource settings like Ethiopia. By aligning technology design with local infrastructure and human resource capacities, this approach addresses critical gaps in the oncology care continuum and provides a replicable framework for other low- and middle-income countries implementing digital health solutions for cancer control.

#1115 Expression of annexin A4 in cancer: A tissue microarray study involving 6,058 cancers from 105 tumor entities.

Cosima Volkel[1], Nayma Malas[1], Fiete Gehrisch[1], Nina Schraps[1], Anne Menz[1], Florian Lutz[1], Viktoria Chirico[1], Florian Viehweger[1], David Dum[1], Ria Schlichter[1], Andrea Hinsch[1], Christoph Fraune[1], Christian Bernreuther[1], Seyma Buyucek[1], Martina Kluth[1], Claudia Hube-Magg[1], Georgia Makrypidi-Fraune[1], Katharina Moller[1], Andreas M. Luebke[1], Patrick Lebok[1], Guido Sauter[1], Maximilian Lennartz[1], Till S. Clauditz[1], Andreas H. Marx[2], Ronald Simon[1], Eike Burandt[1], Natalia Gorbokon[1], Maria C. Tsourlakis[1], Sarah Minner[1], Till Krech[1], Morton Freytag[1], Viktor Reiswich[1], Stefan Steurer[1]

[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Department of Pathology, Academic Hospital Fuerth, Fuerth, Germany

Annexin A4 (ANXA4) is a member of the annexin family of calcium-dependent phospholipid-binding proteins. In line with its capability to bind to phospholipid membranes, it has roles in processes related to membrane dynamics such as membrane trafficking, vesicle aggregation, membrane organization, and ion channel regulation. ANXA4 dysregulation can contribute to abnormal cell migration, proliferation, and resistance to apoptosis. ANXA4 overexpression has been described in several cancer types and has been linked to tumor aggressiveness and treatment resistance. Due to its differential expression in tumors versus normal tissues, ANXA4 is being investigated as a diagnostic biomarker. To learn more on the role of ANXA4 in cancer, ANXA4 expression was analyzed by immunohistochemistry (IHC) on tissue microarrays (TMAs) containing 6,058 samples from 105 different tumor types. ANXA4 staining was seen in 3,649 (75.4%) of the 4,839 analyzable tumors, and was considered weak in 11.3%, moderate in 17.5%, and strong in 46.6% of cases. Of 105 tumor categories, 100 (95.2%) showed ANXA4 expression in at least one case, 92 (87.6%) showed ANXA4 staining in more than 50% of cases, and 90 (85.7%) included at least one case with strong ANXA4 positivity. Highest rates of strong ANXA4 positivity occurred in adenocarcinoma of the ampulla Vateri (100%) and ductal adenocarcinoma of the pancreas (96.0%), gallbladder adenocarcinoma (100%), gastric adenocarcinoma (93.0-99.1%), clear cell (97.7%), papillary (97.4%) and chromophobe (94.9%) renal cell carcinoma (RCC), Brenner tumor (96.4%), colorectal adenocarcinoma (95.0%), clear cell carcinoma of the ovary (94.7%), adenocarcinoma of the esophagus (94.7%), oncocytoma od the kidney (94.6%), hepatocellular carcinoma (91.8%), mucinous carcinoma of the ovary (90.9%), cholangiocarcinoma of the liver (88.6%), adenocarcinoma of the cervix uteri (87.0%), endometrioid endometrial carcinoma (76.1%), endometrioid carcinoma of the ovary (66.7%), and in urothelial carcinoma of the kidney pelvis (66.7%). The 1,219 evaluable breast cancers of no specific type (NST) represented the largest subset of tumors from one entity. In these tumors, ANXA4 staining was negative in 642 (52.7%), weak in 84 (6.9%), moderate in 169 (13.9%), and strong in 324 (26.6%) cases. A comparison with tumor phenotype revealed that low ANXA4 expression was linked to advanced pT-stage ($p<0.0001$), high grade of malignancy ($p=0.0018$), and nodal metastasis ($p=0.0247$). In summary, our data provide a comprehensive overview on ANXA4 expression in cancer. They demonstrate, that ANXA4 is often expressed at high levels in a broad range of different tumor entities. At least in breast cancer NST, a low level of ANXA4 expression is a feature of high cancer aggressiveness.

#1116 A scalable multimodal framework for unbiased risk biomarker discovery across multiple cancer types.

Constantin Petrescu, Lisa Schmunk, Jack Monahan, Abbas Salami, **Thomas M. Stubbs**

Hurdle.bio/Chronomics Ltd., London, UK, United Kingdom

Background: Most existing cancer risk models are built on single modalities and hand-selected features. Systematic, unbiased integration of germline genetics, plasma proteomics, and deep clinical phenotyping holds promise for revealing novel risk biomarkers across diverse cancer types.
Methods: We developed a multi-modal biomarker discovery engine that can be used for discovering risk, diagnostic, prognostic, predictive and monitoring biomarkers. Currently the framework handles:

- Germline genetics and polygenic risk scores
- High-dimensional plasma proteomics (Olink)
- Longitudinal primary-care records, hospital episodes, laboratory results, lifestyle questionnaires, and cancer registry linkages

Key design features include modular cohort handling, automated data preprocessing, and machine-learning models (including: gradient boosting and neural networks).
Application: The platform is currently deployed on the UK Biobank (n = 502,505 participants; >46,000 incident cancers across 22 cancer types) with active model training and biomarker discovery in progress. The architecture is cohort-agnostic and ready for direct application to emerging large-scale resources including Our Future Health and the All of Us Research Program.
Poster presentation: We will demonstrate the platform's configurability through examples of cancer-risk modelling in the UK Biobank, showcasing: (i) comparative performance of individual modalities versus multimodal ensembles, (ii) cancer-specific patterns of modality contribution, and (iii) the effect of time-window filtering on separating true predictive signals from prevalent disease effects.
Conclusions: By eliminating bias in feature engineering and supporting seamless integration of diverse health data streams, this scalable framework provides a robust foundation for data-driven discovery of multimodal cancer risk biomarkers, paving the way for next-generation precision prevention strategies.

#1121 Detection of postoperative minimal residual disease in colorectal cancer using a novel ultrasensitive whole-genome sequencing-based ctDNA test.

Maria Honholt[1], Tenna V. Henriksen[1], Mads H. Rasmussen[1], Christina Demuth[1], Thomas Kolbro[2], Peter Bondeven[3], Jeppe Kildsig[4], Per V. Andersen[5], Anders Tottrup[6], Nis H. Schlesinger[7], Claudia Jaensch[8], Ole Thorlacius-Ussing[9], Christensen Peter[10], Alessio Monti[11], Yingyu Wang[12], Tam Berntsen[12], George Yeung[12], Paul Tang[12], Tobias Wittkop[12], Malek Faham[12], Li Weng[12], Lene Hjerrild Iversen[13], Kare A. Gotschalck[14], Claus L. Andersen[1]

[1]Department of Molecular Medicine, Aarhus University and Aarhus University Hospital, Aarhus, Denmark,[2]Odense University Hospital, Odense, Denmark,[3]Aarhus University Hospital, Aarhus, Denmark,[4]Department of Surgery, Copenhagen University Hospital, Herlev, Denmark,[5]Department of Surgery, Odense University Hospital, Odense, Denmark,[6]Department of Surgery, Regional Hospital Viborg, Viborg, Denmark,[7]Department of Surgery, Copenhagen University Hospital, Bispebjerg, Denmark,[8]Department of Surgery, Regional Hospital Godstrup, Herning, Denmark,[9]Department of Gastrointestinal Surgery, Aalborg University Hospital, Aalborg, Denmark,[10]Department of Surgery, Aarhus University Hospital, Aarhus, Denmark,[11]Department of Surgery, North Denmark Regional Hospital Hjorring, Hjorring, Denmark,[12]AccuraGen, Inc., San Jose, CA,[13]Department of Surgical Oncology, Aalborg University Hospital, Aalborg, Denmark,[14]Department of Surgery, Regional Hospital Horsens, Horsens, Denmark

Introduction:
Accurate detection of minimal residual disease (MRD) after curative intent surgery remains a major limitation in colorectal cancer (CRC) management. Current ctDNA assays identify only 30-50% of patients who later develop clinical recurrence, restricting their utility for both escalation and safe de-escalation of adjuvant therapy. We evaluated a novel, ultrasensitive, tumor-informed, whole-genome sequencing (WGS)-based ctDNA test engineered to maximize detection sensitivity while simplifying clinical implementation by eliminating the need for bespoke patient-specific capture panels, reducing turnaround time, and requiring only 1mL of plasma.
Methods:
Pre- and postoperative plasma samples (drawn 14 and 30 days after operation) from 300 stage II-III CRC patients (median follow-up 35.7 months) were collected. At the time of abstract submission, 161 patients have been analyzed, but complete cohort results (n = 300) will be presented at AACR 2026. The test (*AccuScan*) utilizes rolling-circle amplification to convert single-stranded cfDNA into concatemers, enabling >1000-fold error suppression at modest sequencing depth (median 28×). Tumor-informed variant tracking was derived from paired tumor/germline WGS. ctDNA detection was done blinded to clinical information. Performance was evaluated against recurrence outcomes.
Results:
Among the 161 analyzed patients, 43 (26.7%) recurred. A median of 11,822 tumor-derived variants per patient were tracked with a mean error rate of 4.97×10^{-7}. Preoperatively, the novel WGS test detected ctDNA in 98.1% of samples. Postoperatively, ctDNA was detected in at least one sample (day 14 or 30) in 69.8% of recurrence patients with a specificity of 91.5%. Sensitivity and specificity were 55.8% and 96.6% at day 14 and 62.8% and 94.1% at day 30. ctDNA levels in recurrence patients reached as low as 2.7 ppm (median 162 ppm). Extrapolating the performance to an unselected stage III population indicates a ~10% 3-year recurrence rate for postoperative ctDNA-negative individuals, comparable to low-risk stage II disease, for which adjuvant therapy is generally not recommended. Postoperative ctDNA status was a strong predictor of recurrence-free survival (HR 11.9; 95% CI, 6.2-23.1; p<0.001). In a head-to-head comparison, tumor-informed digital PCR using 8mL plasma aliquots achieved substantially lower sensitivity both preoperative (75.4%) and postoperative (33.3% day 14; 51.5% day 30).
Conclusion:
The novel WGS-based test delivers exceptional sensitivity in both preoperative and postoperative settings while requiring minimal plasma. The streamlined workflow is compatible with real-world clinical implementation. Sensitive detection at day 14 offers an opportunity for earlier therapeutic intervention, and the assay's performance supports its use in future therapy de-escalation trials.

#1122 Methylation-based tumor fraction monitoring identifies patients with putative molecular progression who may benefit from comprehensive genomic profiling.

Jun Zhao[1], Rihao Qu[1], Katie Quinn[1], Tingting Jiang[1], Jack Tung[1], Carin R. Espenschied[2], Samantha I. Liang[3], Vishnu Ramani[1], Jing Wang[1], Sean Gordon[1], Martina Lefterova[1], Darya Chudova[1]

[1]Guardant Health, Palo Alto, CA,[2]Guardant Health, Spokane, WA,[3]Parker Institute for Cancer Immunotherapy, San Francisco, CA

Background: Longitudinal monitoring of circulating tumor DNA (ctDNA) using methylation-based tumor fraction (TF) provides sensitive detection of disease dynamics in cancer patients over time. Patients with increasing TF may be undergoing molecular progression (MP) preceding clinical progression. They may have developed clinically relevant variants (CRVs, associated with response or resistance to targeted therapies) detectable by comprehensive genomic profiling (CGP) that can guide treatment options. Here, we describe a workflow that applies TF change thresholds to identify patients with putative MP, maximizing detection of CRVs.
Methods: To establish the thresholds for significant TF change, we used in-silico dilutions (ISD) from clinical samples to train an input-dependent model targeting 90% analytical specificity. We also determined an absolute TF threshold to maximize detection of CRVs. These thresholds were analytically evaluated by comparing two aliquots from the same blood draw (n=1061, simulating “no TF change” between consecutive samples), as well as longitudinal pan-cancer samples from patients undergoing treatment (n=2103, representing real-world TF changes). The model was also clinically evaluated in the RADIOHEAD cohort[1] (n=116) in which patients with advanced solid tumors received standard-of-care immune checkpoint inhibitors (ICI). Adjusted hazard ratios (aHR) and p-values (p) were determined via Cox proportional hazards with sex, age, and baseline TF as covariates.
Results: Significant TF change between consecutive timepoints of >50% increase, along with an absolute TF of >0.1% were yielded from simulation and optimization approach as thresholds for putative MP assessment. When evaluated in replicate plasma samples that simulate no biological change, these thresholds demonstrated empirical specificity of 97%. In serial samples from advanced cancer patients undergoing treatment, 29.5% met the criteria for MP. Critically, 55% of patients with putative MP harbored CRVs not detected at baseline. In the RADIOHEAD cohort, patients with putative MP had significantly worse real-world progression-free survival (rwPFS) compared to those with stable/decreasing TF (HR=4.30, 95% CI: 2.93-6.33, p<0.001). Among patients with putative MP, 65.1% had new CRVs, compared to 26.2% in patients with TF decrease.
Conclusions: We developed criteria for putative MP that achieve 97% specificity and are associated with shorter rwPFS in patients receiving ICI. CGP in patients meeting these criteria detects new actionable variants in 55-65% of cases, supporting its utility for guiding therapeutic decision-making upon MP during longitudinal ctDNA monitoring.

Background: Determination of the tissue of origin (TOO) of cancer is essential for appropriate clinical management and treatment selection. Liquid biopsy using circulating cell-free DNA (cfDNA) offers a non-invasive approach for cancer detection and TOO prediction. Circulating tumor DNA (ctDNA), a tumor-derived fraction of cfDNA, carries genomic and epigenomic signatures reflective of its origin. Recent advances in machine learning have enable the development of models to predict TOO from cfDNA profiles. However, current methods show variable performance, particularly in samples with low ctDNA fractions (ctDNA < 3%), and accuracy remains inconsistent across different cancer types.

Methods: We developed a TOO classifier using whole genome cfDNA profiles from 1814 patients across 17 cancer types. Multiple distinct cfDNA features were extracted to reveal diverse cancer-associated alterations, including copy number variations, repeat elements, fragment end motifs associated with DNA methylation, fragment size distribution and coverage, microsatellite instability, mutational signatures, nucleosome occupancy, tissue-specific fragmentation patterns, and the presence of cancer-associated viral DNA. Model performance was evaluated in an independent external cohort of 1221 patients. Additional tests were conducted in cohorts of patients with cancers of unknown primary (CUP) and multiple primary cancers (MPC).

Results: Our cancer classifier achieved an overall top 1 accuracy of 78% and top 2 accuracy of 89% in the training cohort, with consistently high accuracy across all cancer types. In the independent validation cohort, the model maintained robust performance, with top 1 and top 2 accuracies of 80% and 90%, respectively. Sensitivity increased with the advancing cancer stage, improving from 66.8% in stage I to 86.2% in stage IV. Among 612 low-ctDNA samples, 435 cases (71.1%) were correctly classified. The classifier also showed strong potential in CUP, with 11 of 15 cases (73.3%) aligning with the clinically suspected primary site. Furthermore, among 20 MPC cases with two primary sites, both were correctly identified within the top three predictions in 9 cases. In 3 MPC patients with three primary sites, two of the three sites were accurately captured among the top three predictions.

Conclusion: Our cfDNA-based machine learning classifier provides a robust, non-invasive approach for accurate cancer tissue-of-origin identification. Integrating 11 distinct cfDNA-derived fragmentomic, genomic, epigenomic, and microbiomic features, the model achieved high accuracy across multiple cancer types and maintained strong performance in low-ctDNA samples. Its promising results in CUP and MPC further highlight its potential clinical utility in resolving diagnostically challenging cases and guiding precision oncology applications.

#1124 cfDNA fragmentomics enables sensitive early detection and tissue-of-origin prediction in gynecologic cancers.

Jin Li[1], Xun Zhang[2], Song Wang[3], Xiaoying Wu[3], Jinpeng Zhang[3], Hua Bao[3], Shanhui Liang[1], Xiaotian Han[1], Jiangchun Wu[1], Hao Wen[1], Hairong Bao[3], **Haimeng Tang**[3], Xue Wu[3], Xiaohua Wu[1], Zhao Wu[2], Xiaoqiu Li[4]

[1]Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center, Shanghai, China,[2]Department of Obstetrics and Gynecology, Sichuan Provincial People's Hospital, Chengdu, China,[3]Nanjing Geneseeq Technology Inc., Nanjing, China,[4]Department of Pathology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Early detection of gynecologic cancers remains challenging due to nonspecific symptoms and limited sensitivity of conventional biomarkers. We aimed to develop and validate cfDNA-based models for cancer detection and tissue-of-origin (TOO) classification.

Methods: We prospectively enrolled 1,007 participants from two hospitals, of whom 763 passed eligibility and quality control. The training set (N=363; 173 cancer, 190 non-cancer) was used to develop models integrating four cfDNA features reflecting fragmentation, chromatin architecture, and epigenetic regulation via machine learning. The internal test set (N=158; 86 cancer, 72 non-cancer) and an independent external test set (N=242; 127 cancer, 115 non-cancer) were used for validation.

Results: The diagnostic model achieved area under the curve (AUC) values of 0.974 (95% confidence interval [CI]: 0.954-0.994) and 0.975 (95% CI: 0.959-0.992) in the internal and external cohorts, with sensitivities of 83.7% and 82.7% at 98% specificity. High performance was observed across ovarian (AUC: 0.992 and 0.999), cervical (AUC: 0.972 and 0.989), and endometrial (AUC: 0.948 and 0.937) cancers, including stage I disease (AUC: 0.955 and 0.961). The model detected over 77% of cancers that were missed by CA125. Interception modeling projected a 26.4-68.9% increase in stage I diagnoses and 11.6-37.8% 5-year survival gains. The TOO model achieved >73% overall accuracy, with the highest accuracy for ovarian (81.3-86.7%), followed by cervical (70.7-73.3%) and endometrial (59.1-62.7%) cancers. Analytical validation demonstrated robust performance even at ultra-low sequencing depths of 1x, supporting scalability for population screening.

Conclusions: cfDNA fragmentomics enables sensitive detection and tissue-of-origin classification of gynecologic cancers, complementing conventional biomarkers. These models hold promise for cost-effective, population-level early detection and risk stratification.

#1125 Characterizing the cfDNA fragmentome in patients with hepatocellular carcinoma.

Hope Orjuela[1], Carter Norton[1], Shashikant Koul[1], Daniel C. Bruhm[1], Akshaya V. Annapragada[1], Sarah Short[1], Keerti Boyapati[1], Adrianna Bartolomucci[1], Vilmos Adleff[1], Nicholas A. Vulpescu[1], Kaui Lebarbenchon[1], Jacob Carey[2], Carter Portwood[2], Andrei Sorop[3], Razvan Iacob[3], Speranta Iacob[3], Liana Gheorghe[3], Simoni Dima[3], Katherine A. McGlynn[4], Manuel Ramirez-Zea[5], Jillian Phallen[1], Robert B. Scharpf[1], John Groopman[1], Victor E. Velculescu[1], Zachariah Foda[1]

[1]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[2]DELFI Diagnostics, Baltimore, MD,[3]Center of Digestive Diseases and Liver Transplantation, Fundeni Clinical Institute, Bucharest, Romania,[4]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[5]Research Center for the Prevention of Chronic Diseases, Institute of Nutrition of Central American and Panama (INCAP), Guatemala City, Guatemala

Hepatocellular carcinoma (HCC) is the third leading cause of cancer death globally and is one of the most rapidly increasing causes of cancer mortality in North America and Europe due to metabolic and emerging risk factors. Here, we show that cell-free DNA (cfDNA) fragmentation profiles reflected underlying disease biology and that a machine learning classifier detected HCC across diverse populations and was enhanced by incorporating patient clinical risk and protein concentrations. Characteristics of the cfDNA fragmentome, including genome-wide chromatin, repeat elements, methylome, and mutational profiles, were altered in patients with HCC, including those with metabolic risk factors and aflatoxin exposure. Novel whole-genome tissue-of-origin deconvolution analyses identified increased representation of cfDNA originating from hepatocytes ($p=2.4x10^{-10}$) and CD8+ T cells ($p=5.8x10^{-7}$) and decreased contribution of NK cells ($p=3.0x10^{-6}$) in patients with cancer. Using a previously locked fragmentome classifier for liver cancer detection, we analyzed 377 individuals with and without HCC from two distinct geographic cohorts. We found that the cfDNA fragmentome classifier detected HCC across all stages and diverse etiologies with a sensitivity of 70% (95% CI=65%-75%) and specificity of 94% (95% CI=90%-97%), outperforming the commonly used alpha-fetoprotein (AFP) biomarker which had a sensitivity of 62% (95% CI=57%-67%) and specificity of 93% (95% CI=88%-96%). A combined approach using cfDNA fragmentomes, AFP, and clinical risk achieved a sensitivity of 74% (95% CI=66%-80%) at a specificity of 85% (95% CI=78%-89%) in transplant curable disease (Milan criteria) in both cohorts and was more sensitive than standard-of-care AFP and ultrasound performance for early-stage disease (reported 63% sensitivity at 84% specificity). This study provides insights into the origins of altered cfDNA and circulating proteins for populations at risk of liver cancer and supports the use of a genome-wide fragmentome approach for non-invasive detection of HCC.

#1126 Pervasive early dissemination in pancreatic cancer uncovered by tissue-paired plasma whole-genomes.

Yuanchang Fang[1], Michelle Chan-Seng-Yue[2], Karen Ng[3], Amy Zhang[2], Tuan Hoang[1], Gun Ho Jang[2], Sabiq Chaudhary[2], Catia Gaspar[3], Eugenia Flores-Figueroa[3], Daniela Bevacqua[3], Stephanie Ramotar[3], Ayelet Borgida[3], Shawn Hutchinson[3], Anna Dodd[3], Barbara Grunwald[4], Julie Wilson[2], Robert Grant[3], Erica Tsang[3], George Zogopoulos[5], Masoom Haider[1], Jennifer Knox[3], Steven Gallinger[3], Faiyaz Notta[1]

[1]University of Toronto, Toronto, ON, Canada,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]University Health Network, Toronto, ON, Canada,[4]University Hospital Essen, Essen, Germany,[5]McGill University, Montreal, QC, Canada

In pancreatic cancer, 50% of the patients are diagnosed at the metastatic stage due to a lack of symptoms. The overall survival rate dramatically reduces from 44% in early-stage resectable patients to 3% in metastatic cases. However, even in early-stage patients, >75% of them still recur after resection and adjuvant therapies. Therefore, there is an urgent need to develop a sensitive strategy to detect this disease earlier before it spreads. Characterizing circulating tumor DNA (ctDNA) in plasma is an effective approach to detect and monitor cancer. Whole-genome sequencing (WGS) tracks all the tumor mutations simultaneously, and has a higher sensitivity than targeted approaches, especially in samples with extremely low tumor burden. In this study, to investigate the ctDNA dynamics and early dissemination in pancreatic cancer, we established a cohort of 1,013 samples from 277 donors, including plasma WGS at 20-60x, alongside germline DNA WGS, tissue WGS and transcriptomic sequencing. Using a tumor-guided approach, we found that the early-stage resectable cases shed very little ctDNA (<1% tumor fraction, TFx). Plasma TFx levels were elevated at the metastatic stage, but were also dependent on metastatic tissue site, where patients with liver metastases had higher TFx than the ones with only non-hepatic lesions. We further discovered the tumor-intrinsic features that were related to increasing ctDNA shedding, such as whole-genome duplication (WGD), high cell cycle activity and non-glandular morphology, as well as extrinsic features related to reduced shedding, including a reactive microenvironment and B cell immunity. Our analysis on tumor clonal architecture revealed that subclonal mutations were more frequently detected than the clonal ones in plasma samples with low ctDNA levels or from early-stage patients, which strongly suggests that dissemination from early-stage primary tumors mostly derived from subclones. In the longitudinal plasma, we observed that subclones seeded metastasis years before imaging diagnosis. This study with a unique large cohort of paired tumor and plasma sequencing data provided a comprehensive insight on ctDNA dynamics, disease monitoring and early detection in pancreatic cancer.

#1127 Interim analysis of tumor-informed ctDNA detection in head and neck squamous cell carcinoma: The PECAN trial.

Paul van der Leest[1], Joris Elbers[2], Amy Greer[3], Sten Cornelissen[1], Theodora C. Linders[1], Mirthe Lanfermeijer[1], Kalpana Ramkisoensing[1], Ellen Verner[3], Laura Smit[1], Mark Sausen[3], Abrahim Al-Mamgani[4], Daan van den Broek[1]

[1]Netherlands Cancer Institute, Amsterdam, Netherlands,[2]Erasmus MC Cancer Institute, Rotterdam, Netherlands,[3]Labcorp, Baltimore, MD,[4]Amsterdam University Medical Center, Amsterdam, Netherlands

Background: Head and neck squamous cell carcinomas (HNSCC) are a heterogeneous group of malignancies of the upper aerodigestive tract, encompassing multiple tumor (sub)sites and entities. Current treatment often relies on radiotherapy, with or without concurrent chemotherapy. Clinical surveillance remains the sole indicator of recurrent disease, despite relapse rates of 25-40%. There is a clear unmet clinical need for biomarkers that can predict treatment efficacy prior to and during (chemo)radiotherapy and that can identify residual disease and cancer recurrence early during surveillance.
Methods: Seventy-two HNSCC patients were enrolled in the PECAN trial. Plasma and saliva samples were collected at baseline; during (chemo)radiotherapy; and at 2 weeks, 3 months, 6 months, 1 year, and 2 years after treatment. Tumor-informed whole-genome sequencing (WGS) was performed on circulating cell-free DNA (ccfDNA) extracted from plasma for 57 evaluable patients. Molecular findings were correlated with treatment response and clinical outcome. Analysis of the remaining patients, saliva samples, human papilloma virus (HPV) abundance, and imaging are ongoing.
Results: At baseline, circulating tumor (ctDNA) was detectable in 92% HNSCC patients based on tumor-informed molecular fingerprinting. All patients with undetectable baseline ctDNA remained negative throughout the monitoring period, and none experienced disease recurrence. Among patients with detectable ctDNA, 84% cleared ctDNA during (chemo)radiotherapy; however, ctDNA clearance during treatment was not predictive of recurrence. In landmark analysis at 3 months after treatment, ctDNA was detected in 6% of patients, all of whom subsequently developed recurrence. During the entire 2-year surveillance period, no ctDNA was detected in patients who remained relapse-free. In case ctDNA was detected recurrence was always diagnosed, resulting in a positive predictive value of 100%. ctDNA detection at end of follow-up (EoF), whether due to recurrence or completion of surveillance, was associated with reduced progression-free survival (hazard ratio [HR] = 5.9) and overall survival (HR = 7.1).
Conclusion: This interim analysis of the PECAN trial demonstrates the clinical relevance of ctDNA monitoring following (chemo)radiotherapy, showing substantially reduced survival in patients with detectable ctDNA during surveillance. These data suggest that ctDNA serves as a robust biomarker for recurrence detection and could guide initiation of follow-up treatment. Sensitivity of ctDNA detection in the heterogeneous disease spectrum of HNSCC may be improved by complementary analysis of saliva samples and alternative biomarkers (e.g., HPV). For this cohort, the added value of incorporating additional time points, saliva-based detection, HPV abundance, and imaging correlations for all evaluable cases will be presented at AACR.

#1128 Personalized cell-free DNA fragmentation dynamics in early-stage NSCLC in TRACERx.

Jonathan C. M. Wan[1], Wing Kin Liu[2], James R. M. Black[2], Alexander Mark Frankell[3], Alexander Azizi[1], Olivia Lucas[1], Woody Z. Zhang[3], Chris Bailey[1], Nnennaya Kanu[2], Mariam Jamal-Hanjani[2], Charles Swanton[1]

[1]The Francis Crick Institute, London, United Kingdom,[2]University College London (UCL) Cancer Institute, London, United Kingdom,[3]University of Cambridge, Early Cancer Institute, Cambridge, United Kingdom

Background: Plasma cell-free DNA (cfDNA) fragmentation reflects underlying chromatin organization and can be disrupted in cancer. Circulating tumor DNA (ctDNA) fragments differ from non-tumor cfDNA in size, genomic distribution, and end-motif characteristics. Recent studies have shown that fragmentomic profiles can distinguish individuals with and without lung cancer, and fragment sizes from targeted sequencing can be leveraged for cancer detection.
In the TRACERx study, personalized ctDNA sequencing has previously been used to monitor individuals with stage I-III non-small cell lung cancer (NSCLC) who underwent curative-intent surgery, enabling prognostication at baseline and post-operative landmark timepoints. Here, we investigate the dynamics of ctDNA and cfDNA fragmentation in response to surgery, relapse and systemic therapies.
Methods: We characterised cell-free DNA (cfDNA) fragmentation in 1,069 longitudinal plasma samples from 197 individuals using Anchored multiplex PCR and targeted sequencing. We developed a computational pipeline to extract fragment size distributions and end-motif features from tumor-derived and non-tumor cfDNA fragments.
Results: Distinct cfDNA fragmentation dynamics were observed across clinical timepoints, and mutant fragments were shorter than non-mutant fragments. Treatment effects on fragmentation were observed: a transient release of non-tumor cfDNA was observed post-surgery, plus systemic therapies were associated with alterations in fragmentation pattern. Associations between fragmentation metrics, clinicopathologic features, and biological variables such as extrachromosomal DNA, were explored.
Conclusion: Targeted plasma sequencing within TRACERx enables integrated evaluation of tumor- and non-tumor-derived cfDNA. Fragmentation dynamics reflect treatment and disease status, suggesting their potential as a complementary non-invasive marker for monitoring and mechanistic insights in early-stage NSCLC.

#1129 Analytical and clinical sensitivity of tumor-informed and tumor-naïve ctDNA residual disease detection during neoadjuvant immune checkpoint inhibition in resectable cancers.

Paul K. Lee[1], Blair V. Landon[1], Ezgi Oner[1], Jaime Wehr[1], Qiong Meng[1], Amna Jamali[1], Mimi Najjar[2], Gavin Pereira[1], Samira Hosseini-Nami[1], Rachel Keogh[1], Chen Hu[1], Ronan J. Kelly[3], Joshua E. Reuss[4], Patrick M. Forde[5], Mark Sausen[6], Vincent K. Lam[1], Robert B. Scharpf[1], Noushin Niknafs[1], Valsamo (Elsa) Anagnostou[1]

[1]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD,[2]Cleveland Clinic, Cleveland, OH,[3]Charles A. Sammons Cancer Center, Baylor University Medical Center, Dallas, TX,[4]Department of Hematology/Oncology, Georgetown University, Washington, DC,[5]Trinity St. James's Cancer Institute, Trinity College Dublin, Dublin, Ireland,[6]Labcorp, Baltimore, MD

Background: Circulating tumor DNA (ctDNA) has become a key biomarker for minimally invasive detection of residual disease during neoadjuvant immunotherapy. However, its integration into routine clinical decision-making remains limited by modest sensitivity and the practical constraints of current assays. **Methods:** We performed multi-modality matched tumor, white blood cell (WBC), and cell-free DNA (cfDNA) next-generation sequencing (NGS) of 520 biospecimens (56 tumor, 105 WBC, 359 plasma) from 32 patients with operable gastroesophageal (GE) cancer (NCT03044613) and 30 patients with resectable pleural mesothelioma (PM; NCT03918252). ctDNA residual disease analyses were performed at baseline, before each cycle of neoadjuvant immunotherapy, and preoperatively. For the tumor-informed approach, whole genome sequencing (WGS) data of matched tumor, WBC, and cfDNA (80x, 40x, and 30x coverage) were integrated through a random forest machine learning model and calibrated using a reference set of noncancerous cfDNA to determine cfDNA tumor fraction (TF). In parallel, we performed orthogonal tumor-naïve, fixed-gene-panel targeted error-correction NGS of cfDNA and WBC (30,000x), filtering germline and clonal hematopoiesis variants. **Results:** Overall, the tumor-informed assay showed significantly higher sensitivity, evidenced by a higher ctDNA detection rate at all evaluated timepoints compared to the tumor-naïve assay. In the GE cohort, the tumor-informed assay detected ctDNA for 22 of 25 (88%), 20 of 25 (80%), 18 of 26 (69%), and 5 of 21 (24%) patients at baseline, cycle 2, cycle 3, and preoperatively, respectively. By contrast, 13 of 30 (43%), 12 of 30 (40%), 11 of 30 (37%), and 5 of 25 (20%) had detectable ctDNA by the tumor-naïve assay at corresponding timepoints. In detectable cases, cfDNA TFs were highly concordant between approaches ($R = 0.85$, $p < 0.001$). In the PM cohort, 12 of 26 (46%), 11 of 25 (44%), 7 of 21 (33%), and 13 of 25 (52%) had ctDNA detected by the tumor-informed assay at baseline, cycle 2, cycle 3, and preoperatively, respectively. Having demonstrated higher analytical sensitivity with the tumor-informed approach in the GE cohort, we applied the tumor-naïve approach only in cases with detectable ctDNA by the tumor-informed assay. Of these, 6 of 14 (43%), 6 of 13 (46%), 5 of 8 (63%), and 7 of 15 (47%) had ctDNA detected at corresponding timepoints. cfDNA TFs were concordant at timepoints when ctDNA was detectable by both approaches ($R = 0.63$, $p = 0.002$). Tumor-informed ctDNA residual disease preoperatively was associated with shorter progression-free survival (log-rank, $p = 0.0059$). **Conclusion:** Tumor-informed WGS-based liquid biopsies reliably measure ctDNA residual disease during neoadjuvant immunotherapy, demonstrating greater sensitivity compared to a tumor-naïve approach, supporting their clinical value.

#1130 Tracing tumor-specific EV-miRNA signatures via patient-derived explant models to advance liquid biopsy in non-small cell lung cancer.

Miranda Burdiel[1], Carlos Rodriguez-Antolin[1], Ana Arauzo-Cabrera[1], Olga Pernia[1], Rocio Moreno-Velasco[2], Laura Gutierrez-Sainz[1], Oliver Higuera[1], Olga Vera[1], **Javier de Castro**[1]

[1]Hospital Universitario La Paz, Madrid, Spain,[2]CIBERONC, Madrid, Spain

Background: Non-small cell lung cancer (NSCLC) remains a leading cause of cancer mortality, largely due to late diagnosis and limited early-stage biomarkers. Liquid biopsy offers noninvasive monitoring, but most circulating markers lack clear tissue origin, limiting clinical interpretation.
Methods: We developed a patient-derived explant workflow to trace the origin of extracellular vesicle-associated microRNAs (EV-miRNAs) and evaluate their clinical utility in plasma. Fifteen resected lung adenocarcinoma specimens and matched normal tissues were cultured ex vivo to collect tissue and secreted small EVs. Small-RNA sequencing of 60 samples (30 EV, 30 tissue) and RNA-seq of 30 tissues identified neuro-metabolic mRNA targets potentially regulated by miRNA shifts. 77 miRNAs were differentially sorted into tumor versus control EVs; 25 candidates were selected for validation. A custom TaqMan OpenArray™ panel demonstrated high concordance with qPCR, enabling high-throughput profiling.
Results: We quantified these 25 EV-miRNAs in three cohorts: (1) 38 resectable patients with paired baseline and recurrence plasma; (2) 292 treatment-naïve patients across stages I-IV; and (3) 50 healthy controls. Six miRNAs - three “tumor-high” (miR-21-3p, miR-409-3p, miR-503-5p) and three “tumor-low” (miR-486-5p, miR-486-3p, miR-451a) - tracked recurrence in >50% of relapsing patients but remained stable in non-relapsers. Cross-sectional analysis showed stage IV patients recapitulated EV dysregulation (miR-21-3p high, miR-486-5p low), while localized disease mirrored controls. Prognostic modeling revealed stage-specific patterns: in stage III, low EV-miR-21-3p, miR-503-5p, and miR-486-3p predicted shorter progression-free survival; in stage IV, high EV-miR-21-3p correlated with worse overall survival, whereas high EV-miR-486-5p trended favorably. Exploratory Kaplan-Meier curves combining miR-503-5p/miR-486-5p for PFS and miR-21-3p/miR-486-5p for OS suggested risk stratification potential.
Conclusions: Our explant-to-liquid biopsy approach identifies EV-miRNA signatures that reflect tumor biology, monitor recurrence, and stratify prognosis across NSCLC stages. These findings support clinical validation of miR-21-3p, miR-486-5p, and miR-503-5p as prognostic biomarkers and highlight patient-derived explants as a powerful platform for biomarker discovery.

#1131 A novel detection strategy for an emerging biomarker: *MTAP* loss detection with circulating tumor DNA (ctDNA).

Lauren S. Welch[1], Radhika Gutta[2], Fawzi Abu Rous[2], Bindu R. Potugari[2], Sudha Sadasivan[2], **Shirish M. Gadgeel**[2]

[1]Guardant Health, Inc, Palo Alto, CA,[2]Henry Ford Cancer Center, Henry Ford Health System, Detroit, MI

Background: Methylthioadenosine Phosphorylase (*MTAP*) is a tumor suppressor gene frequently deleted in cancer, most often through loss of the 9p21 locus (*MTAP*, *CDKN2A*, *CDKN2B*). *MTAP* loss is an emerging biomarker with investigational therapies, yet detection has relied on tissue analysis, with prevalence estimates of 10-18% in advanced (adv) non-small cell lung cancer (NSCLC). Detection of large gene deletions by ctDNA is technically difficult and *MTAP* loss is not reported on most commercial ctDNA panels. Given the convenience of liquid biopsy and potential to expand trial eligibility, we analyzed the prevalence and genomic landscape of *MTAP* loss in lung cancer using a commercial ctDNA assay.

Methods: Patients (pts) with adv lung cancer who had Guardant360® Liquid testing between 7/2024-6/2025 were identified from the Guardant Health database. The start date aligned with assay expansion (>740 genes/epigenomics) and inclusion of *MTAP* loss reporting. *MTAP* loss was defined as bi-allelic loss by homozygous deletion (HomDel) or single copy deletion (del) with a co-occurring loss of function variant; prevalence and co-alterations (co-alt) were assessed by histology and tumor fraction (TF). Co-alt comparisons used two-sided Fisher's Exact Test ($p<0.05$ significant).

Results: *MTAP* loss was detected in 1.9% (330/17,333) of all lung cancer pts, 2.1% (55/2591) squamous, and 1.8% (244/13,745) non-squamous (nsq), regardless of TF; 94% (310/330) were NSCLC. Median (m) age was 69; 54.2% were male. For adv NSCLC, prevalence increased with TF, reaching 10.9% (294/2706) in pts with TF ≥10%, consistent with tissue-based rates. In nsqNSCLC, frequently co-altered genes included *CDKN2A* (96%), *TP53* (73%), *EGFR* (43%), *KRAS* (28%), *KEAP1* (27%), *STK11* (26%), *RB1* (25%), and *CCNE1* (24%). Compared to nsqNSCLC without *MTAP* loss, *CDKN2A (*mostly HomDel), *CCNE1*, *EGFR*, *BRCA2*, *KEAP1*, *STK11*, *RB1*, and *FGFR1* were enriched ($p<1\times10^{-}10$). mTF and bTMB were higher in the *MTAP* loss cohort (30.9% vs 0.7%; 15.1 vs 12.5 mut/Mb). Oncogenic *EGFR* mutations (muts) occurred in 16.4% (54/330), including exon 19 del (46%), L858R (23%), exon 20 insertion (11%), and other muts (20%); mTF was 28.1% (range 7.7-90%). Oncogenic *KRAS* muts were present in 19.1% (63/330), most commonly G12X (70%), with mTF of 26.3% (range 1.6-80.7%). Overall prevalence of *MTAP* loss in *EGFR* and *KRAS* mutated NSCLC was 2.3% (54/2304) and 2.0% (63/3172), respectively.

Conclusion: This first ctDNA analysis of *MTAP* loss prevalence and co-mutational landscape in NSCLC demonstrates that *MTAP* loss can be detected by ctDNA across histologies when TF is sufficient, offering a practical alternative when tissue is unavailable or rapid results are needed. ctDNA detection of *MTAP* loss may be further enhanced by methylation approaches for low-shed cases. Broader use of ctDNA testing could expand *MTAP* loss detection, increasing clinical trial eligibility and access to new therapies.

#1132 Malignant effusions for cfDNA/RNA genotyping and drug testing: Turning malignant fluids into personalized cancer models.

Elba Marin[1], Silvia Garcia-Roman[1], Cristina Aguado[1], Marta Vives[1], Sonia Rodriguez[1], Susana Munoz[1], Noelia Armiger[1], Alejandro Martinez-Bueno[2], Maria Gonzalez-Cao[2], Ana Velasco[3], Serafin Morales[4], Reyes Roxana[5], Ekaterina Meshoulam[2], Andres Aguilar[2], Clara Mayo de las Casas[1], Miguel Angel Molina-Vila[1]

[1]Pangaea Oncology, Hospital Universitari Dexeus, Barcelona, Spain,[2]Instituto Oncologico Dr. Rosell, Hospital Universitari Dexeus, Barcelona, Spain,[3]Institut de Recerca Biomedica de Lleida (IRBLleida), Lleida, Spain,[4]Hospital Universitari Arnau de Vilanova, Lleida, Spain,[5]Instituto Oncologico Dr. Rosell, Hospital Teknon, Barcelona, Spain

Introduction and objectives: Malignant effusions (MEs), including pleural, ascitic and pericardiac fluids, occur in 33% of patients with solids tumors, either at diagnosis and/or at progression to therapy. These fluids are very valuable when tumor tissue samples are inaccessible, as circulating free DNA/RNA (cfDNA/RNA) obtained from MEs enable accurate molecular diagnosis. Primary cultures can be established from tumor cells present in MEs, allowing for the *in vitro* testing of antitumor drugs and being of help in treatment selection due to their similarity with the patient's tumor. In this study, we aimed to incorporate MEs analysis into the routine clinical practice to determine clinically relevant alterations and to establish 2D and 3D primary culture models to be used in drug testing.
Materials and methods: MEs from patients with solid tumors were prospectively collected, with volumes ranging from 5-5,000 mL. cfDNA/RNA was extracted from all fluid samples and subjected to genotyping using a 30-gene DNA next generation sequencing (NGS) panel and a commercial mRNA nCounter panel containing 770 mRNA hybridization probes. In parallel, tumor cells contained in the MEs were isolated by centrifugation of the entire volume, cultured in complete culture media to establish 2D and 3D in vitro models, and molecularly characterized by NGS and nCounter. In successfully established pure tumor primary cultures (PTPC), cell viability assays were performed with chemotherapeutic agents and/or targeted therapies based on the detected alterations. Clinical follow-up data were collected to evaluate prognostic associations. Results We collected 382 MEs from 314 solid tumor patients. Of them, 49.7% (n=190) were collected at therapy progression, 28.3% (n=108) at baseline and 8.4% (n=32) while the patient was still on treatment. In 13.6% (n=52) cases, no data regarding collection time was available. Genotyping of cfDNA/RNA from 334 samples identified clinically relevant alterations in 77.3% (n=258), including mutations, amplifications, and/or fusions at variant allele frequencies (VAF) ranging from 0.33 to 93%. Among these, 35.3% (n=91) were considered targetable. Information on paired cytology samples was available in 11.6% (n=93) cases, showing a concordance rate of 80% with cfDNA/RNA genotyping. PTPCs could be successfully established from 61 MEs, mainly from pleural effusions (70.5%, n=43) and lung cancer cases (54.1%, n=33). Drug sensitivity assays were performed in 47 PTPCs (77%), including chemotherapy and targeted therapies. In 14 cases (29.7%) correlation between treatment received and sensitivity results could be analyzed, showing a 93% agreement.
Conclusions: MEs can be prospective collected in the clinical setting and used for a dual purpose. cfDNA and cfRNA can be isolated from the fluid fraction and employed for genotyping, while cells can be cultured and antitumor drugs tested.

#1133 Urine cell-free RNA captures tumor-reflective long intergenic noncoding and circular RNA programs in bladder cancer.

Pradeep Chauhan[1], Li Lin[2], Irfan Alahi[1], Jessica Linford[1], Lilli J. Greiner[1], Ayesha Hashmi[1], Anushka Viswanathan[1], Nathan Colon[3], Faridi Qaium[1], Peter K. Harris[2], John Sheng[2], Jacob J. Orme[1], Eric H. Kim[4], Zachary L. Smith[5], Woodson Smelser[2], Christopher A. Maher[2], Aadel A. Chaudhuri[1]

[1]Mayo Clinic, Rochester, MN,[2]Washington University School of Medicine, Saint Louis, MO,[3]Hoag Foundation, Newport Beach, CA,[4]University of Nevada Reno, Reno, NV, Reno, NV,[5]Advent Health, Orlando, FL

Introduction: Long intergenic noncoding RNAs (lincRNAs) and circular (circ) RNAs have been shown to play key roles in carcinogenesis and tumor progression. Urine represents a promising source of tumor-reflective signals shed directly from the urothelial microenvironment in bladder cancer (BC) patients. Here, we evaluate the urine cell-free (cf) RNA transcriptome in a cohort of 50 patients with localized BC.
Methods: A total of 50 localized BC patients and 24 healthy adults were enrolled. Pre-operative urine (collected on the day of radical cystectomy) was processed to isolate cfRNA from urine supernatant. Libraries were prepared using an Illumina tagmentation-based RNA enrichment workflow and sequenced to 100M paired-end reads per sample on a NovaSeq X. FASTQ files were concatenated per sample and QC-checked with RNA-SeQC and Samtools. Reads were aligned to GRCh38/hg38 with STAR, and gene counts were generated using Feature Counts. Linear differential expression analysis (DEA) was performed with DESeq2. For discovery we used random halves of TCGA-BLCA and healthy urine cfRNA samples, alongside a second DEA with random halves of urine BC cfRNA vs. controls; overlapping upregulated genes were validated in the remaining samples. For circular (circ) RNAs, annotations from MiOncoCirc were used; junctions with ≥5 supporting reads were retained, and DEA was conducted with edgeR.
Results: In this study, the median age was 68 years, and 80% (40/50) were male. Among the cohort, 66% (33/50) had muscle-invasive bladder cancer (MIBC), of whom 54% received neoadjuvant chemotherapy. Differential expression analysis of TCGA-BLCA tumors and BC urine cfRNA, identified 27 genes commonly upregulated, with 23 of the 27 shared genes strikingly being long intergenic noncoding RNAs (lincRNAs). These BC/urine-specific lincRNAs—including LINC00930, LINC01004, DLG5-AS1, APTR, PSORS1C3, and SERPINB9P1—have known roles in proliferation, EMT, metabolism, and immune signaling. Outside of lincRNAs, tumor-reflective coding transcripts in BC/urine were enriched for autophagy, driven by MAP1LC3B2.TCGA-BLCA survival analysis showed that LINC00930 and PSORS1C3 were associated with worse overall survival. Expanding beyond linear RNA sequences, analysis of urine circRNAs from BC patients revealed a strong cancer-specific dysregulation pattern, with 77 circRNAs significantly upregulated compared with healthy controls. Upregulated urine circRNAs arose from host genes involved in BC-relevant pathways, including invasion (*DOCK1*, *ARHGAP5*), autophagy/ER stress (*VMP1*, *ERN1*), and luminal differentiation (*GRHL2*, *ESRP1*).
Conclusion: Cell-free RNA profiling reveals a distinct transcriptomic signature including differential lincRNA- and circRNA-driven autophagy, EMT, proliferation, metabolic, differentiation, and immune signaling programs in the urine of bladder cancer patients.

#1134 Cell-free DNA fragmentomes capture response to immuno-radiotherapy in metastatic non-small cell lung cancer.

Noushin Niknafs[1], Lavanya Sivapalan[1], Bahar Alipanahi[2], Gavin Pereira[1], Amna Jamali[1], Jaime Wehr[1], Daniel Rabizadeh[1], Christopher Cherry[1], Bryan Chesnick[2], Nicholas C. Dracopoli[2], Jamie Medina[2], Stephen Cristiano[2], Willemijn S. Theelen[3], Robert Scharpf[1], Lorenzo Rinaldi[2], Victor E. Velculescu[1], **Valsamo (Elsa) Anagnostou**[1]

[1]Johns Hopkins School of Medicine, Baltimore, MD,[2]Delfi Diagnostics, Baltimore, MD,[3]Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Timely assessment of response to immune checkpoint inhibition (ICI) is critical but often limited by the heterogeneity of radiographic responses. Mutation-based analyses of cell-free DNA (cfDNA) circumvent these challenges, but are, in turn, prone to artifacts arising from clonal hematopoiesis. Plasma cfDNA fragmentome analyses using low-pass whole genome sequencing (WGS) may enable a scalable approach to evaluate systemic tumor burden in a tumor- and mutation-naïve manner.
Methods: cfDNA fragmentome analyses were performed following low-pass WGS of 244 plasma samples from 62 patients treated with pembrolizumab +/- radiotherapy (NCT02492568). A locked instance of the DELFI-TF, a random forest regression model based on genome-wide fragmentation patterns and aneuploidy, was applied to determine cfDNA fragmentome-based estimates of tumor fraction. The 95th percentile of tumor fraction in a non-cancer reference set established the limit of blank (LOB). Fragmentome-based landmark molecular response was defined as ctDNA below LOB at 6 weeks. Baseline tumor samples (n=24) patients were analyzed by RNA sequencing to characterize transcriptomic profiles stratified by cfDNA fragmentome profiles. Clinical outcomes were evaluated by RECIST 1.1 (at 6 and 12 weeks), progression-free survival (PFS), and overall survival (OS).
Results: At baseline, DELFI-TF values were correlated with radiographic tumor burden (R=0.32, P=0.017). Notably, tumors from patients with high DELFI-TF showed an enrichment in gene sets related to cell cycle, DNA replication and repair (adjusted P<0.05), suggesting that fragmentome TF accurately captured cellular turnover. At 6 weeks, 73% (8 out of 11) of patients with radiographic response attained fragmentome molecular response, while the subset of patients with radiographically stable or progressive disease was more heterogeneous in their fragmentome molecular response (24 out of 50, 48%). Fragmentome molecular response was more concordant with best overall response (BOR) at 12 weeks (Fisher's exact P=0.018). Analysis of baseline tumors from patients achieving fragmentome molecular response revealed an inflamed tumor microenvironment (adjusted P-value <0.001). Among patients with stable or progressive disease at the first radiographic evaluation, fragmentome response predicted longer PFS (logrank P=0.0096) and OS (logrank P=0.012). Similarly, fragmentome molecular response predicted PFS (logrank P=7.4e-5) and OS (logrank P=0.00028) across the entire cohort.
Conclusions: Plasma cfDNA fragmentome-derived tumor fraction reflects cellular turnover and lung cancer biology within the context of immunotherapy, while also enabling reliable, cost-effective, and scalable molecular response evaluations.

#1135 Lung cancer subtyping using cell-free DNA fragmentomes and protein biomarkers.

Stephen Cristiano[1], Paul van der Leest[2], **Jamie Medina**[1], Zachary Skidmore[1], Milou M. Schuurbiers[3], Garrett Graham[1], Alessandro Leal[4], Bryan Chesnick[1], Kim Monkhors[2], Nicholas C. Dracopoli[1], Robert Scharpf[5], Peter B. Bach[1], Daan van den Broek[2], Amoolya Singh[1], Victor E. Velculescu[5], Sian Jones[1], Michel M. van den Heuvel[3], Lorenzo Rinaldi[1]

[1]Delfi Diagnostics, Palo Alto, CA,[2]Netherlands Cancer Institute, Amsterdam, Netherlands,[3]Department of Pulmonary Diseases, Radboud University Medical Center, Nijmegen, Netherlands,[4]NYU Langone Health Perlmutter Comprehensive Cancer Center, New York, NY,[5]Sidney Kimmel Comprehensive Cancer Ctr., Baltimore, MD

Introduction: Lung cancer is the leading cause of cancer-related mortality worldwide. Accurate histological subtyping to differentiate between lung adenocarcinoma (LUAD), lung squamous cell carcinoma (LUSC), and small cell lung cancer (SCLC) is critical for guiding optimal therapeutic strategies. However, up to 20% of patients lack sufficient tissue for conventional histopathological classification. Liquid biopsies using cell-free DNA (cfDNA) fragmentomics offer a promising non-invasive alternative for cancer characterization when tissue is not available.

Methods: We examined 761 patients with newly diagnosed, treatment-naive lung cancer of all stages, including lung adenocarcinoma (n=468), squamous cell carcinoma (n=156), small cell carcinoma (n=42), large cell carcinoma (n=15) and other subtypes (n=80) from the prospective Lung Cancer Early Molecular Assessment trial (LEMA, NCT02894853). Low-coverage whole genome sequencing of cfDNA plasma samples was performed to derive genome-wide fragmentation features. Circulating tumor DNA (ctDNA) burden was estimated from fragmentation using the DELFI-TF method. We developed a machine learning classifier trained exclusively on the tissue-based copy number signatures from the Clinical Lung Cancer Genome Project (CLCGP) and applied it to patient cfDNA samples to predict lung cancer subtypes.

Results: This tissue-trained subtyping algorithm was evaluated on all available plasma samples, achieving an AUC of 0.99 (95% CI = 0.98-1.00) for distinguishing NSCLC from SCLC and an AUC of 0.91 (95% CI=0.87-0.95) for differentiating LUAD from LUSC. The model correctly classified 88% of SCLC, 80% of LUAD and 87% of LUSC cases where the tumor fraction was ≥0.3% (n=276). Among a subset of 361 NSCLC patients, integration of five blood protein biomarkers resulted in a multimodal model that differentiated LUAD from LUSC across all tumor fractions with high performance (AUC=0.85, 95% CI=0.80-0.90), an improvement over cfDNA ($p<0.01$; AUC=0.78, 95% CI=0.74-0.82) or protein-only classifiers ($p<0.001$; AUC=0.70, 95% CI=0.62-0.78).

Conclusions: These findings establish cfDNA fragmentation and protein biomarkers as a viable non-invasive approach for lung cancer subtyping when tissue is unavailable, with potential to expedite subtype-specific treatment selection and improve clinical outcomes

#1136 Analytical evaluation of a whole genome tumor-informed molecular residual disease detection assay with high sensitivity and specificity.

Weida Gong[1], Sung Kim[2], Guidantonio Malagoli Tagliazucchi[3], Tevfik Umut Dincer[1], Megha Ghildiyal[2], Magdalena Gantuz[2], Grace Kim[2], Quyen Bui[2], Yuan Ding[2], Jacob Gibson[2], Leland Mencik[2], Ambrose Vuong[2], Marcus Valancius[2], Kimberly Gietzen[2], Jennifer Becq[3], Carey Davis[2], Josh Bernd[2], Martin Chian[1], Dan Schmidt[2], Eileen de Feo[1]

[1]Illumina, Inc., Foster City, CA,[2]Illumina, Inc., San Diego, CA,[3]Illumina, Inc., Cambridge, United Kingdom

Introduction: Molecular residual disease (MRD) testing involves the detection of circulating tumor DNA (ctDNA) in plasma after cancer treatment. Tumor-informed Whole Genome Sequencing (WGS) workflows for the qualitative detection of MRD have been shown to be highly sensitive. We present an automated and scalable solution for patients with bladder, breast, melanoma, non-small cell lung (NSCLC), and colorectal (CRC) cancers with turnaround as fast as 8 to 9 days. This includes automation of DNA extraction, library preparation, sequencing, data analyses, and reporting. Here, we summarize the analytical performance of a research use only workflow intended as a service for research and clinical partners, such as pharmaceutical companies.
Methods: The workflow requires 3 different sample types: formalin-fixed, paraffin-embedded (FFPE), Buffy Coat, and 2 to 4ml plasma aliquots. The optimal inputs are: i) 5ng (minimum 2ng) cell-free DNA (cfDNA) from plasma, ii) 100ng (minimum 50ng) tumor tissue DNA, and iii) 50ng DNA from Buffy Coat. DNA is extracted from different sample types with WGS libraries preparation and sequencing on NovaSeq™ 6000. Sequencing analyses, fingerprint generation, and MRD detection are performed using DRAGEN™. The assay uses a patient's tumor and germline sample to generate a patient-specific somatic variant list, *i.e.* fingerprint. Subsequently, the cfDNA sequence data is evaluated against the fingerprint to determine the presence or absence of tumor DNA indicative of MRD. Both clinical and contrived samples were used to evaluate accuracy, analytical sensitivity, analytical specificity and precision.
Results: Twenty-five clinical samples (5 samples for each cancer type) resulted in 100% overall percent agreement (OPA) in MRD status relative to a reference method, with ctDNA concentration as low as 0.035%. A panel of 20 healthy plasma samples assessed against 25 fingerprints across multiple cancer types resulted in a 100% negative percent agreement. Sensitivity analysis demonstrated 100% detection rate at variant allele frequency of 0.003% for NSCLC, 0.005% for bladder and CRC, and 0.006% for melanoma and breast samples. Precision was evaluated using all specimen types across multiple operators, instruments, and library preparation start days. There was 100% OPA in MRD status across intra-run and inter-run replicates at ctDNA concentrations of 0.009% to 0.018%.
Conclusions: We present a whole genome fully automated workflow capable of generating tumor- informed MRD status with high analytical sensitivity and specificity. The assay requires low DNA input from plasma samples and enables a sample-to-report turnaround time as fast as 8 to 9 days. The results demonstrate that the WGS MRD detection platform is a scalable, robust, and highly sensitive assay for multiple cancer types.

#1137 Validation of a sensitive, tissue-free blood test for biomarker discovery and tumor burden assessment.

Zeliang Deng, Xiaoling Li, Xinyue Kang, Jiayue Xu, Jing Su, Xianrong Chen, Qiancheng You, Xingyu Yang, **Zhihong Zhang**, Bingsi Li

Research and Development, Burning Rock Biotech, Shanghai, China

Background: Rapid progress in molecular and computational technologies for circulating tumor DNA (ctDNA) analysis is transforming precision oncology, allowing tumor detection, relapse surveillance, and treatment selection without invasive tissue sampling. Among these approaches, methylation profiling of ctDNA offers a sensitive and quantitative measure of tumor burden. However, signal-to-noise ratios varies across cancer types and technologies, underscoring the need for tumor-specific assay optimization and rigorous validation. We previously developed a tissue-free, methylation-based assay and demonstrated its clinical validity in lung, colorectal, and liver cancers. Here we report expanded, larger scale validation across additional tumor types, including pancreatic cancer (PDAC) and bile tract cancer (BTC).

Methods: The CanCatch® Surf classifier was trained and subsequently locked, as previously described. The total analytical performance testing dataset comprises >1,000 contrived and clinical samples (10-30 ng input). In this study, we constructed dilution series of PDAC- and BTC-derived cell-line and cfDNA mixtures spanning 0.001-0.5% tumor allele fraction (TAF). The *in-silico* titration dataset was generated by digitally blending sequencing reads from PDAC and BTC patients with those from cancer-free donors at defined proportions (0.001-0.5%). Probit regression identified the limit of detection (LoD) as the lowest TAF detected with ≥95% probability; the limit of blank (LoB) was the per-sample positivity rate in age-matched cancer-free donors.

Results: The analytical sensitivity for PDAC and BTC reached 0.02% for *in silico* mixtures, cell-line dilutions and cfDNA titrations, with no false positives among 72 age-matched cancer-free donors (0 %; 95% CI 0-5.0%). Evaluation of 176 pre-treatment plasmas (57 PDAC, 50 BTC, 69 controls) demonstrated a sensitivity of 84.2% for PDAC (stage I 75.0 %, II 86.7%, III 83.3%, IV 100%) and 82.0% for BTC (stage I 71.4%, II 66.7%, III 93.3%, IV 92.3%), both at 98.6 % specificity; larger cohorts are in progress, and updated results will be presented as available.

Conclusions: CanCatch® Surf's non-invasive approach to ctDNA detection in solid tumors has demonstrated performance comparable to traditional tissue-based methods, thus holding promise for broader clinical use in monitoring disease recurrence and assessing treatment effectiveness.

#1138 Clinical grade circulating tumor DNA methylation predicts outcome to brigatinib plus local consolidative therapy in patients with ALK rearranged NSCLC - Liquid biopsy correlates from the BRIGHTSTAR trial.

Simon Heeke[1], Saumil Gandhi[1], Hai T. Tran[2], Lauren Averett Byers[1], Don Gibbons[3], Carl M. Gay[1], Mehmet Altan[3], Mara B. Antonoff[3], Xiuning Le[1], Janet Tu[3], Anne S. Tsao[4], Tina Cascone[1], Marcelo V. Negrao[1], George R. Blumenschein[5], John V. Heymach[1], Yasir Y. Elamin[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Associate Professor, Dept. of Cancer Medicine, UT MD Anderson Cancer Center, Houston, TX,[3]MD Anderson Cancer Center, Houston, TX,[4]Associate Professor, Div. of Cancer Medicine, UT MD Anderson Cancer Center, Houston, TX,[5]Associate Professor of Medicine, Dept. of Thoracic/Head & Neck Med. Oncology, UT MD Anderson Cancer Center, Houston, TX

Background: The phase II BRIGHTSTAR trial assessing the combination of brigatinib with local consolidative therapy in patients with ALK rearranged non-small cell lung cancer demonstrated promising clinical activity with a 5-year progression-free survival rate of 51% (Elamin et al. WCLC. 2025). To better characterize patients that would benefit of this treatment regimen, we performed clinical grade ctDNA methylation analysis for the detection of residual disease and prognostic.

Methods: We profiled 84 samples from 29 patients with stage IV or recurrent non-small cell lung cancer (NSCLC) and confirmed *ALK* rearrangement that were treated with local consolidative therapy (LCT) and brigatinib (BRIGHTSTAR; NCT03707938). Sample timepoints included baseline prior to therapy, at 8 weeks of brigatinib induction prior to local consolidative therapy (Pre-LCT) as well as after local consolidative therapy (Post-LCT) and at progression. Samples were profiled using the Guardant INFINITY platform for the detection of ctDNA using DNA methylation. Data was correlated to progression-free survival on treatment using Kaplan-Meier analysis and cox proportional hazard ratio.

Results: Circulating tumor DNA was persistently detected across timepoints with detection rates of 72% (N = 21/29) at baseline, 39% Pre-LCT (N = 11/28), 29% Post-LCT (N = 7/24) and 80% at progression (N = 4/5) demonstrating insufficient ctDNA clearing by brigatinib plus LCT treatment regimen. However, patients without detectable ctDNA at baseline using the DNA methylation classifier ($ctDNA^{METH}$) had significantly longer progression-free survival compared to patients with detectable ctDNA (38.2 months versus not reached; log-rank p = 0.04; HR = 0.16 (95% CI: 0.02-1.19)). No statistically significant difference in outcome was reported for patients who clear ctDNA Pre- or Post-LCT and patients with persistently detected ctDNA compared to pretreatment timepoint.

Conclusions: Clinical grade ctDNA methylation analysis allows the sensitive detection of ctDNA in patients with ALK rearranged NSCLC and is prognostic of outcome to brigatinib plus LCT therapy.

#1139 Early detection of treatment failure and disease dissemination inBCG-treated NMIBC using liquid biopsies and urine proteomics.

Trine Strandgaard[1], Tine Ginnerup Andreasen[1], **Iver Nordentoft**[1], Nathalie Demuth Fryd[2], Philippe Lamy[3], Julie Pedersen Harrits[1], Boris Oklander[4], Danielle Afterman[4], Tal Katz-Ezov[4], Imane Bourzgui[4], Jorn Jakobsen[5], Kristian Juul[5], Jorgen Bjerggaard Jensen[1], Lars Dyrskjot[1]

[1]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark,[2]Department of Urology, Aarhus University Hospital, Aarhus N, Denmark,[3]Department of Molecular Medicine,, Aarhus University Hospital, Aarhus, Denmark,[4]Veracyte, Inc., Haifa, Israel,[5]Ferring Pharmaceuticals, A/S, Kastrup, Denmark

Only about 40% of patients with non-muscle invasive bladder cancer (NMIBC) respond to Bacillus Calmette-Guérin (BCG) therapy. While immune cell exhaustion has been linked to BCG resistance, early disease dissemination (i.e., occult muscle-invasive disease) may also contribute to BCG failure. We assessed whether serial analysis of urine and plasma samples could reveal signs of immune exhaustion, residual disease, and early dissemination, predictive of BCG outcome. In a prospective cohort of 102 BCG-treated NMIBC patients (median follow-up 28 months; inclusion ended April 2024), whole-genome DNA sequencing (WGS) was used to generate patient-specific genomic-wide tumor-based signatures (Veracyte) from paired buffy coat and tumor or urine pellet (UPEL) DNA. These were applied to cfDNA WGS data from 271 urine and 329 plasma samples collected before, during, and after treatment to detect urinary tumor (ut)DNA and circulating tumor (ct)DNA. In parallel,344 urine supernatants were profiled using Olink immuno-oncology panels, and total RNA sequencing was performed on 55 tumors. Updated follow-up will be presented at the meeting. Plasma ctDNA was detected pre-BCG in 5 (6%) patients; three later developed high grade (HG) recurrence or progressed. Pre-treatment ctDNA positivity was associated with higher recurrencerisk (HR = 6.88) but not with tumor stage ($p > 0.42$) or grade ($p = 0.91$). Urine utDNA was detected in 58%, 51% and 27% of patients before, during, and after BCG, respectively. utDNA-positivity during or after BCG correlated with shorter recurrence-free survival. Recurrence was observed in 10/22 (45%) patients with detectable post-BCG utDNA and in 11/49 (22%) patients without measurable utDNA ($p=0.022$). On average, utDNA preceeded clinical detection with 133 days (range: 4-405). UPEL DNA enabled patient-specific model generation and ctDNA/utDNA detection in cases with limited tumor material (CIS only). BCG therapy induced increased urinary immuno-oncology proteins. Tumor-associated proteins (MMP-12, IL6, IL8) were elevated pre-BCG, while eight immunemodulatory proteins - including HO-1, GZMA, GZMB, LAP TGF-beta-1 and TRAIL were upregulated early during treatment in HG-recurrent versus non-HG-recurrent cases. Pre-treatment ctDNA identified patients at high risk of HG recurrence or progression, supporting a role as a potential restaging tool. UPEL DNA was a reliable tumor proxy and useful when tissue was limited (e.g., CIS). utDNA detection identified patients at high risk of recurrence and earlier than cystoscopy. Urine proteomics mirrored BCG-induced immune responses, with distinct early on-treatment profiles in recurrent versus non-recurrent patients. Together, ctDNA/utDNA and proteomic monitoring may enable early detection of treatment failure and guide timely therapeutic interventions.

#1140 Longitudinal tumor-informed cell-free DNA whole genome sequencing coupled with transcriptomic analysis captures tumor burden dynamics in resectable gastroesophageal cancer.

Blair V. Landon[1], Jaime Wehr[1], Rachel Keogh[1], Noushin Niknafs[1], Christopher Cherry[1], Nisha Rao[1], Gavin Pereira[1], Mark Sausen[2], Richard J. Battafarano[3], Stephen C. Lam[1], Valsamo (Elsa) K. Anagnostou[1]

[1]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Labcorp, Baltimore, MD,[3]Department of Surgery, Johns Hopkins University School of Medicine, Baltimore, MD,[4]Department of Radiation Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[5]Allegheny Health Network Cancer Institute, Allegheny Health Network, Pittsburgh, PA,[6]The Charles A. Sammons Cancer Center, Baylor University Medical Center, Dallas, TX

Introduction: Circulating tumor DNA (ctDNA) has been established as a promising biomarker for detecting residual disease and monitoring therapy response across the cancer care continuum, however its utility to assess response to neoadjuvant immune checkpoint inhibition (ICI) is still being investigated. We utilized a tumor-informed cell-free DNA (cfDNA) whole genome sequencing (WGS) approach to molecularly monitor tumor burden dynamics and link clinical outcomes with transcriptomic assessment of baseline tumors based on ctDNA status in gastroesophageal cancer treated with neoadjuvant ICI.
Methods: We performed WGS on tumor (n=28), matched white blood cell (WBC, n=28), and serial plasma samples (n=97) from patients with resectable gastroesophageal cancer treated with neoadjuvant ICI and chemoradiation prior to surgical resection (NCT03044613). Tumor and WBC sequence data was used to identify tumor-specific single nucleotide variants (SNVs). High quality SNVs were utilized to determine the presence of ctDNA in plasma through a random forest machine learning model. ctDNA status and tumor fraction (TF) were assessed across four timepoints (baseline, post-ICI cycle 1, post-ICI cycle 2, and pre-operatively). Results were compared with tumor-naïve gene panel ctDNA targeted NGS (n=32 patients, n=152 samples) and correlated with clinical outcomes. Additionally, bulk RNA sequencing (RNAseq) was performed on baseline tumor samples (n=28) and utilized for gene set enrichment analyses (GSEA).
Results: Patients with pre-operative ctDNA TF above the median had a significantly shorter overall survival (OS) compared to those with ctDNA TF below the median or undetectable ctDNA (logrank $p < 0.0001$). Among patients who were undetectable pre-operatively via the tumor-naïve targeted NGS panel, individuals with detectable ctDNA via the tumor-informed WGS approach attained a numerically shorter OS compared to individuals with undetectable ctDNA (logrank p=0.1). Similarly, patients with ≥95% reduction in cfDNA TF pre-operatively had longer recurrence-free (logrank p=0.002) and OS (logrank p= 0.0001). GSEA of RNAseq data from baseline tumors revealed enrichment of G2/M cell cycle checkpoint and E2F targets in tumors from individuals with detectable baseline ctDNA via the tumor-informed WGS approach (FDR-adjusted p=2.31e-12), suggesting that cfDNA TF detection captures cellular turnover in the blood stream. The upregulation of proliferation and cell cycle progression-associated gene sets was not observed in stratified analyses by ctDNA detection utilizing the tumor-naïve approach.
Conclusions: Tumor-informed cfDNA WGS analyses accurately capture tumor burden dynamics and cellular turnover during neoadjuvant immunotherapy, opening a window of opportunity for further therapeutic intervention and optimization.

#1141 A liquid biopsy-based predictive model identifies potential candidates for bladder preservation after neoadjuvant chemotherapy in muscle-invasive bladder cancer.

[1]Department of Molecular Medicine, Aarhus University Hospital, Aarhus N, Denmark,[2]AstraZeneca US, Gaithersburg, MD,[3]Department of Urology, Herlev Hospital, Herlev, Denmark,[4]Department of Oncology, Herlev Hospital, Herlev, Denmark,[5]Department of Urology, Aalborg University Hospital, Aalborg, Denmark,[6]Department of Oncology & Clinical Cancer Research Center, Aalborg University Hospital, Aalborg, Denmark,[7]Department of Pathology, Aalborg University Hospital, Aalborg, Denmark,[8]Department of Urology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark,[9]Department of Oncology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark,[10]Department of Urology, Odense University Hospital, Odense, Denmark,[11]Department of Oncology, Odense University Hospital, Odense, Denmark,[12]Veracyte, Haifa, Israel,[13]Department of Oncology, Aarhus University Hospital, Aarhus N, Denmark,[14]Department of Urology, Aarhus University Hospital, Aarhus N, Denmark

Detection of circulating tumor DNA (ctDNA) and urinary tumor DNA (utDNA) after neoadjuvant chemotherapy (NAC) has been shown to predict treatment response and outcome in muscle-invasive bladder cancer. Pathological complete response (pCR) is associated with improved survival outcomes and serves as a proxy for treatment response. We hypothesize that combining ctDNA, utDNA, and clinical variables in a predictive model could improve prediction of treatment response and outcome and potentially be used to identify candidates for bladder preservation.

We analyzed a unique dataset of urine and plasma samples together with detailed clinical measures and outcomes from 167 patients with localized muscle-invasive bladder cancer treated with at least three cycles of cisplatin-based NAC followed by radical cystectomy. ctDNA and utDNA measurements were performed using a tumor informed whole genome sequencing approach (TrueMRD, Veracyte) before (at baseline) and after NAC. pCR was defined as ypT0N0M0 at the time of radical cystectomy. Gradient boosting models were trained on 70% of the data using clinical variables alone and in combination with utDNA status and/or ctDNA dynamics and baseline ctDNA levels as well as imaging results from CT scans during NAC. Testing was done on the remaining 30% of data. Model performance was evaluated using the area under the precision-recall curve (AUCPR), and associations with ctDNA-free survival were investigated using Kaplan-Meier analyses.

For prediction of pCR, a model including baseline clinical variables as well as utDNA status, ctDNA dynamics, baseline ctDNA levels and imaging results gave an AUCPR of 0.93 and a negative predictive value (NPV) of 0.80. Using this model, patients with predicted pCR had a significantly better 1-year ctDNA-free survival (HR = 0.2, p = 0.03). A model including clinical variables, utDNA status, ctDNA dynamics and baseline ctDNA levels had a similar performance (AUCPR = 0.90; NPV = 0.82). A model including only the baseline clinical variables performed poorly (AUCPR = 0.54; NPV = 0.50). Adding either imaging results (AUCPR = 0.52; NPV = 0.48), utDNA status (AUCPR = 0.81; NPV = 0.65), or ctDNA dynamics and baseline ctDNA levels (AUCPR = 0.73; NPV = 0.62) did only make minor improvements.

Our findings demonstrate that integration of ctDNA dynamics and utDNA status, as well as imaging results into predictive models significantly enhances prediction of response to NAC and enables a clinically meaningful stratification of patients. Future independent testing in clinical trials is required, but our results support the development of liquid biopsy-guided bladder-sparing strategies in muscle-invasive bladder cancer.

#1142 Ultra-sensitive CRISPR-based NGS (MUTE-Seq) of pancreatic cyst fluid: KRAS variant allele fraction as an early marker of malignant potential.

Min Kyu Sung[1], Jungmin Kim[2], Yoon-Ho Won[3], Sung Sun Koo[3], In Seon Lee[3], Woohyung Lee[1], Ki Byung Song[1], Jae Hoon Lee[1], Dae Wook Hwang[1], Jin-Soo Kim[4], Seong Hyeok Ye[3], Junseok W. Hur[5], Song Cheol Kim[1]

[1]Department of Surgery, Asan Medical Center, Seoul, Korea, Republic of,[2]Genomic R&D Center, Korea Univ. College of Medicine, Seoul, Korea, Republic of,[3]GeneCker Co., Ltd., Seoul, Korea, Republic of,[4]Department of Oncology, Seoul National University Boramae Medical Center, Seoul, Korea, Republic of,[5]Department of Neurosurgery, Korea Univ. College of Medicine, Seoul, Korea, Republic of

Background: Conventional cytology of pancreatic cystic fluid from endoscopic ultrasound-guided fine-needle aspiration offers limited sensitivity for malignant potential of pancreatic cystic neoplasm. This proof-of-concept study aims to explore the clinical utility of cyst fluid next generation sequencing (NGS) using the ultra-sensitive MUTE-Seq assay.
Methods: Twenty-two patients who underwent surgical resection for pancreatic cystic lesions at Asan Medical Center, Korea, between November 2019 and July 2025 were prospectively enrolled. Approximately 1 mL of pancreatic cyst fluid was obtained intraoperatively from the resected specimens, from which cell-free DNA (cfDNA) was isolated and subjected to targeted NGS using the MUTE-Seq assay, a CRISPR-based technology that enhances cancer-associated variant detection by selectively suppressing cfDNA from normal cells. Custom primers amplified genomic regions of interest across 14 cancer-associated genes (AKT1, APC, BRAF, EGFR, KRAS, PDGFRA, PIK3CA, TP53, BRCA1, CTNNB1, ERBB2, IDH1, MYCN, and NRAS).
Results: Twenty-two patients with a median age of 60.5 years were analyzed. Initial pathologic diagnoses included serous cystic neoplasm (SCN, n = 4), mucinous cystic neoplasm (MCN, n = 4), intraductal papillary mucinous neoplasm-low grade (IPMN-LG, n = 7), IPMN-high grade (IPMN-HG, n = 4), pancreatic adenocarcinoma (PDAC, n = 2), and MCN with invasive carcinoma (n =1). Across the 14-gene panel, mutations in ERBB2, IDH1, PIK3CA, and AKT1 were sporadically detected in low-grade lesions without a discernible relationship to neoplastic grade. One PDAC case harbored a high TP53 variant allele fraction (VAF) of 47.475%.
In contrast to these sporadic findings, KRAS VAFs measured by MUTE-Seq demonstrated the strongest pathologic correlation. SCN had a median VAF of 0.14% (IQR 0-0.64), and MCN demonstrated a median VAF of 0% (IQR 0-0.12). High-grade lesions showed consistently elevated values, with IPMN-HG exhibiting a median of 41.04% (IQR 37.35-43.19) and PDAC a median of 31.545%. The case of MCN with invasive carcinoma showed a high KRAS VAF of 29.67%. KRAS VAFs in IPMN-LG were heterogeneous: three cases had low values (median 0.35%, IQR 0.3-0.75), while four cases showed high values (median 41.73%, IQR 36.56-42.63). Notably, one IPMN-LG case with a high KRAS VAF progressed to pancreatic carcinoma within three years, suggesting potential prognostic value.
Conclusions: Quantitative assessment of KRAS VAF using MUTE-Seq reliably distinguishes benign from neoplastic pancreatic cystic lesions, sensitively detects lesions with mixed invasive pathology, and may offer early molecular clues to malignant transformation, even in cases with borderline histology. Further study with additional specimens is underway to refine performance metrics and establish a clinically meaningful cutoff value for KRAS VAF.

#1143 Enspyre: A novel enrichment technology enables ultra-sensitive ctDNA detection with 98% reduction in sequencing requirements.

Paul Labrousse[1], Sophie Hackinger[2], Hugh Russell[1], Daniel Stetson[1], David Shera[3], Paulina Powalowska-Picton[2], Katarzyna Anton[2], Maria Litovchenko[2], Ernesto Lowy-Gallego[2], Amy Lovell[2], Magdalena Stolarek-Januszkiewicz[2], Barnaby Balmforth[2], James Hadfield[4]

[1]AstraZeneca, Waltham, MA,[2]Biofidelity, Cambridge, United Kingdom,[3]AstraZeneca, Philadelphia, PA,[4]AstraZeneca, Cambridge, United Kingdom

Background: Circulating tumor DNA (ctDNA) liquid biopsies show promise for minimal residual disease (MRD) detection, but clinical implementation is limited by high sequencing costs and the need for ultra-deep coverage to detect ctDNA at levels ≤100 parts per million (ppm). Current tumor-informed assays require >500 million reads per sample, necessitating sample batching and high-throughput platforms, which limits accessibility and increases turnaround times.

Methods: We evaluated Enspyre (Enrichment by selective pyrophosphorolysis and release), a novel enrichment technology that enables selective enrichment of specific variant molecules rather than just target regions. Eight lung cancer patients underwent whole genome sequencing of FFPE tumor tissue (median coverage 118x) for personalized probe design targeting a median of 1,995 somatic variants. Patient plasma samples were diluted to create a concentration series (5-1000 ppm) using healthy donor plasma. Enspyre enrichment was performed on low-input cfDNA samples (median 7.67 ng) followed by sequencing on NextSeq 550 with only 9.6 million read pairs per sample. ctDNA detection and quantification were performed using a Bayesian MRD estimation model, with analyses conducted blinded to ground truth concentrations.

Results: Enspyre demonstrated exceptional analytical performance across 72 patient samples and 8 controls. The assay achieved 100% sensitivity at 10 ppm (6/6 samples detected) and 20% sensitivity at 5 ppm (1/5 samples detected) without molecular barcodes. 100% specificity was maintained with no false positives in control samples (10/10 correctly called negative). Quantitative ctDNA estimates showed strong linear correlation with expected values ($r=0.90$, $p<2.2\times10^{-16}$), with estimates averaging 1.22-fold of target concentrations. Performance was maintained despite low DNA inputs, with successful detection from as little as 0.84 ng cfDNA. Compared to standard hybrid capture methods, Enspyre achieved equivalent sensitivity with a 98% reduction in sequencing depth (10M vs 500M reads per sample).

Conclusions: Enspyre enables ultra-sensitive ctDNA detection at 10 ppm with dramatically reduced sequencing requirements, addressing key barriers to clinical implementation. The technology's ability to maintain performance with low DNA inputs and simplified workflows makes ctDNA testing accessible on benchtop sequencers, potentially enabling broader adoption in clinical trials and community oncology. Sample throughput increases from 1 to 40 samples per NextSeq run represent a 40-fold improvement in accessibility. These results support Enspyre's potential to democratize ctDNA-based MRD detection while maintaining the analytical rigor required for clinical decision-making.

#1144 Tumor genomic features and postsurgical ctDNA status in patients with stage I-IV uterine cancer.

Tara Berman[1], Bhakti Dwivedi[2], Carly B. Scalise[3], Punashi Dutta[2], Adam ElNaggar[2], Minetta Liu[2], Casey Cosgrove[4]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Natera, Austin, TX,[3]Natera, Autin, TX,[4]James Cancer Hospital Solove Research Institute, Columbus, OH

Introduction: Molecular residual disease (MRD) detection using personalized, tumor-informed circulating tumor DNA (ctDNA) is a promising biomarker for early detection of recurrence and treatment response in uterine cancer (UC). However, the biological and genomic correlates of ctDNA positivity remain poorly understood in this setting. This study aimed to evaluate the prevalence and dynamics of ctDNA in UC patients, and associations with key genomic alterations derived from Altera™ comprehensive genomic profiling.

Methods: A retrospective cohort of 200 UC patients with available post-surgical ctDNA testing (Signatera™, Natera, Inc.) and Altera™ profiling from the same primary tumor tissue were analyzed. Inclusion criteria required blood collection within 2 months of surgery, and availability of at least one additional timepoint during adjuvant or surveillance period. Associations between ctDNA status/dynamics and Altera-reported genomic results were assessed.

Results: Among 200 evaluable UC patients, 43% (86/200) were ctDNA-positive (+) and 57% (114/200) were ctDNA-negative (-) within the MRD window. When stratified by stage, 15% (12/82) of early-stage (ES, stages I-II) and 63% (74/118) of late-stage (LS, stages III-IV) patients were ctDNA(+), indicating a higher MRD burden in advanced/aggressive disease. Genomic correlation analyses demonstrated that during the MRD window, ctDNA status was significantly associated with MSI-H/MSS status (chi-square test, $p<0.05$). ctDNA positivity rate was 78% (66/85) and 22% (19/85) among MSS and MSI patients, respectively. *POLE* exonuclease mutations (N=11; ctDNA(+): 18% [2/11]; ctDNA(-): 82% [9/11]) were seen in 55% (6/11) of MSS and 45% (5/11) of MSI-H patients. Among MSS patients with *POLE* mutations (N=6), 17% (1/6) were ctDNA(+) and 83% (5/6) were ctDNA(-). Similarly, among MSI-H patients with *POLE* mutations (N=5), 20% (1/5) were ctDNA(+) and 80% (4/5) were ctDNA(-). Notably, all MSS patients without an MMR alteration were ctDNA(+). When analyzed longitudinally, 93% (14/15) of MMR-altered ctDNA(-) patients remained serially ctDNA(-) throughout adjuvant/surveillance period, while 50% (4/8) of MMR-altered ctDNA(+) patients cleared ctDNA. Conversely, in the non-altered MMR group, 81% (18/95) of ctDNA(-) patients remained serially ctDNA(-), and 27% (21/77) of ctDNA(+) patients cleared ctDNA.

Conclusions: Post-surgical ctDNA status and dynamics are associated with disease stage and genomic features. Overall, ctDNA status within the MRD window was associated with MSI status. Post-surgical lack of ctDNA positivity and sustained clearance of ctDNA in the adjuvant period were associated with POLE alterations and/or MMR-altered phenotype, consistent with better prognosis. Given high prognostic value of ctDNA status and dynamics, integrating ctDNA-based MRD monitoring may aid in recurrence risk assessment and guide adjuvant therapy decisions.

#1145 Genome-wide cell-free DNA fragmentomes from blood and saliva enable early detection of head and neck cancers.

Akshaya Vijaya Annapragada[1], Shanaya Patel[2], Sarah Short[1], Keerti Boyapati[1], Shashi Koul[1], Hope Orjuela[1], Alice Eastman[1], Aditi Patel[2], Shreya Lotia[2], Vaishnavi Patel[2], Jason Zavras[1], Adrianna Bartolomucci[1], Dushyant Mandlik[3], Kaustubh Patel[3], Vivek Tanavde[2], David Sidransky[1], Mariana Brait[1], Rob Scharpf[1], Victor Velculescu[1], Jillian Phallen[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Ahmedabad University, Ahmedabad, India,[3]HCG Cancer Centre, Ahmedabad, India

INTRODUCTION: Over a billion people globally are impacted by risk factors for head and neck squamous cell carcinoma (HNSCC) - primarily smoking and smokeless tobacco, alcohol and human papillomavirus (HPV) - and may benefit from screening programs if they were available (five-year survival more than doubles for early-stage compared to metastatic disease across tumor sites but currently only 30% of cancers are diagnosed in early stages). We previously developed non-invasive blood tests for multiple cancer types using cell-free DNA (cfDNA) fragmentation profiles (DELFI) and repeat landscapes (ARTEMIS). These tests use cost-effective low-coverage whole-genome sequencing (WGS) to analyze millions of cfDNA fragments whose length, composition, and genome-wide distribution reflect cancer-related genetic and epigenetic changes. Here, we expand these analyses to another non-invasively sampled biofluid, saliva, and demonstrate their use for HNSCC detection.

METHODS: We established a prospective single-center collection of blood and saliva samples from individuals with and without HNSCC (n=329). These include 68 healthy individuals without high-risk exposures, 62 healthy individuals who use chewing tobacco, 17 individuals with high-risk leukoplakia, and 182 individuals with cancer, including 39, 37, 27, and 79 with stages I-IV of HNSCC respectively. We extracted cfDNA from blood (all, n=329) and saliva (subset, n=96), performed low-coverage WGS, and split individuals into Discovery (n=244) and Validation (n=85) cohorts. We evaluated genome-wide fragmentation profiles (DELFI) and repeat landscapes (ARTEMIS) in blood and saliva. We cross-validated three ARTEMIS-DELFI classifiers using blood, saliva, or features from both biofluids when available in the Discovery Cohort, and evaluated the locked models in the held-out Validation Cohort.

RESULTS: Genome-wide fragmentomes were concordant between blood and saliva samples from the same patients (median correlation coefficient r=0.76, IQR 0.64 - 0.87), and reflected cancer-related alterations including chromosomal changes such as 8q gain and 3p and 9p loss. In the Discovery Cohort, individuals with HNSCC were detected with high performance (AUC=0.87, 95% CI=0.83-0.91 and AUC=0.85, 95% CI=0.76-0.94 for plasma and saliva, respectively), and a combined model using features from both biofluids achieved an AUC of 0.89 (95% CI 0.82-0.97). In the Validation Cohort, at locked thresholds corresponding to 90% specificity, 65%, 71%, and 71% of cancers were detected by the blood, saliva and combined models, respectively. Across cohorts, sensitivity for Stage I tumors was >= 50% for all models.

CONCLUSIONS: We demonstrated that cfDNA fragmentation profiles and repeat landscapes can be obtained from both blood and saliva. These approaches may enable accessible, high-performance screening for HNSCC in global high-risk populations.

#1149 Multimodal liquid biopsy of Ewing sarcoma reveals high sensitivity prior to radiotherapy.

Roman O. Kowalchuk, Lilli J. Greiner, Yohan Kim, Rubia Noori, Jeffrey Szymanski, William S. Harmsen, Pradeep S. Chauhan, Adam C. Amundson, Andrea M. McMahon, Peter J. Schoettler, Wendy A. Allen-Rhoades, Stephanie F. Polites, Peter S. Rose, Kelly M. Bailey, Linda M. McAllister-Lucas, Anita Mahajan, Fabrice Lucien-Matteoni, Nadia N. Laack, Aadel A. Chaudhuri

Mayo Clinic Cancer Center Minnesota, Rochester, MN

Introduction: Detectable circulating tumor DNA (ctDNA) is associated with inferior outcomes in Ewing sarcoma (ES); however, ctDNA clears in nearly all patients within 2 of the 6 chemotherapy cycles before radiotherapy (RT) or surgery. Given a 3-year EFS of 37% on AEWS 1221 (metastatic) and 5-year EFS of 78% on AEWS 1031 (localized), current ctDNA testing fails to predict most relapses. Extracellular vesicles (EVs) are microscopic particles studied as a biomarker in multiple cancer types. We hope to improve the sensitivity of ctDNA in ES and provide the first application of EVs in ES.
Methods: cfDNA was isolated from 1mL plasma, quantified by Qubit, and sequenced as NEBNext Enzymatic Methyl-seq v2 libraries. We performed a systematic unsupervised clustering analysis of 27 ES plasma cfDNA profiles using 4 differentially methylated regions (DMR) subsets (63 strong DMRs, top 30, top 15, and 10 promoter-proximal loci), 3 clustering algorithms (k-means, Ward hierarchical, PAM), and k=2-5 clusters, testing associations with tumor burden and progression. EV analysis involved antibody detection against ES surface markers, including LINGO1, ENPP1, CDH11, and CD99. Concentrations of EVs were determined by standardized and calibrated high-resolution flow cytometry then analyzed with custom-built software to automatically determine and apply gates. Samples were de-identified, randomly coded, and run in triplicates. The senior research technologist responsible for EV analysis was blinded to patient information and clinical data.
Results: EV analysis included 36 pre-RT samples from 16 metastatic and 20 localized ES patients from a prospectively maintained biobank, with 27 pre-RT samples in the cfDNA analysis and 19 healthy donor (HD) samples. 35 of 36 patients had chemotherapy before sample collection. cfDNA concentrations were markedly elevated in ES patients compared with HD (24.4 vs 4.6 ng/mL, $p<0.0001$), and 74% of ES samples exceeded the HD 95th-percentile detectability threshold (7.0 ng/mL). Across clustering configurations, ES cfDNA profiles consistently exhibited reproducible methylation substructure. One configuration (PAM clustering, k = 5, 63 strong DMRs) showed a modest but permutation-supported association with primary tumor size (nominal $p \approx 0.04$; empirical $p \approx 0.03$-0.04). ES samples had increased EV concentration compared to HD ($p<0.001$), with AUC 0.988 for distinguishing between ES and HD ENPP1 ($p<0.0001$). The highest ENPP1 EV values were in patients with large primary tumors (>8 cm vs. ≤ 8cm) and metastatic disease ($p=0.066$).
Conclusions: cfDNA- and EV-based liquid biopsy provide encouraging signals for high ES detectability pre-RT. We also show the first study of EVs as a novel biomarker in ES, which may provide complementary information to ctDNA. Multimodal liquid biopsy in ES may identify candidate patients for systemic or local therapy escalation and facilitate personalized care.

#1150 Combining CDK4/6 inhibitor with TMZ and radiation alters cell states for synergistic responses in orthotopic DIPG models.

Zilu Huang[1], Tongchao Jiang[2], Milagros M. Suarez Palacios[2], Tommy Ouyang[2], Aalaa Abdallah[2], Long Niu[2], Jinnan Chen[2], Xin Zhai[2], Emily Ciolak[2], Wenan Qiang[2], Runxin Wu[3], Nitin Wadhwani[4], Alicia Lenzen[4], Michael DeCuypere[4], Sandi Lam[3], Shi-Yuan Cheng[5], Ching Man Wai[6], Brian Wray[6], Matthew John Schipma[6], Xinkun Wang[4], Wan-Yee Teo[7], Daniel J. [1]Department of Radiation Oncology, Sun Yat-Sen University Cancer Center, Guangzhou, China,[2]Pediatrics, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[3]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[4]Ann & Robert H. Lurie Children's Hosp. of Chicago, Chicago, IL,[5]Professor, Northwestern University, Chicago, IL,[6]NUSeq Core Facility, Center for Genetic Medicine, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[7]National Cancer Center, Singapore, Singapore,[8]Professor, Dept. of Path. & Lab Med., Northwestern University, Chicago, IL,[9]Department of Radiation Oncology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Background: To develop effective therapies for DIPG at different clinical stages, we examined efficacy and mechanisms of action of a combination therapy—abemaciclib (a CDK4/6 inhibitor), temozolomide (TMZ), and radiation (XRT)—in two patient-derived orthotopic xenograft (PDOX) models derived from treatment-naïve (IBs-9119DIPG) and autopsied (IBs-A0317DIPG) tumors.
Methods: In vitro synergistic anti-tumor activities were examined in tumor organoids, and in vivo efficacy in the PDOX models treated with abemaciclib (75 mg/Kg × 14 days), TMZ (50 mg/Kg × 5 days) and XRT (2 Gy/day × 5 days) alone and in combination (n=10/group, 60 mice/model). Changes of animal survival times were analyzed with log-rank analysis. Mechanisms of treatment response and resistance were elucidated by immunohistochemistry and scRNA-seq analysis.
Results: The triple therapy generated synergistic anti-tumor effects in organoids and significantly extended survival times in both PDOX models ($P<0.05$) despite their strong cellular state differences. scRNAseq identified reduction of oligodendrocyte-progenitor-like (OPC-like) cells in both models and astrocyte-like (AC-like) cells in IBs-A0317DIPG as response mediators; and revealed expansion of neural progenitor-like (NPC-like) cells in IBs-A0317DIPG and of mesenchymal-like (MES-like) and mitotic-like cells in IBs-9119DIPG as resistance contributors. Pseudotime trajectory analysis uncovered the exit of stemness into differentiation in oligodendrocyte-progenitor-like (OPC-like) cells as a novel mechanism of resistance in the treatment-naïve IBs-9119DIPG, in contrast to the enrichment of stem-like cells in the recurrent model IBs-A0317DIPG. A radiation-resistant subpopulation with novel candidate targets (*NPAS3, TBC1D5, INPP4B*) was also discovered.
Conclusions: This study demonstrated strong anti-DIPG capacities of the triple therapy in both untreated and recurrent DIPG tumors by acting on distinct cellular and molecular targets, and identifies previously unrecognized mechanisms underlying DIPG therapy response and resistance.

#1151 Targeting high risk osteosarcoma: MYC modulation alters metastasis.

Emily Seiden[1], Scott Sauer[2], Emma Hiscock[1], Nha Nhu Le[1], Ainsley Hellens[1], Monica Inda[1], Andrew Fuller[1], Sridhar M. Veluvolu[3], Rachael Hinshaw[1], Zachary P. Tolstyka[1], Elissa Levine[1], Rashmi Chugh[1], Theodore W. Laetsch[3], Nouri Neamati[4], Heather Wilson-Robles[5], Chand Khanna[6], David Warshawsky[2], Patrick J. Grohar[1]

[1]University of Michigan Medical School, Ann Arbor, MI,[2]Healx USA, Inc, Hoboken, NJ,[3]Children's Hospital of Philadelphia, Philadelphia, PA,[4]Univ. of Michigan College of Pharmacy, Ann Arbor, MI,[5]Ethos Discovery, Washington D.C, DC,[6]Ethos Discovery, Washington D.C., DC

Osteosarcoma (OS) is a bone tumor that affects human and canine patients. Standard of care is neoadjuvant chemotherapy and surgery resulting in a 5 year survival rate for patients with localized disease of ~70%. However, patients with metastatic disease and relapsed disease have a 5 year overall survival of less than 30%. Therefore, there is a critical need for improved therapies and a better understanding of the biological underpinnings of high risk disease. A subset of patients with particularly poor outcomes are known to have copy number amplification of MYC. However, it is not known if MYC contributes to the high risk phenotype by driving metastatic progression or drug resistance. Importantly, 20 compounds have been described as MYC inhibitors and perturb different steps of MYC driven transcription. In this report, we found that MYC drives cell migration and outgrowth but does not appear to contribute to drug resistance in OS cells. More precisely, MYC silencing reversed the metastatic phenotypes of migration and outgrowth of OS cells. Further, MYC downstream targets play an important role in metastatic progression. Silencing of MYC in 5 different cell lines revealed 45 common induced targets, many of which are known to modulate different steps in the metastatic cascade. We screened all 20 compounds previously shown to interfere with MYC transcription using an approach designed to capture the compound that modulates both MYC activity and the metastatic phenotype. Fourteen compounds modulated expression of MYC and/or downstream targets in 4 different OS models. Of those,10 compounds had a profound impact in cell viability in both 2D and 3D assays. Five of these showed selective toxicity in 3D relative to 2D; a phenotype linked to metastatic progression. Importantly, not all compounds that modulated MYC showed therapeutically favorable effects on migration or metastatic organization and outgrowth with at least 2 compounds driving a dramatic increase in migration despite suppressing expression of MYC. Nevertheless, 2 compounds, samuraciclib and THZ531, blocked MYC expression, downstream target expression, cell migration, metastatic organization and outgrowth. We confirmed these results and showed reversal of metastatic competence and complete reversal of metastatic outgrowth using the in vivo/ex vivo pulmonary metastasis assay (PuMA). We are now working to integrate CUT&Tag with BRUseq, an assay of nascent transcription, to determine if modulation of different steps in MYC transcription drives diverse cellular phenotypes as we hypothesized. Nevertheless, the top hit of the screen, samuraciclib, convincingly reverses MYC activity and the associated metastatic phenotype and is undergoing additional testing in metastatic OS mouse models and a canine clinical trial is under development. Correlative biology such as spatial transcriptomics will be used to guide the translation of samuraciclib to patients with high risk osteosarcoma.

#1152 Targeting *Yap1*-B7-H3 signaling stimulates CD8$^+$ anti-tumor response preferentially in male SHH medulloblastoma.

Nourhan Abdelfattah*[1], **Maryam Faisal***[1], Han Nhat Tran[1], Thomas Wong[1], Freddys Rodriguez[2], Carston R. Wagner[2], Kyuson Yun[1]

[1]Neurology, Houston Methodist Research Institute, Houston, TX,[2]Medicinal Chemistry, University of Minnesota, Minneapolis, MN

Sex-biased mechanisms in cancer remain poorly understood. We recently reported an unexpected sex-biased function of *Yap1*, an oncogene dysregulated in many human cancers, in murine models of SHH medulloblastoma (MB). *Yap1* deletion significantly extends survival preferentially in male animals and enhances immune infiltration, in part by attenuating the expression of the immune checkpoint molecule *Cd276* (B7-H3) in MB cells. These findings are clinically relevant because male patients with MB, the most common pediatric brain malignancy, exhibit worse survival and a higher incidence.

Here, we investigate the sex-specific consequences of *Yap1* loss and evaluate therapeutic targeting of CD276 using systemically administered CD276-targeting chemically self-assembled nanorings (CD276-CSANs).

Extensive characterization of the immune microenvironment in *Yap1*-deleted male and female tumors, conducted via single-cell RNA sequencing and high-parameter flow cytometry, revealed a significant increase in CD8+ T cells exhibiting cytotoxic properties in males, but not in females. In contrast, *Yap1*-deleted females had higher numbers of exhausted CD8+ T cells and regulatory T cells. Further, *in vivo* CD8 T cell depletion abolished the survival advantage seen in *Yap1*-deleted male MB, confirming the functional importance of these cells.

T-cell proliferation assays demonstrated that in male MB cells, targeting either *Yap1* or CD276 restored T-cell activation. In contrast, females, which have higher baseline CD276 expression, required both *Yap1* deletion and CD276 blockade/deletion to achieve similar activation. Consistently, CD276 blockade with CD276-CSANs phenocopied the male-biased survival advantage of *Yap1* deletion and increased CD8+ T-cell infiltration *in vivo*.

Overall, these findings reveal that *Yap1* promotes male-biased MB progression via *Cd276*-mediated CD8+ T cell suppression, resulting in immune evasion and highlighting CD276 as a promising therapeutic target for improving male MB prognosis.

#1153 Genome-driven molecular stratification and clinical impact in pediatric solid tumors: Results from the STREAM program.

Ji Won Lee[1], **June-Young Koh**[2], Chang Yeon Kim[2], Joo Whan Kim[3], Jung Yoon Choi[3], Seung Ah Choi[3], Seung-Ki Kim[3], Se Hoon Kim[4], Ji Hoon Phi[3], STREAM Consortium

[1]Samsung Medical Center, Seoul, Korea, Republic of,[2]Inocras Inc., San Diego, CA,[3]Seoul National University Hospital, Seoul, Korea, Republic of,[4]Yonsei University College of Medicine, Seoul, Korea, Republic of

The STREAM (Strategic TREatment And Magic for pediatric cancers) program, launched in March 2023, is a nation-wide precision-medicine platform for paediatric solid tumours and, unlike prior WGS studies centred on relapsed or high-risk disease, predominantly captures newly diagnosed patients. The programme integrates tumour-germline whole-genome sequencing, transcriptome and methylome profiling, in-vitro drug-response testing, centralised pathology review and multidisciplinary interpretation. Among 308 patients, somatic drivers were identified in 253 (82.1%), totalling 1,082 events across 404 genes. Pathogenic germline variants occurred in 32 of 303 evaluable patients (10.4%). Genomic profiling refined diagnosis in 85 cases, informed prognostic stratification in 20 and revealed 117 actionable targets across 99 patients. In-vitro drug screening from 58 patients yielded 496 sensitive and 1,376 resistant drug-tumour interactions. The genomic landscape showed lower mutational burden than adult cancers and was dominated by key pathways in cell-fate commitment, organ development and cell-cycle control. Using driver-gene alterations mapped to curated signalling programmes, we performed unsupervised clustering, identifying ten molecular sub-clusters. Several represented biologically coherent groups not captured by morphology: MAPK-driven pilocytic astrocytoma, Langerhans-cell histiocytosis and PLNTY formed one cluster; atypical teratoid/rhabdoid tumour and supratentorial ependymoma aligned through shared cell-cycle and epigenetic dysregulation; and medulloblastoma segregated into WNT, SHH and heterogeneous Group 3-4, the latter marked by SBS39 exposure linked to homologous-recombination deficiency. For prognostic evaluation, we analysed primary-diagnosis solid tumours (n=185), excluding relapse samples and haematologic malignancies. Survival differed significantly across clusters (OS p=0.0071). Cluster 6, composed mainly of Ewing sarcoma and rhabdomyosarcoma with growth-factor-receptor and secondary-signalling alterations, showed the highest mortality and relapse frequency and was the only group with a reached median OS. Clusters 2, 7 and 9 showed no deaths; Cluster 2 comprised Hedgehog-dominant medulloblastoma and related fibro-osseous tumours; Cluster 7 consisted of Group 3-leaning medulloblastoma and DNA-repair-altered tumours; and Cluster 9 included proliferative-signal-driven sarcomas and neuroblastoma, with no relapses observed. These molecular subgroups also showed strong concordance with in-vitro drug-response patterns. In this nation-wide cohort, molecular sub-clustering enhances diagnostic resolution, reveals pathway-defined biology missed by morphology and provides clinically meaningful prognostic stratification.

#1154 Multi-omic profiling of cellular heterogeneity and microenvironmental remodeling underlying treatment resistance in neuroblastoma.

Eun Seop Seo[1], JI WON LEE[1], In Woo Hwang[1], Woong-Yang Park[2], Jun Sun Kim[1], Ki Woong Sung[1]

[1]Samsung Medical Center, Seoul, Korea, Republic of,[2]Geninus, Seoul, Korea, Republic of

Background: Relapse and therapy resistance in high-risk neuroblastoma (NBL) remain major clinical challenges. The dynamic evolution of neuroblasts and their tumor microenvironment (TME) during treatment is not fully characterized. We established a multi-omic, longitudinal cohort to dissect the cellular and molecular mechanisms driving therapeutic failure.
Methods: We established a multi-omic longitudinal cohort of high-risk neuroblastoma. This included single-cell RNA sequencing (scRNA-seq) on 18 tumors (7 pre-treatment, 5 post-treatment, 6 relapsed), complemented by matched Xenium spatial transcriptomics for spatial mapping. Parallel Nanopore sequencing was conducted on a longitudinal NBL cohort to define the genomic and epigenomic landscape. A validation cohort of 76 bulk RNA-seq samples was used to correlate findings with clinical outcomes.
Results: Our scRNA-seq analysis identified a distinct ADRN_proliferating neuroblast subtype. In our validation cohort (n=76), the signature of this subtype was significantly associated with poor prognosis and correlated with the poorest response to induction chemotherapy. Longitudinal sampling showed that induction chemotherapy drives a predominant ADRN to MES shift in neuroblasts, while relapsed tumors exhibit the re-emergence of ADRN-like cells. However, this re-emergence was accompanied by markedly increased spatial heterogeneity.
Methylation profiling revealed an epigenetically post-imprinted ADRN program at relapse; these cells retained post-treatment-like methylation patterns in key TFs, such as GATA3, distinct from their treatment-naïve state. The TME underwent progressive remodeling from pre- to post-chemotherapy toward a more unfavorable, immunosuppressive state characterized by enrichment of $SPP1^{+}$ macrophages and other myeloid populations. This unfavorable TME was largely maintained at relapse, even as MES-like tumor cells reverted toward an ADRN phenotype, creating a highly treatment-refractory ecosystem. Ligand-receptor analysis implicated monocyte- and neutrophil-derived RTN4R signaling to neuroblasts and NOTCH signaling from Schwann cells as potential mediators of this relapse-prone niche.
Conclusion: Our multi-omic analysis demonstrates that NBL relapse is not a simple reversion but the emergence of a novel, epigenetically primed ADRN state co-evolving with a sustained, immunosuppressive TME.

#1155 High-throughput screening identifies synergistic drug interactions between CDK8/19 and DHFR inhibitors in rhabdomyosarcoma.

Ukhyun Jo[1], Ying Wu[2], Lisa M Jenkins[3], Tapan Kumar Maity[4], Seth P Zimmerman[5], Chris M. Counter[6], Assil Fahs[7], Corinne Linardic[5], Craig J. Thomas[3], John F. Shern[8]

[1]National Cancer Institue, Bethesda, MD,[2]Frederick National Laboratory for Cancer Research, Frederick, MD,[3]National Cancer Institute, Bethesda, MD,[4]Senior Research Fellow, Medical Oncology Branch, NCI-CCR, Bethesda, MD,[5]Duke University, Chapel Hill, NC,[6]Professor, Duke University Medical Center, Durham, NC,[7]Duke University, Durham, NC,[8]Clinical Fellow, Pediatric Oncology, NCI-CCR, Bethesda, MD

Rhabdomyosarcoma (RMS) is an aggressive pediatric soft-tissue sarcoma marked by substantial treatment-related morbidity and poor outcomes, particularly in metastatic or recurrent disease. Although diagnostic and therapeutic approaches have improved, survival remains low for patients with high-risk molecular features, including tumors harboring the PAX3::FOXO1 fusion. This fusion protein drives an aberrant transcriptional program that promotes tumor progression and resistance to therapy, underscoring the need for new treatment strategies. In this work, we investigated therapeutic vulnerabilities created by inhibiting the transcription-regulatory kinases CDK8/19. Using a high-throughput drug combination screen, we tested several CDK8/19 inhibitors against a library of 2,803 preclinical, investigational, and approved small molecules. The screen identified a strong synergistic interaction between CDK8/19 inhibitors and dihydrofolate reductase (DHFR) inhibitors. Unsupervised hierarchical clustering showed that multiple DHFR inhibitors formed a distinct cluster with highly similar patterns of synergy, supporting the robustness of this interaction. Follow-up viability assays confirmed synergy in both PAX3::FOXO1-positive and fusion-negative RMS cell lines. To define the biological basis of this synergy, we examined effects on transcriptional regulation, cell-cycle dynamics, and apoptosis. Annexin-V/DAPI staining demonstrated that combined treatment produced significantly higher apoptosis and G1 arrest than either drug alone. EdU incorporation assays showed a strong decrease in DNA replication, indicating impaired nucleotide synthesis. Transcriptomic profiling, including gene set enrichment analysis, revealed that CDK8/19 inhibitors upregulated PAX3::FOXO1 fusion targets, MYC-regulated genes, and oxidative phosphorylation pathways, whereas DHFR inhibitors primarily induced immune-related and KRAS signaling programs. The transcriptional responses to each drug class were largely distinct, and combination treatment reversed expression patterns driven by single agents. Importantly, DHFR inhibition triggered compensatory activation of pyrimidine biosynthesis genes, a response that was suppressed by CDK8/19 inhibition, providing a mechanistic basis for the observed synergy. ChIP-seq and proteomic data further supported these findings. Additionally, CDK8/19 inhibition amplified DHFR inhibitor-induced DNA damage, reflected by elevated γH2AX accumulation. Overall, these results highlight a therapeutic strategy that concurrently disrupts PAX3::FOXO1-driven transcriptional programs and nucleotide-dependent DNA repair. The combination of CDK8/19 and DHFR inhibitors may therefore overcome resistance mechanisms and enhance treatment efficacy in RMS.

#1157 Preclinical evaluation of PEG-[SN22]$_4$ (PEEL-224), a multivalent polymeric camptothecin prodrug, in pediatric solid tumor patient-derived xenograft models.

Filemon S. Dela Cruz[1], Kristina C. Guillan[1], Samantha Brosius[1], Armaan H. Siddiquee[1], Glorife Ibanez Sanchez[1], Daoqi You[1], Kristen Victor[1], Paul Calder[1], Trent Fowler[2], Joshua D. Schiffman[2], Andrew L. Kung[3]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Peel Therapeutics, Salt Lake City, UT,[3]Chair, Division of Pediatric Hematology/Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Background:
PEEL-224 is a multivalent polymeric prodrug of the topoisomerase I inhibitor SN22 designed to sustain intratumoral exposure and reduce transporter-mediated efflux. Desmoplastic small round cell tumor (DSRCT) and osteosarcoma (OS) are high-risk sarcomas of children and adolescents/young adults where irinotecan+temozolomide (I/T) provides modest, short-lived benefit. Early-phase clinical evaluation of PEEL-224 is ongoing (NCT06709495, NCT06721689, NCT05329103). However, the comparative activity of PEEL-224±TMZ versus irinotecan-based therapy has not been defined in disease-relevant models, prompting evaluation in DSRCT and OS patient-derived xenografts (PDXs).
Methods:
PDX-bearing NSG mice were randomized to vehicle, irinotecan, I/T, PEEL-224, or PEEL-224+TMZ. Tumor growth was assessed using Vardi's test for area-under-the-curve comparisons. Event-free survival (EFS) was defined as time to progression (≥100% relative tumor volume [RTV] increase from baseline) or euthanasia for tumor burden and analyzed by Kaplan-Meier with log-rank tests. Response criteria: PD = ≥100% RTV increase or euthanasia; SD = <100% increase and ≤50% reduction; PR = >50% reduction; CR = >95% reduction. Objective response rate (ORR) was the proportion achieving PR or CR. Treatment arms were expanded in an adaptive manner based on disease control to increase cohort size for key comparisons.
Results:
In DSRCT, tumor volume comparisons showed significantly greater control with PEEL-224 monotherapy vs irinotecan (p=0.04), while PEEL-224+TMZ and I/T showed similar control at this stage; cohort expansion is ongoing. EFS analysis showed PEEL-224 significantly prolonged EFS vs irinotecan (p=0.01) and PEEL-224+TMZ vs I/T (p=0.02). At end of therapy (Day 29), ORR was 0% (vehicle), 20% (irinotecan, 1/5 PR), 20% (I/T, 1/5 PR), 100% (PEEL-224, 5/5 PR), and 100% (PEEL-224+TMZ, 5/5 PR). At end of study (Day 113), irinotecan and I/T had 0% ORR, while PEEL-224 maintained 60% (3/5 PR, 2/5 SD) and PEEL-224+TMZ 100% (5/5 PR). Regimens were well tolerated. In OS, PEEL-224±TMZ produced disease stabilization and early regression, though statistical significance has not yet emerged (n=3/arm); expansion is ongoing.
Conclusions:
PEEL-224 demonstrated superior disease control as monotherapy and in combination over irinotecan-based therapy in DSRCT and early activity in OS. These preclinical data, alongside ongoing clinical evaluation, support advancement of PEEL-224 for high-risk pediatric and AYA sarcomas.

#1158 Hypermutation patterns shape tumorigenesis and immunotherapy response in mismatch repair deficient glioma.

Nicholas R. Fernandez[1], Yuan Chang[1], Nuno M. Nunes[1], Jose R. Dimayacyac[1], Adrian Levine[1], Amit Ringel[1], Logine Negm[1], Ayse B. Ercan[1], Julian Hess[2], Olfat Ahmad[3], Caitlin Lee[1], Lucie Stengs[1], Vanessa Bianchi[1], Melissa Edwards[1], Sheradan Doherty[1], Jiil Chung[1], Liana Nobre[4], Julie Bennett[1], Andrew J. Dodgshun[5], David TW Jones[3], Stefan M. Pfister[6], Anita Villani[1], David Malkin[1], Vijay Ramaswamy[1], Annie Huang[1], Eric Bouffet[1], Melyssa Aronson[7], Peter B. Dirks[1], Adam Shlien[1], Gad Getz[2], Yosef E. Maruvka[8], Birgit Ertl-Wagner[1], Cynthia Hawkins[1], Anirban Das[1], Uri Tabori[1]

[1]Hospital for Sick Children, Toronto, ON, Canada,[2]Broad Institute of MIT and Harvard, Cambridge, MA,[3]Hopp Children's Cancer Center (KiTZ), Heidelberg, Germany,[4]Stollery Children Hospital, Edmonton, AB, Canada,[5]Christchurch Hospital, Christchurch, New Zealand,[6]Pediatric Neurooncology, Hopp Children's Cancer Center Heidelberg (KiTZ), Heidelberg, Germany,[7]Zane Cohen Centre for Digestive Diseases, Toronto, ON, Canada,[8]Technion-Israel Institute of Technology, Tel Aviv, Israel

Primary mismatch repair deficient (priMMRD) glioma are deadly cancers comprising 5-10% of gliomas in children and young adults. PriMMRD glioma are characterized by universal hypermutation, resistance to chemo-irradation, and striking, but hetergeonous, responses to anti-PD1 immunotherapy. To elucidate the impact of replication-error driven mutagenesis on priMMRD glioma evolution and their heterogenous clinical courses, we analyzed genomic, methylomic, immune, and clinical data on a large cohort of priMMRD glioma (n=162) from the the International Replication Repair Deficiency Consortium. MMRD contributed to high microsatellite instability and hypermutation resulting in global DNA hypomethylation compared to non-MMRD gliomas and potentially affecting their classification. Recurrent somatic driver mutations in replicative polymerases and *IDH1* stratified priMMRD gliomas into 3 distinct genetic and clinical subgroups: priMMRD1 (MMRD+*POLE/POLD1*, 56%), priMMRD2 (MMRD-only, 27%), and priMMRD3 (MMRD+*IDH1*, 17%). PriMMRD1 gliomas, which harbor complete replication repair deficiency, originated from germline biallelic MMRD (CMMRD), occurred at young ages, and exhibited ultrahypermutation. PriMMRD2 gliomas were enriched for monoallelic germline MMRD (Lynch syndrome) and older ages. Finally, *IDH1*-driven priMMRD3 gliomas harboured germline mutations in MutSα (*MSH2*/*MSH6*), lower mutation burden, and distinct imaging patterns. Subgroups also utilized different mechanisms of genomic instability: while priMMRD1 gliomas harboured frequent point mutations in glioma drivers, priMMRD2 and priMMRD3 gliomas had higher rates of copy alteration in the same genes, including *CDKN2A* ($P<0.0001$) and *PTEN* ($P<0.0001$). Driver mutations observed in MMRD-driven gliomagenesis could be explained by the specific trinucleotide contexts that compose MMRD mutational signatures. Hotspot mutations in *TP53* and *IDH1* occurred in contexts commonly mutated by MMRD, while pediatric glioma drivers (*BRAF*/*H3-3A)*, which do not arise from frequently mutated contexts, were rare. Using mutational signatures and variant allele fractions, we built a model of MMRD gliomagenesis where TP53 mutations occur early, followed by secondary mutations in *POLE/POLD1*, *IDH1*, and other glioma drivers. PriMMRD glioma subgroups differed in their immune microenvironment and response to immunotherapy: priMMRD1 gliomas were associated with the highest 2-year overall survival on anti-PD1 monotherapy (75%), exhibited pro-immune expression signatures, and high CD8+ T-cell infiltration, contrasting priMMRD2 (24%) and priMMRD3 gliomas (0%). These findings suggest that MMRD mutagenesis shapes the unique landscape of priMMRD glioma through driver mutation acquisition and responses to immunotherapy, providing a rational approach for the refinement of subgroup-specific immunotherapy combinations.

#1159 Trans-species analysis of replication repair deficient medulloblastoma and response to immune checkpoint inhibition: An IRRDC report.

Nicholas R. Fernandez[1], Anirban Das[2], Adrian Levine[2], Kyle Smith[3], Evan Wang[2], Melissa Galati[2], Zoya Aamir[2], Jiil Chung[2], Logine Negm[2], Hope Friedman[2], Katharine O'Flaherty[2], Owen Crump[2], Quang M. Trinh[4], Nuno M. Nunes[2], Vanessa Bianchi[2], Lucie Stengs[2], Melissa Edwards[2], Lincoln Stein[4], Eric Bouffet[2], Michael D. Taylor[5], Paul Northcott[3], Vijay Ramaswamy[2], Cynthia Hawkins[2], Uri Tabori[2]

[1]Sick Children's Hospital, Toronto, ON, Canada,[2]Hospital for Sick Children, Toronto, ON, Canada,[3]St. Jude Children's Research Hospital, Memphis, TN,[4]Ontario Institute for Cancer Research, Toronto, ON, Canada,[5]Baylor College of Medicine, Houston, TX

Replication repair deficiency (RRD), caused by germline biallelic mutations in mismatch repair, leads to hypermutant brain tumour development in children and adolescents. RRD medulloblastoma have been reported but how RRD driven mutagenesis contributes to their clinical, genomic, and immune profiles is unknown. Through the International RRD Consortium, we enrolled 43 RRD medulloblastoma, analysed their exomes, methylomes, transcriptomes, and clinical outcomes. To better understand the mechanisms underlying their development and to assess preclinical responses to immunotherapy, we analyzed the histology and exomes of embryonal brain tumours developed in RRD mouse models (Nestin-Cre^{+}/*MSH2*$^{LoxP/LoxP}$/*POLE*$^{S459F/+}$). RRD medulloblastoma were enriched for anaplasia (61%), localised disease (77%), and harboured hypermutation and microsatellite instability, contrasting with “quiet” genomic profiles of non-RRD medulloblastoma ($p<0.0001$). Point mutations were frequent in *POLE/POLD1* (80%), *TP53* (48%), SHH pathway genes (56%) and, notably, glioma driver genes (*ATRX*, *NF1*, *RB1*: 50%). *TP53* hotspot mutations were distinct from non-RRD medulloblastoma and occurred in trinucleotide sequence contexts which were highly mutated by RRD mutational signatures, suggesting that replication errors shape their genetic evolution. Copy-number changes were infrequent (<20%) and inversely correlated with tumour mutation burden. While most did not classify with high confidence (>0.9) on DNA methylation subtyping tools, RRD medulloblastoma shared methylation programs with SHH medulloblastoma. Non-promoter genomic regions were hypomethylated relative to non-RRD medulloblastoma, partially explaining their failure to perform in DNA methylation classifiers. Transcriptomics reflected shared expression programs between RRD and SHH medulloblastomas. RRD medulloblastoma demonstrated high CD8^{+} T-cell infiltration and response to anti-PD1 monotherapy, with 60% three-year progression-free survival. Outcome was worse for tumours with *TP53*-mutation ($p=0.04$). Recurrent/progressive RRD medulloblastoma treated with anti-PD1 monotherapy had prolonged survival compared those which were not ($p = 0.02$), including responses in *TP53*-mutant tumours. RRD mouse models developed tumours that mirrored histological and genetic profiles of human disease and responded to anti-PD1 monotherapy, highlighting their relevance for future preclinical studies. Human RRD medulloblastoma are distinguished by their unique spectrum of driver mutations and hypomethylation profiles, shaped by RRD mutagenesis. Mouse models recapitulate human features and offer a mechanistic model for tumorigenesis and immunotherapy responses. Importantly, immune-hot microenvironments in RRD medulloblastoma contribute to successful salvage therapy for tumours failing chemo-radiation.

#1160 Characterizing neddylation as a potential vulnerability in MYC-amplified medulloblastoma.

Qiyun (Rachel) Shao, Vijay Ramaswamy

The Hospital for Sick Children, Toronto, ON, Canada

Background: Medulloblastoma (MB) is the most common malignant pediatric brain tumor. Children with MYC-amplified MB almost universally fail current treatments, highlighting a critical need for targeted therapeutic strategies. Our previous data revealed an enrichment of protein synthesis pathways in MYC-amplified MB, pointing toward protein turnover as a potential target. Neddylation is a post-translational modification process that plays a role in protein turnover through proteasomal degradation. We hypothesize that characterizing neddylation in MYC-amplified MB will identify novel therapeutic vulnerabilities, and that targeting neddylation is a rational therapeutic strategy for MYC-amplified MB.
Methods: Cell viability assay was conducted in four MYC-amplified MB cell lines and normal human astrocyte (NHA) control after 96hr treatment of neddylation inhibitor MLN4924 or TAS4464. Western blot was performed in TAS4464-treated MYC-amplified MB cell lines to evaluate MYC protein dynamics. To characterize neddylation proteome in MB, Co-Immunoprecipitations (Co-IP) were performed using lysates from MB or NHA models with NEDD8 or IgG (negative control) antibodies. Protein identification and quantification were carried out via mass spectrometry (MS), and the resulting dataset was subjected to STRING-based pathway enrichment analysis.
Results: All MYC-amplified MB cell lines exhibited significant sensitivity to TAS4464 compared to NHA. Western blot analysis revealed a transient accumulation of MYC followed by a sustained depletion, consistent with the disruption of neddylation-dependent turnover mechanisms. Nearly 1,000 conserved neddylation substrates were identified across MB cell lines, with the majority representing previously unidentified targets. MB-specific high-confidence targets are enriched in components comprising the mRNA splicing pathway and spliceosome complex. Further functional validation using distinct RNA splicing inhibitors induced potent, dose-dependent cytotoxicity in MYC-amplified MB, with markedly reduced sensitivity observed in NHA.
Conclusion: These findings establish neddylation as a critical dependency in MYC-amplified MB, essential for maintaining MYC protein stability and tumor cell survival. The potency of TAS4464 provides preclinical validation for targeting neddylation pathway. Our proteomics data unveiled a previously unrecognized dimension of neddylation in MB, identifying mRNA splicing machinery as a targetable vulnerability. This study represents the first link between neddylation driving splicing in MYC-amplified MB, suggesting a previously undescribed critical and actionable vulnerability that provides a mechanistic rationale for clinical investigation of neddylation inhibitors in very high-risk MYC-amplified MB.

#1161 Comprehensive pediatric biobanking and model development in the Beat Childhood Cancer Research Consortium.

Divya Gandra[1], Katherine McClain[1], Meenakshi Shukla[1], Laura Vazquez[1], Mohammad Haque[1], Jonathan Lerch[1], Muhammad Younis[1], Thussenthan Walter Angelo[1], Jeremy Hengst[1], Giselle Saulnier Sholler[2]

[1]Penn State College of Medicine, Hershey, PA,[2]Penn State Health Children's Hospital, Hershey, PA

The Pediatric Oncology Translational Research Lab (POTRL) at Penn State University (PSU) provides a critical centralized, LIMS-tracked repository of over 70,000 pediatric cancer specimens and patient-derived models, enabling validated resources for innovative translational research in precision-oncology through the Beat Childhood Cancer (BCC) Research Consortium.

Background:

Reliable translational research depends on high quality, well characterized patient materials. BCC operates a centralized repository managed through the POTRL at PSU. POTRL receives, processes, and stores biospecimens from multiple BCC clinical trials representing children with neuroblastoma, CNS tumors, sarcomas, and other solid malignancies. The repository includes tumor tissue, tissue slides, paraffin-embedded blocks, and blood/plasma that are processed for ctDNA, buffy coats, immune cells, cytokines, and biomarker analyses.

Methods:

All specimens are accessioned and tracked in Freezerworks LIMS to ensure accurate labeling and storage. Patients are consented to the BCC-BIO-001 study (NCT04715178) which collects whole exome and whole transcriptome sequencing of tumors, clinical diagnosis, pathology, treatment and outcomes of patients. Upon receipt, samples are inspected for integrity and temperature compliance. Cell lines, organoids and xenografts are generated from tumor tissue and bone cores/aspirates each of which undergo authentication at IDEXX BioAnalytics using short tandem repeat profiling with concurrent mycoplasma testing and matched patient references. Tumor line validation is performed by flow cytometric analysis using tumor-specific marker panels such as Ewings sarcoma (CD99); neuroblastoma (GD2, CD56, Synaptophysin); or medulloblastoma (CD56, Synaptophysin).

Results:

The repository currently houses more than 70,000 specimens from over 5,000 pediatric patients. Over 750 patient-derived cell lines and 150 patient-derived xenograft models have been established. Implementation of LIMS-based tracking has improved specimen organization and data consistency allowing for tracking of sequential patient samples. Each sample is correlated to timepoints in treatments and outcomes stored in the REDCap database. Development of patient-derived organoid models has recently begun and is ongoing across multiple tumor types, maintaining marker profiles consistent with primary tumors.

Conclusions:

POTRL provides an integrated platform for the collection, validation, and model generation of pediatric cancer specimens. These well characterized resources support translational research projects at Penn State and are shared throughout the BCC research centers nationally and internationally to accelerate biomarker discovery, preclinical testing, and precision-oncology studies for pediatric cancers.

#1162 Revealing the transformative role of METTL13 in human hematopoietic stem cells and progression of pediatric leukemia.

Sabina Enlund[1], Chae-Eun Lim[2], Isabella Hoang[2], Sonali Joshi[2], Amanda Ramilo Amor[1], Cecilia Thomsson[1], Maria Rivera[2], **Adena Pepich**[2], Indranil Sinha[1], Shahrzad S. Fard[1], Anna Nilsson[1], Ola Hermanson[1], Qingfei Jiang[2], Frida Holm[1]

[1]Karolinska Institutet, Stockholm, Sweden,[2]UC San Diego, La Jolla, CA

Childhood leukemia's five year survival rate has been improving over the last 40 years, but still only reaches 86.3% relative survival in the United States according to the Surveillance, Epidemiology, and End Results (SEER) program in 2025. Aberrant post-transcriptional RNA modifications, specifically N6-methyladenosine (m6A) methylation and adenosine to inosine (A-to-I) editing have previously been shown to push malignant transformations of hematopoietic stem cells (HSC). In order to unravel the mechanism behind these RNA modifiers and decipher whether methyltransferases (METTLs, such as METTL3 and METTL14) catalyzing m6A methylation work in concert with the A-to-I editing enzymes, adenosine deaminase acting on RNA 1 (ADAR1) to drive malignant transformation of HSCs. By first exploring differentially expressed genes in lentiviral over-expressed ADAR1 hematopoietic cells and progenitor cells we observed downregulation in the m6A complex (i.e. METTL3, METTL14, and other METTLs), except METTL13. While METTL13 knockdown converged with the other m6A complex knockdown results in immune signaling and survival, METTL13 knockdown uniquely affected cancer related pathways compared to other METTLs. Using publicly available RNA sequencing data from TARGET, we determined that increased METTL13 expression, in both T cell ALL and B cell ALL correlated to poor patient prognosis. Additionally, functional studies for cell proliferation and survival, both in vitro and in vivo, demonstrated METTL13's role in T-ALL when it is removed or lost. Overall these findings display the oncogenic role of METTL13 in T-ALL pathogenesis and pre-leukemic transformations, while revealing a continued research into this potential novel target for new therapies.

#1163 Combined AKT and XPO1 inhibition to target chimeric transcription factor-driven pediatric sarcoma pathogenesis.

Cameron Bumbleburg, Suprina Neupane, Henry Schrecker, Megan VanGarven, Janaia Jackson, Allison Reno, Emma Saunders, Jacob Lenski, Reid Barker, Hannah Gulbronson, Jamie Silverman, Kajol Patel, Elizabeth Maahs, C. A. Colvert, Abasi-ama Udeme, Moriah Heifetz, Jenna Schwesig, Margaret Taquey, Abbigayle Szcinski, Abigail Miller, Benjamin Caiello, Joshua Monts, B. J. Kendrick, Evan Bagley, **Casey G. Langdon**

The Medical University of South Carolina, Charleston, SC

Ewing sarcoma (EwS) is the most common chimeric transcription factor-driven pediatric bone cancer. One third of EwS patients are refractory to multimodal therapy (combination chemotherapy, surgery, radiation), especially those with recurrent or metastatic disease. New targeted therapies for EwS are urgently needed. We posit targeted combination therapies will be most effective at thwarting sarcoma pathogenesis. Examining reverse phase protein array data from the Cancer Dependency Map (DEPMAP), we found elevated expression or phosphorylation of phosphatidylinositol-3-kinase (PI3K) pathway members in EwS cell lines, highlighting the importance of PI3K pathway activity for EwS. We identified a subset PTEN-deficient EwS cell lines which was associated with increased sensitivity to AKT inhibition. Lower *PTEN* gene expression in EwS tumors is associated with poorer overall survival. Modulating PTEN levels or enhancing AKT activity altered PI3K pathway inhibition response, with AKT inhibitors showing a distinct effect compared to other pathway-targeting agents. Specifically, PTEN loss or increasing AKT phosphorylation heightened sensitivity to AKT blockade, whereas restoring PTEN expression conferred resistance. For EwS cells with high PTEN protein expression, PTEN was both cytoplasmic- and nuclear-localized. We hypothesized treating EwS cells with a nuclear export inhibitor could block PTEN trafficking out of the nucleus, reactivate the PI3K pathway, and synergize with AKT inhibition to thwart EwS pathogenesis. Indeed, we showed treating EwS cells with selinexor, an FDA-approved exportin 1 (XPO1) inhibitor, increased nuclear PTEN protein levels. Additionally, treating EwS cells with selinexor further activated the PI3K pathway. Dual AKT and XPO1 inhibition also synergized to limit EwS cell viability, induced cytotoxicity, and decreased xenografted tumor volume. Furthermore, combined AKT and XPO1 inhibition was also effective against other pediatric sarcomas driven by chimeric transcription factors, including desmoplastic small round cell tumors (EWSR1::WT1), PAX3::FOXO1-positive rhabdomyosarcomas, and clear cell sarcomas (EWSR1::ATF1). In conclusion, we demonstrated that PI3K pathway signaling is elevated in EwS cells and that low *PTEN* gene expression correlates with poor survival outcomes. Nuclear export inhibition altered PTEN subcellular localization and increased PI3K activity, contributing to the synergy between AKT and XPO1 inhibition. This combination therapy displayed efficacy across multiple fusion-driven childhood sarcomas, supporting its potential as an effective combination targeted therapeutic strategy for chimeric transcription-factor driven pediatric sarcomas.

#1164 Pacritinib mitigates doxorubicin resistance in osteosarcoma by inhibiting WNT/β-catenin, efflux proteins and receptor tyrosine kinase network.

Marina Curcic, **Sanjay Kumar Srivastava**

Texas Tech University Health Sciences Center, Abilene, TX

Chemoresistance remains the major obstacle to desirable responses in osteosarcoma (OS). We have previously identified pacritinib (PCT), an FDA-approved JAK2 inhibitor, as a modulator of the AXL/β-catenin axis. In parental osteosarcoma cells, pacritinib treatment reduced proliferation, induced apoptosis, and suppressed β-catenin-dependent transcription. Our docking studies, using Seam Dock server, supported direct engagement of both AXL and β-catenin with pacritinib. In vivo experiments showed growth inhibition of K7M3 tumors by pacritinib treatment in mice without any toxicity. Here, we evaluated the effect of pacritinib in sensitizing doxorubicin-resistant (DXR) osteosarcoma cells to doxorubicin.To determine key players in causing resistance, we first performed RNASeq analysis in doxorubicin-resistant (DXR) MG63 osteosarcoma cells and compared with parental MG63 sensitive -cells, with or without 1.5 μM pacritinib treatment for 24 hours. Gene-set enrichment from transcriptome data revealed significant activation of WNT/β-catenin programs in DXR cells compared to sensitive counterparts, with increased expression of canonical targets and receptors (e.g., WNT ligands, FZD receptors, TCF/LEF targets) and reciprocal loss of antagonists (DKK/SFRP/WIF1). Notably, drug-efflux machinery mainly ABCB1/MDR1 was elevated in MG63-DXR cells. In addition, receptor tyrosine kinase (RTK) network including AXL was also enhanced in DXR cells. The signature proteins identified by RNASeq analysis were further confirmed in MG63-DXR cells. Western blots confirmed the overexpression of AXL, β-catenin, and MDR1 in MG63-DXR cells relative to sensitive MG63 cells. Sulforhodamine-B cell viability assay showed that pacritinib reduced the growth of MG63-DXR cells in a dose-dependent manner. Growth suppressive effects were more pronounced in MG63-DXR cells when treated with pacrinitib in combination with doxorubicin, as compared to any individual treatments, showing synergism. Pacritinib treatment decreased AXL and β-catenin protein levels, attenuated downstream β-catenin targets, as well as reduced MDR1 in MG63-DXR cells. Notably, RNA-seq data of pacritinib-treated MG63-DXR cells showed a “reversal” trend: transcripts that were elevated in DXR (including β-catenin and efflux genes) were reduced by pacritinib treatment, whereas WNT antagonists increased, supporting pathway-level inhibition. An in vivo experiment is currently underway to validate that pacritinib exhibits synergistic effect with doxorubicin in suppressing MG63-DXR tumors in mice.Taken together, our data indicates that pacritinib synergistically enhances the effects of doxorubicin in suppressing the growth of MG63-DXR osteosarcoma tumors through a well-defined mechanism.

#1165 Vps34 inhibition enhances immunogenicity and immune-mediated killing in MYCN-amplified neuroblastoma.

Elisabetta Bartolini[1], Teresa L. Ramos[2], Ruize Gao[2], Bassam Janji[2]

[1]University of Luxembourg, Luxembourg, Luxembourg,[2]Luxembourg Institute of Health, Luxembourg, Luxembourg

Neuroblastoma is the most common extracranial solid tumor in children, accounting for approximately 10% of all pediatric cancers and 15% of cancer-related deaths in children under 15 years of age (1). High-risk neuroblastoma, often characterized by MYCN amplification, remains a major therapeutic challenge due to its aggressive behavior and an immunosuppressive tumor microenvironment (TME), which limits the efficacy of current immunotherapies.

Based on our previous findings (2), we assessed the therapeutic potential of targeting the autophagy regulator class III phosphatidylinositol 3-kinase (PIK3C3, also known as Vps34) to enhance anti-tumor immunity in high-risk neuroblastoma cells.

Transcriptomic analysis on murine MYCN-amplified neuroblastoma cells (NHO2A) treated with two distinct Vps34 inhibitors revealed marked upregulation of the pro-inflammatory chemokines CCL5 and CXCL10, both of which are critical for the recruitment of cytotoxic immune cells into the TME. Gene set enrichment analysis (GSEA) further demonstrated significant enrichment of immune activation, cytokine production pathways and biological oxidations, indicating increased tumor immunogenicity upon Vps34 inhibition.

Our preliminary results further suggest that Vps34 inhibition may trigger features consistent with immunogenic cell death (ICD), as treatment with Vps34 inhibitors significantly increased ATP release. Additional ICD markers are currently being investigated.

At the functional levels, in vitro co-culture assays demonstrated that Vps34 inhibition enhances CD8+ T cell-mediated cytotoxicity against MYCN-amplified neuroblastoma cells, confirming the immunostimulatory potential of Vps34 targeting.

Collectively, our findings underscore the potential of Vps34 inhibition as a promising strategy to render high-risk neuroblastoma cells more susceptible to immune-mediated killing. In vivo studies are currently ongoing to evaluate the therapeutic efficacy of combining Vps34 inhibitors with anti-PD-1 therapy which may pave the way for novel immunotherapeutic approaches for aggressive neuroblastoma.

#1166 Genetic and pharmacologic suppression of pink1 prolongs survival in sonic hedgehog driven medulloblastoma and related mouse model.

Bahauddeen M. Alrfaei[1], Amani Almuaysib[1], Ahmed Aloraidi[2], Ali Assiri[3]

[1]Blood and Cancer Research, King Abdullah International Medical Research Center, Riyadh, Saudi Arabia,[2]Neurosurgery, King Abdulaziz Medical City, Riyadh, Saudi Arabia,[3]Pathology and Laboratory Medicine, King Abduaziz Medical City, Riyadh, Saudi Arabia

Mitochondrial quality control plays a key role in helping cancer cells survive, but its impact on medulloblastoma is still not well understood. Here, we examined how the mitochondrial kinase PINK1 contributes to medulloblastoma growth by blocking its activity pharmacologically and by genetic loss-of-function approaches in mouse brain tumor models. Human medulloblastoma cells, MB004 and D425, were pretreated with a PINK1 inhibitor prior to orthotopic implantation. Kaplan-Meier analysis demonstrated significantly prolonged survival in mice receiving PINK1-inhibited tumor cells compared with controls (MB004: $p = 0.0288$; D425: $p = 0.0284$), indicating that disruption of PINK1 enhances therapeutic vulnerability. To further assess the role of Pink1 in vivo, we generated a genetically engineered mouse model without Pink1 in a Trp53-/-; Ptch1+/- background. This is a spontaneous tumor formation model at 90% rate. Pink1 deletion significantly increased survival compared with Pink1-active Trp53-/-; Ptch1+/- mice ($p = 0.0491$), supporting a tumor-promoting role for Pink1 in Sonic Hedgehog-driven medulloblastoma. Histopathological analysis of hematoxylin and eosin stained brain sections presented normal brain structure in the control animals, while Trp53-/-; Ptch1+/- mice developed high-grade tumors. Interestingly, Trp53-/-; Ptch1+/-; Pink1-/- brains showed reduced tumor burden and retained more tissue structure, consistent with the observed survival advantage. Together, these findings demonstrate that PINK1 is required for efficient medulloblastoma growth and that its inhibition—either through acute pharmacologic targeting or permanent genetic disruption—improves survival and reduces tumor pathology. Targeting mitophagy pathways such as disruption of PINK1 activity may therefore represent a promising therapeutic strategy for medulloblastoma, particularly in resistant or high-risk disease.

#1167 The pan-CLK DYRK inhibitor SM09419 prolongs animal survival times in a subset of pediatric medulloblastoma patient-derived orthotopic xenograft mouse models.

Xin (Alice) Zhai[1], Zilu Huang[1], Milagros Suarez Palacios[2], Tongchao Jiang[2], Aalaa Abdallah[3], Jinnan Chen[4], Yiming Mei[1], Emily Ciolak[1], Nitin Wadhwani[5], Alicia Lenzen[5], Yuchen Du[6], Xiao-Nan Li[6]

[1]Northwestern University - Chicago, Chicago, IL,[2]Northwestern University, Chicago, IL,[3]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[4]Ann & Robert H. Lurie Children's Hosp. of Chicago,[5]Lurie Childrens Medical Group, Inc., Chicago, IL,[6]Ann & Robert H. Lurie Children's Hosp. of Chicago, Chicago, IL

Background: Aberrant RNA splicing contributes to oncogenic transcriptional dysregulation in pediatric brain tumors. SM09419 is a potent pan-CLK/DYRK inhibitor that modulates alternative splicing and Wnt-related signaling pathways. SM09419 is a closely structurally related analog of Cirtuvivint (SM08502), another CLK/DYRK inhibitor from Biosplice Therapeutics, TenaRx, Inc., which has been studied in two completed Phase I clinical trials for treatment in adult solid tumors (NCT03355066 and NCT05084859), and is currently being studied in adults with AML or MDS (NCT06484062), Soft tissue sarcomas (NCT07032285), Ovarian cancer (NCT06856499) and Small cell lung cancer (NCT07155200).. The objective of this study is to evaluate antitumor efficacy as a single CLK/DYRK targeting agent in different molecular subtypes of medulloblastoma (MB) in a panel of patient-derived orthotopic xenograft (PDOX) models.
Methods: Eleven MB PDOX models including G3 (ICb-1572MB, ICb-1595MB, ICb-2555MB, ICb-5301MB), SHH (ICb-5610MB, ICb-3854MB, ICb-984MB, ICb-4989MB) and WNT (ICb-1192MB, ICb-1140MB, ICb-S1218MB) were treated with SM09419 (25 mg/kg, oral, once daily for 21 days). Changes of animal survival times were assessed by Gehan-Breslow-Wilcoxon tests. Cell proliferation (Ki-67) and (apoptosis cleaved-PARP1, cleaved-Caspase-3) was quantitatively evaluated by Visiopharm-aided immunohistochemistry.
Results: Significant extension of survival times were generated by SM09419 in three MB models, increasing median survival times from 27 days (control) to 36 days (treated) (33.3%) ($P = 0.0143$) in ICb-1572MB (G3); from 38.0 to 46.0 days (21.1%) ($P = 0.0029$) in ICb-5610MB (SHH) and from 154.0 days to 219.0 Days (42.2%) ($P = 0.0359$) in ICb-3854MB (SHH), accompanied by a significant reduction of Ki-67 ($P < 0.05$) and increased trends in cleaved-PARP1 and cleaved-Caspase-3 levels ($P > 0.05$) in ICb-1572MB and ICb-5610MB. No significant changes of animal survival times were detected in 7 models ($P > 0.05$), while the last model exhibited decreased survival times ($P < 0.05$) following drug treatment.
Conclusions: SM09419 produced significant therapeutic efficacy a subset of MB PDOX models characterized by decreased proliferative activity. Our findings highlight the biological heterogeneity among MB subtypes and support continued investigation of splicing-modulatory CLK/DYRK inhibitors as potential targeted therapies for pediatric brain tumors.

#1168 Development of RT-dPCR-based functional release assays for the *RPS19* gene therapy for Diamond-Blackfan anemia.

Neshat Masud, Sabina Ranjit, Nana Liu, Madhuri Kalathur, Senthil Bhoopalan, Catherine Willis

St. Jude Children's Research Hospital, Memphis, TN

Diamond-Blackfan Anemia (DBA) is a congenital ribosomopathy primarily caused by heterozygous loss-of-function mutations in *RPS19*, a key component of the 40S ribosomal subunit. RPS19 haploinsufficiency disrupts ribosome biogenesis, triggers p53-dependent cellular stress, and impairs the survival of erythroid progenitor cells. Beyond severe anemia, DBA patients exhibit a slightly elevated risk of hematologic and solid malignancies, highlighting a direct link between ribosomal dysfunction and cancer predisposition. Currently, the only curative approach for DBA is allogeneic bone marrow transplantation which is associated with risk of graft failure and graft-versus-host disease. Gene addition using a third-generation self-inactivating lentiviral vector encoding RPS19 (SJEFS-S19 LV) offers a promising strategy to restore functional RPS19 expression in patient hematopoietic stem and progenitor cells (HSPCs) while maintaining genomic safety and avoiding immune toxicities. Preclinical studies demonstrate that SJEFS-S19 LV effectively corrects erythropoietic defects, restores pre-rRNA processing, and generates a polyclonal, genomically stable population of HSPCs. LVs predominantly integrate into open chromatin regions associated with active transcription. To ensure product quality and functional integrity, we developed a reverse transcription digital PCR (RT-dPCR)-based release assay designed to detect and quantify *RPS19* transcript originating specifically from the integrated lentiviral vector following transduction. This approach partitions nucleic acid samples into thousands of micro-reactions, enabling absolute quantification with minimal amplification bias. For determining the RPS19 LV functionality, HEK293 *RPS19*-heterozygous knockout cells were transduced at varying multiplicities of infection (MOI), and total RNA was extracted for one-step RT-dPCR targeting the LV-derived codon-optimized *RPS19* sequence. Increasing MOI correlated with higher normalized *RPS19* transcript copies per ng genomic DNA, confirming successful vector integration and expression. This assay provides a robust, quantitative measure of functional gene expression, supporting critical quality attribute assessment of SJEFS-S19 LV. This functional assay concept is being translated into a critical release assay for the RPS19 Gene Therapy Drug Product in transduced CD34+ cells. Overall, this assay platform enables precise assessment of vector performance and provides a framework for translating LV gene therapy toward clinical applications in DBA patients, with potential implications for understanding how restoration of ribosomal protein function may impact oncogenic susceptibility.

#1169 Global proteomic analysis of pediatric T-cell acute lymphoblastic leukemia patient samples reveals distinct protein upregulation signature.

Irina Pushel[1], Thomas Gremminger[2], Lisa Lansdon[1], Michaella Rekowski[2], Midhat S. Farooqi[1], Michael Washburn[2], Keith August[1]

[1]Children's Mercy Kansas City, Kansas City, MO,[2]University of Kansas Medical Center, Kansas City, KS

Acute lymphoblastic leukemia (ALL) is one of the most frequently diagnosed pediatric cancers. Despite significant improvements in overall survival rates, children with T-cell ALL (T-ALL), accounting for approximately 15% of pediatric ALL cases, have worse outcomes than children with B-cell ALL, particularly upon relapse. Although T-ALL cases have been extensively profiled at the genomic and transcriptomic levels, the molecular mechanisms underlying poor therapeutic response remain unclear. To address this gap and identify novel putative therapies, we utilized mass spectrometry-based global proteomic profiling to reveal potential targetable features unique to this leukemia. In this study, we identified eight pediatric T-ALL patients treated at Children's Mercy with bone marrow aspirate samples collected at both diagnosis and remission banked in the Children's Mercy Biorepository. We generated global proteomic profiles for paired diagnosis and remission samples via data independent acquisition (DIA) using the timsTOF HT (Bruker). Data were searched in DIA-NN using the Bruker spectral library and human protein database downloaded from Uniprot on 05-05-2024. Downstream data analysis was performed in R 4.3.3 including differential expression analysis using limma 3.58.1 and pathway enrichment using gProfiler 0.2.3. Differential expression analysis identified 374 proteins more highly expressed at diagnosis and 434 proteins more highly expressed at remission ($p < 0.05$, $|\log2FC| > 1$). Pathways upregulated at diagnosis include cell cycle processes, cellular senescence, and nucleoside triphosphate diphosphatase activity. A number of proteins including CD7, CD38, HDAC1, HDAC2, and IL3RA (CD123) show elevated expression at diagnosis compared to remission, consistent with prior flow cytometry and/or gene expression studies of T-ALL. Surprisingly, several tumor suppressors including PTEN and BRCA2 also show elevated expression at diagnosis. While constitutive expression of PTEN has previously been reported in leukemias, it has typically been associated with mutations in the *PTEN* gene, which were not observed in these patients. This cohort of T-ALL patients shows upregulation of several proteins at diagnosis which are not seen in our analyses of other leukemias including B-cell ALL and acute myeloid leukemia. Global proteomic analysis comparing paired T-ALL samples from diagnosis and remission recapitulates increased expression of known proliferation and T-cell specific markers at diagnosis, as well as unexpected elevation of tumor suppressor protein expression. Further investigation of kinase activity and validation of these findings may reveal novel therapeutic targets to improve outcomes for pediatric T-ALL patients.

#1170 Proton-induced exosomal signatures reveal radiation response pathways in pediatric diffuse midline glioma.

Ann Morcos[1], Yeonkyu Jung[1], Nathan R. Wall[2]

[1]James M. Slater, MD Proton Treatment & Research Center Department of Radiation Medicine, Loma Linda University, Loma Linda, CA,[2]Assistant Professor of Basic Sciences, Pediatrics & Rad. Med., Loma Linda University, Loma Linda, CA

Diffuse intrinsic pontine glioma (DIPG) primarily affects children between five and ten years of age and carries a poor prognosis, with median survival of nine to twelve months. Standard treatment options are limited and typically include radiation therapy, which provides only temporary improvement, while chemotherapy and targeted therapy trials remain ongoing. DIPG remains one of the most lethal pediatric brain tumors, and emerging evidence suggests that extracellular vesicles such as exosomes may contribute to treatment resistance by carrying cargo that regulates apoptosis, DNA damage signaling, and intercellular survival pathways. Despite growing interest in exosome-mediated communication, the radiation-dependent dynamics of exosome release in DIPG remain understudied and poorly defined. This study aims to characterize radiation response features in DIPG1 and DIPG16A by comparing proliferation behavior, cell cycle distribution, and apoptosis and necrosis patterns after proton exposure, while establishing early and late exosomal dynamics through quantification of exosome release and size distribution. Here, we provide early evidence that proton radiation induces distinct cellular stress phenotypes accompanied by measurable and time-dependent exosomal output, suggesting an active radiation-responsive vesicle program. DIPG16A was derived from a treatment-naïve pretreatment biopsy specimen, whereas DIPG1 was obtained from a post-treatment autopsy specimen following exposure to radiation and multiple chemotherapeutic regimens. Both cell lines were cultured under standard conditions, exposed to graded proton doses, and exosomes were isolated and analyzed using nanoparticle tracking. A summary analysis of global treatment response revealed model-specific differences that may reflect prior therapeutic exposure and intrinsic tumor biology. Proliferation assays demonstrated that DIPG16A was more sensitive to radiation than DIPG1. DIPG16A showed a higher apoptotic population after irradiation, while both models displayed minimal necrosis and neither line showed detectable cell cycle arrest. Nanoparticle tracking analysis confirmed measurable exosome release at both early and late intervals in each line, establishing the foundation for future work investigating how apoptosis inhibitor proteins within exosomes may contribute to exosome-mediated radiation resistance in diffuse midline glioma. Collectively, these findings highlight proton-induced exosomal signaling as a potentially important and previously underappreciated component of treatment response in pediatric diffuse midline glioma and support further mechanistic exploration of exosome-carried survival factors. Generative artificial intelligence was used only for text editing and clarity, and all scientific content was produced and verified by the authors.

#1171 Copy number variation in Sonic hedgehog-medulloblastoma with unique p53 mutations: Inhibition of PI3K/AKT/mTOR pathways with HDAC inhibitors can serve as therapeutic options.

Austin Carpenter[1], Mohan Das[1], Raphael Salles S Medeiros[2], Sidnei Epelman, Epelman,[3], Nelci Zanon[4], Chirag D. Gandhi[1], **Meena Jhanwar-Uniyal**[1]

[1]Department of Neurosurgery, New York Medical College/Westchester Medical Center, Valhalla, NY,[2]Divisao de Anatomia Patologica, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil,[3]Department of Pediatric Oncology, Hospital Santa Marcelina, Sao Paulo, Brazil,[4]Department of Neurology and Neurosurgery,, Sao Paulo, Brazil, Brazil

The Sonic hedgehog subgroup of medulloblastoma (SHH-MB) originates from the cerebellar granule neuron progenitor (CGNP) population that relies on SHH pathway signaling for its perinatal expansion. Copy number variation (CNV) is a genomic structural variation that causes abnormal gene copy numbers including gene amplifications, gains, and losses. It is a vital factor regulating the expression of both protein-coding and non-coding genes, affecting various signaling pathways. Based on p53 mutations, the WHO has classified SHH-MB into two distinct prognostic categories. Here, we decipher the genomic patterns of SHH-MB tumors and evaluate the use of PI3K and HDAC inhibitors as therapeutic options. We utilized SHH-MB tumors (IRB-approved) from the Brazilian population to evaluate the genomic abnormalities using OncoScan CNV Plus-Assay and ChAS 4.2 software. Presence of isochromosome 17q [i(17q)] was determined by FISH. Effects of small molecule inhibitors targeting PI3K (Buparlisib; BKM-120) and HDAC (LBH-589) in SHH-MB cells (Daoy), were assessed via functional assays, such as cell proliferation, migration, cell cycle, and drug resistance. Results demonstrated: 1. Approximately 30% of patients exhibited i(17q) with multiple p53 mutations in the hotspot zone of the gene; 2. Other frequent genetic aberrations in IDH2:p.R140Q:c.419G>A (40%); PTEN:p.P248fs*5:c.741_742insA (60%); and KRAS:p.Q61H:c.183A>C (60%); 3. Some patients display aberrant chromosome 9; 4. Treatments with BKM-120 or LBH-589 or combined treatments inhibited cell proliferation, migration, cell cycle entry, and tumor formation of SHH-MB cells; 5. SHH-MB cells displayed resistance to BKM-120 treatments; 6. Western blotting analysis revealed that BKM-120 suppressed the activation of Akt and downstream target of mTOR, S6K, as evident by reduced levels of phosphorylation. In conclusion, we observed discrete genetic alterations in SHH-MB in a specialized population. The presence of i(17q) may define a poor prognosis and aberrant p53 is possibly an essential criterion for disease progression leading to therapy resistance. Furthermore, small molecule PI3K and HDAC inhibitors suppressed PI3K/AKT/mTOR pathways inhibiting cell proliferation, migration, and tumor formation. These studies provide evidence of genomic anomalies as well as treatment options for SHH-MB.

#1172 Inhibition of GSK3B signaling in pediatric brain tumors.

Mohammad Haque[1], Elizabeth Wert[1], Jeremey Hengst[1], Muhammad Younis[1], Katherine McClain[1], Tarlan Arjmandi[2], Meenakshi Shukla[2], Jonathan Lerch[2], Thussenthan Walter Angelo[2], Giselle L. Saulnier Sholler[2]

[1]Penn State University, Hershey, PA,[2]Penn State College of Medicine, Hershey, PA

Advances in genomic profiling have enabled increasingly precise molecular classification of pediatric embryonal brain tumors. However, the five-year overall survival rate for atypical teratoid/rhabdoid tumors (ATRT) and embryonal tumors with multilayered rosettes (ETMR) remains below 30%, despite intensive multimodal therapies. 9-ING-41 is a potent GSK3B inhibitor that has been shown to cross the blood-brain barrier and have biological activity against patient-derived intracranial xenograft models of other brain tumors, as well as good tolerability in recent Phase I human clinical trials. Previously we demonstrated that 9-ING-41 decreases ETMR and ATRT cell viability through apoptosis and increases p53 signaling, however the exact mechanism is unknown. The primary objective of this study was to determine whether GSK3B inhibition using 9-ING-41 could effectively suppress ATRT and ETMR growth by modulating p53 signaling pathway. ATRT and ETMR cell lines were grown for 24 hours prior to 9-ING-41 treatment in DMEM and Neurocult medium, respectively. Cell viability was assessed after 72hrs of treatment using Cell Titer Glo 2.0. Cells treated with IC50 determined dosing for 24-72 hours were collected for Western blot analysis of key proteins responsible for apoptosis and p53 signaling molecules. Cells were harvested for RNA isolation using Qiagen RNeasy kit. Transcriptomic profiles were established by RNA seq. Neurosphere assays were done by seeding two cells per well in a 96-well plate followed by treatment with 9-ING-41. In vivo xenograft models were established by orthotopic injection of ATRT 2141 cells into the mice brain through intra cranial stereotaxic system followed by treatment with either vehicle or 70mg/Kg 9-ING-41 by I/P injection for 9 weeks. In vitro analyses using multiple ATRT and ETMR cell lines revealed a significant therapeutic response to GSK3B inhibitor within clinically relevant dosing ranges. The IC50 of 9-ING-41 in BT183, CHLA02-ATRT, ATRT-2187, ATRT 2141 are 145.5, 481.2, 503.1, and 528.3nM respectively. Whole-exome and RNA sequencing of treated cells demonstrated upregulation of p53 tumor suppressor genes and downregulation of Shh pathway genes, supporting a tumor-suppressive mechanism. Protein expression analyses of p53 negative regulator further confirmed that 9-ING-41 treatment enhanced the activation of apoptotic pathways through p53 signaling pathway. In vivo studies showed a significant improvement in overall survival in mice treated with 9-ING-41 increased survival from 35 days to 55 days ($P < 0.0001$). Mechanistic evaluation of tumor tissues revealed increased p53 expression and marked downregulation of Ki-67, indicating reduced proliferative activity.

#1173 Trans-species analysis of mismatch repair deficient IDH1 mutant gliomas reveals a unique genomic and immune landscape resulting in favorable response to combination immune and targeted therapy.

Vienna Mazzoli[1], Nicholas R. Fernandez[1], Zoya Aamir[1], Olha Kos[1], Emma Gattoni[1], Owen Crump[1], Lucie Stengs[1], Nuno M. Nunes[1], Katharine O'Flaherty[1], Hope Friedman[1], Olfat Ahmad[2], Abigail Suwala[2], Kevin Bielamowicz[3], Gadi Abebe-Campino[4], Shani Caspi[4], Per Nyman[5], Richard Graham[6], John Y. H. Pfister[2], Peter B. Dirks[1], Eric Bouffet[1], Cynthia E. Hawkins[1], Anirban Das[1], Uri Y. Tabori[1]

[1]The Hospital for Sick Children, Toronto, ON, Canada,[2]German Cancer Research Centre, Heidelberg, Germany,[3]Arkansas Children's Hospital, Little Rock, AR, Canada,[4]Chaim Sheba Medical Center, Ramat Gan, Israel,[5]Crown Princess Victoria Children's Hospital, Linkoping, Sweden,[6]Cincinnati Children's Hospital Medical Center, Cincinnati, OH,[7]Kaiser Permanente, Oakland, CA,[8]Karolinska Universitetssjukhuset, Stockholm, Sweden,[9]Great Ormond Street Hospital, London, United Kingdom,[10]Schneider Children's Medical Center of Israel, Petah Tikva, Israel,[11]University Hospital 12 de Octubre, Madrid, Spain,[12]University of California San Francisco, San Francisco, CA,[13]Johns Hopkins University School of Medicine, Baltimore, MD

High-grade gliomas are deadly tumors in children and young adults (CAYA). Mismatch Repair Deficiency (MMRD) is present in 5-10% of CAYA gliomas and is typically associated with favorable response to immune checkpoint inhibitors (ICI). Interestingly, a subset of MMRD-CAYA gliomas harboring *IDH1* mutations fails to respond to ICI. At the molecular level, the interaction of MMRD with mutant IDH (mIDH) and the causes of ICI resistance are not well understood.

To tackle this challenge and develop effective therapeutic strategies for these cancers, we performed trans-species clinical, multi-omic, and immune analysis of human and murine tumors.

Molecularly, MMRD-mIDH gliomas displayed a profile resembling mismatch repair proficient (MMRP) astrocytomas, characterized by frequent *TP53* (83%) and *ATRX* (76%) mutations and absence of oligodendroglioma-associated alterations (1p/19q codeletion). Nevertheless, in contrast to MMRP-mIDH gliomas, which more commonly present as low-grade tumors, >91% of MMRD-mIDH gliomas were high-grade, exhibiting significantly worse outcomes ($p<0.001$). Compared with MMRD-IDH wildtype gliomas, MMRD-mIDH gliomas exhibited reduced tumor mutation burden (TMB, 113 vs 28 mutations/Mb, $p<0.05$) and immune infiltration, quantified by Tumor Inflammation Signature and CD8+ T cell density, partially explaining their inferior survival under ICI treatment.

In order to study tumor development, metabolic and immune profiles, as well as response to combination therapy, we developed a novel MMRD-mIDH glioma mouse model (*Olig2-Cre*$^{+}$*/Msh2*$^{LoxP/LoxP}$*/Trp53*$^{LoxP/LoxP}$*/LSL-Idh1*$^{R132H/+}$). Mouse MMRD-mIDH gliomas displayed characteristic features of human gliomas, including TMB (20 mutations/Mb), altered glioma driver genes (*ATRX, NF1)*, diffuse cerebral involvement, and low immune infiltrates ($p<0.05$) as compared with MMRD-IDH wildtype models. Preliminary data reveals that mIDH inhibition does not impact proliferative and stemness capacity of MMRD-mIDH mouse glioma cells *in vitro,* while detailed analysis of the effect of mIDH inhibition on genomic, transcriptomic, and immune profiles are ongoing.

Strikingly, informed by our trans-species analysis, an initial trial using the addition of IDH inhibitor to ICI (n=13 patients) led to objective radiological responses and prolonged survival at 12-months compared to ICI monotherapy ($p=0.01$).

MMRD-mIDH gliomas are a genetically and biologically distinct group of tumors with limited therapeutic options. Molecular and immune profiling of MMRD-mIDH gliomas, from both patients and a novel mouse model, enables investigation of the biology underlying glioma development and testing of improved therapeutic approaches.

Poster Session

#1177 Prognostic implications of circulating Hepsin in prostate cancer.

Taylor Wadley[1], Adam Cole[2], Blake P. Johnson[3]

[1]Navaux, Inc., Little Rock, AR,[2]TruCore Pathology, Little Rock, AR,[3]Navuax, Inc., Little Rock, AR

Introduction and Objective: Hepsin, a type II transmembrane serine protease, has been implicated in prostate tumor progression and metastasis. Recent studies have uncovered its proteolytic auto-activation and ectodomain shedding, supporting its potential as a circulating serum biomarker. We developed a quantitative sandwich ELISA to detect non-membrane-associated (circulating) Hepsin and evaluated its clinical relevance across benign prostatic hyperplasia (BPH), primary prostate cancer, and biochemical recurrence (BCR) following radical laparoscopic prostatectomy (RALP).
Methods: A proprietary ELISA was established using two monoclonal antibodies screened against ovarian ascites to identify native circulating Hepsin. Antibodies were further validated using recombinant extracellular Hepsin containing a thrombin cleavage site, mimicking auto-activation and shedding. The detection antibody was characterized via High-Mass MALDI mapping to the poorly conserved non-catalytic domain of Hepsin. Retrospective analyses were performed on data from an IRB-approved prospective study (2018-present) including 543 patients undergoing prostate evaluation, stratified by Hepsin status. Clinicopathologic variables (BPH, tumor stage, metastasis) were compared between Hepsin-positive and -negative groups using Chi-square or Fisher's Exact tests. Among 200 RALP patients, BCR-free survival was analyzed by Kaplan-Meier and Cox regression.
Results: Hepsin positivity occurred in 109 of the 543 (20%) patients. Compared to Hepsin-negative patients, positive patients showed higher cancer incidence vs BPH ($p<0.05$), advanced stage (≥pT3a) ($p<0.05$), and metastasis ($p<0.05$). Kaplan-Meier analysis demonstrated significantly reduced recurrence-free survival in Hepsin-positive patients (log-rank $p < 0.001$), with a Cox hazard ratio of 4.2 (95% CI 2.3-7.8). Notably, circulating Hepsin was determined to be an independent predictor of BCR ($p = 0.0001$). Furthermore, in comparison to CAPRA-S low-risk with concurrent Hepsin-negativity, Hepsin-positivity rendered an additive prognostic potential in patients with concurrent high CAPRA-S scores ($p = 0.0003$) compared to CAPRA-S high alone ($p = 0.0007$).
Conclusions: This study provides early evidence regarding Hepsin's ability to identify prostate cancer patients harboring a significantly elevated risk of BCR and adverse pathology post-RALP. These data highlight a novel role for non-invasive, longitudinal evaluation of circulating Hepsin levels in the prostate cancer setting.

#1178 STING-induced cytokine profiles in tumor fragments correlate with recurrence in head and neck cancer patients.

Animesha Krishnamurthy, Shuyue Ye, Vijay Basava, Oreoluwa Onabolu, Baran Sumer, Qiang Feng, Jinming Gao

UT Southwestern Medical Center, Dallas, TX

Only about 20% of head and neck squamous cell carcinoma (HNSCC) patients respond to immune checkpoint blockade (ICB), underscoring the need for alternative immunotherapeutic strategies and functional assays to assess patient-specific immune function. Activation of the stimulator of interferon genes (STING) pathway has emerged as a promising, tumor-agnostic approach capable of enhancing cytotoxic immune activity and overcoming ICB resistance. Our lab previously developed PolySTING, a polymeric STING agonist whose efficacy is mediated by cDC1-driven myeloid activation. To assess interpatient heterogeneity in STING responsiveness, we established an ex vivo patient-derived tumor fragment (PDTF) platform using resected HNSCC specimens that preserves native tumor architecture and resident immune populations. Cytokine profiling of tumor fragments following PolySTING treatment revealed distinct immune response phenotypes across patients, associated with *innate immune signaling, adaptive immune activation, or acute inflammatory states*. These immune response phenotypes correlated with the baseline immune composition of each tumor and, notably, with clinical outcomes, particularly post-surgical recurrence in the source patients. Our findings suggest that ex vivo STING perturbation of HNSCC tumor fragments captures clinically relevant immunosuppressive states and provide a functional biomarker to identify patients at risk of post-surgical recurrence.

#1179 *BRAF* copy number alterations and ultralow *BRAF* mRNA expression are prognostic for poor overall survival in prostate cancer.

Jesenia Marie Perez[1], David R. Moline[2], Hedyeh Ebrahimi[3], Ella Boytim[2], Eamon Toye[4], Stamatina Fragkogianni[5], Emmanuel S. Antonaraki[2], Alexander Chehrazi-Raffle[3], Justin Hwang[2]

[1]Department of Pharmacology, University of Minnesota, Minneapolis, MN,[2]Department of Medicine, University of Minnesota, Minneapolis, MN,[3]Department of Medical Oncology, City of Hope Comprehensive Cancer Center, Duarte, CA,[4]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[5]Tempus AI, Inc, Chicago, IL

Background. Prostate cancer (PC) is the second most common cancer among men in the US, with adenocarcinomas being the most prevalent histologic subtype (≥99%). Emerging evidence suggests that *BRAF* alterations, mostly annotated by protein altering mutations, may be drivers of prostate cancer progression in up to 6% of patients. Here we characterized, to our knowledge, the largest cohort of whole-exome and -transcriptome sequenced *BRAF*-altered PCs. We aimed to interrogate molecular features and clinical outcomes in *BRAF*-altered PCs.

Methods. The Tempus Lens Platform (Tempus AI, Inc., Chicago, IL) was used to query the Tempus multimodal de-identified database and establish a cohort of 485 patients with prostate adenocarcinoma with xT (DNA) and xR (RNA) testing. Of those, 137 had *BRAF* alterations while the remaining 348 were considered *BRAF* wildtype (wt). *BRAF* alterations were defined as including a copy number alteration (CNA) or a single nucleotide variant (SNV) resulting in a short variant mutation. Of the *BRAF*-wt group, 94 were primary-tumor biopsies while 43 were metastatic biopsies. Within the *BRAF-wt* group, there were 210 primary tumors and 138 metastatic biopsies. RNA expression data was normalized and quantified as transcripts per million (TPM). *BRAF* mRNA expression from metastatic tissue were grouped as ultra-low (10th percentile), low (25th percentile), mid (50th percentile), and high (75th percentile). Overall survival (OS) was defined as the time from biopsy collection to death or loss to follow up and conducted using risk set adjustment through Cox proportional hazard analysis and reported by hazard ratios (HR).

Results. We confirmed prior studies in that Class 2 *BRAF* mutations (p.K601) were the predominant form of alteration in PC (46%, 63 of 137). CN gains were the second most common *BRAF* alteration (15%, 21 of 137). Patients with *BRAF* Class 1, 2, 3 mutations demonstrated no significant difference in OS. However, metastatic PC patients with *BRAF* CN gain had worse OS relative to *BRAF-wt* (HR: 2.4, CI 95% 1.18-4.85, p=0.01). Among *BRAF*-wt PCs from metastatic tissues, those with ultra-low *BRAF* mRNA expression (bottom 10% within metastatic patients) exhibited worse OS compared to mid *BRAF* expression (HR:2.43, CI 95% 1.22-4.84, p=0.01). The median OS for PC patients with CN gain and ultralow *BRAF* gene expression were at 9.4 and 6.6 months, as compared to the wt group of metastatic patients at 15.6 months.

Conclusions. The current paradigm for reporting *BRAF* status in PC patients requires revision. In addition to SNVs (class 1,2,3), we recommend reporting *BRAF* CN gain and *BRAF* mRNA ultralow expression - both may be indicative of a subset of prostatic adenocarcinomas with very poor OS. Future studies should examine the functional consequences of these *BRAF* perturbations in larger cohorts of PC patients as well as their therapeutic implications.

#1180 Integrating methylation-based circulating tumor DNA analysis with PSMA-PET/CT primary staging for enhanced risk stratification in *de novo* metastatic prostate cancer.

Karoline Kondrup[1], Mads Ryo Jochumsen[2], Laura Iisager[1], Paul V. Salachan[1], Maibritt Norgaard[1], Philippe Lamy[1], Bodil G. Pedersen[3], Michael Borre[4], Karina D. Sorensen[1]

[1]Department of Molecular Medicine, Aarhus University Hospital, Aarhus, Denmark,[2]Department of Nuclear Medicine, Aarhus University Hospital, Aarhus, Denmark,[3]Department of Radiology, Aarhus University Hospital, Aarhus, Denmark,[4]Department of Urology, Aarhus University Hospital, Aarhus, Denmark

Background: Metastatic prostate cancer (mPC) is associated with high mortality. Newly diagnosed PC patients suspected of metastasis can undergo imaging-based primary tumor staging by PSMA PET/CT. Accurate staging is crucial for treatment selection, as localized PC may be cured by surgery or radiation therapy, while de novo mPC is treated systemically and with intensification for high-volume disease. However, the prognostic value of PSMA PET/CT remains unclear and novel biomarkers are needed to improve risk stratification and inform treatment selection. To this end, analysis of plasma cell-free DNA (cfDNA) offers promising biomarker potential, as detection of tumor-derived cfDNA (ctDNA) has demonstrated prognostic value in multiple cancer types. In this study, we aimed to establish a methylation-based approach for detecting ctDNA in plasma from mPC patients and evaluate its utility as a prognostic biomarker.

Methods: We generated cfDNA methylome profiles for 68 castration-resistant mPC (mCRPC) patients and 62 controls using methylated cfDNA immunoprecipitation and sequencing. From a subset of the cohort (27 mCRPCs, 10 controls), we established an mPC-associated multi-region methylation signature (cfMeCaP). A ctDNA detection cutoff was defined using mean cfMeCaP methylation of controls, yielding 93% sensitivity and 96% specificity in the remaining cohort (41 mCRPCs, 52 controls). Next, to test cfMeCaP ctDNA detection in mPC at diagnosis, we generated cfDNA methylome profiles for another cohort of 117 PC patients who had undergone PSMA PET/CT for primary tumor staging upon suspicion of de novo mPC. Based on PSMA PET/CT findings, patients were grouped into localized PC (n=24), low-volume mPC (n=61), and high-volume mPC (n=28).

Results: Using cfMeCaP, ctDNA was detectable in 32/117 (27%) PC patients at primary tumor staging. Highest sensitivity was observed in patients with high-volume mPC (15/28, 54%) relative to low-volume mPC (14/61, 23%) and localized PC (2/24, 8.0%). Mean cfMeCaP methylation was positively correlated with the total tumor volume, as estimated from the PSMA PET/CT scans (ρ=0.47, $p<0.01$). This correlation was largely driven by the total metastatic tumor volume (ρ=0.52, $p<0.01$) rather than the total primary tumor volume (ρ=0.16, p=0.08). In mPC patients, ctDNA detection at primary tumor staging was associated with significantly shorter time to mCRPC progression as compared to ctDNA negative patients (median PFS of 25.6 months vs median PFS not reached, p=0.01), suggesting ctDNA positive low-volume mPC patients represent a high-risk subgroup that may benefit from treatment intensification.

Conclusion: These findings highlight the promising potential of plasma ctDNA as a minimally invasive biomarker to improve risk stratification in patients with de novo mPC, warranting large-scale clinical validation.

#1181 Transcriptomic analysis of NDRG1 amplification in aggressive breast cancer.

Emilly S. Villodre[1], Ganiraju Manyam[2], Xiaoding Hu[1], Isabella L. Rizzo[1], Lan H. L. Phi[1], Kiros H. Tesfamariam[1], Azadeh Nasrazadani[3], Rachel M. Layman[3], Bora Lim[3], Vicente Valero[3], Savitri Krishnamurthy[4], The MDACC IBC Team, MDACC Rare Tumor Initiative Team, Jing Wang[2], Xiaoping Wang[5], Naoto Ueno[5], Wendy A. Woodward[6], Bisrat G. Debeb[1]

[1]Breast Medical Oncology, MDA Morgan Welch Inflammatory Breast Cancer Clinic and Research Program, UT MD Anderson Cancer Center, Houston, TX,[2]Bioinformatics & Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[3]Breast Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[4]Pathology, MDA Morgan Welch Inflammatory Breast Cancer Clinic and Research Program, UT MD Anderson Cancer Center, Houston, TX,[5]University of Hawai'i Cancer Center, Honolulu, HI,[6]Experimental Radiation Oncology, MDA Morgan Welch Inflammatory Breast Cancer Clinic and Rsch Program, UT MD Anderson Cancer Center, Houston, TX

Background: Inflammatory breast cancer (IBC) is a rare but highly aggressive variant of breast cancer, accounting for 10% of breast cancer-related deaths. We have identified NDRG1, located on chromosome 8q24.3 near MYC within a commonly amplified region, as a key promoter of tumor growth and progression in IBC models and is associated with poor survival outcomes. Unlike many oncogenes, NDRG1 is rarely deleted or silenced and is more frequently expressed in IBC compared to non-IBC tumors. A recent study reported NDRG1 amplification in 42% of triple-negative IBC cases. We hypothesize that NDRG1 amplification in triple-negative IBC is associated with distinct gene expression profiles and enrichment of oncogenic pathways that contribute to the aggressive phenotype of the disease.

Methods: RNA sequencing data from 19 triple-negative IBC tumors (8 NDRG1 amplified, 11 non-amplified) were analyzed using DEseq2 package. Heatmaps were generated to visualize clustering and expression differences. Gene Set Enrichment Analysis (GSEA) was performed using Hallmark and KEGG pathway databases. Publicly available TCGA and METABRIC breast cancer datasets were used to assess NDRG1 amplification and its association with mRNA/protein expression and survival outcomes.

Results. Among the 19 triple-negative tumors analyzed, 8 (42%) exhibited *NDRG1* amplification, which was significantly correlated with increased RNA expression ($p = 0.05$). Differential expression analysis identified *CALCA*, *RHO*, *DPYSL5*, *GPR101*, *ZIC3*, and *IRS4* as the most upregulated, and *SERPINA6*, *SCGB3A1*, *PI3*, *LRG1*, *DAPL1*, *MYEOV* as the most downregulated in *NDRG1*-amplified tumors. GSEA revealed enrichment of DNA repair, cell cycle, mTOR signaling, and MYC target pathways, and downregulated pathways included interferon gamma response, estrogen response and NFkB pathway. TCGA and METABRIC analyses confirmed that NDRG1 amplification correlates with elevated mRNA expression ($p<0.0001$) and elevate protein levels ($p<0.0001$) and poorer overall survival ($p=0.013$, TCGA; $p=0.0002$, METABRIC).

Conclusions: *NDRG1* amplification marks a transcriptionally distinct subset of triple-negative IBC, enriched in proliferative and DNA repair pathways. These molecular features highlight its potential as a biomarker of aggressive disease biology and potential target for further mechanistic investigation and therapeutic intervention.

#1182 A unified clinical and molecular framework to standardize chromosomal instability assessment in gastric, GEJ, and esophageal cancer (GEC).

Jierui Xu, Charlton Tsai, Henry Walch, Patrick Evans, Jessica Posada, Samuel Cytryn, Steven Maron, Adam Bass, Kevin M. Boehm, Francisco Sanchez-Vega, Nikolaus Schultz, Walid K. Chatila, Yelena Y. Janjigian

Memorial Sloan Kettering Cancer Center, New York, NY

Background:
Chromosomal instability (CIN) is a dominant molecular feature of gastroesophageal adenocarcinomas and is associated with poor outcomes to standard chemotherapy and chemo-immunotherapy. Given its high prevalence and the absence of standardized, clinically deployable methods to identify CIN, we sought to develop a unified clinical and molecular framework to quantify CIN across real-world and phase III datasets and to build NGS- and histopathology-based tools for routine CIN classification.
Methods:
We analyzed 3,822 tumors across complementary platforms: 2,613 patients profiled with MSK-IMPACT, 587 RNA-seq and whole-exome sequencing samples from patients treated on Phase III CheckMate-649 (CM649) trial, and 622 TCGA samples. CIN was defined by fraction of genome altered (absolute $\log_2$ deviation >0.2) and complemented by arm-level and focal copy-number metrics using FACETS. Clinicopathologic, molecular, and outcome associations were evaluated across CIN strata. CIN will be integrated with CM649 transcriptomic programs and survival to assess predictive value for chemotherapy with and without nivolumab.
Results:
CIN was present in 63% of tumors within the MSK-IMPACT cohort, including 76% in esophageal, 68% in GEJ, and 47% in gastric cancers. Among 2,445 microsatellite-stable tumors, CIN tumors were enriched for TP53 mutations (79% vs 64%), CDKN2A loss (24% vs 10%), and focal amplifications in CCND1, MYC, EGFR, ERBB2, VEGFA, and CCNE1 (FDR <0.001), whereas CDH1 and RHOA mutations were enriched in non-CIN tumors. CIN exhibited a graded spectrum, with higher FGA associated with increased aneuploidy and a greater number of unique metastatic sites. Deep-learning models trained on H&E whole-slide images are being developed to infer CIN, with validation alongside CM649 clinical outcomes ongoing. Matched primary-metastatic and longitudinal samples are additionally being analyzed to define CIN evolutionary trajectories.
Conclusions:
We provide a unified genomic and histologic framework to standardize CIN assessment across clinical and phase III esophagogastric cancer samples. By linking CIN to reproducible molecular features and treatment outcomes—and by developing NGS- and H&E-based tools compatible with routine pathology workflows—this work lays the foundation for integrating CIN as a practical biomarker for patient stratification, risk enrichment, and future trial design targeting chromosomal instability.

#1183 Early ctDNA quantification by ctFE outperforms Max VAF for survival stratification across locally advanced and oligometastatic NSCLC treated with radiotherapy.

Ayesha Hashmi[1], Jessica Linford[1], Pradeep S. Chauhan[1], Kaushal Parikh[1], Rotem Ben-Shachar[2], John Guittar[2], Malvika Pillai[2], Jyoti Patel[2], Matteo Bergsagel[1], Nicholas P. Semenkovich[3], Kenneth R. Olivier[1], Sean S. Park[1], Dawn Owen[1], David M. Routman[1], Katie N. Lee[1], Alex D. Sherry[1], Aaron S. Mansfield[1], Daniel Morgensztern[4], Ramaswamy Govindan[4], Clifford G. Robinson[4], Carmen Bergom[4], Saiama N. Waqar[4], Bruna Pellini Ferreira[5], Gregory R. Vlacich[4], Aadel A. Chaudhuri[1]

[1]Mayo Clinic, Rochester, MN,[2]Tempus AI Inc, San Francisco, CA,[3]Medical College of Wisconsin, Milwaukee, WI,[4]Washington University, Division of Oncology, Washington University, MO,[5]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Personalizing chemoradiotherapy (chemoRT) for locally advanced non-small cell lung cancer (LA-NSCLC) is limited by the lack of early biomarkers that inform response during treatment. Current circulating tumor DNA (ctDNA) molecular residual disease assays predict post-treatment outcomes but lack mid-treatment utility. ctDNA burden estimation has traditionally relied on variant-centric metrics such as maximum variant allele fraction (Max VAF), which rely on mutation-specific signals and may be confounded by histology-dependent shedding variability, allelic imbalance, and clonal hematopoiesis. Here we present circulating tumor fraction estimate (ctFE), a machine-learning composite score that integrates VAF distributions, copy-number alterations, and germline B-allele frequency deviations to approximate global tumor burden using a widely available, tumor-naïve clinical platform.

Methods: A burden-based ctFE threshold was derived using pre-treatment plasma from a prospective phase II clinical trial of MR-guided hypofractionated chemoRT (LA-WU, n=26), locked, and applied unchanged to early mid-treatment samples (day 10-14). To test scalability and generalizability, its prognostic performance was validated in two real-world cohorts: 94 LA-NSCLC patients receiving definitive chemoRT (LA-RW) and 309 oligometastatic NSCLC patients receiving consolidative RT (OM-RW). ctFE and Max VAF were compared as continuous predictors across cohorts.

Results: ctFE consistently outperformed Max VAF. In LA-WU, pre-treatment ctFE was associated with overall survival (OS HR=1.15, p=0.04) and progression-free survival (PFS HR=1.84, p=0.009), whereas Max VAF was not. Mid-treatment ctFE remained prognostic for PFS (HR=1.14, p=0.026). Early ctFE dynamics defined three molecular response groups with marked OS separation: consistently low, responder, and nonresponder groups (median OS 60.8 vs 13.0 vs 2.9 months, respectively; p<0.001). In multivariable models including both biomarkers, higher ctFE remained independently associated with worse survival in LA-RW (OS HR=1.88, p=0.010) and OM-RW (OS HR=1.37, p=0.040; PFS HR=1.45, p=0.008), whereas Max VAF did not. The locked ctFE threshold stratified OS across all cohorts (LA-WU HR=5.93; LA-RW HR=9.08; OM-RW HR=2.26; all p<0.001).

Conclusion: ctFE provides clinically meaningful pre- and mid-treatment risk stratification and consistently outperforms Max VAF across locally advanced and oligometastatic NSCLC cohorts. We show that ctFE is a biologically informative, clinically generalizable and scalable ctDNA burden metric measurable using a tumor-naïve, off-the-shelf assay, supporting its practical utility in biomarker-adapted radiotherapy strategies.

#1184 IHC-based prognostic sub-stratification of ovarian endometrioid carcinoma.

Gamaliel Taengwa[1], Hunter J. Atkinson[1], Bryan M. McCauley[1], Sebastian M. Armasu[1], Chen Wang[1], Jennifer A. Doherty[2], Holly R. Harris[3], Ellen L. Goode[1], Martin Koebel[4], Stacey J. Winham[1]

[1]Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[2]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[3]Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, WA,[4]University of Calgary, Calgary, AB, Canada

Ovarian endometrioid carcinoma (OEC) is the second most common histotype associated with the most favorable prognosis among ovarian carcinomas. Similar to endometrial carcinoma, OEC exhibit significant molecular diversity. We aimed to develop a practical immunohistochemical (IHC) prognosticator by integrating IHC biomarkers with clinical substage, and surgical outcomes. This multi-institutional study included participants with primary invasive OEC from the Alberta Cancer Registry (AOVT), Mayo Clinic, and Disease of the Ovary and their Evaluation Study (DOVE). Pathology review excluded misclassified high-grade serous and mesonephric carcinomas leaving 422 OEC cases (AOVT N=158; DOVE N=143; Mayo N=121) with available tumor biospecimens who did not receive neoadjuvant treatment. Clinical characteristics included age, stage, grade, residual disease and 5-year survival. Clinical risk group was defined by combining stage and residual disease: Low (FIGO stage IA/IB & no macroscopic disease), Intermediate (stage IC-II& no macroscopic disease), High (stage III/IV or macroscopic disease). Tissue microarrays were stained for TP53, PMS2, MSH6, PGR, and CTNNB1 using IHC and were scored by a single pathologist. Tumors were hierarchically categorized as TP53-abnormal (TP53abn)/PGR-loss, mismatch-repair deficient (MMRd, via PMS2 and MSH6), nuclear-CTNNB1 (nCTNNB1), or no-specific-immunohistochemical-profile (NSIP). Overall survival (OS) at 5 years was compared across clinical risk and biomarker groups using Cox regression, adjusted for age and site to generate hazard ratios (HR), and 5-year survival rates (5-YSR). High clinical risk group was associated with worse 5-year OS compared to low & intermediate risk ($p<0.0001$). Hierarchical IHC biomarker groups were also associated with 5-year OS, adjusted for age and study site ($p<0.0001$), with consistently worse survival for combined TP53abn/PGR-loss (n=17, HR=6.07, 95% CI 2.78-13.26), PGR-loss only (n=55, HR=4.17, 95% CI 2.19-7.94), TP53abn only (n=29, HR=2.04, 95% CI 0.85-4.90), and better survival for nuclear-CTNNB1 (n=146, HR=0.22, 95% CI 0.07-0.65) compared to NSIP (n=132). Within the low-risk group, MMRd, nCTNNB1, or NSIP had greater than 97% 5-YSR, while OEC with TP53abn/PGR-loss or PR-loss only had less than 75% 5-YSR. Within the intermediate group, only nCTNNB1 exceeded a 5-YSR of greater than 97%. Within the high-risk group, 5YSR for nCTNNB1 OEC was 90.9%, compared to only 16.7% for TP53abn/PGR-loss. This IHC-based algorithm refines prognosis beyond clinical substage. It identifies low-risk patients with unfavorable prognosis (TP53abn/PGRloss, PGR loss only) who may benefit from adjuvant therapy, and also patients with favorable prognosis within the intermediate group for whom adjuvant therapy could be de-escalated. Further patient selection for chemo vs. hormone therapy in the high-risk group may be improved by biomarkers.

#1185 Radiographic thymic health as host-intrinsic determinant of immunotherapy outcomes across cancer types.

Simon Bernatz[1], **Vasco Prudente**[1], Suraj Pai[1], Asbjorn Kjar[2], Alessandro Di Federico[3], Andrew Rowan[4], Selvaraju Veeriah[5], Lars Dyrskjot[6], Leonard Nurnberg[1], Joao Victor M. Alessi[3], Patrick Ott[3], Elad Sharon[3], Allan Hackshaw[7], Nicholas McGranahan[8], Christopher Abbosh[9], Raymond H. Mak[1], Danielle S. Bitterman[10], Mark M. Awad[3], Biagio Ricciuti[3], Charles Swanton[4], Mariam Jamal-Hanjani[11], Nicolai Juul Birkbak[2], Hugo JWL Aerts[1]

[1]Mass General Brigham, Boston, MA,[2]Aarhus University, Aarhus, Denmark,[3]Dana-Farber Cancer Institute, Boston, MA,[4]The Francis Crick Institute, London, United Kingdom,[5]University College London, London, United Kingdom,[6]Aarhus University, Aarhus N, Denmark,[7]Cancer Research UK & UCL Cancer Trials Centre, London, United Kingdom,[8]UCL London Cancer Institute, London, United Kingdom,[9]Christopher Abbosh (Individual), London,[10]Brigham and Women's Hospital, Boston, MA,[11]University College London (UCL) Cancer Institute, London, United Kingdom

Background: Immune checkpoint inhibitors (ICIs) depend on effective T-cell priming and renewal, yet current biomarkers focus primarily on tumor-intrinsic features (PD-L1, TMB). Because the thymus maintains naïve T-cell output and repertoire diversity, we hypothesized that an individual's thymic health represents a host-intrinsic determinant of ICI benefit.
Methods: We developed a self-supervised deep learning model to quantify thymic function, here termed thymic health, from routine CT scans. Thymic health was independently evaluated in 3,476 patients treated with ICI for tumors of various entities. Associations with PFS and OS were assessed using multivariable Cox models adjusting for key epidemiological and clinical factors. Sensitivity analyses evaluated the incremental contribution of thymic health. Biological validation was performed in treatment-naïve NSCLC patients from TRACERx (n=464) using T-cell receptor (TCR) sequencing and plasma proteomics.
Results: In patients with NSCLC (n=1,218), high thymic health was associated with significantly reduced risk of progression (HR 0.65; 95% CI, 0.54-0.77) and death (HR 0.56; 95% CI, 0.46-0.68); preserved after full multivariate adjustments for sex, age, PD-L1, TMB, ECOG, histology, treatment line and stratification by treatment type ($P<0.001$). Adding thymic health improved model fit beyond demographic, clinical, and tumor-intrinsic variables (likelihood ratio $P<0.001$). Importantly, including thymic health did not attenuate PD-L1 or TMB effects, indicating complementary, non-redundant prognostic information. Across PD-L1 and TMB strata, higher thymic health was consistently associated with improved PFS and OS ($P<0.03$). In TRACERx, thymic health was positively associated with T cell receptor excision circles, i.e., T cell output, and correlated with greater peripheral and intratumoral TCR diversity and with proteomic signatures of adaptive immune activation, biologically supporting its role as a radiographic proxy for immune competence. Pan-cancer analyses across 2,258 ICI-treated patients (melanoma, renal, breast, and others) showed consistent positive associations between thymic health and improved outcomes.
Conclusions: Thymic health was consistently associated with improved immunotherapy outcomes across cancer types and added independent information beyond PD-L1, TMB, and standard clinical variables. These findings support thymic health as a possible non-invasive, host-intrinsic biomarker with potential to refine patient stratification and advance precision immuno-oncology.
Clinical trial identification: ClinicalTrials.gov: TRACERx, NCT01888601

#1186 Plasma proteomic profiling of lung cancer blood samples reveals immune-related inflammatory signatures as prognostic biomarkers.

Akila Wijerathna-Yapa[1], Aaron Kilgallon[1], Clara Lawler[1], James Monkman[2], Nathaniel Robichaud[3], Alyssa Rosebloom[4], William Mullaly[5], Ken O'Byrne[6], **Arutha Kulasinghe**[1]

[1]Frazer Institute, University of Queensland, Brisbane, Australia,[2]The University of Queensland, Woolloongabba, Australia,[3]Nomic Bioscience, Quebec, Australia,[4]Nomic Biosciences, Quebec, QC, Canada,[5]Cancer Care Services, Princess Alexandra Hospital, Brisbane, Australia,[6]Princess Alexandra Hospital, Brisbane, Australia

Background. Lung cancer presents a significant global burden of mortality. Predictive biomarkers are urgently needed to help stratify patient populations for targeted and systemic therapies. Here, we performed comprehensive proteomic profiling using the nELISA technology to identify baseline and post treatment proteomic signatures associated with clinical outcomes to immune checkpoint immunotherapy (ICI).

Methods. Plasma were prepared from 66 patients who underwent ICI (63 pre-treatment samples, 19 post-treatment samples). The nELISA assay (Nomic Bio, Canada) was used to detect the abundance of 969 proteins. Data QC, Differential expression, survival modelling, and pathway enrichment was performed to understand associations with clinical endpoints.

Results. Baseline blood samples from patients who experienced disease progression demonstrated coordinated activation of three interconnected pathways: coagulation, complement cascade, and IL-6/JAK/STAT3 signalling. This pattern was consistent across PFS events ($p<0.001$), OS events ($p<0.001$), and progressive disease comparisons (RECIST, PR vs PD: $p=0.002$). In contrast, baseline samples from patients with better clinical outcomes exhibited enrichment of type I/II interferon responses, DNA damage response and intact apoptotic machinery. Notably, patient responders maintained balanced inflammation with high interferon signalling, while patient non-responders showed high inflammatory markers paradoxically paired with low interferon activity, suggesting dysfunctional, immunosuppressive inflammation. Analysis of paired PRE/POST samples (n=19) revealed that patients who progressed exhibited marked treatment-induced increases in TNFα/NFκB signaling, inflammatory responses, combined with decreases in IL-2/STAT5-mediated T cell signalling. This pattern, consistent across OS ($p=0.001$), PFS ($p=0.002$) suggests treatment-related immune dysregulation or failed immune reconstitution despite checkpoint blockade. Importantly, the coagulation signature present at baseline decreased post-treatment in poor-outcome patients, possibly reflecting consumption coagulopathy during systemic inflammatory states. Post-treatment proteomic changes in deceased patients included shifts from fatty acid oxidation toward adipogenesis with concurrent decreases in myogenesis, collectively indicating cancer cachexia-associated metabolic reprogramming that may contribute to treatment intolerance and mortality.

Conclusion. We identified two distinct baseline immunophenotypes predictive of immunotherapy outcomes including an “immune inflammed” and “thrombo-inflammatory.” The protein signatures warrant prospective validation as predictive biomarkers for immunotherapy patient selection and response monitoring, with potential to guide precision medicine approaches.

#1187 Serological detection of Type XVII collagen shedding suggests prognostic relevance in esophageal adenocarcinoma.

Eleonora Moroncini[1], Andrea Ponzetta[2], Rene Thieme[3], Stefan Niebisch[3], Ines Gockel[4], Magnus Nilsson[5], Fredrik Klevebro[5], Rebecca Maltez de Sousa[2], Nora Noren[5], Nicholas Willumsen[1], Morten Karsdal[1]

[1]Nordic Bioscience, Copenhagen, Denmark,[2]Karolinska Insitutet, Stockholm, Sweden,[3]University Hospital Leipzig, Leipzig, Germany,[4]St Clara Hospital Basel, Basel, Switzerland,[5]Karolinska Institutet, Stockholm, Sweden

Esophageal adenocarcinoma (EAC) is an aggressive malignancy with poor prognosis and rising incidence in Western countries. Identifying reliable, non-invasive biomarkers for prognostic stratification and disease monitoring remains a clinical challenge. Type XVII collagen is a transmembrane protein mediating epithelial-basement membrane adhesion. Its aberrant expression and ectodomain shedding have been linked to epithelial damage and tumor progression. Interestingly, COL17A1 has been reported to be downregulated in EAC compared to Barrett's esophagus and healthy tissue, suggesting loss of epithelial integrity during malignant transformation. In this study, we evaluated the serological biomarker potential of PRO-C17, which quantifies the shed ectodomain of type XVII collagen, in two independent cohorts of treatment-naïve EAC patients.

PRO-C17 levels were measured by competitive ELISA in EDTA plasma from 57 treatment-naïve EAC patients (Cohort I, Karolinska University Hospital). A second cohort (Cohort II, University of Leipzig) included 64 serum samples from treatment-naïve EAC patients. All samples were collected at diagnostic endoscopy prior to oncologic treatment. For both cohorts, 20 healthy controls were included, matched for sample matrix, age, and gender.

Prognostic associations with overall survival (OS) were assessed in resectable patients (n=54 in Cohort I; n=44 in Cohort II) using Kaplan-Meier and multivariate Cox models. Cohort-specific median PRO-C17 levels were used as cut-offs.

In Cohort I, PRO-C17 levels were significantly lower in EAC patients compared to controls ($p<0.001$); in Cohort II, no significant difference was observed, though a similar trend was noted. In both cohorts, high baseline PRO-C17 levels were independently associated with poorer OS (Cohort I: $p=0.01$, HR=2.63, 95% CI: 1.20-5.56; Cohort II: $p=0.013$, HR=2.85, 95% CI: 1.22-6.71). Among early-stage patients, elevated PRO-C17 identified individuals with significantly worse OS, suggesting that PRO-C17 may reflect tumor aggressiveness even in clinically early-stage disease. No significant differences were seen in late-stage subgroups. In Cohort II, lower baseline PRO-C17 was also associated with better tumor regression grades (TRG), suggesting potential predictive value for treatment response.

PRO-C17 shows consistent prognostic value across two independent EAC cohorts with different sample matrices. Elevated levels were associated with poorer OS, particularly in early-stage disease, supporting its use as a non-invasive biomarker for risk stratification. Increased ectodomain shedding may reflect tumor aggressiveness, while the overall lower PRO-C17 levels in EAC vs. healthy controls may reflect COL17A1 downregulation during tumor progression. These findings support prospective validation of PRO-C17 as a clinically relevant biomarker in EAC.

#1188 Associations between Breast Cancer Index and MSK-IMPACT genomic and transcriptomic profiles in HR+ breast cancer.

Hong Zhang[1], Niloufar Khojandi[2], Natalia Siuliukina[2], Julia Ah-Reum An[1], Darya Dahi[1], Luca Boscolo Bielo[1], Subhiksha Nandakumar[1], Enrico Moiso[1], Edaise M. da Silva[1], Mehnaj Ahmed[1], Lisa Loudon[1], Konner Nelson[1], Kevin Murphy[1], Jade Oghoanina[1], Mark E. Robson[1], Sarat Chandarlapaty[1], George Plitas[1], Amanda K. L. Anderson[2], Yi Zhang[2], Pedram Razavi[1], Kai Treuner[2]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Biotheranostics, Inc. A Hologic Company, San Diego, CA

Background: The Breast Cancer Index (BCI) is a gene expression-based assay that stratifies patients based on their risk of overall (0-10 years) and late (beyond 5 years) distant recurrence. In addition , BCI can also predict the benefit of extended endocrine therapy in early-stage, HR+ breast cancer. In this study, we assessed the relationships between BCI and risk of distant recurrence and explored associations between BCI classification and the tumor genomic and transcriptomic profiles of HR+ patients who experienced metastatic relapse.

Methods: Primary tumors from patients with metastatic or recurrent HR+ breast cancer underwent BCI testing, MSK-IMPACT targeted sequencing (up to 505 cancer genes), and mRNA sequencing. Time to DR (TTDR) was defined as the time from surgery to first distant recurrence. A 5-year cutoff was used to distinguish early versus late DR groups. Kaplan-Meier and Cox proportional hazards analyses were used to assess BCI's prognostic value. Wilcoxon tests were applied for pairwise comparisons of BCI scores between early and late DR groups, and Fisher's exact tests were used to identify genomic alterations differing by BCI groups as well as DR groups. Given the limited cohort size, multiple testing correction was not applied. Transcriptomic data (N=91) were analyzed for differentially expressed genes by comparing BCI high-risk vs. low-risk tumors and early vs. late DR groups ($|\log_2 FC|>1$, adjusted $p<0.05$).

Results: The study included 180 HR+ patients (47% post-menopausal, 61% N+, 65.3% grade 3). Most tumors were classified as BCI high risk (86.7%), and patients classified as high risk by BCI had earlier recurrence than those classified as low risk (median TTDR: 3.0 years vs. 4.7 years; HR = 1.89, 95% CI: 1.20-2.96; p = 0.0053). BCI scores differ significantly between early and late DR groups (p = 0.005). The genomic landscape was consistent with high-risk luminal tumors and showed frequent *TP53* mutations (38%). *PIK3CA* and *TBX3* mutations were more common in BCI low-risk tumors (71% vs. 41%, p=0.007; 21% vs. 5%, p=0.01). *CDKN2A* deletions and *MCL1* amplifications were enriched in early DR, whereas *ERBB2* and *SPOP* amplifications as well as *NOTCH3*, and *MAP2K4* mutations were more frequent in late DR ($p<0.05$). Transcriptomic analysis revealed downregulation of cell cycle, p53 signaling, senescence, and progesterone-mediated oocyte maturation pathways in BCI high-risk tumors. The cell cycle pathway was also downregulated in late recurrences, suggesting reduced proliferative activity associated with delayed relapse.

Conclusion: BCI remained a strong prognostic indicator in this HR+ metastatic cohort, with higher scores predicting shorter TTDR. Integrated genomic and transcriptomic profiling highlighted distinct molecular programs associated with BCI classification providing insight into biological mechanisms underlying early versus late relapse in HR+ breast cancer.

#1190 Decoding the multiomic signatures of oral cancer progression.

Maple Lei[1], Kelly Yi Ping Liu[2], Steven John Jones[3], Catherine FY Poh[4]

[1]Canada's Michael Smith Genome Sciences Centre, Vancouver, BC, Canada,[2]University of British Columbia, Vancouver, BC, Canada,[3]BC Cancer Agency, Vancouver, BC, Canada,[4]Associate Professor, University of British Columbia Faculty of Dentistry, Vancouver, BC, Canada

Oral cavity squamous cell carcinoma (OCSCC) is frequently preceded by oral epithelial dysplasias (OEDs), yet current clinical tools provide limited ability to identify which OPMLs will progress. This study applied an integrated multiomics approach to identify molecular features of progression and define biomarkers that may improve risk assessment.

We analyzed well-annotated flash-frozen oral tissues collected at surgery, with concurrent blood samples for germline DNA. Tissue samples were pathologically reviewed and microdissected to be labelled as “premalignant” or “malignant”. Short-read whole-genome sequencing (≥80× tumor, ≥30× germline) and RNA sequencing (≥200 million reads per library) were used to characterize somatic mutations, copy number alterations, and transcriptional differences. A subset of samples underwent long-read nanopore sequencing (20× coverage) to refine methylation patterns and their relationship to expression. Data were integrated using established pipelines, and candidate features were evaluated through machine learning-based classification. AI was used to enhance abstract clarity.

A total of 305 patient samples were submitted of which 96% (138 OED, 154 OSCC) were successfully sequenced. Mutational landscapes were similar across premalignant and malignant groups, sharing alterations in *TP53*, *CDKN2A*, *FAT1*, *NOTCH1*, and *CASP8*. *HLA-A* emerged as the top differentially mutated gene, pointing to altered immune-related pathways. Differential expression analysis showed clear separation of sample types, with broad increases in expression in OSCC. TPM values from 961 genes were used to train a proof-of-concept random forest classifier after iterative feature elimination, yielding a model with 92% confidence and 96% AUC. The most informative features aligned with top differentially expressed genes, and pathway analysis indicated enrichment in signaling, adhesion, and structural organization. Differential methylation analysis (75 OED, 40 OSCC) showed higher CpG island methylation in OSCC samples. Top differentially methylated genes included *ARHGEF17* and *PHLDB1*, which participate in cell cycle regulation and signaling, and *MIR27B*, previously described as a regulator of cellular growth and movement in oral epithelial models.

Using one of the largest, most comprehensively profiled OED cohorts to date, this work shows that lesions harbor distinct genomic, epigenomic, and transcriptional changes detectable before malignant transformation. Convergent key markers identified support development and validation of clinically actionable tests to be applied to formalin-fixed paraffin embedded samples for early identification of higher-risk lesions. Ongoing efforts integrate these molecular signatures with longitudinal clinical outcomes and map them to biological pathways and molecular oral cancer subtypes to advance screening, early intervention, and individualized patient management.

#1191 Depth of immunoparesis predicts time to first therapy in newly diagnosed monoclonal B-cell lymphocytosis and chronic lymphocytic leukemia.

Yuan Yao[1], Kari G. Rabe[2], Eli Muchtar[1], Paul Hampel[1], Yucai Wang[1], Lindsey Roeker[1], Saad Kenderian[1], Amber Koehler[1], Catherine Wagner[1], Amy Behnken[1], Jose F. Leis[3], Mazie Tsang[3], Talal Hilal[3], Ricardo Daniel Parrondo[4], Susan M. Schwager[1], Min Shi[5], Curtis A. Hanson[5], Celine M. Vachon[6], Shaji Kunnathu Kumar[1], Esteban Braggio[7], Neil E. Kay[1], Susan Slager[8], Sameer A. Parikh[1]

[1]Division of Hematology, Mayo Clinic, Rochester, MN,[2]Division of Clinical Trials and Biostatistics, Mayo Clinic, Rochester, MN,[3]Division of Hematology and Medical Oncology, Mayo Clinic, Phoenix, AZ,[4]Division of Hematology-Oncology, Mayo Clinic, Jacksonville, FL,[5]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[6]Division of Epidemiology, Mayo Clinic, Rochester, MN,[7]Division of Hematology and Medical Oncology, Mayo Clinic, Phoenix, MN,[8]Division of Hematology; Division of Computational Biology, Mayo Clinic, Rochester, MN

Background: Hypogammaglobulinemia at the time of CLL diagnosis predicts shorter time to first therapy (TTFT). However, the depth of immunoparesis and its impact on TTFT in newly diagnosed MBL/CLL remains unexplored.
Methods: We identified previously untreated MBL/CLL patients from Mayo Clinic CLL Database (2000-2024) who had serum immunoglobulin (Ig; IgG, IgM and IgA) and monoclonal protein assessed within 1 year of diagnosis. Immunoparesis was evaluated: a) qualitatively by classifying patients into preserved, partial and full Ig suppression, based on the number of suppressed Igs; and b) quantitatively by calculating the average relative difference (ARD), defined as the mean percentage below normal for all Igs. For both methods, only uninvolved Igs were considered for those with monoclonal protein. TTFT was estimated by Kaplan-Meier with competing risk of death. Cox models estimated hazard ratios (HR) and 95% confidence intervals (CI).
Results: Among 1420 patients, median age at diagnosis was 65 (range 28-96); 954 (67%) were male; 493 (44.8%) had unmutated *IGHV*, and 86 (6.8%) had *TP53* disruption. The median [range, mg/dL] serum IgG, IgA, and IgM were 889 [111-5290], 132 [1-4880], and 49 [4-9480]. Low IgG was present in 472 (33.2%), low IgA in 223 (16.4%), and low IgM in 530 (37.3%) patients. An M-spike was detected in 122 (8.6%) patients; distribution was: IgG (73), IgM (30), IgA (6), or multiple (13). By qualitative assessment, preserved Ig were seen in 664 (46.8%), partial Ig suppression in 604 (42.5%), and full suppression in 152 (10.7%) patients. By quantitative assessment, median ARD was 0.6 (-0.8 to 11.3); 280 (19.7%) patients had negative ARD, and 1140 (80.3%) had positive ARD. In those with negative ARD, 128 (9%) had partial Ig suppression and 152 (10.7%) had full Ig suppression; in those with positive ARD, 664 (46.8%) had preserved Ig and 476 (33.5%) had partial Ig suppression. Median follow-up was 14.7 years; 510 patients progressed requiring therapy. Median TTFT was 9.6 years. Median TTFT for patients with preserved Ig was 12.6 years, 8.0 years for partial Ig suppression (HR 1.4, 95%CI 1.1-1.7), and 1.8 years for full Ig suppression (HR 3.1, 95%CI 2.4-4.0). The median TTFT was 2.3 and 12.1 years for patients with negative vs positive ARD; negative ARD was associated with shorter TTFT (HR 2.4, 95%CI 2.0-2.9). After adjusting for sex and CLL-International Prognostic Index (CLL-IPI) score, full Ig suppression (HR 2.9, 95%CI 2.2-3.9) and partial Ig suppression (HR 1.6, 95% CI 1.3-2.0) were associated with shorter TTFT (model 1, c-stat 0.77); and negative ARD (HR 2.4, 95%CI 2.0-2.9) was associated with shorter TTFT (model 2, c-stat 0.76). Negative ARD identified an additional 9% of patients at higher risk for shorter TTFT beyond full Ig suppression.
Conclusions: The depth of immunoparesis at diagnosis predicts TTFT and enhances risk stratification in newly diagnosed MBL/CLL.

#1192 Survival trends in the management of carcinoid heart disease among patients with neuroendocrine tumors.

Sarah Gyojin Jung[1], Rebecca Steinberg[2], Angel Xi[3], Jeffrey Switchenko[3], Olatunji Alese[4]

[1]Emory University School of Medicine, Atlanta, GA,[2]Department of Medicine, Division of Cardiology, Duke University, Durham, NC,[3]Biostatistics Shared Resource, Winship Cancer Institute of Emory University, Atlanta, GA,[4]Department of Hematology/Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, GA

Background: Nearly 20% of patients diagnosed with neuroendocrine tumors (NET) will develop carcinoid syndrome (CS), with 20-25% of CS patients developing carcinoid heart disease (CHD). The risk factors for developing CHD and prognostic variables in the current day of NET management are lacking.
Objectives: The main objectives of this study were to describe the clinical, laboratory, and imaging risk factors for developing CHD in CS patients, and to identify predictors of survival in NET patients.
Methods: A single-institution, retrospective analysis of patients with well-differentiated NET from January 2010 to December 2024 was conducted. Cox proportional hazard regression assessed the association between baseline covariates and CHD development (primary endpoint), and overall survival (OS; secondary endpoint). CHD was defined as moderate or severe tricuspid regurgitation on echocardiogram, consistent with prior studies. Survival curves for OS and CHD development were estimated using the Kaplan-Meier method. A p-value of 0.05 was considered statistically significant.
Results: We identified and included 270 patients with NET in the study. Median age was 64.5 years, 52% were male and 5.6% were diagnosed with CHD. CS was present in 10% of patients (n=27), and 41% of those with CS developed CHD. The most common primary tumor sites were
lung (26%), pancreas (17.4%), and small intestine (16.2%). On multivariable analysis, right ventricular (RV) dilation was also associated with shorter time to CHD diagnosis (hazard ratio [HR] 7.65, 95% CI: 1.03-56.78, p=0.047). The diagnosis of CHD was associated with a higher number of hospitalizations overall and the use of systemic or multimodal therapies.For the secondary endpoint of OS, median OS for patients with CHD was 90.8 months, while median OS was not reached for the full NET cohort. CHD development was independently associated with worse OS in extended Cox models (HR 7.09; 95% CI 1.84-27.40, p=0.004), highlighting its strong prognostic impact beyond baseline tumor factors. The use of systemic therapy (HR 8.97; 95% CI: 1.78-45.25, p=0.0101) and high-grade (G3) tumors were associated with worse OS (HR 6.92; 95% CI: 2.40-19.92, p<0.001).
Conclusion: Among patients with NET, the diagnosis of CHD, use of systemic/multimodal therapy, and high-grade tumors were associated with worse overall survival. Although the incidence of CHD is low, close monitoring for early diagnosis and intervention remain critical in the management of these patients.

#1193 Breast cancer recurrence risk stratification using rapid, cost-effective TempO-Seq profiling and an XGBoost classifier outperforms Oncotype DX.

Juan Barrasa[1], Salvatore Camiolo[1], Hanna Ha[1], Zhoutao Chen[2], Joanne M. Yeakley[2], Joel McComb[2], **Bruce Seligmann**[2]

[1]BioClavis, LTD., Glasgow, United Kingdom,[2]BioSpyder Technologies, Inc., Carlsbad, CA

Introduction: The market standard Oncotype DX 21 gene Recurrence Score predicts risk of distant recurrence in HR+/HER2- breast cancer, has a 7-14 day turnaround (TAT), requires 50-300 ng total RNA from FFPE sections with ≥5 mm² tumour, and costs ~$4,000. The low-cost extraction free targeted sequencing TempO-Seq® assay uses lysates of FFPE without RNA extraction or reverse transcription, has a 2 day TAT, and measures the whole transcriptome or any actionable subset of genes. We evaluated if TempO-Seq profiling of lysates from a single 1 mm^2 tissue microarray (TMA) core could match or surpass the clinical performance of Oncotype DX.
Methods: A TempO-Seq panel of the 21 Oncotype DX signature genes was implemented which incorporated attenuation of highly expressed gene signals. Sample processing and reaction conditions were optimized to deliver robust data from a single 5 µm thick, 1 mm diameter TMA core.
Results: Biological reproducibility of the TempO-Seq workflow was robust, with a median intercore correlation r>0.80. We developed a Support Vector Machine (SVM) learning model using 70% of the samples from a cohort of 86 patients, for which we had 10-year recurrence data and Oncotype DX scores from matched sections. Testing the other 30% of patients, this model accurately identified 100% of the patients with recurrence and 71% of the patients without recurrence. In comparison, Oncotype DX identified 65% of the patients with recurrence as high/intermediate risk and 52% of the patients without recurrence as low risk. Recognizing that TempO-Seq's performance could have been biased by training and testing on the same dataset, we trained an XGBoost algorithm, which is more reliable for handling independent cohorts with potential batch effects, using 70% of an independent cohort of 245 samples for which we only had 10-year recurrence data. Testing with the remaining samples, the XGBoost model correctly identified 80% of the patients with recurrence and 48.7% of the patients with no recurrence. Additionally, the model maintained its consistency when classifying all the samples in the 86 sample cohort, correctly identifying 76.8% of the patients with recurrence and 48.9% of the patients with no recurrence. We also trained the model to classify 90% of patients with recurrence as high risk, and 31% of patients with no recurrence as low risk.
Conclusions: TempO-Seq outperformed Oncotype DX results from the 86 patient cohort in classifying patients with recurrence, and models classifying patients from multiple cohorts could be built that were equivalent to or outperformed published Oncotype DX data. Thus, TempO-Seq enables accurate and reproducible prediction of recurrence from a minimal FFPE input, suggesting its potential as a fast TAT, lower cost alternative for risk stratification in $HR^+/HER2^-$ breast cancer.

#1194 A novel ferroptosis-related lncRNA-miRNA-mRNA genes signature for predicting prognosis and tumor immune microenvironment in endometrial cancer.

Hikaru Murakami, Junlong Wang, Herbert Yu

Cancer Molecular Epidemiology, University of Hawai'i Cancer Center, Honolulu, HI

Ferroptosis, an iron-dependent form of cell death, is known to be involved in cancer process and tumor immunity, and to be regulated by not only coding (mRNA) but also non-coding genes such as long non-coding RNA (lncRNA) and microRNA (miRNA). However, little is known about the involvement of ferroptosis in endometrial cancer (EC). The aim of this study is to identify comprehensive ferroptosis-related lncRNA-miRNA-mRNA interactions and to construct a ferroptosis-related lncRNA-miRNA-mRNA model for predicting overall survival (OS) and tumor immune microenvironment in EC. Tumor transcriptomes and corresponding clinical data of 544 EC patients were extracted from TCGA, and the ferroptosis database, FerrDb, was used to identify ferroptosis-related coding genes (FRGs) (mRNAs). Ferroptosis-related lncRNAs and miRNAs were selected based on their correlations with FRGs. Univariate, multivariate, and Lasso Cox regression analyses were conducted to construct a prognostic model based on ferroptosis-related lncRNA-miRNA-mRNA genes. EC patients were grouped into high- and low-risk categories based on the risk score which is constructed using the expression levels of ferroptosis-related transcripts. Kaplan-Meier (K-M) analysis and receiver operating characteristic (ROC) curves were used to evaluate the prognostic value. Gene Set Enrichment Analysis (GSEA) was conducted to explore biological pathways between the high- and low-risk groups. Besides, the proportion of infiltrating immune cells and the expression level of immune checkpoints between the risk groups were compared. All signature RNAs were validated using an independent CPTAC cohort (n = 213). Sixteen ferroptosis-related RNAs (10 lncRNAs, 2 miRNAs, and 4 mRNAs) were identified as prognostic markers. A ferroptosis-related lncRNA-miRNA-mRNA co-expression network was constructed. K-M analysis demonstrated that patients in the high-risk group had a worse OS ($P < 0.001$). ROC curves showed that the area under curve (AUC) values of the model were 0.731, 0.749, and 0.768 for 1, 3, and 5 years of survival, respectively, and the model had a better ability to predict the prognosis of EC patients than other clinical factors (age, grade, and stage). Moreover, the predictive nomogram suggested that our model could offer an independent prognostic evaluation with high accuracy. GSEA revealed that patients in the high-risk group had an enrichment of cancer-related pathways. Tumors in high-risk patients had lower levels of antitumor immunity, and there were several differences in the expression of immune checkpoints between the groups. In the CPTAC dataset, these RNAs were confirmed to be similarly associated with EC prognosis. This study provides new insight into ferroptosis-related molecular mechanisms and novel directions for prognostic assessments, immunotherapies, and targeted treatments of EC.

#1195 Prognostic value of circulating CD11b$^+$CD33$^+$myeloid cells in localized prostate cancer.

Viola Moscarda[1], Sara Merler[1], Daniele Braga[1], Bianca Cali[1], Federica Cetti[1], Giuseppe Reitano[2], Filippo Carletti[2], Gianmarco Randazzo[2], Davide Minardi[2], Sara Zumerle[3], Mirko Minini[4], Anna Sordo[5], Giovanna Pecoraro[6], Nicola Fossati[7], Andrea Gallina[7], Ricardo Pereira Mestre[6], Silke Gillessen[6], Alessandro Morlacco[2], Fabrizio Dal Moro[2], Andrea Alimonti[1]

[1]IOR - Institute of Oncology Research, Bellinzona, Switzerland,[2]Department of Surgery, Oncology and Gastroenterology; Urologic Unit, University of Padova, Padova, Italy,[3]IOV - Istituto Oncologico Veneto, Padova, Italy,[4]Sorbonne Universite, Inserm, Centre de Recherche Saint-Antoine (CRSA), Paris, France,[5]CRC - Centro ricerche cliniche, Verona, Italy,[6]Oncology Institute of Southern Switzerland (IOSI), Ente Ospedaliero Cantonale (EOC), Bellinzona, Switzerland,[7]Urology Service, Department of Surgery, Ente Ospedaliero Cantonale (EOC), Lugano, Switzerland

Risk stratification in localized prostate cancer (PCa) relies on clinical and pathological parameters, as well as molecular assays that are often limited in accessibility. While circulating myeloid cells are associated with poor prognosis in advanced disease, their role in primary PCa remains unclear. This study aimed to determine whether circulating CD11b$^+$CD33$^+$ myeloid cells could serve as a minimally invasive, cost effective prognostic biomarker in localized PCa.

We analyzed a prospective cohort of 79 patients with localized PCa undergoing radical prostatectomy. Circulating CD11b$^+$CD33$^+$ myeloid cells were quantified by flow cytometry. Associations between CD11b$^+$CD33$^+$ frequency and clinical parameters were evaluated, including EAU risk group, postoperative pathological features and biochemical recurrence (BCR). RNA sequencing was performed on FACS sorted circulating CD11b$^+$CD33$^+$ cells from 39 patients, including 15 from this prostatectomy cohort and 24 from an independent biopsy cohort.

Circulating CD11b$^+$CD33$^+$ cell frequency was significantly higher in patients classified as high risk at diagnosis, versus intermediate ($p = 0.0419$) and low risk ($p = 0.0087$), and associated with adverse pathological features such as ISUP grade 4 and 5 ($p = 0.0034$) and perineural invasion ($p = 0.0303$). Transcriptomic profiling of these cells revealed distinct transcriptional programs in high risk versus intermediate risk patients, with enrichment of tumor promoting and immunosuppressive gene signatures. Higher circulating CD11b$^+$CD33$^+$ frequency associated with shorter BCR free survival ($p = 0.028$), particularly in high risk patients, after a median follow up of 31.8 months. Notably, the frequency of these cells outperformed the EAU risk classification, identifying a subset of high risk PCa patients at highest risk of early recurrence.To validate these findings, we analyzed the TCGA cohort of localized PCa patients ($n = 329$); although only tumor transcriptomic data were available, high intratumoral CD11b$^+$CD33$^+$ gene expression was associated with shorter disease free survival, especially in high risk patients. A custom four gene myeloid signature derived from genes upregulated in our cohort further refined risk stratification, predicting early relapse in high risk cases.

Higher frequencies of circulating CD11b$^+$CD33$^+$ myeloid cells are observed in high risk localized PCa and associate with shorter BCR free survival. Remarkably, this myeloid expansion occurs even in organ confined disease, revealing an early systemic immune response previously unrecognized in localized PCa. Transcriptomic profiling confirmed enrichment of immunosuppressive and tumor promoting programs in these cells. Circulating CD11b$^+$CD33$^+$ frequency and associated gene signatures represent a novel prognostic biomarker, with potential to improve risk stratification in localized PCa, warranting validation in larger cohorts.

#1196 A pre-treatment cfDNA methylation signature linking prognosis and drug-resistance biology in pancreatic ductal adenocarcinoma.

Ashish Manne[1], Lianbo Yu[1], Wancai Yang[1], M Khalid Khan Niazi[1], Ravi Paluri[2], Anup Kasi[3], Prachi Bajpai[4], Alejandro Leyva[1], Upender Manne[4]

[1]The Ohio State University, Columbus, OH,[2]Atrium Health Wake Forest Baptist, Winston Salem, NC,[3]University of Kansas Medical Center, Kansas City, MO,[4]University of Alabama at Birmingham, Birmingham, AL

Pre-treatment risk-stratification of pancreatic ductal adenocarcinoma (PDAC) can individualize response monitoring and streamline trial triage. We refined the previously reported treatment resistance-associated, literature-curated protein-informed cell-free DNA (cfDNA) methylation signature for baseline prognostication. Notably, the panel includes genes whose protein products are implicated in resistance to commonly used PDAC therapies. The goal was to identify high-risk PDAC populations before administration of the current standard of care first-line chemotherapy (FLC) combinations, such as FOLFIRINOX (FFX) or gemcitabine and nab-paclitaxel (G-NP). The study included PDAC patients treated at The Ohio State University between 2010 and 2022 who had plasma samples available before initiation of first-line chemotherapy. Targeted enzymatic methylation sequencing was performed for cfDNA methylation profiling. In our 45-patient retrospective cohort the distribution was as follows, Stage at diagnosis (StD): 18 early stage (ES = borderline/resectable), 13 metastatic (met), and 14 locally advanced (LA); Ultimately, 18 had surgery (SR) (9 upfront surgery (UpS) and 9 had neoadjuvant therapy (NAT)) and 27 had palliative therapy (PT, 2 LA had surgery and 2 ES progressed to met); FLC in PT-group, 10 FFX, 15 GA, 2 others; Most of the patients who received NAT (7/9) or adjuvant (AT) after UpS (5/9) received FFX. A fixed 16-gene signature (cfMeth-OS16) was scored per patient (continuous z-score) and dichotomized at the study median into high-risk (HR) and low-risk (LR) groups; overall survival (OS) was modeled with Cox regression, discrimination summarized by Harrell's C-index, and survival compared by log-rank. cfMeth-OS16 separated the population significantly (HR vs. LR: 11 vs. 39 months (m); hazard ratio (HR) of 7; C-index of 0.8, p-value -<0.01). Adding StD improved the cfMeth-OS's performance (7 vs. 39m; 12; 0.87; <0.01) while FLC (FFX vs. G-NP vs. other) in any setting (PT, NAT, or AT in UpS) did not substantially improve it (10 vs. 39m, 12, 0.83; <0.01). A comprehensive model (cfMeth-OS + FLC + age + gender + RS (yes/no) + radiation received (yes/no)) achieved a higher C-index with a large, adjusted HR (7 vs. 39; 34; 0.89, <0.01). Compared to our previous signature derived from a cohort that included some post-treatment samples, cfMeth-OS showed modestly increased discrimination and extended long-survival estimates (vs. 10 vs. 33m; 8.7; 0.78). cfMeth-OS16 provides independent risk stratification for PDAC beyond FLC selection and routine clinical factors. The study's limitations include its modest sample size, single-center retrospective design, and heterogeneity in treatments and stages, which may constrain generalizability. Prospective, multi-institutional validation will be critical to confirm the robustness and potential predictive value of cfMeth-OS16

#1198 Stage-dependent expression of Fanconi anemia pathway genes in HPV-negative head and neck squamous cell carcinoma.

Olivia A. Swaim, Alexander Straughan, Beverly Wuertz, Frank Ondrey

University of Minnesota Medical School, Minneapolis, MN

The Fanconi Anemia/BRCA DNA repair pathway plays a critical role in genomic stability and treatment response in head and neck squamous cell carcinoma (HNSCC). However, whether FA pathway gene expression changes with tumor stage in sporadic HNSCC is insufficiently understood. We examined stage-dependent expression patterns of 23 FA pathway genes in HPV-negative HNSCC. We analyzed mRNA expression data (RNA-seq Z-scores) from 415 HPV-negative HNSCC tumors in The Cancer Genome Atlas via cBioPortal. Twenty-three FA pathway genes were examined across core complex, ID2 complex, homologous recombination, nuclease, and associated components. Tumors were stratified by AJCC stage into early-stage (I/II, n=84) and late-stage (III/IV, n=292) groups, eliminating 39 unstaged patients. Lymph node staging data was available for 402 patients (96.9%), with late-stage tumors showing significantly higher rates of lymph node involvement compared to early-stage disease (67.1% vs 1.2% N+, $p<0.001$). We performed differential expression analysis using two-sample t-tests with Benjamini-Hochberg FDR correction for multiple testing ($\alpha=0.05$). Effect sizes were calculated using Cohen's d. Late-stage tumors demonstrated more aggressive clinical features with increased lymph node metastases. After FDR correction, only RAD51C showed significant differential expression ($q=0.046$), with higher expression in late-stage disease (mean±SD: 7.86±0.62 vs 7.65±0.51, log2 FC=-0.21, $p=0.002$, $d=-0.37$). Six additional genes showed nominal significance ($p<0.05$) but did not survive FDR correction. Four genes were elevated in early-stage tumors: BRCA2 (log2 FC=0.33, $p=0.006$), ERCC4 (log2 FC=0.16, $p=0.022$), SLX4 (log2 FC=0.12, $p=0.023$), and BRIP1 (log2 FC=0.24, $p=0.042$). Two genes were elevated in late-stage tumors: FANCE (log2 FC=-0.20, $p=0.009$) and UBE2T (log2 FC=-0.21, $p=0.025$). All effect sizes were small ($|d|=0.24$-0.37). Most FA pathway genes in the RNA-seq dataset (16/23, 70%) showed no stage-dependent differences, including BRCA1, PALB2, RAD51, and most core complex members. RAD51C is uniquely upregulated in late-stage HPV-negative HNSCC after correction for multiple testing, distinguishing it from other FA pathway genes. This finding suggests that RAD51C could be a targetable weakness specifically in advanced HNSCC, which deserves further investigation for stage-directed therapies. Because the six additional genes which showed nominal significance did not survive FDR correction, this suggests that aside from RAD51C, the FA pathway appears to be preserved during HNSCC progression. For both Fanconi Anemia cancers and sporadic non-Fanconi HNSCC, the next step would be examining mutations in these genes to see how they affect function in stage-dependent pathophysiology.

#1200 Spatially resolved tumor-cell MHC class II shapes adaptive immunity and therapeutic response in triple-negative breast cancer.

Yi Liu[1], Sachin Kumar Deshmukh[2], Thiti Susiriwatananont[1], Panuch Eiamprapaporn[1], Bogang Wu[3], Heikki Joensuu[4], Roberto A. Leon-Ferre[5], David Zahrieh[6], Judy C. Boughey[7], James Newell Ingle[8], Fergus J. Couch[9], Sharon Wu[2], Shipra Gandhi[10], Maryam Lustberg[11], George W. Sledge[2], Matthew P. Goetz[9], Keith L. Knutson[1], E Aubrey Thompson[1], Jodi Carter[12], **Saranya Chumsri**[1]

[1]Mayo Clinic Florida, Jacksonville, FL,[2]Caris Life Sciences, Phoenix, AZ,[3]Mayo Clinic Phoenix, Phoenix, AZ,[4]University of Helsinki, Helsinki, Finland,[5]Mayo Clinic, Rochester, MN,[6]Health Sciences Research, Mayo Clinic, Rochester, MN,[7]Radiation Oncology, Mayo Clinic, Rochester, MN,[8]Professor, Dept. of Oncology, Mayo Clinic College of Medicine, Rochester, MN,[9]Mayo Clinic College of Medicine and Science, Rochester, MN,[10]Emory University School of Medicine, Atlanta, GA,[11]Yale School of Medicine, New Haven, CT,[12]University of Alberta, Edmonton, AB, Canada

Background: MHC class II molecules are normally restricted to professional antigen-presenting cells. Prior TNBC studies have focused on immune-compartment MHC-II. Using spatial transcriptomics, we recently identified aberrant tumor-cell MHC-II expression. Here, we characterized the immune architecture surrounding HLA-DRA-expressing tumor cells.
Methods: High-plex single-cell spatial transcriptomics (CosMx^{TM} SMI) was performed on treatment-naïve TNBC (Mayo TMA, n=65) and two neoadjuvant pembrolizumab cohorts (Mayo n=8; Emory n=4). Spatial neighborhoods were mapped relative to HLA-DRA-high tumor cells. Differential expression and adaptive immune gene-set scores were evaluated. Clinical relevance was assessed using FinXX (n=114), I-SPY2 (n=364), and Caris CODEai (n=3,662).
Results: HLA-DRA-high tumor regions showed significant enrichment of adaptive immune subsets within ≤50 μm, including B cells, CD8$^+$ T cells, NK cells, macrophages, and plasmacytoid dendritic cells. In pembrolizumab-treated cohorts, responders exhibited higher proportions of HLA-DRA-high tumor cells and greater numbers of B cells, plasmablasts, CD4$^+$ and CD8$^+$ T cells, and macrophages near tumor cells. Responders' tumors showed upregulation of antigen-presentation machinery, B-cell/plasma-cell programs, CXCL13, and NOTCH3/DLL1. Across I-SPY2 and FinXX, higher HLA-DRA correlated with pathologic complete response and improved survival. In CODEai TNBC, high HLA-DRA expression correlated with higher CXCL13 (median TPM 7.5 vs. 1.1, $q<0.05$) and longer overall survival (24.2 vs. 18.5 months, HR 0.77, 95% CI 0.71-0.83, $p<0.0001$). This association was TNBC-specific. High CXCL13 also predicted improved survival (26.6 vs. 16.5 months, HR 0.64, 95% CI 0.59-0.69, $p<0.0001$).
Conclusions: Tumor-cell HLA-DRA expression defines a highly organized adaptive immune niche enriched with B cells and activated T-cell populations in close proximity. Adaptive immune programs—including enhanced antigen presentation and CXCL13-mediated B-cell/plasma-cell pathways—consistently associate with improved outcomes across TNBC cohorts treated with chemotherapy and immune checkpoint blockade. Aberrant tumor-cell MHC-II expression may contribute to antitumor immunity and warrants further investigation as a potential therapeutic target.

#1201 Spatial 3D and multi-omics mapping of diffuse gastric cancer evolution from preinvasive to invasive lesions in CDH1 mutation carriers.

Yunhe Liu[1], Idania Carolina Lubo Julio[2], Wei Lu[2], Alejandra G. Serrano[2], Jean R. Clemenceau[3], Amber Famiglietti[4], Karen Colbert[5], Yibo Dai[1], Yang Liu[1], Jun Wang[1], Jeremy L. Davis[6], Mingyao Li[7], Paul F. Mansfield[8], Tae Hyun Hwang[3], Luisa M. Solis-Soto[9], Linghua Wang[1]

[1]Department of Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Translational and Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Surgery, Vanderbilt University Medical Center, Nashville, TN,[4]National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD,[5]Department of Clinical Cancer Prevention, The University of Texas MD Anderson Cancer Center, Houston, TX,[6]BioChemistry&Molecular Biology, University of Maryland School of Medicine, Baltimore, MD,[7]University of Pennsylvania, Philadelphia, PA,[8]Vice President, Acute Care Services, UT MD Anderson Cancer Ctr., Houston, TX,[9]Department of Translational Molecular Pathology, the university of MD Anderson cancer center, Houston, TX

Background: Hereditary diffuse-type gastric cancer (DGC) lacks a defined precursor sequence. Germline CDH1 loss-of-function mutations confer a high lifetime risk, and prophylactic gastrectomies in asymptomatic carriers frequently reveal numerous occult intramucosal signet-ring cell (SRC) foci that can remain indolent for years. The biological mechanisms underlying the progression from these indolent SRC foci to invasive DGC remain largely unknown.
Methods: We profiled primary DGCs from 26 patients, sampling the full histologic continuum from SRC foci to invasive lesions and overtly invasive fronts. Whole-slide sections were pathologist-annotated for tumor subtype and key microenvironmental features. Serial sections were assayed with complementary spatial multi-omics platforms: GeoMx DSP, Visium, Xenium Prime 5K with post hoc Codex (IO60), and CosMx (WTX). Selected specimens also underwent high-plex spatial multi-omics sequencing (transcriptome/protein/TCR/BCR) using Singular G4X, as well as 3D modeling with both Singular G4X and holotomography (HT-X1). Cross-platform datasets were co-registered to common coordinates; cell segmentation, phenotype annotation, and neighborhood/niche mapping quantified transcriptomic dynamics and tumor-microenvironment interactions across regions spanning preinvasive to invasive lesions. Integration of Singular G4X and Label-free holotomography provided 3D context.
Results: Spatial transcriptomic profiling revealed invasion-associated transcriptional programs along the SRC-to-invasive continuum. The meta-programs (MPs) associated with discrete stages of progression were defined. Histology-integrated analyses highlighted invasion-depth-dependent shifts in cell-cycle, EMT, and stress-metabolism pathways, and trajectory/differentiation analyses supported a continuous invasion axis. Copy-number inference indicated two evolution trajectories, linear and branched. Single-cell-resolution spatial multi-omics refined tumor cell-state signatures and their spatial neighborhoods, revealing lymphocyte-dominant microenvironmental states at early lesions and stromal/myeloid remodeling with deeper invasion, corroborated by multiplex proteomics (IO60). Cross-section registration with label-free 3D holotomography generated volumetric reconstructions mapping coherent clonal sectors and concordant TME remodeling along the invasion axis.
Conclusions: We present a spatial multi-omic atlas of DGC progression. The work delineates subtype- and region-specific gene programs, clonal architectures, and TME remodeling at high spatial and molecular resolution, modeling disease progression in 3D. Our findings identify candidate biomarkers of progression, risk stratification, and potential therapeutic interception of SRC tumorigenesis in CDH1 mutation carriers.

#1202 Spatially-resolved transcriptome analysis of renal tumors with sarcomatoid/rhabdoid dedifferentiation uncovers underlying biology and new biomarkers relevant to these tumors.

Minjun Kim[1], Mustafa Soytas[1], Burge Ulukan[2], Tamiko Nishimura[1], Senthilkumar Kailasam[1], Ariel Madrigal[1], Zohreh Mehrjoo[1], Kate Glennon[1], Eleonora Scarlata[3], Madeleine Arseneault[1], Morag Park[4], Hamed Najafabadi[1], Fadi Brimo[5], Ozgur Sahin[2], Simon Tanguay[3], Yasser Riazalhosseini[1]

[1]Victor Phillip Dahdaleh Institute of Genomic Medicine, McGill University, Montreal, QC, Canada,[2]Department of Biochemistry and Molecular Biology, Hollings Cancer Center, Medical University of of South Carolina, Charleston, SC,[3]Division of Urology, Department of Surgery, McGill University, Montreal, QC, Canada,[4]Goodman Cancer Institute, McGill University, Montreal, QC, Canada,[5]Department of Pathology, McGill University, Montreal, QC, Canada

The presence of sarcomatoid (Sarc) and rhabdoid (Rhab) dedifferentiation in renal cell carcinoma (RCC) is linked to poor clinical outcomes and higher risk of metastatic disease. Previous molecular studies on renal tumors with these dedifferentiated features lacked spatial resolution to distinguish these aggressive regions from classical RCC histology, leaving the biology underlying these aggressive phenotypes poorly understood. We applied spatial whole transcriptome profiling (GeoMx DSP) to 370 regions exhibiting Sarc, Rhab, clear cell, papillary, or benign kidney from 54 RCC tumors. We combined these spatial transcriptome profiles with our single-cell RNA-sequencing atlas consisting of different RCC subtypes to investigate Sarc/Rhab biology and verified clinical significance of our findings using public databases such as The Cancer Genome Atlas (TCGA) and Clinical Proteomic Tumor Analysis Consortium (CPTAC). Deconvolution of the spatially resolved transcriptome data revealed substantial gene expression reprogramming in Sarc/Rhab regions. Notably, Sarc/Rhab areas featured a high fibroblast-like gene expression pattern and a loss of cytokeratin expression as a defining hallmark of Sarc and Rhab dedifferentiation, reflecting their histological nature. We established cancer cell-intrinsic gene expression signatures of Sarc and Rhab tumors and found they are highly correlated with higher tumor grade in the ccRCC cohorts from both TCGA (n=485) and CPTAC (n=103). Importantly, these signatures significantly predicted poor disease-free survival in clinically low-risk (Stage 1-2) ccRCC patients. In the ccRCC cohort of TCGA, tumors with high Sarc gene signature levels were enriched for mutations in *SETD2*, *PTEN*, *MTOR*, and *KDM5C*, as well as specific copy-number variations, notably loss of 14q, 9, 18, and 6p and gain of 20, 12, and 8q, compared to other tumors. Pathway enrichment analyses suggested that genes related to extracellular matrix organization, coagulation, and epithelial-mesenchymal transition were highly enriched in Sarc/Rhab regions compared to classical ccRCC regions, while pathways for oxidative phosphorylation, adipogenesis, and amino acid metabolism were decreased.These findings provide novel insights into the biology of Sarc/Rhab dedifferentiation in RCC, paving the way for the development of improved prognostic markers and targeted therapeutic strategies.

#1203 Spatial archetypes of conserved and cancer-specific immune-stromal niches.

Tian Chu[1], Jimin Min[2], Yunhe Liu[1], Yang Liu[1], Yibo Dai[3], Kyung Serk Cho[3], Xueshuai Han[3], Kai Yu[3], Fuduan Peng[3], Anirban Maitra[4], Humam Kadara[3], Linghua Wang[3]

[1]Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX,[2]Medicine, New York University Grossman School of Medicine, New York, NY,[3]UT MD Anderson Cancer Center, Houston, TX,[4]Department of Pathology, New York University Grossman School of Medicine, New York, NY

Background: Spatially organized immune-stromal interactions critically shape tumor progression, yet a systematic characterization of conserved and cancer-specific microenvironmental architectures across human tumors remains limited. Recent advances in high-resolution spatial transcriptomics provide an exceptional opportunity to define these spatial niches, characterize cellular neighborhoods in situ, and delineate their clinical relevance as potential diagnostic or prognostic biomarkers.

Methods: We performed single-cell spatial profiling using the Xenium 5K platform on 40 cancer tissues across eight cancer types and paired uninvolved normal tissues, generating a spatial atlas of over ten million cells. By integrating transcriptional similarity, spatial proximity, and cellular composition, we defined spatial niches using an unsupervised framework. We then dissected the structural and functional characteristics of tumor microenvironments (TME). Association between transcriptional signatures and TME were further validated using public spatial-omics datasets.

Results: We identified 31 spatial niches (SNs), including both tumor-associated and tissue-specific niches. Some SNs were conserved across multiple cancer types, whereas others were enriched in organ-specific tissues and cancers, suggesting both universal and context-dependent TME programs. Spatial heterogeneity was most pronounced at tumor-stroma interfaces, where niche diversity markedly increased. Several niches were enriched for distinct CAF subsets or myeloid populations such as macrophages and neutrophils, indicating diverse stromal remodeling dynamics across tumors. $CD8^+$ T cell-enriched niches exhibited distinct spatial localization and transcriptional features, with $CD8^+$ T cell states ranging from activated to terminally exhausted, illustrating how cytotoxic responses are shaped by local context. These immune niches differed not only in $CD8^+$ T cell states but also in their surrounding cellular ecosystems, such as co-enrichment with regulatory T cells or chemotactic myeloid cells. Notably, in two immunotherapy cohorts, higher baseline abundance of SN11—a niche characterized by strong CD8-tumor interactions—was associated with better response to immune checkpoint blockade.

Conclusions: This study presents a large-scale spatial framework to characterize immune and stromal compartments across tumors. We define conserved and cancer-specific microenvironmental architectures, including spatially distinct immune niches with potential clinical relevance. The distinct spatial and cellular compositions of these niches highlight their potential as spatially resolved biomarkers of immune state, tumor progression, and therapeutic response, with implications for early detection and patient stratification in oncology.

#1204 Spatial multiomic characterization of spontaneous lung tumors in aged mice.

Adam Thiesen[1], Sema Akkurt[1], Javad Noorbakhsh[1], Te-Chia Wu[2], Andrew Salner[3], Peter Yu[3], Susan Airhart[4], Olga Anczukow[1], Ron Korstanje[4], Karolina Palucka[5], Jeffrey H. Chuang[5]

[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[2]Jackson Laboratory, Farmington, CT,[3]Hartford Hospital, Hartford, CT,[4]The Jackson Laboratory, Bar Harbor, ME,[5]The Jackson Laboratory, Farmington, CT

Introduction: Lung cancer is one of the most common malignancies and is the leading cause of cancer related deaths worldwide. While lung cancer incidence has decreased over time with the success of smoking and tobacco cessation campaigns, a significant burden of disease remains among non or never-smokers. Advancing age is a key risk factor for lung cancer, with incidence escalating most steeply in the fifth decade. Here we show that laboratory mice also spontaneously develop lung tumors with age. Additionally, we show that these tumors are often malignant adenocarcinomas as opposed to the adenomas traditionally described. Using spatial transcriptomic and proteomic approaches we aimed to study whether the adenocarcinomas that develop spontaneously in aged mice were similar to human never-smoking tumors.

Methods: Diversity Outbred (DO) and UM-HET3 mice were housed and aged to 24 months. At 24 months, necropsies were performed on more than 600 mice, and all tissues were examined for the presence of tumors. The identified lung lesions were annotated by pathologists on hematoxylin and eosin (H&E)-stained sections to assess tumor type. Those annotated as adenocarcinomas were assessed for 2mm diameter regions of interest (ROIs) to be incorporated into Tissue Microarrays for downstream Xenium spatial transcriptomics and Codex spatial proteomic profiling. The Spacec package was used for codex and Scanpy was generally used for Xenium analysis. These data were compared against publicly available TCGA bulk RNA-seq as well as Xenium data collected from patients at local hospitals.

Results: About 40% of mice developed lung lesions, with 30% of those being adenocarcinomas. Unsupervised leiden clustering of the Xenium single cell data revealed a common signature between mouse epithelial tumors defined by inflammatory markers (*Chil1*). Other clusters associated more aggressive tumor progressions. Codex analysis revealed tumors with pockets of high P21 protein expression distributed throughout the tumor but found closer to the stromal boundary compared to the interior ($p < 0.05$). When we compared aggressive mouse tumor signatures to TCGA bulk RNA-seq signatures these patients have worse survival outcomes. *CD2AP* was a shared transcript significantly up-regulated in both mouse and human tumors ($P < 0.05$). Additionally, the microenvironment of these aggressive tumors often contained p21 positive potentially senescent dendritic cells, which colocalize with T cells.

Conclusion: Genetically diverse mice develop spontaneous lung adenocarcinomas that can develop into higher grade states. Multimodal analysis has revealed common pathways between spontaneously occurring mouse and human adenocarcinomas.

#1205 Trajectory-aware spatial transcriptomics deconvolution *via* image representation of RNA-seq data.

Junyan Liu, Md Tauhidul Islam, Lei Xing

Stanford University, Palo Alto, CA

Introduction: Intra-tumor heterogeneity across malignant clones, immune infiltrates and hypoxic niches drives spatially variable radiosensitivity within the same lesion. Spot-based spatial transcriptomics (ST) affords location-resolved gene expression across whole sections, yet each spot aggregates multiple cell types and states, obscuring the micro-ecologies that define the tumour microenvironment (TME). Although single-cell-resolution ST (e.g., imaging-based transcriptomics) can localize transcripts at sub-cellular scales, its cost, assay time and specialized infrastructure currently limit routine deployment in clinical settings. Accurate deconvolution of spot profiles into cell-type/state proportions is therefore essential to derive mechanistic biomarkers such as subtype-specific radiosensitivity scores or hypoxia indices that can guide biologically adaptive radiotherapy. However, existing deconvolution approaches that directly match ST expression to pre-measured reference profiles are vulnerable to technical variation, including batch effects and gene dropouts, particularly when references and ST are generated on different platforms. In this study, we present an optimal transport (OT) framework for ST deconvolution that leverages the geometry of the gene-expression manifold to stabilize estimates, yielding robust quantification of spot composition.

Methods: We represent each spot's gene expression profile as a "genomap" image, ensuring a consistent 2D arrangement of genes across samples. From these per-spot genomap embeddings, we learn a graph using our previously developed "genoTrajectory" method to capture the manifold of spots. To estimate cell-type compositions, we align the graph to a single-cell reference atlas using optimal transport that integrates both gene-expression similarity and manifold geometry, where the loss function consists of transcriptomic dissimilarity between spots and reference cells, and the geodesic distances between the graphs.

Preliminary Results: We applied the geometry-aware deconvolution to a breast cancer dataset with paired single-cell-resolution ST (Xenium) and spot-based Visium measurements. Using Xenium as the reference ground truth, our method achieved a mean Pearson correlation of r = 0.68 between predicted per-spot cell-type proportions and the Xenium-derived proportions.

Conclusion: Current results demonstrate promising performance for characterizing tumor microenvironment. Future work will expand validation to additional datasets, benchmarking against state-of-the-art methods, and extend analysis to the immune landscape and hypoxia status, with the goal of linking these features to radiotherapy response.

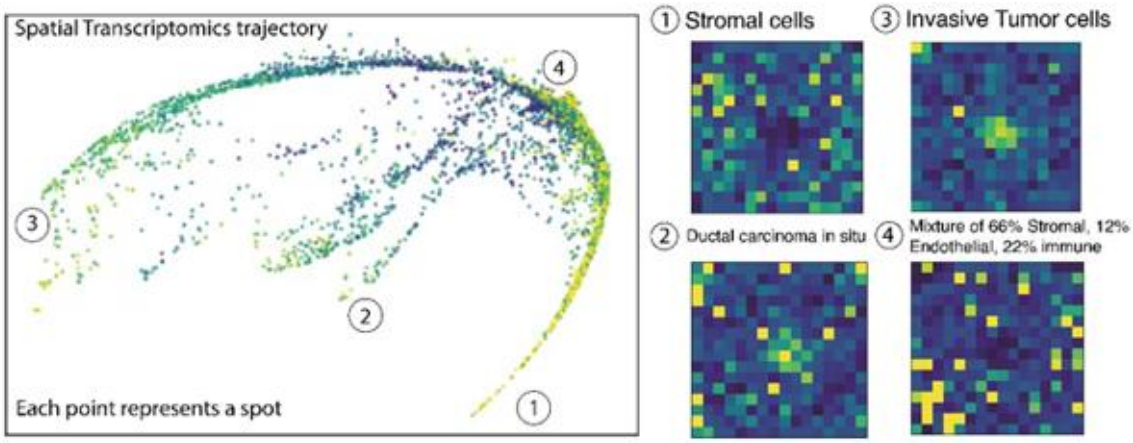

Figure 1. Genomaps and genoTrajectory derived from spot-based ST.

#1206 Large-scale spatial molecular profiling uncovers distinct macrophage activation states across meningioma methylation classes.

Domenico Calafato[1], Yiheng Tang[1], Gleb Rukhovich[1], Elyas Heidari[1], Leonille Schweizer[2], Michael Weller[3], Christine Haberler[4], Till Acker[5], Bhuvic Patel[6], Abigail Suwala[7], Felix Sahm[7], Felix Hartmann[8], Moritz Gerstung[1]

[1]Division of Artificial Intelligence in Oncology, DKFZ German Cancer Research Center, Heidelberg, Germany,[2]Institute of Neurology (Edinger Institute), University Hospital Frankfurt, Goethe University, Frankfurt am Main, Germany,[3]Department of Neurology, Clinical Neuroscience Center, University Hospital and University of Zurich, Zurich, Switzerland,[4]Division of Neuropathology and Neurochemistry, Department of Neurology, Medical University of Vienna, Vienna, Austria,[5]Institute of Neuropathology, University hospital Giessen, Giessen, Germany,[6]Department of Neurosurgery, Washington University School of Medicine, St. Louis, MO,[7]Department of Neuropathology, University Hospital Heidelberg, Heidelberg, Germany,[8]Division of Systems Immunology and Single cell Biology, DKFZ German Cancer Research Center, Heidelberg, Germany

Recent advances in neuro-oncology have highlighted the meninges as a key immunological hub at the interface between systemic immunity and the central nervous system (CNS). While meningiomas are primarily benign, ~20% exhibit high-grade features including brain invasion, recurrence, and treatment resistance. Macrophages in the tumor microenvironment are of particular interest due to their high abundance and phenotypic plasticity. While many studies have investigated macrophage diversity in cancer, this study spatially resolves myeloid activation programs in their native tissue context, exploring correlates with clinical parameters including meningioma molecular subtypes and recurrence. We combine spatial transcriptomics (Xenium) with multiplexed ion beam imaging (MIBI), integrating gene expression and high-dimensional protein data at single-cell resolution. Our large multi-center retrospective cohort of 368 FFPE samples includes cases with detailed molecular and clinical annotations. To enable scalable spatial analysis, we sampled pathologist-annotated regions and imaged tissue-micro-arrays (TMAs). Myeloid activation programs were discovered using cNMF. Delaunay algorithms delineated niches in Xenium data, while CellCharter discovered tissue niches in MIBI data. Spatial protein and transcriptomic data from consecutive sections reveal spatially segregated biological processes. The myeloid compartment in meningioma makes up a significant part of the tumor bulk, especially in low-grade tumors. Protein-level analysis shows clear tissue zonation marked by specific metabolic marker expression such as MCT1 and differential infiltration by microglia-like macrophage subsets. Spatial transcriptomics revealed at least 5 nuanced transcriptional myeloid activation programs that differ across methylation classes of over 320 cases. These differential enrichments were accompanied by distinct infiltration patterns and cell-type co-localization suggesting interaction-driven activation of myeloid programs. Overall, tumor-associated macrophages (TAMs) exhibit context-dependent prognostic significance across cancer types, most evidence supports their association with poor prognosis. In meningiomas, dense TAM infiltration is a key feature of benign subtypes. This study provides spatial context to meningioma methylation classes and addresses critical questions regarding the microenvironmental cues that shape TAM diversity and whether specific TAM activation programs have prognostic value, potentially revealing novel therapeutic avenues.

#1207 Multimodal profiling of STIC lesions identifies precursor states with genomic features of high grade serous ovarian cancer.

Duaa Hassan Al-Rawi[1], Nataly Naser Al Deen[1], Cristina Sotomayor-Vivas[1], Kerstin Thol[1], Herman Chui[1], Aveline Filliol[1], Areej Alsaafin[1], Hunter Green[1], Danguole Norkunaite[1], Mercedes Duran[1], Nicholas Ceglia[1], Kara Long-Roche[1], Britta Weigelt[2], Andrew McPherson[1], Scott W. Lowe[1], Sohrab Shah[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Assistant Member (Level 1), Dept. of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY

High-grade serous ovarian cancer (HGSC) is a lethal malignancy marked by near-universal *TP53* mutation and chromosomal instability (CIN) due late stage diagnosis. Surgical removal of fallopian tubes (FT) is the only effective prevention strategy. Even after surgery, a subset of individuals develops primary peritoneal carcinoma (PPC). When serous tubal intraepithelial carcinoma (STIC) is identified in the FT, PPC risk exceeds 30-fold. To study the steps required for HGSC initiation and identify features of high risk STICs, we assembled a 201-patient cohort spanning HGSC development from normal FT, p53 signatures, STIC, early and advanced-stage HGSC. All specimens underwent multiplexed immunofluorescence (mpIF), and 45 samples from 36 patients were profiled by Visium HD spatial transcriptomics generating >20million 8μM bins of data. We analyzed epithelial state transitions and inferred copy number variation (CNV) using inferCNV. In one case we validated CNV calls with matched FFPE single-cell whole-genome sequencing. mpIF revealed variable emergence of cGAS staining in STIC lesions, indicating evolving tolerance to CIN prior to invasion. Using unsupervised clustering of the epithelial bins, we found that STIC lesions formed distinct transcriptional clusters that faithfully mapped to STIC histologic features. Trajectory analyses suggests a putative precursor state bridging ciliated and secretory lineages. STIC clusters were enriched for NFκB and TGF-β signaling but lacked evidence of JAK/STAT signaling observed in advanced HGSC. inferCNV showed that normal fallopian tube/p53 signature lesions were largely chromosomally stable, whereas STICs displayed broad, genome-wide alterations, reminiscent of advanced HGSC, including losses affecting *TP53*, *BRCA1*, and *BRCA2* and amplifications of *MYC* and *CCNE1*. In a germline *BRCA2* patient, we identified polyclonal STICs with distinct CNV profiles. Pseudotime trajectory analysis in this case suggested early copy number changes within an expanded secretory population, followed by loss of chromosome 17 (*TP53*), loss of chromosome 13 (*BRCA2*), and subsequent oncogene amplifications (e.g., *MYC*). As STIC lesions become invasive, we observed spatial bins with unique inferred copy number profiles, indicating the emergence of neighborhoods of clonally related invasive cells. These tumor neighborhoods exhibit different microenvironments, including differences in fibroblast phenotypes and vascularization. This multimodal map of fallopian tube transformation supports a model in which *TP53* loss precedes *BRCA1/2* inactivation and indicates that STICs are genomically similar to advanced HGSC. Together, these data provide a framework for studying early HGSC evolution and may inform strategies for risk reduction and early interception.

#1208 The MONSTAR-SCREEN-3 Spatial Atlas: Pan-cancer TME archetypes and clinically relevant tumor-immune ecosystems.

Mitsuho Imai[1], Eun Seop Seo[2], Jiyeon Hyeon[3], Shingo Sakashita[4], Yuka Nakamura[4], Tadayoshi Hashimoto[4], Shin Kobayashi[4], Jun Yuda[1], Riu Yamashita[4], Taro Shibuki[4], Takao Fujisawa[4], Masataka Amisaki[4], Kensuke Matsuda[1], Shun-ichiro Kageyama[5], Michiko Nagamine[5], Takeshi Kuwata[6], Hideaki Bando[7], Woong-Yang Park[3], Takayuki Yoshino[7]

[1]National Cancer Center Hospital East, Kahsiwashi, Japan,[2]GxD Inc, Seoul, Korea, Republic of,[3]GxD Inc, Kashiwashi, Japan,[4]National Cancer Center Hospital East, Kashiwashi, Japan,[5]National Cancer Center Hospital East, Kashiwanoha, Japan,[6]Pathology, NCCHE, Kashiwa, Japan,[7]National Cancer Center Hospital East, Kashiwa, Japan

Background: The SCRUM-Japan MONSTAR-SCREEN consortium is a nationwide molecular profiling initiative spanning all solid tumors except lung cancer and hematologic malignancies. The next-generation MONSTAR-SCREEN-3 (M3) project incorporates spatial transcriptomics to achieve a "quantum leap" by integrating novel modalities to decode the tumor microenvironment (TME) architecture governing therapeutic response. This study presents the foundational pan-cancer spatial atlas from the initial M3 dataset.
Methods: MONSTAR-3 enrolls ~3,200 cases, and spatial analysis is being performed on eligible specimens. Among these, 331 FFPE tumors across 21 solid types were analyzed. Spatial profiling used the Xenium 5K platform within a standardized NCCE-GxD workflow (NCCE tissue preparation, GxD Xenium processing; ~10-week pipeline). Cell types were annotated using a consensus framework across four pipelines. Malignant epithelial cells were distinguished from benign epithelium through integrated spatial context, transcriptional features, and pathologist-guided review. We quantified malignant program heterogeneity and identified shared and distinct spatial niches linked to clinical variables.
Results: We generated a high-confidence spatial atlas comprising ~20 million cells. Across 21 tumor types, TME was organized into conserved, pan-cancer spatial ecosystem archetypes that stratified prognosis and therapeutic response. Spatial heterogeneity in malignant programs correlated with advanced disease. We also defined 15 conserved pan-cancer cellular niches (metaclusters), each with distinct compositions and spatial architectures. Among these, two tumor-stromal interface archetypes emerged: MC9, an innate-immune-rich interface, and MC5, a lymphocyte-dominant interface. The MC9 niche was significantly enriched in the advanced-stage tumors, showed increasing prevalence with higher TNM stages, and its derived signatures were associated with poor prognosis in legacy cohorts (e.g., TCGA). Conversely, B-cell-dominant (MC10) and B-cell/CD4+ T-cell-rich (MC14) niches were associated with favorable outcomes. These lymphocyte-dominant structures were further resolved into simple aggregates, primary follicles, and secondary follicles indicative of TLS formation. Secondary follicle signatures correlated with improved prognosis and response in an independent immunotherapy-treated cohort.
Conclusions: This study presents one of the largest pan-cancer spatial transcriptomic atlases and establishes a foundational component of the M3. We provide a robust framework for analyzing spatial transcriptomics and conserved, clinically actionable spatial ecosystems. This resource paves the way for spatially-driven patient stratification, next-generation biomarker development, and accelerated precision oncology within the SCRUM-Japan framework.

#1209 *FGFR2* translocated sinonasal adenocarcinoma: A biphasic seromucinous adenocarcinoma with a distinctive and targetable molecular phenotype.

Diana Bell[1], Randal S. Weber[2], Miao Zhang[2], Michelle Afkhami[3], Raja R. Seethala[1]

[1]University of Pittsburgh, Pittsburgh, PA,[2]University of Texas MD Anderson Cancer Center, Houston, TX,[3]City of Hope, Duarte, CA

Sinonasal adenocarcinomas (SNACs) are the second most common carcinoma category in the sinonasal tract after squamous cell carcinomas and include intestinal type adenocarcinoma, non-intestinal type adenocarcinomas and salivary-type adenocarcinomas. Surgery with postoperative radiation therapy is standard treatment for SNAC. Molecular characterization lists provisional subtypes (*BRAF V600E*-mutated sinonasal ductal-like tumors, *MAPK / PI3-K* altered SNAC, *CTNNB1*-mutated sinonasal carcinoma, fusion-kinase associated SNAC e.g. *ETV6::NTRK3*, *FGFR*-rearranged biphasic SNAC).We report a biphasic/basaloid SNAC (maxillary sinus epicenter, extending into nasal cavity; pT4N0M0) with a novel *FGFR2::SORB3* fusion. Targeted NGS was performed with a solid tumor comprehensive assay including DNA sequencing and RNA sequencing. RNA expression profiles of 1392 genes, related to tumor-immune interaction was generated. Representative SNAC region was subjected to 10X Genomics Visium Spatial Gene Expression analysis. NGS showed 9 clinically significant variants: *BMPR1A* loss; *DICER1* loss, *FGFR2* amplification, *GATA4* loss, p*MITF*, p*NF2*, *PIK3R1*, *PTEN* loss, p*PTEN*; TMB low, MSI stable; a novel *FGFR2::SORBS3* fusion was noted on RNAseq. *FGFR2* breakapart FISH showed a complex rearrangement with loss of the 3' signal and concurrent amplification of the 5' signal. The HTG panel showed the top upregulated IL DEGs(*IL12A*, *SPP1*, *IL12RAP*), with *SOX2* most downregulated.ST analysis of the annotated spots demonstrated 5 distinct clusters corresponding to histologically distinct compartments (biphasic-2 clusters; monophasic/ solid/ clear-1 cluster; stroma-1 cluster; tumor-stroma interface-1 cluster). Top shared upregulated DEG were *OLFM4*, *LTF* and *KRT14* while the top downregulated DEG were *BPIFA1*, *ALOX15*, and *C20orf85*. GSEA across several MSigDB collections showed muscle cell differentiation pathway upregulation. Phosphorylation and intracellular signaling cascade pathways PI3K-AKT, JAK, STAT3, IL6, IFNɣ response was identified in most clusters. Stromal/ tumor-stromal interface clusters were enriched for EMT pathways, followed by inflammatory response, angiogenesis, K-Ras signaling up. *FGFR2* translocated SNAC may represent a distinct basaloid biphasic tumor with a seromucinous phenotype. Morphology and muscle cell differentiation enrichment suggests homology with salivary epithelial-myoepithelial carcinoma, but the 'hotter' immune microenvironment sets it somewhat apart from most salivary type carcinomas. *FGFR2::SORBS3* is rare even among the 150+ identified partners in other tumor types (i.e. cholangiocarcinoma) but appear to function similarly, upregulating phosphorylation pathways. Recognition of this tumor subtype could help select patients potentially amenable to FDA- approved oral FGFR2 inhibitors (pemigatinib, futibatinib).

#1210 Integrated spatial and single-cell profiling uncovers a pre-existing, treatment-resistant subclone that drives early local relapse in luminal breast cancer.

Kazutaka Otsuji[1], Tomo Osako[2], Yoko Takahashi[3], Chikako Shibata[4], Sumito Saeki[4], Asumi Iesato[1], Tetsuo Noda[5], Kengo Takeuchi[2], Takayuki Ueno[3], Reo Maruyama[4]

[1]NEXT-Ganken Program, Japanese Foundation for Cancer Research, Koto-ku, Tokyo, Japan,[2]Division of Pathology, Cancer Institute, Japanese Foundation for Cancer Research, Koto-ku, Tokyo, Japan,[3]Breast Oncology Center, Cancer Institute Hospital of JFCR, Japanese Foundation for Cancer Research, Koto-ku, Tokyo, Japan,[4]Division of Cancer Epigenomics, Cancer Institute, Japanese Foundation for Cancer Research, Koto-ku, Tokyo, Japan,[5]Director's room, Japanese Foundation for Cancer Research, Koto-ku, Tokyo, Japan

Background
Early local relapse during adjuvant endocrine therapy in hormone receptor (HR)-positive breast cancer, although uncommon, may reflect selection of pre-existing subclonal populations with intrinsic resistance. While endocrine resistance has been linked to aberrant cell-cycle activation and attenuated estrogen signaling, the spatial organization and transcriptional evolution of resistant subclones within tumors remain insufficiently resolved.
Methods
We performed multimodal profiling of paired primary and early local-relapse tumor specimens using the 10x Visium and Xenium spatial transcriptomics platforms. Additionally, a diagnostic core-needle biopsy obtained from the relapse lesion before resection underwent single-cell (sc) RNA sequencing. Spatial inferCNV was applied to Visium data to delineate clonal architecture and identify putative malignant subclones in an unbiased manner. Clone-specific transcriptional programs were characterized through differential expression and pathway enrichment analyses. Gene signatures derived from relapse scRNA-seq clusters were computationally projected onto the matched spatial transcriptomics data to map subclone-specific transcriptional phenotypes with high spatial resolution. Xenium profiling of the primary tumor was used to evaluate local microenvironmental features associated with resistant and responsive clones.
Results
Spatial inferCNV revealed marked clonal remodeling between the primary and relapse tumors: a minor primary-tumor subclone with distinct copy-number features expanded disproportionately and became the dominant malignant population at relapse. scRNA-seq demonstrated that transcriptional clusters corresponding to this conserved clone exhibited increased E2F target and G2/M checkpoint activity, concomitant with reduced estrogen-responsive signaling, consistent with an estrogen-independent proliferative phenotype. Single-cell resolution analysis of Xenium data from the primary tumor revealed that regions enriched for the resistant clone exhibited lower T-lymphocyte density compared to areas dominated by treatment-responsive subclones, suggesting early spatial segregation and microenvironmental differences that may have facilitated selective survival under endocrine therapy.
Conclusions
This integrated spatial and single-cell analysis of a rare rapid-relapse HR-positive breast cancer case demonstrates that a transcriptionally distinct, estrogen-independent, E2F-driven subclone was already embedded within the primary tumor and later seeded early local recurrence. These findings highlight the power of multimodal transcriptomics to uncover clinically occult resistant subclones and provide a framework for identifying patients at risk of early relapse despite standard adjuvant endocrine therapy.

#1211 Spatial transcriptomics uncovers pharmacokinetic barriers and tumor-intrinsic determinants of resistance to trastuzumab deruxtecan in breast cancer.

Changhee Park[1], Minki Choi[2], Jiwon Koh[3], Sungwoo Bae[4], Hongyoon Choi[4], Kwon Joong Na[4], Dae-Won Lee[1], Kyung-Hun Lee[1], Han Suk Ryu[3], Seock-Ah Im[1]

[1]Seoul National University Hospital, Seoul, Korea, Republic of,[2]Pathology, Asan Medical Center, Seoul, Korea, Republic of,[3]Pathology, Seoul National University Hospital, Seoul, Korea, Republic of,[4]Portrai Inc., Seoul, Korea, Republic of

Introduction: Trastuzumab deruxtecan (T-DXd) is an antibody-drug conjugate (ADC) that is effective for both HER2-positive and HER2-low metastatic breast cancers (MBC). While correlation between HER2 expression levels and response to T-DXd was identified, effective biomarkers and mechanisms of sensitivity or resistance remain elusive, partly due to complex pharmacokinetics of T-DXd. Our goal is to delineate spatial transcriptomic (ST) features which is associated with therapeutic response and resistance to T-DXd.
Methods: We performed ST with the 10x Genomics Visium HD on formalin-fixed paraffin-embedded tumor tissues from patients with MBC treated with T-DXd. Responders to T-DXd were defined as patients who experienced objective response or stable disease for more than 6 months, and non-responders were defined as otherwise. Fragments of pre-treatment biopsy samples from patients classified as responders were designated as "sensitive fragment" while that of pre-treatment biopsy samples from non-responders or post-progression biopsy samples from responders were defined as "resistant fragment". Various transcriptome analyses were performed including the compartment modeling-based methods for estimating antibody and payload concentrations from T-DXd pharmacokinetic profiles.
Results: A total of 20 tumor tissues from 13 patients were available including matched pre- and post-treatment biopsied in 5 patients. After quality check, 11 T-DXd-sensitive (19 fragments) and 7 resistant tissue samples (27 fragments) were included for analysis. Utilizing autocorrelation-related indices, spatial heterogeneity of *ERBB2* gene expression influenced outcomes, with more dispersed *ERBB2* gene expression distributions by cancer cells correlating with improved response. In HER2-positive tumors, resistant fragments showed downregulation of *ERBB2* gene expression and activation of PI3K and EGFR pathways, with autocrine amphiregulin-EGFR signaling emerging as a candidate resistance mechanism. In HER2-low tumors, resistance was notably associated with pharmacokinetic barriers: resistant fragments exhibited increased cancer-vessel distance, reduced colocalization of *ERBB2* expression with cathepsin linker-cleaving enzymes and diminished predicted tumor-to-non-tumor payload concentration ratio. Exploratory longitudinal analyses of paired pre- and post-treatment samples revealed temporal increases in vessel-cancer distance at resistance.
Conclusion: These findings highlight potential determinants of T-DXd efficacy. Our study demonstrates the utility of ST for uncovering ADC response mechanisms in clinical samples and potential novel therapeutic strategies.

#1212 Spatial transcriptomics reveals distinct SPP1-CD44 signaling networks in neoadjuvant osimertinib treated EGFR mutant non-small cell lung cancer.

Whitney Tamaki[1], Daniel L. Kerr[2], Wei Wu[1], Grant Eilers[3], Anatoly Urisman[3], Yu-Ting Chou[1], Philippe Gui[1], Shigeki Nanjo[4], Johannes Ruediger Kratz[1], David Jablons[1], Trever G. Bivona[1], Collin M. Blakely[5]

[1]UCSF, San Francisco, CA,[2]University of Washington, Seattle, WA,[3]Anatomic Pathology, UCSF, San Francisco, CA,[4]Kanazawa Univ. Hospital, Kanazawa, Japan,[5]Clinical Fellow, Medical Oncology, UCSF, San Francisco, CA

Background: Lung cancer is the leading cause of cancer mortality, and despite improvements in treatment, tumors typically respond incompletely and resume growth after acquisition of drug resistance. Recent completion of a neoadjuvant osimertinib Phase II trial treating patients with surgically resectable stage I-IIIA EGFR-mutated non-small cell lung cancer (EGFRm NSCLC) (NCT03433469) has highlighted the importance of further identifying non-genomic, transcriptionally adapted mechanisms of persistence and resistance to targeted therapy.

Methods: We analyzed these patient samples to identify transcriptionally regulated signaling patterns enriched at Residual Disease (RD) after neoadjuvant osimertinib treatment compared to treatment naïve samples (TN. Spatially resolved transcriptomic sequencing was performed, using the 10X Genomics Visium platform, on 36 tissue sections (n=9 TN, n=19 RD, n=4 Progressive Disease (PD), n=4 Tumor Adjacent Normal), from 25 patients. TN and PD samples were from standard-of-care surgical resections. 18 of 19 RD samples were from NCT03433469. After quality control, 91,582 array spots remained for downstream analysis.

Results: We identified high confidence tumor array spots annotated both as “Cancer” by a board-certified pathologist and with tumor characteristic copy number variations. We applied disease-matched single-cell RNA-sequencing reference profiles to deconvolute the spatial transcriptomic data and estimate cell-type abundances. Analysis of cell-cell signaling networks identified significantly enriched or abundant SPP1-CD44 interactions between macrophage subtypes and tumor cells at the RD state. Specifically, PDPN+ Macrophages were identified as a primary source of SPP1 expression. Additional differential gene analysis identified significant upregulation of TM4SF4 and SERPINA3, known genes up and downstream, respectively, of SPP1, in the RD tumor nest, as compared to TN. SERPINA3 has previously been shown to positively regulate PI3K/AKT signaling pathway.

Conclusion: The interaction between macrophages and tumor cells through SPP1-CD44 signaling significantly contributes to EGFRm targeted therapy-induced tolerance and resistance. Future studies will focus on elucidating the regulatory mechanisms governing the TM4SF4/SPP1/SERPINA3 axis and evaluating its contribution to therapy resistance, as well as its potential as a therapeutic target, using preclinical models.

#1213 Mitochondrial transcriptome profiles associated with clinical responses to CAR-T therapy in aggressive lymphoma.

Jacqueline Turner[1], Panwen Wang[2], Patrizia Mondello[1], Melinda Tan[3], Christoph Schaefers[1], Chen Wu[4], Andre de Menezes Silva Corraes[4], Kevin Regan[4], Zuoyi Shao[4], Ma Audrey[4], Arushi Khurana[4], Nora N. Benanni[4], Yucai Wang[4], Paul Hampel[4], Saad J. Kenderian[4], Jonas Paludo[4], Urshila Durani[4], Patrick B. Johnston[5], Jose Caetano Villasboas[4], Stephen M. Ansell[6], Haidong Dong[1], Ying Li[4], Zeng Hu[4], Yi Lin[7]

[1]Mayo Clinic College of Medicine and Science, Rochester, MN,[2]Mayo Clinic, Scottsdale, AZ,[3]Mayo Clinic Cancer Center Minnesota, Rochester, MN,[4]Mayo Clinic, Rochester, MN,[5]Hematology, Mayo Clinic College of Medicine, Rochester, MN,[6]Assistant Professor, Div. of Hematology, Mayo Clinic College of Medicine, Rochester, MN,[7]Asst. Professor, Div. of Hemat., Mayo Clinic, Rochester, MN

Introduction: Therapeutic outcomes in B-cell non-Hodgkin's lymphoma (B-NHL) have substantially improved with the introduction of chimeric antigen receptor T-cell (CAR-T) therapy. Yet, persistent immune dysfunction and underlying metabolic dysregulation remain major obstacles to achieving durable clinical responses in B-NHL. We hypothesize that mitochondrial pathways play a critical role in mediating anti-tumor immunity during CAR-T therapy.
Methods: Peripheral blood mononuclear cells were collected from healthy controls (CNTRL, n=5) and patients with advanced stage lymphoma (LYM) who received FDA approved CAR-T (n=32). Samples were collected before lymphodepletion (BL), at peak CAR-T expansion (PK) and one-month post-infusion (M1). Single-cell RNA sequencing was used to interrogate differential mitochondrial gene expression. Samples were obtained from LYM patients with complete remission for ≥6 months (CR), primary refractory (PD1), or relapsed (PD2) disease.
Results: Compared to CNTRLs, LYM patients exhibited reduced expression of cytochrome c oxidase. At BL, CR patients demonstrated broader mitochondrial differential gene expression across all T-cell subsets relative to PD1 and PD2 and showed higher expression of *MT-ATP-6*, *MT-ATP-8*, and *MT-CO3*. Following CAR-T infusion, global mitochondrial gene expression increased across patients corresponding with expansion of CD8 effector T cells (Tem tumor circulating) and activated peripheral memory T cells (Tpm). Certain mitochondrial genes, such as *MT-CO1*, were durably expressed across LYM patients at BL, PK, and M1 in peripheral and central memory T cells (Tpm, Tcm). At PK, cytochrome c oxidase and ATP synthase genes were upregulated in CR Tpm and Tcm. At M1, *MT-ATP-6*, *MT-ATP-8*, *MT-CO3* were significantly upregulated in CD8 memory precursor effector T-cells (MPECs) of CR patients compared to both PD1 and PD2. While CR and PD2 patients appeared clinically responsive at M1, CR samples maintained significantly higher *MT-ATP-8* expression across T cell subsets (CD8 MPECS, Tpm, Tcm) compared to PD2 (p values 0.008; <0.0001; <0.0001).
Conclusions: We report a temporal shift in immunometabolism with CAR-T therapy in LYM. Clinical responders exhibited sustained mitochondrial activity characterized by persistent expression of ATP synthase in CD8 MPECs and cytochrome c oxidase in Tpm and Tcm. In sum, mitochondrial programming may distinguish effective versus dysfunctional T cells and identify targets for therapeutic development.

#1214 SPACE: Spatially resolved multiomic analysis for high-throughput CRISPR screening in 3D models.

Mengwei Hu[1], Yi Cui[2], Qianhui Huang[1], Khoi Chu[1], Sierra McKinzie[2], Michael Patrick[2], Sharanya Iyengar[1], Maerjianghan Abuduli[1], Marianne Spatz[1], Nandita Joshi[1], Brendan Miller[1], Shams Vellarikkal[1], Timothy Riordan[2], Danny Bitton[3], Jan Lubojacky[3], Iya Khalil[1], Federica Piccioni[1], Michael Rhodes[2], Alex Tamburino[1], Shanshan He[2], Joseph Beechem[2], Vanessa Peterson[1]

[1]Merck & Co., Inc, Cambridge, MA,[2]Bruker Spatial Biology, Seattle, WA,[3]MSD, Prague, Czech Republic

High-content single-cell perturbation screens are pivotal for elucidating gene functions and uncovering novel biology, yet conventional methods necessitate cell dissociation, forfeiting critical spatial information essential for dissecting cell-cell interactions and tissue architecture in complex microenvironments. While spatial CRISPR screening mitigates this partially, existing technologies are constrained by hypothesis-driven phenotyping panels limited to sparse RNA or protein coverage, curtailing comprehensive gene function assessment and discovery breadth.To overcome these barriers, we developed SPACE (SPAtial Cell Exploration), a pioneering platform that fuses whole-transcriptome profiling, CRISPR perturbations, and multiplexed protein detection at single-cell resolution within intact 3D tissue contexts. SPACE delivers unbiased, transcriptome-wide readouts alongside compatibility for up to 76 protein markers, vastly expanding phenotypic landscapes in spatial screens. As the highest-plex multimodal spatial CRISPR assay to date, SPACE achieves this at unprecedented scale and affordability and largely outperforms sequencing-based alternatives in efficiency.We applied SPACE across 42 gene perturbations in cancer-associated fibroblasts (CAFs) co-cultured with tumor cells in 3D spheroids, yielding multidimensional multiomic datasets from hundreds of spheroids. High-confidence guide RNA detection was coupled with robust endogenous mRNA characterization. Unbiased analyses uncovered new insights on CAF-tumor dynamics: extracellular matrix (ECM) remodeling, spatially resolved ligand-receptor interactions, and perturbation-specific gene variability.Notably, *ISG20* knockout in CAFs profoundly suppressed multiple matrix metalloproteinases - an unreported link validated orthogonally - implicating *ISG20* in novel ECM regulation and tumor progression. Some perturbations were further revealed to reshape intercellular signaling, revealing knockout-dependent spatial ligand-receptor shifts and coordinated expression signatures that underscore microenvironmental crosstalk in tumor phenotypes.Culminating in a landmark demonstration, SPACE simultaneously captured whole transcriptomes, CRISPR identities, and 68 protein markers on one slide, enabling holistic perturbation phenotyping. This transformative technology propels spatial CRISPR screening into translational realms, facilitating target and biomarker identification in multicellular models mirroring human tissue intricacy. By merging high-throughput perturbations with spatially resolved multiomics at transcriptome scale, SPACE catalyzes discovery in heterogeneous tissues. SPACE datasets will fuel generative AI models for causal biology inference, accelerating drug discovery and precision medicine.

#1215 Spatial transcriptomic analysis of primary melanomas with extreme clinical outcomes.

Prachi Bhave[1], Marie Trussart[2], Anthony T. Papenfuss[2], Grant A. McArthur[3]

[1]The Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, Australia,[2]Walter & Eliza Hall Institute of Medical Research, Melbourne, Australia,[3]Peter MacCallum Cancer Centre, Melbourne, Australia

Introduction: Most patients that die from melanoma do so after recurrence of early stage disease. There is, therefore, an urgent need to improve the identification and management of patients with early stage melanoma at high risk of recurrence. The tumour microenvironment (TME), subclonal tumour cell intrinsic features and cellular interactions likely play key roles in melanoma recurrence. Spatial transcriptomics (ST) is optimally positioned to characterize these factors and may provide novel insights and strategies to overcome early stage melanoma recurrence.

Methods: We examined 12 early stage (thick, T4b) FFPE primary melanoma samples with extreme clinical outcomes, identified from the prospectively collected Melanoma Research Victoria database. Of these, 7 patients had T4b melanoma with an unexpectedly good outcome of no recurrence ≤5 years of diagnosis and 5 patients had T4b melanoma with an expectedly poor outcome of recurrence ≤5 years of diagnosis (late and early recurrence groups, respectively). Samples were interrogated using 10X CytAssist Visium with comparisons between the two groups. Comprehensive bioinformatics analyses were performed including Bayespace and Harmony for initial spot clustering; SingleR for cluster annotation; RCTD deconvolution to refine cluster identification; edgeR on pseudo-bulk counts and gene set testing of differentially expressed genes (DEG); sscomp for differential cellular composition; SPIAT for spatial immune-tumor architecture analysis and non-negative matrix factorization (NMF) and SpaceMarkers for exploration of gene expression patterns and interacting regions.

Results: Key cell types were revealed within each sample, including tumor cells, diverse immune cell subsets, fibroblasts, macrophages and keratinocytes. Tissue architecture including dermis, epidermis and invasive tumour front were well characterised. DEG identified downregulation of SLC5A10, PFKFB2, FBXO32, GABRB3, SMIM38 and CDH7 in the late group relative to the early group. Gene set analysis revealed upregulation of the hallmark hypoxia, angiogenesis, EMT, glycolysis, IL2, TNFa and TGFb pathways in the late relative to the early group. Cellular compositions varied across the two groups, with the late group having significantly lower tumour purity and higher abundance of immune cells than the early group. NMF revealed specific patterns associated with tumor and immune cells, with significant downregulation of IGHA2, CYP4X1, RBMXL3 and AIRE at the interacting region between tumor and immune cells in the late relative to the early group.

Conclusion: This study is one of the first to analyze primary melanoma samples with extreme clinical outcomes using ST. Our results reveal that differences in cellular composition of primary melanomas as well as differential expression of key genes involved in immune activation, inflammation and metabolism may be associated with melanoma recurrence.

#1216 Profiling colon cancer architecture with spatial transcriptomics identifies clinically relevant stromal ecotypes.

Antoine Cazelles[1], Camilla Pilati[1], Delphine Le Corre[1], Gadea Cabrejas[1], Marine Sroussi[1], Claire Mulot[1], Claire Gallois[1], Gilles Manceau[1], Mehdi Karoui[1], Isaias Hernandez-Verdin[1], Antoine Bougouin[1], Wolf-Herman Fridman[1], Aurelien de Reynies[1], Come Lepage[2], Thierry Andre[3], Jean-Francois Emile[4], Theo Z. Hirsch[1], Julien Taieb[1], Pierre Laurent-Puig[1], **Sophie Mouillet-Richard**[1]

[1]Centre de Recherche des Cordeliers, Paris, France,[2]University of Burgundy and Franche Comte, Dijon, France,[3]Hopital Saint-Antoine, Paris, France,[4]Ambroise-Pare Hospital, Boulogne, France

Despite progress in the understanding of intra-tumor heterogeneity in colon cancer, the spatial organization of the cell types and states that compose colon tumors remains to be fully delineated. We constructed a large spatial transcriptomic atlas of 48 stage III colon cancers and identified recurrent, biologically relevant spatial ecosystems, including tumor and stromal ecotypes. Analysis of recurrence-associated profiles revealed a stromal-specific upregulation of a set of genes that includes the regenerative/revival-stem cell (REC/RSC) marker *ANXA1*. Disease recurrence was accompanied by stromal-specific enrichment of REC/RSC and YAP activation signatures, together with increased associations between levels of *ANXA1* and those of collagen-expressing genes. Dissection of the stromal compartment uncovered hidden heterogeneity and sub-cluster-specific enrichment in *ANXA1* and related markers in patients with relapse. Further profiling at single cell resolution with Visium HD allowed spotting *ANXA1*-expressing tumor cells within an environment marked by abundant collagen-producing cancer-associated fibroblasts (CAFs). Finally, we translated these findings to bulk transcriptomics by performing univariate and multivariate analyses and demonstrated the prognostic value of gene signatures derived from the spatial ecotypes and stromal sub-clusters across three independent cohorts comprising >3,500 stage II and stage III colon cancer patients. By mapping cellular ecosystems in localized colon cancer, this work lays the foundation to elucidate mechanisms of disease recurrence and inform therapeutic strategies. The validation of the spatially-derived prognostic signatures in bulk transcriptomic data paves the way for their potential integration into clinical practice to improve patient stratification.

#1217 Multi-omics integration of bulk, single-cell, and spatial transcriptomics identifies robust prognostic biomarkers in head and neck salivary adenoid cystic carcinoma.

Gopikrishnan Bijukumar[1], Kathryn J. Brayer[2], David Lee[2], Scott A. Ness[3], Jeremy S. Edwards[1], **Viswanathan Palanisamy**[4]

[1]Chemistry and Chemical Biology / Cancer Research Facility, University of New Mexico, Albuquerque, NM,[2]University of New Mexico, Albuquerque, NM,[3]Professor, Dept. of Molec. Genetics & Microbiol., University of New Mexico School of Medicine - Albuquerque, Albuquerque, NM,[4]Internal Medicine / Comprehensive Cancer Center, University of New Mexico Health Sciences, Albuquerque, NM

Adenoid Cystic Carcinoma (ACC) of the head and neck is a rare malignancy with a paradoxical clinical course, slow-growing yet highly invasive, with limited therapeutic options and no validated molecular prognostic biomarkers. To address this unmet need, we implemented a comprehensive multi-omics strategy integrating bulk RNA sequencing (n=20), single-cell RNA sequencing (n=24), and high-resolution spatial transcriptomics (4 Visium HD samples) from ACC tumors spanning eight distinct anatomical subsites. Clinical metadata enabled stratification into “poor” (<2-year survival) and “good” (>5-year survival) prognosis groups. In the absence of definitive cause-of-death data, we developed a machine learning-based classifier to define transcriptomic prognosis subgroups, revealing biologically coherent clusters aligned with clinical outcomes.Our biomarker discovery pipeline encompassed three key phases:

1.Cross-Modality Differential Expression and Pathway Profiling: We identified conserved gene expression signatures and dysregulated pathways distinguishing poor from good prognosis tumors across bulk, single-cell, and spatial modalities. High-risk tumors exhibited consistent enrichment of oncogenic signaling (e.g., MYC, NOTCH), immune suppression, and stromal activation programs across shared cell types and anatomical regions.

2. Spatially Resolved Cellular Ecosystem Mapping: Integration of single-cell and spatial transcriptomics enabled precise localization of malignant cell states and immune niches associated with poor prognosis. Spatial analyses revealed intratumoral “hotspots” characterized by elevated oncogenic activity, immune exclusion, and stromal remodeling. Ligand-receptor interaction networks, validated by spatial proximity, uncovered key signaling axes (e.g., CXCL12-CXCR4, TGFB1-TGFBR2) driving tumor progression.

3. Development of a Prognostic Biomarker Panel: We constructed a machine learning-derived multi-gene signature reproducible across all modalities. This panel demonstrated superior risk-stratification performance compared with existing ACC gene sets, with prognostic accuracy independent of clinical features. Importantly, the biomarker panel is amenable to clinical translation via bulk RNA profiling, offering immediate utility for patient stratification and therapeutic decision-making. In summary, our integrative multi-omics approach reveals robust molecular programs and spatially defined cellular ecosystems underlying poor prognosis in ACC. The resulting biomarker panel offers a powerful tool for precision prognostication and lays the foundation for targeted therapeutic development in this challenging malignancy.

#1218 Development of a proximity ligation-imaging mass cytometry platform for spatially resolved immune checkpoint analysis.

Ghazal Lessan Toussi[1], Lars Muhl[2], Anna Gorbunova[1], Austin James Rayford[3], Amanda Lindberg[4], Neda Hekmati[4], Viktoria Thurfjell[4], Aglaia Schiza[4], Agata Zieba Wicher[5], Patrick Micke[4], **Carina Strell**[4]

[1]Department of Clinical Medicine, University of Bergen, Bergen, Norway,[2]Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden,[3]Department of Biomedicine, University of Bergen, Bergen, Norway,[4]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden,[5]Navinci Diagnostics AB, Uppsala, Sweden

Introduction: Immune checkpoint inhibitors (ICIs) have transformed cancer therapy, yet durable clinical benefit remains limited to a subset of patients. Current biomarkers, such as PD-L1 immunohistochemistry (IHC), reflect protein abundance rather than functional receptor-ligand engagement and therefore provide only modest predictive value. To address this, we previously demonstrated that mapping PD1-PD-L1 interactions using a proximity ligation assay (PLA) outperforms PD-L1 IHC in predicting immunotherapy response in non-small cell lung cancer (NSCLC) [1].

Methods: Building on these findings, we developed a triplex PLA detecting PD1-PD-L1, PD1-PD-L2, and CD8-MHC I interactions and integrated it with Imaging Mass Cytometry (IMC). This approach enables high-plex (≈40 markers) spatial quantification of active immune signaling pathways alongside detailed immune phenotyping. The platform was applied to human tonsil tissue as a biological control and to pre-treatment NSCLC and triple-negative breast cancer (TNBC) biopsies to map checkpoint engagement, antigen recognition, and T-cell functional states within the tumor microenvironment.

Results: In tonsil, PD1-PD-L1 and PD1-PD-L2 interactions were observed primarily between $CD8^+$ T cells and follicular B cells, while additional PD1-PD-L1 interactions occurred between $CD8^+$ T cells and $CD68^+$ macrophages. These patterns suggest partly distinct cellular contexts for PD-L1 and PD-L2 engagement in lymphoid tissue. Consistent with this, preliminary tumor data indicate that PD1-PD-L2 interactions are relatively rare in TNBC compared with NSCLC, suggesting that PD-L2 involvement varies across tissue types and immune environments.

Conclusion: PLA-IMC provides a functional, spatially resolved platform for screening and quantifying active immune checkpoint signaling directly in tissue. This approach holds promise to identify functional biomarkers for refined patient stratification and mapping of context-specific checkpoint activity to guide rational immunotherapy combinations in solid tumors.

#1219 Spatial multi-omic profiling to capture functional signatures in HER2-heterogeneous FFPE breast cancer tissue.

Dongyoon Shin[1], Sumin Lee[2], **Young June Jeon**[3], Jeongwoo Hong[4], Sohyun Yang[5], Amos Chungwon Lee[4], Han Suk Ryu[5], Youngsoo Kim[1], Sungwoo Cho[6], Song-A Park[6], Sihun Cho[7], Sungho Ko[6], Junho Park[8]

[1]CHA Research Institute, CHA Bundang Medical Center, Seongnam-si, Korea, Republic of,[2]Meteor Biotech Co., Ltd., Seoul,[3]Department of Life Sciences, CHA University, Seongnam-si, Korea, Republic of,[4]Meteor Biotech, Seoul, Korea, Republic of,[5]Seoul National University Hospital, Seoul, Korea, Republic of,[6]Humanase Co, Seongnam, Korea, Republic of,[7]CHA University, Department of Biotechnology, Seongnam-si, Korea, Republic of,[8]School of Medicine, CHA University, Seongnam-si, Korea, Republic of

Intratumoral heterogeneity in human epidermal growth factor receptor 2 (HER2)-positive breast cancer can lead to variable therapeutic responses, but its spatially resolved molecular characteristics in formalin-fixed, paraffin-embedded (FFPE) tissue are not fully characterized. In this study, we applied spatial multi-omic profiling to investigate how regional differences in HER2 expression within the same HER2-positive breast cancer tissue are reflected at the proteome and transcriptome levels. Using hematoxylin and eosin (H&E) and HER2 immunohistochemistry (IHC)-guided spatially resolved laser-activated cell sorting (SLACS), we isolated 200 μm × 200 μm × 10 μm regions of interest (ROIs) corresponding to HER2-high and HER2-low areas from FFPE tumor sections and analyzed them with an optimized trace-level LC-MS workflow. To extend the analysis to the multi-omics level, we additionally performed RNA sequencing on adjacent ROIs from the same tissue sections. This approach consistently quantified an average of more than 4,400 proteins per ROI (approximately 60-80 cells), yielding a total of 6,116 identified proteins and revealing 1,188 differentially expressed proteins (DEPs) between HER2-high and HER2-low regions. Protein-protein interaction network analysis of DEPs upregulated in HER2-high regions revealed tightly connected functional modules mainly related to protein synthesis, metabolism, intracellular trafficking, and cellular stress responses, whereas DEPs upregulated in HER2-low regions were enriched in modules associated with mitochondrial and energy metabolism, extracellular matrix organization, and cellular differentiation and cytoskeletal regulation. Canonical pathway analysis further showed that hallmark HER2 signaling in breast cancer, together with PI3K/AKT and mTOR-related pathways, were predicted to be activated in HER2-high regions, while several tumor microenvironment-associated pathways and sirtuin signaling pathways were predicted to be inhibited, indicating region-specific rewiring of oncogenic and microenvironmental signaling networks. Although HER2-related pathways were enriched in both transcriptomic and proteomic data, pathway activation was more clearly resolved in the proteome, suggesting post-transcriptional regulation and highlighting the added functional information obtained from proteomics. Collectively, these results indicate that spatial multi-omic profiling of HER2-heterogeneous FFPE breast cancer tissue captures region-specific pathway activities and biological functions associated with varying HER2 expression.

#1220 Spatial transcriptomics revealed potential resistance and response factors of sacituzumab govitecan in metastatic breast cancer.

Mengni He[1], Charles J. Robbins[2], Julia Benanto[2], Thazin Nwe Aung[2], Yalai Bai[2], Ian E. Krop[2], David L. Rimm[2]

[1]Yale University, New Haven, CT,[2]Yale School of Medicine, New Haven, CT

Background: Sacituzumab govitecan (SG) is a TROP2-targeting antibody-drug conjugated that is approved in metastatic and locally advanced hormone-receptor positive HER2 negative and triple negative breast cancer. Its clinical trials showed significant improvement in clinical benefits, but the reported objective response rates were about 30%. Biomarkers associated with response or resistance to SG are poorly understood.

Methods: GeoMx® DSP was performed on tissue transfer arrays generated from 17 biopsies of SG-treated metastatic breast cancer patients. Patients with long time-on-treatment (≥ 10 cycles) were considered responders (N = 7) whereas patients with short time-on-treatment (≤ 4 cycles) were considered non-responders (N = 10). Expression of the whole human transcriptome represented by over 18,000 genes were profiled within the cytokeratin labeled tumor segments and stroma segments. Differentially expressed genes between responders and non-responders were calculated using the linear mixed model with Benjamini-Hochberg procedure. Gene set enrichment analysis (GSEA) was performed using the Reactome pathway database.

Results: Over 10,000 gene targets in 117 segments passed the quality control pipeline and therefore used for analysis. In the tumor segments, 7 genes were upregulated in responders including immunoglobin heavy chain genes IGHG2, IGHG3, and IGHG4. 25 genes were upregulated in non-responders, including genes encoding for extracellular matrix (ECM) proteins (TNC, MMP11, MMP14, COL1A, FKBP10, and POSTN). GSEA indicated that ECM organization and proteoglycan regulating pathways are highly expressed in non-responders whereas eukaryotic translation termination pathways, regulation of ornithine decarboxylase, and mitotic G1 phase and G1/S phase transition pathways are upregulated in responders. In the stroma segments, 6 genes were upregulated in the responders including immune related genes (C7, IGHG2, IGHG3, and IGHG4) and lipid metabolism regulating gene APOC1. 11 genes were upregulated in the non-responders, including ECM protein encoding genes (MMP11, COL11A1, COL12A1, and CA2) and immune related genes (HLA-DQA1, PIP, and TSPAN1). GSEA also showed that ECM organization pathways and elastic fiber formation pathways are upregulated in non-responders whereas eukaryotic translation termination, interferon α/β signaling, B cell related signaling, and plasma lipoprotein assembly, remodeling and clearance pathways are upregulated in responders in the stroma segments.

Conclusions: Our study identified differential expressed genes between SG-responding and -resistance tumors. Specifically, the upregulation of immune-related genes is associated with response and upregulation of ECM organizations and remodeling are associated with resistance. Validation of these observations is underway.

#1221 Imaging mass cytometry of pelareorep treated early breast cancer samples reveals developing tertiary lymphoid structures.

Julian P. Olea[1], Homa Dadrastoussi[1], Kaijin Wu[1], Harley Wu[1], Paniz Zarand[1], Claudia Villa Celi[1], Jennifer S. Carew[2], Steffan T. Nawrocki[2], Xuelian Chen[1], Richard Trauger[3], Thomas C. Heineman[3], Kevin R. Kelly[1]

[1]Hematology, Keck School of Medicine of USC, Los Angeles, CA,[2]Hematology and Oncology, University of Arizona Cancer Center, Tucson, AZ,[3]Oncolytics Biotech, Inc., Calgary, AB, Canada

AWARE-1 is a window-of-opportunity study evaluating the effects of the oncolytic virus (OV) pelareorep in early-stage breast cancer patients. This analysis focuses on Cohort 2 (n = 8), consisting of HR+ HER2- patients who received pelareorep on days 1, 2, 8, 9; letrozole on days 1-21; and atezolizumab on day 3. Biopsies were collected pre-treatment, on day 3, and on day 21. Tissue was stained using an imaging mass cytometry (IMC) antibody cocktail targeting a variety of immune cell subsets to characterize changes over time in the tumor immune microenvironment (TiME) and the subsequent development of tertiary lymphoid structures (TLS) in select subjects. Unsupervised PhenoGraph clustering identified 18 distinct phenotypes, including T helper (Th), activated T helper (ATh), cytotoxic T cells (CTC), B cells (BC), differentiated B cells (DBC), and dendritic cells (DC). CTC's were significantly increased from screening to day 21 samples ($p = 0.04$) and from day 3 to day 21 samples ($p = 0.04$). Further analysis of these cell types and how they interact is performed using cellular neighborhood analysis, which identifies common arrangements of certain cell types throughout the samples. Cellular neighborhood analysis yielded an interesting neighborhood cluster comprising CTC, DC, TH, BC, DBC, and M2 Mac cells - defined as the TLS neighborhood. Visualization of the TLS neighborhood showed progressing stages of T cell and B cell organization, with T cells and B cells being largely diffuse and unstructured at screening and concentrating into zones of BC - BC aggregates surrounded by CTC, TH, and ATH cells at day 21. Pairwise permutation-based interaction analysis was applied to the cells comprising the TLS neighborhood to validate significant biological organization. At day 21 BC - TH, DBC - BC, and DBC - DBC interactions were significantly more likely to occur than at screening. Other interactions of note were between tumor - ATH, tumor - CTC, tumor - DC, CTC - ATH, and CTC - CTC interactions were significantly increased at surgery. This study is the first of its kind to identify and spatially validate the unique cell-cell interactions in the TiME of early breast cancer patients treated with the OV pelareorep as developing TLS's, highlighting coordinated TiME reorganization and novel cell-cell interaction dynamics associated with TLS formation.

#1222 Spatial transcriptomics of trastuzumab deruxtecan-treated metastatic breast cancer identifies candidate response and resistance factors.

Charles J. Robbins, Mengni He, Julia Benanto, Thazin Nwe Aung, Yalai Bai, Ian E. Krop, David L. Rimm

Yale School of Medicine, New Haven, CT

Background: Trastuzumab deruxtecan (T-DXd) is a HER2-targeting antibody-drug conjugate approved for metastatic breast cancer (mBC) with HER2-positive, low, and “ultralow” expression. However, reliable tissue biomarkers for predicting response or resistance are poorly understood. We applied GeoMx® digital spatial profiling to 41 T-DXd-treated mBC samples from Yale New Haven Hospital to identify spatially-informed gene expression markers linked to therapy outcomes.
Methods: Biopsies from 41 mBC patients treated with T-DXd (5 HER2+, 28 HER2-/HR+, 8 TNBC) were collected. Patients were classified as responders (time-on-treatment >6 months, N=26) or non-responders (≤6 months, N=15). Tissue transfer arrays from these samples were prepared for digital spatial profiling. Spatial profiling was performed on tumor (CK+), immune (CD45+), and stroma (CK- and CD45-) segments using the GeoMx® human whole transcriptome atlas RNA assay. Sequencing data was processed on the Nanostring platform. For each segment, differentially expressed genes (DEGs) between responders and non-responders were identified using a linear mixed model with Benjamini-Hochberg correction. Over-representation analysis used Enrichr gene sets; gene set enrichment analysis (GSEA) used KEGG and Reactome pathways.
Results: Over 10,000 genes in 511 segments from 41 patient biopsies passed quality control. In tumor segments, 20 genes upregulated in responders included early estrogen response (MUC1, MLPH, MAST4), extracellular matrix (ECM1), and integrin signaling pathways (COL4A5, NTN4). Non-responders showed upregulation of 37 genes enriched for ubiquitin-specific proteases (ADRM1, PSMB1, PSMA7, UBA52). GSEA indicated increased APC/Cdc20 mediated degradation pathways in non-responder tumor segments. In immune and stroma segments, 12 upregulated genes in responders included negative regulators of immune cell trafficking (RGS1, RGS5). Non-responders upregulated 53 genes, including markers of tumor-associated macrophages (APOE, APOC1, SPARC, SERPINA1) and cancer-associated fibroblasts (FN1, POSTN, COL1A1/2). GSEA showed enrichment for immunoglobulin-mediated immune response, antigen processing, and ECM organization pathways in responder immune and stroma segments.
Conclusions: Spatial transcriptomics revealed DEGs associated with T-DXd response and resistance in mBC. Responders were enriched for early estrogen response and ECM/integrin signaling pathways, whereas non-responders showed upregulation of ubiquitin-proteasome pathways and tumor-associated macrophage/cancer-associated fibroblast gene signatures. Validation of these findings is underway with the goal of finding biomarkers that provide predictive value beyond measurement of ADC target.

#1223 Spatial transcriptomics identifies a suppressive T-cell excluded tumour microenvironment in extramedullary multiple myeloma.

Nicholas E. Bingham[1], Julie R. Boiko[2], Daniel C. Jones[3], Daniel Wong[1], Tiffany Khong[1], Sridurga Mithraprabhu[1], Kathleen S. Ensbey[2], Anna E. Elz[3], Evan W. Newell[4], Andrew Spencer[1], Geoffrey R. Hill[2]

[1]Australian Centre for Blood Diseases, Alfred Health - Monash University, Melbourne, Australia,[2]Translational Science and Therapeutics Division, Fred Hutchison Cancer Centre, Seattle, WA,[3]Vaccine and Infectious Diseases Division, Fred Hutchison Cancer Centre, Seattle, WA,[4]Vaccine and Infectious Diseases Division, Fred Hutchinson Cancer Centre, Seattle, WA

Introduction: Extramedullary disease (EMD) in multiple myeloma (MM) is associated with poor prognosis due to aggressive disease kinetics and therapy resistance. Bone marrow (BM) restricted MM is highly dependent on the BM microenvironment for survival, putatively contributing to drug-resistance. In EMD, the biology and particularly the role of the tumor microenvironment (TME) is unknown.

Methods: Eight biopsies from 8 patients with hematogenous EMD were analyzed using 10x Xenium In Situ Prime 5K. Subsequent analysis utilized the recently described high resolution ProSeg cell segmentation algorithm.

Results: A total of 500,102 cells from 8 samples were included. Plasma cells (PC) in EMD maintain a PC transcriptome with expression of *XBP1*, *IRF4* and *PRDM1* without significant expression of *PAX5*, *FOXP1*. After dimensionality reduction, like BM-restricted MM, PC clustering was driven primarily by inter-patient variability. The TME was assessed. The most numerous immune cells were macrophages, specifically those with an immune-suppressive 'M2' phenotype, demonstrated by expression of markers such as *CD163* and *MRC1*. Infiltrating CD8+ T-cells co-expressed cytotoxicity and exhaustion genes. Cancer associated fibroblasts were the most common non-immune cell in the TME. Spatial analysis was performed with recurrent microenvironments identified: immune suppressed (IS), immune excluded (IE) and immune permissive (IP). The IS niches, characterised by macrophages, fibroblasts and endothelial cells, were enriched for immune cells and more proliferative PC subsets. The bulk of tumors (>70%) comprised the IE niche, with a very high proportion of PC (>90% cells) with the lowest proportion of T-cells. Rarer areas with increased T-cells and interferon-reactive macrophages, presumed IP regions, were present in two samples.

Predicted cell-cell interactions identified a complex, bidirectional network. PC interactions with the TME via signals including *TGFB1/3*, PGE2 and *THBS1* were evident, predicted to drive a suppressive macrophage phenotype and a fibrotic extracellular matrix. Conversely, macrophages in the TME expressing *APRIL* and *BAFF* are predicted to promote PC survival via canonical ligands including BCMA, *CXCR4* and *CD38*. This bidirectional signalling between suppressive myeloid cells in the TME and PC thus putatively promote myeloma growth directly whilst concurrently constraining anti-myeloma immunity. The presence of the suppressive and excluded niches in all samples suggests an important role in EMD biology.

Conclusions: Our findings provide new insights into the spatial organisation of MM EMD and identify prominent suppressive macrophage rich niches in the context of T cell exclusion within the TME, together with proliferative signalling networks in PC, that represent new clinically tractable targets.

#1224 Antibody-drug conjugate immuno-oncology panel for comprehensive characterization of the tumor and associated microenvironment.

Sandra F. Lam, Kevin Gallagher, Maryam Rohafza, Courtney Todorov, Harry Nunns, Marianne Thio, Flora Sahafi, Kathy Pham, Victoria Gomez, Erinn A. Parnell, Qingyan Au

NeoGenomics Laboratories, Aliso Viejo, CA

Antibody-drug conjugates (ADCs) represent a rapidly advancing class of targeted therapeutics that integrate the specificity of monoclonal antibodies with the potent cytotoxicity of small-molecule drugs. By coupling antibodies to highly active payloads through linkers, ADCs enable selective delivery of cytotoxic agents to tumor cells while minimizing systemic toxicity. Pivotal studies have shown compelling evidence that this strategy of anti-cancer therapeutics can dramatically improve outcomes for patients. Despite notable success, challenges such as tumor heterogeneity and predicting clinical efficacy have been difficult to overcome. Because ADCs rely on precise spatial localization of target antigens to optimize treatment efficacy, subcellular resolution of protein expression is required. To provide insight into spatial patterns and heterogeneity within a tumor, we used the Paletrra™ (NeoGenomics Laboratories, Inc) platform. Paletrra™ is a proprietary multiplex immunofluorescence (mIF) platform for the visualization and characterization of up to 60 protein biomarkers in a single FFPE section and offers high-resolution spatial and quantitative analysis of protein expression in tissue samples. Herein we report the design and use of a novel panel of commercially available antibodies to support ADC development in lung and breast cancer samples. The panel can measure common ADC targets such as B7-H3, B7-H4, c-MET, EGFR, HER2, HER3, and TROP2 combined with a membrane marker to enable subcellular differentiation between membrane and cytoplasmic expression. Quantitative image analysis enables normalization of protein expression and computation of membrane-to-cytoplasmic expression ratio, providing enhanced biological context. Moreover, because ADCs have been shown to modulate the tumor immune microenvironment, additional markers in the panel provide insight into immunogenicity, cellular relationships, and overall structural biology within the tumor samples. Application of this assay supports translational research and clinical development of ADCs, facilitating identification of patients with optimal target expression and localization.

#1225 3D spatial multiomics characterization of ovarian cancer tissue samples.

Lena Nolte[1], Diogo Bessa-Neto[1], Salpy Baghdo[1], Bernadett Szabo[1], Fabio El Yassouri[1], Emily Neil[2], Robert Pinard[2], Werner Muller[1], Dominik Eckardt[1], Christoph Herbel[1], Andreas Bosio[1]

[1]Miltenyi Biotec, Bergisch Gladbach, Germany,[2]Miltenyi Biotec, Waltham, MA

The complex interplay between genetic alterations, cellular environments, and immune responses in ovarian cancer demands advanced analytical approaches to inform personalized therapies. Conventional two-dimensional analyses fail to capture the tumor's complex three-dimensional (3D) architecture and cellular organization, limiting insight into immune dynamics and the tumor microenvironment. To overcome this, we developed a fully automated spatial biology workflow integrating 3D multiomics. This workflow combines RNAsky® technology for precise RNA detection with multiplexed protein profiling using recombinant REAfinity™ and REAdye_lease™ antibody conjugates, analyzed via the MACS® iQ View - Spatial Biology Image Analysis Software for accurate 3D segmentation. The inclusion of multiple layers in the z-dimension allows precise annotation of individual cells, and thus precise RNA and protein localization at the single-cell level. By analyzing ovarian cancer tissues with an immuno-oncology antibody panel and a complementary RNA panel, we characterized primary, untreated ovarian cancer tissues and their microenvironment. This enabled spatial mapping of diverse lymphoid cell populations including T-cells, B-cells, and NK cells, as well as cells of myeloid lineage such as dendritic cells and macrophages. Additionally, cancer cells were characterized and the stromal compartment encompassing fibroblasts, endothelial and neuronal cells were identified. These aspects revealed structural and immunological features which may influence tumor progression and treatment response. The 3D analysis uncovered spatial relationships among various cell types, in particular, 3D analysis resolved key anatomical features of tissue architecture, which play crucial roles in tumor growth and metastasis. By correlating these 3D spatial data with clinical outcomes, the workflow may provide insights into resistance mechanisms, potential biomarkers, and therapeutic targets. This integrated 3D multiomics workflow offers a holistic, high-resolution view of tumor organization and immune contexture, advancing the understanding of ovarian cancer biology and supporting precision medicine across cancer types.

#1227 Enhancing individualized interventions with machine learning: A better approach?.

Wonshik Chee[1], Jiwon Baek[2], Dongmi Kim[2], Seulgi Ryu[2], **Yeeun Kim**[2], Eun-Ok Im[2]

[1]Department of Kinesiology and Health Education, College of Education, University of Texas at Austin, Austin, TX,[2]School of Nursing, University of Texas at Austin, Austin, TX

Background: Asian American breast cancer survivors face additional cultural, linguistic, and access barriers that impede optimal pain self-management and timely mental-health care. These challenges underscore the need for culturally responsive, scalable interventions. Building on preliminary Cancer Pain Management Program (CAPA) work, we developed the Cancer Pain Management: A Technology-Based Intervention Program (CAI) that augments CAPA with depression-focused components for survivors reporting depressive symptoms and a machine learning feature for individualized support.
Methods: As part of an ongoing randomized controlled trial, 106 Asian American women with a history of breast cancer were randomized: 58 to the intervention group and 48 to the active control group. The intervention group used the CAI and the active control group used the CAPA. CAI and CAPA were culturally tailored, multi-component, web-based interventions identical in structure, except CAI included depression-focused content and machine learning-driven personalization. Primary outcomes included pain (Cancer Pain Management [CPM], Brief Pain Inventory-short form [BPI-SF]), symptom burden (Memorial Symptom Assessment Scale-Short Form: MSAS-SF), depression (Center for Epidemiologic Studies Depression Scale: CES-D), and quality of life (Functional Assessment of Cancer Therapy Scale-Breast Cancer: FACT-B). Assessments occurred at baseline (T0), 1 month (T1), and 3 months (T2). Mixed-effects growth models tested group, time, and interaction effects.
Results: At baseline, groups were well balanced; no significant differences were observed in sociodemographic variables, breast cancer-related characteristics, or primary outcome measures (all $p > 0.05$). Significant improvements over time were observed for pain (BPI-SF, $p < 0.001$), depression (CES-D, $p < 0.001$), and quality of life (FACT-B, $p < 0.001$). However, no significant group or group-by-time interaction effects emerged (all $p > 0.05$), indicating that CAI did not outperform CAPA despite its machine learning component.
Conclusion: Both interventions improved outcomes over time; however, CAI, which incorporated machine learning-driven individualization, showed greater improvements than CAPA, although these differences were not statistically significant. These findings highlight the need for further research to evaluate and optimize personalization strategies using machine learning.

#1228 Disparities in post-survivorship psychiatric diagnoses among adult cancer patients in a multi-center academic health system.

Suraj Manohar Rajan[1], Vivian Tran[1], Carol Y. Ochoa[2], Joshua Demb[1], Melody Schiaffino[1], James Murphy[1], Brent S. Rose[2], Matthew P. Banegas[3]

[1]UCSD Moores Cancer Center, La Jolla, CA,[2]UC San DIego Moores Cancer Center, La Jolla, CA,[3]Cancer Prevention Fellow, UC San Diego, San Diego, CA

Background: Cancer patients experience substantial psychological burden, yet mental health conditions often remain unrecognized and untreated. Disparities in psychiatric care may exist across demographic groups, though comprehensive multi-cancer analyses examining these patterns are limited.

Methods: We conducted a retrospective cohort study of 1,161,370 adult patients diagnosed with ten common cancers between January 2015 and September 2025 within the University of California Health system. Patients with pre-existing psychiatric diagnoses (12 months prior) or palliative-intent treatment were excluded. Primary outcomes were new-onset depression and anxiety diagnoses following cancer diagnosis. Multivariable logistic regression identified predictors of psychiatric diagnosis, adjusting for age, sex, race, ethnicity, insurance type, cancer type, and diagnosis year.

Results: Of 1,161,370 patients (mean age 66.1 years, 52.9% female), 258,076 (22.2%) received new psychiatric diagnoses: 8.4% anxiety only, 5.7% depression only, and 8.2% both conditions. While 22.5% of patients with both conditions were diagnosed within one month of cancer diagnosis, 32-43% received diagnoses beyond 12 months, indicating delayed recognition. Significant demographic disparities emerged. Female patients had higher odds of depression (aOR=1.35, 95%CI:1.32-1.38) and anxiety (aOR=1.57, 95%CI:1.54-1.61) diagnoses than males. Asian patients had substantially lower odds of depression (aOR=0.58, 95%CI:0.56-0.59) and anxiety (aOR=0.56, 95%CI:0.55-0.58) compared to White patients. Hispanic/Latino patients had 51% lower odds of depression diagnosis (aOR=0.49, 95%CI:0.37-0.56). Patients with Medicaid had elevated odds of both depression (aOR=1.40, 95%CI:1.37-1.44) and anxiety (aOR=1.12, 95%CI:1.09-1.14) compared to privately insured patients. Breast cancer patients had the highest psychiatric diagnosis rates across cancer types, while prostate cancer patients had substantially lower odds (depression aOR=0.79, anxiety aOR=0.63).

Conclusions: Nearly one-quarter of cancer patients receive new psychiatric diagnoses, yet substantial disparities exist by sex, race, ethnicity, insurance status, and cancer type. Delayed recognition with most diagnoses occurring beyond 12 months post-cancer highlights missed opportunities for early intervention. These findings suggest inequitable mental health recognition and care delivery in oncology. Systematic implementation of culturally appropriate screening, enhanced provider training, improved behavioral health integration throughout the cancer continuum, and policy reforms ensuring equitable mental health access are essential to address these disparities.

#1229 Suicidal ideation endorsed by long-term survivors of blood or marrow transplantation: A BMTSS report.

Ritika R. Samant[1], Devika Bhatia[2], Qingrui Meng[1], Yanjun Chen[1], Lindsey Hageman[1], Liton Francisco[1], Sarah Palmer[1], Eunice Choe[1], Nora Balas[1], Alysia Bosworth[3], Ravi Bhatia[1], Lennie Wong[3], Daniel Weisdorf[4], Wendy Landier[1], Saro Armenian[3], Smita Bhatia[1]

[1]University of Alabama at Birmingham, Birmingham, AL,[2]University of Colorado, Denver, CO,[3]City of Hope, Duarte, CA,[4]University of Minnesota, Minneapolis, MN

Background: High intensity therapeutic exposures and prolonged immune suppression place blood or marrow transplant (BMT) survivors at a higher risk of long-term physical and psychological morbidity that could lead to suicidal ideation endorsed by survivors.
Methods: We examined suicidal ideation in BMT survivors who received autologous or allogeneic BMT between 1974 and 2014 at one of three transplant programs (City of Hope, University of Minnesota, or University of Alabama at Birmingham) and survived ≥2y after BMT. Overall, 3,841 BMT survivors and 1,261 siblings completed a 255-item survey at age ≥18y were included in this analysis. The survey assesses sociodemographics, chronic health conditions, and psychological health.
Results: Overall, 5.7% of the BMT survivors and 3.1% of the siblings reported suicidal ideation. BMT survivors were at a 1.9-fold greater odds of endorsing suicidal ideation compared with siblings (95%CI=1.34-2.68, p-value=0.003). Multivariable analysis adjusting for age at survey, sex, income, and insurance, severe/life-threatening chronic health conditions, pain, and depression to the model, mitigated the difference in suicidal ideation between BMT survivors and siblings (OR=1.04; 95%CI=0.71-1.53, p=0.84). Restricting the analysis to BMT survivors, we found that younger age at study (18-34y: OR=2.2, 95%CI=1.4-3.6, p=0.002; reference: age >65y), lower income (<$75,000: OR=1.43, 95%CI=1.0-2.0; reference: ≥$75,000, p=0.04), depression (OR=9.81, 95%CI=7.2-13.4), and pain (OR=1.65, 95%CI=1.2-2.3, p=0.002) were associated with suicidal ideation.
Conclusions: The higher prevalence of pain, depression, and chronic health conditions explain the higher odds of suicidal ideation endorsed by BMT survivors compared with siblings. BMT survivors with lower income, depression and pain are at the highest risk of endorsing suicidal ideation. These findings suggest a need for increased surveillance and intervention for suicidal ideation among at-risk BMT survivors.

#1230 Surviving to thriving: Empowering breast cancer survivors through community-based health coaching.

Cameron J. Arriaga[1], Emily L. Cauble[1], Uloma S. Nwogu[1], Mitchell Rodenbaugh[2], Madisen Novelo[1], David Gorman[3], Jessica Clague DeHart[1]

[1]Claremont Graduate University, Claremont, CA,[2]Pitzer College, Claremont, CA,[3]Columbia Vagelos College of Physicians and Surgeons, New York, NY

Background: Breast cancer survival rates are improving, yet the collateral damage of successful treatment is often overlooked. Over 4 million survivors are left in silence asking “now what?”— many facing ongoing struggles with their physical abilities, emotional well-being, quality of life, and adverse health outcomes that often go unaddressed in a traditional survivorship care plan.
Objective: LYTE (Living Your Truth Empowered) Foundation with Claremont Graduate University piloted a novel approach to address this gap: a personalized health coaching program designed to empower survivors to reclaim their health, rebuild their confidence, improve their quality of life, and thrive, not just survive.
Methods: This one-arm quasi-experimental pilot study was designed to evaluate the program’s feasibility and effectiveness on the quality of life, physical health, and well-being of breast cancer survivors. Female, adult breast cancer survivors (N=9) completed a 9-week health coaching program consisting of weekly, live virtual coaching sessions. Participants completed pre and post in-person assessments (body composition, metabolic health, and physical ability) and online surveys (physical activity/function, nutrition, quality of life and self-confidence).
Results: The coaching program demonstrated strong feasibility, with all 9 participants completing the intervention and high approval of Zoom utilization (89% participants reported ‘very much’ easy to use). Post-intervention, participants reported improvements in functional physical activity and reduced difficulty of everyday tasks, including climbing stairs, walking and shopping. Participants engaged in more frequent and longer sessions of vigorous and moderate physical activity, accompanied by an increase in self-reported walking pace. Psychological and environmental barriers to physical activity improved, and confidence in daily movement and physical activity increased. A few challenges (time constraints and financial limitations) persisted or slightly increased. In-person assessment data supported self-reported survey data. Participants showed gains in right-hand grip strength and high-density lipoprotein (HDL) levels and decreases in weight, BMI, and blood pressure. There was also a statistically significant increase in the participants post-intervention walking distance ($p=0.0005$).
Conclusion: LYTE’s health coaching program offers an innovative, survivor-centered approach to improving quality of life, physical health, and well-being. The findings from this pilot study demonstrate feasibility and effectiveness of a health coaching program and lays the groundwork for a larger, randomized control trial. Most importantly, the study highlights the potential of personalized health coaching to help breast cancer survivors illuminate their brightest path forward.

#1231 Breaking the ice: Prostate cancer advocacy and awareness programs in Nigeria and their role in changing men's health narratives.

Catherine Adebukola Oladoyinbo, African Behavioral Research Center

Nutrition and Dietetics/ABeR, Federal University of Agriculture Abeokuta, Abeokuta, Ogun, Nigeria

Prostate cancer (CaP) stands among the leading cancers responsible for male mortality worldwide. Statistics reveal that approximately 397,430 men across the globe have lost their lives to this disease in 2022. Research further confirms that CaP tends to be more aggressive in Black men coupled with late presentation, making it a major cause of death within this group. With this reality, it becomes paramount that advocacy and awareness efforts be intensified. The African Behavioural Research (ABeR) center set up three channels for CaP advocacy in order to increase awareness, knowledge and screening uptake. The first initiative was the CaP advocacy training program which was conducted using the Mayo Clinic Advocacy Training Manual. The training was specifically designed to equip men especially CaP survivors with skills for CaP advocacy. Seven (7) CaP survivors from across West Africa received training in the science of advocacy. Following this, they were supported with pilot grants to implement CaP awareness projects within their respective communities. The second initiative was the development and validation of a CaP awareness video among three hundred and twenty-two (322) men. This was translated into four (4) indigenous Nigerian languages. The third initiative was the creation of a platform to educate men aged 40years and above on the signs, symptoms, regular screening CaP (Nutrition Rx)Results from the CaP survivors pilot projects showed that 420 men were reached by three of the survivors and one hundred and seventy (170) men were screened for CaP. The CaP awareness video after validation, showed a significant increase in CaP knowledge (P=0.0001) among the participants(https://drive.google.com/file/d/1mE857ZHr7dUA97vtvmEmwxgzdQhnj3Ey/view?usp=sharing). The translated video have been deployed for use at the urology clinic of the Federal Medical Center Abeokuta. The Nutrition Rx program has successfully reached over 2000 men across Nigeria and West Africa. The platform has been used to distribute healthy food items and also to educate men on prostate health. The advocacy initiatives by the center has proven to be effective in improving CaP knowledge and raise awareness on the importance of screen for early detection.

#1232 The impact of a culturally tailored technology-based cancer pain management program on the quality of life by psychosocial factors among Asian American breast cancer survivors.

Yeeun Kim, Jiwon Baek, Dongmi Kim, Seulgi Ryu, Wonshik Chee, Eun-Ok Im

The University of Texas at Austin, Austin, TX

Background: Breast cancer survivors face challenges in maintaining their quality of life during their treatment and survivorship process. Especially, Asian American breast cancer survivors frequently encounter constrained social supports and difficulties in accessing adequate emotional and practical support. Cultural barriers are often the major cause of the difficulties. This study aimed to explore the impact of a culturally tailored technology-based cancer pain management program on the quality of life (QoL) by psychosocial factors among Asian American breast cancer survivors.

Methods: This is a part of an ongoing randomized controlled trial among Asian American women breast cancer survivors. Data was collected at T0 (baseline), T1 (after 1 month; during intervention), and T2 (after 3 months; post intervention) during the 3-month intervention process. Only the data from 57 participants who completed the intervention were included in this analysis. The instruments included the Perceived Isolation Scale, (PIS) and the Questions on Attitudes, Self-Efficacy, Perceived Barriers, and Social Influences (QASPS), and the Functional Assessment of Cancer Therapy Scale-Breast Cancer (FACT-B). K-means cluster analysis was conducted using baseline data. The optimal number of clusters (k=2) was selected using NbClust package in R. The participants were classified into two clusters, which were then crossed with the interventions form a total of four groups. Longitudinal trajectories were examined using linear mixed model (LMM) to test interaction effects between Time, Cluster, and Intervention

Results: Two clusters emerged from the K-means analysis. Cluster 1 (n=18; CAI=9, CAPA=9) showed higher loneliness, lower social support, less positive attitude and self-efficacy, and more perceived barriers, whereas Cluster 2 (n=39; CAI=26, CAPA=13) showed the opposite pattern. LMM analysis revealed significant effects of Time and Cluster on the QoL. In both groups, the QoL improved over time (T1 vs T0: p=.003, T2 vs T0: p<.001). Cluster 2 reported higher QoL (Cluster 2 vs Cluster 1: p=.002) than Cluster 1. Except Time 2 x Cluster 2 interaction (p=.040), no other significant interaction effects were found.

Conclusion: This study demonstrated that technology-based interventions can positively impact QoL for breast cancer survivors, regardless of participants' level of psychosocial factors. However, caution is required when interpreting the results due to the small sample size and imbalance between clusters. Future studies should include a large enough sample size to confirm the long-term effects of Intervention CAI.

#1233 Exploring the spiritual detriments of the quality of life among patients with advanced cancers undergoing palliative chemotherapy.

Jiyeon Son[1], Jieun Lee[2], **Suhyeon Hwang**[2], Junglyun Kim[2]

[1]Dankook Univ. Hospital, Cheonan-si, Korea, Republic of,[2]Chungnam National University, Daejeon, Korea, Republic of

Background: Cancers account for 28.7% of total deaths, with the leading cause of death, and this trend is steadily increasing. In South Korea, cancer survival rates have also consistently improved, from 45.2% to 72.9% between 1991 and 2022. As 7 out of 10 cancer patients now survive more than five years, the interest of healthcare providers has shifted beyond merely improving survival rates to enhancing quality of life (QoL). QoL is recognized as an essential indicator in cancer treatment and recovery processes. Especially in patients with advanced cancer, improving QoL during their remaining life span becomes a key therapeutic goal, requiring continuous assessment and interventions. Although existing cumulative evidence for QoL in the cancer population, understanding the spiritual determinants of QoL among patients with advanced cancers undergoing palliative chemotherapy is still limited. This study aimed to explore the spiritual detriments of the QoL among patients with advanced cancers undergoing palliative chemotherapy.
Methods: This cross-sectional, descriptive study utilized convenience sampling to recruit participants undergoing palliative chemotherapy at a university hospital between September 2023 and March 2025. Uncertainty, Cancer coping, Spiritual well-being, and QoL were measured by the Korean version of the Mishel Uncertainty in Illness Scale - Adult Form, the Cancer Coping Questionnaire, the Functional Assessment of Chronic Illness Therapy-Spiritual Well-being Scale, and the Cancer-Specific Quality of Life scale, respectively. Demographic and Clinical data were obtained from electronic health records or demographic questionnaires. Multiple regression analysis was performed using SPSS version 30.0.
Results: Among a total of 165 participants, 88 (53.3%) were males; the mean age was 54.86 (SD = 8.34) years; 62(37.6%) were diagnosed with colorectal cancers. The average number of chemotherapy sessions was 17.16 (SD =17.03). Pain (β=-.221, p=.001), uncertainty (β=-.250, p=<.001), and spiritual well-being (β=.316, p=<.001), Colorectal cancer (β=.250, p=.002) explained 37.2% of the variance (adjusted R^2 of .372) in QoL.
Conclusion: To improve the QoL of patients with advanced cancers undergoing palliative chemotherapy, maintaining spiritual well-being is crucial. Holistic assessment of QoL, including spiritual components and management of pain, providing treatment information in a timely manner to reduce uncertainty, should be included in the intervention strategy to improve QoL in patients with advanced cancers.

#1234 Bioelectrical impedance analysis-derived body composition metrics as prognostic biomarkers in lung cancer.

Jeongung Cha[1], Yeong Hak Bang[2], Narin Kim[3], Juwon Jung[2], Hyunsu Kim[2], Jinyong Kim[2], Sungyoon Cho[3], Aekyeong Jin[3], HeeHwan Kim[3], Sehhoon Park[2]

[1]Department of Health Sciences and Technology, Samsung Advanced Institute of Health Sciences and Technology, Sungkyunkwan University, Seoul, Korea, Republic of,[2]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[3]InBody Co., Seoul, Korea, Republic of

Background: Body composition changes are common in lung cancer and relate to poor outcomes, but their treatment-related changes and prognostic value are not well defined. This study serially evaluated body composition metrics in patients with lung cancer receiving palliative treatment.

Methods: In this study, we prospectively and serially evaluated body composition metrics in patients with lung cancer receiving palliative treatment, using bioelectrical impedance analyzer (InBody 770 and S10, InBody Co., Seoul, Korea). The patients were scheduled for a minimum of 12 weeks of treatment, and the analysis was conducted every 3 weeks, in addition to collecting clinical data. The optimal thresholds of the death and progression prediction model were identified based on area under curve (AUC) and F1 score.

Results: A total of 141 patients were enrolled in the study. The median follow-up duration was 21.3 months (range, 13.2-24.9 months). Nearly half of the cohort was aged ≥65 years (N=75, 53.2%). The majority of patients had non-small cell lung cancer (N=127, 90.1%), with a smaller subset having small cell lung cancer (N=14, 9.9%). Among the enrolled patients, 92 (65.2%) received palliative cytotoxic chemotherapy (CTx group), and 49 (34.8%) received palliative tyrosine kinase inhibitor therapy (TKI group). From baseline to the end of treatment, CTx group showed a decrease in phase angle (from 4.7 ± 0.78 to 4.48 ± 0.71; $p < 0.001$) and an increase in extracellular water (ECW) ratio (from 0.392 ± 0.008 to 0.395 ± 0.008; $p < 0.001$). Whereas no significant changes of metrics were observed in TKI group. For death prediction using time-point-specific body composition metrics, the CTx group showed the highest performance for events occurring within 1 year, whereas the TKI group performed best for events within 2 years. For progression prediction, the CTx group performed best for 6-month events, while the TKI group showed the best performance for 18-month events. In the CTx group, the prediction models achieved AUCs of 0.899 for death and 0.831 for progression, with corresponding F1 scores of 0.708 and 0.790. In the TKI group, the AUCs were 0.961 for death and 0.829 for progression, with F1 scores of 0.640 and 0.817, respectively. Shapley Additive exPlanations (SHAP) analysis identified percent body fat (PBF) and skeletal muscle index (SMI) as the most influential predictors for both outcomes.

Conclusions: Serial body composition metrics assessments captured treatment-related body composition changes in lung cancer, and models based on these metrics showed prognostic performance. These findings support the use of longitudinal body composition monitoring in personalized patient management.

#1235 Exercise volume, skeletal muscle maintenance, and plasma IL-6/IL-6R in patients with PDAC.

Guanshu Liu[1], Sumedha Pareek[1], Truong Lam[1], Nathan Parker[2], Naveen Garg[3], Matthew HG Katz[4], Laura Prakash[4], Jian Wang[5], An Ngo-Huang[6], Keri Schadler[1]

[1]Department of Pediatrics Research, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Health Outcomes & Behavior Program, Moffitt Cancer Center, Tampa, FL,[3]Department of Abdominal Imaging, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Department of Surgical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[5]Department of Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX,[6]Department of Palliative, Rehabilitation, and Integrative Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Pancreatic ductal adenocarcinoma (PDAC) is often accompanied by debilitating muscle wasting, which is associated with reduced treatment tolerance and survival. IL-6 and IL-6 receptor (IL-6R) have been implicated in cancer-associated muscle loss and as exercise-responsive myokines, though variable results have made the roles of IL-6 and IL-6R in muscle wasting unclear. This study investigated the relationship between skeletal muscle, plasma IL-6/IL-6R levels, and exercise in PDAC patients undergoing neoadjuvant therapy. The PancFit randomized controlled trial (NCT03187951) included a usual care and an exercise intervention arm in which patients with borderline resectable PDAC were asked to perform ≥ 150 minutes/week of moderate intensity aerobic exercise and ≥ 2 strength training sessions per week during the time of neoadjuvant treatment. Physical activity was monitored by Fitbits and self-reported by Godin-Leisure Questionnaire. Skeletal Muscle Index (SMI) was measured by CT images obtained at study enrollment (baseline) and at pre-operative re-staging (end of neoadjuvant therapy and intervention) in 112 patients. Plasma IL-6 and IL-6R were measured by ELISA at the same timepoints in 26 patients. Due to variability in quantity of exercise in both arms, we performed post hoc analysis in which all patients were pooled, then regrouped based on average weekly strength sessions (≥2 vs. <2 sessions/week) or average very active minutes (VAM, by Fitbit/ week). Spearman rank correlations or student's t-test were used for analysis. Patients who completed <2 strength training sessions / week had an average SMI loss of -3.9% ± 8.9 SD from enrollment to pre-operative staging, while those who performed ≥ 2 strength training sessions per week had an average SMI maintenance of +0.35% ± 9.5 SD ($p = 0.03$). There was no correlation between VAM and SMI. There were no significant correlations between the change in SMI from baseline to pre-op and plasma IL-6 at baseline, IL-6 at pre-operative restaging, or in the change in IL-6 between timepoints. However, there was a significant negative correlation between the change in SMI and plasma IL-6R at baseline ($p=0.002$, $r = -0.5$), pre-operative restaging ($p <0.0001$, $r = -0.67$), and in the change in IL-6R over time ($p=0.03$, $r = -0.38$), and between SMI and IL-6R at pre-operative restaging ($p=0.02$, $r =-0.41$). No correlations were observed between VAM and plasma IL-6 or IL-6R at any timepoint. Strength training may be one method to maintain SMI for patients with PDAC undergoing neoadjuvant therapy. Plasma IL-6R, but not IL-6, may be a blood biomarker of SMI. A future randomized controlled trial focusing on strength training is needed to further understand these relationships.

#1236 FOLFIRINOX represents the preferred therapeutic option for patients with pancreatic acinar cell carcinoma: A multi-center study.

Guoliang Qiao

The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China

Background: Pancreatic acinar cell carcinoma (PACC) is a rare pancreatic malignancy, and evidence guiding systemic therapy remains limited. To address this unmet need, we conducted a multi center study to characterize real world treatment patterns and clinical outcomes, with the goal of informing evidence-based therapeutic recommendations for PACC.
Methods: Clinical and treatment data were collected from 156 patients with PACC across eight pancreatic centers in China. Analyses focused on systemic therapy regimens and survival outcomes. Additional stratified analyses were performed among patients who underwent surgical resection to assess the therapeutic value of FOLFIRINOX in neoadjuvant and adjuvant settings.
Results: A total of 156 patients were identified. The median age at diagnosis was 65.3 years, and 48.6% of patients underwent surgical resection. Most patients presented with abdominal pain or pancreatitis (69%). Laboratory parameters showed no correlation with tumor size, metastatic status, or survival. The median overall survival (OS) was 18.9 months from diagnosis, with significant differences based on metastatic status (15.6 vs. 31.8 months). Both surgical resection and FOLFIRINOX were associated with improved OS. Among surgically treated patients, neoadjuvant or adjuvant FOLFIRINOX conferred a significant OS advantage compared with gemcitabine- or capecitabine-based regimens ($p = 0.001$). In a multivariable Cox regression model, both surgical resection and FOLFIRINOX remained independent predictors of superior OS.
Conclusions: This multi center study provides the largest real-world evidence to date supporting FOLFIRINOX as the preferred systemic therapy for PACC. Ongoing incorporation of international cohorts and expanded stratified analyses will further refine treatment recommendations. The overarching objective of this project is to establish standardized, evidence-based guidelines for the management of PACC.

#1237 Effects of a home-based walking intervention on serum metabolomic profiles in men with prostate cancer on active surveillance.

Rebecca E. Graff[1], Ritu Roy[1], Oliver Fiehn[2], Adam Olshen[1], Erin Van Blarigan[1], Stacey Kenfield[1], Jeffry P. Simko[1], Anthony Luke[1], Lee Jones[3], Matthew R. Cooperberg[1], Peter R. Carroll[1], **June M. Chan**[1]

[1]University of California, San Francisco, San Francisco, CA,[2]University of California, Davis, Davis, CA,[3]City of Hope, Duarte, CA

Introduction: The potential for long-term exercise to affect the metabolome in healthy individuals is well established. Given the metabolic underpinnings of prostate cancer, it is important to investigate whether long-term exercise similarly alters the metabolome in disease-affected men. This study is among the first to characterize metabolic changes in individuals with prostate cancer, comparing those assigned to a home-based walking program to those assigned to printed materials with physical activity recommendations.
Methods: Fifty-one men with prostate cancer on active surveillance were randomly allocated to the exercise or control intervention. Metabolomic profiling of primary metabolism, complex lipids, and biogenic amines was performed at the West Coast Metabolomics Center on serum samples collected at baseline and after the 16-week interventions; data were successfully generated for 22 participants in the exercise arm and 23 participants in the control arm. To identify intervention-related differences in metabolic changes, we performed hierarchical clustering and fit mixed-effects models including an arm x time interaction.
Results: Hierarchical clustering indicated limited separation in metabolic profiles between the exercise and control groups at 16 weeks. Although none of the 1,220 named metabolites exhibited statistically significant differences in change between the two groups (q<0.10), 85 (7.0%) demonstrated nominal significance (p<0.05). Among the 15 metabolites with the smallest p-values, six (40%) were sphingolipids - specifically sphingomyelins - though sphingolipids comprised only 11% of all named metabolites. All six sphingomyelins decreased more over time in the exercise group than in the control group.
Conclusions: Although metabolic profiles were not significantly altered overall, a walking intervention may promote the reduction of sphingomyelins, thereby shifting lipid signaling toward pathways that enhance mitochondrial function and reduce inflammation. Such changes are consistent with biologically plausible mechanisms through which exercise could favorably influence prostate cancer biology, even in the absence of broad metabolomic shifts.

#1238 Ketamir-2, a novel oral ketamine analogue for chemotherapy-induced peripheral neuropathy.

Itzchak Angel[1], caraco Yoseph[2], **Erez Aminov**[1]

[1]MIRA Pharmaceuticals Inc., Miami, FL,[2]Clinical Pharmacology Unit, Hadassah Medical Center, Jerusalem, Israel

Background: Ketamir-2 is a next-generation ketamine analogue designed to improve oral bioavailability and safety relative to existing ketamine-based pain therapies. It acts as a low-affinity N-methyl-D-aspartate (NMDA) receptor antagonist with selective binding to the phencyclidine (PCP) site, a mechanism believed to underlie its analgesic potential while reducing dissociative effects.
Methods and Results: In preclinical studies, oral administration of Ketamir-2 (pamoate salt) produced significant analgesic activity across established rodent models of neuropathic pain, including the Chung spinal nerve ligation model in rats and the paclitaxel-induced mechanical allodynia model in mice. In both models, Ketamir-2 demonstrated superior efficacy compared with oral ketamine and the standard neuropathic pain agents pregabalin and gabapentin, which served as positive controls. Pharmacological profiling confirmed robust oral bioavailability and lack of P-glycoprotein (P-gp) substrate activity, supporting its efficient penetration across the blood-brain barrier—an essential property for central nervous system (CNS) therapeutics. Notably, Ketamir-2 exhibited a favorable safety profile with no evidence of dissociative or psychedelic side effects typically observed with ketamine.
Clinical Development: Results from the first-in-human (FIH) study will be presented. This randomized, double-blind, placebo-controlled Phase 1 trial, conducted at the Clinical Pharmacology Unit of Hadassah Medical Center, evaluated the safety, tolerability, and pharmacokinetics of Ketamir-2 in healthy adult volunteers. A total of 56 participants were enrolled across single-ascending-dose (SAD) and multiple-ascending-dose (MAD) cohorts.
Conclusions: These findings support Ketamir-2 as a promising oral NMDA-receptor modulator for the treatment of chemotherapy-induced peripheral neuropathy (CIPN) and other neuropathic pain disorders, offering a differentiated profile combining efficacy, safety, and oral convenience.

#1239 Clinical outcomes of Ayurveda Rasayana therapy (ART) in advanced pancreatic cancer patients: A retrospective study.

Yogesh Bendale[1], Priyanka Shirole[1], Poonam Birari-Gawande[1], Avinash Kadam[1], **Mukta Marathe**[2]

[1]Rasayu Cancer Clinic, Pune, India,[2]AatharvaN Ayurved & Yog, LLC, Phoenix, AZ

Purpose: A significant proportion, 25-60%, of pancreatic cancer patients cannot receive standard chemotherapy or surgery, usually due to poor performance status, advanced disease, or significant comorbidities. The median survival of these patients is only 3-6 months, and the primary therapeutic goals are improvement of Quality of Life (QoL) and extension of survival. This study evaluates the role of Ayurveda Rasayana Therapy (ART) in this category of patients.

Method: We retrospectively analyzed data from 17 patients with advanced, inoperable pancreatic cancer who were ineligible for chemotherapy. Patients were treated exclusively with Ayurvedic Rasayana preparations primarily containing preparations like *Heeraka Bhasma (diamond)*, *Suvarna Bhasma (gold)*, and *Tamra Bhasma (copper)*, *Shankha Bhasma (Conch)*, *Moutika Bhasma (Pearl)*. Health-related QoL was assessed by the FACT-G questionnaire, and performance status was measured by the ECOG scale at baseline and on day 90. The patient's anorexia was measured by the Anorexia-Cachexia Scale (ACS).

Results: The patients mean age was 62.75±9.14. Treatment significantly improved FACT-G overall quality of life scores (48±14.71 vs 56.35±10.85; $p < 0.05$). ECOG performance status showed significant improvement as compared to baseline (2.29±0.84 vs 1.85±0.79; $p < 0.05$). A significant reduction in anorexia was also noted (19±35 vs 28.35±8.20; $p < 0.05$). Partial tumour response was recorded for two patients. The average survival seen in this group was 316±248.76, days which surpassed the expected range of 3 to 6 months.

Conclusions: This preliminary data indicates that Ayurveda Rasayana Therapy may be a beneficial intervention to improve quality of life, reduce disease-related distress, and extend survival in pancreatic cancer patients with no standard treatment options. As these results are based on observations from a small sample size, they should be interpreted with caution and need further rigorous investigation.

#1240 Pain severity is related to molecular pathways underlying aggressive disease and poor survival in OSCC.

Minh Phuong Dong[1], Gary Yu[2], Michele Arambula[1], Bac An Luong[1], Paul Walker[1], Traeden Wilson[1], Khanh Nguyen[1], Carissa M. Thomas[3], Yi Ye[4], Bradley Aouizerat[4], Chi Viet[5]

[1]Loma Linda University, Loma Linda, CA,[2]Columbia University, New York, NY,[3]University of Colorado, Aurora, CO,[4]New York University, New York, NY,[5]Loma Linda University, Loma Linda, NY

Pain is one of the worst symptoms experienced by patients with oral squamous cell carcinoma (OSCC), which impairs patients' function and quality of life. Yet its clinical and molecular determinants remain poorly defined. The objective of this study was to investigate how pain, quality of life (QoL), and tumor biology intersect to improve prognostication and patient-centered care. This prospective multi-institutional study enrolled 196 OSCC patients from Loma Linda University (LLU) and the University of Alabama at Birmingham (UAB). Pain was assessed using the UCSF Oral Cancer Pain Questionnaire and, Brief Pain Inventory (BPI). Functional and symptom disturbance (QoL) were characterized using EORTC QLQ-C30/H&N35. Flash frozen tumors were collected at surgery for RNA-Seq. Data were analyzed using Spearman correlation, Wilcoxon, Kruskal-Wallis tests, ANCOVA, Kaplan-Meier log-rank test, and Cox hazard regression. Our results revealed that patients reporting high pain demonstrated significantly lower overall QoL, including reduced functional scores (physical, role, emotional, cognitive, and social functioning) and higher symptom burden ($p<0.05$), entirely independent of their cancer stage at diagnosis. Additionally, morphine milligram equivalents (MME/day) were strongly correlated with pain severity and worse QoL metrics ($p<0.05$). Kaplan-Meier analysis showed that high pain (UCSF and BPI), higher symptom score, and higher H&N35 score, lower global health status score and functional score, and opioid use were associated with worse survival ($p<0.05$). After adjustment for confounders (age, sex, race, pathologic stage, PNI, LVI, smoking status), Cox hazard regression analysis revealed functional score (HR = 0.5, CI 95% [0.287-0.873]), symptom score (HR = 2.144, CI 95% [1.169-3.934]), HN35 scores (HR = 2.192, CI 95% [1.195-4.023]) and opioid use (HR = 2.665, CI 95% [1.510-4.706]) as independent predictors of survival. RNAseq analysis of 128 patients comparing high- and low-pain tumors identified significant enrichment in GO pathways related to axonogenesis, neuron to neuron synapse, and in KEGG involved pathways of neurodegeneration-multiple disease, Alzheimer's, and Huntington's disease pathways. In addition, the top dysregulated GO pathways in patients with low function (low functional score) were cytoplasmic translation, ribosome biogenesis, and regulator of signal transduction by p53 class mediator. In conclusion, these findings demonstrated that pain severity, opioid requirement, and diminished quality of life are tightly linked to aggressive tumor features and poorer survival in OSCC. Molecular analyses highlight the potential of neural-associated dysregulation in OSCC pain.

#1241 Early outcomes of an AI-driven chatbot application for symptom management in patients with cancer: Interim analysis of a prospective digital health study.

Hyun Woo Lee[1], Tae Jun Park[1], Seok Yun Kang[2], Jang Hee Kim[2]

[1]Ajou University School of Medicine, Suwon, Korea, Republic of,[2]Ajou university school of medicine, suwon, Korea, Republic of

Background:Cancer patients frequently experience persistent symptoms such as pain, fatigue, and treatment-related distress. Despite guideline-based recommendations, real-time symptom monitoring and supportive care delivery remain suboptimal. We developed an AI-based chatbot application designed to provide personalized symptom management education, self-management guidance, and interactive support. This study evaluates user experience, self-efficacy, psychological distress, and early clinical impact.
Methods:A prospective digital-health intervention study was conducted using an AI chatbot delivering education aligned with NCCN supportive-care guidance. A total of 192 participants were enrolled, including both solid tumor and hematologic malignancy patients. Validated instruments included UMUX-Lite for usability, SEMCD-6 for self-management self-efficacy, DT for psychological distress, perceived usefulness (PU), engagement frequency, and e-health literacy measures (instrument details in slide deck). Outcomes were assessed at baseline and follow-up. Group × time effects were analyzed using mixed-effects models.
Results: User experience remained consistently high throughout the study period, with favorable UMUX and PU scores. Although short-term and mid-term objective improvements were modest, the intervention group demonstrated significantly greater improvements in key patient-reported outcomes, including:- Reduced psychological distress (P = 0.013)- Improved self-efficacy domains (multiple SEMCD items showing significant change; P = 0.008 in primary domains) Higher e-health literacy was associated with larger improvements in self-efficacy and perceived usefulness. Subgroup analyses suggested heterogeneous treatment effects, with males, lung-cancer patients, and individuals with lower educational attainment showing greater unmet needs and requiring tailored support. Engagement (days of chatbot use per week) showed a positive dose-response trend with outcome improvement.
Conclusions: The AI chatbot application demonstrated high sustained user satisfaction and early signals of benefit in psychological distress reduction and self-management confidence among cancer patients. While objective clinical markers showed limited short-term changes, differential effects across demographic and diagnostic subgroups highlight the need for targeted personalization. Ongoing analyses will evaluate mediators such as digital literacy, therapeutic alliance, intervention usability, and long-term clinical outcomes.

#1242 Cannabis use during cancer treatment: Patterns and perceptions of cannabis use among cancer survivors at a Wisconsin cancer center.

Apoorva C. Reddy[1], Jennifer Dykema[2], Betty Chewning[3], Kristine Kwekkeboom[4], Heather Neuman[1]

[1]Department of Surgery, Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[2]Survey Center, University of Wisconsin-Madison, Madison, WI,[3]University of Wisconsin-Madison School of Pharmacy, Madison, WI,[4]University of Wisconsin-Madison School of Nursing, Madison, WI

Background:Cancer survivors increasingly use cannabis products to manage treatment-related symptoms. Yet, little is known about their perceptions of the helpfulness of cannabis products for symptom relief or what barriers shape their use. We aimed to characterize cannabis product use and perceptions among cancer patients.
Methods:We administered a cross-sectional survey to 650 adult patients at UW Health/Carbone Cancer Center clinics who had received treatment within the last 3 months, with a response rate of 54% (54 patients died, 320 responded). Patients who reported using cannabis products after being diagnosed with cancer (n=92) were eligible for this analysis. The survey captured demographics, perceived symptom change with cannabis product use, and barriers to use. Descriptive analyses and Kendall-Wei Rank were completed using STATA and R.
Results: Patients who responded had a median age of 62 (IQR: 53-67) years; 51% were women, 89% were White, 34% had an annual income of $100,000 or more, 50% had completed college or technical school, and 35% used tobacco in the past year. Half the patients had metastatic cancer (48%). Most patients received chemotherapy (55%) and/or radiation (54%) within the prior 3 months. Patients were most likely to report that cannabis products improved their pain (76%) and nausea/vomiting (76%) (Table 1). Patients' most-reported barriers to cannabis product use were cost (35%) and concern about legal risk (32%). Most patients were in favor of legalizing the medicinal use of THC (94%) and CBD (96%). Most patients were very or extremely likely to use cannabis products in the future (66%).
Conclusion:In this cohort of Wisconsin patients with cancer who used cannabis products after diagnosis, the majority perceived cannabis products to be beneficial in managing cancer symptoms, particularly pain. Despite the reported benefits, cost and legality are barriers to cannabis use among Wisconsinites.

Table 1. Patient self-report of receiving benefit (i.e., symptoms or side effects improved) from can

Symptom	**Number of patients reporting this symptom**	**Benefit n (%)**
Pain	72	55 (76%)
Lack of appetite	67	48 (72%)
Sleep loss	78	53 (68%)
Irritability	67	46 (69%)
Anxiety	70	42 (60%)
Nausea/vomiting	58	44 (76%)
Depression	61	30 (49%)
Fatigue or low energy	78	31 (40%)
Headache	51	22 (43%)
Neuropathy	57	13 (23%)
Lack of sexual interest or activity	61	12 (20%)
Sweating, including hot flashes or night sweats	56	6 (11%)

#1243 Cancer survivors' acceptance of technology-based tools for stress management and effective communication.

Ana C. Sala[1], Liliana Castro Jimenez[2], Brenda Torres[2], Zaydelis Tamarit[3], Marievelisse Soto-Salgado[3], Vivian Colon-Lopez[3]

[1]Department of Cancer Medicine, Comprehensive Cancer Center University of Puerto Rico, San Juan, PR,[2]Biostatistics and Bioinformatics Core, Comprehensive Cancer Center University of Puerto Rico, San Juan, PR,[3]Division of Cancer Control and Population Sciences, Comprehensive Cancer Center University of Puerto Rico, San Juan, PR

Cancer survivors process complex diagnosis and treatment information making medical appointments a source of stress. Uncertainty about medical decisions heightens stress limiting quality of communication during appointments. Artificial intelligence (AI) tools are emerging as approaches to enhance patient support yet use with Spanish-speaking cancer survivors is limited. This study sought to characterize stress levels of Puerto Rican cancer survivors and assess preparedness before meeting with physicians. We also assessed openness to use technology for stress management and communication with physicians. We hypothesized survivors would report high stress levels, low preparedness, and acceptance of technology. In this cross-sectional study, 169 cancer survivors aged ≥21 were recruited prior to their appointment in oncology waiting rooms. Upon consenting, they completed a survey to assess stress, preparedness, and openness to technology. Stress levels in the past 30 days, prior to appointments, and regarding the current visit were measured. Preparedness for the visit was assessed with a 1-10 scale and asking if they had prepared a list of questions for their physicians. Openness to technology was assessed with questions about willingness to: *use a phone/tablet for a relaxation exercise and submit questions electronically for physicians to read before appointments.* Statistical analyses were performed using R. Descriptive statistics were used to assess variables of interest. Most study participants (68.6%) were women; mean age 57.8 (SD=14.5). Average age at cancer diagnosis was 55 (SD=14.7). Reasons for visit included routine follow-up (61.7%), test results discussion (9%), first appointment (9%), and follow-up for new symptoms (4.2%). More than a third (36.3%) reported usually/always feeling stress in the past 30 days, 55.6% reported stress prior to appointments, and 53% about their current visit. Despite an average self-reported preparation score of 8.4 (out of 10) and 92% indicating they felt prepared for the visit, only 27% had written a list of questions to guide the conversation with their physician. As for acceptance to technology-based tools, 68% indicated they would benefit from a stress management exercise before appointments and 66% were willing to send questions electronically to their physicians. Among those unwilling, the most common reason was preference for in-person discussion (27.2%). Stress may impair memory interfering with survivors' intentions to ask questions during visits. Findings confirm high pre-appointment stress among cancer survivors and a low tendency to write questions to aid communication. This highlights a need for strategies to enhance emotional readiness and preparedness. Results suggest openness to AI-assisted tools for stress management and improved patient-physician communication, supporting its integration into standard cancer care.

#1244 Health-related quality of life in EGFR-mutant lung cancer survivors: SEER-MHOS analysis.

Shuyan Qiu, Yiwey Shieh, Christine Garcia, Eunji Choi

Weill Cornell Medicine, Cornell University, New York, NY

Introduction: The proportion of lung cancer among never-smokers is rising, with EGFR mutations observed in approximately 40-60% of these cases. Given that EGFR-mutated (EGFRmt) lung cancer is more prevalent in non-smokers, females, and individuals of Asian ancestry, their survivorship needs likely differ from the typical lung cancer cohort, which primarily consists of older males with a history of heavy smoking. This study examined the mental and physical health outcomes, including perceived changes in health status, among three distinct groups: EGFRmt lung cancer patients, non-EGFRmt lung cancer patients and non-cancer controls.

Methods: We utilized linked data from SEER registries, the Medicare Health Outcomes Survey (MHOS), and Medicare Part D prescription records to identify adults aged ≥65 years with lung cancer and receipt of EGFR tyrosine kinase inhibitors (TKIs) between 2007 and 2020. We identified non-EGFRmt lung cancer patients matched to EGFRmt cases by diagnosis year and cancer stage. Non-cancer controls were selected by matching to all lung cancer patients on survey age and survey year. Primary outcomes included (1) mental and physical health, assessed using the Veterans RAND instrument, and (2) perceived changes in mental and physical health compared with the previous year. Primary outcome information was derived from the MHOS survey nearest to the initial lung cancer diagnosis. Multinomial logistic regression models were applied to identify survivorship needs among EGFRmt and other lung cancer patients relative to non-cancer controls, adjusting for sex, race, and smoking status.

Results: A total of 130 EGFRmt lung cancer patients, 520 non-EGFRmt patients, and 650 non-cancer controls were identified. EGFRmt patients were more frequently female (65% vs. 49% of non-EGFRmt patients and 62% of non-cancer controls), of Asian ancestry (18% vs. 4.8% and 4.5%), and less likely to be active smokers (13% vs. 25% and 7.4%). In adjusted multinomial logistic models, EGFRmt patients had a 1.20-fold higher likelihood of poor mental health (odds ratio [OR] = 1.20, 95% CI 1.02-1.39), while non-EGFRmt patients had a 1.14-fold higher likelihood (OR = 1.14, 95% CI 1.04-1.26), relative to non-cancer controls. Similarly, EGFRmt patients were most likely to report worsened mental health compared with non-cancer controls (OR = 2.81, 95% CI 1.66-4.76), whereas non-EGFRmt patients also demonstrated an elevated risk, though to a lesser degree (OR = 1.86, 95% CI 1.30-2.67). Across all lung cancer patients, poor outcomes in social and physical functioning, vitality, bodily pain, and general health were more prevalent than among non-cancer controls.

Conclusion: Patients with EGFRmt lung cancer experience more deterioration of mental health than other lung cancer patients and non-cancer individuals. Targeted mental health interventions may improve long-term survivorship outcomes in this growing patient population.

#1245 Suicide Risk in Oncology: Sex and Cancer Type Differences in a Case-Control Study.

Brandy M. Byrwa-Hill[1], Eric T. Monson[1], Emily DiBlasi[1], Hilary Coon[1], Danli Chen[1], Michael J. Staley[2], Amanda V. Bakian[1]

[1]Department of Psychiatry, Spencer Fox Eccles School of Medicine and Huntsman Mental Health Institute, University of Utah, Salt Lake City, UT,[2]Utah State Office of the Medical Examiner, Utah Department of Health and Human Services, Salt Lake City, UT

Background: Suicide risk among people with cancer may vary by sex and cancer site, reflecting different biological, psychosocial, and care-system pathways. We used statewide linked mortality and clinical data to examine whether cancer history and sex-specific cancer types differentially relate to pre-death suicidality and suicide mortality.
Methods: We conducted a two-step study using population-level data from Utah linking suicide mortality, cancer, and electronic health records. First, we compared suicide decedents with versus without a prior cancer diagnosis (n=14,644) on suicidal ideation (SI), self-injurious behavior (SI), prior suicide attempts (SA), psychiatric and medical comorbidities. Second, we performed an age-and sex-matched case-control analysis of suicide decedents (cases; n=1,015) and living controls (n=9,173) to estimate adjusted odds of suicide death associated with any cancer history and specific cancer types, stratified by sex. Logistic regression models adjusted for prior suicidality, diagnosed mental and substance use disorders (SUD), and chronic medical morbidity. We also characterized the temporal sequencing of first-recorded encounter types (mental health, SUD, chronic medical, or cancer-related).
Results: Among suicide decedents, those with any history of a cancer diagnosis had higher odds of pre-death SA (OR=1.27, 95% CI 1.09-1.49), SII (OR=1.34, 1.12-1.60), and SI (OR=1.29, 1.07-1.56) than decedents without cancer. Mental-health burden was substantially greater among female than male decedents (OR=7.90 vs 2.07). In case-control analyses, a history of any cancer was associated with lower overall odds of suicide death, but this aggregate effect masked heterogeneity by sex and cancer type. Among women, cervical cancer/dysplasia was over-represented in cases compared to controls (OR=1.53, 1.13-2.06), suggesting elevated risk in sex-specific, identity-salient cancers. Among men, prostate cancer was inversely associated with suicide death (OR=0.73, 0.59-0.91). First encounters for mental health and substance use were over-represented among cases of both sexes, while chronic-condition encounters suggest additional risk in men.
Conclusions: In this study, any history of a cancer diagnosis was linked to greater pre-death suicidality but lower overall odds of suicide death, with important sex-and cancer-type specific differences. Patterns may support a dual-pathway model in which psychosocial/identity-related mechanisms may predominate among women with sex-specific cancers, whereas functional or disease-burden pathways may predominate among men with high-burden cancers. Tailored, sex-and cancer-type-specific suicide risk screening that leverages mental health and substance use encounter history may improve prevention in oncology settings.

#1246 The comprehensive outcomes for after cancer health (COACH) study: Interim analysis of baseline demographic and patient reported outcome data for individuals with advanced cancer.

Kelly J. Brassil[1], Trudy Buckingham[2], Anneliese Gonzalez[3], Michael Harrison[4], Kaukab Jafry[3], Abbey Kaler[5], Hilda H. Lewis[6], Jennifer Loftis[4], Kathrin Milbury[7], Darcy Ponce[8], Michelle Schumacher[6], Meagan Whisenant[8], Cosmina Hogea[2]

[1]Medical Affairs, Quest Diagnostics, Houston, TX,[2]Gilead Sciences, Foster City, CA,[3]UT Health Houston, Houston, TX,[4]Medical Affairs, Quest Diagnostics, Secaucus, NJ,[5]Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[6]Radiation Oncology, Montefiore Medical Center, Bronx, NY,[7]Behavioral Science, The University of Texas MD Anderson Cancer Center, Houston, TX,[8]UT Health Houston Cizik School of Nursing, Houston, TX

Background: Patients with metastatic cancer face complex self-management challenges requiring symptom monitoring, care coordination, and psychosocial support. Digital tools, including electronic patient-reported outcomes (ePROs), wearables, and health coaching (DHC), have demonstrated improvement outcomes, including overall survival for individuals with cancer, yet less is known about their effect for individuals with advanced breast (aBC) or lung(aLC) cancer. The COACH trial (NCT05349227) evaluates a comprehensive DHC program combining clinical, ePRO, wearable, and gut microbiome data to address survivorship needs in these unique groups.

Methods: This multicenter, randomized, wait-list controlled trial enrolls 675 adults (≥18 years) within one year of completing primary therapy or with metastatic disease, across 8 sites. Subpopulations include aBC (n=150) and aLC (n=100). Participants are randomized to 6 months of DHC or control, with crossover at month 6. All participants are provided with activity trackers (Fitbit), complete ePROs over the course of 12 months, and provide fecal microbiome specimens and dietary data at baseline and month 6.

Interim Outcomes: As of November 2025, 91 aBC participants have been enrolled, of whom 75 have completed baseline ePRO assessments, and 41.5% have connected their Fitbit device to the cloud for data collection. Baseline PROMIS scores for 61 participants with data available for analysis are presented in the Table.

Conclusion: Interim data suggest that individuals with metastatic cancer have numerically higher anxiety and lower cognitive and physical functioning compared to population mean scores. Outcomes from this study will evaluate if and how DHC can be used to address these challenges. Multimodal data derived from this study is intended to enhance understanding of the potentially unique survivorship needs of individuals with advanced cancer.

Table. Consented Participant Demographic Data and Mean Baseline Scores for The National Institutes o

Demographic Data (n=75)	**Mean (SD)/n(%)**
Age	57.09 (12.65)
Sex	Female: 75 (100%)
Race and Ethnicity (Participants could select >/= 1 response)	
Asian	3 (4.0%)

Disabled due to illness	12 (16%)
Unemployed	4 (5.3%)
Unknown	3 (4%)
Patient Reported Outcomes Measurement Information System (PROMIS) Tool Baseline Scores (n)*	Mean Score (SD; Range; *Population average for individuals with cancer*)
Anxiety (60)	53.1 (9.1; 37.1-75.1; *50.6*)
Cognitive Function (61)	46.8 (9.4; 24.4-63.9; *49.9*)
Depression (61)	49.8 (8.5; 38.2-74.3; *50-53*)
Physical Function (61)	43.6 (8.7; 25.2-61.9; *46.1*)

#1247 Efficacy of pain neuroscience education compared to conventional therapy in managing oncologic pain: A controlled clinical trial.

Leidy T Ordonez-Mora[1], Rocio Guil[2], Ilem D. Rosero[3], Marco Morales-Osorio[4], Juan M Henao-Bermudez[5], Giovanna Rivas-Tafurt[6], Juan Avila-Valencia[7], Julian Agudelo[8]

[1]Universidad Santiago de Cali, Valle del Cauca, Colombia,[2]Universidad de Cadiz, Cadiz, Spain,[3]Universidad Santiago de Cali, Cali, Colombia,[4]Universidad San Sebastian, Concepcion, Chile,[5]Instituto departamental de Bellas Artes, Valle del Cauca, Colombia,[6]Clinica de occidente, Cali, Colombia,[7]Clinica de Occiente, Valle del Cauca, Colombia,[8]Clinica de occidente, Valle del Cauca, Colombia

Background: Pain is a multifaceted sensory and emotional experience that may arise even without evident tissue injury. Among individuals undergoing cancer treatment, it represents one of the most prevalent and burdensome symptoms, frequently resulting from surgical interventions, radiotherapy, or treatment-related toxicity. Oncologic pain profoundly impacts functional capacity, emotional well-being, and overall quality of life. Given its multidimensional nature, it involves complex interactions between cognitive, affective, and neurophysiological mechanisms, including processes of central sensitization and altered pain modulation. These complexities highlight the need for integrative approaches that move beyond traditional biomedical management. Educational strategies such as Pain Neuroscience Education (PNE) have emerged as promising interventions aimed at reshaping maladaptive pain beliefs, reducing fear and catastrophizing, and fostering more effective self-management.
In this context, the present study aimed to determine the efficacy of Pain Neuroscience Education compared to conventional therapy in managing oncologic pain.
Methods: A randomized controlled clinical trial with a parallel-group design and blinded outcome assessment was performed following the CONSORT recommendations (ClinicalTrials.gov ID: NCT05581784). The intervention comprised a structured nine-session program centered on the application of neuroscience principles to pain education, based on a previously published manual. All outcome measures were collected after a 10-week period. The primary endpoint was the variation in pain intensity, assessed using the Visual Analog Scale (VAS), comparing baseline and post-intervention scores between groups.
Results: A total of eighty-two patients with oncologic pain were included in the study. The most common cancer diagnosis was breast cancer. Regarding disease stage, 63% of participants were classified as stage III, 31.8% as stage IV, and 4.5% as stage V. In the intervention group (PNE), mean pain intensity decreased from 5.32 ± 2.12 at baseline (T1) to 3.85 ± 1.98 after the intervention (T2), reflecting a statistically significant reduction of 1.47 points ($p < 0.001$). Conversely, in the control group, pain intensity values were 5.57 ± 2.29 at T1 and 5.39 ± 2.15 at T2, showing no significant change ($p = 0.46$). The reduction in pain intensity observed in the PNE group represents a clinically meaningful improvement compared with the control condition.
Conclusion: The intervention grounded in Pain Neuroscience Education (PNE) led to a statistically and clinically meaningful decrease in pain intensity. These findings support the inclusion of individualized educational approaches as a complementary component of oncologic pain management.

#1248 Perspectives on cancer survivorship: Voices of family caregivers.

Opeyemi Oreoluwa Bolajoko[1], Jada Melton[1], Mary Ellen Young[2], Folakemi T. Odedina[1]

[1]Mayo Clinic Florida, Jacksonville, FL,[2]Inclusive Cancer Care Research Equity, Jacksonville, FL

Background: Cancer survivorship requires significant contributions from family caregivers at home. This role can be burdensome because family members play a vital role in the physical, functional, and emotional well-being of patients diagnosed with cancer. Although optimum care throughout the care continuum requires significant caregiver support at home, family caregivers' contribution to survivorship care is usually neglected. We provide the preliminary outcomes of caregivers' challenges and experiences in providing care and survivorship support to Black cancer survivors. We also identified ways to provide support for family caregivers.
Methods: This qualitative study obtained information from 8 caregivers who care for Black cancer survivors who have completed treatment in the United States. The study used a phenomenological design to obtain data from participants. In-depth interviews focused on participants' lived experiences caring for Black patients with cancer. The study captured caregivers' personal stories of how they dealt with diagnosis, feelings, emotions, reactions, understanding of the disease, prognosis, and treatment options and decision process, as well as survivorship of their care recipients. All interviews were video recorded and transcribed verbatim. The transcript of each participant's interview was reviewed, analyzed, and coded, with emerging themes interpreted.
Results: The major cahllenges identified were (1) lack of knowledge of cancer, the disease and treatment course before the diagnoses; (2) home care burden, which include the challenges of combining care for a sick person at home with caring for other members of the family and taking care of domestic chores; (3) patient care navigation, including identifying healthcare professional for specialist care, adequate health insurances, scheduling doctors' appointment, transportation, insurance and treatment paperwork; (4) financial challenges, especially keeping up with job, family income reduction, increase out of pocket spendings, as well as expensive drugs and treatment co-pays. Most of the caregivers agreed that they neglected their personal health while caring for their care recipient. All caregivers wished they received more information and training on how to care for a patient with cancer. Possible solutions identified were care packets providing information on cancer and how to provide care at home, patient care navigation to social determinants of health and financial support programs, counselling for mental health and emotional support, peer support groups for caregivers, health checks, and a contact to call for support.
Conclusion: Caring for cancer patients at home is very challenging; having a care packet and caregiving training is important to support survivorship and reduce the caregiving burden experienced by family caregivers.

#1249 The inverse association between non-melanoma skin cancer and alopecia areata: A systematic review and meta-analysis.

Simonetta I. Gaumond[1], Alireza Abdshah[2], Isabella Kamholtz[2], Peyton V. Warp[2], Keyvan Nouri[3], Antonella Tosti[3], Joaquin Jimenez[4]

[1]Department of Biochemistry and Molecular Biology, Department of Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL,[2]Dr Phillip Frost Department of Dermatology and Cutaneous Surgery, University of Miami Miller School of Medicine, Miami, FL,[3]Dr Phillip Frost Department of Dermatology and Cutaneous Surgery, Dr Phillip Frost Department of Dermatology and Cutaneous Surgery, University of Miami Miller School of Medicine, Miami, FL,[4]Department of Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL

Non-melanoma skin cancers (NMSC), including basal cell carcinoma (BCC) and squamous cell carcinoma (SCC), are the most common malignancies worldwide and remain clinically relevant in survivorship care. While many autoimmune diseases carry increased cancer risk, alopecia areata (AA), a T cell-mediated autoimmune disease, may instead confer enhanced cutaneous tumor immunosurveillance. We conducted a systematic review and meta-analysis to evaluate NMSC risk in AA and assess its potential as a human model of immune-mediated cancer protection. PubMed, Embase, Scopus, and ClinicalTrials.gov were searched through July 2025 for observational studies reporting BCC or SCC incidence in AA versus controls. Effect estimates were pooled using random-effects models with REML and Hartung-Knapp adjustment. Heterogeneity was assessed with I^2 and leave-one-out sensitivity analyses. Eight retrospective cohorts (n = 854,000 AA patients) met inclusion criteria, four reported BCC and five SCC outcomes. Across studies, AA patients consistently demonstrated lower skin cancer incidence compared with controls (OR 0.58; 95% CI, 0.27-1.22). Pooled estimates suggested reduced risk for BCC (OR 0.43; 95% CI, 0.11-1.75) and SCC (OR 0.66; 95% CI, 0.28-1.57), though neither reached statistical significance. Between-study heterogeneity was high (I^2 > 80%), reflecting differences in study design, case ascertainment, and adjustment for UV exposure, phototype, and treatment history. Sensitivity analyses confirmed stability of the protective direction, with no evidence of publication bias detected. These findings support a possible inverse association between AA and NMSC, contrasting with malignancy patterns seen in other autoimmune conditions. AA may represent a natural model of heightened cutaneous immune surveillance, with relevance to understanding cancer risk in the context of JAK inhibition and immune signaling. Further prospective studies with standardized outcome definitions, including diverse patient populations, are warranted to validate this association and explore translational implications for cancer prevention and survivorship care.

#1250 N-acetylcysteine pharmacokinetics and neuroprotection in a translational ovarian cancer model of cancer-related cognitive impairment.

Naomi Lomeli[1], Diana C. Pearre[2], Javier J. Lepe[1], Thomas H. Taylor[1], Daniela A. Bota[1]

[1]Neurology, UCI School of Medicine, Irvine, CA,[2]Gynecologic Oncology, Providence Cancer Institute, Burbank, CA

Background: Platinum-based chemotherapy is part of the standard of care for ovarian cancer treatment, yet more than 70% of patients develop cancer-related cognitive impairment (CRCI) during and after treatment. Cisplatin-induced CRCI is associated with alterations in plasma cytokines, mitochondrial dysfunction, and glutathione depletion. In an ovarian cancer xenograft rat model, the antioxidant N-acetylcysteine (NAC; 250 mg/kg, i.p.) prevented cisplatin-induced CRCI. To inform a Phase 1 study of oral NAC for CRCI prevention in ovarian cancer patients, we compared oral and i.p. NAC administration on brain and blood glutathione, plasma cytokines, circulating NAC levels, and cognition in female rats with or without ovarian cancer.
Methods: Female RNU rats bearing SKOV3.ip1 xenografts received cisplatin (5 mg/kg, i.p.) biweekly for four cycles with or without NAC (250 mg/kg/day, i.p.) administered for five days during each cycle, 10 hours after cisplatin. Cognitive testing (novel object recognition, NOR) was performed 6-7 weeks after treatment completion. For NAC pharmacokinetic studies, 70 female non-tumor-bearing Sprague Dawley rats were randomized to vehicle, 250 mg/kg NAC i.p., and 159, 212, 265, 370, 476 mg/kg oral NAC, with or without cisplatin. Plasma, whole blood, and brain tissue were collected 2 hours after one cycle, and plasma NAC levels were quantified by mass spectrometry.
Results: Ovarian tumor-bearing rats treated with or without cisplatin (OvT+VEH, OvT+CDDP) showed reduced NOR discrimination ratios (≤0.5) compared with non-tumor-bearing controls (NT+VEH, P=0.0207). NAC prevented cisplatin-induced impairments in the NOR task (OvT+CDDP vs. OvT+CDDP+NAC, P=0.0343). Cisplatin significantly reduced hippocampal and frontal cortex glutathione levels within 48 h, which was prevented by 250 mg/kg NAC, i.p. administration. NAC did not alter cisplatin's anti-cancer activity or survival. Comparative analysis of plasma NAC levels after oral vs. i.p. administration is ongoing.
Conclusions: NAC prevents cisplatin-induced CRCI in a clinically relevant ovarian cancer rodent model. Ongoing pharmacokinetic analyses will guide the design of a Phase 1 study of oral NAC in patients with ovarian cancer.

#1251 Real-world evaluation of multimodal AI: Foundation model-driven multimodal AI for GBM, NSCLC, and PDAC.

Aakash Gireesh Tripathi[1], Asim Waqas[2], Evan W. Davis[3], Jennifer B. Permuth[4], Jack Farinhas[5], Yasin Yilmaz[6], Matthew B. Schabath[4], Ghulam Rasool[7]

[1]Machine Learning, H. Lee Moffitt Cancer Center, Tampa, FL,[2]Cancer Epidemiology, Moffitt Cancer Center, Tampa, FL,[3]H. Lee Moffitt Cancer Center, Tampa, FL,[4]Moffitt Cancer Center, Tampa, FL,[5]Diagnostic Imaging and Interventional Radiology, Moffitt Cancer Center, Tampa, FL,[6]University of South Florida, Tampa, FL,[7]Machine Learning, Moffitt Cancer Center, Tampa, FL

Purpose: Translating multimodal AI from curated research datasets to real-world clinical practice remains a critical challenge in precision oncology. In this study, we adapted HONeYBEE, a foundation model-driven multimodal AI platform, for real-world oncology workflows. We focused on three cancers, glioblastoma (GBM), non-small cell lung cancer (NSCLC), and pancreatic ductal adenocarcinoma (PDAC), using routine clinical documentation, radiology/ pathology reports, and imaging studies to improve survival prediction and cohort stratification.

Methods: We curated 3 cohorts (GBM n=160, NSCLC n=580, PDAC n=171), spanning 911 patients from single NCI-designated Cancer Center. The framework processed multimodal embeddings generated via HONeYBEE. Unlike curated research datasets, these cohorts had incomplete available data (8.2-47% missing), heterogeneous documentation and imaging protocols. We employed cross-modal attention mechanisms to dynamically learn hierarchical relationships between modalities while incorporating 99.96% dimensionality reduction. Cross-validation was used to evaluate concordance index (C-index), risk stratification for survival outcomes, and three attribution methods that quantify per-modality contributions.

Results: The framework achieved C-indices of 0.637±0.087 for GBM, 0.598±0.021 for NSCLC, and 0.679±0.029 for PDAC, demonstrating consistent performance across cancer types despite substantial missing data. Risk stratification for survival outcomes identified clinically meaningful groups with four-fold (GBM: low 28 months vs. high-risk 6 months), five-fold (NSCLC: low 60 months vs. high-risk 12 months), and three-fold (PDAC: low 100 months vs. high-risk 35 months) differences in median survival. Attribution analysis revealed disease-specific patterns reflecting clinical reality. Text reports dominated GBM predictions (43.7%), capturing critical clinical information, imaging data drove NSCLC predictions (49%), reflecting central role of CT in staging, and balanced contributions characterized PDAC (31-35% per modality), aligning with guidelines emphasizing comprehensive assessment. Patient-level attribution demonstrated that high-risk individuals relied heavily on adverse imaging features, while low-risk patients showed balanced modality contributions, providing actionable insights for clinical review.

Conclusions: This work successfully extends research from datasets to real-world clinical environments, demonstrating practical utility for treatment stratification and prognostic assessment across three challenging malignancies. Framework's modular architecture enables seamless integration with existing systems. By generating standardized patient embeddings with incomplete and heterogeneous data, we provide a scalable infrastructure for deploying multimodal AI in routine oncology care.

Poster Session

#1256 A novel therapeutic approach to overcome metabolic reprogramming in lung cancer.

Nicholas Blazanin, Xiaobing Liang, **Yonathan Lissanu**

University of Texas MD Anderson Cancer Center, Houston, TX

Lung cancer remains the leading cause of cancer-related deaths. Genomic studies have identified frequent mutations in subunits of the SWI/SNF chromatin remodeling complex, particularly in *SMARCA4* and *ARID1A*, in non-small cell lung cancer, with mutations occurring in up to 33% of advanced cases. Previously we have shown that *SMARCA4*-mutant lung cancers are highly dependent on oxidative phosphorylation (OXPHOS). However, OXPHOS inhibitors as single agents have failed to show substantial efficacy in clinical trials. Thus, like other therapeutics aimed at cancer metabolism, the most feasible route for further development of OXPHOS inhibitors is through rational combination strategies. To this end, we undertook a functional genomics screen to identify combination strategies by utilizing a CRISPR-Cas9 library targeting genes with FDA approved therapeutics in genetically defined lung cancer models. Importantly, we utilized very low doses of the OXPHOS inhibitor IACS-10759 that are known to be well-tolerated in patients. Among our top hits was ROCK1/2. We show that Belumosudil, a clinically-utilized ROCK inhibitor known for its robust safety and tolerability profile, exhibits profound synergistic anti-tumor activity when combined with IACS-10759 in cell lines as well as in multiple mouse xenograft and human PDX models. Mechanistically, metabolic profiling reveals that the combination of ROCK and OXPHOS inhibition triggers bioenergetic stress and cell cycle arrest. This is primarily attributed to the inhibition of the adaptive increase in glycolysis that occurs following OXPHOS inhibition by ROCK, via suppression of GLUT1-mediated glucose uptake. Through quantitative proteomics, phospho-proteomics and kinase motif analysis, we identified several direct ROCK substrates including PPP1R12A and PPP1R12C that play critical roles in actin cytoskeleton regulation and glucose transport. Taken together, we identified the mechanistic underpinnings of a highly synergistic combination strategy that overcomes adaptive metabolic reprograming which has been a central challenge in the successful development of therapeutics targeting cancer metabolism.

#1257 Synergistic inhibition of PARP and ATM leads to unresolved DNA damage and cohesin-mediated collapse in pediatric osteosarcoma.

Janeala Morsby[1], Sona Kocinsky[2], Estevez Prado Daniel[3], John Harper[4], Charlie Wright[3], Monika Weirdl[3], Caroline Wechsler[5], Gabriela Alexe[6], Kimberly Stegmaier[6], Paul Geeleher[7], Lillian Guenther[1]

[1]Molecular Oncology, St. Jude Children's Research Hospital, Memphis, TN,[2]Tufts University, Trumbull, CT,[3]Molecular Oncology, St. Jude Childrens Research Hospital, Memphis, TN,[4]St. Jude Childrens Research Hospital, Memphis, TN,[5]University of Pennsylvannia, Philadelphia, PA,[6]Dana Farber Cancer Institue, Boston, MA,[7]Computational Biology, St. Jude Childrens Research Hospital, Memphis, TN

Osteosarcoma (OS) is the most common malignant bone tumor in children. Currently, metastatic and relapsed patients with OS have long-term survival of less than 30% with available therapies. Due to high levels of genomic instability and tumor heterogeneity, novel therapeutic development has been challenging in OS. Recently, homologous recombination deficiency (HRD) has been observed using computational signatures in OS, which has led to investigations of efficacy of PARP inhibitors (PARPi) in this disease. PARPi are FDA approved for use in other HRD-marked cancers; however, in pre-clinical models, single agent PARPi has had mixed efficacy in OS. Thus, we aimed to investigate synergistic targets with PARPi in OS, with the hypothesis that we could increase the utility of this drug class, deepen understanding of the biology of DNA damage repair (DDR) in OS, and circumvent drug resistance which is seen with many targeted therapies, including PARPi. To explore rational combinations with PARPi in OS, we performed a genome-scale CRISPR-Cas9 screen in the presence of the PARPi olaparib in two OS cell lines. *ATM* emerged as a top druggable sensitizer to PARPi across both models. We first performed lentiviral CRISPR knockout (KO) of *ATM* in OS cell lines and treated with a range of PARPi doses and observed a signal of increased efficacy to PARPi, validating our screen. Next, we tested a small molecule ATM inhibitor (ATMi), AZD1390, combined with multiple PARPi, using a novel drug synergy platform in a panel of OS including low-passage patient-derived cell lines, observing profound synergy across OS models compared to non-OS cell lines using ATP-based assays and live cell imaging. Dual ATMi/PARPi demonstrated significantly increased DNA damage by immunofluorescence, G2/M cell cycle arrest by flow cytometry, and DNA replication stress by immunoblotting (IB), which led to increased apoptosis measured by increased caspase 3/7 and annexin V dyes. Given the known contribution of ATM to regulation of the cohesin complex, we next investigated modulation of the cohesin complex by ATMi/PARPi by IB. In combination-treated cells, we observed a marked reduction in the cohesin release factor WAPL across cell lines at early time points. Bortezomib therapy rescued dual-treated cells from WAPL depletion and partially rescued apoptosis in dual treated cells, confirming proteasomal degradation in this context. Based on our data, we propose that the combination reduces cohesin unloading, thereby changing chromatin accessibility and increasing DDR, leading to unresolved DNA damage and, ultimately, apoptosis. *In vivo* work has confirmed an increase in survival in mice bearing OS tumors treated with the combination compared to control. We are repeating these experiments to confirm the clinical relevance for OS patients using synergistic low doses to achieve efficacy without toxicity.

#1258 Harnessing combinatorial nanomedicine for simultaneous BRD4 degradation and stromal disruption against pancreatic ductal adenocarcinoma.

Drishti Rathod, Ketankumar Patel

St. John's University, Queens, NY

Pancreatic ductal adenocarcinoma (PDAC) will become the second leading cause of cancer death by 2030 yet remains largely untreatable. Limited therapeutic options and desmoplastic microenvironment collectively result in poor clinical outcome. This necessitates dual targeting strategies that can simultaneously disrupt the microenvironment barrier and eliminate oncogenic protein drivers. Focal adhesion kinase inhibitor: PND 1186 was selected to compromise the tumor stromal barrier while BRD4 degrading PROTAC was explored to inhibit the proliferation. To overcome pharmacokinetic barriers, we designed a dual-route nanomedicine platform: oral self-nanoemulsifying PND-1186 (PNDnano, FAK inhibitor) and intravenous albumin-anchored ARV-825 nanoliposomes (AAnano, BRD4 PROTAC). This study aims to: (a) develop and characterize PND and ARV nanoformulations, (b) evaluate anticancer efficacy in 2D/3D PDAC models, and (c) assess therapeutic efficacy in xenograft studies. PNDnano was developed by screening different excipients and ones exhibiting superior solubility of PND were selected for developing SNEDDS. AAnano was formulated via modified hydration method using DGS-NTA-Ni for surface conjugation of histidine-tagged human serum albumin. Both nanoformulations showed 2-3-fold higher *in-vitro* cytotoxic effect in PDAC cells compared to individual drugs alone. Combenefit analysis revealed robust synergistic cytotoxicity between ARV and PND in MIA PaCa-2, achieving maximum synergy (score = 28) at 0.5 µM ARV and 2 µM PND with a combination index of 0.8. Scratch assay revealed potent anti-migratory effects, with ARV+PND achieving superior inhibition (1.9-fold in MIA PaCa-2; 2.7-fold in BxPC-3) versus monotherapies. Clonogenic assays demonstrated >90% reduction in the number and area of colonies in PDAC cells, with complete eradication in MIA PaCa-2, following ARV+PND treatment. Combination treatment showed 4.4-fold decrease in invadopodia length, enhancing inhibition in invasiveness of spheroids. 3D spheroid assays revealed significant growth inhibition with the monotherapies and ~63% reduction with combination therapy by day 8, demonstrating superior clinical relevance in PDAC. The anticancer effect of AAnano+PNDnano in the mice bearing subcutaneous tumor (MIA PaCa-2) xenograft model achieved 56.9% tumor suppression surpassing monotherapies. All treatment groups maintained stable body weights, indicating excellent tolerability with no systemic toxicity. This dual-targeting approach provides robust antitumor efficacy without systemic toxicity, addressing a critical unmet need in PDAC treatment. This strategy that simultaneously disrupts stromal barriers and eliminates oncogenic drivers, transcending conventional chemotherapy limitations and providing a translational framework for treating desmoplastic malignancies.

#1260 LIPA inhibition enhances the therapeutic efficacy of DNA-damaging agents in ovarian cancer through induction of ER stress and enhancing DNA damage.

Durga Meenakshi Panneerdoss[1], Tae-Kyung Lee[2], Khaled Mohamed Nassar[1], Gaurav Sharma[1], Scott Terry Elmore[2], Henry Neal[2], William Cole Arnold[1], Edward Kost[1], Suryavathi Viswanadhapalli[1], Jung-Mo Ahn[2], Ganesh V. Raj[3], Ratna K. Vadlamudi[1]

[1]UTHSA, San Antonio, TX,[2]UT Dallas, Dallas, TX,[3]EtiraRx, Dallas, TX

Background: Ovarian cancer (OCa) is the most lethal gynecologic malignancy in the United States, largely due to the lack of effective early detection strategies and the development of chemoresistance following initial treatment. These challenges emphasize the urgent need for improved therapeutic approaches. Recently, our team identified ERX-208, a potent tris-benzamide molecule (IC_{50}-100 nM) with strong activity against OCa cells. ERX-208 targets lysosomal acid lipase A (LIPA), inducing endoplasmic reticulum (ER) stress, disrupting protein synthesis, and promoting apoptosis. The objective of this study is to evaluate the potential of ERX-208 in enhancing the efficacy of FDA-approved chemotherapeutics.

Methods: In our study, we performed in vitro screening of 147 FDA-approved chemotherapy drugs in combination with ERX-208 to assess their effects on the viability of OCa model cells. The drug combination dose-response data were analyzed using the SynergyFinder Plus software. To validate the synergistic effects, we conducted several in vitro assays, including tests for cell proliferation, colony formation, cell cycle progression, DNA damage, comet assays, apoptosis, and invasion. Furthermore, preclinical studies were carried out using patient-derived organoids (PDO) and xenograft (PDX) models to evaluate the combination's efficacy in a more clinically relevant setting.

Results: Combination therapy screening of 147 FDA-approved chemotherapeutic agents with the LIPA inhibitor ERX-208 identified multiple synergistic drug pairs in OCa models. SynergyFinder analysis revealed strong combination sensitivity and synergy scores for several DNA-damaging agents. ERX-208 monotherapy inhibited OCa cell growth in vitro and in vivo, consistent with its mechanism of inducing LIPA-dependent ER stress. Combination treatments with paclitaxel or cisplatin further amplified these effects, significantly reducing cell viability across OCa cell lines compared to monotherapy. Mechanistic studies demonstrated enhanced gamma-H2AX accumulation, increased DNA damage, robust induction of ER stress markers, and reduced invasion following combination therapy. In PDO and PDX models, ERX-208 combined with DNA-damaging agents produced marked tumor growth suppression beyond monotherapies, confirming the translational relevance of the synergy. Furthermore, ERX-208 effectively reduced the viability of therapy-resistant OCa models in vitro and inhibited xenograft growth in vivo. These findings support ERX-208 as a potent ER stress-inducing agent that enhances the therapeutic efficacy of standard chemotherapies in OCa models.

Conclusions: Our findings demonstrate that combining ERX-208 with DNA-damaging agents significantly enhances therapeutic efficacy, highlighting the potential of ERX-208-based combination therapy for treating OCa.

#1261 Mutation-dependent sensitivity to the dual TTK/PLK1 inhibitor BAL0891 in patient-derived gastric cancer organoids.

Chan Hee Park[1], Jinsoo Jang[2], Woo Sun Kwon[1], Tae Soo Kim[3], Seunghyun Ma[4], Minkyung Kang[5], Sun Young Rha[1]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Song-Dang Institute for Cancer Research,, Seoul, Korea, Republic of,[3]Song-Dang Institute for Cancer Research, Seoul, Korea, Republic of,[4]Sillagen Biotherapeutics, San Francisco, CA,[5]Sillajen Biotherapeutics, Inc., Jung District

Background: BAL0891 is a first-in-class dual inhibitor of threonine tyrosine kinase (TTK, Mps1) and polo-like kinase 1 (PLK1), which cooperatively regulate the spindle assembly checkpoint (SAC) to maintain mitotic fidelity. Dysregulated SAC signaling contributes to chromosomal instability and tumor progression, particularly in gastric cancer. Targeting the SAC through dual kinase inhibition has emerged as a promising approach to exploit mitotic vulnerabilities in solid tumors.
Methods: The pharmacologic effects of BAL0891 were evaluated across 40 patient-derived gastric cancer organoids representing distinct molecular subtypes. Cytotoxicity (IC_{50}) was analyzed in relation to TTK and PLK1 protein expression and compared across mutation-defined subgroups, including *KRAS*, *SMAD4*, *PTEN*, *PIK3CA*, and *BRAF* alterations identified by WGS. LC/MS-MS was additionally performed to characterize SAC-associated signaling and mitotic regulatory networks linked to BAL0891 response.
Results: Among the 40 patient-derived gastric cancer organoids analyzed, six harbored KRAS alterations, while the remaining samples were wild-type. In the KRAS-mutant, TTK expression was significantly higher in drug-sensitive organoids than in resistant ones. In contrast, PLK1 expression showed no significant association with drug response, suggesting that KRAS-driven mitotic signaling preferentially relies on TTK-mediated regulation. Excluding KRAS-mutant cases, additional alterations were detected in PTEN (n = 3), PIK3CA (n = 2), and BRAF (n = 1). In these mutation contexts, both TTK and PLK1 expression tended to be higher in resistant samples ($p = 0.078$ and $p = 0.087$, respectively), implying that enhanced PLK1/TTK activity stabilizes the SAC and promotes survival through PI3K-AKT or MAPK signaling, thereby conferring relative resistance. Overall, these findings demonstrate that the relationship between mitotic kinase expression and drug response is context-dependent: KRAS-altered tumors with high TTK expression exhibit increased sensitivity due to heightened SAC dependency, whereas PTEN, PIK3CA, and BRAF mutant tumors with elevated kinase activity maintain checkpoint stability and survival signaling, resulting in reduced responsiveness to BAL0891.
Conclusion: BAL0891 effectively disrupts mitotic checkpoint signaling through simultaneous inhibition of TTK and PLK1. The therapeutic outcome is genotype-dependent: KRAS-mutant tumors exhibit TTK-driven SAC dependency and higher sensitivity, whereas PTEN, PIK3CA, and BRAF mutants show relative resistance due to compensatory survival signaling. These findings identify SAC dysregulation as a predictive biomarker for BAL0891 responsiveness in gastric cancer.

#1262 Depletion of dominant-negative mutant p53 improves the efficacy of mutant p53 reactivators.

Allison St. John, Mrinalini Bhosale, Alejandro Parrales, Atul Ranjan, Tomoo Iwakuma

Children's Mercy Research Institute, Kansas City, KS

TP53 (p53) forms a tetramer and functions as a transcription factor to upregulate mRNA expression of genes involved in cell cycle progression and apoptosis, thereby functioning as a tumor suppressor. P53 is the most commonly mutated gene in human cancers, and approximately 75% of p53 mutations are missense mutations. When p53 is mutated, the mutant p53 (mutp53) is no longer able to bind DNA, losing its transcriptional and tumor suppressor activities. Missense mutp53 is roughly classified as DNA contact mutants with a relatively intact p53 structure and conformation or structural mutants with a misfolded p53 structure. This cancer-specific missense mutp53 represents a critical target for the development of innovative precision therapies. Mutp53-targeting reagents include “depleters” that suppress mutp53-addicted tumors by reducing mutp53 protein levels and “reactivators” or “stabilizers” that restore the transcriptional activity of p53. Depleters include HSP90 inhibitors that induce degradation of both DNA contact and conformational mutp53, as well as statins or HSP40/DNAJA1 inhibitors that primarily deplete conformational mutp53. Reactivators include APR-246 ($PRIMA1^{met}$) and arsenic trioxide (ATO). While APR-246 and ATO have been in several clinical trials, successful outcomes have not yet been reported, despite the evidence that these reactivators efficiently restore the intact conformation of p53 in culture. Thus, it remains unclear how to efficiently reactivate p53 in mutp53-expressing cancers and why the reactivated p53 cannot efficiently induce tumor suppression. We hypothesize that reactivated p53 (R-p53) is dominant-negatively bound by non-reactivated mutp53 (NR-mutp53), making the reactivator not fully effective; hence, the combination of reactivators with depleters to eliminate NR-mutp53 would improve the treatment efficacy of reactivators, leading to improved tumor suppression. To test this hypothesis, we used conformation-specific antibodies detecting NR-mutp53 and R-p53 to confirm their interactions in multiple cancer cell lines with conformational and DNA contact mutp53. Our study revealed that NR-mutp53 interacted with R-p53 in cells treated with the reactivator alone, while this interaction was eliminated when reactivators were combined with depleters. Moreover, our RT-PCR studies demonstrated that the combination of reactivator with depleters significantly increased mRNA expression of p53 downstream targets, as compared to that of the reactivator treatment alone. These results strongly suggest that the combination of reactivator drugs with depleter drugs could improve the treatment efficacy of reactivators to suppress mutp53-carrying tumors.

#1263 Development of a novel selective CDK4 inhibitor for HR+/HER2- breast cancer.

Apeng Liang #,*, Meihua Li #,*, Kai Wang, Yi Long, Hui Xu, Haoyun Li, Jian Zhu, Guangbin Liu, Ling Fang, Xi Wang, Yiming Cai, Xiang Zhang, Shengli Dong, Yu Yu, Xinlong Yang, Chao Zhou, Teng Zhou, Wei Wu, Chengshan Niu, Shaoqing Chen, Jun Li*, Yusheng Wu

TYK Medicines, Inc., Changxing, Zhejiang, China

Targeting cell cycle-dependent kinases 4 and 6 (CDK4/6) has been proven to be a successful strategy for blocking oncogenic cell cycle progression in breast cancer cells. FDA-approved CDK4/6 inhibitors have delivered significant clinical benefits in patients with HR+/HER2- breast cancer. However, despite remarkable clinical and commercial success, dual CDK4/6 inhibitors are associated with severe on-target toxicity, leading to serious adverse events (SAEs), such as neutropenia in clinical settings. The mechanism underlying these hematologic adverse events was attributed to CDK6, rather than CDK4, for its direct mediation of myeloid cell differentiation when CDK6 expression is upregulated. To avoid CDK6 toxicity, we sought to develop selective and potent CDK4 inhibitors that in ideal cases only inhibit CDK4 activity with no impact on CDK6 or other CDKs in HR+/HER2- breast cancer cells to improve the hematologic safety of the therapeutic approach targeting the cancer cell cycle. TYK Medicines has been making continuous efforts to develop better CDK4 inhibitors with higher selectivity, potency, and lower hematologic toxicity. The candidate CDK4 inhibitor discussed in this abstract exhibits strong selectivity for CDK4 over CDK6 compared to palbociclib, confirming its identity as a selective CDK4 inhibitor rather than a dual CDK4/6 inhibitor. The compound confers a dose-dependent reduction in phosphorylated RB (Ser780) in HR+/HER2-breast cancer cell lines following a 48-hour treatment with the cells. The antiproliferative effects of the candidate compounds were evaluated via CTG cell viability assays after 5-day incubation in three cell lines: MCF7, JEKO-1, and MOLM13. Palbociclib potently inhibited MCF7/T47D cells because of its dual CDK4/6 kinase activity. In contrast, the selective CDK4 inhibitor strongly inhibited JEKO-1 cells and had no inhibitory effect on MOLM13 cells expressing high levels of CDK6. In a MCF7-xenograft mouse model, the compound significantly suppressed tumor growth in a dose-dependent manner. It also exhibited synergistic antitumor effects when combined with fulvestrant, with good tolerability evidenced by stable animal body weight throughout the study. Given the genetic diversity of HR+/HER2-breast cancer patients, targeting CDK4 may present a keystone strategy in a spectrum of combinatorial therapies. Preliminary in vitro combination studies revealed that pairing the selective CDK4 inhibitor with a CDK2 inhibitor or a PI3K inhibitor produced significant synergistic inhibitory effects on MCF7 and palbociclib-resistant MCF7 cells. Optimization of the lead compound is ongoing with the goal of identifying a preclinical candidate (PCC) for IND-enabling studies.

# Apeng Liang and Meihua Li contributed equally to this work.

#1264 Limited apoptotic response in RBM10 wild type/deficient EGFR-mutant lung cancer patient-derived models overcome by combined EGFR and BCL-2/BCL-xL inhibition.

Jonathan Wesley Riess, Hongyong Zhang, Jasmine Diaz Sezati, Peyton Apruzzese, Dongguang Wei, Tiffany Le, Luis G. Carvajal-Carmona

University of California, Davis, CA

Background: Loss of RBM10, an RNA splicing regulator, occurs in ~8-10% of *EGFR*-mutant NSCLC and has been associated with reduced apoptosis and a poor response to EGFR-TKIs. RBM10 deficiency decreases the pro-apoptotic Bcl-xS/Bcl-xL ratio, thereby limiting osimertinib-induced cell death. We investigated whether combined inhibition of EGFR and BCL-2/BCL-xL overcomes this apoptotic defect using lung cancer organoids and PDXs harboring EGFR mutations with or without RBM10 deficiency.
Methods: Patient-derived organoids from two EGFR-mutant PDX models—LG-0591 (RBM10-deficient/RBM10 wild type) and LG-0807 (RBM10-intact)—were treated with osimertinib, ABT-263 (navitoclax), or the combination—dose-response assays (CellTiter-Glo) quantified viability. Parallel in vivo studies were performed in NSG mice bearing LG-0591 PDXs treated for 28 days. Tumors harvested on treatment days 5 and 28 were analyzed by immunoblotting for EGFR, AKT, ERK, mTOR, 4EBP1, RBM10, Bcl-2 family proteins, Ki-67, cleaved PARP, and cleaved caspase-3.
Results: RBM10-deficient, EGFR mutant organoids (LG-0591) showed reduced sensitivity to osimertinib monotherapy and minimal induction of cleaved PARP and caspase-3 relative to RBM10-normal organoids (LG-0807). RBM10 deficiency was associated with elevated Bcl-2/Bcl-xL and reduced Bcl-xS expression. ABT-263 alone showed modest activity; however, osimertinib + ABT-263 produced strong synergistic killing, restoring apoptosis and significantly lowering IC50 values in RBM10-deficient organoids. In vivo, osimertinib treatment suppressed EGFR/AKT/ERK signaling at day 5, but apoptosis remained limited in RBM10-deficient tumors, leading to tumor regrowth by day 28. ABT-263 alone modestly affected growth. The combination therapy achieved sustained suppression of downstream signaling, markedly increased cleaved PARP and cleaved caspase-3, and produced the most significant tumor regression with no observed toxicity. These effects were durable through day 28.
Conclusions: RBM10 deficiency mediates intrinsic resistance to osimertinib by impairing mitochondrial apoptosis. Combined EGFR and BCL-2/BCL-xL inhibition fully restores
apoptotic signaling and provides superior and durable antitumor activity in RBM10-deficient EGFR-mutant lung cancer, even if not RBM10 mutant. These findings support the clinical actionability of cotargeting EGFR and BCL-2/BCL-xL in patients with EGFR-mutant/RBM10-deficient NSCLC.
Keywords: EGFR, RBM10, NSCLC, osimertinib, ABT-263, BCL-xL, apoptosis, organoids, PDX

#1265 PRKDC regulates CDK2 expression and pancreatic neuroendocrine cancer sensitivity to chemotherapy.

Subin Kim[1], Mahnaz Norouzi[1], Courtney M. Townsend[2], B. Mark Evers[3], Piotr Rychahou[1]

[1]University of Kentucky, Lexington, KY,[2]University of Texas Medical Branch, Galveston, TX,[3]UK Markey Cancer Center, Lexington, KY

Background: Pancreatic neuroendocrine tumors (pNETs) frequently present with extensive inoperable metastases that develop resistance to DNA-damaging chemotherapy. This study evaluated DNA-PK inhibition as a strategy to enhance doxorubicin efficacy against metastatic tumors and examined the DNA-PK-CDK2 axis, with PRKDC identified as a regulator of CDK2 expression.
Methods: DNA double-strand breaks were induced using the topoisomerase II inhibitor doxorubicin. DNA-PK activity was inhibited with peposertib or via siRNA-mediated DNA-PK knockdown in BON and QGP-1 neuroendocrine cell lines. Transcriptomic data from DNA-PK knockdown cell lines were analyzed to identify gene expression relationships. Dose-dependent effects of doxorubicin on CDK2 levels were evaluated by western blot and confocal microscopy. The effect of DNA-PK inhibition and knockdown on doxorubicin-induced CDK2 expression was assessed by western blot. Therapeutic efficacy of combined low-dose doxorubicin (2 mg/kg, i.p.) and peposertib (100 mg/kg, oral gavage) was evaluated in a BON metastatic lung colonization mouse model using bioluminescence imaging to quantify metastatic burden.
Results: In BON and QGP-1 cells, doxorubicin consistently induced CDK2 upregulation, and both Western blotting and confocal microscopy showed a dose-dependent increase in CDK2 protein levels, implicating a chemotherapy-activated program of adaptive resistance. Transcriptomic analyses revealed a positive correlation between PRKDC (encoding the DNA-PK catalytic subunit) and CDK2 expression. Importantly, PRKDC knockdown or pharmacologic DNA-PK inhibition prevented this CDK2 induction, establishing a PRKDC-dependent mechanism of CDK2-mediated chemoresistance and identifying DNA-PK as a therapeutic target to block the adaptive response. Consistent with these in vitro findings, two cycles of low-dose doxorubicin combined with peposertib markedly suppressed pulmonary metastatic growth and limited extrathoracic dissemination in a BON lung metastasis model.
Conclusions: These findings support a role for DNA-PK in mediating CDK2 upregulation in response to chemotherapy and highlight the clinical relevance of low PRKDC and CDK2 expression with improved survival in NET patients. Collectively, these findings identify a PRKDC-CDK2 survival axis as a driver of chemoresistance and demonstrate that sustained, low-intensity DNA damage, when coupled with selective DNA-PK inhibition, disrupts this adaptive program, substantially reduces metastatic burden, and delivers more durable responses in pNETs.

#1268 Targeting PRMT5 enhances ferroptosis in B-cell lymphomas.

Yunxia Liu[1], Ruoyu Chen[1], Xiaoyue Gao[1], Fen Zhu[1], Qinyu Ni[1], Zhuoyan Zai[1], Paul D Bates[1], Victoria Ann Obernberger[1], Christian Capitini[1], Lixin Rui[2]

[1]Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[2]University of Wisconsin School of Medicine, Madison, WI

Protein arginine methyltransferase 5 (PRMT5) catalyzes the symmetric arginine dimethylation of proteins to regulate gene expression. PRMT5 expression is upregulated in B-cell non-Hodgkin lymphomas, including the most common diffuse large B-cell lymphoma (DLBCL) and the currently incurable mantle cell lymphoma (MCL). Ferroptosis is a form of regulated cell death driven by the accumulation of iron-dependent lipid reactive oxygen species (ROS) on cellular membranes, distinguishing it from other types of cell death. This process is initially triggered by the inhibition of system Xc^- or GPX4 activity, which ultimately leads to cell death. Lymphoma-related pathways, such as the p53 pathway, MYC, and the PI3K-AKT-mTOR signaling pathway, are involved in the regulation of ferroptosis. We and others have shown that upregulated PRMT5 enhances cell proliferation and survival in lymphoma cells by activating various mechanisms, including the PI3K-AKT signaling pathway and MYC target genes. However, whether PRMT5 is involved in ferroptosis in B-cell lymphoma remains unknown. Therefore, understanding and targeting ferroptosis in B-cell lymphoma is an urgent clinical need. Our lab previously performed PRMT5 knockout RNA sequencing. Re-analysis of the RNA-seq data revealed several metabolic-related pathways affected by PRMT5 knockout in both OCI-Ly7 and TMD8 cells, including the fatty acid metabolism pathway. Treatment of DLBCL and MCL cells with various PRMT5 inhibitors or genetic knockdown alone did not induce lipid peroxidation but enhanced DMF-induced lipid peroxide accumulation. Interestingly, PRMT5 knockout or inhibition in DLBCL and MCL cells increased sensitivity to DMF treatment. Moreover, the combination of DMF and GSK3326595 exhibited a significant synergistic effect. Mechanistically, PRMT5 inhibition reduced system Xc^- expression by targeting the PI3K-AKT-MYC signaling pathway. To determine whether PRMT5 inhibition promotes lipid peroxidation in various cell lines in response to DMF and other ferroptosis-inducing agents (FINs), we treated multiple DLBCL and MCL cell lines with different concentrations of the GPX4 inhibitor RSL3 and the SLC7A11 inhibitor Erastin, both alone and in combination with the PRMT5 inhibitor GSK3326595. Both RSL3 and Erastin demonstrated significant synergistic effects across different DLBCL and MCL cell lines. More importantly, a combination of GSK3326695 and DMF achieved a greater anti-tumor effect compared with either drug alone in patient-derived xenograft MCL models. In summary, we demonstrate that targeting PRMT5 through pharmacological inhibition and genetic knockdown sensitizes DLBCL and MCL cells to DMF-induced lipid peroxidation and ferroptosis. These findings provide a rationale for developing a new therapeutic strategy that induces ferroptotic cell death to treat lymphoma patients with relapsed or refractory disease.

#1269 Silencing of ACACA sensitizes acute myeloid leukemia cells to venetoclax.

Akansha Jalota[1], Anna Skwarska[1], Yen Bao Huynh[2], Fumiaki Sato[3], Christina Glytsou[4], Iannis Aifantis[5], Yoko Tabe[3], Stefano Tiziani[6], Marina Konopleva[1]

[1]Department of Oncology, Albert Einstein College of Medicine, Bronx, NY,[2]Department of Nutritional Sciences, College of Natural Sciences, The University of Texas at Austin, TX,[3]Laboratory of Pathophysiology, Faculty of Pharmacy, Juntendo University, Chiba, Japan,[4]Department of Chemical Biology, Ernest Mario School of Pharmacy, Rutgers, The State University of New Jersey, Piscataway, NJ,[5]Department of Pathology, New York University Grossman School of Medicine, New York, NY,[6]Department of Nutritional Sciences, Dell Pediatric Research Institute, College of Natural Sciences & Dell Medical School, The University of Texas at Austin, Austin, TX

Introduction: Acute myeloid leukemia (AML) is an aggressive blood cancer marked by malignant myeloid stem/progenitor cell proliferation in the bone marrow, with a long-term survival rate below 30%. The FDA-approved BCL-2 inhibitor venetoclax (VEN), combined with Azacitidine, is a standard-of-care therapy in older, unfit for chemotherapy AML patients, but this treatment achieves only about 50% clearance of minimal residual disease. AML cells rely on oxidative phosphorylation and fatty acid oxidation, along with other amino acids metabolism for survival. Acetyl-CoA-carboxylases are known to regulate fatty acid metabolism. While ACACA is involved in fatty acid synthesis, ACACB governs fatty acid oxidation. Thus, we hypothesize that fatty acid oxidation (FAO) inhibition by ACACA knockdown might sensitize AML cells to BCL-2 inhibitors (Venetoclax).
Methods: Knockout of ACACA was performed using CRISPR Cas9 system in AML cell lines and patient samples. Cell viability was assessed by CTG assay and colony assay was performed using methylcellulose-enriched media. Medium and long-chain fatty acid profiling was conducted via a gas chromatography mass spectrometry approach. Seahorse assay was performed to measure fatty acid oxidation.
Results: Genome-wide CRISPR screen in human AML cells treated with BH3 mimetics combinations (Glytsou et al., Cancer Discovery, 2023), demonstrated enrichment of fatty acid metabolism. We found that genes involved in both FAO, such as CPT1b, and fatty acid synthesis, such as Acetyl-CoA Carboxylase Alpha (ACACA), are top significant synthetic lethal targets with VEN/AZA. We first tested the efficacy of ND-630, known to inhibit ACC carboxylases (ACACA and ACACB) in combination with VEN. The combination was found to be effective in VEN-resistant THP-1, OCI-3 and SKM-1 cell lines in 1% FBS media. In THP-1 cell line, ND-630 reduces colony formation by 35±8%, VEN by 29±6% and the combination yielded 62±3% reduction. VEN-resistant patient samples (n=2) responded well to the combination as compared to VEN-sensitive primary AML samples (n=1). Ablating ACACA through CRISPR Cas9 system led to a reduction in colony formation in THP-1 and SKM-1 cells (36±8% and 28±4%, respectively). There was 26±4% reduction in cell viability in ACACA KO VEN-resistant primary AML cells treated with lower doses of Ven (100nM) as compared to the control. Additional primary samples are being tested and will be reported. Knockdown of ACACA resulted in a reduction of fatty acid synthesis in primary AML sample. Seahorse fatty acid oxidation assay was performed in THP-1 cell line after ACACA knockdown. We found that maximal respiration in ACACA knockdown cells was reduced compared to control cells, suggesting limited fatty acid oxidation.
Conclusion: These findings suggest that VEN-resistant AML rewire metabolism through ACACA-driven fatty acid synthesis and that inhibition of Acetyl-CoA-carboxylase restores VEN sensitivity in AML.

#1270 Immunotoxin GB13 Targets GBM and H3.3K27M DIPG with the activation of Golgi-to-ER retrograde transport pathways.

Nanyun Tang[1], Yue Hao[2], Valerie DeLuca[2], Charles Caleb Shaffer[3], Randy Schrecengost[4], Michael E. Berens[2]

[1]Clinical Genomics and Therapeutics Division, Translational Genomics Research Institute, Phoenix, AZ,[2]TGen (The Translational Genomics Research Institute), Phoenix, AZ,[3]Beckman Research Institute, City of Hope, Duarte, CA,[4]Targepeutics, Inc, Hummelstown, PA

GB13, an IL13Ra2-targeted immunotoxin, shows potent therapeutic potential against Glioblastoma (GBM) and H3.3K27M mutant Diffuse Midline Glioma (DIPG). The toxin, comprising Pseudomonas exotoxin A and IL-13 mutein, binds to IL13Ra2, which is frequently overexpressed on the surface of GBM and DIPG with histone 3.3 (H3.3) K27M mutation. GB13 is internalized through this binding and processed via Golgi-to-ER pathway. The active domain of the toxin is translocated to ADP-ribosylating eukaryotic elongation factor 2 (eEF-2) and halts protein synthesis, inducing apoptosis. *In vitro* drug dose-response assays demonstrated a 280-300 fold differential response in patient-derived GBM and DIPG models. Sensitivity correlated with IL13RA2 abundance and the H3.3K27M mutation. Gene Set Enrichment Analysis confirmed that sensitivity is linked to activated Golgi-to-ER retrograde transport pathways, the required trafficking route for GB13's cytotoxic release. Furthermore, these transport pathway scores negatively correlate with patient age in the TCGA-GBM dataset, suggesting demographic dependence. PBT29, the most sensitive H3.3K27M mutant DIPG line, showed the highest transport pathway enrichment. GB13's selective activity and its association with a Golgi-to-ER retrograde transport, as a predictive signature make it a highly promising candidate for these devastating diseases. The presence of these molecular signatures of vulnerability (mSov) could serve as an inclusion criterion for patient enrollment in clinical trials.

#1272 Targeting autophagy sensitizes cancer cells to proteasome inhibitors.

Jing Li[1], Yi Bao[1], Ava Cardenas[2], Ariba Saoda[2], Fengyu Su[1], Yuanyuan Qiao[1], Xuhong Cao[1], Arul M. Chinnaiyan[1]

[1]Michigan Center for Translational Pathology, University of Michigan, Ann Arbor, MI,[2]University of Michigan, Ann Arbor, MI

Eukaryotic cells preserve proteostasis and organelle integrity through two interconnected degradation machineries: the ubiquitin-proteasome system (UPS) and autophagy. Together, these pathways constitute a coordinated quality control network that orchestrates the selective turnover of misfolded proteins and damaged organelles. Proteasome inhibitors have achieved clinical success in hematologic malignancies, but their activity is limited by intrinsic and acquired resistance, which varies substantially across cancer types. In this study, we hypothesize that autophagy inhibition can overcome resistance to proteasome inhibition. Mechanistically, proteasome inhibition induces endoplasmic reticulum (ER) stress in sensitive cancer cells but fails to elicit this response in resistant ones. Co-treatment with autophagy inhibitors restore ER stress induction and synergistically enhances cytotoxicity in the resistant cells. In multiple in vivo cancer models including pancreatic and triple-negative breast cancers, combined inhibition of autophagy and UPS synergistically inhibited tumor growth and improved survival outcomes. At the molecular level, this dual blockade activates the PERK-pEIF2α-ATF4 signaling axis effectively, leading to apoptotic cell death. Collectively, our findings identify a mechanistic basis for overcoming resistance to proteasome inhibitors and provide a rationale for future clinical evaluation of autophagy-UPS combinatorial therapy across diverse malignancies.

#1273 Antitumor activity of PARPi and POLQi combination therapy in a BRCA-mutated PDAC model.

Chani Stossel[1], Dikla Atias[1], Yulia Glick-Gorman[1], Josep Forment[2], Lee Mulderrig[2], Gali Altman[1], Hanita Ovadia[1], Liora Chouchan[1], Elina Haimov-Talmoud[1], Tamar Beller[1], Talia Golan[1]

[1]Sheba Medical Center, Tel Hashomer, Israel,[2]Oncology Targeted Discovery Bioscience, AstraZeneca, Cambridge, United Kingdom

Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest cancers. BRCA1/2-mutated PDAC is a unique subgroup with exceptional responses to platinum chemotherapy/PARP inhibition (PARPi). A spectrum of responses is observed, from refractory to long term-remission Despite this promising strategy, most patients develop resistance. Inhibition of DNA-polymerase theta (POLQ), a key component in DNA-repair, may further sensitize cancer cells to platinum/PARPi in combination with a PARP1-selective (AZD5305/saruparib) or non-selective PARP inhibitor (olaparib). We conducted a long-term *in vivo* experiment testing PARPi and POLQi combination utilizing a platinum-sensitive, BRCA2 mutated PDAC PDX model to investigated the potential to prolong response and reduce resistance. Simultaneously, this combination was tested in accordance to the maintenance approach in clinical setting: a cisplatin induction followed by maintenance PARPi, POLQi and their combinations. A total of 159 tumor-bearing mice were randomized to: vehicle control; olaparib; saruparib; POLQi; saruparib+POLQi; olaparib+POLQi, and maintenance treatment groups by cisplatin induction for four weeks followed by switch to: vehicle control; POLQi, saruparib and saruparib+POLQi (n=8-19/group). POLQi alone had no effect on tumor growth. Both PARPi (olaparib/saruparib) monotherapies significantly delayed tumor growth, with saruparib displaying a trend towards prolonged effect vs olaparib (saruparib 69% complete responders (CR) vs control p=0.0014; olaparib 47% CR vs control p=0.0052). Combination therapy of olaparib and POLQi also showed a trend towards extended duration of response compared to olaparib monotherapy (olaparib vs control p=0.005; olaparib+POLQi vs control p=0.00017). Acquired resistance developed in seven mice (22%) with PARPi monotherapy (olaparib n=4, saruparib n=3) and was only seen in five (13%) mice in combination therapy with POLQi (saruparib+POLQi n=3; olaparib+POLQi n=2). In the maintenance study, cisplatin induction initiated a strong anti-tumor effect that was not maintained after switching to vehicle (22% CR by end of study). Addition of saruparib maintenance alone or in combination with POLQi significantly extended the duration of responses (60-70% CR by end of study). Our pre-clinical *in vivo* data indicate that 1) saruparib displayed a trend towards increased efficacy vs olaparib; 2) combined PARPi and POLQi therapy showed a trend towards extending the duration of response and delaying resistance; 3) cisplatin induction produced a strong antitumor effect which remained with maintenance PARPi±POLQi. Tumors with acquired resistance are undergoing extensive molecular analyses to determine the mechanisms of resistance.This preclinical study enables further understanding and investigation of this unique subtype with the aim to develop alternative treatments to prevent acquisition of resistance.

#1274 Integrated multiomics analysis identifies defective CoQ10 interactome in human kidney cancers.

Gregory M. Miller[1], Nischal Mahaveer Chaud[1], Catarina M. Quinzi[2], Brian Berman[1], **Vivek K. Vishnudas**[1], Vijay Modur[1], Vlatcheslav Akmaev[1], Niven R. Narain[1], Stephane Gesta[1], Michael A. Kiebish[1]

[1]BPGbio, Waltham, MA,[2]Columbia University, New York, NY

Defective energy metabolism has been established as a hallmark of cancer; however, the specific genetic basis underlying this relationship across cancers remains unclear. Ubiquinone (CoQ10) plays an essential role in regulating efficient generation of mitochondrial ATP and reactive oxygen species levels. Multi-omics assessment of the CoQ10 biosynthesis pathway genes in The Cancer Genome Atlas Program (TCGA) revealed Kidney Clear Cell Carcinoma (KIRC) and Kidney Papillary renal cell carcinoma (KIRP) as cancers that demonstrated a significant relationship between poor prognosis and low expression or copy number deletions in the CoQ10 biosynthesis genes. However, the link between deletions and low expression in CoQ10 biosynthesis genes and poor outcomes remains unknown. Towards this aim, we defined the CoQ10 interactome as a set of 37 protein encoding genes that bind with CoQ10, along with enzymes involved in downstream pathways impacted by CoQ10 homeostasis, based on literature review. We then investigated this CoQ10 interactome for their association with outcomes for KIRC and KIRP patients in TCGA datasets. First, patients were grouped into low/high expression groups based on median gene expression levels for the indication. We then investigated the association of outcome measures Overall Survival (OS) and Progression Free Interval (PFI) with expression groups in KIRC (n=530) and KIRP (n=288) patients. Our results found that low gene expression in 21 of 37 CoQ10 interactome genes in KIRC, and 3 of 37 CoQ10 interactome genes in KIRP were associated with significantly worse OS and PFI. Next, we analyzed copy number deletions and their association with patient outcomes. Patients were grouped as having a deletion in the gene or not. In line with the prior analysis, we observed that deletions in 9 of 37 CoQ10 interactome genes, and 12 of 37 CoQ10 interactome genes were associated with significantly worse OS and PFI in KIRC and KIPR, respectively. Notably, we observed that deletions in ETHDH (KIRC OS HR = 1.95, *q-value* = 0.0045, n deletion = 75; KIRP OS HR = 5.42, *q-value* = 0.00008, n deletion = 28) and PRODH (KIRC OS HR = 2.06, *q-value* = 0.0144, n deletion = 41; KIRP OS HR = 2.71, *q-value* = 0.01866, n deletion = 60) were associated with significantly poorer OS and PFI in both KIRC and KIRP. These results demonstrate that CoQ10 and its interactome are significantly impacted in kidney cancer subtypes and deletions or low expression in these key genes are associated with poorer survival outcomes for patients. This data indicates potential for therapeutic intervention with BPM31510, a nanoparticle formulation of oxidized CoQ10, which is currently in Phase 2 clinical trials for oncology indications.

#1275 Phospholipase D1 overexpression drives metabolic survival and stress resistance in cervical cancer.

Sung Wan Kang[1], Dong Woo Kang[1], Yu-na Noh[1], Young-Jae Lee[1], Min-Seo Lee[1], Yong-Man Kim[2], Shin-Wha Lee[1]

[1]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]CHA Bundang Medical Center, CHA University School of Medicine, Seoul, Korea, Republic of

Background: Cervical squamous cell carcinoma (SCC) and adenocarcinoma (ADC) are clinically and biologically distinct subtypes, yet the metabolic drivers of SCC aggressiveness remain poorly understood. Phospholipase D1 (PLD1), a lipid-modifying enzyme involved in oncogenic signaling and cancer metabolism, has been reported to be elevated in various malignancies. However, its subtype-specific expression pattern and functional relevance in cervical cancer have not been clearly delineated.
Methods: PLD1 expression was evaluated using TCGA datasets and validated in primary cervical tumors by qRT-PCR, PLD activity assays, and immunohistochemistry. Functional studies were performed in primary SCC and ADC cells using shRNA-mediated PLD1 knockdown or a PLD1-selective inhibitor. Apoptosis, ATP levels, glycolytic activity, clonogenic survival, and invasion were measured under basal and metabolic stress conditions.
Results: PLD1 was significantly overexpressed in SCC compared with ADC at the mRNA, protein, and enzymatic activity levels. PLD1 inhibition markedly decreased SCC cell survival, whereas ADC cells exhibited minimal sensitivity. PLD1 blockade reduced glycolytic flux and ATP production and increased apoptosis under serum starvation, glucose restriction, and hypoxia. PLD1 knockdown also impaired clonogenic survival and suppressed invasion. These effects were further enhanced by co-treatment with the glycolysis inhibitor 2-deoxy-D-glucose, highlighting a strong dependency of SCC cells on PLD1-mediated metabolic regulation.
Conclusions: PLD1 is selectively upregulated in cervical SCC and serves as a key regulator of glycolysis, energy homeostasis, and adaptation to metabolic stress. The pronounced metabolic dependence on PLD1 identifies it as a promising therapeutic target in SCC, and PLD1 inhibition may effectively exploit metabolic vulnerabilities unique to this tumor subtype.

#1276 Dual epigenetic-kinase targeting to overcome resistance and immune evasion in hepatocellular carcinoma.

Kyounghyun Kim[1], HongDuck Yun[2], Gabin Kwon[2]

[1]University of Arkansas for Medical Sciences, Little Rock, AR,[2]Pharmacology & Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR

Hepatocellular carcinoma (HCC) incidence and mortality continue to rise in the United States, largely driven by increasing rates of chronic liver disease, viral hepatitis, and metabolic dysfunction. Despite progress in immunotherapy, first-line immune checkpoint inhibitor (ICI)-based combinations benefit only a subset of patients, and many individuals with HCC are ineligible due to contraindications such as varices, autoimmune disorders, or immunosuppression. Second-line agents, including the multi-kinase inhibitor lenvatinib, provide only modest and short-lived clinical responses. These persistent challenges—tumor heterogeneity, rapid development of therapeutic resistance, and limited options for patients with hepatic dysfunction—underscore the urgent need for innovative, durable, and widely accessible treatment strategies for HCC. Epigenetic dysregulation mediated by the histone demethylase LSD1 (KDM1A) is a key driver of HCC stemness, plasticity, and immune evasion. LSD1 is frequently overexpressed in HCC and strongly associated with poor survival. Notably, high LSD1 expression correlates with adverse clinical outcomes in both $CD8^+$ T cell-enriched and $CD8^+$ T cell-exhausted tumors, highlighting its role in establishing a cold or immunosuppressed tumor microenvironment. Thus, we hypothesize that LSD1 inhibition will suppress aggressive tumor phenotypes, limit intratumoral heterogeneity, delay therapeutic resistance, and enhance anti-tumor immunity, with enhanced efficacy when combined with lenvatinib. Our preliminary data support this hypothesis. Pharmacologic inhibition or genetic depletion of LSD1 with or without Lenvatinib treatment significantly reduces HCC cell proliferation and aggressive tumor behaviors—including migration, invasion, tumor sphere formation, and xenograft tumor growth. Importantly, the combination of LSD1 inhibition and lenvatinib further enhances $CD8^+$ T cell-mediated immune surveillance and restores immune killing capacity against HepG2 cells, which are typically resistant to immune-mediated cytotoxicity. These findings provide a strong mechanistic and translational rationale for advancing LSD1-targeted epigenetic therapy, alone or in combination with lenvatinib, as a promising therapeutic strategy for patients with advanced HCC who are underserved by current ICI-based treatments. By directly targeting LSD1-driven epigenetic reprogramming and overcoming key resistance mechanisms, this project addresses a critical unmet medical need and establishes a robust foundation for future clinical evaluation of combined LSD1-Lenvatinib therapy.

#1277 Overcoming glioblastoma resistance by targeting its heterogeneity with a synergistic approach: TTFields stimulation and tmCLIC1 impairment.

Francesca Cianci[1], Elisa Meraviglia[1], Guido Rey[2], Stefania Castiglione[1], Antonio M. Polito[1], Sara Torabi[3], CHIARA MERCURIO[3], Dietmar Krex[3], Tatiana Vorobyov[4], Kerem Wainer-Katsir[5], Martin Gabay[3], YAARA PORAT[3], Roni Blatt[3], Ori Braten[6], Tullio Florio[3], Itai Tzchori[3], **Michele Mazzanti**[1]

[1]University of Milan, Milan, Italy,[2]University of Milan, Milano, Italy,[34]Novocure, Baar, Switzerland,[5]Israel,[6]Novocure, Haifa, Israel

Glioblastoma (GB) is the most malignant and aggressive primary brain tumor in adults, characterized by rapid growth, diffuse infiltration, and strong resistance to treatments. As a result, most patients inevitably experience tumor recurrence, and median survival remains around 15 months. In this context, Tumor Treating Fields (TTFields) have emerged as an innovative and noninvasive therapy. Although clinical use of TTFields has shown survival benefits, most patients relapse, highlighting adaptive mechanisms that enable GB cells to survive prolonged treatment. To better understand the molecular basis of TTFields resistance, we created an experimental model that mimics clinical exposure by applying long-term TTFields stimulation to patient-derived GB cultures representing different molecular subtypes. Initial responses to therapy varied among cell lines; however, after extended exposure, all resistant groups developed a typical mesenchymal-like phenotype, indicating a shared adaptive response. Transcriptomic analysis of paired patient samples before and after treatment further showed that TTFields-treated tumors tend to upregulate pathways related to myelin formation, consistent with a mesenchymal-like phenotype. While these pathways reflect a shift toward a more invasive and therapy-resistant state, they offer limited options for direct drug targeting. We identified the transmembrane form of Chloride Intracellular Channel 1 (tmCLIC1) as a potential target. tmCLIC1 has been linked to GB stem cell metabolism, regulation of oxidative stress, and tumor growth, suggesting it plays a critical role in maintaining resistance to TTFields. Based on these findings, we tested the therapeutic benefit of concomitant treatment of TTFields and metformin, a well-known antidiabetic drug that inhibits tmCLIC1 in GB. Remarkably, this combination produced a strong synergistic effect, significantly reducing GB cell viability in vitro and slowing tumor growth in vivo. These results show that prolonged TTFields exposure pushes GB cells toward a mesenchymal-like, therapy-resistant phenotype and highlight tmCLIC1 as a key player in this adaptive process. Targeting tmCLIC1 with metformin offers a promising strategy to sensitize resistant cells and improve the effectiveness of TTFields. This work provides a mechanistic framework for developing combination therapies to overcome treatment resistance and enhance long-term outcomes for GB patients.

#1279 Exploiting Wnt-induced DNA damage repair vulnerability with PARP inhibitors to overcome chemoresistance in multiple myeloma.

Kaushlendra Tripathi, Gabriella Santos, Camila Pacocha, Shadika Panta, Emma Younger,, Trevor Stepanyan,, Lauren Fowler,, Brandon Smith,, Ryan O'Hare,, Xavier Noel Pin Harry,, Daniel Ross,, Bidyut Mohanty,, David Eagerton,

Microbiology and Immunology, Edward Via College of Osteopathic Medicine-Carolinas Campus, 350 Howard St. Spartanburg, SC 29303, Spartanburg, SC

Multiple Myeloma (MM) is a plasma cell malignancy characterized by the clonal proliferation of malignant plasma cells in the bone marrow, leading to the excessive production of monoclonal immunoglobulin. This proliferation and the subsequent interaction with the bone microenvironment result in significant end-organ damage, classically represented by the CRAB criteria: Calcium elevation (hypercalcemia), Renal failure, Anemia, and Bone lesions (lytic lesions, pain, and fractures). It is a highly aggressive and lethal cancer, notorious for high recurrence rates and a lack of effective targeted therapies. While PARP inhibitors (PARPi) are potent agents, their clinical benefit is narrowly restricted to the small patient subset harboring BRCA mutations. We present a strategy to expand PARPi efficacy in MM. We discovered that the Wnt signaling transcription factor, beta-catenin, controls the expression of the critical Fanconi Anemia DNA repair protein, FANCD2 and cohesion protein CTCF in MM cells. Crucially, inhibiting beta-catenin in initially resistant MM cells (those that are homologous recombination, or HR, proficient) induces a BRCA-like deficiency known as BRCAness and severe replication stress. This combination—beta-catenin inhibition paired with PARPi—shows enhanced DNA damage, striking synergistic lethality in cell models, and powerful anticancer activity in organoid models. This dual-targeting approach offers a novel and effective strategy to overcome resistance in MM.

#1280 Pathway-based radiosensitivity and therapeutic targeting in triple-negative breast cancer subtypes.

Jaitri Joshi[1], Jenna Jacoby[2], Shan Xu[2], Noelle Francois[2], Tiziana DeAngelis[2], Anuradha Shastri[2], Adeseye Adekeye[2], Nicole L. Simone[2]

[1]University of Minnesota Medical School, Minneapolis, MN,[2]Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA

Triple-negative breast cancer (TNBC) is an aggressive and heterogeneous disease with subtypes that differ in therapy response and radiosensitivity. Experimental models suggest that pathway-level modulation may provide more actionable insights into resistance mechanisms. Using syngeneic, aggressive murine models of breast cancer (4T1), 60 female Balb/c mice were randomized after palpable tumor formation to six treatment arms: ad libitum feeding (AL), radiation alone (8 Gy), caloric restriction (CR, 30% reduction in intake), CR+RT, curcumin alone, and curcumin+RT. CR evoked a marked delay in tumor growth, with AL mice reaching a 1 cm^3 tumor volume at ~24 days post-injection, while CR mice reached this threshold at ~37 days. CR also increased overall survival and markedly reduced pulmonary metastases: at 35 days post-injection, the total metastatic burden was 1360 mm^3 in AL-fed mice compared to 150 mm^3 in CR mice. Transcriptome profiling of CR-treated tumors revealed 18 dysregulated pathways, including downregulation of c-MYC, PIK3CA, and androgen receptor, suggesting a mechanistic basis for radiosensitization. Tumor volume trajectories in curcumin-treated groups revealed non-monotonic growth patterns, while curcumin combined with a 3-dose 2 Gy radiation regimen between days 6-10 resulted in a flatter post-radiation trajectory. During the radiation window, curcumin alone tumors expanded by +815 mm^3, whereas curcumin + RT increased by +568 mm^3, representing a ~30% smaller rise. Over the full 20-day study, curcumin + RT showed a 28% lower cumulative volume increase (1026 vs 1434 mm^3) and a reduced daily growth rate (51 vs 72 mm^3/day). These trends suggest that curcumin may modulate stress adaptation and survival signaling under radiation exposure. Mouse weights remained stable across all arms, supporting tolerability. In conclusion, pathway-level interventions such as caloric restriction and curcumin demonstrate potential to enhance radiosensitivity in preclinical TNBC models. Therefore, interventions such as caloric restriction and curcumin may enhance radiosensitivity by modulating pathways relevant to established radioresistant BL2 and M TNBC subtypes. Ongoing cell line studies in HCC1806 (BL2) and MDA-MB-231 (Mesenchymal) can test whether these mechanisms observed in vivo are recapitulated in defined subtype models. By refining these strategies and integrating pathway biology into subtype classification, translational radiosensitization approaches may be improved.

: Liquid Biopsy: Multi-Analyte and Multi-Omic
Poster Session

#0094 Liquid biopsy profiling of the tumor microenvironment to determine response to immunotherapy regimens across solid tumors.

Erin L. Brown[1], Wubing Zhang[1], Abul Usmani[2], Noah Earland[2], Ayesha Hashmi[3], Chibuzor Olelewe[3], Anushka Viswanathan[3], Pradeep S. Chauhan[3], Minji Kang[1], Chloe B. [1]Stanford University School of Medicine, Stanford, CA,[2]Washington University in St. Louis, St. Louis, MO,[3]Mayo Clinic, Rochester, MN,[4]Oslo University Hospital and University of Oslo, Oslo, Norway,[5]Medical College of Wisconsin, Milwaukee, WI,[6]Yale University School of Medicine, New Haven, CT,[7]Columbia University, New York, NY,[8]University of Rochester School of Medicine, Rochester, NY

Background: Spatial cellular ecosystems in the tumor microenvironment (TME) form dynamic signaling hubs that critically influence cancer disease progression and response to therapy, including response to immune checkpoint inhibitors (ICIs). However, tumor sampling bias and the impracticality of acquiring serial tumor biopsies have made it challenging to profile the TME clinically. To address this challenge, we developed Liquid EcoTyper, a multi-analyte AI framework to quantify TME spatial cellular ecosystems—termed spatial ecotypes (SEs)—noninvasively from cell-free DNA (cfDNA) methylation data.
Methods: In previous work, we discovered nine spatial ecotypes, including SEs associated with ICI response (e.g., SE7 with benefit, SE4 with resistance), and quantified them from 1,249 bulk tumor RNA-seq profiles of melanoma, non-small cell lung cancer (NSCLC), and bladder cancer (BC) patients (*Cancer Res* (2025) 85 (8_Supplement_1): 153). Here we trained Liquid EcoTyper, an interpretable deep learning model, to transfer SE profiling to cell-free DNA using CpG methylation profiles. Performance was quantified using simulated and real data, including methylation profiles (EM-seq) of plasma cfDNA paired with tumor biopsy-derived SE levels determined by EM-seq (n=20 pairs) or 10x Visium (n=15 pairs). Clinical outcome prediction was evaluated using pretreatment plasma from patients treated with ICI alone (n=78 melanoma pts), chemotherapy and ICI (n=25 NSCLC pts), and enfortumab vedotin and ICI (n=10 localized muscle-invasive BC (MIBC) pts). Tumor mutational burden (TMB), tumor PD-L1, or circulating tumor DNA (ctDNA) were profiled as a comparator where possible.
Results: We observed striking concordance between plasma-derived SE levels and tumor biopsy-confirmed SE levels from the same patients, demonstrating that liquid biopsy analysis of cfDNA methylomes can recapitulate TME spatial biology. Underscoring specificity, no reliable SE signal was detectable from peripheral blood mononuclear cells. In pre-ICI plasma, liquid SE levels were significantly associated with ICI-based response (SE7) versus resistance (SE4) in patients with melanoma, NSCLC, and MIBC, with a mean cross-cancer area under the curve (AUC) of 0.87 for SE7 (range 0.8-0.97) and 0.81 for SE4 (range 0.76-0.85)—far surpassing TMB, tumor PD-L1, and ctDNA in evaluable patients, both in binary analyses of response and multivariable models of survival. Our results also showed potential to predict pathologic complete response in the neoadjuvant setting.
Conclusion: Liquid EcoTyper is a scalable noninvasive AI-based framework for spatiotemporal assessment of the TME. By enabling TME-informed risk stratification without surgical biopsies, Liquid EcoTyper has potential to enable more precise and actionable decision making in patients with solid tumors.

#0095 PlasmaCHORD- A machine learning method for identifying clonal hematopoiesis variants in liquid biopsies.

Daniel J. Rabizadeh[1], Jenna VanLiere Canzoniero[1], Ilias Ziakas[1], Jaime Wehr[1], Archana Balan[1], Amna Jamali[2], Blair V. Landon[1], Susan Combs Scott[1], Gavin Pereira[1], Vincent K. Lam[1], Christine L. Hann[1], Christine M. Lovly[3], Jessica Tao[1], Patrick M. Forde[1], Joseph C. Murray[1], Mark Sausen[4], Gerrit A. Meijer[5], Geraldine Vink[6], Remond J. A. Fijneman[5], Victor E. Velculescu[1], Jillian Ayn Phallen[1], Robert Scharpf[1], Valsamo Anagnostou[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD,[3]Vanderbilt University Medical Center, Nashville, TN,[4]LabCorp, Baltimore, MD,[5]Department of Pathology, Netherlands Cancer Institute, Amsterdam, Netherlands,[6]Research, Netherlands Comprehensive Cancer Organisation, Urecht, Netherlands

Introduction: Genomic profiling of circulating tumor DNA (ctDNA) through liquid biopsies has become an important diagnostic method in clinical oncology. However, detection of variants related to clonal hematopoiesis (CH) is a major confounder that impairs the clinical utility of liquid biopsies. Strategies that reduce biological noise from CH in plasma NGS include deep sequencing of matched WBC DNA and/or tumor tissue sequencing. While these methods effectively distinguish most CH variants, the need for extra biospecimens and sequencing raises costs and limits feasibility.

Methods: Using a training cohort of 426 variants identified in ctDNA NGS from 225 patients with stage I-IV solid tumors, we developed plasmaCHORD, a machine learning model (MLM) that includes fragmentomic, variant, and patient-level features to distinguish between tumor- and CH-origin for mutations detected by fixed gene panel hybrid capture NGS. Model performance was assessed by comparison to the reference origin of each plasma variant determined from matched WBC and tumor NGS. Following locking the model parameters, we applied plasmaCHORD to an independent validation cohort of 1,412 plasma variants detected in 114 patients with metastatic cancers, as well as to cfDNA NGS from patients enrolled in a prospective liquid biopsy-informed clinical trial (NCT05585684).

Results: PlasmaCHORD predicted tumor versus CH-origin in the training set with high accuracy (cross-validated AUC=0.94), outperforming individual features such as variant allele frequency and canonical CH genes. Model performance remained robust when restricted to mutant DNA fragments supported by 3-5 mutant reads (AUC = 0.84). plasmaCHORD was locked for evaluation using a score of 0.5 as cutoff for distinguishing tumor- versus CH-origin variants. In the independent validation cohort, the locked model maintained similar overall accuracy (AUC=0.9) with a sensitivity of 82%, specificity 80.3% and accuracy of 80.2%. Our approach was shown to be highly reliable in classifying variant origin in clinically actionable genes not canonically associated with CH, including *AKT1, ATM, BRCA1, BRCA2,* and *EGFR,* as well as adjudicating cellular origin for *TP53* mutations that are encountered in both solid and hematologic malignancies. Performance was consistent across cancer types, sequencing platforms, mutation classes, and a wide range of allele fractions. When applied to clinically challenging cases in the context of a precision oncology clinical trial, plasmaCHORD precisely determined variant origin, preventing mismatches with genotype-targeted therapies.

Conclusions: plasmaCHORD, a multi-feature machine-learning classifier, can significantly enhance the ability to identify *bona fide* tumor variants in routine plasma-only NGS, addressing a critical need in implementing liquid biopsy-guided therapy by minimizing misinterpretation caused by CH.

#0096 Real time multimodal ctDNA and imaging assessment enables adaptive treatment in HPV related oropharyngeal cancer.

Bill H. Diplas[1], David N. Brown[1], Xin Pei[1], Yingjie Zhu[1], Achraf Shamseddine[1], Chiharu Graybill[2], W. Michael Korn[3], Emily Westheimer[2], Luc GT Morris[1], Richard J. Wong[1], Sean M. McBride[1], Alan L. Ho[1], Heiko Schoder[1], Eric Sherman[4], Robert Daber[2], Nora Katabi[1], Jorge Reis-Filho[1], Britta Weigelt[1], Nancy Lee[1], Nadeem Riaz[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Labcorp, San Francisco, CA,[3]Biocartis, Itasca, IL,[4]Memorial Sloan-Kettering Cancer Center, New York, NY

Purpose: Circulating tumor DNA (ctDNA) has emerged as a sensitive biomarker for minimal residual disease detection, but its potential for real-time adaptation during curative therapy remains unexplored. Integrating ctDNA dynamics with imaging could enable more precise, risk-adapted treatment modifications beyond current radiological monitoring alone. HPV-associated oropharyngeal cancer (OPC) presents an ideal context given high cure rates, active treatment de-escalation efforts, and protracted chemoradiation courses allowing mid-treatment adaptation. We sought to determine whether longitudinal ctDNA profiling integrated with multimodal MRI could inform response-adapted treatment strategies.

Methods: A total of 158 patients with HPV OPC were enrolled on a personalized de-escalation trial (NCT03323463). Blood samples for ctDNA analysis were collected pre-treatment and weekly during therapy, with 980 longitudinal samples obtained from 119 patients over up to 126 weeks (mean 8.2 samples/patient). We developed a dual Personalized Cancer Monitoring (PCM)-HPV ctDNA assay combining patient-specific tumor-informed variant detection (average 47 variants/patient) with probes targeting high-risk HPV subtypes, especially E6 and E7 genes of HPV-16 and HPV-18, both using anchored multiplex PCR (AMP) followed by high-throughput sequencing with Invitae (now Labcorp, San Francisco, CA). Weekly MRIs (T2-weighted) were performed concurrently to determine tumor volume.

Results: Integrating somatic mutations with viral ctDNA detection increased baseline ctDNA detection from 80.3% (HPV ctDNA only) and 89.4% (PCM ctDNA only) to 93.9%. Baseline circulating HPV levels correlated with tumor volume, apoptotic signaling, necrosis, and primary tumor viral load (combined R^2=0.54). During treatment, ctDNA showed broader dynamic range and faster kinetics than volumetric imaging. Critically, absolute ctDNA fraction at week 2 of treatment predicted patients requiring treatment intensification (p=0.0003). A multimodal model integrating on-treatment ctDNA assessment and imaging improved identification of patients with high-risk disease, surpassing either modality alone.

Conclusions: Early on-treatment ctDNA dynamics capture aggressive disease biology during a critical window for adaptation. Multimodal integration of molecular and imaging assessments provides superior risk stratification, demonstrating that they capture complementary biology early in therapy and establishing a framework for real-time treatment personalization.

#0098 Surveillance for recurrent bladder cancer using Oncuria-Monitor, a urine-based multiplex immunoassay.

Sunao Tanaka[1], Charles Rosser[1], Yair Lotan[2], Menghan Liu[3], Takashi Kobayashi[4], Sima P. Porten[5], Yuki Kita[6], Yingye Zheng[7], Zhen Zhang[8], Hideki Furuya[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Associate Professor of Urology, UT Southwestern Medical Ctr., Dallas, TX,[3]Fred Hutchinson Cancer Center, Seattle, WA,[4]Postdoctral Research Fellow, Dept. of Urology, Kyoto University Graduate School of Medicine, Kyoto, Japan,[5]UCSF, San Francisco, CA,[6]Institute for Virus Research, Kyoto Univ., Kyoto, Japan,[7]Fred Hutchinson Cancer Research Ctr., Seattle, WA,[8]Associate Professor, Dept. of Pathology & Oncology, Johns Hopkins University School of Medicine, Baltimore, MD

Introduction - Over 50% of patients with non-muscle invasive bladder cancer (NMIBC) will have a recurrence, necessitating a rigorous surveillance schedule. As urinary cytology's performance is poor, cystoscopy is standard of care in surveilling these patients. Oncuria-Monitor, a liquid biopsy to detect recurrent bladder cancer from a single voided urine sample demonstrated favorable performance.
Methods- To investigate whether Oncuria-Monitor, a multiplex immunoassay that detects a bladder cancer associated diagnostic signature composed of 10 proteins in voided urine could improve bladder cancer detection while surveilling patients with a history of bladder cancer. From February 2017 through August 2020, 7 academic, private practice, and hospital facilities in the US and Japan prospectively enrolled 300 consecutive patients with a history of bladder cancer into this longitudinal study, which followed patients for two years. Diagnosis of bladder cancer recurrence, based on cystoscopy with biopsy, was accepted as the reference standard. At each cystoscopic clinic visit during the two years, patients provided a urine sample for analysis of Oncuria-Monitor (analyzed in a blinded manner), BladderChek and urine cytology. The performance of Oncuria-Monitor was compared with BladderChek and urine cytology as an aid to cystoscopy to detect recurrent bladder cancer.
Results - Recurrent bladder cancer was diagnosed in 93 of the 300 patients (31%) by histopathological evaluation. Oncuria-Monitor detected 61 of 92 cancers with a sensitivity 74.2% (95% CI, 67.5-81.8%), specificity of 39.2% (95% CI, 34.6-43.1%) and negative predictive value (NPV) of 73.9% (95% CI, 68.6-79.9%), while sensitivity, specificity and NPV of BladderChek were 12.9%% (95% CI, 7.9-17.8%), 99.1% (95% CI, 98.1-99.8%) and 66.1% (95% CI, 63.9%-70.8%), respectively and sensitivity, specificity and NPV of urinary cytology were 28.8% (95% CI, 21.1-36.7%), 97.0% (95% CI, 95.3-98.4%) and 71.1% (95% CI, 62.7%-83.8%), respectively.
Conclusions - In this large prospective trial, Oncuria-Monitor, had a substantially superior sensitivity compared to both BladderChek and urinary cytology in detecting recurrent bladder cancers.

#0099 Enhanced detection of EML4-ALK fusions through integration of complex genomic rearrangements in DNA-based assays.

Aidan C. Manning, Sante Gnerre, Jamie Hutchins

Guardant Health Laboratory, Redwood City, CA

Introduction: *ALK* fusions, particularly *EML4-ALK*, are well-established therapeutic biomarkers in non-small cell lung cancer (NSCLC) and other malignancies. In DNA-based fusion detection, genomic rearrangements at *ALK* loci can be complex, often involving non-canonical or fragmented configurations. These include events where *EML4* and *ALK* breakpoints are both detected, but occur at separated genomic positions, sometimes bridged by intergenic sequences or intervening genes. Such configurations may still yield functional *EML4-ALK* transcripts yet fall outside canonical DNA-based fusion-calling rules. In this study, we explore the potential impact of broadening reporting criteria to include these distanced non-canonical *EML4-ALK* rearrangements and assess their clinical relevance.

Methods: We analyzed paired DNA and RNA sequencing data from 7,810 tissue samples (Guardant360 Tissue; Guardant Health, Inc. Palo Alto, CA) and DNA sequencing data from 151,517 liquid samples (Guardant 360 Liquid; Guardant Health, Inc. Palo Alto, CA) from advanced stage patients across cancer types to determine the prevalence of *EML4-ALK* fusions. DNA-based fusions were classified as canonical (*EML4-ALK* with direct adjacency) or non-canonical (*EML4-ALK* with separated intra-chromosomal breakpoints). For tissue samples with paired RNA data, we compared results across the two assays to evaluate concordance and to determine whether RNA evidence supported transcriptionally active *EML4-ALK* fusions from these complex, non-canonical DNA events.

Results: Among pan-cancer tissue samples, 45 (0.57%) harbored canonical *EML4-ALK* fusions, while 5 (0.06%) contained non-canonical EML4-*ALK* rearrangements with preserved *ALK* kinase domains. All five were confirmed by RNA and found exclusively in lung cancers. In liquid, 612 (0.40%) cases with a canonical event and 55 (0.04%) with non-canonical events were observed; 91% retained a complete kinase domain, and 73% were found in lung cancer patients. The genomic distance between *EML4* and *ALK* breakpoints typically fell within a few kilobases to several megabases but within the same chromosomal context, suggesting structural complexity. Including non-canonical events improved fusion detection sensitivity by ~13% in tissue and ~8% in liquid while maintaining high cancer-type specificity.

Conclusions: A subset of *EML4-ALK* fusions exhibit non-canonical, intra-chromosomal breakpoints detectable at the DNA level yet yield functional, targetable, *EML4-ALK* fusion products at the RNA level. These rearrangements preserve the *ALK* kinase domain and are highly enriched in NSCLC, supporting their biological and therapeutic relevance. Expanding DNA fusion criteria to capture these complex, functional events could enable the identification of additional *ALK*-positive NSCLC patients eligible for targeted therapies by NGS, improving precision oncology outcomes.

#0100 Blood-based integration of epigenomic profiles, TMB, and MSI to predict immune checkpoint inhibitor response in advanced non-small cell lung cancer (aNSCLC).

Sean Gordon, Jing Wang, Shile Zhang, Marisa Juntilla, Tingting Jiang, Matthew Ellis, Vishnu Ramani, Reagan Barnett, Bernard Herrman, Justin Odegaard, Darya Chudova

Guardant Health, Palo Alto, CA

Introduction. Immune checkpoint inhibitors (ICIs) have transformed cancer treatment, yet identifying patients most likely to benefit remains challenging. Established biomarkers such as tumor mutational burden (TMB) and microsatellite instability (MSI) have performance limitations. We hypothesized that combining MSI and TMB with epigenomic features of tumor-intrinsic immune regulation and the tumor microenvironment from pretreatment plasma would improve prediction. We developed and validated a multimodal immunotherapy response score (MIRS-Score) that integrates MSI, TMB, and epigenomic signatures (Guardant360 Liquid) to identify patients likely to respond to ICI alone or in combination with chemotherapy.

Methods. From the de-identified GuardantINFORM database we identified 695 advanced NSCLC (aNSCLC) patients treated with first- or second-line ICI monotherapy or ICI+chemotherapy and randomly split them into training (n=483) and test (n=212) sets. A literature-curated, data-driven epigenomic signature associated with real-world time to treatment discontinuation (rwTTD) was combined with MSI and TMB to train the multimodal model. Patients ≥80th MIRS percentile were labeled MIRS-High. Cox proportional hazards models adjusted for sex, age, therapy type (mono vs combo), line of therapy, and baseline tumor fraction provided adjusted hazard ratios (aHR); median rwTTD was estimated by Kaplan-Meier.

Results. In the independent test set (n=212), MIRS-High patients had longer rwTTD (median 8.7 vs 5.1 months; aHR 0.61, 95% CI 0.41-0.93, p=0.02) and improved overall survival (OS) (aHR 0.33, 95% CI 0.16-0.68, p<0.005). In the ICI monotherapy subgroup (n=69), MIRS-High showed median rwTTD 11.0 vs 4.9 months (aHR 0.31, 95% CI 0.13-0.75, p=0.01) and longer OS (aHR 0.18, 95% CI 0.04-0.79, p=0.023). MIRS-High was not associated with rwTTD in patients treated with chemotherapy alone (aHR 1.16, 95% CI 0.94-1.44, p=0.18).

Conclusions. A pretreatment plasma-based score combining MSI, TMB, and epigenomic signatures identifies aNSCLC patients with superior outcomes on ICI and outperforms MSI or TMB alone. The ICI treatment-specific stratification and strong association with both rwTTD and OS support the clinical utility of this multimodal approach, warranting further evaluation to assess the potential for guiding ICI treatment decisions.

#0101 Fragmentomics-based cancer type and subtype classification in 60,000 cell-free DNA samples.

Zhenjia Wang, Kevin Cabrera, Yanmei Huang, Daniel S. Lieber, Justin Y. Newberg, Ethan S. Sokol, Zoe Fleischmann

Foundation Medicine Inc., Boston, MA

Purpose: Tissue-of-origin prediction and tumor subtyping enable more precise treatment selection, especially for cancers of unknown primary (CUP) or without a defined subtype, though these remain a challenge in liquid biopsy applications. Current genomic approaches include methylation profiling or whole-genome sequencing, which require additional laboratory workflows on top of comprehensive genomic profiling, or may utilize multiple detected somatic alterations, which may not be present in low tumor fraction liquid biopsy samples. Cell-free DNA fragmentation patterns reflect tissue-specific chromatin architecture and gene expression programs. We evaluated whether fragmentomic features could enable cancer type and subtype classification on our comprehensive genomic profiling platform.

Methods: We analyzed 60,000 FoundationOne® Liquid CDx samples and extracted fragmentomic features for research use only across 10,510 genomic target regions. Disease classification was performed in lung, breast, prostate, and colorectal cancer using a feedforward neural network classifier with an 80/20 training-test split using cross-entropy loss. Subtype classifiers were developed in lung cancer for histological subtype and in breast cancer for hormone receptor status.

Results: We developed a 4-disease classifier using fragmentomic features in samples with circulating tumor DNA (ctDNA) fraction of 1% or greater. A high AUC was achieved across diseases (lung: 0.95, breast: 0.97, prostate: 0.97, colorectal: 0.97), with performance maintained even at low shed level (ctDNA fraction of 1-2%, AUCs 0.94-0.98). The lung histological subtype classifier achieved >90% accuracy in distinguishing between adenocarcinoma, squamous cell carcinoma, and small cell carcinoma. A breast cancer hormone receptor status classifier achieved >95% accuracy using inferred status from genomic data.

Conclusions: Fragmentomic features in liquid biopsy samples enable accurate cancer type and histological subtype classification at ≥1% tumor fraction without requiring somatic variant detection. This approach has promise to address unmet needs in precision oncology.

#0102 TAPS+ enables direct 5mC/5hmC-resolved genomic and methylation profiling of CNS tumors in CSF-derived ctDNA and FFPE.

Johnathan Rafailov[1], Eloise Freitag[1], Aditya Deshpande[1], Kevin Hadi[1], Camila Fang[1], Alexa Oviedo[1], Emma Hanley[1], August Kolb[1], Neha Dhasmana[1], Hannah Weiss[1], Chanel Schroff[1], Yiying Yang[1], Jonathan Serrano[1], Kazimierz Wrzeszczynski[1], Stergios Zacharoulis[2], Daniel Orringer[1], Alexandra M. Miller[1], Marcin Imielinski[1], Matija Snuderl[1]

[1]NYU Langone Health, New York, NY,[2]Columbia University Irving Medical Center, New York, NY

DNA methylation profiling has become a critical tool in the classification of CNS tumors, helping to refine diagnoses when histology or imaging are inconclusive. In parallel, liquid biopsy approaches analyzing circulating tumor DNA (ctDNA) from cerebrospinal fluid (CSF) offer minimally invasive windows into tumor biology, with applications in diagnosis, treatment monitoring, and relapse detection. A unified method that profiles both methylation and somatic alterations from low-input DNA—such as CSF-ctDNA and FFPE—would provide substantial clinical value. TET-Assisted Pyridine-Borane Sequencing (TAPS+) enables such integrated profiling through a bisulfite-free workflow that preserves DNA integrity while detecting CpG methylation, mutations, indels, copy-number changes, and gene fusions from a single library. We applied TAPS+ to 139 CSF samples and 61 FFPE CNS tumors to evaluate analytical performance and clinical utility.

Methods: CSF samples were collected through the Perlmutter Cancer Center liquid biopsy program and FFPE CNS tumors from archival tissue. TAPS+ libraries were prepared from 1-100 ng DNA using the Watchmaker Genomics kit and sequenced to 10-80× depth. Somatic variants were called using the nf-gOS pipeline. The Rastair methylation framework was extended to incorporate strand-discordance logic and probabilistic CpG scoring to distinguish true variants from methylation-derived C>T transitions.

Results: Across six matched FFPE tumors, Heidelberg classifier confidence improved after applying our CpG-probability and strand-discordance model, increasing from a mean of 0.20 to 0.81, with all samples gaining 0.50-0.79 and low-confidence calls converted to high-confidence predictions. CpG methylation sensitivity improved from 0.78 to 0.99 while maintaining high specificity (0.998→0.991), enabling accurate discrimination of methylation-derived artifacts from true variants. In CSF-derived ctDNA, excluding 11 QC failures, TAPS+ detected ≥1 tissue-confirmed variant in 43 of 67 evaluable samples (64%), while 24 (36%) were ctDNA-negative despite adequate coverage. TAPS+ also recovered canonical CNS tumor drivers across tissue and CSF, including 1p/19q codeletion, trisomy 7, chromosome 10 loss, EGFR and MET amplification in GBM, ERBB2 amplification, IDH pathway mutations, MN1::CXXC5 and EGFRvIII fusions, and MGMT promoter methylation concordant with array-based calls.

Conclusions: TAPS+ enables accurate, bisulfite-free profiling of methylation and somatic alterations from low-input and degraded DNA. Improved classifier performance in FFPE tumors and reliable variant recovery in CSF support TAPS+ as a unified genomic-epigenomic assay.

#0103 A multiomic ensemble-based approach for high-specificity detection of clonal hematopoiesis in cfDNA liquid biopsy.

Patrick C. Fiaux, Mingyang Cai, Jeffrey L. Werbin, Andrew Gross, Che-Yu Lee, Marisa Juntilla, Tingtin Jiang, Reagan Barnett, Errin Lagow, Shile Zhang, Martina Lefterova, Darya Chudova

Guardant Health, Palo Alto, CA

Introduction: Variants arising from clonal hematopoiesis (CH, or CHIP) can be misclassified as tumor-derived in liquid biopsy, and are a challenge especially in expanded gene panels. Sequencing both buffy coat and plasma samples can help adjudicate CH but is costly and limited by the sensitivity of buffy coat sequencing at low allele fractions and its inability to capture somatic variants of non-tumor and non-peripheral blood origin. To address this we developed a high-specificity plasma-only CH classifier for late-stage cancer patients and applied it to clinical data for insights into CH prevalence and potential clinical impact.
Methods: This multiomic classifier categorizes non-germline variants as CH- or tumor-derived and is an ensemble model leveraging fragmentomics, methylation tumor fraction (mTF), variant allele frequency (VAF) and variant- and sample-level metadata from over 250,000 Guardant Health samples and public data bases (GnomAD, COSMIC). A total of 1033 samples consisting of paired buffy coat and plasma (N=686) or paired tissue-plasma (N=305) from patients with cancer, and samples from cancer-free individuals (N=42) were used for training and testing, reflecting the age (median: 65) and cancer type distribution of the intended use population. Population-level CH characteristics were evaluated in 30,000 late-stage cancer samples (median age: 67).
Results: Feasibility results of 185 testing samples showed panel-wide sensitivity and specificity over 90% in genes with recurrent CH variants (N≥6). In nearly 30,000 late-stage cancer samples, CH variant rates were elevated in prostate cancer relative to other cancer types. Somatic variant counts increased with rising mTF, whereas CH variant counts remained relatively stable. In samples with mTF of 1% or higher, our approach revealed that for 16.9% of samples the maximum variant allele frequency (VAF) corresponded to a CH variant. Finally, we recapitulated previously reported findings that lymphoid-associated CH variants increase less rapidly with age compared to myeloid-associated CH variants.
Conclusion: We present a plasma-only CH classifier, applied on cancer patients run on the Guardant360 Liquid test (GuardantHealth, Palo Alto, CA). Feasibility data shows panel-wide sensitivity and specificity above 90%, enabling population-scale characterization of CH. Notably, in almost 17% of samples with mTF of 1% or greater the lead variant was determined to be non-tumor-derived, highlighting that this approach allows for disambiguation of CH variants that contribute to total VAF in cfDNA (maxMAF).

#0104 A machine learning approach to predict and mitigate artifact variants for molecular residual disease detection.

Violeta B. Guthrie, Aamir Shahpurwalla, Daryanaz Dargahi, Onur Sakarya, Spenser Alexander, Tina Wang, Fei Lu, Alexander Hsieh, Ryan Ptashkin, Matthew Rabinowitz, Eser Kirkizlar, Ahmet Zehir

Natera, Inc., Austin, TX

Tumor-informed molecular residual disease (MRD) detection requires removal of artifacts from tissue whole-genome sequencing (WGS), which can cause false positive calls in plasma, even in healthy donors (HDs). To address this, we developed a machine-learning framework to score the reliability of tissue variants, thereby improving the specificity and sensitivity of tissue-informed MRD detection. We used retrospective WGS data from 47 tumor and matched normal (T&MN) samples across a diverse set of cancer types. Somatic single nucleotide variants (SNV) were identified via a consensus calling strategy from multiple variant callers. We extracted variant features from each caller relating to signal amount and quality, and subsequently engineered additional features to qualify strand bias, variant- and locus-specific characteristics. To generate training labels, SNV were evaluated in matched patient plasma and 107 HD plasmas. Variants with high mean VAF across the HD plasma samples were labeled as likely artifacts (~16k), while those with high VAF in the matched patient plasma were labeled as true tumor variants (~187k). An extremely randomized trees model was then trained using 17 informative, uncorrelated features. Model performance was measured by calculating the area under the curve (AUC) from a receiver operating characteristic (ROC) analysis. Our model distinguished true tumor variants from likely artifacts with a cross-validated ROC AUC of 0.94 and an average precision of 0.99. Key predictive features from the tissue included tumor VAF, mutant allele count, and a read orientation quality metric. In each patient, the model-derived confidence score demonstrated a strong and negative correlation with the mean VAF in the HD plasma samples (median Spearman $\rho = -0.30$), outperforming a previous method (median $\rho = -0.17$). This work provides a data-driven framework that systematically ranks and filters tissue variants by their likelihood of being artifacts. By enhancing the reliability of mutation calls from the tissue sample, this method can improve the accuracy of tissue-informed MRD detection.

#0105 Quantification of circulating tumor DNA (ctDNA) in patients using cancer-specific, methylation-based, tissue-free tests for the detection of molecular residual disease (MRD).

Princy Parsana, Tzu-Chun Chen, Nathan Liang, Amanda Kennedy, Veronica Rodriguez, Jie Zhang, Boris Gutman, Ehsan Haghshenas, **Garima Kushwaha**, Breeana L. Mitchell, Minetta Liu, Ehsan Tabari, Joshua Babiarz, Trupti Kawli, Johannes G. Reiter, Matthew Rabinowitz, Alexey Aleshin

Natera, Inc., Austin, TX

While MRD detection by differential methylation patterns has been shown to predict disease recurrence, clinical decision-making and disease management are increasingly dependent on the exact level of the measured biomarker. We assessed quantitative results by methylation-based MRD assays designed for colorectal (CRC), breast, lung, and muscle-invasive bladder cancer (MIBC). Each cancer-specific, methylation-based, tissue-free ctDNA assay uses next-generation sequencing to query regions of the human genome that are differentially methylated in patients with colorectal, breast, lung, or MIBC cancer compared to cancer-free individuals. Plasma samples from Signatera-tested cancer patients with stage I-IV disease (CRC N=105, breast N=112, lung N=113, MIBC N=60) and from cancer-free individuals (N=223, sex-matched for breast cancer) were analyzed in a cross-validation setup. We compared ctDNA levels measured by the methylation-based assay (estimated by the fraction of differentially methylated alleles for circulating cell-free DNA targets across regions, DMAF) with those from a bespoke, tumor-informed ctDNA assay (SignateraTM, measured as variant allele fraction, VAF), which served as the reference, by calculating the mean squared error (MSE) and Pearson's Correlation Coefficient (ρ). For each comparison of the cancer-specific, tissue-free, methylation-based assay with the personalized tumor-informed assay, DMAF and VAF were strongly correlated for patients with CRC (VAF median [range]: 1.43% [0.003-8.26%], MSE: 0.064, ρ: 0.955), breast cancer (VAF median [range]: 1.08% [0.002-7.80%], MSE: 0.161, ρ: 0.863), lung cancer (VAF median [range]: 0.93% [0.005-12.9%], MSE: 0.179, ρ: 0.829), and MIBC (VAF median [range]: 2.33% [0.005-9.26%], MSE: 0.079, ρ: 0.954). Among patients with breast cancer, the correlation between DMAF and VAF was maintained across subtypes, including HR+ (MSE: 0.132, ρ: 0.888), HER2+ (MSE: 0.272, ρ: 0.815), and triple-negative (MSE: 0.109, ρ: 0.897). Similarly, the correlation between DMAF and VAF was strong across lung cancer subtypes, non-small cell lung cancer (MSE: 0.207, ρ: 0.802) and small cell lung cancer (MSE: 0.069, ρ: 0.941). For all cancer-specific, tissue-free, methylation-based assays, DMAF levels were independent of patient characteristics such as sex (excluding breast), age, and stage (I-III), as well as cell-free DNA input. These data demonstrate that the abundance of differential methylation in patients with CRC, breast, lung, or MIBC cancer correlates with tumor-informed ctDNA levels, supporting each tissue-free methylation-based assay as a promising tool for informing prognosis and patient management. Future studies will investigate the quantitative abilities of the tissue-free assay in different patients with specific clinicopathological features.

#0106 Integrated plasma multi-omics profiling identifies circulating predictive biomarkers and biological pathways associated with treatment response in NSCLC.

Laura Heeb[1], Polina Shichkova[2], Sandra Schar[2], Luca Rass[2], Arthur Viode[2], Martin Mehnert[2], Tobias Treiber[2], Esther Wortmann[3], Gordian Adam[3], Alice Limonciel[3], Markus Joerger[4], Jana Musilova[4], Stefanie Hayoz[4], Anurag Gupta[1], **Yuehan Feng**[2], Alessandra Curioni-Fontecedro[5]

[1]Faculty of Science and Medicine, University of Fribourg, Fribourg, Switzerland,[2]Biognosys AG, Schlieren, Switzerland,[3]Biocrates Life Sciences GmbH, Innsbruck, Austria,[4]Swiss Group for Clinical Cancer Research (SAKK), Bern, Switzerland,[5]Clinic of Oncology, HFR Hospital Fribourg, Fribourg, Switzerland

In non-small cell lung cancer (NSCLC), identifying circulating predictive biomarkers is critical to optimize patient selection and improve therapeutic outcomes. Plasma-based biomarkers offer a minimally invasive and serially accessible approach for monitoring treatment response; however, the low abundance of disease-relevant analytes within a background of highly abundant plasma proteins presents significant analytical challenges. Highly sensitive and reproducible multi-omics assays are therefore required to detect subtle but biologically relevant changes associated with therapy.

To address this, we implemented a plasma multi-omics workflow integrating unbiased mass spectrometry (P2 DIA-MS), the NULISA inflammation panel, and targeted metabolomics using the Biocrates MxP Quant 1000 kit. This workflow was applied to longitudinal plasma samples from patients with NSCLC enrolled in the multicenter phase II clinical trial SAKK 17/18. Parallel profiling quantified approximately 6,000 plasma proteins, 250 inflammation-related markers, and more than 1,200 metabolites and lipids, enabling cross-platform integration of proteomic, cytokine, and metabolic signatures.

For predictive biomarker discovery, we applied a machine learning framework to integrate proteomic, inflammatory, and metabolic data. Incorporation of multi-omics features improved the stratification of responders versus non-responders compared with single-omic models, underscoring the complementary nature of each dataset. To further investigate biological relationships among omics layers, we evaluated several data integration methods, including Multi-Omics Factor Analysis (MOFA), to identify shared sources of variation and linked biological pathways. This analysis revealed coordinated processes connecting plasma proteomic changes with inflammatory and metabolic networks. For example, immune activation signatures arising from the integration of unbiased proteomics with inflammation markers, and metabolic stress adaptation reflected in proteomic-metabolomic associations.

In conclusion, this plasma multi-omics approach demonstrates the potential of integrated proteomic, inflammatory, and metabolic profiling to identify predictive circulating biomarkers and to elucidate biological mechanisms of treatment response in NSCLC. The workflow provides a scalable and clinically applicable strategy for biomarker discovery and response monitoring in oncology.

#0107 An expanded negative prediction algorithm for actionable mutations utilizing genomic and epigenomic profiling in cfDNA.

Andrew M. Gross, Hao Wang, Brandy Freschi, Keelia Clemens, Marisa Juntilla, Martina Lefterova, Justin Odegaard, Darya Chudova

Guardant Health Laboratory, Redwood City, CA

Introduction: When using cell-free DNA (cfDNA) for comprehensive genomic profiling, it is important to differentiate between true biomarker-negative status and absence of the biomarker due to low tumor shed. This could inform whether treatment decisions can be made in the absence of tissue testing, potentially impacting time to treatment and cost of diagnostic workup. Here we expand our 'negative prediction' algorithm to eleven tumor types, leveraging both epigenomic and genomic signals to provide a posterior confidence of a sample being truly negative for specific clinically actionable biomarkers.

Methods: The algorithm utilizes population prevalence of specific alterations, locus-specific sequencing coverage, sample-level epigenomic tumor fraction, and sub-detection level genomic evidence to inform the estimate of an alteration and posterior probability for the absence of clonal, somatic FDA-approved biomarkers. Leveraging a clinical cohort of >80,000 cfDNA samples (Guardant360 Liquid, Guardant Health, Palo Alto, CA) across 11 tumor types, we compiled prior likelihood tables for actionable variants spanning diverse classes. This builds on the previous release on colorectal carcinoma and non-small lung cancer to include breast, prostate, pancreatic, bladder, endometrial, ovarian, gastric/gastroesophageal, cholangiocarcinoma, and melanoma tumor types. We expanded our probabilistic approach to model the likelihood of homozygous deletions, and refined our approach towards assessing microsatellite instability, fusions, and focal amplifications.

Results: Positivity rates for clinically actionable biomarkers varied across tumor types from 5% in pancreatic cancer to 47% in breast cancer. Among negative samples, at least 49% of samples were associated with either a biomarker-positive or a 'confident negative' status (confidence >90%). Variability in confidence of negative samples was associated with tumor shedding profiles, as well as biomarker prevalence and composition, with more complex variants, such as homozygous deletions and gene fusions, reducing confidence levels. As an initial accuracy assessment, we compiled a cohort of >350 subjects with matched tissue and plasma genotyping results, among which 81/84 (96%) of confident negative samples were confirmed as negative in tissue. Finally we assessed discordances between plasma and tissue, which highlighted clonal/resistance dynamics as the major source of discrepancies.

Conclusion: Here we demonstrate our ability to assess the confidence of biomarker negative samples across diverse cancer types. This helps address a known potential limitation for liquid biopsy and may be able to assist in therapy making decisions and accelerate time to treatment initiation, particularly in cases where tissue NGS is not available.

#0108 Fragmentomics powers improved classification of somatic mutations in liquid biopsy.

Mouses Stamboulian, Anton Valouev, Tingtin Jiang, Jamie Hutchins

Bioinformatics, Guardant Health, Palo Alto, CA

Introduction: Accurate discrimination between somatic and germline variants in cell-free DNA (cfDNA) is critical for precision oncology. Somatic variant calling in liquid biopsy can be challenging, particularly for variants with high mutant allele frequency (MAF) in high tumor fraction samples. We developed a fragmentomics-based machine learning model to improve somatic variant classification in liquid biopsy.

Methods: We benchmarked our model on 4,250 clinical samples from 3,313 unique patients processed on Guardant360 Liquid (Guardant Health, Palo Alto, CA), where variant germline status could be confidently derived from longitudinal data. Training data comprised 5,253 unique variants; independent test data included 11,612 variants. We engineered 55 fragmentomics features and multiple classifiers were evaluated; optimal performance was demonstrated with logistic regression with L2 penalty using fragment length and relative VAF features. We chose a cutoff threshold for classification scores to maintain less than 10% false positives by the model. The model was integrated as an additional correction step to re-evaluate variants classified as germline by a baseline calling algorithm.

Results: Starting with a truth set of 26,900 variants from 2,874 unique samples whose somatic or germline origin were known from longitudinal data, 22,687 had a truly somatic origin and 4,213 were germline. Our baseline calling algorithm assigned germline status to 770/22,678 somatic variants and likelihood of mis-assignment was associated with a high ctDNA tumor fraction. The fragmentome-assisted approach was able to 'rescue' 558 of the mis-assigned variants including 226 with direct clinical actionability. In terms of sensitivity (true somatic variant/true somatic variant+somatic variant called germline) and specificity (true germline variant/true germline variant+germline variant called somatic), our approach improved sensitivity compared to the baseline calling algorithm from 96.61% to 99.07%, while specificity decreased from 99.00% to 93.38%. Despite the drop in specificity, accuracy and F1 score increased by 1.18% and 0.76%, respectively. The logistic regression model demonstrated robustness across cancer types and varying fragment profiles, with the most predictive features being di-nucleosome fragment lengths and relative allele frequencies over fragments ranging between 180 to 220 bases.

Conclusions: Inclusion of model-based fragmentomics signals in a cfDNA germline-somatic discrimination caller significantly improves somatic variant detection sensitivity while maintaining high accuracy, enabling confident reporting of additional clinically actionable alterations. The boost in sensitivity at the expense of specificity is clinically acceptable given the intended use of the test for detection of targetable somatic alterations.

#0109 Integrative analyses of the cfDNA fragmentome and TCR repertoires capture chemo-immunotherapy response in diffuse pleural mesothelioma.

Jinny Huang[1], Jennifer Li[1], James R. White[1], Shashikant Koul[1], Gavin Pereira[1], Nisha Rao[1], Jennie Yao[1], Julie R. Brahmer[1], Robert B. Scharpf[1], Rachel Karchin[1], Victor E. Velculescu[1], Zhouxin Sun[2], Suresh S. Ramalingam[3], Patrick M. Forde[1], Noushin Niknafs[1], Valsamo (Elsa) K. Anagnostou[1]

[1]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Winship Cancer Institute of Emory University, Atlanta, GA

Background: Immunotherapy-containing therapies have shown promise for patients with unresectable diffuse pleural mesothelioma (DPM), yet there are no reliable strategies to monitor therapy response. By expanding the compendium of cancer-associated alterations profiled, including genome-wide fragmentation patterns, cell-free DNA (cfDNA) whole genome sequencing (WGS) enables tracking of tumor dynamics. In tandem, while understudied, T cell clone dynamics may be informative in capturing early immunotherapy response.

Methods: Using 314 tumor and peripheral blood biospecimes, we analyzed serial plasma cfDNA samples (n=135) from 55 patients with unresectable DPM, who received durvalumab with platinum-based chemotherapy (NCT02899195). Following cfDNA extraction and genomic library preparation, cfDNA at baseline (C1D1), Cycle 2 Day 1 (C2D1), and Cycle 5 Day 1 (C5D1) underwent low-coverage (1-2x) whole genome sequencing. Tumor- and mutation-naive estimates of tumor fraction were derived by applying the DELFI tumor score (DELFI-TS) model, which integrates genome-wide fragmentation patterns and chromosomal arm aneuploidy. In parallel, we performed TCR Vβ CDR3 next-generation sequencing on tumor (n=43) and peripheral serial blood (n=136) samples. The TCR repertoire was characterized using clonality, TCR clonotype/cluster dynamics, and the Morisita-Horn similarity index to assess repertoire similarity across samples. Clinical outcomes were assessed by radiographic response, progression-free (PFS), and overall survival (OS).

Results: Patients with distant metastasis (M1) had higher DELFI-TS levels (p=0.038). At baseline, DELFI-TS levels were numerically higher for radiographic non-responders (SD/PD) vs responders (CR/PR). Using the 92th percentile of DELFI-TS in non-cancer cfDNA control samples to determine the limit of blank, patients with detectable baseline DELFI-TS (ctDNA^{+}) had shorter PFS and OS (log-rank p<0.001). Patients that attained a radiographic response had more clonal peripheral TCR repertoires at both baseline and on-therapy timepoints compared to non-responders (p=0.037 at C1D1; p=0.007 at C2D1; p=0.042 at C5D1). Morisita-Horn similarity between C1D1 and on-therapy was lower in non-responders than responders (p=0.019 for C1D1 vs C2D1; p=0.036 for C1D1 vs C5D1). In contrast, a more diverse intra-tumoral TCR repertoire was noted for patients with an OS of 12 or more months (p=0.018).

Conclusions: Our findings provide proof-of-concept that cfDNA fragmentomic analyses can quantify pre-treatment cfDNA tumor fraction that may capture clinical outcomes with chemo-immunotherapy response for patients with DPM. Longitudinal analyses of peripheral TCR
repertoires can further differentiate responding from non-responding DPM, supporting the notion that joint analyses may more accurately capture immunotherapy response.

#0110 Clinical utility of landmark ctDNA molecular response as an early indicator of immunotherapy outcomes in lung cancer.

Jaime Wehr[1], Noushin Niknafs[1], Lavanya Sivapalan[1], Archana Balan[1], Gavin Pereira[1], Samira Hosseini-Nami[1], Iiasha Beadles[1], Aliyah Pabani[1], Kristen Marrone[1], Qing K. Li[1], Joseph Christopher Murray[1], Mark Sausen[2], Bryan Chesnick[3], Lorenzo Rinaldi[3], Christine L. Hann[1], Susan Combs Scott[1], Josephine Feliciano[1], Vincent K. Lam[1], Benjamin Levy[1], Patrick M. Forde[1], Julie R. Brahmer[1], Valsamo (Elsa) Anagnostou[1]

[1]Johns Hopkins University, Baltimore, MD,[2]LabCorp, Baltimore, MD,[3]Delfi Diagnostics, Inc., Baltimore, MD

Background: Circulating tumor DNA (ctDNA) analyses are informative as an early indicator of immunotherapy response in advanced non-small cell lung cancer (NSCLC), however the clinical role of ctDNA molecular response requires further validation.
Methods: As part of a prospective clinical protocol (NCT05995821), we performed ctDNA (n=328) and matched white blood cell DNA (WBC; n=109) targeted 521 fixed gene panel next-generation sequencing (Elio Plasma Complete) from 109 patients with advanced/metastatic NSCLC who received anti-PD-(L)1 as monotherapy or in combination with chemotherapy. Following variant cellular origin resolution, landmark molecular response (mR) was defined as undetectable ctDNA within 3-9 weeks of treatment initiation. For a subset of patients (n=34), whole-exome sequencing of baseline tumors was performed and used in benchmarking ctDNA detection and therapy response assessment.
Results: Among 2,818 plasma variants, 23% were clonal haematopoiesis-related, which confounded the interpretation of driver gene associations with clinical outcomes and assessment of molecular responses. Implementing a tumor-naïve WBC DNA-informed approach increased the number of evaluable cases while maintaining the overall accuracy of landmark ctDNA molecular responses. Pre-treatment ctDNA burden but not blood tumor mutation burden, predicted survival. Overall, 77 patients were evaluable for landmark molecular response assessment; of these, 29 patients (38%) attained a mR. Landmark evaluation of molecular response enabled evaluation of all cases, was highly specific (92%), and achieved a higher sensitivity (66%) compared to clearance or ctDNA reduction from baseline (sensitivity 59%). In predicting landmark progression-free survival (PFS) at 6 months (durable clinical benefit, DCB), the tumor-agnostic WBC-informed approach strikes a balance between sensitivity (71.4%) and specificity (100%) compared to plasma-only (sensitivity=14.3%, specificity=100%) or tumor-informed (sensitivity=78.6%, specificity=71.4%) approaches. A significant enrichment in landmark ctDNA mR was noted among patients with DCB with immunotherapy (p=2.5e-05) and chemo-immunotherapy (p=0.02). Patients in the landmark mR group attained longer PFS (p=1.6e-06) and overall survival (p=2.5e-05) compared to those with molecular progression. The association between landmark molecular response and survival remained significant (PFS and OS, $P < 0.001$) after accounting for clinical covariates, line of therapy, and baseline ctDNA levels.
Conclusions: Our findings indicate that landmark ctDNA molecular response at 3-9 weeks on treatment provides a real-time and accurate approach for monitoring immunotherapy clinical outcomes. Although not currently validated for regulatory use, these findings demonstrate the potential utility of ctDNA as an early endpoint in clinical trials.

#0111 Integrated, base-resolution profiling of genetic and epigenetic signatures in cell-free DNA.

Xingyu Yang, Jing Su, Chen Yang, Xiaoling Li, Si Zhang, Xianrong Chen, **Zhihong Zhang**, Bingsi Li

Research and Development, Burning Rock Biotech, Shanghai, China

Background: Epigenetic and genetic alterations synergistically drive cancer initiation and progression, yet one blood draw rarely yields enough cell-free DNA (cfDNA) to profile both modalities. Current co-detection strategies either demand high tumor burden or custom chemistry and cannot be retro-applied to existing datasets. We present MMcall, a computational tool that reconstructs the original four-base genome from conventional bisulfite-sequencing reads and simultaneously detects mutations and methylation variants without new benchwork, delivering fully integrated genomic/epigenomic signatures from one single library.
Methods: MMcall reconstructs the original four-base genome from standard bisulfite-converted reads by jointly modeling complementary top- and bottom-strand base counts. Because the G nucleotide on the strand opposing a C is unaffected by bisulfite conversion, the strand-specificity principle is used to restore pre-conversion sequence. A machine-learning error-suppression module is then applied to suppress the high technical noise inherent to bisulfite treatment. The algorithm simultaneously outputs methylation-variant allele frequency (MVAF) and somatic-variant allele frequency (SVAF) from the same library, enabling epigenetic and genetic profiling without additional wet-lab steps.
Results: Benchmarked against 0 -1% tumor-fraction serial dilutions of Seraseq® ctDNA Reference Material and an in-house standard (OverC Monitor panel; 1000X methylation depth, 20000X mutation depth), MMcall demonstrated near-perfect concordance with expected methylation levels (R^2>0.99) and detected mutations down to 0.25%. At 0.5-1% VAF, SVAF measurements by MMcall closely matched those obtained by ultra-deep sequencing (HS-UMI, 35000X), yielding > 99.7% NPA (95% CI: 99.3-99.9%) and > 86.9 % PPA (95 % CI: 77.8-93.3%). No false-positive calls were observed across predefined hotspot loci in any negative control, confirming robust suppression of technical noise.
Conclusion: MMcall jointly calls mutations and methylation variants at single-base resolution without additional bench steps. The method offers a cost-effective route to richer molecular information for early cancer detection and minimal residual disease monitoring.

#0112 Analytical performance of an enhanced variant (EV) pipeline for improved circulating tumor DNA (ctDNA) detection in samples with low tumor burden.

Dina Hafez, Bin Dong, Aamir Shahpurwalla, Bharat Sridhar, Alexander Hsieh, Jordan Feeney, Vu Ngo, Noura Tbeileh, Alexey Aleshin, Matthew Rabinowitz, Himanshu Sethi, Chenlu Hou, Ryan Ptashkin, Eser Kirkizlar, Ahmet Zehir

Natera, Inc., Austin, TX

EVs represent a distinct class of genomic events, offering opportunities in cancer diagnostics. Tumor-informed ctDNA detection, a sensitive and specific approach for monitoring molecular residual disease (MRD) in plasma, continues to evolve with the discovery of novel biomarkers. Developing methodologies for unbiased EV detection could enhance assay performance. Here, we report on the performance of a novel EV caller. EV caller performance was evaluated using 2 cancer cell lines and their matched normal cell lines. EV truth sets were established based on the pure cell lines (100%; no dilution). Contrived genomic DNA samples were prepared to emulate 3 different tumor purity levels relative to normal (50%, 25%, 10%) and analyzed using whole genome sequencing. The results from the titrations were compared to the 100% tumor cell line (“truth set”) to estimate the EV caller’s performance. Finally, to assess the performance of the EV caller in detecting ctDNA, a custom cfDNA-based mPCR primer design strategy was developed and applied to EVs in a tumor:normal cell line dilution series (range, 1:500 - 1:200,000), with 2-5 replicates for each condition. Each cancer cell line had approximately 700 EVs detected. Across all emulated tumor purity levels, the EV caller demonstrated a positive predictive value (PPV) of 90-95% at 5-10% variant allele frequency (VAF) and >99% PPV at >10% VAF. A positive percent agreement of >95% at >10% VAF was observed. For cell line ctDNA titrations, the EV caller showed target-level detection down to 0.0006% VAF. The target-level specificity was 99.99%. At the sample level, EVs were detected at the lowest tested dilution level (1:200,000). These analytical results demonstrate the exceptional performance of the EV caller algorithm to detect targets with high precision and specificity. EVs represent promising biomarkers that could enhance ctDNA assay sensitivity and specificity, particularly in samples with low tumor burden.

#0113 Assessment of sequencing error rates in healthy plasma samples across two whole genome sequencing platforms.

Aamir Shahpurwalla, Zach Montague, Fei Lu, Spenser Alexander, Garima Goyal, Dina Hafez, Matthew Rabinowitz, Eser Kirkizlar, Ahmet Zehir

Natera, Inc., Austin, TX

Accurate detection of error signals in healthy samples is critical for improving assay specificity and sensitivity in ctDNA analysis. Sequencing artifacts and biological noise, arising from PCR, oxidative damage, or clonal hematopoiesis variants, can obscure low-frequency tumor somatic mutations. This study aims to systematically characterize error profiles in healthy plasma samples and develop context-aware filtering and models to distinguish true variants from background noise. Whole-genome sequencing data were generated from 80 healthy plasma samples (pWGS) using two sequencing platforms (sequencer A: N=52; sequencer B: N=28). Mutation-specific features were computed across sequencing fragments using a custom pWGS analysis module that incorporated information both at the fragment- and the position-level. We compared a probabilistic classifier (Model 1) and an advanced deep learning based model (Model 2) trained on the same feature set, incorporating features that we identified as key predictors of sequencing error. Error rates within the plasma samples were quantified at genomic positions corresponding to tumor mutation target sets identified from 26 tissue samples (breast N=4, lung N=5, ovarian N=10, N=7 bladder). Using sequencing platform A, error rates showed strong dependence on fragment-level and sequence-context features. Error rates were not evenly distributed among variant types. Error rates were elevated near fragment ends and within GC-rich regions (>55% GC). Median raw error rates across cancer indications ranged from 19 to 59 parts per million (ppm). Application of Model 1 reduced background error rates by up to 65%, while Model 2 achieved up to a 90% reduction, with minimum error rates approaching ~5 ppm. Sequencing data from platform B that were processed with a base quality > 50 filter achieved comparable coverage (~65×) and similar error rates (~5 ppm). Across both sequencing platforms, further reductions are possible by incorporating additional fragment-level features and leveraging more advanced modeling approaches. This work establishes a foundational framework for pWGS error characterization and demonstrates the effectiveness of fragment- and context-based modeling in reducing sequencing noise.

#0114 Unraveling tumor- and tissue-specific gene expression patterns from plasma-derived cfRNA.

Maria Savchenko, Tatiana Nemchaninova, Alexey Dudakov, Aleksandr Serdiukov, Daria Shafranskaya, Artemiy Nikitin, Anastasia Tarabarova, Desiree Schenk, Alexandr Zaitsev, Anastasia Yudina, **Michael F. Goldberg**, Alexander Bagaev

BostonGene Corporation, Waltham, MA

Minimally invasive plasma-derived cell-free RNA (cfRNA) profiling captures blood-derived clinical markers when white blood cells (WBCs) are unavailable, harboring potential for molecular diagnostics and disease monitoring. Our study explored cfRNA analysis as a promising method for deconvolving signals from tumors and various tissues from a single blood draw, expanding its utility to include functional genomics that reveals gene expression patterns and their impact on disease status.

Plasma cfRNA was obtained from 207 healthy donors and 214 cancer patients. For comparison, 96 paired tumor whole exome sequencing (WES) and 208 paired WBC RNA-seq samples were used. Gene expression was quantified using pseudo-alignment with *Kallisto* and signature scores were computed by single-sample gene set enrichment analysis. Statistical significance was assessed with the Mann-Whitney *U* test. Somatic single nucleotide variants (SNVs) identified by tumor WES were cross-checked for detection in matched plasma cfRNA.

Extracellular matrix organization, cell proliferation, and T- and B-cell recruitment signatures were significantly elevated in cfRNA compared with WBCs (p values 1.1×10^{-55}, 3.8×10^{-63}, and 2.8×10^{-62}, respectively). These cfRNA (but not WBC) signatures effectively distinguished cancer patients from healthy donors (p value 6.5×10^{-11}, 1.1×10^{-4}, and 2.3×10^{-5}, respectively). The epithelial signature was enriched in carcinoma cfRNA, with higher scores corresponding to larger numbers of metastatic sites (p value 1.5×10^{-7}). Conversely, this score remained low in sarcomas originating from non-epithelial tissues.

SNVs identified by tumor WES were detected in cfRNA in 20/29 (68.9%) of breast, 8/14 (57.1%) of colorectal, 7/13 (53.8%) of lung, and 5/11 (45.4%) of pancreatic cancer cases. The number of variants detected per patient trended positively with cancer stage. In colorectal cancer, samples with detected variants had higher epithelial and colon tissue signature scores, which aligns with reported cfDNA shedding levels for the diagnosis . Fisher's exact test showed the cfRNA-tumor variant overlap to occur significantly more often (p-value = 9×10^{-129}) in matched pairs than in random sample comparisons, indicative of the reliability of our approach for detecting tumor-related signals.

This proof-of-concept study shows that cfRNA harbors tumor- and tissue-specific expression patterns that complement blood cell-based RNA-seq, providing additional biological and clinical information. Our framework integrates genomic and transcriptomic data to deconvolve tumor-related and systemic tissue signals from plasma, supporting cfRNA signatures as a clinically relevant resource for patient stratification, discovery of novel drug targets and plasma-based biomarkers, and disease progression and treatment response monitoring, with prospects for better trial design and treatment optimization.

#0116 Comprehensive ctDNA profiling reveals molecular and prognostic landscapes in Korean pan-cancer patients.

Jiwon Kim[1], Kyong Hwa Park[2], Soohyeon Lee[2], Jwa Hoon Kim[2], Ju Won Kim[2], Ji Won Lee[2], Ji Yoon Lee[1], You Jin Song[1], Dayoung Lee[1], Hyeonmin Jeong[1], Wooseok Lee[1], Yoon Ji Choi[2], Jason K. Sa[1]

[1]Korea University, Seoul, Korea, Republic of,[2]Korea Univ. Medical Center, Seoul, Korea, Republic of

Liquid biopsy offers a non-invasive approach for capturing essential molecular profiles to make informed decisions within a clinical framework. However, large-scale, population-specific studies evaluating its clinical utility remain scarce. To address this unmet need, we established a Korean advanced pan-cancer circulating tumor DNA (ctDNA) atlas and systematically evaluated its clinical feasibility. We also assessed concordance with tissue-based sequencing, explored East Asian-specific molecular disparities, and quantified the prognostic impact of genomic alterations using a newly developed prognostic framework. We analyzed 1,243 ctDNA samples across 17 tumor types, integrating genomic alterations with long-term clinical follow-up. Somatic mutations were identified and clinically interpreted using the OncoKB database, and compared with the MSK-ACCESS cohort to identify population-level genomic differences. To quantify the degree of prognostic significance, we developed the Molecular-Prognostic Index (MPI), a unified metric capturing the magnitude and significance of survival effects for individual genomic alterations at both pan-cancer and individual tumor levels. Using this framework, we identified key alterations and pathways shaping patient survival and therapeutic sensitivities. East Asian cancer patients demonstrated distinctive mutational profiles compared with MSK-ACCESS, including a higher prevalence of *MTOR*, and *FGFR3* mutations in NSCLC and enriched *BRCA2* alteration in breast cancer. Comparison with tissue-based sequencing revealed higher *TP53* mutations detected in tissue, whereas clinically actionable *ESR1* E380Q and Y537S (OncoKB Level 1), were more prevalent in ctDNA. Pathway-level enrichment analysis exhibited strong concordance between tissue and ctDNA profiles in intestinal and prostate cancers, but marked discrepancies in lung and breast cancers, underscoring tumor type-specific biological and shedding differences. Across multiple tumor types, increased tumor mutation burden (>= 3) was significantly associated with poor clinical outcomes. *BRAF* V600E predicted an unfavorable prognosis in patients diagnosed with NSCLC and colorectal cancer. MPI analysis further identified *PIK3R1* alterations as high-risk predictors in breast cancer and *TP53* Y220C as a poor prognostic marker in prostate cancer, while *NOTCH1* mutations emerged as a favorable biomarker in intestinal tumors. This large-scale ctDNA-based analysis in parallel with long-term clinical follow-up of East Asian solid tumors provides a comprehensive reference for understanding tumor propagation and therapeutic vulnerabilities. We demonstrated that ctDNA recapitulates key tumor characteristics and reveals prognostic insights. The newly developed MPI framework stratifies patient risk based on ctDNA features, and supports liquid biopsy for precision oncology.

#0117 Single-cell transcriptomic and CNV profiling reveal distinct circulating tumor cell signatures in pancreatic ductal adenocarcinoma.

Se-Eun Choi[1], **Jihyun Lee**[2], Hyunjung Kee[3], Moon Jae Chung[4], Jungwon Kim[2], Semin Lee[1]

[1]Department of Biomedical Engineering, Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of,[2]CytoGen, Inc., Seoul, Korea, Republic of,[3]Institute of Gastroenterology Research, Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive malignancy with poor prognosis and limited early detection methods. Circulating tumor cells (CTCs) provide a minimally invasive opportunity to investigate tumor heterogeneity and disease progression, yet their reliable identification among peripheral blood cells remains challenging. In this study, peripheral blood samples were collected from PDAC patients and healthy controls. CTCs were enriched using CytoGen's Smart Biopsy™ Platform, and the CTC-enriched fractions were analyzed using single-cell RNA sequencing (Cell Ranger 8.0.1). Low-quality and doublet cells were filtered (nFeature_RNA > 500, percent.mt < 10, doublet score < 0.25). Dimensional reduction and clustering (resolution 0.8) enabled cell type annotation, and copy number variation (CNV) profiles were inferred at the subcluster level (k=5) to assess potential malignant characteristics. Consequently, Distinct cell clusters exhibiting PDAC-associated transcriptional signatures were identified. CNV pattern analyses revealed that certain clusters displayed genomic variability distinct from typical immune and blood cell populations. Comparison with TCGA-PAAD reference data indicated partial resemblance to tumor-like CNV profiles. Moreover, CNV-based stratification tended to distinguish PDAC-derived CTC-enriched clusters from those observed in healthy blood, suggesting potential diagnostic utility. Overall, these integrative single-cell transcriptomic and CNV analyses provide valuable insights into CTC heterogeneity in PDAC and suggest that CNV-informed profiling may enhance the identification of putative CTC populations and facilitate future biomarker development for liquid biopsy-based cancer monitoring.

#0118 Detecting early cancer using cfDNA methylation signatures with nanopore sequencing.

Yi Yang Hou[1], Nicholas Cheng[1], Jared T. Simpson[2], Philip Awadalla[3]

[1]Molecular Genetics, University of Toronto, Toronto, ON, Canada,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]Oxford University, Oxford, United Kingdom

Early cancer screening improves survival by enabling timely treatment before the disease progresses. However, current population-wide screening tools are limited to a few cancer types, highlighting the need for novel detection methods that can be routinely used to detect multiple cancers. Plasma tumour-derived cell-free DNA (cfDNA) carries the tumour's genetic and epigenetic alterations and can be used to develop new screening methods. Here, we aim to identify precancerous and early tumour-associated cfDNA methylation signatures. We analyzed nanopore sequencing data performed on plasma collected up to 10 years before clinical diagnosis from patients with breast or prostate cancer, and stage II diagnostic plasma from breast cancer patients. Preliminary data revealed global hypomethylation and increased inter-patient variability in the diagnostics breast cancer samples, both of which were more pronounced in younger patients. Notably, global hypomethylation was found in Triple Negative Breast Cancer (TNBC) and ER+/HER2- Breast Cancer, but not in other subtypes. These global alterations were not observed in precancerous lesions in both cancer types, suggesting such epigenetic alterations may arise or become detectable during malignant transformation rather than early tumour initiation. To identify loci that are associated with precancerous epigenetic alterations, differentially methylated regions (DMRs) were selected across different functional elements in the genome. Using these DMRs, an ensemble random forest model was built in the discovery cohort (pre-breast: n = 33; pre-prostate: n = 35) for each cancer type. The trained model showed moderate discriminability for both breast (AUC = 0.76, pre-breast: n = 12; stage II breast: n = 12) and prostate (AUC = 0.83, n = 5) cancer in the validation set, and both models performed better in the older age group. In addition, promoter methylation signatures are also capable of stratifying patients into high-risk and low-risk of developing breast cancer. Pathway enrichment analysis will be performed to investigate the oncogenic relevance of selected features. Success in this project will define how early cancer can be detected through liquid biopsy and advance the timeline of early detection. This project has the potential to develop a single blood test for multi-cancer detection and monitoring.

#0119 A lightweight self-supervised deep learning framework for automated detection of circulating tumor cells and cancer-associated fibroblasts.

Hyeongjung Woo[1], Seonghwan Park[2], Jungmin Lee[3], Inkyu Moon[2], Minseok S. Kim[1]

[1]Department of New Biology, Daegu Gyeongbuk Institute of Science and Technology (DGIST), Daegu, Korea, Republic of,[2]Department of Robotics & Mechatronics Engineering, Daegu Gyeongbuk Institute of Science and Technology (DGIST), Daegu, Korea, Republic of,[3]CTCELLS Inc., Seoul, Korea, Republic of

Circulating rare cells (CRCs), including circulating tumor cells (CTCs) and circulating cancer-associated fibroblasts (cCAFs), serve as valuable liquid biopsy biomarkers, yet their detection remains challenging due to extreme rarity and morphological heterogeneity. Current identification methods predominantly rely on fluorescence-based imaging and manual, time-consuming assessments by trained experts, which limit high-throughput analysis, reproducibility, and clinical implementation. Moreover, the strong dependence on subjective visual judgment makes CRC calling highly operator-dependent, introducing substantial inter- and intra-observer variability and complicating assay standardization across centers. To overcome these constraints, we developed a self-supervised deep learning framework that enables robust and interpretable detection of CRCs using minimal labeled data and with reduced dependence on fluorescence signals. Our approach employs a two-stage training strategy in which a model is first pretrained on large-scale white blood cell (WBC) datasets using contrastive learning, allowing it to learn generalizable morphological representations from abundant, morphologically similar cells. In the next step, knowledge distillation is used to transfer this learned knowledge into a lightweight student model that is subsequently fine-tuned on limited CRC data. This distillation process significantly reduces model complexity while preserving detection accuracy, thereby enabling real-time inference that is suitable for clinical workflows. In our experiments using samples from 27 patients with early-stage breast cancer, conventional fluorescence-based analyses manually identified both CTCs and cCAFs. When applied to the same dataset, the proposed framework achieved CRC detection sensitivity and specificity exceeding 90% while operating with minimal computational burden and showed high concordance with manual expert assessment. Compared with conventional fluorescence-based manual annotation, our approach offers substantial gains in speed, consistency, and scalability, while eliminating inter-observer variability inherent to expert-dependent assessments. These results suggest that self-supervised representation learning combined with knowledge distillation provides a practical and clinically viable strategy for automated CRC detection, with potential applications in early cancer diagnosis, longitudinal disease monitoring, and treatment response assessment.

#0120 Two integrative molecular subtypes of hepatocellular carcinoma with predictive therapeutic potential: Toward liquid biopsy-guided precision medicine.

Jiyon Lyu[1], **Woo Young Kwon**[2], Sung Hwan Lee[3]

[1]CHA University School of Medicine, Pocheon, Korea, Republic of,[2]CHA Bundang Medical Center, CHA Universit, Seongnam, Korea, Republic of,[3]Department of Surgery, CHA Bundang Medical Center, Seongnam, Korea, Republic of

Hepatocellular carcinoma (HCC) is the third leading cause of cancer mortality worldwide, with a variety of therapeutic options in the advanced stage. Although immune checkpoint inhibitors (ICIs) and targeted therapies have transformed treatment paradigms, clinical decision-making regarding first-line therapy and subsequent lines remains challenging. Existing molecular classifications provide biological insights but often lack direct clinical translation. We aimed to identify robust, reproducible molecular subtypes of HCC that not only reflect tumor biology but also predict differential therapeutic responses, thereby advancing the potential for liquid biopsy-guided precision medicine.

Transcriptomic data from the CCLE served as a discovery set and were validated with six cohorts, including TCGA. We identified two distinct molecular subtypes—METabolic and Immune—from the HCC cell line transcriptome using non-negative matrix factorization (NMF) at the REACTOME pathway level. Subtype-specific features were characterized by drug sensitivity, signaling pathway, cross-omics integration, and tumor microenvironment (TME) analyses. Therapeutic benefits from current first lines were validated across IMbrave150 and BIOSTORM. Serum proteomic and somatic mutation data from 35 patients were analyzed to identify predictive biomarkers.

The METabolic subtype was characterized by elevated MET expression and enrichment of signaling pathways associated with cell survival, growth, and differentiation. In contrast, the Immune subtype exhibited prominent immune infiltration—particularly macrophages/monocytes, regulatory T cells, and $CD8^+$ T cells—along with activation of PD-1/CTLA-4 pathways and poorer overall survival (OS). In the IMbrave150 cohort, the Immune subtype showed superior survival outcomes to atezolizumab-bevacizumab ($p < 0.0001$). Conversely, the METabolic subtype was associated with 100% recurrence after sorafenib treatment, suggesting potential benefit from MET inhibitors after sorafenib failure. A machine learning model using mutations and serum biomarkers (myoglobin, IL-6R beta, *TP53*, *CTNNB1*) achieved robust performance (AUC = 0.88; accuracy = 87.1%) for subtype prediction.

This study establishes clinically relevant HCC subtypes associated with distinct responses to currently recommended therapies and proposes a liquid biopsy-based approach using four predictive biomarkers. We provide rationale for the early use of MET inhibitors such as cabozantinib in the first-line setting, given its potential resistance to both sorafenib and ICI-based therapies. Additionally, our study suggests the Immune subtype is an optimal candidate for immunotherapy combined with anti-VEGF(R) agents. Further validation in larger, prospective cohorts is warranted to translate these findings into clinical practice.

#0121 Single stranded ligation enhances the performance of the duet evoC 6-base assay, enhancing value in low DNA input applications including liquid biopsy.

Tom Charlesworth, Audrey Vandomme, Jens Fullgrabe, Ermira Lleshi, Lidia Prieto-Lafuente, Edyta Bocian-Canepa, Elena Pahiti, Rebecca Ellwood, Mengjie Li, Marjana Lila, Robert Crawford, Robert J. Osborne, **Brett Evans**

biomodal Ltd, Cambridge, United Kingdom

The 6-base genome, provided by duet evoC, provides the canonical 4-base genome whilst simultaneously distinguishing 5-methylcytosine from 5-hydroxymethylcytosine to provide the 5th and 6th, epigenetic, bases. The 6-base genome has been shown to be a powerful tool for the discovery of biomarkers of early biological change and provides mechanistic insight across important applications including oncology, liquid biopsy and neurology. In these applications it is important to maximise the information derived from precious DNA samples, both in terms of multiomic data and material recovery. [RO1] Here we present the next evolution of the duet product portfolio. Through implementation of a novel single-stranded ligation approach, we demonstrate marked improvements[RC2] in assay performance including material recovery and DNA methylation calling sensitivity, whilst maintaining high genetic and epigenetic accuracy. These improvements derive from the ability of single-stranded ligation to maintain the original cfDNA strands. In contrast, end-repair can fill-in 5' overhangs with unmodified cytosines (reducing methylation detection sensitivity) and can introduce errors at 5' overhangs in addition to nicks and gaps. In addition, end-repair can remove information by degrading 3' overhangs. The single-stranded ligation method also captures both single and double stranded cfDNA, maximizing recovery of unique molecules. This is a critical parameter for liquid biopsy applications, where it is important to assay as many circulating-tumor (ctDNA) molecules as possible. We anticipate that these improvements will further enhance the power of the duet portfolio to reveal powerful novel biomarkers and provide mechanistic insight in sample-constrained liquid biopsy applications.

#0122 Using the 6-base genome for full multiomic analysis of cfDNA through combined methylation and fragmentomic analysis to enhance classification of clinical cancer cfDNA samples.

Tom Charlesworth, Fabio Puddu, Luke Sarre, Elena Pahiti, Lidia Prieto-Lafuente, Aurelie Modat, Robert Crawford, Simeone Angela, Robert J. Osborne, **Steven Ciaramaglia**

biomodal Ltd, Cambridge, United Kingdom

Sensitive detection of circulating tumour DNA (ctDNA) within the total pool of cell-free DNA (cfDNA) is crucial for the early diagnosis of cancer via liquid biopsy, and for monitoring ctDNA levels during treatment and remission. This enables earlier monitoring of treatment response, identification of minimal residual disease, and early detection of cancer. However, ctDNA typically represents only a minor fraction of overall cfDNA, posing significant challenges for conventional biomarker-based detection methods. Recently, fragmentomics-based approaches have shown promising results for ctDNA detection in liquid biopsy samples, with studies demonstrating that analysis of fragment size distributions across genomic regions, the frequency of 5' end motifs, and nucleosome positioning patterns near functional genomic sites can substantially enhance sensitivity and specificity. The advent of advanced methylomic profiling methods, such as 6-base sequencing with duet evoC, which distinguishes 5-methylcytosine (5mC) from 5-hydroxymethylcytosine (5hmC), has further expanded the analytical landscape. Integrating 5mC and 5hmC profiling with ctDNA detection strategies extends the spectrum of discernible fragment end motifs and provides orthogonal data layers to fragment size and nucleosome positioning analysis. These multidimensional epigenetic signatures hold the potential to markedly improve the resolution and accuracy of ctDNA detection. Here, we evaluate the impact of these additional epigenetic layers on ctDNA detection in liquid biopsy samples from a cohort of healthy volunteers and patients with different stages of colorectal cancer. We show that as well as different 5mC and 5hmC profiles between healthy, and early or late stage CRC, there are distinct differences in fragmentomics metrics when comparing across these groups. We identify regulatory regions displaying differences in nucleosome positioning in cfDNA derived from healthy individuals and CRC patients. Finally, we compare the ability of fragmentomics and epigenetic modalities (individually and in combination) to classify CRC patients. These classifiers evidence the utility of full multiomic datasets in cfDNA applications.

#0123 The importance of high analytical sensitivity and specificity of 5 and 6-base assays to enhance the detection of ctDNA in liquid biopsy applications.

Tom Charlesworth, Luke Sarre, Cillian Nolan, Fabio Puddu, Annelie Johansson, Aurelie Modat, Ermira Lleshi, Simeone Angela, Robert Crawford, Robert J. Osborne, **Thao Huynh**

biomodal Ltd, Cambridge, United Kingdom

Sensitive detection of cancer-derived DNA fragments (ctDNA) within cell-free DNA (cfDNA) in liquid biopsy is essential for identifying early-stage cancers, monitoring treatment response and minimal residual disease. A major challenge in these applications is detecting ctDNA, indicative of disease state, when this represents a small fraction of the total cfDNA. Advances in methylomic profiling, including 6-base sequencing with duet evoC which distinguishes 5-methylcytosine (5mC) and 5-hydroxymethylcytosine (5hmC), have enabled high-sensitivity ctDNA detection by analyzing methylation patterns across individual sequencing fragments (fragment level analysis) as opposed to more traditional analyses that average methylation levels at individual CpG loci. We present a comparative analysis of the background error rates in fragment-level methylation analysis between the duet suite of methylation assays from biomodal and alternative methylation sequencing technologies, showing error rates below 10^{-5} for both biomodal assays compared to error rates above 10^{-4} for alternative technologies. We further show how this lower error rate can enable more sensitive detection of ctDNA, and present the application of these technologies to detecting ctDNA in cfDNA from patients diagnosed with stages I-IV colorectal cancer. Our findings further emphasize the power of fragment-level analyses in cfDNA-based applications. They illustrate that it is critical to carefully consider analytical performance to achieve maximum clinical sensitivity and specificity from limited cfDNA samples.

#0127 Riboflavin biosynthesis byproducts increase the vulnerability of cancer to adoptive MAIT TCR-engineered T-cell transfer.

Ying Zheng[1], Pakhi Birla[2], Wanting Shan[1], Samuel Huang[1], Franck Housseau[1], Drew Pardoll[1]

[1]Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Immunity, Transplantation and Infection, Stanford University School of Medicine, Stanford, CA

Introduction: Mucosal-associated invariant T (MAIT) cells are innate-like T lymphocytes expressing a semi-invariant T-cell receptor (TCR) α-chain (TRAV1-2 joined to TRAJ33/12/20) paired with a restricted TCR β repertoire. Unlike conventional T cells that respond to peptide antigens, MAIT cells recognize and kill infected or transformed cells presenting non-polymorphic MHC class-I (MR1) molecule covalently loaded with microbial riboflavin (vitamin B2) biosynthetic intermediates. A key riboflavin precursor, 5-amino-6-D-ribitylaminouracil (5-A-RU), undergoes non-enzymatic condensation to form potent MR1 ligands such as 5-OP-RU, which can prime tumor cells to express MR1. These features make MAIT TCRs an attractive platform for adoptive T-cell therapy across cancer types, independent of HLA molecules or tumor genetics.
Methods: Human CD3+ T cells isolated from healthy donor peripheral blood mononuclear cells (PBMC) were engineered to express MAIT TCRs (TRAV1-2/TRAJ12 or TRAV1-2/TRAJ33) using a CRISPR-Cas12-mediated homology-directed repair (HDR) strategy. TCR knockout (*TRAC*/*TRBC* double-knockout) T cells lacking any introduced TCR served as controls. Antitumor activity was assessed in vitro and in vivo. Cytotoxicity against the human B-cell acute lymphoblastic leukemia line NALM6 was measured by flow cytometry. For in vivo evaluation, luciferase-expressing NALM6 cells were injected intravenously into *NOD/SCID/ Il2rg–/–* (NSG) mice, followed by infusion of engineered T cells. A 5-A-RU prodrug was administered intraperitoneally. Tumor burden was monitored by bioluminescent imaging.
Results: In vitro, MAIT TCR-engineered human T cells exhibited distinct baseline cytotoxicity against NALM6 cells (approximately 60-70% for J12 and ~10% for J33 in the absence of ligand). Addition of 5-A-RU resulted in near-complete tumor cell elimination for both MAIT TCR variants. In xenograft models, neither J12 nor J33 MAIT TCR T cells showed significant antitumor activity without exogenous 5-A-RU. However, intraperitoneal delivery of the 5-A-RU prodrug had no effect in TCR-knockout controls but markedly enhanced the antitumor activity of both MAIT TCR-engineered T-cell products. Mice receiving MAIT TCR T cells plus 5-A-RU showed delayed tumor progression and significantly improved survival compared with controls.
Conclusion: MAIT TCR engineering confers potent antitumor activity to human T cells, which is strongly augmented by riboflavin pathway metabolites such as 5-A-RU. These findings support a model in which metabolite supplementation prime tumor cells to express MR1 and redirect MAIT TCR-engineered T cells cytotoxic activity towards tumor. Further studies are underway to define the therapeutic window, evaluate potential toxicities, and identify the breadth of tumor types responsive to MAIT TCR-based adoptive cell therapy.

#0128 Synthetic reprogramming of γδ CAR T cells with the LTBR gene optimizes function in the TME and overcomes effector limitations.

Mitchell S. Wang, Ivan Reyes-Torres, Kristen C. Vogt, Caroline K. Hanlon, Ashley N. Thornal, Maria Guarino, Eric M. Johnson, Mark P. Roberto, Navamallika G. Reddy, Miao Chen, **Theodore Giavridis**, Mateusz Legut

OverT Bio, New York, NY

Cell therapies have transformed outcomes in hematologic cancers, yet their efficacy in solid tumors remains limited by the profoundly immunosuppressive tumor microenvironment (TME), which employs multiple, overlapping mechanisms to suppress immune activity. Current armoring strategies address these barriers individually, leaving key vulnerabilities, while autologous approaches remain costly and difficult to scale. Allogeneic γδ CAR T cells represent an attractive, off-the-shelf platform, but their persistence and potency within the solid tumor TME require enhancement.

To advance scalable and effective solid tumor therapies, we pursued a data-driven strategy to optimize γδ T cell biology while increasing TME resilience. Owing to limited knowledge of γδ T cell functional states in antitumor response, we implemented an empirical approach integrating genome-scale discovery and AI-driven analytics to uncover pathways governing γδ CAR T function. We conducted a genome-wide overexpression screen to identify reprogramming genes that protect CAR T cells from adenosine, TGF-β, immunosuppressive macrophages, and regulatory T cells while improving persistence. Among 12,000 genes screened, 51 candidates conferred protection against three or more suppressive mechanisms. Lymphotoxin beta receptor (LTβR)—a TNF superfamily receptor not normally expressed in T cells—emerged as the top hit, reprogramming T cells into highly proliferative, persistent, and multifunctional states, as confirmed by bulk and single-cell RNA-seq.

In high-stress assays, LTβR expression conferred broad resistance to immunosuppression, including complete abrogation of Treg-mediated inhibition. In γδ CAR T cells, LTβR induced an αβ-like effector program characterized by enhanced cytotoxicity, persistence, and cytokine modulation. scRNA-seq revealed new mechanisms of γδ CAR T exhaustion and effector differentiation distinct from αβ CAR T cells. In vivo, LTβR-armored αβ and γδ CAR T cells targeting CLDN6 mediated complete, durable regressions in an aggressive ovarian cancer model where controls were ineffective.

Finally, we established a GMP-compatible manufacturing process tailored to γδ T cell biology, producing highly pure, potent cells suitable for multi-patient allogeneic use. Together, this work defines a comprehensive next-generation engineering and manufacturing framework that overcomes γδ CAR T cell limitations and enables durable activity in solid tumors.

#0130 Expanding the ACT paradigm: B cell engineering via spherical nucleic acids for cancer immunotherapy.

Maryam Balibegloo[1], Yingying Li[1], Abu Baker[1], Jie Fan[1], Ping Xie[1], Mi Ran Choi[1], Catalina Lee Chang[2], Vinzenz Mayer[3], Michael Evangelopoulos[3], Chad A. Mirkin[3], Bin Zhang[4]

[1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Northwestern Univsity, Chicago, IL,[3]Northwestern University, Evanston, IL,[4]Northwestern University - Chicago, Chicago, IL

Adoptive cellular therapy (ACT) has revolutionized cancer immunotherapy, yet its focus remains largely on T cells. B cells, despite their potent antigen-presenting capacity and role in adaptive immunity, have been underutilized due to inefficient antigen delivery and activation. We developed an ex vivo strategy leveraging spherical nucleic acids (SNAs) to license B cells for ACT. This platform synchronizes pH-controlled co-delivery of tumor antigen peptides and TLR9 agonists into shared endosomal compartments, enabling sustained antigen presentation and robust cross-priming of tumor-specific $CD8^+$ T cells, resulting in epitope spreading and durable antitumor immunity.SNA-trained B cells exhibited lymphoid homing and secreted CCL3/CCL4, establishing a CCR5-dependent chemotactic axis that recruited effector $CD8^+$ T cells and cDC1, creating spatial immune hubs within tumors. Multiplex immunohistochemistry analysis revealed clustering of transferred B cells, $CD8^+$ T cells, and cDC1 in draining lymph nodes, facilitating antigen handoff and reciprocal activation. Mechanistic studies confirmed that CCR5 blockade or $CD8^+$ T-cell depletion abrogated efficacy. Across multiple murine and humanized tumor models, SNA-trained B cells outperformed controls, reduced metastasis, and synergized with PD-1 blockade to improve survival. Single-cell transcriptomics and BCR-seq demonstrated progression toward plasma cell differentiation, oligoclonal expansion, and IgG2 class switching.This work introduces a nanomaterial-based platform to reprogram B cells for ACT, overcoming limitations in immunologically “cold” and checkpoint-refractory tumors. SNA-trained B cells broaden the ACT paradigm beyond T cells, offering a versatile and well-tolerated strategy for durable antitumor immunity.

#0131 Enhanced feeder-free expansion, survival, potency and post manufacture stability of NK cells for CAR-NK therapies using human platelet lysate.

Vanesa Alonso-Camino, Andrew Sullivan

Mill Creek Life Sciences, Rochester, MN

Natural killer (NK) cells have emerged as a promising platform for chimeric antigen receptor (CAR) engineering, offering inherent anti-tumor activity and a favorable safety profile compared to CAR-T cells. Unlike T cells, NK cells belong to the innate immune system and do not require prior antigen sensitization, making them attractive for “off-the-shelf” allogeneic therapies. Clinical interest in CAR-NK cells has surged, with over 50 trials registered globally, driven by their reduced risk of cytokine release syndrome and graft-versus-host disease. Despite these advantages, the widespread adoption of CAR-NK therapies faces two major challenges: achieving clinically relevant NK cell numbers and ensuring post-manufacturing stability. NK cells are less abundant than T cells, exhibit limited in vitro expansion capacity, and have a short lifespan. Traditional methods rely on feeder cell co-culture, often using tumor-derived lines, which introduces technical and regulatory hurdles and yields inconsistent results. To address these limitations, we developed a feeder-free expansion protocol using human platelet lysate (hPL), enabling robust NK cell proliferation while preserving phenotype and cytotoxic function. Beyond expansion, we focused on a critical bottleneck in CAR-NK manufacturing—cryopreservation. Using proprietary cryopreservation solutions and protocols following hPL-based culture, we achieved significantly improved NK cell survival, maintenance of activating receptor expression, and retention of anti-tumor potency post-thaw. This advancement mitigates the logistical challenges of CAR-NK production, supporting scalable, ready-to-use cell therapy products. Our integrated approach—combining efficient feeder-free expansion with optimized cryopreservation—represents a major step toward reliable, high-quality CAR-NK therapies for clinical application.

#0132 Improving effector cells for CAR-NK immunotherapy against colorectal cancer.

Marco Cortese, Alice D'Andrea, Alfonso Navarro Zapata, Sahar Taebi, Consalvo Petti, **Enzo Medico**

Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy

Chimeric Antigen Receptor (CAR)-based immunotherapy targeting carcinoembryonic antigen (CEA) represents a promising strategy for the treatment of colorectal cancer (CRC), a leading cause of cancer-related mortality worldwide. With respect to CAR-T cells, whose activity against solid tumors is limited by significant side effects, CAR-NK cells represent a potentially safer alternative, offering reduced toxicity while maintaining effective anti-tumor activity. We therefore worked at developing and optimizing CEA-specific CAR-NK cells against CRC, along three research lines: (i) selection and validation of a reference CEA CAR in the NK-92 model; (ii) further engineering of CEA.CAR-NK-92 cells with interleukins, and (iii) exploration of additional NK effector types. To select the reference CEA CAR construct, second generation CARs based on two scFvs with different affinities (hMN-14 and BW431/26, respectively higher and lower affinity) were constructed. Stable NK-92 clones were generated for each construct (higher affinity: NK-92.F3 clone; lower affinity: NK-92.G8 clone) and functionally characterized. *In vitro*, the NK-92.F3 clone exhibited stronger killing activity against CEA-positive CRC cells. *In vivo*, in NOD/Scid mice bearing CEA+ CRC xenografts, the two clones displayed comparable activity, both significantly reducing tumor progression and confirming their therapeutic potential. Considering the higher affinity and the better *in vitro* performances, the hMN-14-based CAR was selected as the reference CAR for subsequent evolutions of the NK platform. To enhance CAR-NK-92 performances, wild-type NK-92 and NK-92.F3 cells were engineered to constitutively express different interleukins. Functional assays demonstrated that specific interleukin expression markedly increased cytotoxicity and activation, highlighting cytokine engineering as an effective strategy to potentiate CAR-NK activity. To overcome the major intrinsic limitation of NK-92 cells, i.e. the need for irradiation before infusion, we investigated induced pluripotent stem cell (iPSC)-derived NK cells (iNKs) as a renewable and clinically scalable alternative NK source. Four iPSC-to-NK differentiation protocols were compared, three based on 3D embryoid body intermediates and one on 2D monolayer. Of these, one 3D and the 2D protocol proved more reliable. iPSC cells were then transduced with the reference CEA CAR, cloned, differentiated into NK and validated for functionality and cytotoxic performances. In conclusion, this work identified a robust reference CEA-CAR construct and established two complementary strategies, cytokine engineering to enhance effector function and iPSC-derived NK cell generation to overcome NK-92 limitations, providing a foundation for the development of safer, scalable, and next-generation CAR-NK therapies for colorectal cancer.

#0133 NEO-201-recognized truncated Core 1 O-glycans represent a new target for CAR-NK therapy in AML.

Joseph A. Clara[1], Nile Liu[1], Mala Chakraborty[2], Kwong Y. Tsang[3], Massimo Fanitni[3], Philip M. Arlen[3], Richard W. Childs[2]

[1]Division of Hematology and Oncology, University of Virginia, Charlottesville, VA,[2]National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD,[3]Precision Biologics, Inc, Bethesda, MD

Introduction: Acute myeloid leukemia (AML) continues to have poor long-term outcomes, particularly in high-risk and relapsed/refractory disease. Progress in AML immunotherapy has been hindered by the scarcity of antigens selectively expressed on leukemic cells while sparing hematopoietic stem/progenitor cells (HSPCs). AML-restricted surface glycans represent an underexplored class of targets. NEO-201 is a humanized IgG1 monoclonal antibody that binds truncated Core 1 O-glycans expressed by several solid tumors, circulating neutrophils, and select leukemia cell lines, with limited reactivity to most normal tissues and an acceptable safety profile in a phase I solid tumor trial (NCT03476681). We evaluated the NEO-201-recognized truncated O-glycan antigen as an AML-associated antigen, characterized its expression across AML subtypes, and developed a CAR NK cell therapy directed against this target.

Methods: Ten AML cell lines representing diverse molecular subtypes were analyzed for NEO-201 binding by flow cytometry. NK cells from healthy donors were expanded ex vivo using lymphoblastoid feeder cells and IL-2. CAR NK cells were generated via retroviral transduction with a second-generation CAR, incorporating a NEO-201-binding domain, CD8α transmembrane region, 4-1BB co-stimulation and CD3ζ signaling domains, and a truncated CD34 (tCD34) marker. Cytotoxicity was assessed in co-culture assays using calcein-AM-labeled AML targets at varying effector-to-target ratios. Antigen expression across hematopoietic maturation stages was evaluated by flow cytometry in G-CSF-mobilized peripheral blood to assess potential on-target/off-tumor toxicity.

Results: The NEO-201-recognized antigen was expressed at >40% in 6 of 10 AML cell lines, spanning FLT3-ITD-mutated, MLL-rearranged, biphenotypic, and core-binding factor leukemias. Expression ranged from 41-100% in positive lines: THP-1 (100%), MOLM-14 (88%), MV4-11 (60%), U-937 (45%), HL-60 (44%), and ME-1 (41%). NEO-201-based CAR NK cells demonstrated potent antigen-dependent cytotoxicity, including against lines with lower antigen density. At a 10:1 E:T ratio, CAR NK cells lysed 61% of THP-1, 45% of HL-60, and 40% of MOLM-14 targets. Antigen expression was minimal or absent on $CD34^+$ HSCs (0-1%), low on early myeloid progenitors (10-15%), and enriched in mature neutrophils (~99%), consistent with restricted expression during late myeloid maturation.

Conclusion: This study identifies Core 1 O-glycans recognized by NEO-201 as a novel AML-associated antigen present across multiple subtypes and largely absent from early hematopoietic progenitors. The potent antileukemic activity of NEO-201CAR NK cells in preclinical systems highlights the promise of this approach and sets the stage for advancing O-glycan-directed CAR NK therapy into translational and clinical development.

#0134 Anti-tumor activity of engineered iPSC-derived NK cells against metastatic uveal melanoma cells.

Nadia Anikeeva[1], Tong Zhang[1], Sota Deguchi[1], Sergei Koshkin[1], Masashi Yamada[2], Kouichi Tamura[2], Hironobu Kimura[2], Vitali Alexeev[3], Yuri Sykulev[1], Takami Sato[3], Mizue Terai[3]

[1]Medical Oncology, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA,[2]Kobe Research institute, HEALIOS K.K, Kobe, Japan,[3]Medical Oncology, Sidney Kimmel Comprehensive Cancer Center, Thomas Jefferson University, Philadelphia, PA

Background:Uveal melanoma (UM) preferentially metastasizes to the liver, leading to a poor prognosis. The immunosuppressive microenvironment of the liver and the low mutation burden of metastatic UM (MUM) contribute to the limited efficacy of immunotherapies, including immune checkpoint inhibitors and adoptive T-cell transfers. Existing evidences highlight the crucial role of Natural Killer (NK) cells in monitoring and targeting circulating MUM cells, suggesting that therapeutic strategies that enhance NK cell activity may offer clinical benefits. Donor variability and limited expansion capacity restricted clinical application of primary NK cells. NK cells derived from induced pluripotent stem cells (iPSCs) present distinct benefits, especially in their ability to be genetically modified to produce cells with improved antitumor characteristics. Therefore, we investigated the antitumor activity of iPSC-NK cells against MUM.
Methods:The functions of iPS-NK cells were enhanced by gene editing, resulting in the production of engineered iPS-NK cells (eNK) that express NKG2D, CD16, CCR2, and secrete CCL19 and IL-15. eNK is being developed as AKT-01/HLCN061 through a collaboration between Akatsuki Therapeutics Inc. and Healios K.K.. The functional properties of eNK cells against UM cell lines, UM001 and UM004, were evaluated in comparison with the intact highly cytotoxic NK92 cell line or with NK92 cells genetically modified with CD16 (NK92-CD16). The activities of the NK cells were assessed using (i) cytotoxic assay; (ii) ADCC assay with anti-GD2 antibodies; (iii) CD107a degranulation assay; and (iv) intracellular cytokine staining. The migration of eNK cells toward UM was evaluated using a transwell migration assay.
Results:The eNK and NK92 cells exhibit a comparable effectiveness in targeting UM001 cells, killing up to 50% of the tumor cells and showing similar frequency of the cells that produce detectable levels of cytolytic granules and IFNγ (5-10%). The cytolytic activity of NK92 cells against UM004 cells was negligible, as was the frequency of cells releasing cytolytic granules and expressing IFNγ. In contrast, eNK cells killed approximately 25% of the UM004 cells, upregulating CD107a membrane expression and intracellular IFNγ production to a similar extent as in the case of UM001 cells. ADCC against UM004 cell lines in the presence of anti-GD2 antibodies was similar (~15%) for both eNK and NK92-CD16 cells. The TNFα intracellular staining in response to UM cells targets was observed only for eNK cells. Importantly, TNFα treatment increased CCL2 production by the UM cell lines. In accordance with this, eNK cells exhibited enhanced migration into chambers containing supernatants from TNFα-stimulated UM001 or UM004 cells.
Conclusions:The data indicated that eNK cells have anti-tumor activity and potential as improved adoptive cell therapeutics in the treatment of MUM.

#0135 Memory-like NK cell targeting to CD123 and CD33 improves killing of acute myeloid leukemia.

Emily Phillips[1], Lyra Morina[1], Lynne Marsala[1], Wilbur Song[1], Michelle Becker-Hapak[1], Yoojin Ahn[1], Sushanth Pureti[1], Elizabeth Juarez Diaz[1], Sadia Afrin[1], Pamela Wong[1], Jennifer Tran[1], Joseph Rueve[1], Allison Burdi[1], Nancy Marin[1], Melissa Marie Berrien-Elliott[1], Martin Felices[2], Jeffrey S. Miller[3], Todd A. Fehniger[1]

[1]Washington University School of Medicine in St. Louis, St. Louis, MO,[2]Masonic Cancer Center, Minneapolis, MN,[3]University of Minnesota, Minneapolis, MN

Background: Memory-like natural killer (ML NK) cells are NK cells which upon stimulation with IL12/15/18 undergo a differentiation process to develop improved metabolic fitness and enhanced killing capabilities of different types of malignant cells. They are a promising cellular therapeutic against acute myeloid leukemia (AML), for which the prognosis remains dismal for both pediatric and adult patients who experience relapse of their AML. Phase I studies of adoptive ML NK cell therapy in adult and pediatric patients showed promising results with several patients achieving complete responses, but many go on to relapse after a few months. We investigate two strategies to improve recognition of AML by memory like NK cells by targeting them to AML surface antigens CD33 and CD123.

Objective: We target ML NK cells to CD123 by engineering ML NK cells to express a chimeric antigen receptor (CD123 CAR ML NK). We target ML NK cells to CD33 via a trispecific killer engager (CD33 TriKE) that enhances the immune synapse by engaging CD16 on the ML NK cell and CD33 on AML. The CD33 TriKE also contains IL-15 to enhance ML NK activation and survival. We also explore whether both technologies function synergistically to prevent immune escape.

Methods: Treatment of AML with ML NK cells vs CD123 CAR ML NK cells, ML NK cells plus CD33 TriKE, or the combination, was compared in series of short and long-term assays. AML targets include MOLM13, THP-1, and Primary AML blasts. Interferon gamma production was assessed in a 6-hour co-incubation. In-vitro killing was assessed at 4-hours using a flow-based killing assay, and at 24 hours using a luciferase-based assay. Tumor control was assessed over 5 days using Incucyte (live cell imaging). Tumor control and survival *in vivo* was assessed using an THP-1 Xenograft model in NSG mice. Primary AML xenografts using NSG-S mice is under development. Results: Both targeting strategies demonstrate an antigen-specific killing response. Both strategies significantly increase interferon gamma production compared to ML NK cells (CAR vs MOLM13: +16.57%, p=0.0002, Primary AML #34: IFNg +9.1% p=0.0092; CD33 TriKE vs MOLM13: +24.42%, p=.0015, AML34: +9.1% p=0.0092). Both strategies also demonstrated increased AML killing at various E:T ratios (CAR vs MOLM13: p=.0011; AML34: p=.0006; CD33 TriKE vs MOLM13: p<.0001; AML34 p=.0026). Both CD123 CAR and CD33 TriKE improved THP-1 control in vivo (bioluminescence at 23 days-CD123 CAR: p=0.004, CD33 TriKE: p<.0001). Both therapies improved median survival by about 3 weeks (CD123 CAR: p<.0001, CD33 TriKE: p=.0001).

Conclusion: CD123 CAR ML NK cells and ML NK cells treated with CD33 TriKE both enhance the abilities of ML NK cells to kill AML *in vitro* and *in vivo*, and prolong time of survival of THP-1 bearing mice. Treatment of CD123 CAR ML NK cells with CD33 TriKE may prevent antigen escape. Either of these targeting strategies are highly translatable to the clinical setting.

#0136 Surface engineered-NK/trastuzumab cells as a novel immunotherapy for HER2-low breast cancer.

Maria Jose Godoy Calderon[1], Manali Patwardhan[1], Shruti Rodrigues[2], Saanvi Sethi[1], Eric Gauchat[3], Vk Gadi[1]

[1]University of Illinois at Chicago, Chicago, IL,[2]University of Illinois College of Med. at Chicago, Chicago, IL,[3]University of Illinois Chicago, Chicago, IL

Purpose: HER2-low breast cancers, which account for most metastatic cases, remain challenging to treat. Although trastuzumab-deruxtecan has shown clinical benefit, its use is limited by high toxicity and disease progression, underscoring the need for safer, more effective, and more accessible targeted options. These tumors disproportionately affect underserved populations, amplifying disparities in care. Building upon our previous development of a murine HER2-low model and NK/Trastuzumab (Tz) surface-engineering platform, we now evaluated the therapeutic potential and selectivity of SE-NK/Tz cells against HER2-low human and murine tumors, including 3D tumor spheroids.

Methods: SE-NK cells were generated by embedding 25 µg of Tz onto the mouse-derived LNK cells or human NK92 cells using a hydrophobic linker, and conjugation efficiency was verified by flow cytometry and confocal imaging. HER2-specific cytotoxicity was evaluated by luciferase-based killing assays in 2D and 3D cultures of 4T1-HER2-low murine cells (generated in our lab) and HER2-low MDA-MB-175 human breast cancer cells. HER2-negative cells were used to assess specificity.

Results: SE-LNK/Tz cells exhibited significantly enhanced cytotoxicity against 4T1-HER2-low targets (86 ± 1 % vs 55 ± 2 %, $p < 0.0001$ at E:T 10:1), consistent across multiple effector-to-target ratios (20:1-2.5:1), compared with unmodified NK cells. SE-NK92/Tz cells similarly increased cytotoxicity against MDA-MB-175 targets (57 ± 1% vs 42 ± 3 %, $p < 0.01$ at E:T 1:1). Importantly, SE-NK/Tz cells showed markedly lower killing of HER2-negative cells (mouse 6 ± 5% vs 69 ± 2%; human 42± 1% vs 57± 1 %, $p < 0.0001$), confirming HER2-specific targeting. SE-LNK/Tz cells maintained activity in 3D spheroid assays, indicating effective tumor penetration.

Conclusions: This study advances our surface-engineering NK platform from proof-of-concept to functional validation in both murine and human HER2-low systems, including 3D culture models. SE-NK/Tz cells display potent and selective cytotoxicity against HER2-low breast cancer, supporting their potential as a next-generation, low-toxicity immunotherapy for this underserved patient population. Ongoing work focuses on exploring mechanisms of immune activation and therapeutic efficacy in diverse in vivo HER2-low models.

#0137 Harnessing allogeneic CAR-iNKT cells for next-generation treatments in oncology and autoimmunity.

Yuhua Wan[1], Dexian Quan[1], Feng Xu[2], Yuzhu Cui[2], Jian Hua[1], Jingyu Li[2], **Hua Zhang**[2]

[1]SPH Biotherapeutics (Shanghai) Limited, Shanghai, China,[2]SPH Biotherapeutics (HK) Limited, Hong Kong, Hong Kong

Background: Chimeric antigen receptor (CAR)-engineered invariant natural killer T (iNKT) cells have demonstrated promising outcomes in clinical studies for both cancer and autoimmune disorders. Their distinctive ability to recognize and eliminate tumor cells, coupled with efficient infiltration into solid tumors and modulation of the tumor microenvironment (TME), positions them as a compelling therapeutic strategy for solid malignancies. Moreover, because iNKT cells do not trigger graft-versus-host disease (GvHD), they are particularly well-suited for allogeneic, off-the-shelf cell therapy approaches.
Methods: Two CAR constructs targeting CD19 and GPC3 were independently generated to evaluate therapeutic efficacy. For CD19 CAR-iNKT cells, NSG mice were intravenously inoculated with 1×10^6 Nalm6 cells per mouse, allowed to engraft for two days, and subsequently treated with either a single dose or three sequential doses of 1×10^6 CAR^+ iNKT cells per mouse administered on days 2, 4, and 6. In parallel, the activity of GPC3 CAR-iNKT cells engineered with PD-1 deletion was assessed in NOG-hIL15Tg mice. Each mouse was implanted with 1×10^6 Hep3B cells three days prior to treatment and then received three tail-vein injections of 18×10^6 GPC3 CAR-iNKT cells (50% CAR^+) or untransduced iNKT cells on days 3, 6, and 9.
Results: In bioluminescent imaging, three sequential doses of CD19 CAR-iNKT cells achieved marked clearance of CD19-positive Nalm6 cells compared with unmodified iNKT cells or a single CD19 CAR-iNKT injection, underscoring their therapeutic potential in B-cell malignancies and autoimmune disorders such as ALL, CLL, and SLE. In contrast, within the Hep3B xenograft model, only GPC3 CAR-iNKT cells engineered with PD-1 deletion,rather than conventional GPC3 CAR-iNKT cells induced tumor regression beginning on day 10, ultimately achieving complete elimination by days 24 and 31 without evidence of graft-versus-host disease.
Conclusions: These findings highlight iNKT cells as a potent allogeneic platform for CAR-based immunotherapy, with broad applicability across cancer and autoimmune diseases, thereby establishing a robust basis for continued clinical investigation.
Ethics Approval: The study was approved by Medicilon's Ethics Board, approval number SWSH(YF)2025-034.

#0138 Generation of scalable off-the-shelf iNKT therapies.

John J. Swain[1], Eoin C. Whelan[2], Chiquita Hanindya[3], Peter Keller[3], **Antonia Rotolo**[4]

[1]Pathobiology, University of Pennsylvania, Philadelphia, PA,[2]Biomedical Sciences, University of Pennsylvania, Philadelphia, PA,[3]BlueWhale Bio, Philadelphia, PA,[4]Pathobiology, Penn Vet Cancer Center, University of Pennsylvania, Philadelphia, PA

Invariant natural killer T cells (iNKTs) are rare T lymphocytes, emerging as an off-the-shelf platform for the treatment of blood and solid tumors, severe viral infections, and graft-versus-host disease. These features hold promise for improving global and equitable access to advanced cellular immunotherapies. However, limited scalability and persistence of donor-derived iNKT products hinder worldwide impact. We set out to establish large-scale iNKT off-the-shelf products capable of extended *in vivo* persistence, including enhanced tumor-redirected iNKTs engineered with chimeric antigen receptors (CAR-iNKT).

Methods. To investigate clinically relevant methods to expand large-scale off-the-shelf products, we tested: 1) activating beads coated with αCD3/αCD28 antibodies; 2) α-galactosylceramide (αGC)-loaded artificial antigen-presenting cells (aAPCs), generated by engineering K562 cells expressing CD80/CD83/CD86/41BBL with the iNKT-specific antigen CD1d; and 3) cell-derived nanoparticles (CDNPs, Synecta T1), a feeder-free platform engineered to display membrane-bound OKT3, co-stimulatory ligands, and IL-7/IL-15 cytokines in a scalable, closed-system format, providing key aAPC-like stimulation cues without using live cell lines. To determine the resulting therapeutic potential, we assessed iNKT purity, yield, memory/exhaustion phenotype, and anti-tumor efficacy via *in vitro* 4h killing and cytokine assays and *in vivo* NSG xenografts.

Results. All activation systems produced pure iNKT products. aAPCs induced the highest iNKT yield, as expected from antigen-specific CD1d-αGC stimulation. CDNPs were as effective as αCD3/αCD28 beads in sustaining proliferation after repeated stimulations. Phenotypically, aAPCs induced the highest CD62L levels, a known predictor of persistence, whereas CDNPs exhibited the most favorable effector profile, including the lowest LAG-3 and TIM-3 expression. CDNPs also showed the strongest *in vitro* cytotoxicity against tumor targets, with up to 60% killing as compared to aAPCs 25% and αCD3/αCD28 beads 35%. *In vivo*, aAPC-manufactured CAR-iNKTs persisted in osteosarcoma-bearing NSG xenografts for 90 days after a single infusion — the longest persistence reported in such a model — associated with complete and durable tumor eradication. Bead-expanded CAR-iNKTs eradicated tumors but were not detected at comparable late time points.

Conclusions. We established clinically scalable iNKT/CAR-iNKT manufacturing workflows yielding high-purity cells. All products exhibited potent anti-tumor activity, but aAPC-expanded CAR-iNKTs resulted in exceptional persistence *in vivo*, superior to bead-expanded cells. The CDNP platform provides a clinically translatable, feeder-free activator that achieves superior functional potency, reduced exhaustion, and regulatory readiness (FDA-reviewed DMF), enabling scalable off-the-shelf iNKT/CAR-iNKT therapy for a broad range of applications.

#0139 Functional profiling of an allogeneic NK cell therapy product in NSCLC patient-derived organotypic tumor spheroids.

Chunxiao Cui[1], Anthony Attardo[1], Mei Rosa Ng[2], Yana Wang[2], **Michael A. Perricone**[3]

[1]XSphera Biosciences, Inc., Cambridge, MA,[2]Takeda Pharmaceuticals International Company, Cambridge, MA,[3]Xsphera Biosciences, Inc., Cambridge, MA

Allogeneic natural killer (NK) cell therapies offer an off-the-shelf strategy for targeting solid tumors, but their functional activity within complex human tumor microenvironments remains poorly defined. We evaluated an allogeneic NK-cell therapy product design (NK cells) and tested its performance using the Xsphera platform, which incorporates patient-derived organotypic tumor spheroids (PDOTS) embedded in extracellular matrix (ECM) and cultured in microfluidic devices that preserve tumor-immune-stromal architecture ex vivo. Assay conditions were first optimized using LS1034 tumor cell spheroids as target cells and cryopreserved NK cells to identify parameters that maximized NK cell activity, including ECM concentration, effector-to-target (E:T) ratio, exposure duration, and media composition. Under optimal conditions, NK cells induced up to 40% tumor spheroid killing, as quantified by live/dead imaging using Hoechst and propidium iodide staining. We next applied these conditions to PDOTS generated from five non-small cell lung cancer (NSCLC) patients. NK cells were introduced at an estimated 2:1 E:T ratio and cultured for 96 hours. Live/dead imaging revealed significant cytotoxic responses in 2 of 5 PDOTS, with live tumor area reductions of up to 50%. The NK cells expressed activation markers (NKG2D, CD69) and secreted elevated levels of interferon-γ, tumor necrosis factor, and granzyme B. Transcriptomic profiling of the media revealed enrichment of interferon-stimulated genes and cytotoxic effectors. Notably, these molecular features did not correlate with tumor responsiveness. These findings demonstrate the utility of the PDOTS platform for functionally profiling NK cell potency in physiologically relevant tumor models and support its use in the rational development of next-generation NK cell therapy products for solid tumors.

#0140 Allogeneic CAR-iNKT cell therapy targeting CLDN18.2-positive gastric and pancreatic cancers.

Clinton M. Heinze[1], Elisa Landoni[2], Michelle Ferguson[1], Nicole van der Weerden[1], **Robson Dossa**[1], Simon Poon[1], Kelvin Yip[1], Jacqui Cumming[1], Alfie Baker[1], Sandford Sarah[1], Michael J. Baker[1], Barbara Savoldo[2], Gianpietro Dotti[2]

[1]Arovella Therapeutics, Melbourne, Australia,[2]University of North Carolina, Chapel Hill, NC

Allogeneic cell therapy offers the advantage of immediate and scalable access to healthy and potent effector cells for the treatment of solid tumors, overcoming patient immune dysfunction and potential manufacturing delays, while enabling durable anti-tumor responses. Invariant natural killer T (iNKT) cells are a rare, specialized subset of unconventional T cells that represent an ideal allogeneic cell therapy platform. They express a semi-invariant T cell receptor (iTCR) that recognizes glycolipid antigens presented by the monomorphic, MHC-like molecule, CD1d. Previous studies have shown that iNKT cells do not induce acute graft-versus-host disease, and iNKT cells engineered to express chimeric antigen receptors (CARs) have demonstrated therapeutic potential. In addition to tumor recognition via the CAR, iNKT cells can engage tumors via the endogenous iTCR binding to glycolipid-bound CD1d and via the NKG2D receptor. CAR-iNKT cells offer distinct advantages in the treatment of solid tumors due to their natural ability to home to tissues, infiltrate tumors, and modulate the tumor microenvironment.

Claudin 18.2 (CLDN18.2) has emerged as a high-priority target for novel cancer therapies. Under normal physiological conditions, its expression is limited to tight junctions between epithelial cells and remains inaccessible on the cell surface. However, in several malignancies, including gastric, esophageal, and pancreatic cancers, CLDN18.2 becomes surface-exposed as tumor cells lose normal tissue architecture during growth and invasion. This aberrant presentation in malignant tissue makes CLDN18.2 an attractive target for CAR-directed cell therapies.

Here, we present the first PBMC-derived CAR-iNKT cell therapy product targeting CLDN18.2. This second-generation CAR features a short chain variable fragment (scFv) derived from SPX-101, a novel monoclonal antibody engineered for enhanced affinity and selectivity for CLDN18.2. To support iNKT cell function, membrane-bound IL-12 (IL-12-TM) was incorporated to provide cytokine armouring, which has been shown to enhance CAR-iNKT cell activity. In this work, iNKT cells were isolated from healthy donor PBMCs, activated, transduced to express the CLDN18.2 CAR with and without IL-12-TM co-expression, and expanded in culture. Cytotoxic activity and effector expansion were evaluated using a serial tumor re-challenge assay against CLDN18.2-positive gastric and pancreatic cancer cell lines. CLDN18.2 CAR-iNKT cells exhibited potent and sustained cytotoxic activity against CLDN18.2-positive tumor cells, and co-expression of IL-12-TM improved the persistence and durability of response under repeated high tumour burden. These findings support the potential of cytokine-armoured CLDN18.2-directed CAR-iNKT cells as an allogeneic cell therapy for the treatment of gastric and pancreatic cancers.

#0141 Selecting cord blood-derived NK cells enriched in mature subsets optimizes CAR-NK cell-based anti-tumor therapy.

Ye Ethan Li, Huihui Fan, Rafet Basar, Wilson Jeffrey, Patrick Zhang, Katayoun Rezvani

UT MD Anderson Cancer Center, Houston, TX

Background: CAR-modified natural killer (CAR NK) cell therapy offers a promising "off-the-shelf" cell therapy, with promising clinical activity with a favorable safety profile. Clinical efficacy, however, varies between umbilical cord blood (CB) donors. A deeper understanding of the cellular and molecular factors driving this variability is essential to improve the manufacturing and performance of CAR NK therapies.

Methods: We analyzed products from our first-in-human clinical study of CB-derived CAR19/IL-15 NK cells in B cell malignancies (NCT03056339). We had shown that donor selection affected clinical outcome, with some donors linked to better responses and longer progression free and overall survival, and others to poorer outcomes. To define the cellular basis for this effect, we returned to those specific donors and performed integrated single-cell RNA and antibody-derived tag (ADT) sequencing on their NK cells both before manipulation and after *ex vivo* expansion using the same protocol used for the trial. We then related donor intrinsic states and specific cellular subsets with clinical responses.

Results: Unsupervised clustering identified two distinct NK cell subsets based on their expression of CD16 and CD161. A double-negative (DN) subset ($CD56^{bright}CD16^{-}CD161^{-}$) and its expanded progeny showed reduced expression of key activating receptors and adaptor molecules, consistent with limited effector function signatures after expansion. Conversely, the double-positive (DP) subset ($CD56^{dim}CD16^{+}CD161^{+}$) maintained a robust adaptive-like cytotoxic profile, characterized by stronger membrane-proximal activation signaling and high effector-gene expression that persisted through expansion. Notably, trial CAR-NK cell products generated from CB donors enriched for the DP subset were associated with superior clinical benefits, whereas enrichment for the DN subset was associated with worse outcomes.

Conclusions: Our single-cell multiomic analysis reveals previously underappreciated donor-intrinsic diversity within CB-NK cells, which may explain the functional heterogeneity among CAR NK cell products. These results provide a mechanistic foundation for donor selection strategies and for targeted genetic improvements that can raise the consistency and potency of future allogeneic CAR NK cell therapies.

#0142 A universal multi-receptor NK cell platform engineered for synergistic combination with antibody and T-cell engager therapies.

Rafet Basar[1], Bin Liu[1], Nadima Uprety[1], Francia Reyes Silva[1], Rejeena Shrestha[1], Sunil Acharya[2], May Daher[1], Ana K. Nunez Cortes[1], Deqiang Zhang[1], Bingqian Hu[1], Silvia Tiberti[1], Madison Moore[1], Ye Ethan Li[1], Pinghua Liu[1], Hila Shaim[1], Jeong-Min Park[1], Mecit Kaplan[1], Xingliang Guo[1], Mayra Shanley[1], Ping Li[1], Paul Lin[1], Pinaki Banerjee[1], Huihui Fan[1], Patrick Zhang[1], Enli Liu[1], Seema Rawal[3], Elizabeth Joan Shpall[4], Katayoun Rezvani[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Molecular and Cellular Oncology, UT MD Anderson Cancer Center, Houston, TX,[3]Postdoctoral Fellow, UT MD Anderson Cancer Center, Houston, TX,[4]Professor of Medicine, Dept. of Stem Cell Transplant & Cell Therapy, UT MD Anderson Cancer Center, Houston, TX

Background: Monoclonal antibodies (mAbs) and T-cell engagers (TCEs) redirect immune effector cells toward malignant targets, yet their efficacy is often limited by patient T- and NK-cell dysfunction. Conventional CAR strategies target a single antigen, requiring new construct design, GMP production, and separate regulatory pathways for each target. To combine the strengths of engager- and cell-based approaches, we developed PluraliNK cells, a universal multireceptor NK-cell platform activated through CD3/TCR- and Fc-dependent pathways. This enables redirection by any approved mAb or TCE without additional engineering, creating a flexible plug-and-play NK therapy.

Methods: NK cells were engineered using two polycistronic vectors to express the full CD3 complex, IL-15 for cytokine support, high-affinity CD16A (F158V) for enhanced Fc engagement, and an invariant TCR α/β (iTCR) to stabilize CD3 and permit CD1d-restricted recognition. This dual-activation system allows PluraliNK cells to respond to CD3- or CD16-mediated signals and to pair with diverse mAbs or TCEs without further modification.

Results: PluraliNK cells showed potent cytotoxicity across hematologic and solid tumor models when combined with approved mAbs (rituximab, trastuzumab) or TCEs (blinatumomab, glofitamab, elranatamab), consistently outperforming mAb/TCE monotherapy or unmodified NK cells. The platform supports simultaneous engagement by multiple antibodies or TCEs, enabling clearance of heterogeneous tumor populations and reducing antigen escape. Dual-input signaling enhanced activation, serial killing, and resistance to exhaustion, an advantage in solid tumors with spatial heterogeneity and lineage plasticity. Because PluraliNK activation depends on an external mAb or TCE, the system provides an additional safety layer compared with constitutively active CAR constructs. In NSG xenograft models, PluraliNK cells combined with mAbs or TCEs achieved superior tumor clearance, improved infiltration, and enhanced in vivo persistence without off-target toxicity.

Conclusions: This universal NK-cell platform enables multiantigen targeting and integration with existing mAbs and TCEs, addressing tumor heterogeneity and immune escape without requiring antigen-specific CAR redesign. A first-in-human clinical trial of PluraliNK cells with antibody therapy has been initiated.

#0143 Enhancing γδ CAR T cell function through alternative CD3 cytoplasmic domains.

Philipp Metzger[1], Marina Zintchenko[2], Susana Minguet[2], Cynthia Obodozie[1], **Holger Weber**[1]

[1]Reaction Biology Europe GmbH, Freiburg, Germany,[2]Signaling Research Centres BIOSS and CIBSS; Department of Synthetic Immunology, Faculty of Biology, University of Freiburg, Freiburg, Germany

Gamma delta (γδ) T cells are a unique subset of lymphocytes that possess innate and adaptive immune functions. Unlike conventional αβ T cells, γδ T cells recognize antigens in an MHC-independent manner. This allows them to detect a wide range of stress-induced ligands that are commonly expressed on tumor cells. This property makes γδ T cells particularly attractive for cancer immunotherapy, especially in cases where tumors evade immune surveillance by downregulating MHC molecules. Recent advances in cellular engineering have made it possible to generate γδ T cells that express chimeric antigen receptors (CARs), which combines their natural tumor-recognition capabilities with the targeted specificity of CARs. γδ CAR T cells offer several advantages over αβ CAR T cells, including lower graft-versus-host disease risk, suitability for allogeneic applications (“out-of-the-shelf”), and enhanced solid tumor infiltration due to tissue-homing properties. These properties provide a strong rationale for investigating γδ CAR T cells as a novel cancer therapy approach and underscore the importance of continued optimization to realize their full therapeutic potential.

This study explores strategies to improve the intracellular signaling domain of CAR constructs with a focus on γδ T cells. The CD3ζ domain has traditionally been used as the primary activation motif in CAR design. However, emerging evidence suggests that it may not be optimal for all T cell subsets. Therefore, we investigated alternative CD3 subunits, specifically, CD3δ, CD3ε, and CD3γ, as intracellular signaling domains in CAR constructs. Our in vitro data show that CARs with these alternative CD3 cytoplasmic tails are more effective than conventional CD3ζ-based CARs in terms of activation and cytotoxicity. In vivo validation of αβ CAR T cells incorporating alternative CD3 subunits has demonstrated enhanced antitumor efficacy. To extend these findings, in vivo experiments are currently underway using the NALM-6_luc (luciferase expressing) xenograft model, a well-established system for evaluating next-generation cellular therapies. These experiments aim to explore whether similar benefits apply to γδ CAR T cells. If confirmed, these results would underscore the potential of leveraging alternative CD3 signaling domains to optimize CAR T cell performance, particularly in γδ T cell-based therapies.

Our findings provide a compelling rationale for reevaluating CAR construct design, suggesting that alternative CD3 subunits could significantly enhance the therapeutic potential of γδ CAR T cells in cancer treatment.

#0144 *In vivo* CAR mRNA engineering of both adaptive and myeloid cells enables potent anti-tumor control of solid cancers.

Junming Tong[1], Moore Chen[2], Kevin Sek[1], Meghan Harris[3], Jerome Chal[3], Colin Pouton[2], Angus Johnston[2], Daniel Getts[3], Robert Hofmeister[3], Phil Darcy[1], **Jian Ding**[3]

[1]Sir Peter MacCallum Department of Oncology, University of Melbourne, Peter MacCallum Cancer Centre, Melbourne, Australia,[2]Drug Delivery, Disposition and Dynamics, Monash Institute of Pharmaceutical Sciences, Monash University, Parkville, Australia,[3]CREATE Medicines, Cambridge, MA

Background: In solid tumors, chimeric antigen receptor (CAR) T cell therapies are limited by their inability to overcome poor trafficking, antigen heterogeneity and the immunosuppressive myeloid cells in the tumor microenvironment (TME). Here, we introduce in vivo multi-immune cell programming designed to precisely and simultaneously program multiple immune cell types using a single engineered product. This approach builds on the clinical experience with in vivo CAR-mRNA engineered CAR myeloid cells that created a pro-inflammatory tumor environment. Combining non-targeted and targeted LNP delivery, optimized mRNA, and cell-specific CAR architecture, we endow myeloid cells, NK cells and T cells with tailored effector functions.
Methods: Anti-HER2 CAR mRNAs optimised for myeloid, NK or T cell signalling were encapsulated in LNPs and delivered intravenously. Anti-tumor efficacy was evaluated in immunocompetent hHER2 transgenic mice bearing syngeneic hHER2-MC38 colon adenocarcinoma tumors.
Results: In a colorectal tumor model, myeloid- and NK-cell reprogramming with CAR mRNA/LNPs drove tumor regression, prolonged survival, remodeling of the tumor microenvironment, greater antigen presentation, and enhanced T-cell infiltration and activation. Likewise, T cell engineered with CAR mRNA/tLNPs elicited robust anti-tumor activity. Notably, co-delivery of cell-specific CAR mRNA/LNPs to both myeloid and T-cell compartments produced even stronger tumor control, highlighting the power of coordinated multi-lineage immune engineering.
Conclusions: This work demonstrates that simultaneous In vivo engineering of myeloid cells, T cells, and NK cells with CARs can orchestrate the coordinated actions of both innate and adaptive immunity for potent anti-tumor activity. This strategy offers a scalable and off-the-shelf approach for cell therapy and establishes a new therapeutic paradigm for overcoming the complexity of solid tumors.

#0145 CD8 nanobody-targeted lipid nanoparticles encapsulating CD13 nanoCAR circular RNAs for in situ CAR-T cell eradication of acute myeloid leukemia.

Wilson Huang[1], Diva Chen[1], Yun-Chin Chou[1], Tsung-Chih Chen[1], Chia-Jen Wu[2]

[1]Citil Pharma, Cambridge, MA,[2]Academia Sinica, Taipei, Taiwan

Acute myeloid leukemia (AML) is an aggressive and recurrent cancer with a high mortality rate. Chimeric antigen receptor (CAR)-T cell therapy is an FDA approved therapy for acute lymphoblastic leukemia (ALL) but not for AML mainly due to hematopoietic stem and progenitor cell side effects. This is driven by persistent CD13, CD33, CD123 targeting from lentivirus-transduced CAR-T cells. Yet, CD13, a prognostic marker for AML, identifies 95% of the AML blasts and most leukemic stem cells (LSCs). AML is also a heterogenous cancer with diverse antigen profiles, posing treatment challenges. Finally, current CAR-T cell therapies are immensely costly due to cumbersome ex vivo T cell and viral procedures, restricting patient access.

We aim to overcome these technical challenges by leveraging the low tonic signaling of VHH-based nanobodies, transient expression of circular RNAs (circRNAs), and non-viral properties of lipid nanoparticles for effective eradication of AML while minimizing negative hematopoietic effects. Specifically, we attached CD8 nanobodies to lipid nanoparticles, constructed CD13 nanoCARs on circRNA backbones, and assembled the targeted circRNA lipid nanoparticle complexes. These complexes enable in situ, cell-specific engineering of splenic human CD8+ T cells and generate cytotoxic CD13 nanoCAR-T cells that target the prevalent AML population. We demonstrated the feasibility of this approach by generating a CD8 nanobody with 86% reactivity toward human CD8+ T cells. We then customized the CD8 nanobody with a negatively charged polyglutamic acid tail to form strong electrostatic associations with our positively charged, proprietary lipid nanoparticles. We produced CD13 nanoCAR circRNAs with undetectable levels of double-stranded RNA impurities through cellulose purification and encapsulated them in the lipid nanoparticles by microfluidic mixing. The entire targeted circRNA lipid nanoparticle complex selectively transfected 24% of the human CD3+ lymphoid T cells in the spleen of NPG mice previously reconstituted with human PBMCs. We then assayed and selected the THP-1 human AML cell line showing high CD13 expression and low nonspecific T cell killing in vitro. In an immunodeficient NPG CDX mouse model, CD8 nanobody-targeted lipid nanoparticles encapsulating CD13 nanoCAR circRNAs exhibit specific and effective in vivo killing of a subcutaneously engrafted THP-1 tumor.

#0146 *In vivo* lentiviral CAR-T gene delivery demonstrates high specificity and potent anti-tumor activity in a humanized B cell lymphoma model.

Ilian Radichev[1], Devin Stranford[2], Hailey Edelstein[2], Oanh Pham[1], Destanie Rose[1], Jiwon Yang[1], Mahdy Yassine[2], Henry Schirmer[2], Teresa Nikolich[2], Joshua Leonard[2], James Keck[1], Matteo Stoppato[2]

[1]Innovation and Product Development, The Jackson Laboratory-West, Sacramento, CA,[2]Syenex, Inc, Evanston, IL

Introduction: Chimeric Antigen Receptor T (CAR-T) cell therapies have revolutionized treatment for hematologic malignancies, particularly B cell cancers, and show promise in autoimmune diseases and solid tumors. Despite this success, the conventional approach to CAR-T manufacturing presents several limitations: it requires leukapheresis, PBMC isolation, ex vivo genetic modification and expansion, and reinfusion back into the patient. These steps are time-consuming, costly, and logistically complex, limiting scalability and patient accessibility. Furthermore, current CAR-T therapies have shown limited efficacy against solid tumors due to poor trafficking, immunosuppressive microenvironments, and antigen heterogeneity.

Methods: To improve the cost-inefficient and time-consuming challenges of the standard CAR-T therapy, Syenex developed Vivo-T, a novel T cell-specific lentiviral vector (LVV) platform enabling in vivo delivery of CAR constructs, eliminating the need for ex vivo manipulation and personalized CAR-T manufacturing. This system was evaluated in JAX PBMC-humanized B cell lymphoma mouse model. NSG-MHC I/II double knockout mice were irradiated and injected intravenously with 2.5×10^5 Raji-Luc cells. Five days later, mice were engrafted with 1×10^7 human PBMCs. Between 4-24 hours post-engraftment, mice received intravenous doses of T cell-targeted LVVs encoding anti-CD19 CARs. Tumor burden was monitored via IVIS imaging for 3 weeks. Toxicity was assessed through body weight, clinical observations, and serum cytokine analysis. CAR-T engraftment and expansion were evaluated by flow cytometry of peripheral blood.

Results: In vivo delivery of the CAR construct resulted in efficient T cell transduction, with rapid and robust CAR-T expansion surpassing that of ex vivo-engineered CAR-T control. Notably, significant anti-tumor activity was observed as early as 7 days post-LVV administration. Initial signs of toxicity were primarily attributed to high viral titers; however, these effects were mitigated by reducing the viral load, without compromising the antitumor efficacy of the treatment. These findings validate the efficacy of the in vivo CAR-T system and support its potential for clinical translation.

Conclusion: The Vivo-T system represents a transformative approach to CAR-T therapy by simplifying manufacturing, reducing costs, and enabling scalable, off-the-shelf immunotherapy.

#0147 A multipronged approach to improve gene delivery efficiency for *in vivo* CAR-T using CD3 and CD7 retargeted LVVs.

Longshan Liu[1], Cheng Luo[1], Yangyang Tang[1], Lianqu Li[1], Hai Huang[1], Mangmang Li[1], **Yu Liang**[2]

[1]Probio Inc, Nanjing, China,[2]Probio Inc, Pennington, NJ

Chimeric antigen receptor (CAR)-T therapies have advanced cancer treatment; however, for conventional *ex vivo* CAR-T therapies, patient access is often hindered by high costs, long manufacturing times, lymphodepleting chemotherapy needed to precondition the patient, and the inconvenience to travel to specialized treatment centers. To address these limitations, strategies have recently emerged to generate CAR-T cells *in situ*. These approaches, comprising the field of *in vivo* CAR-T, are based on delivering the CAR construct to T cells *in situ* typically using either lentiviral vectors (LVV) or lipid nanoparticles (LNP) decorated with T cell-specific antibodies. *In vivo* CAR-T approaches have demonstrated encouraging efficacy in preclinical and early clinical studies, but still face challenges in terms of efficiency, specificity, durability, and scalability. CD3 and CD7 are well-established T cell targets used in current *in vivo* CAR-T delivery vehicles, and such LVV and LNP-based approaches are showing encouraging efficacy in CAR gene delivery to T cells *in situ*; however, the efficiency of current approaches based on monospecific CD3 or CD7 antibodies for *in vivo* gene delivery still remains low, thereby limiting their therapeutic potency. By using internally developed CD3 and CD7 VHH antibodies, we implemented a multipronged approach to improve the gene delivery efficiency *in vivo*, including 1) incorporation of a CD3+CD7 bispecific antibody in the LVV particle; 2) inclusion of a HIV component in the LVV particles that counteracts host antiviral defense mechanisms to enhance transgene expression; 3) co-administration of an approved cardiovascular drug that enhances CD7 expression in T cells. *In vitro* assays in a T cell line and primary T cells and in vivo studies with mice and non-human primates demonstrated that these novel approaches and their combinations substantially improved CAR gene expression compared with CD3 or CD7 monospecific-targeted LVVs.

#0148 *In vivo* CAR-T T-LNP system (GT801) drives potent B cell depletion and clinical feasibility in hematologic and autoimmune conditions.

Jingwei Sun[1], Xi Zhu[2], Jiahui Jin[1], Yiyang Tan[1], Liang Lin[1], Zhao Xu[1], Jingman Wang[1], Dalang Li[2], Hong Chen[2], Jiaming Ren[2], Jun Cui[1], Jing Yu[1], **Pin Wang**[3], Yarong Liu[4]

[1]Grit Biotechnology, Shanghai, China,[2]Shanghai Vitalgen Biopharma, Shanghai, China,[3]University of southern california, Los Angeles, CA,[4]Vivacta Biotechnology (Shanghai) Co., Ltd., Shanghai, China

Background: CAR-T therapies have revolutionized hematologic malignancies treatment but remain constrained by complex autologous manufacturing, high cost, and lymphodepletion toxicity. In vivo CAR-T approaches aim to overcome these barriers by engineering T cells directly in patients, which requires targeted delivery, durable CAR expression, potent cytotoxicity, and re-dosing potential. Toward this goal, we present the development, preclinical data, and preliminary clinical results for GT801, a novel anti-CD19 in vivo CAR-T candidate.

Methods: GT801 uses T cell-targeted lipid nanoparticles (T-LNPs) encapsulating chemically modified linear mRNA encoding an anti-CD19 CAR. T-LNPs were surface-engineered with a VHH antibody using the CLAMP platform, enabling site-specific antibody attachment, controlled ligand density, and efficient, selective T-cell uptake. Formulation and mRNA design were optimized for targeting specificity, robust CAR expression, and functionality. B-cell depletion, PK, and preliminary toxicology of GT801 were assessed in vitro and in humanized NOG mouse models.

Results: With optimized mRNA chemistry, the T-LNP platform achieves robust and durable CAR expression in human PBMCs for >14 days in vitro. Targeted delivery at 0.1 mpk reached receptor-saturating levels across multiple lymphoid tissues, while off-target uptake remained <1%. In human PBMC-engrafted NOG mice, a single i.v. dose as low as 0.01 mpk achieved >95% B-cell depletion, and 0.1 mpk achieved near-complete clearance (<0.1%) across multiple lymphoid tissues. CDX models demonstrated potent antitumor activity and enhanced CAR-T expansion upon repeat dosing, suggesting good in vivo fitness post-transfection and expansion driven by B cell depletion. Primary B-cell killing was robust in PBMCs from healthy donors and autoimmune patients at only 0.1 μg within 24 hours. Serial-dose toxicology elicited minimal cytokine release (IL-6, TNF-α) and no organ toxicity in any tested organs, supporting the platform's good safety profile. Preliminary clinical data with B-cell hematological malignancies and autoimmune diseases demonstrated high in vivo CAR expression and confirmed repeat-dosing feasibility.

Conclusion: These findings demonstrate that our T-LNP platform enables efficient, targeted, and sustained in vivo CAR expression with a favorable safety profile and scalable manufacturing. The platform's robust preclinical B cell depletion efficacy, validated by preliminary clinical data confirming high in vivo CAR expression and repeat dosing feasibility, successfully validates the system for clinical use. Ongoing patient accrual will further inform clinical outcomes.

#0149 Erythrocyte-mediated mRNA delivery enables *in vivo* generation of CAR-myeloid cells for cancer immunotherapy.

Xiaoqian Nie, Yuehua Liu, Xiaofei Gao

Westlake University, Hangzhou, China

Background: Engineering myeloid cells with chimeric antigen receptors (CARs) holds great therapeutic promise, yet their generation *in vivo* remains challenging. Despite the success of COVID-19 vaccines, targeted mRNA delivery to immune cells remains inefficient. Conventional lipid nanoparticles (LNPs) primarily target the liver upon systemic administration, limiting their utility for lymphoid organs. Moreover, LNPs suffer from low endosomal escape rate and may induce off-target toxicities. Here, we developed an erythrocyte-mediated mRNA delivery system in which mRNA-loaded LNPs are covalently conjugated to erythrocyte membrane proteins in a “plug-and-play” manner, termed mRNA-LNP-Ery. Leveraging erythrocytes’ natural splenic homing, mRNA-LNP-Ery enables selective spleen-specific targeting and efficient mRNA delivery to immune cells for cancer immunotherapy.
Method: We characterized the biodistribution of mRNA-LNP-Ery across multiple mRNA cargoes. To elucidate internalization mechanisms, time-course confocal imaging was performed. Anti-HER2 and anti-CD19 CAR mRNAs were delivered via erythrocytes, and the therapeutic efficacy was assessed in corresponding syngeneic tumor models.
Result: Exploiting erythrocytes’ intrinsic splenic homing capacity, mRNA-LNP-Ery achieved highly selective and efficient mRNA delivery to the spleen while minimizing hepatic uptake. Cellular characterization showed preferential targeting of splenic $CD11b^+$ myeloid cells. Mechanistically, mRNA-LNP-Ery was internalized through phagocytosis while escaping lysosomal degradation, resulting in markedly enhanced mRNA translation and protein expression. To evaluate the therapeutic potential of this platform, we delivered mRNAs encoding CARs targeting HER2 or CD19, which generated functional CAR-myeloid cells *in vivo*, which adopted a pro-inflammatory, antigen-presenting phenotype. These cells migrated to tumors, eliminated cancer cells, and remodeled the tumor microenvironment, leading to increased infiltration of effector T and NK cells. Functionally, mRNA-LNP-Ery induced stronger and more durable tumor regression than conventional mRNA-LNPs across multiple tumor models, including immune-cold tumors, despite using only one-tenth the mRNA dose. The antitumor effect was abolished in splenectomized mice and partially diminished in nude mice, indicating dependence on both CAR-myeloid formation in the spleen and crosstalk with adaptive immunity. Moreover, mRNA-LNP-Ery induced minimal systemic toxicity, underscoring the safety and translational potential of this spleen-targeted delivery approach.
Conclusion: Together, our findings establish a clinically translatable erythrocyte-based mRNA platform that integrates with existing LNP technology to enable direct *in vivo* immune cell programming and advance CAR-immune cell therapies for solid tumors.

#0150 T-cell specific transcriptional control eliminates CAR-mediated off-target transduction by CD3-retargeted lentiviral vectors, enabling safe *in vivo* generation of potent αBCMA-CAR T cells.

Karina Krotova[1], Nandakumar Packiriswamy[1], MD Yeashin Gazi[1], Collin Gwilt[1], Chia-Hsuan Chin[1], Ajay Kumar[1], Aaron Hawkes[1], Gopal Naik Nenavath[1], Thipparat Suwanmanee[2], Darren Phung[2], Luke W. Breigenzer[2], Timothy Carey[1], Christian Kinney[1], Hamid Salimi[1], Patrycja Lech[2], Kah-Whye Peng[2], Stephen Russell[2]

[1]Imanis Life Sciences, Rochester, MN,[2]Vyriad, Rochester, MN

CAR T-cell therapy is a transformative treatment for hematologic malignancies. A key milestone to expand access to this technology is to enable CAR-T generation directly within the patient. For in vivo therapy, the CAR delivery vehicle must resist serum neutralization, target T cells and exhibit minimal or no off-target effects. We recently developed the CD3-targeted lentiviral vector LV-169 which delivers a BCMA CAR transgene to lymph node-resident primary T cells in vivo. LV169 incorporates a VSV-G protein that has been detargeted (blinded) from its natural LDL receptor and re-targeted to T cells via a displayed CD3-specific scFv. However, CAR proteins incorporated into the LV-169 envelope during packaging can induce off-target transduction of malignant plasma cells. Here, we reversed the orientation of the CAR transgene and placed it downstream of the human distal Lck promoter. In contrast to the EF1α promoter, the Lck promoter was transcriptionally silenced in 293 suspension cells but was insufficiently active in Jurkat cells and primary T cells. We therefore inserted a TATA box and a CMV enhancer into the Lck promoter (Lck1.3). The reverse-orientation Lck1.3-driven CAR construct (R-Lck1.3) did not express the BCMA-CAR protein in transfected 293 LV producer cells but was highly active in LV-transduced Jurkat cells and primary human T cells. Western blotting confirmed the high abundance of CAR protein in EF1a-driven vector particles and its absence in R-Lck1.3 particles. Therapeutic efficacy of LV169-R-Lck1.3 vectors encoding the BCMA-CAR was evaluated in human PBMC-engrafted NSG-DKO mice with advanced, disseminated human multiple myeloma. Mice were engrafted with OPM-2-FLuc cells and humanized with PBMCs one week prior to vector infusion. Tumor burden was monitored weekly via luciferase imaging. A single intravenous dose of LV169 (1×10^9 LVP) resulted in complete tumor clearance within 14 days. Circulating anti-BCMA CAR-T cells were detectable 14 days after LV injection but became undetectable once the tumor was eliminated. No severe toxicity was observed, based on stable body weight and cytokine levels in the blood. No tumor growth was observed in treated mice that were re-challenged with OPM-2 on days 22 and 30. In summary, our newly developed LV169-R-Lck1.3 platform encoding the BCMA-CAR demonstrates potent therapeutic activity, and its further clinical translation is underway.

#0151 Combination of cytokines, PM21-particle stimulation, and TGF-β conditioning results in Natural Killer cells with enhanced cytotoxicity and infiltration of solid tumors.

Jeremiah L. Oyer[1], Tayler J. Croom-Perez[1], Javier A. Rivera-Huertas[1], Brian P. Tullius[2], Alicja J. Copik[1]

[1]Burnett School of Biomedical Sciences, University of Central Florida, College of Medicine, Orlando, FL,[2]Pediatric Cellular Therapies, Advent Health for Children, Orlando, FL

In this study, feeder cell-free PM21 particle activation of Natural Killer (NK) cells was combined with cytokine activation and TGF-β conditioning to produce highly proliferative and cytotoxic NK cells that can infiltrate solid tumors. Development of NK cell therapeutics is a promising anti-cancer therapy. For clinical applications, NK cells are typically either *ex vivo* activated with cytokines or expanded with feeder cells or by feeder cell-free methods. One such method for feeder cell-free expansion of highly cytotoxic NK cells uses plasma membrane particles containing surface IL-21 and 41BBL (PM21). Additionally, NK cells expanded with IL-12, IL-15, and IL-18 in combination with PM21 stimulation (CAP-NK cells) exhibit robust proliferation, potent cytotoxicity, and memory-like features. To further improve their activity against solid tumors—a setting often resistant to NK cells—we introduced TGF-β conditioning. Previous studies have shown that ex vivo TGF-β conditioning induces IFNγ hypersecretion. To assess whether this could enhance anti-tumor function, PM21- and CAP-NK cells were expanded in the presence of TGF-β. The CAP-based expansion method still resulted in enhanced NK-cell expansion, even with TGF-β conditioning. CAP-based expansion remained highly effective even with TGF-β conditioning, achieving an average 4000±700-fold expansion by day 14 compared to 1800±60-fold for PM21-NK cells. TGF-β conditioned NK cells retained high viability after cryopreservation (>80% immediately and at 16 h post-thaw) and 99±1% expressed CD25 by day 7. These cells produced significantly more IFNγ upon stimulation than unconditioned CAP-NK cells. Moreover, TGF-β conditioned CAP-NK cells acquired a tissue-resident-like phenotype (CD103+, CD49a+, CD300a–) not observed in PM21- or CAP-NK cells, which would be expected to enhance their ability to infiltrate tumors. To test this, labeled TGF-β conditioned CAP-NK and PM21-NK cells were co-cultured with large lung tumor spheroids and monitored via live-cell imaging. TGF-β conditioned NK cells penetrated tumors faster and deeper than PM21-NK cells, which remained mostly at the periphery, resulting in greater spheroid killing—even in tumors overexpressing TGF-β.TGF-β conditioning also enhanced cytotoxicity against multiple solid tumor cell line spheroids, including lung, pancreatic, and neuroblastoma. Overall, these findings support TGF-β conditioned CAP-NK cells as a potent cellular therapy candidate for solid tumors.

#0152 Toward an *in vivo* anti-BCMA/CD19 CAR-T cell treatment of B cell-mediated autoimmune diseases.

Alexander J. Najibi, Denise Wong, Jeff Wood, Tharani Sivanandam, Han K. Lee, Josue Figueroa, Kelly Nichols, Yao Wei, Emily T. Beura, Shannon Grande Contrastano

Kelonia Therapeutics, Boston, MA

B cell-mediated autoimmune disorders, including systemic lupus erythematosus (SLE), can represent lifelong inflammatory conditions with limited therapeutic options. Autologous CD19-specific CAR-T cells have been demonstrated as an effective treatment option. However, access to CAR-T cell therapies and the use of preparative chemotherapy will ultimately limit the reach of this powerful modality. Moreover, recent data suggest that CD19-negative pathogenic plasma cells can emerge and contribute to SLE disease etiology, suggesting that development of CAR-T cells addressing both CD19-positive and CD19-negative pathogenic B cells is warranted. Here, we describe the preclinical development of an engineered lentiviral vector (LVV) previously shown to specifically modify T cells in vivo (in vivo gene placement system (iGPS®)), encoding a chimeric antigen receptor (CAR) that recognizes both CD19 and B-cell maturation antigen (BCMA) antigens ("tandem CAR"). The operative arms of the tandem CAR were identified by screening a panel of human anti-BCMA and anti-CD19 antibodies incorporating a variety of design features. Candidate tandem CAR constructs were expressed in T cells from healthy donors and SLE patients using iGPS particles. The constructs that caused antigen-specific in vitro T cell activity, assayed by cytotoxicity and cytokine release to cell lines expressing BCMA and/or CD19, were tested in several animal models. First, an SLE mouse model was established using immunocompromised mice humanized with peripheral blood mononuclear cells from SLE patients. After a single dose of the lead tandem CAR iGPS particle, CAR-T cells were generated and expanded in vivo resulting in complete elimination of SLE B cells in the blood, spleen, and bone marrow. In a second mouse model treating an aggressive B cell lymphoma, the iGPS particle delivering the lead tandem CAR caused effective tumor control after a single treatment. These data demonstrated the potential of a tandem anti-BCMA/CD19 CAR-T cell generated in vivo with iGPS particles as an effective treatment of autoimmune disorders. Moreover, persistent CAR-T cells generated using an LVV may provide a single, off-the-shelf treatment capable of eliminating both pathogenic CD19-positive B cells and emergent CD19-negative plasma cells and provide a needed therapy for patients.

#0153 Improvement of monoclonal antibody therapy against cancer through engineering stem cell-derived CD16-enhanced universal NKT cells.

Yan-Ruide Li, Yichen Zhu, Yanqi Yu, Lili Yang

Department of Microbiology, Immunology & Molecular Genetics, University of California, Los Angeles, Los Angeles, CA

Monoclonal antibody (mAb)-based immunotherapies have revolutionized cancer treatment, yet their efficacy remains limited in many solid and hematologic malignancies due to insufficient effector cell engagement, tumor antigen loss, and immunosuppressive tumor microenvironments. To overcome these limitations and enhance the therapeutic potential of mAb therapy, we developed an allogeneic invariant natural killer T (NKT) cell platform through hematopoietic stem cell (HSC) engineering and feeder-free in vitro differentiation. Specifically, we introduced an invariant NKT T cell receptor (TCR) and a high-affinity, non-cleavable CD16a (FcγRIIIa) receptor into HSCs, enabling the generation of CD16-enhanced HSC-engineered NKT (^{CD16}HSC-NKT) cells. These cells can be produced at high yield and purity in a scalable, feeder-free culture system. The resulting ^{CD16}HSC-NKT cells preserve the hallmark NKT phenotype and exhibit robust cytokine secretion, cytotoxicity, and tumor infiltration capacity. Functionally, ^{CD16}HSC-NKT cells mediate potent antibody-dependent cellular cytotoxicity (ADCC) both in vitro and in vivo when combined with tumor-specific monoclonal antibodies, leading to synergistic tumor regression. Beyond direct cytotoxicity, ^{CD16}HSC-NKT cells also display multi-targeted antitumor mechanisms, including recognition of CD1d-presented glycolipid antigens and engagement of stress-induced NK ligands. In preclinical tumor models, ^{CD16}HSC-NKT cells demonstrated superior persistence and metabolic fitness compared with conventional peripheral blood-derived NKT cells. Importantly, ^{CD16}HSC-NKT cells were found to reshape the tumor microenvironment by selectively depleting immunosuppressive tumor-associated macrophages (TAMs) and myeloid-derived suppressor cells (MDSCs), thereby promoting a more pro-inflammatory and immune-permissive milieu. No evidence of graft-versus-host disease, cytokine release syndrome, or long-term organ toxicity was observed, supporting a favorable safety profile. Collectively, our study establishes ^{CD16}HSC-NKT cells as a universal, off-the-shelf cellular immunotherapy that can be flexibly paired with diverse monoclonal antibodies to enhance their efficacy, overcome resistance, and expand the therapeutic reach of antibody-based cancer treatment.

#0154 Robust engraftment of human γδ T cells in humanized NSG™-SGM3-IL-15 × MHC I/II double knockout mice for the evaluation of γδ T cell-based therapeutics.

Kevin Tsai, Beau Parry, Destanie Rose, James G. Keck, Li-Chin Yao

Innovation and Product Development, The Jackson Laboratory, Sacramento, CA

Background Gamma delta (γδ) T cells represent a minor subset of T lymphocytes capable of recognizing a wide range of universally conserved antigens expressed by cancer cells. Unlike conventional T cells, their recognition is independent of MHC, making them strong candidates for next-generation universal cancer therapeutics targeting various malignancies. Our preliminary donor screening results demonstrated that engrafting human peripheral blood mononuclear cells (PBMCs) into irradiated NSG™-SGM3-IL-15 × MHC I/II DKO (SDKO) mice could lead to the expansion of circulating γδ T cells to a concentration comparable to those in human and robust γδ T cell recovery from tissues. To demonstrate our PBMC-SDKO mice platform for *in vivo* evaluation of γδ T cell related therapeutics, we conducted γδ T cell engraftment experiments using irradiated SDKO mice and PBMC from 9 donors. We also assessed the anti-cancer functionality of these isolated γδ T cells from PBMC engrafted mice using *in vitro* co-culture experiments with human lymphoma or triple-negative breast cancer cell lines.

Methods Irradiated SDKO mice were engrafted with PBMCs from 9 different human donors. Leukocyte engraftment in the periphery was monitored weekly post PBMC injection using flow cytometry to enumerate the frequency and numbers of αβ T cells, γδ T cells and their subpopulations Vδ1, and Vδ2. γδ T cells engrafted in spleen and lungs were isolated using antibody conjugated magnetic beads and then co-cultured *in vitro* with Raji or MDA-MB-231 cells to assess their anti-tumor functionality.

Results We found that circulating γδ T cells expanded greatly in engrafted SDKO mice. In some of the donors, the concentration of γδ T cells reached up to 4×10^2 cells/μL - a level comparable to that of circulating human B cells, which is a major population in peripheral blood. Among the γδ T cell subsets, the Vδ2 subset exhibited the most robust and consistent expansion, while other γδ T cell subsets such as the Vδ1 were donor dependent. In addition to peripheral blood, we also observed robust engraftment and recovery of γδ T cells from the lungs and spleens of engrafted SDKO mice. Our *in* vitro co-culture experiments demonstrated that the γδ T cells isolated from the spleens and lungs of SDKO mice showed elevated cell surface expression of CD69, granzyme B secretion in response to cancer cells and reduced the number of Raji or MDA-MB-231 cell numbers at effector to target ratios of 1:1 and 3:1. Our results suggest that γδ T cells can be robustly expanded and recovered from the SDKO mice and that the recovered cells possess potent cytolytic activity against tumor cells.

#0158 PI3Kδ in CD4⁺ T cells protects against lung metastases through IFNγ-induced tumor senescence.

Leqi Tang[1], Grace Cooper[1], Linsey Porter[2], Seung joon Kim[3], Erick Armingol[4], Oliver Burton[1], James E. Thaventhiran[5], Walid T. Khaled[6], Roser Vento-tormo[4], Rahul Roychoudhuri[1], Klaus Okkenhaug[1]

[1]Department of Pathology, University of Cambridge, Cambridge, United Kingdom,[2]Cambridge Stem Cell Institute, Cambridge, United Kingdom,[3]University of Oxford, Oxford, United Kingdom,[4]Wellcome Sanger Institute, Cambridge, United Kingdom,[5]MRC Toxicology Unit, Cambridge, United Kingdom,[6]Department of Pharmacology, University of Cambridge, Cambridge, United Kingdom

PI3Kδ is a key lymphocyte signaling hub for manipulating antitumor immunity. In cancer, most work has centered on inhibiting PI3Kδ, particularly in regulatory T cells, to relieve immunosuppression and enhance effector T cell control of established tumors. Yet lung metastasis remains a leading cause of cancer mortality, and the impact of PI3Kδ modulation on metastatic outgrowth remains incompletely understood. Inspired by gain-of-function PIK3CD mutations that cause activated PI3Kδ syndrome (APDS), we ask whether enhancing PI3Kδ signaling can be harnessed to prevent melanoma lung metastases. Here, we demonstrate that hyperactivation of PI3Kδ confers robust protection against pulmonary melanoma metastases in a CD4⁺ T cell - dependent manner that drives IFNγ-mediated tumor cell senescence.

We employed mice with germline or conditional hyperactive PI3Kδ, challenged intravenously with B16F10 melanoma to establish lung metastasis. Cell-specific Cre systems identified critical immune populations mediating metastasis rejection. Single-cell RNA-seq and spectral cytometry defined immune remodeling, while depleting and neutralizing antibodies as well as CRISPR-edited melanoma lines revealed underlying mechanism.

Germline hyperactive-PI3Kδ mice developed markedly fewer lung metastases than wild-type controls, and inducible activation of hyperactive PI3Kδ in the hematopoietic compartment was sufficient to confer protection. Protection was dependent on CD4⁺ T cells - CD4⁺ T cell specific PI3Kδ hyperactivation recapitulated germline protection, while B cell, NK cell and CD8⁺ T cell specific PI3Kδ hyperactivation did not. Antibody depletions confirmed that CD4⁺ depletion abolished protection while CD8⁺ depletion had no effect. Hyperactive PI3Kδ CD4⁺ T cells showed enhanced Th1 differentiation with increased IFNγ and IFNγ-neutralization eliminated the protection against metastasis. Mechanistically, tumor control required IFNGR1/JAK1 signaling in cancer cells but not TNFR1, and operated independent of tumor MHC-I or MHC-II expression. The protective mechanism converged on IFNγ-induced tumor senescence, as lung metastases from hyperactive-PI3Kδ mice displayed increased SA-β-gal activity, indicating that CD4⁺ T cells halt metastatic progression by enforcing tumor cell senescence.

Our findings reveal a novel protective axis where hyperactive PI3Kδ signaling in CD4⁺ T cells drives a type 1-skewed pulmonary anti-metastasis microenvironment. This elevates CD4⁺ T cells from "helpers" to anti-metastatic effectors using IFNγ-dependent tumor-intrinsic senescence to achieve durable immune control. These results reveal hyperactive PI3Kδ as a double-edged sword: while pathogenic in APDS, it reinforces immune surveillance of metastasis, offering new therapeutic avenues for preventing metastatic progression by enhancing PI3Kδ signaling.

#0159 Itaconate promotes memory CD8$^+$ T cell development by epigenetic modification and glucose flux redirection in viral infection and cancer.

Xiao Yang, Mengyao Su, Jiacheng Wang, Yue Deng, Lingyi Kong, Kunyu Yang, Chao Wan

Huazhong University of Science and Technology, Wuhan, China

Background: Coordinated metabolic alterations and epigenetic remodeling are known to critically influence T cell fate decisions and functional states. However, the specific extrinsic metabolic signals that guide CD8$^+$ T cell memory differentiation remain to be fully elucidated.

Methods: Naïve CD45.1$^+$ OT-I CD8$^+$ T cells were adoptively transferred into Listeria monocytogenes-infected CD45.2 mice to track in vivo differentiation trajectories. Tumor-infiltrating CD8$^+$ T cells were analyzed by single-cell RNA sequencing to delineate T cell subclusters. Mechanistically, we profiled global chromatin accessibility of CD8$^+$ T cells under itaconate treatment using ATAC-seq, revealing its epigenetic remodeling effects. Through a combination of surface plasmon resonance (SPR) and complementary biochemical assays, we demonstrated that itaconate directly binds to lysine demethylase 5B (KDM5B) and functionally antagonizes α-ketoglutarate (α-KG). Furthermore, metabolic flux analyses, along with direct measurements of NADPH and GSH levels, confirmed that itaconate drives metabolic reprogramming in CD8$^+$ T cells to sustain redox balance and memory differentiation capacity.

Results: We found that itaconate, induced during immune responses, is a critical promoter of memory T cell (T_M) differentiation. Mechanistically, itaconate directly binds to KDM5B and acts as an α-KG antagonist, competitively inhibiting KDM5B-dependent demethylation of H3K4me3. This inhibition leads to increased chromatin accessibility at genes essential for T_M cell differentiation. Furthermore, itaconate redirects glucose flux from glycolysis to the PPP, thereby ensuring high levels of NADPH and glutathione in TM cells to alleviate oxidative stress.

Conclusions: Our results identify itaconate as a key immunometabolic regulator that promotes durable immune memory in viral infections and cancer by concurrently modulating epigenetic programming and metabolic fitness. This machinery presents a potential therapeutic target to enhance the stem-like phenotype and persistence of CAR T cells.

#0160 FGFR3 impairs DC1s/CD8$^+$ T cell clustering in bladder cancer preventing the PD-1/PD-L1 blockade-induced CD8$^+$ T cell phenotypes associated with immunotherapy efficacy.

Andrea Ziblat, Ken Hatogai, Anthony A. Fernald, Danny E. Kim, Hyunsik Lee, Alexander T. Pearson, Madeleine S. Torcasso, Randy F. Sweis

Medicine, University of Chicago, Chicago, IL

Background: Despite advances in immunotherapy, median survival for advanced bladder cancer remains under 3 years, and mechanisms governing PD-1/PD-L1 blockade efficacy remain ill defined. Activation of fibroblast growth factor receptor-3 (FGFR3) has been shown to be linked to a non-T cell-inflamed tumor microenvironment (TME) and with resistance to checkpoint blockade. Using human bladder tumors and murine models, we investigated mediators of immunotherapy response and how FGFR3 shapes the immune landscape affecting PD-1/PD-L1 treatment efficacy.
Methods: Multiplex immunofluorescence (mIF) and RNAscope were performed on 47 human bladder tumors to assess immune infiltrates and FGFR3 expression. A second cohort of 21 bladder tumors collected before anti-PD-1/PD-L1 therapy was analyzed by mIF and spatial transcriptomics (ST). CD8+ T cell and DC1 clustering was evaluated using an unbiased computational analysis (K-cross, a modified Ripley's K function). ST was used to investigate the effect of FGFR3 expression on immune cells spatial distribution and transcripts. In vivo, subcutaneous and orthotopic MB49 models expressing FGFR3 G370C activating mutation, FGFR3 kinase-dead mutant (K508M), or control vector were used with/without anti-PD-L1. FTY720 was used to assess the requirement for new T cell entry into the TME for anti-PD-L1 efficacy. Tumor growth and immune phenotypes were analyzed by spectral flow cytometry.
Results: FGFR3-activated tumors showed reduced CD86+ DC1s in tumor-draining lymph nodes (tdLN), impaired CD8+ T cell activation, greater exhaustion, and fewer TCF-1+ progenitor-exhausted CD8+ T cell (TPE) in the TME after anti-PD-L1 treatment. Blockade of new T cell entry to the TME abrogated the anti-PD-L1-induced accumulation of TPE in control tumors. FGFR3-kinase-dead mutation resulted in higher TPE frequencies in tumors, tdLN, and spleen, and reduced CD8+ T cell exhaustion. In human tumors, clinical response to PD-1/PD-L1 blockade was associated with CD8+/DC1 clustering rather than absolute cell numbers. FGFR3 expression inversely correlated with CD8+ and DC1 abundance and co-localization. Within tumors, FGFR3+ regions showed fewer DC1s, CD8+ T cells, reduced co-localization, and diminished expression of chemokines that recruit these cells. CD8+ T cells in FGFR3+ areas exhibited lower activation/effector and TPE gene expression and higher exhaustion/inhibitory-related transcripts, compared to those in FGFR3 negative areas.
Conclusions: Our results indicate that DC1/CD8+ T cell clustering is essential for PD-1/PD-L1 efficacy in bladder cancer, and FGFR3 activation drives resistance by disrupting this interaction, preventing CD8+ T cells from acquiring phenotypes required for effective immunotherapy.

#0161 Adenosine signaling promotes double-negative t-cell anticancer responses in conditions of CD8 t-cell lymphopenia.

Brionna King[1], Zhi Huang[1], Laura Naldi[1], Lucio Miele[2], Giulia Monticone[2]

[1]Genetics, LSU Health New Orleans, New Orleans, LA,[2]LSU Health New Orleans, New Orleans, LA

CD8 T-cells lymphopenia is a feature of several pathological conditions and is associated with decreased survival and increased risk of developing cancer and infections. Increase in Double-Negative T-cells (DNTs), a subset of T-cells which lack CD8 and CD4 receptors, has been found in both human patients and mice with lymphopenia. DNTs could be either suppressive or immunoprotective. Generating immunoprotective DNTs could be useful to compensate for the lack of CD8 T-cells, but how to stimulate them remains unclear. Forodesine (Foro) is a nucleoside analog which has known antileukemic activity. Foro can also stimulate T-cell function, but the mechanism behind this effect and what type of T-cells is targeted by the drug is still unclear. In this study, we investigated strategies to promote immunoprotective antitumor DNTs in conditions of CD8 T-cells lymphopenia using the antileukemic drug Foro. To determine whether and how Foro stimulates T-cells, we tested Foro in an orthotopic syngeneic triple-negative breast cancer model (C0321-FVB mice). Foro significantly reduced tumor growth and stimulated tumor-infiltrating CD8 T-cells, suggesting that CD8 T-cells modulation mediates its effect. However, when CD8 T-cells were depleted to mimic CD8 T-cells lymphopenia, Foro showed an even stronger anticancer effect. Interestingly, Foro increased CD69+ DNTs in tumors and in circulation, in blood, and this increase correlated with smaller tumors, suggesting that Foro stimulates anticancer DNTs responses when there is a lack of CD8 T-cells. We next studied how Foro could promote antitumor DNTs. Our previous work showed that nucleoside analogs, like Foro, can modulate immunity by blocking the A2A receptor (A2AR). Consistently, blocking A2AR with the antagonist ZM-241385 (ZM) also increased CD69+ DNTs in immunocompetent mice, mimicking Foro treatment. To confirm whether the immunomodulatory effect of Foro in DNTs is based on its capacity to modulate A2AR, we: (i) predicted the interaction between A2AR and Foro using our validated molecular docking modeling; (ii) found that Foro reduced adenosine-induced cyclic AMP (cAMP), the second mediator of A2AR, in A2AR-expressing cells, like ZM; (iii) observed increased Notch1 activation, which is downstream of A2AR, in CD69+ DNTs in Foro-treated mice. Finally, we found that CRISPR-KO of Notch1 significantly reduced CD69+ DNTs, suggesting that Notch1 is critical for the generation and function of DNTs, in response to Foro. Our results indicate that blocking the A2AR signaling promotes Notch1 activation leading to the generation of anticancer CD69+ DNTs, a T-cell subpopulation which could compensate for the lack of CD8 T-cells when lymphopenia occurs. This can be achieved pharmacologically using compounds with A2AR antagonistic properties like Foro. Our work put forward a new rationale for the treatment of cancer patients affected by lymphopenia.

#0162 Early CD8⁺T and NK cell interactions orchestrate preemptive immunosurveillance to potentiate optimal cytotoxicity that blocks tumor antigen-escape variants.

Thanigaivelan Kanagasabai[1], Salvador Gonzalez Ochoa[1], Roman V. Uzhachenko[1], Maria Teresa P. de Aquino[1], Harshana Rajakaruna[2], Muna A. Mohammed[3], Jane Tonello[1], Maria Johnson Irudayam[2], Alla V. Ivanova[1], Anil Shanker[1]

[1]Department of Biochemistry, Cancer Biology, Neuroscience and Pharmacology, Meharry Medical College, Nashville, TN,[2]The Office for Research and Innovation, Meharry Medical College, Nashville, TN,[3]Department of Biomedical Sciences, Meharry Medical College, Nashville, TN

Background: Tumor antigen-escape variants pose a major barrier to immunotherapy by disrupting lymphocyte effector pathways and reconfiguring tumor-immune landscapes. A deeper understanding of immune networks during tumor development is required. We assessed whether homeostatic CD8⁺ T cell-NK cell interactions can preemptively block tumor antigen escape.

Methods: Adoptive CD8⁺ T cell transfers were performed either before tumor implantation (D_{-7}, homeostatic pre-priming) or after tumor establishment (D_{+1}) in $Rag1^{-/-}$ and $Rag1^{-/-}\gamma c^{-/-}$ mice. Antigen presentation, immune activation, proliferation, cytotoxicity, and memory differentiation were quantified using multiparameter flow cytometry, live bioluminescence imaging, and high-resolution confocal microscopy. Intercellular interactions were modeled through monoculture, co-culture, and a 3D silica nanofiber carpet that recapitulates basement-membrane-like architecture. Phospho-signaling arrays and cellular motion metrics (Speed-Distance Index, deceleration) were employed to assess activation dynamics and coordination. Human ligand-receptor pairs implicated in CD8⁺ T-NK cell crosstalk were identified through in silico analyses.

Results and Discussion: Our study shows that pre-tumor (D_{-7}) CD8⁺ T cell transfer establishes a preemptive immune surveillance network by orchestrating NK cell activation and effector function. These early T cells enhance NK cytotoxicity (CD25, CD69, CD107a, T-bet, GzmB) and promote $CD62L^{+}CD44^{+}$ central-memory CD8⁺ T (T_{CM}) precursors, providing immediate and long-term protection. Spatial analyses reveal that early T cells reposition NK cells toward tumors, increasing synapse formation and infiltration effects absent in post-tumor (D_{+1}) transfers that allow antigen-loss variants despite potent T cell cytotoxicity. Mechanistically, CD8⁺ T-NK interactions via pseudopodial nanotubes enable bidirectional membrane/vesicle exchange and coordinated STAT, Akt, AMPK, and mTOR signaling, enhancing NK metabolic fitness, mitochondrial potential, and T_{CM} differentiation. In silico analyses identify conserved human adhesion and co-signaling networks (CD200-CD200R, PD-L1-PD-1, CD18/CD11a-DNAM-1, TIGIT-PVR, NTB-A/SLAM) regulating adhesion, activation thresholds, and cooperative effector functions, with translational relevance. Precise molecular signaling remains under investigation.

Conclusion: Early CD8⁺ T-NK crosstalk establishes preemptive immunosurveillance by integrating metabolic, cytokine, and adhesion signals to potentiate optimal cytotoxicity blocking tumor antigen escape. This axis represents a targetable checkpoint and a framework for next-generation preventive immunotherapies against antigen-loss tumors.

#0163 Allogeneic double-negative T cells induce an innate-like cytotoxic function in CD8$^+$T cells against acute myeloid leukemia.

Leanne Palichuk[1], **Enoch Tin**[1], Pauline Douglas[1], Ruzena Filandrova[1], David Schriemer[1], Juan Arteaga[1], Michele Nawata[1], Sandeep Kaur[2], Sonia Cerquozzi[2], Michelle Geddes[2], Lynn Savoie[2], Jongbok Lee[1]

[1]Arnie Charbonneau Cancer Institute, University of Calgary, Calgary, AB, Canada,[2]Department of Medicine, University of Calgary, Calgary, AB, Canada

Background: Acute myeloid leukemia (AML) is characterized by malignant cells of myeloid origin and poor long-term survival due to relapse following conventional therapies. $CD3^+CD4^-CD8^-$ double-negative T cells (DNTs) are a rare T-cell subset that can kill AML cells without causing graft-vs-host disease in preclinical models. A prior phase I trial demonstrated the feasibility, safety, and potential efficacy of healthy donor-derived allogeneic DNT therapy among patients with relapsed AML. However, the interaction between allogeneic DNTs and host immune cells remains unclear.

Purpose: This study aims to investigate how allogeneic DNTs invigorate $CD8^+$ T cells to better target AML.

Methods: $CD8^+$ T cells were collected from patient samples or healthy peripheral blood mononuclear cells after incubation with DNTs or various activation factors (anti-CD3/CD28 beads, AML cells, or AML cells with DNTs), respectively, followed by CD8 positive selection. Proteomic and single-cell RNA-sequencing (scRNA-seq) techniques were performed to identify unique immune pathways in DNT-activated $CD8^+$ ($CD8^{DA}$) T cells to kill AML cells. Findings of $CD8^{DA}$ T cells were verified through cytotoxic co-culture assays, immunophenotyping, genetic knockouts (KOs), and inhibition assays.

Results: $CD8^+$ T cells from AML patient samples co-cultured with DNTs were highly activated and exhibited potent cytotoxicity against autologous AML blasts, compared to those cultured in the absence of DNTs. Mass spectrometry identified a unique proteomic profile in $CD8^{DA}$ T cells, which were enriched for innate immune response markers relative to the other forms of activation. Interestingly, a higher $CD8^{DA}$ T-cell signature score in patients' $CD8^+$ T cells correlated with a response to anti-CTLA4 and decitabine treatment. Furthermore, $CD8^{DA}$ T cells can target MHC^{KO} AML cells, while anti-DNAM-1 antibodies reduce $CD8^{DA}$ T-cell potency, indicating an innate-like immune mechanism. ScRNA-seq conducted on co-cultures of $CD8^+$ T cells with AML, in the presence of DNTs or anti-CD3/CD28 beads, revealed an enrichment of ferroptosis-related genes in AML cells in the group cultured with DNTs. Using various cell-death inhibitors, only ferroptosis inhibitor Liproxstatin-1 significantly reduced the cytotoxic function of $CD8^{DA}$ T cells. Clinically, lower expression of *GPX4* or *AIFM2* (FSP1), negative regulators of ferroptosis, resulted in better survival among two AML cohorts.

Conclusion: DNTs stimulate an innate-like ability in $CD8^+$ T cells to kill AML in an MHC-independent, DNAM-1-dependent manner through ferroptosis, yielding a potential clinical benefit for patients with AML.

#0164 Restoring TUSC2 function boosts NK cell cytotoxicity and antitumor immunity in vivoand in vitro.

Muna Ahmed Eltayeb A. Mohammed[1], Salvador Gonzalez Ochoa[1], Jane Tonello[1], Thanigaivelan Kanagasabai[1], Mark S. Berger[2], Alla Ivanova[3], Anil Shanker[4]

[1]Meharry Medical College, Nashville, TN,[2]Genprex, Austin, TX,[3]Alla Ivanova (Individual),[4]Biochemistry and Cancer Biology, Meharry Medical College, Nashville, TN

Background: Tumor Suppressor Candidate 2 (TUSC2), located on chromosome 3p21.3, is frequently deleted in multiple human cancers, including non-small cell lung carcinoma (NSCLC), small cell lung carcinoma (SCLC), mesothelioma, breast cancer, and head-and-neck cancers. Loss of TUSC2 is associated with reduced survival and increased tumor aggressiveness. Although TUSC2 is known to suppress tumor cell proliferation and induce apoptosis, its regulatory role in the immune system—particularly in innate lymphoid populations—remains insufficiently defined. Building on our prior work identifying TUSC2 as a mitochondrial protein involved in calcium regulation and immune modulation, we hypothesized that TUSC2 exerts antitumor effects in part by enhancing NK cell cytotoxicity.

Methods Tusc2 knockout (Tusc2 KO) and wild-type (Tusc2 WT) mice were challenged with syngeneic tumor cells (344SQ) and treated with TUSC2-expressing lipoparticles (quaratusugene ozeplasmid, Quar Oze). The therapeutic group received Quar Oze after tumor establishment starting at day 8 from cell line injection, while prophylaxis group received Quar Oze before tumor establishment, starting 2 days before injection of cell lines. Control groups received empty lipoparticles. After three weeks from cell line injection, tumor volumes were assessed, and mice were euthanized for collection of tumors, spleens, and tumor-draining lymph nodes (TDLN). Immune cell phenotypes and cytotoxic markers were analyzed using flow cytometry. *In vitro* studies evaluated NK cell cytotoxic function following Quar Oze treatment by measuring CD107a degranulation and CellTrace Violet-based proliferation

Results In the therapeutic treatment group, 67% of Tusc2 KO mice and 33% of Tusc2 WT mice achieved complete tumor regression, with all remaining mice showing significant tumor reduction compared with controls. Prophylactic administration did not induce complete tumor clearance but consistently reduced tumor growth across all mice. Immune profiling of the tumor microenvironment revealed that Quar Oze robustly enhanced NK cell cytotoxicity, particularly increasing granzyme B and perforin expression. *In vitro* assays confirmed that TUSC2 restoration significantly increased NK cell degranulation and proliferation, supporting the *in vivo* findings.

Conclusion TUSC2 acts as a critical enhancer of innate antitumor immunity by boosting NK cell cytotoxic function. Therapeutic delivery of TUSC2 *via* Quar Oze suppresses tumor progression and, in many cases, drives complete tumor elimination. These results highlight TUSC2 as a potent immunomodulatory tumor suppressor and support its development as a dual-function therapeutic that directly targets tumor cells while also activating NK cell-mediated immunity

#0165 Role of SRC-3 in regulatory T cells as a modulator of activation and immunological memory.

Davis A. Graham, Yan Xia, Subhashree Pradhan, Amrit Koirala, Xiaobin Yu, Adam M. Dean, Bryan C. Nikolai, Aiden L. Moser, Jianming Xu, Cristian Coarfa, Bert W. O'Malley, David M. Lonard

Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX

While Steroid Receptor Coactivator 3 (SRC-3) is best known for its role in promoting proliferation of breast cancer cells, our group has recently identified a key role for SRC-3 in regulatory T cells (Tregs). Treg specific knockout (KO) of SRC-3 results in the long-term eradication of primary tumors in a syngeneic model of triple negative breast cancer. SRC-3 KO Treg mice also can resist rechallenge with a second dose of tumor cells. This long-term anti-tumor immunity points to the potential that SRC-3 KO Treg cells are differentiating into T memory cells. Our data shows that SRC-3 KO Tregs express higher levels of the T memory cell markers CD44 and CD62L than wild type Tregs and that SRC-3 KO Tregs downregulate inducible T-cell co-stimulator (ICOS), c-MAF, and interleukin 10 (IL-10). Utilizing single cell multiome sequencing and subsequent functional assays, we aim to further delineate the role of SRC-3 in Tregs and the impact of SRC-3 KO Tregs on the broader effector immune system. Through these assays we will gain insight into the role that SRC-3 has on T memory cell formation and function and the impact of SRC-3 KO Tregs on other immune cells. This work aims to provide a mechanistic delineation of the long term anti-tumor effects of SRC-3 KO Tregs.

#0166 Rewiring the dendritic cell: Regulatory T cell axis sensitizes prostate cancer to immunotherapy.

Jessica C. Hill, Kade R. Copple, Collin Jugler, Phuong Nguyen, Nilika Bhattacharya, Jessica N. Lancaster, **Casey R. Ager**

Mayo Clinic Arizona, Phoenix, AZ

Introduction: The prostate cancer (PCa) tumor microenvironment (TME) is immunosuppressive and resistant to immune checkpoint blockade (ICB). Based on multi-omic single cell correlatives of response to neoadjuvant Fc-enhanced (FcE) αCTLA-4 in high-risk localized PCa (NCT04301414), we explored how modulating the balance between regulatory T cells (Tregs) and dendritic cells (DCs) in the PCa TME affects sensitivity to ICB.

Methods: We leveraged three single cell transcriptomic atlases of PCa to assess how Tregs and DC frequencies are dynamically regulated during PCa progression. To investigate responses to Treg depletion (via FcE-αCTLA-4) alongside DC expansion (via Flt3L-Ig) and stimulation (via STING agonist ADU-S100) in PCa, we employed the castration-sensitive MycCaP PCa model and 45-parameter spectral flow cytometry. To investigate novel direct mechanisms of DC stimulation by FcE-αCTLA-4 via Fcγ receptor (FcγR) engagement, we optimized reductionist *in vitro* assays involving bone marrow-derived DCs (BMDCs) from wild-type (WT) mice or mice deficient in activating FcγRs (*Fcer1g*$^{-/-}$) or inhibitory FcγRIIb (*Fcgr2b*$^{-/-}$). To validate this effect *in vivo* we established a tumor antigen-specific T cell priming assay with both flow cytometry and *ex vivo* 2-photon live cell imaging readouts.

Results: In three independent single cell transcriptomic PCa atlases, we find cDC2 frequencies are significantly decreased in advanced PCa while effector Tregs (*TNFRSF9*$^{+}$) increase in proportion. Hypothesizing that excessive Treg function and DC insufficiency drive ICB resistance in PCa, we find *in vivo* DC expansion (Flt3L-Ig) prior to hormonal therapy, Treg depletion (FcE-αCTLA-4), and *in situ* DC stimulation (ADU-S100) drives robust control of established MycCaP tumors, with 87% of animals tumor-free 40-days post-treatment (27/31). Using 45-parameter spectral flow cytometry we find FcE-αCTLA-4 drives DC activation prior to Treg depletion in the TME, supporting a novel direct mechanism of DC modulation by FcE-αCTLA-4. *In vitro*, we find cell-associated FcE-αCTLA-4 is sufficient to drive BMDC maturation in an FcγR-dependent manner. *In vivo*, FcE-αCTLA-4 augments DC-mediated T cell priming in an FcγR-dependent manner. Ongoing experiments are investigating how FcE-αCTLA-4 shapes DC-T cell interactions via FcγR engagement and how DC/Treg axis modulation can be optimized to improve long-term curative response rates in the MycCaP model.

Conclusions: DC insufficiency and effector Treg differentiation are hallmarks of advanced PCa. Enhancing DC number and function concomitant with Treg depletion can drive effective antitumor immunity in a pre-clinical PCa model. Direct DC modulation via FcγR engagement represents a novel mechanism of response to CTLA-4-targeted ICB. These findings will inform ongoing translation of FcE-αCTLA-4 agents and development of novel immunotherapy strategies for PCa.

#0167 Preclinic study of src3-ko regulatory T cells in mouse breast cancer model.

Yan Xia[1], Yosef Gilad[1], Davis Graham[1], Bert W. O'Malley[2], David M. Lonard[1]

[1]Baylor College of Medicine, Houston, TX,[2]Professor & Chairman, Dept. of Cell Biology, Baylor College of Medicine, Houston, TX

Introduction: Regulatory T cells (Tregs) play a critical role in balancing immune responses to prevent autoimmune disease through their immunosuppressive activities. However, the suppressive activity of Tregs can be coopted by cancers to evade immune surveillance, leading to tumor progression. Steroid receptor coactivator 3 (SRC-3) is highly expressed in Tregs and we have discovered that genentically engineered mice with SRC-3 specifically knocked out in Tregs are resistant to breast cancer growth, suggesting SRC-3-KO Tregs are a potential therapy for breast cancer patients. In this study, we explored the therapeutic effect of SRC-3 KO Tregs in a mouse model of triple negative breast cancer (TNBC).

Method: A mouse syngeneic, immune-intact breast cancer model was produced by injecting luciferase expressing E0771 TNBC cells into the fourth mammary pad. To closely mimic a clinical scenario, Treg cells were isolated from the spleens of tumor-bearing C57BL/6J donor mice. After disrupting the SRC-3 gene by CRISPR/Cas9 targeting, Tregs were allowed to recover and proliferate in vitro for 4 days before collecting them for adoptive cell therapy (ACT) into C57BL/6J recipient mice with established breast cancer. Wild type Treg cells without gene editing were used as control. Tumor growth was monitored by bioluminescence imaging twice a week for 3 weeks. By the end of experiment, mice were sacrificed and spleen, blood, and tumors were collected for flow cytometry analysis as well as immunofluorescence staining.

Results: ACT of SRC-3 KO Tregs significantly reduced tumor growth or cleared tumosr in all treated mice. SRC-3KO Treg treatment also prolonged mice overall survival. Both ACTed WT and SRC-3KO Tregs were detected in the spleen, blood, and tumors of recipient mice. Moreover, many more cytotoxic T cells, including CD8 and granzyme B+ cells were found in SRC-3-KO Treg treated tumor-bearing mice, compared to WT Treg treated controls.

Conclusion: Deleting the SRC-3 gene in Tregs derived from tumor-bearing donors possess potent anti-tumor effects in an immune-intact mouse breast cancer model. These SRC-3 KO Tregs exert their effects by enhancing the cytotoxicity of effector CD8+ T cells in the tumor microenvironment. Our results reinforce the clinical potential of using SRC-3 KO Treg cells as an effective immunotherapy for TNBCs.

#0168 Harnessing TLS-derived B cells through STING and LTβR activation reveals a novel opportunity to antibody-mediated immunotherapy in pancreatic cancer.

Maxwell Duah[1], Yasuhiro Kikuchi[2], Fumiaki Kanamori[2], Tomoko Stansel[3], Gabrielle Brown[2], Masanobu Komatsu[2]

[1]Johns Hopkins School of Medicine/ All Children's Hospital, Saint Petersburg, FL,[2]Cancer and Blood Disorders Institute, Johns Hopkins School of Medicine/ All Children's Hospital, Saint Petersburg, FL,[3]Shared Resources, Johns Hopkins All Children Hospital, Saint Petersburg, FL

B cells are increasingly recognized as key orchestrators of anti-tumor immunity, yet their therapeutic potential remains far less developed than T cell-based strategies. Tumor-infiltrating B cells often assemble into tertiary lymphoid structures (TLS), which associate with improved immune activation and favorable clinical outcomes across multiple malignancies. However, whether TLS-resident B cells directly mediate tumor control has remained unresolved. We recently demonstrated that concurrent activation of STING and lymphotoxin β receptor (LTβR) signaling reliably induces mature, germinal center-like B cell-rich TLS across diverse tumor models. Here, we investigated the functional requirement for TLS formation using CD79a-deficient mice, which lack B cells and therefore cannot generate TLS. In parallel, we used hybridoma technology to isolate monoclonal antibodies secreted by TLS-derived B cells. In wild-type pancreatic tumor models, dual STING+LTβR activation induced high endothelial venules, promoted robust TLS maturation, and drove the development of class-switched IgG+ memory B cells and long-lived plasma cells. This intervention constrained tumor growth, improved responsiveness to anti-PD-1 therapy, and when deployed as neoadjuvant treatment, prevented recurrence and conferred complete protection upon tumor rechallenge. TLS induction was observed across distinct tumor types and anatomical locations. Hybridoma clones derived from intratumoral TLS-B cells secreted tumor-reactive IgG that activated NK cells and stimulated the release of cytotoxic effector molecules, including Granzyme B, TNF-α, IFN-γ, and Perforin, consistent with potent antibody-dependent cellular cytotoxicity. In contrast, CD79a-deficient mice, despite maintaining T cell infiltration and forming high endothelial venules, failed to develop TLS and exhibited significantly reduced survival following rechallenge, underscoring the essential contribution of B cells and TLS-derived humoral immunity to durable anti-tumor effect. We are now leveraging the TLS-derived IgG for antibody therapy and antigen discovery. Using immunoprecipitation pull-down assays followed by mass spectrometry, we aim to identify novel tumor-associated antigens in pancreatic cancer as candidate therapeutic targets. Together, these findings show that therapeutically induced TLS function as in situ factories for generating potent, tumor-specific antibodies and reveal a promising B cell-centered strategy to overcome the resistance of immune-cold pancreatic tumors.

#0169 A TNF-producing neutrophil subset drives age-dependent hepatotoxicity.

Jin Lee[1], Yiming Gao[1], Yufei Zhang[1], Aaron Havas[2], Peter Adams[2], Gerald S. Shadel[3], Susan M. Kaech[3], Gen-Sheng Feng[1]

[1]University of California San Diego - UCSD, La Jolla, CA,[2]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA,[3]Salk Institute for Biological Studies, La Jolla, CA

The mechanisms by which aging contributes to the detrimental effect of cancer therapy remain poorly understood. Herein we show that while a synthetic dsRNA (polyIC) effectively suppresses liver tumors in young mice, it induces lethal liver necrosis in aged mice. Single-cell and functional analyses unearthed a $CD14^+$ neutrophil subset featured by robust TNFα induction by polyIC exclusively in the aged liver. Impaired NR3C1 expression and elevated NF-κB and AP-1 signaling drive a skewing toward Tnf^+ over $Saa1^+$ neutrophils in the aged liver. TNF neutralization rescued polyIC-induced mortality, while also enhancing its antitumor effect in aged mice. Bioinformatic analysis revealed significant association of a Tnf^+Saa1^- neutrophil gene signature with reduced survival in liver cancer patients over 60. This study uncovers a previously unknown detrimental mechanism in the aged liver, which is undetectable under basal conditions. We provide a new strategy to improve therapeutic outcomes in elderly patients by mitigating treatment-associated toxicity.

#0170 Biphasic, time-dependent neutrophil biology in glioblastoma revealed by *in vivo* survival and flow cytometry with single-cell transcriptomic corroboration.

Matthew Alexander Abikenari[1], John Choi[1], Justin Liu[2], Adam Sjoholm[2], George Nageeb[1], James Poe[1], Brandon Hwa-Lin Bergsneider[3], Andrew Tran[1], David Bakalov[4], Ravi Medikonda[1], Lily Kim[1], Rohit Verma[3], Caren Wu[1], Kwang Bog Cho[1], Matei Banu[2], Michael Lim[2]

[1]Neurosurgery, Stanford University School of Medicine, Stanford, CA,[2]Neurosurgery, Stanford University School of Medicine, Stanford, CA, United States, Stanford, CA,[3]Stanford University School of Medicine, Stanford, CA,[4]Physician Scientist Training Program, University of Utah, Salt Lake City, UT, United States, Salt Lake City, UT

Introduction: Tumor-associated neutrophils (TANs) are abundant in glioblastoma (GBM), yet their functions are phase-dependent. We investigated whether TANs are differentially transcribed from peripheral blood neutrophils (PBNs), if they acquire antigen-presenting functions in situ, and if neutrophil depletion timing influences survival and intratumoral immunity
Methods: Transcriptomics: Integrated analysis of publicly deposited recent human GBM data sets (bulk RNA-seq and scRNA-seq; Seurat standard pipeline, stringent QC, integration/UMAP, Wilcoxon DE). Prespecified modules: co-stimulation (CD83/CD86/CD40/ICOSLG), MHC-II (HLA-DRB3/A, DPA1/DPB1), and antigen-processing/chaperones (CD74, CALR, PSME2, HLA-DMA/DMB).
In vivo survival: Orthotopic CT2A and GL261; anti-Ly6G (1A8) or isotype on two schedules, (day −1 pre-implantation through ≥day 14) and delayed (start day +8). Kaplan-Meier/log-rank; Cox models (HR, 95% CI).
Ex vivo flow (day 8): Bead-normalized spectral cytometry; CD45+ leukocytes; CD11b+ myeloids (Ly6G+ neutrophils; Ly6C^hi monocytes), F4/80+ TAMs with MHC-II, CD3+/CD8+ T cells. Two-sided Mann-Whitney; FDR where indicated. Ly6G epitope masking identified; depletion confirmed by CD11b+SSC^hi back-gating and weekly blood counts.
Results: Transcriptomics: TANs vs PBNs showed coherent upregulation of APC/co-stimulatory programs (CD83/CD86/CD40/ICOSLG; HLA-DR/DP; CD74/CALR/PSME2/HLA-DMA/DMB), in line with dendritic-like, non-cytotoxic TAN states.
Survival (biphasic): Previous anti-Ly6G impaired outcomes, CT2A (n=9/arm) median 17 vs 23 days; HR 1.95 (1.10-3.46), p=0.018. Subsequent depletion abrogated this penalty, CT2A HR 1.23 (0.68-2.22), p=0.49;
Flow (day 8): Early-depleted tumors contained more Ly6C^hi monocytes (of CD45+: 29% vs 18%, p=0.006), fewer CD8+ T cells (3.2% vs 6.1%, p=0.011), and lower CD8:Ly6C^hi ratio (0.11 vs 0.36, p=0.004). Directional but non-significant aggregates: CD11b+ myeloids (68% vs 55%, p=0.07), CD3+T cells (9% vs 14%, p=0.09), reduced MHC-II on F4/80+ TAMs (p=0.08), reduced CD11c^{+}MHC-II^hi APCs (q≈0.12).
Conclusion: Human TANs take up APC/co-stimulatory programs, and timing is critical: pre-implantation neutrophil depletion imposes a myeloid-skewed, antigen-poor, T-cell-depleted setting, augments survival, while late targeting diminishes this. These observations favor phase-specific TAN modulation. maintenance or re-education of early TANs and suppression of late suppressive programs selectively, to regulate biomarker-based GBM immunotherapies.

#0171 KEAP1 loss-of-function suppresses immunogenic ferroptosis and limits PD-1 blockade efficacy through an NRF2-FSP1 pathway.

Xinfeng Wang[1], Yuxin Yao[1], Tomi Jun[2], Kuan-lin Huang[2], Nan Sun[1], Jie He[1]

[1]Department of Thoracic Surgery, Chinese Academy of Medical Sciences Cancer Hospital, Beijing, China,[2]Department of Genetics and Genomic Sciences, Center for Transformative Disease Modeling, Icahn School of Medicine at Mount Sinai, New York, NY

Background Loss-of-function mutations in KEAP1 frequently occur in lung adenocarcinoma and are associated with poor prognosis and limited benefit from immunotherapy. However, the mechanisms linking KEAP1 deficiency to immune evasion remain elusive.
Methods We combined patient data analysis, in vivo tumor models, and in vitro co-culture systems to investigate how KEAP1 deficiency shapes dendritic cell (DC) biology and response to PD-1 blockade. Ferroptosis induction assays, damage-associated molecular patterns (DAMPs) quantification, cytokine profiling, and mechanistic interrogation of the FSP1-CoQ10 axis were performed to delineate underlying pathways.
Results Clinically, KEAP1 mutations correlated with poor response to PD-1 blockade and reduced DC infiltration. In murine models, KEAP1-deficient tumors exhibited marked resistance to anti-PD-1 therapy. Mechanistically, KEAP1 loss impaired DC function in vitro, as evidenced by reduced maturation, phagocytosis, and naïve $CD8^+$ T-cell priming capacity. This defect was linked to two complementary mechanisms. First, KEAP1-deficient tumor cells resisted ferroptosis and failed to release immunogenic DAMPs, including extracellular ATP, HMGB1, and calreticulin. Second, KEAP1 deficiency reprogrammed the cytokine secretion profile, with downregulation of CCL2, IL-6, CXCL1, and CXCL2, thereby diminishing DC recruitment and inflammatory signaling. Notably, inhibition of the FSP1-CoQ10 antioxidant axis restored ferroptosis-associated immunogenic cell death.
Conclusions Our study identifies KEAP1 deficiency as a driver of immune-cold tumor microenvironments and resistance to PD-1 blockade, acting through impaired ferroptosis-induced immunogenic cell death and disrupted DC function. Targeting the FSP1-CoQ10 pathway may restore DC function and sensitize KEAP1-mutant lung cancers to immunotherapy.

#0172 Investigating how host TLR5 signaling modulates FLT3 ligand therapeutic efficacy for ovarian cancer.

Cara Hatzinger, Mitchell McGinty, Simona Bajgai, Mika Poblete, Akshita Mirani, Audrey Putelo, Mirna Perusina Lanfranca, Una Miagkov, Melanie Rutkowski

Microbiology, Immunology, and Cancer Biology, University of Virginia School of Medicine, Charlottesville, VA

Ovarian cancer continues to be the most fatal gynecological malignancy, and survival rates of individuals with this disease have remained relatively unchanged for the past 30 years. Though immunotherapies such as immune checkpoint blockades have drastically improved survival outcomes for other cancers, they rarely induce a therapeutic response for ovarian cancer. We have identified toll-like receptor 5 (TLR5) signaling, the only known ligand of which is bacterial flagellin, as a host- intrinsic factor that orchestrates the failure of checkpoint therapy for ovarian cancer. Mechanistically, ovarian tumors induce chronic gut leakage, enabling dissemination of flagellin into the ovarian tumor microenvironment (TME). Chronic TLR5 signaling disrupts the accumulation of IL-12+ anti-tumorigenic dendritic cells (DCs) in the ovarian TME and promotes expansion of PD-L1 expressing immature myeloid populations, culminating in failure of immune checkpoint blockade. One strategy to overcome this deficit is to promote further expansion of DCs via administration of the DC growth factor fms-like tyrosine kinase receptor 3 ligand (FLT3L). Although no benefit was observed for wild type (WT) mice with intact TLR5 signaling, an observation consistent with poor clinical efficacy of FLT3L therapy, FLT3L administration in TLR5-deficient (TLR5KO) mice resulted in prolonged and durable survival for over 80% of animals when combined with PD-L1 blockade. These data suggest that in the absence of TLR5 signaling, the ovarian TME becomes more responsive to immunotherapy, and justifies further investigation into how TLR5 signaling is disrupting FLT3L expanded DCs. High dimensional flow cytometry data show that in the absence of ovarian tumors, FLT3L significantly expands the proportion of DCs in multiple tissues, including the peritoneal cavity, in both TLR5KO and WT mice. Phenotypic profiling of tumor nodules and the peritoneal cavity in ovarian tumor- bearing TLR5KO and WT animals 24 hours after FLT3L treatment ceases shows significantly higher frequencies of DCs in the peritoneal cavity of TLR5KO mice as compared to WT. Analysis of tumor nodules also reflects a significant increase in the frequency of dendritic cells infiltrating tumors as compared to WT mice. These preliminary results suggest TLR5 signaling is impacting the expansion and/or recruitment of dendritic cells into the ovarian tumor microenvironment. Ongoing and future experiments will assess chemokines and cytokines the periphery, peritoneal washes, and tumor lysates to define TLR5-mediated signaling pathways that inhibit DC maturation and recruitment. Our results aim to mechanistically define how chronic TLR5 signaling is impacting FLT3L efficacy, and further elucidate how TLR5 signaling is a host intrinsic process whereby the microbiome is driving resistance to immune therapies.

#0173 Targeting tumoral GLI1 in triple-negative breast cancer: A novel strategy to reverse the immunosuppressive microenvironment.

Qiang Shen

University Health Network, Toronto, ON, Canada

Triple-negative breast cancer (TNBC) comprises 15-20% of breast cancer cases, is highly aggressive, lacks effective treatment options and represents a disproportionately high number of BC-related deaths. Despite the clinical success of immune checkpoint blockade (ICB) in many malignancies, ICB has failed to demonstrate a similar response in TNBC, where most cases are highly infiltrated by tumor-associated macrophages (TAMs), which can dampen CD8+ cytotoxic T-lymphocyte (CTL) function and promote resistance to ICB. The hedgehog (HH) signaling pathway is highly activated in TNBC and higher expression of GLI1 is associated with worse overall survival. Recent pan-cancer analyses highlight a significant correlation between activated HH signaling and characteristics of immune evasion.

Results: To examine how activated HH signaling regulates the tumor immune microenvironment (TIME) in TNBC, murine KBP (K14-*cre*; Brca1*fl/fl*; P53*fl/fl*) TNBC cells were transfected with CRISPR/Cas9 + sgRNA targeting GLI1 or GLI2 (GLI1/2). KBP and KBP-GLI1/2-KO cells were orthotopically injected into the mammary fat pads of FVB mice and allowed to grow for 6-8 weeks. Compared to wild-type KBP tumors, KBP-GLI1-KO tumors, but not KBP-GLI2-KO tumors, were smaller. Flow cytometric analyses showed that KBP GLI1-KO tumors were infiltrated with fewer F4/80+ CD11b+ TAMs, particularly the CD206+ pro-tumoral M2-like subtype. This was accompanied by increased CD8+ and CD4+ T cells. Similar results were observed in the modified murine TNBC KBP transgenic mouse model where either GLI1 or GLI2 was genetically deleted in tumor cells. In GLI1 (but not GLI2) KBP mice reduced delayed tumor onset and growth were accompanied by reduced M2-like TAM and increased CD8+ and CD4+ T cells infiltration in TIME. Moreover, compared with the low responsiveness of KBP tumors to anti-PD1, the therapeutic benefit of anti-PD1 in KBP-GLI1-KO tumors was markedly improved and was accompanied by increased activated, anti-tumoral CD8+GrB+ T cell infiltration.

Conclusion: here we demonstrate that tumoral GLI1, but not GLI2, promotes tumor growth and supports an immunosuppressive TIME in TNBC. Targeted deletion of GLI1 reduces TAMs, increases CTLs, and re-shapes TIME towards a pro-inflammatory ‘hot’ tumor phenotype, potentiating anti-PD1 ICB in immunocompetent mouse models of TNBC. Overall, these preliminary findings identify GLI1 as a potential therapeutic target to improve ICB response in TNBC.

#0174 Tumor-reactive CD8 lymphocyte isolated from melanoma brain metastasis show that a subset of the total population is better at controlling tumor growth after adoptive transfer into a xenograft model.

Jeffrey Wu[1], Mike Beymer[1], Rebekka Duhen[2], Venkatesh Rajamanickam[1], Colin Thalhofer[3], Prakash Ambady[1], Andrew D. Weinberg[1]

[1]Earle A. Chiles Research Institute, Portland, OR,[2]Oregon Health and Science University, Portland, OR,[3]Agonox, Portland, OR

Previously, we demonstrated that the vast majority of CD8 T cell tumor reactivity was found within the CD39+ CD103+ (Double Positive, DP) population when isolated from the tumor microenvironment. These cells can be sorted and expanded from thousands to billions in defined culture conditions. After adoptive cell transfer, they can cause tumor regression in vivo in a human melanoma xenograft model that constitutively secrete human IL-2 (NOGhIL-2). In the current study, we found that DP CD8 tumor infiltrating lymphocytes (TILs) isolated from a melanoma brain metastasis could not regress autologous tumor in the NOGhIL-2 mice. After adoptive transfer tumors progressed in mice that received DP TIL and grew at a similar rate compared to CD8 T cells that had little to no tumor reactivity. Co-culture experiments with the total CD8 DP TIL population and autologous tumor showed that there was a subset of T cells that greatly upregulated 4-1BB+ CD25+ over an extended period of time (~5-10% of total population). We sorted this subset away from the total DP TIL population and expanded them in culture. When the sorted population was compared to the parental CD8 DP TIL population in tumor co-culture experiments there was an increase in 4-1BB expression and 3 to 8-fold higher interferon gamma levels. Upon adoptive transfer into the tumor xenograft model, the sorted subset completely regressed autologous tumor, whereas the tumors grew progressively in mice receiving the unsorted population. Single cell TCRseq and RNA profiling revealed interesting differences between these two populations. Our findings suggest that specific subsets within the CD8 DP TIL total population might play an important role in controlling brain metastases in cancer patients with recurrent disease.

#0176 Intrinsic failure of immune activation in *NRAS*-mutant melanoma reveals a targetable mechanism of checkpoint resistance.

Inyoung Cho[1], Sung Eun Kim[2], Joong-Bae Ahn[3], Sang Joon Shin[3]

[1]Department of Clinical Drug Discovery and Development, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Department of Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Seoul, Korea, Republic of

Background: Melanoma is frequently driven by MAPK pathway mutations, most prominently BRAF (~50%) and NRAS (20-30%). Unlike *BRAF*-mutant melanoma, which benefits from effective targeted therapies, *NRAS*-mutant melanoma responds poorly to MEK inhibition and lacks approved targeted options, contributing to poorer outcomes. This limitation has encouraged immunotherapy-based combinations, yet responses to immune checkpoint blockade (ICB) remain variable. We found that *NRAS*-mutant melanoma exhibits high immune-gene activity in cancer cells alone but shows suppressed inducibility upon immune stimulation, indicating an intrinsic failure to activate immune programs that may limit ICB responsiveness.

Methods: DEG and pathway analyses were performed using DESeq2 and GSEA with TCGA-SKCM (tumor biopsy) and CCLE/DepMap (cell line RNA-seq) datasets. “Shift genes” were defined by comparing relative expression between cell line-intrinsic and tumor datasets, selecting genes with the largest directional changes and significant adjusted p-values (FDR < 0.05, moderated t-tests). Anti-PD-1-resistant cell lines were generated through serial in vivo selection involving repeated implantation and anti-PD-1 treatment of *NRAS*-mutant melanoma until tumor growth matched untreated controls.

Results: RNA expression analysis of *NRAS*-mutant melanoma cell lines revealed strong intrinsic immune-gene activity; however, this activity was markedly reduced in TCGA tumors, indicating suppressed inducibility in the tumor setting. Among the T cell-inflamed GEP genes—an established immune signature highly expressed in tumors responding to anti-PD-1 therapy—MHC class II-related genes and CCL5 showed the most pronounced reduction (≈1.3-1.4-fold), while most others remained stable. Consistent with these findings, *NRAS*-mutant murine melanoma cell lines exhibited high basal immune-gene expression but nearly 200-fold weaker induction following Interferon-γ stimulation—used to evaluate inducible immune-gene responses—compared with wild-type cells. Anti-PD-1-resistant models mirrored this pattern, suggesting that such immune non-responsiveness reflects an inherent characteristic of *NRAS*-mutant melanoma.

Conclusion: The immunotherapy responsiveness of *NRAS*-mutant melanoma remains uncertain, underscoring the need to define its immune features. Our findings indicate that the immune unresponsiveness in this subtype reflects a fundamental, cell-intrinsic limitation rather than an acquired consequence, suggesting a targetable mechanism to improve ICB outcomes.

#0177 In vivo CRISPR screening uncovers Folr1-mediated metabolic remodeling that sensitizes colorectal cancer to PD-1 blockade.

Boping Jing[1], Feng Guo[2], Tadahito Yasuda[2], Mayu Yasuda[2], Hudie Li[3], Fabio Mello[3], Jay Paul Overholser[1], Pravin Kaumaya[1], Yaoqi Alan Wang[2]

[1]IUPUI, Indianapolis, IN,[2]Indiana University School of Medicine, Indianapolis, IN,[3]Indiana University, Indianapolis, IN

Introduction: Colorectal cancer (CRC) is a leading cause of cancer-related mortality worldwide. KRAS mutations are present in approximately 40-50% of CRCs, with G12D being the most prevalent subtype. Accumulating evidence indicates that $KRAS^{G12D}$ CRC responds poorly to immune checkpoint blockade (ICB) therapy, reflecting intrinsic resistance to immunotherapy. To identify key regulators capable of overcoming this resistance, we conducted an in vivo CRISPR/Cas9 genetic screen in a $KRAS^{G12D}$-driven CRC model. Furthermore, we investigated the underlying mechanisms contributing to immune resistance.

Methods: $KRAS^{G12D}$ colorectal cancer cell lines, MC38K and Caco2K were generated. An immune-related sgRNA library was designed using PD-1/PD-L1/MHC-I and ESTIMATE data, and MC38K cells carrying the library were tested under anti-PD1 treatment in vivo. RNA sequencing and metabolic profiling were performed to elucidate immune-related mechanisms, and Seahorse assays were used to validate metabolic alterations. Multiple CRC models were used to evaluate Folr1 inhibition combined with anti-PD1 therapy, and a Folr1-based peptide vaccine was developed to overcome resistance.

Results: $KRAS^{G12D}$ overexpression accelerated tumor growth and conferred anti-PD1 resistance in MC38K models. Through the in vivo CRISPR/Cas9 screen, Folr1 emerged as the top depleted gene, ranking first among all candidates associated with immunotherapy resistance. Notably, Folr1 is a clinically actionable target with existing therapeutic antibody currently approved by FDA. RNA-seq analysis of Folr1-knockout MC38K and Caco2K cells revealed profound metabolic remodeling, particularly involving glycolysis. GSEA demonstrated that hallmark pathways including glycolysis, hypoxia, and mTORC1 signaling were downregulated, validated by qRT-PCR, OCR/ECAR assays, and L-lactate measurements. In multiple in vivo models, Folr1 knockout combined with anti-PD1 therapy significantly delayed tumor growth and extended overall survival. Furthermore, the Folr1-based peptide vaccine also markedly suppressed tumor progression.

Conclusions: Our study identifies Folr1 as the top-ranked gene mediating immunotherapy resistance in $KRAS^{G12D}$-driven colorectal cancer. Targeting Folr1 reprograms tumor metabolism, enhances antigen presentation, and restores responsiveness to anti-PD1 therapy. These findings establish Folr1 as a translationally relevant therapeutic target to overcome immune resistance in $Kras^{G12D}$ CRC.

#0178 Exploring the role of catecholamine signaling in CD8+ T cell immunity to neuroblastoma.

Mark B. Chudnovsky, Daniela Vega-Mendoza, Elinor L. DeCleene, Jose Almeida-Santos, Naomei Lidman, Mingkee Achom, Jared H. Rowe

Pediatric Oncology, Dana-Farber Cancer Institute, Boston, MA

Neuroblastoma (NBL) is the most common extracranial solid tumor in children. NBL tumors arise from the malignant transformation of sympathoadrenal precursor cells in the developing neural crest. The origin of NBL cells leads to their retention of the ability to synthesize catecholamines, which normally regulate our stress response. Recent studies have demonstrated that immune responses are also modulated by catecholamine signaling through beta-adrenergic receptors expressed on T cells. Particularly, catecholamines derived from sympathetic neurons can signal CD8+ T cells via the beta-adrenergic receptor (ADRB1). In tumors this signaling is associated with the progressive loss of CD8+ T cell function, a process known as “exhaustion.” We hypothesized that in catecholamine producing tumors, like NBL, the excessive ADRB1 signaling T cells will suppress antitumor immunity. To investigate the cell-intrinsic role of beta-adrenergic signaling in CD8+ T cell function in protection from NBL we selectively ablated the ADRB1 (*Adrb1*) gene in murine T cells using an *in vivo* immune competent NBL model. A syngeneic NBL cell line was engineered to express ovalbumin (OVA) as a surrogate tumor-specific antigen. Cas9-expressing T cell receptor transgenic (TCR) T cells for OVA (Cas9-OT-I) were transduced with *Adrb1*-gRNA and adoptively transferred into recipient mice prior to implantation of 9464D-OVA. Surprisingly, we found that *Adrb1*-deficient CD8+ T cells had inferior tumor control compared to T cells transduced with non-gene targeting control gRNA. Despite this observation, *Adrb1*-deficient CD8+ displayed a competitive advantage in the tumor microenvironment compared to control T cells. This suggests that the loss of ADRB1 is impacting the function of anti-NBL T cells. These findings directly contrasted the robust protection of *Adrb1*-deficient CD8+ T cells in a model of melanoma (B16-OVA). Interestingly, we found that pharmacologic treatment of melanoma bearing mice with the selective ADRB1 antagonist atenolol was sufficient to control some tumors and promote animal survival. NBL bearing mice receiving atenolol had no effect on tumor growth or animal survival. Ongoing experiments are addressing how the timing (i.e. pre-activation, post-exhaustion) and context (whole body, T cell-intrinsic, tumor microenvironment) of ADRB1 blockade impacts the function of T cells in NBL. These preclinical studies will support ongoing efforts to target catecholamine signaling to reduce exhaustion and support the function of cellular therapies against NBL.

#0182 Systemic immune reprogramming by extracranial melanoma reshapes the melanoma brain metastasis microenvironment.

Prabhjeet Singh, Saurabh Sharma, Jay Chadokiya, Amanda Kirane

Surgery, Stanford University, Stanford, CA

Introduction: Melanoma brain metastases (MBM) remain a critical unmet need, with median survival of only ~6 weeks after immune checkpoint blockade (ICB) failure. This lethality is driven by an immunosuppressive tumor immune microenvironment enriched for tumor-associated macrophages (TAMs) and dysfunctional dendritic cells (DCs). Emerging evidence suggests bidirectional crosstalk between extracranial and intracranial tumors may reshape systemic immunity and influence therapeutic outcomes, yet the mechanisms remain unclear. We therefore investigated how an extracranial melanoma alters the cranial tumor-immune microenvironment and modulates ICB efficacy.
Methodology: A multi-site murine MBM model was established using YUMM1.7 melanoma cells. Subcutaneous (extracranial) tumors were implanted 48 h prior to stereotactic intracranial injection. Tumor progression was monitored by bioluminescence imaging (BLI). At day 21, blood and major tissues (skin, brain, and organs) were excised and analyzed using flow cytometry (tumor and TAMs, DC, T-cell profiling) and Lunaphore COMET™ multiplex immunofluorescence (mIF) imaging for PD-1/PD-L1, and LRP-1 expression on TAMs/DCs/T-cells, to better understand the tumor-immune microenvironment modulation in both intracranial and extracranial site. Kaplan-Meier survival was plotted to determine the tumor growth dynamics.
Results: The multi-site MBM model was successfully generated and validated by BLI and histologic immune cell infiltration at both tumor sites. Mice bearing both intracranial and extracranial tumors showed significantly delayed intracranial tumor growth compared with mice bearing intracranial tumors alone ($p<0.05$), indicating systemic immune reprogramming driven by the extracranial tumor. mIF further revealed differential expression of PD-1/PD-L1 interactions and LRP-1 on TAMs, DCs, and T cells in multi-tumor mice relative to intracranial-only controls ($p<0.05$), highlighting dynamic modulation of the intracranial TiME.
Conclusion: Extracranial melanoma reshapes the cranial immune landscape and attenuates intracranial tumor progression through systemic tumor-immune microenvironment reprogramming. PD-1/PD-L1 and LRP-1 emerge as key regulators of immunosuppression in MBM, supporting combinatorial ICB strategies targeting these axes. Ongoing studies leveraging LRP-1 knockout models aim to refine mechanistic understanding and improve immunotherapeutic efficacy in MBM, addressing a major gap in neuro-oncology.

#0183 NOX2-driven macrophage reprogramming enhances breast cancer metastasis.

Mustafa Kaya[1], Olivia Johnsson[1], Nuttida Issdisai[1], Hugo Soderberg[1], Ilayda Altinonder[2], Roberta Kiffin[1], Xavier Tekpli[2], Kristoffer Hellstrand[1], **Anna Martner**[1]

[1]University of Gothenburg, Gothenburg, Sweden,[2]Oslo University Hospital and University of Oslo, Oslo, Norway

Tumor-associated macrophages (TAMs) are considered key determinants of breast cancer progression, yet the molecular mechanisms shaping their immunosuppressive phenotypes remain incompletely understood. The NOX2 enzyme of myeloid cells generates antimicrobial reactive oxygen species (ROS) in myeloid cells, but its potential contribution to macrophage programming within the tumor microenvironment is largely unknown. This study aimed at identifying the potential role of NOX2 in regulating M2-like macrophage polarization for breast cancer growth and dissemination. Analysis of single-cell RNA sequencing data from 100 human breast tumors revealed selective upregulation of NOX2 in M2-like TAM clusters, associated with an immunosuppressive transcriptional profile. Consistently, transcriptional data showed that macrophages from *Nox2*-deficient mice displayed a shift toward a pro-inflammatory, M1-like state, marked by altered transcription factor networks and enrichment of inflammatory gene signatures. *In vitro*, pharmacologic or genetic inhibition of NOX2 blocked M2 polarization induced by colony-stimulating factor-1 (CSF-1) (P=0.0006, n=4-11/group, one-way ANOVA) or breast cancer-derived conditioned media (P=0.02, n=4/group, Mann-Whitney test), implying that NOX2 activity is required for tumor-driven macrophage reprogramming. Mechanistically, our results suggested that NOX2-derived ROS activated NRF2-dependent transcriptional pathways that stabilized the M2-like phenotype. In two distinct murine breast cancer *in vivo* models, *i.e.* orthotopic EO771 implantation and the genetically engineered MMTV-PyMT model, genetic deletion of *Nox2* entailed reduced abundance of M2-like TAMs (P=0.006, n=4-7/group), enhanced intratumoral T cell infiltration (P=0.04, n=4-7/group), and markedly suppressed primary tumor growth (P=0.01, n=4-7/group) and metastatic spread (P=0.02, n=6-8/group, Mann-Whitney test for all). Mining of public datasets revealed that high expression of M2-associated markers and NRF2 target genes correlated with inferior survival in human breast cancer (P=0.02 for CD206 and P=0.04 for HO-1, n=65, log-rank test). These findings position NOX2 as a key driver of immunosuppressive macrophage plasticity in breast cancer and highlight the NOX2-NRF2 axis as a potential therapeutic target to counteract metastasis-promoting myeloid programming.

#0184 TNF-alpha plays pleiotropic role in innate immune activation and blood-brain barrier disruption driving brain metastasis.

Neva Celiker[1], Fulya Koksalar Alkan[1], Hilmi K. Alkan[1], Ahmet Caglayan[2], Aminal Lawal[1], Morhaf Al Achkar[1], Wicha S. Max[3], Hasan Korkaya[1]

[1]Oncology, Wayne State University, Detroit, MI,[2]University of Michigan, Ann Arbor, MI,[3]Department of Internal Medicine, University of Michigan, Ann Arbor, MI

Tumor necrosis factor-α (TNFα) is a central inflammatory cytokine with paradoxical functions in cancer, capable of promoting robust innate immune activation while simultaneously inducing tissue damage that facilitates metastatic dissemination. Our preliminary data show that TNFα triggers membrane localization and secretion of HSP70 in murine EMT6 breast cancer cells, enabling HSP70 to function as a potent tumor-associated antigen that activates innate immunity and mediates clearance of disseminated tumor cells. To extend these in vivo, we investigated the pleiotropic effects of TNFα in EMT6 orthotopic models, where TNFα-treated EMT6-conditioned medium (EMT6-CM) unexpectedly induced both early systemic immunization and late development of brain metastases.Our preliminary data reveal that EMT6-CM derived from TNFα-treated cells contains high concentrations of soluble TNFα that compromise blood-brain barrier (BBB) integrity, generating a permissive niche for metastatic colonization. Besides, the same CM harbors HSP70-rich extracellular vesicles that promote anti-tumor immune priming in peripheral tissues. Thus, TNFα exerts a paradoxical influence: beneficial through HSP70-mediated innate immune activation, yet detrimental through TNFα-driven BBB disruption that facilitates brain metastatic outgrowth.To mechanistically separate these opposing functions in our ongoing studies, we are selectively depleting TNFα from EMT6-CM using immunoabsorption approaches while preserving HSP70-containing vesicles and soluble fractions. TNFα-depleted CM will be used to immunize BALB/c mice for 1-2 weeks, followed by orthotopic challenge with EMT6-Luc cells. We hypothesize that mice receiving TNFα-depleted, HSP70-enriched CM will reject EMT6-Luc tumors, demonstrating that HSP70-driven immunogenicity is sufficient for tumor protection in the absence of TNFα-induced BBB damage. Successful rejection will validate our model in which TNFα is necessary for BBB disruption but dispensable for HSP70-mediated anti-tumor immunity.Collectively, our findings reveal a previously unrecognized dichotomy in TNFα biology, with significant implications for cytokine-based immunotherapies and mechanisms underlying breast cancer brain metastasis. Understanding how to uncouple TNFα's immunostimulatory and pathological effects may guide development of safer and more effective immune-modulating strategies.

#0185 Thyroid hormones modulate the lung immune microenvironment to regulate breast cancer metastasis.

Gonzalo Gonzalez, Florencia Menay, Johanna Diaz Albuja, Maria M. Debernardi, Lucero Alvarado, Maria A. Paulazo, Cinthia Rosemblit, Florencia Cayrol, Graciela A. Cremaschi, **Helena A. Sterle**

Instituto de Investigaciones Biomedicas (BIOMED-UCA-CONICET), Buenos Aires, Argentina

Thyroid disorders and breast cancer (BC) are both more prevalent in women, yet the influence of thyroid hormones (THs) on BC progression and metastasis remains poorly understood. We previously showed that hyperthyroid mice bearing 4T1 BC tumors display accelerated primary tumor growth, whereas hypothyroid mice develop slower-growing tumors but a higher number of lung metastases. To elucidate the mechanisms underlying these effects, we first evaluated the direct influence of THs on 4T1 cell migration using wound-healing assays. We then examined the impact of thyroid status on the immune subpopulations and cytokine milieu in the lungs. For this, female Balb/c mice were induced to a hyperthyroid state by daily thyroxine (T4) administration for 4 weeks, to a hypothyroid state by propylthiouracil (PTU) for 2 weeks, or to a reverted euthyroid condition by supplementing triiodothyronine (T3) after PTU treatment. Mice were subsequently inoculated with 4T1 cells orthotopically or intravenously. In vitro, T3 and T4 did not modify 4T1 cell migration, indicating that THs regulate metastasis indirectly through host mechanisms. In vivo, thyroid status profoundly altered the pulmonary immune landscape. Lungs from hyperthyroid mice exhibited increased proportions of cytotoxic T lymphocytes, natural killer (NK) cells, and B cells, accompanied by higher IFN-γ and IL-2 levels ($p < 0.05$), consistent with a more cytotoxic microenvironment. In contrast, lungs from hypothyroid mice displayed increased myeloid-derived suppressor cells (MDSCs) and elevated CCL5, CCL17, and CCL22 levels ($p < 0.05$), which are associated with heightened immunosuppression, cell recruitment, and metastasis formation. These alterations were reverted by short-term T3 treatment. Moreover, hyperthyroid mice intravenously inoculated with 4T1 cells also showed increased NK cell levels, whereas hypothyroid mice exhibited higher MDSCs, suggesting that this effect is independent of the primary tumor. Collectively, our findings demonstrate that thyroid hormones do not directly affect BC cell migration but critically modulate the immune microenvironment in metastatic target organs. Hyperthyroidism promotes cytotoxic and humoral immune responses that may restrain metastasis, while hypothyroidism drives an immunosuppressive cytokine network that favors lung colonization. Understanding how thyroid hormones influence immune responses is key to developing more effective therapeutic strategies for breast cancer.

#0186 Thyroid hormones as systemic regulators of melanoma progression and dissemination.

Helena Andrea Sterle, Maria M. Debernardi, Gonzalo Gonzalez, Lucero Alvarado, Florencia Menay, Maria A. Paulazo, Graciela A. Cremaschi, Florencia Cayrol

Instituto de Investigaciones Biomedicas (BIOMED-UCA-CONICET), Buenos Aires, Argentina

Melanoma (ME) is the most lethal form of skin cancer, and resistance to immune checkpoint inhibitors remains a major clinical challenge. Thyroid hormones (THs) are master regulators of metabolism, proliferation, and differentiation, yet their role in melanoma biology remains poorly defined. This study aimed to elucidate both the direct and systemic effects of THs on melanoma progression.
We first assessed the expression of nuclear (TR) and membrane (integrin αVβ3) TH receptors in human (A375, WM35) and murine (B16F10, B16F1) melanoma cell lines. Both receptor types were detected at mRNA and protein levels in all cell lines analyzed. Functional assays demonstrated that physiological and supraphysiological TH concentrations increased ME cell proliferation by 20-40% ($p<0.01$), an effect prevented by the αVβ3 inhibitor cilengitide ($p<0.05$), indicating that THs promote melanoma growth predominantly through αVβ3-mediated signaling. Consistently, TCGA-SKCM data showed co-expression of αV and β3 integrins in patient melanoma samples, supporting αVβ3 as a potential therapeutic target.
To evaluate systemic effects of THs, syngeneic B16F1 and B16F10 melanoma models were established in euthyroid, hypothyroid, and hyperthyroid mice. In both models, hyperthyroid mice exhibited significantly increased tumor growth rates compared with euthyroid controls ($p<0.05$), whereas hypothyroidism did not markedly affect primary tumor expansion. In contrast, in experimental metastasis assays using B16F10 cells, hypothyroid mice developed a significantly higher number and larger size of lung metastatic foci ($p<0.01$), indicating that TH deficiency facilitates metastatic dissemination.
Immune profiling of tumor-infiltrating cells did not reveal significant differences among experimental groups. However, tumor-draining lymph nodes from hyperthyroid mice showed reduced cytotoxic $CD8^+$ T lymphocytes ($p<0.05$), while spleens from hypothyroid mice exhibited increased B lymphocytes ($p<0.01$) and myeloid-derived suppressor cells ($p<0.05$), suggesting that TH status modulates systemic immune cell distribution.
Overall, these findings demonstrate that thyroid hormones exert dual and context-dependent effects on melanoma: TH excess enhances primary tumor growth through integrin αVβ3 signaling, whereas TH deficiency promotes metastatic dissemination, likely through modulation of systemic antitumor immunity. The thyroid axis emerges as a novel systemic regulator and potential therapeutic target in melanoma.

#0188 Commensal dysbiosis mediates changes in mammary tissue mast cells and fibroblasts to promote HR$^+$breast tumor dissemination.

Simona Bajgai[1], Alkaid Feng[1], Audrey Putelo[1], Mika Poblete[1], Scott Dunn[2], Mirna Perusina Lanfranca[1], Cara Hatzinger[1], Akshita Mirani[1], Una Miagkov[1], Melanie R. Rutkowski[3]

[1]Microbiology, Immunology, and Cancer Biology, University of Virginia School of Medicine, Charlottesville, VA,[2]Chemistry, University of Virginia, Charlottesville, VA,[3]University of Virginia School of Medicine, Charlottesville, VA

We aim to uncover host-intrinsic factors influencing HR$^+$ breast cancer metastasis by focusing on interactions between mast cells and fibroblasts, two mammary tissue-associated cell types involved in the orchestration of metastatic breast cancer. Metastatic dissemination remains a significant barrier to reducing mortality associated with HR$^+$ Her2$^-$ breast cancer. Dissemination occurs early and is driven by immune-mediated crosstalk between the tumor microenvironment and the adjacent tissue. We have demonstrated that commensal dysbiosis, an inflammatory gut microbiome with low biodiversity, promotes long-term cellular and molecular changes in normal (non-tumor-bearing) mammary tissues. When commensal dysbiosis is established in a mouse model before tumor initiation, dissemination of HR$^+$ breast tumor cells is significantly increased, whereas primary tumor growth remains unaffected. Gut microbiome changes have been associated with relapse and metastatic disease in women with breast cancer, highlighting the importance of defining how the gut microbiome regulates breast cancer through modulation of the mammary tissue environment. Our preliminary data suggest that dysbiosis activates a mast cell/fibroblast axis in the normal mammary tissue that enhances HR$^+$ tumor dissemination. We are using a combination of methods including but not limited to untargeted proteomics, spatial profiling, high-dimensional flow cytometry, scRNAseq, coupled with various *in vivo* and *in vitro* assays to define the contribution of this axis to early metastasis. Flow cytometry analysis and experiments using mast cell-deficient sash mice have demonstrated that dysbiosis increases the number of mammary tissue mast cells and causes changes in their phenotype. We have also observed that dysbiosis increases mammary tissue fibroblast activation in a mast cell-dependent mechanism. Supporting the role of mast cells in programming fibroblasts to promote breast tumor metastasis, spatial transcriptomic analysis has revealed a correlation between fibroblast activation and proximity to mast cells. Orthotopic transfer of fibroblasts from dysbiotic and non-dysbiotic mice has demonstrated that fibroblasts from the mammary tissues of dysbiotic mice are sufficient to increase early tumor dissemination. By uncovering mechanisms of mast cell-fibroblast crosstalk, our findings have the potential to inform the development of therapeutic and diagnostic strategies aimed at targeting tissue remodeling in patients at risk for metastatic disease. Ultimately, this work lays the foundation for repurposing clinically available drugs that target mast cell function or tissue fibrosis to prevent HR$^+$ breast cancer metastasis.

#0190 Breast cancer liver metastasis: Primary tumor predictors and histopathologic characteristics of metastatic lesions.

Hatun Duran Cete, Alexandra Bartlett, Michelle Kayoko Ozaki, Jackie Phipps, Pepper Schedin

Knight Cancer Institute, OHSU, Portland, OR

Background: Breast cancer metastasis to the liver (BCLM) has poor outcomes because predicting patients at risk for liver metastasis remains elusive as does effective targeting of metastatic lesions. Known risk factors for BCLM include young patient age and primary breast cancer diagnoses of high grade, late stage and triple negative or HER2+ subtypes. Prognostic sensitivity is currently low. Further, lack of histopathologic characterization of BCLM tumors in the literature limits development of targeted therapeutics.
Methods: We collected retrospective and prospective BCLM tissues from forty-seven breast cancer patients who underwent liver biopsy (87%) or surgical resection (13%) for clinical indications of BCLM at OHSU Portland, Oregon. Patients were enrolled regardless of age or breast cancer subtype. Patient clinicopathological characteristics at time of primary breast cancer diagnosis were used to identify breast cancer attributes associated with liver metastasis. Histological and immunohistology analyses of formalin fixed paraffin (FFPE) embedded BCLM tissues were employed to assess metastatic tumor and tumor niche characteristics within the liver.
Results: At primary breast cancer diagnosis, 38% of cases were ≤45 years of age, with 72% of these young cases diagnosed within 10 years of childbirth. Regardless of patient age, 85% of the primary cancers were ER+, 60% luminal A, 57% low grade, and 73% early stage. The majority of the BCLM lesions were also ER+, while ~10% of the ER+ primary lesions converted to ER- in metastasis. Progesterone receptor switching from ER+PR+ primary to ER+PR- BCLM occurred in ~50% of ER+PR+ cases. High GATA3 staining was observed in 86% of the BCLM tumors, supporting luminal breast cell origin. Replacement growth pattern was dominant, observed in 87% of cases, with immunohistology and immunofluorescence evidence that breast tumor cells utilize existing sinusoidal architecture to establish and maintain metastatic outgrowth.
Conclusions: In our single institution cohort, we find that recent pregnancy, young age and proximity to recent childbirth are associated with breast cancer metastasis to the liver. We found most primary cancers that progressed to liver metastasis were ER positive, luminal A, low-grade and early-stage, suggesting these classically-good prognostic indicators in breast cancer may not remain good indicators when accompanied by metastasis to the liver. Finally, improved understanding of the dominant replacement growth pattern and the relation between tumor cells and the liver sinusoids may lead to new drug targets and precision therapies.

#0191 Pulmonary tuberculosis as a modifier of molecular features and survival in lung cancer patients.

Cristina Torres-Mallma[1], Ronald Calle Valdez[2], Yomali Aroa Ferreyra[3], Natalia Valdiviezo[1], Rossana Ruiz[1], Ofelia Coanqui[4], Marco Galvez-Nino[5], Enriqueta Felip[6], Luis Mas[1]

[1]AUNA - Oncosalud, Lima, Peru,[2]Hospital Nacional Alberto Sabogal Sologuren, Lima, Peru,[3]Health Innovation Laboratory, Institute of Tropical Medicine "Alexander von Humboldt", Universidad Cayetano Heredia, Lima, Peru,[4]Medical Oncology Department, Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru, Lima, Peru,[5]Inst. Nacional de Enfermedades Neoplasicas, Lima, Peru,[6]VHIO Vall D'Hebron Institute of Oncology, Barcelona, Spain

Pulmonary tuberculosis (TB) may influence lung tumor biology through chronic inflammation and immune dysregulation, but its clinical and molecular implications remain poorly understood in high TB-burden regions. This study aimed to evaluate the impact of active and prior TB on molecular characteristics and survival outcomes in patients with non-small cell lung cancer (NSCLC). We conducted a retrospective observational study including 219 patients diagnosed with NSCLC at the Instituto Nacional de Enfermedades Neoplásicas (INEN), Lima, Peru, between 2010 and 2023. Patients were classified as having active TB (a-TB, n=45) or prior TB (p-TB, n=174) according to clinical and radiologic data. Clinical, pathological, and molecular variables were collected. The primary endpoint was overall survival (OS); secondary endpoints included molecular profile distribution and progression-free survival (PFS). The median age was 57 years in a-TB and 64 years in p-TB. Adenocarcinoma was the predominant histology (94%). EGFR mutations and ALK rearrangements were found in 10.5% and 4.1% of the overall cohort, respectively. PD-L1 expression <1% was frequent (82.3%) and significantly associated with prior TB (p=0.004). In multivariable analysis, the absence of a driver mutation was independently associated with inferior OS in both a-TB (HR 2.94; p=0.046) and p-TB (HR 1.78; p=0.040) groups. Among patients with p-TB, longer TB exposure (>30 years) was associated with poorer OS (HR 1.47; p=0.039). In conclusion, pulmonary tuberculosis, particularly remote infection, was linked to immunosuppressive tumor profiles and decreased survival in NSCLC. These findings suggest that TB history may act as a biological modifier of tumor behavior and should be considered in the prognostic assessment and therapeutic planning of lung cancer patients in endemic regions.

#0192 Chronological evolution of immune tumor microenvironment (TME) from esophageal dysplasia (ED) to esophageal squamous cell carcinoma (ESCC).

Jhe-Cyuan Guo[1], Yen-Lin Huang[2], Chia-Lang Hsu[3], Tsung-Che (Nathan) Wu[3], Chien-Huai Chuang[3], Ta-Chen Huang[3], Wen-Lun Wang[4], Chih-Hung Hsu[3]

[1]National Taiwan University Cancer Center (NTUCC), Taipei City, Taiwan,[2]National Chung Hsing University, Taichung, Taiwan,[3]National Taiwan University Hospital, Taipei, Taiwan,[4]Department of Internal Medicine,E-Da Hospital/I-Shou University, Kaohsiung, Taiwan, Institute of Clinical Medicine,National Cheng Kung University Hospital, College of Medicine, Nationa, Kaohsiung City, Taiwan

Background: Previous studies have shown that ED, a precancerous stage of ESCC, exhibits genetic alterations and genomic instability similar to those observed in ESCC. Other factors—such as alterations in immune surveillance—may also contribute to the progression from dysplasia to invasive cancer.
Methods: Patients with a history of ED prior to the diagnosis of ESCC were enrolled for gene expression profiling (GEP) study of esophageal lesions and patients with early stage ESCC treated with endoscopic submucosal dissection (ESD) were enrolled for immunohistochemistry (IHC) study. Formalin-fixed paraffin-embedded tissues (FFPEs) from ED diagnosed more than 6 months prior to the diagnosis of ESCC (denoted as dysplasia-1), ED diagnosed within 6 months prior to the diagnosis of ESCC (denoted as dysplasia-2), and ESCC were retrieved. Transcriptomic data were generated by NanoString nCounter platform with Human PanCancer Immune Profiling panel and were further analyzed for the expression levels of infiltrating immune cells by CIBERSORT. FFPEs from another cohort of patients with early stage ESCC treated with ESD were stained with anti-CD68 (Rabbit polyclonal, abcam, UK) and anti-CD163 (Rabbit polyclonal, Synaptic Systems GmbH, Göttingen, Germany). Their expression levels were semi-quantitatively determined in the stroma and intratumoral fields and were compared among the areas of normal mucosa, dysplasia, and ESCC in the same patient.
Results: Seventeen ESCC patients were enrolled for GEP study. The median time periods from the diagnosis of dysplasia-1 to that of ESCC and from the diagnosis of dysplasia-2 to that of ESCC were 8.6 months and 3.0 months, respectively. The analysis of immune cell signatures defined by NanoString platform revealed that multiple cell types were significantly increased in ESCC compared with dysplasia-1 (mast cell, macrophage, and dendritic cell, all $P < 0.05$) and in ESCC compared with dysplasia-2 (macrophage, mast cell, CD8 T cell, dendritic cell, total TIL, T cell, and regulatory T cell, all $P < 0.05$). No significant difference was found between dysplasia-1 and dysplasia-2. Immune cells classified by CIBERSORT showed an increase of M2 macrophage and a decrease of M1/M2 ratio in ESCC compared with dysplasia-1 or dysplasia-2 (both $P < 0.05$). Eighty-two early ESCC patients were enrolled for IHC study. A progressive increase in the expression levels of CD68 and CD163 was found from mucosa to dysplasia then to ESCC (all $P < 0.001$)
Conclusions: The increased expression of M2 macrophages in the ESCC TME compared with precancerous dysplasia supports the hypothesis that immune TME alterations may drive the progression from dysplasia to ESCC. (Funded by MOST 107-2314-B-002-199-, MOST 109-2314-B-002-231-, MOHW114-TDU-B-221-144006, NSTC 114-2314-B-002 -206 -MY3, NTUCCS-110-10, and NTUCCS-111-05)

#0193 Tumor-agnostic analysis identified pan-cancer immune archetypes and CD8⁺FoxP3⁺ cells as novel in situ predictors of survival.

Immune infiltration shapes anti-tumor responses and is associated with patient outcomes. Yet, comprehensive studies comparing infiltration patterns and their clinical impact across cancer types are scarce.We profiled the tumor immune microenvironment across 16 solid tumor types from more than 2,700 patients using multiplex immunofluorescence with pathologist-curated image analysis to quantify major lymphoid and myeloid subsets and their spatial organization in situ.Across all cancer types, lung, endometrial, and high-grade serous ovarian cancers were highly infiltrated, whereas prostate and ER-positive breast cancers were comparatively “immune cold”. Cancer-agnostic consensus clustering resolved four reproducible immune archetypes with distinct outcomes, including an immune-hot group enriched for CD4, CD8, and B cells that associated with the best survival ($p<0.001$). Notably, the tumor type accounted for only a part of the immune contexture, as most cancers spanned multiple immune signature groups. Nevertheless, a machine-learning classifier trained on immune compositions distinguished tumor types with high accuracy (AUC = 0.96), confirming that each cancer maintains a recognizable immune imprint even among pan-cancer archetypes.Analysis of survival associations of individual cell classes revealed a rare CD8⁺FOXP3⁺ T-cell phenotype that emerged as a strongest positive prognostic factor across cancers (HR=0.79, 95%CI:[0.70-0.89], p=0.002). Single-cell RNA sequencing data indicated that CD8⁺FoxP3⁺ cells exhibit two distinct gene programs, with regulatory and cytotoxic capacities. Spatial mapping suggested context-dependency in the function of CD8⁺FoxP3⁺ cells, as their proximity to CD8 T cells was linked to better survival (enrichment at 10um: HR=0.76, 95%CI:[0.67-0.90], p=0.0006), whereas proximity to tumor cells was associated with worse prognosis (enrichment at 10um: HR=1.29, 95%CI:[1.12-1.49], p=0.0005).Together, our findings define pan-cancer immune archetypes that are both shared and disease-specific, explaining why “immune hot” and “cold” states are not synonymous with pure infiltration quantities. We identified CD8⁺FoxP3⁺ immune cells as a cell type with strong biomarker potential independent of cancer type.

#0194 Lung adenocarcinoma promotion by chemokine CXCL13.

Xiao-Liang Jie, Yang-Tong Liu, Yi-Shuai Tan, San-Hui Gao, Zheng Wang, Gui-Zhen Wang, **Guang-Biao Zhou**

Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China

Chemokine C-X-C motif ligand 13 (CXCL13) is a B lymphocyte chemoattractant that plays an important role in immune system and is involved in the pathogenesis of a number of benign and malignant diseases. Previously, we reported that deficiency in Cxcl13 significantly attenuated air pollutant-induced lung cancer in mice. In this study, we established Cxcl13-overexpressing mouse models to investigate its cancer initiating activity. We found that 15 (51.7%) of 29 mice that received an intratracheal injection of Cxcl13-encoding lentivirus developed lung adenocarcinoma (LUAD), as detected by hematoxylin-eosin (H&E) staining and confirmed by immunohistochemistry for TTF1 in the lung tumor tissues. Of the 21 surfactant protein C (SPC) promoter-driven Cxcl13 transgenic mice, 7 (33.3%) developed LUAD. By single-cell RNA sequencing, we identified a fraction of Ecm1-expressing M2 type macrophages and Itga2^{+} cancer cells that expressed high level of wnt/β-catenin carcinogenic pathway. Overexpression of CXCL13 in cancer cells promoted CD47 accumulation on the surface of tumor cells to shield themselves from macrophage phagocytosis. Targeting CXCL13 combined with CD47 pathway blockade exerted synergistic anti-tumor efficacy in patient-derived xenograft models of NSCLC. Collectively, our findings indicated that the up-regulation of CXCL13 in lung epithelial cells promotes tumorigenesis, and targeting CXCL13 may provide a potential therapeutic approach for NSCLC.

#0195 IL-33/JAK2/RAB21/PLD4-Sphingolipid network drives gastric carcinogenesis.

Hui Liu, Yunxiao Ge, Yubing Zhou, Hangrui Liu, Zigang Dong

Department of Pathophysiology, Zhengzhou University, Zhengzhou, China

Gastric cancer (GC), the fifth most prevalent malignancy and fourth leading cause of cancer mortality globally, is synergistically promoted by *Helicobacter pylori* infection and alcohol consumption through exacerbated gastric mucosal inflammation. To delineate key biomarkers in the gastritis-to-cancer transition and identify actionable targets for primary prevention and therapy, we integrated proteomic and metabolomic analyses of *Helicobacter pylori* plus alcohol induced GC mouse model and human gastritis/GC tissues. It revealed that significant Ras-related protein RAB21 is upregulated in gastritis and gastric cancer tissues, and metabolomics identified sphingolipid metabolism reprogramming is a key signature in GC tumorigenesis. *In vitro* experiments showed that RAB21 downregulation suppressed GC cell proliferation, and *in vivo* studies including RAB21 conditional knockout mice further demonstrated that RAB21 depletion inhibited GC tumorigenesis. Mechanistically, RAB21 binds to tyrosine-protein kinase JAK2 and is phosphorylated at tyrosine 88 by JAK2, regulating expression and phospholipase activity of 5'-3' exonuclease PLD4. *Helicobacter pylori* plus alcohol induced upregulated interleukin-33 (IL-33) promotes JAK2 and RAB21 expression via forkhead box protein P3 (FOXP3), promoting RAB21 nuclear translocation to regulate PLD4 expression, and converged with the phosphatidic acid-sphingosine kinase-sphingosine-sphingosine 1-phosphate (PA-SPHK-SPHG-S1P) metabolic flux to drive GC tumorigenesis and progression. This study elucidates the protein-metabolic network in gastric carcinogenesis and provides experimental rationale for targeting IL-33/JAK2/RAB21/PLD4-sphingolipid metabolism axis for GC prevention and treatment.

#0196 Lung inflammation accelerates tumor progression in a mouse model of oncogenic KRAS driven lung adenocarcinoma.

Samantha A. Nelson, Jacob Kassama, Christina M. Cabana, Alexandria M. Jefferson, Tyler E. Jacks

Biology, Massachusetts Institute of Technology (MIT), Cambridge, MA

Recent studies of human tissue samples in various organs including the lung have revealed the presence of canonical oncogenic mutations at rates higher than known incidence rates of cancers associated with these tissues. Other work has linked diverse inflammatory diseases to increased incidence rates of cancers associated with the involved organs. In the context of lung adenocarcinoma (LUAD), inflammatory lung diseases may produce a favorable environment for the outgrowth of tumors, and characterizing how this may occur could uncover avenues for LUAD prevention. Using a transgenic mouse model where LUAD is initiated by inducing expression of oncogenic KRAS and the fluorophore tdTomato in normal alveolar type II cells via delivery of Cre-expressing virus into the lung, we demonstrated that a range of inflammatory insults accelerated early tumor growth. Modelling of idiopathic pulmonary fibrosis and bacterial or viral lung infections in these tumor bearing mice each resulted in an increase in average tumor size and total tumor burden at both early and late timepoints of tumor progression, despite showing many divergent impacts on lung immune populations and signaling factors as characterized through flow cytometry, RNA sequencing, and ELISAs. Immunofluorescence staining of early lesions allowed us to quantify the increase in lesion size under inflammatory conditions and to investigate the association of immune cells with these small lesions, revealing that KI-67+ F4/80+ macrophages showed increased density proximal to lesions under all inflammatory conditions. We are actively working to uncover the points of communication between immune populations and early cancer cells that result in this accelerated tumor growth under these conditions. We have observed that in our LUAD mouse model tumor growth is accelerated by exposure to lung inflammation, and through characterization of the inflamed immune microenvironment and communication between immune and cancer cells during inflammation that mediate accelerated growth, this project aims to identify molecular targets for LUAD prevention.

#0197 LPS-induced superoxide anion-dependent macrophage extracellular traps by store-operated calcium entry.

Ngoc Thang Nguyen, Wen-Tai Qiu

Department of Biomedical Engineering, National Cheng Kung University, Tainan City, Taiwan

Macrophage extracellular traps (METs) contribute to chronic inflammation in the tumor microenvironment, promoting cancer progression via necroptosis-induced extracellular matrix degradation. This study investigates the role of store-operated calcium entry (SOCE) in calcium-induced MET formation, a process that amplifies pro-tumorigenic inflammatory responses in macrophages. Mouse macrophage RAW264.7 and human monocyte U937 cells were stimulated with lipopolysaccharide (LPS) or phorbol myristate acetate (PMA), with or without pretreatment using Ca^{2+} chelator BAPTA-AM, mechanical Ca^{2+} channel inhibitor $GdCl_3$, SOCE inhibitors SKF96365 or YM58483, or superoxide anion scavenger thymoquinone (TQ). METotic cells were identified via immunofluorescence staining for Lamin B after digitonin permeabilization. LPS and PMA triggered SOCE-mediated Ca^{2+} influx, leading to elevated cytoplasmic Ca^{2+} levels that activated NADPH oxidase (NOX) to produce superoxide anions, culminating in MET formation. Pharmacological inhibition of SOCE attenuated Ca^{2+} influx and superoxide anion, whereas superoxide scavenging significantly inhibited METosis without altering NOX1/2 protein levels, indicating Ca^{2+}-dependent NOX activation. These results reveal a SOCE-NOX-superoxide axis driving LPS-induced METosis, highlighting its potential in tumor progression. Targeting SOCE could disrupt macrophage-mediated inflammatory circuits in cancer initiation and progression

#0198 The IL-33/ST2 signaling reshapes the immune landscape and promotes leukemia transformation in acute myeloid leukemia.

Yu-Hsuan Fu, Man Li, Ying-Chieh Chen, Lianjun Zhang, Wancheng Guo, David E. Frankhouser, Denis O'Meally, Jihyun Irizarry, Jennifer Rangel Ambriz, Ziang Chen, Bin Zhang, Sergio Branciamore, Guido Marcucci, Russell Rockne, Ya-Huei Kuo

City of Hope National Medical Center, Duarte, CA

Acute myeloid leukemia (AML) is an aggressive malignancy with a 5-year survival rate of ~30%, largely due to relapse and immune evasion. Using a state-transition modeling framework on time-series RNA-seq from a *Cbfb::MYH11* (CM) knock-in AML mouse model, we identified *IL1RL1* (ST2), the receptor for IL-33, as a leukemia-promoting gene upregulated early in leukemogenesis. Similarly, ST2 expression is elevated in AML patients —particularly in inv(16) and t(8;21) subtypes— and correlates with poor prognosis (TCGA, n = 139, $p < 0.001$). ST2 regulates inflammatory responses, including Th2 immune response and mast cell activation. The $ST2^+$ regulatory T cells (Treg) have been shown to exert immune suppression function in AML, whereas ST2's impact on the other immune cells and the molecular mechanisms remain largely unexplored. We first generated CM mice with ST2 knockout (CM-ST2-KO), which showed delayed leukemia onset, reduced circulating blasts, and extended survival compared to CM mice (median survival 192 days vs. 103 days; $p < 0.0001$). The scRNA-seq of leukemic stage bone marrow from CM mice revealed high ST2 expression in leukemia-enriched cell types (stem cells, erythrocytes, and mast cells). Further cell-cell communication analysis via CellChat discovered enhanced crosstalk between leukemic cells and immune cells in CM mice, which was reduced in CM-ST2-KO mice. Dysregulation of immunosuppressive pathways were identified, including PD-L1 and ALOX5, both elevated in CM and reversed in CM-ST2-KO mice. Experimental validation by ectopically overexpressing ST2 enhanced PD-L1 and ALOX5 expression, upon IL-33 stimulation. By flow cytometry, enhanced PD-L1 level was found in hematopoietic stem and progenitor cells (HSPCs) and myeloid populations, which were skewed toward immunosuppressive subsets [i.e, M2 macrophages, $PD\text{-}L1^{high}$ Ly6C+ myeloid-derived suppressor cells (MDSCs)] with reduced $PD\text{-}L1^{low}$ Ly6G+ MDSCs in CM mice. Moreover, increased expression of T cell checkpoint markers was shown, including PD-1 and TIGIT on CD8+ T cells and CD160 on CD4+ T cells. These immunosuppressive phenotypes were all reversed in CM-ST2-KO mice. Furthermore, direct co-culturing T cells from healthy mice with the Lin^-cKit^+ cells (LK cells) from CM mice suppressed T cell proliferation compared to LK cells from WT, which can be rescued in CM-ST2-KO co-culture. In summary, we identified ST2 as a key regulator of leukemia progression and immune suppression in AML. Our data indicates that ST2 promotes leukemic transformation and reshapes the bone marrow immune landscape by upregulating ALOX5 and PD-L1, expanding immunosuppressive myeloid populations, and enhancing T cell exhaustion. Genetic knockout of ST2 reverses these immunosuppressive phenotypes and prolongs survival, supporting the therapeutic potential of targeting ST2 to improve immune-based therapies in AML.

#0199 Identification of oncohistone-dependent changes in chromatin accessibility and the tumor microenvironment in a new inducible and reversible H3.3K27M mouse model of diffuse midline glioma (DMG).

Mostafa M. H. Ibrahim[1], Niloofar Khairkhah[1], Sienna L. Galban[2], Megan Faunce[1], Yue Zhao[3], Stefanie Galban[1]

[1]Department of Radiology, University of Michigan Medical School, Ann Arbor, MI,[2]Davidson School of Chemical Engineering, Purdue University, West Lafayette, IN,[3]Gilbert S. Omenn Department of Computational Medicine and Bioinformatics, University of Michigan Medical School, Ann Arbor, MI

Tumor recurrence remains a major obstacle to the successful clinical management of H3K27M-altered diffuse midline glioma (DMG), a pediatric high-grade tumor arising in the brain stem. Currently available therapies do not prevent tumor recurrence, observed in nearly all treated patients. A desperate need remains to understand epigenetically, H3K27M-driven gene expression and the remodeling of the tumor immune/stromal microenvironment to prevent tumor recurrence.

Here, we introduce new inducible and reversible H3.3 and H3.1K27M cell and mouse models of DMG that enable the evaluation of the biological effects on tumor growth and recurrence of oncohistone expression, and at the same time, the characterization of changes in the microenvironment and epigenome upon H3K27M activation, inactivation and re-activation. Tetracycline-inducible and reversible PiggyBac-based expression vectors for H3.3K27M and H3.1K27M were utilized to engineer patient- and murine-derived DMG cell and *in vivo* models. Inducibility and reversibility of H3K27M in cells and tumors was validated by live cell flow cytometry for fluorescent marker expression and intracellular flow cytometry and western blotting for expression of the oncohistone. We detected characteristic morphological changes and repression of astrocytic markers upon H3K27M re-expression in KO cells. Furthermore, decrease in tumor growth upon oncohistone expression was observed in DMG *in vivo* models using bioluminescence imaging, providing proof-of-concept for inhibiting oncohistone expression in progressing tumors. In addition, we demonstrated changes in chromatin accessibility between ON, OFF and OFF-ON cells and importantly, identified mechanisms of immunosuppression through regulation of PD1 in the ON and OFF-ON groups, providing rationale for future targeted therapies. Single-cell RNA sequencing (scRNA-seq) of tumors in ON and OFF groups showed a complex TME that is modulated by expression of the oncohistone.

In conclusion, these newly developed iH3.3 and H3.1K27M cell and mouse models are ideal to study oncohistone dependent pathobiological consequences, as they allow controlled expression of the oncohistone in physiologically relevant and immune proficient settings. Furthermore, they lend themselves to comparative studies between H3.3 and H3.1 expression in DMG. Our studies will provide future strategies for targeting immune and stromal compartments with the potential to prevent tumor recurrence and inform the feasibility of future CRISPR editing strategies for targeting the oncohistone directly.

#0200 Spatiotemporal analysis reveals tsMHC-I downregulation-induced neutrophil extracellular traps as a driver of lung adenocarcinoma neoplastic evolution.

Yanhua Tian[1], Jian-Rong Li[2], Bo Zhu[1], Jared Fradette[1], Hong Chen[1], Zhubo Wei[1], Jie Ye[1], Shao-Wei Lu[1], Andrew Y. Liu[1], Samrat T. Kundu[1], Haoyi Wu[1], Shucheng Miao[1], Xiuning Le[1], Linghua Wang[1], Jia Wu[1], Alexandre Reuben[1], John V. Heymach[1], Andy Futreal[1], Honami Naora[3], Chao Cheng[2], Don L. Gibbons[1], Jianjun Zhang[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Baylor College of Medicine, Houston, TX,[3]Associate Professor, Dept. of Systems Biology, UT MD Anderson Cancer Center, Houston, TX

Background: Loss of tumor-specific MHC class I (tsMHC-I) is a recurrent feature of lung adenocarcinoma (LUAD) progression and is associated with immune escape and poor outcomes. However, how tsMHC-I downregulation shapes tumor evolution and remodels the immune microenvironment remains unclear.
Methods: We integrated single-cell RNA sequencing, spatial transcriptomics, and multiplex imaging from human LUAD samples spanning precancerous lesions to advanced tumors, together with longitudinal genetically engineered mouse models (GEMMs). Functional assays—including neutrophil co-culture, assessment of neutrophil extracellular traps (NETs), and in vivo tumor studies—were performed to define mechanistic consequences of tsMHC-I loss.
Results: Progressive tsMHC-I downregulation was observed across LUAD evolution and validated in GEMMs. Single-cell trajectory analysis showed that reduced tsMHC-I is linked to loss of alveolar type II identity, increased chromosomal instability, heightened tumor plasticity, and acquisition of epithelial-mesenchymal transition (EMT) programs. Functionally, tsMHC-I^{Low} malignant cells displayed increased invasiveness and metastatic capacity. Spatial and immunophenotypic profiling revealed that tsMHC-I downregulation reshapes the tumor microenvironment toward a neutrophil-enriched, cytotoxic cell-excluded niche. tsMHC-I^{Low} regions exhibited dense tumor-associated neutrophil aggregates and depletion of CD8^{+} T cells, NK cells, and other effector populations. Mechanistic studies showed that tsMHC-I^{Low} malignant cells induce robust NET formation. In vitro assays identified Annexin A2, a tumor-secreted protein, as a key driver of NET induction. Annexin A2 expression and secretion were consistently elevated in tsMHC-I^{Low} cells across human and mouse models, and Anxa2 knockdown markedly reduced NET formation. Targeting NETs in vivo with DNase I selectively suppressed growth and metastatic spread of tsMHC-I^{Low} tumors, restored cytotoxic immune infiltration, and reversed the immune-excluded phenotype. In tsMHC-I heterogeneous tumors, combining NET inhibition with anti-PD-1 enhanced tumor control and survival.
Conclusions: Our integrated analyses reveal that tsMHC-I downregulation drives neutrophil recruitment and NET formation through Annexin A2 secretion, creating an immunosuppressive barrier that promotes LUAD progression and limits immunotherapy response. These findings identify a previously unrecognized tsMHC-I-NET axis as a therapeutic vulnerability in LUAD.

#0201 Development of an immunocompetent orthotopic mouse model recapitulating metastatic endometrial cancer.

Keun Cheon Kim, Cassandra Schmidt, Eunhee M Jeong, Tae Hoon Kim, Jae-Wook Jeong

University of Missouri, Columbia, MO

Endometrial cancer (EC) is the most common gynecologic malignancy. However, progress in developing new therapeutic strategies has been limited by the lack of immunocompetent animal models that faithfully recapitulate human EC, including intact immune responses and the ability to form distant metastases. To address this gap, we developed an orthotopic, immunocompetent EC mouse model using the GFP-labeled mouse endometrial cancer cell line MECPK (Pten-deleted, Kras-activated). Following uterine abrasion, 50,000 MECPK cells were injected into the uterine lumen of recipient mice. Uterus tissues with EC were collected from mice at 4, 5, 6, and 8 weeks post-induction using a fluorescence-guided dissecting microscope. Samples were processed for hematoxylin and eosin (H&E) staining and immunohistochemistry for E-cadherin, followed by AI-based image analysis. Tumor initiation was first detectable at 5 weeks after induction, and 66.7% of mice (6/9) developed distant lung metastases by 8 weeks. All tumor-bearing mice succumbed to disease before 10 weeks post-transplantation. We performed quantitative IHC analysis of PD-L1, MLH1, and MSH2 to evaluate biomarkers associated with immunotherapy response. PD-L1 was highly expressed at all stages of tumor progression. While MLH1 expression did not differ significantly between EC and normal regions, MSH2 expression was remarkably reduced during cancer progression. MSH2 expression in primary cancer at 5 weeks (246.55 ±6.39) was not significantly different from that in normal epithelium (256.15 ±10.96). However, MSH2 levels were significantly decreased in primary cancer at 6 weeks (95.65 ±17.88, $p<0.001$) and 8 weeks (133.16 ±12.98, $p<0.001$), as well as in metastasis endometrial cancer in lung at 8 weeks (110.89 ±19.26, $p<0.001$). These findings establish a robust immunocompetent orthotopic EC model that recapitulates primary tumor progression and distant metastasis, providing a valuable platform for mechanistic studies and preclinical evaluation of emerging therapies, including immunotherapy.

#0202 The early immune landscape of breast cancer and the role of tertiary lymphoid structures.

Thila Vanhulst[1], Soizic Garaud[2], Alexandre De Wind[3], Anais Boisson[1], Pauline Delvaux[1], Doina Sofronii[1], Mireille Langouo Fontsa[1], Karen Willard-Gallo[1]

[1]Molecular Immunology Unit, Institut Jules Bordet, Brussels, Belgium,[2]Universite Brest, Inserm, Brest, France,[3]Departement of Pathology, Institut Jules Bordet, Brussels, Belgium

Ductal carcinoma *in situ* (DCIS), stage 0 breast cancer (BC), is defined by tumor cells confined to the duct. Tumor infiltrating lymphocytes (TIL) are prognostic for invasive ductal carcinoma (IDC) of the breast; however, their role in DCIS remains unknown. Some DCIS studies have analyzed TIL subpopulation balances with a few identifying tertiary lymphoid structures (TLS) but their roles in progression and recurrence remains unclear due to contradictory findings. The aim of this study is to investigate the functionality and organization of TIL into TLS in pre-invasive BC lesions. Fresh tumor samples were obtained at surgery from patients with DCIS (n=19), IDC (n=19) and mammary reductions (MR; n=8 controls) for the prospective cohort. Tissues were dissociated without enzymes and immunophenotyped by flow cytometry. A retrospective cohort of FFPE tissue blocks (DCIS n=30, IDC n=30) were dual-stained by chromogenic immunohistochemistry (cIHC) for CD3+CD20 and PD-1+Ki67 and scored for TILs and TLS, with selected patients (DCIS n=10, IDC n=10) also stained by multiplex IHC (mIHC). We extended our analyses by re-analyzing public scRNA-seq datasets (DCIS n=6, IDC n=6) to further explore the immune landscape. Patients were matched by BC molecular subtypes to control variation between subtypes. In the prospective cohort, a higher proportion of B cell and T follicular helper (Tfh) TIL were detected in DCIS vs. MR, with the former paralleling IDC levels and potentially signaling a TLS presence. In the retrospective cohort, TLS were detected by dual cIHC in 75% of DCIS compared to 58% of IDC, the latter consistent with our previous analysis of >300 IDC patients. Spatial mIHC analysis of CD3, CD20, AID and CD23 revealed that while AID^+ B cells were less frequent in DCIS-TLS the number of $CD23^+$ mature FDC were comparable with IDC. Thus, DCIS-TLS have a mature stroma but limited Ig diversification, suggesting these structures are at an earlier stage of differentiation. Tfh cells play a crucial role in B cell maturation and antibody production. Flow cytometric data from the prospective cohort detected lower frequencies of functional $CXCR5^+PD1^{hi}ICOS^{int}$ Tfh cells in DCIS vs IDC. scRNA-seq analysis revealed that DCIS Tfh were more naïve, whereas IDC Tfh had enhanced effector signatures. In the prospective cohort, CXCL13-producing $CXCR5^-PD1^{hi}ICOS^{int}$ Tfh cells, known for their critical role in IDC-TLS formation, were also reduced in DCIS with CXCL13 expression primarily detected in podoplanin$^+$ stromal cells within DCIS-TLS. Our data show that while high densities of TIL and TLS are observed in DCIS, adaptive immunity responses are less mature and therefore less functional than in IDC. This may partly explain why dense TIL and TLS in DCIS are not consistently associated with a good prognosis, unlike IDC. Our findings highlight the need to further dissect, beyond simple quantification, the immune composition and spatial organization across BC stages.

#0206 Dependencies of diffuse large B-cell lymphoma on EBV oncoproteins.

Lily Catherine Foreman Wenger[1], Quincy Rosemarie[2], Eric C. Johannsen[2]

[1]McArdle Laboratory for Cancer Research, University of Wisconsin-Madison, Madison, WI,[2]University of Wisconsin - Madison, Madison, WI

Background: Up to 14% of diffuse large B-cell lymphomas (DLBCL) are Epstein-Barr virus-positive (EBV+), and their growth and survival are dependent on EBV latency gene products. DLBCL is a heterogeneous group of aggressive lymphomas, and we previously found that EBV is associated with the BN2 LymphGen subtype. Additionally, multiple genes were mutated at lower frequencies in EBV+ tumors relative to EBV-, suggesting viral oncogenes functionally replace host driver mutations. To identify the EBV oncogenes essential for EBV+ DLBCL and the functional consequences of their inactivation, we are conducting CRISPR/Cas13d screens in EBV+ DLBCL cell lines.
Methods: EBV+ DLBCL cell lines (Farage, BCKN1, IBL1, and IBL4) were characterized using whole-exome sequencing (WES), RNA sequencing (RNA-seq), and immunoblotting. We compared the mutational and transcriptomic profiles of EBV+ tumors and cell lines to inform CRISPR/Cas13d functional screens. These screens aim to identify EBV gene product dependencies in EBV+ DLBCL and the impact on cell growth and survival.
Results: WES analysis revealed the genetic subtype of each EBV+ DLBCL cell line: Farage was classified as ST2, and the rest were classified as “Other”. RNA-seq and immunoblotting revealed that all expressed an atypical latency III program, characterized by the absence of LMP2A expression. This novel latent gene program was also observed in the EBV+ DLBCL tumors. All cell lines were infected with EBV1, except IBL1, which, to our knowledge, is the only known cell line infected with an EBV1/EBV2 intertypic recombinant. By employing Cas13d for our knockdown screen, we can determine the specific transcripts within the complex EBV latent transcriptome that are essential for the growth and survival of EBV+ DLBCL. Targeting RNA also avoids excessive DNA damage and low sensitivity that arises from targeting 10-20 copies of EBV DNA per cell with Cas9. We have stably expressed two different Cas13d orthologs in each cell line and are optimizing their RNA knockdown efficiency using a FACS-based transient knockdown strategy. Use of clones achieving the most efficient knockdown will allow us to identify essential EBV latent genes and determine the phenotypic consequences (growth arrest, apoptosis, etc.) of inactivating each essential viral oncogene.
Conclusions: EBV+ DLBCL exhibits distinct host mutation and gene expression profiles, including the replacement of several subtype-defining mutations with EBV oncogenes. The available EBV+ DLBCL cell lines faithfully model the ST2 or “Other” LymphGen subtypes and exhibit the same atypical EBV latent gene expression pattern as tumors. By determining EBV oncogene dependencies and the effects of their inactivation, we aim to uncover how EBV cooperates with host driver mutations in the pathogenesis of EBV+ DLBCL. Understanding these therapeutic vulnerabilities will provide a foundation for precision therapy.

#0207 Decoding the circRNA-miRNA-mRNA regulatory network in hepatitis B Virus-driven hepatocellular carcinoma.

Kainat Ahmed[1], Anwaruddin Mohammad[2], Nan Chaiyariti[3], Danya Sankaranarayanan[1], Pankaj Kumar[2], Sudhakar Jha[1]

[1]Oklahoma State University, Stillwater, OK,[2]University of Virginia, Charlottesville, OK,[3]Mahidol University, Bangkok, Thailand

Integration of the hepatitis B virus (HBV) genome into the host chromosome of infected patients poses a threat to those with HBV-associated hepatocellular carcinoma (HCC) due to challenges in early diagnosis and poor prognosis. CircRNAs are known for their oncogenic and biomarker potential in various cancers, including HBV-HCC, by sequestering tumor suppressive miRNAs, which, when free, can silence the expression of oncogenic mRNAs. Therefore, we aimed to identify the circRNA-miRNA-mRNA axis in HBV-integrated HCC cell lines to find prognostic biomarkers specific to HBV-HCC patients. We identified dysregulated host circRNA and mRNA from HBV-negative and HBV-integrated cells using RNA-seq followed by differential gene expression analysis with DESeq and performed pathway analysis using GSEA. Junctional sequences of the circRNAs were validated by Sanger sequencing of the amplified products. RT-qPCR further confirmed the dysregulation of 9 randomly selected circRNAs chosen from those with the highest fold-change and adjusted p-values. The miRNA partners for each of the circRNA idenfied using mirDB. miRNA expression validation was performed using the publicly available GEO database of same cells and cumulative distribution plots were generated to assess the fold change of mRNAs in potential binding miRNA partners. The mRNA targets for 10 miRNA ECDF plots were subjected to GO and KEGG pathway analysis, and hub genes were identified using STRING cytohubba protein-protein interaction (PPI) analysis. Survival analysis of hub genes was plotted, and a competitive endogenous RNA (ceRNA) network was constructed using Cytoscape.We identified 494 dysregulated circRNAs, 311 dysregulated miRNAs and 10,419 dysregulated mRNA in HBV-integrated cells. circADGRL2 (~25-fold) showed the highest upregulation and miR-361-5p acted as a central node of multiple circRNAs: circADGRL2, circPROX1 and circPALS2. BDNF, a target mRNA of miR-361-5p, was identified as the highest risk ratio in HBV-HCC patients, suggesting a possible circADGRL2-miR-361-5p-BDNF axis. The target mRNAs of miRNAs were found to be associated with several cancer pathways, such as MAPK and RAS. Our data indicate that HBV integration reprograms the circRNA-miRNA-mRNA axis, leading to a poor prognosis for HBV-HCC patients.

#0208 HERV-K env gene promotes tumorigenicity and metastasis through multiple signal pathways, including the Ras/ERK signaling pathway and epithelial-mesenchymal transition (EMT), in breast cancer cells.

Feng Wang-Johanning[1], Gary Johanning[1], Fuling Zhou[2], Edward Njoo[3]

[1]SunnyBay Biotech, Fremont, CA,[2]Zhongnan Hospital of Wuhan University, Wuhan, China,[3]Aspiring Scholars Directed Research Program (ASDRP), Fremont, CA

Background: Overexpression of the human endogenous retrovirus type K (HERV-K) envelope (*env*) gene was demonstrated in various cancers. However, its precise role as a "driver" (initiating tumor development) or "passenger" (simply a consequence of the cancerous state) is still a subject of ongoing research and debate within the scientific community.

Methods: The role(s) of HERV-K expression was investigated in multiple cell lines by stably transfecting with the full length HERV-K *env* gene.

Results: Enhanced expression of K-Ras and its activity were detected in normal breast cells after expressing the HERV-K *env* gene. Enhanced expression of multiple oncogenes was also observed in cancer cells that expressed HERV-K *env*. Upregulation of expression of EMT markers and β-Catenin accompanied upregulation of HERV-K expression. Importantly, metastasis to multiple organs was discovered *in vivo*. Of interest, cancer prevention was demonstrated in mice immunized with HERV-K surface (SU) to a greater extent than with transmembrane protein (TM), due to increased CD8 T cells, decreased Treg cells, and increased Th1 cytokine secretion.

Conclusion: The HERV-K *env* gene is an oncogene that promotes tumorigenesis and metastasis through upregulated expression of the Ras/Raf/MEK/ERK, EMT, and PI3K/AKT pathways. In addition, the HERV-K SU domain but not the TM domain is a tumor-associated antigen (TAA) that can trigger immune responses.

#0209 Unexpected identification of tumor-infiltrating H. pylori or human papillomavirus (HPV) 16 in three exceptional responders in immunochemotherapy-treated esophageal cancer.

Sabrina A. James[1], Hannah S. Fuchs[1], Thomas M. Carroll[1], Phil F. Xie[1], Joseph A. Chadwick[1], Brittany-Amber Jacobs[1], Tim Waterboer[2], Michal Bassani-Sternberg[3], Florian Huber[3], Duncan Parkes[1], Simon Lord[4], Lucinda Bones[5], Tim Underwood[6], Ioannis Karydis[6], Russell D. Petty[7], Benjamin Schuster-Boeckler[1], Richard P. Owen[1], Mark R. Middleton[4], Xin Lu[1]

[1]Ludwig Institute for Cancer Research, University of Oxford, Oxford, United Kingdom,[2]German Cancer Research Center, Heidelberg, Germany,[3]Ludwig Institute for Cancer Research, University of Lausanne, Lausanne, Switzerland,[4]Department of Oncology, University of Oxford, Oxford, United Kingdom,[5]Oncology Clinical Trial Office (OCTO), Department of Oncology, University of Oxford, Oxford, United Kingdom,[6]University of Southampton, Southampton, United Kingdom,[7]University of Dundee, Dundee, United Kingdom

Background: Understanding why only few patients achieve durable responses to therapy remains challenging. Of 38 metastatic esophageal cancer (EC) patients treated on the LUD2015-005 trial (NCT02735239), three achieved >7 year ongoing survival following anti-PDL1/CTLA4 immunochemotherapy, in contrast to the median survival of 9-12 months under then standard of care. While microbial pathogens are increasingly recognized for their role in modulating tumor immunogenicity, their role in EC remains controversial.

Methods: Bulk and single-cell RNA sequencing, including B and T cell receptor (TCR) analysis, were performed on serial tumor biopsies. Humoral responses to HPV16 were assessed via multiplex serology, using patient plasma and recombinantly expressed tumor-infiltrating antibodies. ELISpot assays were performed against HPV16-derived peptides. Subsequent TCR sequencing of peptide-stimulated immune cells was used to identify antigen-specific clones for recombinant expression and validation.

Results: Transcriptomic profiling of all three long-term survivors unexpectedly revealed intratumoral presence of H. pylori (n=1) and HPV16 (n=2), alongside a highly pro-inflammatory tumor microenvironment. Based on available material, the contribution of HPV16 in one patient's durable response was further investigated. Upon 4 weeks of immunotherapy, complete tumor clearance was accompanied by an HPV-targeted host response: serological analysis identified a systemic response against the E6 oncoprotein as well as an intratumoral B cell clone targeting E2. ELISpot assays revealed broad virus-specific T cell reactivity and led to the identification of nine novel HLA-A*02:01-restricted TCRs specific for E2 (2 epitopes) and E6 (1 epitope), each demonstrating high avidity (nM EC_{50}). Notably, clonally expanded T cells expressing these TCRs were also identified within the tumor where they exhibited a tissue-resident memory phenotype, consistent with antigen-driven activation and long-term immune surveillance.

Conclusions: Our findings demonstrate that H. pylori and HPV16 can be detected in EC. We show that HPV16-derived antigens are targeted by both peripheral and tumor-resident immune cells and, alongside the striking response to immunotherapy, suggest that virus-specific immunity may play a role in tumor clearance and long-term disease control. The naturally derived, HPV16-specific TCRs identified here represent promising candidates for adoptive immunotherapy across a range of HPV-driven cancers. More broadly, detection of microbial signatures alongside a robustly activated tumor microenvironment in all three exceptional responders supports the exploration of pathogen-directed therapies in cancers not typically linked to infection, opening new avenues to enhance immunotherapy outcomes.

#0210 Bivalent nanoparticle vaccine elicits cross-protective antibody against oncogenic herpesviruses.

Mu-Sheng Zeng[1], Chu Xie[1], Cong Sun[1], Pei-Huang Wu[1], Peng-Lin Li[1], Bing-Zhen Cheng[2], Ge-Xin Zhao[3], Guo-Long Bu[1], Wen-Ting Du[1], Zi-Ying Jiang[1], Hang Zhou[1], Xin-Yan Fang[2], Xian-Shu Tian[1], Yan-Lin Yang[1], Sen-fang Sui[2], Zheng Liu[2]

[1]Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China,[2]Southern University of Science and Technology, Shenzhen, China,[3]Columbia University, New York, NY

Background: Epstein-Barr virus (EBV) and Kaposi's sarcoma-associated herpesvirus (KSHV) are oncogenic γ-herpesviruses causally linked to multiple malignancies but lack approved vaccines. As virus-associated cancers represent a substantial global tumor burden, preventive vaccination offers a rational approach to cancer prevention. Both viruses depend on the conserved gHgL heterodimer for receptor engagement and entry, suggesting gHgL as a shared vaccine target for broad γ-herpesvirus protection.
Methods: We developed a bivalent nanoparticle vaccine (bi-NP) that co-displays EBV and KSHV gHgL on the self-assembling I53-50 scaffold and compared its immunogenicity and protecting efficacy with single-antigen and soluble counterparts. Structural and antigenic integrity of immunogens were validated by size-exclusion chromatography, negative-stain electron microscopy and binding to specific monoclonal antibodies. Immunogenicity was evaluated in mice, rabbits, and non-human primates (NHPs), while in vivo protection was evaluated using heterologous (murine γ-herpesvirus 68, MHV-68) and homologous (EBV/KSHV co-infection in humanized mice) challenge models.
Results: The bivalent gHgL nanoparticle elicited consistently higher and more balanced antibody responses against both EBV and KSHV across species, effectively blocking viral infection of their respective susceptible cell types. Bi-NP immunization induced cross-reactive antibodies recognizing conserved gHgL epitopes, increasing the frequency of B cells cross-binding both EBV and KSHV gHgL in rabbits, eliciting antibodies cross-neutralizing MHV-68, and conferring in vivo cross-protection against MHV-68 mice challenge. Moreover, passive transfer of IgG purified from bi-NP-immunized macaques protected humanized mice from EBV/KSHV co-infection, markedly reducing viral DNA copies, preventing weight loss, and diminishing $EBER^+$ and $LANA^+$ pathology.
Conclusions: This study establishes gHgL as a rational bivalent vaccine target and demonstrates that nanoparticle co-display of EBV and KSHV antigens elicits cross-reactive, broadly protective antibodies across divergent γ-herpesviruses. The findings highlight a promising platform for preventive strategies against γ-herpesvirus-associated cancers and potential zoonotic infections.

#0211 Association between prior smoking and the time between HPV16-E6 seroconversion and development of oropharyngeal squamous cell carcinoma.

Stale Nygard[1], Lea Schroeder[2], Marie Gulla[1], Aida Ferreiro-Iglesias[3], Paul Brennan[3], Hilde Langseth[1], Giske Ursin[1], Aimee R. Kreimer[4], Mattias Johansson[3], Hilary Robbins[3], Tim Waterboer[2], Mari Kiens Nygard[1]

[1]Cancer Registry of Norway, Norwegian Institute of Public Health, Oslo, Norway,[2]Infections and Cancer Epidemiology, German Cancer Research Center (DKFZ), Heidelberg, Germany,[3]Genomic Epidemiology Branch, International Agency for Research on Cancer, Lyon, France,[4]NCI Div. of Cancer Epidemiology & Genetics, Bethesda, MD

Background and aims: Human papillomavirus (HPV) type 16 E6 oncoprotein antibodies in peripheral blood are a strong marker of oropharyngeal squamous cell carcinoma (OPSCC). In a previous study, HPV16-E6 seroconversion was observed from 6 to 28 years before cancer diagnosis. In the present study, the serology measurements were complemented with DNA and RNA genotyping of HPV from cancer tissue from the same OPSCC patients. We aimed to refine estimates of timing of and age at HPV16-E6 seroconversion before HPV-driven OPSCC and to investigate their dependence on notable covariates such as tobacco use.
Patients and methods: 307 OPSCC cases were identified from the prospective Janus Serum Bank Cohort in Norway enrolled from 1972 to 2004. Pre-diagnostic samples were analyzed for antibodies against proteins of HPV16 and other oncogenic HPV types by multiplex serology. Diagnostic formalin-fixed paraffin-embedded tumor blocks were obtained from different hospitals and HPV DNA and RNA genotyped by Multiplex Papillomavirus Genotyping and HPV type-specific E6*I RNA assays. Cancers positive for DNA *and* RNA of the same HPV type were regarded as *HPV-driven*. Information about smoking status was available from questionnaires. For every HPV16-driven cancer, an age and time interval for HPV16-E6 seroconversion was inferred and the Turnbull estimator for interval-censored data was applied.
Results: Out of 242 OPSCC cases with a retrieved and successfully sectioned tumor block, 221 (83.7%) had a valid HPV DNA/RNA cancer tissue test. The proportion of OPSCC driven by HPV increased rapidly from 1990 (0%) to 2010 (over 60%). The majority of the HPV-driven OPSCC cases were caused by HPV16 (55.2% of all OPSCC cases), followed by HPV33 (5.4%). All patients developing HPV16-driven cancer within 10 years from blood draw were HPV16-E6 seropositive at blood draw. The estimated median age of HPV16-E6 seroconversion for HPV16 driven cancers was 43 years with an interquartile range (IQR) of 41-46, and the median time from seroconversion to HPV16-driven cancer was 16 years (IQR: 12-22). Current smokers had a much shorter time from seroconversion to cancer than former and never smokers (median of 14 vs 18 and 21 years).
Conclusions: The high sensitivity and specificity of HPV16-E6 seropositivity makes it a promising early biomarker for HPV-driven OPSCC. HPV16-E6 seropositive individuals that were smokers at the time of blood draw developed HPV16-driven OPSCC 8 years earlier than seropositive individuals that never smoked, suggesting intensified follow-up of HPV16-E6 seropositive smokers. The age at HPV16-E6 seroconversion indicates that many cancer-causing HPV infections are acquired after mid-20s, with the implication that young adults would benefit from HPV vaccination for prevention against oropharyngeal cancer.

#0212 Targeting STAT3 promotes cell death and enhances T-cell activity in HPV-associated cancer.

Ruben Prins, Daniel Fernandez, W. Martin Kast

Immunology and Immune Therapeutics, University of Southern California, Los Angeles, CA

Human papillomavirus oncoproteins early (E)6 and E7 are crucial for sustaining chronic infection and driving malignant transformation in stratified epithelia when the immune system fails to clear the virus. In addition to impairing the cellular surveillance systems that maintain genomic integrity and promoting cell cycle progression, these oncoproteins increase interleukin-23 (IL-23) production by tumor-associated macrophages in HPV$^+$ cancers, leading to suppression of local tumor-specific T-cell immunity. IL-23 signaling through the IL-23 receptor (IL-23R) on HPV-specific CD8$^+$ T cells reduces their cytotoxicity and proliferative capacity. Downstream, IL-23R activates signal transducer and activator of transcription 3 (STAT3), a transcription factor known to drive multiple cancer hallmarks. To investigate how STAT3 signaling affects both the progression of HPV+ tumors and specifically the T-cell response against its E6 and E7 proteins, we employed the C3.43 syngeneic murine tumor model, which expresses the full length HPV16 genome under its native promoters, and used the cisplatin derived small molecule inhibitor CPA-7 to inhibit STAT3. IL-23R signaling induces phosphorylation of STAT3 monomers (pSTAT3), leading to their dimerization and subsequent nuclear translocation, where they bind DNA. CPA-7 prevents dimerized STAT3 from binding DNA and functionally reduces overall pSTAT3 levels. In vitro treatment of HPV$^+$ C3.43 tumor cells with CPA-7 revealed that STAT3 inhibition induces tumor cell death. In vivo, mice challenged with C3.43 tumor cells and treated with CPA-7 completely eradicated their tumors, with 4 of 10 mice demonstrating durable immune memory upon tumor re-challenge. Remarkably, even established, late-stage HPV$^+$ tumors were fully eradicated upon CPA-7 treatment. Full eradication required an intact adaptive immune system, as CPA-7 treatment failed to eliminate HPV$^+$ tumors in mice lacking both CD4$^+$ and CD8$^+$ T cells. Together, these data demonstrate that STAT3 promotes HPV$^+$ tumor cell survival and suppresses the adaptive, tumor-specific T-cell immune response. Targeting STAT3 may therefore represent a promising strategy to induce tumor cell death and counteract IL-23-induced, STAT3-mediated immune suppression in HPV-associated cancers.

#0213 Targeting lytic cycle with ciclopirox derivative in Epstein-Barr Virus+ gastric cancer.

YUXIN ZHUANG[1], Srishti Chakravorty[2], Shrinidhi Annadka[3], Marwa G. M. Elnaggar[4], Luopin Wang[3], Subhransu S. Sahoo[1], Abigail H. Lee[1], Shyaman Jayasundara[5], My An Nguyen[3], Steven Chang[6], Jason A. Hanna[3], Behdad Afzali[7], Matthew Olson[3], Bo Zhao[8], Daniel P. Flaherty[3], Yoon Yeo[9], Majid Kazemian[3]

[1]Biochemistry, Purdue University, West Lafayette, IN,[2]Merck, South San Francisco, CA,[3]Purdue University, West Lafayette, IN,[4]Industrial pharmacy, Purdue University, West Lafayette, IN,[5]Computational Science, Purdue University, West Lafayette, IN,[6]Computer Science, Purdue University, West Lafayette, IN,[7]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD,[8]Brigham and Women's Hospital, Boston, MA,[9]Industrial and Molecular Pharmaceutics, Purdue University, West Lafayette, IN

Epstein-Barr Virus (EBV) is a ubiquitous human herpesvirus that infects around 90% of the global adult population. Upon infection, the virus typically establishes latency within the host cell, expressing viral genes that promote tumorigenesis, inhibit apoptosis, and suppress immune recognition of infected cells. Induction therapy was introduced to counter these effects by driving the switch from latent to lytic phase, which is a process called lytic reactivation. This transition results in cell lysis with viral particle release and the expression of viral proteins that can be targeted by antiviral agents and the immune system. Here, we developed a novel in-silico drug prediction method to identify compounds capable of inducing the EBV lytic cycle in various EBV+ epithelial malignancies. In vitro treatment of top candidates has successfully triggered lytic reactivation on EBV+ gastric cancer cell lines, namely, SNU719 and AGSBX1. Among these candidates, Ciclopirox (CPX), a clinically used antimycotic agent that has a fungistatic and iron chelation capability, showed strong activity in inducing the EBV lytic cycle, inhibiting proliferation and survival of EBV+ gastric cancer cells by blocking the cell cycle. RNA sequencing revealed that CPX-mediated lytic induction acts primarily through the hypoxia pathway, specifically via hypoxia-inducible factor 1-alpha (HIF1α). CPX treatment increased HIF1α binding to chromatin regions associated with genes involved in gastric cancer proliferation and migration. Co-treatment with a HIF1α inhibitor abolished both the cytotoxic and lytic-inducing effects of CPX, confirming the pathway's central role. Despite its efficacy, a major limitation of CPX is its instability. During CPX administration, excess iron from both intracellular and extracellular environments will lead to degradation and inactivation of CPX. Co-treatment with equal molarity of ferric ion has completely abolished the lytic-inducing ability of CPX. To address this, we adopt the pro-drug strategy by adding a protective group on CPX, creating a protected derivative mCPX. mCPX has shown comparable activity in lytic induction, while significantly improved resistance toward iron-mediated inactivation compared to CPX or another published pro-drug fosciclopirox. Finally, in an SNU719 xenograft, mCPX demonstrated superior in vivo anti-tumor activity relative to CPX. Altogether, using in-sillico drug prediction platform, we have successfully repurposed CPX as a lytic-induction-based anti-tumor agent against EBV+ gastric cancer, and developed the pro-drug mCPX to enhance its in vivo stability.

#0215 Primary cardiac lymphoma and HIV: A nationwide analysis of hospitalizations.

Omar Hozayen[1], Jay Hozayen[1], Benjamin Behers[1], Christoph Stephenson-Moe[1], Maha Hameed[1], Matthew Miller[1], Laura De Jesus Herrera[1], Anas Abu Jad[1], Rheiner Kammer[1], Mohab Idriss[1], Ahmed Aboutaleb[1], Bashar Roumia[1], Patricia Riano[1], Nicolas Riveros Neira[1], Brooke Hartenstein[1], Robert Taylor[1], Manuel Rosario Espinal[1], Brett M. Behers[2], Alya Hozayen[3], Mohamed Ibrahim[4], Karen Hamad[1]

[1]Florida State University - Sarasota Memorial Hospital, Sarasota, FL,[2]Mountain Area Health Education Center, Asheville, NC,[3]American University of Integrated Sciences, Tucker, GA,[4]Mayo Clinic, Jacksonville, FL

Background: Primary Cardiac Lymphoma (PCL) is an exceptionally rare malignancy. While clinical case reports have postulated an association with human immunodeficiency virus (HIV), large-scale epidemiological data corroborating this link are limited.
Objective: To determine whether HIV is associated with increased prevalence of PCL in a large, nationally representative sample of US hospitalizations.
Methods: We performed a retrospective, cross-sectional analysis using the Healthcare Cost and Utilization Project National Inpatient Sample from 2016 to 2019, representing approximately 35 million unweighted hospitalizations. Hospitalizations were identified using a proxy definition for PCL, requiring ICD-10-CM codes for both cardiomyopathy (I42.*) and extranodal non-Hodgkin lymphoma (i.e., C83.39, C85.99). HIV status was identified using codes B20-B24 and Z21. We compared the prevalence of PCL in hospitalizations with versus without HIV and calculated odds ratios using Fisher's Exact Test, reporting corresponding 95% confidence intervals (CI) and p-values.
Results: We identified 569 hospitalizations meeting our operational definition for PCL out of 34,955,252 total discharges. The prevalence of PCL was significantly higher among hospitalizations with HIV (6.2 per 100,000) compared with those without HIV (1.6 per 100,000; $p < 0.0001$). HIV was associated with a 3.86-fold increased odds of PCL (OR: 3.86; 95% CI: 2.23-6.70; $p < 0.0001$).
Conclusion: In this nationwide analysis of 35 million hospitalizations, HIV was strongly associated with a higher prevalence of PCL. Hospitalizations with HIV had nearly 4-fold higher odds of PCL, as defined by co-occurrence of cardiomyopathy and extranodal lymphoma, compared with hospitalizations without HIV. This population-level finding evinces the association previously suggested in clinical case reports.

#0216 Exploring viral influence on susceptibility to retinoblastoma in northern Tanzania, The ENVISION-Tanzania study.
Atukuzwe Kanyandekwe Kahakwa

Kilimanjaro Christian Medical Centre, Moshi, Tanzania, United Republic of

Background Retinoblastoma (RB) is the most common intraocular malignancy in children, with survival rates exceeding 90% in high-income countries but remaining unacceptably low in many low- and middle-income settings. While RB arises primarily from bi-allelic inactivation of the RB1 tumour suppressor gene, emerging evidence suggests that viral oncogenesis particularly from high-risk human papillomavirus (HR-HPV) may also contribute to tumour initiation and progression. The E6 and E7 oncoproteins of HR-HPV disrupt the p53 and pRb pathways, molecular mechanisms central to both HPV-driven malignancies and RB pathogenesis. However, the potential role of HR-HPV in RB remains poorly explored, especially in African populations where both HR-HPV prevalence and RB incidence are high. Generating region specific evidence could reshape understanding of RB biology and inform new preventive strategies
Objective To investigate the association between maternal and tumour HR-HPV infection and the development of retinoblastoma in children in Northern Tanzania
Methods This cross-sectional, hospital-based study will be conducted at Kilimanjaro Christian Medical Centre (KCMC), the principal paediatric oncology referral centre in Northern Tanzania. We aim to recruit 215 children diagnosed with RB and their 215 biological mothers. Enucleated tumour specimens will be processed into formalin-fixed, paraffin-embedded (FFPE) blocks for DNA extraction and HPV genotyping using PCR-based assays. Maternal cervical swabs will be collected and analysed for HR-HPV detection and genotyping. Quantitative RT-PCR will be used to assess E6 and E7 oncogene expression, while immunohistochemistry will localize viral proteins and evaluate the expression of key tumour suppressor proteins (pRb, p53, p16). Logistic regression models, adjusted for clinical and demographic variables, will be used to estimate the association between maternal HR-HPV infection and RB occurrence in offspring.
Status The study is currently in the preparatory phase. Ethical approvals have been obtained, and logistical arrangements for molecular analysis are underway at KCMC's pathology and molecular oncology units.
Expected Impact The ENVISION Tanzania study will generate the first molecular data examining viral contributions to RB in Sub-Saharan Africa. Identifying HR-HPV as a potential co-factor in RB pathogenesis could fundamentally shift paradigms in paediatric oncology by linking viral prevention strategies to childhood cancer control. Beyond its scientific contribution, the project aims to strengthen local molecular oncology capacity, foster North South research collaborations, and build a sustainable platform for infection-related cancer research in Tanzania.

#0217 Advanced OnePCR HPV panel: Fast POCT platform covering complete high, medium & low-risk genotypes.

Bahadur Singh Gurjar, **Giulliana Tessarin**, Nishant Kumar, Namrata Erande

Research & Development, Genes2Me Pvt. Ltd., Gurugram, India

Human Papillomavirus (HPV) is a major global health concern due to its strong association with cervical cancer in women and oropharyngeal cancer in men. With 200+ related viruses, persistent infection with high-risk genotypes can drive malignant transformation. Cervical cancer remains the 4th most common cancer in women, with around 660,000 new cases and 350,000 deaths in 2022 94% occurring in low- and middle-income countries. Early screening, vaccination, and timely treatment are key to reducing this burden.Innovative Diagnostic Platforms Genes2Me delivers advanced HPV detection through two powerful systems: OnePCR System - A fully automated *Sample-IN Result OUT* platform that integrates extraction and real-time PCR in one cartridge. It detects up to 20 targets per sample with zero pipetting steps and provides results in around 100 minutes. Rapi-Q and Rapi-X16 System - A semi-POCT high-throughput solution enabling extraction of up to 16 samples simultaneously and multiplex PCR in 8 tube format, offering scalability and precision for busy laboratories. Comprehensive HPV Genotyping Panels Genes2Me HPV assays use multiplex real-time PCR with fluorescent probes for accurate genotype differentiation. High-Risk Panel (Tube 1): HPV16 (HEX), HPV18 (FAM), 12 pooled HR genotypes (Texas Red); beta-Actin internal control. Low & Medium-Risk Panel (Tube 2): HPV6, 11, 44 and others using FAM/HEX/Texas Red; Cy5 internal control. Expanded Low/Medium Panel (Tube 3): 14 genotypes categorized into FAM / HEX / Texas Red groups with Cy5 internal control.

#0218 Zika virus demonstrates oncolytic efficacy against high-risk rhabdomyosarcoma in both in vitro cultures and in vivo murine xenograft models.

Emily Gearhart, Caroline Finn, Catherine Collins, Rajarajeshwari Venkataraman, Peter Phelan, Kenneth Alexander

Biomedical Research, Nemours Children's Hospital, Lake Nona, FL

High-risk rhabdomyosarcoma (RMS) carries a poor prognosis, with 5-year survival rates of ~30%, emphasizing the urgent need for novel therapeutic strategies. Zika virus (ZIKV), which causes asymptomatic or mild infection in children and adults, has emerged as a promising oncolytic agent. Previous work from our group and others has demonstrated ZIKV's antitumor activity in a variety of tumor models, including ovarian cancer, neuroblastoma, and glioblastoma multiforme. ZIKV exhibits a natural tropism for cells expressing AXL and CD24 making these markers potential indicators of ZIKV susceptibility. Because RMS cells lines (RH30, RH41, RD) express AXL and CD24 observed by both transcript and surface marker expression, we investigated the efficacy of two FDA-approved replication-competent ZIKV strains (ZIKV-A1, ZIKV-A2). In vitro plaque assay demonstrates both ZIKV strains replicated efficiently and induced cell lysis in all 3 RMS cell lines. In vivo, NOD-SCID-IL2Rγ^{null} (NSG) mice bearing subcutaneous RD or RH30 cell-derived tumors were given intratumor injections of ZIKV-A1 or ZIKV-A2. Both strains dramatically reduced tumor volume within 11 days post-viral injection compared to control mice. ZIKV infection was confirmed in tumor tissue by qPCR, immunoblot, and histological detection of the ZIKV non-structural (NS1 and NS2B) and envelope proteins. In a dual-tumor xenograft model, intratumor ZIKV-A1 injection reduced the growth and size of both the injected and contralateral untreated tumors, suggesting that systemic viral dissemination by lymphatic and/or hematogenous spread is sufficient to treat widespread tumors. These findings open the door to clinical trials of subcutaneously administered ZIKV for the treatment of pediatric and adult RMS cancers.

#0219 Spondweni virus is highly oncolytic in endometrial carcinoma-derived HEC-1-A cells.

Catherine Collins, Emily Gearhart, Caroline Finn, Rajarajeshwari Venkataraman, Peter Phelan, Kenneth Alexander

Nemours Children's Health, Orlando, FL

Endometrial adenocarcinoma accounts for approximately 80% of all endometrial cancers, affecting more than 400,000 women per year. With advanced disease, the 5-year survival rate drops from 81% to 15%. Previously, our laboratory found that Zika virus (ZKV) has promising oncolytic and anti-tumor activities, reducing tumor volume in murine xenograft models of ovarian and endometrial cancer. Spondweni (SPN) is a flavivirus phylogenetically related to but immunologically distinct from ZKV. Like ZKV infection, most human SPN infections are asymptomatic. We hypothesized that SPN would exhibit oncolytic activity like that of ZKV. The endometrial adenocarcinoma cell line HEC-1-A, which was derived from a stage IA endometrial tumor, was selected for infection with three ZKV strains (MR766, ZIKV-A1, and ZIKV A-2) and one SPN strain (SPN A-1). Using viral plaque assays, AlamarBlue™ cell viability assays, and western blots, we examined viral replication in ZKV- and SPN-infected HEC-1-A cells, measuring NS-1 and viral envelope protein expression, and comparing rates of cell death following viral infection. Our data indicated that HEC-1-A cells are more susceptible to SPN than to ZKV. This discovery provides insight into SPN as an oncolytic therapy and opens the door to exploring its use in other cancer types.

#0220 Investigating nonsense-mediated decay (NMD) as a restriction factor for EBV-reactivation.

Emilie Greene[1], Eric C. Johannsen[2]

[1]Oncology, McArdle Laboratory for Cancer Research, University of Wisconsin-Madison, Madison, WI,[2]Department of Medicine, Division of Infectious Disease, University of Wisconsin, Madison, Madison, WI

Approximately 0.01% of adults infected with Epstein-Barr virus (EBV) will develop an EBV-associated cancer which equates to 200,000 annual cases globally. EBV malignancies are dependent on EBV latency gene products for continued growth and survival, making the disruption of latency a promising therapeutic approach. Despite this vulnerability, EBV-targeting strategies have yet to be successfully translated into therapy for EBV-associated cancers. “Lytic induction therapy” combines small molecules capable of reactivating EBV from latency with antiviral drugs to increase toxicity to tumor cells and prevent EBV particle production. Although this therapeutic strategy has been well tolerated in clinical trials, current induction agents display low efficacy. The full potential of this approach will require the development of second-generation induction agents, necessitating a greater understanding of EBV biology and host-pathogen interactions. Recent studies have identified nonsense-mediated decay (NMD), a host regulatory pathway, is a key restriction factor for EBV reactivation. The EBV transcript encoding Rta, one of the two viral transcription factors responsible for entry into the lytic cycle, contains multiple splice junctions downstream of its stop codon. Consequently, the Rta transcript is rapidly degraded by NMD. This previously unrecognized post-transcriptional regulation revealed that strategies inducing the lytic cycle cannot focus solely on activating Rta and Zta transcription; they must include approaches to stabilize the Rta transcript, likely by NMD inhibition. To investigate this phenomenon, we developed an NMD reporter based on a previously described dual-fluorophore system. By combining this reporter with an EBV fluorescent reporter virus that indicates Zta (red) and Rta (green) promoter activity, we can assess the effects of NMD on Rta expression and lytic activation (measured as the change in blue and far-red fluorescence). This system enables us to determine whether EBV can only reactivate under NMD-low conditions and evaluate how various induction agents influence NMD activity. We can also identify EBV gene products that may act as NMD antagonists, which would establish a positive feedback loop for promoting lytic cycle entry. The insights gained from these studies will provide a deeper understanding of the mechanisms governing viral reactivation and inform the development of next generation lytic induction therapies.

#0221 Single-cell ATAC-sequencing profiling of HPV18 positive head and neck cancer cells reveals heterogeneity of HPV18 genome accessibility and its association with cancer progression.

Chongwen Cao[1], Weiyi Gong[2], Haichang Li[2], Bo Zhao[3], Qingqing Wu[2], Priyanka Bhateja[2], Dukagjin Blakaj[2], Jenny Li[2], Xuefeng Liu[1]

[1]The Ohio State University, Columbus, OH,[2]The Ohio State University College of Medicine, Columbus, OH,[3]Brigham and Women's Hospital, Boston, MA

Background: HPV is a major oncogenic driver of head and neck cancers (HNC). However, the epigenomic heterogeneity of the HPV genome—particularly single-cell chromatin accessibility patterns—and its relevance to cancer progression remain unclear. This study characterizes the chromatin-accessibility landscape of patient-derived HPV positive HNC cells to identify regulatory signatures associated with tumor heterogeneity and potential aggressive subpopulations.
Methods: Primary HPV18$^+$ HNC cells were generated using the conditional reprogramming cell method from patient tumor biopsies. Single-cell ATAC-sequencing was performed to assess chromatin accessibility using a combined human-HPV18 reference genome. Accessibility patterns across the HPV18 genome were encoded by a binary peak matrix. We applied UMAP on genome-wide accessibility profiles and used kernel density estimation to examine the distribution of cells with distinct HPV18 peaks. Differential accessibility, peak-to-gene linkage, and pathway-enrichment were performed across HPV18 accessibility groups.
Results: We identified three major accessible peaks within the HPV18 genome. Cells positive for Peak 1 or Peak 3 showed a dispersed, unbiased distribution on UMAP, whereas Peak 2-positive cells were strongly enriched in discrete clusters, suggesting that accessibility of this peak represents a key marker of intratumoral heterogeneity. We also observed heterogeneous HPV18 integration linking different HPV18 peaks to distinct human genomic loci across cells from the same patient, associated with locus-specific accessibility changes. Sequencing-depth analysis confirmed that differences in HPV18 peak patterns were biological rather than technical artifacts. Peak-to-gene linkage analysis revealed that UGGT1 and COL5A1 transcription start sites were more accessible in the Peak-2-positive subpopulation. Both genes correlate with poor prognosis in cervical cancer and HNC based on TCGA data. Pathway enrichment demonstrated activation of programs associated with neuron migration, epithelial morphogenesis, and tissue morphogenesis, indicating that this subpopulation may possess enhanced invasiveness and stemness features.
Conclusions: This study provides the first single-cell chromatin accessibility map of patient-derived HPV18$^+$ HNC cells and reveals substantial heterogeneity within the HPV18 viral genome. A specific HPV18-accessible peak (Peak 2) marks a distinct, potentially aggressive cellular subpopulation characterized by accessibility of poor-prognosis-associated genes and stemness-related pathways. These findings highlight a novel viral-epigenomic marker that may contribute to HNC progression and could be explored for prognostic or therapeutic applications.

#0222 Aberrant T cell proliferation in HIV associated clonal hematopoiesis.

Haocong Katherine Ma[1], Tsung-Chih Chen[1], Alokkumar Jha[2], Benjamin A. Youngblood[3], Jennifer M. Kwan[1], Irini Sereti[4], Ya-Chi Ho[1]

[1]Yale School of Medicine, New Haven, CT,[2]Weill Cornell Medicine, New York, NY,[3]St. Jude Children's Research Hospital, Memphia, TN,[4]National Institutes of Health, Bethesda, MD

Introduction: Clonal hematopoiesis (CH) is a precursor for acute myeloid leukemia (AML) and predictor of the development of hematologic cancers. Despite suppressive antiretroviral therapy, people living with HIV (PLWH) have higher incidence of clonal hematopoiesis, particularly mutations in *DNMT3A*. While DNMT3A mutations increase inflammation in myeloid cells and increase CD8+ T cell proliferation, the role of DNMT3A mutations in CD4+ T cells remain elusive. Given that CD4+ T cells are the major HIV reservoir, we postulate that HIV-induced systemic inflammation increases DNMT3A mutation, accelerates CD4+ T cell proliferation, and thus promotes HIV persistence in CD4+ T cells.

Methods: To examine the impact of DNMT3A on CD4+ T cell proliferation, we spiked in HIV- and DNMT3A-specific primers in single-cell ECCITE-seq (GoT-seq) and paired HIV- and DNMT3A-targeted long-read sequencing (MAS-ISO-Seq) on peripheral blood CD4+ T cells from four strata (HIV+CH+, HIV+CH-, HIV-CH+, and HIV-CH-). We simultaneously captured HIV RNA, cellular transcriptome, surface proteins, T cell clonality, and *DNMT3A* mutations in the same single cell.

Results: After QC, we captured 420,837 CD4+ T cells from 27 participants (7 HIV+CH+, 7 HIV+CH-, 5 HIV-CH+, and 8 HIV-CH-). Short-read scRNA-seq detected *DNMT3A* RNA in 32,554 cells (10.3%), while Long-read sequencing captured *DNMT3A* in 19,898 cells (8.6%), reflecting low *DNMT3A* expression levels in peripheral blood CD4+ T cells. Importantly, we overcame the 5' sequencing bias of short-read sequencing and captured 767 cells carrying single nucleotide polymorphisms (SNPs) within the DNMT3A. For HIV, short reads identified 170 RNA+ cells (0.055%), whereas long reads detected 3,842 HIV-infected cells, representing a 22-fold increase in sensitivity, and resolved 98 intact proviruses. TCR analysis reconstructed 22,648 unique T cell clones from 76,819 cells having mapped CDR3 region. Larger CD4+ T cell clones were enriched in cytotoxic CD4+ T cells expressing high GZMB/GZMH. Notably, we identified 100 HIV-infected cells (58.8%) in T cell clones. Clone sizes were greater in CD4+ T cells from HIV- CH+ than HIV-CH- donors, consistent with CH-driven T cell proliferation. Importantly, CD4+ T cells from HIV+ CH+ patients exhibited significantly greater clonal expansion and larger clones than those from HIV+CH- patients, suggesting CH mutations also promotes the proliferation of HIV-infected cells. Of note, age distributions did not differ across groups, which excluded age as a confounder for clonal expansion.

Conclusion: Paired single-cell multi-omics with long-read genotyping reveal CH mutations drive the aberrant CD4+ T cell proliferation and promote HIV persistence, highlighting virus-host interaction that elevates cancer risk despite suppressive antiretroviral therapy.

#0223 HPV16 variant lineage in response to treatment in locally advanced cervical cancer.

Monica Morales[1], Jinneth Acosta[2], Gina Malaver[2], Maria Cristina Alarcon[2], Juan G Rodriguez[3], Juan Anzola[3], Nicolas Magne[4], **Pablo Moreno Acosta**[1]

[1]National Cancer Institute, Bogota, Colombia,[2]Universidad Nacional de Colombia, Bogota, Colombia,[3]Corpogen, Bogota, Colombia,[4]Institute Bergonie, Bordeaux, France

Cervical cancer in Colombia ranks third in incidence/mortality, with HPV16 being the most frequent high-risk oncogenic type. The aim of this study was to characterize HPV16 variant lineages in the LCR, E6, and E7 regions and evaluate their association with treatment response in locally advanced cervical cancer. We conducted a retrospective cohort study using 300 formalin-fixed, paraffin-embedded tissue samples from patients with FIGO stages IB1 to IVA cervical cancer treated at National Cancer Institute of Colombia (INC-Colombia) HPV detection was performed using GP5+/GP6+ PCR, with 261 samples successfully sequenced on the Illumina MySeq platform. A custom bioinformatics pipeline was implemented for comprehensive analysis, including viral typing using Mothur Bayesian classifier with PaVE database, and deep sequencing of LCR, E6, and E7 regions using PrimalScheme-designed primers. Variant classification involved reference mapping (BWA), variant calling (FreeBayes), and functional impact analysis (SnpEff) and treatment response were evaluated using RECIST 1.1 criteria, with complete response and non-complete response, encompassing partial response, stable disease, or progression. Statistical analyses were done using Stata 11, R 4.5.0, and jamovi 2.7. Of 300 patients, 227 (75.7%) showed complete treatment response. HPV was detected in 274 cases (91.3%), with HPV16 identified in 242 (80.7%). Among 185 sequenced HPV16 samples, lineage A predominated (76.8%), followed by lineage D (23.2%), mainly D2 (11.4%). No significant differences in SNP frequency (E6, E7, LCR) between response groups were observed, indicating no clear association with treatment outcome. However, However, specific variants E7T678C, LCR 7488T-ins, and LCR 7861del showed suggestive trends ($p < 0.15$), possibly reflecting subtle biological effects warranting further investigation. In summary, while HPV16 lineage A was more frequent than lineage D in this cohort, our findings do not establish an association between HPV16 variant lineages or specific SNPs and treatment response, a result consistent with other studies. Our findings do not allow us to establish an association between HPV16 variant lineages and treatment response, which is consistent with other studies. Our results demonstrated distinct HPV16 lineage distribution patterns in the Colombian cohort. These findings contribute to understanding HPV16 genetic diversity in cervical cancer and its potential implications for treatment response. These results underscore the need for large scale prospective trials to definitively evaluate the role of HPV16 genetic diversity in therapeutic outcomes and encourage further research into viral variants and treatment resistance.

#0224 Analytical validation of viral detection in tumor-derived cell-free DNA.

Hao Wang[1], Lauren Lawrence[2], Jamie Hutchins[1], Tingting Jiang[3]

[1]Bioinformatics, Guardant Health, Palo Alto, CA,[2]Clinical Development, Guardant Health Laboratory, Redwood City, CA,[3]Bioinformatics, Guardant Health, San Diego, CA

Background: Epstein-Barr virus (EBV) and human papillomavirus (HPV) are oncogenic viruses linked to specific malignancies, yet their detection in tumors often goes unassessed in clinical practice. EBV-positive gastric cancer patients may benefit from immunotherapy, but viral status is rarely evaluated routinely. Similarly, HPV-associated malignancies can be missed in cases with unknown primary sites. Cell-free DNA (cfDNA) analysis offers a non-invasive approach to identify these clinically actionable viral signatures. Here, we established the analytical performance of EBV and HPV detection in Guardant360 Liquid (Guardant Health, Palo Alto, CA), a comprehensive blood-based molecular profiling assay for patients with advanced cancer.
Methods: Guardant360 Liquid targets EBV and 14 high-risk HPV genotypes using a targeted hybridization capture cfDNA assay. We evaluated analytical sensitivity, specificity, accuracy, and precision. Accuracy was assessed using 75 clinical samples with orthogonal viral testing results (43 HPV, 33 EBV) and 43 samples with BD Onclarity HPV Assay (Becton Dickinson, Franklin Lakes, NJ) genotyping results. LoB was determined using 120 replicates from 30 self reported cancer-free donor samples. LoD was established through serial titration of WHO HPV reference standards and in-silico down-sampling of clinical samples and reference materials. Precision was evaluated using clinical samples tested in replicate.
Results: For viral detection status, Guardant360 Liquid demonstrated a positive percent agreement (PPA) of 93.48% and a negative percent agreement (NPA) of 96.55% compared to orthogonal methods. For HPV genotyping, PPA was 100% and NPA was 97.39%. The false positive rate was 0% for HPV and 0.83% for EBV in cancer-free donor samples. The class-level LoD was established at 3.36 viral copies per human genome with ≥95% detection rate. Precision testing showed 100% PPA across all replicates at 1-5X LoD.
Conclusions: Guardant360 Liquid demonstrates high analytical sensitivity, specificity, accuracy, and reproducibility for detecting EBV and high-risk HPV genotypes in cfDNA. This validated, non-invasive approach enables viral detection in advanced cancer patients, with potential clinical applications including the identification of EBV-positive gastric cancer patients who may benefit from immunotherapy, and optimization of site-specific treatment pathways for HPV-positive cancers. This capability expands the clinical utility of liquid biopsy beyond genomic profiling to include actionable viral biomarker detection.

#0225 Accelerating precision immunotherapy for HPV-driven cancers.

Tithi Ghosh Halder[1], sam Giannakoulias[2], Juan Montesinos[3], Daniel-Paul Bednarik[3], Corey Casper[4], Ken Carter[3], Raffaella Soldi[1], Sunil Sharma[1]

[1]Honor Health Research Institute, Scottsdale, AZ,[2]Sentauri, Frederick, AZ,[3]Black Canyon Bio, Middletown, MD,[4]University of Arizona, Tucson, AZ

Background: HPV-related cancers affect nearly 48,000 Americans annually, with HPV16-driven cervical and oropharyngeal malignancies progressing rapidly and often outpacing current therapeutic timelines. Despite the success of prophylactic HPV vaccines in preventing infection in uninfected individuals, these agents provide no therapeutic benefit for patients with established invasive disease and fail to address the full spectrum of oncogenic HPV variants. To address this gap, we developed SNAP (Selective Neoantigen Peptide), a personalized therapeutic vaccine platform tailored to each patient's tumor-specific neoantigen expression profile. SNAP has demonstrated potent immunogenicity and tumor control in preclinical models, validating its promise for precision immunotherapy. However, the extended manufacturing timeline-typically exceeding 12 weeks-for generating personalized SNAP vaccine severely limits applicability in rapidly progressing HPV16-positive tumors. To overcome this limitation, we have developed a dual-vaccination strategy that integrates an off-the-shelf (OTS) therapeutic vaccine for immediate immune priming with subsequent administration of the personalized SNAP vaccine. This study covers the development of the OTS HPV vaccine.
Methods: The OTS vaccine is a poly-epitope construct targeting conserved HPV16 oncoproteins E6, E7, and E2, plus recurrent PIK3CA hotspot mutations (detected in >40% of HPV+ cancers), Candidate OTS peptides underwent comprehensive in silico predictive modeling. We used a multi-tiered computational pipeline to identify and prioritize immunogenic peptides for vaccine development, anchored by ProtIQ, a modular antigen selection tool. Top 100 peptides were ranked by immunogenicity, coverage and stability. A subset was synthesized and validated via biolayer interferometry (BLI) for binding kinetics. Human IFN-γ ELISPOT on HLA-matched donor PBMCs assessed T-cell activation to select final candidates.
Results: In silico prediction of OTS peptides yielded high-confidence epitopes with high median immunogenicity scores, across prevalent HLA class I and II alleles. BLI confirmed stable peptide-MHC complexes (KD range 102-103 nanomoles) in a validated subset. ELISPOT on individual peptide pulsed HLA-matched healthy donor PBMCs demonstrated robust IFN-γ responses. Top 30 peptides with highest ELISPOT signals were selected as vaccine candidates. To check the vaccine efficacy in vivo, mouse TC-1 cells engineered to express E2 and PIK3ca mutations will be used as HPV preclinical animal model.
Conclusions: This project will deliver a clinically actionable off-the-shelf vaccine platform that enables early immunologic intervention in HPV16-driven cancers. By priming the immune system ahead of personalized therapy, we aim to reduce time-to-treatment, enhance therapeutic outcomes, and expand access to precision immunotherapy.

#0226 Stochastic mutagenesis at lncBART-KDM5B-bound genomic loci in Epstein-Barr virus-associated nasopharyngeal carcinoma.

Wei Dai[1], Lai Shun Dittman Chung[2], Jiayan Liu[2], Kiu-Wai Cheng[1], Kazi Anisha Islam[2], Zhonghua Liu[3], Honglin Chen[4]

[1]The University of Hong Kong, Pokfulam, Hong Kong,[2]The University of Hong Kong, Hong Kong, Hong Kong,[3]Columbia University, New York, NY,[4]Microbiology, The University of Hong Kong, Hong Kong, Hong Kong

Introduction: The mechanisms linking Epstein-Barr virus (EBV) infection to mutagenesis in nasopharyngeal carcinoma (NPC) remain poorly understood.

Methods: By integrating whole-genome sequencing of 216 NPC tumors with multi-omics profiling, including chromatin isolation by RNA purification (ChIRP)-seq for lncBARTs binding sites, CUT&RUN for the binding sites of KDM5B and CTCF and histone mark H3K27ac, 4C-seq for virus-host chromatin interactions, and ATAC-seq for chromatin accessibility, we uncover a multi-layered model of virus-driven mutagenesis.

Results: We first show that cellular epigenetic regulators CTCF and KDM5B independently define genomic domains of significantly elevated mutation burden (2-fold more than matched controls, $P<0.0001$). Crucially, the viral lncBART does not increase mutation rates but fundamentally reshapes their distribution, randomizing mutations into a stochastic, Poisson-distributed pattern within KDM5B-bound domains ($p=0.3665$), which otherwise exhibit clustered, non-random mutagenesis ($p<0.001$). Furthermore, the lncBART binding sites enriches specific mutation signatures, namely G>T transversions (2.1-fold increase, $p=0.005$) and G>A transitions (1.3-fold increase, $p=0.05$), indicative of oxidative damage and replication stress, without altering the overall mutation density. We developed a computational model that predicts mutation patterns based on CTCF, KDM5B, and lncBART binding together with enhancer status and chromatin accessibility, demonstrating that these factors partially define the landscape of genomic instability. Incorporation of the data from ChIRP-seq and Capture RNA-Protein interactions (CARPID) following mass spectrometry analysis revealed that lncBARTs may act as a central scaffold that directly co-recruits key members of NuRD complex to create chromatin states against large processive mutagens and blockade of the base excision repair (BER) machinery.

Conclusions: Our work establishes a novel paradigm in which a virus co-opts and modulates host epigenetic machinery to create a context-dependent mutagenic environment, providing a new framework for understanding virus-driven cancer evolution.

Minisymposium

#1321 Synthbody™- A novel multivalent multispecific antibody drug conjugate platform demonstrates combinatorial logic-gated "synthetic" targeting of cancer antigens with log order enhanced internalization and potency.

R. Baliga, K. Li, K. Mai, H. Horwitz, Z. Dai, S. Ahmed, V. Rao, P. Yakkundi, M. Leabman, **D. S. Chen**;
Synthetic Design Lab, San Carlos, CA

Antibody Drug Conjugates (ADCs), such as trastuzumab deruxtecan, achieve complete responses >20% and duration of response >30 months in patients with metastatic Her2+ breast cancer[1]. However, other mono/bi-specific ADCs have not achieved similar clinical benefit, likely due to the 10-100x higher expression levels of Her2 vs other ADC targets, as well as known heterogeneity of target expression, down-regulation of targets in response to treatment and in some cases, competition from soluble target release.

To address these fundamental limitations, we developed a novel class of engineered multifunctional multivalent multispecific therapeutics (Synthbody™) that enable targeting of combinatorial "synthetic" cancer targets incorporating 6-12 tumor antigen binding domains. This replicates Her2-like high expression and specificity for ADC therapeutics in most tumors without high levels of expression of a single specific tumor antigen.

We engineered an initial human multiple myeloma targeting Synthbody™, referred to as SDF-061390E, that includes affinity-tuned binders for BCMA, GPRC5D and CD38. SDF-061390E (and SDF-061390E-MMAF) demonstrates >30x greater internalization and >80x greater potency when compared, respectively, with the BCMA-targeting antibody Belantamab and Belantamab mafodotin in human myeloma cells. Enhanced internalization and potency are similarly observed when compared against matched mono/bi-specific controls. Additionally, SDF-061390E can bind human myeloma cell lines with both high and low expression of each of the three targets and effectively eliminate low-BCMA expressing cancer cells in ADC killing assays. Further, SDF-061390E can evade impact of soluble BCMA at clinically relevant and higher concentrations, in contrast to belantamab. Similar results are also observed with a NHL targeting Synthbody™, supporting the broad applicability.

Due to biophysical characteristics that can be controlled in the design of Synthbody™ constructs, we generate emergent properties, including conditional activity determined by the geometry and biophysical relationships between the cancer cell antigens, epitopes, and the Synthbody™. This architecture enables the Synthbody™ ADCs to include AND BETTER logic-gated control, layered with AND safety gates and MULTIPLIER functions, yielding synergistic multifunctional activity absent from ADCs. Optimized Synthbody™ constructs show excellent production in CHO cells, developability and IgG-like PK *in vivo*.

The novel Synthbody™ platform demonstrates broad utility as ADC and biologic therapeutics, with capabilities for coordinated targeting, advanced logic-gated control and multifunctional action that may complement or ultimately replace current IgG-based biologics.

[1] *Cortes et al. Nat Med 2024*

#1322 M7437, a novel anti-Ly6E antibody-drug conjugate (ADC) with topoisomerase 1 (TOP1) inhibitor payload: Preclinical antitumor activity and safety.

S. Krah[1], **F. Hart**[1], J. Anderl[1], D. Huels[1], C. Knuehl[1], S. Brandstetter[1], J. N. S. Pereira[1], S. Sweeney-Lasch[1], N. Rasche[1], S. Dickgiesser[1], J. Jabs[1], R. Schneider[1], C. Amendt[1], J. Vahl[1], P. D. Lyne[2];
[1]the healthcare business of Merck KGaA, Darmstadt, Germany, [2]EMD Serono, Billerica, MA

Background: Ly6E, a glycosylphosphatidylinositol (GPI)-anchored protein, is involved in fetal-placenta fusion, immune regulation, and virus-host interaction. It promotes tumor growth, vascularization, and immune evasion. Ly6E is highly expressed across several tumor types including breast cancer, non-small cell lung cancer (NSCLC), ovarian, pancreatic, gastric, and head and neck cancers, and its expression is reported to be correlated with poor survival. M7437 is a novel, highly stable anti-Ly6E ADC with a potent TOP1i payload (exatecan) site-specifically conjugated via an enzyme-cleavable linker.
Methods: The binding of M7437 to cancer cells was assessed using flow cytometry. M7437 potency and bystander effect were tested in viability assays using cancer cell lines. Antitumor activity was evaluated in patient-derived xenograft (PDX) mouse models. In a GLP repeat-dose toxicity study, cynomolgus monkeys were treated 3 times in a Q3W schedule with M7437.
Results: M7437 demonstrated specific binding to and selective killing of Ly6E-positive cancer cells with sub-nanomolar potencies. A potent bystander effect of M7437 was demonstrated in co-culture experiments. Treatment with 7-9 mg/kg M7437 caused strong and long-lasting antitumor activity in PDX models across several indications (triple-negative breast cancer, squamous cell carcinoma of the head and neck, NSCLC, ovarian, pancreatic, and gastric cancer), including models where published TOP1i ADCs showed limited activity. In a pivotal repeat-dose toxicity study in cynomolgus monkeys, the pharmacologically relevant species, M7437 was well-tolerated. M7437 demonstrated favorable pharmacokinetic properties and linker-payload stability in cynomolgus monkey.
Conclusions: M7437 demonstrated strong antitumor activity in PDX models, including a broad range of indications and a potent bystander effect indicating the potential to treat tumors with heterogeneous target expression. Together with an acceptable toxicity profile and favorable pharmacokinetic properties, the observed preclinical data support the clinical development of M7437.

#1323 Preclinical evaluation of target-mediated clearance and alternative payloads in CDH17-directed antibody drug conjugates.

N. A. O'Brien, J. Zhang, M. S. McDermott, K. Gong, M. Lu, B. Hoffstrom, M. Liang, W. Jia, T. Luo, A. M. Madrid, R. Ayala, J. A. Glaspy, L. Presta, D. J. Slamon;
UCLA - University of California Los Angeles, Los Angeles, CA

Cadherin 17 (CDH17), is an emerging target for antibody-based therapeutics in colorectal cancer (CRC), with multiple CDH17-directed chimeric antigen receptor-T/natural killer, bispecific antibodies and antibody drug conjugates (ADCs) in preclinical and early-stage clinical development. Success of these molecules depends on their ability to overcome high expression of P-glycoprotein (P-gp) pumps in CRCs and CDH17 in normal gut epithelium. Here, we investigate the therapeutic potential of CDH17-directed ADCs.High frequency expression of CDH17 in patient tumor microarrays and cell line derived xenografts (CDXs) was confirmed by IHC assay. CDH17-directed ADCs were generated through conjugation of a fully humanized CDH17 mAb to either an anti-mitotic (CDH17-MMAE) or topoisomerase 1 inhibitor (CDH17-exatecan) payload via a cleavable linker. Selective ADC binding and internalization were confirmed by flow cytometry and immunofluorescence.CDH17-MMAE treatment induced significant anti-tumor activity in 5/5 CDH17+ CRC CDXs models, with the strongest and most prolonged responses observed in xenografts that were P-gp low/negative. Head-to-head comparison of CDH17-MMAE and CDH17-exatecan payloads demonstrated improved efficacy for CDH17-exatecan over CDH17-MMAE in high P-gp expressing models. The functional role of P-gp in resistance to MMAE-based ADCs was confirmed using cell lines engineered to either overexpress P-gp through transfection or to lose P-gp expression through CRISPR knockdown. Forced overexpression of P-gp in SNUC1 CDH17+ cells conferred resistance to CDH17-MMAE, while sensitivity to CDH17-exatecan remained. Conversely, CRISPR knockdown of P-gp in CDH17+ LS513 cells reversed resistance to CDH17-MMAE. These findings were confirmed in xenograft studies.Due to lack of binding of the anti-human CDH17-ADCs with mouse or rat CDH17, a mouse model expressing human CDH17 extracellular ECD (B-hCDH17 mice) was used in pharmacokinetic (PK) studies. In wild-type mice, both ADCs exhibited PK profiles consistent with those typically observed for most ADCs. However, in humanized B-hCDH17 mice, both CDH17-MMAE and CDH17-exatecan ADCs were completely cleared from mouse serum less than 96 hours post-dosing, indicating that CDH17 expression in normal colon and ileum may act as a clearance sink for the ADCs.Data presented here support use of topoisomerase 1 inhibitor payloads in cancers where P-gp expression is high. Target-mediated clearance driven by normal gut CDH17 expression presents a pharmacokinetic challenge that may limit clinical utility and require dose optimization or alternative dosing strategies to achieve sufficient tumor exposure while managing potential on-target, off-tumor toxicity.

#1324 Preclinical assessment of HWK-016, a next-generation, MUC16-targeting ADC with novel bioconjugation and linker-payload technology.

Kathy S. Keegan[1], Shihe Hou[1], Ashwini B. Pai[1], Enrico Bellomo[1], Erik Kratzer[1], Victor Peykov[1], Bryan Ball[1], Yifeng Wang[2], Yaohua Hu[2], Xia Wang[2], Zhuozhi Wang[2], Siwei Nie[2], Yunying Chen[2], Jijie Gu[2], David J. Lennon[1], **David Dornan**[1]

[1]Whitehawk Therapeutics, Morristown, NJ,[2]WuXi Biologics, Shanghai, China

Mucin 16 (MUC16) is a cell-surface protein that plays a key role in cancer progression by facilitating tumor cell proliferation, adhesion, invasion, and immune evasion. Proteolytic cleavage of the N-terminal region of MUC16 is known to generate and shed the well-known cancer antigen and biomarker, CA125. MUC16 is highly expressed in multiple tumor types, including ovarian, endometrial, cervical, pancreatic, and lung cancers, and has relatively low expression in normal tissues, making it an attractive target for antibody-drug conjugates (ADCs), chimeric antigen receptor T-cell (CAR-T) therapy, and T-cell engagers. Early clinical trials of MUC16-targeted ADCs, DMUC5754A and DMUC4064A, showed promising efficacy but were limited by targeting an epitope within the shed extracellular domain (ECD) of MUC16, leading to off-target binding to circulating CA125, which created an antigen sink. HWK-016 is a next-generation, MUC16-targeting ADC that was designed to bind to the non-shed ECD of MUC16. HWK-016 comprises an Fc effector-attenuated IgG1 antibody that delivers a novel topoisomerase I inhibitor payload, CPT116. It contains a highly stable, cleavable linker developed using novel bioconjugation technology (carbon bridge cysteine re-pairing) designed to maximize intracellular delivery while minimizing systemic exposure of free payload. HWK-016 has a drug-to-antibody ratio of 6. The mechanism of action of HWK-016 was investigated in preclinical cancer models. Results showed that HWK-016 bound specifically to cell lines expressing the MUC16 non-shed ECD, was internalized through receptor-mediated endocytosis into lysosomes, and induced DNA damage which resulted in loss of cell viability. In contrast to DMUC5754A, addition of exogenous CA125 did not reduce HWK-016 mAb cell-surface binding and internalization, or the effect of HWK-016 on cell viability *in vitro*. Potent antitumor activity was observed in the high CA125-shedding OVCAR-3 xenograft tumor model at lower doses than DMUC5754A, with tumor regression observed with a 1 mg/kg single dose of HWK-016. A bystander killing effect was observed with HWK-016 *in vitro*, suggesting the ability to elicit activity against heterogeneous tumors. HWK-016 demonstrated a favorable pharmacokinetic profile and high stability in cynomolgus monkey and human plasma. Repeat-dose toxicology studies in non-human primates indicated a highest non-severely toxic dose (HNSTD) of 60 mg/kg. Together with preclinical efficacy studies, these data support a therapeutic index suitable for evaluation in humans. In summary, HWK-016 is a highly potent, MUC16-targeted ADC directed to the MUC16 non-shed ECD to avoid circulating CA125 binding. A phase I dose-escalation study is planned to evaluate HWK-016 in patients with advanced malignant solid tumors.

#1325 Preclinical assessment of BT5528 anti-tumor activity in cell-line-derived xenograft (CDX) models of head and neck squamous cell carcinoma (HNSCC).

Lukas Stanczuk[1], Daniel A. Peterson[2], Inma Rioja[1], Michael Method[2], Michael Skynner[1], **Gavin Bennett**[1]

Background: Erythropoietin-producing hepatocellular receptor A2 (EphA2) is a receptor tyrosine kinase critical for cell development; it is highly expressed in a range of solid tumors, and its expression correlates with higher grade, later stage disease, and poor prognosis. There is high unmet need for patients with EphA2-expressing tumors, including HNSCC, which has one of the highest EphA2 expression levels across solid tumors. BT5528 is a Bicycle® Drug Conjugate (BDC®), comprising a highly selective EphA2-targeting bicyclic peptide conjugated to the cytotoxin MMAE via a stable valine-citrulline cleavable linker. BT5528 has low molecular weight (4.4 kDa), enabling rapid and efficient delivery of the BDC® to the tumor and subsequent payload release, with minimal systemic exposure to the conjugate. Here we evaluate anti-tumor activity of BT5528 in murine CDX models of HNSCC.
Methods: Three HNSCC CDX models were generated with female NOD SCID (SCC-9 [tongue]) or Balb/c nude (Fadu [hypopharynx] and Cal27 [tongue]) mice by subcutaneous inoculation of cell-line-derived HNSCC tumor cells into the right abdominal flank. Tumor-bearing mice were treated once weekly with either vehicle or BT5528 at 1, 3, or 5 mg/kg IV (n=6 per treatment group per CDX model) once average tumor volume reached ~160 mm^3. EphA2 expression in cell lines was assessed by quantitative FACS. Tumor growth was monitored by caliper measurements and tumor volume calculated as ($width^2$ x length)/2. Average tumor growth inhibition (TGI) was calculated twice weekly for each treatment group per model for up to 28 days.
Results: Average EphA2 expression (receptors/cell) was 29,000 (Fadu, low expression), 46,000 (SCC-9, medium expression), and 135,000 (Cal27, high expression), which are comparable to expression levels observed in previous preclinical work in CDX and patient-derived xenograft models, and which correlated with BT5528 anti-tumor activity. Compared with vehicle treated mice, significant anti-tumor activity was observed for all three models. For Cal27, TGI reached 53% and 92% at 3 and 5 mg/kg IV, respectively, on Day 28 ($p<0.001$ and $p<0.0001$). For SCC-9 and Fadu, the day of measurement was the last day all vehicle-treated mice survived. TGI reached 101% and 107%, respectively, for SCC-9 on Day 21 ($p<0.0001$); and 95% and 107%, respectively, for Fadu on Day 25 ($p<0.0001$). Assessment of tumor volume over time demonstrated a clear dose response for all models tested, with Fadu and SCC-9 being the most sensitive. BT5528 was generally tolerable in line with previous studies.[1]
Conclusions: BT5528 has shown potent preclinical anti-tumor activity in EphA2-expressing CDX models of HNSCC at clinically relevant doses. These data support the potential to further evaluate BT5528 in HNSCC.

#1326 PRISM AIR: A high-throughput platform for functional validation of ADC targets and antibody candidate prioritization.

J. Eskra, A. Kalathungal, A. Golabi, B. Porter, U. Widocki, A. Bino George, M. Kocak, M. Ronan, M. Rees, J. Roth;
Broad Institute, Cambridge, MA

The development of antibody-drug conjugates (ADCs) remains a resource-intensive process, often hampered by the lack of scalable, early functional assays for validating new tumor targets and prioritizing candidate antibodies with therapeutic potential. To address this technological innovation gap, we developed PRISM AIR (Antibody Internalization Reporter), an assay designed to facilitate discovery of novel cell surface targets and accelerate development of ADCs through integration of large-scale functional cell viability screening with comprehensive molecular data. PRISM AIR utilizes a universal secondary Fab-MMAF conjugate targeting the Fc domain of primary human IgGs. By coupling a secondary drug conjugate with a primary antibody, we hypothesized that we could achieve selective drug delivery mimicking the mechanism of an ADC. This approach would enable early functional screening of candidate antibodies without the need for resource-intensive conjugation of individual antibodies. We screened a panel of antibody and ADC test agents across the entire PRISM cell set of 957 genomically characterized cancer cell lines, validating the platform against several targets including HER2, TROP2, tissue factor and transferrin receptor. Results showed consistent potent, target-selective killing that correlated with antigen expression and analogous conventional ADC efficacy, confirming the assay's ability to functionally prioritize lead candidates. Integration of viability data with comprehensive baseline genomic and perturbational profiles allowed us to disentangle antibody versus linker and payload activity and identify predictive biomarkers. Notably, comparative profiling of AIR against ADCs with distinct payloads revealed differential activity, identifying GPX2 and AKR1C3 as resistance biomarkers specific to deruxtecan versus MMAF. We also identified the lysosomal transporter SLC46A3 as a critical sensitivity biomarker for non-cleavable linkers, a role previously unreported for MMAF conjugates. In conclusion, PRISM AIR represents a significant technological innovation for the antibody field. It is a robust, high-throughput platform that empowers researchers to identify novel ADC targets, prioritize lead candidates based on optimal internalization and functional cytotoxicity, and discover biomarkers predictive of response or resistance. By enabling these critical assessments early in the discovery pipeline, this next-gen tool for ADC development has the potential to significantly streamline the translation of new cancer immunotherapies from bench to clinic.

#4446 STRO-004, an exatecan-based next-generation tissue factor (TF)-targeted ADC, demonstrates superior efficacy across TF-expressing solid tumors in a comprehensive single-mouse PDX trial.

G. Hernandez, K. A. Doshi, M. Armanini, H. Kiefel, S. Zhou, B. Vuillemenot, G. Xu, X. Li, W. Rubas, G. Yin, H. Gerber, A. Yam; Sutro Biopharma, Inc., South San Francisco, CA

Tissue Factor (TF) is aberrantly expressed in multiple solid tumors, including cervical cancer, head and neck squamous cell carcinoma (HNSCC), non–small cell lung cancer (NSCLC), pancreatic ductal adenocarcinoma (PDAC), and colorectal cancer (CRC), and is associated with poor clinical outcomes. Although TF-targeted antibody–drug conjugates (ADCs) such as tisotumab vedotin have demonstrated clinical activity, their utility is limited by on-target/off-tumor and systemic, platform toxicities associated with premature payload release. This study evaluated the preclinical efficacy and safety of STRO-004, a novel site-specific DAR8 β-glucuronidase–exatecan ADC engineered for enhanced stability, reduced off-target toxicity, and an expanded therapeutic index compared with first-generation TF-directed ADCs.Anti-tumor activity was assessed in a single-mouse PDX (patient-derived xenograft) trial comprising diverse solid tumor indications (HNSCC, NSCLC, PDAC, and CRC; up to n=20 models each). Mice were randomized to receive vehicle, STRO-004, or benchmark approved ADCs administered as a single 5 mg/kg dose, which is considered clinically relevant**.** Tumor growth inhibition, best overall response (BOR), and biomarker-response relationships were evaluated. In interim analysis, STRO-004 demonstrated superior anti-tumor activity across all tumor types tested, with complete responses (CR) observed in multiple models. In HNSCC, STRO-004 produced sustained tumor regression in >50% more models vs. benchmark at the same 5 mg/kg dose, confirming enhanced potency at therapeutically translatable exposures. In NSCLC, activity was greater than or comparable to benchmark, with responses in both non-squamous and squamous histologies. STRO-004 also induced robust tumor regression in PDAC and CRC. Biomarker analysis in HNSCC revealed anti-tumor activity across a broad TF-expression range, while limited responses in some TF-high models suggest target-independent resistance mechanisms. In vitro, STRO-004 exhibited reduced cytotoxicity toward corneal and skin epithelial cells relative to approved TF ADC. It was well tolerated in NHPs up to 50 mg/kg, with no ocular or hematologic toxicity and approximately 15-fold higher Cmax and 50-fold greater AUC than first-generation TF ADCs.These data demonstrate that STRO-004 achieves broad, durable responses at clinically relevant dosing, with an improved safety profile and therapeutic index compared with approved TF ADC. Because the single-mouse PDX trial design better reflects patient diversity in human trials, these results provide strong support for STRO-004 as a potential best-in-class TF-targeted ADC. The first-in-human Phase 1 study of STRO-004 is ongoing in solid tumor indications that are expected to have high TF expression or prevalence (NCT07227168).

Neuroendocrine prostate cancer (NEPC) is a lethal prostate carcinoma subtype that arises through neuroendocrine (NE) transdifferentiation in response to androgen deprivation therapy (ADT) and androgen receptor pathway inhibitors (ARPIs). This process involves profound epigenetic and transcriptional reprogramming, causing loss of luminal features and acquisition of NE traits. Lineage-specific transcription factors (TFs), such as ASCL1, FOXA2, SOX2, and PROX1, have been implicated in orchestrating lineage transition. Critically, both the activation and functional engagement of these TFs depend on upstream chromatin remodeling, which dynamically shapes the chromatin landscape to facilitate lineage reprogramming. The significance of chromatin remodeling in NEPC is underscored by the characteristic “salt and pepper” nuclear morphology, reflecting extensive chromatin reorganization. Together, these molecular and histological features highlight chromatin remodelers as critical regulators of NEPC development and aggressiveness. However, the specific upstream remodelers remain poorly defined.Through integrated analysis of longitudinal RNA-seq data from the clinically relevant LTL331/331R PDX model, which captures the complete temporal progression from adenocarcinoma to castration-induced NEPC, we identified CHD7 as a key chromatin remodeler that is upregulated early during NEPC development, with its expression preceding NE trait acquisition and further increasing in terminal NEPC. Functional studies demonstrated that CHD7 overexpression facilitates NE transdifferentiation of adenocarcinoma cells under AR signaling suppression, while knockdown (KD) in NEPC cells reduces DNA synthesis and cell survival, increases apoptosis, and suppresses NE markers and key NE-TFs. RNA-seq analysis of CHD7-KD cells revealed downregulation of pathways governing NE differentiation, cell cycle progression, and DNA damage response (DDR), further supporting CHD7 in regulating NE-lineage commitment and maintaining genomic stability of NEPC cells. Additionally, CHD7 ChIP-seq and ATAC-seq analysis revealed direct binding and regulating accessibility of regulatory elements of these NE-TFs, supporting its upstream regulatory role in NEPC. Notably, we uncovered that CHD7 modulates replication stress via regulating the ATR-CHEK1 axis. CHD7-KD impairs CHEK1 phosphorylation at key activation sites, leading to DNA damage accumulation and heightened sensitivity to genotoxic stress. Therapeutically, CHD7-KD cells show increased cisplatin susceptibility and pharmacological inhibition of CHEK1 synergistically enhances cisplatin-induced cell death, suggesting that exploiting the CHD7-dependent CHEK1 axis could potentiate cisplatin-based combination therapy in NEPC.

#1357 The essential role of KDM5B/SOX9 signaling Axis in the development and progression of therapy-induced neuroendocrine prostate cancer.

G. Li[1], S. Celada[1], Q. Wang[1], R. Jin[2], T. Kanagasabai[1], Q. Shao[1], B. Liu[1], S. E. Adunyah[1], P. Hurley[3], Z. Chen[1];

Therapy-induced neuroendocrine prostate cancer (t-NEPC) represents a subset of lethal prostate cancer (PCa) resistant to androgen deprivation therapy (ADT). Current intervention strategies for t-NEPC are largely undefined, underscoring the urgent need to better understand its molecular mechanisms. Lysine (K)-specific demethylase 5B (KDM5B), a key epigenetic regulator, is frequently elevated in advanced PCa and t-NEPC. Similarly, the transcription factor sex-determining region Y (SRY)-box 9 (SOX9) is a critical regulator of prostate development and has been implicated in PCa. In this study, we investigated the functional role of the KDM5B/SOX9 signaling pathway on the development and progression of t-NEPC. We found that the levels of KDM5B and SOX9 are abnormally elevated in human NEPC cells. Remarkably, KDM5B depletion led to a significant reduction in mRNA and protein levels of SOX9 and neuroendocrine markers (Neuron-specific enolase and Synaptophysin) in PC3 cells. Conversely, KDM5B add-back to KDM5B knockout (KO) cells restored their levels in a dose-dependent manner. Importantly, the recurrent tumors of castrated Pten/Trp53 mice displayed the malignant features of t-NEPC, along with elevated Kdm5b and Sox9 levels. Surprisingly, Kdm5b deficiency abrogated the t-NEPC progression in Pten/Trp53/Kdm5b mutant mice, indicating the essential role of Kdm5b in t-NEPC progression in vivo. Furthermore, we observed an increase in KDM5B and SOX9 levels in LNCaP-MDV cells, a LNCaP-derived NEPC cell line. Mechanistically, KDM5B regulated SOX9 signaling in PCa cells by directly binding to the SOX9 promoter. To further elucidate the contributions of the KDM5B/SOX9 signaling axis to t-NEPC progression, we generated SOX9 KO PCa cells using CRISPR/Cas9 technology. Our results showed that SOX9 KO significantly decreased the proliferation and the levels of neuroendocrine markers in PCa cells, without impacting KDM5B levels. In conclusion, our findings in vitro and in vivo demonstrate the essential role of KDM5B/SOX9 signaling pathway in the development and progression of t-NEPC, suggesting that targeting this pathway could represent a novel and effective therapeutic strategy for controlling t-NEPC.

#1358 Promoter methylation gains in aging and cancer are independent of replication.

S.-J. Thursby[1], Z. Jin[1], N. Patel[1], Y. Tao[1], Y. Bhandari[1], D. Petkovich[1], S. Lu[1], L. Yang[1], T.-H. Wang[1], T. R. Pisanic II[2], S. B. Baylin[3], H. Easwaran[1], J. Blum[1];

DNA methylation alterations are observed across multiple cancers, occurring early during tumor initiation. However, the evolution of these changes remains poorly understood and difficult to assess at the clonal level. We addressed the clonal evolution of DNA methylation using our previously established mouse organoid model of *BRAF*^{V600E} oncogene-induced colon cancer (CC) tumorigenesis. We developed a method for profiling genome-wide DNA methylation from low DNA amounts and applied it to that organoid model. Single organoid clones, derived from single stem cells, were profiled every month for 5 months to map nucleotide-level dynamic heterogeneity in methylation changes. Uninduced control organoids exhibit a pattern of epigenetic drift leading towards clonal convergence but not until 5 months. Whereas *BRAF*^{V600E}-induced organoids exhibit a step-wise divergence throughout the different time points, likely explained by progressive clonal takeovers. Although there are differences in the clonal dynamics of epigenetic states in the control and *BRAF*^{V600E}-induced organoids, there is a common basis for the DNA methylation changes in both the lineages explained by the age-in-culture associated methylation changes. This is revealed by the observation that unlike currently proposed models, *BRAF*^{V600E} did not induce or increase the degree of DNA methylation gains. Furthermore, the CpG sites affected in the control and *BRAF*^{V600E} comparison were not shared but mapped to the same genomic elements, indicating common drivers of methylation changes regardless of oncogene. Additionally, investigation of promoter CpG-island methylation gains revealed that they are decoupled from replication. External validation in other pre-cancerous/CC datasets and experimental cell line datasets, show that methylation gains at regulatory elements are a function of “biological aging” and independent of replication or cell division cycles. The sites that acquire DNA methylation changes in *BRAF*^{V600E} -induced organoids, compared to control organoids, are enriched for transcription factor motifs important in colorectal cancers, such as Cdx1, Cdx2, and Pparg. In contrast, control organoids show enrichment for transcription factors involved in stress and viral pathways. Our studies provide new insights into the early epigenetic changes involved in *BRAF*^{V600E}driven carcinogenesis, which is mainly rooted in the age-dependent drivers of epigenetic alterations, and are potentially subject to clonal selection in the context of uncontrolled growth due to oncogenic signaling.

#1359 Cooperativity between DNMT and EZH2 activity drives neuroendocrine phenotype in advanced prostate cancer.

R. Singh[1], V. B. Venkadakrishnan[2], E. Imada[1], N. J. Brady[1], Y. Yamada[2], L. Marchionni[1], B. D. Robinson[1], D. S. Rickman[1], H. Beltran[2];

[1]Weill Cornell Medicine, New York, NY, [2]Dana-Farber Cancer Institute, Boston, MA

Introduction: Upon prolonged anti-androgen treatment, 15-20% of castration resistant prostate cancer (CRPC) progresses to poorly differentiated, androgen-independent neuroendocrine prostate cancer (NEPC) that express neural markers. Studies on clinical samples have elucidated distinct DNA methylome of NEPC tumors compared to other subtypes, suggesting the importance of epigenetic regulation in lineage plasticity of advanced CRPCs.EZH2, catalyzer of repressive H3K27me3, is reported to be overexpressed in NEPC and has been studied as a therapeutic target in advanced prostate cancer. Although evidence from embryonic stem cell studies suggest possible interplay between the two mechanisms, how it contributes to lineage plasticity in advanced CRPCs is unaddressed.

Methods: DNA methylome and H3K27me3 of patient-derived xenografts/organoids and murine model with *MYCN* induction and *Pten/Rb1* co-loss (PRN) were analyzed. DNA methylome upon EZH2 deletion and H3K27me3 profile upon DNMT1 deletion was studied in human and murine NEPC models. To understand their transcriptional impact, expression profiles were analyzed upon EZH2/DNMT1 deletion.

Results: Both DNA methylome and H3K27me3 profile shifts during progression of CRPC to NEPC. H3K27me3 was enriched at hypomethylated regions of NEPC Vs. CRPC tumors across models and was independent of genomic context. EZH2 loss changed DNA methylome in NEPC at regions known to have differential DNA methylation during lineage plasticity. Neuron-related genes were hypomethylated and upregulated while, morphogenesis-related and bivalent genes were hypermethylated and downregulated upon EZH2 deletion. Conversely, DNMT1 deletion altered H3K27me3 landscape in NEPC. Neuron-related genes and bivalent genes were downregulated and enriched with H3K27me3 but upregulated and had depleted H3K27me3 in CRPC upon DNMT1 deletion. H3K4me3 was also decreased upon DNMT1 knockout in NEPC at these regions suggesting loss of bivalency. Short-term DNMT inhibition in NEPC PDX showed similarly altered H3K27me3 as noted in DNMT deleted NEPCs.

Conclusions: DNMT1 and EZH2 activity overlaps and together reprograms the epigenome during lineage plasticity of advanced CRPCs. EZH2 loss was partially compensated by DNMT activity leading to further neuroendocrine differentiation while DNMT1 loss shifted H3K27me3 leading to suppression of neuron-related genes.

#1360 Targeting the ubiquitin reading function of DNMT1 as a next-generation approach for epigenetic cancer therapy.

J. A. Kuleape, Y. Liu, J. A. Hrit, R. Tiedemann, S. B. Rothbart;
Van Andel Institute (VAI), Grand Rapids, MI

DNA methyltransferase 1 (DNMT1) is the key enzyme supporting the epigenetic inheritance of DNA methylation patterns during DNA replication, a process frequently dysregulated across nearly all human cancers. Abnormal DNA methylation patterning is an appreciated mechanism of tumor suppressor gene (TSGs) silencing and immune evasion, motivating the clinical development of DNA methyltransferase inhibitors (DNMTi's). While nucleoside analog DNMTi's are the most clinically advanced epigenetic cancer therapies, their utility has been limited due to pharmacokinetic barriers and adaptive resistance mechanisms. New approaches to inhibit abnormal DNA methylation patterning are therefore needed. Here, we define the DNMT1 ubiquitin interacting motifs (UIMs), which recognize UHRF1-dependent histone H3 mono-ubiquitination, as targetable domains to allosterically inhibit DNMT1 catalytic activity, and we identify a pharmacophore that can be used as a starting point for UIM inhibitor development. To characterize the functional significance of the DNMT1 UIMs, we developed a genetic complementation system in two human colon cancer cell lines to cover the loss of endogenous DNMT1 with wild-type or loss-of-function mutants with disrupted catalytic or UIM activities. Disruption of DNMT1 UIM function mirrored DNMT1 knockdown, catalytic-dead mutant cover, and exposure to nucleoside- and non-nucleoside catalytic DNMT inhibitors. These effects included widespread DNA hypomethylation that correlated with the re-expression of epigenetically silenced TSGs and transposable elements, reduced colony formation, impaired cell proliferation, and impaired growth of xenografted tumors. A pilot screen of a chemical library revealed four compounds with a shared pharmacophore able to disrupt the interaction of DNMT1 with ubiquitinated nucleosomes. Collectively, these studies demonstrate that the oncogenic properties of DNMT1 are supported by its ubiquitin reading function and provide a roadmap for developing next-generation DNMT1 inhibitors targeting this allosteric site.

#1361 KDM2A-driven epigenetic reprogramming promotes barrett's esophagus progression to adenocarcinoma.

Shilpa S. Dhar[1], Johnson Amoah[2], Ferhad Mongal[3], Liyong Zeng[2], Aryana S. Bhati[2], Xueshuai Han[4], Fang Cao[5], Tanaya Alexander Washington[2], MelissaPizzi Pizzi[2], Bansi Vanparia[2], Calena J. Brown[2], Gengyi Zou[1], Min Gyu Lee[6], Linghua Wang[2], Jaffer A. Ajani[2]

[1]GI Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]UT MD Anderson Cancer Center, Houston, TX,[3]University of Houston, Houston, TX,[4]Genome Medicine, UT MD Anderson Cancer Center, Houston, TX,[5]Peking University Health Science Center, Beijing, China,[6]Dept. of Molec. & Cellular Onc., UT MD Anderson Cancer Center, Houston, TX

Purpose: Esophageal adenocarcinoma (EAC), a rapidly increasing and highly lethal cancer arising from Barrett's esophagus (BE), lacks effective preventive strategies. Our study investigates the histone demethylase KDM2A as an early epigenetic driver of BE-to-EAC progression and evaluates whether its inhibition can suppress oncogenic reprogramming and tumorigenesis.
Experimental Procedures: We performed high-plex spatial transcriptomics (COSMx, 1K human panel) on patient tissues spanning BE, low- and high-grade dysplasia, and EAC (n = 20), integrating these results with immunohistochemistry, immunofluorescence, and TCGA (n = 186) datasets. Functional studies employed patient-derived organoids (PDOs), xenografts, and CRISPR-based KDM2A perturbation models. Chromatin profiling (CUT&RUN for KDM2A, ATAC-seq, RNA-seq) was used to map KDM2A-dependent enhancer activation and tumor suppressor repression.
Results: Spatial transcriptomics identified 13 transcriptional clusters delineating epithelial, stromal, and immune compartments. Progression from BE to EAC was characterized by expansion of stem-like epithelial clusters and loss of differentiation markers. PSCA and SPINK1 were consistently upregulated in EAC and correlated with increased EGFR expression, suggesting a convergence of these pathways in promoting therapy resistance and malignancy. KDM2A expression, validated by IHC/IF, was elevated in 4/6 EAC versus 1/3 BE samples and strongly correlated with PSCA and SPINK1. Analysis of TCGA-EAC confirmed KDM2A amplification and overexpression, which correlated with ERBB2, MYC, EGFR, and poor overall survival ($p=8.67\times10^{-3}$). Downstream analysis revealed repression of tumor suppressors DMBT1 and PFN1, implicating KDM2A in chromatin remodeling that silences protective loci while activating oncogenic enhancers. In organoid models, genetic or pharmacologic inhibition of KDM2A reduced PSCA/SPINK1 and EGFR signaling, restored differentiation, and suppressed proliferation.
Conclusions: KDM2A acts as a master chromatin regulator linking histone demethylation, tumor suppressor silencing, and activation of the PSCA-SPINK1-EGFR oncogenic axis during BE-to-EAC progression. Co-targeting KDM2A with EGFR/HER2 or MYC/CDK9 inhibitors represents a rational therapeutic strategy for early intervention and prevention. This study provides mechanistic insight into how epigenetic deregulation establishes a stem-like, therapy-resistant state in EAC and identifies KDM2A as a promising preventive and therapeutic target.

#1362 KMT2D is a master epigenetic regulator of lineage plasticity in lung squamous cell carcinoma.

Y. Jiang[1], **M. Wu**[2], U. Saran[1], L. Campos Clemente[1], S. Jiang[1], A. Ghosh[1], I. Flores[1], D. Morales[1], W. Lu[1], K. Khan[1], L. Zhang[1], L. Maren Solis Soto[1], I. Wistuba[1], M. Gyu Lee[1], K. Rai[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX

Background The cellular origin of lung squamous cell carcinoma (LUSC) remains poorly understood due to the absence of native squamous epithelium in the lung. While LKB1 loss can promote lung adenocarcinoma (LUAD)-to-LUSC lineage switching, this mechanism does not explain many cases. KMT2D, a histone H3K4 methyltransferase mutated in ~20% of LUSC, is associated with poor outcome in early-stage disease. We investigated whether Kmt2d loss drives initiation of lung adenosquamous (LUAS) lesions and promotes lineage infidelity in AT2 and Club cells.

Methods We evaluated whether Kmt2d loss is necessary and sufficient to induce LUSC in Pik3ca^{H1047R}/p53$^{-/-}$ (PP) and Kras^{Mut}/p53$^{-/-}$ (KP) mouse lung cancer models. A R26-LSL-Tdtomato (TdT) reporter allele was crossed into KP mice, and TdT^{+} tumor cells were isolated at the moribund stage for 10x single-nuclei multiomics profiling (snRNA-seq and snATAC-seq). To define mechanisms underlying Kmt2d-loss-mediated transdifferentiation, cell lines representing different tumor states and histologies were subjected to histone mark ChIP-seq (H3K4me1, H3K4me3, H3K27ac, and H3K27me3) and CUT&RUN for key transcription factors (TFs) and chromatin regulator (FOXA1, FOXA2, SOX2, and MENIN).

Results Kmt2d loss promoted squamous lineage transition and accelerated tumorigenesis in both PP and KP models. Single-nuclei multiomic analyses revealed that Kmt2d deficiency disrupts endodermal differentiation programs, promoting a transition from a highly plastic Itg$\alpha6^{+}/\beta4^{+}$ stem-like adenocarcinoma state toward squamous identity. Regions gaining accessibility in Kmt2d-null tumors were enriched for chromatin remodelers and stress-response TFs, including SMARCC1, EP300, AP-1 members (JUN, FOS), and NFE2L2 (Padj <= 0.01). Mechanistically, KMT2D cooperates with FOXA1/FOXA2 to maintain lineage-specific enhancers and TFs networks required for endodermal differentiation. Upon KMT2D loss, FOXA1 partners with the KMT2A/B-MENIN complex, activating aberrant squamous programs that accelerate tumorigenesis. Consequently, Kmt2d-null cells become dependent on MENIN for their excessive proliferation. NFE2L2 is identified as a key aberrantly activated oncogene contributing to the growth of Kmt2d-null cells.

Conclusions Our findings identify KMT2D as a critical guardian of lung lineage fidelity and reveal how its loss reconfigures core regulatory programs to drive squamous transdifferentiation and aggressive tumor progression.

#1283 Asymmetric emergence of cardiovascular disease in hematologic malignancy survivors: A national real-world analysis.

Y. Song[1], P. Ma[1], H. Liang[2];
[1]Washington University in St. Louis, Saint Louis, MO, [2]UT MD Anderson Cancer Center, Houston, TX

Background: The link between hematologic malignancies and cardiovascular disease (CVD) is recognized as bidirectional, wherein each condition potentially promoting the onset of the other, thereby creating a complex interplay with significant clinical implications. However, the comparative risk and temporal dynamics of these situations are not clearly established in extensive, heterogeneous populations.
Methods: We utilized Electronic Health Record (EHR) data from the *All of Us* Research Program to construct two real-world cohorts: 5,786 hematologic malignancy survivors (leukemia, lymphoma, multiple myeloma, myelodysplastic syndromes [MDS]) without a history of CVD, and 77,617 CVD patients free of prior blood cancer. We assessed the bidirectional risk of incident disease in both modalities by comparing cumulative incidence, median time-to-event, and risk ratios (RRs), while adjusting for disease subtype, age, sex, race, and socioeconomic status.
Results: Among 5,786 hematologic malignancy survivors, 1,881 (32.5%) experienced new-onset CVD throughout 20-years. The risk was predominantly exhibited in the initial phase, with cumulative incidence reaching 14.7% by year 2, 22.2% by year 5, and 27.7% by year 10. Conversely, merely 1,451 (1.87%) of CVD patients reported a hematologic malignancy by the tenth year. The progression to CVD occurred more rapidly than that of developing cancer after CVD (median: 2.4 vs. 4.0 years; $P<0.0001$), indicating pronounced temporal asymmetry.The extent and duration of CVD risk are affected by the type of malignancy. Survivors of lymphoma and leukemia exhibited a relative risk approximately 20 times greater for developing CVD compared to the risk of cancer development in CVD patients (year 1 RR =19.1 and 20.6, respectively). Multiple myeloma survivors faced even higher risk (year 1 RR = 28.6), remaining elevated at year 10 (RR = 17.1). Among all subtypes, MDS conferred the highest risk during follow-up, with survivors ~40 times more likely to develop CVD in the first year (year 1 RR = 39.9, year 10 RR = 19.9). The incidence of CVD subtypes also varied among hematologic malignancy survivors. Arrhythmias were the most frequent event (10-year incidence: 13.8%), followed by heart failure (8.9%). Patients aged 18-39 had a diminished risk relative to other age groups (OR: 0.78, 95% CI: 0.66-0.91), while female patients similarly demonstrated a reduced risk (OR: 0.86, 95% CI: 0.77-0.96) after controlling for race and ZIP code poverty level.
Conclusion: Survivors of hematologic malignancies face an elevated, immediate risk of CVD that far exceeds the risk of developing cancer following CVD. This asymmetry indicates influences beyond common risk factors and emphasizes the critical necessity for integrated cardio-oncology monitoring, especially within the initial five years post-diagnosis, to alleviate this rapid cardiovascular decline.

#1284 Decoding melanoma immunogenicity: A comprehensive proteogenomic, immunopeptidomic, and metabolomic atlas.

P. Wang, CPTAC Proteomics Characterization Melanoma Study Working Group;
Icahn School of Medicine at Mount Sinai, New York, NY

Melanoma's robust immunotherapy responses are driven by a high mutational load and diverse antigen landscapes, yet the mechanisms linking these features to immune outcomes remain incompletely understood due to the absence of a system-level view. To address this gap, the Clinical Proteomic Tumor Analysis Consortium (CPTAC) performed a large-scale, multi-omics melanoma study spanning 164 primary tumors and metastases. We integrated 13 omic layers — including, for the first time at this scale, immunopeptidomics, metabolomics, and ubiquitination and glycosylation post-translational modifications (PTMs) — to construct a holistic view of tumor immunogenicity. Mass-spectrometry-based HLA-I immunopeptidomics identified 315,225 unique HLA-I-bound peptides, including 1,138 tumor antigen candidates. Of these, 33% are tumor-associated antigens and 22% are lineage-specific antigens, consistent with recent findings that most tumor antigens in cancers derive from unmutated genomic sequences. Tumor antigen load correlates significantly with CD8+ T cell infiltration. Notably, antigens from a few MAGEA-family genes correlates with CD8+ T cell percentages, suggesting MAGEA antigens may drive CD8+ T cell recruitment. We provided the most comprehensive tumor-derived metabolomic profiling in melanoma to date, linking metabolic states to tumor biology and the immune context. In a subset of patients with relatively low tumor antigen loads and limited immune infiltration, ether lipid metabolism emerges as a regulator of primary tumor homeostasis, whereas metastases exhibit upregulated mitochondrial metabolism. Unsupervised clustering of protein ubiquitination data identifies a subgroup with markedly worse survival, characterized by high ubiquitination of the IFN signaling pathway and ubiquitination-dependent activation of AKT1. This ubiquitin-IFN cluster is not detectable in global proteomics, highlighting ubiquitination-mediated regulation of inflammatory signaling and tumor progression. Glycoproteomics-based clustering reveals a lysosome-active subgroup, supported by upregulation of lysosome-associated degradative and lipid-metabolizing pathways. We also observe sex-specific differences: in males, lysosome-active glyco-cluster membership associates with significantly worse survival, a pattern not seen in females. Although sex differences in immunotherapy responses have been reported, mechanisms remain unclear; these data offer insights into sex-specific immunotherapy outcomes. Collectively, this multi-layer resource links tumor genetics, transcriptomics, proteomics, PTMs, and metabolomics to antigen presentation and immune signaling. It unravels the molecular logic underlying immune evasion, offering a comprehensive multi-omic atlas to inform patient stratification and design of combination immunotherapies in melanoma.

#1285 Endocrine therapy adherence and 10-year risk of cardiometabolic outcomes among women with hormone receptor-positive breast cancer.

J. R. Ledesma[1], J. Nugent[1], C. A. Laurent[1], S. R. Thadani[2], R. K. Cheng[3], J. M. Specht[3], J. M. Roh[1], R. Liu[4], H. Greenlee[5], M. L. Kwan[1];

[1]Kaiser Permanente - Northern California, Pleasanton, CA, [2]Kaiser Permanente - Northern California, South San Francisco, CA, [3]University of Washington, Seattle, WA, [4]Kaiser Permanente - Northern California, San Francisco, CA, [5]Fred Hutchinson Cancer Center, Seattle, WA

Background

Adjuvant endocrine therapy (ET) reduces breast cancer (BC) recurrence and mortality but may adversely affect cardiometabolic health. We evaluated, for the first time, the association between ET adherence duration and 10-year cumulative incidence (CI) of hypertension, dyslipidemia, and diabetes among women with hormone receptor-positive BC.

Methods

We conducted a prospective cohort study of 8,365 postmenopausal women with stage I-III hormone receptor-positive BC within Kaiser Permanente Northern California who initiated ET between 2005 and 2013. Adherence was categorized annually over five years and summarized into adherence durations from 0 to 5 years. Cardiometabolic outcomes were identified from diagnoses, labs, and medication dispensings. We estimated 10-year CI under varying adherence durations using sequentially doubly robust (SDR) estimation with Super Learner to flexibly model treatment and outcome mechanisms. Analyses accounted for all-cause death as a competing risk and stratified by ET type (aromatase inhibitor [AI] vs tamoxifen [TAM]).

Results

Overall, 40.8% were adherent for ≥5 years. Compared with never-adherent women, those adherent for ≥5 years were younger (aged 50-70: 73.7% vs 64.0%), lived in higher-income neighborhoods ($80,395 vs $70,417), more often received chemotherapy (34.1% vs 20.9%), and less likely to smoke (5.92% vs 10.5%). Among women never adherent, adjusted 10-year CI of hypertension, dyslipidemia, and diabetes were 22.7% (20.6-24.9), 25.6% (23.3-27.8), and 8.91% (7.65-10.2). Among those adherent for 5 years, CI were 29.1% (27.0-31.2), 32.4% (30.3-34.6), and 12.6% (11.5-13.8), corresponding to CI differences of 6.37% (3.36-9.37), 6.83% (3.79-9.94), and 3.73% (2.06-5.40). CI generally increased with each additional year of adherence. In ET-stratified analyses, 5-year AI adherence was associated with hypertension (CI difference=6.85% [3.74-10.0]), dyslipidemia (8.32% [4.94-11.7]), and diabetes (4.21% [2.28-6.13]) compared with those never adherent. TAM adherence was associated only with hypertension (5.83% [0.53-11.1]). Compared directly with TAM, AI adherence resulted in higher CI of dyslipidemia (difference=10.2% [4.33-16.1]) and diabetes (2.96% [0.07-5.85]).

Conclusion

Longer adherence to AIs was associated with increased 10-year risk of hypertension, dyslipidemia, and diabetes, while TAM use was associated only with elevated hypertension risk. With over 4.3 million breast cancer survivors in the US, findings highlight the need for further research to optimize patient selection for ET, balancing BC benefits with potentially higher cardiovascular disease risk, and strategies for early cardiometabolic management during ET.

#1286 Comprehensive phenotypic mapping of alternative lengthening of telomeres (ALT) regulation expands the landscape of targetable suppressors.

Bill Diplas, Oluchi Ezekwenna, Madison Rex, Mingxuan Wei, Agnel Sfeir

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Alternative lengthening of telomeres (ALT) is used by 10-15% of all cancers as a telomerase-independent mechanism of telomere maintenance. Despite the identification of several ALT regulators, targeting has been challenging due to incomplete penetrance across cell lines and a limited understanding of the broader regulatory landscape. A major barrier to systematic discovery has been the lack of scalable assays compatible with high-throughput screening approaches.
Methods: Native fluorescence in situ hybridization (FISH) detecting ALT-specific single-stranded telomeric DNA was adapted and optimized for hybridization in-suspension with a fluorescent G-rich telomere PNA probe (TelG-647) and fluorescence-activated cell sorting (ALT-FlowFISH). Genome-wide CRISPR knockout screens using the TKOv3 library were performed, followed by selection and ALT-FlowFISH at one week following transduction and selection. Cells with the highest and lowest Native FISH signals were sorted (candidate ALT suppressors and promoters, respectively) and integrated sgRNA sequences were amplified and sequenced. Significantly enriched guides were identified as candidate ALT suppressors and promoters and were validated using targeted depletion (sgRNA/Cas9 RNP) and pharmacological inhibition followed by ALT assay validation (Native FISH and C-circle assay).
Results: ALT-FlowFISH was validated using depletion of established regulators FANCM (suppressor) and BLM (promoter), which resulted in expected increase and decrease of native FISH signal, respectively. Genome-wide phenotypic screens were performed in ALT-positive cell lines U2OS and RPE-ALT, followed by ALT-FlowFISH. These identified established ALT promoters, including components of the BTR complex, and suppressors, including FANCM, validating the screening approach. Overall, ALT suppressors were significantly enriched for known essential genes compared to ALT promoters. Importantly, we discovered and validated multiple novel ALT suppressor pathways, including components of the proteasome, the polyadenylation complex, RNA polymerase II machinery, and previously unrecognized members of the Fanconi anemia pathway. To confirm the functional relevance of these findings, we treated multiple ALT-positive cell lines with the proteasome inhibitor bortezomib, which recapitulated the suppressor phenotype observed in the genetic screens, demonstrating therapeutic potential.
Conclusions: This study establishes the first scalable ALT activity assay and provides the most comprehensive functional map of ALT regulation to date. Our identification of the proteasome and transcriptional machinery as novel ALT suppressors reveals potential precision medicine opportunities for targeting ALT-positive malignancies.

#1287 A spatiotemporal proteome map of chemotherapy response in metastatic breast cancer.

X. Zhao[1], J. Gao[1], G. Qian[1], R. Tiwari[2], J. N. Hansen[3], A. Forget[2], S. Nourreddine[1], Y. Doctor[1], J. Parker[1], P. Mali[1], N. Krogan[2], E. Lundburg[3], T. Ideker[1];

[1]UC San Diego, La Jolla, CA, [2]UC San Francisco, San Francisco, CA, [3]Stanford University, Palo Alto, CA

Cells are not simply aggregates of molecules; they are highly organized entities with dynamic structures and functions that evolve in response to external stimuli, such as drug treatments. Understanding how tumor cells reorganize these structures and functions, both spatially and temporally, is essential for unraveling the mechanisms underlying tumor behaviors including treatment response. Through the NIH Bridge2AI Cell Maps for AI (CM4AI) data generation project, we profiled spatiotemporal proteomics in metastatic breast cancer cells across untreated and chemotherapy-treated conditions using complementary proteomics technologies: immunofluorescence imaging (~11,000 images covering >100,000 single cells to map subcellular localization of >500 proteins), mass spectrometry (protein interactions of >500 proteins and complex organization across >5000 proteins), and single-cell CRISPR sequencing (>120,000 single-cell transcriptomes across 200 gene perturbations). Using self-supervised contrastive learning, we fuse protein embeddings across modalities while preserving treatment-induced protein dynamics. Our analyses reveal that chemotherapy triggers substantial protein reorganization. For example, in untreated cells, HDAC8 forms an assembly in close proximity to TET1, SETDB2, PHF6 and YWHAG. However, after paclitaxel treatment, its expression increases substantially and relocates from cytosol to nucleus. It forms a new seven-protein assembly with PARP1, KAT6B, DNMT3A, HDAC9, HDAC2, and BRD4. Building on this foundation, we will construct an integrated map that (a) delineates how individual proteins assemble into complexes and higher-order structures; (b) annotates these subcellular components with their functional states; and (c) models the dynamics of specific cellular components across drug treatment contexts.

#1288 The protein phosphatase EYA4 is a druggable target for the treatment of breast cancer.

Daniela A. Garcia[1], Chandler Heupel[2], Hannah Palacios[1], Eloise Dray[3]

[1]Greehey Children's Cancer Research Institute, The University of Texas Health Science Center at San Antonio, San Antonio, TX,[2]Neuroscience, Developmental, and Regenerative Sciences, The University of Texas at San Antonio, San Antonio, TX,[3]Department of Biochemistry and Structural Biology, The University of Texas Health Science Center at San Antonio, San Antonio, TX

Eyes Absent Homolog 4 (EYA4) is a dual-specificity phosphatase re-expressed in triple-negative breast cancer (TNBC) through methylation of repressive transcription factor marks. Its overexpression correlates with advanced disease and promotes genomic instability by deregulating Rad51-mediated homologous recombination (HR) and non-homologous end joining (NHEJ), throughout the cell cycle. Here, we characterize a novel property of EYA4: its ability to bind single-stranded DNA (ssDNA), and present a small-molecule inhibitor that abolishes its tyrosine phosphatase activity, possibly through the weakening of the DNA binding. Using a combination of chimeric EYA4 fragments and mutants, mobility shift assays, and biophysical methods including nuclear magnetic resonance (NMR) spectroscopy and microscale thermophoresis (MST), we mapped the DNA-binding interface and identified key residues mediating this interaction. ssDNA binding was found to stimulate the tyrosine phosphatase activity of EYA4, and our small-molecule inhibitor disrupts the phosphatase activity with an IC50 of 1 μM, indirectly suppressing enzymatic function. Functional assays, including homologous recombination reporter systems, immunofluorescence for DNA damage markers, MTT viability assays, and live-cell imaging using the Incucyte system (Essen), showed that EYA4 inhibition impairs HR, leads to DNA double-strand break accumulation, reduces proliferation, and increases apoptosis in MDA-MB-231 TNBC and TKCC PDAC models at concentrations of 1-5 μM. Fluorescent Ubiquitination-based Cell Cycle Indicator (FUCCI) imaging further revealed cell cycle defects, including mitotic failure and chromosomal segregation errors, consistent with disrupted repair during replication. Testing conducted on large panels of patient derived cell lines with the EYA4 inhibitor alone and in combination with standard of care demonstrated broader therapeutic relevance. These findings support targeting EYA4's DNA-binding function as a valid strategy to suppress tumor growth and enhance the efficacy of DNA-damaging therapies in HR-deficient (HRD+) cancers.

#1289 ASP2998, a TROP2-targeted immunostimulatory antibody drug conjugate (iADC) with dual payloads, demonstrates potent efficacy and a favorable safety profile in nonclinical models.

M. Orr[1], T. Chaen[2], M. Shibata[2], N. Ishikawa[2], T. Matsuda[2], Y. Fujita[2], G. Haggerty[3], Y. Ochiai[2], H. Tanaka[2], M. Akaiwa[2], X. Li[4], K. A. Doshi[4], W. Mahauad-Fernandez[4], K. Bajjuri[4], G. Yin[4];

[1]Astellas Pharma Global Development, Inc., Seattle, WA, [2]Astellas Pharma Inc., Tsukuba, Japan, [3]Astellas Research Institute of America LLC, Northbrook, IL, [4]Sutro Biopharma Inc., South San Francisco, CA

Objective: Trophoblast cell surface antigen-2 (TROP2) is a transmembrane glycoprotein implicated in various intracellular signaling pathways that promote cancer cell proliferation, migration, and invasion. TROP2 is frequently overexpressed across multiple tumor types. ASP2998 is a novel TROP2-directed immunostimulatory antibody drug conjugate (iADC) that incorporates two distinct payloads: a cytotoxic topoisomerase 1 inhibitor and an immunomodulator STING agonist. A series of nonclinical studies have been conducted to evaluate the nonclinical efficacy and safety of ASP2998.

Methods: In vitro cytotoxicity, immune cell activation, and cytokine production were assessed using co-culture assays of TROP2-positive cancer cells and human peripheral blood mononuclear cells (PBMCs). Immune cell subsets (dendritic cells, $CD4^+$ and $CD8^+$ T cells, and NK cells) and cytokines (IL-6, IL-1β, TNFα, IFNγ, and IP-10) were analyzed.Tumor immune environment (TME) modulation was evaluated in mice bearing human TROP2-expressing MC38 (MC38-hTROP2) tumors. ASP2998 was administered intravenously and immune cell populations in tumors were analyzed by flow cytometry on Day 5.Primary antitumor efficacy and tumor rechallenge responses were compared between ASP2998 and a TROP2-directed toxin ADC, in a MC38-hTROP2 tumor model.A 4-week GLP-compliant toxicity study (QW x 4) was conducted in cynomolgus monkeys at ASP2988 doses of 3, 10, and 30 mg/kg/week.

Results: ASP2998 exhibited potent cytotoxic activity against TROP2-positive cells and induced dose-dependent activation of human dendritic cells, $CD4^+$ and $CD8^+$ T cells, and NK cells, along with increased secretion of IL-6, IL-1β, TNFα, IFNγ, and IP-10.In vivo, ASP2998 at 1 mg/kg increased the frequency of total monocytes and activated ($CD80^+$) monocytes and dendritic cells in tumors. It also significantly enhanced infiltration and activation ($CD69^+$) of NK cells and increased the frequency of granzyme B^+ NK and $CD8^+$ T cells at both 0.3 and 1 mg/kg.ASP2998 surpassed the efficacy of a TROP2-directed toxin ADC against MC38-hTROP2 in vivo and provided greater protection against tumor rechallenge. ASP2998 demonstrated an acceptable safety profile in monkeys. Target organs included skin, cornea, kidney, urethra, trachea, and red blood cells. The highest non-severely toxic dose (HNSTD) was determined to be 10 mg/kg (QW x 4). Toxicokinetic profiles of the total antibody and ADCs were comparable, with minimal exposure to free payloads.

Conclusion: ASP2998 is a first-in-class dual payload iADC that combines cytotoxic and immuno-stimulatory mechanisms to enhance antitumor efficacy and promote durable antitumor immunity while demonstrating a favorable safety profile in nonhuman primates. A first-in-human (FiH) clinical study is planned.

Exhaustion of CD8+ T cells in the tumor microenvironment is intertwined with metabolic dysfunction. Thus, metabolic reinvigoration of T cells is a promising cancer immunotherapy strategy. Here, we identify dipeptidyl peptidase 4 (DPP-4) as an immune checkpoint molecule driving the hypometabolic state of exhausted CD8+ T cells. We found that DPP-4 is highly expressed by CD8+ T cells infiltrating brain tumors, and its expression levels increase with terminal exhaustion. Pharmacological inhibition of DPP-4 with the FDA-approved sitagliptin, which is used for the management of type II diabetes, transcriptionally and metabolically reprogrammed CD8+ T cells to upregulate lymphocyte activation pathways and enhance mitochondrial spare respiratory capacity. Functionally, DPP-4 inhibition increased proliferation, antigen-specific cancer cell killing capability, and cytotoxic mediator production of mouse CD8+ T cells and IL13Ra2 CAR T cells in vitro. Mechanistically, inhibiting DPP-4 upregulated glutamate decarboxylase 1 (GAD1), an enzyme that feeds glutamate into the tricarboxylic acid (TCA) cycle. Pharmacological inhibition of GAD1 abrogated sitagliptin-mediated T cell proliferation and metabolic reprograming of mouse and human CD8+ T cells, underscoring a new role for this enzyme in T cell functional regulation. Systemic inhibition of DPP-4 prolonged survival in preclinical glioblastoma (GBM) models in a CD8+ T cell-dependent manner. Furthermore, retrospective analysis indicated that GBM patients on DPP-4 inhibitors, gliptins, have better outcomes compared to those receive standard of care alone or in combination with metformin. Collectively, our results support repurposing the clinically used and well-tolerated class of DPP-4 inhibitors to enhance cancer immunotherapy responses.

#1339 On-demand GLUT3 expression augments CAR-T cell metabolic fitness and antitumor efficacy while preventing toxicity in glioblastoma models.

K. Watanabe[1], J. Yamaguchi[2], A. Nakamura[2], Y.-T. Lin[1], K. Itahashi[3], S. Koyama[1], D. Sugiyama[2], S. Kato[2], A. Nagata[1], H. Nishinakamura[1], Y. Shiraki[2], A. Enomoto[2], S. Maeda[2], F. Ohka[2], K. Motomura[4], Y. Tsukada[5], M. Ito[5], Y. Maeda[1], R. Ueda[2], A. Natsume[6], R. Saito[2], H. Nishikawa[1];

[1]National Cancer Center Japan, Tokyo, Japan, [2]Nagoya University Graduate School of Medicine, Nagoya, Japan, [3]National Cancer Center Japan, Kashiwa, Japan, [4]Shizuoka Cancer Center, Nagaizumi, Japan, [5]National Cancer Center Hospital East, Kashiwa, Japan, [6]Institute of Innovation for Future Society of Nagoya University, Nagoya, Japan

The clinical success of chimeric antigen receptor T (CAR-T) cell therapy in hematologic malignancies has prompted its application to refractory solid tumors, including glioblastoma (GBM). However, CAR-T cell efficacy against solid tumors remains modest. Here, we demonstrate that the dysfunction of CAR-T cells in GBM is attributed to glucose deficiency in the tumor microenvironment (TME) and that on-demand, but not continuous, metabolic replenishment significantly improves the antitumor efficacy of CAR-T cells. Massive consumption of glucose by cancer cells reduces the glucose level in the TME of GBM, consequently impairing CAR-T cells. Modifying CAR-T cells with stable expression of GLUT3, a high-affinity glucose transporter restored their cytokine production and killing activity. However, while CAR-T cells with stable GLUT3 expression induced tumor reduction in a GBM model, their overactivation led to T-cell apoptosis, exhaustion, and terminal differentiation as well as adverse events and mouse death. On-demand GLUT3 CAR-T cells, in which GLUT3 transcription is driven by the nuclear translocation of nuclear factor of activated T-cells (NFAT) by target antigen stimulation, exhibit enhanced metabolic fitness and increased antitumor efficacy, leading to long-lasting tumor control in intracranial human GBM cell xenograft models while preventing adverse events. Cognitive dysfunction testing and histological analysis using a neuron damage marker, fluoro-Jade C (FJC), in mice treated with on-demand GLUT3 CAR-T cells did not show any signs of toxicity. We propose that on-demand, but not stable, metabolic fitness, such as at the time of exposure to tumor antigens, is a novel concept for maximizing the antitumor efficacy of CAR-T cells against solid tumors.

#1340 The zinc finger 7 motif of TNFAIP3/A20 enforces a critical block in exhausted CD8 T cell degranulation and represents a potent target for enhancing adoptive cellular therapies for cancer.

A. Blaisdell, S. Bachl, L. R. Sandoval, C. Ching, M. Prabandham, R. Advincula, N. Lenci, A. Marson, C. J. Ye, B. A. Malynn, J. Eyquem, J. Carnevale, A. Ma;
University of California San Francisco, San Francisco, CA

Introduction: CD8 T cells eliminate tumors through effector cytokines (IFNgamma, TNF) and cytotoxic granule protein release (perforin, granzymes). The relative contribution of these mechanisms varies across tumor contexts, suggesting distinct modes of regulation. CD8 T cell exhaustion within the tumor microenvironment limits their cytotoxic potential and poses a major obstacle for cancer immunotherapy and adoptive cellular therapies (ACTs). While most studies of exhausted CD8 T cell (Tex) dysfunction have focused on impaired cytokine production, the regulation of perforin- and granzyme-mediated cytotoxicity, as well as the pathways governing CD8 T cell degranulation in general, remain poorly defined.

Methods & Results: We performed a genome-wide CRISPR knockout screen in repetitively stimulated human T cells and identified the multifunctional ubiquitin-modifying enzyme tumor necrosis factor alpha-induced protein 3 (*TNFAIP3*, or A20) as a key suppressor of T cell persistence and cytotoxicity in the face of exhaustive stress. Using a large language model, base editor tiling screen, and tumor models in hypomorphic A20 knock-in mice, we pinpointed the zinc finger (ZF7) motif of A20 as the crucial regulator of CD8 T cell cytotoxicity. We then incorporated base-editing into standard human ACT production workflow to introduce a single inactivating missense mutation in ZF7 that significantly improved ACT efficacy in preclinical leukemia and melanoma models. Although ZF7-edited T cells produced more IFNgamma and TNF, genetic ablation experiments revealed these cytokines were dispensable for improved tumor control. Instead, through in vivo and in vitro functional assays, we revealed an underappreciated block in perforin and granzyme degranulation — rather than expression — that was relieved by ZF7 ablation. Finally, genetic epistasis analyses uncovered a surprising role for receptor-interacting serine/threonine-protein kinase 3 (RIPK3) — a canonical activator of necroptosis without a defined role in CD8 T cell effector function — as the critical orchestrator of degranulation in ZF7-deficient cells.

Conclusions: Our findings highlight an underrecognized yet critical post-translational block in Tex degranulation, regulated independently of cytokine production, and relieved upon targeted disruption of the ZF7 motif in a RIPK3-dependent manner. These results demonstrate that selective targeting of central suppressors such as A20 can not only reverse CD8 T cell exhaustion but also engage alternative signaling programs to unleash cytotoxicity. These insights address critical gaps in our understanding of the biological networks that restrain perforin-dependent cytotoxicity in Tex and provide a foundation for enhancing the potency and durability of ACTs.

#1342 Expression of Galectin-1 in exhausted CD8$^+$T cells restrains their antitumor effector functions.

M. A. Scheidegger[1], J. P. Merlo[2], M. Massaro[1], J. M. Perez Saez[1], S. G. Gatto[1], R. M. Morales[1], A. J. Cagnoni[1], T. Dalotto-Moreno*[1], G. A. Rabinovich*[1];

[1]Instituto de Biologia y Medicina Experimental (IBYME-CONICET), Buenos Aires, Argentina, [2]Instituto de Biologia y Medicina Experimental (IBYME-CONICET); UADE - INTEC, Buenos Aires, Argentina

Antitumor immune responses are constrained by a plethora of inhibitory mechanisms that promote immune evasion. Galectin-1 (GAL1), a glycan-binding protein recognizing N-acetyllactosamine residues in complex N- and O-glycans promotes immunosuppression by expanding regulatory T cells, inducing tolerogenic dendritic cells and activating immunosuppressive circuits in myeloid-derived suppressor cells (MDSCs). Through single-cell RNA sequencing analysis, we identified elevated GAL1 expression in exhausted CD8$^+$ tumor-infiltrating T cells (Tex) compared to effector cells. We validated this observation at the protein level in *in vitro*-generated Tex (iTex) compared to early-activated T cells. *Lgals1*$^{-/-}$ CD8$^+$ Tex cells infiltrating B16 tumors displayed decreased expression of exhaustion-associated transcription factor TOX ($p<0.01$), suggesting a potential role of GAL1 in promoting CD8$^+$ T cell terminal differentiation. To test this hypothesis *in vivo*, we used CRISPR-Cas9 editing on OVA-restricted OT-I CD8$^+$ T cells to generate control and GAL1-deficient antigen-specific T cells (sg*Lgals1*), which we adoptively transferred into B16-OVA tumor-bearing *Rag2*$^{-/-}$ mice. Flow cytometry and RNA-sequencing analysis revealed that sg*Lgals1* tumor-infiltrating Tex conserved effector functions as evidenced by elevated Granzyme B, IFN-γ and TNF-α expression compared to control T cells ($p<0.001$). Mechanistically, we explored whether soluble GAL1 may contribute to T cell exhaustion by interacting with immune checkpoint receptors. Using lectin blot and solid-phase binding assays, we demonstrated that Gal1 differentially binds to a set of immune checkpoint receptors (including VISTA, PD-1, CTLA-4, LAG3, and TIGIT, but not TIM3) in a glycan-dependent manner, as binding was inhibited by lactose. To further pursue this observation, we performed isothermal titration calorimetry and confirmed GAL1-VISTA interaction with a dissociation constant (Kd) of 2.78 µM and GAL1-LAG3 interaction with a Kd of 12.75 µM. Then, we profiled VISTA expression on B16 tumor-infiltrating immune cells and found it to be highly expressed within the myeloid compartment, with minimal or absent expression in the lymphoid compartment and in tumor cells. Collectively, our results suggest a dual function for GAL1 in the tumor microenvironment. Endogenous GAL1 expression by CD8$^+$ Tex cells may promote a terminal dysfunctional state in an autocrine fashion, while simultaneously driving an immunosuppressive phenotype on myeloid cells through paracrine engagement of checkpoint receptors. Thus, targeting Gal1 may have therapeutic implications in cancer immunotherapeutic regimens including immune checkpoint blockade and adoptive cell transfer. Our future perspectives will be to focus both on signaling pathways triggered by GAL1 engagement of checkpoint receptors and on GAL1 intracellular functions during T cell exhaustion.

#1344 PTPN2/N1 inhibition drives a STAT3-mediated response in exhausted T cells and underscores targetable counter-regulatory mechanisms for T cell improvement.

Y. Senent[1], K. Bi[1], H. Keshishian[1], N. Kormshchikov[1], N. Knudsen[1], S. Carr[1], D. Sen[2], K. Yates[1], R. Manguso[1];
[1]Broad Institute of MIT and Harvard, Cambridge, MA, [2]MGH/Harvard Medical School, Cambridge, MA

New strategies to improve T cell function for immunotherapy and cell therapy are urgently needed. PTPN2 and PTPN1 are phosphatases that dephosphorylate members of the JAK–STAT signaling pathway and downstream TCR signaling kinases, positioning them as key negative regulators of cytokine signaling and T cell activation. Genetic deletion of PTPN2 or PTPN1 induces striking T cell–mediated anti–tumor immunity. However, despite the extensive knowledge on the enzymatic targets of PTPN2/N1, the signaling mechanisms leading to enhanced T cell function downstream of PTPN2/N1 loss are unclear. To address this, we performed transcriptional and phospho–proteomic profiling of human T cells treated with a PTPN2/N1 inhibitor (AC484) during chronic antigen stimulation. Using the CytoSig cytokine signaling inference method, we found that PTPN2/N1 loss drives robust activation of STAT3 signaling, accompanied by a counterintuitive inhibition of STAT5 activity. This pattern was consistent across both chronically stimulated human T cells and murine tumor–infiltrating T cells treated with AC484. Phospho–proteomic analyses confirmed a strong upregulation of phosphorylated STAT3, but a marked downregulation of JAK1/2/3 and STAT5 phosphorylation in PTPN2/N1 inhibitor–treated T cells. Conversely, acute PTPN2/N1 inhibition transiently increases STAT5 activity. Transcriptomic analyses further revealed potential mechanisms of feedback inhibition on JAK–STAT5 signaling, as several STAT3–driven counter regulatory factors were highly upregulated in chronically stimulated PTPN2/N1–deficient cells, such as SOCS3. SOCS3 is a well–established inhibitor of JAK1, JAK2, and TYK2, and can dampen STAT5 signaling; our results position SOCS3 as a strong candidate to mediate feedback inhibition. We hypothesize that PTPN2/N1 inhibition causes STAT3–mediated phenotypic changes in T cells, and while this is beneficial for enhancing T cell function, STAT3 also elicits upregulation of counter–regulatory factors that limit JAK–STAT5 signaling during chronic antigen stimulation and may ultimately restrain the persistence of PTPN2/N1–deficient T cells. Our next studies will elucidate the dynamic changes in signaling circuitry in PTPN2/N1–deficient T cells and leverage this knowledge to propose new strategies to counteract T cell exhaustion. These insights could inform the development of next–generation small molecule and cellular immunotherapies with improved efficacy and durability.

Biodesix, Inc., Louisville, CO

Non-small cell lung cancer (NSCLC) is a highly prevalent and genetically heterogeneous disease, making molecular profiling critical for guiding targeted therapy decisions. However, establishing on-site testing can be complex and costly and thus represents an unmet need in the community. The advent of liquid biopsy has increased accessibility of testing in rural and underrepresented groups in the United States, catalyzing large scale molecular profiling analyses. Data surrounding variant-level mutation frequencies across diverse U.S. populations remain limited, particularly from real-world settings in the community. This study evaluated more than 350,000 tests and 20 ethnically diverse groups for variant level frequencies of actionable molecular markers across the four major mutation classes (Single Nucleotide Variants/INDELs, Fusions, Amplifications, and Exon Skipping) in NSCLC, as identified from send-out liquid biopsy amplicon-based NGS and ddPCR testing over the past 10 years. The overall ddPCR positivity rate over the testing period was 1.5%. Among positive ddPCR results, KRAS G12C was the most frequent mutation (3.9%). NGS testing showed a 46% positivity rate for SNV/INDEL variants, with TP53 as the most frequently mutated gene (34%). NGS fusion positivity was 15%, with EML4-ALK.E6aA20.AB374361 being the most prevalent (12.95%). A disproportionate burden of NSCLC mutations was observed in African American patients, highlighting disparities in lung cancer prevalence. Geographically, the highest positive variant distributions were concentrated in the Southeastern U.S. region. These findings emphasize the utility of centralized molecular testing and the importance of including underrepresented populations in molecular profiling studies. Together, this data may help guide treatment decisions in the community setting.

#1302 Distinct Histology of Lung Cancer inpeople who have never smokedand Prognostic Determinants in Non-Mucinous Adenocarcinoma.

T.-V. Tran[1], M. Saha[1], H. Hoang[1], P. Bhawsar[1], R. Homer[2], M. K. Baine[3], L. M. Sholl[4], P. Joubert[5], C. Leduc[6], W. Travis[3], R. Pfeiffer[1], J. S. Almeida[1], D. R. Jones[3], G. Rocco[3], S. Yang[3], M. Landi[1];

[1]National Cancer Institute, National Institutes of Health, Rockville, MD, [2]Yale School of Medicine, New Haven, CT, [3]Memorial Sloan Kettering Cancer Center, New York, NY, [4]Brigham and Women's Hospital, Boston, MA, [5]Institut universitaire de cardiologie et de pneumologie de Quebec - Universite Laval, Quebec, QC, Canada, [6]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada

Purpose: Lung cancer in people who have never smoked (LCINS) is biologically distinct from smoking-related lung cancer yet remains histologically under-characterized. Prognostic frameworks, including the International Association for the Study of Lung Cancer (IASLC) grading system for non-mucinous adenocarcinoma, were developed in smoker-dominant cohorts and remain untested in LCINS. We characterized the LCINS histologic landscape and, within non-mucinous adenocarcinoma, evaluated the prognostic value of IASLC grade and additional histologic features. To our knowledge, this is the first large-scale study dedicated exclusively to LCINS histopathology.**Methods:** We established the LCINS histologic landscape using the Sherlock-Lung study. Sherlock-Lung H&E-stained whole slide images (n=844) were reviewed independently by ≥2 thoracic pathologists, with consensus resolution. Tumors were classified per WHO 5th edition. Prognostic analyses included non-mucinous adenocarcinoma from Sherlock-Lung (n=634, stage I-IV) and an external MSK cohort of R0-resected stage I-II patients (n=169). We used Kaplan-Meier and Cox models adjusted for age, ancestry, sex, and tumor stage. We evaluated IASLC grade, and pathologist-scored features not included in WHO classification—tumor-infiltrating lymphocytes (TILs; intense/not intense, “intense” indicating high lymphocyte density) for their impact on overall survival (OS) in Sherlock-Lung, and IASLC grade and STAS for OS and disease-free survival (DFS) in MSK.**Results:** LCINS were predominantly adenocarcinomas (84%; 75% non-mucinous), whereas carcinoid tumors accounted for 8%. In Sherlock-Lung (median follow-up 52 months; 202 deaths), Grades 1-2 had significantly better 5- and 10-year OS versus Grade 3 ($HR_{5\ years}$=0.30, 95%CI 0.18-0.50; $HR_{10\ years}$=0.36, 95%CI 0.24-0.53), most strongly in stage I ($HR_{10\ years}$=0.29, 95%CI 0.16-0.53; $p_{interaction}$=0.03). Intense TILs independently improved long-term OS ($HR_{5\ years}$=0.64, 95%CI 0.36-1.11; $HR_{10\ years}$=0.51, 95%CI 0.30-0.86). In MSK (median follow-up 43 months; 21 deaths, 30 DFS events), grades 1-2 showed consistently better OS and DFS, although not statistically significant (OS: $HR_{5\ years}$=0.91, 95%CI 0.28-3.02; DFS: $HR_{5\ years}$=0.61, 95%CI 0.26-1.43) and STAS was not associated with either endpoint.**Conclusion**: In the largest LCINS cohort to date, we defined distinct histologic features and verified the prognostic value of the IASLC grading system, with Grade 3 indicating worse survival. TIL assessment further refined risk stratification, highlighting the need for further smoking-specific histological evaluation and larger prospective studies.

#1303 Real-world overall survival with trastuzumab deruxtecan versus standard chemotherapy in HER2-amplified MSS metastatic colorectal cancer.

Sumbal Aziz[1], **Zunairah Shah**[2], Mariam H. Ahmad[2], Jayasree Krishnan[2], Sohaib Asghar[1], Woojoo Lee[1], Sheheryar Kabraji[2], Kannan Thanikachalam[2]

[1]Adventhealth, Sebring, FL,[2]Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: HER2-positive (HER2-amplified, IHC3+) microsatellite-stable (MSS), metastatic colorectal cancer (mCRC) represents a small but clinically meaningful subgroup with aggressive biology and limited responsiveness to standard chemotherapy. Trastuzumab deruxtecan (T-DXd), a HER2-targeted antibody-drug conjugate, has shown encouraging activity in DESTINY-CRC01 and DESTINY-CRC02. However, real-world effectiveness of T-DXd remains unclear due to variability in comorbidities, performance status, treatment sequencing, and prior therapy exposure. This study evaluated real-world overall survival (OS) with T-DXd versus standard chemotherapy in patients with MSS, HER2-amplified mCRC to assess effectiveness outside trial settings.
Methods: De-identified TriNetX data (2010-2025) were used to identify adults (>18 years) with HER2-amplified mCRC treated with either second-line chemotherapy (FOLFOX, FOLFIRI, or CAPOX ± bevacizumab) or T-DXd as second-line of treatment. Because anti-EGFR therapy is ineffective in HER2-amplified disease, cetuximab- or panitumumab-treated patients were excluded. Patients were assigned to cohorts based on the line in which T-DXd or standard chemotherapy was initiated. Propensity score matching (1:1) balanced age, sex, comorbidities, metastatic burden, and prior therapies. OS was evaluated using Kaplan-Meier estimates, log-rank tests, and Cox proportional hazards models. Hazard ratios (HRs) with 95% confidence intervals (CIs) were reported; significance was defined as two-sided $P \leq 0.05$.
Results: Two cohorts were identified: standard chemotherapy (n = 9,135) and T-DXd (n = 1,977). Before matching, the T-DXd cohort was slightly older (67.4 ± 13.1 vs 66.5 ± 12.8 years; p = 0.006) and had more females (71% vs 49%; p = 0.0001). Both groups had received one prior line of systemic therapy. After 1:1 propensity score matching (n = 1,870 each), demographics, clinical characteristics, and prior treatments were well balanced. In the matched population, 1-year OS was only slightly different (83.0% vs 84.8%; p = 0.03). However, 5-year OS favored T-DXd (66.6% vs 62.1%; p = 0.0046). Multivariable Cox regression demonstrated a significantly higher mortality risk with standard chemotherapy compared with T-DXd (HR 1.14; 95% CI, 1.05-1.24; p = 0.0024).
Conclusion: Although DESTINY-CRC01 evaluated T-DXd in the third-line or later setting, where patients had received a median of four prior therapies, this real-world analysis demonstrates that T-DXd is associated with improved long-term survival even when used in the second line setting, with fewer treatment-related adverse events. In patients with HER2-amplified mCRC, T-DXd showed a meaningful 5-year overall survival advantage compared with standard chemotherapy.

#1304 Cancer risk with initiation of angiotensin receptor blockers (ARBs) vs. angiotensin converting enzyme inhibitors (ACEIs).

C. Himbert[1], D. K. Addo[1], Y. Xu[1], T. He[1], C. G. Derington[2], T. Greene[1], J. B. Cohen[3], A. Bress[1], S. Hardikar[1];
[1]University of Utah, Salt Lake City, UT, [2]University of Colorado, Aurora, CO, [3]University of Pennsylvania, Philadelphia, PA

Background: The comparative long-term effects of initiation of an angiotensin receptor blocker (ARB) and angiotensin-converting enzyme inhibitor (ACEI) on cancer risk remain uncertain. The objective of this study was to compare risks of cancer and non-cancer mortality between ARB and ACEI initiators among US veterans.
Methods: This prospective cohort included 2,658,758 veterans with hypertension and no history of cancer who initiated either an ARB or an ACEI within the Veterans Health Administration between January 1, 2000, and December 31, 2017. Participants were followed from treatment initiation until the first occurrence of an outcome, death, loss to follow-up, or December 31, 2022 (the end of study). Initiation of ARB or ACEI treatment was determined from pharmacy dispensing records, excluding those with a history of cancer or who filled ARB or ACEI before the study period. The index date (baseline) was defined as the date of initiating either treatment. Inverse probability (IP) of treatment weighting was applied to adjust for 27 baseline covariates and estimate the intent-to-treat effect of ARB versus ACEI initiation. The co-primary outcomes were time to any cancer (ascertained from the VA Cancer Registry) and non-cancer mortality. Secondary outcomes included all-cause mortality, the composite of any cancer or death, incidence of specific cancers, and non-cancer-specific mortality. Cumulative incidence functions and risk ratios (RRs) with 95% confidence intervals (95% CI) were calculated using IP-weighted Aalen-Johansen estimator in the competing risks setting.
Results: Among 2,658,758 veterans (median follow-up, 10 years; mean age, 63 years; 5% women; 76% non-Hispanic White; 15% Black), 90% initiated ACEIs and 10% initiated ARBs. ARB initiation was associated with a lower 10-year risk of any cancer (RR, 0.79; 95% CI, 0.75-0.83) and a similar 10-year risk of non-cancer mortality (RR, 1.03; 95% CI, 0.88-1.07) compared with ACEI initiation. Associations were consistent across most cancer types, except for inconclusive findings for breast and renal cancers. In subgroup analyses, a stronger inverse association between ARB initiation compared to ACEI initiation and cancer risk was observed among older patients (≥70 years).
Conclusions and Relevance: ARB initiators had a lower risk of developing any cancer compared with initiation of ACEIs, with no observed difference in non-cancer or all-cause mortality. We also reported stronger inverse association for ARBs in older adults in subgroup analyses. Further research should clarify underlying biological mechanisms, confirm causality in randomized trials, and evaluate personalized antihypertensive strategies that incorporate cancer risk considerations.

#1305 Assisted reproductive technology and the risk of female sex hormone-related cancers.

E. P. Lin[1], C.-H. Lin[2], C.-Y. Hsu[3], W.-S. Lin[2], J.-C. Chang[2], B.-T. Huang[1], H.-N. Ho[1], Y. Shyr[3];
[1]Taipei Medical University, Taipei, Taiwan, [2]Taichung Veterans General Hospital, Taichung, Taiwan, [3]Vanderbilt University Medical Center, Nashville, TN

Background: Whether assisted reproductive technology (ART) treatment is associated with the risk of female sex hormone-related cancers is inconclusive.
Methods: This study leveraged the national data from Taiwan to assemble the largest ART cohorts. The primary objective was to assess the associations of ART with the risk of breast, ovarian, and endometrial cancers. The secondary objectives included the associations of ART cycle numbers, age at the first ART treatment, and history of childbirth with the risk of these cancers. Cox proportional hazards regression models were used for data analysis.
Results: The cohorts with or without ART exposure for breast, ovarian, or endometrial cancer risk assessment included 104,486, 104,936, or 104,913 subjects, respectively. The results showed that ART was independently associated with an increased risk of breast (HR, 1.11; 95% CI, 1.04 to 1.19) and ovarian (HR, 1.38; 95% CI, 1.13 to 1.69) cancers, but not endometrial cancer. The data also revealed a dose-response relationship between ART cycle numbers ($\geq$2 versus 1) and the risk of breast (HR, 1.13; 95% CI, 1.03 to 1.25) and ovarian (HR, 1.45; 95% CI, 1.10 to 1.90) cancers. No statistically significant associations between age at the first ART and the risk of these cancer types were observed. Subgroup analyses suggested protective effects of childbirth against ovarian and endometrial cancers.
Conclusions: This study demonstrated a statistically significant increase in the risk of breast and ovarian cancers among women with ART treatment. The results suggested that regular checkups for cancer should be considered once ART exposure is established.

#1306 Developing a real-world clinical genomic platform to deliver precision oncology in underrepresented populations.

Shubhankar Sood[1], Daniel Hubschmann[2], Jennifer Wischhusen[3], Andreas Trumpp[3]

[1]Global Precision Medicine (GPM), Heidelberg Institute for Stem Cell Technology and Experimental Medicine, Heidelberg, Germany,[2]Pattern Recognition and Digital Medicine, Heidelberg Institute for Stem Cell Technology and Experimental Medicine, Heidelberg, Germany,[3]Stem Cells and Cancer, Heidelberg Institute for Stem Cell Technology and Experimental Medicine, Heidelberg, Germany

Around 14% of the world's population currently represents more than 75% of oncology clinical trials and genomic datasets, with the majority derived from individuals of Caucasian ancestry. Precision oncology drugs developed over the past decade have been validated largely on this skewed representation. As a result, targeted therapies often perform inconsistently in regions with the highest cancer burden, leading to reduced effectiveness, increased toxicity, and substantial economic losses from failed clinical applicability. To address this unmet need, we developed a global real-world clinical genomic platform through a bilateral collaboration between India and Germany. This platform links major oncology centers in India with the Global Precision Medicine research group in Heidelberg, one of Europe's largest precision-oncology and clinical-trial hubs. At its core, we developed a novel digital interface for structured clinical data capture at source, supported by clinician training and AI-based integration of epidemiological, diagnostic, imaging, and pathology information. We also introduced deep whole genome sequencing with tumor-matched controls using a nationwide snap-frozen workflow, coupled with tumor transcriptome sequencing as part of our multi-omics program. All multimodal data are processed through a validated analytical framework for alignment, variant calling, expression profiling, biomarker annotation, and molecular tumor board integration.

With our platform, we aim to generate real-world multi-omics data for 10,000 genetically diverse patients across India, forming one of the largest clinically annotated oncology datasets from underrepresented populations globally. Initial integration shows that multi-institutional datasets can be harmonized with European pipelines, enabling high-quality sequencing and structured clinical annotation. Early analyses suggest genomic and transcriptional differences compared to European cohorts, including variation in mutational signatures, copy-number profiles, and immune-related states. These insights support the development of context-specific biomarkers and decision-support modules tailored to underrepresented populations.

In conclusion, our platform delivers two parallel value additions. Clinically, it identifies additional actionable mutations, supports combinatorial therapy recommendations, and reveals missed diagnostics. Scientifically, the high-resolution dataset enables biomarker discovery, patient-stratification models, and early identification of therapeutic vulnerabilities. Together, our clinical genomics platform provides a scalable blueprint for integrating underrepresented populations into global cancer genomics and positions these cohorts as essential contributors to the future of precision oncology.

#1307 Pan-cancer landscape of alternative lengthening of telomeres revealed by machine learning analysis of clinical sequencing data.

Harshit Sahay, Bill H. Diplas, Oluchi C. Ezekwenna, Divya Koyyalagunta, Simran Chhabria, Madison Darmofal, Quaid Morris, Agnel Sfeir

Memorial Sloan Kettering Cancer Center, New York, NY

Replicative immortality is a hallmark of cancer, achieved by activating telomere maintenance mechanisms (TMMs), which prevent telomere shortening and senescence. While the majority of tumors achieve this via the reactivation of telomerase, a significant subset (10-15%) relies on alternative lengthening of telomeres (ALT), a recombination-driven mechanism of telomere maintenance. ALT is highly tumor type-specific, most frequently seen in mesenchymal tumors. ALT is strongly associated with inactivating mutations in chromatin remodeling genes ATRX and DAXX, however, many ALT tumors lack alterations in these genes. Additionally, ATRX loss alone in in vitro models is insufficient for triggering ALT. Together, these underscore that the underlying mechanisms of ALT remain incompletely understood. A critical gap has been incomplete characterization of the genetic landscape of ALT, as laborious detection assays restrict studies to specific histologies or to tumors with limited genetic profiling.

To address this, we sought to use the MSK-IMPACT clinical cohort. MSK-IMPACT is an FDA-approved targeted sequencing panel used for routine genetic profiling of tumors, with >100,000 patients profiled across 80+ tumor types. We developed a machine learning framework to infer ALT status by leveraging typically discarded off-target reads. These reads contained telomeric sequences, enabling us to quantify telomere content and repeat composition. We then assessed the presence of ALT experimentally using the C-circle assay (CCA) for 700 patient samples. ATRX/DAXX truncations were strongly associated with ALT but did not show complete correspondence. Using telomeric features from 300 tumors with high-confidence CCA results, we trained an ensemble of Random Forest classifiers with stratified five-fold cross-validation to predict ALT status, achieving robust performance (mean ROC-AUC = 0.84; PRC-AUC = 0.76). Models were then calibrated and ensembled to generate predictions for 78,704 patient tumors in MSK-IMPACT. Model predictions corresponded well with known ALT patterns. Highest prevalence was seen in sarcomas, gliomas, and neuroendocrine tumors, particularly in ATRX/DAXX mutant tumors, with low or no prevalence in TERT-altered tumors. Interestingly, the model predicted low but notable ALT prevalence in ATRX/DAXX wild-type tumors within ALT-relevant pathologies. MSK-IMPACT annotations enabled identification of ALT-associated genetic factors beyond ATRX/DAXX in these tumors.

Our framework enables scalable ALT detection from routine clinical sequencing data and provides an updated picture of ALT prevalence across a wider range of tumor types than previously possible. This resource can be used to identify novel genetic associations, assess differential treatment response and prognosis, and guide therapeutic decisions targeting TMMs.

Minisymposium

#1329 Preclinical development of EFTX-G12V, a first-in-class EGFR-directed KRAS G12V selective inhibitor.

Lyla J. Stanland[1], Hayden Huggins[1], Snehasudha S. Sahoo[2], Alessandro Porrello[2], Yogitha Chareddy[2], Salma Azam[2], Jillian Perry[2], Pradeep S. Pallan[3], Kristina Whately[2], Lincy Edatt[2], William D. Green[2], Matthew C. Fleming[4], Jonah Im[2], Christina Gutierrez-Ford[2], Imani Simmons[2], Alyaa Dawoud[2], Katherine I. Zhou[2], Vandanaa Jayaprakash[1], Rani Sellers[5], Gabriela de la Cruz[5], Albert Wielgus[5], Justin Milner[2], Martin Egli[3], Albert A. Bowers[2], Chad V. Pecot[2]

[1]EnFuego Therapeutics Inc, Morrisville, NC,[2]Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC,[3]Biochemistry, Vanderbilt University, Nashville, TN,[4]Eshelman School of Pharmacy, University of North Carolina, Chapel Hill, NC,[5]Pathology and Laboratory Medicine, University of North Carolina, Chapel Hill, NC

The KRAS proto-oncogene encodes a small GTPase that is crucial for the activation of intracellular signaling pathways that control cell proliferation, survival and differentiation. *KRAS* is frequently mutated in cancer resulting in its constitutive activation and dysregulation of downstream signaling pathways that drive oncogenic transformation. KRAS G12V is the second most common KRAS mutation in cancer, and occurs frequently in lung, colon and pancreatic cancers. However, while significant advancements have been made in developing KRAS G12C, G12D and pan-KRAS inhibitors, there remain no direct KRAS G12V inhibitors in the clinic. Previously, we developed EFTX-G12V, a fully-modified, mutant-selective, ligand-conjugated siRNA that shows significant anti-tumor activity in multiple cancer models. EFTX-G12V inhibits KRAS G12V expression at both the mRNA and protein level while completely sparing KRAS WT. Further, EFTX-G12V significantly inhibited cancer cell growth *in vitro* and displays no concerning off-target effects. Importantly, our approach takes advantage of high tumor expression of EFGR where our siRNA is conjugated to an EGFR linear ligand that enables high tumor-to-normal tissue payload delivery in models with varying levels of EGFR expression. EFTX-G12V significantly inhibited KRAS G12V mRNA and protein *in vivo* and showed significant anti-tumor activity in lung, colon and pancreatic xenograft models. Critically, EFTX-G12V showed no off-target effects on WT KRAS in somatic tissues. Unexpectedly, we found that EFTX-G12V showed improved efficacy in comparison to a pan-KRAS siRNA which we found is due to increased inhibition of tumor angiogenesis in EFTX-G12V treated groups. Here, we describe further preclinical evaluation of EFTX-G12V including pharmacokinetics in mouse xenograft models and the efficacy and safety profile in an immunocompetent mouse model. We performed a pharmacokinetic evaluation of the antisense strand of EFTX-G12V in plasma, tumors, skin, kidney and liver tissue following a single injection. We observed clearance of the siRNA from the plasma within four hours and uptake of a therapeutic dose level in tumor tissue through 96 hours post injection, with limited exposure to somatic tissues. We evaluated EFTX-G12V in an immunocompetent mouse model and observed significant tumor reduction and a robust anti-tumor immune response that was not a result of a systemic inflammatory response and displayed no concerning toxicities. Lastly, we recently completed non-GLP safety studies in rat and mini-pig models and observed no test article related clinical observations, no injection site reactions and initial gross pathology detected no visible lesions across all tissues. Together these data indicate that EFTX-G12V has therapeutic efficacy in multiple cancer models, is delivered to tumor tissue with minimal somatic tissue exposure, and may be well tolerated.

#1330 Targeting Aurora kinase A for potentiating colorectal cancer to KRAS targeted therapy.

Zhaojin Liu[1], Ning Wei[2], Suisui Hao[1], Xinyan Lu[1], Jian Yu[3], Lin Zhang[3]

[1]USC - University of Southern California, Los Angeles, CA,[2]Montefiore Comprehensive Cancer Center, Bronx, new york, NY,[3]USC Norris Comprehensive Cancer Center, Los Angeles, CA

Colorectal cancer (CRC) is one of the most prevalent and lethal types of cancer worldwide. The development and progression of CRC are driven by the activation of multiple oncogenes, notably KRAS. Mutations in KRAS are among the most common oncogenic alterations, occurring in ~45% of CRC cases. KRAS plays a pivotal role in cell signaling by serving as a binary switch of MAPK/ERK and PI3K/AKT pathways downstream of the epidermal growth factor receptor (EGFR). Two $KRAS^{g12c}$ inhibitors, sotorasib and adagrasib, have been approved for monotherapy against non-small cell lung cancer (NSCLC). However, both drugs have shown limited efficacy in CRC, indicating an intrinsic resistance mechanism. Similarly, the recently developed pan-RAS inhibitor RMC-6236 exhibits only modest activity in KRAS-mutant CRC, highlighting the urgent need for rational combination strategies to overcome therapeutic resistance. Anticancer therapies commonly suppress tumor growth by inducing apoptosis, a major form of programmed cell death. However, $KRAS^{g12c}$ inhibitors alone have been shown to fail in inducing apoptosis in $KRAS^{g12c}$ CRC cells. In this study, we investigated strategies to enhance apoptosis and sensitize KRAS-mutant CRC to KRAS-targeted therapies. We identified Aurora kinase A (AURKA), an oncogenic kinase that regulates the G2/M transition in cell cycle, as a key suppressor of apoptosis in KRAS-mutant CRC cells under KRAS inhibition. Co-inhibition of AURKA and KRAS elicited potent anti-tumor effects both *in vitro* and *in vivo*. Mechanistically, AURKA inhibition enhanced apoptosis by downregulating the anti-apoptotic Bcl-2 family member Mcl-1. Concurrent AURKA blockade suppressed the rebound activation of KRAS downstream signaling, facilitating the degradation of Mcl-1 mediated by GSK3β. Moreover, Mcl-1 inhibition further sensitized KRAS-mutant CRC cells to KRAS inhibitors. Collectively, our findings support AURKA inhibition as a promising combination strategy to overcome intrinsic resistance to KRAS-targeted therapies in CRC.

#1331 The Kinase Library: A global atlas of the human protein kinome and its applications in cancer.

Tomer M. Yaron-Barir[1], Jared L. Johnson[1], Benjamin E. Turk[2], Michael B. Yaffe[3], Lewis C. Cantley[1]

[1]Cell Biology, Dana-Farber Cancer Institute / Harvard Medical School, Boston, MA,[2]Yale University, New Haven, CT,[3]Koch Inst. for Integrative Cancer Research at MIT, West Roxbury, MA

Mass-spectrometry-based phosphoproteomics now profiles phosphorylation at proteome scale, yet converting site-level measurements into coherent, kinase-centered biology remains a persistent barrier to interpretation and action. *The Kinase Library* addresses this gap with the first-in-class, unbiased, experimentally characterized motif atlas of the human kinome, coupled to enrichment frameworks that translate phosphoproteomics data into quantitative maps of kinase activity. Rather than relying on heterogeneous annotations or heuristic rules, KL grounds inference in experimentally derived kinase-substrate relationships, providing a principled basis for comparative signaling analysis. The Kinase Library has broad utility across discovery and translational applications. It enables mechanism-of-action profiling for small molecules and combinations; delineates adaptive signaling and resistance trajectories; supports time-course and dose-response studies to resolve pathway dynamics; and stratifies models and patients in *low-N-high-D* (few samples with high dimensionality of data) settings where conventional statistics underperform. In clinical and preclinical contexts alike — cell lines, organoids, xenografts, and patient specimens — the Kinase Library delivers harmonized, interpretable kinase signatures that are readily integrated with genomic, transcriptomic, and phenotypic readouts to generate and prioritize actionable hypotheses. The novelty of the Kinase Library is twofold. First, scope and provenance: an experimental, unbaised atlas spanning the entire kinome, with comprehensive inclusion of the dark kinome. Second, operationalization: a unified enrichment paradigm that yields robust, rank-ordered kinase programs suitable for decisionmaking — whether the objective is target nomination, combination design, biomarker discovery, or comparative benchmarking across cohorts and studies. Looking forward, the Kinase Library is positioned to empower emerging frontiers in proteomics: single-cell and spatial phosphoproteomics; longitudinal “N-of-1” monitoring to guide therapy; cross-species translation for model selection; and cloudnative workflows that interoperate with community pipelines and public datasets. By elevating kinases from disparate lists of regulated sites to coherent, testable signaling hypotheses, the Kinase Library reframes what phosphoproteomics can deliver — shifting the field from descriptive measurement toward predictive, mechanism-guided intervention.

#1332 Selective targeting of the α3β4 nicotinic acetylcholine receptor by DISCO (dual interacting subunit complex) CAR T cells.

Patrick M. Schurch[1], Vincent P. Zecchino[1], Anna M. Giudice[1], Rebecca S. Kaufman[1], Evan Cresswell-Clay[1], Guillem Pascual-Pasto[1], Sydney L. Roth[1], Brendan C. McIntyre[1], Rawan Shraim[1], Amber K. Hamilton[1], Kush Parikh[1], Karina L. Conkrite[1], Khanh B. Trang[1], Grant P. Grothusen[1], David Groff[1], Pamela Mishra[1], Simona Lombardi[1], Tyler Skinner[1], Andrew D. Wells[1], Struan F. A. Grant[1], Daniel Martinez[1], Wei Li[2], Sharon J. Diskin[1], Kristopher R. Bosse[1]

[1]Division of Oncology, Children's Hospital Of Philadelphia, Philadelphia, PA,[2]Department of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA

Developing effective chimeric antigen receptor (CAR) T cell therapies for pediatric solid tumors requires discovery of highly tumor-selective cell surface molecules. Using a multimodal immunotherapeutic target discovery platform, we identified a receptor composed of the nicotinic acetylcholine receptor subunits α3 and β4 as a new previously unrecognized immunotherapeutic target in neuroblastoma. *CHRNA3* (α3) and *CHRNB4* (β4) are robustly differentially overexpressed in neuroblastoma compared with normal tissues, driven by a super-enhancer upstream of the *CHRNA3/B4* locus on chromosome 15q25 that is occupied by neuroblastoma core regulatory transcription factors and physically engages both promoters. Neuroblastoma cells exhibit abundant α3 and β4 protein, which bind and assemble into a stabilized α3β4 complex displayed at high levels on the neuroblastoma cell surface. Functionally, genetic depletion of α3 also reduced β4 levels, induced mesenchymal cell state-associated marker expression, and increased proliferation and invasion in neuroblastoma cell line models. To therapeutically exploit this tumor-restricted α3β4 receptor expression, we engineered Dual Interacting Subunit COmplex (DISCO)-specific single chain variable fragments (scFvs) designed to recognize an epitope requiring simultaneous engagement of both α3 and β4 subunits of the α3β4 cell surface receptor. DISCO CAR T cells generated from these scFvs bound selectively to and were potently activated by the α3β4 receptor, but not either subunit individually. α3β4-targeted DISCO CAR T cells demonstrated potent and selective cytotoxicity across diverse neuroblastoma cell lines and three patient-derived xenograft (PDXs) models, significantly extending the survival of mice harboring PDXs with a range of α3 and β4 expression ($P < 0.05$). Beyond neuroblastoma, *CHRNA3* and *CHRNB4* are also highly expressed in small cell lung cancer (SCLC) and retinoblastoma, among several other tumors. The identical super-enhancer is associated with high levels of *CHRNA3* and *CHRNB4* in SCLC, suggesting similar mechanisms of tumor-driven overexpression. In an intraocular retinoblastoma xenograft model, a single intravitreal dose of α3β4-redirected DISCO CAR T cells achieved marked tumor control and significantly extended ocular survival ($P = 0.0015$), collectively showing disease-relevance and targetability beyond neuroblastoma. Together, these findings broaden the repertoire of actionable CAR T cell targets in pediatric and adult solid tumors by validating the α3β4 receptor, and more broadly the nicotinic acetylcholine receptor family, as bona fide immunotherapeutic candidates. Moreover, these studies demonstrate that CARs can be designed to recognize disease-relevant subunit configurations within multidomain surface receptors.

#1333 REST represses neuroendocrine transcriptional programs and enables anti-tumor immunity in SCLC.

Jackson P. Fatherree, Kelly Heard, Alex Doan, Joseph Hiatt, Daniel S. Hippe, Feinan Wu, Shivani Srivastava, David MacPherson

Fred Hutchinson Cancer Center, Seattle, WA

Small-cell lung cancer (SCLC) is a devastating neuroendocrine carcinoma in critical need of new therapeutic approaches. While a small subset of patients responds well to standard of care chemo-immunotherapy, durable responses are rare. Recent studies have revealed substantial transcriptional and functional heterogeneity, including the identification of multiple low-neuroendocrine SCLC subtypes, which we and others have linked to increased inflammation and response to immunotherapy. A major mediator of neuroendocrine state in SCLC is the transcription factor REST, which is a repressor of neuronal/neuroendocrine genes. While REST is typically silenced in SCLC, it is active in inflamed, low-neuroendocrine SCLC. However, links between REST and immune phenotypes in SCLC have been understudied. To explore the interplay between REST/neuroendocrine status, immune infiltration and response to clinically relevant therapies, we first generated an autochthonous mouse model of SCLC in the *Rb*/*p53*-null (RP) background with conditional REST expression (RP-REST). Transcriptionally, REST expression promoted a low-neuroendocrine SCLC phenotype with decreased expression of ASCL1 target genes compared to RP controls. In contrast, RP-REST tumors displayed a striking enrichment of antigen presentation and inflammatory response gene signatures, which correlated with increased infiltration of CD8+ T cells and F4/80+ macrophages, confirming that REST expression generates inflamed, low-neuroendocrine SCLC. We then overexpressed REST in a panel of murine SCLC cell lines derived from the RP mouse model and confirmed REST-driven repression of a neuroendocrine gene signature. Moreover, REST overexpression potentiated responses to interferon-γ resulting in increased MHC-I antigen presentation and phospho-STAT1. Using murine cell lines to generate syngeneic allografts in immunocompetent mice, we found that REST overexpression sensitized tumors to PD1 checkpoint blockade *in vivo*. Multiparameter flow cytometry reveals that these responses were associated with increased infiltration of activated CD8+ T cells, in addition to an expansion of M1 macrophages. Further, scRNAseq of the tumor compartment identifies a subset of cells in REST-expressing tumors with exceptionally high levels of inflammatory signaling, including secreted cytokines that may serve to recruit the abundant immune cells found in these tumors. Tumor heterogeneity is a critical variable in determining patient outcomes clinically. Here, we show that REST drives a low-neuroendocrine, inflamed SCLC phenotype in an autochthonous mouse model, which is corroborated by isogenic models showing reduced neuroendocrine markers, increased antigen presentation and sensitivity to immunotherapy.

#1334 Age related phenotypic changes in melanoma create a tumor vulnerability to ferroptosis.

Murilo Ramos Rocha[1], Yash Chhabra[2], Alexis Erasta Carey[3], Cheyenne M. Palm[1], Kevin Y. Zhang[3], Joanne Kotelawala[1], Elizabeth Harper[1], Fan Huang[1], Ashani Weeraratna[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[2]Fox Chase Cancer Center, Philadelphia, PA,[3]Johns Hopkins University School of Medicine, Baltimore, MD

Aging is an independent poor prognostic factor for melanoma, the most aggressive form of skin cancer. Among the characteristics of aging, the accumulation of iron, polyunsaturated fatty acids, and reactive oxygen species can reshape the skin microenvironment and lead to changes in how melanoma progresses in the aged skin. Here, we investigate the impact of these characteristics of the aged tumor microenvironment and how phenotypic changes in melanoma cells create a tumor vulnerability to ferroptosis, a caspase-independent lipid peroxidation-mediated type of cell death, a possible therapeutic opportunity for older patients. KEGG pathway enrichment analysis on the proteomic data from young and aged mice shows an enrichment in the ferroptosis pathway. Through immunohistochemistry, we confirmed this pro-ferroptosis signature in the skin and using human aged dermal fibroblasts in vitro, observed that their secretome enhanced the cytoxicity of ferroptosis inducers such as RSL-3 (a GPX4 inhibitor) on melanoma cells. To understand how ferroptosis impacts tumor growth in young and aged mice, we used a syngeneic tumor model with intra-dermal administration of Yumm1.7 cells and the treatment with a lipid peroxidation inducer (imidazole ketone erastin - IKE). Although showing a general effect, IKE treatment significantly reduced tumor growth in older mice. Tumors from aged mice showed stronger immunoreactivity to 4-HNE (lipid peroxidation byproduct) when compared to young. This occurred in parallel with increases in AXL and Wnt5a staining. To comprehend the mechanisms driving this age-specific effect, we investigated if the phenotype switch that occurs in melanoma cells present in the aged TME would favor ferroptosis. Correlation between transcriptomic (TCGA-SKCM) and sensitivity data (CTD^2) confirmed that phenotype-switching markers, such as Wnt5a, showed a strong correlation with ferroptosis-related transcripts and an inverse correlation with ferroptosis resistance. Using a panel of melanoma cell lines with distinct Wnt5a levels, we confirmed this association and observed that critical regulators of lipid peroxidation are downregulated with high Wnt5a high: GPX4, AIFM2, and GCH1. The association between Wnt5a levels and ferroptosis regulators were confirmed experiments with the knock down or overexpression of Wnt5a. In a 3D in vitro model, RSL-3 inhibited the invasion of melanoma cells. These results indicate that ferroptosis modulation could be used to prevent metastatic dissemination and is a promising avenue for combined treatment with existing clinical strategies.

#1335 The ubiquitin E3 ligase $SCF^{Skk2/Cks1}$ complex: A critical node coupling cell cycle control, tumorigenesis, and lineage fidelity in small cell lung cancer (SCLC).

Saumen Karan[1], Hongling Zhao[2], Yingjiao Xue[2], Xinrui Zhang[1], Bang Hoang[3], Luc Girard[4], Benjamin Drapkin[4], John D. Minna[4], Edward L. Schwartz[5]

[1]Oncology, Albert Einstein College of Medicine, Bronx, NY,[2]Albert Einstein College of Medicine, Bronx, NY,[3]Orthopedic Surgery, Albert Einstein College of Medicine, Bronx, NY,[4]UT Southwestern Medical Center, Dallas, TX,[5]Oncology & Molecular Pharmacology, Albert Einstein College of Medicine, Bronx, NY

Background: Mutation and inactivation of *RB1* and *TP53* are required and sufficient to drive small cell lung cancer (SCLC) tumorigenesis, both clinically and in mouse genetic models. We previously reported that the knockout of the Skp2 component of the ubiquitin E3 ligase $SCF^{Skp2/Cks1}$ protected *Rb1/Trp53*-deficient mice from SCLC tumorigenesis but also increased the frequency of lung tumors with non-SCLC phenotypes. To explore this observation, we used a SCLC mouse model in which tumorigenesis was induced by CGRP-Cre-mediated deletions of *Rb1, Trp53*, and *Pten* (RPPt) in the neuroendocrine cells of the lungs. We crossed these to mice with either *Skp2* knockout or the knockin (KI) of a mutated, inactivated SCF^{Skp2} accessory protein, Cks1 ($Cks1^{N45R}$), that prevents the binding of p27 to SCF^{Skp2}.

Methods: We generated mouse lung cancer models using neuroendocrine cell-specific *Rb1; Trp53; Pten* triple-knockout mice with Skp2-KO or with $Cks1^{N45R}$ KI. Tumorigenesis, survival, and metastasis were monitored. Lung tumors were analyzed for neuroendocrine, SCLC subtype, squamous and other markers. Primary cell lines were established from lung tumors and characterized for lineage fidelity and sensitivity to cytotoxic and targeted drugs *in vitro* and *in vivo.*

Results: Skp2 mRNA was elevated in human SCLC cell lines and PDXs. In RPPt mice, both *Skp2*-KO and $Cks1^{N45R}$ KI reduced lung tumor and liver metastasis incidence, increased survival, and caused a striking phenotypic shift. RPPt mouse tumors were SCLC with neuroendocrine staining. In contrast, tumors in both Skp2-KO and $Cks1^{N45R}$ KI mice lacked neuroendocrine markers and had squamous cell histology with staining for Sox2, KRT5, and p63. RPPt lung tumors were $ASCL1^{+}$ and $YAP1^{-}$. Conversely, the Skp2-inactivated tumors were $ASCL1^{-}$ and $YAP1^{+}$ and retained SMARCA4 expression. Cell lines derived from the RPPt lung tumors grew more rapidly and were more sensitive to cisplatin and etoposide than were the lung tumor cells from the RPPt-$Cks1^{N45R}$ KI mice. The RPPt lung tumor cells were also more sensitive to growth inhibition by the $SCF^{Skp2/Cks1}$ inhibitors C1 and pevonedistat and the CDK1/2/5/9 inhibitor dinaciclib. Finally, pevonedistat inhibited RPPt tumor growth *in vivo*.

Conclusion: These findings are consistent with the hypothesis that the *Rb1/Trp53*-deficient SCLC neuroendocrine phenotype is not a fixed feature but can vary with the presence of other oncogenic drivers, and document $SCF^{Skp2/Cks1}$ as one such driver. This could reflect an early, deterministic lineage redirection toward a YAP1-high, SMARCA4-intact, non-neuroendocrine phenotype. $SCF^{Skp2/Cks1}$ mediates lung cancer heterogeneity, plasticity and sensitivity to standard cytotoxic and targeted drugs. Furthermore, the *in vivo* efficacy of the neddylation inhibitor pevonedistat highlights SCF^{Skp2} complex assembly as a promising therapeutic target for SCLC.

#1292 Multimodal modeling of detailed cancer subtypes and molecular features from >60,000 patients with co-registered H&E images and clinical tumor sequencing.

K. M. Boehm, M. Darmofal, A. Patha, A. Aukmerman, R. Lim, E. Seffar, T. Pollard, N. Rekhtman, J. Chang, J.-F. Chen, A. Kohli, D. Moore, J. Gao, G. Asimomitis, A. Begum, H. Al-Ahmadie, M. F. Berger, N. Schultz, S. P. Shah, F. Sanchez-Vega;
Memorial Sloan Kettering Cancer Center, New York, NY

Background: Optimal oncology treatment depends upon detailed cancer subtyping and molecular characterization. However, due to small datasets, prior digital pathology work often grouped detailed histologic subtypes by anatomy. Furthermore, the role of digital pathology as a complement to DNA sequencing rather than a surrogate remains underexplored. This study develops machine learning for H&E whole-slide images (WSIs) to model detailed cancer subtypes, identify phenotypically-associated biomarkers, and evaluate the added information of digital pathology to clinical tumor sequencing.
Methods: A pan-cancer cohort of 367,535 WSIs matching clinical sequencing data from 62,460 patients across 163 OncoTree subtypes was curated. The first model, Aeon, used a knowledge graph and transformer to classify subtypes from WSIs using self-supervised features. The second model, Paladin, tested the association of molecular features with tumor histopathologic features, conditioned on detailed tumor subtype. This conditioning critically allows the model to identify more detailed phenotypic subtypes than already clinically established. Two independent test sets were used.
Results: Aeon achieved AUROC 0.992 across 163 detailed subtypes, outperforming a genomics-based classifier for 151 subtypes. Reclassified cancers of unknown primary (CUP) exhibited expected prognostic and genomic associations (corrected log-rank $p<0.05$, corrected Fisher's $p<0.05$). For biomarker inference (single nucleotide variants, pathway-level alterations, and higher-order features), Paladin achieved AUROC ≥0.80 for 165 (5%) of 3,541, improving on benchmarks. Importantly, the model also identified phenotype associations for functional states of KEAP1 variants of unknown significance (VUS) in lung adenocarcinoma; VUS cases with H&E-inferred functional significance exhibited shorter overall survival (OS; log-rank $p<0.01$). For STK11, discordant H&E phenotyping and sequencing identified cases with occult phenocopying, supported by immunohistochemistry (H&E score higher for cases with STK11 loss on IHC; Mann-Whitney U (MWU) $p<0.01$) and STK11 RNA abundance (MWU $p<0.01$). This phenocopying had prognostic consequences: wildtype (WT) cases with STK11-mutant phenotype on H&E formed an intermediate prognostic group between STK11-mutant cases and WT cases without STK11-mutant phenotype (log-rank $p=0.01$).
Conclusions: Digital pathology effectively classifies 163 granular tumor subtypes using H&E WSIs, advancing an order of magnitude from the prior state of the art, outperforming a genomics classifier, and clarifying CUP diagnoses. We further established the role of digital pathology in complementing DNA sequencing via VUS annotation and identification of phenocopying, with molecular validation of these phenotypes and prognostic implications.

#1293 A multimodal AI framework integrating spatial omics and radiomics for recurrence prediction in glioblastoma.

J. Louw[1], T. N. Nandi[2], E. Calabrese[1], R. E. Mclendon[3], Y. Sun[1], J. Hickey[1], J. Jepson[1], A. Corcoran[1], K. Zhang[1], R. K. Madduri[2], M. Khasraw[4];

[1]Duke University, Durham, NC, [2]US Department of Energy, Chicago, IL, [3]Duke University Medical Center, Durham, NC, [4]Duke Cancer Institute, Durham, NC

Introduction/Rationale: Glioblastoma (GBM) has a dismal prognosis, yet times to recurrence vary substantially. We integrated multimodal data to identify tumor- and microenvironment-level features associated with timing of recurrence.
Methods: Primary GBMs tumors with documented time to recurrence were analyzed by Xenium spatial transcriptomics (ST). ST data were processed with Seurat, manually annotated, and organized into five reproducible spatial niches. Differential expression was performed within tumor-dense niches comparing that shortest recurrence (SR) and those with the longer time to recurrence (LR). ST embeddings were extracted using the graph attention network based Novae foundation model (FM), while embeddings from the pathology whole-slide Hematoxylin and Eosin (H&E) images were obtained using the vision transformer-based UNI FM and reviewed by a neuropathologist. CODEX spatial proteomics (SP) embeddings will be generated using the vision transformer-based KRONOS FM, and pre-operative MRI features will be incorporated via a PyRadiomics pipeline. Multimodal embeddings from all platforms are being used to train an interpretable tree-based survival model predicting time to recurrence.
Results: ST analyses show that there are marked microenvironmental differences between SR and LR tumors. SR tumors showed malignant-cell infiltration across nearly all spatial niches, indicating disruption of immune and stromal architecture. LR tumors retained distinct vascular, immune, and endothelial-rich regions, reflecting maintained compartmentalization; H&E review confirmed these patterns. Malignant-cell composition also diverged: SR tumors were dominated by AC-like cells (83%) with minimal MES-like (1%), OPC-like (1%), and NPC-like (15%) states. LR tumors were more heterogeneous, with balanced AC-like (38%) and MES-like (36%) fractions and increased OPC-like (16%) and NPC-like (9%) representation. Pseudo-bulk differential expression identified 367 genes (313 up in SR; 54 in LR). SR tumors overexpressed CD38, HLA-DQA1, CX3CR1, TMEM119, and P2RY12, indicating microglial activation and inflammatory signaling. LR tumors upregulated POSTN, LOX, ACKR1, VEGFA, and CAV1, consistent with extracellular matrix organization, angiogenesis, and vascular remodeling. SR GBM exhibits widespread tumor infiltration and immune activation, whereas LR tumors preserve structured vascular-immune niches and more diverse malignant-cell states.
Conclusion: ST, SP, pathology slide H&E imaging, and MRI radiomics provides complementary insights into the cellular and microenvironmental determinants of GBM recurrence. While multimodal model training involving embeddings from all the modalities is ongoing, the preliminary findings highlight the importance of spatial organization of the tumor-immune-vascular interface as a key determinant of recurrence timing.

#1294 Deciphering single-cell heterogeneity and cellular ecosystem dynamics during prostate cancer progression.

F. Zhao[1], H. Zeng[2], J. Zeng[3], C. Chen[1], X. Zhao[1], T. Zhang[1], K. Wang[1], G. Sener[1], J. Liu[4], G. V. Thomas[1], R. C. Sears[1], J. J. Alumkal[5], A. Moran[6], G. B. Mills[7], E. S. Eksi[7], J. Zheng[2], P. S. Nelson[8], Z. Xia[1];
[1]Oregon Health & Science University, Portland, OR, [2]Xinqiao Hospital, Chongqing, China, [3]The University of Texas MD Anderson Cancer Center, Houston, TX, [4]Urologic Surgery Center, Xinqiao Hospital, Chongqing, China, [5]Rogel Cancer Center, Ann Arbor, MI, [6]OHSU, Portland, OR, [7]OHSU Knight Cancer Institute, Portland, OR, [8]Fred Hutchinson Cancer Center, Seattle, WA

Prostate cancer (PC) progresses from benign epithelium through pre-malignant lesions, localized tumors, metastatic dissemination, and castration-resistant stages, with some cases exhibiting phenotype plasticity under therapeutic pressure. However, high-resolution insights into how cellular phenotypes and ecological interactions shift across these successive stages remain incomplete. Here, we present the Prostate Cancer Cell Atlas (PCCAT) by integrating ~710,000 single cells from 197 human samples covering a spectrum of tumor stages. By further incorporating bulk transcriptomic cohorts, spatial transcriptomics, and experimental validations, this comprehensive analysis dissects the multicellular landscape of PC and identifies key epithelial, stromal, and immune programs associated with disease progression. We highlight a dynamic and heterogeneous continuum of malignant and non-malignant epithelial states, and uncover several cell states strongly linked to aggressive progression and poor prognosis, including lineage plasticity-like malignant cells, neuroendocrine tumor cells, matrix cancer-associated fibroblasts (mCAFs), and SPP1-expressing macrophages (SPP1+ Mph). Furthermore, we identify shared immune-suppressive states enriched in advanced disease, including proliferative T cells, activated regulatory T cells, exhausted $CD8^+$ T cells, and SPP1+ Mph, highlighting convergent microenvironmental mechanisms of immune evasion. Among these, SPP1+ Mph emerge as a key immunosuppressive population, progressively accumulate along PC progression, exhibiting an M2-like immunosuppressive phenotype, associating with bone metastasis, and spatially colocalizing with mCAFs at the tumor-stroma interface in NEPC. Functionally, SPP1 blockade restrains bone metastatic progression and alleviates cancer-induced bone pain by reprogramming tumor-associated macrophages and reshaping CAF and $CD8^+$ T-cell phenotypes. Lastly, by integrating PCCAT with spatial transcriptomics, we identify distinct spatial cellular neighborhood (CNs) that transition from epithelial-dominated to stroma-enriched ecosystems along PC evolution. Among tumor-associated CNs, CN1 reflects neuroendocrine and lineage-plasticity features, whereas CN4 captures aggressive luminal malignant programs. Among microenvironmental CNs, mCAF-enriched CN7 expands with tumor progression and predicts adverse prognosis, while iCAF-enriched CN8 diminishes and associates with favorable outcome. Notably, a CN7-CN8-derived ecosystem index robustly predicts biochemical recurrence across multiple patient cohorts. Overall, our study provides a high-resolution reference of PC cellular ecosystems and reveals the dynamic cell states, spatial niches, and immunoregulatory interactions that shape disease progression, offering mechanistic insights and therapeutic opportunities.

#1295 Deep-learning profiling of regulatory somatic variants across clonal cancer evolution.

K. Sokolova, V. N. Kristensen, O. G. Troyanskaya;
Princeton University, Princeton, NJ

Somatic noncoding mutations are abundant in cancer genomes, yet their regulatory functional consequences remain poorly understood. To address this gap, we generated a pan-cancer atlas of variant regulatory effects by profiling >35M SNVs within +/-20 kb of transcription start sites across more than 8,000 TCGA samples. Chromatin impact was predicted with the Sei deep-learning model (>20,000 features across 40 sequence classes), and clonal architecture was inferred with PyClone-VI, enabling genome-wide, evolution aware annotation of proximal regulatory alterations. We then aggregated these variant-level functional predictions into gene-level and patient-level representations of regulatory dysregulation. Despite comparable mutation counts near COSMIC Tier1/2 and non-COSMIC genes, the atlas revealed substantially higher predicted regulatory impact in promoter-proximal mutations, uncovering a noncoding functional dimension not detectable from burden alone. Aggregating these predicted effects into a personalized somatic dysregulation representation across COSMIC Hallmark genes produced a patient-level promoter-proximal regulatory effect score. In a multivariable Cox model of progression-free interval stratified by cancer type and adjusted for log1p(FGA), HRD score, non-silent mutations per Mb, and age at diagnosis, this regulatory score was a strong and independent predictor of adverse progression (HR = 1.10, 95% CI 1.04-1.15, $P < 0.005$), whereas noncoding mutation count contributed no additional information. Partitioning regulatory burden by evolutionary timing revealed distinct processes: clonal promoter-proximal disruption consistently predicted worse pan-cancer outcomes and showed stronger within-cancer associations, whereas subclonal burden was prognostic only in specific cancers. For example, subclonal promoter-proximal disruption within Hallmark genes was significantly associated with progression in Uterine Corpus Endometrial Carcinoma (HR = 1.36, 95% CI 1.10-1.70, $P = 0.01$), possibly indicating late-arising regulatory programs contributing to tumor progression. Finally, deep-learning regulatory sequence classes mapped to tissue-specific vulnerabilities: lower-grade glioma showed disproportionate impact from the E3 brain/melanocyte enhancer class, whereas sarcoma was most strongly associated with PC4 polycomb/bivalent stem-cell-linked disruption. Together, these results show that functional promoter-proximal disruption, not mutational load, captures clinically relevant noncoding dysregulation, shaped by context-specific and evolution-linked regulatory programs. This atlas provides a scalable foundation for integrating noncoding regulatory functions into prognostic modeling and will be made available to the research community.

#1296 Integrated single cell spatial multi-omics landscape of WHO grades 2-4 diffuse gliomas identifies locoregional metabolomic correlates of glioma plasticity and proliferation.

Yanxia Ma[1], Shamini Ayyadhury[2], Sanjay Singh[1], Yashu Vashishath[3], Cagri Ozdemir[3], Keziah Liebenberg[4], Trevor McKee[2], Nhat Nguyen[1], Akshay V. Basi[5], Duncan Mak[5], Javier A. Gomez[5], Jason T. Huse[6], Sana Noor[2], Sharon Wariko[2], Dan Winskowski[7], Regan Baird[8], Jeffrey S. Weinberg[1], Frederick F. Lang[1], Jared K. Burks[5], Livia S. Eberlin[9], Serdar Bozdag[3], Erin Seeley[10], **Chibawanye I. Ene**[1]

[1]Department of Neurosurgery, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Astraea Bio LLC, Tomball, TX,[3]University of North Texas, Denton, TX,[4]Baylor College of Medicine, Houston, TX,[5]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX,[6]Department of Anatomical Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX,[7]Visiopharm A/S, 2970 Horsholm, Denmark,[8]Visiopharm, 2970 Horsholm, Denmark,[9]Division of Surgical Oncology, Baylor College of Medicine, Houston, TX,[10]Department of Chemistry, The University of Texas at Austin, Austin, TX

Introduction: Diffuse infiltrating gliomas are aggressive tumors of the central nervous system driven by intra-tumoral heterogeneity and aberrant normal-tumor cell-cell interactions. Grade-specific and locoregional metabolic dependencies associated with aberrant transcriptional cell-states linked to treatment resistance and proliferation of gliomas remain elusive. We hypothesize that identifying metabolic surrogates of plasticity- and treatment-resistant glioma transcriptional cell states at the recurrence-prone tumor edge will lead to new therapeutic strategies for gliomas.

Methods: We applied spatial transcriptomics (stRNAseq), imaging mass cytometry (IMC) and mass spectrometry imaging (MSI; metabolites, peptides and glycans) to the core and edge tumor tissue from patients with World Health Organization (WHO) grades 2-4 diffuse infiltrating gliomas including isocitrate dehydrogenase (IDH) mutant (mut) oligodendrogliomas (WHO Grades 2 and 3, n= 5) and IDH wildtype (wt) astrocytomas including 'anaplastic' astrocytoma (prior 2016 WHO histological grade 3, n = 3) and IDHwt glioblastoma (GBM, WHO grade 4). To determine if any differentially expressed genes between the core and edge of IDHwt GBM influenced overall survival (OS), we analyzed the association between OS and gene expression levels (low vs. high) in IDHwt GBM samples from the cancer genome atlas (TCGA). To identify grade specific and tumor edge unique metabolites that correlate with plasticity- and therapy-resistance-associated glioma transcriptional cell states and proliferation (Ki-67^{+}), we integrated data from stRNAseq, IMC and MSI within each diffuse glioma grade.

Results: High expression of Neuronatin (NNAT) and Heparin Sulfate-Glucosamine 3-Sulfotransferase 2 (HS3ST2) mRNA, which were significantly over-expressed in the IDHwt GBM edge relative to the core, were associated with significantly worse OS (NNAT^{hi} HR=1.8, *p-value= 0.0043* and HS3ST2^{hi} HR=2, *p-value=0.0096).* Integration of stRNA seq and MSI-derived metabolite expression identified edge unique metabolites overlapping with glioma transcriptional cell states and proliferative states across gliomas profiled.

Conclusion: This comprehensive pan-diffuse infiltrating glioma multi-omics study could serve as a resource for not only uncovering region-specific metabolic signatures of transcriptionally defined cell states across WHO 2-4 diffuse gliomas, but also guide surgical extent of resection in real time, by using metabolic signatures as surrogates for plasticity associated transcriptional cell states and proliferation especially in the infiltrative and non-enhancing portion of the glioma edge.

#1297 ADTnorm enables scalable and interpretable single cell proteomics integration across technologies for incorporating historical cancer data.

T. Le[1], Z. Luo[2], Y. Yan[3], **Y. Zheng**[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Yale University, New Haven, CT, [3]Beijing University of Technology, Beijing, China

CITE-seq enables paired measurement of surface protein and mRNA expression in single cells using antibodies conjugated to oligonucleotide tags. Due to the high copy number of surface protein molecules, sequencing antibody-derived tags (ADTs) allows for robust protein detection, improving cell type identification. However, variability in antibody staining leads to batch effects in the ADT expression, obscuring biological variation, reducing interpretability, and obstructing cross-study analyses. We present ADTnorm (https://github.com/yezhengSTAT/ADTnorm), a normalization and integration method designed explicitly for ADT abundance. Benchmarking against 14 existing scaling and normalization methods, we show that ADTnorm accurately aligns populations with negative- and positive-expression of surface protein markers across 13 public datasets, effectively removing technical variation across batches and improving cell-type separation. ADTnorm enables efficient integration of public CITE-seq datasets, each with unique experimental designs, paving the way for atlas-level analyses. Beyond normalization, ADTnorm includes built-in utilities to aid in automated threshold-gating as well as assessment of antibody staining quality for titration optimization and antibody panel selection. Beyond CITE-seq, single-cell proteomics data are increasingly generated from diverse platforms, including flow cytometry, CyTOF, multimodal assays such as scCUT&Tag-pro, and spatial methods like CODEX. Each technology introduces distinct data characteristics, creating challenges for cross-platform integration. Harmonizing these heterogeneous datasets is essential for leveraging historical cancer data and linking proteomic profiles to clinical outcomes. To address this, we incorporate large language model APIs into ADTnorm for automated parameter tuning tailored to each technology's data characteristics, improving landmark identification and alignment across modalities. We further developed an online platform (https://pvdetector.streamlit.app/) that provides free computational resources for proteomics analysis, with the option to install locally or deploy on servers for enhanced scalability (https://github.com/letian0102/PVdetector). While integration remains grounded in interpretable statistical models, the use of LLMs enables adaptive, data-driven parameter optimization, extending ADTnorm's utility across a broad spectrum of proteomic technologies.

#1298 Structure-sequence integration for peptide:MHC class II binding prediction using AI foundation models (AlphaFold 3 and ESM2).

K. Lahouel[1], M. Mulazimoglu[1], J. Soria-Bustos[1], K. Bates[1], E. Kelley[2], L. Woods[3], K. Upadhyaya[1], G. J. Acevedo[4], S. Penisson[1], M. Munini[1], E. Variani[5], M. E. Feeney[4], J. A. Altin[2], C. Tomasetti[1];

[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ, [2]TGen North (The Translational Genomics Research Institute), Flagstaff, AZ, [3]TGen (The Translational Genomics Research Institute), Phoenix, AZ, [4]University of California San Francisco, San Francisco, CA, [5]Google Research, Mountain View, CA

Background:
Accurate prediction of CD4 T cell epitopes is essential for vaccine design and immunotherapy development but remains challenging due to MHC class II polymorphism and the complexity of antigen presentation. We present a foundation-model-based framework that integrates structural representations from AlphaFold 3 (AF3) and sequence embeddings from ESM2 within a graph neural network (GNN) to predict peptide:MHC II binding.
Model and Experimental Procedures:
For each peptide-MHC II complex, AF3 was used to generate a 3D structural model, from which we constructed a residue-level graph where edges represent geometric proximity. Node features combined AF3-derived spatial descriptors with contextual embeddings from ESM2 corresponding to each amino-acid token in the peptide sequence. The hybrid GNN was trained on experimental data from a multiplexed MHCII-PepSeq assay, a high-throughput platform that directly measures binding of thousands of synthetic peptides across diverse MHC class II molecules (~52,000 non-binders and 633 binders). The model was evaluated on an independent held-out test set encompassing multiple HLA alleles.
Results:
The AF3 + ESM2 GNN achieved an AUC of 0.782 (95% CI: 0.751-0.813), matching exactly the performance of NetMHCIIpan 4.3, a leading model for peptide:MHC II binding prediction on the Immune Epitope Database (IEDB) benchmark—despite being trained on a dataset that is orders of magnitude smaller. A combined ensemble of NetMHCIIpan with the AF3 + ESM2 model further improved performance, reaching an AUC of 0.810. The AF3-only GNN yielded an AUC of 0.775, indicating that ESM2 sequence embeddings may contribute complementary contextual information that enhances prediction accuracy.
Conclusions:
By unifying structure- and sequence-based protein foundation models, our approach achieves state-of-the-art, data-efficient prediction of peptide:MHC II binding. Comparable in accuracy to the gold-standard NetMHCIIpan while trained on orders-of-magnitude smaller datasets, this framework enables scalable and interpretable modeling of antigen presentation. Such structure-informed prediction can accelerate the discovery of CD4 T-cell epitopes relevant to neoantigen identification, vaccine development, and TCR/CAR-T engineering, where precise understanding of peptide:MHC recognition is essential. More broadly, our findings highlight the potential of foundation models to bridge molecular immunology and therapeutic design by providing generalizable, low-data solutions to complex antigen-presentation problems.

: Liquid Biopsy Frontiers: ctDNA, Fragmentomics, and MRD to Guide Precision Oncology Minisymposium

#1310 Serial plasma comprehensive genomic profiling detects therapy resistance and guides management of metastatic non-small cell lung cancer.

W. Bowers[1], M. Conroy[1], J. Wehr[1], V. V. Altiery De Jesus[1], A. Balan[1], S. Scott[1], B. Levy[1], K. A. Marrone[1], V. K. Lam[1], J. Feliciano[1], C. Hann[1], A. Pabani[1], J. Naidoo[2], J. R. Brahmer[1], P. M. Forde[1], J. C. Murray[1], V. Anagnostou[1];
[1]Johns Hopkins University, Baltimore, MD, [2]Beaumont RCSI Cancer Centre, Dublin, Ireland

Introduction: Although plasma comprehensive genomic profiling (pCGP) shows significant potential as a minimally invasive alternative to tissue genotyping in non-small cell lung cancer (NSCLC), its precise clinical utility remains insufficiently studied. To bridge this gap, we conducted a single-center retrospective study of 718 patients with NSCLC who had undergone pCGP in our institution from 2015 through 2022.
Methods: Integrated clinical and genomic data were extracted from the Precision Medicine Analytics Platform as part of a standard workflow of the Johns Hopkins Lung Cancer Precision Medicine Center of Excellence. Fixed gene panel hybrid capture next-generation sequencing (Guardant 360, n = 572 samples and Guardant 360CDx, n = 246 samples) data were retrieved, followed by variant characterization and annotation by an ensemble approach.
Results: Across 718 patients with 818 instances of pCGP, including 79 (11%) patients with serial pCGP, liquid biopsies uniquely informed management in 92 (13%) patients. This primarily occurred when tissue testing was not possible (44%), although pCGP also contributed to clinical decision-making as an adjunct to tissue testing, by improving turnaround time, and by detecting plasma-only mutations. In a subset analysis of first instance of pCGP obtained at the time of diagnosis (n = 427), patients with undetectable ctDNA had significantly prolonged overall survival (OS) (log rank $p < 0.0001$), with similar results when patients were classified as ctDNA undetectable, 1-2 mutations, or 3 or more detected mutations (log rank $p < 0.0001$). Importantly, receipt of genotype-matched therapy informed by pCGP was associated with a significant improvement in OS (log rank $p < 0.0001$). Focusing on 214 patients with *EGFR* mutant (*EGFR*m) NSCLC, pCGP uniquely guided patient management in 28% of cases, benefiting both newly diagnosed patients and those on their second or third iteration of genotyping. Among patients progressing on EGFR tyrosine kinase inhibitors (TKI), 31 (22%) had actionable pCGP findings, of whom 18 (58%) were matched to targeted therapy. pCGP captured differential on-target and off-target resistance genomic alterations based on TKI line of therapy and type of TKI (first or second generation vs. third generation). Mutations in *PIK3CA* most commonly emerged after first-line therapy with third generation TKI, while mutations in the RAS pathway were more frequently detected after third-line therapy, highlighting differential activation of resistance pathways.
Conclusions: Serial pCGP captures actionable genomic alterations and the emergence of drivers of therapy resistance, enabling longitudinal care and timely, effective interventions for patients with NSCLC.

#1311 Feasibility of plasma ctDNA for detecting brain metastasis-specific alterations in lung cancer.

L. P. Stabile[1], K. Shaverdashvili[2], P. H. Rumde[2], X. Wu[3], A. Gaither Davis[2], P. O. Zinn[1], A. Habib[2], N. N. Gecici[2], R. Zhang[4], P. Du[4], S. Jia[4], Y. Huang[4], G. Sica[5], T. F. Burns[6];

[1]UPMC Hillman Cancer Center, University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh and Tsinghua University, Pittsburgh, PA, [4]Predicine, Hayward, CA, [5]Winship Cancer Institute, Emory University, Atlanta, GA, [6]James Cancer Hospital Solove Research Institute, The Ohio State University, Columbus, OH

Brain metastases (BM) are a frequent and devastating complication of non-small cell lung cancer (NSCLC). Molecular divergence between primary NSCLC and BM is common, highlighting the need for non-invasive approaches to detect BM-specific genomic alterations that could guide precision therapy. To address this, we evaluated the feasibility of circulating tumor DNA (ctDNA) to identify BM-specific or enriched alterations by analyzing matched pre- and post-craniotomy plasma samples and corresponding BM tissue. Twenty-eight metastatic NSCLC BM patients undergoing craniotomy were enrolled. Peripheral blood was collected pre-surgery (Day 0, P1) and post-surgery (≥ 8 days, P2) before systemic therapy initiation, and BM tissue was collected during surgery. Following exclusion of 4 patients with insufficient viable tumor, samples from 24 patients were sequenced using the PredicineCARE NGS assay, and data were analyzed using DeepSea, Predicine's proprietary bioinformatics pipeline. After excluding cases with a tumor fraction <0.005 or failed QC, we analyzed 13 complete sets (BM with matched P1/P2 plasma), 3 partial sets (BM with P1 plasma only) and 7 BM tissue-only samples (23 BM samples total). The most frequently detected BM alterations were *TP53* (22/23, 96%), *PIK3CA* (12/23, 52%), *RB1* deletion (del)/mutation (mut), *EGFR* amplification (amp) and *CDKN2A/B* del (each in 11/23, 48%). Additional alterations were found in *BRCA1/2* (10/23, 44%), *MYC* (9/23, 39%), *NF1* (8/23, 35%), and *PTEN* or *BAP1* (7/23, 30%). *MET* amp, *AKT3* amp, or *KRAS* mut were each found in 6/23 patients (26%). Targetable alterations, including *EGFR* (ex19del, L858R, ex20ins), and *KRAS* (G12C) were each detected in 3 patients (13%). While many alterations were shared between BM tissue and the two plasma samples, complete loss of an alteration in post-craniotomy P2 plasma that was detected in both P1 and BM was rare, occurring in only 1/13 patients (*EGFR* amp). However, a decrease of >50% variant allele frequency was seen for multiple variants in an additional 2/13 patients despite similar tumor fractions, suggesting that detecting ctDNA shed from BM is possible. Notably, *NF1*, *KEAP1* and *CD274* del and *ERBB2* amp was only detected in BM and only 1/6 *MET* amps were detected in plasma. Interestingly, one patient who received post-craniotomy brain radiation therapy (RT) one day before P2 collection exhibited new *MET* and *MYC* amps and *TP53* del in P2 plasma. These variants were initially detected in BM but absent in P1, suggesting that RT may enhance tumor DNA shedding. These findings indicate that reliable ctDNA detection of BM-specific alterations may require assays with greater sensitivity, as well as optimized sample collection timing, such as post-RT, to improve yield and clinical utility. To our knowledge, this is the only study that includes pre-/post-craniotomy samples along with matched BM tissue to directly assess the ability of ctDNA to detect BM-specific alterations.

#1312 *AXL* mRNA overexpression in CTCs as a new potential liquid biopsy biomarker in NSCLC.

A. Ntzifa[1], E. Themistokli[1], A. Strati[1], M. Zavridou[1], E. Tsaroucha[2], A. Sfika[3], A. Psyrri[4], A. Kotsakis[5], V. Georgoulias[6], **E. Lianidou**[1]; [1]Analysis of Circulating Tumor Cells, Lab of Analytical Chemistry, Department of Chemistry, National and Kapodistrian University of Athens, Athens, Greece, [2]7th Department of Pulmonary Diseases, "Sotiria" General Hospital of Athens, Athens, Greece, [3]Oncology Unit, 2nd Department of Surgery, Aretaieio Hospital, Medical School, University of Athens, Athens, Greece, [4]Medical Oncology Unit, 2nd Department of Internal Medicine, "Attikon" General Hospital of Athens, Athens, Greece, [5]Department of Medical Oncology, University General Hospital of Larissa, Larissa, Greece, [6]First Department of Medical Oncology, Metropolitan General Hospital, Athens, Greece

Background: AXL is a receptor tyrosine kinase that is over-expressed in NSCLC. It is involved in epithelial-to-mesenchymal transition (EMT), cell survival, invasion, metastasis, and resistance to epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) and immune checkpoint inhibitors (ICIs). Nowadays, clinical trials are investigating the efficacy of AXL-inhibitors such as bemcentinib, that has already received US FDA fast-track designation for the treatment of advanced or metastatic NSCLC combined with a PD-L1 inhibitor. In this study we evaluated *AXL* mRNA expression in circulating tumor cells (CTCs) isolated at different time points from two groups of NSCLC patients: a) under osimertinib treatment and b) under immunotherapy.

Materials and Methods: Group A: Peripheral blood (PB) (15mL) was collected from 39 *EGFR*-mutant NSCLC patients before osimertinib (n=39), after one cycle of treatment (n=31), every 3 months during therapy (n=81) and at progression of disease (PD) (n=30). Group B: PB (10mL) was collected from 116 NSCLC patients before immunotherapy (n=116), after 3 or 4 cycles of treatment with ICIs (n=71) and at PD (n=10). CTCs were enriched using the Parsortix^{TM} system (CellBxHealth plc, UK) and further harvested in Trizol reagent, followed by extraction of total RNA and cDNA synthesis. An RT-qPCR assay was developed and analytically validated for the detection of *AXL* mRNA expression in CTCs using the COBAS z480 system (Roche). PB from healthy donors (n=46) was processed in the same way and used as control group for the estimation of overexpression, based on the $2^{-\Delta\Delta Ct}$ approach.

Results: In Group A (*EGFR*-mutant NSCLC), *AXL* mRNA overexpression in CTCs was detected in 5/39 (12.8%) patients' samples before osimertinib, in 5/31 (16.1%) after one cycle of treatment, in 7/81 (8.6%) samples during treatment and in 4/30 (13.3%) samples at PD. In Group B (treatment with ICIs), *AXL* mRNA overexpression in CTCs was detected in 7/116 (6.0 %) patients prior to treatment, in 8/71 (11.3%) after 3 or 4 cycles of treatment, while no *AXL* transcripts were detected in CTCs at PD.

Conclusions: This is the first time that *AXL* overexpression is detected in CTCs of NSCLC patients undergoing immunotherapy. Our results indicate that NSCLC patients with overexpression of *AXL* in CTCs could benefit from combination therapies with AXL-inhibitors to either overcome resistance to targeted therapies or enhance immune responses. The role of *AXL* as a potential biomarker and therapeutic target in advanced NSCLC needs to be further confirmed through larger clinical studies including liquid biopsy approach.

#1313 Circulating tumor cell (CTC) informed pipeline for rapid personalization of synergistic cytokine-armed CAR-NK cell therapy in PDAC.

Y. Zou[1], M. Tarannum[2], S. Fouladdel[1], Y. Zhang[1], N. Peterson[1], V. Sahai[1], D. Nagrath[1], R. Romee[2], S. Nagrath[1];
[1]University of Michigan, Ann Arbor, MI, [2]DFCI/Harvard Medical School, Boston, MA

Introduction: Pancreatic ductal adenocarcinoma (PDAC) remains highly lethal due to treatment resistance heterogeneity and an immunosuppressive microenvironment, necessitating personalized therapeutics. CAR-NK cell therapy shows promise but faces challenges including target identification in heterogeneous tumors and rapid exhaustion within the TME. Cytokine-armed CAR-NK cells that self-secrete immune-activating cytokines may overcome these barriers. Circulating tumor cells (CTCs) offer dynamic insights into tumor biology, including mutation and protein profiles, enabling personalized CAR target identification. We present a pipeline integrating CTC-informed antigen selection with cytokine-armed CAR-NK therapy, leveraging minimally invasive CTC sampling and allogeneic CAR-NK potential for rapid, adaptive personalized immunotherapy.
Method & Result: Using label-free CTC isolation, we performed multi-omics analysis and identified mucin4 (MUC4) and mesothelin (MSLN), two highly prevalent PDAC antigens, in CTCs across patients (n=13; 6 metastatic, 7 localized). MUC4+CTCs were exclusively detected in 67% of metastatic patients, whereas 92% of all patients exhibited MSLN+CTCs, revealing the potential complementary coverage and enabling patient stratification for dual MUC4&MSLN CAR-NK treatment. We generated anti-MUC4 and anti-MSLN CAR-NK cells showing robust cytotoxicity against target-matched PDAC cell lines.To enhance efficacy, we tested IL-12 (for NK activation) and IL-15 (for NK proliferation) armed CAR-NK cells individually and combined. Anti-tumor efficiency improved in all cytokine-armed CAR-NK cells in short-term assays with no advantage of dual versus single cytokine arming. However, synergistically armed CAR-NK cells displayed drastically higher tumor-specific interferon-γ secretion post 18-hour exposure (4208 pg/mL vs 244 pg/mL for tumor-stimulated vs resting NK) compared to single cytokines (1819 & 252 pg/mL for IL-12 & IL-15), indicating sustained activity. In serial killing assays with repeated 72-hour tumor exposures at 2:1 NK: tumor ratio, unarmed CAR-NK lost efficacy by round 2, IL-15 by round 3, IL-12 by round 4, while synergistically armed CAR-NK sustained cytotoxicity through six rounds (16 days). Suggesting cytokine synergy is not only more physiologically relevant than solo-cytokine, but also more effective in immunotherapy activation.
Summary: Our platform enables adaptive precision immunotherapy, leveraging minimally invasive CTC sampling to identify patient-specific target for rapid CAR-NK administration, while synergistic cytokine arming ensures durable activity against hostile PDAC TME. This real-time molecular monitoring allows dynamic therapeutic adjustments as tumor profiles evolve.

#1314 Circulating tumor DNA (ctDNA) clearance dynamics in microsatellite instability-high metastatic (MSI-H) colorectal cancer (CRC) treated with immune checkpoint inhibitors (ICI).

H. R. Robinson[1], C. H. Lieu[1], V. N. Aushev[2], A. Tin[2], D. Nousome[2], J. Ortiz[2], S. Sharma[2], R. Lentz[2], A. Jurdi[2];
[1]University of Colorado, Aurora, CO, [2]Natera, Inc., Austin, TX

Background: ICI offers durable responses in MSI-H CRC. However, factors for long-term disease control and the optimal ICI duration are unclear, and radiographic assessments can be challenging. ctDNA provides an opportunity to monitor molecular changes during treatment. This retrospective analysis evaluated ctDNA clearance patterns and their relationship to survival in a large real-world cohort of patients with MSI-H metastatic CRC treated with first-line ICI.
Methods: We selected MSI-H metastatic CRC patients treated with first-line ICI (March 2021-June 2025) from Natera's real-world cohort and analyzed Signatera™ ctDNA data linked to an insurance claims database (Forian, CHRONOS™). ctDNA status was assessed pre ICI (within 12 weeks) and longitudinally. ctDNA clearance was defined as early (within 4 months) or sustained (≥6 months of ctDNA negativity). Descriptive analyses assessed ctDNA clearance frequency, timing, and correlation with overall survival (OS).
Results: A total of 465 patients with MSI-H metastatic CRC, treated with first-line IO, predominantly pembrolizumab (67%), ipilimumab + nivolumab (14%), and nivolumab (12%), were identified. Post-IO ctDNA-negativity was observed in 60.5% within 4 months and in 83.5% at any time point. Among 146 patients with pre-ICI ctDNA results, 44% had prior chemotherapy for localized disease, and 77% (106/146) were baseline ctDNA-positive. Of these, 37.7% (40/106) patients had early clearance, 65.1% (69/106 achieved anytime ctDNA clearance (median time to clearance 96 days (range: 12-777), and 19.8% (21/106) remained persistently positive. Of those who cleared, 77.4% achieved sustained ctDNA clearance with a median duration of ctDNA-negativity of 526 days (range: 105-1564). In the entire cohort (N=465), patients ctDNA-positive at their first post-IO ctDNA test had shorter OS (HR 4.75, 95%CI 2.26-9.96, $p<0.0001$) with an estimated 3-year OS of 96% versus 75% for ctDNA-negative versus -positive, respectively. Persistent ctDNA positivity after IO initiation was associated with inferior OS compared to anytime ctDNA negativity (HR 10.04, 95% CI 4.84-20.83, $p<0.0001$).
Conclusions: These findings suggest ctDNA kinetics as a reliable tool for evaluating benefit from ICI in patients with metastatic MSI-H CRC. ctDNA monitoring tracked distinct clearance trajectories. Consistent with ICI efficacy, most patients achieved ctDNA clearance. Importantly, early ctDNA clearance was strongly prognostic for improved OS, while persistent ctDNA-positivity was associated with markedly inferior OS. This supports prospective evaluation of ctDNA to guide ICI use in MSI-H CRC.

#1315 Genomic signatures in red blood cell DNA enable early non-invasive detection of colorectal neoplasia: A multicenter clinical study.

X. Yao[1], H. Sun[1], C. Liu[2], Y. Jiao[2], X. Kong[2], J. Jin[3], K. Ding[2], J. Li[2], X. Gao[4];

[1]Westlake University, Hangzhou, China, [2]Department of Colorectal Surgery and Oncology, Key Laboratory of Cancer Prevention and Intervention, Ministry of Education, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [3]Timing Biotech, Hangzhou, China, [4]Research Center for Industries of the Future and School of Life Sciences, Westlake University, Hangzhou, China

Background: Colorectal cancer (CRC) causes substantial mortality, yet most cases arise from precursor lesions that are preventable if detected early. Existing non-invasive tests have limited sensitivity for advanced adenomas (AA), leaving a critical gap in early detection. Cytoplasmic DNA, including micronuclei and chromatin fragments, reflects genomic instability and systemic stress. Solid tumors can remotely induce DNA damage in hematopoietic progenitors, generating persistent DNA remnants in red blood cells (rbcDNA). We recently demonstrated that rbcDNA harbors tumor-associated genomic alterations that can detect early cancers with high accuracy. Here, we report the multicenter validation of an rbcDNA-based assay for early colorectal neoplasia detection.

Methods: We enrolled 1,251 individuals who underwent colonoscopy with histopathologic confirmation and categorized them into three groups: CRC (n = 360), AA (n = 330), and non-advanced neoplasia controls (non-AN, n = 561). rbcDNA was extracted from 1-2 mL peripheral blood using our established workflow (Sun et al., PMID: 40341742), including red blood cell isolation, rbcDNA purification, library preparation, and low-coverage whole-genome sequencing (~2×). Participants were randomly assigned in an 8:2 ratio into a discovery cohort and an internal test cohort, with comparable demographic characteristics. The discovery cohort was used to identify CRC- and AA-associated rbcDNA genomic features and to develop an integrated detection model, which was then evaluated in the internal test cohort to determine the optimal classification cutoff. The locked model was externally validated in two independent cohorts from the Second Hospital of Shandong University (n = 80) and Wenzhou Central Hospital (n = 110).

Results: At a fixed 90% specificity cutoff determined in the internal test cohort, the classifier achieved sensitivities of 85% for AA and 95% for CRC. External validation in two independent cohorts from Shandong and Wenzhou confirmed consistent performance for colorectal neoplasia, with sensitivities of 78% and 80%, respectively. Notably, in the Wenzhou cohort, rbcDNA also detected AA and early-stage CRC cases that were negative by fecal occult blood testing.

Conclusions: Our findings demonstrate that rbcDNA isolated from just 1-2 mL of peripheral blood enables accurate detection of AAs and early-stage CRC, supporting its potential utility for early diagnosis in clinical practice. A larger prospective clinical study (NCT05875584) will further validate the application of rbcDNA in early cancer detection.

#1316 A methylation-based molecular tumor typing classifier for tissue samples from cancers of unknown primary.

E. Forouzmand, L. Lawrence, J. Tung, S. Solomon, W. W. Young Greenwald, **Y. He**;
Guardant Health, Palo Alto, CA

Introduction: Determining tissue of origin is critical for guiding treatment decisions in cancers of unknown primary (CUP), metastatic tumors with ambiguous diagnostic findings, and cases where molecular confirmation may inform therapy selection. We developed a methylation-based molecular tumor type (MTT) prediction algorithm for malignant tissue samples, designed to operate robustly across a wide range of tumor fractions, to aid in determining cell of origin as an adjunct to conventional histopathology and immunohistochemistry.
Methods: The classifier was trained on 24 of the most prevalent solid cancers using the methylation profiles of more than 2,000 differentially methylated regions derived from Guardant360 Tissue (Guardant Health, Palo Alto, CA) from 6,047 FFPE tissue samples. Each MTT prediction was assigned a confidence score between 0 and 1, and the highest-confidence predictions were reported for evaluable samples. Evaluability criteria required a confidence level of the top prediction being greater than 0.5. The MTT classifier reports up to two top predictions based on the confidence scores. Performance was evaluated in 6,056 non-CUP samples and 191 CUP samples (including 35 CUP samples with a suspected diagnosis).
Results: The MTT classifier was first evaluated on 6,056 tumor tissue samples against the clinical diagnoses provided on the test requisition forms. 97.85% (5,926/6,056) were evaluable. The overall accuracy was 91.56% (5,426/5,926) for primary predictions and 93.76% (5,556/5,926) for the top 2 predictions. Among evaluable samples, 91.29% (5,410/5,926) have high-confidence primary predictions, with an accuracy of 94.05% for primary prediction in this subset.A notable subset of discordant primary predictions was among tumor types that could include mixed or closely related subtypes, such as nonsmall cell lung carcinoma (NSCLC) subtypes (22.20% (111/500)), or tumor types with related histogenesis, such as pancreaticobiliary tumors (7.60% (38/500)). The overall accuracy increases to 94.08% (5,575/5,926) and 95.46% (5,657/5,926) for top-1 and top-2 predictions, respectively, when NSCLC subtypes are merged into a single category and the pancreatic and biliary categories are merged to form a pancreaticobiliary category.The MTT classifier was also tested on 191 CUP samples; 88.48% (169/191) were evaluable. In 35 CUP samples with suspected diagnosis, evaluability was 97.14% (34/35) with accuracy of 85.29% (29/34) for primary predictions and 91.18% (31/34) for top-2 predictions.
Conclusions: This methylation-based MTT classifier demonstrates high evaluability and accuracy in determining tissue of origin for both non-CUP and CUP samples, providing valuable information to guide clinical decision-making when used as a supplement to conventional diagnostic methods.

Minisymposium

#1347 A bone repair external state program drives cancer cell dedifferentiation and immune evasion in melanoma.

J. A. Weir[1], A. Wong[1], P. Liu[1], D. Alakwe[1], J. Wu[1], M. Sade-Feldman[1], N. Hacohen[2], F. Chen[2];
[1]Harvard University, Cambridge, MA, [2]Broad Institute, Cambridge, MA

The spatial organization of immune and stromal cells in the tumor microenvironment is emerging as an important predictor of effective cancer immunity. To systematically probe how multicellular circuits within the melanoma microenvironment drive cancer and immune cell state, we profiled 27 fresh-frozen human melanoma sections with Slide-tags snRNA-seq from 16 patients spanning common metastatic sites. We discovered six recurrent immune hub types representing conserved multicellular structures across melanoma, including an anti-inflammatory niche composed of SPP1+ macrophages, and POSTN+ fibroblasts, and an immune effector hub with NK cells and tumor-specific CD8+ T cells. Using spatial TCR sequencing, we observed a striking enrichment of expanded CD8+ T cell clonotypes in immune effector hubs and an enrichment of singleton CD8+ T cell clonotypes in anti-inflammatory hubs. Further, we found CD8+ T cells in the anti-inflammatory hubs to be more exhausted and less stem-like. Next, we sought to understand how immune niches interact with the malignant compartment. We identified 18 high-quality malignant transcriptional programs spanning the conventional de-differentiation trajectory in melanoma. We revealed that neural crest-like program usage is strongly predicted by the neighborhood presence of SPP1+ macrophages and POSTN+ fibroblasts, but negatively predicted by immune effector hub cells. We find that malignant cells that are more melanocytic-like and less de-differentiated are more immune infiltrated and have less SPP1+ macrophages and POSTN+ fibroblasts in their neighborhoods. Hypothesizing that ligands from the anti-inflammatory niche are shaping tumor state, we perturbed melanoma cell lines with SPP1 and POSTN. We found that when we treat melanocytic-like cells with POSTN, the tumor cells downregulate melanocytic markers and shift towards a more neural crest-like state. Further, when we treat neural crest-like cells with SPP1, the cells become protected from IFNg and TNFa killing. Our integrated spatial and functional analysis delineates six conserved immune hub architectures in metastatic melanoma and maps the spatial trajectory of $CD8^+$ T-cell activation, expansion, and exhaustion. We demonstrate that anti-inflammatory niches composed of $SPP1^+$ macrophages and $POSTN^+$ fibroblasts not only exclude effector T cells but also drive tumor de-differentiation and cytokine resistance. In sum, our results illustrate how specific microenvironmental niches influence CD8 T cell responses, malignant de-differentiation, and tumor cell immune evasion in melanoma.

#1348 Tumor-specific antibodies elicited by engineered bacteria promote bladder cancer immunotherapy.

M. Rouanne[1], N. Chen[2], D. Mariuzza[1], Z. Yang[1], F. Li[1], T. Savage[2], K. de los Santos-Alexis[2], R. Vincent[3], C. L. Mendelsohn[2], T. Danino[1], N. Arpaia[2];

[1]Columbia University, New York, NY, [2]Columbia University Irving Medical Center, New York, NY, [3]Baylor College of Medicine, Houston, TX

The intratumoral microbiome has recently emerged as a new hallmark of cancer, with implications for response or resistance to therapy. While bacteria can either promote or inhibit cancer growth, intratumoral bacteria can also be engineered using synthetic biology to remodel the tumor microenvironment. Here, we engineered the probiotic bacterium *E. coli* Nissle 1917 (EcN) to express the human chemokine CXCL13, a critical component of germinal center (GC) formation. The GC reaction is a fundamental aspect of adaptive immunity by which antibody affinity develops in secondary lymphoid organs for defense against pathogens. Using orthotopic models of bladder cancer, engineered CXCL13-expressing EcN colonized bladder tumors and elicited GC responses in bladder tumor-draining lymph nodes after intravesical delivery. Furthermore, when combined with PD-1 blockade, engineered EcN amplified the antitumor antibody response and promoted long-term survival and protective immunity upon tumor rechallenge. Thus, we demonstrate that synthetically engineered CXCL13-expressing EcN can enhance the efficacy of PD-1 checkpoint blockade immunotherapy by amplifying tumor-specific humoral immunity.

#1349 Deletion of host-derived GPNMB positively regulates anti-tumor response by reprogramming tumor-associated macrophages.

R. Tonea, S. J. Riesenfeld, T. F. Gajewski;
University of Chicago, Chicago, IL

Recent work has suggested that poor T cell infiltration and activation in non-responding tumors to immunotherapy is associated with immunosuppressive tumor-associated macrophages (TAMs). GPNMB is a glycosylated type I transmembrane protein found to be upregulated in multiple human cancers, with several cancer mouse models showing that it is expressed in an anti-inflammatory, highly differentiated subtype of TAMs. Analysis of human breast cancer single-cell RNA-seq data showed GPNMB to be upregulated in the myeloid compartment of non-responders to anti-PD1 therapy, suggesting a possible salvage immune suppressive role. Full knockout (KO), Vav1-Cre, and LysM-Cre GPNMB mouse models were generated to study the effect of this gene on tumor progression in the subcutaneous B16.SIY and orthotopic EO771 tumor systems. KO of GPNMB in the host, but not in tumor cells, led to markedly reduced B16.SIY and EO771 tumor growth. Tumors from KO hosts had more $CD8^+$ T cells, MHC-II^{high} $CD86^+$ macrophages, and enhanced $CD8^+$ T cells activation. $CD8^+$ T cell depletion or in vivo IFN-γ blockade eliminated the difference in the pro-inflammatory macrophages, and depletion of all T cells led to complete loss of tumor control. Single-cell RNA-seq revealed no differences at baseline between WT and KO mice in bone marrow, spleen, and lymph nodes, suggesting GPNMB deficiency did not disrupt normal tissue function. However, it showed significant differences in immune cells isolated from tumors. Relative to WT, KO mice had expanded populations of pro-inflammatory macrophages expressing IFN-induced genes, and smaller populations of macrophages expressing either mitochondrial genes involved in oxidative phosphorylation or lipid metabolism genes. The KO also led to significant changes in the transcriptional profiles of two anti-inflammatory subtypes of macrophages, high in Spp1 and C1q expression respectively. IFN-induced, complement, and inflammasome related genes were upregulated in the KO. Macrophages isolated from tumors of KO mice showed decreased suppression of $CD8^+$ T cells in an in vitro co-culture assay. To better understand the role of host versus bone-marrow-derived GPNMB for tumor control, we generated bone-marrow (BM) chimeras where GPNMB was deleted either from the host only or from the BM only. Slower tumor growth was observed when GPNMB was deleted from the host, and faster tumor growth when GPNMB was deleted from the BM. Conditional deletion of GPNMB in hematopoietic cells using Vav1-Cre mice showed no tumor control, while its conditional deletion in myeloid cells using LysM-Cre mice showed significant reduction in tumor growth. Taken together with previous data showing that the LysM-Cre targets populations of tissue-resident macrophages that the Vav1-Cre does not, those results suggest a potential role of GPNMB-expressing tissue resident-macrophages in shaping anti-tumor immunity.

#1350 Vaccine stimulation of bystander t cells in the lymph node unexpectedly promotes tumor-specific host immunity to regress solid tumors.

L. Ma[1], T. Grzywa[1], R. Tannir[1], G. L. Beatty[2], A. Huang[3];

[1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Alexander Huang (Individual)

Personalized neoantigen cancer vaccines have been at the forefront of therapeutic vaccination. However, although these neoantigen vaccines do induce neoantigen-specific T cell responses, the clinical effects are limited. Logistical challenges, such as the time required for developing personalized neoantigen vaccines, also limit their clinical utility. We were recently intrigued by a case at Penn where one of our patients had a 7.6 cm melanoma tumor and experienced a complete response after receiving the COVID-19 vaccine *alone,* consistent with a recent report that cancer patients who received the SARS-CoV-2 vaccination had improved survival. Further studies identified abundant SARS-CoV-specific T cells present in both the draining lymph node (LN) and in the necrotic tumor bed. At the same time, our preliminary experiment in mice showed a similar phenomenon that the activation of tumor-irrelevant CAR T cells by vaccination reinvigorated the host's tumor-specific immunity and regressed established solid tumors. Specifically, when we used our recently developed lipid polymer vaccine (Ma et al, Science, 2019; Cell, 2023; Grzywa et al, Nat BME, 2025) carrying a chemical ligand Fluorescein (FITC) to specifically stimulate adoptively transferred bystander FITC-targeting chimeric antigen receptor (CAR) T cells in vivo in the lymph node as a negative control, yet unexpectedly we observed distal tumor regression to a level that's comparable to vaccine stimulation of tumor-specific CAR T in syngeneic mouse models of pancreatic cancer and melanoma. In both settings, tumor volume was reduced by>70% within the first 72 hours, and this effect persisted for up to 2 weeks (with some cures of the melanoma). This marked antigen-independent tumor control is completely lost in Rag1-knockout (no endogenous T cells) and BatF3-knockout (deficient in antigen cross-presentation) recipient mice. FITC vaccine boosting of bystander FITC-CAR T induced a rapid and transient cytokine and chemokine release that distally remodels the tumor microenvironment. Notably, IFNg blockade completely abolished this tumor control. In the pancreatic cancer model, IFNg significantly upregulated PD-L1 expression in cancer cells. As a result, co-administration of anti-PD-L1 markedly extended long-term tumor control and animal survival. Collectively, these unexpected findings in both the melanoma patient and syngeneic mouse models of solid tumors suggested a previously unappreciated anti-tumor bystander effect associated with vaccine-mediated T cell activation.

#1351 IL-18 secreting CAR-T cells uncover divergent immune mechanisms of antigen-heterogeneous solid tumor clearance.

A. May, E. Sotillo, P. Xu, A. Malhotra, K. Ho, C. Mackall;
Stanford University School of Medicine, Stanford, CA

CAR-T therapy has improved the outcome for patients with refractory hematological malignancies, however this success has not translated to solid tumors, largely due to an immunosuppressive tumor microenvironment (TME) and heterogenous antigen expression. CAR-Ts capable of reshaping the TME and recruiting endogenous immune cells, could improve outcomes by eradicating cells with low or absent expression of the CAR targeted antigen. However, the biological mechanisms necessary to induce endogenous anti-tumor T cell responses remain unclear. Previous studies have reported that CAR-T cells engineered to secrete IL-18 induced immune priming and an endogenous anti-tumor response. We sought to study tumor clearance rates and endogenous immune responses induced by control and IL-18 secreting CAR-T cells by administering murine CAR-Ts targeting human CD19 (huCD19.28.z-CARs) to mice bearing a mixture of B16F10-Ova+huCD19+/- cells. We profiled endogenous lymphoid and myeloid compartments, as well as engineered CAR-Ts, during tumor clearance within lymphoid and tumor tissues at 14 and 26 days post CAR-T treatment. Additionally, we assessed the induction of CD8 T cells reactive to tumor-derived peptides using ELISPOT. IL-18 secreting CARs demonstrated robust antigen-heterogenous tumor control compared to the control. By day 26 post treatment, tumor measurements in IL-18 secreting CAR-T treated mice were undetectable, while control tumors averaged 680 mm^3. Despite improved tumor control, IL-18 secreting CAR treated mice generated fewer CD8s reactive to Ova, a tumor neoantigen, compared to the CAR only control. Instead, IL-18 secretion induced a strong type II interferon response, skewing effector differentiation of lymphocytes and initiating expansion and activation of myeloid cells, including macrophages and neutrophils. This work reveals that enhanced clearance of heterogenous solid tumors by cytokine secreting CAR-Ts may occur through distinct immunological programs. CAR-Ts secreting IL-18 cleared mixed antigen expressing tumors most effectively, but induced a low/absent anti-tumor CD8 T cell response. In contrast, CAR-Ts alone failed to control tumors, but effectively induced priming of CD8s towards a tumor expressed neoantigen. These findings suggest activated innate myeloid cells as key mediators in eradicating antigen negative cells within a heterogeneous tumor and illustrate distinct biology between tumor clearance via innate immune responses versus induction of persistent adaptive immunity to tumor associated antigens. Taken together, this study can inform next-generation CAR-T design by underscoring the importance of balancing effector potency with durable endogenous anti-tumor immunity to engineer sustained efficacy in solid tumors.

#1353 Emergency myelopoiesis drives immunosuppressive monocyte programming in lymphoma-associated secondary hemophagocytic lymphohistiocytosis.

H. Cho[1], J.-E. Kwak[1], J.-Y. Koh[2], J. Byun[1], Y. Koh[3], J. Hong[1], D.-Y. Shin[1], I. Kim[1], H. Ju[4];
[1]Seoul National University Hospital, Seoul, Korea, Republic of, [2]UCSD, San Diego, CA, [3]Seoul National University School of Medicine, Seoul, Korea, Republic of, [4]Samsung Medical Center, Seoul, Korea, Republic of

Lymphoma-associated secondary hemophagocytic lymphohistiocytosis (sHLH) is a highly fatal manifestation of cancer-induced immune dysregulation, yet how lymphoma reshapes myelopoiesis to generate pathogenic myeloid cells remains unclear. To define the malignant immune ecosystem, we performed single-cell RNA sequencing on paired bone marrow and peripheral blood samples from patients with B-cell lymphoma with sHLH (n=14) or without sHLH (n=7), with primary HLH carrying *PRF1* or *UNC13D* mutations (n=6) included to distinguish cancer-driven remodeling from inherited immune defects (total 110,943 cells). Lymphoma-associated sHLH exhibited tumor-driven emergency myelopoiesis with expansion of myeloid-biased hematopoietic stem cells and granulocyte-monocyte progenitors (GMPs). These progenitors displayed activation of inflammatory pathways (TNF-α, IFN-γ) and were pre-imprinted with the MS1 immunosuppressive transcriptional program (*S100A8/9*, *IL1R2*, *PLAC8*, low *HLA-DR*), indicating that monocytic dysfunction originates at the progenitor stage within the tumor-altered bone marrow niche. MS1-like monocytes diverged into two terminal lineages; one lineage was preferentially expanded in sHLH and expressed pro-inflammatory cytokines (*CXCL2*, *CXCL3*, *IL6*), the regulatory cytokine *IL10*, and multiple immune checkpoint ligands (*VSIG4*, *LILRB4*). Cell-cell interaction and regulon analyses revealed an IL-6/IL-10-STAT3 signaling loop that reinforces MS1 programming and creates a self-sustaining immunosuppressive circuit. Functionally, the abundance of MS1-like monocytes inversely correlated with $CD4^+$ and $CD8^+$ T-cell frequencies, accompanied by loss of conventional dendritic cells, impaired antigen presentation, and metabolic hyperactivation of T cells with increased *PD-1*, *TIM-3*, and *LAG-3* expression, suggestive of dysfunctional activation rather than classical exhaustion. These findings uncover a cancer-driven immunopathogenic mechanism in which lymphoma hijacks myelopoiesis to generate STAT3-dependent immunosuppressive monocytes that simultaneously amplify hyperinflammation and blunt anti-tumor immunity. Targeting emergency myelopoiesis or monocytic STAT3 signaling represents a therapeutic strategy for restoring immune competence in lymphoma-associated sHLH.

Minisymposium

#1383 Defining the role of the Daam2 R414W germline variant in familial glioma.

T. J. Choy[1], Q. Ye[1], M. L. Bondy[2], H. Lee[1];
[1]Baylor College of Medicine, Houston, TX, [2]Stanford Cancer Institute, Stanford, CA

Malignant glioma is the most common primary brain tumor in adults, with high morbidity and mortality due to its aggressive nature and limited treatment options. While advances in molecular genetics have improved glioma classification, these systems rely predominantly on sporadic somatic mutations that cannot predict individual glioma risk. In contrast, the 5-10% of gliomas occurring in families with hereditary predisposition offer a powerful opportunity to identify germline variants that increase glioma susceptibility and may serve as biomarkers for risk assessment. Dysregulation of developmental signaling pathways has been increasingly implicated in gliomagenesis. Through whole-exome sequencing of familial glioma patients, we identified five germline mutations in *Daam2* (Dishevelled associated activator of morphogenesis 2), a key regulator of Wnt signaling. *Daam2* encodes a formin protein crucial for glial differentiation and highly enriched in glial cells. Our prior work demonstrated that Daam2 is sufficient to promote gliomagenesis and essential for glioma growth, prompting us to investigate whether these variants affect tumor progression. We overexpressed each variant in patient-derived glioma stem-like cells and orthotopically xenografted them into immunodeficient mice. Among the variants, Daam2-R414W significantly promoted tumor cell proliferation in vitro and in vivo. To model this patient-observed mutation in an immunocompetent system, we generated a Daam2-R414W knock-in mouse model. Mutant mice exhibited an increased number of proliferating glial progenitor cells in the subventricular zone compared to wildtype (WT) controls, suggesting that Daam2-R414W expands the glial progenitor pool to facilitate glioma initiation. Since the patient harboring the Daam2-R414W mutation was diagnosed with oligodendroglioma, a low-grade glioma (LGG), we induced LGG in Daam2-R414W mutant mice and observed increased tumor cell proliferation and decreased survival compared to WT LGG-bearing mice, suggesting that Daam2-R414W accelerates malignant progression. To identify molecular mechanisms underlying these phenotypes, we performed bulk RNA-sequencing on LGG tumors from Daam2-R414W mutant and WT mice. Sequencing revealed increased expression of Wnt pathway components, actin cytoskeletal genes, and oligodendrocyte progenitor cell (OPC) markers in Daam2-R414W tumors compared to WT. Among these changes, marked upregulation of TCF3, a key transcription factor in canonical Wnt signaling, points to enhanced pathway activation in mutant tumors. These findings suggest that Daam2-R414W accelerates tumor progression by amplifying Wnt-driven proliferative signaling programs that drive glioma growth. Overall, this study identifies a hereditary glioma-predisposing variant and demonstrates how germline mutations in developmental regulators can disrupt normal cellular function to promote malignancy.

#1384 Aging amplifies oncogenic mutant pik3ca 1047R signaling and accelerates mammary tumorigenesis.

T. Mohan, J. Mackay, M. McLaughlin, Y. Li, A. Nazarullah, L.-Z. Sun;
The University of Texas at San Antonio Health Science Center, San Antonio, TX

Breast cancer incidence increases with age, and hormone receptor positive (HR+) and HER2 negative tumors represents the most prevalent subtype among older women. Approximately 70% of early-stage breast cancers are HR+/HER2−, frequently harboring the *PIK3CA* H1047R mutation, a driver of heterogeneous mammary carcinomas. Understanding how PIK3CA H1047R mutant interacts with the aging microenvironment is important for elucidating age-related susceptibility and may enlighten age-specific therapeutic strategies. In this study, we investigated age-dependent susceptibility to PIK3CA H1047R-driven tumorigenesis using intraductal delivery of lentivirus expressing human PIK3CA H1047R in FVB/NJ mice across three age groups (young: 2 mo, n=10; middle-aged: 14 mo, n=8; aged: 22 mo, n=7). Mice were monitored for up to 6 months, and the time to palpable tumor formation was used to generate tumor-free survival curves. qPCR analysis confirmed age-dependent differences in *PIK3CA* H1047R genomic integration and expression. Ductal morphology and histopathology were evaluated using carmine whole-mount and hematoxylin and eosin staining. Morphometric characterization was performed using BD FACS Discover S8 Cell Sorter. High-dimensional flowcytometric analysis (t-SNE, FlowSOM, Cluster Explorer) was used to identify epithelial subsets most susceptible to transformation. Middle-aged and aged mice displayed significantly higher tumor incidence and shorter latency compared with young mice, consistent with increased *PIK3CA* integration and expression. Morphometric analysis revealed that luminal cells ($CD49f^{low}CD24^{high}$) expressed maximal PIK3CA H1047R protein concentration (Max Intensity MFI) than basal cells ($CD49f^{high}CD24^{low}$). Further, Eccentricity and Radial movement imaging features revealed age- and lineage-specific oncogenic responses. Together, these findings indicate that aging is not merely a risk factor but actively modifies PIK3CA-driven oncogenic signaling. These age-associated alterations in mammary epithelial cell populations may inform development of targeted therapies for older patients with HR+/HER2− breast cancer. A limitation of this study is the use of a murine intraductal model, which may not fully capture human breast cancer biology. Further studies incorporating stromal and immune components are needed to comprehensively understand how aging influences oncogenic PIK3CA signaling.

#1385 Evaluation of kinase inhibitor efficacy and cancer-associated fibroblast-organoid crosstalk in a CRISPR-edited mouse model of bladder cancer.

T. Haque, H. Valentine, U. Satyal, L. Bukavina, R. Arya, P. H. Abbosh;
Fox Chase Cancer Center, Philadelphia, PA

Background: The PI3K/AKT/mTOR pathway is altered in more than 40% of bladder cancers (BCa), yet it remains untargeted therapeutically. We developed an immunocompetent, CRISPR-edited BCa mouse model that recapitulates common mutations in this pathway. The tumor microenvironment, particularly cancer-associated fibroblasts (CAFs), plays a critical role in BCa progression, and the molecular mechanisms underlying tumor-CAF crosstalk are incompletely understood in BCa. We focused on identifying genotype-specific kinase inhibitor combinations and elucidating cytokine-mediated crosstalk between CRISPR-edited organoids and CAFs.
Methods: Urothelial organoids from Rosa26-LSL-Cas9/GFP mice were CRISPR-engineered with Trp53 knockout plus either Rb1 knockout or deletion of the region homologous to human chromosome 9p21. A third mutation in the mTOR pathway (PIK3CA H1047R hotspot mutation) was then introduced. Gene edits were confirmed and cell lines were characterized for kinase inhibitor sensitivity. Engraftment studies were assessed in immunocompromised and immunocompetent mice to evaluate therapeutic targeting of genotype-specific kinase inhibitors via bladder engraftment or subcutaneous injection. CAFs were purified from carcinogen-induced murine bladder tumors. Organoid-CAF co-injection experiments were performed to assess CAF dependency for tumorigenesis. Cytokine profiling was performed on organoid monocultures, CAF monocultures, and organoid-CAF co-cultures. GM-CSF knockout organoids were generated and co-cultured with CAFs to evaluate cytokine-mediated crosstalk.
Results: Triple-mutant organoids formed tumors in immunocompromised mice and exhibited sensitivity to PI3K inhibitor treatment (pictilisib or alpelisib) vs double-mutant controls, validating our genotype-specific targeting approach. However, the same organoids were non-tumorigenic in immunocompetent hosts. Co-engraftment with CAFs promoted tumor formation, demonstrating CAF dependency for tumorigenesis in immunocompetent hosts. Cytokine profiling revealed elevated IL-6 and GM-CSF secretion from organoid-CAF co-cultures but not monocultures, with GM-CSF by organoids and IL-6 secreted by CAFs. GM-CSF knockout in organoids reduced IL-6 secretion from CAFs, supporting cytokine-mediated CAF-organoid crosstalk.
Conclusions: Our findings suggest GM-CSF and IL-6 critically mediate CAF-dependent tumor engraftment and targeting this cytokine axis may disrupt CAF-organoid crosstalk to inhibit tumor growth in immunocompetent models. Future studies will evaluate immune contributions and dual cytokine targeting. These findings support precision medicine combining genotype-specific kinase inhibition with microenvironment-directed therapies for BCa patients harboring mTOR pathway alterations.

#1386 NSCLC patient-derived organoids recapitulate tissue signalling and impairment of infiltrated immune cell activation predicting patients' response to therapy.

A. Pasto[1], H. Al-Serori[1], M. Fankhaenel[1], Z. Mokhtari[2], D. Mukherjee[1], R. Drews[1], P. Barber[1], J. Davis[1], L. Wedeken[3], V. Yankova[1], J. Loskutov[3], J. Monypenny[4], N. Patel[4], M. Htun[1], M. Finn[1], S. Ndagire[4], E. Karapanagiotou[5], E. Moon[6], C. Gillett[7], A. Bille[8], T. Ng[1]; [1]GlaxoSmithKline plc, Stevenage, United Kingdom, [2]GlaxoSmithKline plc, Heidelberg, Germany, [3]GlaxoSmithKline plc, Berlin, Germany, [4]King's College of London, London, United Kingdom, [5]Cancer Centre at Guy's St Thomas, London, United Kingdom, [6]GlaxoSmithKline plc, Upper Providence, PA, [7]King's College of London, London, United Kingdom, [8]Guy's and St Thomas' Hospital, London, United Kingdom

Non-small cell lung cancer (NSCLC) with its rapid growth and early metastasis onset, represents the most common cause of cancer-related deaths worldwide. Current treatments offer limited long-term survival, necessitating novel approaches. Immunotherapy, specifically anti-PD1 and anti-PD-L1, has transformed NSCLC treatment, but only a small percentage of patients respond. There is an unmet need to predict immuno-therapy susceptibilities, achieve a cancer patient risk stratification and identify targeted therapies. Patient-derived organoids (PDOs) are in vitro 3D structures that recapitulate the complexity of the tumours from which they derived, showing a great potential as preclinical model for drug screening and tailored treatment. We used 12 PDO models established from chemotherapy-naïve high-risk NSCLC patients tissues collected at the Guy's Hospital, London. Patients' follow-up was performed for more than 24 months post resection/biopsy/surgery. PDOs were treated with cisplatin, then co-cultured with pre-activated immune cells in the presence of IO drugs and subjected to multiple assays including imaging, flow cytometry, genomic and transcriptomic analysis and proteomic from exosome isolation. This multi-omics approach allows for simultaneous analysis of different biological parameters before and after treatment to understand tumour cell interaction with immune cells and drug-induced changes. According to patients' clinical response to standard of care treatment, PDOs were classified as responder (R) and not responder (NR). Cisplatin IC50, elaborated from PDOs cytotoxicity analysis, correlated with R and NR dichotomy, predicting the response status of the patients in vivo. When PDOs were cocultured with PBMC, counterintuitively, we observed a higher immune cells infiltration after cisplatin treatment in the NR-PDOs. Neither baseline CD45 infiltration nor the composition of infiltrating PBMC differed between NR and R-PDOs. However, in the baseline condition, the $CD8^{pos}$ cells infiltrating NR-PDOs presented a predominantly exhaustion profile. Transcriptomic analysis of untreated PDOs revealed higher activation of inflammatory response signalling in the NR-PDOs compared to responders, and the same signalling upregulation was identify from spatial transcriptomic analysis on primary tumour tissues derived from NR patients. Proteomic analysis of extracellular vesicles cargo also identified different protein content in R vs NR-PDO supporting the involvement of EV in the crosstalk between PDO and immune cells. We found that PDOs maintain the transcriptomic profile of the tissue they derived from with different activation of specific signalling that contributes to the creation of an inflammatory microenvironment and correlates with drug response status.

#1387 Live cell visualization of RNA splicing dynamics upon APOBEC3 lentiviral transduction in aged bone marrow using a 3D biosensing nanobioreactor.

E. Klacking[1], I. van der Werf[1], J. Isquith[1], J. Pham[1], T. Whisenant[1], A. A. Khachatrian[2], L. B. Alexandrov[1], C. H. Jamieson[1];
[1]UCSD, La Jolla, CA, [2]Scripps, La Jolla, CA

Background: During aging, hematopoietic stem and progenitor cells (HSPCs) undergo a progressive decline in regenerative capacity, exhibit skewed differentiation toward the myeloid lineage, show increased sensitivity to stressors, and accumulate somatic mutations, a process known as clonal hematopoiesis (CH), which increases susceptibility to hematological malignancies. Additional hallmarks of aging, include genomic instability, chronic inflammation, upregulation of inflammatory cytokines, and deregulated RNA splicing. Prior work demonstrated age-associated splice isoform expression in aged bone marrow (ABM) derived HSPCs (Crews⋯Jamieson, Cell Stem Cell, 2016). Here, we apply a 3D biosensing nanobioreactor (Pham⋯Jamieson, Cell Stem Cell, 2025) to track RNA splicing in aged bone marrow (ABM) derived HSPCs in real-time using confocal microscopy and evaluate age-related splice dysregulation linked to malignant evolution.

Methods: Nanobioreactors were constructed from transparent, gas-permeable, 2-port fluoroethyl polymer (FEP) film bags with a porcine gelatin sponge matrix. Mononuclear ABM cells were isolated by Ficoll density centrifugation, and $CD34^+$ cells were purified by magnetic bead selection. $CD34^+$ cells were lentivirally transduced with a dual fluorescent splicing reporter (van der Werf et al., *Cell Reports Medicine*, 2023), cultured for 48 hours, and co-cultured with autologous $CD34^-$ stromal cells in the nanobioreactor at a 1:4 ratio.

Results: In ABM-derived $CD34^+$ cells, lentiviral transduction of the dual fluorescent splicing reporter resulted predominantly in red fluorescence protein (RFP) expression, indicating exon inclusion, as assessed by confocal microscopy. Based on preliminary whole-transcriptome sequencing analyses showing increased exon-skipping events, we hypothesize that APOBEC3C drives exon skipping in aged HSPCs. To test this, $CD34^+$ selected cells from ABM aspirates were lentivirally transduced with the splicing reporter, followed by either APOBEC3C overexpression or pCDH vector control. Confocal imaging revealed a fluorescence shift consistent with increased exon skipping in APOBEC3C-transduced cells, confirming the reporter's ability to capture dynamic splicing changes in response to APOBEC3C activity.

Conclusion: We developed a 3D biosensing niche nanobioreactor system that enables live-cell visualization of RNA splicing dynamics in primary human HSPCs. Using this platform, we identified predominant exon inclusion in aged bone marrow-derived HSPCs and demonstrated that APOBEC3C overexpression induces exon skipping, a molecular signature associated with leukemic transformation. Future studies will compare aged and young bone marrow to delineate age-related splicing alterations and define RNA splicing-based biomarkers predictive of hematopoietic aging and malignant evolution.

#1388 Ex vivo micro-tumor testing platform to guide patient stratification for clinical development of ADCs.

Esmee Koedoot[1], **Felix M. Behr**[1], Timothy JP Sijsenaar[1], Dieudonne J. van der Meer[1], Lea Le Large[1], Farbod Khoraminia[1], Nelleke Ottevanger[2], Judith R. Kroep[3], Cor D. de Kroon[4], Willemijn Vader[1]

[1]VitroScan, Leiden, Netherlands,[2]Radboud University Medical Center, Nijmegen, Netherlands,[3]Dept. of Medical Oncology, K1-P, Leiden Univ. Medical Ctr., Leiden,[4]Leiden Univ. Medical Ctr., Leiden, Netherlands

Background Antibody-Drug Conjugates (ADCs) are revolutionizing cancer therapy. Yet, more than 90% fail to reach approval and ADC efficacy often poorly correlates with target expression, emphasizing the high need for improved prediction of patient responses to ADCs. Ex vivo micro-tumor testing enables near-clinical evaluation across drug classes, including ADCs, and has been shown to predict clinical responses to platinum therapy (Koedoot et al., npj Precision Oncology, 2025). This study evaluates ex vivo sensitivity to clinically relevant ADCs in ovarian (OC), non-small cell lung (NSCLC), and colorectal (CRC) cancer, aiming to identify predictive biomarkers and guide patient stratification to optimize clinical benefit.

Materials and Methods Ex vivo evaluation of patient specific responses to ADCs was performed by testing mirvetuximab-soravtansine (MIRV) in OC patient samples (N=25), ifinatamab deruxtecan (IFI) in CRC patient samples (N=5) and telisotuzumab vedotin (TEL) in NSCLC patient samples (N=10). Tumor tissue was processed within 48 hours. Enriched patient micro-tumors with preserved tumor microenvironment (TME) were embedded in hydrogel and exposed to standard of care therapy, ADCs and their respective payloads. Screening plates were fixed, stained and imaged, followed by high-dimensional image analysis and phenotypical feature extraction. Drug sensitivity profiles were established based on anti-tumor activity. Target protein expression profiling was performed by immunofluorescence staining of ex vivo micro-tumors.

Results Ex vivo testing of OC, NSCLC and CRC patient samples revealed patient-specific sensitivity to the respective ADCs. For MIRV, 32% (8/25) of the OC patients demonstrated strong sensitivity (Emax < 50%), 48% (12/25) of the patients demonstrated intermediate sensitivity (Emax 50-90%) and 20% of the patients (5/25) demonstrated complete MIRV resistance (Emax > 90%). Reproducible responses were observed for different drainages from the same patient (N=3). A strong correlation was observed between MIRV and paclitaxel sensitivity (R = 0.86), both of which target tubulin. A reduced correlation was observed for MIRV and carboplatin (R = 0.59), that acts by crosslinking DNA. Target protein expression profiling revealed inter- and intra-tumor heterogeneity. Some patients exhibited low target protein expression in all micro-tumors, while others exhibited high expression in a fraction of micro-tumors.

Conclusions This study reports an ex vivo micro-tumor testing platform that enables near clinical assessment of patient responses to ADCs. The platform is future-ready, offering multimodal capabilities including tumor microenvironment (TME) characterization, target protein profiling capturing patient heterogeneity, and assessment of bystander and synergistic responses. The next step is to correlate the ex vivo sensitivity to actual clinical outcome.

#1389 Defining immune phenotypes of checkpoint inhibitor response in human live tumor fragments preserving the native tumor microenvironment.

E. von Euw[1], J. Zweng[1], N. Dana[1], C. Sood[1], H. R. Hernan[1], L. C. F. Hrycyniak[1], P. McDonnell[1], P. Adstamongkonkul[1], C. Johnson[1], N. Marhefke[1], A. Nasreen[1], T. S. Ramasubramanian[1], K. Rexroad[1], S. Schneider[1], C. Scribano[1], A. Sunil[1], E. Wargowski[1], C. Vivelo[1], L. Vedder[1], S. Caenepeel[1], D. A. Braun[2], H. J. Gierman[1], H. Ramos[1];

[1]Elephas Biosciences, Madison, WI, [2]Yale School of Medicine, New Haven, CT

Background: Immune checkpoint inhibitors (ICIs) provide durable benefit for a subset of patients, yet current FDA-approved biomarkers (eg, PD-L1, MMR/MSI, TMB) inaccurately predict clinical response. To address this gap, we have developed an ex vivo platform using live tumor fragments (LTFs) and multiplex cytokine profiling to accurately predict ICI response in patients ($P<0.05$). Ex vivo cytokine profiling of LTFs produced from clinically relevant tumor specimens provides a unique opportunity to elucidate the biology and mechanisms of action of ICI response in the context of the native tumor microenvironment (TME).

Methods: Fresh core needle or forceps biopsy specimens collected as part of three ongoing observational clinical trials (NCT05478538, NCT05520099, NCT0634962) and a biobank biopsy collection study were profiled on the platform. Biopsy specimens were cut into LTFs, encapsulated in hydrogel and treated with ICI (αPD-1, αPD-L1, αPD-1+αCTLA-4 or αPD-L1+αCTLA-4) ex vivo. Longitudinal profiling of 46 cytokines was performed on 193 patient samples representing multiple solid tumor types. Unsupervised hierarchical clustering with Wards method was used to identify cytokine-based response patterns and classify specimens into primary responder and non-responder clusters. Upregulated cytokines within the response cluster were defined using Mann-Whitney-U tests with Bonferroni correction for multiple comparisons, annotated for their function, and subclusters were classified into immune phenotypes.

Results: Comparison of response and non-response clusters identified 21 significantly upregulated cytokines ($P<0.05$) known to be associated with immune response to ICI. Additionally, response subcluster analysis identified 4 distinct tumor-type agnostic immune phenotypes: (1) T-cell inflamed with regulatory counterbalance, (2) mixed regulatory T-reg/myeloid (3) cytotoxic inflamed with T-reg-VEGF counterbalance, and (4) polyfunctional activated with myeloid angiogenic remodeling. Furthermore, subcluster assignment was consistent in 6 of 7 (85%) patient specimens with multiple replicates, demonstrating that profiles of response, when present, are reproducible between replicates from the same tumor. To date, patients with available clinical response data to an ICI therapy were identified across different subclusters.

Conclusions: The ex vivo platform identifies distinct and expected immune phenotypes in response to ICI treatments. These data underscore the platform's potential to accurately predict clinical response to ICI. Future studies will help to understand the relationship between these immune phenotypes and the depth and durability of ICI response in patients.

: Noncoding RNA Regulation of Cancer Hallmarks, Therapeutic Resistance, and Biomarker Discovery Minisymposium

#1365 Regulation of ribosomal RNA synthesis in acute myeloid leukemia.

P. J. Hung, J. A. Henrich, C. Antony, V. R. Paralkar;
University of Pennsylvania, Philadelphia, PA

Acute myeloid leukemia (AML) is an aggressive blood cancer with high rates of relapse and limited second-line treatment options, resulting in a five-year survival of 20-30%. A defining feature of AML cells is their prominent nucleoli, which demarcate sites of active ribosomal RNA (rRNA) synthesis. rRNAs are specialized non-coding RNAs that form the catalytic cores of ribosomes, and their transcription by RNA polymerase 1 (Pol1) is the rate-determining step in ribosome biogenesis. We hypothesized that AML cells require increased rRNA synthesis and protein translational capacities to support their growth and survival. To test this premise, we developed a “FISH-Flow” assay to measure the relative levels of nascent and mature rRNAs in different cell-types across the human hematopoietic tree. Profiling over twenty bone marrow aspirates from healthy donors and AML patients, we found that rRNA synthesis varies widely throughout normal hematopoiesis – peaking in the stem/progenitor cell populations (CMPs, GMPs, MEPs) – and is elevated by 1.5 to 2-fold in AML cells. Our analysis of publicly available single-cell RNA-seq data further showed that the Pol1 gene signature is overexpressed in AML cells.

To assess whether rRNA “hyper-synthesis” is essential for AML cell fitness, we generated a HoxA9 transgene-driven mouse AML cell-line with POLR1A (the catalytic subunit of Pol1) fused to an FKBP degron domain, which enables targeted degradation of Pol1 by a small molecule dTAG. Pol1 depletion led to a rapid decrease in rRNA synthesis, G1 cell cycle arrest, and monocytic differentiation, as evidenced by downregulation of the stem cell marker c-Kit and upregulation of the mature monocyte marker Ly6C. Additionally, dTAG treatment synergized strongly with Bcl-2 inhibitors to induce apoptosis in these cells. This synergy did not extend to other AML chemotherapy agents, such as daunorubicin or cytarabine, indicating a unique, synthetically lethal interaction between the rRNA synthesis and Bcl-2 signaling pathways in AML cells.

In summary, we demonstrate that rRNA synthesis and Pol1 expression are amplified in AML cells to sustain an oncogenic, stem-like state that renders them more resistant to apoptotic stimuli. Notably, our findings identify rRNA synthesis as a therapeutic vulnerability in AML cells and uncover a novel synthetic lethality with Bcl-2 inhibition.

#1366 CYP4A22-AS1-YBX1 axis drives radiation resistance in cervical adenocarcinoma via PGK1 transactivation.

Mingyi Zhou, Chunlai Li, Cristina Ivan, Simone Anfossi, Linda Fabris, Melanie Winkle, Recep Bayraktar, Meng Chen, Lan Pang, Masayoshi Shimizu, Francois Claret, George Calin

The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Cervical adenocarcinoma exhibits poor responsiveness to radiotherapy and inferior survival compared with squamous cell carcinoma. The molecular mechanisms underlying its intrinsic radiation resistance remain largely unknown.
Methods: Integrative analysis of TCGA and our RNA-seq cohort identified CYP4A22-AS1 as one of the most upregulated lncRNAs in cervical adenocarcinoma. qRT-PCR confirmed higher CYP4A22-AS1 expression in tumors with short disease-free survival (DFS). RNA pulldown, mass spectrometry, and RIP assays defined YBX1 as a direct CYP4A22-AS1-binding partner. Immunofluorescence and ChIP-qPCR assays examined YBX1 nuclear localization and promoter occupancy of PGK1, respectively. Functional effects of CYP4A22-AS1, YBX1, and PGK1 silencing were assessed by CCK-8, colony, EdU, and TUNEL assays in HeLa and C33A cells, and validated in xenograft models.
Results: CYP4A22-AS1 was markedly overexpressed in cervical adenocarcinoma relative to normal cervix. Clinically, high CYP4A22-AS1 and PGK1 levels correlated with shorter DFS. Mechanistically, CYP4A22-AS1 binds YBX1 and enhances its nuclear translocation, thereby promoting YBX1 recruitment to the PGK1 promoter and activating glycolytic metabolism. Knockdown of CYP4A22-AS1 or PGK1 suppressed proliferation and markedly increased radiosensitivity both in vitro and in vivo.
Conclusions: This study identifies CYP4A22-AS1 as a novel oncogenic lncRNA that drives radiation resistance through YBX1-mediated PGK1 transactivation. Clinically, CYP4A22-AS1 overexpression predicts poor outcome, while its inhibition restores radiation sensitivity. Targeting the CYP4A22-AS1-YBX1-PGK1 signaling axis offers a promising therapeutic strategy to overcome radioresistance in cervical adenocarcinoma.

#1367 Dual remodeling of RCC-associated fibroblasts via miR-196b antagomir and COUP-TFII inhibitor ultrasmall lactoferrin-lipid nano-assemblies augments immunotherapy.

A. Ziada[1], L. Escalante Gonzalez[2], Z. Sideeka[3], A. Jarrous[4], A. Mayer[5], L. Ren[6], A. Park[5], A. Ajay[4], C. Xin[4], A. Elzoghby[4]; [1]Amherst College, Amherst, MA, [2]Tecnologico de Monterrey, Monterrey, Mexico, [3]The George Washington University, Washington, DC, WA, [4]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [5]Northeastern University, Boston, MA, [6]Rice University, Houston, TX

Renal cell carcinoma (RCC), a type of kidney cancer, is among the 10 most common cancers in both men and women. Despite the advanced progress of cancer immunotherapy, many RCC patients show resistance to immune checkpoint inhibitors. Cancer-associated fibroblasts (CAFs) play a key role in promoting immunosuppression in RCC, which markedly impairs the antitumor immune response. Several oncogenic miRNAs (OncomiRs) are upregulated in RCC fibroblasts where they drive their differentiation into CAFs by modulating the expression of target genes involved in phenotypic changes associated with CAFs. Moreover, COUP-TFII is an unexplored transcription factor implicated in the differentiation of kidney fibroblasts. In our study, microarray-based miRNA sequencing analysis showed upregulation of some miRNAs (e.g., miR 196b) in RCC patient-derived CAFs compared to normal kidney fibroblasts. Therefore, we engineered novel ultrasmall recombinant lactoferrin (LF)-stabilized lipid nano-assemblies (NAs) co-loaded with antagomir (anti-miR 196b) and COUP-TFII inhibitor (CIA-1) to induce synergistic remodeling of renal CAFs into a quiescent phenotype. LF, a GRAS (Generally Regarded as Safe) glycoprotein, targets tumor fibroblasts through natural tropism to LRP1 and intelectin-1 receptors, over-expressed in fibrotic tissues. In addition, the recombinant form of human lactoferrin (rhLF) has high batch-to-batch consistency, reduced immunogenicity, precise molecular tailoring for drug incorporation and surface modification, and well-tolerated following systemic administration. The rhLF-lipid NAs exhibited ultrasmall and uniform size (5-7 nm) with discoidal morphology. Moreover, the NAs were successfully internalized into RCC patient-derived CAFs without inducing remarkable toxicity. The NAs reprogrammed renal CAFs into quiescence as evidenced by downregulation of fibroblast activation (e.g., αSMA, FAP, and S100A4) and extracellular matrix (e.g., Col1α1, Col3α1, fibronectin, periostin, and tenascin C) markers as well as upregulation of the quiescence marker p27. In addition, the secretion of IL-6, IL-8 and MCP1 by renal CAFs was significantly reduced after treatment with the NAs. Further treatment of renal cancer cells with conditioned media of CAFs pre-treated with the engineered NAs resulted in reduced migration and downregulation of stemness, epithelial to mesenchymal transition and proliferation markers. *In vivo*, the ultrasmall size and LF-targeting properties promoted higher accumulation of the IRDye 800CW-coupled fluorescent NAs in kidney tumors relative to liver and spleen following *i.v.* injection into orthotopic syngeneic kidney tumor-bearing mice. Our strategy represents a paradigm shift in RCC treatment, as it addresses the immunosuppressive role of CAFs by dual mechanistic nano-engineering approach.

#1368 Mitochondrial tRNA fragments as modifiers of breast cancer development and metastasis.

K. L. Swancutt[1], S. Quijano[1], G. Fisette[1], E. Schueddig[1], D. C. Koestler[1], I. Rigoutsos[2], Y. Jing[2], D. R. Welch[1];
[1]University of Kansas Cancer Center, Kansas City, KS, [2]Thomas Jefferson University, Philadelphia, PA

Metastasis accounts for most cancer related morbidity and mortality and is strongly influenced by host genetic background. Using inbred mouse strains, germline single nucleotide polymorphisms (SNP) can shape the tumor microenvironment, immune response, and systemic physiology to permit or restrict metastatic spread. Given the central role of mitochondria in regulating metabolism and cellular signaling, mitochondrial genetics represent an additional, and largely unexplored, dimension of host control over metastasis. To isolate mitochondrial from nuclear contributions, we compared wild-type to mitochondrial nuclear exchange (MNX) mice, in which nuclear genomes from one inbred strain are paired with mitochondrial genomes from another. Across multiple oncogenic drivers, mtDNA significantly alters primary tumor growth and metastatic efficiency. No broad-scope alterations in metabolism distinguish MNX from nuclear genome-matched wild-type mice. So, we focused on a SNP localized to the mitochondrial tRNA for arginine (mt-TR), where distinct SNP correlate with differences in metastasis, nuclear gene regulation, immune profiles, and gut microbial composition. Since nucleus encoded tRNA regulate diverse cellular processes (including transcription, translation, stress responses, and metastasis) via formation of tRNA-derived fragments (tRF), we hypothesized that mitochondrial tRF can function similarly. Using northern blotting, we identified previously unreported mt-TR-derived tRF and found that their expression varies by SNP, sex, and tissues. The fragment patterns indicate that mt-TR undergoes defined site cleavage rather than random degradation. We deduced that tRF derived from mt-TR are highly modified molecules with terminal end modifications and/or base methylations that prevent detection by standard small RNA sequencing. After enzymatic removal of these modifications, the fragments were sequenced, allowing us to map cleavage sites and resolve SNP-dependent fragment populations. These molecules constitute some of the earliest evidence that mitochondrially encoded tRF may contribute to the regulation of complex cancer phenotypes such as metastasis. Ongoing work will determine the molecular interactors which will define molecular networks influenced by mt-tRF. This work has the potential to identify previously unrecognized pathways and metastasis-regulatory mechanisms that can be leveraged to identify new targets for cancer therapy.

#1369 Urinary extracellular vesicle microRNA profiling enables noninvasive early detection and prognostic stratification of lung cancer.

Y. Ando[1], A. Kiritani[2], S. Mori[2], T. Nojiri[3], J. Watanabe[2], H. Yamaguchi[1], M. Mizunuma[1], Y. Ichikawa[1], Y. Kato[4], J. Araya[2], T. Ohtsuka[2], M. Higashiyama[3], Y. Fujita[2];

[1]Craif Inc., Tokyo, Japan, [2]The Jikei University School of Medicine, Tokyo, Japan, [3]Higashiosaka City Medical Center, Osaka, Japan, [4]Keio University School of Medicine, Tokyo, Japan

Background: Lung cancer remains the leading cause of cancer-related mortality worldwide, and recurrence frequently occurs even after curative-intent therapy. Reliable tools for early detection, prognosis prediction, and recurrence monitoring are critically needed to improve outcomes.

Methods: For early detection of lung cancer, a multicenter case-control study was conducted using urine samples from 278 patients with lung cancer (LC; 50% early-stage) and 213 participants without cancer (NC) collected at four institutions in Japan. Participants were randomly assigned to a training set (208 LC and 159 NC) and a test set (70 LC and 54 NC). Urinary extracellular vesicles-derived microRNAs (EV-miRNAs) were profiled by small RNA sequencing, and machine learning models were developed to evaluate diagnostic performance. For prognosis prediction, urinary miRNA profiles and four-year recurrence-free survival (RFS) were analyzed. Additionally, paired preoperative and postoperative urine samples from 100 surgically treated patients were analyzed, and a subset of patients also provided samples after recurrence to explore temporal miRNA changes during follow-up.

Results: The urinary EV-miRNA classifier demonstrated high diagnostic accuracy, with AUCs of 0.942 (95% CI, 0.918-0.966) in the training and 0.941 (95% CI, 0.899-0.983) in the test sets. Sensitivity and specificity for early-stage LC were 82.0% (95% CI, 73.3%-88.3%) and 92.5% (95% CI, 87.3%-95.6%) in the training set, and 88.2% (95% CI, 73.4%-95.3%) and 87.0% (95% CI, 75.6%-93.6%) in the test set, respectively. Eleven miRNAs were significantly associated with RFS, and a prognostic three-miRNA panel (hsa-miR-181a-5p, hsa-miR-185-5p, and hsa-miR-943) was constructed via fivefold cross-validation, yielding a hazard ratio of 8.3 (95% CI, 1.9-37.0). Furthermore, twelve miRNAs decreased after surgery and re-elevated after recurrence in exploratory analyses, indicating preliminary potential for postoperative monitoring.

Conclusions: This urinary EV-miRNA-based assay enables highly sensitive, noninvasive early detection of LC and demonstrates potential for prognostic assessment and recurrence monitoring. These findings suggest that a urinary EV-miRNA single-assay concept could provide a multifaceted approach for lung cancer management, supporting early detection, risk stratification, and postoperative surveillance.

#1370 Developing MTX-5-FU-Gem-miR-15a as a multimodal therapeutic strategy to overcome olaparib resistance in epithelial ovarian cancer.

Amartya Pal, Anushka Ojha, Hersh Bendale, Iwao Ojima, Jingfang Ju

Stony Brook University, Stony Brook, NY

Epithelial ovarian cancer (EOC) is the deadliest gynecological cancer, mainly because of late diagnosis, high relapse (~70%), and drug resistance, including resistance to PARP inhibitors (PARPi). Olaparib, a common PARP inhibitor, is most effective in homologous recombination-deficient (HRD) tumors. However, resistance often develops by activating other DNA repair pathways, such as the ATR/CHK1/WEE1 axis. Several studies show that blocking this pathway can restore olaparib sensitivity in resistant EOC models. miR-15a is often decreased in EOC and targets important regulators of DNA repair, cell-cycle progression, and survival, like WEE1, CHK1, BCL2, and YAP1, indicating that restoring miR-15a could help re-sensitize resistant tumors to PARPi. To enhance therapeutic efficacy, stability and tumor cell specificity, we engineered a multimodal MTX-5-FU-Gem-miR-15a combining the therapeutic power of tumor suppressor miR-15a with methotrexate (MTX), 5-fluorouracil (5-FU), and gemcitabine (Gem). MTX improves tumor specificity by targeting overexpressed folate receptor in EOC cells. Furthermore, the incorporation of 5-FU and Gem allows the construct to both disrupt DNA repair pathways and increase DNA damage burden. Hence, we hypothesized that miR-15a mimic treatment could suppress these pathways and re-sensitize resistant EOC to PARPi.MTX-5-FU-Gem-miR-15a robustly inhibited viability of olaparib-resistant EOC cells (IC50: 5–15 nM) without a delivery vehicle, induced S-phase arrest, and markedly increased apoptosis. The therapeutic efficacy of MTX-5-FU-Gem-miR-15a was improved by over 1000-fold compared to that of Olaparib. Combining MTX-5-FU-Gem-miR-15a with olaparib was significantly more effective than either agent alone. (BLISS Synergy score: 13.2). Transcriptomic profiling revealed downregulation of pathways linked to PARPi resistance, and suppression of pro-survival signaling including PI3K–AKT, mTOR, WNT pathways, consistent with broad disruption of resistance-associated networks. The mimic also retained potency in cancer stem–like (CSCs) spheroids (IC50: ~3 nM) without any delivery vehicle. To evaluate therapeutic efficacy *in vivo*, a metastatic olaparib-resistant EOC model was established by tail-vein injection of olaparib resistant EOC cells into NOD/SCID mice. MTX-5-FU-Gem-miR-15a treatment (3.75 mg/kg) reduced tumor burden by >5.5-fold (~80%) and significantly improved survival without observable toxicity or weight loss. Statistical significance was determined using Student's t-test or two-way ANOVA ($p < 0.05$). Overall, these findings demonstrate that MTX-5FU-Gem-miR-15a is a powerful multimodal miRNA-based therapeutic as it has the potential to exert strong antitumor effects in EOC and overcome drug resistance, supporting its potential as a next-generation strategy to improve patient outcomes.

#1371 POLR1B-derived circular RNA hsa-POLR1B_0014 orchestrates RNA polymerase I transcription and oncogenic hallmarks in lung adenocarcinoma through miR-181b-5p-mediated regulatory networks.

DEEPIKA ANTIL[1], Mansi Sharma[1], karmakar Arpita[1], Srivatsava Naidu[2]

[1]Indian Institute of Technology, Ropar, Rupnagar, India,[2]Biomedical Engineering, Indian Institute of Technology Ropar, Ropar, India

RNA Polymerase I (Pol I) transcription is hyperactive in lung adenocarcinoma (LUAD), underpinning various hallmarks of cancer, including therapeutic resistance. However, the molecular mechanisms, particularly the role(s) of non-coding RNAs, that couple the Pol I transcriptional machinery to oncogenic pathways remain poorly defined. Here, we identify hsa-POLR1B_0014, a circRNA derived from POLR1B gene encoding the core subunit of Pol I, is up-regulated in LUAD in concert with its parent gene. RNA-sequencing analysis of a stable hsa-POLR1B_0014 knockdown LUAD cell line (A549) revealed upregulation of several miRNAs associated with oncogenic pathways. Among these, miR-181b-5p emerged as a key effector predicted to regulate LUAD-relevant malignant networks. Consistently, integrative analyses of public transcriptomic datasets, and LUAD tissues confirmed miR-181b-5p downregulation in LUAD. Furthermore, back-splice junction pull-down and AGO2-RNA immunoprecipitation assays validated a direct interaction between hsa-POLR1B_0014 and miR-181b-5p, with circRNA knockdown enhancing miRNA enrichment, thereby confirming its miRNA-decoy function. Functionally, loss of hsa-POLR1B_0014 elevated miR-181b-5p levels, leading to suppression of TAF1A, an essential Pol I transcription factor, thereby diminishing rRNA synthesis. This reveals a positive feedback circuit in which a Pol I-derived circRNA sustains Pol I output through sequestration of an inhibitory miRNA. Notably, miR-181b-5p also directly targets mTOR, a master regulator of Pol I transcription and malignant proliferation, inducing G1/S cell cycle arrest, apoptosis, and downregulation of Bcl2. Furthermore, miR-181b-5p suppression of ZEB1 attenuates migration, invasion, and enhances chemosensitivity to doxorubicin and cisplatin. In vivo, xenografts derived from hsa-POLR1B_0014-depleted LUAD cells exhibited markedly reduced tumor burden, rRNA synthesis, and Ki-67 expression, and increased apoptosis. Our findings uncover a previously unrecognized Pol I-derived circRNA-miRNA regulatory axis that coordinates ribosome biogenesis, cell growth, and therapeutic resistance in LUAD. By linking Pol I machinery to multiple oncogenic pathways, hsa-POLR1B_0014 emerges as both a driver and a vulnerability within the cancer Pol I network. These results highlight circRNA-mediated regulation of Pol I transcription as a central node controlling cancer hallmarks and a promising therapeutic target in LUAD.

#1374 Adherence to the EAT-Lancet reference diet in adolescence and risk of invasive breast cancer among US women.

P. Le[1], W. Willett[1], B. Rosner[1], W. Y. Chen[2], M. D. Holmes[3], A. Romanos-Nanclares[3], A. Eliassen[1];
[1]Harvard T. H. Chan School of Public Health, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Brigham & Women's Hospital, and Harvard Medical School, Boston, MA

In 2019, the EAT-Lancet Commission recommended a dietary pattern that is both good for human health and environmentally sustainable. The EAT-Lancet reference diet emphasizes high consumption of vegetables, fruits, whole grains, legumes, nuts, and unsaturated oils, low to moderate intake of seafood and poultry, and no to low intake of red meat, processed meat, added sugar, added saturated fat, refined grains, and starchy vegetables. The Planetary Health Dietary Index (PHDI) was subsequently developed to quantify adherence to this reference diet. Adolescence is marked by rapid breast tissue development and hormonal changes, presenting a susceptible window for breast carcinogenesis. Exposures during this period, including diet, could influence breast cancer risk.This study examines the association between the PHDI during adolescence and subsequent risk of invasive breast cancer in adulthood. We analyzed data from 47,355 women aged 33-52 years old in the Nurses' Health Study II (NHSII) who recalled their adolescent diet using a food frequency questionnaire in 1998. PHDI scores were calculated to reflect adherence to the EAT-Lancet reference diet in adolescence. Participants were followed from 1998 until breast or other cancer diagnosis, death, loss to follow-up, or the end of 2019, whichever occurred first. Multivariable Cox Proportional Hazards models were used to estimate hazard ratios (HR) and 95% confidence intervals (CI).Over 896,674 person-years of follow-up, 1945 invasive breast cancer cases were documented, including 1245 estrogen receptor (ER) - positive and 233 ER-negative cases. Adolescent PHDI was not significantly associated with overall invasive breast cancer risk (HR for highest vs. lowest quartile = 0.89; 95% CI: 0.78, 1.02 ; p trend = 0.29), or with ER-positive breast cancer (HR = 1.00; 95% CI: 0.85, 1.18; p trend = 0.50). However, higher PHDI during adolescence was significantly associated with reduced risk of ER-negative breast cancer (HR = 0.69; 95% CI: 0.47, 1.00; p trend = 0.05), which was slightly attenuated after adjusting for weight change since age 18 (HR = 0.70; 95% CI: 0.48, 1.01; p trend = 0.06). The association between PHDI during adolescence and overall invasive breast cancer risk did not differ by menopausal status or by subgroups of body mass index at age 18.In conclusion, adherence to the EAT-Lancet reference diet during adolescence may reduce the risk of more aggressive breast cancer subtypes, particularly ER-negative cases, but not overall breast cancer. These findings highlight a dietary pattern that could be both health-promoting and environmentally sustainable during a key developmental period.

#1375 Cardiorespiratory multimorbidity and lung cancer risk: A population-based cohort study.

P. Wang[1], Y. Zhang[2], H. Du[1], H. Dai[1], **K. Chen**[1];
[1]Tianjin Medical University Cancer Institute & Hospital, Tianjin, China, [2]Tianjin Medical University, Tianjin, China

Background: Studies have suggested close links between cardiorespiratory diseases and lung cancer. The coexistence of respiratory disease (RD) and cardiovascular disease (CVD) is common. However, the impact of cardiorespiratory multimorbidity (CRM) and its progression trajectory remains poorly understood. This study aimed to explore the relationship of CRM with lung cancer risk and characterize disease trajectories from healthy state through RD, CVD, or subsequent CRM to lung cancer.
Methods: We included 365,735 UK Biobank participants who were free of cancer, RD, or CVD at baseline and had a follow-up time of more than one year. CRM was defined as the co-occurrence of ≥1 RD and ≥1 CVD. RD comprised COPD and asthma. CVD included angina, myocardial infarction (MI), atrial fibrillation (AF), heart failure (HF), peripheral vascular disease (PVD) and stroke. The study outcome was incident lung cancer. Time-varying Cox regression models and accelerated failure time (AFT) regression models were used to assess the associations of CRM with risks of lung cancer incidence and onset time of lung cancer. Multi-state model was further constructed to characterize progression trajectory from healthy state through RD, CVD, or CRM to lung cancer, and to estimate the transition intensity, transition probability and transition time from each state to lung cancer.
Results: During a median follow-up of 13.7 years, 3,464 of the 365,735 participants were diagnosed with lung cancer. Cox models showed that CRM was associated with the highest risk of lung cancer incidence (hazard ratio [HR]=4.11, 95% CI: 3.48-4.85), followed by RD (HR=3.39, 95% CI: 3.01-3.81) and CVD (HR=1.52, 95% CI: 1.36-1.70). AFT models indicated that participants with CRM also showed an earlier onset time of lung cancer (time ratio [TR]=0.20, 95% CI: 0.17-0.23) than those with RD (TR = 0.25, 95% CI: 0.22-0.28) or CVD (TR = 0.53, 95% CI: 0.48-0.59). The multi-state model showed that 22.0% of participants with RD progressed to CRM, compared with 4.9% of those with CVD. The transition proportion to lung cancer was highest for CRM (2.8%), followed by RD (2.1%) and CVD (0.8%). The transition intensity and transition probability curves revealed that the transition intensity and probability from CRM to lung cancer was greater than that from RD or CVD to lung cancer. Additionally, CRM was associated with a significantly shortened progression time to lung cancer (12.39 years) than RD (12.64 years) or CVD (12.87 years).
Conclusion: CRM is associated with a higher lung cancer risk and more rapid progression than individual RD or CVD. These results emphasize CRM may serve as a high-risk clinical phenotype in lung cancer prevention and underscore the potential value of incorporating CRM management into lung cancer prevention strategies.

#1377 Generational immigration status and gastric cancer incidence among Japanese descendants: An analysis of the Multiethnic Cohort study.

Haejin In[1], **Katherine A. De la Torre-Cisneros**[1], Alexandra Adams[1], Chunxia Chen[1], Brijesh Rana[1], Lynne R. Wilkens[2], Meira Epplein[3]

[1]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[2]University of Hawaii, Manoa, HI,[3]Duke University Medical Center, Durham, NC

Background: Racial and ethnic minorities in the US experience disproportionately higher rates of gastric cancer (GC) compared to the general population. However, the impact of immigration history on these disparities is not well understood. We aimed to evaluate the association between immigration generation and GC risk among Japanese descendants.
Methods: We conducted analyses using the population-based Multiethnic Cohort Study (MEC), which enrolled residents of Hawaii and California between 1993 to 1996. Individuals who self-identified as being of Japanese ethnic or racial background were included, excluding those who were born or had parents born in locations other than the US or Japan. Cox proportional hazard models were used to examine the association between immigration generation of Japanese descendants and the risk of GC overall and by anatomical subtype, adjusting for demographic, dietary, and lifestyle variables.
Results: Among 94,232 individuals (median age: 61 years; male 47.4%), 716 primary GC cases were identified. The risk of developing GC was higher among all three generations of Japanese descendants compared to non-Hispanic Whites (NHWs). First generation had the highest risk (HR: 4.62, 95%CI 3.24-6.59), followed by the second generation (US-born, with both parents Japan-born; HR: 3.66, 95%CI 2.89-4.64; US-born, with one parent Japan-born, HR: 3.39, 95%CI 2.55-4.50), and the third generation (HR: 2.57, 95%CI 1.93-3.42). The association was strongest among non-cardia GC, with HRs of 5.93, 4.48, and 3.28 for the first, second, and third generations, respectively.
Conclusions: GC risk declined across successive generations of Japanese descendants but remained significantly higher than in NHWs. Recognizing and monitoring these persistently high-risk populations may guide targeted screening and inform research into environmental, biological, and transgenerational factors underlying gastric cancer susceptibility.

Table 1. HRs of gastric cancer incidence by generation status among Japanese descendants

	NHW	1st Generation	2nd Generation, both parents Japanese	2nd Generation, one parent Japanese	3rd Generation	p-trend

#1378 Development and validation of a parsimonious electronic health record model for pancreatic cancer risk stratification.

L. A. Mavromatis[1], V. Zlatanic[1], E. Agarunov[1], L. Chen[2], S. A. Sanoba[1], L. I. Horwitz[1], N. Razavian[1], A. Maitra[1], T. A. Gonda[1], M. E. Grams[1];

[1]NYU Grossman School of Medicine, New York, NY, [2]New York University, New York, NY

Background Pancreatic ductal adenocarcinoma (PDAC) is projected to become the second leading cause of cancer death in the United States by 2030. Early detection of PDAC improves outcomes. However, screening is impractical in the general population due to low disease incidence. We previously developed a PDAC prediction model using machine learning in an institutional electronic health record (EHR) database. Here, we aimed to improve generalizability, interpretability, and parsimony by developing and validating a Cox model in a national EHR database.

Methods We used Optum Labs DataWarehouse (OLDW), a U.S. EHR and claims database, to develop a Cox model predicting incident PDAC in adults ages ≥40 years in 23 health systems (training cohort; N = 4,836,428). Elastic net with 10-fold cross-validation selected from candidate risk predictors, which included demographics, diagnoses/symptoms measured by International Classification of Diseases (ICD) codes, and routine laboratory values. Performance was assessed by 3-year area under the receiver operating characteristic curve (AUC) and calibration slope and intercept in 31 distinct health systems (validation cohort; N = 5,607,398). Sensitivity analyses excluded adults <50 years, those with abdominal imaging in the prior year, and PDAC diagnosed in the first 6 months, and stratified participants by sex. International validation was performed in the UK Biobank (UKB) (N = 498,754).

Results In the training cohort (mean age 60.4 years), 14,405 patients developed PDAC, with a crude incidence rate (IR) of 56 per 100,000 person-years (PY); in the validation cohort (mean age 60.2 years), 11,693 patients developed PDAC (IR, 55/100,000 PY). The final elastic net model included 19 predictors. Top predictors included chronic pancreatitis and other gastrointestinal conditions, prior cancers, type 2 diabetes, elevated aspartate aminotransferase, current smoking, and male sex. 3-year AUC was 0.75 in both the training and validation cohorts; discrimination was equivalent in males and females. 3-year calibration in the validation cohort was excellent. The hazard ratio of PDAC in the top percentile of predicted risk compared to the 45^{th}-55^{th} percentile was 7.63 (95% CI, 6.85-8.49) and NNS in the top percentile was 128 (95% CI, 117-141). Performance was similar after excluding patients with recent abdominal imaging, PDAC diagnosed in the 6 months following index, and patients under 50. In UKB (IR, 44/100,000 PY), AUC was 0.71 with acceptable calibration.

Conclusions A parsimonious EHR-based PDAC risk model developed in diverse U.S. health systems demonstrated strong 3-year discrimination and good generalizability to cohorts in the United States and United Kingdom. A subsequent prospective validation study will assess the feasibility of EHR-driven PDAC case-finding.

#1379 Age-related differences in predicted basal metabolic rate and survival outcomes after colorectal cancer in the ColoCare Study.

R. Ji[1], P. Erickson[1], T. Lin[1], Y. Zhao[1], J. Van Onselen[1], M. N. Ilozumba[1], I. Strehli[1], M. Mclaws[1], L. Huang[1], J. Cohan[1], E. Siegel[2], M. Extermann[2], A. T. Toriola[3], D. Shibata[4], C. I. Li[5], J. C. Figueiredo[6], D. A. Byrd[2], V. Damerell[7], B. Gigic[7], C. M. Ulrich[1], **S. Hardikar**[1]; [1]University of Utah, Huntsman Cancer Institute, Salt Lake City, UT, [2]Moffitt Cancer Center, Tampa, FL, [3]Washington University School of Medicine, St. Louis, MO, [4]University of Tennessee Health Science Center, Memphis, TN, [5]Fred Hutchinson Cancer Center, Seattle, WA, [6]Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA, [7]Heidelberg University Hospital, Heidelberg, Germany

BACKGROUND Basal Metabolic Rate (BMR), a key indicator of resting energy expenditure, reflects overall metabolism and varies by age, sex, weight, and height. Younger and overweight/obese individuals exhibit a higher BMR, which has been linked to an increased risk of obesity-related cancers, including colorectal cancer (CRC). The role of BMR in survival after CRC remains unexplored. This study investigates the association between BMR at CRC diagnosis and overall (OS) and CRC-specific survival, evaluating differences by age of onset and obesity status.

METHODS We analysed 3876 patients with stage I-IV CRC from seven ColoCare Study sites. Baseline BMR was estimated using the WHO/FAO/UNU Schofield equation and categorized into sex-specific tertiles. Anthropometric measurements (height, weight) and vital status were obtained through medical records, follow-up mailings and linkage with cancer and death registries. Covariates (demographic, lifestyle, and clinical characteristics) were collected via baseline questionnaires. Cox proportional hazards regression models estimated hazard ratios (HR) and 95% confidence intervals (CI), stratified by age (<50, 50-65, >65 yrs) and BMI (normal weight, overweight, obese) for 5- and 10-year survival. Multivariate models were adjusted for age at diagnosis, study center, sex, BMI, clinical and lifestyle factors.

RESULTS Overall, 25% of participants were <50 yrs old, 43% were 50-65 yrs and 32% were ≥65 yrs; 44% were female. Colon cancer accounted for 51% of the diagnoses and 20% had stage III CRC. Mean BMR was 1673±304 kcal/day with higher values observed among men compared to women (3rd tertile: 2136 ± 202 vs. 1670 ± 156 kcal/day). 74% of participants in the 3rd tertile of BMR were obese compared to only 2% normal weight. BMR declined with age (3rd tertile: 34% in <50 yrs vs.16% in ≥65 yrs). At 5-years post-diagnosis, higher BMR was associated with significantly improved OS [HR (95%CI): 0.84(0.65-1.08)], independent of BMI. This association varied by sex and age, younger men in the 3rd tertile had better survival [HR (95% CI): 0.34 (0.12-0.95)] compared to younger women and older men [HR (95% CI): 0.51 (0.15-1.74)) and 1.46 (0.82-2.61), respectively]. Similar patterns were observed for CRC-specific survival. No significant associations were observed for OS or CRC-specific survival at 10-years post-diagnosis, suggesting that BMR may influence short- rather than long-term survival.

CONCLUSION In the ColoCare Study cohort, BMR varied substantially by sex, age and obesity status. Higher BMR, particularly among younger men, was associated with improved short-term OS, independent of BMI, but not for long-term follow-up. These findings highlight the potential of BMR for early risk stratification in CRC. Incorporating metabolic assessment at diagnosis could inform personalized interventions and targeted survivorship strategies.

#1380 Patient-level and claim-level analysis of telehealth disparities in cancer care: Lower uptake but higher intensity among racial or ethnic minority groups and older adults.

Sakshith Reddy Chintala[1], Margaret Meagher[2], Ceser Delgado[2], Amir Salmasi[2], Micheal Liss[2], Brett Meyer[2], Richard Cripps[3], Elena Martinez[4], Hala Madanat[3], James Murphy[2], Juan Javier-DesLoges[2], Humberto Parada[3]

[1]Radiation Medicine and Applied Sciences, University of California, San Diego, San Diego, CA,[2]University of California, San Diego, San Diego, CA,[3]San Diego State University, San Diego, CA,[4]UCSD Moores Cancer Center, San Diego, CA

Background: Telehealth use expanded rapidly during the COVID-19 pandemic including for cancer care, however, disparities in telehealth access among cancer patients remain poorly understood. While prior studies examined patient-level telehealth adoption, claim-level utilization patterns may reveal different mechanisms.

Methods: We conducted a population-based cohort study using Medicare claims data of patients aged 65+ years diagnosed with bladder, breast, colorectal, gastric, lung, or prostate cancer (2020-2022) with continuous Part A/B enrollment. We examined telehealth utilization within one year of cancer diagnosis using multivariable logistic regression to estimate adjusted odds ratios (aORs) and 95% confidence intervals (CIs) at two levels: (1) patient-level analysis of any telehealth use,and (2) claim-level analysis restricted to cancer-related care identified by cancer-related provider specialties to assess telehealth delivery patterns.

Results: Among 573,328 patients generating 5,276,398 cancer-related claims, 60.6% used telehealth within one year of diagnosis, representing 14.6% of cancer care encounters. At the patient level, compared to non-Hispanic White patients, Asian/Pacific Islander (aOR 0.85, 95%CI 0.82-0.88), Black (aOR 0.78, 95%CI 0.77-0.80), and Hispanic (aOR 0.89, 95%CI 0.86-0.91) patients had lower odds of any telehealth use. Compared to ages 65-69, older adults showed steep age gradients, with 85+ having 52% lower odds (aOR 0.48, 95%CI 0.47-0.484). Rural patients had higher uptake versus urban (aOR 1.17, 95%CI 1.16-1.19). At the claim- level for cancer care delivery, disparities substantially attenuated or reversed: Asian/Pacific Islander (aOR 1.15, 95%CI 1.13-1.17), Hispanic (aOR 1.07, 95%CI 1.06-1.09), Black (aOR 0.96, 95%CI 0.95-0.97), and 85+ years (aOR 0.92, 95%CI 0.92-0.94) . Compared to physicians, advanced practice providers had higher delivery (aOR 1.28); female providers versus male (aOR 1.12) and academic versus non-academic centers (aOR 1.08) showed higher use.

Conclusions: Telehealth disparities in cancer care may be primarily driven by initial access barriers rather than engagement once accessed. Racial/ethnic minorities and older adults who overcome uptake barriers demonstrate high-intensity telehealth use for cancer treatment, suggesting substantial unmet need. Interventions should prioritize addressing initial access barriers such as digital literacy, technology access, and language services-to ensure equitable cancer care delivery.

#1381 The Confluence Project: Largest multi-ancestry genome-wide association study of breast cancer identifies 469 susceptibility loci in over two million participants.

T.-. National Cancer Institute, African-ancestry Breast Cancer Genetic Consortium, Breast Cancer Association Consortium, Consortium of Investigators of Modifiers of BRCA1/2, Latin America Genomics of Breast Cancer Consortium, Male Breast Cancer Genetics Consortium;
National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Bethesda, MD

Background: Genome wide association studies (GWAS) of breast cancer have identified over 230 susceptibility loci, yet much of its heritable risk remains unexplained. Moreover, previous large GWAS included mostly European-ancestry samples, restricting the scope of genetic variation studied and limiting the generalizability of polygenic risk scores trained in these studies. The Confluence Project is a large, international collaboration of breast cancer consortia, biobanks, and other individual studies, studying breast cancer in females, males, and carriers of breast cancer susceptibility genes. With over 300 studies from 62 countries, Confluence includes over 400,000 breast cancer cases and 1,600,000 controls, nearly tripling the effective sample size of previous GWAS and substantially increasing sample diversity (approximate number of cases / controls, by genetic ancestry group: African (AFR)= 24,000 / 67,500, East Asian (EAS) = 49,000 / 429,000, Admixed American (AMR) = 28,500 / 78,000). Confluence is designed as a resource to address a range of breast cancer genetic questions by contributors and the wider scientific community.

Methods: We conducted a multi-ancestry GWAS of overall breast cancer risk (variants analyzed=47,790,460, min allele frequency = 0.03%). Individual-level genotyping data was available on 322,332 cases and 269,357 controls, including 53,058 *BRCA1/2* carriers, 24,883 of which were breast cancer cases. This data was processed through a harmonized quality-control pipeline and imputed by array to the TOPMed reference panel. GWAS were performed separately by array using REGENIE, adjusting for the first ten principal components. Resulting summary statistics were combined with similar statistics from 18 external biobanks (101,579 cases and 1,373,259 controls) through fixed-effect meta-analysis. Novel signals were declared if located more than +/-1Mb from any known locus that were based on previously published GWAS.

Results: We identified 469 independent genome-wide significant loci ($P<5x10^{-8}$) of which 249 (53%) were novel. Among the 240 loci previously reported, 220 (92%) were associated at $p<5x10^{-8}$. Assuming shared effect-sizes across populations, while accounting for ancestry-specific allele frequency differences, the 249 discovered loci increased the logit-scale variance relative to previously known loci from approximately 29% (in AFR) to 36% (in EAS).

Conclusion: This study represents the largest and most ancestrally diverse GWAS of breast cancer. The novel loci identify new candidate genes, substantially improves the proportion of heritability explained, and lay the groundwork for an expanded understanding of breast cancer biology. Ongoing analyses will extend these findings to sex-, ancestry-, and subtype-specific risk, including *BRCA1/2* carriers, and polygenic risk prediction.

: Cancer and Aging: Implications for Outcomes
Poster Session

#2460 Deficit accumulation as a predictor of lung cancer risk in older adults.

Seung Jun Shin[1], Shuyan Qiu[2], Yushu Shi[3], Eunji Choi[3]

[1]Cornell University, Ithaca, NY,[2]Weill Cornell Medicine, New York, NY,[3]Weill Cornell Medicine, Cornell University, New York, NY

Introduction: Lung cancer affects older adults, with a median age at diagnosis of 71. While low dose CT screening is recommended for high-risk smokers, 25% of cases occur in non-smokers, and few risk factors can be repeatedly assessed for early detection, especially in older adults. Age is a major cancer risk factor, and many cancer patients show accelerated biological or epigenetic aging before diagnosis, but chronological age may not reflect their true physiological condition. Deficit accumulation—a geriatric index of multisystem decline and vulnerability—may better reflect overall health than chronological age and has been reported to signal risk for age-related chronic diseases. However, its role in predicting lung cancer is unclear. We examined whether deficit accumulation predicts lung cancer beyond established predictors.
Methods: We analyzed data from the linked SEER-Medicare Health Outcomes Survey (MHOS), including adults aged ≥65 who completed at least one MHOS survey between 1998-2011, followed via 2020. Incident lung cancer was identified using SEER registry data, and all-cause deaths were treated as competing events. Deficit accumulation was measured using a validated 25-item deficit accumulation index for cancer patients (range 0-1), categorized as robust (0-0.2), frail (0.2-0.5), and severely frail (>0.5). For individuals who later developed lung cancer, deficit accumulation was assessed within one year prior to diagnosis. Cause-specific Cox models estimated hazard ratios (HRs) for the association between deficit accumulation and incident lung cancer, adjusting for established predictors including age at survey, sex, smoking, body mass index (BMI), education, and prior cancer history. Variable importance metrics were used to quantify the relative contribution of model features to lung cancer risk.
Results: Among 11,440 older adults, 1,011 developed lung cancer and 115 had a competing event of death before lung cancer diagnosis during follow-up. Frail and severely frail individuals had 1.45 (95% CI: 1.27-1.66) and 1.72 (95% CI: 1.40-2.12) times higher risk of developing lung cancer, respectively, compared with robust older adults. Other established predictors performed as expected, with increased risk associated with smoking and prior cancer history, and decreased risk associated with higher BMI and education. The pre-diagnostic deficit accumulation measure ranked as the third most influential predictor of lung cancer, followed by smoking history and prior cancer history. The predictive effect of deficit accumulation on lung cancer risk was more intensified among non-smokers (vs. active smokers), but interaction terms were not statistically significant.
Conclusions: The 1-year pre-diagnostic deficit accumulation measure was predictive of lung cancer risk in older adults. This finding may help identify high-risk individuals who could benefit from early detection efforts.

#2461 Aging reprograms early oncogenic responses to *Braf*^{V600E} activation in colon organoids through altered growth phenotype, senescence, and secretory signaling.

Shilpa Bisht[1], Kaavya Mahadevan Iyer[1], Akash Sureshkumar[2], Rachael Powers[3], Ying Cui[1], Jinxiao Liang[1], Lijing Yang[4], Daniel Petkovich[5], Damilola Killanin[6], Ray-Whay C. Yen[1], Tina Largent[1], Stephen B. Baylin[1], Rafael de Cabo[7], Hariharan P. Easwaran[1]

[1]Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Mathematics, Emory University, Atlanta, GA,[3]Department of Neurology, University of Michigan, Ann Arbor, MI,[4]Radiation and Medical Oncology, Zhongnan Hospital of Wuhan University, Hubei, PR, China,[5]Champions Oncology, Rockville, MD,[6]National Institute of Dental and Craniofacial Research, National Institute of Health, Bethesda, MD,[7]Experimental Gerontology, National Institute on Aging, Baltimore, MD

Colorectal cancer (CRC) incidence increases with advanced age, yet how aging affects early epithelial responses to oncogenic mutations remains poorly understood. *Braf*^{V600E} mutation is a major driver of serrated pathway of CRC, but the initial molecular events caused by *Braf*^{V600E} activation in aged intestinal stem cells are largely undefined. In the present study, we used proximal colon organoids (COs) derived from young (2 months) and aged (22 months) male and female mice carrying heterozygous Cre-activable *Braf*^{V600E} (termed Braf$^{+/LSL}$) transgene at the endogenous *Braf* locus and Cre-activable gene encoding red fluorescence marker protein, TdTom (termed TdTom$^{+/LSL}$) to model age-dependent responses to oncogenic *Braf*^{V600E}. We found that *Braf*^{V600E} activation differentially affects epithelial growth depending on age. Following Cre-mediated *Braf*^{V600E} induction, young male and female COs exhibited a pronounced proliferative burst, followed by a sharp growth collapse later passage, indicating an initial oncogene-induced senescence (OIS) response. In contrast, aged COs showed sustained growth across serial passages, indicating a failure to mount an OIS program. qPCR analysis aligned with these phenotypes: in young organoids, senescence-associated genes (*p21*, *p16*, *Cxcl2*, *Il6*) showed strong induction specifically at passage 4, coinciding with growth attenuation. Aged COs showed markedly reduced or absent induction of these transcripts at all passages, supporting an age-related loss of senescence competence. Loss of senescence competence is specific to oncogene response, not to general DNA damaging agents. The secretary profile further distinguished these responses with increases in CXCL2 and IL-6 secretion in young *Braf*^{V600E} activated COs, reflecting SASP activation, whereas aged COs produced minimal amounts of these cytokines. Additionally, IGF2 secretion was significantly diminished in aged COs compared to young counterparts, suggesting altered growth factor signaling that may facilitate continued proliferation under oncogenic stress. Genome wide transcriptome and epigenome analyses indicate emergence of pro-tumorigenic epigenetic states in colon epithelium, which includes disrupted senescence and metabolic pathways. These findings are especially significant given the widely held view that aging is accompanied by increased stem cell senescence. Our studies reveal a paradox: aged epithelial cells exhibit a diminished senescence response when exposed to oncogenes. This novel observation reveals that the ability of aged cells to bypass OIS, together with a reduced inflammatory response, plays a key role in the increased susceptibility to tumor initiation observed with aging.

#2462 Longitudinal change in epigenetic aging and telomere length in breast cancer survivors.

Judith E. Carroll[1], Cynthia Kusters[2], Catherine M. Crespi[3], Michael R. Irwin[1], Patricia A. Ganz[4], Laura Petersen[5], Julienne E. Bower[6]

[1]Psychiatry & Biobehavioral Sciences, UCLA - University of California Los Angeles, Los Angeles, CA,[2]Epidemiology, UCLA - University of California Los Angeles, Los Angeles, CA,[3]University of California, Los Angeles, Los Angeles, CA,[4]Professor, Div. of Cancer Prevention & Control Res., UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA,[5]UCLA - University of California Los Angeles, Los Angeles, CA,[6]Psychology, UCLA - University of California Los Angeles, Los Angeles, CA

PURPOSE: Cancer treatments may accelerate biological aging, but longitudinal studies of biological markers of aging are needed to better characterize patterns of biological aging over time.
METHODS: We followed 184 women with breast cancer (stage 0-III) from diagnosis to 18 months post treatment. We evaluated biological aging in three treatment groups: chemotherapy (with or without radiotherapy), radiotherapy (without chemotherapy), and neither chemotherapy or radiotherapy. Measures of epigenetic age (PCPhenoAge, GrimAge, DunedinPACE) and telomere length were obtained. Linear mixed models estimated within-group change from pre-treatment to immediate post, 6, 12, and 18 months post-treatment.
RESULTS: Women who received chemotherapy exhibited increased epigenetic age in PCPhenoAge, GrimAge, and DunedinPACE and shortening of telomere length acutely following treatment (Ps<0.001). The change attenuated but remained significantly different than baseline for GrimAge, DunedinPACE, and telomere length out to 18 months. Women treated with radiotherapy exhibited a trend for increases in PCPhenoAge and significant telomere length shortening 6 months following treatment that remained modified at 18 months (Ps<0.05). There were no significant changes in epigenetic age or telomere length among women who did not receive either chemotherapy or radiation.
CONCLUSION: We observed an acceleration of epigenetic age, an increase in the pace of aging, and telomere shortening among women receiving treatment for breast cancer. The effect was predominantly amongst women who received chemotherapy with or without radiation, pointing to this treatment regimen having the most damaging effects. These results support the premise that cancer treatment may accelerate aging and support further research to identify key clinical and biological targets to remediate these effects.

#2463 Microbiota-dependent complex dietary polysaccharide degradation suppresses inflammaging and colorectal cancer susceptibility.

Rekha Jalandra, Mousumi Bhattacharjee, Ruchika Maurya, Radhika R. Gudi, Jayda S. Gilliard, Caroline Westwater, Chenthamarakshan Vasu

The Medical University of South Carolina (MUSC), Charleston, SC

Aging is associated with systemic low-grade inflammation (inflammaging) and increased susceptibility to infections, chronic diseases, and colorectal cancer (CRC). Age-associated gut dysbiosis contributes to a decline in beneficial microbial metabolites, particularly short-chain fatty acids (SCFAs), fostering a pro-inflammatory intestinal microenvironment that promotes tumorigenesis. Dietary strategies that restore microbial balance and enhance SCFA production could mitigate inflammaging and CRC risk. Fermentation of complex dietary polysaccharides (CDPs) by gut microbiota can generate host-beneficial metabolites, including SCFA, and help maintain epithelial barrier integrity and suppress aging-associated inflammation. In this study, using high-pure beta-glucans (BGs) from yeast (yeast beta-1,3/1,6-glucan; YBG) and microalgae (algal beta-1,3-glucan; paramylon, PM), we show that the CDP degradation process alters microbiota composition and metabolite profiles in vitro and in vivo, suppresses aging-associated inflammation and cancer susceptibility in the azoxymethane/dextran sulfate sodium (AOM/DSS) model of CRC. Dietary treatment using BGs significantly altered gut microbial composition, notably increasing the abundance of *Akkermansia muciniphila*, a mucin-degrading bacterium known to produce SCFAs. Fecal microbial cultures of aged mice with BGs showed elevated levels of anti-inflammatory metabolites and reduced levels of pro-inflammatory factors. Aged mice treated with BGs showed significantly lower colorectal tumor burden and disease severity. Bulk RNA sequencing of colon tissue of BG-treated mice revealed suppressed expression of oncogenes, metastasis-related genes, and pro-inflammatory cytokines, along with increased expression of anti-inflammatory cytokines and *Muc2*, a key gene involved in mucin production and gut barrier function. Our findings suggest that the CDP degradation process can rejuvenate the aging gut microbiota, restore host beneficial metabolite production and gut integrity, and suppress inflammaging. Ongoing studies using gnotobiotic animals and colonoid cultures aim to further elucidate the mechanisms by which CDP degradation by gut microbiota modulates gut integrity, inflammation, and CRC susceptibility. Collectively, this work demonstrates the potential of microbiota-targeted dietary strategies for promoting healthy aging, rejuvenating gut microbiota, and reducing CRC risk in elderly populations.

#2464 Novel mechanism driving p53 loss that dictates bladder cancer aggressive phenotypes.

Sabir Salim[1], Sreenidhi Mohanvelu[1], Poorvi Subramanian[1], Afsana Parveen Jahir Hussain[1], Sheeja Aravindan[2], Natarajan Aravindan[1]

[1]Department of Physiological Sciences, Oklahoma State University, Stillwater, OK,[2]OU Health Stephenson Cancer Center, Oklahoma City, OK

Bladder cancer (BLCA) remains a clinically heterogeneous disease, characterized by high mutational burden, recurrence rates, and poor survival in advanced stages. Identifying molecular drivers of progression and therapy resistance is crucial for improving patient outcomes. In muscle-invasive bladder cancer (MIBC), loss of p53 is a major molecular hallmark that drives aggressive basal/squamous-like subtypes, conferring resistance to cell killing and immune evasion. However, the mechanisms underlying p53 inactivation/loss remain thus far unrealized. We previously showed that Retinal Degeneration Protein 3 (RD3) is widely expressed in the body and plays a tumor-protective role. In this study, we investigated the clinical significance of RD3 loss and its interplay with p53 status in a cohort of 107 BLCA patients. Using a custom-archived tissue microarray, RD3 expression was profiled (immunohistochemistry). We observed a complete loss of RD3 in aggressive BLCA tumors when compared with clinically favorable non-muscle invasive bladder cancer (NMIBC). RD3 loss strongly correlated with advanced tumor stage (MIBC), disease dissemination, therapy resistance, metastasis, and recurrence. Survival analysis indicated a strong trend toward decreased overall survival (OS), progression-free survival (PFS), and relapse-free survival (RFS) in RD3-deficient cases. In parallel, p53 expression in the same cohort demonstrated similar associations, confirming that compromised p53 is a defining feature of advanced BLCA. More importantly, our findings indicate a linear association of RD3 loss with p53 loss. Owing to the upstream effector function of RD3 regulating p53 competitor NFκB, the findings throw light on the RD3→p53 signaling flow-through in BLCA evolution. This dual loss could represent a synergistic axis driving disease progression and therapeutic failure in BLCA. These results position RD3 as a potential prognostic biomarker and therapeutic target, especially in p53-deficient tumors. The current focus of our studies are in the line of delineating the RD3-p53 regulatory network and its implications for precision medicine for high-risk BLCA patients.

#2465 Social support as a predictor of deficit accumulation in older breast cancer survivors and non-cancer controls.

Eunji Choi[1], Iwalola Awoyinka[2], Jaeil Ahn[3], Tim A. Ahles[4], Ashley L. Artese[5], Traci N. Bethea[3], Judith E. Carroll[6], Harvey Jay Cohen[7], Heather S. Jim[8], Brenna C. McDonald[9], Zev Nakamura[10], Sunita Patel[11], James C. Root[4], Andrew J. Saykin[9], Brent Small[10], Ying Wang[3], Wanting Zhai[3], Jeanne S. Mandelblatt[3]

[1]Population Health Sciences, Weill Cornell Medicine, New York, NY,[2]Medical College of Wisconsin, Wauwatosa, WI,[3]Georgetown University, Washington, DC,[4]Memorial Sloan Kettering Cancer Center, New York, NY,[5]Florida Atlantic University, Boca Raton, FL,[6]UCLA - University of California Los Angeles, Los Angeles, CA,[7]Walter Kempner Professor of Med., Duke University Medical Center, Durham, NC,[8]Moffitt Cancer Ctr., Tampa, FL,[9]Indiana University, Indianapolis, IN,[10]University of North Carolina at Chapel Hill, Chapel Hill, NC,[11]City of Hope Comprehensive Cancer Center, Duarte, CA

Introduction: Deficit accumulation is an important construct in oncology, associated with chemotherapy toxicity, cognitive decline, quality of life, and survival. However, longitudinal patterns of deficit accumulation among cancer survivors remain poorly characterized, and the influence of social health on these trajectories is even less understood. We examined long-term deficit accumulation trajectories in older breast cancer survivors compared with non-cancer controls and evaluated the role of social health in predicting these trajectory memberships.

Methods: We included 380 breast cancer survivors and 359 frequency-matched controls enrolled from 2010-2022, each with at least three annual follow-ups through 2024. Social health measures included emotional and tangible support using the Medical Outcomes Study Social Support (MOS-SS) tool, social and family well-being using the Functional Assessment of Cancer Therapy-General (FACT-G) subdomain, and social network size (number of close friends/relatives; categorized as >3 vs. ≤3). Deficit accumulation was assessed at each visit using a 46-item index. Group-based trajectory modeling identified distinct deficit accumulation patterns, and multinomial logistic regression examined predictors of trajectory membership.

Results: Three trajectories were identified: 204 rapid decliners (28%; 5-year increase 0.06 [0.012/year], $p<10^{-5}$), 362 slow decliners (49%; 0.005 increase [0.001/year], p=0.3), and 173 non-decliners (23%; 0.005 decrease [-0.001/year], p=0.4). Breast cancer survivors were more likely to follow a rapid-declining trajectory than non-cancer controls. Among survivors, those who received chemotherapy were most likely to experience rapid deficit accumulation, suggesting persistent treatment-related vulnerability. Higher emotional support predicted lower odds of declining trajectories: each 10-point increase in emotional social support was associated with a 14% lower probability of being a slow decliner (aOR 0.86 [0.74-1.01]) and a 23% lower probability of being a rapid decliner (aOR 0.77 [0.65-0.92]). Higher social and family well-being similarly predicted 15% (aOR 0.85 [0.73-0.99]) and 21% (aOR 0.79 [0.68-0.93]) lower odds of being slow and rapid decliners, respectively. Having more than 3 close friends predicted a 65% lower probability of becoming a rapid decliner (aOR 0.38 [0.17-0.87]).

Conclusions: Deficit accumulation trajectories in older women are heterogeneous, and breast cancer diagnosis and chemotherapy appear to contribute to more rapid deficit accumulation. Social health—including emotional support, social and family well-being, and larger social networks—emerged as a strong protective factor, slowing the pace of deficit accumulation among both breast cancer survivors and non-cancer controls.

#2466 The association between sleep and physical function in the longitudinal TLC cohort study of women.

Cynthia Kusters[1], Wanting Zhai[2], Xingtao Zhou[2], Zev Nakamura[3], Jaeil Ahn[2], Ashley L. Artese[4], Deena Graham[5], Chloe Casagrande[6], Kathleen van Dyk[7], Tim A. Ahles[8], Traci N. Bethea[2], Harvey Cohen[9], Claudine Isaacs[2], Heather S. Jim[10], Brenna McDonald[11], Sunita Patel[7], James C. Root[8], Andrew Saykin[12], Brent Small[3], Jeanne S. Mandelblatt[2], Judith E. Carroll[1], TLC-Age Research Group

[1]UCLA - University of California Los Angeles, Los Angeles, CA,[2]Georgetown University, Washington, DC,[3]University of North Carolina, Chapel Hill, NC,[4]Florida Atlantic University, Boca Raton, FL,[5]Hackensack University Medical Center, Hackensack, NJ,[6]Georgetown, Washington, DC,[7]City of Hope, Duarte, CA,[8]Memorial Sloan Kettering Cancer Center, New York, NY,[9]Duke, Durham, NC,[10]Moffitt Cancer Ctr., Tampa, FL,[11]Indiana University, Indianapolis, IN,[12]Indiana University, Indianapoli, IN

Background: Sleep disturbances, such as insomnia, are common in postmenopausal women and may negatively impact physical functioning. These disturbances are more frequent in breast cancer survivors than in the general female population. Limited data exist on how sleep affects physical function in older breast cancer patients. We analyzed whether sleep quality influences physical function at a one-year follow-up, and vice versa.

Methods: Data were from the Thinking and Living with Cancer study, a multicenter, longitudinal study involving women aged 60 and older, newly diagnosed with breast cancer and frequency-matched non-cancer controls. Participants were followed annually for up to five years. Sleep quality was assessed with the PSQI (range 0-21; higher scores indicate poorer sleep quality); physical functioning was measured by the SF-12 physical component score (PCS) and the Timed Up and Go (TUG). A 3-5 point SF-12 PCS decline was considered clinically meaningful. Random intercept cross-lag panel models (RI-CLPM) analyzed associations using data from 767 women (339 controls and 428 survivors), adjusting for age, race, comorbidities, and recruitment site.

Results: Mean age of participants was 69.5 years (70.0 in survivors vs. 69.3 in controls). Disrupted sleep was more common among survivors at baseline (PSQI above 5: 43.9% vs. 29.0%; p less than 0.001) and remained more prevalent during follow-up. Survivors showed a clinically meaningful decline in PCS (-2.8 points in year 1; -3.0 points over two years), whereas controls had a small, gradual, non-clinically meaningful decline (≈ -0.5 points/year). There was no clear trajectory for TUG, and the RI-CLPM revealed no significant associations between PSQI and TUG.

In survivors, each 1-point higher PSQI predicted 0.4-0.5 points (P less than 0.001) lower SF-12 PCS at the subsequent annual visit during the first three years, decreasing to 0.3 points by year 4 (P = 0.03). Among controls, effects were small initially (-0.25 points, p = 0.10) but from years 2 to 5 a 1-point PSQI increase predicted 0.4-0.65 points lower SF-12 PCS (p = 0.01 to less than 0.001).

For both survivors and controls, a 10-point worsening in a woman's PSQI relative to her usual level would be expected to correspond to about a 4-point lower SF-12 PCS one year later, assuming a 0.4-point decrease in PCS per 1-point increase in PSQI.

Conclusion: Sleep disruption is associated with subsequent declines in physical function among survivors and controls, which can reach clinically meaningful magnitudes as sleep quality worsens. Given the high prevalence of sleep problems among breast cancer survivors, routine monitoring for sleep disturbances and timely intervention may help preserve function in the growing population of older cancer survivors, particularly in the early years following treatment.

This work was conducted with contributions from the entire TLC-Age research team.

#2467 Aging and cancer in the Caribbean: Incidence and mortality trends among older adults during Covid-19: Population-based analysis from Martinique, 2008-2022.

Adrian Puello[1], Murielle Beaubrun-Renard[2], Jonathan Macni[2], Stephen Ulric-Gervaise[2], Manon Boullard[2], Mylene Vestris[2], Aimee Pierre-Louis[2], Sophia Hl George[3], Moustapha Drame[4], Clarisse Joachim[1]

[1]Registre General des Cancers de la Martinique, Pole de Cancerologie-Hematologie-Urologie, CHU Martinique & EpiCliV Research Unit, Faculty of Medicine, University of the French West Indies, Fort de France, France,[2]Registre General des Cancers de la Martinique, Pole de Cancerologie-Hematologie-Urologie, CHU Martinique, Fort de France, France,[3]Department of Obstetrics, Gynaecology and Reproductive Sciences, Miller School of Medicine, University of Miami, Miami, FL,[4]EpiCliV Research Unit, Faculty of Medicine, University of the French West Indies, Fort de France, France

Background: Prostate, breast, stomach, colon-rectum, lung, and hematologic cancers represent a regional public health burden among older adults in the Caribbean. We analyzed 15-year trends in incidence and mortality among older adults in Martinique, including the COVID-19 period, to describe changes in cancer burden, screening and treatment.
Methods: We conducted a population-based cohort study (2008-2022) from the population-based cancer registry of Martinique. Patient selection on all registered residents irrespective of nationality. Segi/WHO age-standardized incidence and mortality rates (ASR) were calculated using the world standard population and Annual Percent Change (APC) in patients ≥65 years, by tumor site and sex with 95% CI.
Results: We recorded 15,400 incident cancers; 9,913 (64.4%) occurred in men. An indicating overall stability with a slight increase from the first to the later periods in age-standardized incidence rates (ASR per 100,000) were 847.80 (95% CI: 801.80-893.90) in 2008-2012 to 862.10 (821.2-903.0) in 2018-2022. Prostate cancer mortality declined; rising female breast cancer incidence with stable mortality; stable colorectal cancer incidence with varying mortality; and declines in stomach cancer incidence and male lung cancer mortality.
Conclusions: Over fifteen years, cancer burden among older adults in Martinique patterns were consistent with Caribbean and global observations, with differences in magnitude and timing by site and sex, reflecting changing screening intensity, new therapeutics, and COVID-19 disruptions. These findings support tailored cancer control strategies for older adults, emphasizing equitable access to diagnostics and treatment, and resilience planning for service interruptions. Future research should integrate socioeconomic and comorbidity factors.

: Community-Engaged Approaches to Equity Across the Cancer Journey: From Prevention to Trial Design
Poster Session

#2471 Accelerating early detection through community-driven cancer wellness hubs and ambassador trainings: Evidence of knowledge gains and real-world impact.

Eduardo B. Ibarra[1], Carolina Aristizabal[1], Elena Nieves[1], Rosa Barahona[1], Freddie Muse[2], Lourdes Baezconde-Garbanati[3]

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]The Men's Cancer Network, Los Angeles, CA,[3]Keck School of Medicine of USC, Los Angeles, CA

Background: Communities with limited access to preventive care continue to face higher burdens of late-stage cancer diagnoses and mortality. Persistent barriers including delayed screening, limited navigation support, and low trust in medical institutions slow progress despite national declines in cancer deaths. Sustainable advances in these settings require models that strengthen local capacity, expand screening pathways, and equip residents as credible messengers of cancer information.
Methods: The USC Norris Comprehensive Cancer Center, Office of Community Outreach and Engagement (COE) implements a dual strategy across its catchment area of Los Angeles County and northern Orange County: (1) Cancer Wellness Hubs (CWHs) situated in trusted venues (community centers, YMCA branches, and The Men's Cancer Network Inc.) and (2) Evidence-informed Cancer Ambassador Trainings open to community members. Trained bilingual/bicultural community health workers provide on-site education, navigation to insurance enrollment, cancer screening, and referrals for diagnostic follow-up or clinical-trial enrollment. Ambassador Trainings are two-hour sessions covering epidemiology, risk reduction, early symptoms, treatment basics, survivorship, and effective communication. Standardized pre/post surveys measure knowledge, self-efficacy, and intent to share information.
Results: In 2025, 19 CWHs engaged 714 community members, delivering culturally and linguistically congruent cancer education and resources. Of these, 29 individuals requiring follow-up (screening, diagnostic, or treatment navigation) were successfully connected to USC Norris COE patient navigators.
Twenty-six participants completed Cancer Ambassador Trainings in Los Angeles in 2025. Aggregate knowledge scores increased from 65.0% (pre) to 79.3% (post), with the largest gains observed in pancreatic and prostate cancer awareness. Ninety-six percent of trainees reported intent to disseminate learned information within their social networks. At one prostate-cancer-focused training, nine men aged ≥40 received on-site free PSA screening.
Conclusions: The integrated Cancer Wellness Hub and Cancer Ambassador Training model demonstrates high acceptability, significant knowledge gains, and rapid translation into community action, including direct screening uptake and peer-to-peer education. By training and empowering residents as credible messengers and co-locating services in trusted spaces, this scalable, asset-based approach effectively bridges gaps in prevention, early detection, and clinical-trial access. These findings underscore the value of sustained, bidirectional community-academic partnerships in dismantling structural barriers and accelerating the reduction of cancer differences in underserved populations.

#2472 Using multi-method approaches to develop and refine a tobacco cessation workflow within a Federally Qualified Health Center.

Linda Salgin[1], Jerel P. Calzo[1], Jennifer K. Felner[1], David Strong[2], Marva Seifert[2], Borsika A. Rabin[2]

[1]School of Public Health, San Diego State University, San Diego, CA,[2]The Herbert Wertheim School of Public Health and Human Longevity Science, University of California San Diego, San Diego, CA

Background: The incorporation of implementation science approaches into tobacco control program delivery remains limited. Programs developed using these approaches, including co-creation, are often more feasible and sustainable, as they are designed to consider the operational and cultural context of an organization. This study utilized multiple implementation science approaches to co-create a tobacco cessation workflow within a Federally Qualified Health Center, where tobacco use is disproportionately higher than the national average.

Methods: In this study we conducted six structured meetings across two advisory groups between July-September 2025. Multiple implementation science methods (i.e., forms and functions, brainwriting premortem, and Practical, Robust Implementation and Sustainability Model (PRISM) assessments) were integrated to optimize the tobacco cessation workflow along with co-creation and evaluation methods (i.e., ethnographic observations, engagement survey) to evaluate advisory board engagement. Qualitative and quantitative data were collected and analyzed simultaneously using rapid qualitative analysis and descriptive statistics allowing for a comprehensive understanding and iterative incorporation of the results.

Results: Thirteen individuals participated in this study as co-creation partners who were between the ages 27 to 69 years (M = 31). Participants represent various roles within the FQHC including front-line staff, administrators, providers, and patients. Workflow Optimization: Participants identified 5 core functions and 16 forms in the refinement of the tobacco cessation workflow. Brainwriting Premortem resulted in 29 unique failures and 19 solutions within the workflow across PRISM contextual domains, of which 16 were integrated. The final version of the co-created workflow had high acceptability (M=4.8), appropriateness (M=4.6), and feasibility (M=4.5).

Participant Engagement: A total of 394 interactions were identified across meetings. The most frequent interaction was giving information (53%), followed by seeking information (18%). The quality and frequency of advisory board engagement was rated favorably (average 4.7 of 5). Rapid qualitative analysis of open-ended responses highlighted the value of co-creation with participants stating: “I am glad I participated in this advisory panel... and I am able to bring [this information] back to my team to help our patients.”

Conclusion: This study highlights how co-creation through multiple implementation science methods can be used to conceptualize, adapt, and refine programs responsive to FQHC needs.

#2473 A unified Indigenous Knowledge System (IKS)-integrated biosocial and digital health model to reduce cancer disparity in rural India.

Rupam Das[1], Lekhika Pathak[2], Shirsajit Mitra[2], Tulika Sarma[3], Chayanika Das[3], Upasha Sarmah[2], Riya Kanodia[2], Partha Saikia[2], Sonali Das[4], Manisha Canteenwala[4], Mallika Maral[3], Nayan Bhattacharjee[5], Hem Bhai[5], Uday Shanker Dixit[1], Bikul Das[2]

[1]Center of Indian Knowledge System, Indian Institute of Technology, Guwahati, India,[2]Department of Medical Humanity, KaviKrishna Laboratory, Guwahati, India,[3]KaviKrishna Telemedicine Care, Sualkuchi, India,[4]Department of Medical Humanity, Thoreau Lab for Global Health, Lowell, MA,[5]Center of Indian Knowledge System, KaviKrishna Laboratory, Sualkuchi, India

Background: Through a three decades of community based participatory action research (CBPAR) (Ref.1), we are studying cancer disparity. Since 2010, the "KaviKrishna Satra" program has developed a long-term cancer disparity research platform through an Indigenous Knowledge System (IKS)-based social-network framework (Ref.2) and using ethnography + phenomenology (Ref. 3), plus pancha-padika education (1-2). We are developing a digital IKS-based intervention (KaviKrishna HealArt App + Nigudah Yoga + nutrition + Focussed group discussions/FGDs) and a biosocial resilience scale (Sahasa-Ojash) rooted in Vedic Jiva Upakara Cikitsha Tantra, an Avatar-Kosha-based biosocial healing system (Ref. 1 & 4). We hypothesize that cancer disparity in rural India is a biosocial phenomenon that can be reduced by combining IKS-based communication systems, digital health connectivity, and psychosocial care.
Methods: We mapped the social-support networks of 200 rural cancer patients through home visits, interviews, FGDs, and clinician-interaction analysis to detect the emergence of an IKS-based communication system through CBPAR. We measured Sahasa-Ojash in the first 35 patients, and will longitudinally measure all 200 patients through the Heal-Art app for continuous biosocial analytics. We also evaluated the continuity of care (adherence to scheduled follow-ups, completion of treatment, and persistence in telemedicine contact over 12 months).
Results: The integrated digital-IKS intervention produced measurable biosocial and clinical impact: 1) Sahasa-Ojash increased 2-3-fold after the intervention *(mean increase, p = 0.065; trend toward significance due to sample size).* 2) Fatigue and insomnia reduced by 35-45% *(p = 0.046), whereas appetite increased by 50-60% (p = 0.032)*. 3) Treatment adherence and follow-up continuity increased 3-fold through the KaviKrishna HealArt App. 4) Preliminary IKS-network analysis showed reactivation of indigenous social-communication pathways resembling historical IKIN structures, improving patient navigation and trust. 5) Patients reported greater psychological resilience, enhanced self-care, and improved communication with oncologists. 6) Clinical co-morbidities decreased (anemia, hypertension fluctuations, and GI disturbances). These biosocial gains correlated with a 3-fold improvement in continuity of care, greater chemotherapy completion, and markedly reduced treatment dropout.
Conclusion: We have developed a unified, scalable, and cost-effective IKS-integrated cancer disparity model that Maps biosocial determinants using ethnography and phenomenology.

#2474 Non-completion of colorectal cancer screening among Alaska Native people in an intervention trial.

Diana Redwood[1], Christie A. Flanagan[1], Lauren Jeffries[1], Melissa Toffolon[2], Joseph Klejka[3], Lila J. Finney Rutten[4], Judith S. Kaur[5], John B. Kisiel[4]

[1]ANTHC, Alaska Native Epidemiology Center, Anchorage, AK,[2]Actionable Data Consulting, Anchorage, AK, AK,[3]Yukon Kuskokwim Health Corporation, Anchorage, AK, AK,[4]Mayo Clinic, Rochester, MN,[5]Mayo Clinic Florida, Jacksonville, FL

Background: The Alaska Tribal Health System is working to increase colorectal cancer (CRC) screening among Alaska Native peoples. It is unknown why people who initially agree to screening might not follow through to complete their screening.
Methods: As part of a larger intervention investigating multi-target stool DNA (mt-sDNA) test use in rural Alaska communities, we interviewed Alaska Native people who had agreed to scheduling a colonoscopy or having a mt-sDNA kit sent to their home but who did not complete their selected test.
Results: Of 531 Alaska Native people who initially agreed but did not complete screening, 299 (56%) were able to be contacted for a follow-up survey. Of those, 256 (86%) answered the survey; 187/224 (83%) who had chosen mt-sDNA, and 69/75 (93%) who had chosen colonoscopy. Reported reasons for non-completion of stool DNA test kits included being busy or forgetting, being uncomfortable doing a stool test, and not knowing how to do the test or concerns over how to return the kit for processing. Reasons for non-completion of colonoscopy included scheduling issues, physical health issues, travel, and housing barriers, as well as cost, fear, and being too busy. Of note, many respondents in both groups indicated they would still be interested in CRC screening in the future or were currently pursuing screening.
Conclusions: This was the first exploration of reasons for non-adherence to CRC screening after initial test request by Alaska Native people. Many of the identified themes are amenable to health care system changes for future interventions to improve screening outreach and uptake.

#2475 Resource limitations and cancer care access for Native Hawaiian/Pacific Islander veterans in the Pacific region.

Troy Helenihi[1], Akanksha Jain[2], Claire Phibbs[3], Ranak Trivedi[4], Nainwant Singh[5]

[1]Human Biology, Stanford University, Stanford, CA,[2]MD Program, University of Southern California, Keck School of Medicine, Los Angeles, CA,[3]Data Science, University of San Diego, San Diego, CA,[4]Department of Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA,[5]Research & Development, VA Sierra Nevada Health Care System, Reno, NV

Native Hawaiian/Pacific Islander (NHPI) populations may experience poorer cancer-related outcomes, shaped by social determinants such as higher poverty rates and underrepresentation in national data. NHPI Veterans face heightened vulnerability due to military-related exposures and the need to navigate distinct Veterans Health Administration (VHA) pathways for care, adding complexity not experienced by civilians. Limited oncology services across Hawai'i and the U.S.-Affiliated Pacific Islands (USAPI), compounded by geographic isolation and workforce shortages, increase risk for delayed diagnosis and treatment. This qualitative analysis from the PaCiPIC Veterans Study examines key challenges and opportunities to improve access to cancer care among NHPI Veterans residing in the USAPI. Semi-structured interviews were conducted with NHPI Veterans residing within the VA Sierra Pacific Network 21 (n = 8 to date, target = 15-20). Interviews were recorded, transcribed, de-identified, and analyzed thematically in ATLAS.ti. Codes were iteratively developed through team consensus by a multidisciplinary team with clinical, psychological, and qualitative research expertise, guided by Fortney's Access to Care Framework. Veterans described challenges with community care referrals, including delays and uncertainty over follow-up. Many felt resources on the islands remain limited, noting few, if any, noticeable improvements in services or access over time despite advocacy. Long-distance travel for diagnostics and treatment created financial and logistical strain from airfare, lodging, and caregiver support unless Veterans met specified service-related criteria. Teleoncology was viewed as a potential acceptable alternative to reduce travel burden for follow-up care, though Veterans emphasized core aspects—laboratory testing, imaging, and procedures—required in-person encounters. Family and community networks emerged as essential support systems, providing transportation, coordination, and emotional care bridging gaps. Preliminary findings highlight resource limitations as key insular barriers to cancer care for NHPI Veterans in the Pacific, consistent with clinician perspectives from our previously published works. Building on these insights, we will identify feasible strategies to address system-level constraints and inform implementation of services in the region.

#2476 Science and Storytelling: Using a multi-component evidenced based strategy for successful recruitment of Black women with high-risk endometrial cancer to The SISTER Study.

Kemi M. Doll, Julianna Alson, Adrienne Moore, Alvine Ngouonga, Patrice Williams, Liz Sage, Bryan Comstock, Sarah Monsell, The SISTER Study Consortium

University of Washington, School of Medicine, Seattle, WA

Introduction: Black women are underrepresented in national randomized clinical trials. To address known structural and interpersonal barriers to enrollment and for accurate recruitment planning, detailed enrollment statistics from screening to randomization are needed.
Methods: The Social Interventions for Support in Endometrial Cancer Treatment and Recurrence (SISTER) Study is a 13-site national randomized trial that recruited Black/African American women with high-risk EC who were enrolled in the time window between diagnostic confirmation and treatment initiation. In a community-engaged process with Black EC survivors, we created a novel multi-component, evidenced-based recruitment and enrollment process to enhance recruitment and enrollment that was deployed at all SISTER Study sites. In partnership with ECANA, a Black EC cancer advocacy group, we created print and web enrollment materials focused on community-building and self-empowerment during treatment. We also developed an enrollment video that featured the PI and Black EC survivors sharing personal stories about the racial disparities in EC and the importance of the study alongside graphic depictions of randomization and intervention arms. Using an ‘early contact’ and ‘waiting room’ strategy, we identified participants at or prior to their first oncology visit and initiated live conversations occurring several days to weeks prior to their eligibility window. All participants considered for the study were prospectively captured and logged in the study portal allowing for accurate reporting on screening and enrollment rates.
Results: From September 2021 to September 2025, 609 individuals were identified, and 540 officially screened for the trial. Of those screened, 31% (n=166) were ineligible based on clinical and non-clinical exclusion criteria. Of the remaining 374, 16% (n=59) declined being approached. Of the 315 approached for consent, 85% (n=269) consented and 13% (n=46) declined. The trial enrollment goal of 252 was met, representing 41% of all identified, 47% of those official screened, 67% of those eligible, and 80% of those approached for consent.
Conclusions: When approached and invited to participate, Black women with high-risk EC chose to enroll in a randomized controlled interventional trial. Using evidenced-based community-engaged strategies, we successfully enrolled this long-standing underrepresented group requiring active treatment during a narrow eligibility window. Our enrollment rates can be used to accurately plan for appropriate representation of Black women in endometrial cancer trials, and the multi-component strategy can be used nationally to increase equitable clinical trial representation across historically excluded communities.

#2477 Graphic medicine: A patient-centered approach to oncology.

Alexandra Bartholomew[1], Pui Cheng[2], Amelia Jernigan[1], Tara Castellano[1], Counti McCutchen[3], Julia Cazabon[1], Audrey Marsh[1], Ronja Bodola[1], Siyi Cheng[1], Jason Mussell[1]

[1]Louisiana State University Health Sciences Center - New Orleans, New Orleans, LA,[2]Touro Infirmary, New Orleans, LA,[3]University of Chicago, Chicago, IL

Graphic medicine combines graphic narrative with medicine. In this study, we aimed to investigate the potential usefulness of graphics and comics as a therapeutic and teaching tool for gynecologic oncology patients by creating, distributing, and evaluating a narrative about a patient with a newly diagnosed cancer. This project was a multistage mixed methods study. To guide direction and content, focus groups were conducted with members of a gynecologic oncology support group. It was determined that a graphic on coping strategies would be most useful. The first draft underwent several modifications and was translated into Spanish and Vietnamese. The final graphic and survey were implemented into four gynecologic oncology clinics. Patients of any age and at any stage in their treatment were eligible. The survey included demographic questions as well as questions on the usefulness, relatability, and likability of the comic. For statistical analysis, descriptive statistics were used to summarize the study population. The chi-square goodness-of-fit test was used to determine whether participant responses were evenly distributed or skewed in a particular direction. The ANOVA test was used to compare participant responses across categories. 155 patients took the survey. The vast majority found the graphic enjoyable, relatable, useful, and helpful for reducing anxiety ($p<0.001$). Our results suggest that graphic medicine interventions are useful in a gynecologic oncology setting. The project was guided heavily by patient input. This study was successful in determining that graphic medicine interventions are a feasible method of delivering healthcare information to gynecologic oncology patients.

#2478 Advancing equitable preventative cancer screening on the Inova Saville mobile health bus.

Nikita N. Sawant, Elizabeth Stark, Rebecca Kaltman, Victoria Thomas, Bryan Bassig

Saville Cancer Screening and Prevention Center, Inova Health System, Fairfax, VA

Purpose: The INOVA Saville Mobile Health Bus (SMHB), launched in January 2025, aims to expand access to breast and cervical cancer screenings and novel research trials among medically underserved communities in Northern Virginia. Using de-identified, aggregated data, this analysis assessed early program reach, identified race/ethnic and geographic gaps in utilization, and used these insights to improve equitable access to preventive care.

Methods: Screening encounters from February 2025 through August 2025 were summarized by race/ethnicity, ZIP code, and screening type, and encounters were grouped into pre- and post-intervention periods to monitor changes over time. The SMHB catchment area includes five Northern Virginia jurisdictions; the City of Alexandria, Fairfax, Prince William, Loudoun, and Arlington Counties; covering more than 70 ZIP codes. To identify areas with potentially lower breast and cervical cancer screening uptake by race and ethnicity, we used publicly available racial/ethnic demographic data from the U.S. Census Bureau's American Community Survey. Descriptive statistics and geographic information system (GIS) mapping were used to compare bus encounters to community race/ethnic distributions and highlight underserved ZIP codes. Those findings guided adjustments to routes and outreach efforts.

Results: Hispanic/Latino individuals represented 30.5% of early screening encounters, exceeding county estimates (14.4%-24.3%). Several groups were underrepresented: Asian participants accounted for 5.8% of screenings despite representing 10.3%-20.6% of county populations, and Black/African American participation was 4.9% compared to county estimates (7.7%-21.5%). ZIP codes with limited engagement guided new partnerships with community organizations serving Black/African American and Asian residents. After these efforts, participation increased modestly among targeted groups. From January-August to September-mid-November, Black/African American participation increased from 5.9% to 6.6%. Asian participation increased from 8.7% to 13.6%. Hispanic/Latino participation remained stable (29.3% to 28.7%).

Conclusions: This analysis during the early phase of the SMHB program enabled timely identification of outreach inequities and guided practical changes to improve equity in preventive cancer screening. Targeted partnerships with trusted community organizations, including groups serving Black/African American and Asian communities, contributed to early increases in engagement among these populations. These findings underscore the importance of grounding mobile health outreach in continuous quality improvement, community collaboration, and culturally responsive strategies. This approach offers a sustainable framework for building more inclusive and accessible mobile health services as the program continues to expand.

#2479 Embedding community voices in clinical research: The value of community scientists in IIT protocol review.

Reener Balingit[1], Lourdes Barajas[1], Oscar Arroyo[1], Karen L. Reckamp[2], Zul Surani[1]

[1]Cedars Sinai Cancer Center, Los Angeles, CA,[2]Cedars-Sinai Medical Center, Los Angeles, CA

Introduction: Investigator-Initiated Trials (IITs) advance scientific discovery, test interventions, and address unmet clinical needs; however, traditional research processes often overlook the perspectives of communities most affected by cancer disparities, leading to protocols that unintentionally reinforce barriers to participation among underrepresented groups. *Community Scientists*, comprising patients, caregivers, health professionals, and community leaders, offer lived expertise to ensure that study materials, eligibility criteria, and recruitment strategies reflect the realities of the populations affected by cancer.

Methods: Cedars-Sinai Cancer Center Community Outreach & Engagement (COE) identified and trained 11 lay community members as Community Scientists, equipping them with foundational knowledge in clinical trial design, ethical and informed consent considerations, and practical approaches to mitigating participation barriers. COE facilitated engagement between clinical researchers and Community Scientists by integrating them into the IIT protocol review process, resulting in 18 IITs and 243 PRMC reviewed in the past 3 years. To assess the integration and impact of Community Scientist recommendations, COE surveyed 14 clinical researchers (11 initiated, 5 fully completed). Recommendations focused on gender-neutral language, language accessibility, financial toxicity, transportation support, food insecurity, navigation and referral pathways, and health literacy.

Results: Clinical researchers rated COE and Community Scientists as *effective* or *very effective* (80%, n=5) in providing valuable recommendations on IIT protocols, resulting in increased participation and retention of underrepresented communities in clinical trials (1-2 patient referrals yearly from COE). Qualitative feedback from clinical researchers highlighted meaningful practice changes, highlighting that Community Scientists' recommendations were *either already adopted* or *being considered for future studies:* "We adjusted our discussion with patients to improve engagement and retention in trials". Adoption was highest for recommendations related to interpretation and translation services, parking voucher availability, financial and social support navigation, and warm handoffs to internal and external community partners (60%, n=5, respectively).

Conclusion: Clinical researchers recognized the value of collaboration with COE and Community Scientists, and expressed a strong interest in expanding Community Scientists' involvement in early-stage study design, translational and therapeutic science, protocol development, dissemination of findings, and participation in educational activities. The contributions meaningfully enhance the cultural relevance, feasibility, and inclusivity of investigator-initiated trials.

#2480 Exploring social, environmental, and health correlates of lung and bronchus cancer incidence in HMNCC catchment area.

Preeti Sohoni[1], Weishan Bai[2], King David Oware[2], Gang Han[2], Jennifer Cullen[1], Nestor Esnaola[1], **Arica Brandford**[1]

[1]Houston Methodist, Houston, TX,[2]Texas A&M University, College Station, TX

Background: Lung and bronchus cancer drives cancer mortality in the Houston Methodist Neal Cancer Center (HMNCC) catchment area, with profound geographic and racial disparities threatening health equity. The eight-county catchment area exhibits stark variations in demographics, industrial exposures, and health resource access. Characterizing community-level drivers of this excess risk is imperative for targeted prevention strategies that address these inequities.
Methods: County level cancer incidence (2018-2022) was collected through U.S. Cancer Statistics. The sociodemographic, clinical, behavioral, and environmental factors were obtained from the CDC PLACES and ACS 5-year estimates. GIS mapping identified the spatial patterns within the 8 counties: Harris, Montgomery, Fort Bend, Galveston, Brazoria, Chambers, Liberty, and Jefferson. Weighted Spearman correlations (population-weighted) and weighted univariate linear regressions of the log transformed incidence were used to assess the associations. Holm adjustment controlled for multiple testing.
Results: The population-weighted median incidence of lung and bronchial cancer in the eight counties was 77.6 per 100,000 (IQR: 77.6-77.6), with the county-wide rate ranging from 32.5 to 77.6 per 100,000. GIS analyses showed consistently elevated incidence in Liberty, Jefferson, and Chambers counties, with Black residents experiencing the highest race-specific burdens. Several factors exhibited strong positive correlations with incidence, including obesity ($r=0.998$), depression ($r=0.984$), binge drinking ($r=0.976$), asthma ($r=0.893$), and COPD ($r=0.721$) (all raw $p\leq0.05$). After Holm adjustment, obesity, depression, and binge drinking remained significant. Strong negative correlations were observed for the population under 18 ($r= -0.839$), Black ($r= -0.767$), and Asian race ($r= -0.723$), although none survived Holm correction. In weighted univariate regression, depression showed the strongest association with incidence ($\beta=0.102$, $SE=0.013$, $p<0.001$), followed by obesity ($\beta=0.078$, $SE=0.016$, $p=0.003$) and binge drinking ($\beta=0.129$, $SE=0.032$, $p=0.007$). Associations for asthma ($\beta=0.288$, $SE=0.078$, $p=0.010$) and COPD ($\beta=0.130$, $SE=0.047$, $p=0.032$) were also significant. Sensitivity analyses using non-parametric models produced nearly identical rankings.
Conclusion: Across the HMNCC catchment, lung cancer incidence clusters geographically and align closely with modifiable behavioral and clinical risk indicators, especially depression, obesity, and binge drinking. These findings highlight priority communities and population-level factors for targeted prevention, early detection, and community-engaged interventions aimed at reducing inequities in lung cancer burden.

#2481 Psychosocial profiles and pain management patterns among Asian American breast cancer survivors: A cluster analysis.

Dongmi Kim, Jiwon Baek, Seulgi Ryu, **Yeeun Kim**, Wonshik Chee, Eun-Ok Im

The University of Texas at Austin, Austin, TX

Background: Asian American breast cancer survivors represent a diverse population with unique psychosocial needs, yet limited research has identified subgroups based on psychological well-being, pain management beliefs, and social support. Understanding heterogeneity in psychosocial profiles may inform culturally tailored survivorship care. This study aimed to identify distinct psychosocial subgroups among Asian American breast cancer survivors and examine differences in depressive symptoms, pain management attitudes and barriers, social influence, quality of life, coping self-efficacy, loneliness, and perceived social support among the subgroups.
Methods: This is part of an ongoing clinical trial among Asian American breast cancer survivors. Only the baseline data were used for this analysis. A total of 106 women were included in the analysis. K-means cluster analysis was conducted on psychosocial variables, including depressive symptoms, attitudes, and perceived barriers to cancer pain management, social influence, self-efficacy, loneliness, and social support. The optimal number of clusters ($k = 3$) was determined by silhouette analysis. One-way ANOVA with Tukey post-hoc tests compared psychosocial outcomes across clusters.
Results: Three meaningful clusters emerged. Cluster 1 (resilient and supported survivors, $N = 30$) displayed the lowest depressive symptoms, strongest social support, positive pain attitudes, and highest quality of life and coping self-efficacy. Cluster 2 (psychologically vulnerable and socially isolated survivors, $N = 30$) demonstrated the highest depressive symptoms, greatest pain management barriers, and lowest levels of coping self-efficacy, quality of life, and perceived social support, along with the highest loneliness scores. Cluster 3 (moderately coping survivors, $N = 46$) showed intermediate levels across all psychosocial indicators and perceived attitudes towards pain and pain management barriers. All psychosocial and quality-of-life outcomes significantly differed across subgroups ($p < .001$).
Conclusion: Asian American breast cancer survivors demonstrate significant psychosocial heterogeneity. Future culturally responsive, tailored interventions need to target the psychologically vulnerable, socially isolated subgroup, and address emotional distress, social connection, and pain-related attitudes in survivorship care. Findings support cluster-informed personalization strategies in technology-based survivorship programs.

#2482 The CAHR-model: A culturally adaptive hybrid recruitment strategy for Asian American breast cancer survivors.

Dongmi Kim, Seulgi Ryu, **Yeeun Kim**, Wonshik Chee, Eun-Ok Im

The University of Texas at Austin, Austin, TX

Background: Asian American breast cancer survivors remain underrepresented in survivorship and behavioral health research due to cultural stigma, linguistic diversity, and privacy concerns. To address these barriers, culturally aligned outreach strategies leveraging trusted relationships and ethnic-preferred communication channels are needed. This study describes the *Culturally Adaptive Hybrid Recruitment Model (*CAHR-Model), which integrates community consultants with ethnic-specific digital outreach to recruit Asian American breast cancer survivors in the United States.

Methods: The CAHR-Model was developed through an integrative approach combining evidence synthesis, community collaboration, pilot implementation, and iterative refinement. A review of prior research identified barriers such as language discordance, stigma, and privacy concerns as well as facilitators such as collectivist values, community trust, and increasing technology-based communication. Recognizing growing digital connectivity within Asian communities, the research team incorporated technology-enabled outreach as a core strategy. Guided by these insights, consultations with community leaders, survivor advocates, healthcare professionals, and faith-based connectors mapped culturally congruent communication pathways across Korean, Chinese, and Japanese subgroups. Community consultants played a key role in reaching potential participants through trusted networks and providing feedback to refine recruitment messages and delivery. This iterative process led to a dual-channel framework integrating community trust with targeted digital outreach to enhance recruitment.

Results: This hybrid approach enhanced trust, expanded geographic reach, and fostered culturally meaningful engagement. Community consultants, especially healthcare-affiliated connectors such as community health workers and survivor peers, achieved the highest enrollment conversion rates through personal referrals. Korean participants most often engaged digital platforms through *KakaoTalk* and *MissyUSA*, Chinese through *WeChat and RED,* and Japanese survivors through Vivinavi. Digital outreach also effectively reached younger survivors and those less connected to formal networks.

Conclusion: Anchored in community trust and ethnic-specific digital ecosystems, the CAHR-Model demonstrated effectiveness in recruiting Asian American breast cancer survivors. This culturally adaptive and scalable framework offers a practical model to strengthen participation and representation in future breast survivorship and behavioral health research.

#2483 Survivorship and sexual health: What we learned from Black men in community town halls.

Parisa Ghasemi[1], Gaurav Kumar[1], Ernest T. Kaninjing[2], Adanma Ayanambakkam[1], Yaw A. Nyame[3], Amy Siston[4], Jordan M. Neil[1], Adam C. Alexander[1], Andrew G. McIntosh[1], Yan Zhao[1], Zsolt Nagykaldi[1], Kathleen A. Dwyer[1], Mary Ellen Young[5], Sabrina Dickey[6], Daniel Morton[1], Opeyemi Bolajoko[7], Darla E. Kendzor[1], Motolani E. Ogunsanya[1]

[1]University of Oklahoma Health Campus, Oklahoma City, OK,[2]Georgia College & State University, Milledgeville, GA,[3]University of Washington, Seattle, WA,[4]University of Chicago Medicine, Chicago, IL,[5]Mayo Foundation for Medical Education and Research, Jacksonville, FL,[6]Florida State University, Tallahassee, FL,[7]Mayo Clinic Comprehensive Cancer Center, Jacksonville, FL

Background: Prostate cancer (CaP) is among the most common cancers in U.S. men, with Black men experiencing a 1.7-fold higher incidence and nearly twice the mortality rate compared with non-Hispanic White men. While early detection has improved survival, differences remain in recovery and quality of life (QoL). Sexual dysfunction after treatment affects identity, relationships, and well-being, yet stigma, cultural norms, and limited access to patient-centered care prevent open discussion. Few initiatives address the intersection of identity, stigma, and survivorship in this population. Community town halls provide a trusted, culturally responsive space for shared learning, peer connection, and open dialogue on survivorship and sexual health.
Methods: Two community-engaged CaP town halls were convened by the Multidisciplinary Health Outcomes Research and Economics (MORE) Lab at the University of Oklahoma Health Campus (OUHC) to explore survivorship issues among Black CaP survivors. The first, held virtually in June 2024, included watch parties in Georgia and Texas. The second, in November 2024, was hybrid, hosted at OUHC and via Teams with a watch party at the Willa D. Johnson Recreation Center, a community center in Oklahoma City. Panelists included oncologists, psychologists, survivors, partners, and Community Advisory Board members. Both town halls featured survivor storytelling, provider Q&A, and interactive discussion. Post-event surveys captured demographics, satisfaction, and impact. Open-discussion transcripts were analyzed using Braun and Clarke's reflexive thematic analysis, guided by a constructivist framework.
Results: A total of 124 participants attended both town halls. Survey respondents (n=17; 13.7%) provided demographic and satisfaction data; remaining insights came from all participants who engaged in open dialogue. Respondents ranged in age from 19-76 years (mean=48.7 ± 21.8). Of the 17 respondents, 93% rated the events as very good or excellent; 23.5% were CaP survivors, all identifying as Black. Five themes emerged: (1) Masculinity, stigma, and silence limit help-seeking; (2) Sexual dysfunction and identity loss cause major emotional burdens; (3) Navigation challenges highlight systemic barriers; (4) Spousal and psychological support aid coping; and (5) Survivorship empowerment. Participants valued hearing "real stories from real men," validating their experiences.
Conclusions: Community town halls are a feasible and culturally relevant strategy to engage Black CaP survivors in survivorship and sexual health discussions. By centering lived experiences and facilitating two-way communication between survivors, clinicians, and researchers, these events build trust and reduce stigma. Future work will assess changes in knowledge, engagement, and confidence in care navigation and explore scaling this community-academic model to improve survivorship QoL.

#2484 Exercise preferences and barriers in minority cancer patients undergoing chemotherapy.

Huimin Yan[1], Samin Amini[1], James D. Cannon[2], Anton Pecha[1], Rebekah L. Wilson[2], Cami N. Christopher[2], Mary K. Norris[2], Christina M. Dieli-Conwright[2]

[1]University of Massachusetts, Boston, MA,[2]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: Physical inactivity and comorbid disease burden are disproportionately high among Black and Latinx cancer patients receiving chemotherapy, yet participation in exercise oncology trials remains low in these groups, despite known benefits. The Testing Home-based ExeRcise Strategies to Improve Exercise Participation and CardioVascular Health in UndersErved Minority Patients with Cancer Undergoing Chemotherapy (THRIVE) trial tests the feasibility and acceptability of supervised and unsupervised home-based exercise during chemotherapy in these underrepresented groups. This analysis describes exercise preferences collected through a structured questionnaire administered prior to randomization.

Methods: Participants enrolled in the THRIVE trial completed baseline questionnaires assessing exercise interest, preferred modalities, timing, perceived benefits, and anticipated barriers. Eligible patients were sedentary, self-identified as Black or Hispanic/Latinx, and diagnosed with breast, colorectal, or prostate cancer. Descriptive statistics were used to summarize patient characteristics and survey responses. The Benefit Anticipation Questionnaire was scored using a 7-point Likert scale ranging from −3 (very much harmful) to +3 (very much beneficial). The Exercise Barrier Questionnaire was scored using a 7-point Likert scale, ranging from 1 (not at all) to 7 (very much). Data are reported as mean ± standard deviation.

Results: Nineteen Black or Latinx participants enrolled in the study to date, and 13 participants returned the questionnaire (mean age 55 ± 12 years), including 12 female breast cancer patients and 1 male prostate cancer patient. Most participants expressed interest in participating in an exercise program (84.6%) and felt capable of doing so (76.9%). Walking (69.2%) and strength training (53.8%) were the most preferred modes. Light- or Moderate-intensity exercise (38.5%) performed 30-60 minutes per session (84.6%) three times per week (69.2%) was most common. Surprisingly, the most preferred time to start an exercise program was during cancer treatment (61.5%), followed by before cancer treatment (30.8%). Participants reported high anticipated benefits for the proposed program, with 91.7% rating the impact as “very much beneficial” for both overall quality of life (M = 2.9 ± 0.3) and physical functioning (M = 2.8 ± 0.9). The most frequently cited barriers were feeling sick/not feeling well (M = 4.3 ± 2.1) and feeling tired or fatigued (M = 4.1 ± 2.0), followed by cost (M = 3.8 ± 2.5) and traveling to the fitness center (M = 3.8 ± 2.1).

Conclusion: Black and Latinx cancer patients expressed strong interest and confidence in home-based, supervised exercise programs during cancer treatment. Tailoring exercise schedules and addressing symptoms such as sickness and fatigue may enhance participation. Addressing barriers such as cost and travel may further support adherence.

#2485 Role of social determinants of health on survival in children with acute lymphoblastic leukemia in a Southern California cohort.

Daniel Lee[1], Dennis Kuo[2], Victor Wong[2], Anusha Preethi Ganesan[2], William Roberts[2], Oscar Ramirez[3], Paula Aristizabal[4]

[1]University of California San Diego School of Medicine, San Diego, CA,[2]Department of Pediatrics, University of California San Diego/Rady Children's Health, San Diego, CA,[3]POHEMA Foundation Research Unit, Cali, Colombia,[4]Department of Pediatrics, University of California San Diego/Rady Children's Health & Moores Cancer Center, San Diego, CA

PURPOSE: While survival for Acute lymphoblastic leukemia (ALL) has improved, outcome disparities remain, partly due to limited characterization of Social Determinants of Health (SDoH) and low participation of ethnic minorities. We evaluated clinical outcomes and SDoH in youth with ALL at Rady Children's Health (2015-2023).
METHODS: We assessed demographics, clinical characteristics, outcomes, and parental SDoH (language, interpretation use, acculturation, insurance, neighborhood vulnerability). Analyses included Kaplan-Meier (5-year EFS), multivariable logistic regression (aORs), and Cox regression (aHRs), adjusted by age, clustered by diagnosis year, with 5000 bootstrap replicates.
RESULTS: We included 211 youth, 59% (n=124/211) were male, 64% (n=134/211) were White, 27% (n=56/211) multiracial, 8% (n=16/211) Asian/Pacific Islander/American-Indian, 2% (n=5/211) Black, and 55% (n=117/211) Hispanic. The cohort's median age was 6 years (y), [IQR, 4-13], and 13% of youth was 15-18y (n=28/211). Eighty-seven percent of patients (n=183/211) had B-ALL [SR=57% (n=104/183), HR=35% (n=65/183), VHR=8% (n=14/183)]; and 13% (n=28/211) had T-ALL [SR+IR=68% (n=19/28), HR=32% (n=9/28)]. Eight percent of patients (n=17/211) relapsed once, and 2% (n=4/211) twice. Twenty-two percent of patients (n=46/211) developed bacteremia, and ICU admission occurred in 28% of youth 1-4y vs. 54% of youth 15-18y (P=0.039). Spanish for medical communication was used by 22% of parents (n=46/211). Interpretation use was 85% in parents of youth 1-4y vs. 14% of youth 15-18y (P=0.001). Parental acculturation differed by age: 36% in parents of youth 10-14y vs. 29% of 15-18y (P=0.004). The aOR of public insurance for bacteremia was 3.31 (95%CI 1.47-7.47). Bacteremia was not associated with neighborhood vulnerability (aOR 0.82, 95%CI 0.34-1.96). The cohort's 5-year EFS was 85.7% (SE 2.8%) and differed by age and neighborhood vulnerability (higher vs. lower): In 15-18y, EFS was 57% vs.90% (high vs. low; P=0.036), and in 1-10y, EFS was 78.9% vs.92.9% (high vs. low; P=0.001). The aHR of neighborhood vulnerability for relapse/death was 2.87 (95%CI 1.30- 6.33).
CONCLUSION: In this diverse ALL cohort, we found age-related and SDoH-associated disparities. Adolescents had worse survival, more ICU admissions, and lower interpreter use. Higher neighborhood vulnerability was independently linked to increased mortality, underscoring the need for targeted support for vulnerable groups.

#2486 Racial differences in clinical and cytogenetic features of pediatric acute myeloid leukemia.

Sara Elbanna[1], Hassan Mohammed Abushukair[2]

[1]Jordan University of Science and Technology, Ar-Ramtha, Jordan,[2]University of Oklahoma Stephenson Cancer Center, Oklahoma City, OK

Introduction: Racial disparities in pediatric acute myeloid leukemia (AML) outcomes are well documented, yet the biological basis for these differences remains poorly understood. Despite the availability of molecular technologies, their use in characterizing ancestry-associated disease variation has been limited. In this study, we aimed to profile race-associated clinical and molecular features in pediatric patients with AML.

Methods: We utilized the pediatric TARGET AML 2018 cohort, which included samples from 899 patients with clinical, genomic, and transcriptomic data. All data were retrieved and analyzed through the cBioportal data repository. Analyses were limited to race groups with at least 20 cases (White, Black/African American, and Asian). X2 and Kruskal-Wallis tests were used to compare categorical and continuous features, respectively.

Results: Of 899 patients, 836 patients had data reported on race, of which the majority were White (n = 644, 77.03%), followed by Black/African American (n = 102, 12.20%), Asian (n = 43, 5.14%), and other racial minorities (n=47, 5.62%). Age at diagnosis was comparable across race groups (median 11-12), and there was a trend for increased female percentage in Asian patients (61.22%) compared to Black/African American (50.88%) or White (46.55%) patients (p = 0.255). Compared to White patients, Black/African American patients had worse overall survival (OS) probability (HR: 2.12, 95% CI: 1.46-3.1), while Asian patients did not have a significant difference (HR: 1.65, 95% CI: 0.98-2.8). Median OS was not reached, 59, and 37 months for White, Asian, and Black/African American patients, respectively. Measurable residual disease (MRD) percentage at the end of the first course of treatment varied significantly by race (median: 0, 0, 0.12% in White, Black/African American, Asian, respectively, p = 0.0064). Among cytogenetic abnormalities, t(6;11)(q27;q23) (p = 0.0022) and t(8;21) (p = 0.0059) were most enriched in Black/African American patients (n = 6, 5.26%, n = 23, 20.18%) compared with White (n = 9, 1.29%, n = 82, 11.78%) and Asian patients (n = 1, 2.08%; n = 6, 12.5%) p = 0.0022). In contrast, inv(16) occurred most frequently in White patients (n = 100, 14.34%) compared with Black/African American (n = 10, 8.77%) and Asian patients (n = 1, 2.08%; p = 0.0029). FLT3-ITD positivity was the highest in Asian patients (n = 14, 28.57%), followed by White (n = 134, 18.16%) and Black/African American patients (n = 9, 7.96%, p = 0.0039).

Conclusion: Our findings highlight race-associated clinical variability in outcomes and cytogenetic attributes across pediatric AML patients. Black/African American patients had worse outcomes and more adverse-risk lesions. These patterns show that, beyond socioeconomic factors, potential underlying biological heterogeneity may contribute to racial disparities in AML outcomes and warrant further ancestry-driven investigations.

#2487 Integrating clinical and multiomics data to characterize ethnic disparities in breast cancer on the gulf coast.

Luis del Pozo Yauner[1], **Maha Babker**[1], Rosetta Campbell[1], Veronica Ramirez-Alcantara[2], Huseyin Kilic[1], Elba Turbat-Herrera[2], Hector Chavarria Bernal[1], Bahaaeldin Youssef[1], Ateeqa Mujeeb Ullah[1], Wei Yang[3], Guillermo A. Herrera[1], Ajay Pratap Singh[4]

[1]Pathology, University of South Alabama College of Medicine, Mobile, AL,[2]USA Health Biobank and Histology Service, University of South Alabama College of Medicine, Mobile, AL,[3]Bruker Spatial Biology, Seattle, WA,[4]SOM-Cell and Molecular Biology, School of Medicine at the University of Mississippi Medical Center, Jackson, MS

Ethnic disparities in breast cancer (BC) incidence, subtype distribution, and outcomes remain a significant public health concern in the United States. African American women (AAW) are disproportionately affected by aggressive disease, particularly triple-negative BC (TNBC). Whether these disparities are mirrored in Gulf Coast populations and whether tumor-level molecular features contribute to them remains unclear. This study integrates clinical data with tumor multiomics profiling to characterize ethnic differences among women diagnosed with BC within the USA Health System. Clinical and demographic information from 1,229 women diagnosed with BC from 2016 to 2024 was reviewed; 1,059 women (447 AAW, 612 WAW) with complete datasets were included. Age at diagnosis and BC subtype distribution were compared between ethnic groups. Tumor samples from 20 women (13 TNBC, seven non-TNBC; both AAW and WAW represented) and three normal breast tissues were analyzed using the NanoString BC360 transcriptomic and MO protein panel. Multiomics analyses investigated differences in signaling pathways associated with ethnicity and subtype. AAW exhibited approximately twice the frequency of TNBC observed in WAW and were more often diagnosed before age 55. These patterns parallel national trends and highlight a significant local disparity in disease presentation. The nCounter multiomics assay revealed substantial differences in gene and protein expression profiles between breast cancers from AAW and WAW. At the transcriptomic level, CCNA1, PIK3CA, SOX2, DDX39A, BRCA2, TMPRSS4, and BMP6, among others, showed lower expression in AAW tumors than in WAW tumors.In contrast, CD24 and RAC3 showed higher expression in the former group than in the latter. At the protein level, cyclin A2 and the insulin receptor were underexpressed in AAW tumors. Insulin, Notch1, melanoma GP100, and cIAP2, among others, were overexpressed in AAW tumors compared to those from WAW women. These findings demonstrate that the ethnic disparities in breast cancer observed nationally are also present in the Gulf Coast region and are accompanied by distinct molecular signatures at both the transcriptomic and protein levels. The differential expression of key oncogenic, immune, metabolic, and signaling pathway markers between tumors from AAW and WAW suggests that biological factors may contribute to the more aggressive disease patterns seen in AAW. Further studies with larger cohorts are warranted to validate these results and to explore their implications for personalized risk stratification and targeted therapeutic strategies.

This study was funded by a grant from the Breast Cancer Research Foundation of Alabama (BCRFA) to LPY.

#2488 Transcriptomic landscape for African-specific low-grade prostate cancer.

Eva F. Jensby[1], Korawich Uthayopas[2], Mehedi Hasan[2], Riana Bornman[3], Shingai B. A. Mutambirwa[4], Phillip D. Stricker[5], Karina D. Sorensen[1], Vanessa M. Hayes[2]

[1]Department of Molecular Medicine, Aarhus University, Aarhus, Denmark,[2]Ancestry and Health Genomics Laboratory, Charles Perkins Centre, School of Medical Sciences, University of Sydney, Sydney, Australia,[3]School of Health Systems & Public Health, University of Pretoria, Pretoria, South Africa,[4]Department of Urology, Sefako Makgatho Health Science University, Dr George Mukhari Academic Hospital, Medunsa, South Africa,[5]Department of Urology, St Vincent's Hospital, Darlinghurst, Australia

BACKGROUND

Prostate cancer (PCa) is characterized by large geo-ethnic disparity, with African ancestry being a recognized risk factor of aggressive disease. Globally, ISUP Grade Group 1 (GG1) PCa is considered indolent and is typically treated with active surveillance rather than active treatment. However, this approach is unfeasible in Sub-Saharan Africa due to limited access to PSA testing, imaging, and repeat biopsies. Moreover, ISUP grading developed in European ancestral populations may not reflect African PCa biology.

AIM

This project aimed to explore transcriptional differences between African and European ancestral men presenting with GG1 PCa.

METHODS

Focusing on men from Southern Africa, we performed total RNA sequencing of fresh-frozen (FF) diagnostic prostate biopsy samples from 60 African men with either GG1 PCa (n=28) or without PCa (non-PCa, n=32). FF prostatectomy samples from 47 Australian men of European ancestry with GG1 PCa were sequenced in parallel. This unique data resource enabled ancestry-specific differential gene expression and pathway analysis.

RESULTS

Principal component analysis of the top 1000 most variably expressed genes showed no clear separation between PCa and non-PCa; however, we observed a clear separation between South African and European men. From 24,008 genes, 4,641 were differentially expressed (DE) between African and European-derived GG1 tumors ($P < 0.05$, BH-adjusted). The top 5 candidate genes included downregulation of the tumor suppressor *JUN* in African ancestral tumors. Gene set enrichment analysis (GSEA) of all 24,008 genes and overrepresentation analysis (ORA) of the significant DE genes revealed downregulation of several immune and metabolic pathways ($P < 0.05$, BH-adjusted, NES < -1), indicative of more aggressive PCa driven by unique molecular pathways. Cell type analysis demonstrated lower immune cell, stromal cell, and angiogenesis scores in African compared to European-derived tumors, with stromal cells and angiogenesis reaching statistical significance (P-value < 0.05). The latter indicative of a less diverse tumor microenvironment in African PCa.

Analysis of African ancestry PCa vs. non-PCa identified only 12 DE genes ($P < 0.05$, BH-adjusted). The limited number of significant genes after adjustment may reflect the small sample size or undetected disease in the non-PCa group, which would reduce contrast between the groups. However, GSEA and ORA showed upregulation of proliferative pathways and androgen response ($P < 0.05$, BH-adjusted, NES > 1), which is the expected pattern of PCa vs. non-PCa.

CONCLUSIONS

In this first-of-its-kind study, we reveal distinct transcriptomic profiles between prostate tumors derived from men of African vs. European ancestry. Our results suggest that current active surveillance strategies may not be safe for African ancestral patients with GG1 PCa.

#2489 Distinct HER2- breast cancer traits among subethnic Hispanics of South Florida.

Janice Darkwah[1], Mira G. Spillane[1], Tonya Omlor[1], Sunwoo Han[2], Fei Ye[3], Hoyan Ng-Chen[4], Glenn Fonte[4], **Suzy D. C. Bianco**[4]

[1]University of Miami, Sylvester Comprehensive Cancer Center, Miami, FL,[2]Biostatistics and Bioinformatics Shared Resource, Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL,[3]Division of Biostatistics and Bioinformatics, Department of Public Health Sciences, Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL,[4]Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL

Introduction: Studies with representative numbers of the predominant Caribbean and South American subethnic Hispanics of South Florida (SHFL) are limited. This study explored traits potentially linked to breast cancer susceptibility risk among SHFL, which comprise 45% of Sylvester Cancer Center's breast cancer patients.

Methods: A cohort of 971 SHFL females with breast cancer records between 1/1/2019 and 12/1/2024 was extracted from our medical record database. Data included age, ethnicity, menopausal state, cancer stage, menarche age, BRCA variants, hormone receptors (HR) and HER2 status. Human Epidermal growth factor Receptor-2 negative (HER2-) tumors (n=802) were re-evaluated for reclassification to HER2-Low using criteria: HER2 immunohistochemistry (IHC) = 1+ *or* 2+ with fluorescence *in-situ* hybridization (FISH) negative. Association of risk factors with Triple-Negative Breast Cancer (TNBC) vs non-TNBC (defined as positivity for HR and/or HER2) was assessed using logistic regression. Multiplicity in univariable analysis was reported by Q-values (p-values adjusted for false discovery rate).

Results: At diagnosis, 47% of the cohort was pre-menopausal, with 25% aged ≤45 and 13% aged ≤40. Among those diagnosed with stage 4, 24% were also aged ≤45. 71% of HR+/HER2- tumors were reclassified to HER2-Low, along with 50% of all TNBC. Univariable logistic analysis showed that younger ages (≤45 vs >45: OR=1.69, 95%CI: 1.11-2.56; q=0.042) and greater BRCA burden (1-unit increase OR=2.70, 95%CI: 1.38-5.28; q=0.017) were significantly associated with TNBC. Multivariable analysis including age, HER2-, HER2-Low, BRCA and interaction terms revealed significant positive interaction between BRCA and TNBC ($p_{interaction}$=0.018) which was weakened in HER2-Low tumors. Later cancer stages were associated with less years of estrogen exposure when compared to stages 0/1 (p=0.008 for stages 2/3 and p=0.038 for stage 4). Prevalence of early menarche (age <10) was 7% whereas late menarche (age >14) was 14%.

Conclusions: Our findings reveal distinct patterns and novel associations of BRCA burden, HER2-Low patterns, estrogen exposure and ages at diagnosis and menarche in SHFL with breast cancer. For instance, in contrast to the usual association of breast cancer with older women, nearly half of our cohort was pre-menopausal, with one quarter aged 45 or younger. This is concerning as younger patients may not be old enough to benefit from preventive mammograms and are more likely to have TNBC (the most aggressive tumors with the least treatment options). Reclassification of most HER2- tumors into HER2-Low potentially expands their therapy options to include the first trastuzumab-based therapy for HER2-Low. A weakened interaction of BRCA with TNBC in HER2-Low suggests distinct genetic basis compared to HER2- IHC=0 tumors. Lastly, prevalence of both early and late menarches was elevated compared to the general population.

#2490 Systemic molecular disparities in Black vs. White breast cancer survivors: Beyond socioeconomic determinants.

Ritam Adhikari[1], Chiranjeev Dash[2], Rabindra Roy[3]

[1]The Quarry Lane School, Dublin, CA,[2]Dept. of Oncology, Georgetown Lombardi Comp. Cancer Center, Washington,[3]Georgetown Lombardi Comprehensive Cancer Ctr., Washington

Objective: Mortality from breast cancer (BC) is 27% higher among non-Hispanic Black (NHB) than among non-Hispanic White (NHW) women. The objective of this study is to investigate molecular mechanisms underlying the higher mortality rate in NHB BC survivors, independent of lifestyle and socioeconomic factors.
Experiment: Buffy coats were collected from NHW and NHB BC survivors (n=12 each, 6 months - 3 years post-treatment) and from cancer-free participants (n=6 each). Principal Component Analysis (PCA) and Fisher's exact tests were performed on clinical variables. Gene expression was measured with the nCounter Immunology Panel (594 genes), Metabolic Pathways Panel (768 genes), and Qiagen RT² Profiler PCR Array Human DNA Repair Kit (84 genes). Differential expression analysis was performed for two comparisons: (A) Black vs. White BC survivors, and (B) Black vs. White non-cancer controls. A two-sample Student's t-test with multiple testing correction (Benjamini-Hochberg false discovery rate (FDR)) was performed with $\log_2$FC and filtered for significance ($p < 0.05$, FDR < 0.25, |fold change| > 2). An Ingenuity Pathway Analysis (IPA) was performed, and pathways with -log p value>=1.3 and Z-score >=2 or <=-2 were considered significant.
Result: PCA of clinical factors (age, BMI, and treatments) and stage distribution (Fisher's exact test) showed similar profiles between NHB and NHW BC survivors, suggesting that molecular differences in downstream analyses are unlikely to be driven by clinical or lifestyle factors. Differential expression analysis suggested that only two genes were significantly different between non-cancer NHB and NHW controls, but 92 genes, including IL8 and POLB, were significantly altered between cancer survivors. These findings suggest that the differential expression patterns are driven by cancer survivorship rather than baseline racial differences. Ninety-two genes were then analyzed with IPA, and 17 pathways were deemed significant. The Th1 and TP53 expression and degradation pathways were more active. Abasic site repair pathways were found to be inhibited in NHB survivors, consistent with our previous report.
Conclusion: Our pilot study showed that despite similar clinical profiles, NHB and NHW BC survivors exhibit distinct molecular signatures. In the future, we plan to validate these pathways and use public databases such as TCGA to evaluate how these genes affect cancer survival. Addressing these pathway differences may be key to achieving true equity in breast cancer survivorship.

#2494 Prospective organoid drug profiling and clinical response correlation for patients with primary or recurrent ovarian carcinoma (OC) in the PROSPERITY study.

Elizabeth M. Swisher[1], Payel Chatterjee[2], Isabel Rodriguez[1], Kalyan Banda[3], Faith Beers[2], Asal Patterson[4], Enna Manhardt[1], Mayumi Rubin-Saika[2], Emiko Oshima[2], Melanie Dillon[2], Rachele Rosati[5], Vaishnavi Pallem[2], Lauren R. Appleyard[2], Alex C. Rajewski[2], Shalini Pereira[2], Soledad Jorge[2], Renata R. Urban[2], Elise J. Simons[2], John B. Liao[1], Barbara Goff[2], Carla Grandori[6], Christopher J. Kemp[7]

[1]University of Washington, Seattle, WA,[23]University of Washington, School of Medicine, Seattle, WA,[4]Washington State, Pullman, WA,[5]Tempus AI, Inc.,[6]SEngine Precision Medicine, Bothell, WA,[7]Fred Hutchinson Cancer Center, Seattle, WA

We evaluated drug sensitivity profiling of primary and recurrent OC patient-derived organoids (PDOs) from 42 patients prospectively enrolled to the PROfiling Ovarian cancerS to improve PERsonalIzed TherapY (PROSPERITY) study. A total of 50 biopsy samples from 36 participants were received including paired pre- and post- chemo samples for 8 and paired samples from 2-3 different metastatic sites for 6 participants. Short-term PDOs were generated by SEngine Precision Medicine (TEMPUS) and assessed for drug response to a panel of 47 chemotherapeutic or targeted drugs. A filter-based algorithm was applied to each concentration-response curve to generate a sensitivity numerical score (SPM score) ranking drug responses from 15 to 1. Additional metrics were employed to group and assign categories: SPM PDO scores of 15-14 were categorized as exceptional responses, 13-12 as good, 11-9 as moderate to low, and below 9 as no response. Tumor origin and driver mutations were confirmed using whole-exome sequencing. Patient clinical response was assessed post-PARIS test using radiologic response, chemotherapy response score, and KELIM CA-125 kinetics and categorized as concordant or non-concordant relative to the PDO prediction. Drug profiling was successful in 43/50 (86%) samples with a median turnaround time of 20 days for pre-treatment samples and 26 days for post-chemo samples. Tested samples included 16 primary OC collected before chemotherapy, 20 collected after 3-4 cycles of neoadjuvant chemotherapy, and 7 recurrent OCs. 7/21(33%) post-chemo samples failed quality control (QC) metrics compared to 2/17 (11.7%) pre-chemo. Of 9 technically and clinically evaluable primary OC obtained pre-chemo, clinical response to carboplatin-based therapy was concordant with PDO prediction in 7 (77.8%). Of the 9 post-chemo evaluable cases, 6 (66.6%) were clinically concordant with PDO prediction. Of the 6 evaluable participants with recurrent OC, none were treated with a PARIS-guided therapy, preventing assessment of clinical concordance. In both the primary and recurrent OCs, unique PDO drug sensitivity profiles were identified in all profiled samples that would not have been predicted by standard molecular profiling, suggesting actionability. In 5 cases tested at two different metastatic sites, SPM scores were highly concordant (Spearman ranks, 0.48-0.77), one pair in the sixth case failed QC and was non-evaluable. In conclusion, drug profiling of both primary and metastatic OC derived organoids is highly feasible and shows promise for clinically relevant drug response predictions with high concordance in samples from more than one metastatic site. Coverage of off-label drugs with predicted exceptional and good responses has been a major barrier to clinical utilization of PDO profiling in the recurrent setting.

#2495 Rapid clinical diagnostic classification and risk stratification in acute myelogenous leukemia (AML) using whole genome sequencing (WGS).

Wayne M. Jepsen[1], Jonathan J. Keats[1], Sara A. Byron[1], Cherie Wesley[1], Bryce Turner[1], Christophe Legendre[1], Tyler Izatt[1], Tracey White[1], Amy Stouffer[1], Lucy Ghoda[2], Yeneka Campana[1], Courtney Holden[1], Jonathan Beteran[1], Michelle Afkhami[2], Anthony Stein[2], Tibor Kovacsovics[3], Guido Marcucci[2], Jeffrey Trent[1]

[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ,[2]City of Hope, Duarte, CA,[3]City of Hope, Phoenix, AZ

Waiting for test results is a primary cause of delay in the diagnostic classification and risk stratification of patients with AML. With conventional cytogenetic, FISH, and targeted NGS approaches taking a median turnaround time (TAT) of 7-15 days, there is a significant unmet need to deliver these results faster using a more comprehensive testing platform. We have very recently developed, and demonstrated Analytical Validity (AV), Clinical Validity (CV) and Clinical Utility (CU) in accordance with MolDX L38047, for a rapid Whole Genome Sequencing (WGS) approach for AML (DEX Z-Code Z04C0). Importantly, this test (termed ALTseq) was specifically designed to deliver clinically actionable genomic results that encompass those from cytogenetics, FISH, and targeted NGS in under 48 hours (TAT mean = 33 hours). This accelerated turnaround time was enabled by streamlining laboratory workflows, enhancing bioinformatic pipelines, and expediting variant approval for reporting. The assay captures single nucleotide variants, indels (including FLT3-ITDs and KMT2A-PTDs), and 155 distinct structural variants including KMT2A rearrangements, and genome-wide copy number alterations. Additionally, we have recently developed a method to measure monosomal and complex karyotypes from WGS sequencing data. By deploying WGS we are able to gain insight in all genes in the human exome, with the curated clinical reporting covering all current key AML-related aberrations. These include mutations in NPM1, TP53, RUNX1, IDH1/2, FLT3, MEN1, rearrangements involving KMT2A, MECOM, NUP98, and canonical translocations such as PML::RARA, RUNX1::RUNX1T1, and BCR::ABL1. ALTseq has a limit of detection of 9%, 8%, 10%, and 7% for SNVs, indels, CNAs, and SVs, respectively, with sensitivities of 96%, 96.4%, 95.7%, and 100%, respectively. The positive predictive value for all variant types is ≥99.5%. Since implementation, ALTseq has been used in 66 AML cases, achieving a mean TAT of 33 hours from sample receipt to report delivery. Recent evidence of clinical utility includes the incorporation of Mylotarg in induction therapy based on the identification of CBFB::MYH11 fusion gene, and the inclusion of Revumenib for a KMT2A rearrangement that could not be identified with standard breakaway FISH probes. In summary, we will describe the clinical deployment of a high-throughput, fast-turnaround WGS platform for AML, capable of delivering comprehensive genomic profiling in <48 hours from sample receipt to clinical reporting enabling earlier, more informed treatment decisions.

#2496 *In silico* screeening of therapeutics candidates targeting minimal residual disease in glioblastoma.

Feinberg School of Medicine, Chicago, IL,[3]Professor, Dept. of Path. & Lab Med., Northwestern University - Evanston, IL, Chicago, IL,[4]Department of Laboratory Medicine and Pathology, Mayo Clinic Jacksonville, Chicago, IL,[5]Pathology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[6]Radiation Oncology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[7]Neurology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[8]Duke Cancer Institute, Durham, NC,[9]Neuro-Oncology, University of California San Francisco, San Franscisco, CA,[10]Ctr. for Neuro-Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: Glioblastoma recurrence is inevitable despite aggressive surgical resection of contrast enhancing (CE) tumor. Unlike the deep molecular characterization of CE glioblastoma, unresected infiltrating tumor, representing minimal residual disease (MRD) has not been well profiled. Increasingly, clinical trials are being conducted in the MRD setting for glioblastoma patients, necessitating understanding of unresected infiltrating tumor for targeted therapeutic development.

Methods: Visium HD spatial transcriptomics was used to profile a cohort of newly diagnosed, treatment-naïve glioblastoma patients that underwent supramaximal resection, with both core and infiltrating *in situ* components. Spatial profiles generated expression signatures of infiltrative and CE tumor. For i*n silico* prediction of therapeutics targeting the MRD, expression signatures of infiltrative and CE tumor were compared with drug perturbation signatures from the NIH L1000 database using the sRGES method to predict reversal of disease expression patterns. IC_{50} data from human cell lines were aggregated from the Genomics of Drug Sensitivity in Cancer or individual study data while blood-brain barrier (BBB) penetrance was predicted using the CNS-MPO approach.

Findings: Infiltrative tumor expression profiles were enriched for genes corresponding to neural and oligodendrocyte progenitor like cells. In contrast CE glioblastoma displayed mesenchymal and astrocytic programs, suggesting spatial concentration of glioblastoma states within MRD and CE tumor. For CE glioblastoma, proteasome inhibitors and glucocorticoid receptor agonists were predicted to have the highest antitumor activity. In contrast, histone deacetylase inhibitors (HDACi) were highly ranked for MRD while exhibiting low predicted efficacy in CE tumor. Synergy analysis of drug candidates provided multiple dual treatment options for both the CE and MRD contexts.

Conclusions: Cumulatively, these data indicate that the resected tumor does not reflect the MRD state, providing clarity on why targeted therapeutics for glioblastoma have not been particularly successful. Spatial profiling of the MRD demonstrates vulnerability to unique drug targets, which if utilized in the correct setting could confer greater survival benefit.

#2497 A human pcVMT platform for personalizing chemotherapy route and regimen selection in peritoneal carcinomatosis.

Aaqil M. Khan[1], **Stephanie J. Hachey**[2], Vinodh Kumar Radhakrishnan[2], Fatemeh Tajik[2], Melanie Roman[2], Christopher C. W. Hughes[2], Maheswari Senthil[1]

[1]University of California, Irvine, Irvine, CA,[2]Uc-Irvine, Irvine, CA

Peritoneal carcinomatosis (PC) is a clinically aggressive metastatic disease state marked by diffuse peritoneal involvement and limited responsiveness to systemic chemotherapy due to poor penetration across the mesothelial barrier. Although intraperitoneal (IP) therapy offers a mechanistically rational alternative, clinicians currently lack human-relevant platforms to determine which patients will benefit most from systemic therapy, IP therapy, or a combination of both.To address this unmet need, we developed a dual-chamber peritoneal carcinomatosis vascularized micro-tumor (pcVMT) platform that recreates a human mesothelial-lined peritoneal cavity adjacent to a perfused vascular network, enabling patient-specific, route-specific chemotherapy testing. The pcVMT supports stable vascular perfusion, intact mesothelial barrier function, and tumor adhesion and invasion using both PC cell lines and patient-derived peritoneal metastases. High-resolution confocal imaging confirms robust tumor-stromal-vascular organization across multiple clinical samples.The platform facilitates testing of clinically relevant regimens, including vascular FOLFOX, IP paclitaxel, and bidirectional systemic+IP delivery, and permits real-time visualization of route-dependent tumor responses within each patient's microenvironment. Early patient-derived experiments demonstrate feasibility of individualized assessment, including successful IP paclitaxel administration with observable changes in tumor architecture.By enabling controlled comparison of systemic, IP, and combined delivery strategies within a physiologic human peritoneal model, the pcVMT provides a precision-oncology tool designed to identify the most effective therapy and delivery route for each patient. Ongoing studies will expand patient-derived testing and explore correlations with clinical decision-making to guide personalized treatment selection and future systemic-IP combination strategies in PC.

#2498 OncoKB™, MSK's precision oncology knowledge base: 2025 updates.

Sarah Phillips Suehnholz[1], Ritika Kundra[1], **Moriah Heller Nissan**[2], Calvin Lu[1], Nicole Fernandez[1], Kelly Cavender[1], Kinisha Gala[1], Benjamin Preiser[1], Reshma Ramaiah[1], John Konecny[1], Xiang Li[1], Subhiksha Nandakumar[3], Kseniya Petrova-Drus[1], Mark Ewalt[1], Nikita Mehta[1], Yonina R. Murciano-Goroff[1], James Du[1], Anoop Balakrishnan Rema[1], Aijazuddin Syed[1], A. Rose Brannon[1], Ahmet Dogan[1], Diana Mandelker[1], Zsofia K. Stadler[1], Alexander Drilon[1], David B. Solit[1], Ross L. Levine[4], Maria E. Arcila[1], Marc Ladanyi[1], Michael F. Berger[1], Jianjiong Gao[1], Nikolaus Schultz[1], Debyani Chakravarty[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Memorial Sloan Kettering Cancer Center, San Diego, CA,[3]Memorial Sloan Kettering Cancer Center, Ann Arbor, MI,[4]Assistant Member, Human Onc. Pathogenesis Prog., Memorial Sloan Kettering Cancer Center, New York, NY

OncoKB™, a precision oncology knowledgebase developed at Memorial Sloan Kettering Cancer Center (MSK), provides expert-reviewed interpretations of the biological function and clinical actionability for >8,000 somatic alterations in 950 cancer-associated genes. It remains the only somatic cancer variant knowledgebase partially recognized by the U.S. FDA. At MSK, OncoKB™ has annotated over 100,000 patient sequencing reports so far and it supports thousands of cBioPortal daily users for their variant interpretation needs. In addition, thousands of users globally are utilizing OncoKB™ for annotating and interpreting cancer variants. OncoKB™ is publicly accessible at www.oncokb.org. It can be used for free for academic research and requires a fee-based license for clinical and commercial use.

OncoKB™ classifies alterations based on the level of evidence supporting the alteration as a predictive biomarker of drug response in a specific cancer subtype. To date OncoKB™ includes 58 Level 1 genes as well as MSI-H and TMB-H (included in the FDA drug label), 6 Level 2 genes (included in professional guidelines), 10 Level 3A genes (predictive of response in well-powered clinical studies), 1 Level 4 gene (predictive of response based on compelling biological evidence), and 12 R1/R2 resistance genes.

In 2025, OncoKB™ added 3 novel level 1 biomarkers based on the FDA approval of dordaviprone in *H3F3A, H3C2,* and *H3C3 K28M*-mutant diffuse midline glioma. OncoKB™ also promoted *NPM1* mutations in acute myeloid leukemia and *KRAS* mutations in low-grade serous ovarian cancer to level 1 based on FDA approvals of revumenib and avutometinib + defactinib, respectively. Multiple *EGFR* alterations, including exon 19 in-frame insertions and kinase domain duplications, were also elevated to level 1 following FDA approval of datopotamab deruxtecan for *EGFR* mutant non-small cell lung cancer (NSCLC). NCCN guidelines for pancreatic cancer and NSCLC added erdafitinib for *FGFR1/2* fusion-positive and *FGFR1/3*-mutant tumors, respectively, establishing these as OncoKB™ level 2 biomarkers. Similarly, the NCCN small bowel adenocarcinoma guidelines listed sotorasib and adagrasib for *KRAS* G12C-mutant tumors, and the NCCN breast cancer guidelines listed neratinib + trastuzumab + fulvestrant for tumors with *ERBB2* mutations, also designating level 2 status in these indications. In sum, 3 novel clinically actionable biomarkers and 20 follow-on precision oncology therapies for existing leveled biomarkers were incorporated into OncoKB™ in 2025.

OncoKB™ has started annotating germline variants to enable integrated interpretation of paired tumor-normal sequencing results. Other ongoing efforts include updates to diagnostic and prognostic biomarker annotations, a clinical trial matching module, and piloting AI-based curation workflows to expand OncoKB™ annotation for biomarkers detected by whole genome or transcriptome sequencing and immunohistochemistry.

#2499 Single-cell transcriptomic comparison of tumor before and after chemotherapy reveals therapeutic vulnerabilities in chemo-tolerant osteosarcoma cells.

Parisa Vahidi Ferdowsi[1], Kenny Yeo[1], Tiruneh Adane[1], Qian Wang[1], Nisitha Jayatilleke[1], Sin Wi Ng[1], Janith Seneviratne[1], Daniel R Carter[1], Antoinette Anazodo[2], Richard Boyle[3], Paul Stalley[3], Maurice Guzman[3], Daniel Franks[3], Belamy B. Cheung[1], Glenn Marshall[1]

[1]Children's Cancer Institute, Sydney, Australia,[2]Kids Cancer Centre, Sydney, Australia,[3]Royal Prince Alfred Hospital, Sydney, Australia

Relapse remains the leading cause of treatment failure and mortality in osteosarcoma (OS). There is currently no reliable clinical approach to predict relapse at diagnosis or to inform early, personalised treatment strategies aimed at avoiding relapse. This study aims to address this gap by profiling OS tumors with single-cell RNA sequencing (scRNA-seq) at diagnosis (Dx), after chemotherapy (Rx), and at relapse (Rel). By mapping gene-expression changes across these stages, we identify resistance-associated genes and pathways, define persister cell populations, and prioritise translational combination therapies for high-risk patients. We performed scRNA-seq on 17 primary OS tumor samples (11 Dx, three Rx, and three Rel) from 12 patients including two Dx/Rx and three Dx/Rel pairs. After removing low-quality cells, batch effects were corrected in Seurat using Harmony. Cell types were annotated based on canonical markers, and malignant cells were inferred from copy-number variation (CNV) profiles using CONICSmat. To further increase our sample size and statistical power, we integrated an additional 12 diagnostic and 15 after chemotherapy OS scRNA-seq data from 27 patients using publicly available datasets, applying Harmony to correct for sequencing platform differences and minimise inter-dataset batch effects. Differential expression in malignant cells was assessed between Dx and Rx/Rel using pooled and paired analyses. Genes upregulated at Rx/Rel were prioritised using four filters: patient prognostic association in NCI TARGET, supporting evidence from published studies, gene dependency in DepMap, and small molecule inhibitors suitable for *in vivo* studies. Five candidate genes were selected for functional validation: SNHG6, PFKFB3, MRE11, PLCβ4, and S100A13. PFKFB3 and PLCβ4 were tumor-specific and induced by cisplatin and doxorubicin. Their silencing by siRNA or pharmacologic inhibition with the selective inhibitor sensitised OS cells to chemotherapy. Gene set enrichment identified epithelial-mesenchymal transition (EMT) as the top pathway in Rx/Rel, consistent with therapy-tolerant states. SB-431542, a TGF-β-induced EMT inhibitor, sensitised cisplatin-resistant OS cells to cisplatin and reduced migration of OS cells. Taken together, these findings define chemoresistant tumor states and identify actionable targets and pathways, including PFKFB3 and EMT, for rational combination therapies. They support a scRNA-guided framework for risk stratification and precision treatment selection in high-risk OS.

#2500 *CMTR2* deficiency defines a novel RNA splicing-driven subtype of lung adenocarcinoma with therapeutic vulnerabilities.

Takashi Nakaoku[1], Shigenari Nukaga[1], Kouya Shiraishi[1], Akifumi Mochizuki[1], Hamaguchi Yu[1], Hitomi Nishinakamura[1], Yoshihisa Kobayashi[1], Ayako Ui[2], Yasushi Goto[3], Shun-ichi Watanabe[3], Yasushi Yatabe[3], Hiroyoshi Nishikawa[1], Ryuji Hamamoto[1], Takashi Kohno[1]

[1]National Cancer Center Research Institute, Tokyo, Japan,[2]Institute of Development, Aging and Cancer, Tohoku University, MIyagi, Japan,[3]National Cancer Center Hospital, Tokyo, Japan

Background: RNA splicing is frequently perturbed in cancer, yet upstream genomic drivers and tractable vulnerabilities remain incompletely defined in lung adenocarcinoma (LUAD). CMTR2 catalyzes 2′-O-methylation at the mRNA cap (Cap2), a modification implicated in mRNA maturation. The oncologic significance of *CMTR2* alterations and their impact on splicing have not been systematically characterized. We performed comprehensive splicing analysis to identify novel therapeutic targets in LUAD.

Methods: We analyzed 1,017 primary lung cancer specimens with integrated DNA- and RNA-sequencing to map alternative splicing (AS) events (rMATS) to identify alternative splicing events. t-SNE visualization revealed distinct splicing patterns. *CMTR2* variants were functionally profiled using CRISPR knockout models. Splicing changes were validated by orthogonal assays, including long-read direct RNA sequencing. Physical links between CMTR2 and the spliceosome were assessed by proteomics/Co-IP. Therapeutic dependencies were tested using the RBM39-degrader splicing modulator indisulam in vitro and in vivo, and by evaluating response to anti-PD-1 immune checkpoint blockade (ICB) and combination regimens in immunocompetent models.

Results: Genomic profiling identified 3.8 % of LUAD harboring truncating or functionally impaired *CMTR2* alterations, which associated with a distinct AS signature across multiple event classes. CMTR2 physically interacted with spliceosomal components; these interactions were compromised by truncating variants or loss of *CMTR2*, coinciding with widespread shifts in exon usage and intron retention detected by both short- and long-read sequencing. *CMTR2*-deficient cells exhibited heightened sensitivity to splicing modulation with indisulam, producing robust anti-tumor effects in xenograft models. In immunocompetent settings, *CMTR2* loss increased tumor susceptibility to ICB; combining indisulam with anti-PD-1 further enhanced tumor control. Together, these data establish a mechanistic link between cap modification, spliceosome engagement, and therapeutic vulnerability.

Conclusions: *CMTR2* alterations constitute an upstream genomic driver of splicing dysregulation in LUAD and unveil an exploitable liability to splicing modulation and ICB therapy. Cap-dependent RNA maturation and spliceosome coupling represent a convergent axis of vulnerability with immediate translational potential for patient stratification and combination strategies.

Clinical Relevance: *CMTR2* status may serve as a biomarker to identify patients likely to benefit from splicing modulators and/or ICB, and provides a rationale for clinical exploration of CMTR2-targeted combinations in lung cancer.

#2501 Epigenetic screening in organoids identify KMT5A inhibition as a therapeutic strategy via PGK1in endometrial cancer.

Jingyao Chen, Yinhua Tan, Zhichang Liu, Tong Wang, Kai Xiao, Feifei Na

West China Hospital, Sichuan University, Chengdu, China

Endometrial cancer is the most common malignancy of the female reproductive tract, with a continuously rising incidence in recent years. Genomic analyses, including whole-genome and exome sequencing of large tumor cohorts, have revealed widespread epigenetic abnormalities in endometrial cancer. However, the underlying mechanisms driving tumorigenesis remain unclear, highlighting an unmet clinical need for novel therapeutic targets and drugs. Previously, we established genetically defined endometrial cancer organoids with mutations of Trp53, Pten, and amplification of Myc, which recapitulate the tumor heterogeneity and pathology of the disease. In this study, we employed these organoids to perform a high-throughput screen of an epigenetic-targeted compound library. One of the top candidates was UNC0379, an inhibitor of KMT5A. CRISPR/Cas9-mediated genetic inhibiton of KMT5A, encoding the H4K20me1 methyltransferase, consistently suppressed cell viability in both endometrial cancer organoids and cell lines. To further validate the role of KMT5A in vivo, we applied a gene-delivery approach to knock out KMT5A in tumor cells, which significantly inhibited tumor growth in mouse models. Multi-omics analyses were then utilized to investigate the molecular mechanisms underlying KMT5A function. We found that KMT5A deficiency led to significantly reduced ribosome biogenesis, a corresponding decrease in ribosome number, and dysregulated amino acid metabolism. CUT&Tag revealed that KMT5A directly regulated the expression of PGK1 through histone modification. Moreover, inhibition of PGK1 recapitulated both the anti-tumor effects and the abnormal ribosome biogenesis observed upon KMT5A loss.Clinically, high expression of KMT5A was associated with poor prognosis in endometrial cancer patients. Together, this study identifies the KMT5A/PGK1 axis as a key driver of tumor growth in endometrial cancer, revealing a potential therapeutic target for this malignancy.

#2503 Lung cancer organoid-based diagnostic response prediction (CODRP) for predicting anticancer drug response and progression-free survival.

Seung Joon Kim[1], Sang-Yun Lee[2], Yu-Jeong Seong[1], Yongki Hwang[1], Hyobin Won[1], Eunyoung Lee[1], Dong Woo Lee[3]

[1]The Catholic University of Korea, Seoul, Korea, Republic of,[2]Chungnam National University, Daejeon, Korea, Republic of,[3]Gachon Univ. of Medicine and Science, Suwon-si

Background: Anticancer drug sensitivity analysis using patient-derived lung cancer organoids is being actively investigated as a means to predict individual responses to anticancer therapies. Conventional drug sensitivity analysis methods typically rely on the area under the dose-response curve (AUC) or the half-maximal inhibitory concentration (IC_{50}) to distinguish drug-sensitive and drug-resistant phenotypes, yet these approaches have notable accuracy limitations. To address this issue, we developed Cancer Organoid-based Diagnostic Response Prediction (CODRP), a multiparametric analytical method that integrates AUC values, patient-derived organoid (PDO) growth rates, cancer stage. In progression-free survival (PFS) analyses, CODRP demonstrated superior prognostic accuracy compared with conventional AUC-based methods.

Methods: Lung cancer cells obtained from patient-derived tissue were used to generate PDOs that mimic the characteristics of the original lung cancer tissue. Because patient-derived lung cancer cells could only be obtained in limited amounts, a disposable nozzle-type cell spotter, which enables the precise distribution of minimal cell numbers, was employed for high-throughput screening. The key characteristics of the PDOs were validated through pathological comparison with the corresponding patient tissue slides. Anticancer drug sensitivity testing was performed using the PDOs, and PFS was analyzed according to the therapeutic agents prescribed to the patients.

Results: Anticancer drug sensitivity analysis was performed using lung cancer PDOs derived from 12 patients. The conventional AUC-based approach failed to clearly differentiate drug-sensitive from drug-resistant cases. In contrast, the CODRP index showed strong concordance with actual clinical treatment outcomes. Moreover, whereas AUC analysis revealed only modest differences in PFS between responders and non-responders, CODRP identified a distinct separation, demonstrating its superior predictive capability.

Conclusions: CODRP-based anticancer drug response analysis using lung cancer PDOs provides an effective approach for forecasting and evaluating treatment outcomes in patients with lung cancer. This method has the potential to be incorporated into precision medicine workflows, supporting more individualized treatment planning and enhancing the clinical relevance of therapeutic decision-making.

#2504 Activation of alternative receptor by CCL5 is associated with non-small cell lung cancer disparities.

Briana Alicia Brock, Murugesh Eswaran, Hina Mir, Shailesh Singh

Morehouse School of Medicine, Atlanta, GA

Background and Significance: Lung cancer remains the leading cause of cancer-related mortality in the United States, with persistently lower survival rates among African Americans (AAs) compared to European Americans (EAs). Emerging evidence suggests that race-associated molecular differences in chemokine receptor-ligand networks may underlie these disparities. Chemokine signaling through CC chemokine receptor 5 (CCR5) and its ligand CCL5 has been implicated in tumor growth and immune modulation; however, chemokine ligands often exhibit receptor promiscuity. Hence, in this study, we have demonstrated the activation of other chemokine receptors when CCL5 is unable to activate CCR5, as well as its association with disparities in NSCLC.
Methods: An ELISA assay was used to quantify CCL5, and PCR Immunoprecipitation followed by Western blot was used to evaluate mRNA transcripts and protein expression of CCL5, CCR5, CCR3, and CCR1. An anti-CCR5 antibody and/or a small molecule inhibitor of CCR5 were used during the functional assay, with or without CCL5 stimulation, and blocking other receptors that also share CCL5 as a ligand.
Results: Our findings reveal that CCL5-driven signaling in NSCLC is not restricted to CCR5 and that alternative receptor engagement, such as CCR3 activation, may sustain tumor-promoting pathways. The differential expression of chemokine receptors in AA- versus EA-derived lung cancer cells suggests that ligand-receptor selectivity and compensatory signaling could contribute to racial disparities in lung cancer biology and outcomes. Ongoing work targeting CCR3 will determine whether this receptor mediates escape signaling when CCR5 is unavailable, thereby identifying precision-based therapeutic strategies to disrupt redundant chemokine circuits that reinforce tumor progression and inequities in disease burden.
Conclusions and Implications: These findings highlight the complexity of chemokine signaling in lung cancer, where ligand promiscuity and receptor redundancy can sustain the proliferation and migration of cancer cells. Differences in CCR3, CCR5, and GPR75 expression, cancer-related gene activity, and migratory behavior in AA and EA-derived cells suggest that differences in chemokine receptor utilization may play a crucial role in shaping the molecular landscape and cellular behaviors that contribute to racial disparities in lung cancer outcomes

#2505 Dual siRNAs for precision targeting of synthetic lethal vulnerabilities in Diffuse Pleural Mesothelioma.

Yelixza I. Avila[1], Anand Singh[2], Vivek Singh[3], So-Hyun Yoon[4], Smrity Sahu[3], Nathanael Pruett[3], Chuong D. Hoang[5]

[1]National Cancer Institute, Bethesda, MD,[2]NCI, Bethesda, MD,[3]National Cancer Institute, BETHESDA, MD,[4]NIH-NCI, Bethesda, MD,[5]Assistant Professor, Dept. of Thoracic Surgery, National Cancer Institute, Bethesda, MD

Diffuse pleural mesothelioma (DPM) remains a lethal malignancy with limited benefit from existing therapies, underscoring the urgent need for molecularly precise treatments that act directly at the disease interface. Previously, we identified WEE1 and PKMYT1 as consistently overexpressed in DPM and demonstrated that their combined inhibition induces synthetic lethality. Here, we evaluate a dual-siRNA therapeutic strategy targeting this kinase pair and position it within a platform engineered for localized RNA delivery. Across three DPM subtypes (epithelioid, sarcomatoid, and biphasic), siRNA constructs achieved robust knockdown of WEE1 and PKMYT1, with >70% reduction in mRNA levels at 48-96 h post-transfection. Single-gene silencing induced only modest reductions in cell viability, with >70-80% survival across most lines relative to controls. In contrast, combined WEE1/PKMYT1 knockdown consistently elicited a marked decrease in viability, ranging from 60% to 85% depending on the cell line ($p < 0.001$). Cell-cycle analysis revealed that dual knockdown, unlike individual siRNAs, induced significant G2/M arrest accompanied by a depletion of S-phase cells, indicating disruption of DNA damage checkpoints. Flow cytometry demonstrated a 3- to 5-fold increase in apoptotic cell fractions compared with single knockdowns and controls ($p < 0.0001$), confirming synergistic induction of programmed cell death. These data show that although individual siRNAs exert limited effects, their combination produces robust anti-proliferative, pro-apoptotic, and cell-cycle disruptive phenotypes consistent with synthetic lethality. Collectively, these data validate dual-siRNA synthetic lethality as a promising therapeutic approach for DPM and underscore the potential of a nanoparticle-hydrogel delivery system that we have developed for precise, localized RNA therapy. This work paves the way for RNA nanomedicine in mesothelioma and other anatomically restricted, treatment-refractory cancers.

#2506 Genomic-driven targeted therapy evaluation using patient-derived organoids and xenografts in gastric cancer.

Honyong Zhang, Nicole Halmai, Jasmine Diaz Sezati, Ana Estrada, Luis G. Carvajal-Carmona

University of California, Davis, CA

Background: Gastric cancer (GC) exhibits significant molecular heterogeneity that hampers the effectiveness of standard therapies. Reliable preclinical models that accurately reflect patient-specific biology are urgently needed to inform precision treatments. Patient-derived organoids (PDOs) and xenografts (PDXs) provide complementary platforms for assessing targeted therapies.
Methods: We developed gastric cancer organoids (GCOs) representing diverse molecular subtypes, along with matched PDX and organoid-derived xenograft (ODX) models. Histology, IHC, whole-exome sequencing, and copy-number analysis were used to verify their fidelity to patient tumors. Targeted drug screening was conducted based on actionable genomic alterations (TP53 mutation, PIK3CA mutation/amplification, CDK4/6 amplification). In vivo therapeutic efficacy and resistance mechanisms were evaluated using PDX models, including a Palbociclib-resistant line (3CG-278R) generated through prolonged exposure.
Results: GCOs retained the morphological, immunophenotypic, and genomic features of their parental tumors and PDX counterparts, including recurrent amplifications in PIK3CA, AKT1-3, MTOR, CCND1, CCNE1, and CDK4/6. Genomic-guided drug screening revealed distinct vulnerabilities: CDK4/6-amplified GCOs showed strong sensitivity to Palbociclib (IC_{50} ~0.01 μM); PIK3CA-mutant GCOs exhibited potent responses to PI3K inhibitors (IC_{50} = 0.004-0.013 μM); TP53-mutant GCOs responded robustly to MDM2 inhibitors with clear p53/p21 pathway reactivation. In vivo, Palbociclib and the AKT inhibitor Ipatasertib significantly delayed tumor progression (>40 days to endpoint) and improved survival in CDK4/6-amplified PDXs with minimal toxicity. The Palbociclib-resistant PDX model (3CG-278R) showed CDK6 overexpression and transcriptional reprogramming marked by NF-κB and AP-1 activation, mucin upregulation, and decreased FOX-family tumor suppressor activity. Combination therapy with Palbociclib plus Ipatasertib restored apoptotic signaling and effectively overcame resistance.
Conclusions: This integrated PDO/PDX/ODX platform accurately models gastric cancer biology, supports genomic-guided therapeutic stratification, and uncovers actionable mechanisms behind targeted therapy resistance. These patient-derived systems provide a strong translational framework for discovering effective precision treatments and rational drug combinations in gastric cancer.

#2507 Causal machine learning personalizes endocrine therapy selection for ductal carcinoma *in situ*.

Emma Graham Linck[1], Alex Spicer[2], Marina N. Sharifi[3], Guanhua Chen[1], Mark Craven[1], Nataliya Uboha[3], Mark Burkard[4], Matthew Churpek[2]

[1]Dept of Biostatistics and Medical Informatics, Univ. of Wisconsin Madison School of Medicine & Public Health, Madison, WI, [2]Dept of Medicine, Univ. of Wisconsin Madison School of Medicine & Public Health, Madison, WI,[3]Carbone Cancer Center, Univ. of Wisconsin Madison School of Medicine & Public Health, Madison, WI,[4]Holden Comprehensive Cancer Center, University of Iowa, Iowa City, IA

Background: Standard treatment of ductal carcinoma in situ (DCIS) in post-menopausal women is breast conserving surgery/mastectomy, radiotherapy, and adjuvant endocrine therapy (ET) with either tamoxifen or an aromatase inhibitor. Despite the need to individualize selection of ET based on patient characteristics and side effects, limited tools exist for this purpose. NSABP-B-35, a phase III trial evaluating anastrozole vs tamoxifen in post-menopausal women with DCIS, found that younger patients may benefit more from anastrozole. We hypothesized that causal machine learning methods, which predict treatment effect by accounting for complex interactions between baseline characteristics, would identify treatment benefit more accurately than age alone.
Methods: Individual-level data from the NSABP-B-35 trial (n = 3104) were obtained from the NCI NCTN Data Archive, with administrative approval from NCI. Trial eligibility included: DCIS with no invasive component, hormone receptor positive, and previous lumpectomy (with clear margins and negative nodes), followed by whole-breast irradiation. Baseline variables included age, tumor palpability, presence of comedo necrosis, body mass index (BMI), and black race. The outcome was disease-free survival (DFS). The causal machine learning method, a T-learner with accelerated failure time-Bayesian Additive Regression Trees (AFT-BART), predicted the individualized treatment effect (ITE) of anastrozole vs tamoxifen on the difference in restricted mean survival time at 116 months, conditional on patient characteristics. Three repeats of five-fold cross-validation were used to generate out-of-sample predictions for each patient. Statistical significance ($p < 0.05$) was determined by an aggregate Cauchy association test (ACAT) calculated on the out-of-sample Qini coefficient p-values, a metric that quantifies how well the model orders patients by most to least benefit. Variable importance was quantified using kernelSHAP.
Results: The AFT-BART ITE model was able to significantly prioritize patients in order of most to least benefit from anastrozole vs tamoxifen (p-value = 0.03). Predicted ITE ranged from an increase of DFS by 2.9 months to a decrease in DFS by 4.5 months when on anastrozole vs tamoxifen. Younger age, presence of comedo necrosis, and black race best predicted anastrozole benefit. No statistically significant heterogeneity was found when patient age alone was used to rank patients from most to least benefit (p-value = 0.6).
Conclusions: Our causal machine learning model accurately predicted who would benefit from anastrozole vs tamoxifen, outperforming treatment selection based on age alone. Once validated, this model may help clinicians optimize treatment selection for post-menopausal women with DCIS. This work was supported by NLM 5T15LM007359.

#2508 New precision treatments for glioblastoma.

Lateef Owolabi Anifowose[1], Zhi Sheng[2]

[1]Translational Biology, Medicine, and Health, Virginia Tech, Roanoke, VA,[2]Fralin Biomedical Research Institute, Virginia Tech, Roanoke, VA

The main goal of this study is to develop precision treatments for glioblastoma (GBM). GBM is a deadly brain tumor with few treatment options, mainly due to high intra- and inter-tumoral heterogeneity manifested by diverse genetic alterations and cellular components within an individual tumor or among different patients. Previous efforts targeting molecular features have focused on three molecular subtypes — Classical (CL), Mesenchymal (ME), and Pro-Neural (PN) — but no effective treatments have been developed for each subtype. To overcome this challenge, we recently employed a machine learning algorithm to identify 31 essential survival genes, forming a new GBM progression gene signature (GBM-PGS) that divided patients into high- or low-risk (HR vs LR) of poor prognosis. Because these genes are functionally vital for cancer cell survival/growth, GBM-PGS predicts the progression of GBM patients more accurately than existing biomarkers such as EGFR, MGMT, and IDH1. Given the functional relevance of GBM-PGS to tumor cell survival and disease progression, we hypothesize that combining GBM-PGS with molecular subtyping will stratify GBM patients into distinct treatment groups, enabling the repurposing of FDA-approved drugs for precision medicine in this fatal disease. We stratified TCGA GBM patients and DepMap glioma cell lines into six subgroups: HR-CL, HR-ME, HR-PN, LR-CL, LR-ME, and LR-CL using GBM-PGS and molecular subtyping. The survival of TCGA subgroups was assessed using Kaplan-Meier analysis, and potential drug targets for the HR and LR groups were analyzed using Gene Ontology. Moreover, candidate precision treatments for each subgroup were identified from the DepMap PRISM Repurposing Drug Screen dataset and further verified in a range of GBM cell lines. The LR-PN displayed a significantly better prognosis than the other subgroups. Drugs targeted for HR GBMs were functionally different from those for LR GBMs. The six treatment subgroups exhibited diverse responses to chemical compounds, including FDA-approved drugs. Candidate drugs for each subgroup were validated in GBM cell lines. Our results have verified the crucial roles of GBM-PGS and molecular subtyping in patient stratification and in the development of subgroup-specific precision treatments. Overall, this study has the potential to transform the GBM therapeutic landscape.

#2509 Building a Precision Therapeutics program at a tertiary care Children's Hospital.

Anish Ray[1], Luke Hamilton[1], Riyaz M. Basha[2], Kelly L. Vallance[1], Diana Carrasco[1], Kaitlin Smith[1], Aly Anthony[1], Alejandra Dominguez[3], Megan Gibbs[1], Danielle Miller[1], Heidi Trinkman[1]

[1]Cook Children's Medical Center, Fort Worth, TX,[2]University of North Texas Health Science Ctr., Fort Worth, TX,[3]TCU Burnett School of Medicine, Fort Worth, TX

Background: Pediatric medicine is shifting from population-based approaches to precision medicine, fueled by advances in genomics, pharmacogenomics, and multi-omic data integration. Children, who are disproportionately affected by genetic and rare diseases, stand to benefit significantly from individualized diagnostics and targeted therapies. Cook Children's Health Care System (CCHCS) launched a Precision Therapeutics Program to unify and advance efforts in oncogenomics, pharmacogenomics, genetics, research, and education, establishing a scalable model for pediatric precision care.
Objective: To develop and evaluate a comprehensive, cross-disciplinary precision medicine infrastructure integrating molecular diagnostics, clinical care, research, and education, with measurable outcomes in pediatric oncology and rare disease management.
Methods: CCHCS implemented a unified precision medicine model built on four pillars: oncology-targeted therapeutics, pharmacogenomics, clinical genetics/genetic oncology, and research-education infrastructure. Multidisciplinary teams—led by physician-scientists, pharmacists, geneticists, and informaticians—coordinated efforts across hospital departments. The model included molecular tumor board discussions, precision medicine clinics, pharmacogenomic consultations embedded in the electronic medical record, and genetic oncology surveillance. Utilization, integration, and educational reach were prospectively tracked.
Results: Since 2019, the Molecular Tumor Board has reviewed over 150 pediatric oncology cases, delivering actionable therapies and achieving cost savings through coordinated pharmaceutical oversight. The Precision Medicine Clinic extended targeted and investigational therapies to non-oncologic conditions, improving patient access. Pharmacogenomics services were fully integrated into Epic within 15 months, completing over 100 consultations with high satisfaction and automated decision support. The Genetic Oncology Clinic identified 54 patients with heritable cancer syndromes, enabling early detection and familial cascade testing. Institution-wide education—including monthly accredited conferences, student involvement, and public engagement—further promoted adoption.
Conclusion: The CCHCS Precision Therapeutics Program demonstrates that structured, multidisciplinary integration of genomics, pharmacogenomics, and informatics is feasible and transformative in pediatric care. The model highlights collaboration, education, and patient partnership, offering a replicable framework for other institutions seeking to implement sustainable precision medicine ecosystems. Ongoing innovation, research alignment, and family engagement will be crucial for expanding precision care across pediatric specialties.

#2510 Comprehensive genomic profiling drives precision oncology and expands accessibility to targeted therapies in Uzbek populations.

Zilola Olimova[1], Gowhar Shafi[2], Djuraev Farrukh[1], Yashodhara Bhattacharya[3], Aarthi Ramesh[4], Sandhya Iyer[4], Mohan Uttarwar[4], Hrishita Kothavade[4], Alain D'Souza[4], Bhagwat Jadhav[4], Sangeeta Prajapati[4], Madhura Basavalingegowda[3], Kanchan Hariramani[3]

[1]ILBOZA Med Hospital, Tashkent, Uzbekistan,[2]OneCell Diagnostics India Private Limited, Pune, India,[3]OneCell Diagnostics Pvt Ltd, Mumbai, India,[4]

Background: The current, mortality-to-incidence ratio of 67% indicates most cancers are detected at advanced stages in Uzbekistan. In addition, symptoms appear only when the cancer is large or metastatic and advanced cancer is expensive, difficult to treat, and often fatal. Sophisticated infrastructure requires large funding, trained professional and expensive screening procedures. In several instances, treatment regimen is also administered without information on tumor sensitivity and efficacy. Eventually, patients suffer severe toxicity from multiple tests and treatments. To address these events, personalized molecular tests and treatment monitoring approaches are necessary. This study shows the efficacy of comprehensive genomic profiling (CGP) to append the molecular spectrum of cancer patients from Uzbekistan. This may open several treatment and monitoring possibilities in non-invasive scale.
Methods: A total of 124 genomically profiled patients by our CGP assay were retrospectively investigated for mutational spectrum. All patients belonged to Uzbek ethnicity with ages between 25 to 85 years. CGP was performed on these patients using next-generation sequencing (NGS) with the OncoIndx® panel.

Results: Of the 124 patients profiled genomically, 331 pathogenic/likely pathogenic variants were detected with *TP53* constituting 20.2% (67) of all variants. Several frameshift and truncated *TP53* variants were identified suggesting an impairment of TP53 protein thereby potentially leading to oncogenic stress, DNA damage, and several major pathway malfunctioning. Further, variants in *PIK3CA, APC, KRAS, EGFR, PTEN*, and *BRCA1/2* were also present with high frequencies in the patient cohort at 8.5% (28), 6.3% (21), 6% (20), 4.5% (15), 2.7% (9), and 1.8% (6) respectively. Together, these variants may suggest major impairments in cell proliferation, and DNA repair pathways. Mismatch Repair (MMR) genes including *MSH6, MSH3, MLH1, PMS2, MUTYH*, and *MSH2* were also found to be mutated at frequencies of 1.2% (4), 0.9% (3), 0.9% (3), 0.3% (1), 0.3% (1), and 0.3% (1) respectively showing damages in MMR pathway. Three patients in the cohort with colon and lung cancers exhibited high microsatellite instability (MSI) whilst genomic findings showed impairments in cell proliferation, MMR, and DNA repair pathways.

Conclusion: To conclude, this study highlights the benefit of our CGP assay in identifying diverse oncogenic drivers across multiple pathways and in the study population of the Uzbek ethnicity, it added value in expanding targeted therapeutic opportunities to manage critical pathway impairments.

#2511 Ranking therapeutic recommendations of Molecular Tumor Board with an evidence-based algorithm to deliver optimal care and improve outcomes for cancer patients- continuous study.

Yuliang Sun, Rachel Elsey, Crystal Hattum, Bing Xu, Tobias Meissner

Avera Cancer Institute, Sioux Falls, SD

Background: The Molecular Tumor Board (MTB) has brought about significant advancements in precision oncology, but there is a long-standing challenge in selecting the most effective patient-specific therapeutic strategy due to the molecular rationale, disease relevance, and patient-specific issues. We have developed an algorithm that incorporates both molecular and clinical evidence-based criteria to rank therapeutic strategies to deliver optimal care and improve outcomes in patients with malignancy. This part of our studies was to evaluate the effectiveness and accuracy of our novel algorithm.

Methods: History of present illness and comprehensive genomic profiling results of 571 cancer patients were reviewed by Avera MTB from June 2021 to December 2024. Therapeutic recommendations were provided with the Ranking Score (R, -1 to 12). The progression free survival (PFS) and overall survival (OS) of the patients that received recommended treatments (Cohort 1) or not (Cohort 2) were then assessed.

Results: The median duration of follow-up was 14.1 months by the data cut-off on July 31, 2025. Of the 571 patients, 542 (94.9%) patients with cancer were evaluable in this study, including 286 (52.8%) that received matched therapeutic plans recommended by our MTB, and 256 (47.2%) did not. No significant differences in PFS/OS were observed between patients in Cohort 1 and in Cohort 2. In Cohort1, patients who received early line (≤ line 3, n=236) therapies had longer PFS (median PFS 8.8 vs 4 months, $p<0.0001$) and OS (median OS 24.5 vs 13.7 months, $p=0.0058$) when compared with those that received later lines (> line 3, n=46) of treatment. Among patients in Cohort 1, the median PFS/OS for patients with R≥10 (n=218, 8.6/23.9 months) were longer than patients with R<10 (n=68, 4.9/13.1 months), $p=0.036$/ 0.0009; the OS of patients that received Standard of Care treatments with R≥9 (n=230, 22.2 months) were longer than R<9 (n=27, 13.1 months), $p=0.0053$, whereas no significant difference was found in PFS. The PFS/OS of patients who received Off-Label treatments with R≥7 (n=10, 35.6/not reached months) were longer than R<7 (n=5, 3.5/10 months), $p=0.0095/0.012$; however, no significant differences in PFS/OS were observed among patients treated on Clinical trials.

Conclusion: Our novel molecular and clinical evidence-based algorithm may be used to support oncologists' decision-making to utilize the most clinically appropriate and effective therapeutic options to benefit patients. Further validation studies and development of a user-friendly computational ranking platform based on the algorithm are planned in order.

#2512 A real time imaging based functional precision medicine (FPM) assay for glioblastoma.

Thomas Quinn[1], Anand Panigrahy[1], Dina ElHarouni[1], Mariam A. Oumelloul[2], Smitha Yerrum[1], Kin-Hoe Chow[1], **Sonam Bhatia**[1], Keith L. Ligon[3]

[1]DFCI/Harvard Medical School, Boston, MA,[2]Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland,[3]Assistant Professor of Path., Dept. of Med. Onc., Dana-Farber Cancer Institute, Boston, MA

Functional precision medicine (FPM) assays, which test drug effects on live patient tumor cells, have the potential of personalizing therapy guidance for cancer patients. A number of FPM assays have been developed, the most common being based on measurements of “cell growth”. However, the majority of these measure “growth” of cells indirectly via bulk viability (e.g. Cell Titer Glo) as a surrogate for increased cell numbers within the assay by a defined time point but interpretation of such low dimensional data from complex tissues is often. We hypothesize that such assays could be improved if one were to ensure that patient cells being tested are healthy and growing before treatment *ex vivo* and could be analyzed for identity and morphology via single cell measurements. Furthermore, overall <50% of patient primary cells are expected to grow in culture and so faster measures could aid in more efficient testing for more patients. To address these areas and provide a simple assay able to be widely implemented in research or clinical labs, we designed and validated a miniaturized real-time growth assay based on Incucyte imaging of patient cells to monitor drug sensitivity response using the brain tumor glioblastoma (GBM) as an example. *Ex vivo* growth response was evaluated for the DNA damaging agent, Temozolomide (TMZ) – currently used as the standard of care for GBM patients, and KRT-232 – an MDM2 inhibitor currently in clinical trials. Patient cells were monitored every 6 hours until they met our treatment enrollment growth criteria of 3 consecutive increases of cell confluence and a minimum confluence of 10%. Patient cells were then eligible to be “enrolled” to the study, cultured as 2D cells in serum-free stem cell media, and treatments were then added. Cells were monitored every 6 hours for an additional 7 days. Initial validation of the method using long-term patient derived cell lines was performed followed by a co-clinical trial conducted in parallel with fresh GBM patient samples following patient consent. To date, 45 GBM patients have been screened in the study with 20/45 (44%) meeting the pre-determined growth enrollment criteria for ex vivo treatment and prospectively followed for which matched the expected rate of long term growth for GBM patient samples under these conditions. The assay was able to be successfully completed, and results generated for 17/20 (85%) of the subjects enrolled. Analysis of the *ex vivo* response profiles from the cohort were correlated with clinical parameters and known biomarkers of response — MGMT and TP53. Initial results suggest positive correlation with known parameters and reveal novel potential patterns of response. These results show feasibility and value of incorporating real-time functional growth monitoring to improve quality-control in functional precision medicine patient diagnostics. With further validation, this assay could become a valuable therapy guidance tool for clinicians.

#2513 Exploring *Ziziphus jujuba* phytochemicals against oral cancer: Network-based profiling and molecular dynamics analyses.

Abdullah A. Assiri[1], Ahmad Alamri[1], Najeeb Khan[2]

[1]King Khalid University, Saudi Arabia, Saudi Arabia,[2]The University of Agriculture Peshawar, Saudi Arabia, Saudi Arabia

Oral cancer remains a major global health challenge due to its complex molecular heterogeneity, limited therapeutic efficacy, and high recurrence rate. This study aimed to identify potential multi-target natural therapeutics derived from *Ziziphus jujuba* using an integrative computational approach. Network pharmacology was employed to map phytochemical-target interactions relevant to oral oncogenic pathways, focusing on EGFR, BCL2, SRC, STAT3, and CTNNB1. Molecular docking was performed to evaluate binding affinities, followed by 200 ns molecular dynamics simulations and MM-GBSA analyses to assess complex stability and energetics. Among the screened compounds, oleanonic acid demonstrated the most favorable interaction profile, with docking scores of approximately -9.0 kcal/mol for BCL2 and -9.3 kcal/mol for EGFR, outperforming reference inhibitors. MD trajectories indicated stable RMSD plateaus, low active-site RMSF, and consistent Rg and SASA profiles, reflecting robust ligand-receptor stability. MM-GBSA results revealed dominant van der Waals and hydrophobic contributions to complex stabilization. Collectively, these findings highlight oleanonic acid as a promising multi-target phytochemical from *Z. jujuba* with potential therapeutic relevance in oral cancer. Further *in vitro* and *in vivo* studies are warranted to validate these computational predictions and advance its development as a candidate for oral cancer management.

#2514 Patient-driven multi-omic longitudinal research study reveals novel insights into uveal melanoma progression.

Amber Smith[1], Ben Kamphaus[1], Katie Campbell[2], Robin Kageyama[1], Benjamin G. Vincent[3], Christopher Heery[1], **Christine N. Spencer**[1], Marshall Thompson[1]

[1]Rare Cancer Research Foundation, Durham, NC,[2]UCLA - University of California Los Angeles, Los Angeles, CA,[3]University of North Carolina at Chapel Hill, Chapel Hill, NC

Introduction: Amid a surging trend in patient engagement in cancer research and the broader cultural shift toward self-advocacy and technology adaptation in healthcare, this study reports findings from a patient-partnered project investigating the mechanistic underpinnings of metastatic uveal melanoma (UM) progression.
Methods: The patient consented voluntarily on IRB-approved protocols under PRISM, a patient-centered research program overseen by The Rare Cancer Research Foundation. Sample collection, processing and distribution for advanced testing was done in collaboration with multiple academic treatment centers and empowered by Pattern.org biologistics and biobanking services. Advanced molecular diagnostic testing was performed on samples collected over a 2 year period from multiple lesion locations, including longitudinal WES/RNA-seq, proteomics, multiplexIF staining, and organoid drug testing. Response to treatment was monitored using longitudinal PET/CT imaging with individual lesion tracking using Mint Medical software, and minimal residual disease monitoring using SignateraTM cell-free DNA testing. All clinical and research data was integrated into the Pattern.org Data Commons (PDC) for downstream analysis.
Results: This patient presented with metastatic UM, initial sequencing revealed germline POT1 (Arg363) and somatic GNAQ (Q20P) and BAP1 (E398, LOF) genetic alterations. Organoid-based drug screening results did not reveal any obvious drug sensitivities to targeted treatment options. The patient experienced disease stabilization with minimal toxicity for 6 months while receiving Pembro/Ipi and an endogenous T Cell therapy. During the course of stable disease, longitudinal sequencing revealed consistent genetic alterations across timepoints and multiple lesion samples. Upon disease progression, defined by increased volumetric measurements in tumor size and increased circulating tumor cfDNA, a new EZH2 (Y641H) variant was identified using WES. Differential variant calling and gene expression analysis collected from samples before and after disease progression highlighted potential resistant mechanisms to immune-based therapies. Further, a comparative study on the tumor microenvironment using multiplex IF staining sheds additional insight into the complexities of UM metastasis and disease progression.
Conclusion: This patient-driven study utilizing multi-omic disease characterization and longitudinal monitoring illuminates immune therapy resistance mechanisms and tumor microenvironment complexities in UM metastasis.

#2515 Preserving predictive power with minimal PDOs: Accelerated drug testing for personalized therapy in metastatic CRC.

Yasmine Abouleila[1], Roel Verkerk[1], Mayke Doorn[1], Timo Voskuilen[1], Gakuro Harada[2], Masahiko Watanabe[2], Lidwien Smabers[3], Hideaki Kyan[2], Takahiko Kumagai[2], Yuichi Hikichi[2], Rene Overmeer[1], Jeanine Roodhart[3], Kiyotaka Matsuno[2], **Carla S. Verissimo**[1], Robert G. J. Vries[1], Sylvia F. Boj[1]

[1]HUB Organoids B.V., Utrecht, Netherlands,[2]Yamaha Motor, Shizuoka, Japan,[3]University Medical Center Utrecjt (UMCU), Utrecht, Netherlands

Patients with relapsed or metastatic colorectal cancer (CRC) face limited treatment options, significant side effects, and prolonged delays in identifying effective therapies. Patient-derived organoids (PDOs; HUB Organoids®) provide a clinically relevant platform that faithfully mirrors individual tumour biology, enabling personalised drug testing. However, conventional drug screening formats typically require several hundred organoids per well, limiting the feasibility of using PDOs to guide real-time treatment decisions at diagnosis or relapse. Translational speed is critical: in metastatic CRC, there is a narrow window to select effective therapy before disease progression or treatment-related toxicity occurs. Traditional preclinical models often take weeks to months, which is too slow to inform immediate patient care. To address this limitation, we developed an automated organoid-handling workflow using the Yamaha CELL HANDLER™ system, enabling precise transfer and image-based quantification while requiring far fewer organoids per well. Miniaturisation reduced input material by 96% (from 250 to 10 PDOs per well) compared to conventional screening. Drug sensitivity of PDOs measured using the miniaturised assay closely mirrored that of conventional screening ($R=0.67$-0.85, $p<0.03$). PDO responses in the miniaturised assay also correlated with patient outcomes, including progression-free survival ($R = -0.85$, $p < 0.01$).By combining automation, miniaturisation, and quantitative readouts, this platform preserves the predictive power of PDOs, drastically reduces the need for organoids, and shortens turnaround time.

#2516 Genomic landscape and patterns of homologous recombination deficiency in Indian ovarian cancer: Clinical implications for precision therapy.

Rahul Katara, Sourabh Kumar, Aditi Agarwal, Kiran Kumar, Deepak K. Sharma, Yuvaraj M, Hardeep Singh, Vipin Kumar, Shivani Sharma

Molecular Pathology, Core Diagnostics, Gurugram, India

Introduction: Ovarian carcinoma remains a leading cause of cancer-related mortality among women globally. However, the genomic characteristics of ovarian cancer in the Indian population are not well defined, limiting insights into ancestry-specific tumor biology and potential therapeutic targets.

Methodology: Whole-exome sequencing data from 619 ovarian tumor samples from Indian patients were analyzed. After stringent quality control and filtering, 5,244 prioritized somatic variants were curated and classified according to AMP guidelines. Homologous recombination deficiency (HRD) scores were integrated with clinical metadata to examine associations between homologous recombination repair (HRR) gene alterations, HRD status, and clinicopathological features.

Results: The median HRD score across the cohort was 47, with 47% of tumors classified as HRD-positive. Among clinically reported variants, 28.2% were classified as pathogenic or likely pathogenic (P/LP), 49.5% as variants of uncertain significance (VUS), and 22.1% remained unclassified. Recurrently altered driver genes included *TP53* (64.9%), *BRCA1* (38.6%), *RAD50* (37.5%), *CHEK1* (21.2%), and *POLE* (17.9%), indicating extensive disruption of DNA damage response (DDR) and HRR pathways. *BRCA1/2* P/LP variants were detected in approximately 40.7% of tumors. HRD positivity was identified in both *BRCA*-mutated (48.0%) and non-*BRCA*-mutated tumors (46.3%), suggesting that HRR deficiency extends beyond *BRCA1/2* alterations to include genes such as *RAD50*, *MRE11*, *CHEK1*,*CHEK2*,*FANCA,andFANCD2.*Age-stratified analysis showed consistent frequencies of *BRCA1/2* alterations and HRD positivity across all age groups (40-50% per stratum), indicating that HRR pathway disruption is widespread across clinical subgroups.

Conclusions: This study represents one of the largest exome-based analyses of ovarian cancer in the Indian population. Nearly half of the tumors demonstrated HRD, and HRR pathway disruption was frequent even in the absence of *BRCA1/2* mutations. These findings highlight the importance of comprehensive HRR gene testing and HRD evaluation to inform precision oncology approaches, including the use of PARP inhibitors and platinum-based therapies, for Indian ovarian cancer patients.

Keywords: Ovarian carcinoma, Indian population, exome sequencing, homologous recombination deficiency, *BRCA1*, *TP53*, DNA repair, PARP inhibitors, precision oncology.

#2517 Real-world clinical performance of a combinatorial functional precision platform, Optim.AI™, in hematological malignancies.

Masturah Rashid[1], Weng Tong Ho[1], Jhin Jieh Lim[1], Sharon Pei Yi Chan[1], William YK Hwang[2], Edward Kai-Hua Chow[1]

[1]KYAN Technologies, Singapore, Singapore,[2]National Cancer Centre, Singapore, Singapore, Singapore

Background:
Ex vivo drug sensitivity testing has been explored for nearly five decades as a strategy to individualize treatment, especially for patients without actionable biomarkers or who have exhausted standard options. Historically, adoption has been limited by challenges such as scarce tumor samples, difficulty recreating indication-specific microenvironments, and inconsistent correlation with clinical outcomes. Advances in functional precision medicine now enable more reliable translation. Optim.AI™, a combinatorial functional precision medicine platform, has shown prospective clinical utility in hematologic malignancies and sarcoma. Here, we report real-world performance data from its use in a clinical-certified laboratory for hematological cancers.
Methods:
Tumor cells from solid tissue, peripheral blood, or bone marrow aspirates were isolated and exposed to 12 FDA-approved chemotherapy and targeted agents in combinatorial formats. Post-treatment cell viability was quantified to generate Optim.AI™ rankings of actionable treatment combinations. Clinical outcomes were retrospectively assessed for patients who subsequently received Optim.AI™-guided therapies.
Results:
Among 154 hematological samples, 91% yielded sufficient cells for testing and 94% of these produced successful reports. Concordance with prior resistance patterns was high: 88% of cases demonstrated predicted normalized cell viability (NCV) > 0.6, consistent with clinically observed resistance. Retrospective analysis of five acute myeloid leukemia (AML) patients treated according to top-ranked Optim.AI™ recommendations showed that the platform was clinically useful in all five cases. Three patients responded to Optim.AI™-guided therapy, including two complete remissions—one successfully bridged to transplant. For the two patients who did not respond, the Optim.AI™ profiles accurately predicted non-response (NCV > 0.6) and supported timely decisions to limit further futile therapy, including transition to palliative care. Across these cases, NCV < 0.3 effectively stratified responders from non-responders.
Conclusion:
Consistent with prior prospective studies, these real-world results validate Optim.AI™'s ability to predict treatment responses in hematological malignancies. Importantly, the platform demonstrated clinical utility in all evaluated patients—by identifying effective therapeutic options when available and by guiding physicians toward appropriate palliative approaches when further intensive therapy was unlikely to help. Larger prospective studies across diverse indications will strengthen its path toward broader clinical adoption.

#2518 Feasibility study of an *ex vivo* functional precision medicine platform, Optim.AI™, in guiding treatment for gynecological cancers.

Masturah Rashid[1], Jhin Jieh Lim[1], Sharon Pei Yi Chan[1], Manavi Sachdeva[2], Hidayah Nabillah Nasit[2], Natalie Ngoi[2], John Chia[3], David Tan[2], Edward Kai-Hua Chow[1]

[1]KYAN Technologies, Singapore, Singapore,[2]National University Hospital, Singapore, Singapore,[3]Curie Oncology, Singapore, Singapore

Background:
Gynecological cancers, like ovarian and endometrial, face therapeutic challenges due to their molecular heterogeneity and high rates of relapse following standard platinum-based chemotherapy. Access to genetic information, such as BRCA mutation and homologous recombination deficiency (HRD) status, can predict potential responders to PARP inhibitors. However, these actionable mutations are amenable for a subset of patients only, underscoring the need for complementary functional precision medicine approaches. This ex vivo screening strategy could potentially support patient treatment management. Optim.AI™, a combinatorial functional precision medicine platform, has previously validated clinical utility for hematological cancers and sarcoma. In this feasibility study, we explored the application of Optim.AI™ on ovarian and endometrial cancers.
Methods:
Tumor cells were isolated from tissue samples from both biopsies and resections. Short-term patient-derived organoids were formed before combinatorial treatment with 12 drugs containing both FDA-approved chemotherapy and targeted drugs. Cell viability was quantified post-drug treatment for Optim.AI™ analysis, ranking all possible top combinatorial therapies for report generation. Retrospective concordance analysis was carried out after clinical responses were collected.
Results:
Based on the samples received, minimum tissue mass of 0.0835g and 0.368g for ovarian and endometrial samples respectively yielded sufficient cells to proceed with Optim.AI™ testing. Reports were successfully generated for 94% of these samples, with a mean turnaround time of seven working days. Z' factor, a statistical, quality measure for high-throughput screening, was demonstrated to be more than 0.5 for all reports generated, indicative of very good assays. Across the eight ovarian cancer reports generated, Gemcitabine-based combinations were among the most frequently top-ranked treatments. Notably, for HRD-negative patients, Optim.AI™ predictions commonly suggested increased sensitivity to gemcitabine paired with doxorubicin and paclitaxel Preliminary retrospective concordance analysis highlights Optim.AI™'s ability to predict response, where general correlation was observed between lower NCV and higher chemotherapy response score.
Conclusion:
This study showcases Optim.AI™ as a viable clinical-decision support platform for aiding treatment management for gynecological cancers, particularly for patients who do not harbor actionable mutations. Prospective clinical concordance analysis of Optim.AI™-guided treatments would further validate its clinical utility in these cancers and provide potential precision medicine insights for HRD-negative patients.

#2519 Characterization of BRAF fusions and their therapeutic and resistance implications in NSCLC.

Kai Wang[1], Chao Yi[2], Xiong Ning[3], Dalin Xiong[3], Song Wang[4], Xiaoying Wu[4], Hua Bao[4], **Haimeng Tang**[4], Xue Wu[4], Yuan Jiang[5], Hongyu Deng[5], Faqing Tang[5]

[1]Pathology Department, Zunyi Medical University Affiliated Hospital, Zunyi, China,[2]Department of Respiratory and Critical Care Medicine, Chongqing University Affiliated Three Gorges Hospital, Chongqing, China,[3]Department of Thoracic Surgery, Yan'an Affliated Hospital of Kunming Medical University, Kunming, China,[4]Nanjing Geneseeq Technology Inc., Nanjing, China,[5]Department of Clinical Laboratory, The Affiliated Cancer Hospital of Xiangya School of Medicine, Changsha, China

Background: *BRAF* fusions are rare but clinically relevant oncogenic events in non-small cell lung cancer (NSCLC). Their molecular characteristics and optimal management remain incompletely understood.

Methods: We retrospectively analyzed 97 NSCLC patients harboring kinase domain-retaining *BRAF* fusions, stratified as *de novo* (N=43) or acquired (N=54). Genomic and clinical features were compared between subgroups and against other oncogenic driver cohorts.

Results: We identified 104 *BRAF* fusions involving 53 unique 5' partners, 29 of which were novel. Frequent partners included *AGK* (12.5%), *IGR* (11.5%), *ZC3HAV1* (7.7%), *TRIM24* (5.8%), and *MKRN1* (5.8%). *IGR*- and *DTNB-BRAF* fusions were enriched in *de novo* cases, while *AGK-BRAF* predominated in the acquired setting. Among *de novo* cases, 65.1% lacked co-occurring drivers. *ZNF703* mutations and NRF2 pathway alterations were recurrent in *BRAF* fusion-only tumors, whereas *CTNNB1* and *NKX2-1* mutations were enriched relative to *ALK*-rearranged cases. *BRAF* fusions co-occurring with other drivers showed enrichment of *KMT2C* and RTK-RAS pathway mutations, and *TP53* mutations were more frequent compared to *RET*-rearranged tumors. One patient harboring *TRIM24-BRAF* and *EGFR* exon 19 deletion achieved clinical benefit from combined MEK and EGFR inhibition. Acquired *BRAF* fusions predominantly emerged after EGFR-TKI therapy (63.0%), consistent with a role in treatment resistance. Median progression-free survival on prior EGFR-TKIs aligned with clinical trial benchmarks.

Conclusions: *BRAF* fusions in NSCLC are molecularly heterogeneous, with distinct genomic landscapes between *de novo* and acquired cases. Their frequent emergence post-EGFR-TKI highlights a key resistance mechanism and supports comprehensive genomic profiling to guide individualized therapy.

#2520 Clinical impact of the personalized medicine for neuroblastoma patients: Six years of experience of the PREME program.

Francesca Parisi[1], Eleonora Ciampi[2], Veronica Bensa[2], Federica Serafino[3], Matilde Tirelli[4], Laura De Rosa[4], Vito A. Lasorsa[4], Mario Capasso[5], Chiara Brignole[2], Loredana Amoroso[6], Massimo Conte[1], Mirco Ponzoni[2], **Fabio Pastorino**[2]

[1]U.O.C. Pediatric Oncology, IRCCS Istituto Giannina Gaslini, Genoa, Italy,[2]Lab Experimental Therapies in Oncology, IRCCS Istituto Giannina Gaslini, Genoa, Italy,[3]University of Genoa, IRCCS Istituto Giannina Gaslini, Genoa, Italy,[4]CEINGE Advanced Biotechnologies Franco Salvatore, Naples, Italy,[5]University of Naples Federico II, Naples, Italy,[6]UO Pediatric Oncology Umberto I Polyclinical University Hospital, Rome, Italy

Background: PREME (PeRsonalizEdMEdicine) program is an Italian, multicentric, prospective study focused on research of possible molecular therapeutic targets for early and relapsed/refractory neuroblastoma (NB).
Methods: From 2019 to 2024, 86 patients were enrolled out of 106 eligible. Molecular alterations (MA) were detected by whole-exome-sequencing (WES) and by Cancer Gene Panel (CGP) sequencing. Somatic Point Mutations (SPM) were classified as either Very-High-Priority (VHP) or High-Priority (HP).
Results: MA, including somatic, germline or copy-number-variations (CNVs): 9 were detected at first diagnosis and 43 at relapse. Specifically, SPM were detected in 94% of patients (n=49), 9 at disease-onset and 40 at relapse. Around 35% (n=17) had VHP alterations, 43% (n=21) HP and 22% (n=11) both. Samples from 11 patients were analyzed at different times during the course of disease: first diagnosis and relapse (n=3), primary and further relapses (n=8); in 9 of those, assessment of molecular tumor changes were detected. An actionable target emerged in 75.5% of patients with SPM (n= 37). A molecular target-therapy was proposed by the study-expert-board, which was implemented in 21 patients. *ALK* was the most frequent mutated gene (43%), but other potentially actionable alterations were detected, both in tumor at first diagnosis and at relapse. Among tumor samples at relapse, from WES analysis emerged alterations in gene encoding for mitogen-activated protein kinase (*MAPK*; 12% of cases), *ATM* mutation (4%), in gene encoding for proteasome subunit member proteins (*PSMC/B*; 6%) and other less common SPMs, such as *CULA4*, *TP53*, *TNKS*, *PIK3R1*, *mTOR*, and *ATR* mutations in 6 corresponding patients. Targeted-therapy was implemented in 11 patients with *ALK* mutations, in 2 patients with *MAPK* alterations, in one patient with *PSMC/B* mutation, in one patient with *ATM* mutation and in those 6 patients harboring the less common SPMs. Generally, among all patients treated, a complete remission was obtained in 3 patients, a partial response in 13, and stable disease as best response in 2 cases. A progression disease and subsequent death occurred in 3 patients. Somatic CNVs were detected in 31 patients (59.61%); among them, 3 patients showed no SPM and a targeted-therapy potentially actionable somatic CNVs was proposed for one of those harboring *TSC2*-deletion. Germline alterations were found in 19.2% of patients (n=10).
Conclusions: PREME program is a useful tool to improve the prognosis of refractory/relapsing NB.

#2521 Illuminating the kinase starmap in NSCLC via tyrosine phosphoproteomics.

Jinfeng Yuan[1], Ying Hu[2], Yilin Wang[1], Tianhui Zhang[3], **Aijuan Yu**[4], Yi Liu[4], Hui Zhou[4], Chao Zhou[4], Junjie Hou[4], Yinyin Xu[4], Xinxin Xu[5], Huan Ding[4], Yuxin Zhang[4], Rujie Zhong[1], Mengjia Yang[1], Chunyan Chang[1], Hongxuan Yan[1], Yuanyuan Shang[1], Weicong Ren[1], Shanshan Li[1], Hongdong Zhong[4], Yun Xiao[4], Zhang Zhang[5], Naizhong Zheng[4], Ming Han[6], Yu Pang[1]

[1]Department of Bacteriology and Immunology, Beijing Chest Hospital, Capital Medical University/Beijing Tuberculosis and Thoracic Tumor Research Institute, Beijing, China,[2]Department of Medical Oncology, Beijing Chest Hospital, Capital Medical University/Beijing Tuberculosis and Thoracic Tumor Research Institute, Beijing, China,[3]Department of Thoracic Surgery, Beijing Chest Hospital, Capital Medical University/Beijing Tuberculosis and Thoracic Tumor Research Institute,, Beijing, China,[4]DeepKinase Biotechnologies Ltd., Beijing, China,[5]State Key Laboratory of Bioactive Molecules and Druggability Assessment, Jinan University, Guangzhou, China,[6]Department of Thoracic Surgery, Beijing Chest Hospital, Capital Medical University/Beijing Tuberculosis and Thoracic Tumor Research Institute, Beijing, China

In lung cancer treatment, understanding kinase activity, particularly tyrosine phosphorylation, is crucial but incomplete. We studied tyrosine phosphoproteomics in 74 patients with non-small-cell lung cancer (NSCLC) using SH2-Superbinder and data-independent acquisition mass spectrometry. We constructed a tyrosine phosphorylation starmap, This starmap is presented as an interactive force-directed network, providing dynamic visualization of intricate signaling pathways that are active in tumor tissues or normal adjacent tissues (NATs). Unlike the dense, unstructured distribution observed in NATs, the tumors showed four well-defined subnetwork constellations: adherens junctions, cytoskeletal dynamics, immune signaling, and blood. Subsequently, patients were stratified by kinase activity for multiple precision medicine perspectives.

#2522 Exploring the impact of RAS mutations in abdominopelvic Rosai Dorfman disease on responsiveness to targeted therapies: A case control study.

Rebecca Denson[1], Fnu Amisha[2], David Pottinger[2], Ling Zhang[3], Lubomir Sokol[2], Samuel Benjamin Reynolds[2]

[1]Medicine, Weill Cornell Medicine, New York, NY,[2]Hematology, Moffitt Cancer Center, Tampa, FL,[3]Hematopathology, Moffitt Cancer Center, Tampa, FL

Introduction: Rosai Dorfman Disease (RDD) is a non-Langerhans cell histiocytic neoplasm characterized histologically by S100, CD68 and CD163 positive sinus histiocytosis with variable emperipolesis. Abdominopelvic RDD represents a rare disease subtype, for which the molecular landscape and associated responses to targeted therapies remain poorly characterized.

Methods: We conducted a single-center matched case-control study comparing 4 patients with *RAS*-mutated multifocal abdominopelvic RDD to 4 with RAS wild-type disease. All patients had confirmed histopathologic diagnoses of RDD with evidence of abdominopelvic disease, confirmed by either direct lesional biopsy or imaging demonstrating extension from a primary extra-abdominal site. Comprehensive genomic profiling was performed for each patient using a next-generation sequencing platform capable of detecting at least 50 mutations and/or fusions. Independent case review was conducted by a panel of investigators to validate diagnoses, molecular findings, and disease localization.

Results: Four similarly aged patients (64-70 years) with *RAS*-mutated abdominopelvic RDD (3 with *KRAS* mutations, 1 with *NRAS* mutation) were evaluated at a single center. Disease localization included peri-colonic soft tissues in 3 patients and with encasement of the abdominal aorta in one patient. Two patients were also diagnosed with clonal hematopoiesis of indeterminate potential, one each respectively harboring DNMT3A and RTEL1 mutations. All 4 patients received frontline cobimetinib with 3 achieving at least a partial response and two demonstrating near-complete resolution of all known disease sites. Dose attenuations were required in three patients due to toxicities. One patient eventually progressed during dose reduction and was transitioned to trametinib; another passed from non-RDD cardiac causes.

We also reviewed an age-matched cohort (63-79) of 4 patients with abdominopelvic RDD lacking baseline RAS/MAPK pathway or other driver mutations. Lesions were collectively identified in the pancreas, lower pelvis, inguinal lymph nodes and soft tissues proximal to the lumbar spine. Management strategies varied as only two patients received frontline systemic therapy, one sequentially with bexarotene followed by rituximab and the other with vinblastine. Three patients underwent radiation during their disease course, one as monotherapy for localized disease and two in consolidation following the systemic therapy. The remaining patient was observed off treatment.

Conclusions: Patients with RAS-mutated abdominopelvic RDD tend to experience a more aggressive disease course compared to wildtype but demonstrate marked sensitivity to MAP Kinase pathway-targeting therapies. The findings of this study are limited by small sample size; ongoing efforts are underway to expand with a multi-center cohort.

#2526 Non-invasive biomarker discovery and validation for the early detection of pancreatic cancer.

Roopali Roy[1], Rama Aldakhlallah[2], Stephen Cobbs[2], Noundy Mazile[3], Kiana Mahdaviani[3], Matthew Kulke[3], Christopher Heaphy[3], Jeanette Dupree[4], David Zurakowski[5], Sarah Danielle Legrand[4], Erkut Borazanci[6], Marsha A. Moses[1]

[1]Vascular Biology Program and Department of Surgery, Boston Children's Hospital and Harvard Medical School, Boston, MA,[2]Vascular Biology Program, Boston Children's Hospital, Boston, MA,[3]Section of Hematology and Medical Oncology, Boston University and Boston Medical Center, Boston, MA,[4]Honor Health Research Institute, Scottsdale, AZ,[5]Department of Anesthesiology, Critical Care and Pain Medicine, Boston Children's Hospital and Harvard Medical School, Boston, MA,[6]Honor Health Research Institute, John Shufeldt School of Medicine and Advanced Medical Engineering ASU, Scottsdale, AZ

Introduction: Pancreatic malignancies are the fourth leading cause of all cancer-related deaths in the United States and this high mortality rate can be attributed to a lack of diagnostic tests for early detection. A majority of patients with pancreatic ductal adenocarcinoma (PDAC) present with advanced disease due to a lack of specific symptoms suggesting that early detection may significantly improve patient outcomes. CA19-9, the only FDA-approved blood biomarker for PDAC, is insufficiently sensitive and specific for detection or surveillance. The goal of our study is to discover and validate non-invasive biomarkers for early PDAC detection.

Methods: We have established a biomarker discovery initiative whose objective is to identify differentially expressed proteins in the urine of cancer patients and validate their diagnostic and prognostic efficacy. For PDAC, our target population(s) include Stage I or II PDAC patients, high risk individuals (HRI, individuals under surveillance for genetic or familial causes) and age- and sex-matched healthy controls (HC). In this study, we have analyzed urinary markers including CTGF, CYR61, TIMP1 and ADAM12, proteins reported to contribute to PDAC development and progression, with the goal of determining their potential to differentiate early (Stage I-II) PDAC from HC, HRI and advanced disease (Stage III-IV).

Results: Urinary TIMP-1 (uTIMP-1) levels were significantly (~19-fold) higher in PDAC patients (all stages; *n*=64) compared to HC (*n*=60) and significantly (~3.5-fold) higher in PDAC patients (all stages) compared to those with benign pancreatic conditions including IPMN (intraductal papillary mucinous neoplasm) or pancreatic cysts (*n*=10). When comparing the HRI cohort (*n*=70, no evidence of disease, NED) to all groups, we found that uTIMP-1 levels were significantly (~13-fold) higher in PDAC patients (all stages) compared to those at high-risk (*n*=37). uADAM12 levels were significantly (~17-fold) higher in PDAC patient samples (all stages) compared to those from HC and significantly (~1.6-fold) higher in PDAC patients compared to those with benign disease, whereas uADAM12 levels were significantly (~5-fold) higher in PDAC patients (all stages) compared to the HRI cohort. While CYR61 levels did not differ between any of the groups tested, CTGF levels were significantly (~700-fold) higher in PDAC patients (all stages) compared to patients with benign disease and significantly (~1500-fold) higher in PDAC patients (all stages) compared to the HRI cohort.

Conclusions: Taken together, our results suggest that the non-invasive detection of uTIMP-1, uADAM12 and uCTGF levels may have diagnostic value in the early detection and/or clinical monitoring of disease status in patients with PDAC.

#2528 Effect of COPD diagnosis on TP53-mutated colony size distribution in airway epithelium of subjects with or without lung cancer.

James C. Willey[1], Andrew Boring[2], Erin L. Crawford[3], Daniel J. Craig[3], Chen Heidi[4], Rami Ahmad[3], Kevin Lei[3], Mohamed Omballi[3], Stephen A. Deppen[4], Eric Grogan[4], Thomas M. Blomquist[5]

[1]University of Toledo, Toledo, OH,[2]University of Toledo College of Medicine and Life Sciences, Toledo, OH,[3]University of Toledo Health Science Campus, Toledo, OH,[4]Vanderbilt University Medical Center, Nashville, TN,[5]Medicine, University of Toledo, Toledo, OH

Background: We previously identified a biomarker for the early detection of lung cancer (LC) based on the prevalence of TP53-mutated colonies in airway epithelium, and determined that this biomarker performs well in subjects with or without COPD. To better understand the biological basis for this biomarker, we compared TP53-mutated colony size distributions in subjects with or without COPD and/or LC.

Methods: Airway epithelial cell specimens were collected from subjects undergoing bronchoscopy under an IRB-approved research protocol. DNA was extracted from each specimen and ultra-sensitive NGS was used to measure TP53 mutations, with variant allele fraction (VAF) as low as 0.01%. TP53-mutated colony size was estimated assuming cells were heterozygous for the mutation. Specimens from 59 subjects were assessed in four cohorts: lung cancer with COPD [LC-CO) (N=14), non-lung cancer with COPD (NLC-CO) (N=7), lung cancer without COPD (LC-NCO) (N=16) and non-lung cancer without COPD (NLC-NCO) (N=22). Colony size distributions were assessed by piecemeal slope analysis and Kaplan-Meier analysis.

Results: A total of 192 unique TP53 mutations were identified among the 59 subjects, distributed among the cohorts as follows: LC-CO, 72; NLC-C0, 19; LC-NCO, 87; and NLC-NCO, 14. The mutation VAF values ranged from 0.01% (0.0001) to 6% (0.06), corresponding to a TP53-mutated colony size range of 200 to 30,000 cells. For each cohort, colony prevalence was inversely proportional to colony size, and there was an inflection point (IP1) at 400-600 cells/colony. Prior to IP1 there was little change in colony number relative to size; after IP1 the decline had a steep slope. The IP1 value was smaller for CO subjects (400 cells) than for NCO subjects (600 cells). There was a second inflection point (IP2) at about 1,800 cells, after which there were few surviving colonies for NLC subjects, but many surviving colonies for LC subjects. According to Kaplan-Meier analysis, among LC-CO subjects the higher prevalence of colonies >1,800 cells in LC was key to accuracy of the TP53 biomarker. In contrast for LC-NCO subjects there was a higher prevalence of colonies across the range of sizes.

Conclusions: Interactions between TP53 mutated colonies and the microenvironment are different in CO vs non-CO subjects. This difference may be partly due to the increased adaptive immune inflammation characteristic of CO lung tissue.

#2529 High throughput immunoproteomics for cancer biomarker discovery.

Joshua LaBaer[1], Jin Park[1], Ji Qiu[1], Lusheng Song[1], Karen S. Anderson[2], Jennifer Molloy[1], Gomati Nandedkar[1], Daniel Woodley[1], Deborah Adams[1], Candyce McDaniel[1], Andruw Fierro[1], Renee Turzanski Fortner[3], Toria Trendler[1], Mingyue Wang[4], Leonid Dzantiev[5], Anu Mathew[5], Martin Stengelin[5], Wohlstadter Jacob[5]

[1]Arizona State University, Tempe, AZ,[2]Arizona State Univ. Biodesign Institute, Scottsdale, AZ,[3]German Cancer Research Center (DKFZ), Heidelberg, Germany,[4]Meso Scale Diagnostics, LLC, Rockville, MD,[5]Meso Scale Diagnostics LLC, Rockville, MD

Background: Early detection of lung cancer (LC) remains a critical unmet need. While computed tomography (CT) screening saves lives by detecting cancer at early stages, its utility is limited by high false positive rates and insufficient sensitivity. These limitations lead to unnecessary surgeries and missed malignancies, particularly in individuals presenting with indeterminate pulmonary nodules (IPNs).
Objective: Our overarching goal is to develop circulating biochemical biomarkers that improve the specificity of CT screening for LC by differentiating malignant from benign IPNs.
Methods: We applied a high-throughput systems immunoproteomics strategy to discover serum biomarkers able to discriminate between malignant and benign IPNs. This integrated approach profiles three classes of circulating biomarkers: autoantibodies, anti-microbial antibodies, and serum proteins.
Results: In the discovery phase, we profiled IgG and IgA autoantibodies using Nucleic Acid Programmable Protein Array (NAPPA) against 13,330 full-length human proteins, along with microbial antibodies against 8,820 microbial antigens. These analyses were conducted using serum from 144 lung cancer cases and 143 benign controls from Vanderbilt University Medical Center. Antibodies with significant enrichment in cases (odds ratio $p < 0.05$ in the top decile) were prioritized, yielding 112 autoantibodies and 70 microbial antibodies associated with malignancy, as well as 50 autoantibodies and 230 microbial antibodies associated with benign disease. In the validation phase, we assessed the prioritized antibody candidates in 319 subjects from the Detection of Early Lung Cancer Among Military Personnel (DECAMP-1) cohort using our Multiplexed In-Solution Protein Array (MISPA). In parallel, we quantified 19 well-reported cancer-associated serum proteins across the same samples. A multimodal panel comprising 7 autoantibodies, 4 microbial antibodies, and 4 serum proteins achieved an area under the curve (AUC) of 0.81 in the discovery cohort and 0.74 in independent validation cohorts, showing improved discrimination of malignant versus benign nodules compared to clinical models alone. Additionally, to demonstrate clinical scalability, we confirmed performance of top markers in 46 cases and 230 controls from the German Lung Cancer Screening Intervention Study (LUSI) using the Meso Scale Discovery (MSD) electrochemiluminescence platform.
Conclusions: These results demonstrate a fully integrated immunoproteomics pipeline for the discovery, validation, and potential clinical translation of multiplex antibody and protein biomarkers for lung cancer detection.

#2530 The ELF5 clock: A predictive marker for accelerated breast tissue aging and cancer susceptibility.

Masaru Miyano, Mark A. Labarge

Beckman Research Institute of The City of Hope, Duarte, CA

Aging is the most significant risk factor for breast cancer (BC). It is associated with transformative changes, notably a striking loss of lineage fidelity in luminal epithelial cells. This loss is characterized by a decline in lineage-specific gene expression and the acquisition of EMT- and myoepithelial-like features, along with increased transcriptional and methylome variability. In young women harboring pathogenic mutations in BRCA1, BRCA2, and PALB2, these aging-associated phenotypes, including loss of lineage fidelity in luminal epithelial cells, are accelerated. These changes warrant closer examination as luminal epithelial cells are the likely cells of origin for the BC subtypes most associated with aging. We hypothesize that the loss of lineage fidelity is a critical factor underlying the increased susceptibility to malignant transformation in mammary epithelia. A key age-related alteration in luminal cells is the decreased expression of the transcription factor ELF5. ELF5 is crucial for mammary gland development, maintaining the ER- luminal epithelial cell state, and its dysregulation is observed in BCs. Changes in ELF5 expression and promoter-proximal methylation serve as a biological clock for breast tissue. The expression of ELF5 decreases in luminal cells in an approximately linear fashion with chronological age, driven by changes in regulatory binding factors and promoter-proximal DNA methylation. The age-associated reduction in ELF5 expression, mirrored by alterations in its target genes, suggests that a decline in ELF5 may be a pivotal event leading to the loss of lineage fidelity. We demonstrate that the ELF5 clock predicts breast biological age within ±3 years of chronological age in women at average risk. High-risk carriers of BRCA1, BRCA2, or PALB2 variants, exhibit a biological age acceleration of 10-40 years relative to their chronological age. We hypothesize that ELF5 expression levels in luminal cells reflect the susceptibility of breast tissue to cancer, independent of specific environmental, epigenetic, genetic, or age-related factors contributing to increased risk. We propose that measuring ELF5 could serve as a molecular “canary in the coal mine” for BC risk or as a clinical correlate for monitoring preventive interventions.

#2531 Plasma levels of Serphin-E1 (PAI-1) are significantly increased in patients with colorectal cancer compared to patients with benign colonic disease.

Chandana S. K. Herath Mudiyanselage[1], Yi-Ru Chen[1], Hiromichi Miyagaki[2], Neil Mitra[1], Monica S. Naparst,[1], Vesna Cekic[1], Richard L. Whelan[1]

[1]Department of Surgery, Northwell Health, Lenox Hill Hospital, New York, NY,[2]Department of Surgery, Otemae Hospital, Osaka, Japan

Introduction: Plasminogen activator inhibitor-1 (PAI-1), is an inhibitor for urokinase-type plasminogen activator (uPA) and tissue-type plasminogen activator (tPA). PAI-1 has proangiogenic effects and plays a role in epithelial-mesenchymal transition and metastasis. PAI-1 is a modulator of endothelial cell proliferation and migration in vitro and of angiogenesis and tumor growth in vivo. PAI-1 promotes tumor progression by modulating extracellular matrix proteolysis, cellular adhesion, and detachment; it also facilitates invasion/migration of cancer cells. PAI-1 overexpression has been reported in breast and colorectal cancer(CRC). Plasma levels of PAI-1 in CRC patients (pts) have not been well studied. This study's purpose was to compare preoperative (PreOp) plasmaPAI-1 levels in CRC and benign colonic pathology (BCP) patients.

Methods: Patients (pts) who underwent colorectal resection for BCP or CRC were prospectively enrolled in an IRB-approved tissue and data bank. Preop blood samples, demographic and clinical data, and pathology results were collected prospectively. Plasma PAI-1 levels were measured in duplicate (ng/ml) using ELISA, with results presented as median ± 95% CI. PAI-1 expression levels were also assessed in paired tumor/normal tissues for a subset of pts using QRT-PCR; immunohistochemistry (IHC) was also carried out on CRC and normal tissue samples. The ROC curve and AUC were used to assess plasma PAI-1 as a CRC diagnostic marker. The Mann-Whitney test was used for statistical analysis (significance $p<0.05$.)

Results: A total of 156 CRC (71%colon, 29%rectal) and 101 BCP pts (adenoma 57%, diverticulitis 32%, other11%) were studied. The Stage (S) breakdown for the CRC group was: S 1, 29%; S 2, 29%; S 3, 36%; and S 4, 6%. The median CRC plasma PAI-1 levels were significantly higher (11.75, CI: 9.06, 15.32) vs. BCP pts (2.95, CI: 2.33, 3.49; $P< 0.0001$). A non-significant rise in mean PAI-1 levels was observed in Stage II, III, and IV pts compared to S.I (12% - 33%, p=ns). mRNA PAI-1 expression levels were higher ($p<0.05$) in 50% (9/18) of the CRC tissue samples tested vs. paired normal tissues. IHC confirmed the presence of PAI-1 protein in CRC vs. normal colon tissue. The AUC value for the ROC curve was 0.759 (sensitivity 68%, specificity 77%).

Conclusion: The median Preop plasma PAI-1 was 3.9 X higher in the CRC vs. the BCP group. Although not proven, the added PAI-1 found in the plasma of CRC pts is likely produced by tumor cells and the surrounding inflammatory cells. Elevated PAI-1 levels may be related to neovascularization and inflammation-induced tissue remodeling at tumor sites. The AUC results suggest PAI-1 may have value as a CRC prognostic marker in a panel of proteins. Further studies with a larger population of controls and CRC pts are needed to better determine if there is a correlation between plasma PAI-1 levels and cancer stage or progression.

#2532 Innovative label-free and non-invasive urinary metabolite analysis integrating AI and SERS technology for early cancer detection: A retrospective clinical study involving five cancer types.

Jeehee Kim[1], Hyungseok Choi[1], Eun Hye Koh[1], Thi Nhat Linh Vo[1], Geo Ryu[1], Eun Been Lee[1], Daekeon Kwon[2], Soohyun Lew[2], Si Young Song[3]

[1]SOLUM Healthcare, Yongin, Korea, Republic of,[2]JNPMEDI Inc., Incheon, Korea, Republic of,[3]College of Medicine, Yonsei University, Seoul, Korea, Republic of

Background: Accurate early cancer detection remains a critical clinical challenge due to the high cost and limited sensitivity and specificity of conventional diagnostic methods. Indeed, non-invasive approaches capable of molecular-level characterization of biofluids are urgently needed to improve early diagnostic accuracy and patient outcomes. Artificial intelligence-assisted surface-enhanced Raman scattering (AI-SERS) offers a powerful platform to test complex metabolic signatures in urine with exceptional sensitivity. By integrating high-resolution SERS spectra with deep learning-based classification, AI-SERS platform transcends the limitations of conventional assays, enabling highly precise cancer differentiation and unlocking new avenues for the discovery of metabolite-based biomarkers for early cancer detection.

Methods: This study enrolled a total of 287 clinical urine samples across six groups: prostate cancer (PRC, n = 49), pancreatic cancer (PAC, n = 16), ovarian cancer (OC, n = 64), lung cancer (LC, n = 30), breast cancer (BC, n = 29), and normal controls (NOR, n = 99). A minimal volume (10 μL) of clinical urine samples was applied to a patented SERS sensor to enhance metabolite signals, measured using a Raman spectrometer. The resulting SERS spectra were analyzed using a convolutional neural network (CNN)-based deep learning approach.

Results: The SERS spectra of urine samples from 6 different groups exhibited sharp Raman spectral peaks, providing significant information for analysis. Using the developed CNN model, all cancer types combined could be distinguished from normal controls with an accuracy of 96.6%, sensitivity of 99.3%, and specificity of 94.0%, demonstrating excellent overall classification performance between cancer and non-cancer samples. Further analysis of individual cancer types versus normal controls showed robust predictive performance, with accuracy, sensitivity, and specificity of 98.0%, 98.6%, and 97.3% for PRC; 97.9%, 97.9%, and 97.9% for OC; 97.8%, 97.8%, and 97.8% for LC; and 98.9%, 97.7%, and 100% for BC, respectively. These results demonstrate the strong predictive capability of the AI-SERS platform for noninvasive, cancer-specific detection.

Conclusions: The noninvasive, label-free urine analysis using the AI-SERS platform revealed remarkable test performance in classifying cancers from normal controls, offering a rapid cancer screening approach and highlighting its potential for early cancer diagnosis. Ongoing clinical studies aim to identify cancer-type-specific metabolic biomarkers to further improve diagnostic specificity and contribute to enhanced patient outcomes.

#2533 Blood-based mRNA signature detects pancreatic cancer and distinguishes IPMNs: Discovery and preliminary verification study.

Moritz Robert Eidens[1], Timea Torok[1], **Niamh Nolan**[1], Patrick Lilley[2], Guido Baechler[1], Robert Scott Bresalier[3]

[1]Research, Mainz Biomed Germany GmbH, Mainz, Germany,[2]Liquid Biosciences Inc., Aliso Viejo, CA,[3]Dept. of Gastroenterology, Hepatology & Nutrition, UT MD Anderson Cancer Center, Houston, TX

Purpose: Currently, carbohydrate antigen 19-9 (CA19-9) is recommended for monitoring treatment response and recurrence in PDAC, but its poor sensitivity and lack of expression in ~5-10% of patients limit its use for screening in current guidelines. To address this gap, we sought to discover and verify a dedicated set of blood-based mRNA biomarkers and an algorithmic model that (i) differentiates PDAC from benign/healthy states and (ii) discriminates among healthy, IPMN (high-risk), and PDAC.
Methods: Phase 1 (discovery): Publicly available datasets [NIH Dataset ID GSE68086, GSE28735, GSE18670] including 96 PDACs and 301 controls (including healthy individuals and non-pancreatic cancers) were analyzed. Using machine learning (ML) algorithmic models trained using a quantitative evolutionary-computing platform (Emerge, Liquid Biosciences Inc.), 18 candidate mRNAs with translational feasibility were identified with strict training/selection/test partitioning and cross-dataset validation. Phase 2 (preliminary verification): We performed RNA sequencing on blood PBMCs from 30 individuals (healthy n=15, IPMN n=5, PDAC n=10) sourced from Crown Bioscience Germany GmbH, Hamburg, Germany. Six independent binary classifiers (PDAC vs healthy + IPMN) were trained using distinct subsets of the 18 mRNAs. We assessed diagnostic performance, redundancy, and a simple “voting” scheme (defined as majority vote across our six independent binary models) across the models.
Results: In Phase 1, discovery on blood and tissue/CTC across the three datasets, weighted test performance reached ~95% sensitivity and 98% specificity with multiple ≤6-gene subsets achieving perfect test accuracy on individual datasets. The robust signal was confirmed across diverse modalities and supported reagent availability for all 18 mRNAs, with multiple cross-validated subgroups suitable for clinical translation. In Phase 2 (n=30, PBMCs), the weakest binary model distinguishing between PDAC vs healthy + IPMN made 3/30 errors (all false positives; 100% sensitivity, 85% specificity at 90% accuracy), two models had two errors, two had one, and one model had zero errors. To enhance robustness, we aggregated the six independent binary models via our simple majority voting; the ensemble achieved 100% sensitivity and 100% specificity in the 30-subject cohort. The tri-state classifier achieved 100% three-way accuracy, requiring a minority subset of the 18 biomarkers to resolve healthy, IPMN, and PDAC.
Conclusions: A cross-validated set of blood mRNAs enables accurate PDAC detection and simultaneous discrimination of IPMN. While Phase 2 findings are compelling, they derive from a limited, banked and retrospective cohort and warrant confirmation in a larger study including samples from individuals with other high-risk profiles for PDAC and IPMN types that include malignant and benign characteristics.

#2534 Genomic transposable elements, repetitive sequences, in early-onset melanoma and prostate cancer among West Africans in Nigeria.

Faruk Mohammed[1], Sani Ibrahim[2], Rebecca Garnham[3], Ines Hosni[3], Halimatu Sadiya Musa[3], Sani Kamarudeen Owolabi[4], Adoke Kasimu Umar[4], Jane Carr-Wilkinson[3], Emma Scott[5], Ahmad Bello[2], Kevin Petrie[3]

[1]Ahmadu Bello University, Zaira, Nigeria,[2]Ahmadu Bello University, Zaria, Nigeria,[3]University of Sunderland, Sunderland, United Kingdom,[4]Federal Teaching Hospital, Birnin Kebbi, Nigeria,[5]Newcastle University, Newcastle, United Kingdom

Genomic transposable elements (TEs) constitute a substantial portion of the non-protein-coding genome and play crucial roles in gene expression, regulation, evolution, and genomic variation. The human genome comprises both protein-coding and non-protein-coding regions, the latter often referred to as the “dark genome.” Key components of this non-coding region include non-coding RNAs (ncRNAs), transposable elements (TEs) or “jumping genes,” protein-coding genes of unknown function (e.g., SLX4IP, HSF2BP, and ELFN), and repetitive sequences such as Long Interspersed Nuclear Elements (LINEs), Short Interspersed Nuclear Elements (SINEs), and Human Endogenous Retroviruses (HERVs). While approximately 23,000 genes are known to encode proteins, nearly 98% of the genome is non-coding, previously dismissed as “junk DNA.” This non-coding compartment is composed of LINEs (~21%), SINEs (~15%), HERVs (~8%), and other repetitive elements (~54%). Importantly, transcriptional activation of normally silenced transposable elements, often driven by epigenetic dysregulation such as DNA methylation loss, is a hallmark of cancer. This aberrant activation contributes to malignant transformation and tumor immunogenicity, although the underlying mechanisms remain poorly understood. Notably, HERVs, an important class of repetitive sequences, function as tumor-associated antigens, expressed on the surface of cancer cells, where they influence both innate and adaptive immune responses. The role of HERVs, particularly in early-onset melanoma and prostate cancer (CaP), remains underexplored, especially with respect to prognostication and disease progression. In this study, we investigated the expression and clinical significance of HERV type R (*HERV-R*) in melanoma and CaP. Using malignant melanoma tissues from Nigeria, benign prostatic samples from African men, and comparative tissues from men of European ancestry in Nigeria and the United Kingdom, we applied transcriptomic and molecular biology techniques to characterize *HERV-R* activity. Our findings demonstrate marked expression of HERV-R in malignant melanoma, in glandular regions of metastatic CaP tissues, and in both glandular and partially stromal compartments of benign prostatic lesions. These observations suggest that *HERV-R* holds promise as a prognostic biomarker and potential target for early detection in melanoma and CaP. Furthermore, the consistent glandular expression of HERV-R in both cancerous and benign prostate tissues supports the hypothesis of a mutator phenotype, implicating *HERV-R* in tumor initiation and progression. Collectively, these results underscore the therapeutic and diagnostic potential of *HERV-R* and highlight the urgent need for further investigation into *HERV-R* biology in melanoma and CaP.

#2535 High-resolution mapping of tumor-associated antigens for autoantibody-based lung cancer detection.

Swaralee Kulkarni, Russell D. Williams, Saiful Islam, Ofer Shapira, Jimmy C. Lin, Richard Bourgon, Tanya A. Moreno, Victor Chubukov, Sergey Boyarskiy

Freenome, Inc., South San Francisco, CA

Introduction
Non-invasive, blood-based screening for lung cancer is a promising approach to early cancer detection, but is challenged by low concentrations of tumor-derived biomarkers, especially in early-stage disease. Auto-antibodies (AAbs) are a compelling class of biomarkers to address this gap, leveraging the body's amplified humoral immune response to tumor antigens and providing a unique source of signal not directly linked to tumor shedding. However, natural variation in human immune profiles makes identification of true cancer-specific antigens challenging.
Methods
In this work, we used a Phage Immunoprecipitation and sequencing (PhIP-Seq) method to identify AAbs differentially present in patients with lung cancer. Unlike traditional proteome-wide PhIP-Seq approaches, we used cancer mutation data along with tumor-specific protein expression patterns from GTEx and TCGA databases to narrow the search space to ~4000 proteins with high probability of generating a cancer-specific immune response. By densely tiling these proteins with overlapping 54-mer peptides and requiring overlapping peptides for hit calling, we maximized technical reproducibility while also mapping cancer-specific antigenic regions within proteins to high resolution. Applying this approach to 1,200 samples enabled us to differentiate cancer-specific signals from background antigenicity.
Results
We screened 400 samples from patients with lung cancer and 800 samples from age- and sex-matched healthy controls. Our hit-calling pipeline identified antigens showing significant AAb signal in plasma from multiple cancer patients and little or no signal in healthy controls, taking into account both technical and biological noise. Based on this pipeline, we identified 90 cancer-specific peptide antigens spanning 68 human proteins, including established lung cancer biomarkers such as p53 and NY-ESO-1 as well as proteins not previously associated with lung cancer autoimmunity. Importantly, even in well-established tumor-associated antigen (TAA) proteins, we identified regions with high AAb positivity in healthy individuals, showing that selecting specific antigenic regions of TAA proteins could be crucial for maximizing signal-to-noise. Moreover, we observed distinct AAb profiles across different patient subsets, indicating that a large panel of antigens may help achieve higher sensitivity in a blood-based cancer detection assay.
Conclusions
This work represents a significant step forward in mapping the cancer humoral immunome. By performing PhIP-Seq based AAb profiling in the largest cohort of lung cancer patients and matched healthy controls published to date, and enabling deep peptide-level characterization of the auto-antibody response, we maximize confidence in identification of cancer-specific biomarkers and provide a path to a more accurate AAb-based cancer detection test.

#2537 PD-L1 expression in oral premalignant and malignant lesions and its association with p53 expression.

Oh Run Kim[1], Lewei Zhang[1], Miriam Rosin[2], Cathie Garnis[3], Denise M. Laronde[1]

[1]University of British Columbia, Faculty of Dentistry, Vancouver, BC, Canada,[2]BC Cancer Research Institute, Vancouver, BC, Canada,[3]Dept. of Surgery, University of British Columbia, Faculty of Medicine, Vancouver, BC, Canada

Introduction: Programmed death-ligand 1 (PD-L1) is a key immune checkpoint molecule that allows tumor cells to evade immune surveillance by promoting T-cell exhaustion within the tumor microenvironment (TME). Oral malignant lesions, of which 90% are oral squamous cell carcinoma (OSCC), are known to express abnormally high levels of PD-L1. Extensive research has explored PD-L1 in carcinogenesis and immunotherapy. The tumor suppressor protein p53 is often mutated in cancer, and its immunohistochemistry (IHC) assessment has been found to help predict malignant potential in oral premalignant lesions. Emerging evidence suggests p53 may influence immune activity in the TME by altering PD-L1 levels. However, how developing tumors modify the TME during the premalignant stage, and the role of p53 in this process, remain unclear. This study aims to evaluate the relationship between PD-L1 and p53 in oral premalignant and malignant lesions.

Methods: A comparative cross-sectional study was conducted using patient data and oral tissue samples from the Oral Cancer Prediction Longitudinal Study and the BC Oral Biopsy Service. Inclusion criteria were biopsy confirmed oral epithelial dysplasia (OED) or OSCC. Exclusion criteria included HPV or EBV associated OED or OSCC, actinic cheilitis, and verrucous hyperplasia. IHC was performed on formalin-fixed, paraffin-embedded tissue to assess PD-L1 and p53 expression. We hypothesized that the malignant group (MA), defined as severe OED, carcinoma in situ (CIS), or OSCC, would show increased PD-L1 and mutant p53 expression compared with the premalignant group (PMA), which consists of mild or moderate OED. Samples were considered PD-L1 positive if ≥5% of dysplastic or tumor cells showed moderate to strong membranous staining. p53 was classified as mutant when showing either overexpression or complete loss. Fisher's exact test assessed group differences in categorical variables.

Results: To date, 38 of 138 samples have undergone IHC analysis. PD-L1 positivity was higher in MA than PMA (40% and 17.4%), though not statistically significant with the current sample size. A significantly higher proportion of mutant p53 was observed in MA compared with PMA (86.7% and 34.8%, p=0.002). Thus far, no significant association was observed between PD-L1 and p53 expression, although an inverse trend in expression was noted. Additional samples are being processed to further evaluate expression patterns.

Conclusion: Significant differences in p53 expression were observed between MA and PMA, while PD-L1 expression did not differ significantly between groups. Nonetheless, higher PD-L1 positivity in malignant lesions suggests its potential relevance and warrants further investigation. These findings contribute to a better understanding of immune checkpoint regulation and tumor suppressor dysfunction in the progression of oral premalignant lesions to malignancy.

#2538 Machine learning-derived circulating ncRNA signature for early detection of breast cancer.

Yuanyuan Fu, Mayumi Jijiwa, Zhanwei Wang, Hua Yang, Youping Deng

University of Hawai'i at Manoa, Honolulu, HI

Background: Breast cancer is the most commonly diagnosed cancer and a leading cause of cancer-related mortality among women in the United States. Early detection substantially improves survival, yet current imaging-based screening modalities are limited by reduced sensitivity in certain populations and high false-positive rates. Circulating non-coding RNAs (ncRNAs) represent stable and non-invasive biomarkers with significant potential to complement mammography and enhance diagnostic accuracy. This study aimed to develop and validate a robust circulating ncRNA-based signature for early breast cancer detection using an integrated machine learning framework.

Methods: Circulating ncRNA profiles were generated for 413 individuals (216 breast cancer; 197 non-cancer). A three-stage design—discovery, internal testing, and external validation—was implemented. In the discovery cohort (n=248), we evaluated a broad ensemble of 12 machine learning frameworks and 111 model combinations to establish a consensus-based diagnostic signature (ncRNASig) comprising 16 circulating ncRNAs. Model development emphasized stability, reproducibility, and cross-cohort generalizability. The resulting ncRNASig was evaluated in an independent internal testing cohort (n=175) and further validated using multiple external datasets from The Cancer Genome Atlas (TCGA) and Gene Expression Omnibus (GEO).

Results: The 16-ncRNA diagnostic signature demonstrated high discriminatory power in the discovery cohort, achieving an AUC of 97.4% for distinguishing breast cancer from non-cancer samples. The ncRNASig also differentiated cancer from benign conditions (AUC = 96.1%) and cancer from normal controls (AUC = 100%). Subtype analyses showed consistently strong performance for Luminal A, Luminal B, HER2-enriched, and triple-negative breast cancers (AUCs 96-98%). These results were reproducible in the internal testing cohort and across multiple independent external datasets, supporting the robustness and generalizability of the ncRNASig.

Conclusion: This study identifies and validates a circulating ncRNA-based signature with strong diagnostic performance across breast cancer subtypes and independent cohorts. The findings support the potential of integrating ncRNA-driven liquid biopsy assays with current screening approaches to enhance early breast cancer detection. Further development and clinical translation are warranted.

#2539 miRNA profiling of prostate tissues reveals a molecular continuum from benign to tumor through peritumoral tissue.

Cesar A. Payan-Gomez[1], Dayana Rodriguez-Morales[2], Elizabeth Vargas-Castellanos[2], Jovanny Zabaleta[3], **Rafael Parra-Medina**[2]

[1]Universidad Nacional de Colombia, La Paz, Cesar, Colombia,[2]Pathology, Instituto Nacional de Cancerologia, Bogota, Colombia,[3]Interdisciplinary Oncology, LSU Health New Orleans, New Orleans, LA

Background: Histologically, peritumoral tissue (PTT) or normal adjacent prostate tissue (NAT) surrounding tumors, is considered unaffected by the malignant process. However, emerging evidence suggests that the peritumoral microenvironment may harbor early molecular alterations. We hypothesize that PTT represents an intermediate molecular state between benign (BT) and tumor tissue (TT).

Methods: Micro-RNA sequencing was performed on matched prostate tissues from 40 patients with prostate adenocarcinoma (after quality control 39 Tumor Tissues TT, 38 PTT, and 40 Benign Tissues BT). Differential miRNA expression (DEmiRNAs) was determined using DESeq2 (FDR ≤ 0.05), using BT as the reference group for the contrasts TT vs. BT and PTT vs. BT. Unsupervised principal component analysis (PCA), hierarchical clustering, fold-change comparisons, and pathway over-representation analysis of predicted miRNA targets (miRNet, KEGG/Reactome) were conducted.

Results: PCA of global miRNA profiles revealed a molecular continuum along PC2 (18% of variance), with BT clustering at the negative extreme, TT at the positive extreme, and PTT distributed intermediately between both groups. Comparison of TT vs. BT identified 102 DEmiRNAs, while PTT vs. BT identified 57 DEmiRNAs. Remarkably, 39 miRNAs (68% of PTT vs. BT signature) were shared between both comparisons, and all 39 displayed concordant directional changes, indicating that a substantial fraction of the tumor-associated miRNA dysregulation is already present in PTT. Direct TT vs. PTT comparison revealed only 30 DEmiRNAs, confirming greater molecular similarity between TT and PTT than either with BT. Hierarchical clustering of the top 30 most significant TT vs. BT DEmiRNAs showed that PTT samples formed a distinct cluster with expression levels consistently intermediate between BT and TT, reinforcing the idea of a continuum molecular landscape between BT, PTT and TT. Pathway analysis of miRNA targets showed that nearly all significantly enriched pathways in PTT vs. BT were also altered in TT vs. BT, including key cancer-related pathways (e.g., tight junction, transcriptional dysregulation in cancer, chemical carcinogenesis-receptor activation). Magnitude analysis of the 39 shared DEmiRNAs confirmed stronger dysregulation in TT than PTT, consistent with progression along a continuum rather than an abrupt transition.

Conclusions: miRNA profiling demonstrates that histologically PTT is molecularly altered and occupies an intermediate position between benign and fully malignant states. This molecular continuum supports the existence of a pre-malignant field effect driven by miRNA dysregulation and shared pathway alterations. These findings highlight PTT as a critical component of the tumor ecosystem and a potential source of early detection biomarkers or preventive therapeutic targets.

#2540 A combined bioinformatics, deep learning analysis, and immunohistochemistry approach to define the biomarker potential of advanced glycosylated end products (AGER) complex proteins in colon cancer progression.

Jorge Alberto Guadarrama-Orozco[1], Monica Serrano Arevalo[2], Ariadna Heredia Pulido[3], Jennifer Ramirez-Puente[4], Jose Diaz-Chavez[2]

[1]Tijuana General Hospital, Tijuana, Mexico,[2]Instituto Nacional de Cancerologia, Ciudad de Mexico, Mexico,[3]Oncos Patologia Tijuana, Tijuana, Mexico,[4]Hospital Angeles Tijuana, Tijuana, Mexico

Background: Despite recent advances in colorectal cancer (CRC) diagnosis and population screening programs, the identification of patients with preneoplastic lesions or with early CRC stages remains challenging and is essential for reducing CRC incidence and increasing patients' survival.
Methods: Our study comprehensively investigated the clinical significance and relationship among AGER complex protein/N-Glycosilation genes (DDOST, PRKCSH, and GALECTIN 3) and colon cancer progression in colorectal cancer through a bioinformatics data mining process (STRING, UALCAN, HPA, GEPIA2, TNMplot), their interaction (DMFold-Multimer), and followed by experimental validation. We analyzed 112 colorectal tissue samples originating from CRC stages I to IV, including normal tissue and adenomas. The characterization of three biomarker candidates was performed using immunohistochemistry on normal tissue, precancerous, and cancerous lesions with increasing CRC stages. We selected the ROI in QuPath and analysed it in ImageJ using the DeepLIIF extension to calculate expression percentage.
Results: The distributions of PRKCSH, DDOST, and GALECTIN 3 were validated in tissues, showing different expression levels, especially in early stages of CRC, compared to normal and preneoplastic tissues.
Conclusion: We highlighted three proteins that require further investigation to better characterize their role in early CRC carcinogenesis and their potential as markers of CRC progression.

#2541 Circulating sphingolipids and colorectal cancer risk in African American adults.

Sara Salas[1], Stephanie Richardson[1], Danxia Yu[2], Alan Maschek[1], James E. Cox[1], Joshua Alvarez[1], Emmanuel Onyegba[1], Monowarul Siddique[1], Steve Moore[3], Marc Gunter[4], Anna Ibele[1], Xiao-Ou Shu[5], Scott A. Summers[1], Cornelia M. Ulrich[1], Mary Playdon[1]

[1]University of Utah, Salt Lake City, UT,[2]Vanderbilt University, Nashville, TN,[3]National Cancer Institute, Bethesda, MD,[4]Imperial College London, London, United Kingdom,[5]Vanderbilt, Nashville, TN

Background: Obesity-related metabolic dysfunction may promote colorectal carcinogenesis through sphingolipid pathways. Ceramides and related species regulate insulin resistance, inflammation, and intestinal stem-cell proliferation; however, prospective data linking circulating sphingolipids to colorectal cancer (CRC) are limited, particularly in African Americans.
Methods: We conducted a nested case-control study within the Southern Community Cohort Study (SCCS) including 373 African American CRC cases and 373 matched control participants. Targeted lipidomic analysis quantified 165 sphingolipids including 78 ceramides, 36 sphingomyelins, 30 neutral glycosphingolipids, 14 glycerophosphocholines, 4 sphingoid base-1-phosphates, 4 sphingoid base homologs, and one ceramide-1-phosphate. Conditional logistic regression estimated odds ratios (OR) and 95% CI per standard deviation (SD), adjusting for age, sex, number of aliquot freeze-thaw cycles, education, body mass index, smoking status, physical activity, energy intake, fiber intake, red/processed meat intake, and alcohol intake.
Results: Participants were aged 54±9 years, and 55% were female. In fully adjusted models, several very-long-chain ceramides and one sphingomyelin showed statistically significant inverse associations with CRC risk with adjustment for multiple comparisons at FDR $q<0.05$, including Cer(d16:1/23:0), Cer(d16:1/22:0), Cer(d17:1/22:0), Cer(d17:1/23:0), Cer(d18:2/23:0), and SM(d16:1/23:0) (OR per SD range 0.76 to 0.80, p range 0.001 to 0.009). Some long-chain dihydroceramides and ceramides previously linked to metabolic diseases were positively associated with CRC, though results did not reach statistical significance (e.g., dhCer(d18:0/18:0), OR 1.15, 95% CI 0.98-1.35; Cer(d18:1/18:0), OR 1.08, 95% CI 0.92-1.26).
Conclusions: Pre-diagnostic very-long-chain ceramide species showed protective associations with CRC incidence in African Americans. Findings highlight potential metabolically actionable pathways for CRC prevention.

#2542 Assessing the TP53 mutation prevalence biomarker for lung cancer in subjects without COPD.

Andrew Boring[1], Erin Crawford[2], Kevin Lei[1], Daniel Craig[2], Chen Heidi[3], Steven A. Deppen[3], Rami Ahmad[2], Eric L. Grogan[3], Mohamed Omballi[2], James C. Willey[2]

[1]University of Toledo College of Medicine and Life Sciences, Toledo, OH,[2]Department of Medicine, University of Toledo College of Medicine and Life Sciences, Toledo, OH,[3]Vanderbilt University Medical Center, Nashville, TN

Background: COPD increases the risk for lung cancer, but two-thirds of LC cases occur in individuals without COPD. Further, more than half of lung cancers (LC) occur in individuals who do not meet age and/or smoking history eligibility criteria low-dose CT (LDCT) lung cancer screening. Thus, there is a need to develop biomarkers that improve on current demographic criteria to determine eligibility for screening. We previously identified a biomarker for the early detection of lung cancer by quantifying the prevalence of TP53 mutations present in the large airways. In this study we evaluated performance of this LC biomarker in subjects with or without COPD.
Methods: Subjects undergoing standard of care bronchoscopy were recruited into an IRB-approved research study wherein soft brush biopsies of airway epithelial cells (AEC) from the large airways were collected. DNA extracted from bronchial brush specimens was sequenced by PCR-amplicon library NGS. Using synthetic internal standards to control for sequencing error, variant allele fraction (VAF) was observable down to 0.01%. The TP53 biomarker was measured in AEC DNA from 38 non-COPD subjects, including 16 with cancer and 22 without cancer, and 21 COPD subjects, 14 with cancer, and 7 without cancer.
Results: The TP53 biomarker differentiated between cancer and non-cancer subjects in the absence of COPD with a receiver operator characteristics (ROC) area under the curve (AUC) value of 0.84. The TP53 biomarker also differentiated between cancer and non-cancer in patients diagnosed with COPD with an AUC of 0.78 in ROC analysis.
Conclusions: The TP53 biomarker performed well differentiating between cancer and non-cancer status in both COPD and non-COPD subjects. Application of the TP53 mutation prevalence biomarker is expected to have particular value when applied to identify non-COPD subjects at risk for lung cancer. Subjects without COPD who develop lung cancer typically were ineligible for LDCT screening due to correspondingly lower smoking history and age. We plan to validate these associations in larger case-control studies. If validated, this biomarker, alone or in combination with demographic criteria, may enable identification of a large number of subjects at high risk for lung cancer who currently do not qualify for LDCT screening based on demographic criteria alone.

#2543 Serum calreticulin as a promising biomarker for cancer screening.

Jasmine Watts[1], Lucinda Ann Hall[2], Lorenzo Thompson[3], Jacqueline L. Mudd[4], Steven Forsythe[1], Yuvasri Golivi[2], Roheena Panni[4], William E. Gillanders[5], Li Ding[5], Ryan C. Fields[6], Benjamin Larimer[7], Rachael Guenter[1], John B. Rose[2]

[1]Department of Surgery, University of Alabama at Birmingham, Birmingham, AL,[2]University of Alabama at Birmingham, Birmingham, AL,[3]Immunology Institute, University of Alabama at Birmingham, Birmingham, AL,[4]Department of Surgery, Washington University School of Medicine, St. Louis, MO,[5]Washington University School of Medicine, St. Louis, MO,[6]Department of Surgery, University of Rochester Medical Center, Rochester, NY,[7]Department of Radiology, University of Alabama at Birmingham, Birmingham, AL

Background: Calreticulin (CALR) is an endoplasmic reticulum chaperone protein that can translocate to the plasma membrane during cellular stress. Despite its known roles in cancer, CALR levels in the blood have not been extensively studied in cancer patients. We hypothesized that serum CALR is elevated in cancer patients and may serve as a noninvasive biomarker for early detection.
Methods: Serum samples were collected from patients diagnosed with pancreatic ductal adenocarcinoma (PDAC), breast cancer (BC), colorectal cancer (CRC), and healthy donors. CALR concentration was quantified using a RayBiotech Human CALR Sandwich ELISA. Statistical analyses were performed using Mann-Whitney U tests for group comparisons and ROC analysis for evaluating diagnostic performance on GraphPad Prism.
Results: 80 PDAC patients, 25 BC patients, 25 CRC patients, and 60 healthy donors were included in the study. Median (IQR) CALR level increased from 36.22 pg/mL (5.09-264.6) in healthy individuals to 363.1 pg/mL (226.5-729.7) in PDAC patients, 182.5 pg/mL (108.1-344.0) in CRC patients, and 584.9 pg/mL (381.2-823.4) in BC patients. Pairwise testing confirmed significantly higher CLAALR levels in PDAC vs. healthy ($p < 0.0001$), BC vs. healthy ($p < 0.0001$), and CRC vs. healthy ($p = 0.0021$).ROC analysis demonstrated strong diagnostic potential of serum CALR for distinguishing PDAC from healthy individuals (AUC = 0.799). The optimal cutoff, determined using Youden's Index, was 147 pg/mL with a sensitivity of 89% and specificity of 71.7%. Differentiating healthy donors from BC was also significant (AUC = 0.844) with sensitivity of 88% and specificity of 73.33% at the optimal cutoff value of 308.7 pg/mL. CRC was also distinguishable from healthy donors with an optimal cutoff of 52.81 pg/mL, yielding a sensitivity of 96% and specificity of 58.3% (AUC = 0.72).
Conclusion: Serum CALR is significantly elevated in patients with PDAC, BC, and CRC compared to healthy individuals and demonstrates strong diagnostic accuracy. These findings identify CALR as a promising noninvasive biomarker for cancer detection and justifies future validation studies assessing combinatorial biomarker panels.

#2544 Blood- and tissue-derived extracellular vesicle signatures in HPV-positive cervical disease.

Angie Gabriela Rivera-Ramos[1], Mariano Molina Beitia[2], Rafael Parra-Medina[3], Alba Lucia Combita-Rojas[3], Metoboroghene Mowoe[4], Daniel Hagey[4]

[1]Department of Medicine, National University of Colombia, Bogota, Colombia,[2]Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden,[3]Pathology, Instituto Nacional de Cancerologia, Bogota, Colombia,[4]Department of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden

Background: Extracellular vesicles (EVs) represent promising sources of biomarkers for cervical disease detection. However, optimal EV isolation strategies combining liquid and solid biopsies remain underexplored, particularly in resource-variable clinical settings.
Methods: We implemented a dual-source EV isolation approach in a Colombian clinical cohort of HPV-positive women. Plasma samples and solid biopsies were collected from 17 participants (9 squamous intraepithelial lesion [SIL] cases, 8 controls). Plasma-derived EVs were isolated directly, while tissue-derived EVs were obtained from primary fibroblast cultures established through optimized enzymatic and mechanical dissociation protocols. EVs were characterized using nanoparticle tracking analysis, transmission electron microscopy, and flow cytometry immunophenotyping. mRNA and protein cargo were prepared for RNA sequencing and proteomic analysis.
Results: The dual-source approach successfully yielded EVs from both plasma and tissue samples with appropriate quality and quantity for downstream analysis. Nanoparticle tracking analysis confirmed expected size distributions, while transmission electron microscopy validated EV morphology from cultured cells. Flow cytometry immunophenotyping identified characteristic EV surface markers. The optimized tissue dissociation workflow generated robust primary cultures capable of producing analyzable EVs. Preliminary mRNA sequencing of plasma-derived EVs revealed candidate molecular signatures that distinguished SIL cases from controls and showed association with lesion grade.
Conclusions: This dual-source EV strategy is feasible in Colombian clinical settings and supports the development of liquid biopsy biomarkers for early detection and risk stratification of HPV-related cervical disease. The approach enables comprehensive molecular profiling from complementary biological sources, warranting further validation in larger cohorts.

#2545 Genome-wide analysis of ctDNA-derived DNA palindromes for early detection of breast cancer.

Fumie Igari[1], Hisashi Tanaka[2], Tamami Hyodo[1], Yuko Ishikawa[1], Tomoyuki Fujita[1], Michael Murata[2], Ryan Urbanowicz[2], Armando Giuliano[2]

[1]Juntendo University, Tokyo, Japan,[2]Cedars Sinai Medical Center, Los Angeles, CA

Background and Objective:
Circulating tumor DNA (ctDNA) in the blood provides valuable information about all aspects of patient care, including real-time tumor burden and therapeutic targets. While ctDNA tests currently focus on detecting small mutations and abnormal DNA methylations in targetedgenomic regions, structural variants (SVs) are also common in tumors and could serve as important cancer biomarkers. Despite the growing use of liquid biopsy in cancer detection and management, an effective agnostic SV detection method remains a missing piece. To address this, we target DNA palindromes, a chromosomal structural abnormality also known as fold-back inversions and inverted repeats. We explored the potential of an approach called GAPF-Seq (Genome-wide Analysis of Palindrome Formation: GAPF with NGS) for ctDNA detection. GAPF-seq enriches palindromic DNA from very small amounts of genomic DNAthrough intramolecular annealing (Tanaka et al., Nat Genet 2005). Next-generation sequencing (NGS) analysis of the enriched DNA would enable us to identify SVs across the genome.
Methods:
Breast tumor DNA was processed by the successive denaturation and renaturation. DNA from palindromes would form double-stranded DNA by intramolecular annealing, while normal and nonpalindromic DNA would remain single-stranded, which would be eliminated by S1 nuclease. Tumor-derived DNA palindromes were amplified by PCR, sequenced by NGS, and subjected to bioinformatic analysis, including ROC validation and chromosomal distribution profiling.
Results:
(1) ROC analysis demonstrated high diagnostic accuracy. Using the top 1000 high coverage bins(HCBs) among the 1 million 1-kb bins in the genome, we found that the AUC value for tumor DNA calling was 0.9885, with sensitivity 92.3% and specificity 97.4%, enabling robust distinction between cancer and normal samples, including Stage I tumors. Comparable performance was achieved between 30 ng and 100 ng of DNA.(2) As GAPF-Seq is based on Structural variant detection genome-wide, it allows comprehensive genome-wide screening beyond single-gene mutation or a subset of CpG methylation analyses. Chromosomal mapping revealed uniform distribution of top 1000 HCBs in normal samples, while tumor samples exhibited chromosome-specific enrichment of HCBs. Subtype-specific analysis showed accumulation around the *CCND1* gene on chromosome 11 in Luminal type, and enrichment near the *ERBB2* gene on chromosome 17 in HER2 type.
Conclusion:
GAPF-Seq has the potential to enable accurate detection of early breast cancer even from minimal DNA input. Its agnostic, genome-wide profiling capability provides an additional benefit. Potential clinical applications include cancer screening and monitoring minimal residual disease.

#2546 An alternative screening method for prostate cancer to serum prostate specific antigen.

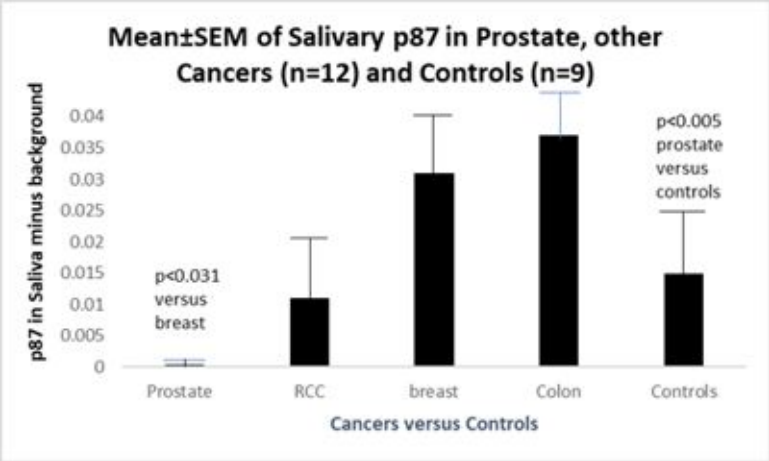
Yosef Tobi[1], Altin Miraka[2], Noreen F. Rossi[3], Mike Lawson[4], Martin Tobi[5]

[1]Medicine, Medical College of New York, Valhalla, NY,[2]Dept. Surgery, Saginaw VAMC VHA, Saginaw, MI,[3]Detroit VAMC, Detroit, MI,[4]University of California, Sacramento, Davis, Sacramento, CA,[5]Saginaw VAMC, Saginaw, MI

Introduction: After 23 years of follow-up, a recent long-term study by Roobol et al showed a relative reduced mortality rate of 13% and an absolute risk reduction of 0.22% in a group screened for prostate cancer (DOI: 10.1056/NEJMoa2503223). Most prostate cancers (ProC) are not lethal and the death rate is about 15% for lethal tumors versus a majority of more indolent tumors. Prostate Specific Antigen (PSA) blood test is used for screening, but within the grey zone of 4-10ng/mL the positive predictive rate is only 25%, leading to unnecessary invasive biopsies. A more effective non-invasive test would be beneficial.

Methods: Self-collected, unstimulated saliva was obtained. A dot blot p87 assay was performed using Adnab-9 monoclonal antibody (mAb) with binding minus background recorded. The mAb reacts with secretory products in the GI tract usually associated with Paneth cell secretions.

Results: In the figure below, in patients with ProC, the salivary p87 was significantly lower than non-cancer controls ($p<0.005$). We found correlations between salivary products such as blood lysozyme, blood, and stool cancer biomarkers. p87 saliva in breast cancer patients was significantly higher (0.031 ± 0.01) than in prostate cancer patients' saliva ($p<0.031$).



Conclusions: Lower concentrations of salivary lysozyme have been found to be associated with other GI and hemopoietic cancers (Sun et al. https://doi.org/10.1155/2016/8701423). With larger numbers we hope to show that reduced levels of salivary p87, lysozyme, and other biomarkers might be able to detect more aggressive ProC, reducing unnecessary invasive procedures and anxiety.

#2547 Translating to targeted: Bridging discovery lipidomics to multi-omic clinical diagnostic application in ovarian cancer detection.

Rachel Culp-Hill[1], Charles M. Nichols[1], Yu Han[1], Brendan M. Giles[1], Moises Zapata[1], Mattie Goldberg[1], Robert A. Law[1], Enkhtuya Radnaa[1], Shannon Kilkenny[1], Maria Wong[1], Connor Hansen[1], Vuna S. Fa[1], Cory Bystrom[2], Liang Zhao[3], Kim Ekroos[4], Abigail McElhinny[1]

[1]AOA Dx, Denver, CO,[2]Ultragenyx Pharmaceutical Inc., Novato, CA,[3]CompleteOmics, Halethorpe, MD,[4]Lipidomics Consulting Ltd., Espoo, Finland

Ovarian cancer (OC) is often diagnosed at late stages due to a lack of robust diagnostic tools, resulting in one of the highest mortality rates of any gynecologic malignancy. Dramatically altered lipidomic signatures have been observed in OC serum, but barriers exist in translating findings from discovery mass spectrometry (MS) applications to a targeted, clinical diagnostic assay. Discovery lipidomics experiments are challenged by the magnitude of features detected paired with the structural diversity of lipids. This work highlights the importance of feature characterization and identification to discover novel, robust biomarkers for the detection of early-stage OC.Serum samples representing individuals experiencing symptoms of OC as well as OC patients across all stages and a range of subtypes were obtained from University of Colorado, University of Manchester, and commercial vendors . Multi-omic analysis was performed using untargeted and targeted lipidomics and a panel of immunoassay protein biomarkers (CA125, HE4, MUC1, FOLR1). Discovery lipidomics used LCMS/MS with data-dependent acquisition (ddMS2). Data were processed for feature alignment, deconvolution, background rejection, identification, and statistical analysis. Feature exclusion included: (1) no library ID, (2) present in <10% samples, (3) exogenous origin, (4) high technical variability, and (5) not detected. Machine learning (ROC/AUC analysis) and univariate analyses identified features for targeted development. MRM transitions were generated from ddMS2 or targeted MS2 spectra, and targeted MRM methods were built. MRM features were experimentally verified in each polarity. Features were subjected to custom algorithm-informed internal standard normalization prior to inclusion in the model.Our published proof-of-concept multi-omic model reproducibly detects OC with AUCs of 92% (95% CI: 87%-95%) for OC v. controls and 88% (95% CI: 83%-93%) for early-stage OC. We then transferred the discovery lipidomics method to a targeted MRM assay, improving precision and analytical performance, while retaining directionality and/or significance in 82.5% features. Updated multi-omic models using targeted data show reproducible performance with AUCs >90% in an independent cohort of serum samples consistent with the discovery proof-of-concept multi-omic model (lipids + proteins). Here, we describe a workflow for translating discovery lipidomics into a targeted MRM method for a clinical diagnostic assay. Combining feature filtering, statistical analysis, machine learning, and experimental validation across cohorts, we identified a collection of robust lipid biomarkers that reproducibly detect OC. These features, combined with protein biomarkers, are being further developed into a multi-omic assay designed to detect OC earlier in the symptomatic population.

#2548 Circulating proteomic signatures for subtyping NF1 associated peripheral nerve sheath tumors.

Chloe M. Sachs[1], Andrea M. Gross[2], Brigitte C. Widemann[3], Jack F. Shern[4], Russell T. Sundby[1]

[1]Pediatric Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]Division of Oncology, Cincinnati Children's Hospital, Cincinnati, OH,[3]Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD,[4]Pediatric Oncology, National Cancer Institute, Bethesda, MD

Purpose: Early detection and interception of malignant transformation in Neurofibromatosis Type 1 (NF1) associated peripheral nerve sheath tumors are challenging due to insensitive clinical symptoms, limited specificity of standard of care imaging, and the limited negative predictive value of invasive tissue biopsy. Novel non-invasive and tumor site-agnostic surveillance assays provide potential for early diagnosis and intervention, especially during the critical transformation from benign plexiform neurofibromas (PN) to pre-malignant atypical neurofibromas (AN), defined by histopathology. We hypothesize that circulating proteins in the plasma accurately distinguish the spectrum of PN, AN, and malignant peripheral nerve sheath tumors (MPNST).

Methods: 118 plasma samples (Healthy $n = 10$, PN $n = 29$, AN $n = 25$, and MPNST $n = 54$) from 79 patients seen at the NIH were analyzed using a proximity extension assay (PEA) panel for 1461 proteins (*Olink*). Unique protein signatures were identified using a one-versus-all comparison: PN-versus-all (PvA) with ANOVA and post-hoc Tukey honestly significant difference (HSD) of normalized protein expression (NPX) outputs from PEA. Significant proteins had an NPX difference ≥ 1.2 and p adj <0.05. Individual proteins' performances were assessed using Youden's index and a receiver operating characteristic (ROC) curve. Given PN's high prevalence in NF1 and the high specificity of the identified proteins, a PN-specific predictive signature was prioritized for downstream analysis due to its clinical utility. Individual PN-associated protein signatures were integrated using a Support Vector Machine Learning Model (SVM) with leave-one-out cross-validation (NPX difference ≥ 1.2 and p adj <0.05).

Results: 114 proteins were significant for PvA comparisons. Individual protein's performance for PvA had a median AUC of 0.64 (IQR: 0.62-0.67), median sensitivity of 0.38 (IQR: 0.33-0.47), and median specificity of 0.97 (IQR: 0.86-1.0). SVM significantly improved the PN-signature's (AUC: 0.954),sensitivity (0.69, 20/29 PN), and specificity (0.99, one AN was misclassified as PN). The integrated PN protein signature predicts with high confidence whether a patient's tumor burden remains PN or has transformed to AN or MPNST (PPV: 0.95, NPV: 0.91).

Conclusions: This pilot demonstrates that circulating proteomics non-invasively distinguish PN from pre-malignant and malignant disease states in NF1. The PN protein profile shows significant dysregulation of protein expression, protein-protein interactions, and biological pathways. Finally, PEA uses just 40 µL of plasma per sample, enabling the integration of non-invasive orthogonal biomarkers, such as cell-free DNA, from a single tube of blood.

#2549 Association of CXCL12 rs1801157 G/A single-nucleotide polymorphism with prevalence and risk of breast cancer in Bangladeshi women.

Md Mustafizur Rahman[1], Shahin Kadir[1], Md Abdur Rahman[1], Amir Hossain[2]

[1]Pharmacy Discipline, Khulna University, Khulna, Bangladesh,[2]Department of Pharmacy, Dhaka International University, Dhaka, Bangladesh

Background: Breast cancer remains the most common cancer among women in Bangladesh. Chemokines play an important role in facilitating intracellular signaling after binding with CXCR4 to promote cell proliferation. CXCL12 plays a pivotal in different stages of tumor development and cancer metastasis. The case-control study assessed the impact of the single-nucleotide polymorphism (SNP) rs1801157 G/A in CXCL12/SDF1 gene in breast cancer patients.
Objective: This study aimed to investigate the association of the single-nucleotide polymorphism (SNP) rs1801157 in CXCL12/SDF1 gene with the prevalence and risk of breast cancer among Bangladeshi women. We also aimed at finding correlation between pathophysiologic variables and polymorphic genotypes in breast cancer patients.
Materials and Methods: The study included 130 breast cancer patients and 142 age matched healthy controls. Genomic DNA was isolated from venous blood collected from breast cancer patients and healthy controls. Genotyping was carried out by PCR-RFLP (polymerase chain reaction followed by restriction fragment length polymorphism) using a restriction enzyme.
Results: The frequencies of the wild type homozygous G/G, heterozygous G/A and variant homozygous A/A were 59%, 31%, and 10% in breast cancer cases whereas in controls were 56%, 38%, and 8%, respectively. The crude genotypic frequencies in breast cancer cases were almost similar to those of the controls. Compared with the homozygous G/G genotype of CXCL12, heterozygous G/A genotypes (OR= 0.7992, 95% CI=0.4784 to 1.3352, p=0.3921) and variant homozygous A/A genotypes (OR= 1.7105, 95% CI = 0.6715 to 4.3572, p=0.2605) were found not to be significantly associated breast cancer prevalence. The G and A content were 74% and 26% respectively for patients whereas it was 75% and 25% for control group, respectively. However, when compared with pathophysiologic characteristics, we found that variant genotypes increased the risk of breast cancer 11 times in non-breast-feeding individuals when compared to breast feeding individuals (X^2 = 11.4953; p =.00319).
Conclusions: rs1801157 SNP may have impact on breast cancer risk among Bangladeshi females. However, Further studies with higher sample size are required to conclude the findings.

#2550 Engineering next-generation EV diagnostics by integrating nanoplasmonic sensing and multiplex enrichment for early PDAC detection.

Tony Hu

School of Biomedical Engineering, Tsinghua University, Beijing, China

Background: Pancreatic ductal adenocarcinoma (PDAC) is typically diagnosed at an advanced stage, when curative options are limited. Circulating extracellular vesicles (EVs) provide a minimally invasive window into tumor biology, yet existing EV assays are slow, sample-intensive, and incompatible with clinical workflows requiring speed, reproducibility, and minimal sample input.
Methods: To confront these challenges, we established a sequential EV liquid-biopsy pipeline that integrates three complementary nanoengineered platforms for PDAC detection. First, a nanoplasmon-enhanced scattering (nPES) assay directly captures EVs from microliter plasma and quantifies tumor-enriched EphA2-positive EVs through dual antibody-nanoparticle coupling, simultaneously enabling the discovery of additional EV surface markers associated with PDAC. Second, we introduce FLARE (Fluctuation-enhanced simultaneous Labeling And Rapid Enrichment), which employs a low-frequency vibrating membrane and a peroxidase-mimicking nanozyme to synchronously enrich, label, and wash EVs in a single 45-minute operation, eliminating the need for multistep centrifugation and improving analytical performance. Third, we refined our plasmonic platform into a multiplex fluorescence assay that assembles plasmonic substrates in situ to enhance EV surface protein emission from unprocessed plasma, allowing simultaneous profiling of multiple PDAC-associated markers within one run.
Results: The EphA2-EV nPES assay enabled highly sensitive quantification of tumor-derived EVs in both small-volume animal samples and patient plasma, distinguished PDAC from pancreatitis and healthy donors, and revealed dynamic EV changes before and after therapy. FLARE achieved more than ten-fold higher EV recovery than conventional methods while maintaining high labeling efficiency, and its amplified colorimetric output enabled smartphone-based quantification of multiple EV biomarkers, discriminating early-stage PDAC with an area under the curve of 0.95. The multiplex plasmon-enhanced fluorescence assay further improved signal-to-noise ratios for rare EV protein detection, enabling multi-marker readout from minimal plasma without prior EV isolation, facilitating personalized prognosis.
Conclusions: By combining plasmonic scattering, vibration-assisted nanozyme enrichment, and plasmon-enhanced fluorescence, this EV-centered pipeline establishes a rapid, low-cost, and sample-sparing framework for PDAC liquid biopsy. Together, these platforms support scalable early detection, longitudinal treatment monitoring, and large-cohort translational studies across both clinical and preclinical settings.

#2551 Dual recognition of β-sheet proteinopathy and glycan moieties enables noninvasive detection of pancreatic ductal adenocarcinoma.

Alfred Akinlalu, Dali Sun

University of Denver, Denver, CO

Early detection of pancreatic ductal adenocarcinoma (PDAC) remains a formidable challenge due to the absence of reliable and accessible screening tools. In contrast to other cancers with established diagnostic methods, PDAC is often detected only after metastasis, resulting in poor survival outcomes. Current biomarkers such as CA19-9 offer limited diagnostic accuracy and frequently yield false positives, emphasizing the urgent need for a more specific and cost-effective approach. Here, we introduce EV-FRET, a biosensing assay that detects PDAC through fluorescence resonance energy transfer (FRET) signaling from tumor-derived extracellular vesicles (EVs). EV-FRET focuses on the molecular cargo of EVs secreted by cancer cells, by simultaneously targeting β-sheet-rich misfolded proteins, indicative of tumor proteinopathy, and N-acetyl-D-galactosamine (GalNAc), a glycan enriched in pancreatic epithelial cells. The assay uses thioflavin T (ThT) and fluorescein-labeled *Dolichos biflorus* agglutinin (FITC-DBA) as the donor-acceptor pair, generating a quantifiable FRET signal only when both tumor and organ markers coexist on EV surfaces. Without requiring EV isolation, the assay provides a single-step, reproducible (coefficient of variation < 4%) and low-cost method. The diagnostic performance revealed an AUC of 0.95 compared with 0.72 for CA 19-9, demonstrating improved specificity. EV-FRET demonstrates the potential for noninvasive PDAC detection and presents a flexible framework for adapting protein structure based diagnostics to other malignancies.

#2552 Cell-free RNA urogentital cancer biomarker detection from urine.

Carrie Ziemniak, Andrea J. O'Hara, Jeff Tio, Yongjun Fan, Haythem Latif

GENEWIZ, LLC, South Plainfield, NJ

Background: Urogenital cancers encompass a variety of tumor types including kidney, bladder and prostate cancer, the most prevalent cancer in men. Current early detection methods rely on blood screening of prostate-specific antigen (PSA), however this method is associated with overdiagnosis and overtreatment, has a high rate of false positives, and the subsequent procedures carry risks. As a result, the search for alternative biomarkers is of much interest. Urine is an ultra-non-invasive analyte ideal for urogenital cancer detection, including prostate cancer. Use of cell free RNA (cfRNA) is ideal for biomarker identification for use in diagnostics, treatment monitoring, and tumor tissue of origin prediction.
Methods: Here we describe urine cfRNA extraction and RNA-Seq analysis on a series of urogenital cancer affected urine samples and normal control urine samples. Several extraction kits were tested, including a novel cfRNA isolation technique that has highly efficient recovery rates of cfRNA with variable input amounts of 1-100 mL of sample. Following extraction, quantitative and qualitative QC were performed directly from the isolate, as well as functional downstream testing via RNA-Seq to assess recovery, transcriptome complexity, and detectability of known cancer biomarkers.
Results: Preliminary testing of the cfRNA isolation methods showed that traditional extraction methods did not achieve the yield required for detection of low-abundance biomarkers. In contrast, the novel extraction method demonstrated high efficiency cfRNA recovery. Along with traditional quantitative and qualitative QC of the extracted cfRNA, functional testing was performed using RNA-Seq. RNA-Seq results demonstrated detection of rare transcripts and cancer-associated biomarkers, confirming this is a reliable method for biomarker detection.
Conclusion: As these results show, cfRNA can be extracted from urine, with the detection of rare biomarkers associated with disease. The high-efficiency extraction method enables sensitive detection of low-frequency transcripts, addressing limitations of conventional techniques. This method is not limited to urine and cfRNA, with the potential for application in other biofluids including plasma and other nucleic acid types such as mitochondrial DNA.

#2553 Multi-omics liquid biopsy approach for sensitive detection of lung cancer via cfDNA and extracellular vesicles-RNA.

Vidyodhaya Sundaram[1], Nisshanthini Sambasivam Durairaju[1], Elim Cheung[1], Vinh Lam[2], Wei Zheng[2], Edwin Haghnazari[3]

[1]BioChain Institute Inc, a CellBio Scientific Company, Newark, CA,[2]System Biosciences Inc, a CellBio Scientific Company, Palo Alto, CA,[3]CellBio Scientific, Newark, CA

Background: Early detection of lung cancer remains challenging due to tumor heterogeneity and the limitations of single-analyte assays. Circulating cell-free DNA (cfDNA) captures genomic alterations, including mutations, copy number variations, and methylation patterns, but does not reflect gene activity. Circulating extracellular vesicles (EVs) carry varieties of small non-coding RNAs reflecting dynamic tumor processes, especially miRNAs that are implicated in regulating the expressions of oncogenes and tumor suppressors in cancer progression.

Methods: Under IRB approval, plasma from 5 normal subjects and 10 pathology-confirmed lung cancer patients, collected with informed consent from BioChain Institute's repository, was analyzed. cfDNA was isolated using BioChain's bead-based automatable cfPure® MAX Cell-Free DNA Extraction Kit and profiled with a targeted lung cancer gene panel. EV-RNA was extracted using SBI's SmartSEC EV isolation kit and EVery EV RNA Isolation Kit, followed by RNA-sequencing. Human normal Cell-Free DNA Control from 5 pooled normal donors from BioChain Institute was used as a control. Integration of cfDNA and EV-RNA readouts was performed to assess complementary genomic and transcriptomic signals.

Results and Conclusions: Combined cfDNA targeted NGS and EV-RNA sequencing from a single plasma sample is feasible and provides complementary insights into tumor biology. This multi-omics liquid biopsy approach reduces false negatives compared with single-analyte tests and enables identification of biomarkers that may be overlooked when assessing DNA or RNA alone. Together, cfDNA and EV-RNA profiling offer a more comprehensive, non-invasive strategy for early detection, monitoring disease progression, and informing treatment decisions in lung cancer.

[1]Cancer Inflammation and Immunity Group, Cancer Research UK Manchester Institute, Manchester, United Kingdom,[2]Visualisation, Irradiation and Analysis, Cancer Research UK Manchester Institute, Manchester, United Kingdom,[3]Computational Biology Support, Cancer Research UK Manchester Institute, Manchester, United Kingdom,[4]Cancer Research UK National Biomarkers Centre, Manchester, United Kingdom,[5]Biostatistics Research Group, Population Health Sciences Institute, Newcastle University, Newcastle, United Kingdom,[6]Institute of Medical Research at St James's, University of Leeds, Leeds, United Kingdom

Melanoma is the form of skin cancer responsible for most patient deaths. Treatment with immune checkpoint blockade (ICB) has led to a significant improvement in outcomes. However, half of melanoma patients do not derive long-term benefit, and improved understanding of this is required to identify novel mechanisms of resistance and treatment. We screened a range of topical treatments, used in non-melanoma skin diseases, for anti-cancer activity in an ICB-refractory murine melanoma model. In particular, and building on previous work by us and others, we focused on topical treatments that had the potential to influence the inflammatory response within tumors, which in turn may improve anti-tumor immune responses.

In a story recently published in *Cancer Discovery*, we found topical glucocorticoids to uniquely trigger acute tumor shrinkage. After just two doses, GC-treated tumors shrank, whereas control-treated tumors doubled in volume. Intriguingly, this effect was lost in *Rag1*$^{-/-}$ mice (deficient in B and T cells) or in mice depleted of CD8^{+}T cells, uncovering a key role for T cells in GC-induced tumor growth control. Of eight cancer models tested for GC-responsiveness, half experienced immune-depended control, and half were unresponsive.

GCs downregulated the expression of Glycoprotein A repetitions predominant (GARP) on the surface of melanoma cells. GARP is a cell-surface protein that plays a critical role in the activation of TGFβ from its inactive latent form. Targeted mutagenesis and genetic knockout confirmed GC-induced GARP downregulation reduced TGFβ signalling, allowing CD8^{+} T cell tumor killing. Of the eight tumor models tested, only the four GC-responsive tumors also responded to TGFβ inhibition, suggesting that GCs triggered immune-dependent tumor control when tumors make use of TGFβ signalling for immune evasion.

Unpublished data expands on this story. We examined the efficacy of using an anti-GARP antibody in mice, with and without immunotherapy, in order to identify further translational opportunities of this finding. Moreover, we have examined in-house melanoma patient biopsies to identify the immune environment of GARPhigh tumors vs GARPlow tumors, and correlated this with response to immunotherapy.

We discovered a paradoxical immune-dependent shrinkage induced by GCs in certain tumor models. Given the widespread use of GCs in patients receiving immunotherapy, these unexpected findings have the potential to result in significant clinical impact. The GARP/TGFβ axis therefore represents a cancer-cell intrinsic immune evasive pathway targetable by steroids, and further studies investigating the approach of inhibiting GARP on tumor cells directly investigate its use as a therapeutic strategy.

#2558 Multi-omic single-cell assessment of castration-resistant prostate cancer patients receiving ^{177}Lu-PSMA-617 and pembrolizumab shows timing of radioligand therapy alters immune response.

Anusha Muralidhar[1], Karen Law[1], Zenghua Fan[2], Shloka Shukla[1], Aram Lyu[1], Serena Kwek[2], David Y. Oh[2], Michael Evans[2], Rahul R. Aggarwal[2], Lawrence Fong[1]

[1]Fred Hutchinson Cancer Center, Seattle, WA,[2]University of California San Francisco, San Francisco, CA

Background: Prostate cancer, a leading cause of cancer-related death in men, is refractory to checkpoint inhibition.[1-3] Lutetium-177-labeled PSMA-617 (^{177}Lu-PSMA, Pluvicto) is an FDA-approved radioligand therapy in CRPC. We have shown that a single dose of ^{177}Lu-PSMA is immunomodulatory, and can be safely combined with the PD-1 blockade, pembrolizumab, in a phase 1 clinical trial (NCT03805594).[4] However, the schedule by which these treatments should be combined is unknown.

Methods: In our phase 1 clinical trial, patients with mCRPC received a single dose of ^{177}Lu-PSMA either before (Schedule 1, n=30), concurrently with (Schedule 2, n=6), or after pembrolizumab (Schedule 3, n=6). Serial peripheral blood mononuclear cells (PBMCs) were collected and analyzed using multi-omic single-cell RNA sequencing (scRNA-seq) to dissect the immune responses with these 3 schedules.

Results: We found that a single dose of ^{177}Lu-PSMA in monotherapy led to an expansion of CD4+ effector T cells as well as in Tregs indicative of direct immunomodulatory activity. This was accompanied by a reduction in NK and B cells. When ^{177}Lu-PSMA was combined with pembrolizumab, we saw dynamic changes in non-Treg T cell subsets ($CD4^+$ and $CD8^+$ T cells), dendritic cells (DCs), NK cells, and B cells across all three dosing schedules. Schedules 1 and 2 demonstrated stable T cell levels accompanied by a gradual increase in DCs, whereas Schedule 3 was characterized by low T cell frequencies and a progressive decline in DCs relative to baseline.

Conclusions: Our study demonstrates the critical importance of treatment sequencing to fully harness the immunomodulatory potential of RLT using a single dose of ^{177}Lu-PSMA and optimize synergy with PD-1 blockade in mCRPC. While initiating with either ^{177}Lu-PSMA or concurrently starting ^{177}Lu-PSMA with pembrolizumab resulted in an increase in DCs, starting with pembrolizumab first resulted in lower frequencies T cells and DCs suggesting that this schedule could be detrimental to immune outcomes.

#2559 Identifying cancer cell intrinsic regulators of radiation-induced interferon signaling.

Olivia Kaneko[1], Bon Ham Yip[1], Arnav Mehta[2], Nir Hacohen[2], Ryan J. Park[1]

[1]Experimental Radiation Oncology, MD Anderson Cancer Center, Houston, TX,[2]Broad Institute, Cambridge, MA and Massachusetts General Hospital, Charlestown, MA, Charlestown, MA

Induction of anti-tumor immunity by radiation therapy (RT) has been observed in multiple preclinical models and in selected patients and can lead to durable systemic tumor regression. Modulation of anti-tumor immunity by RT is thought to act primarily via cGAS-STING activation leading to type I interferon (IFN) response pathways, which coordinate T cell priming and recruitment and adaptive resistance such as PD-L1 induction. Individual studies have demonstrated both immune activating and immune suppressive effects of RT in various contexts, and the determinants of this wide variability are poorly understood. Discovering divergent and convergent mechanisms of type I IFN response to RT across diverse cancer cell states may thus define biomarkers and treatment strategies to enhance RT-driven immune activation. We treated 100 human cancer cell lines with 2 Gy or 8 Gy RT or the STING agonist DiABZI and performed single cell RNA sequencing. We scored cell lines using a composite of IFN response genes as well as individual IFN response genes including ISG15, MX1, CXCL10 and IFNB. We then selected four cell lines with high radiation-induced IFN response for mechanistic studies: two derived from pancreatic ductal adenocarcinoma and two from breast carcinoma. We observed distinct kinetics of ISG15 and MX1 activation between 2 Gy and 8 Gy RT and DiABZI as well as between cell lines. Notably, knockout of STING abrogated DiABZI response but paradoxically increased ISG15 induction by radiation in MDA-MB-231, but not SUIT-2. Our study highlights wide variability among cancer cell states in modulation of IFN response signatures by radiation and emphasizes the need to elucidate mechanisms of radiation-induced immune activation and suppression across diverse cancer types.

#2560 Radiotherapy shapes memory T cell dynamics and region-specific PD-1 expression in the glioblastoma microenvironment.

Hsin-Yu Sherry Liu, Sanghee Lee, Itzel Gutierrez, Jasmine Borroel, Paris Offor, Emily Eastwood, Javier Rodriguez, Kristen Buck, Derrick Gorospe, Elizabeth Valencia, Catherine Elix, Bridget Corcoran, Manuel Reyes, Samantha Lin, Raffaella Pippa

Certis Oncology Solutions, San Diego, CA

Glioblastoma (GBM) is the most common and aggressive malignant brain tumor in adults, where radiation therapy (RT) remains standard care. However, the precise immunomodulatory effects of RT-specifically on T cell checkpoint receptor profiles and memory T cells dynamics -within the tumor microenvironment are not fully elucidated. In this translational study, we utilized an orthotopic patient-derived xenograft (PDX) model, CRT361, engineered with a Luc+ reporter. This system was supported by an HLA-matched peripheral blood mononuclear cell (PBMC) humanization platform, providing a clinically relevant context for immune analysis. CRT361 cells were implanted intracranially into the right hemisphere, and tumors progression was monitored via multimodal imaging, bioluminescence imaging (BLI) and magnetic resonance imaging (MRI). Following successful PBMC engraftment and a single-dose focal irradiation (2 Gy), T cells were harvested from both peripheral blood and distinct brain hemispheres for profiling via spectral flow cytometry. Our results demonstrate that focal irradiation increased the frequency of both $CD8^+$ and $CD4^+$ central memory T cells (T_{CM}) in both blood and brain. Furthermore, irradiation led to elevated programmed cell death protein 1 (PD-1) expression on both $CD8^+$ and $CD4^+$ T_{CM} and naïve T cells in peripheral blood. Crucially, we observed an inverse response in the central nervous system: $CD8^+$ T_{CM} within the brain exhibited lowerPD-1 expression levels exclusively in the irradiated right hemisphere.These novel findings provide critical insight into the capacity of radiotherapy to dynamically influence T cell phenotypes and checkpoint receptor landscapes in a tissue-, region-, and cell type-specific manner within the GBM microenvironment. This study design and results establish a robust foundation for the rationale design and optimization of combinatorial strategies leveraging both radiation and emerging immunotherapies.

#2562 Quantitative and functional immune reprogramming induced by a nanomedicine in breast cancer model.

Mathilde Dacos[1], Lea Plantureux[2], Sarah Giacometti[1], Joseph Ciccolini[1], **Raphaelle Fanciullino**[3]

[1]COMPO SmartC, Aix-Marseille University, Marseille Cedex 07, France,[2]CVN AMUTICYT, Aix-Marseille University, Marseille Cedex 07, France,[3]Aix-Marseille University, Marseille Cedex 07, France

Nanoparticles (NPs) are emerging as a promising strategy in oncology, offering optimised drug delivery and the potential to modulate immune responses. In this study, we developed an innovative nanoparticle encapsulating docetaxel and functionalised with trastuzumab for precise targeting of HER2-positive tumours (called ANC for Antibody Nanoparticle Conjugate). Immunomodulatory effects were performed in C57BL/6 mice administered free docetaxel (1.6 mg-kg-^{1}) and trastuzumab (135 ng-kg-^{1}) by intraperitoneal injection (n = 29) or ANC (nanoparticles at the same docetaxel and trastuzumab doses as the free drugs, n = 40). Immune profiling was performed in blood (J0-J21) and tumor tissue (J21) to evaluate quantitative and functional changes in major lymphoid and myeloid subsets involved in antitumor immunity. Flow cytometric analyses included B cells, T cells ($CD4^+$, $CD8^+$), activated T-cell subsets, NK cells, regulatory T cells (Treg), myeloid-derived suppressor cells (MDSC), and regulatory B cells (Breg). In blood, no significant differences were observed between groups for B cells, NK cells, $CD4^+$ or $CD8^+$ T cells, or their activated subsets. A trend toward reduced Treg frequencies was detected in the ANC group compared with controls ($p = 0.053$), suggesting early systemic modulation of immunosuppressive activity. MDSC levels remained unchanged across all groups. In tumors, global B-cell levels were comparable between groups, but ANC-treated mice showed an increased proportion of Breg, indicating a potential local immunosuppression. NK-cell infiltration and activation tended to be higher in the ANC group ($p \approx 0.08$), suggesting localized immune stimulation. No differences were detected for $CD4^+$ T cells, whereas a reduction in $CD8^+$ T-cell frequency was observed in ANC-treated tumors. Treg levels also showed a decreasing trend ($p = 0.07$), consistent with a partial reduction in immunoregulatory pressure within the tumor microenvironment. MDSC levels did not differ significantly between conditions. ANC formulation exhibited subtle yet biologically relevant immunomodulatory trends, including reduced Treg frequencies and increased activated NK cells within the tumor, potentially favoring antitumor responses. Conversely, the elevated Breg population in ANC-treated tumors may counterbalance these effects by promoting local immunosuppression. These findings suggest that ANC may fine-tune the tumor immune landscape without inducing major systemic alterations. Further investigation with extended cohorts and functional assays will be required to confirm these trends and clarify their implications for therapeutic efficacy.

#2563 mTOR inhibition augments antitumor immune response by reprogramming the *TP53*-mutant, immune-cold HNSCC tumor microenvironment.

Priyatosh Nath, Alok Khandelwal, Tara Moore-Medlin, Chun Li, Cherie-Ann Nathan

Department of Otolaryngology-Head and Neck Surgery, LSUHSC-S, Shreveport, LA

Head and neck squamous cell carcinoma (HNSCC) with *TP53* mutations presents significant therapeutic challenges, characterized by high recurrence rates and treatment resistance. Using a *TP53*-mutant, PD-1 resistant syngeneic mouse flank tumor model, we investigated the immunomodulatory effects of mTOR inhibition (mTORi) followed by comprehensive bulk RNA sequencing analysis. Our transcriptomic analysis revealed profound alterations in multiple biological pathways, indicating significant shifts in the tumor microenvironment (TME). Treatment with the mTOR inhibitor Everolimus increased immune cell infiltration into the tumor through upregulated cytokine, chemokine activity, and enhanced chemokine receptor binding. mTORi also significantly altered the HIF-1α/VEGF angiogenic pathways, which otherwise promote an immune-cold TME and generate immunosuppressive myeloid-derived suppressor cells (MDSCs). Additionally, mTORi treatment interfered with PD-1/PD-L1 interaction between T cells and tumor cells by reducing PD-1 and PD-L1 expression, thereby augmenting T-cell cytotoxic function. These findings provide molecular evidence supporting mTORi as a promising therapeutic strategy for *TP53*-mutant, immune-cold, and immunotherapy-resistant HNSCC.

#2564 Investigating the combination of natural killer immunotherapy with radiation therapy for muscle invasive bladder cancer.

Fatima Inigo[1], Jose Mansure[1], Eva Michaud[1], Brian Meehan[2], Tanner Connell[3], Ciriaco Piccirillo[4], Wassim Kassouf[5]

[1]Cancer Research Program, McGill University Health Centre, Montreal, QC, Canada,[2]Cancer and Angiogenesis, McGill University Health Centre, Montreal, QC, Canada,[3]Medical Physics Unit, McGill University Health Centre, Montreal, QC, Canada,[4]Microbiology and Immunology, McGill University Health Centre, Montreal, QC, Canada,[5]Surgery, Division of Adult Urology, McGill University Health Centre, Montreal, QC, Canada

Background: Muscle-invasive bladder cancer (MIBC) is commonly treated with radical cystectomy (RC) or radiation therapy (RT). However, both approaches have significant limitations: RC is associated with a major impact on quality of life and a high risk of metastasis, while RT, despite preserving the bladder, has a recurrence rate of about 30%, largely due to the presence of radio-resistant tumors. This study explores the potential of combining adoptive Natural Killer (NK) cell immunotherapy with RT to enhance efficacy and offer a more effective bladder-preserving alternative.

Methods: Three human bladder cancer cell lines (UM-UC3, UM-UC1, RT4) were treated with RT (2 × 3 Gy), NK cells (5 × 10^6 cells IV, twice weekly for two weeks), or the combination. Cell viability was assessed using a colorimetric Kit-8 assay at effector-to-target ratios (1:1, 2:1, 5:1). *In vivo* efficacy was tested in a subcutaneous mouse model. Clinical relevance was examined using NanoString GeoMx spatial transcriptomic data from MIBC patients treated with RT (responders n = 107; non-responders n = 35). NK infiltration and NK-associated gene signatures were analyzed via Singscore and xCell deconvolution.

Results: RT significantly reduced viability in UM-UC3 and RT4 cells ($p<0.01$), and the combination of RT+NK further enhanced cytotoxicity ($p<0.001$). In UM-UC1, NK cells alone markedly decreased viability ($p<0.001$), with no additional reduction observed when combined with RT. *In vivo,* combination therapy produced a sustained reduction in tumor growth compared to RT ($p=0.0117$) or NK therapy alone ($p=0.0004$), demonstrating enhanced therapeutic efficacy. Clinically, responders exhibited higher NK infiltration ($p<0.01$), elevated NK anti-tumor scores ($p<0.01$), and increased expression of MICA, NKG2C, and HLA-E, molecules involved in NK-cell activation and target-cell recognition (all $p<0.05$).

Conclusion: Overall, our results suggest that NK cells can play an important role in improving the response to RT in MIBC. We observed that combining NK cell therapy with RT led to better tumor control in preclinical models, and clinical data supported this by showing that patients who responded to RT had higher NK cell infiltration and expression of key immune markers. While further studies are needed to confirm these findings, this work adds to growing evidence that NK cells could play a role in modulating treatment response. Exploring this further may help identify patients who are more likely to benefit from combination strategies and guide future efforts toward more personalized approaches in MIBC.

#2565 mTOR as a mechanistic biomarker of FLASH radiotherapy: Implications for immune-modulated melanoma treatment.

Madison Hawkins[1], Joshua Knight[1], Camden VanTassell[1], Landen Barnett[1], **Gennie Lynne Parkman**[1], Dani Johnson-Erickson[2], Ramesh Rengan[2]

[1]Weber State University, Ogden, UT,[2]Radiation Oncology, University of Washington, Seattle, WA

FLASH radiotherapy (FLASH-RT), which delivers ultra-high dose rate radiation, has emerged as a promising modality that reduces normal tissue toxicity without compromising tumor control. While preclinical data support its tissue-sparing properties, the underlying biological mechanisms remain incompletely defined. Understanding these pathways is critical for integrating FLASH into multimodal cancer therapy.Melanoma, a highly immunogenic and aggressive skin cancer, is increasingly treated with immune checkpoint inhibitors (e.g., anti-PD-1), yet many patients develop resistance. Radiation can enhance immunogenicity, but toxicity often limits dose escalation. The potential for FLASH to synergize with immunotherapy while minimizing side effects presents an exciting opportunity to optimize melanoma treatment.To investigate the immune contributions to the FLASH effect, female BALB/c mice received proton radiation delivered as FLASH (~80 Gy/s) or conventional (~0.5 Gy/s) at 0, 12, or 14 Gy. At 27 days post-treatment, skin tissues were analyzed using Data Independent Acquisition-Mass Spectrometry (DIA-MS). Machine learning-based feature selection identified tryptic peptides that distinguished FLASH from conventional treatment. mTOR (mammalian target of rapamycin)—a master regulator of immune signaling—and its binding partner Raptor were significantly upregulated in FLASH-treated skin, suggesting a distinct mTOR-driven pathway.Given mTOR's known role in modulating PD-L1 expression and immune suppression via interferon and TGF-β signaling, we hypothesized that FLASH may potentiate the efficacy of immune checkpoint blockade. Using in vitro and in vivo melanoma models, we evaluated responses to FLASH or conventional radiation with or without anti-PD-1 therapy. Mice treated with FLASH plus anti-PD-1 demonstrated promising improvements in survival, supporting potential synergy. Immunoblotting and immunofluorescence confirmed increased phospho-mTOR (Ser2448) and downstream effector activation in both normal and tumor tissues following FLASH.These findings identify mTOR as a candidate biomarker and mechanistic driver of FLASH responses and support further development of mTOR-informed, immune-responsive FLASH strategies in melanoma and other cancers.

#2566 KRAS^{G12D} inhibition enhances macrophage-mediated anti-tumor immunity via STING activation.

Xiaoe He, Xiangyan Jiang, Wengui Shi, Long Qin, Tao Wang, **Zuoyi Jiao**

Lanzhou University, Lanzhou, China

The KRAS^{G12D} mutation is a key oncogenic factor in pancreatic cancer, present in over 40% of cases, making it the most prevalent and the most poorly prognostic mutation. However, KRAS^{G12D} has been considered "undruggable," and thus remains a challenging target for therapeutic intervention. The novel KRAS^{G12D} inhibitor, RMC-9805 (Zoldonrasib), has shown promising efficacy and safety in clinical trials, offering hope to address the therapeutic void in KRAS^{G12D}-driven cancers. In this study, we utilized single-cell RNA sequencing to reveal that Zoldonrasib suppresses the SPP1/CD44 intercellular communication between tumor cells and macrophages, while promoting the antigen-presenting function of tumor-associated macrophages. Mechanistically, we observed that Zoldonrasib treatment induces mitochondrial damage and mtDNA release in tumor cells, leading to the activation of the cGAS/STING signaling pathway. Subsequently, STING-mediated phosphorylation of STAT1 inhibits the transcriptional activity of the key SPP1 transcription factor, STAT3, thereby downregulating SPP1 expression in tumor cells. Zoldonrasib enhances macrophage MHC-I antigen presentation by suppressing SPP1/CD44 signaling. In both immune-competent KPC mice and immune-reconstituted PDX models, the use of a clinical-stage STING1 agonist further promoted macrophage antigen presentation and enhanced the therapeutic efficacy of Zoldonrasib, while also sensitizing pancreatic cancer to immune checkpoint inhibitors. This study uncovers the regulatory role of KRAS^{G12D} inhibition via Zoldonrasib in anti-tumor immunity and proposes a promising combinatorial therapeutic approach for clinical trials.

#2567 Axl is a negative regulator of type I IFN in cDC1s hindering anti-tumor immunity.

Isaac Gonzalez[1], Eslam A. Elghonaimy[1], Qiongwen Zhang[1], Isaac Montgomery[1], Peter Q. Leung[1], Arely P. Rodriguez[1], Rolf A. Brekken[2], **Todd A. Aguilera**[1]

[1]Radiation Oncology, UT Southwestern, Dallas, TX,[2]Surgery, UT Southwestern, Dallas, TX

Background: The receptor tyrosine kinase Axl is widely implicated in tumor progression and immune evasion, yet its role in antitumor immunity remains poorly defined.
Methods: Investigate the role of Axl on tumor growth, using animal models, genetic crosses, cellular assays, and single cell RNAseq from human and mouse tumors.
Results: Here, we uncover Axl as a key negative regulator of type I interferon signaling in dendritic cells, with direct consequences for $CD8^+$ T cell priming and tumor control. Axl-deficient mice exhibited delayed tumor growth that was dependent on $CD8^+$ T cells and BATF3, highlighting a requirement for cross-presenting cDC1s. Conditional knockout models confirmed that Axl loss in dendritic cells—but not macrophages—was sufficient to enhance antitumor immunity through type I interferon pathways. Mechanistically, Axl ablation increased cDC1 cross-priming capacity and amplified the therapeutic effects of a STING agonist and radiotherapy.
Conclusion: These findings position Axl as an intrinsic checkpoint in cDC1s that restrains interferon-driven immunity, revealing a mechanism by which innate regulation of dendritic cells shapes adaptive antitumor responses.

#2568 SIRT1 inhibits T cell infiltration and tertiary lymphoid structure formation to promote radioimmunotherapy resistance.

Yunxing Shi[1], Zongfeng Wu[2], Shaoru Liu[2], Renhan Luo[1], Liang Kang[1]

[1]Department of General Surgery (Colorectal Surgery), The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[2]State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research for Cancer, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Microsatellite stable (MSS) rectal cancer is intrinsically resistant to immunotherapy. Although radiotherapy is often combined with immune checkpoint inhibitor (ICIs) to enhance immunotherapy responses, many immunologically cold tumors remain unresponsive.
Methods: The radiotherapy-induced antitumor immunity effect of SIRT1 inhibition was assessed in murine models. The mechanisms of SIRT1 and DDX5 in tumor immune escape with radiotherapy were determined in vitro and in vivo. The synergistic effects of SIRT1 inhibitor or aspirin plus radiotherapy with PD-1 blockade were also investigated.
Results: We observed a significant increase in electron transport chain activity, acetyl-CoA level, and pan-acetylation level in patients achieving pathologic complete response (pCR) following immunotherapy administered after radiotherapy. Through transcriptomic screening and in vivo experiments, we found that SIRT1, a key executor in regulating protein acetylation, restricted the immunostimulatory effects of radiotherapy. Mechanistically, SIRT1 deacetylates DDX5, promoting its unwinding of irradiation-induced R-loop and inhibiting the accumulation of cytoplasmic RNA: DNA hybrids, thereby suppressing the cGAS/STING pathway and T cell infiltration. Interestingly, we found that radiotherapy forced the tryptophan-SIRT1-SLC36A4 positive feedback, further enhancing SIRT1 activity and competitively uptaking tryptophan in the microenvironment, thereby inhibiting TLS formation and leading to poor efficacy of radioimmunotherapy. Finally, we discovered that both SIRT1 inhibitor and aspirin plus radiotherapy converts ICI-unresponsive rectal cancer into immunogenic tumors that are hyper-sensitive to ICI.
Conclusions: SIRT1 is a potential biomarker and therapeutic target to overcome radioimmunotherapy resistance.

#2569 Particle therapy, ATM and PD-1 inhibition for pMMR rectal cancer.

Cameron M. Callaghan

Radiation Oncology, Mayo Clinic Hospital-Rochester, Rochester, MN

Background and Aims: Colorectal cancer is a leading cause of cancer mortality and most rectal cancers are mismatch repair proficient (pMMR), making them largely resistant to PD-1 inhibitors (PD1i). While PD1i achieves excellent complete response rates in MMR-deficient tumors, these represent <5% of rectal cancers. For the remaining 95% of patients, effective immunotherapy strategies are urgently needed. We evaluated two high-LET radiation approaches to prime pMMR rectal cancers to PD1i and enhance local control: 1) Diffusing alpha emitter Radiation Therapy (DaRT) implants, and 2) LET-optimized (Bragg Peak) protons + ATM inhibitor. An ATM inhibitor was evaluated with protons to evaluate whether it could produce a more alpha/carbon-like effect given the lower comparative LETd achievable in clinical treatment plans.

Methods: In vitro proton irradiation of HCT116, HT29, SW480, and CT26 was performed as previously with dose averaged LET (LETd) values of 2.2 keV/um for ENT and 7.0 keV/um for BP protons. Female Balb/C mice were subcutaneously inoculated with 1×10^6 CT26 cells on one flank and 1×10^5 cells on the contralateral flank to establish primary and secondary (abscopal) tumors, respectively. PD1i monoclonal antibody (RMP1-14 Bio X Cell) was administered i.p. 100ug every 72 hours for 4 total doses. The ATM inhibitor AZD1390 was delivered via oral gavage at 20 mg/kg, PO 1 hour prior to radiation. For in vivo studies, radiation was delivered using a PXI SmART small animal irradiator with opposing lateral beams (225 kVp, 20 mA, 0.3mm Cu filter). Proton irradiation plans were produced as previously described. We used mass cytometry by time of flight (CyTOF) using the TME CD45 lymphocyte subpopulations based on multiple cell markers.

Result: In our preliminary data we demonstrate that both DaRT and BP protons+ATMi synergize with PD1i to dramatically increase complete response rates at both primary and abscopal tumors by increasing DNA damage, activating innate immune pathways, and reducing immunosuppression within the tumor microenvironment. Critically, this effect was observed in a pMMR model which did not respond to PD1i or conventional X-rays+PD1i, highlighting the innovation and potential impact of this work.

Conclusion: DaRT and BP protons ATMi prime pMMR colorectal cancer to PD1i, and all elements are clinically translatable.

#2570 Reprogramming T-cell networks to overcome immune evasion in ovarian cancer relapse.

Denarda Dangaj Laniti

Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

Ovarian cancer (OC) remains a major clinical challenge due to its high recurrence rates and resistance to standard therapies. High-grade serous ovarian cancer (HGSOC), the most common and aggressive OC subtype, often presents with tumor-infiltrating lymphocytes (TILs), yet immune checkpoint blockade (ICB) therapies have shown limited efficacy. Our studies aim to dissect the spatiotemporal evolution of the OC tumor microenvironment (TME), reprogram T cell networks, and develop next-generation immunotherapies to restore anti-tumor immunity. We integrated high-resolution spatial proteomics, single-cell transcriptomics, and computational modeling to map TIL dynamics across primary, recurrent, and treatment-resistant OC. Preclinical models, including syngeneic BRCA1-mutant and wild-type mouse models of OC recurrence, are employed to investigate tumor-intrinsic and TME-driven mechanisms of immune suppression during OC relapse. We utilized digital pathology multiplex immunofluorescence (mIF) to classify 697 ovarian cancer (OC) specimens from five independent cohorts, offering the most extensive CD8+ T cell-based immune profiling to date. Our predictive algorithm identified distinct tumor immune phenotypes in OC (i.e. purely inflamed, mixed inflamed, excluded, and desert) based on TIL infiltration and spatial organization, which correlate with HRD status and predict therapeutic outcomes. We observed significant immune and molecular heterogeneity between these tumor immune phenotypes and their dynamics during disease recurrence. Inflamed HRD tumors, maintained T cell-myeloid niches post-chemotherapy. In preclinical models, this was associated with restoration of genomic rearrangements. Recurrent murine HRD tumors upregulated the immunosuppressive PGE2-EP2/4 pathway and targeting of COX-driven PGE2 production during chemotherapy significantly prolonged relapse and survival in preclinical mouse models, identifying a key vulnerability for the recurrence of human HRD OCs. In contrast, homologous recombination repair proficient (HRP) OC tumors evolved into T-cell excluded or desert phenotypes, characterized by malignant cells overexpressing Nduf4l2/Galectins and Trem2/ApoE overactive tumor-associated macrophages (TAMs). Our data suggest that therapeutically targeting of TREM2 overexpressing TAMs may improve anti-tumor immune responses and delay recurrence after first-line chemotherapy in HRP OC. By unraveling the cellular and molecular networks driving immune evasion in recurrent OC, our findings provide a roadmap for precision immunotherapy. Our work highlights novel immune biomarkers and therapeutic targets that can be exploited to retune anti-tumor T cell responses, paving the way for clinically actionable strategies in recurrent OC and other immune-resistant malignancies.

#2572 Pharmacological targeting of CTPS1 elicits macrophage-mediated anti-leukemia immunity.

Meng Liu[1], Lei Zhang[1], Xin He[1], Haojie Dong[1], Yang Li[1], Shuaishuai Ge[1], Guohua Wu[1], Yadav P. Umesh[1], Wei Chen[2], Pinghui Feng[3], Guido Marcucci[1], Ling Li[4]

[1]Beckman Research Institute, City of Hope National Medical Center, Monrovia, CA,[2]Beckman Research Institute, City of Hope National Medical Center, Duarte, CA,[3]Section of Infection and Immunity, University of Southern California, Herman Ostrow School of Dentistry, Los Angeles, CA,[4]City of Hope National Medical Center, Duarte, CA

Immunotherapy has limited efficacy in acute myeloid leukemia (AML), partly because innate immune cells such as macrophages remain inactive. Nucleotide metabolism regulates key cellular processes, and cytidine triphosphate synthase 1 (CTPS1), the enzyme responsible for de novo CTP synthesis, is essential for cell proliferation. We previously showed (Liu, 2024 ASH) that high CTPS1 activity promotes AML growth and suppresses antitumor immunity. Accordingly, the CTPS1 inhibitor STP-B significantly prolonged the survival of immunocompetent leukemic mice in an immune-dependent manner. Across TCGA cancers, CTPS1 expression negatively correlated with M1-macrophage signatures.Here, we show that STP-B exerts anti-AML activity by (1) inducing myeloid differentiation, especially M1-like macrophage polarization through dNTP imbalance, and (2) activating IFN-I signaling by blocking CTPS1-mediated deamidation of IRF3 and histone H1. In a syngeneic MLL-AF9 (MA9) model, daily oral STP-B (100 mg/kg, 3 weeks) reduced leukemia burden and markedly increased $CD11b^+F4/80^+$ macrophages, enriching the M1-like subset. Macrophage depletion completely abolished the survival benefit. Combination with anti-CD47 produced strong synergy. Transcriptomic analysis of MA9 cells and non-malignant myeloid cells showed induction of M1-associated genes (Il6, Il1a, Cxcl9, Cxcl10). Ex vivo, STP-B-treated BMDMs displayed significantly enhanced phagocytosis of MA9 cells. To evaluate human hematopoietic effects, $CD34^+$ cord blood-engrafted NSG mice were treated with STP-B. While total human $CD45^+$ levels were unchanged, myeloid ($CD33^+CD11b^+$), monocyte ($CD14^+CD64^+$), and $HLA\text{-}DR^+CD86^+$ M1-like macrophage populations increased, with higher expression of myeloid transcription factors and human M1 genes. Metabolomic profiling of THP-1 cells confirmed that STP-B markedly reduced intracellular CTP, indicating nucleotide imbalance. Ribonucleotide reductase inhibition partially restored balance, reversed differentiation, and suppressed STP-B-induced M1-gene expression, supporting a nucleotide-driven differentiation mechanism. GSEA demonstrated induction of IFN-I-responsive genes. STP-B increased γH2AX and nuclear S9.6 staining, consistent with DNA damage caused by inhibition of CTPS1-mediated histone H1 deamidation. STP-B also blocked CTPS1-dependent IRF3 deamidation, enhancing ISG expression. Reconstitution of CTPS1-knockout THP-1 cells with a glutaminase-deficient CTPS1 mutant similarly increased ISGs, indicating that CTPS1 deamidation activity suppresses IFN signaling. Together, these findings show that STP-B promotes macrophage specification and innate immune activation, defining STP-B as a leukemia-ablating agent with strong immunostimulatory properties.

#2573 Identification and characterization of platinum agent-induced chemoimmunomodulation in triple-negative breast cancer.

Mariana Makarem, Kathleen Streeks, Claudia Perez Perez, Iasmim Lopes de Lima, Mohammed Gbadamosi

Department of Pharmacotherapy and Translational Research, University of Florida, Gainesville, FL

Triple-negative breast cancer (TNBC) is the most aggressive breast cancer subtype. Although early-stage outcomes have improved, advanced TNBC (aTNBC) continues to have poor outcomes, with a median overall survival < 18 months and heterogeneous benefit from first-line therapy. Although there have been advances in aTNBC therapy, chemotherapy remains central to curative regimens. Among the most critical dimensions of chemotherapeutic efficacy are immunomodulatory effects elicited by chemotherapy (chemoimmunomodulation; (CIM)). Platinum agents are commonly used in aTNBC and induce CIM through ROS generation, immunogenic cell death, DAMP release, and cGAS-STING/interferon signaling. However, platinum-induced CIM induction is heterogeneous and cell type-dependent, thereby limiting its efforts to optimize its use. The goal of this study was to identify and characterize platinum agent-induced CIM to address this challenge. To achieve this, we applied our Chemoimmunomodulation Induction Classifier (CIMIC) pipeline to delta gene expression values (ΔGE; $\Delta\log_2(\text{TPM}+1)$) derived from human TNBC cell lines (N = 8; 3 biological replicates each) profiled via bulk RNA-sequencing pre- and post-48-hour IC_{30} cisplatin exposure. CIMIC is an iterative unsupervised clustering pipeline that classifies samples into distinct groups based on their induction of 3,100 genes spanning 19 CIM pathways. Two distinct CIM states emerged: a functional (Fun-CIM) and a dysfunctional (Dys-CIM) state. The Fun-CIM state exhibited significantly elevated induction of antitumoral inflammatory markers (*TNFAIP8L1* and *TNSF12*) and reactive oxygen species potentiators *(ABL1*) (Fun-CIM vs Dys-CIM all fold change (FC) > 1.50; $p < 0.05$; FDR < 0.10), whereas the Dys-CIM state exhibited elevated induction of DNA-damage repair molecules (*XRCC4* and *XPA*), unfolded protein response genes (*SEC61G*) , and proteostasis mediators (*RPS3A* and *RPS*) (Dys-CIM vs Fun-CIM all fold change (FC) > 1.12 ; $p < 0.05$; FDR < 0.10) Overrepresentation analysis revealed an enrichment for cytokine production, reactive oxygen species response, and phagocytic potentiation for the genes induced within the Fun-CIM group, and proteostasis programs within the Dys-CIM group ($p < 0.05$ FDR < 0.15) corroborating our findings. Together, these data show that CIMIC hold promise in resolving platinating agent-induced immunomodulation into functional and dysfunctional induction states from paired pre-/post- transcriptomes. Our results highlight CIM heterogeneity in response to platinating agent administered at the same potency and highlight tumor-intrinsic stress-adaptation as a potential key determinant of CIM trajectory. To our knowledge, CIMIC is the first unsupervised pipeline built to classify CIM trajectories. Future work will define baseline predictors of CIM trajectories with respect to platinum agents.

#2574 Identification and characterization of chemoimmunomodulatory induction trajectories in breast cancer via unsupervised transcriptomic analyses of pre- and post-treatment specimens.

Iasmim L. de Lima, Kathleen H. Streeks, Elizabeth Molchan, Mariana S. Makarem, Kennedy L. Coleman, Mohammed O. Gbadamosi

Department of Pharmacotherapy and Translational Research, University of Florida, Gainesville, FL

Chemotherapy is key to curative treatment strategies for aggressive breast cancer (BC). Despite this, the molecular features governing the immunomodulatory effects of chemotherapy (chemoimmunomodulation; CIM), which enable efficacy and synergy with other treatment modalities, are understudied, thereby limiting optimization of chemotherapeutic regimens to improve patient outcomes. A key roadblock to these efforts has been the lack of a robust framework for classifying CIM induction trajectories. To address this challenge, we developed the CIM Induction Classifier (CIMIC), an iterative unsupervised clustering pipeline that uses delta gene expression (Δlog2(TPM+1)) of 3,100 genes across 19 CIM pathways from paired pre- and post-treatment tumor transcriptomes to classify CIM induction trajectories. We applied CIMIC to data from two cohorts (GSE191127 (N = 20) and GSE12845 (N = 16)) of BC patients treated with neoadjuvant chemotherapy to identify distinct CIM trajectories and characterize the tumor-intrinsic and tumor-extrinsic programs underlying CIM heterogeneity. In both cohorts, the classifier consistently assigned patients to one of two CIM trajectories, functional CIM (Fun-CIM; N = 17) or dysfunctional CIM (Dys-CIM; N = 19). Overrepresentation analyses of induced genes showed an enrichment for immunostimulatory programs, including immune-effector differentiation, function, and cell killing (FDR ≤ 0.01) and tumor-intrinsic stress adaptation programs, including proteostasis, unfolded protein response, and mitochondrial homeostasis (FDR ≤ 0.01) for the Fun-CIM and Dys-CIM, respectively. Interestingly, Dys-CIM was overrepresented in the basal-like molecular subtype in both cohorts ($p < 0.05$) and, where data were available, was associated with recurrence ($p = 0.041$; N = 20). To further evaluate the clinical relevance of these induction states, we derived trajectory-specific signatures and applied single-sample gene set analysis to baseline tumors from chemotherapy-treated patients in the METABRIC (N = 412) and SCAN-B (N = 2,774) cohorts. In multivariable Cox models adjusted for treatment, clinicopathological features, and molecular subtype, the high Dys-CIM signature was associated with inferior overall survival (METABRIC, HR = 1.83, $p = 0.041$; SCANB, HR = 1.73, $p = 0.014$), poorer disease-specific survival (METABRIC, HR = 1.94, $p = 0.035$), and lower recurrence-free survival (METABRIC, HR = 1.68, $p = 0.019$), suggesting that a predisposition toward Dys-CIM represents a clinically adverse signature detectable at baseline. Taken together, our findings herein provide rationale for dissecting clinically relevant CIM trajectories and responses, supporting future efforts to link induced CIM trajectories to clinical outcomes and personalized immunomodulation strategies.

#2575 Identification and characterization of anthracycline-induced chemoimmunomodulation in triple-negative breast cancer.

Kennedy L. Coleman[1], Kathleen Streeks[2], Mariana Makarem[3], Iasmim Lopes de Lima[4], Mohammed Gbadamosi[2]

[1]Pharmacotherapy and Translational Research, University of Florida, Gainesville, FL,[2]University of Florida, Gainesville, FL,[3]UF Clinical and Translational Science Institute, Gainesville, FL,[4]Department of Pharmacotherapy and Translational Research, University of Florida, Gainesville, FL

Triple-negative breast cancer (TNBC) is the deadliest breast cancer subtype with a median survival < 24 months in advanced cases. While TNBC treatment has advanced, chemotherapy remains a cornerstone of curative treatment. Despite its central role in TNBC treatment, the molecular drivers underpinning the immunomodulatory effects of chemotherapy (chemoimmunomodulation; CIM), which enable long-term efficacy and synergy with other therapeutic modalities, remain understudied, thereby limiting efforts to optimize chemotherapeutic regimens. This study aims to identify and characterize anthracycline-induced CIM states to address this challenge. To achieve this, we applied our Chemoimmunomodulation Induction Classifier (CIMIC) pipeline to delta gene expression values (ΔGE; $\Delta\log_2(\text{TPM}+1)$) derived from TNBC cell lines (N = 6; 3 biological replicates each) profiled by bulk RNA-sequencing pre- and post-48-hour IC_{30} doxorubicin exposure. CIMIC is an iterative unsupervised clustering pipeline that classifies samples into distinct groups based on their induction of 3,100 genes spanning 19 CIM pathways. Using CIMIC, we identified two discrete CIM trajectories in our samples, a functional one (Fun-CIM; N = 3 cell lines) and a dysfunctional one (Dys-CIM; N = 3 cell lines) that were highly distinct (silhouette = 0.95) and stable as determined via standard clustering metrics across multiple bootstraps; proportion of ambiguous clustering = 0.00; cluster consensus score = 1). The CIM states were characterized by significantly differential induction of antitumoral inflammatory markers, including chemoattractants (*CXCL14*) and immune mediators (*IFNB1* and *IL12A/B*) (Fun-CIM vs Dys-CIM all fold change (FC) ≥ 1.3; $p < 0.05$; FDR < 0.15), and protumoral markers, including tumor surveillance inhibitors (*THBS1* and *TGFB2*), immunosuppressive cell population mediators (*NNMT*), and tumor-intrinsic stress adaptation signals (*EIF2A, YARS1,* and *XPOT*) (Dys-CIM vs Fun-CIM all FC ≥ 1.3; $p < 0.05$; FDR < 0.15). Overrepresentation analysis of induced genes identified an enrichment of proteostasis and mitochondrial homeostasis programs within the Dys-CIM Group and metabolic rewiring within the Fun-CIM group (FDR < 0.01). Altogether, CIMIC enabled classification of distinct CIM induction states from paired pre- and post-treatment transcriptomic analysis, allowing interrogation of CIM in a manner not captured via traditional chemoresistance studies alone, the dissection of CIM heterogeneity, and the discovery of underappreciated molecular programs that may underlie dysfunctional CIM in TNBC. To our knowledge, CIMIC is the first unsupervised pipeline specifically designed to classify CIM trajectories. Future work will focus on characterizing baseline molecular features that may influence these CIM induction states, toward the goal of informing personalized TNBC chemotherapeutic regimen.

#2576 Gut-targeted antibiotic modulation enhances radiotherapy response in NSCLC and uncovers epigenetic and microbiome-driven immune programs enabling live biotherapeutic design.

Steven J. Feigenberg[1], Francesca Costabile[1], Ceylan Tanses[1], Kyle Bittinger[1], Divyansh Agarwal[1], Roddy O'Connor[2], Jeffrey Bradley[2], Amit Maity[1], Benjamin A. Garcia[3], **Andrea Facciabene**[2]

[12]University of Pennsylvania, Philadelphia, PA,[3]Washington University School of Medicine in St. Louis, St. Louis, MO

Stereotactic body radiotherapy (SBRT) can induce immunogenic cell death and stimulate systemic antitumor immunity, yet clinical responses remain heterogeneous. Preclinical studies indicate that the gut microbiome modulates host immune tone and influences responsiveness to therapy. We previously demonstrated in lung cancer and melanoma models that oral vancomycin enhances the antitumor effects of radiotherapy by depleting Gram-positive taxa responsible for generating short-chain fatty acids (SCFAs) and other immunosuppressive metabolites. Based on these observations, we conducted the first randomized clinical pilot study evaluating SBRT with or without oral vancomycin in early-stage non-small cell lung cancer (NSCLC). Patients eligible for SBRT (50 Gy in 4-5 fractions) were randomized to SBRT alone or SBRT plus vancomycin administered for one week before and five weeks after SBRT. Serial stool, serum, and PBMC samples were collected at five predefined time points. Primary endpoints were feasibility and safety, while immune activation; progression-free survival; overall survival; and changes in stool SCFAs served as exploratory endpoints. Seventeen patients enrolled; seven completed vancomycin treatment. No grade ≥3 toxicities occurred, and gastrointestinal symptoms were the most frequent adverse events. Cancer recurrence occurred in four patients, three of whom received SBRT alone, with nodal failure as the predominant pattern. Microbiome sequencing revealed marked reductions in specific Gram-positive taxa and compensatory expansion of vancomycin-resistant organisms. Stool metabolomics demonstrated substantial decreases in SCFAs in the vancomycin arm. RNA sequencing of PBMCs showed robust enrichment of antigen-processing and presentation pathways, together with interferon-related immune activation signatures. To extend these findings, we performed epigenetic and functional validation studies. PBMC chromatin profiling confirmed increased accessibility at interferon- and antigen-presentation-associated regulatory regions in vancomycin-treated subjects. Guided by these results, we evaluated whether the vancomycin effect was microbiome-transferable by engrafting stool from SBRT-alone or SBRT+vancomycin patients into antibiotic-conditioned mice. Mice colonized with post-vancomycin human stool reproduced the enhanced radiotherapy response, demonstrating that the immune effects are mediated by the gut ecosystem. These results provide the mechanistic rationale for developing ViRTuE-LTP (RT-enhancing live biotherapeutic) candidates. Consistent with the clinical observations, a defined 3-strain ViRTuE-LTP consortium enhanced APC activation and potentiated RT responsiveness in complementary murine studies.

#2577 Free and encapsulated tunicamycin significantly enhances the suppression of PD-L1 by gemcitabine through blocking K-Ras^{G12D} expression in pancreatic ductal adenocarcinoma cells.

Axel Hugo Breier[1], Sunil P. Upadhyay[2], Ojaswitha Ommi[3], Stefan Bossmann[3], Sushanta K. Banerjee[4], **Snigdha Banerjee**[4]

[1]Kansas City VA Medical Center, Kansas City, MO,[2]Cancer Research Unit, Kansas City VA Medical Center, Kansas City, MO,[3]Cancer Biology, University of Kansas Medical Center, Kansas City, KS,[4]Pathology and Laboratory Medicine, University of Kansas Medical Center, Kansas City, KS

Pancreatic ductal adenocarcinoma (PDAC) remains one of the leading causes of cancer mortality worldwide, including among U.S. Veterans, and it is expected to become the second leading cause by 2040. The standard treatment options include surgical resection (when possible), chemotherapy, targeted therapy, immunotherapy, and radiation therapy. These treatments can be administered individually or in combination. Unfortunately, these treatment options have not significantly improved overall survival rates for patients with PDAC. Thus, currently, the first-line treatments for PDAC are still FOLFIRINOX (a combination of fluorouracil, leucovorin, oxaliplatin, and irinotecan) and Gemcitabine (GEM), either alone or in combination with nab-paclitaxel. While initial responses to chemotherapy, such as Gemcitabine alone or with other agents, can occur, these are often followed by the development of resistance. This resistance leads to increased programmed death-ligand 1 (PD-L1) expression in PDAC cells via the JAK-STAT pathway, posing a significant challenge for immunotherapy. Consequently, there is an urgent need for targeted therapies to overcome these limitations. Our research has identified Tunicamycin (TM), a glycosylation inhibitor antibiotic, as a potent agent that effectively targets PDAC cells and significantly reduces GEM-induced PD-L1 production. We found that treating Panc-1 and KPC cells with free or nanoencapsulated Tunicamycin (^{NP}TM) at a dose of 0.25 μM for 48 hours can overcome the limitations associated with Gemcitabine. Specifically, we observed that Gemcitabine treatment at 0.5 μM did not suppress PD-L1 expression; however, when combined with TM, Gemcitabine significantly reduced PD-L1 levels in these cells *in vitro* and *in vivo*. Although the mechanism by which TM regulates PD-L1 is not fully understood, previous studies have shown that K-RAS mutations can directly influence PD-L1 expression by activating the MAPK/ERK pathway, which Tunicamycin inhibits. Therefore, we hypothesize that TM reduces PD-L1 expression in PDAC cells by suppressing K-RAS^{G12D}. (These studies are supported by the VA Merit grants)

#2578 Clinical feasibility study of Optim.AI 2.0, a co-culture high-content functional precision platform for predicting combinatorial immunotherapy response.

Sharon Pei Yi Chan[1], Masturah Rashid[1], Jhin Jieh Lim[1], Weng Tong Ho[1], **Edward Kai-Hua Chow**[2]

[1]KYAN Technologies, Singapore, Singapore,[2]KYAN Technologies, Los Angeles, CA

Background: Immunotherapies have advanced cancer treatment, but variable outcomes and the lack of robust predictive biomarkers limit their use. Better patient selection and rational combination strategies could expand their effectiveness. Optim.AI™ is a combinatorial functional precision medicine platform previously shown to identify effective combination treatments for hematologic cancers and sarcoma. Earlier versions guided chemo- and targeted therapy choices but lacked immune components, restricting the drugs assessed. Here, we evaluate the clinical feasibility of Optim.AI™ 2.0, which integrates high-content imaging with tumor-immune ex vivo co-cultures to predict responses to immunotherapy combinations across solid and hematologic tumors.
Methods: For Optim.AI™ 2.0, peripheral blood mononuclear cells and tumor cells (non-Hodgkin lymphomas, gynecological cancers or gastrointestinal cancers) were fluorescently labeled to facilitate cell tracking. Combinatorial drug treatment was carried out on co-culture models with indication-specific 12-drug panels, including monoclonal antibodies, antibody-drug conjugates and bispecific antibodies. High-content imaging analysis of tumor-specific cell death was evaluated for Optim.AI™ 2.0 analysis, which searches 531,441 possible permutations derived from 155 ex vivo test combinations to predictively rank all clinically actionable treatments within the drug panel. Clinically relevant immunotherapies were compared with patient-specific factors—disease stage, subtype, and treatment history—to assess concordance with predicted responses.
Results: Optimized effector-to-target ratios were established to effectively quantify immune-mediated tumor killing, including antibody-dependent cellular cytotoxicity. High-content imaging captured tumor-specific killing and key immune-tumor interactions such as immune cell migration and tumor infiltration. Across multiple indications, Optim.AI™ 2.0 demonstrated feasibility by detecting antigen-dependent responses and identifying context-specific immunotherapy combinations in both hematologic and solid tumor models. It accurately predicted sensitivity or resistance to first-line rituximab in naïve and relapsed/refractory diffuse large B-cell lymphoma and revealed additional immunotherapy combinations with potential utility in later treatment lines.
Conclusion: We developed a high-content functional analytics platform that assesses immunotherapy drug sets in a physiologically relevant tumor-immune co-culture system. With further validation, it could help clinicians select effective immunotherapies. When paired with molecular profiling, Optim.AI™ 2.0 may identify novel immunotherapy combinations for specific patient populations defined by known or emerging biomarkers.

#3806 Development of a novel CAR T-cell therapy targeting thymic carcinoma.

Layla Ahmadi[1], Malak Khalifeh[2], Dimitar Donovski[1], DuyKhanh Pham Ceppa[3], Patrick Loehrer[3], Rohan Maniar[3], Huda Salman[2]

[1]Indiana University School of Medicine, Indianapolis, IN,[2]Indiana University Brown Center for Immunotherapy, Indianapolis, IN,[3]Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN

Introduction: Thymic carcinoma is a rare, highly aggressive mediastinal malignancy with limited effective therapies and considerable toxicity associated with immune checkpoint inhibitors. Although CAR T-cell therapy has revolutionized the treatment landscape for hematologic malignancies, its application to solid tumors, including thymic epithelial tumors, remains challenging due to disease rarity, a paucity of validated surface targets, and the risk of on-target, off-tumor autoimmune toxicity. In this study, we sought to address these barriers by characterizing antigen expression profiles across thymic carcinoma-relevant cell lines, engineering novel CAR constructs against prioritized candidate antigens, and evaluating antigen-specific cytotoxicity. These efforts aim to inform the development of next-generation cellular therapies tailored to the unique biology of this aggressive and understudied tumor type.
Methods: Surface expression of TROP-2, c-KIT, and CD70 was quantified on candidate cell lines using flow cytometry. CAR T-cells were produced from healthy donor PBMCs via lentiviral transduction and expanded ex vivo. CAR expression was confirmed by detection of Fab fragments on $CD3^+$ T cells. Antigen-specific cytotoxicity was evaluated in vitro using co-culture assays with selected antigen-positive cell lines, and target cell killing was quantified by 7-AAD staining and flow cytometric analysis.
Results: Flow cytometry demonstrated robust surface expression of TROP-2 (83%), c-KIT (88%), and CD70 (99%) across the T1889, Kasumi, and U266 cell lines, respectively. Lentiviral transduction yielded CAR^+ T cell populations of 48.2% (TROP-2), 24.7% (c-KIT), and 47.5% (CD70). All three constructs exhibited potent antigen-specific cytotoxicity substantially exceeding GFP^+ $CD3^+$ control T cells, confirming selective recognition and killing of target cells. These findings provide some of the first in vitro evidence supporting TROP-2, c-KIT, and CD70 as viable immunotherapeutic targets for thymic carcinoma and demonstrate effective CAR expression and selective cytotoxicity. This work establishes a foundation for rational multi-antigen CAR T cell design in a historically understudied solid tumor. Ongoing studies include FACS-based CAR enrichment, characterization of exhaustion markers, development of a dual-antigen synNotch CAR to mitigate off-tumor toxicity, and in vivo validation in murine models to support future clinical translation.

Poster Session

#2582 Advancing liquid biopsies via integrated CRISPR-based extracellular vesicle RNA and protein analyses.

Cesar M. Castro[1], Jayeon Song[2], Hakho Lee[3]

[1]Mass General Brigham Cancer Institute, Boston, MA,[2]Sungkyunkwan University, Suwon-si, Korea, Republic of,[3]Center for Systems Biology, Massachusetts General Hospital, Boston, MA

BACKGROUND: We developed REPAIR, an integrated urine-based platform combining extracellular vesicle (EV) mRNA and protein profiling with CRISPR to enable non-invasive, multiparametric disease monitoring. Bladder cancer, our clinical use case, remains the costliest cancer to surveil and treat given the high mortality when advanced. Current surveillance of localized disease relies on invasive cystoscopy, lacking the molecular specificity for risk stratification and frequent treatment monitoring.

METHODS: We significantly advanced our recent mRNA-focused CRISPR-Cas13 assay achieving sub-attomolar sensitivity and single-nucleotide resolution in plasma (*Nature Biotech*, 2025 [cover article]; PMID: 39375445), by: (1) integrating dual EV mRNA *plus* protein detection; (2) automating sample processing with innovative disc-based microfluidics we developed; and (3) translating to urine as the clinical matrix. As proof-of-concept, we designed REPAIR probes targeting EV proteins (CD63, EGFR, EpCAM, PD-L1) and mRNAs (GAPDH, LASS2, GALNT1) also relevant to bladder cancer. For protein detection, aptamers were used as affinity ligands. These aptamers were initially hybridized with complementary RNA sequences (initiator RNAs). When the aptamers bound to targets, the initiator RNAs were released and detected through REPAIR. A non-aptamer based strategy was employed for mRNA detection. Urine samples from 85 bladder cancer patients (mostly non-muscle invasive) undergoing treatment and 98 healthy controls were analyzed using the unified REPAIR protocol.

RESULTS: Multiparametric profiling revealed significantly elevated marker expression in cancer versus control urine ($p<0.05$ for all markers). Integrated logistic regression combining protein and mRNA markers achieved 98% detection accuracy (AUC=0.95; 95% CI: 0.92-0.98). Single-marker analysis showed inferior performance, demonstrating the critical value of a multiparametric CRISPR-based EV approach. Integrated readouts were achieved within 60 minutes.

CONCLUSION: REPAIR greatly facilitates simultaneous EV protein-RNA profiling in urine—a non-invasive, scalable liquid biopsy for bladder cancer surveillance and treatment monitoring. These findings potentially establish a nanotechnology-based platform for same-visit precision monitoring in a disease with an extraordinary economic burden and surveillance challenges. Current experiments in other malignancies where urine serves as a proximal fluid are ongoing.

#2583 Tumor-informed circulating tumor DNA dynamics reflect aggressive histology and radiologic disease status in renal cell carcinoma.

Eric Martin[1], Eun-mi Yu[1], Annika Murthi[1], Hongkun Wang[2], Laura Linville[1], Jeanny B. Aragon-Ching[1]

[1]Inova Schar Cancer Institute, Fairfax, VA,[2]Department of Biostatistics, Bioinformatics, and Biomathematics, Georgetown University, Washington, DC

Introduction: Circulating tumor DNA (ctDNA) enables minimally invasive monitoring of tumor biology and treatment response. Although ctDNA is increasingly used across malignancies, its utility in renal cell carcinoma (RCC) has not been well established. We sought to understand the relationship between ctDNA, tumor histology, and clinical outcomes in locally advanced (laRCC) and metastatic RCC (mRCC).

Methods: Forty-eight patients with laRCC and mRCC underwent serial plasma ctDNA testing with a commercially available, tumor-informed assay (Signatera). Tissue from each patient's tumor was sequenced to identify individualized variants, which were then used to construct a personalized tumor-informed ctDNA assay. Serial plasma testing quantified these patient-specific variants to assess ctDNA dynamics alongside interval imaging. Associations between baseline ctDNA status, peak level of ctDNA in mean tumor molecules per milliliter (MTM/mL), histologic subtype, aggressive morphologic features (sarcomatoid, rhabdoid, necrosis), and radiologic findings were analyzed. Quantitative variables were compared using Kruskal-Wallis and Mann-Whitney U tests. Survival was evaluated using Kaplan-Meier and log-rank testing.

Results: ctDNA was detected at baseline in 39.5% (17/48) of patients overall, including 5.2% (1/19) with laRCC and 55.2% (16/29) with mRCC. Among clear cell (cc) RCC, baseline ctDNA was detected in 66% of cases with aggressive morphologic features (sarcomatoid, rhabdoid, or necrosis) versus 15% of clear cell tumors without these features. Baseline detection in non-clear cell RCC was 42% (3/7). Among ccRCC, the median peak ctDNA level was significantly higher in tumors with aggressive features compared to those without (0.82 vs 0.07 MTM/mL, $p < 0.05$). Peak ctDNA levels were strongly associated with radiologic disease status: patients with progressive disease (PD) had markedly higher median ctDNA levels (8.86 MTM/mL) compared with those demonstrating disease control with complete response (CR, 0.00 MTM/mL), partial response (PR, 0.41 MTM/mL), or stable disease (SD, 0.27 MTM/mL; $H = 9.16$, $p = 0.027$). When stratified by disease control (CR/PR/SD) versus disease progression (PD), patients with disease control exhibited significantly lower peak ctDNA levels (median 0.18 MTM/mL, $n = 12$) than those with progression (median 8.86 MTM/mL, $n = 8$; $p = 0.007$). Conversion from ctDNA-positive to ctDNA-negative during the disease course was associated with improved overall survival ($p < 0.05$). However, baseline ctDNA detection alone did not correlate significantly with survival.

Conclusions: ctDNA may serve as a predictor of aggressive histopathologic features in RCC. Quantitative burden and ctDNA dynamics appear associated with disease status and overall survival. These findings highlight tumor-informed ctDNA as a promising biomarker in RCC.

#2584 Methylation signatures from liquid biopsies predict anti-EGFR therapy response in patients with colorectal cancer.

Xuwen Li[1], Mingyang Cai[1], Shile Zhang[1], Nicole Zhang[1], Reagan Barnett[1], Tingting Jiang[1], Kota Ouchi[2], Yoshiaki Nakamura[3], Kimberly Banks[1], Justin Odegaard[1], Darya Chudova[1]

[1]Guardant Health, Palo Alto, CA,[2]Tohoku University, Sendai, Japan,[3]University of Oxford, Oxford, United Kingdom

Introduction: Anti-EGFR-based regimens are standard treatments for left-sided, *RAS/BRAF* wild-type metastatic colorectal cancer (mCRC), but current biomarkers, including *RAS/BRAF* mutation status and tumor sidedness, do not fully explain the variability in treatment response. Prior tissue-based studies suggest that genome-wide DNA methylation patterns define biologically distinct CRC subtypes. We aimed to develop and validate a circulating tumor DNA (ctDNA)-based methylation classifier to predict anti-EGFR efficacy in mCRC patients.

Methods: Genome-wide methylation profiles from >3,000 CRC liquid biopsy samples were analyzed using Guardant360 Liquid (Guardant Health, Palo Alto, CA). After tumor fraction normalization, unsupervised clustering identified two reproducible subtypes: One cluster exhibited a globally high-methylation pattern consistent with the hypermethylated colorectal cancer (HMCC) state described in prior tissue-based studies, while the other represented a low-methylated colorectal cancer (LMCC) state. A random forest model trained on the top 50 principal components (PCs) of these methylation profiles was applied to a real-world cohort of patients receiving anti-EGFR or anti-VEGF therapies. Real-world survival, measured by time to treatment discontinuation (rwTTD), was assessed by treatment type, methylation status, and genotype (*RAS/BRAF* wild-type vs mutant).

Results: Methylation-based clustering successfully stratified mCRC into HMCC and LMCC groups in samples with evaluable tumor fractions (≥0.5%, N=162). HMCC tumors were enriched for *BRAF* mutations and exhibited significantly shorter PFS on anti-EGFR therapy, particularly among right- or unknown-sided patients. LMCC patients demonstrated improved outcomes on anti-EGFR therapy (HR = 1.76, $p = 0.024$), including in patients with right- or unknown-sided, *RAS/BRAF* wild-type disease, with survival comparable to patients with left-sided disease (HR = 0.94, $p = 0.85$). Combing methylation status with *RAS/BRAF* genotype and tumor sidedness expanded the anti-EGFR-eligible population by 18.8% (from 101 to 120 patients) while maintaining survival comparable to standard eligible patients. Conversely, no significant survival difference was observed between HMCC and LMCC patients treated with anti-VEGF therapy (HR = 1.08, $p = 0.64$), confirming methylation status as a predictive biomarker for treatment selection rather than a purely prognostic factor.

Conclusions: ctDNA methylation profiling enables expanded prediction of anti-EGFR efficacy in mCRC beyond current selection criteria. Methylation-integrated eligibility captures additional patients who might benefit from anti-EGFR therapy that are missed by current sidedness-based guidelines. These findings support ctDNA methylation as a feasible and scalable predictive biomarker for precision therapy in colorectal cancer.

#2585 Plasma cell-free DNA nucleosome footprints in metastatic castration-resistant prostate cancer (mCRPC).

Denisa Bogdan[1], Jan Rekowski[1], George Seed[1], Claudia Bertan[1], Jane Goodall[1], Gemma Fowler[1], Penelope Flohr[1], Christine Geffriaud-Ricouard[2], Mustapha Chadjaa[3], Sandrine Mace[4], Isaac Lazzeri[5], Ellen Heitzer[6], Suzanne Carreira[1], Wei Yuan[1], Johann S. de Bono[1]

[1]The Institute of Cancer Research, London, London, United Kingdom,[2]Medical Oncology Europe Department, Sanofi, Gentilly, France,[3]Clinical Research, Sanofi, Vitry-sur-Seine, France,[4]Sanofi R&D Oncology, Sanofi, Vitry-sur-Seine, France,[5]Division of Oncology, Department of Internal Medicine, Medical University of Graz, Graz, Austria,[6]Institute of Human Genetics, Diagnostic & Research Center for Molecular BioMedicine, Medical University of Graz, Graz, Austria

Background: Transcription factor (TF) activity can be determined by nucleosome footprints in low-pass whole genome sequencing (lpWGS) of plasma cell-free DNA (cfDNA). cfDNA wrapped around nucleosomes is protected from enzymatic digestion, and TFs induce phased nucleosome positioning around their binding sites, which results in oscillatory sequencing coverage and preferential depletion at open chromatin regions. Herein, we quantify nucleosome occupancy at binding sites for hundreds of TFs, evaluating the clinical utility of these functional readouts in plasma taken from subjects treated on the CARD prospective randomized trial of cabazitaxel (CAB) vs second androgen receptor pathway inhibitor (ARPI).
Methods: Plasma cfDNA lpWGS (median coverage ~1.6x) was used to infer nucleosome footprints at TF binding sites (TFBS) of 682 TFs. Overall, 217 CARD trial subjects comprised a Test cohort and 174 patients receiving a taxane on the FIRSTANA and PROSELICA prospective trials comprised a validation set. cfDNA lpWGS of a cohort of 104 healthy participants was used as a control. Hazard ratios (HR) were computed using Cox proportional hazards models. Odds ratios (OR) were computed using logistic regression. Longitudinal changes between baseline and subsequent timepoints were investigated using linear mixed effect models. All analyses were adjusted for tumor fraction.
Results: Out of 682 TFs with available binding site annotations, 357 consistently yielded signal-to-noise ratios of at least 2:1 and were further analyzed. Analytical validation utilizing technical replicates (different samples; same time point) and biological replicates (different samples, taken at baseline and screening, weeks apart) was pursued, determining the dynamic range for these TFs at 1000 TFBS each. Assay limits of detection (LOD) and limits of quantification (LOQ) for sequencing coverage and tumor fraction were determined for each TF. Of 357 TFs, 244 were significantly mCRPC associated (Wilcoxon test, adjusted p-value < 0.05) relative to healthy controls, including AR, NKX3-1, E2F1, MYC, MYCN, and MAZ. Predictive analysis in CARD showed accessibility at UBP1 binding sites at baseline was associated with taxane sensitivity over ARSI (OR 1.44, 95% 1.07-1.95, p-value < 0.05). Furthermore, average FOXP1 accessibility scores increased at progression (average increase 1.76, SE 0.49, p-value 0.02), alongside AR (average increase 1.16, SE 0.49, p-value 0.02) and GRHL2 scores (average increase 1.33, SE 0.53, p-value 0.01). These plasma-derived data suggest patients progress with increased AR signaling.
Conclusions: Evaluating nucleosome footprints at TFBS using lpWGS is a robust approach that identifies valuable functional biomarkers of drug sensitivity. Such studies offer the opportunity to interrogate disease progression through serial clinical samples, where phenotype profiling is otherwise unfeasible.

#2586 Investigating a Wilms tumor DNA methylation signature in liquid biopsies.

Mariusz Shrestha[1], Arteen Torabi-Marashi[1], Marina Dutra[1], Sanaa Choufani[1], Trevor J. Pugh[2], Rosanna Weksberg[1], Jack Brzezinski[3]

[1]The Hospital for Sick Children, Toronto, ON, Canada,[2]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[3]Seattle Children's Research Institute, Seattle, WA

For adult cancers, plasma ctDNA interrogation of genomic alterations has the potential to detect cancers before radiographic evidence, supporting prognostication and monitoring of therapeutic response in real-time. Despite its remarkable potential, ctDNA detection is often limited to advanced disease, with very few low-grade tumors shedding sufficient ctDNA with genomic lesions characteristic of the cancer. In contrast to adult tumors, the genomes of early childhood and embryonal tumors are typically stable with low somatic and copy number alterations that are often benign and heterogeneous, making detection even more difficult. Thus, a diagnostic tool that detects DNA methylation (DNAm) changes in ctDNA in addition to genomic alterations could enable earlier cancer detection and improve outcomes. Wilms tumor (WT) is the most prevalent renal cancer in children. Our group has shown that DNAm aberrations exist in all WTs regardless of the presence of genomic aberrations, and that DNAm alterations are often the earliest pathogenic change in early lesions. Here, we present preliminary findings of our methyl-classifiers' ability to detect WT from plasma cfDNA by enzymatic methyl-sequencing (EM-seq). Using EM-seq, we are currently generating DNAm data from plasma drawn at diagnosis in 35 patients with WT and 24 controls. In the initial pilot analysis of 17 patients with Wilms tumors and 4 controls, our WT-methyl-classifier was not only able to reliably identify patients with WT, but also stratified patient cfDNA samples into two subtypes with methylation profiles similar to those reported in primary WT tissues. Additionally, we showed corroborating evidence of WT ctDNA in plasma cfDNA samples: First, copy number alterations associated with WT were present such as chromosome 1p, 11p, and 16q loss, and chromosome 1q gain. Secondly, methylation at commonly differentially methylated regions in WT plasma samples were concordant with tumor tissue - for example increased and decreased methylation at *H19* and *KCNQ1OT1* imprinting control regions respectively. Thirdly, cfDNA from patients with WT had smaller average DNA fragment size compared to controls - a pattern that has been described in other cancer types. Lastly, the majority of matched tumor tissues shared methylation subgroup profiles and CNAs with their cfDNA counterparts, while discordant cases likely resulted from normal tissue contamination. In summary, we demonstrated that WT ctDNA is robustly detected in cfDNA through measurement of DNAm profiles. As prognostic information such as DNAm subgroup can be derived from these data, this assay is well positioned for translation into clinical molecular diagnostics. We are currently optimizing this assay for early detection of WT in patients with predisposition and for monitoring of treatment response.

#2587 Development of a methylated gene panel for detection of cell-free, metastatic prostate cancer DNA in plasma.

Gang Yu[1], Mary Jo Fackler[1], Liqun Zhang[1], Wenfei Xia[1], Roshni Saravanan[1], Ezra Baraban[2], Eunice Van Den Berg[3], Adam Botha[3], Pamela Michelow[3], Reubina Wadee[3], Maureen Joffe[4], Wenlong Carl Chen[4], Thomas Pisanic[5], Michelle Petri[6], Jun Luo[7], Channing Paller[1], Samuel Denmeade[1], Leslie Cope[1], Saraswati Sukumar[1]

[1]Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Department of Anatomical Pathology, University of the Witwatersrand/National Health Laboratory Service, Johannesburg, South Africa,[4]Strengthening Oncology Services Research Unit, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa,[5]Johns Hopkins University School of Medicine, Baltimore, MD,[6]Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD,[7]Brady Urological Institute, Johns Hopkins University School of Medicine, Baltimore, MD

Purpose: We sought to develop a highly sensitive, reproducible cell-free methylated DNA assay for accurately detecting metastatic prostate cancer (mPCa) in plasma.
Experimental Design: We identified a new 10-marker panel for accurate detection of PCa in the TCGA prostate adenocarcinoma (PRAD) 450K DNA methylation data. Marker sensitivity and specificity were verified in two independent public prostate cancer datasets (GSE112047, GSE76938). A quantitative multiplex methylation-specific PCR (QM-MSP) assay incorporating these markers was validated in archival benign and prostate cancer tissues from the United States (US, 61 cancer, 26 benign) and South Africa (SA, 80 cancer, 24 benign). We used a newly developed cell-free multiplex methylation-specific PCR (cf-MMSP) assay for the 10-marker panel. Intra-assay and intra-operator reproducibility assays tested its robustness. cf-MMSP performance was assessed in a Training set (40 benign, 40 cancer), and an independent Test set (19 benign, 20 cancer) of plasma. Shapley value regression was used to rank performance of the 10 genes in the cf-MMSP assay. We selected a 5-gene panel based on their high performance. Statistical methods used included the Youden index threshold for ROC analysis and Kruskal-Wallis tests.
Results: In tissues, the 10-gene panel detected all stages of prostate cancer: In tissue from the US (n=87), we achieved ROC AUC = 1.00 (CI. 0.99 - 1.00), sensitivity of 98.36% (CI. 91.28 - 99.91) and specificity of 100.00% (CI. 87.13 - 100.00); in SA samples (n=104), ROC AUC was 0.99 (CI. 0.99 - 1.00), sensitivity of 98.28% (CI. 90.86 - 99.91), and specificity of 100.00% (CI. 86.20 - 100.00). cf-MMSP intra-assay test showed low CVs (1.70-5.70% across copy levels) and strong linearity (R^2 = 0.93). The intra-operator test showed excellent reproducibility, with an ICC of 0.99. In plasma, in the training set, the 10-gene panel showed ROC AUC of 0.89 (CI. 0.81-0.97), sensitivity of 75.00% (CI. 59.81 - 85.81) and specificity of 93.88% (CI: 83.48 - 97.90) in distinguishing mPCa from benign. In the test set, the assay performed with ROC AUC of 0.91 (CI. 0.80 -1.00), sensitivity of 85.00% (CI. 63.96 - 94.76), and specificity of 93.88% (CI. 83.48 - 97.90). Using a standardized Shapley value cutoff of 0.07, we identified the five best-performing genes- HAAO, DLEC1, FBN1, TMEM155 and RTDR1. In the training set of plasma, the refined 5-gene panel subset showed ROC AUC of 0.92 (CI. 0.84 - 0.99), sensitivity of 90.00% (CI. 76.95 - 96.04) and specificity of 90.00% (CI. 76.95 - 96.04). In the test set, this 5-gene panel achieved ROC AUC of 0.92 (CI. 0.84 - 0.99), with a sensitivity of 90.00% (CI. 80.00 - 100.00) and a specificity of 84.20% (CI. 53.00 - 100.00).
Conclusions: The 5-gene cf-MMSP panel showed strong performance indices in detecting mPCa in plasma. The assay shows potential for broadly accessible early detection and disease monitoring for molecular management of mPCa.

#2588 Monitoring ESR1 and other mutations linked to resistance with a tumor-informed MRD test: Analytical validation and real world data.

Jason Harris, John M. Lyle, Gabor Bartha, Sean M. Boyle, Josette Northcott, Devayani Bhave, Claudia Aliguillen, Shuyuan Ma, Rachel M. Pyke, Steven Dea, Dan Norton, Erin Ayash, Richard O. Chen

Personalis, Inc., Fremont, CA

Background
Detecting resistance mutations during cancer surveillance can lead to changes in treatment and improve patient outcomes. For example, a recent study showed HR+/HER2- breast cancer patients with ESR1 resistance mutations detected during surveillance had improved outcomes when switched to a second generation selective estrogen receptor degrader (SERD). To address this emerging need, we analytically validated an option in the tumor-informed NeXT Personal® ctDNA MRD test to report on a set of mutations linked to resistance in the literature ("resistance mutations") across 13 genes, including ESR1. We further performed exploratory analysis on real world data to assess the frequency of these mutations detected during circulating tumor DNA (ctDNA) based molecular residual disease (MRD) testing.
Methods and Results
We performed a number of studies to demonstrate the analytical validity for reporting a set of mutations linked to resistance as part of NeXT Personal. Utilizing a cohort of >7,000 MRD-negative samples, we measured the analytical specificity for detecting these resistance mutations at >99.999%. Orthogonal confirmation of positive mutation detections and negative mutation detections was performed using digital droplet PCR. Finally, using a dilution series of the Seraseq ctDNA Mutation Mix v4, we measure the sensitivity and the analytical range measurements (linearity, precision, and limit of quantification).
We also performed an exploratory retrospective analysis of the detection of mutations linked to resistance across >11,000 cfDNA timepoints from >5,300 patients, across multiple cancer types. We examined resistance mutation detection rates in MRD-positive patients and in a "high-MRD" subset, defined as those whose plasma timepoints reached a MRD level of >1,000 parts per million (PPM). Among ~2,500 MRD-positive patients, we detected a resistance mutation in 15%. Restricting to the ~1,200 high-MRD subset, the detection frequency of resistance mutations increased to 27%. Focusing on high-MRD HR+/HER2- breast cancer patients, we detected ESR1 mutations in 29% of patients.
Conclusions
With recent studies showing the importance of detecting ESR1 mutations as part of breast cancer surveillance, here we validate the ability to additionally report on ESR1 and other resistance associated mutations as a part of longitudinal MRD testing for solid tumors. Using real world data, we also show that these mutations are detected in a significant subset of patients, especially as the ctDNA fraction increases. The added ability to report on these mutations has the potential to inform patient management in the future.

#2589 Prospective verification of OvaPrint and multi-omic profiling for precise adnexal mass classification.

Thomas Simon[1], Lynda D. Roman[2], X. Mona Guo[2], Ben Yi Tew[1], Gerald C. Gooden[1], Monica Neuman[3], Emma Barber[4], Elisa Romeo[5], Todd Holscher[5], Renee Wunderley[6], Danielle Goldberg[7], Krishna Morampudi[7], Dalia Daujotyte[7], Monique Spillman[8], Bodour Salhia[1]

[1]Department of Cancer Biology, Keck School of Medicine, University of Southern California, Los Angeles, CA,[2]Division of Gynecologic Oncology, Keck School of Medicine, University of Southern California, Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA,[3]Los Angeles General Medical Center, Los Angeles, CA,[4]Division of Gynecologic Oncology, Feinberg School of Medicine, Northwestern University, Evanston, IL,[5]CpG Diagnostics, Inc., Pasadena, CA,[6]Cpg Diagnostics, Inc., Pasadena, CA,[7]Illumina, Inc., San Diego, CA,[8]Department of Gynecologic Oncology, University of Arkansas Medical Center, Little Rock, AR

Background: Patients with adnexal masses face both overtreatment, when benign disease is misclassified, and undertreatment, when cancers are not managed by gynecologic oncologists. CA125, the most widely used biomarker, lacks specificity. High-grade serous ovarian cancer (HGSOC), the most aggressive subtype of epithelial ovarian cancer (EOC), requires timely specialist management. OvaPrint, a cfDNA methylation liquid biopsy developed to improve adnexal mass evaluation, is currently optimized for HGSOC, with expansion underway. In a prospective multi-site study, we sought to clinically verify OvaPrint, compare it with CA125 and integrate it with 5-base sequencing, next generation proteomics and spatial transcriptomics analysis.
Methods: Plasma was collected from six US sites preoperatively and analyzed with OvaPrint. Eligibility included adnexal mass on imaging without evidence of metastatic disease and planned surgery. Clinical data, including CA125 values, were abstracted from medical records. Diagnosis from surgical pathology reports served as the clinical ground truth. Of 121 cases (7 HGSOC, 16 other EOCs, 5 other cancers, 93 benign), 110 were evaluable (104 had CA125). Endpoints were sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). Samples were also analyzed using the latest Illumina's technology including: Illumina's Protein Preparation (IPP) platform detecting 9500 proteins (80 plasma samples); 5-base sequencing solution for simultaneous whole-genome DNA methylation and variant detection (58 cfDNA samples); spatial transcriptomics for description of the tumor microenvironment (TME) and histologic context (23 fresh frozen tissue samples).
Results: OvaPrint achieved 83.3% sensitivity for HGSOC. Specificity was 96.6% for benign cases and 97.1% for non-HGSOC tumors. The HGSOC-specific PPV and NPV was 62.5% and 99%, respectively. CA125 showed 100% sensitivity for HGSOC but had poor specificity (62.2%, 13% PPV). IPP, 5-base sequencing and spatial transcriptomics data are being evaluated to complement OvaPrint through an integrated multi-omic approach for the discrimination of malignant and benign adnexal masses.
Conclusions: Accurate tools for EOC diagnosis are urgently needed. This prospective, multi-site study demonstrates OvaPrint's exceptional performance for the discernment of HGSOC. The high HGSOC-specific NPV and PPV of OvaPrint means a positive result is a near-certain indicator of HGSOC, supporting timely and appropriate care. OvaPrint is being expanded to other EOCs and is undergoing CLIA validation. Additional integration of other molecular endpoints could further enhance discrimination of adnexal masses. These findings establish it as the first liquid biopsy for HGSOC with potential to transform diagnostic practice and outcomes.

#2590 Urine cfDNA 4-mer end-motif signatures outperform other fragmentomic features for tissue-of-origin classification in genitourinary cancers.

Jessica Linford[1], Pradeep S. Chauhan[1], Irfan Alahi[1], Yohan Kim[1], Arpit Panda[2], Nathan Colon[3], Ryan Mueller[4], Faridi Qaium[1], Eric H. Kim[5], Melissa A. Reimers[4], Zachary L. Smith[6], Woodson W. Smelser[4], Fabrice Lucien-Matteoni[1], Aadel A. Chaudhuri[1]

[1]Mayo Clinic, Rochester, MN,[2]University of Chicago, Chicago, IL,[3]Hoag Foundation, Newport Beach, CA,[4]Washington University School of Medicine, St. Louis, MO,[5]University of Nevada Reno, Reno, NV,[6]AdventHealth Orlando, Orlando, FL

Introduction: Urine cell-free DNA (cfDNA) is a promising ultra-noninvasive analyte for genitourinary cancers (GU) cancers. In this study, we investigated urine cfDNA fragmentomic features and evaluated their ability to predict the tumor tissue of origin.
Methods: A total of 204 GU cancer patients and 34 healthy adults were enrolled in this prospective study. Preoperative urine was collected from 89 bladder cancer (BC) patients (64% muscle-invasive) undergoing cystectomy, 65 renal cell carcinoma (RCC) patients undergoing nephrectomy and 50 metastatic prostate cancer (mPC) patients. Urine cfDNA was isolated and sequenced at 5x genome-wide coverage on a NovaSeq S4 flow cell. To identify malignant tissue of origin, we analyzed somatic copy number alterations (CNAs), genome-wide fragment length ratios, and 4-mer end motifs. CNAs and tumor fraction (TFx) were quantified using ichorCNA in 1-Mb windows, while chromosome arm-level fragment count z-scores and fragment length ratios were calculated in 5-Mb bins across the genome. Relative frequencies of all 256 possible 4-mer end motifs were calculated for each sample. Individual logistic regression models were developed based on each fragmentomic feature using leave-one-out cross validation (LOOCV). Outputs from these models were combined into multi-feature XGBoost models. Cohort-specific end-motif enrichments were identified using Kruskal-Wallis tests with FDR correction. Motifs were then hierarchically clustered based on their cohort-wise median frequencies to define groups of motifs with shared fragmentation patterns.
Results: Across urine cfDNA in the GU cohort, BC showed the highest mean TFx at 10.0%, followed by mPC at 3.6% and RCC at 2.7%. A machine learning model based on 4-mer end motifs achieved a mean ROC AUC of 0.933 with classification accuracies of 63% for healthy, 87% for BC, 72% for mPC, and 83% for RCC. This model outperformed models based on ichorCNA (AUC = 0.767), chromosome arm fragment-count z-scores (AUC = 0.827), and fragment length ratios (AUC = 0.674). Combining end motifs with other fragmentomic features did not improve prediction accuracy. Multi-feature models incorporating end motifs with ichorCNA, chromosome arm-level z-scores, or fragment-length ratios yielded mean AUCs between 0.908-0.924, lower than the end-motif only model. Kruskal-Wallis tests identified 179 of 256 end motifs (79%) as significantly different across healthy, BC, mPC, and RCC. Hierarchical clustering of cohort-level median motifs revealed distinct end motif patterns: Motifs beginning with CT were enriched in RCC; AAAA was strongly enriched in BC; and motifs beginning with CA, AC, and AG were enriched in mPC.
Conclusion: Urine cfDNA 4-mer end motifs capture GU cancer-specific biological patterns that enable accurate tissue-of-origin prediction, underscoring their promise as a diagnostic tool.

#2591 Sequence and structural DNA alterations in the circulation of patients with cancer.

Daniel C. Bruhm[1], Carolyn Hruban[1], Adrianna L. Bartolomucci[1], Akshaya V. Annapragada[1], Sarah Short[1], Shashikant Koul[1], Kaui P. Lebarbenchon[1], Julia S. Johansen[2], Inna M. Chen[2], Andrei Sorop[3], Razvan Iacob[3], Speranta Iacob[3], Liana Gheorghe[3], Simona Dima[3], Katherine A. McGlynn[4], Manuel Ramirez-Zea[5], John Groopman[1], PLCRC-MEDOCC group, Remond J. A. Fijneman[6], Gerrit A. Meijer[6], Zachariah H. Foda[1], Jillian Phallen[1], Robert B. Scharpf[1], Victor E. Velculescu[1]

[1]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Oncology, Copenhagen University Hospital-Herlev and Gentofte, Herlev, Denmark,[3]Center of Digestive Diseases and Liver Transplantation, Fundeni Clinical Institute, Bucharest, Romania,[4]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[5]Research Center for the Prevention of Chronic Diseases, Institute of Nutrition of Central America and Panama (INCAP), Guatemala City, Guatemala,[6]Department of Pathology, Netherlands Cancer Institute, Amsterdam, Netherlands

The properties of cancer-associated genetic changes in cell-free DNA (cfDNA) are not fully understood. We performed whole-genome sequencing (WGS) of cfDNA as well as tumor tissue and white blood cells (WBCs) from 1,807 samples of 1,064 patients across eight common cancer types. Characterization of single base substitutions, small insertions and deletions, structural variants (SVs), and phased variants in single cfDNA molecules revealed unique properties of tumor-derived alterations as well as differences in error rates that spanned orders of magnitude. Given the low error rate associated with detection of tumor-specific rearrangement junctions in cfDNA, we hypothesized that these types of changes could enable detection of circulating tumor DNA (ctDNA) without prior knowledge of the alterations in the tumor tissue. As an example of this approach, we scanned each sequenced fragment genome-wide in cfDNA samples from the CheckPAC trial of patients with metastatic pancreatic cancer treated with radiation and immunotherapy to identify putative rearrangement junctions. We identified 22,010,911 such fragments but only 1,572 (0.007%) and 58,339 (0.27%) of these were present in the matched tumor or WBC samples, respectively, with the remaining identified only in cfDNA. We characterized each cfDNA fragment by the SV type, SV size, microhomology and insertion at the breakpoint junction, fragment size, and the location of the breakpoint with respect to the nearest fragment end, identifying differences depending on the origin of the SV. Machine learning analyses of SVs from cfDNA resulted in a high cross-validated performance for detection of tumor-specific SVs with an area under the curve (AUC) of 0.97 (95% CI: 0.97-0.98). After enriching for fragments most likely to be tumor-derived, we found that the number of cfDNA fragments containing SVs was highly correlated with the number obtained using a tumor-informed approach (Pearson correlation coefficient = 0.87, $p<0.001$), and could recapitulate longitudinal ctDNA levels and clinical outcomes using only low-coverage (~4x) plasma WGS. The universal nature of tumor-associated sequence and structural alterations in cfDNA may be broadly useful for cancer detection.

#2592 Nocturnal rise in circulating tumor DNA in a subset of metastatic colorectal cancer patients.

Ekaterina S. Kuligina[1], Aleksandr S. Martianov[1], Liliya S. Baboshkina[1], Arina S. Perevalova[1], Yana V. Belysheva[1], Anastasia N. Ershova[1], Tatiana A. Laidus[2], Aram A. Musaelyan[3], Ekaterina M. Anokhina[4], Gulfiia M. Teletaeva[1], Aglaya G. Iyevleva[1], Evgeny N. Imyanitov[1]

[1]N.N. Petrov National Medical Research Center of Oncology, Saint Petersburg, Russian Federation,[2]Department of Medical Genetics, St.-Petersburg Pediatric Medical University, Saint Petersburg, Russian Federation,[3]Department of clinical oncology, Pavlov First Saint Petersburg State Medical University, Saint Petersburg, Russian Federation,[4]Department of Antitumor Drug Therapy, St. Luke Clinical Hospital, Saint Petersburg, Russian Federation

Background: Practical use of ctDNA tests is complicated because many tumors shed into the bloodstream vanishingly low amounts of DNA. Significant efforts have been invested in the identification of factors that influence the performance of ctDNA assays. A recent study demonstrated a nocturnal peak in the amount of circulating tumor cells (CTC) during the deep sleep phase (~4 a.m.). This study questioned whether the same peak is characteristic of circulating tumor DNA (ctDNA).

Methods: Plasma samples were collected from 19 *RAS/RAF*-mutated colorectal cancer (CRC) patients at 12 p.m. (day 1), 4 a.m. (night), and 12 p.m. (day 2). 14 subjects provided a single triplet for the study, and five patients underwent the above procedure twice or thrice. *KRAS, NRAS*, and *BRAF* mutations in plasma were quantified via droplet digital PCR (ddPCR).

Results: *RAS/RAF* mutations (>10 copies/mL) were detected in at least one plasma sample in 20 of 25 (80%) triplets. Among these, 15 showed detectable ctDNA at all time points, with intra-individual variation ranging from 1.7% to 74.8%. In five triplets, ctDNA was undetectable during the daytime but present at night. A nocturnal ctDNA peak occurred in 7 of 9 triplets collected during disease control, while all 10 triplets obtained during tumor progression showed other temporal patterns ($p = 0.005$, Fisher's exact test). Patients sampled multiple times displayed differing ctDNA fluctuation patterns depending on disease status.

Conclusions: ctDNA levels exhibit circadian variation, with a 4 a.m. peak observed in patients with disease control. The results align with prior reports on nocturnal surges in CTC in breast cancer patients and suggest that liquid biopsy results are modulated by circadian or sleep-related physiological changes. This work has been supported by the Russian Science Foundation (grant number 25-45-01051)

#2593 Enspyre MRD: Validation of an ultra-sensitive kitted MRD solution at low sequencing depth.

Magdalena Stolarek-Januszkiewicz[1], Sophie Hackinger[1], Sarah Diels[2], Katarzyna Anton[1], Amy Lovell[1], Ernesto Lowy-Gallego[1], Ana-Luisa Silva[1], Maria Litovchenko[1], Bart Tegenbos[2], Emmanuel Riviere[2], Dirk Goossens[2], Nathalie Bernard[2], Justyna Mordaka[1], Iyelola Turner[1], Lisa Van den Bossche[2], Lien Heyrman[2], Jan Van de Velde[2], Pieter Mestdagh[2], Jurgen Del Favero[2], Barnaby Balmforth[1]

[1]Biofidelity Ltd, Cambridge, United Kingdom,[2]CellCarta, Antwerp, Belgium

Detection of MRD post surgery and monitoring of ctDNA during treatment are gaining increasing traction in patient care and drug development. First-generation assays have considerable clinical datasets, but suffer from limited sensitivity due to low numbers of mutations tracked. Recent 'ultra-sensitive' solutions detect ctDNA at <100 parts per million (ppm), but suffer from high sequencing requirements and costs, limiting their use to large central labs.

Enspyre is a novel sample preparation technique that enriches mutated DNA prior to sequencing, significantly improving signal to noise and reducing sequencing requirements. We present results from two independent sites demonstrating the analytical validation of Enspyre MRD, a kit-based MRD solution utilizing Enspyre.

Specificity was tested with >180 replicates from >50 healthy blood donors at two different DNA input levels. LoD and LoQ were determined through >280 replicates using contrived samples in a 2-phase approach. Assay linearity was assessed using an additional 24 replicates spanning 5 orders of magnitude of ctDNA concentration.

Analytical accuracy and precision were assessed using cell free DNA (cfDNA) derived from patients with NSCLC and serially diluted in cfDNA from healthy donors, as well as DNA extracted from cancer cell lines, fragmented to mimic cfDNA. Different blood collection tubes were also assessed using healthy donors.

The effect of variant panel size on performance was assessed through the design of panels from 500 to 2,000 variants and in-silico downsampling.

Enspyre MRD produced consistent results between sites, with sensitivity, specificity and quantitation all exceeding target specifications and meeting or exceeding that achieved by current ultra-sensitive tests.

Specificity was 100% at all input levels, while LoD was <10ppm for 2,000 variant panels at 20 ng input. Sensitivity was positively correlated with panel size, with potential to trade off cost vs performance for different applications/indications, and was inversely correlated with input mass, with an LoD <40 ppm for 2,000 variant panels at 5 ng input.

Results were replicable and precise across >6 operators, >3 reagent lots, >3 runs, and 2 sites. Consistent results were obtained using low- and mid-throughput sequencing platforms.

Importantly, sequencing requirements were reduced from ~500M read pairs using standard techniques to just 5M, while retaining ultra-sensitive ctDNA detection and negating the need for molecular barcoding.

These results demonstrate the potential of Enspyre as an ultra-sensitive MRD solution, in a format that is much more amenable to adoption in mid- and low-throughput laboratories than existing approaches. Through mutated DNA enrichment, Enspyre enables ctDNA detection at <10ppm with a >98% reduction in NGS requirements, facilitating significant cost reductions and decentralization of MRD testing.

#2594 A deep sampling and single molecule digital counting assay for rare molecule detection.

Danny Overman[1], Cindy Wang[2], Jung won Keum[3], Jesse Soliman[3], Emily Blair[3], Eleen Shum[3], Tricia Zwiefelhofer[2]

[1]Laboratory Corporation of America, Burlington, NC,[2]Laboratory Corporation of America - Sequenom, San Diego, CA,[3]Countable Labs, Palo Alto, CA

Rare molecule detection remains a challenge in liquid biopsy applications. Increasing assay sensitivity requires higher DNA input, yet conventional digital PCR (dPCR) systems are constrained by limited input capacity and partition number, restricting analytical range. We evaluated a next generation PCR platform, Countable PCR, which generates approximately 30 million partitions per 50 µL reaction and supports DNA inputs exceeding 1 µg, enabling “deep sampling” for improved rare variant detection. Using the clinically relevant KIT (*D816V*) mutation associated with systemic mastocytosis (SM) as a model, we analytically validated a multiplexed Countable PCR assay across 15 patient blood and bone-marrow samples at multiple testing sites and compared results with a reference dPCR assay. Standard dPCR achieved a 0.03% mutant allele frequency (MAF) limit of detection only by pooling three wells (78,000 partitions, 100 ng input), as higher inputs caused image saturation and loss of precision. In contrast, Countable PCR demonstrated accurate quantification from 150 to 1,452 ng DNA within a single well, maintaining linearity and low background. Across all samples, MAF values showed near-perfect concordance with the orthogonal method (Pearson coefficient = 0.9997; $p = 1.03 \times 10^{-22}$). Synthetic controls achieved 99.95% variant detection accuracy (5 variant-positive vs. 10,026 wild-type partitions), and contrived samples at 300 ng and 1 µg inputs exhibited 100% concordance across expected variant frequencies. These results demonstrate that Countable PCR enables high-input, single-molecule quantification with exceptional sensitivity and reproducibility, supporting streamlined, cost-efficient workflows for rare variant detection and precision molecular diagnostics in clinical laboratory settings.

#2595 A novel dual-strand whole-genome sequencing (WGS) method for ultra-sensitive molecular residual disease detection (MRD).

Andrew Slatter[1], Jessica Moore[1], Esther Musgrave-Brown[1], Dhamayanthi Pugazhendhi[1], Trevor Ho[1], Alex Calderwood[1], Dale Weekes[1], Seong Won Cha[2], Christopher Edlund[2], Sven Bilke[2], Huihong You[2], Chris Truong[2], **Jeff Tsai**[2], Khai Luong[2], Li Liu[2], Yunjiao Zhu[2], Jeff Fisher[2], Traci Pawlowski[2], James Han[2], Fiona Kaper[2], Cande Rogert[2]

[1]Illumina, Cambridge, United Kingdom,[2]Illumina, San Diego, CA

Whole genome sequencing (WGS) of circulating cell-free DNA (cfDNA) enables ultra-sensitive circulating tumor DNA (ctDNA) detection by leveraging genome-wide mutations. However, the detection sensitivity remains limited by errors. Here we describe the performance of a new, high-Q WGS library prep method, which enables >Q60 cfDNA sequencing, and demonstrate its application in molecular residual disease (MRD) testing. The method enables increased accuracy by sequencing both top and bottom strands of double stranded cfDNA fragments without requiring unique molecular identifiers (UMIs). Briefly, oligonucleotide adaptors are attached to cfDNA samples and are subsequently processed to generate a library structure that contains both top and bottom strands. Samples are appended with barcodes and pooled for sequencing on a standard NovaSeq X™ instrument. Errors originating from DNA damage, library preparation or sequencing are informatically detected and masked, creating duplex consensus reads. A novel q-score prediction algorithm is employed to predict the probability a reported base is an error, as well as substitution-specific error probabilities. Empirical q-score was measured using HG002 cell line DNA. To measure performance in tumor informed MRD application, cfDNA samples extracted from healthy donors were sequenced and analyzed against patient-specific somatic variants derived from tissue WGS using the Illumina Oncology WGS prep. Limit of detection (LoD) was assessed using 5 replicates at each of the 7 target VAF levels from 0-50 parts-per-million (ppm) dilutions of the SeraCare MRD reference material, with analysis by the DRAGEN™ MRD pipeline.Libraries prepared from 10 ng cfDNA delivered ~50x deduplicated duplex consensus coverage with >80% of passed-filter clusters delivering high quality duplex consensus reads. The quality of the resulting base calls was empirically measured at >Q60 accuracy, and certain substitution-specific error rates were measured at >Q70. Healthy plasma was used to establish statistical scores for determining ctDNA presence at different analytical specificity goals. These values were subsequently used to determine the detection in the LoD study. In aggregate, the results showed the method can achieve a LoD95 of 2.5 ppm with analytical specificity of 99.8%. The method presented herein demonstrates the potential of highly sensitive and specific ctDNA detection for MRD testing.

#2596 Ultrasensitive multiplex ddPCR for integrated genomic-epigenomic ctDNA detection in colorectal cancer.

Ya Zhou, Yuwei Ni, Xingyu Yang, Qiancheng You, Jing Su, Yunpeng Zhang, Xiaoling Li, Xinyue Kang, Jiayue Xu, **Zhihong Zhang**, Bingsi Li

Research and Development, Burning Rock Biotech, Shanghai, China

Background: Liquid biopsy is rapidly emerging as a cornerstone of precision oncology, offering sensitive and accurate profiling of tumor-derived information in real-time. Although droplet digital PCR (ddPCR) delivers single-molecule sensitivity, its low-plex design has limited it to interrogating one or a few variants at a time. Here we introduce COMET plus, a 25-plex ddPCR assay that simultaneously detects both genetic and epigenetic changes in a single amplification reaction, enabling highly sensitive detection of circulating tumor DNA (ctDNA) in colorectal cancer (CRC).
Methods: Following analysis of over 500 tumor tissue and more than 1,000 cfDNA specimens, we selected 18 methylation variants that simultaneously display (i) robust tumor-specific hyper-methylation, (ii) negligible signal in healthy donor plasma, and (iii) high recurrence across patients. These loci were co-amplified with somatic mutations and microsatellite instability loci (MSI) markers frequently altered in CRC. The assay runs on a 7- or 6-color ddPCR system (D3200 platform, Pilotgene; QX600^{TM}, Bio-Rad). A classifier was trained and subsequently locked to make sample-level calls of ctDNA positivity or negativity using optimized thresholds for each variant. Limit of detection (LoD) for each analyte was determined by Probit analysis of serially diluted contrived cfDNA and cell-line DNA. Limit of blank (LoB) was established from 10 independent replicates of two healthy donor cfDNA pools.
Results: In 30 ng of contrived cfDNA or cell-line DNA we detected actionable KRAS/BRAF mutations at 0.08% VAF and MSI-H DNA at 0.1% in an MSS background. Individual methylation markers were called to 0.08-0.2%, while the aggregate 18-marker signature reached 0.01% (cell-line) or 0.02% (cfDNA); no false positives were observed across 20 blank replicates.
Conclusions: We developed and validated a high-plex ddPCR assay that sensitively and simultaneously quantifies genetic and epigenetic alterations in colorectal cancer. The multiplexing strategy is compatible with most mainstream ddPCR instruments and readily extendable to other tumor types, offering a simple, streamlined workflow for cancer diagnosis, minimal residual disease (MRD) detection, and therapy selection.

#2597 Baseline cfDNA fragmentomics identifies multiple myeloma patients at risk of early progression.

Introduction: Early relapse limits durable remissions in multiple myeloma (MM). Cell-free DNA (cfDNA) fragment patterns capture tumor burden and nucleosome positioning. We tested whether a fragmentomics signature trained at MRD time points stratifies progression-free survival (PFS) when applied to pretreatment plasma.

Methods: We performed 30-40× whole-genome sequencing of plasma cfDNA from 43 newly diagnosed MM patients, with 65 additional MRD timepoint samples from 41 of those patients (post-ASCT n=30; 1-year maintenance n=30; other maintenance n=5) across eight Canadian sites (TFRIM4 and IMMAGINE studies) and one U.S. site (Mayo SPORE). MRD testing used multiparameter flow cytometry for all follow-up samples (n=65) and clonoSEQ in a subset (n=31). Logistic and elastic-net models were trained at MRD timepoints on fragmentomics features (short-fragment burden; a combined model integrating fragment-length distributions with inferred nucleosome positioning at MM-specific chromatin accessibility regions [Ordoñez et al., Genome Res. 2020]). A decision threshold was fixed by the Youden index during training and applied unchanged to diagnosis samples. PFS was analyzed by Kaplan-Meier, log-rank, and Cox models.

Results: After a median follow-up of 49.1 months, 16 of 43 patients (37%) progressed. Using the prespecified locked threshold, patients classified as MRD+ by the proportion-of-short-fragments model had significantly shorter PFS than MRD- patients (HR = 5.12; 95% CI 1.16-22.57; log-rank p = 0.016), with median PFS of 49.2 months for MRD+ cases versus not reached for the MRD- group. Fixed-horizon PFS favored MRD- samples at 24/36/48 months (100/94/87% vs 85/81/53% for MRD+). A combined model integrating weighted fragment lengths with inferred nucleosome positioning also separated outcomes (log-rank p=0.054); the Cox HR was not estimable because no MRD- patients relapsed. At 24, 36, and 48 months, baseline MRD positivity by the short-fragment model identified 100%, 83%, and 86% of patients who relapsed within those intervals (specificity 44%, 43%, and 52%), while the combined model detected all early relapses across the same horizons (specificity 15-21%), indicating consistently high sensitivity but modest specificity for predicting early progression.

Conclusions: A cfDNA fragmentomics signature trained at MRD time points stratified PFS when applied to diagnostic plasma, identifying patients at risk of early relapse. Short-fragment burden was most discriminative, and a combined model with nucleosome positioning recapitulated it with higher sensitivity, albeit lower specificity. These data support cfDNA fragmentomics as a practical liquid-biopsy risk biomarker in MM and suggest higher signals may proxy aggressive disease with greater tumor shedding and chromatin disorganization. Future work will validate findings in larger cohorts and integrate cytogenetic and immune features.

#2598 Analytical validation of an ultra-high sensitivity tumor-informed MRD assay.

Ashley Acevedo, Kelly Colbert, Kyle Trettin, Alexander Ham, Genevieve Gould

Myriad Genetics, Inc., Salt Lake City, UT

Circulating tumor DNA (ctDNA) is a biomarker for molecular residual disease (MRD), i.e., tumor cells that persist during or after cancer treatment. ctDNA can be distinguished from normal cell-free DNA (cfDNA) based on the presence of tumor-specific somatic variants. First-generation tumor-informed MRD assays based on exome sequencing typically interrogate a small number of tumor-specific variants, limiting their sensitivity. We have developed a second-generation, tumor-informed MRD assay using matched formalin fixed paraffin embedded (FFPE) tumor tissue, including core needle biopsies, and normal whole genome sequencing to power expansive variant discovery and selection of panels consisting of up to 1000 targets optimized for assay sensitivity.

Here we validate this assay using more than 100 unique cancer-affected clinical sample sets, more than 30 unique healthy donors and 3 unique sets of matched tumor and normal cell lines. Panels were generated from paired tumor and normal sample sets using as little as 10 ng of DNA, with highly reproducible performance across replicate panel designs. More than 4400 plasma and contrived sample tests were run across a range of assay conditions, including cfDNA input from 7.5 to 40 ng and panel sizes ranging from 500 to 1000 targets. Contrived samples were tested at tumor DNA concentrations ranging from 0.78 to 1,000,000 parts per million (ppm). We found the Limit of Detection with 95% sensitivity (LoD_{95}) to be <5 ppm in units of genome equivalents (comparable to <2.5 ppm in units of variant allele frequency) under typical assay conditions, and that LoD_{95} scales with cfDNA input amount and panel size. We determined the linear range of the assay to be from 1.56 to 1,000,000 ppm, with high quantitative precision down to 18 ppm. Across all tested indications, including breast, renal, colorectal, ovarian, endometrial and lung cancers from stages II-IV, clinical sensitivity is >85% and clinical specificity is >99%, where undetected samples were exclusively in low shedding indications, such as renal and HR+/HER2- breast cancer. Clinical sensitivity is 100% with clinical specificity >99% in colorectal, ovarian, endometrial and lung cancers.

In conclusion, we have developed and validated a quantitative and ultra-high sensitivity tumor-informed MRD assay suitable for challenging, low shedding applications such as breast and renal cancer or post-treatment monitoring.

#2599 Methylation-based circulating tumor DNA predicts recurrence in definitively treated non-small cell lung cancer (NSCLC).

Jisoo Lee, Eun Ji Song, Youngjun Lee, Jongsu Kim, Yuchan Kim, Anthony Wong, Sanghwa Kim, Liam I. Chung, Young Kwang Chae

Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Circulating tumor DNA (ctDNA) is being utilized in detecting molecular residual disease (MRD) and predicting recurrence of non-small cell lung cancer (NSCLC). However, real-world implementation is yet to be reported.
Methods: We retrospectively analyzed 240 longitudinal plasma samples from a real-world cohort of 78 NSCLC patients treated with curative intent, including select stage IV patients who underwent bilateral lung transplantation. MRD was assessed using a tissue-naïve, methylation-based assay (Guardant Reveal), and plasma-based genomic profiling was performed (Guardant360) at the time of MRD positivity. Recurrence-free survival (RFS) and overall survival (OS) were analyzed based on three MRD timepoints post-treatment: within 3 months (Subgroup A, n=42), within 6 months (Subgroup B, n=55), and at any time (Subgroup C, n=78). Recurrence date was determined by biopsy-proven recurrence date when available, otherwise, radiographic recurrence date was used.
Results: 78 patients (median age at diagnosis 65; 33 stage I, 19 stage II, 19 stage III, 7 stage IV) received definitive treatment (surgery alone, n=37; surgery with perioperative therapy, n=33; definitive radiation, n=8). 56 were adenocarcinoma and 21 were squamous cell carcinoma, and 1 was adenosquamous. Targetable alterations (EGFR, ALK, etc.) were found in 31 patients. The median follow-up duration was 22.3 months (range: 2-80.6 months). Among 23 MRD(+) cases, 10 recurrences and 3 deaths occurred, whereas 55 MRD(-) cases showed 5 recurrences and no deaths. MRD(+) was associated with worse OS in all subgroups ($p<0.01$). It was also associated with inferior RFS in Subgroup B (HR = 4.35, 95% CI 1.30-14.50, $p = 0.017$) and Subgroup C (HR = 5.20, 95% CI 1.76-15.30, $p<0.01$), with a similar trend in Subgroup A ($p=0.16$). Among 11 patients who recurred and ever showed ctDNA positivity, ctDNA preceded radiographic relapse in 10 cases with a mean lead time of 5.4 months (range 2 days-20.3 months). In the subset of patients with ≥1 year follow-up from definitive treatment (n=66), MRD(+) showed a sensitivity of 63.6% (7/11) and specificity of 78.1% (43/55) in predicting recurrence. In 13 MRD(+) patients with paired plasma and tissue NGS, 3 (23%) exhibited shared mutations between baseline tissue NGS and post-treatment plasma NGS (matched group). The unmatched group showed a median number of 9 (range 1-14) genomic variations; however, none were biologically relevant.
Conclusion: This is the first real-world analysis evaluating survival outcomes using a methylation-based ctDNA assay in definitively treated NSCLC. MRD(+) can be useful in predicting recurrence and was associated with worse outcomes. Integration of plasma-based NGS may reflect molecular heterogeneity and potential subclonal evolution, supporting its potential utility for personalized post-treatment surveillance.

#2600 Investigating treatment response and resistance in non-small cell lung cancer patients through epigenetic profiling of plasma nucleosomes.

Christoffer T. Maansson[1], Simone Stensgaard[1], Emma Pedersen[1], Anders Lade Nielsen[2], Peter Meldgaard[3], Boe Sandahl Sorensen[1]

[1]Clinical Biochemistry, Aarhus University Hospital, Aarhus N, Denmark,[2]Department of Biomedicine, Aarhus University, Aarhus C, Denmark,[3]Department of Oncology, Aarhus University Hospital, Aarhus N, Denmark

The detection of circulating tumor DNA (ctDNA) through the identification of somatic mutations has shown promising results for monitoring treatment response in cancer patients. However, mutation-based approaches are limited by factors such as clonal hematopoiesis, low sensitivity, and the inability to detect epigenetic tumor signals. Complementary approaches based on epigenetic profiling of cell-free DNA (cfDNA) in liquid biopsies have been developed to infer the gene expression profile in the cells of cfDNA origin. We investigated the application of cell-free chromatin immunoprecipitation (cfChIP) targeting H3K4me3 and H3K36me3 histone modifications of circulating nucleosomes in non-small cell lung cancer (NSCLC) patients treated with immunotherapy or targeted therapies.

ctDNA dynamics were quantified using targeted sequencing of cfDNA to identify molecular responders to treatment based on ctDNA clearance. We performed cfChIP on healthy individuals and cancer patients followed by ddPCR or whole-genome sequencing at baseline, a few weeks after treatment initiation and at progression.

High *FGD2* expression and low *CDH3* expression at baseline were associated with a durable response to immunotherapy. Genes, in which the cfChIP enrichment correlated with ctDNA burden included genes, such as *PLCE1* and *VASH2*, involved in developmental processes. Longitudinal monitoring of *MET* gene activity with H3K36me3 cfChIP ddPCR distinguished patients with crizotinib response from non-responders. cfChIP at progression indicated novel resistance mechanisms to targeted therapy through upregulation of genes such as *FOXG1* and *MT3*, involved in neural development.

In conclusion, cfChIP-seq of cfDNA present in cancer patients' plasma has potential to provide valuable information on tumor specific transcriptional dynamics during treatment in NSCLC. Harnessing this information could enable earlier detection of resistance and guide treatment switching.

#2601 Biomarker tail genes in blood plasma cell-free RNA enable accurate detection of prostate cancer.

Annelien Morlion[1], Philippe Decruyenaere[2], Kathleen Schoofs[1], Jasper Anckaert[1], Nickolas J. Ramirez[1], Justine Nuytens[1], Eveline Vanden Eynde[1], Kimberly Verniers[1], Celine Everaert[1], Guy Brusselle[2], Steven Callens[2], Filomeen Haerynck[2], Dimitri Hemelsoet[2], Eric Hoste[2], Jo Lambert[2], Nicolaas Lumen[2], Fritz Offner[2], Koen Paemeleire[2], Vanessa Smith[2], Lies Van den Eynde[2], Jo Van Dorpe[2], Amber Vanhaecke[3], Hans Van Vlierberghe[2], An Mariman[2], Olivier Thas[4], Jo Vandesompele[1], **Pieter Mestdagh**[1]

[1]Ghent University, Ghent, Belgium,[2]Ghent University; Ghent University Hospital, Ghent, Belgium,[3]Ghent University Hospital, Ghent, Belgium,[4]Hasselt University, Hasselt, Belgium

The purpose of this study was to assess whether transcripts exhibiting strongly deviating abundance in plasma mRNA profiles can reliably differentiate prostate cancer from non-cancer states. To do so, we focused on biomarker tail genes (BTG), defined as protein-coding genes whose cell-free transcript abundance in an individual sample deviates by at least three standard deviations from a healthy control reference distribution. We applied the BTG identification and classification workflow to blood plasma samples from individuals with newly diagnosed prostate cancer (n = 132; 62 early-stage, 70 late-stage) and healthy donors (n = 48). Classification thresholds were established using a train-test cross validation approach (70%), and performance was evaluated in held-out validation samples (30%) and in a separate non-malignant cohort including healthy donors (n=37) and patients with non-malignant conditions (n=88).

Across training and validation analyses, a consensus set of 247 prostate cancer BTG enabled discrimination between prostate cancer samples and healthy controls, with sensitivity and specificity reaching 100% in the validation cohort of male donors. Of note, the number of BTG per plasma sample was not associated with disease stage, and classification remained highly accurate in age-matched subsets, indicating limited influence of age on results. When applied to a cohort of individuals with diverse non-malignant conditions, the established BTG threshold yielded 94.4% specificity, and none of patients with benign prostatic hyperplasia were misclassified (n=5).

To explore redundancy within the BTG set, we evaluated both cluster-derived subsets and algorithmically selected minimal panels. Multiple small subsets, including a ten-gene panel identified by a greedy selection strategy, achieved perfect classification within the validation cohort, demonstrating that strong discriminatory power is retained even when BTG sets are substantially reduced.

In conclusion, blood plasma BTG constitute a highly accurate signature for prostate cancer detection, and the ability of small BTG subsets to reproduce full-set performance highlights opportunities for targeted assays. Further evaluation in broader populations and across cancer stages will refine the potential of BTG-based approaches for early detection and monitoring.

(The last two authors contributed equally to this work)

#2602 Impact of targeted therapies in cancers classified as TMB-high by liquid biopsy: Insights from the Gustave Roussy molecular tumor board.

Adrien Mouren[1], Berenger POIRIER[2], Antoine Italiano[2], Matthieu Roulleaux Dugage[2], Yohann Loriot[3], Antoine Hollebecque[4], Anas Gazzah[2], Barbara Pistilli[2], Christophe Massard[4], Cyril ROUSSEL-SIMONIN[2]

[1]Drug Development Department (DITEP), Gustave Roussy, Villejuif, France,[2]Gustave Roussy, Villejuif, France,[3]INSERM U981 (Gustave Roussy), Villejuif, France,[4]Institute Gustave Roussy, Villejuif, France

Background:
Tumor mutational burden (TMB) has emerged as a biomarker for immunotherapy response, but its predictive value for targeted therapies remains uncertain. In genomically unstable tumors, high TMB may reflect passenger rather than driver events, potentially limiting the efficacy of targeted agents.
Methods:
We retrospectively analyzed adult patients with advanced solid tumors who underwent plasma-based comprehensive genomic profiling (STING master protocol, Foundation Medicine) and had a TMB ≥ 16 mut/Mb. All cases were reviewed by the Gustave Roussy Molecular Tumor Board for orientation toward early-phase trials, phase II-III studies, or MTB-validated off-label targeted therapies. Alterations were classified as driver or non-driver based on integrated molecular and clinical evidence, supported by reference databases such as IntOGen and DriverDB.
Results:
Fifty-six patients were included (mean age 61.6 y; 71% male). The most frequent tumor types were lung (41%), colorectal (11%), and bladder (11%). Brain (20%), bone (38%), and liver (5%) metastases were common; 72% had ≥ 2 metastatic sites. Median plasma TMB was 20 mut/Mb (range, 16-1,450). Patients had received a median 3 prior lines (range 1-6). The most frequent alterations involved *KRAS* (21%), *MET* (11%), and *ERBB2* (11%). Targeted therapies included small-molecule inhibitors (41%), TKIs (27%), ADCs (14%), bispecific antibodies (5%), and PROTACs (5%). Overall, 13 patients (23%) achieved partial response (PR) and 21 (38%) stable disease (SD), resulting in an overall response rate (ORR) of 23% and a disease control rate (DCR) of 61%. Among driver cases (n=43), 12 PR and 17 SD were observed vs 1 PR and 4 SD in non-driver cases (n=13). Median PFS was 3.7 months (95% CI 2.8-4.8). The prior-line PFS was 5.6 months (95% CI 4.0-11.0). A PFS ratio >1/3, indicating clinical benefit compared with the previous treatment line, was achieved in 63.3% of evaluable patients (31/49). Presence of a driver alteration was associated with improved PFS (HR 0.43; 95% CI, 0.22-0.82; p = 0.011). No correlation was found between TMB and PFS (Spearman ρ = 0.10; p = 0.45), and no difference was seen across TMB groups (<20, 20-50, ≥50 mut/Mb).
Conclusions:
Only patients with bona fide driver alterations derived benefit from targeted therapy, irrespective of TMB level. High TMB reflects genomic instability rather than therapeutic sensitivity, underscoring the importance of molecular curation to guide precision oncology decisions. Comparative analyses with TMB-low cases are ongoing to refine the predictive versus confounding role of TMB in targeted therapy response.

#2603 Comparing methylation signatures across 15 cancer types and 7 subtypes.

Harry Mickalide, Joel Rodriguez-Medina, Fernando L. Mendez, Murat Can Cobanoglu, Scott Dashner, Yuqian Jiang, Kevin Chan, Joshua N. Burton, Trupti Kawli, Johannes G. Reiter, Matthew Rabinowitz, Alexey Aleshin

Natera, Inc., Austin, TX

Differentially methylated regions (DMRs), the regions that have a different methylation pattern between tumor and non-tumor genomes, can serve as accurate biomarkers for cancer detection. Here we compare DMRs across 15 cancer types and 7 cancer subtypes. In this retrospective study, tissue samples from 832 patients with 15 different cancer types, including gastrointestinal (GI), genitourinary (GU), gynecological, breast, lung, melanoma, and head & neck cancers, were analyzed to measure methylation levels across genomic regions. Advanced adenoma (AA), an important precursor to colorectal cancer, was also included as a comparator among GI indications. Sets of DMRs were identified in each cancer type based on comparison with methylation levels of healthy samples. DMR signatures were compared across cancer types and subtypes by calculating pairwise overlaps. Across all 15 cancer types, the overlap of shared DMRs ranged from 13% (melanoma vs gastric cancer) to 61% (esophageal cancer vs gastric cancer). Notably, we found strong overlap among GI indications, a group including esophageal, gastric, small intestine, liver, pancreatic, and colorectal cancer, as well as AA. Compared to non-GI cancers, the pairwise overlap of DMRs in GI indications was, on average, 17% higher. Moreover, 65% of DMRs were shared between AA and colorectal cancer, which represented the highest overlap of shared DMRs in any pairwise comparison in this analysis. Among breast and lung cancer samples, we compared subtypes and found strong, but variable, overlap. For instance, among four major subtypes of breast cancer, we found overlaps ranging 53%-68% between subtypes. Among three lung cancer subtypes, overlaps ranged from 34% to 44%. In this study, we demonstrate that each cancer's DMR signature is ultimately unique and can be used as a biomarker for cancer detection even though there is some overlap between DMR signatures of different cancer types. A deeper study of the shared and unique DMR signatures may provide insights into underlying biological mechanisms of cancer development. For example, the high overlap of DMR signatures among GI cancers suggests some shared mechanisms; similarly, while DMR signatures are expected to be similar between subtypes of a cancer, investigation into the patterns unique to each subtype may help resolve observed differences in clinical prognosis and treatment response.

#2604 Postoperative lymphatic exudate as a proximal liquid biopsy source in muscle-invasive bladder cancer.

Zhuosheng Gu[1], Zachary Costliow[1], Seka Lazare[1], Abbey Crittenden[1], Adam Harmon[1], Megan Rivera[1], Ashley Tellis[1], Samuel Espinoza[1], Adam Benson[1], Marra Francis[2], Ankeet Shah[3], Michael R. Abern[4], Gautum Agarwal[5], Wendy Winckler[1]

[1]Droplet Biosciences, Cambridge, MA,[2]Marra S. Francis Consulting, San Antonio, TX,[3]Division of Urology, Duke University Medical Center, Durham, NC,[4]Department of Urology, Duke University School of Medicine, Durham, NC,[5]Mercy Hospital, St. Louis, MO

Introduction: Patients with muscle-invasive bladder cancer (MIBC) experience recurrence rates of up to 50% following radical cystectomy [1,2]. Current monitoring involves imaging scans or peripheral blood ctDNA [3,4], however, there is unmet need for a sensitive molecular test that can identify recurrence early enough to more precisely tailor adjuvant therapy. Our team has pioneered the use of lymphatic exudate collected via surgical drains (“lymph”) as a proximal liquid biopsy fluid. We have previously shown that lymph collected 24 hours after surgery identified molecular residual disease (MRD) in head and neck squamous cell carcinoma (HNSCC) in the immediate post-surgical window [5,6]. Here, we evaluate the feasibility of postoperative lymph to enable sensitive detection of MRD and characterize the dynamics of circulating tumor DNA (ctDNA) in lymph from MIBC patients for 96 hours after surgery.
Methods: Lymph, tumor and whole blood were prospectively collected from 8 MIBC patients undergoing radical cystectomy: 4 patients with disease recurrence (REC) and 4 with no evidence of disease (NED) with >1 year of follow-up. Tumor and peripheral blood were collected at surgery; lymph at 24 ± 6 hours after surgical close. For the serial cohort (n=10), lymph was collected every 8 ± 4 hours for 96 hours after surgery. Next-generation sequencing libraries were prepared from genomic and cfDNA using a 500 gene pan-cancer hybrid capture panel; deduplicated coverage was >250X for tumor and blood and >2500X for lymph. Somatic mutations were identified in tumor with matched blood. Tumor-specific variants were directly genotyped in lymph using a custom bioinformatic pipeline. Mutation calls were filtered by a base-specific error model to eliminate artifacts.
Results: At 24 hours post-surgery, lymph ctDNA was detected in 4 out of 8 patients (50%). Significantly higher variant allele fraction (VAF) was observed in REC lymph than NED ($p = 0.00038$). We classified patients as positive (>1) or negative (<1) for detected mutations and performed a KM survival analysis (sensitivity = 75%, specificity = 75%, Hazard Ratio (HR) = 4.3, $p = 0.17$). To understand the impact of collection timing, serial lymph samples were analyzed. There were no differences across timepoints for either mutation count or mean VAF (repeated measures ANOVA $p = 0.33$ and 0.91, respectively).
Conclusion: We demonstrate the feasibility of analyzing ctDNA in post-surgical lymph in MIBC. ctDNA levels were stable across the first 96 hours after surgery, a pattern consistent with ongoing shed from residual tumor as opposed to decay of DNA from resected tumor debris. While non-significant in this small cohort, the HR and sensitivity in this feasibility pilot are consistent with published larger studies in HNSCC. If these results generalize, postoperative lymph MRD testing has the potential to provide more personalized adjuvant treatment decision-making in MIBC patients.

#2605 Concordance evaluation of plasma whole-exome sequencing (pWES) and tissue whole-exome sequencing (tWES): A pilot study in non-small cell lung cancer (NSCLC).

Bingjie Dong[1], Zhijiao Wang[1], Carol E. Pena[2], Xiaoqiao Liu[1], Gefei Zeng[1]

[1]MSD China, Beijing, China,[2]Merck & Co., Inc., Rahway, NJ

Background: Circulating tumor DNA (ctDNA) analysis by pWES offers the possibility for comprehensive characterization of tumor-derived alterations and longitudinal monitoring of tumor molecular evolution in a minimally invasive manner. Here, we conducted a pilot study to evaluate the analytical performance of a pWES assay with boosted content compared with tWES in NSCLC.
Methods: Cell-free DNA isolated from commercially-acquired plasma samples of patients with stage I-IV NSCLC were analyzed using the PredicineWES+ assay (WES plus a boosted 600-gene panel; Huidu Shanghai Medical Sciences Ltd, China). The copy number burden score (cnbScore; a quantitative measure of genome-wide copy number abnormality as a proxy for tumor fraction [TF]) was derived from low-pass plasma whole-genome sequencing (pWGS). pWES TF was based on the maximum mutation allele fraction of nonsynonymous somatic mutations (single nucleotide variants [SNVs] + indels). Jaccard Index (JI), Spearman correlation (ρ), and Wilcoxon rank-sum test were applied to quantify concordance and differences across measures between pWES and tWES.
Results: 39/40 samples were evaluated by low-pass pWGS (stage II-III, 80%). A high TF (cnbScore ≥5.6) was associated with late-stage tumors and squamous cell carcinoma (SCC) histology. Thirty samples (25 highest and 5 lowest cnbScore samples) were selected for pWES. pWES TF was significantly correlated with pWGS cnbScore ($\rho = 0.64$; $P < 0.001$). Of 30 samples evaluated by pWES, 14 samples were ctDNA-positive (cnbScore ≥5.6) and were included in concordance analyses with tWES. Adenocarcinoma- and SCC-specific driver mutations were highly concordant between pWES and matched tWES (JI = 0.72). NSCLC-dominant smoking-associated mutational signature was identifiable by pWES and was correlated with tWES ($\rho = 0.58$). Considerable concordance of mutation calling was observed between pWES and tWES (median JI = 0.47). Blood tumor mutational burden (TMB) was highly correlated with tissue TMB ($\rho = 0.69$). Compared with nonboosted exome region, boosted region with higher sequencing depth had numerically better TMB correlation ($\rho = 0.81$ vs 0.64) and SNV concordance (median JI = 0.80 vs 0.44) between pWES and tWES. Disconcordant copy number variant results were observed between pWES and tWES, possibly due to low ctDNA TF and copy number gain in tissue.
Conclusions: ctDNA tumor burden metrics by pWES correlated with low-pass pWGS and showed association with tumor stage and histologic subtype of NSCLC. pWES feasibly characterized TMB and SNV in NSCLC especially in ctDNA-positive samples and in the boosted 600-gene WES panel, indicating potential utility for longitudinal tumor profiling and monitoring during treatment.

#2606 A liquid biopsy assay of estrogen receptor activity predicts response to giredestrant in ER+/HER2– advanced breast cancer.

Ann E. Collier[1], Jon Beagan[2], Travis Clark[2], Kristian Cibulskis[2], Corrie Painter[2], Mary McGillicuddy[2], Aparna Gorthi[2], Khoi Nguyen[2], James Sullivan[1], Richard Schwab[1], Jing Zhu[1], Pablo Perez-Moreno[1], Tharu M. Fernando[1], Matthew Eaton[2], Carl J. Barrett[2]

[1]Genentech, Inc., South San Francisco, CA,[2]Precede Biosciences, Boston, MA

Background: Endocrine resistance limits benefit durability in ER+/HER2– advanced breast cancer (aBC), particularly after CDK4/6 inhibition. Prior studies have shown that tumor RNA-based estrogen receptor (ER) activity predicts response to the oral SERD giredestrant and serves as a pharmacodynamic (PD) biomarker of ER pathway suppression. However, tumor RNA profiling requires serial biopsies which are often challenging in aBC. The Precede ER Dependence Index (PERDI) quantifies ER-driven cis-regulatory enhancer activity from circulating chromatin, enabling noninvasive monitoring of ER pathway dependence and treatment response.
Methods: 87 patients (pts) with ER+/HER2– aBC received second or third line giredestrant, alone or in combination. One milliliter of plasma from 87 pre-treatment (tx) and 9 on-tx samples was profiled using Precede's comprehensive epigenomic liquid biopsy assay. PERDI scores were evaluable for 80 pre-tx and 8 on-tx samples. Baseline *ESR1* mutation (m) status was determined using the FoundationOne®Liquid CDx assay. PERDI concordance was assessed against tissue ER activity from matched RNA-seq. Plasma-based gene expression was inferred using Precede's algorithms that integrate enhancer, promoter and DNA methylation features.
Results: Plasma PERDI strongly correlated with tumor tissue ER activity in pts without detectable *ESR1*m and effectively discriminated *ESR1*m status. Plasma-derived predictions of ER signaling-related genes were concordant with tumor RNA-seq results, with identified genes offering biological insights into clinical response. At baseline, PERDI distinguished RECIST 1.1-evaluated responders well compared to tumor ER activity or ctDNA level. Similar to tumor ER activity, a median split of PERDI demonstrated strong predictive power (HR=0.43; CI: 0.20-0.93), with median PFS of 11.4 months in the PERDI-high group and 2.0 months in the PERDI-low group. The effect size was further enhanced when comparing the top versus bottom PERDI tertiles (HR=0.19; CI: 0.07-0.52). PERDI complemented *ESR1*m status and ctDNA levels in predicting response, identifying rapid progressors with *ESR1*m as well as durable responders despite high ctDNA or absent *ESR1*m. PERDI declined on-tx in all partial responders (3/3), suggesting pathway-specific modulation beyond ctDNA effects.
Conclusions: PERDI quantifies plasma-based ER activity and predicts giredestrant benefit, particularly when integrated with *ESR1* genotype or ctDNA tumor fraction. PERDI also showed early evidence of PD change directly from plasma, mitigating the need for serial tumor biopsies. cfDNA-based gene expression modeling enables noninvasive assessment of ER dependence and response-associated transcriptional programs, offering a scalable framework for monitoring endocrine response and adaptation in ER+/HER2– aBC.

#2610 Development and clinical evaluation of ^{64}Cu-RAX301: A next-generation PSMA PET tracer for enhanced detection of metastatic prostate cancer.

Fei Chen[1], Min Hong[2], Xupeng Hu[2], Yang Cao[2], Jie Li[1], Zhao Li[1], Shuanglong Liu[2], **Guangzhou Han**[2], Suping Li[1], Gang Chen[2]

[1]Department of Nuclear Medicine, Affiliated Hospital of North Sichuan Medical College, North Sichuan Medical College, Nanchong, China,[2]RadAlliance Therapeutics Inc., San Diego, CA

Prostate-specific membrane antigen (PSMA) PET imaging is widely used for diagnosing and staging prostate cancer, yet the currently approved ^{68}Ga- and ^{18}F-labeled tracers are limited by short half-lives and high urinary excretion, which can obscure small pelvic lesions. To overcome these challenges, ^{64}Cu-RAX301 was developed as a high-affinity PSMA PET tracer designed for improved biochemical stability and extended imaging flexibility. The RAX301 precursor and its ^{nat}Cu-RAX301 analog were synthesized with high purity, and radiolabeling with ^{64}Cu was optimized to achieve high molar activity (≥2000 mCi/μmol) and radiochemical purity (>95%), and remaining stable for over 48 hours post-formulation. Surface plasmon resonance revealed sub-picomolar binding affinity (Kd < 1 pM) for both the precursor and ^{nat}Cu-RAX301, markedly stronger than PSMA-617 (22 pM). Consistent with this, cell-based assays showed two-fold higher affinity, 1.5-fold greater uptake, and four-fold higher internalization compared with ^{64}Cu-PSMA-617 (≈80% vs. ≈20%). In LNCaP xenograft mice, ^{64}Cu-RAX301 demonstrated intense and persistent tumor uptake, with tumor-to-muscle ratios exceeding one hundred at 4 hours post-injection. PET imaging in *Macaca fascicularis* revealed primarily renal clearance with minimal uptake in other organs. In a first-in-human study of ten patients with metastatic castration-resistant prostate cancer (mCRPC), sequential PET/CT scans were performed first with ^{68}Ga-PSMA-11 (5 mCi; imaging at 1 hour post-injection) and then with ^{64}Cu-RAX301 (5 mCi; imaging at 4 and 24 hours post-injection), separated by 1-7 days. ^{64}Cu-RAX301 detected all lesions identified by ^{68}Ga-PSMA-11 while providing higher lesion uptake and superior tumor-to-background contrast. Notably, ^{64}Cu-RAX301 revealed numerous additional small lesions at various sites, including pelvic lymph node metastases that were frequently missed by ^{68}Ga-PSMA-11 due to early bladder activity. The tracer exhibited an excellent safety profile with no significant adverse events. Collectively, these preclinical and early clinical findings demonstrate that ^{64}Cu-RAX301 possesses ultra-high PSMA affinity, favorable pharmacokinetics, and enhanced lesion visualization compared with ^{68}Ga-PSMA-11, supporting its potential as a next-generation PSMA PET imaging agent with improved sensitivity and diagnostic performance in metastatic prostate cancer. Ongoing clinical studies aim to further define its diagnostic impact and broader clinical utility.

#2611 Prospective evaluation of 68Ga-PSMA PET imaging in advanced hepatocellular carcinoma patients undergoing first line immunotherapy.

Nguyen H. Tran[1], Jacob Hirdler[1], Ajith Antony[2], Jacob Teske[1], Sudhakar K. Venkatesh[1], Amit Mahipal[3], Michael S. Torbenson[1], Scott M. Thompson[1], Thor R. Halfdanarson[1], Zhaohui Jin[1], Lionel Aurelien Kankeu Fonkoua[1], Leslie A. Washburn[1], Alexander Revzin[1], Haidong Dong[1], Robert R. Mcwilliams[1], Aminah Jatoi[1], Hani M. Babiker[4], Mitesh J. Borad[5], Tanios Bekaii-Saab[5], Gregory J. Gores[1], Lewis R. Roberts[1], Geoffrey B. Johnson[1], Ajit H. Goenka[1]

[1]Mayo Clinic, Rochester, MN,[2]MD Anderson, Houston, TX,[3]University Hospital, Cleveland, OH,[4]Mayo Clinic Florida, Jacksonville, FL,[5]Mayo Clinic Arizona, Scottsdale, AZ

Prostate-specific membrane antigen (PSMA) is highly expressed in tumor-associated neovasculature in hepatocellular carcinoma (HCC), highlighting its promise as a theranostic target. This prospective study aimed to evaluate the utility of novel biomarkers derived from PSMA positron emission tomography computed tomography (PET/CT) to assess treatment response in advanced HCC patients (pts) receiving first line immune checkpoint inhibitors (ICI).

Methods: This study (NCT05176223) enrolled unresectable, advanced HCC pts eligible for first-line ICI (atezolizumab/bevacizumab [A/B] or durvalumab/tremelimumab [D/T]) with measurable disease according to RECIST criteria. Primary endpoints: progression-free survival (PFS) per RECIST 1.1 and mRECIST; overall survival (OS); and best overall response. The survival distribution was estimated using the Kaplan-Meier method. Observed agreement is defined as the proportion of pts whose responses, as classified by PET/CT or CT, were concordant. Weighted kappa and Cohen's kappa were used to quantify the strength of agreement between PET/CT and CT. Pts completed up to five 68Ga-PSMA PET/CT scans and blood collections.

Results: Twenty-six pts were enrolled (25 evaluable) between Oct 2022 and Nov 2024. Median follow up was 22.1 months (m) (Q1, Q3: 14.5-23.7). Median age 68 yrs, 72% male, 88% White, 68% Child-Pugh [CP] A, 32% CP B, 32% Barcelona Clinic Liver Cancer [BCLC] stage B, 68% BCLC stage C, 36% with microvascular invasion; 56% received A/B and 40% received D/T treatment. PSMA was positive in 96% of pts at baseline with median SUVmax 14.3 (range 5.1-40.5) and median background liver SUVmax 3.9 (range 2.1-6.8). Median (95%CI) PFS was 5.6 m (4.6-12.5) by both RECIST and mRECIST. Median (95%CI) OS was 18.6 m (7.2-not estimable), with 56% deceased. The observed agreement between PET/CT adapted PERCIST criteria compared to RECIST and mRECIST in determining the best response was 46% and 50% and weighted kappa of 0.63 (95% CI: 0.37-0.90) and 0.66 (0.41-0.92), respectively. Observed agreement between PERCIST compared to RECIST and mRECIST for responders' assessment was 67% and 71% with Cohen's kappa of 0.36 (0.03-0.68) and 0.43 (0.11-0.76), respectively.

Conclusion: In this cohort, PSMA PET/CT avidity was observed in all but one pt with advanced HCC, each demonstrating moderate to high SUVmax values. Median OS and PFS were consistent with outcomes reported in clinical trials. Response assessment using 68Ga-PSMA PET/CT according to PERCIST criteria showed good concordance with both RECIST and mRECIST standards. Analysis of immune biomarkers is ongoing.

#2612 Development and preclinical validation of magnetomotive embolization for enhanced targeting of hepatocellular carcinoma.

Ron C. Gaba[1], **Lobna Elkhadragy**[2], Michael E. Sabo[3], David C. Greenspan[4], Francis M. Creighton[5]

[1]Department of Radiology, University of Illinois at Chicago, Chicago, IL,[2]University of Illinois at Chicago, Chicago, IL,[3]UNandUP LLC, Saint Louis, MO,[4]UN&UP, LLC., Saint Louis, MO,[5]UNandUP, LLC, Saint Louis, MO

Background: Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer and remains a leading cause of cancer mortality worldwide. Catheter-directed transarterial embolization (with or without chemotherapy) is the standard treatment for intermediate-stage HCC, but its survival benefit remains modest, reflecting limitations such as incomplete tumor embolization. To address these limitations, we aimed to develop an embolization approach that improves intratumoral bead localization and tumor embolization through biocompatible magnetic embolization beads and magnetic field guidance.
Methods: A dual-cylinder NdFeB magnet system was engineered to generate focused magnetic fields up to 25 mT at 7.5 cm from the magnet surface, creating a stable magnetic trap. Polycaprolactone-based magnetic embolization beads (40-60 μm) incorporating ~30 nm Fe3O4 iron oxide nanoparticles were synthesized using emulsion polymerization and characterized for morphology, uniformity, and magnetization. Magnet-guided bead delivery was assessed in 3D-printed vascular tumor phantoms and validated in vivo using the rabbit VX2 liver tumor model. Tumor-bearing rabbits (n=12) underwent transarterial embolization and were randomized into magnet-guided (5 Hz alternating rotation, 15 minutes) or control groups (n=6 each).
Results: Microscopic analysis confirmed uniform spherical bead morphology with a narrow size distribution, while SQUID magnetometry demonstrated ferrimagnetic behavior of Fe3O4 nanoparticle cores (magnetization 63.6 emu/g, coercivity 20 Oe at 800 kA/m), confirming strong magnetic responsiveness, and supporting MR-safety. Powder X-ray diffractometry confirmed Fe3O4 with no anomalous peaks suggesting the presence of undesirable iron oxide species. In tumor phantoms, the magnet system successfully concentrated magnetic beads within targeted regions at preclinical relevant distances, achieving reproducible spatial control and contrasting with heterogeneous dispersion in controls. In vivo, transarterial delivery was technically feasible and well tolerated in all tumor-bearing rabbits with no acute complications. Histopathologic analysis demonstrated concentration of the magnetic beads in tumor vasculature in magnet-assisted animals. No device-related toxicity was observed.
Conclusion: This study establishes proof-of-concept for magnetomotive embolization as a novel and feasible locoregional therapy for HCC. The findings demonstrate technical feasibility, procedural safety, and effective intratumoral bead localization in both phantom and preclinical animal models. Building on these results, future work will focus on integrating robotic magnetic field control for dynamic targeting and performing quantitative efficacy and safety studies in large-animal models to advance this technology toward clinical translation.

#2613 Multi-omic characterization of imaging invisible prostate tumors reveals microenvironmental drivers of PET visibility.

Jiyoun Seo[1], Raag Agrawal[2], Pranav Movva[1], Camille Motchoffo Simo[1], Paul C. Boutros[3]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]University of California, Los Angeles, Los Angeles, CA,[3]Sanford Burnham Prebys, La Jolla, CA

Background: Up to 20% of aggressive localized prostate tumors are invisible on PSMA PET or MRI, limiting diagnostic accuracy and treatment selection. As both imaging modalities are routinely used in newly diagnosed patients, defining the molecular basis of imaging visibility is critical for imaging-driven precision medicine. Despite prior evidence implicating stromal and metabolic pathways, the biology of imaging visibility has not been resolved using directly linked multi-omic data. To address this, we analyzed prostate tumors with matched imaging and multi-omic profiles to define molecular programs underlying PET and MRI visibility.
Methods: A total 71 grade group 2-3 prostate tumors were obtained from 59 patients who underwent paired PSMA PET and MRI before prostatectomy. Macrodissected tumor regions underwent bulk RNA sequencing, targeted DNA sequencing, and proteomics. Associations with PET SUVmax and MRI visibility (PIRADS≥4) were tested using multivariable models adjusting for clinico-pathologic features (FDR>0.05). Gene set enrichment was performed on ranked test statistics using preranked GSEA with MSigDB Hallmark, KEGG, and Reactome annotations. Concordant molecular features were cross-referenced across DNA and protein datasets to identify pathways consistently associated with imaging visibility.
Results: MRI-invisible tumors showed downregulation of proliferative and metabolic pathways, including DNA repair and glycolysis, consistent with a quiescent phenotype. PET visibility was associated with transcriptionally and metabolically active states. Furthermore, integrative RNA, DNA, and proteomic analyses converged on extracellular matrix remodeling and immune-regulatory processes as major correlates of PSMA PET signal intensity, indicating that stromal and immune architecture shape imaging detectability. Surfaceome profiling further highlighted cell-surface proteins involved in matrix and immune interactions as candidate alternative biomarkers for PET imaging in PSMA low tumors.
Conclusions: These data suggest PSMA PET visibility reflects biologically active tumor states characterized by DNA damage response and extracellular matrix remodeling, while MRI invisibility corresponds to a more quiescent and metabolically repressed phenotype. Integrated molecular and surfaceome analyses indicate that stromal and immune alterations contribute to PSMA uptake and imaging detectability. Together, these findings support imaging visibility as a biologically driven marker with potential to refine risk assessment and guide precision management in prostate cancer.

#2614 Advancing pancreatic cancer theragnostic through claudin-4-selective radiolabeled peptides: Design, optimization, and preclinical validation.

Marian N. Aziz[1], Nisi Zhang[1], Mallesh Pandrala[2], Jongmin An[3], Yutong Guo[2], Marina Raie[2], SPENCER TUMBALE[2], Basit Jan[2], Katherine W. Ferrara[4]

[1]Stanford University School of Medicine, Palo Alto, CA,[23]Stanford University School of Medicine, Stanford, CA,[4]Stanford University, Palo Alto, CA

Accurate cancer imaging is critical for early diagnosis, guiding therapy, and assessing clinical outcomes. Yet pancreatic ductal adenocarcinoma (PDAC) poses major imaging obstacles, mainly due to its complex microenvironment, extensive stromal composition, and rapid disease progression. Claudin-4 (CLDN4), a tight junction protein, is significantly overexpressed in PDAC, making it a promising diagnostic and therapeutic target. Our spatial transcriptomic and proteomic analyses confirmed a 16-fold increase in CLDN4 expression in PDAC compared with normal pancreas. This significant finding supports its accessibility on tumor cell surfaces and suitability for molecular imaging approaches such as positron emission tomography (PET).Methods:We designed selective CLDN4-targeted peptides using solid-phase peptide synthesis, followed by rational optimization through D-amino-acid substitutions to enhance metabolic stability and dimerization strategies to improve affinity and tumor retention. The peptide structures were conjugated to a DOTA chelator through pegylated linkers of varying lengths and evaluated for serum stability. Binding affinity was measured using biolayer interferometry (BLI). Peptides were radiolabeled with ^{68}Ga and ^{64}Cu and tested in subcutaneous and transgenic PDAC-KPTC mouse models using dynamic PET/CT imaging.Results:The synthesized peptides showed good binding affinity for CLDN4 and were successfully radiolabeled with ^{68}Ga and ^{64}Cu. Serum stability studies revealed that tracers with longer PEG linkers exhibited superior stability after 4 hours of incubation. We found a similar observation with D-amino-acid-modified sequences, which showed better stability than the parent peptide. For preclinical testing, we observed that tumor uptake of the tracers gradually increased during the first hour of the dynamic scan, surpassing 10% ID/g at 40 minutes post-injection. This uptake correlated with TdTomato fluorescence, which marks cells expressing CLDN-4 in our genetically engineered model. The in-vitro imaging in a negative control subsequent model confirms the specificity of our tracers to tumors expressing claudin4. Further studies are ongoing to evaluate preclinical imaging of dimeric peptides and D-amino acid-modified sequences. This peptide-based theragnostic strategy has strong potential to improve early detection and guide targeted therapy in PDAC.

#2615 Diffusion kurtosis imaging to predict tumor hypoxia and recurrence in HPV-associated oropharyngeal cancer.

David Gibbes Miller[1], Ramesh Paudyal[2], Bill H. Diplas[1], James E. Han[1], Vaios Hatzoglou[3], Nadeem Riaz[1], Amita Shukla-Dave[2], Nancy Y. Lee[1]

[1]Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Department of Medical Physics, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: A recent phase II trial demonstrated the efficacy of hypoxia-guided chemoradiation (CRT) de-escalation in human papillomavirus-associated oropharyngeal cancer (HPV+ OPC). 18F-fluoromisonidazole (18F-FMISO) positron emission tomography (PET), used to measure hypoxia, is not widely available, limiting use of hypoxia as an imaging biomarker in research and clinical care. Diffusion kurtosis imaging (DKI) quantifies non-Gaussian water diffusion, especially at higher b-values of diffusion weighted (DW) data. DKI captures microstructural complexity, reflects integrity of cell membranes and cellularity, and may serve as a surrogate for hypoxia.
Methods: DW data were obtained from a phase II trial of hypoxia-guided CRT de-escalation in patients with T0-2/N1-N2c HPV+ OPC. Patients received pre-treatment 18F-FMISO imaging and serial MRI scans from pre-treatment through week 4 of CRT. Longitudinal nodal volume was collected. DKI-derived features Dapp and Kapp (mean values, standard deviation, and skewness) from modeling of the multiple b-values DW data were extracted. Associations with pre-treatment hypoxia and nodal recurrence were evaluated using Wilcoxon rank-sum tests. Random forest (RF) models integrating volume and DKI-derived features were developed to predict hypoxia and recurrence, with feature importance assessed using SHAP values.
Results: 90 of 158 trial patients with longitudinal DW-MRI exams were included. Pre-treatment 18F-FMISO PET demonstrated normoxia in 25 patients (27.8%) and hypoxia in 65 (72.2%). Pre-treatment tumor volume was significantly higher in hypoxic tumors than normoxic tumors (mean 25.7 vs. 11.3 cm^3, $p < 0.001$), while pre-treatment DKI-derived features did not differ significantly. Eight patients had nodal recurrence, all in the de-escalated cohort. An RF model incorporating pre-treatment DKI features and tumor volume predicted pre-treatment hypoxia with good discrimination (AUC = 0.77), outperforming a model using volume alone (AUC = 0.65, $p<0.001$). SHAP analysis identified tumor volume, Dapp skewness, Dapp mean, and Kapp mean as the most meaningful predictors. Longitudinal tumor volume in weeks 2-4 was significantly higher in patients who recurred, while longitudinal DKI features did not differ significantly. The model using week 3 volume and DKI features had the best performance (AUC = 0.79). SHAP analysis identified volume, volume change from pretreatment to week 3, Kapp skewness, and mean Dapp as the most meaningful predictors of recurrence.
Conclusion: Changes in cell architecture and metabolism caused by hypoxia may be associated with restricted movement of water molecules in complex tissues. DKI and volumetric measurement demonstrated good predictive ability for both hypoxia and recurrence risk in HPV+ OPC. These findings support further prospective validation of DKI for assessing tumor hypoxia and recurrence risk.

#2616 ECM profiling of patient-matched endometrial PDX-tumors reveals translational drift and TME remodeling.

Dhruva Dave[1], Rebecca Christian Arend[1], Chelsea Crawford[2], Amr Mahmoud[2], Brahma Mubarak K. Budhwani[2], Khidr Kishan K. Budhwani[2], Hunter Segrest[1], Ashwini Katre[1], Rachael E. Guenter[2], Karim Ismail Budhwani[3]

[1]Obstetrics and Gynecology, University of Alabama at Birmingham, Birmingham, AL,[2]CerFlux, Birmingham, AL,[3]University of Alabama at Birmingham, Birmingham, AL

Background: Extracellular matrix (ECM) remodeling, particularly collagen deposition, have been linked with aggressive features of endometrial. It plays a critical role in tissue architecture, deep myometrial invasion, immune infiltration, and therapeutic response. Patient-derived xenograft (PDX) models are widely used in cancer research; however, their ability to preserve patient-specific ECM organization remains uncertain. This study quantified ECM composition and spatial topology to evaluate species-specific translational drift.

Methods: Formalin-fixed, paraffin-embedded tissue from two primary endometrial tumors and matched PDX tumors underwent dual Picrosirius Red (collagen) and Alcian Blue (hyaluronic acid; HA) staining. High-resolution brightfield images were captured under standardized conditions using an Agilent Lionheart system. ECM profiling was performed using the CerFlux PEER AI/ML imaging pipeline, extracting 63 histomorphometric and spatial parameters, including ECM area fractions, HA:collagen ratios, gray-level co-occurrence matrix (GLCM) texture metrics, and Moran's I spatial autocorrelation. Analyses were cross validated in Fiji. Group comparisons used nonparametric statistics, and principal component analysis (PCA) summarized multivariate ECM signatures.

Results: Patient tumors demonstrated substantially higher collagen area fraction than matched PDX tumors (0.20 ±0.01 vs 0.05 ±0.04; $p<0.05$), while HA levels were similar (0.41 ±0.03 vs 0.33 ±0.14). This yielded a marked shift in HA:collagen ratio, from 2.1 ±0.3 in patients to 7.9 ±2.7 in PDX tumors ($p<0.05$). Texture analysis revealed more heterogeneous collagen organization in patient tumors, with higher entropy (8.22 ±0.10 vs 8.07 ±0.02; $p<0.05$) and lower homogeneity (0.15 ±0.02 vs 0.19 ±0.01; $p<0.05$). HA exhibited a similar pattern of increased uniformity in PDX tumors (homogeneity 0.16 ±0.07 vs 0.10 ±0.01; $p<0.05$). Spatial statistics showed a nearly two-fold increase in collagen Moran's I in PDX tumors (0.51 ±0.02 vs 0.26 ±0.07; $p<0.05$), indicating stronger ECM clustering and reduced spatial heterogeneity relative to patient tissue. PCA cleanly separated patient and PDX samples along PC1 (58% variance), driven by HA:collagen balance, textural heterogeneity, and spatial autocorrelation.

Conclusions: Quantitative ECM profiling demonstrates that patient-matched endometrial PDX tumors undergo pronounced translational drift, including collagen depletion, increased HA:collagen ratio, higher ECM homogeneity, and strengthened spatial clustering. These changes reflect species-specific TME remodeling following xenografting and may influence drug penetration, response, and biomarker interpretation. Assessing ECM fidelity is therefore vital when using PDX models to inform translational research and preclinical decision-making in endometrial cancer.

#2617 Rapid assessment of patient derived cancer organoids using label-free imaging and an automated analysis pipeline.

Amani A. Gillette[1], Angela Hsu[1], Shirsa Udgata[2], Alexa Schmitz[2], Dustin A. Deming[3], Melissa Skala[4]

[1]Morgridge Institute for Research, Madison, WI,[2]Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[3]University of Wisconsin Carbone Cancer Center, Madison, WI,[4]Biomedical Engineering, University of Wisconsin - Madison, Madison, WI

Background: Tumor heterogeneity presents a major challenge in effective cancer treatment, particularly in colorectal cancer (CRC), by limiting the efficacy of therapies and driving resistance. Patient-derived cancer organoids (PDCOs) have emerged as powerful preclinical models that faithfully recapitulate the genomic, morphological, and metabolic profiles of primary tumors. However, current methods for rapidly and reproducibly assessing PDCOs are limited. Label-free imaging methods are a promising tool to measure organoid level heterogeneity and rapidly screen drug response in PDCOs. However, manual analysis of wide-field optical redox images is inefficient and laborious for large-scale drug screens. Here, we developed an automated pipeline for PDCO segmentation, single-PDCO tracking, and background correction in autofluorescence images.
Methods: Wide field optical redox imaging (WF ORI) provided organoid-level measurements of treatment response without labels or additional reagents by measuring the autofluorescence intensity of the metabolic co-enzymes NAD(P)H and FAD, and the optical redox ratio, defined as the fluorescence intensity of [NAD(P)H/NAD(P)H+FAD], was used to measure the oxidation-reduction state of multiple CRC PDCO lines. Development of leading-edge analysis tools, isolating the ORI measurement to a 32μm region at the outer edge of the PDCOs, helped to maximize the sensitivity and reproducibility of treatment response measurements using WF ORI in CRC PDCOs. The automated pipeline includes segmentation using a fine-tuned Cellpose model, automated single-PDCO tracking over time via custom python code, and background correction. Glass's delta (GΔ) is used to measure the PDCO treatment effect size.
Results: Leading-edge analysis improves sensitivity to redox changes in treated PDCOs (GΔ = 1.462 vs GΔ = 1.233). Automated segmentation, when compared to manual masks, achieved mean Dice scores ≥0.8, indicating high reproducibility. Additionally, automated PDCO tracking accuracy exceeded 94% by two metrics, recall and Jaccard index, when compared to manual tracking. Importantly, the automated pipeline resolves single-PDCO responses over time with comparable sensitivity to drug treatment with over 127× faster processing time compared to the manual process.
Conclusion: Overall, we demonstrate that combining PDCOs with accessible imaging and analysis techniques enables high-throughput detailed evaluation of tumor heterogeneity and therapeutic response.

#2618 Thoracic ct-derived muscle indices improve prediction of respiratory function beyond standard L3 sarcopenia measures in lung cancer patients.

Kayleigh R. Erickson, Juan Adrover Claudio, Chi-Chen Hong, Ken Batai, Nicolas F. Schlecht, Sai Yendamuri, Andrew Ray

Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background. L3 skeletal muscle index (SMI) is the CT standard for whole-body sarcopenia but does not assess thoracic musculature and may miss muscle morphology tied to respiratory mechanics and upper-body function. This study evaluated whether thoracic muscle measures provide independent or complementary information beyond L3 SMI for functional and pulmonary performance in lung cancer patients.

Methods. Ninety adults with newly diagnosed lung cancer who completed clinically indicated CT imaging and baseline pre-treatment functional assessments were analyzed. SMI was quantified at L3 and thoracic levels (T4, T6, T8, T10). Functional outcomes included handgrip strength (HGS), gait speed, sit-to-stand, and 6-minute walk distance (6MWT). Pulmonary outcomes included maximal inspiratory and expiratory pressures (MIP, MEP), Forced Vital Capacity (FVC), Forced Expiratory Volume in 1 second (FEV1), and Peak Expiratory Flow (PEF). Outcomes were examined continuously and dichotomized at clinically relevant thresholds: weak HGS (< 28 kg for men; <18 kg for women), impaired 6MWT (<300 m), and respiratory muscle weakness (MIP ≤ 62/83 cmH_2O and MEP ≤ 81/≤ 109 cmH_2O in men/women). Correlations, multivariable linear regression (adjusting for age, sex, body mass index (BMI), smoking, and tumor stage), and logistic regression assessed associations; incremental predictive value of thoracic SMI beyond L3 was evaluated using area under the ROC curve (AUC).

Results. Thoracic SMI showed moderate-strong correlations with HGS, MIP, MEP, and PEF (r = 0.24-0.63, all $p < 0.01$). In adjusted models, thoracic SMIs remained associated with HGS (β = 0.20-0.37, $p \leq 0.007$) and several respiratory measures, including MEP at T4/T10 and FVC and PEF at T6/T8. L3 SMI was not independently associated with MEP, MIP, or PEF ($p > 0.10$), but was more strongly related to whole-body mobility (TUG and gait speed, both $p < 0.02$). To connect functional associations with clinical relevance, predictive performance was examined for clinically defined weakness or impairment. For inspiratory muscle weakness, L3 SMI was not predictive (p=0.30; AUC=0.903), and adding thoracic SMI did not improve discrimination (AUCs 0.898 to 0.904). For weak HGS, L3 SMI was not significant (p=0.42, AUC=0.774), whereas adding thoracic SMI increased AUC by 0.06 to 0.12, with T8 showing the largest gain (AUC 0.893). For 6MWT impairment, L3 SMI was predictive (p=0.039, AUC =0.750), while thoracic SMI was not (all p>0.10) and did not meaningfully improve increase AUC (0.75-0.79).

Conclusion. Thoracic CT-derived muscle indices provide domain-specific value beyond L3 SMI, improving prediction of upper-body strength but not inspiratory muscle weakness or whole-body endurance. Incorporating thoracic muscle metrics with standard L3 assessment may enhance functional risk stratification and prehabilitation planning in lung cancer.

#2619 Quantitative modeling of autofluorescence and non-specific staining allows for improved cell phenotyping and marker assessment in highly multiplexed immunofluorescence studies.

Daria I. Mandel, Anton Luis Villamejor, Anthony Colombo, Simeon Mahov, Akil A. Merchant, Joseph Lownik

Cedars-Sinai Medical Center, Los Angeles, CA

While fundamental in cancer diagnostics, immunohistochemistry (IHC) has several significant limitations, including the inability to simultaneously detect multiple markers per slide, which limits true co-expression analysis. In contrast, sequential immunofluorescence (seqIF), a multiplexed protein biomarker detection method, allows for simultaneous detection of multiple markers on a single slide by using antibodies with distinct fluorophores combined with the repeated automated cycles of staining, imaging, and elution. While seqIF has quantitative and scalability advantages over IHC, its use of fluorescence introduces various challenges for downstream computational analysis such as tissue's autofluorescence and non-specific fluorophore accumulation, which are compound by multiple cycles of staining, imaging and elution. The Lunaphore COMET, a seqIF system, allows for an initial background autofluorescence acquisition at the beginning of the protocol. However, we observed that this single baseline measurement did not account changes in the fluorescence of different regions in various tissue types with subsequent imaging and elution cycles, which significantly affected downstream analysis including cell typing.To further investigate these artifacts, we evaluated both autofluorescent quenching on a variety of tissue types during the imaging cycles as well as the non-specific accumulation of fluorophores in all channels (FITC, TRITC, Cy5, and Cy7). We found that the background autofluorescence decreased with sequential cycles in some, but not all cycles, which led to artificially decreased signal intensity for downstream marker analysis. Additionally, we found that non-specific fluorophore accumulation was channel specific, tissue specific, and subcellular localization specific, further confounding interpretability. Overall, these findings suggest that utilizing a single baseline autofluorescence cycle for background subtraction is insufficient and can lead to significant downstream analytical errors.While performing an additional imaging cycle after each elution cycle and subtracting background accordingly may remedy this problem, it is not always feasible or efficient due to increased time, reagent usage, and file size. We found that a total of 5 imaging cycles post-elution accurately predicted the background fluorescence for 20 cycles using a cell-level cubic spline model ($R^2 = 0.94$). These background signal modeling results are then utilized to calculate background-adjusted marker expression values at a cell level for individual cycles, which improved clustering resolution and interoperability. Overall, we demonstrate issues encountered with autofluorescence in seqIF and present a novel method for mitigating them to improve results.

#2620 Comparison of ^{68}Ga-DOTANOC PET/CT with anatomical imaging in opsoclonus-myoclonus-ataxia syndrome in children: A retrospective analysis.

Anish Bhattacharya[1], Rajender Kumar[1], Harmandeep Singh[1], Jitendra Kumar Sahu[2], Naveen Sankhyan[2]

[1]Nuclear Medicine, PGIMER, Chandigarh, India,[2]Pediatric Medicine, PGIMER, Chandigarh, India

Introduction: Opsoclonus-myoclonus-ataxia syndrome (OMAS), also known as “Kinsbourne syndrome” or “dancing eye syndrome,” is a rare immune-mediated paraneoplastic neurological syndrome that may be associated with pediatric neuroblastoma in approximately 2-3% of children aged 1-3 years. OMAS carries a grave prognosis and is characterised by involuntary eye movements, muscle jerks, ataxia and behavioural changes. Paediatric neuroblastoma may be the only cause of OMAS in up to 50% of children. Routine tests to detect occult neuroblastoma include anatomical imaging of the chest and abdomen with USG/ CT/ MRI. ^{131}I-MIBG scintigraphy has also been used; however, its application is limited by its availability, need for strenuous patient preparation, and high radiation exposure. In this retrospective analysis, we evaluated children presenting with OMAS who underwent ^{68}Ga-DOTANOC PET/CT as a single screening study to detect neuroblastoma and stage the disease, in comparison to traditional anatomical imaging.

Methods: Retrospective data from ^{68}Ga-DOTANOC PET/CT scans of 43 pediatric patients presenting with OMAS from January 2019 to June 2024 were evaluated. A somatostatin receptor (SSTR) expressing lesion with corresponding morphological change on the CT image was considered PET-positive, while no abnormal SSTR expression or lesion was considered PET-negative. The results of ^{68}Ga-DOTANOC PET/CT were also compared with prior anatomical imaging studies, which were available for 32 patients (in both PET-positive and PET-negative groups).

Results: Of 43 patients (21 male, 22 female; mean age 1.5 years), 31 (72.1%) were PET-positive and 12 (27.9%) were PET-negative. The mean SUVmax of PET-positive lesions was 12.1 (SD = 6.6). Prior anatomical imaging studies (USG (n=13)/ CT (n=6)/ MRI (n=13)) were available in 32 patients and compared with ^{68}Ga-DOTANOC PET/CT. Discordance was seen in 5 patients with prior USG and 1 patient with prior MRI, in which lesions were missed in 3 patients on USG and 1 patient on MRI. One suspicious lesion was excluded from diagnosis by ^{68}Ga-DOTANOC PET/CT in 1 patient. According to the International Neuroblastoma Staging System (INSS), 24 (80%) were stage 1, 4 (6.4%) were stage 2, 1 (4%) were stage 3, and 2 (6.4%) were stage 4. Repeat ^{68}Ga-DOTANOC PET/CT was done in 7/31 of stage 1 patients after surgical excision, and all were PET-negative.

Conclusion: In this retrospective analysis, we found that approximately 72% of children presenting with OMAS have neuroblastoma as the primary etiology. ^{68}Ga-DOTANOC PET/CT demonstrated high diagnostic performance, accurately identifying neuroblastoma and providing rapid diagnosis, detection of metastasis, and guidance for optimal management.

#2621 A systematic review of radiogenomic applications in prostate cancer.

Thineskrishna Anbarasan[1], Matilda Dichmont[2], Sandy Figiel[1], Bartlomiej Papiez[1], Alastair Lamb[3], Richard Bryant[1], Ian Mills[1]

[1]University of Oxford, Oxford, United Kingdom,[2]Oxford University Hospitals, Oxford, United Kingdom,[3]Barts Cancer Institute, London, United Kingdom

Introduction: A priority in prostate cancer (PCa) research is development of precise risk stratification tools to enable early identification of men with aggressive tumours while minimizing overtreatment of others with indolent disease. With imaging playing a central role in the diagnosis and management of PCa, radiogenomics has been explored as a personalised medicine approach to improve risk stratification. This study aims to review and describe radiogenomic applications reported in the literature.

Methods: Medline, Embase and Cochrane libraries were systematically searched using variations of search terms for articles reporting radiogenomic applications in PCa after 2010. Articles were included if the following were reported (1) genomic platform used; (2) method of determining region of interest (ROI) for radiomic feature extraction; (3) correlation analyses between radiomics and genomics.

Results: A total of 267 articles were screened and 13 met the inclusion criteria following independent review by two authors. Majority (n=10/13) reported MRI-based applications involving 715 patients. Remaining modalities included ultrasound (n=1) and PET scan (n=2). Most (7/10) studies evaluating an MRI imaging modality, correlated bulk RNA-sequencing with radiomic features. Textural radiomics (n=6) features were most commonly reported to correlate with gene expression followed by histogram (n=2) and volumetric features (n=1). MRI radiomics significantly correlated with hypoxia related genes in 4 studies. The textural feature (Gray Level Co-occurrence Matrix) was seen to correlate with *ANGPTL4* expression in 3 studies. Median AUC for a radiogenomic model to predict presence of clinically significant PCa was 0.746. Only 4 studies (MRI-based n=3, ultrasound-based n=1) externally validated the developed model. Most (9/13) studies used a manual qualitative approach to register imaging loci with site of tissue acquisition for genomic analysis.

Conclusion: There is significant heterogeneity in the reporting and design of prostate cancer radiogenomic studies. A signal suggesting and association of MRI textural radiomic features have been consistently observed in several studies but lack validation

#2625 αTIGIT-guided IL-15 mimetics enable potent and safe antitumor immunity.

Xiangming Liu, Nan Li, **Yang-Xin Fu**, Zaopeng Yang

Changping Laboratory, Beijing, China

Cytokines are powerful modulators of antitumor immunity, but their clinical use is constrained by structural instability and systemic toxicity. Although antibody-based cytokine mimetics have recently emerged to activate immune cells *in vitro*, their therapeutic activity *in vivo* remains uncertain. Here, using interleukin-15 (IL-15) as a model, we engineered bispecific antibody-based IL-15 mimetics guided by AlphaFold3-assisted structural modeling. Comparative screening of multiple formats identified tandem IL-15 mimetics with strong *in vitro* bioactivity, but unexpectedly showed minimal antitumor activity *in vivo*. Strikingly, incorporating TIGIT-directed targeting transformed these mimetics into potent and nontoxic cytokine agonists, resulting in strong tumor control associated with enhanced effector activation and expansion of intratumoral $CD8^+$ stem-like T cells. These findings indicate that current cytokine mimetics have limited activity when used alone and require precise T-cell targeting to achieve therapeutic potency. Our study highlights a strategy to use cytokine mimetics to overcome the mismatch between immune checkpoint blockade and low-potency cis-targeted cytokines, offering a path toward safer and more effective cytokine immunotherapy.

#2626 A cleavable IL10-TCE counteracts TCE-induced T cell dysfunction and eradicates solid tumors without toxicity.

Xinxin Wang, **Yang-Xin Fu**, Zaopeng Yang

Changping Laboratory, Beijing, China

The clinical success of T cell engagers (TCEs) in hematologic malignancies has been difficult to replicate in solid tumors due to limited efficacy and on-target toxicities, partly driven by CD3-directed activation-induced cell death (AICD) and exhaustion of tumor-infiltrating lymphocytes (TILs). To overcome T cell dysfunction in the tumor microenvironment, we found that IL-10 receptor expression is enriched on antigen-specific T cells and that exogenous IL-10 markedly reduces T cell death while preserving overall T cell numbers. Guided by this insight, we engineered a series of IL-10-integrated TCE formats and identified an optimized design in which IL-10 is fused to the N-terminus of the anti-CD3 arm in a cleavable configuration, generating a pro-TCE (IL10-TCE) with favorable biochemical properties and potent antitumor activity without detectable toxicity. The IL10-TCE enhanced effector function and substantially expanded both total and antigen-specific T cells within tumors, resulting in complete regression of established solid tumors and metastatic lesions across multiple syngeneic and xenograft models, including colon cancer, melanoma, and pancreatic cancer. These findings establish IL-10 incorporation as a generalizable strategy to overcome TCE-induced T cell dysfunction, enabling robust tumor eradication and durable immune protection.

#2627 ALX006, a PD-1/VEGF bispecific antibody with best-in-class potential demonstrates superior antitumor activity and favorable PK in preclinical models.

Zenglin Pei, Yupeng Zhu, Jinglu Xia, Zhaojun An, **Barry Duplantis**, Yuhao Wang, Yali Wang, Jia Ge, Xiaojin Zhang, Lingjian Yang, Liang Du, Xiangyu He, Yi Li

Shanghai Ailux Biotechnology Co., Ltd., Shanghai, China

Background: PD-1 and VEGF are frequently co-expressed in the tumor microenvironment. PD-1 blockade reverses tumor-induced immunosuppression, while VEGF inhibition normalizes tumor vasculature and modulates immune cell infiltration. Clinical data from bispecific antibodies, such as Ivonescimab, particularly in advanced non-small cell lung cancer, support the synergistic potential of anti-PD-1 and anti-VEGF therapies to enhance efficacy and reduce systemic toxicity. Here we developed a novel PD-1/VEGF bispecific antibody ALX006 with thoroughly preclinical characterization.
Methods: Binding affinities of ALX006 to PD-1 and VEGF were quantified by surface plasmon resonance (SPR). PD-1/PD-L1 pathway blockade was assessed using a luciferase reporter assay. T-cell reactivation was evaluated by mixed lymphocyte reaction assays. Antitumor activity was tested in A375 cell-derived xenograft (CDX) model in PBMC humanized mice and MC38 syngeneic model in human PD-1/PD-L1/VEGF transgenic mice. Biophysical liabilities and developability were profiled. Pharmacokinetics (PK) were evaluated in Sprague-Dawley rats and cynomolgus macaques.
Results: ALX006 is a 2+2 symmetric IgG1 (Fc-null) bispecific antibody that binds to both targets with high affinity. In the presence of VEGF, ALX006 significantly enhanced PD-1 cell binding and PD-1/PD-L1 signal blockade. ALX006 also increased IL-2 and IFN-γ secretion in a dose-dependent manner in mixed lymphocyte reaction. In addition, ALX006 potently suppressed VEGF-induced endothelial cell proliferation. Importantly, superior antitumor efficacy was observed in the A375 CDX model compared with Ivonescimab and two other clinical-stage bispecifics. Consistent activity was also observed in the MC38 syngeneic tumor model in transgenic mice. ALX006 exhibited favorable biophysical properties and overall developability, with an improved PK profile compared with Ivonescimab.
Conclusions: ALX006, a PD-1/VEGF bispecific antibody with best-in-class potential, demonstrates superior antitumor activity and favorable PK in preclinical models, supporting its potential as a therapeutic candidate for immuno-oncology applications.

#2628 AM109, a PSMA×CD137 bispecific antibody with target-dependent T cell activation and potent anti-tumor activity in prostate cancer.

Dong-Wook Kim, Hyun-Jong Lee, Seong Yeol Kim, Min Yoon, Youngha Lee, In-Sik Hwang, Yoon Lee, Jong-Hoon Kim, Jong-Seo Lee

AbClon, Seoul, Korea, Republic of

Metastatic castration-resistant prostate cancer (mCRPC) remains a fatal malignancy with limited responsiveness to current immunotherapies. To achieve tumor-restricted immune activation, we developed AM109, a bispecific antibody that links a PSMA-targeting humanized antibody to a CD137 (4-1BB) affibody, designed to activate T cells exclusively in the presence of PSMA-expressing tumor cells. AM109 elicited robust $CD8^+$ T-cell activation and cytokine secretion (IFN-γ, IL-2, and Granzyme B) in $PSMA^+$ LNCaP cells, but not in $PSMA^-$ MKN45 cells, confirming its target-dependent mode of action. Cytotoxicity assays demonstrated dose-dependent tumor cell killing that correlated with PSMA expression levels. In vivo efficacy was evaluated using human CD137 transgenic mice bearing hPSMA/MC38 tumors, where AM109 achieved complete tumor regression at doses of 0.1-0.3 mpk, exhibiting superior potency compared with the reference CD137 agonist utomilumab. Structural and functional stability were maintained for at least 12 weeks at 4-40 °C. Pharmacokinetic and single-dose toxicity studies in rodents revealed favorable systemic exposure and good tolerability. Collectively, these findings demonstrate that AM109 selectively activates T cells within the tumor microenvironment, eliciting potent and PSMA-dependent anti-tumor responses with an improved therapeutic window. AM109 therefore represents a promising next-generation immunotherapeutic candidate for the treatment of mCRPC.

#2629 A novel ADAM9 ADC with robust anti-tumor efficacy and remarkable preclinical safety profile.

Ruirui Sui, Yin Lu, Furong Gao, Chen Xu, Jiangbo Song, Guoping Jiang, Liuge Gu, Teddy Yang, Ying Lei, Li Tong, **Fei Peng**

Hongcheng Biopharma, Shanghai, China

ADAM9 (A Disintegrin And Metalloproteinase 9) is a transmembrane metalloproteinase overexpressed in a wide range of solid tumors, where it promotes tumor progression, metastasis, and poor prognosis. Internal immunohistochemistry analysis confirmed ADAM9 expressed at very low levels in most normal tissues, significant ADAM9 upregulation in tumor tissues, makes it a highly attractive and viable target for antibody-drug conjugate (ADC) development. An affinity optimized, humanized monoclonal antibody (HC031) was generated against human ADAM9. HC031 cross reacts with cyno ADAM9 with similar affinity. HC031 exhibited specific binding to human ADAM9 with no detectable binding to other ADAM family isoforms. HC031 selectively binds to membrane form of ADAM9 but not to short soluble ADAM9 predicting a regular pharmacokinetic profile unimpeded by soluble ADAM9. Furthermore, HC031 binding is partially dependent of bivalent cation, which may contribute to an improved safety profile. HC031 ADC was generated through conjugation with a novel, proprietary cytotoxic payload (camptothecin derivatives) via a highly stable linker. The resulting ADC demonstrated potent, target-specific cell killing *in vitro* and induced robust and sustained tumor regression in multiple xenograft models. Exploratory toxicology studies in non-human primates revealed an exceptionally maximum tolerated dose (MTD) of 120 mg/kg. No drug-related severe adverse events or significant abnormalities in hematological, biochemical, or coagulation parameters were observed. HC031 ADC exhibited favorable and dose-proportional PK profiles, with extended exposure of the intact ADC. Critically, the linker-payload demonstrated superior plasma stability.HC031 ADC drives potent anti-tumor activity *in vitro* and *in vivo*. Its exceptional stability in circulation and remarkable preclinical safety profile in NHPs predicts a significantly broader therapeutic window compared to existing ADAM9 ADCs.

#2630 MRG008: A novel EGFR and 5T4 bispecific antibody-drug conjugate (ADC) with potent antitumor activity in preclinical studies.

Yuanyuan Yang[1], **Zhijian Cai**[1], Deliang Li[1], Shoujia Liu[2], Wenci Gong[1]

[1]Lepu Biopharma Co., Ltd., Shanghai, China,[2]Shanghai Miracogen Inc., Shanghai, China

Background: Non-small cell lung cancer (NSCLC) is one of the most challenging cancers with unmet medical needs. EGFR (also known as HER1) is an epidermal growth factor receptor with tyrosine kinase activity implicated in both tumorigenesis and tumor progression, and its validity as a therapeutic target for ADC has been clinically confirmed, as exemplified by our approved drug MRG003. Trophoblast glycoprotein, also known as 5T4, is an oncofetal cell surface antigen widely expressed across multiple cancer types. 5T4 expression levels correlate with disease stage and portend poor clinical outcomes. Notably, EGFR and 5T4 are highly co-expressed in most NSCLC patients, while 5T4 exhibits moderate-to-high expression in subsets with low or absent EGFR. Targeting 5T4 thus effectively overcomes the therapeutic limitation of insufficient EGFR expression in this patient population. MRG008 is a bispecific ADC targeting both EGFR and 5T4, comprising an Fc-silenced bispecific antibody, a cleavable linker, and a topoisomerase I inhibitor payload (Topi) with a superior bystander effect. This differentiated design holds promise for broadening the therapeutic scope in NSCLC patients.

Methods: The biological activity and safety profile of MRG008 were investigated in a series of preclinical studies, including (1) binding ability to 5T4 and EGFR by ELISA, Flow cytometry and Biacore; (2) internalization rate in single- and dual- target-expressing cancer cells evaluated by pHAb Reactive Dye labeling; (3) in vitro cytotoxicity against single- and dual-target-expressing cancer cells; (4) anti-tumor activity evaluated in NSCLC cell line-derived xenograft (CDX) and NSCLC patient-derived xenograft (PDX) mouse models; (5) plasma stability evaluated in human and cynomolgus monkey plasma; (6) an exploratory pharmacokinetic (PK) study in cynomolgus monkey.

Results: MRG008 exhibited comparable binding activity to that of the respective parental monoclonal antibody ADC targeting 5T4 or EGFR. Rapid internalization of MRG008 was observed in both EGFR/5T4 single-expressing and EGFR/5T4 dual-expressing cancer cells. MRG008 demonstrated potent in vitro cytotoxic activity, comparable to that of its parental monoclonal antibody ADCs. MRG008 exhibited robust tumor growth inhibition in NSCLC CDX and PDX mouse models with varying levels of 5T4 and EGFR expression. Additionally, MRG008 showed favorable stability in human plasma and a desirable PK profile in cynomolgus monkeys.

Conclusion: MRG008 is a promising dual-targeted ADC with potent anti-tumor efficacy for the treatment of NSCLC. These preclinical findings provide a strong rationale for advancing MRG008 into IND-enabling and clinical studies.

#2631 LPD002, a novel anti-PD-1/IL-2 fusion protein, demonstrates potent antitumor activity in preclinical studies.

Xiaoli Zhang[1], **Zhijian Cai**[1], Shoujia Liu[2], Wenci Gong[1]

[1]Lepu Biopharma Co., Ltd., Shanghai, China,[2]Shanghai Miracogen Inc., Shanghai, China

Background: The advancement of immunotherapy has significantly improved the survival outcomes for patients with malignant tumors. IL-2 therapy has demonstrated potential in activating tumor-infiltrating antigen-specific T cells and inducing durable anti-tumor responses. However, it often triggers severe systemic toxicities. To improve the therapeutic index, a variety of engineered IL-2 analogs have been developed.

Methods: To overcome the challenges of PD-1 blockade and IL-2 therapies, we engineered a novel fusion protein, LPD002, which combines a humanized anti-PD-1 antibody and an engineered IL-2 mutein. The anti-PD-1 antibody portion delivers the IL-2 mutein payload to PD-1$^+$ tumor-infiltrating T cells while blocking the immune-inhibitory signals of the PD-1 pathway. The IL-2 mutein component of LPD002 has been engineered to retain its binding activity to the IL-2 receptor alpha (IL-2Rα) subunit and attenuated affinity for the IL-2 receptor beta and gamma (IL-2Rβγ) complex, which is designed to maintain peripheral tolerance and activate tumor-infiltrating T cells, thereby mitigating the systemic toxicity associated with IL-2 therapy. We systematically assessed the functional properties of LPD002 through PD-1 blockade and IL-2 signaling assays. The anti-tumor efficacy of LPD002 was investigated using PD-1 humanized mouse models. Meanwhile, we also evaluated its PK performance in cynomolgus monkeys.

Results: In IL-2 reporter assays, LPD002 induced enhanced pSTAT5 signaling in PD-1-expressing reporter cells compared with PD-1-null cells. LPD002 also activated pSTAT5 signaling and promoted the proliferation of both activated CD4$^+$ and CD8$^+$ T cells in human PBMCs. Moreover, in both PD-1-sensitive and PD-1-resistant CDX models, LPD002 demonstrated superior anti-tumor efficacy and was well-tolerated. In cynomolgus monkeys, LPD002 displayed a favorable pharmacokinetic profile.

Conclusion: LPD002 represents a novel immunotherapeutic strategy that integrates PD-1 blockade with tumor-focused IL-2 activation, eliciting potent anti-tumor activity while reducing systemic toxicity. These preclinical findings demonstrate that LPD002 is a promising therapeutic candidate for solid tumors and warrants further clinical investigation.

#2632 DXP-106, an anti-IL1RAP monoclonal antibody with enhanced ADCC activity, exhibits both *in vitro* and *in vivo* anti-tumor effects and has successfully completed IND-enabling studies.

Qinghao Liu, Yaqi Ru, Yan Jiang, Huimin Li, Wenbo Li, Lan Yang, **Qian Shi**

Singlomics Biopharmaceuticals, Beijing, China

Background: The Interleukin-1 Receptor Accessory Protein (IL1RAP) is expressed on cancer cells, stromal cells, and infiltrating immune cells within the tumor microenvironment (TME) across various cancer types. By activating the IL-1 superfamily signaling pathways, IL1RAP contributes to tumor progression at multiple stages, making it a promising therapeutic target for cancer treatment.
Methods: The epitope of DXP-106 was identified using cryo-electron microscopy (Cryo-EM). The antibody's inhibitory activity against IL-1, IL-33, and IL-36 signaling was assessed through a range of assays utilizing reporter cell lines, primary HUVEC cells, and the A431 human squamous cell carcinoma model. In vivo efficacy was evaluated using a cell line-derived xenograft (CDX) model. The DXP-106 therapeutic product was manufactured using FUT8 knockout Chinese hamster ovary (CHO) cell lines to enhance the antibody-dependent cellular cytotoxicity (ADCC) activity.
Results: Cryo-EM-based epitope mapping revealed that DXP-106 binds to a unique site within IL1RAP domain 2, an area that overlaps with the key interfaces of IL1β-IL1R1 and IL1RAP. In vitro studies demonstrated that DXP-106 effectively blocked signaling through all six IL-1 family pathways: IL-1α, IL-1β, IL-33, and IL-36α, IL-36β, IL-36γ. Additionally, DXP-106 exhibited strong ADCC activity in tumor cell killing assays and significantly suppressed tumor growth in xenograft models. A robust and high-yield manufacturing process has been successfully established, yielding clinical-ready product. Nonclinical safety evaluations, including GLP-compliant toxicity studies in non-human primates, showed no significant adverse findings.
Conclusions: DXP-106 is a potent monoclonal antibody that specifically binds to a unique epitope on IL1RAP, broadly inhibits all six IL-1 family signaling pathways, and shows robust anti-tumor activity both in vitro and in vivo. IND-enabling studies have been successfully completed, and the first-in-human (FIH) clinical trial is planned for the first quarter of 2026.

#2633 A T-cell engager antibody targeting the non-shed site of mesothelin in solid tumors.

Eber Antonio Guzman-Cruz[1], Masanori Onda[1], Xiufen Liu[1], Tara O'Shea[1], Qi Zhou[1], Wenlong Liu[1], Jing Bian[2], Chin-Hsien Tai[1], Ira Pastan[1], Mitchell Ho[1]

[1]Laboratory of Molecular Biology (LMB), Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]Collaborative Bioinformatics Resource, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Mesothelin (MSLN) is a cell surface protein that is overexpressed in various cancers, including mesothelioma, pancreatic, and ovarian cancer. Its expression in normal tissue is limited to the mesothelial cells lining the pleura, peritoneum and pericardium; make it an attractive target for antibody-based therapeutics. Many efforts have been dedicated towards the development of these antibody-based approaches but proteases in the tumor microenvironment promote the cleavage of MSLN from cancer cells. High concentrations of shed MSLN in the tumor microenvironment bind to the antibody inhibiting its activity and preventing the death of cancer cells.
To address the presence of shed MSLN, an antibody called 15B6 was designed. It binds the membrane-proximal, protease sensitive region of MSLN that is not shed in the tumor microenvironment. This study investigates the ability of 15B6-targeted bispecific antibodies to eliminate MSLN expressing cancers. We designed humanized and murine versions of a CD3x15B6 bispecific antibody, which binds the CD3 on T cells and the MSLN (15B6) epitope on cancer cells serving as a bridge to promote the activation of T cells to kill MSLN positive cancer cells. These 15B6-based antibodies were compared to SS1-based antibodies that target the distal N-terminal domain of MSLN that is shed by proteases. In-vitro, the SS1 and 15B6 antibodies hold similar cytotoxic activity, but when cocultured with MSLN 296-591, a recombinant protein mimicking shed MSLN, the SS1 antibodies activity is inhibited.
In-vivo, in a human mesothelioma model in immunodeficient mice, tumor shrinkage and growth inhibition were observed when treated with the 15B6-based antibody but not those treated with the SS1-based antibody. In an immunocompetent mouse model, the complete regression of colon and breast tumors was observed when treated with the 15B6-based antibody compared to the SS1 antibody and control samples. Transcriptional analysis revealed that 15B6-treated mice had higher levels of activation of both innate and adaptive immune cells, along with significant upregulation of cytokine and STAT5 signaling pathways. Through in-vitro and in-vivo studies, we have demonstrated that this 15B6-targeted antibody binds to the protease-sensitive region, is highly active against MSLN-expressing cancer cell lines in vitro, is not inhibited by shed MSLN, and promotes upregulation of immune cell populations and signaling pathways that support robust anti-tumor activity.

#2634 HEC-922:A CDH17-4-1BB bispecific antibody targeting CDH17 positive tumors shows potent anti-tumor activity.

Junji Dong, Shushan Lin, Zhou Linjun, Jiang Qiuyue, Chen Cangsha, He Shuiqing, Xiang Li, Ju Peng, Xiaohui Li, Cai Zhao, Ming Li, Xiaoping Li, **Stewart Leung**

HEC Pharma, Dongguan, China

HEC-922 is a novel bispecific agonistic antibody targeting Cadherin-17(CDH17) and the immune agonistic receptor 4-1BB for the treatment of CDH17-positive tumors, particularly gastrointestinal tumors. CDH17 is a tumor associated antigen highly expressed in various tumors, including colorectal cancer, gastric cancer, and neuroendocrine tumors. Activating monoclonal antibodies against 4-1BB have shown clinical efficacy but was limited by systemic toxicity. The design of HEC-922 enables CDH17-dependent agonism of 4-1BB in the presence of CDH17 positive tumor cells, enabling tumor specific T cell activation while minimizing systemic immune toxicity. A high affinity nanobody against CDH17 and a nanobody against 4-1BB were identified for the construction of HEC- 922 containing an ADCC-silenced Fc. HEC-922 shows potent co-binding to both CDH17 and 4-1BB targets and is cross-reactive to the Rhesus macaque. In an assay using 4-1BB high expression 293 cells with NFkB-luciferase reporter, HEC-922 mediated 4-1BB activation in the presence of CDH17 positive cells but not CDH17 negative cells. HEC-922 demonstrated effective tumor growth inhibition in xenograft models of CDH17 positive tumor lines, restored the function of immune cells, reduced the proportion of exhausted T cells, and achieved a sustained and potent anti-tumor effect. Initial drug feasibility and toxicity studies results of HEC-922 were favorable. Overall result demonstrated that HEC- 922 is a promising candidate for CDH17 positive cancer immunotherapy.HEC-921, another bispecific antibody developed on the same 4-1BB platform with Ly6G6D as the targeted tumor antigen, has completed Dose Range Finding (DRF) study in cynomolgus monkeys, with a no-observed-adverse-effect level (NOAEL) of 100 mg/kg, validating the safety of the 4-1BB platform.

#2635 Novel tumor microenvironment (TME) activated interleukin-2 (IL-2) fused to anti-PD-1 or anti-PD-1/VEGF-A antibodies for enhanced anti-tumor immunity.

Rui Zhang, Cheng Liu, **Yuan Liu**

Affinity Biopharmaceutical Co., Ltd., Shanghai, China

IL-2 is a potent immune-activating cytokine that amplifies T-cell responses critical for anti-tumor immunity, yet its clinical use is limited by toxicity. Previous research has focused on receptor-biased IL-2 variants to selectively engage specific IL-2R subunits such as binding only to the dimeric intermediate-affinity IL-2Rβγ rather than the high-affinity trimeric IL-2Rαβγ. IMD-101 is a novel TME-activated WT IL-2 molecule engineered through chemical conjugation with a legumain-cleavable mask entity, which enables full inhibition of IL-2 activity in circulation while restoring WT IL-2 function in the TME. In cynomolgus monkeys, IMD-101 exhibited no-observed-adverse-effect-level (NOAEL) of 2.4 mg/kg with single dose and NOAEL of 0.8 mg/kg with repeated dosing. In phase I dose escalation study, IMD-101 reached markedly reduced systemic toxicity.

Based on this platform, two fusion antibodies, PD1-IL2 TMEAbody (IMD2032) and PD1-VEGF-IL2 TMEAbody (IMD2035), were further developed to match the clinical dose of PD-1 and PD1-VEGF. IMD2032 was conjugated with legumain-cleavable mask entity shielding both the PD-1 antibody and engineered IL-2 (IL-2 receptor abg agonist). IMD2035 was conjugated with legumain-cleavable mask entity blocking the engineered IL-2 (IL-2 receptor a biased agonist). In syngeneic tumor models using PD-1 humanized mice, IMD2032 showed greater tumor growth inhibition compared with the parental anti-PD-1 antibody. And under the same high-dose, once-daily regimen in PD-1 humanized mice, PD1-IL2 antibody induced strong blood lymphocyte elevation and caused 100% mortality by day 4 (after 4 doses), whereas IMD2032 showed no toxicity after 10 days with 10 doses. Similarly, for preclinical tumor models in PD-1/PD-L1/VEGF-A humanized mice, IMD2035 demonstrated superior anti-tumor efficacy relative to parental anti-PD-1/VEGF-A bispecific antibody. Preclinical toxicology studies in cynomolgus monkeys indicated that IMD2035 was well tolerated following repeated doses of 12 mg/kg, exceeding the clinical exposure levels of anti-PD1-VEGF antibodies. Collectively, these findings support the favorable safety profile and therapeutic efficacy of IMD-101, IMD-2032, and IMD-2035, highlighting their potential as next-generation immunotherapeutic candidates for clinical development.

#2636 Tumor microenvironment-activated T-cell engager (TMEA-TCE) targeting claudin 6 demonstrates efficacy without inducing cytokine release syndrome.

Chengli Ding, Cheng Liu, **Yuan Liu**

Affinity Biopharmaceutical Co., Ltd., Shanghai, China

The CD3 protein complex serves as a critical role of T cell activation and signal transduction. While CD3 T-cell engagers (TCEs) are highly potent, they can elicit severe adverse immune effects on various normal tissues due to pervasive T cell activation and excessive inflammatory cytokine release, leading to cytokine release syndrome (CRS) and limiting their therapeutic margin. CLDN6, a member of the claudin family of tight junction proteins, is highly expressed in multiple solid tumors such as ovarian, endometrial, testicular, and gastric cancers, but rarely in healthy adult tissues. The CLDN6-CD3 TCE demonstrates high affinity and specificity for CLDN6, without cross-reactivity to CLDN9 or CLDN4. To enhance tumor selectivity and address CD3-associated toxicity, CLDN6-CD3 TCE is further engineered via chemical conjugation of a legumain-cleavable linker that masks the variable region of the anti-CD3 domain, leading to the formation of a tumor microenvironment-activated (TMEA)-TCEs and the development of CLDN6-CD3 TMEA-TCE (IMD-1743). IMD-1743 can be activated by legumain, an active protease overexpressed extracellularly in the TME, triggering the release of TCE in the TME or in vitro. This activation strategy follows the same proof-of-concept demonstrated by the successful phase 3 studies of legubicin, an albumin-drug conjugate (ALDC). IMD-1743 exhibited dose-dependent anti-tumor activity in human ovarian PA-1 and OVCAR3 as well as human hepatocellular carcinoma HepG2-Luc mouse models at doses of 1, 3, and 10 mg/kg. Complete tumor elimination was observed in the ovarian PA-1 model at 3 and 10 mg/kg, with no associated mouse weight loss. Preclinical toxicology studies in cynomolgus monkeys showed that IMD-1743 was well tolerated after repeated dosing of 15 mg/kg, with no evidence of CRS based on serum cytokine assays. Pharmacokinetic studies in cynomolgus monkeys revealed high concentrations of IMD-1743 and minimal free TCE, indicating that the molecule is highly stable in circulation.
In summary, these findings highlight a favorable therapeutic margin for IMD-1743 as a safe and effective TCE candidate targeting claudin 6. The strong preclinical efficacy combined with its tolerability profile supports further clinical development of IMD-1743 to address the significant unmet medical needs of patients with CLDN6-expressing tumors.

#2637 A DR5-targeting ADC exhibits superior anti-tumor activity and potentially better therapeutic window.

Yang Wang, Lixia Cao, Cui Feng, Yifan Yang, Fangdun Jiang, Lixia Gu, Qi Zhang, Chen Li, Ming Zhou, Cancan Li, Wei Huang, Bonan Yan, Ziping Wei, Yuhong Zhou

Preclinical research & development, Bliss Biopharmaceutical Co., Ltd., Hangzhou, China

Targeting death receptor DR5 with agonist antibody could trigger extrinsic apoptosis via caspase activation in cancer cells while sparing normal tissues. Ozekibart (INBRX109), a tetra-valent anti-DR5 antibody, showed significant efficacy as a monotherapy in patients with advanced or metastatic, unresectable chondrosarcoma, with disease control rate (DCR) of 54%, (compared to 27.5% in the placebo group). Later in a study of advanced Ewing sarcoma, Ozekibart combined with irinotecan and temozolomide demonstrated improved clinical benefit with an ORR of 64% and a DCR of 92%. Encouraged with these results, we designed a DR5-targeting ADC with the aim to synergize the extrinsic apoptosis activity of DR5 engaging and superb cytotoxicity effect of Top-1 inhibitor. In this presentation we show systematic evaluation of this novel ADC including specific tumor cell engaging, anti-tumor efficacy, serum stability, and pharmacokinetics (PK) in target-humanized mice. First, the unique design of the tri-valent DR5-targeting antibody demonstrated superior activity over counterparts. Second,its resulting ADC form showed a robust tumor growth inhibition across diverse xenografts, potentially benefit from its dual mode of action design, surpassing clinically advanced control agents (INBRX109). Our ADC showed dose dependent *in vivo* antitumor activity without hook effect seen with agonist antibodies. Finally, this ADC showed better *in vivo* safety profile: lower on-target off-tumor apoptosis, longer half-life and better tolerability in comparison with that of INBRX109,suggesting a potentially wider therapeutic window. These results may support progression of this novel DR5-tageting ADC into clinical development as a potentially more potent and safer DR5-targeted therapy.

#2638 A rapid patient-derived organoids platform guides the evaluation of ERBB-targeting bispecific T-cell engagers.

Yuhong Liu[1], Chen Wang[2], Jing Zhao[3], Leli Zeng[4]

[1]Centre for Virology, Vaccinology and Therapeutics, The University of Hong Kong, Hong Kong, China,[2]Digestive Diseases Center, The Seventh Affiliated Hospital of Sun Yat-Sen University, Shen Zhen, China,[3]Scientific research centre, The Seventh Affiliated Hospital of Sun Yat-Sen University, Shen Zhen, China,[4]The Biobank, Scientific Research Center, The Seventh Affiliated Hospital of Sun Yat-Sen University, Shenzhen, China

Background: The ERBB receptor family (EGFR/HER1, HER2, HER3, HER4) are well-validated oncogenic drivers. The clinical translation of ERBB-targeted bispecific antibodies (e.g., EGFRxCD3, HER2xCD3,HER2 degrading BsAbs) is bottlenecked by the lack of models that can rapidly and concurrently predict patient-specific efficacy and on-target, off-tumor toxicity. Optimizing these drugs including fine-tuning parameters like affinity, valency, and epitope to maximize the therapeutic window, which requires a predictive platform that provides integrated feedback on both anti-tumor activity and on-target toxicity in a clinically relevant timeframe.
Methods: We established a comprehensive biobank of patient-derived organoids (PDOs) from breast, gastric, and non-small cell lung cancers, alongside matched normal organoids. We developed a high-throughput, standardized co-culture assay with PBMCs or T cells to evaluate a panel of ERBB-targeting bispecific antibodies with varying molecular formats. The entire workflow was designed for speed, generating parallel data on tumor organoid killing and normal organoid toxicity within days.
Results: Our platform delivered robust, quantitative data on the therapeutic index for a series of BsAb candidates within a 3-week window. We demonstrated that affinity-tuning towards tumor-associated antigen levels could preferentially spare normal organoids with low ERBB expression while maintaining potent tumor killing. Furthermore, comparing different BsAbs revealed that certain molecular formats or epitope choices were associated with reduced cytokine release and less severe toxicity in normal organoids, without compromising efficacy in target-positive tumors. This provides a direct, rapid strategy for lead candidate selection and optimization.
Conclusion: We have developed a rapid, reproducible PDO-based platform that not only predicts the therapeutic window of ERBB-targeting BsAbs but also provides critical insights for their molecular optimization. This "fast-feedback" system can significantly de-risk and accelerate the translation of BsAbs by enabling data-driven decisions on affinity, format, and epitope selection early in the drug development process. The ability to rapidly profile multiple candidates against a backdrop of human tumor and normal tissues makes this an invaluable tool for designing safer and more effective bispecific antibodies. This study presents a transformative preclinical optimization tool. By generating predictive safety and efficacy data in weeks, our platform moves beyond mere prediction to active guidance, empowering the rational design of next-generation BsAbs with an inherently improved therapeutic profile for clinical trials.

#2639 Mesothelin-targeted nanobody-drug conjugates to treat pancreatic cancer.

Nisita Dutta[1], Roman Misteli[2], Jessica Hong[1], Julie Becher[2], Francisco Corzana Lopez[3], Christine Alewine[1], Mitchell Ho[1], Goncalo Bernardes[2]

[1]National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]Department of Chemistry, University of Cambridge, Cambridge, United Kingdom,[3]Department of Chemistry, University of La Rioja, La Rioja, Spain

Development of targeted therapies that can penetrate the dense stroma of the pancreatic ductal adenocarcinoma (PDAC) tumor microenvironment (TME) is essential to improve outcomes for pancreatic cancer patients. We have discovered a camel VHH nanobody (A101) using phage display, which effectively binds to mesothelin (MSLN), a cancer antigen that is expressed in PDAC. Using the A101 VHH nanobody with an MMAE payload, we generated nanobody-drug conjugates (NDCs) that can be advantageous compared to existing biologic therapies by enhancing tumor penetration through the PDAC TME and improving pharmacokinetic distribution, while minimizing systemic toxicity.

The structure of the A101 nanobody was computationally predicted and molecular dynamic simulations were run to understand its interaction with MSLN. Site-specific modifications were engineered and small linker-MMAE molecules were synthesized, then bioconjugated to the modified A101 nanobody using maleimide chemistry. The chemical linkers used in these constructs were valine-citrulline, glycine-proline, and AB (a novel small molecule). The NDCs were tested for binding to MSLN via bio-layer interferometry assays. Internalization and cell viability were also assessed using mouse and human PDAC cell lines. Finally, *in vivo* activity was assayed in MSLN+ and MSLN knockout (MLSN-KO) subcutaneous mouse PDAC tumor models to determine efficacy and specificity of each therapeutic.

We found that modified A101 nanobody retains binding to human (K_D = 18 nM) and mouse (K_D = 5.6 nM) MSLN. A101 NDCs displayed a statistically significant difference in internalization into MSLN+ as compared to isogenic MSLN-KO cells. Additionally, the NDCs efficiently killed PDAC cell lines in vitro (IC_{50} = 20-200 nanomolar). In mice, the A101-AB-MMAE NDC (at 20 mg/kg, 3x per week) displayed the most promising inhibition of tumor growth in MSLN+ tumors and had the highest specificity compared to other A101-NDCs tested, showing limited efficacy in analogous MSLN-KO tumors.

We have synthesized A101-based NDCs with high-affinity MSLN binding and promising anti-tumor activity in PDAC cell lines. Our preliminary animal studies suggest that the A101-AB-MMAE conjugate, which has a novel exclusively intracellular cleavable linker, has superior efficacy and specificity compared to other A101-based NDCs tested with known linkers. Future studies will explore A101-AB-MMAE activity in orthotopic humanized MSLN mouse models of PDAC to assess safety, biodistribution, and anti-tumor efficacy.

#2640 XmAb808, a B7H3-targeted CD28 bispecific antibody, costimulates T cells enhancing the anti-tumor activity of clinically active CD3 T cell engagers.

Michael Hedvat, Veronica Zeng, Mayra Montes-Camacho, Charles G. Bakhit, Alex K. Lam, Lizett E. Scott, Jessica Reyes, Heather P. Jimenez, Rosio Padilla, Scott Taylor, Jose Serrato Bucio, Matthew A. Dragovich, Sung-Hyung Lee, Katrina Bykova, Yoon K. Kim, Suzanne Schubbert, Christine Bonzon, Seung Y. Chu, Gregory L. Moore, F. Rena Bahjat, John R. Desjarlais

Xencor, Inc., Pasadena, CA

CD3 bispecific T-cell engagers (CD3-TCEs) represent a promising therapeutic modality for solid tumors, with multiple candidates in clinical development. These agents bridge tumor-associated antigens and CD3 on T cells to form an immune synapse, delivering Signal 1 for T-cell activation. However, solid tumors, unlike professional antigen-presenting cells, typically lack CD28 ligands required for Signal 2 costimulation. T cells receiving Signal 1 without Signal 2 risk developing anergy, potentially limiting CD3-TCE efficacy. A key advancement in costimulatory immunotherapy involves tumor-targeted CD28 bispecific antibodies that strictly depend on concurrent Signal 1 for activation. These bispecifics engage tumor associated antigens to cluster CD28 at the immune synapse, delivering Signal 2 to T cells. We developed XmAb808, a novel B7H3xCD28 bispecific incorporating a nonsuperagonistic, monovalent CD28-binding domain and a high-avidity, bivalent B7H3-binding domain.

In proof-of-concept studies, XmAb808 potently amplified the in vitro and in vivo anti-tumor efficacy of CD3-TCEs targeting prototype tumor antigens. Exploring potential combination opportunities, we found co-expression of B7H3 with CLDN6 in ovarian tumors and co-expression with STEAP1 in prostate tumors. Notably, XmAb808 synergistically enhanced the activity of XmAb541 (CLDN6xCD3) and an analog of xaluritamig (STEAP1xCD3), two programs with clinically observed anti-tumor activity. These XmAb808 combinations induced robust IL-2 secretion from activated T cells, which in turn promoted T cell proliferation and Bcl-xL-dependent survival. Moreover, in a T cell restimulation assay, XmAb808 was able to overcome apparent T cell exhaustion promoted by xaluritamig, strongly recovering xaluritamig’s reduced anti-tumor activity weeks into the assay. The addition of targeted costimulation translated to superior T cell-mediated cytotoxicity in vitro and markedly improved anti-tumor responses in humanized xenograft models, highlighting XmAb808's potential to synergize with TCE-based immunotherapies.

#2642 Pan-cancer GlyTR1 CAR T cells with ‘velcro-like’ density-dependent targeting of β1,6GlcNAc-branched N-glycans.

Paresh Kumar Purohit, Raymond W. Zhou, Michael Demetriou

UC-Irvine, Irvine, CA

Bispecific antibodies and chimeric antigen receptor (CAR) T-cells are some of the most potent cancer immunotherapeutics in clinical use, yet most cancers remain poorly targetable. High-affinity antibodies required to maximize killing detect low antigen expression in normal tissue, risking ‘on-target, off-cancer’ toxicity. This compels identification of cancer-restricted cell surface protein antigens, which are rare and leave most cancers untreatable by CAR T cells. Tumor Associated Carbohydrate Antigens (TACA’s) are the most abundant and widespread cancer antigens known but are poorly targetable by antibodies. With funding from the Cancer Moonshot program at NCI, we recently published in *Cell* a novel pan-cancer immunotherapeutic technology termed Glycan-dependent T cell Recruiter (GlyTR). Unlike antibodies that employ high-affinity ‘key-lock’ binding to target cells regardless of antigen density, GlyTR utilizes high-avidity ‘velcro-like’ lectin binding to kill cells with high but not low TACA expression. The GlyTR1 bi-specific protein binds β1,6GlcNAc-branched N-glycans to overcome immunosuppressive mechanisms in the tumor microenvironment and trigger target-density dependent T cell mediated pan-cancer killing without toxicity in mice having human-like TACA expression. Here we report early development of GlyTR1 CAR T cells, which display similar pan-cancer activity.

#2643 Clinical predictors of cytokine release syndrome in non-single chain CD3 directed therapies among cancer patients.

Harshit Khosla[1], Brian Dinh[1], Rodney Hunter[1], Neha Maithel[1], Natalie Rafaeli[1], Sara Taveras[1], Joan Marie C Bull[2], Syed H. Jafri[1], Adan Rios[3]

[1]The University of Texas Health Science Center at Houston, Houston, TX,[2]Professor of Medicine, Div. of Oncology, UT Health Science Center, Houston, TX,[3]UT Medical School at Houston, Houston, TX

Background: Bispecific T-cell engager (BiTE) antibodies are novel agents in cancer therapeutics which work by simultaneously binding a cancer cell specific antigen and engaging T-Cell. Major safety concern with use of BiTE therapy based on CD3 platforms is cytokine release syndrome (CRS) from massive unchecked T-cell activation. Thus initial dosing of BiTE requires hospitalization for monitoring and treating CRS. This leads to intensive care requirement and mortality if CRS is not identified and intervened early. We assessed the prevalence of CRS in cancer patients receiving non-single chain CD3 based BiTE therapy and contrasted clinical parameters in patient who developed CRS against those who did not.

Methods: A retrospective chart review was performed on patients from our institution who were admitted for the initial and step up dosing of the BiTE therapy for monitoring of CRS between September 2024 - September 2025. The patients were divided in two groups, those who developed CRS and those who did not. Demographic data, previous treatment history, clinical characteristics, laboratory data and duration of hospitalization at the time of admission were noted.

Results: 20 patients were identified with median age of 67 years. 30% were male and 70% were female. 35% received tarlatamab, 30% got glofitamab, 10% got talquetamab and epcoritamab each, 1 patient got mosunetuzumab and linvoseltamab. All 20% patients who had grade two or higher neurotoxicity syndrome had intracranial disease. 35% (n=7) patients had CRS. Three patients had grade I, two patients had grade II and two had Grade IV CRS. Culture data was negative for all CRS patients up to 1 week after the dose. All CRS was seen after first dose of BITE therapy, except 1 patient who developed it after second dose of tarlatamab. Monocyte to lymphocyte (M:L) ratio 24 - 48 hours after the dose of BiTE (1.51 in CRS vs 0.59 in no CRS, p=0.028*), days between diagnosis and BITE therapy (median 864 days in CRS vs 448 days in no CRS patients, p=0.0218*), and previous lines of therapy (LOT)(4 vs 3, p=0.0224*) were noted to be significantly higher in patients with CRS. Logistical regression suggested that only M:L ratio was significantly related to CRS (odds ratio 5.64, p=0.0372*), while previous LOT (OR 6.93, p=0.060) and time of disease before therapy (OR 1.00, p=0.058) were not significantly related.

Discussion: Despite high CRS prevalence in patients receiving BiTE therapy, the literature describing the mechanism of CRS specific to BiTE therapy is very limited. Monocytes get involved in the uncontrolled release of cytokines which may appear early in circulation. The patients who sustain malignancy for longer and had more treatment lines may develop immune build up against the tumor which may increase the chance of CRS in such patients. These factors need to be explored further in the clinical setting to predict CRS and triage clinical resources.

#2644 Enhancing safety to unlock efficacy: A novel class of conditionally-activated T cell engagers for solid tumors.

Aude Segaliny[1], Than Thar Aye[1], Randall Bettman[1], Jui-Yi Chen[2], Yang Zhou[3], Xiaoya Jessie Ma[4], Rodrigo Rivera[5], Ricky Cheng[6], Xianzhi Jiang[3], Yonglei Shang[1], George Wu[1]

[1]Amberstone Biosciences, Inc., Irvine, CA,[2]Valora Therapeutics, San Diego, CA,[3]Aureka Biotechnologies, Laguna Hills, CA,[4]Glaukos Corporation, Aliso Viejo, CA,[5]aTyr Pharma, Inc., San Diego, CA,[6]QLSF Biotherapeutics, Inc., South San Francisco, CA

Background: T cell engagers (TCEs) offer potent anti-tumor activity but remain limited in solid tumors by cytokine release and on-target off-tumor toxicity. Amberstone's Tumor-Microenvironment Activated Therapeutics (T-MATE™) platform enables pH-gated activation of TCEs, exploiting tumor acidity to achieve selective activation within tumors while maintaining potency under heterogenous tumor pHs (up to pH 7.2). We previously demonstrated that T-MATE™ TCEs broaden the therapeutic index and enable selective targeting of tumor antigens such as TROP-2, which were previously intractable due to normal tissue expression.

Methods: The T-MATE technology integrates proprietary pH-dependent anti-CD3 clones identified via *de novo* high-throughput functional screening. These clones undergo pH-dependent conformational changes in their CDRs, conferring tunable affinities and selectivity profiles for plug-and-play integration into next-generation TCEs. ABS-106, a STEAP1×CD3 T-MATE TCE, was evaluated for activity against metastatic castration-resistant prostate cancer (mCRPC) using *in vitro* assays such as cytotoxicity, cytokine release, and repeated-challenge, as well as *in vivo* xenograft models in humanized mice and non-human primates toxicokinetic studies.

Results: ABS-106 demonstrated potent cytotoxicity across tumor-relevant pH ≤7.2 and induced sustained T cell activation and cytokine release comparable to a clinical benchmark TCE. Its pH 7.2 gating minimized activity at physiological pH 7.3-7.5, yielding minimal T cell activation and about 1000-fold lower cytokine release even at high STEAP1 expression. ABS-106 effectively killed STEAP1$^{Med-Low}$ tumor cells and mediated bystander killing of STEAP1^{-} cells, sustaining activity over nine tumor rechallenge cycles. *In vivo*, ABS-106 induced dose-dependent tumor regression with increased intratumoral CD8^{+} T cells infiltration and upregulation of pharmacodynamic markers such as Granzyme B, CD69 and PD-1. ABS-106 is fully cross-reactive to cynomolgus CD3 and STEAP1, and exhibited consistent favorable pharmacokinetics ($t_{1/2}$ 4-5 days) across all animals. Notably, it maintained exposure upon repeat dosing, and was well tolerated at >130× exposure of the benchmark's reported MTD. The molecule demonstrates excellent developability, robust stability under diverse stress conditions, and strong manufacturability characteristics. ABS-106 is currently undergoing IND-enabling studies.

Conclusions: ABS-106 exemplifies the precision-engineered, next-gen T-MATE™ TCE with optimal safety-efficacy balance. This smarter, safer TCE design enables potent anti-tumor efficacy while minimizing systemic toxicity, representing a promising therapeutic strategy for solid tumors and other indications.

#2645 Characterization of osemitamab in pancreatic cancer models and patients.

Fei Teng, Huanhuan Guo, Di Sun, Xinlai Yao, Lei Shi, **Yi Gu**, Chuan Qi, Xueming Qian

Transcenta Therapeutics Co., Limited, Suzhou, China

Background: TST001 (osemitamab) is a high affinity humanized, ADCC enhanced antibody targeting CLDN18.2. It specifically binds to the extracellular domains of CLDN18.2 and eliminates tumor cells by ADCC and CDC. Promising efficacy of TST001 monotherapy in late line G/GEJ cancer patients or plus CAPOX with or without nivolumab as first-line treatment has been observed and reported. TST003 is a novel humanized antibody targeting Gremlin-1, a member of TGF-β superfamily. Gremlin1 promotes epithelial-mesenchymal transition (EMT) and cancer cell proliferation by binding to BMPs and blocking its biological activities. Here we report preclinical anti-tumor activities of TST001 monotherapy or combined with TST003 in pancreatic cancer models and TST001 monotherapy in pancreatic cancer patients.
Methods: The CLDN18.2 expression on the pancreatic cancer cells was evaluated using IHC analysis with 14G11 antibody. The ADCC activity of TST001 on pancreatic cancer cells was assessed by ADCC reporter cell in vitro. Its in vivo anti-tumor activities were investigated in pancreatic cancer models. In a TST001 phase I clinical trial (NCT04495296), pancreatic cancer patients who failed prior available standard therapies were enrolled and received TST001 monotherapy at 10 mg/kg every 3 weeks.
Results: TST001 displayed potent ADCC activities for two pancreatic cancer cell lines (BxPC-3-CLDN18.2 and MIA PaCa-2-CLDN18.2) in vitro. In KRAS wild type BxPC-3-CLDN18.2 model, the tumor growth inhibition (TGI) of TST001 was 61% at 3 mg/kg and 98% at 10 mg/kg. 7 out of 10 mice in the 10 mg/kg group had their tumors completely disappeared from Day 33. In MIA PaCa-2-CLDN18.2 with KRAS mutation, TST001 at 10 mg/kg led to TGI= 49% and combination with gemcitabine (30 mg/kg) improved the TGI to 67%. In the phase 1 trial, a pancreatic cancer patient with liver metastasis and failed prior gemcitabine plus S1 chemotherapy achieved durable clinical benefit. Despite its tumor has low CLDN18.2 expression (5% 1+, 5% 2+, 5% 3+ tested by a validated IHC assay in a central lab) and KRAS G12R mutation (by local test), the primary target lesion shrank 86% at week 6 and complete response was achieved after the patient received TST001 treatment for 270 days. As Gremlin1 is highly expressed in pancreatic cancer, we also tested the anti-tumor activity of the combination of TST001 and TST003 using the BxPC-3-CLDN18.2/Gremlin1 co-expressing tumor model with PBMC co-inoculation. 3 mg/kg of TST001 combined with 30 mg/kg TST003 exhibited significantly better TGI (60%) than monotherapy (34% for TST001 and 28% for TST003).
Conclusions: TST001 displayed significant anti-tumor activity in preclinical pancreatic cancer models and higher efficacy when combined with gemcitabine or TST003. A pretreated pancreatic cancer patient achieved complete response with TST001 monotherapy. These findings support further investigation of TST001 in CLND18.2 positive pancreatic cancer patients.

#2649 Tumor endothelial cell and cancer cell targeting anti-PRND antibody-drug conjugate to treat hypervascular tumors such as glioblastoma and sarcomas.

Byoungmo Kim[1], Ha Kyeong Lee[1], So-Young Choi[2], Sera Lee[2], Sang Yoon Kim[3], **Youngro Byun**[1], Seong Who Kim[4]

[1]Seoul National University College of Pharmacy, Seoul, Korea, Republic of,[2]New Drug Development Center, Osong Medical Innovation Foundation, Osong, Korea, Republic of,[3]Pharosgen Co. LTD, Seoul, Korea, Republic of,[4]Associate Professor, Dept. of Biochem. & Molec. Bio., University of Ulsan College of Medicine, Seoul, Korea, Republic of

Antibody-drug conjugates (ADCs) have emerged as a major class of targeted therapeutics but remain limited by poor tumor penetration, antigen heterogeneity, and a narrow therapeutic window. To overcome these limitations, we developed an anti-PRND ADC targeting PRND (Doppel), a prion-like glycoprotein selectively expressed in tumor endothelial cells (TECs) and cancer cells but absent in normal tissues except in the testis. This localization enables direct vascular targeting without diffusion barriers and provides a unique opportunity for precise drug delivery to the tumor vasculature. The resulting antibody-drug conjugate, 3H9-KGDEVD-MMAE, is a homogeneous ADC (DAR = 8) free of soluble aggregates. It couples a high-affinity anti-PRND antibody (3H9) with a caspase/cathepsin B-cleavable KGDEVD linker that can be specifically cleaved by both cathepsin B and caspase-3/7. This dual activation allows MMAE release through lysosomal cathepsin B and induces apoptosis of PRND positive cells, and caspase-3/7 from the apoptosis of target cells induces the apoptosis of adjacent tumor tissues. The caspase-mediated cleavage establishes an *in-situ* feedback amplification loop that maintains continuous local drug release, sustained cytotoxicity, and producing a potent bystander effect that overcomes antigen heterogeneity. By combining TEC and cancer cell-specific targeting with a caspase/cathepsin-responsive linker, 3H9-KGDEVD-MMAE (anti-PRND ADC), achieves deep intratumoral penetration, robust vascular disruption, and durable antitumor efficacy. In preclinical models of glioblastoma, sarcoma, and renal cell carcinoma (RCC) - hypervascular malignancies with limited ADC options, anti-PRND ADC induced extensive and durable tumor regressions without systemic toxicity. Collectively, these findings establish anti-PRND ADC as a next-generation vascular-disrupting ADC, integrating endothelial docking with apoptosis-triggered drug amplification for potent and selective control of highly vascularized tumors.
Acknowledgments: This research was supported by the Korea Drug Development Fund (HN21C0264) funded by the Ministry of Science and ICT and the National Research Foundation of Korea (NRF) grant (2020R1A2C2015026) funded by the Korea government (MSIT).

#2650 Breaking immune silence: Tumor-targeted molecular therapy reprograms the tumor-immune interface in progressive neuroblastoma.

Loganayaki Periyasamy[1], Sreenidhi Mohanvelu[1], Sheeja Aravindan[2], Poorvi Subramanian[1], Natarajan Aravindan[1]

[1]Oklahoma State University, Stillwater, OK,[2]OU Health Stephenson Cancer Center, Oklahoma, OK

Progressive neuroblastoma (pNB) that defies intensive multimodal clinical therapy remains a challenging pediatric cancer, characterized by swift clinical deterioration, recalcitrance, and a high degree of immune evasion. Our recent investigations recognized retinal degeneration 3 (RD3) deficiency as a central molecular driver of malignant characteristics, correlating with unfavorable outcomes and dictating immune evasion. Herein, we developed precision-engineered nano-immunotherapeutics targeting RD3-deficient ($RD3^{-/-}$) NB. Five different RD3 peptides were strategically designed and enhanced *via* chemical stabilization through capping modifications and were labeled with a fluorescent marker to assess biodistribution and stability *in vivo*. These peptides were encapsulated into GD2-conjugated immunoliposomes (IL), archiving five RD3[GD2]IL formulations tailored for selective delivery to NB. ILs were assessed for uniform nanoscale distribution (NT Analyzer NS300), encapsulation efficiency, and structural integrity via TEM. Therapeutic efficacy was evaluated using an *in vivo* mouse model established using patient-derived stage 4 progressive pNB cells from a retroperitoneal tumor mass. Systemic administration (IV) of RD3[GD2] ILs (5 µM, thrice weekly × 4 weeks) inflicted immune signatures that were compared to the vehicle control (plain liposomes). High-resolution multiplex immune profiling was performed to characterize the tumor immune landscape, assessing the distribution ($CD4^+$ and $CD8^+$) and activation status ($GITR^+$) of immune subsets. Among the five different formulations, RD3[GD2]IL-1 and RD3[GD2]IL-2 exhibited greater immunogenicity, restoring immune surveillance in $RD3^{-/-}$ tumors. RD3[GD2]IL-2 enhanced the infiltration of $CD4^+$ helper and $CD8^+$ cytotoxic T cells, which was associated with a significant increase in the co-stimulatory receptor GITR, an important factor for T-cell activation and survival. Remarkably, RD3[GD2]IL-2 countered T-cell activation and boosted multifunctional T-cell populations, including $CD4^+GITR^+$, $CD8^+GITR^+$, and a rare, highly functional subset of the $CD4^+CD8^+GITR^+$ triple-positive population. Particularly, RD3[GD2]IL-2 demonstrated impressive homing and tolerability, with no observable systemic toxicity or off-target effects. Collectively, our findings highlight RD3[GD2]IL-2 as a promising therapeutic candidate that synergizes precision tumor targeting with immune reinstatement. This next-generation immunoliposomal delivery reinstates immune responsiveness and treatment sensitivity in refractory pNB, offering a scheme for RD3-based therapies in immunosuppressive “cold” tumors, beyond NB.

Funding: This work was funded by DoD-CA-210339, OCAST-HR19-045, and NIH P20GM103639 to Dr. Aravindan and NCI-P30 CA225520, and NIGMS P30GM154635 awarded to the OU Health SCC.

#2652 MGT-1142, an antibody-drug conjugate targeting a novel glycan for small-cell lung cancer.

Su-Yu Tsai, Maomao He, Ju-Mei Li, Ping Chao, Ting-Chun Hung, Mei-Hsuan Tsai, Charng-Sheng Tsai

Marigold Therapeutics, Inc., Taipei, Taiwan

Background: Aberrant glycosylation is a hallmark of many malignancies, driving tumor growth, immune evasion, and metastasis. Certain tumor-associated glycans are highly expressed in small-cell lung cancer (SCLC) but minimally present in normal tissues, making them attractive yet underexplored targets for antibody-drug conjugates (ADCs). MGT-1142 is an exatecan-based ADC engineered with an optimized Fc domain to recognize a tumor-specific glycosylation pattern and selectively deliver a potent topoisomerase I inhibitor payload.
Methods: Comprehensive in vitro and in vivo evaluations were performed to characterize MGT-1142. Binding affinity, internalization, and cytotoxicity were examined across multiple SCLC cell lines. Anti-tumor efficacy was assessed in both cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models. Pharmacokinetic (PK) and dose-range-finding (DRF) studies were conducted in cynomolgus monkeys to determine systemic exposure, half-life, and tolerability.
Results: MGT-1142 exhibited high target specificity with no detectable cross-reactivity to structurally related glycans. It demonstrated strong binding and rapid internalization in glycan-positive cells, resulting in potent inhibition of antigen-positive tumor cell proliferation. In vivo, MGT-1142 achieved dose-dependent tumor growth inhibition across multiple CDX and PDX models. Cynomolgus PK studies revealed linear, dose-proportional exposure and a favorable terminal half-life. Dose range finding studies indicated good tolerability and a wide therapeutic window.
Conclusions: MGT-1142 shows potent and selective anti-tumor activity, favorable pharmacokinetics, and an encouraging safety profile in preclinical studies. These findings support MGT-1142 as a potential first-in-class glycan-targeting ADC for the treatment of small-cell lung cancer.

#2653 Sequencing immune checkpoint inhibitors and BRAF/MEK inhibitors in advanced melanoma: A meta-analysis of Kaplan-Meier-reconstructed individual level data.

Anderson Ruiz Simoes[1], Isabella Michelon[2], Wellington Neto[3], Metamia Ciampricotti[4], Ludimila Cavalcante[5]

[1]Federal University of Sao Paulo (UNIFESP), Sao Paulo, Brazil,[2]Universidade Catolica de Pelotas, Pelotas, Brazil,[3]Universidade de Fortaleza, Fortaleza, Brazil,[4]MSKCC, New York, NY,[5]Division of Hematology & Oncology, University of Virginia (UVA), Charlottesville, VA

Objectives: Optimal sequencing of immune checkpoint inhibitors (ICI) and BRAF inhibitors (BRAFi) for BRAFV600-mutant advanced melanoma remains uncertain. We conducted a meta-analysis of Kaplan-Meier (KM)-reconstructed individual-patient data (IPD) comparing two clinically used sequences: First-line ICI followed by BRAFi (ICI-BRAFi) versus first-line BRAFi followed by ICI (BRAFi-ICI).

Methods: We searched MEDLINE, Embase, and Cochrane for phase II/III studies reporting KM curves for stage III/IV melanoma patients treated with either ICI-BRAFi or BRAFi-ICI. Outcomes were progression-free survival (PFS) and overall survival (OS). Secondary endpoints were toxicity and brain-metastasis-free survival (BMFS). Reconstructed IPD were analyzed with Cox proportional hazards (PH) models. We additionally estimated restricted mean survival time (RMST) up to 24 months (m) (Grambsch-Therneau test, $p<0.05$).

Results: Six studies with 832 patients were included, of which 426 patients received ICI-BRAFi, and 406 BRAFi-ICI. Median PFS was approximately 12 m for both groups ($p=0.1$, log-rank). PFS at 24 m was 42.8 and 29 m for ICI-BRAFi and BRAFi-ICI, respectively. The PFS RMST difference at 24 m was 0.32 m (95% CI: -1.1 - 1.8 months; $p=0.66$). Median OS was 58.2 m for ICI-BRAFi and 40.3 m for BRAFi-ICI. OS at 24 m was 65.9% and 60.7% for ICI-BRAFi and BRAFi-ICI groups, respectively ($p=0.4$; log-rank). The RMST revealed a slight and nonsignificant OS difference of -0.49 m (95% CI: -1.64 - 0.67 months; $p=0.41$). In a pooled analysis including the only two randomized studies SECOMBIT and DREAMseq, we found a median PFS of 31.5 m for ICI and 13.1 m for BRAFi ($p=0.003$); and median OS was NA and 32.7 m for ICI and BRAFi ($p=0.005$).

Conclusion: ICI-BRAFi led to significantly longer PFS and OS than BRAFi-ICI when evaluating only randomized clinical trials, supporting ICI-first sequencing.

Survival data in ICI-BRAFi vs BRAFi-ICI cohorts

	ICI-BRAFi	BRAFi-ICI	p value
Overall median PFS	12.5 months (9.6-23.3)	12 (10.7-14)	0.1
PFS at 24 months	42.8 months (36.9-49.7)	29 months (24.2-34.4)	-
Median PFS with RCT only	31.5 months (13.9-44.1)	13.1 months (11.3-16.7)	0.003
Overall median OS	58.2 months (37.5-NA)	40.3 months (32.4-NA)	0.4
Os at 24 months	65.9 % (60.2-72.1 %)	60.7 % (55.6-66.2 %)	-
Median OS with RCT only	NA (55.5-NA)	32.7 (23.1-59.7)	0.005

#2654 DB-1421, an optimized EGFR/MUC1 bispecific ADC, exhibits improved tumor selectivity, promising efficacy and safety in preclinical studies.

Chenggang Li[1], Jun Yao[1], Yongsheng Nie[1], YANG QIU[2], **Haiqing Hua**[2]

[1]Duality Biologics Ltd, Shanghai, China,[2]Dualitybio Inc., Wilmington, DE

Introduction: Epidermal growth factor receptor (EGFR) is a well-known and validated target for anti-tumor therapies. However, anti-EGFR therapy in clinical showed obvious safety concerns because of broad EGFR expression in normal tissue, and such adverse effects limit the efficacy of these products. Mucin 1 (MUC1) is highly co-expressed with EGFR in multiple tumor types including esophageal squamous cell carcinoma (ESCC), non-small cell lung cancer (NSCLC), breast cancer (BC), colorectal cancer (CRC) and others. Dual targeting of both EGFR and MUC1 is a promising therapeutic strategy to enhance tumor-selective targeting and avoid undesired toxicity observed with anti-EGFR therapeutics. DB-1421 is a bispecific ADC comprised of a fully human EGFR/MUC1 bispecific antibody conjugated to a novel DNA topoisomerase I inhibitor via a cleavable linker. The naked antibody of DB-1421 is constructed by an affinity reduced EGFR binding arm and a tumor-associated MUC1 (TA-MUC1) specific binding arm. Based to this optimized format, DB-1421 showed both high tumor cell selectivity and high tolerable in preclinical models.
Methods: The tumor selectivity of DB-1421 between tumor cell and normal cell was evaluated via FACS analysis. The internalization of DB-1421 to tumor cell was tested by Incucyte. CTG assay was used to evaluate the cancer cell killing of DB-1421 on multiple target positive cell lines. Both cell line-derived xenograft (CDX) models and patient-derived xenograft (PDX) models were established to evaluate the in vivo efficacy of DB-1421 monotherapy. The safety and PK of DB-1421 were evaluated by in vivo monkey studies.
Results: The naked antibody of DB-1421 showed significant higher tumor selectivity than EGFR antibody. Internalization assays demonstrated that unconjugated DB-1421 was endocytosed in tumor cells co-expressing EGFR and TA-MUC1. DB-1421 exhibited strong cytotoxicity in vitro against several tumor cell lines across a range of target expression. DB-1421 inhibited tumor growth in vivo in CDX and PDX models by dose dependent manner. Additionally, it was well tolerated with repeat dose administration up to 80 mg/kg in monkeys.
Conclusions: DB-1421 is an EGFR/MUC1 bispecific ADC with a common light chain bispecific antibody and a DNA topoisomerase I inhibitor. Through rational design and engineer of EGFR and MUC1 binding arm, DB-1421 showed improved tumor selectivity, efficacy and very good safety. The promising efficacy and safety profile warrants further clinical development of DB-1421.

#2655 DB-1323, a next-generation mesothelin targeting antibody-drug conjugate, demonstrated anti-tumor activity and favorable safety profile in pre-clinical models.

Haiqing Hua[1], Xi Li[1], Jun Yao[1], Tao Cheng[1], Junjie Yang[1], Xinyue Chen[1], Sang Pil Lee[2], Jiyong Shin[2], Yunseon Choi[2], Gisun Baek[2], Alexandre Joyeux[2], Jung Chae Lee[2]

[1]Duality Biologics Ltd, Shanghai, China,[2]Fatiabgen, Sejong, Korea, Democratic People's Republic of

Background: Mesothelin (MSLN) is highly expressed in many hard-to-treat solid tumors and is associated with metastasis, poor progression-free survival and lower overall survival. Despite 25 years of drug- development efforts across modalities, no MSLN-directed therapy has been approved, hampered by on-/off-target toxicities, intra-tumoral antigen heterogeneity, poor internalization of MSLN-antibody complexes, and soluble MSLN “sink” effects. DB-1323 is a MSLN-ADC composed of a novel fully human anti-MSLN immunoglobulin G1 (IgG1) monoclonal antibody, covalently conjugated to a proprietary DNA topoisomerase I inhibitor via a maleimide-tetrapeptide cleavable linker. In the present study, we evaluated the efficacy and safety of DB-1323 in comprehensive preclinical models.

Methods: Binding affinity of the anti-MSLN antibody to MSLN-expressing cells was quantified by flow cytometry. Cytotoxicity was assessed in MSLN-positive pancreatic cancer cells. Anti-tumor activity was tested in MSLN-positive pancreatic and ovarian cancer xenograft models compared to that of anetumab ravtansine and other MSLN ADCs. The pharmacokinetics and safety profile were also evaluated in cynomolgus monkeys.

Results: DB-1323 showed high affinity to both Human and Cyno MSLN without detectable off-target binding. DB-1323 has unique MSLN binding characteristics (fast on/off kinetics) that allow it to evade soluble MSLN while maintaining high avidity for MSLN on the surface of tumor cells. DB-1323 has faster and more extensive internalization than anetumab ravtansine, especially in the presence of physiologically relevant soluble MSLN concentrations. In vitro, DB-1323 retained cytotoxicity towards MSLN-expressing pancreatic cancer cells in the presence of soluble MSLN. It also showed dose-dependent anti-tumor activity in a pancreatic cancer xenograft model and ovarian cancer patient-derived xenograft model. Moreover, DB-1323 showed stronger tumor growth inhibition than that of anetumab ravtansine at the same dose. The systemic exposure AUC0-last and Cmax of DB-1323 and total antibody increased dose proportionally from 1mg/kg to 10mg/kg with low free payload in serum. DB-1323 also showed good safety profile with highest non-severely toxic dose (HNSTD) of 60mg/kg in cynomolgus monkeys.

Conclusions: DB-1323 overcomes historical MSLN-targeting liabilities through unique rapid-on/off binding, efficient internalization, and potent topoisomerase I inhibition, delivering superior tumor eradication versus at well-tolerated doses. These data support clinical evaluation of DB-1323 for patients with MSLN expressing tumors.

#2656 DB-1329: A novel antibody-drug conjugate targeting CDCP1 demonstrates potent preclinical anti-tumor activity across multiple solid tumors.

Hui Yang, Yujie Liu, YANG QIU, **Haiqing Hua**

Dualitybio Inc., Wilmington, DE

Background: Antibody-drug conjugates (ADCs) are designed to eradicate cancer cells while minimizing damage to healthy tissues. The identification and prioritization of viable tumor-associated antigen (TAA) targets are crucial for ADC development. To address this, we employed an integrative multi-omics approach to systematically discover and prioritize cell surface targets suitable for ADC development.
Methods: We established an integrative framework for the identification and prioritization of tumor-associated antigen (TAA) targets. Following target identification and validation, ADCs were developed and evaluated for anti-tumor efficacy and toxicology.
Results: Our AI-driven multi-omics-based platform identified CUB Domain-Containing Protein 1 (CDCP1), as a cell surface protein that is significantly upregulated in a large proportion of cancer cells across many solid tumors (notably lung, pancreatic, ovarian, and colorectal cancers) with limited expression in normal tissues. Given its role in promoting metastasis and therapy resistance, CDCP1 represents an attractive therapeutic target. We developed a novel antibody-drug conjugate, DB-1329, which consists of a fully human anti-CDCP1 monoclonal antibody with high affinity and specificity, conjugated via a protease-cleavable linker to a potent camptothecin-based TOP1 inhibitor payload. DB-1329 exhibited rapid and efficient internalization upon binding to CDCP1 and demonstrated potent and specific cytotoxicity in CDCP1-positive cancer cell lines. In vivo, DB-1329 induced profound and durable tumor regression across multiple patient-derived (PDX) and cell line-derived xenograft (CDX) models of lung, pancreatic, and colon cancers, demonstrating superior antitumor efficacy compared to benchmark ADC-treated animals. DB-1329 also displayed a favorable pharmacokinetic profile, was well-tolerated in toxicology studies, and exhibited a manageable safety profile.
Conclusion: These compelling preclinical results establish CDCP1-ADC DB-1329 as a promising therapeutic candidate, with potent and targeted anti-tumor efficacy against multiple CDCP1-positive solid malignancies. Our findings strongly support the continued development and clinical translation of CDCP1-ADC.

#2657 DB-1326, a novel dual-payload TA-MUC1-directed antibody-drug conjugate, shows potent antitumor efficacy in pre-clinical tumor model.

Chenggang Li[1], Lei Yi[2], Jun Yao[1], Yang Qiu[3], **Haiqing Hua**[2]

[1]Duality Biologics Ltd, Shanghai, China,[2]Dualitybio Inc., Wilmington, DE,[3]Duality Biologics, Basking Ridge, NJ

Introduction: Tumor-associated mucin-1 (TA-MUC1) is a glycoform of the MUC1 protein that is aberrantly glycosylated and is highly specific expressed by cancer cells. TA-MUC1 is highly expressed in various human epithelial cancers, making it an attractive target for cancer therapies. Several antibody-drug conjugates (ADCs) targeting TA-MUC1 are in development in clinical and preclinical stage, such as DS-3939a, CAT-09-833. However, their application remains limited by inadequate efficacy, highlighting the unmet clinical need for improving the efficacy of single payload ADCs. This study presents the preclinical evaluation of a novel dual-payload TA-MUC1-targeting ADC, DB-1326, composed of a fully human IgG1 antibody specific recognize TA-MUC1 which is conjugated to a topoisomerase I inhibitor and a novel ecteinascidin derivative. The dual mechanism of DB-1326 results in potent anti-tumor effect across different tumor types with a range of MUC1 expression levels.

Methods: Binding activity of DB-1326 to TA-MUC1 was evaluated by ELISA. The tumor selectivity between tumor cell and normal cell was evaluated via FACS analysis. The internalization of DB-1326 to tumor cell was tested by Incucyte. CTG assay was used to evaluate the cancer cell killing of DB-1326 on multiple target positive cell lines. Both cell line-derived xenograft (CDX) models and patient-derived xenograft (PDX) models were established to evaluate the in vivo efficacy of DB-1326 monotherapy.

Results: The naked antibody of DB-1326 showed strong binding ability to TA-MUC1 but not MUC1 peptide without glycosylation and significant higher tumor selectivity than traditional MUC1 antibody. Internalization assays demonstrated that unconjugated DB-1326 was endocytosed in tumor cells expressing TA-MUC1. DB-1326 exhibited strong cytotoxicity in vitro against several tumor cell lines. DB-1326 exhibited dose-dependent tumor growth inhibition and demonstrated superior anti-tumor activity compared to the single payload ADC in both CDX and PDX models across a range of target expression.

Conclusions: DB-1326 is a novel dual-payload ADC with a TA-MUC1 antibody. It displayed high tumor cell selectivity and superior anti-tumor effects in preclinical studies. These findings support the potential of DB-1326 as a promising advanced therapeutic candidate for tumors.

#2658 Distinct biological and immune microenvironment features of MSI-H BRAF^{V600E}colorectal cancer: Potential for combined PD-1, BRAF, and EGFR inhibition.

Lulu He, Feng Guo

the Affiliated Suzhou Hospital of Nanjing Medical University, Nanjing Medical University, Suzhou, China

Purpose: Immune checkpoint inhibitors (ICIs) have shown remarkable efficacy in microsatellite instability-high (MSI-H) colorectal cancer (CRC). However, a substantial subset of patients fails to achieve durable clinical benefit. BRAF mutations—particularly BRAF^{V600E}—are associated with aggressive tumor behavior and poor clinical outcomes, and targeted therapies provide effective treatment options. Epidemiological studies reveal that BRAF mutations frequently coexist with MSI-H status. Nevertheless, the optimal treatment strategy for MSI-H BRAF^{V600E} CRC remains unclear, including whether these patients benefit most from ICIs alone, targeted therapy alone, or combined ICIs and targeted therapy therapy. This study aims to comprehensively characterize the biological properties and tumor immune microenvironment (TME) in MSI-H BRAF^{V600E} CRC, with the goal of improving therapeutic strategies for MSI-H BRAF^{V600E} CRC.

Experimental Design: MSI-H BRAF^{WT} and MSI-H BRAF^{V600E} cell lines were generated from the MC38 background. The biological behaviors of cells were evaluated using colony formation, CCK-8, transwell, and Western bloting. Flow cytometry and multiplex immunofluorescence were performed to evaluate immune cell infiltration. RNA sequencing was conducted to explore underlying molecular mechanisms. Therapeutic efficacy was assessed in vivo across four groups: vehicle, anti-PD-1, BRAFi+EGFRi, and anti-PD-1+BRAFi+EGFRi.

Results: MSI-H BRAF^{V600E} cells exhibited significantly enhanced malignancy. In vivo, MSI-H BRAF^{V600E} tumors displayed profound alterations in the immune microenvironment, including reduced infiltration of CD8$^+$ T cells, along with decreased IFN-γ and GZMB levels. Conversely, M2 macrophages were significantly increased. Multiplex immunofluorescence confirmed reduced CD8$^+$ T cell infiltration, and elevated PD-1$^+$ cell frequencies. Notably, MSI-H BRAF^{V600E} tumors exhibited an increased proportion of PD-1$^+$CD8$^+$ T cells and greater spatial separation between CD8$^+$ T cells and PD-L1$^+$ tumor cells. In vivo, combined PD-1, BRAF, and EGFR inhibition resulted in the strongest tumor suppression in MSI-H BRAF^{V600E} tumors, demonstrating a marked therapeutic advantage, including decreased infiltration of CD8$^+$ T cells, along with decreased IL-2 and GZMB levels.

Conclusions: MSI-H BRAFV600E CRC exhibits distinct molecular and immunological characteristics. Our findings demonstrate that triple-combination therapy targeting PD-1, BRAF, and EGFR substantially enhances antitumor activity in MSI-H BRAFV600E tumors, outperforming ICIs alone or targeted therapy alone. Collectively, these results support a refined molecular subclassification of MSI-H CRC and provide valuable insights for optimizing personalized immunotherapeutic strategies for CRC patients with MSI-H BRAFV600E .

#2659 CD44v9-targeted antibody-drug conjugate as a novel therapy for advanced breast cancer.

Dileep R. Reddy[1], McKenna E. Flynn[2], Yasuaki Anami[3], Zhaoxuan Yang[4], Jayden Aleman[2], Minji Seo[1], Kyoji Tsuchikama[4], Jennifer A. Maynard[2], Naoto T. Ueno[1], **Jangsoon Lee**[1]

[1]Preclinical Core, Cancer Biology Program, University of Hawai'i Cancer Center, Honolulu, HI,[2]Department of Chemical Engineering, University of Texas Austin, Austin, TX,[3]CrossBridge Bio, Houston, TX,[4]The University of Texas Health Science Center at Houston, Houston, TX

Background: Aggressive breast cancers, including triple-negative and inflammatory subtypes, urgently require novel therapeutic strategies. Antibody-drug conjugates (ADCs) have shown improved outcomes in HER2- and TROP2-positive breast tumors; however, the heterogeneous expression of target antigens and the development of acquired resistance often limit their long-term clinical benefit. Identifying tumor-selective antigens that remain expressed in advanced and ADC-refractory breast cancers is critical. CD44 variant isoform 9 (CD44v9), a splice variant of the CD44 family, is highly expressed in aggressive breast cancers but largely absent in normal tissues. Functionally, CD44v9 promotes cancer stemness, oxidative stress adaptation, and therapeutic resistance, making it a promising ADC target.

Methods: CD44v9 expression was evaluated in human breast cancer cell lines, patient-derived xenografts, and tumor specimens by immunohistochemistry, with comparison to normal tissues. A chimeric anti-CD44v9 monoclonal antibody (clone SUM24.1) was conjugated to the microtubule inhibitor monomethyl auristatin F (MMAF). Binding, internalization, and cytotoxicity were assessed in triple-negative, inflammatory, and ADC-resistant breast cancer models. Antitumor efficacy was tested in TNBC xenografts and T-DXd-resistant breast cancer models.

Results: CD44v9 was abundantly expressed across TNBC models and largely absent from a broad panel of normal human tissues, including peripheral blood mononuclear cells. The anti-CD44v9 antibody demonstrated strong binding to its target and efficient internalization, supporting selective MMAF delivery to cancer cells. Anti-CD44v9-MMAF induced potent, target-dependent cytotoxicity in vitro ($p < 0.0001$) and significant tumor growth inhibition (TGI) in TNBC xenografts (SUM149: 50% TGI at 0.5 mg/kg, 90% TGI at 2 mg/kg; HCC1806: 50% TGI at 0.5 mg/kg, 95% TGI at 2 mg/kg; $p < 0.0001$), accompanied by increased apoptosis, reduced proliferation, and minimal systemic toxicity. Notably, CD44v9 expression persisted in breast cancer cells resistant to trastuzumab deruxtecan (T-DXd) and sacituzumab govitecan, and these models remained sensitive to CD44v9-directed MMAF therapy in vitro ($p < 0.0001$) and in SUM190-T-DXd-R xenografts (70% TGI at 2 mg/kg; $p < 0.0001$), demonstrating CD44v9's therapeutic independence from HER2 and TROP2 pathways.

Conclusion: CD44v9 is a tumor-specific, biologically meaningful target for ADC development in advanced breast cancer. The preclinical efficacy and selectivity of anti-CD44v9-MMAF highlight its potential as a next-generation therapy for patients with CD44v9-positive, treatment-refractory breast cancers.

#2660 AV-P138-ADC (ARR-002), a novel MUC16/NaPi2b dual-target tetravalent ADC, for the treatment of ovarian and endometrial cancers.

Sunil Bhakta[1], Levi Blazer[1], Cristina Abrahams[2], Jiang Liu[1], Coen Kuijl[3], Jarrett Adams[1], Marcin Kowanetz[2], Luna Musib[2], Amy Kim[2], Wanda Kwan[2], Viswanatham Katta[1], Vidya S. Jonnalagadda[1], Reva Raghupathi[1], Paul Polakis[1], Stuart Lutzker[2], Sachdev S. Sidhu[1], **Jagath Reddy Junutula**[1]

[1]Aarvik Therapeutics, Inc., Hayward, CA,[2]ArriVent Biopharma, Inc., Burlingame, CA,[3]VU Medical Center, Amsterdam, Netherlands

Antibody-drug conjugates (ADCs) are a class of precision medicines available to oncology clinical practice since 2000. To date, only 15 single-target ADCs (out of >450 entering clinical development) have been approved by the FDA. Dual-target ADCs aim to overcome challenges underlying the high failure rate of single-target ADCs in the clinic including limited internalization, low payload delivery, and heterogeneous target expression in tumors. We designed AV-P138-ADC (also known as ARR-002), a first-in-class, Mucin-16 (MUC16) and sodium-dependent phosphate transport protein 2b (NaPi2b) dual-target, tetravalent (2+2 format) ADC, with site-specific conjugation to vcMMAE at a DAR of 4. Both these cell surface antigens are expressed in ovarian and endometrial cancers with limited expression in normal tissues, making them ideal co-targets. AV-P138-ADC utilizes Aarvik Therapeutics' proprietary MUlti-epitope Targeting Tetravalent Antibody (MUTTA™) platform to engineer multivalent antibodies with precise conjugation sites to improve targeting and broaden the ADC therapeutic window, especially in tumors with heterogeneous target expression. Characterization of AV-P138-ADC showed it effectively bound MUC16 and NaPi2b individually, engaged both targets simultaneously, and enhanced internalization compared to the single-target antibody controls. Robust in vitro activity was maintained in OVCAR-3 cells with moderately high expression of both MUC16 and NaPi2b, as well as OVCAR-3 variant cells enriched for either MUC16 or NaPi2b only. AV-P138-ADC also exhibited better cytotoxicity compared to the combination of the site-specifically-conjugated single-target ADCs, a bivalent (1+1 format) bispecific MUC16/NaPi2b ADC, and a MUC16 DAR2 clinical comparator surrogate. Superior in vivo efficacy compared to single-target ADCs was further confirmed in the OVCAR-3 xenograft model. AV-P138-ADC also exhibited a PK profile resembling a typical IgG antibody and high conjugation stability. It demonstrated a favorable tolerability profile in cynomolgus monkeys, consisting of reversible hematologic findings at a higher maximum tolerated single dose compared with random-conjugated vcMMAE ADCs, suggesting a wider therapeutic window. In conclusion, AV-P138-ADC is a novel, site-specifically-conjugated, dual-target tetravalent ADC that may overcome the limitations of conventional single-target or bivalent (1+1 format) bispecific ADCs to potentially provide a safer and more effective treatment option for a broad spectrum of ovarian and endometrial cancer patients. Aarvik Therapeutics and ArriVent BioPharma collaborated on the pre-clinical development of AV-P138-ADC. ArriVent subsequently exercised an option for an exclusive global license to the molecule, now known as ARR-002.

#2661 AZD5335, a folate receptor alpha-targeted ADC, exerts anti-tumor responses within lung adenocarcinoma.

AZD5335 is a folate receptor alpha (FRα)-targeted antibody-drug conjugate (ADC), incorporating a topoisomerase-1 inhibitor (TOP1i) payload. This ADC is currently being developed as a treatment option for FRα-expressing ovarian cancer patients (NCT#05797168-FONTANA). Since FRα has been reported to be expressed in lung adenocarcinoma (LUAD), the purpose of these studies was to pre-clinically evaluate AZD5335 efficacy within LUAD. Employing a panel of FRα-expressing lung cancer cell lines, we demonstrated target-mediated cytotoxicity of AZD5335 and correlated the in vitro sensitivities with FRα expression levels. These studies support ongoing in vivo proof-of-concept studies using cell-derived xenograft models to further define the efficacy and pharmacodynamics of AZD5335. Additional AZD5335 efficacy testing was performed within 9 FRα-expressing patient-derived xenograft (PDX) models of LUAD. Five of these 9 models responded to AZD5335 (2.5mg/kg) and exhibited a ≥ 30% reduction in tumor volumes (ORR ≈ 56%); AZD5335-related tumor stasis occurred in three additional models. These pre-clinical efforts indicated FRα is an actionable target in LUAD and supported expanding clinical assessment of AZD5335 to LUAD in FONTANA.

#2662 MGT-1141, an antibody-drug-conjugate targeting DLL3 positive cancers.

Mei-Hsuan Tsai, Maomao He, Su-Yu Tsai, Ju-Mei Li, Ping Chao, Ting-Chun Hung, Charng-Sheng Tsai

Marigold Therapeutics Inc, Taipei, Taiwan

Background: Delta-like ligand 3 (DLL3) is highly expressed on the cell surface of small cell lung cancer (SCLC) and neuroendocrine cancers (NECs)—among the most lethal malignancies—but is minimally or not expressed in normal tissues, making it an attractive target for DLL3-positive cancers. Here, we describe the preclinical activity of MGT-1141, an anti-DLL3 antibody-drug conjugate (ADC) that delivers a topoisomerase I inhibitor (exatecan) payload *via* Marigold's proprietary linker platform. The IND-enabling study of MGT-1141 is currently ongoing.

Methods: Comprehensive *in vitro* and *in vivo* evaluations were performed to characterize MGT-1141. Binding affinity, internalization, and cytotoxicity were examined across multiple DLL3-expressing cell lines. Anti-tumor efficacy was assessed in both cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models. Pharmacokinetic (PK) and pilot dose-range-finding (DRF) studies were conducted in cynomolgus monkeys to determine systemic exposure, half-life, and tolerability.

Results: The MGT-1141 antibody exhibited high target specificity with no detectable cross-reactivity toward other Delta-like ligand family proteins. MGT-1141 demonstrated strong binding affinity and rapid internalization in DLL3-expressing cells. *In vivo*, MGT-1141 showed potent and dose-dependent tumor growth inhibition across multiple CDX and PDX models, with a minimal efficacious dose (MED) of 0.5 mg/kg. Pharmacokinetic studies in cynomolgus monkeys revealed linear, dose-proportional exposure and a favorable terminal half-life. Dose-range finding (DRF) studies indicated good tolerability and a wide therapeutic window.

Conclusion: Preclinical evaluations of MGT-1141 have shown potent and selective anti-tumor activity, favorable pharmacokinetic properties, and a well-tolerated safety profile, supporting its further development toward clinical investigation. Collectively, these findings support MGT-1141 as a promising and potential best-in-class DLL3-targeting ADC for the treatment of SCLC and NECs.

#2663 Targeting YAP/TEAD signaling disturbs RNA polymerase II activity and enhances immunotherapy response via activated cytosolic DNA sensing pathway in gastroesophageal cancer.

Yanting Yann Zhang[1], Ayna Mammedova[1], Dipti Athavale[1], Curt Balch[1], Mikel Ghelfi[1], Xiaodan Yao[1], Gennaro Calendo[1], Songjie Liu[1], David Pulipati[1], Yahui Li[2], Xiaoxin Chen[1], Francis Spitz[2], Generosa Grana[2], Vladimir Khazak[3], Shumei Song[1]

Gastroesophageal adenocarcinoma (GEAC) is a significant global cancer burden. Our previous studies demonstrated that YAP/TEAD are highly expressed in GEAC, and play a critical role in tumor progression, therapy resistance and metastasis. Thus, targeting YAP/TEAD signaling presents a promising therapeutic strategy. Here, we tested a novel YAP/TEAD inhibitor VT00278, a chemical analog of CA3, and showed that VT00278 strongly downregulated YAP/TEAD transcriptional activity, and potently suppressed tumor-promoting phenotypes including proliferation, invasion, tumor sphere formation; induced apoptosis and inhibited tumor growth *in vivo* especially in radiation resistant FLO-1 XTR GEAC cells. Mechanistically, in addition to impairing YAP/TEAD signaling, VT00278 or YAP depletion repressed RNA polymerase II (RNAPII) transcriptional regulators, reduced RNAPII S2 phosphorylation and decreased anti-apoptosis MCL-1 expression. More interestingly, VT00278 strongly induced DNA damage, activated cytosolic DNA sensing pathway, upregulated innate immune genes (e.g., INFβ) and PD-L1 expression. In a syngeneic mouse model, combining VT00278 with anti-PD-1 therapy strongly inhibited tumor growth, increased $CD3^+$ and $CD8^+$ T cell infiltration, and induced the production of INFγ from CD3 and CD8 cells. These findings support VT00278 as a promising candidate for GEAC treatment, either alone or in combination with immunotherapy.

#2664 MGT-1143, a novel CDH17-targeting ADC for gastrointestinal cancers.

Maomao He, Ping Chao, Su-Yu Tsai, Ju-Mei Li, Ting-Chun Hung, Mei-Hsuan Tsai, Charng-Sheng Tsai

Marigold Therapeutics, Inc., Taipei, Taiwan

Background: Pan-gastrointestinal cancers represent a heterogeneous group of malignancies arising from the gastrointestinal tract, including esophageal, gastric, pancreatic, and colorectal cancers, which collectively contribute to a major global cancer burden and mortality. Cadherin-17 (CDH17), a Ca^{2+}-dependent adhesion molecule, is overexpressed across multiple GI cancers and has been associated with poor prognosis. Here, we report the development and preclinical evaluation of MGT-1143, a novel Exatecan-based ADC that integrates a fully humanized anti-CDH17 monoclonal antibody (mAb) with Marigold's proprietary linker platform. MGT-1143 is currently undergoing IND-enabling studies.

Methods: The preclinical activity of MGT-1143 was assessed through a series of in vitro and in vivo studies to characterize its pharmacological and safety profiles. Binding affinity, cross-species reactivity, and target specificity of MGT-1143 were evaluated using ELISA and flow cytometry. Antibody internalization was determined by flow cytometry, while cytotoxicity was assessed using the CellTiter-Glo luminescent viability assay. In vivo anti-tumor efficacy was evaluated in CDH17-positive cell line-derived xenograft (CDX) models.

Results: The MGT-1143 antibody exhibited high target specificity with no detectable cross-reactivity toward other cadherin family members. MGT-1143 demonstrated strong binding affinity and rapid internalization in CDH17-expressing cells, resulting in potent cytotoxicity across multiple CDH17-positive cell lines. Furthermore, MGT-1143 induced robust and dose-dependent anti-tumor activity in xenograft mouse models expressing varying levels of CDH17, confirming its target-dependent efficacy.

Conclusions: Collectively, the preclinical data support the continued development of MGT-1143 as a promising therapeutic candidate for the treatment of CDH17-positive gastrointestinal cancers. Ongoing IND-enabling studies will further define its safety and translational potential.

#2665 The MET/HER3 antibody-drug conjugate with dual payload: A dual-target approach to eliminate tumor escape mechanism.

Yuan-Liang Wang, Chi-Huan Lu, Woan-Eng Chan, **Ting-Yu Chang**, Hong-Syuan Lin, Cheng-Yen Wei, Shin-Jin Lin, Lu-Tzu Lu, Meng-Hsin Liu, Wei-Jhen Huang, Ya-Chi Chen

OBI Pharma, Inc, Taipei City, Taiwan

Clinical evidence supports combination approaches such as EGFR plus MET TKIs, which achieve responses in MET-amplified resistance settings and demonstrate the critical role of MET signaling in acquired resistance. Meanwhile, HER3-directed ADCs have shown meaningful activity in refractory tumors, underscoring the therapeutic relevance of HER3 in resistant and heterogeneous cancer populations. Together, these findings highlight the rationale for co-targeting cMET and HER3, as simultaneous inhibition of these complementary pathways provides a strong foundation for the development of a bispecific ADC (BsADC) to overcome resistance and enhance antitumor efficacy. Our MET/HER3 bispecific ADC was constructed using the proprietary glycan-based site specific platform to simultaneously engage c-MET and HER3. The ADC carries two complementary cytotoxins— a microtubule inhibitor, MMAE and a topoisomerase I inhibitor derivative, exatecan, conjugated through the stable linker for controlled intracellular release and maximize antitumor activity. Blue native PAGE (BN-PAGE) and proximity ligation assay (PLA) data confirmed that simultaneous MET and HER3 engagement promote receptor clustering, enhancing internalization and intracellular payload delivery. In preclinical models, the bispecific dual-payload ADC induced stronger tumor regression than monospecific or parental ADCs. Broad activity was observed in c-MET/HER3 dual-positive non-small cell lung cancer and colorectal cancer models. This glycan-based site specific MET/HER3 bispecific dual-payload ADC warrants further clinical investigation as a promising therapeutic option for refractory tumors co-expressing cMET and HER3.

#2666 An open-label, multicenter Phase I clinical study of CVL006, a novel PD-L1/VEGF bispecific antibody, in advanced solid tumors.

Jin Li[1], Ning Li[2], Shuhang Wang[2], Ye Guo[3], Kai Yao[4], Yanjie Zhu[5], Feng Ye[6], Hao Zeng[7], **Steve Shen**[8], Jin Zhang[5]

[1]Shanghai GoBroad Cancer Hospital China Pharmaceutical University, Shanghai, China,[2]Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China,[3]Shanghai East Hospital, Shanghai, China,[4]Sun Yat-sen University Cancer Center, Guangzhou, China,[5]Renji Hospital, Shanghai Jiao Tong University School of Medical, Shanghai, China,[6]The First Affiliated Hospital of Xiamen University, Xiamen, China,[7]West China Hospital, Sichuan University, Chengdu, China,[8]Convalife Pharmaceuticals, Shanghai, China

Background: CVL006 is a novel bispecific antibody designed for synergic antitumor activity by simultaneously blocking two mechanistically distinct pathways VEGF/VEGFR signaling and the PD-L1/PD-1 axis. In this Open-label, Multicenter Phase I Clinical Study of CVL006, Safety, pharmacokinetics (PK) and preliminary efficacy will be assessed in adult subjects with advanced solid tumors, and, thus, the recommended phase II dose (RP2D) will be established (NCT06621615).
Method: All subjects in this study received CVL006 every 2 weeks (Q2W). Primary objectives were to evaluate safety, tolerability, and clinical efficacy by objective response rate (ORR).
Results: As of the data cutoff date of Nov 14, 2025, 29 subjects with various advanced solid tumors received CVL006 at 0.03-20 mg/kg, 12 subjects in phase Ia, 7 subjects in phase Ib and 10 subjects in phase Ic. Phase Ia and phase Ib were completed and Phase Ic is ongoing. Phase Ia results show that CVL006 is well-tolerate, MTD has not reached, and RP2D is 20 mg/kg. All these AEs were recovered after symptomatic treatment. In the 20 mg/kg dose group, CVL006 showed linear pharmacokinetics and a low incidence of ADA positivity.18 subjects had at least one efficacy assessment. In the 10 mg/kg dose group (N=3), 2 stable disease (SD) cases with lesion shrinkage first appeared. At dose of 20 mg/kg, 9 subjects with different tumour types, were evaluated for efficacy and 6 of 9 subjects had a response : 4 SD and 2 partial response (PR).
Conclusion: CVL006 monotherapy appeared to be well tolerated and had encouraging preliminary efficacy in patients with advanced solid tumors, warranting further investigation.

#2667 TM4SF1 as a novel tumor-associated antigen in biliary tract cancers targetable by immune effector cell therapy.

Lorraine Nuniz*, Julia Pham, Juliette Jacques, Josephine Hinneh, Jocelin Chen, Corynn Kasap, Jon Akutagawa, Chih-Hao Chang, Robin K. Kelley, Arun Wiita, Jonathan Chou, Kwun Wah Wen, Vipul Kumar*, Franklin Huang

University of California, San Francisco, San Francisco, CA

Biliary tract cancers (BTC) are a rare set of genetically heterogeneous and aggressive malignancies associated with late presentation, poor prognosis and limited effective therapies. Thus, there is an unmet clinical need for the development of novel therapeutic strategies. Identification of uniquely expressed cell-surface tumor-associated antigens (TAA) holds promise in epithelial tumors more generally, as they can serve as ligands for a variety of therapeutics, including CAR-T cell therapy. However, TAA identification in BTCs has been limited by expression in normal liver tissue. Here, we identify the cell-surface protein transmembrane 4 L six family member 1 (TM4SF1) as a potential BTC TAA targetable by CAR-T therapy. We find TM4SF1 expression is upregulated in BTC relative to normal hepatic/biliary tissue at the mRNA level in the TCGA dataset. Correspondingly, we find that TM4SF1 in primary BTC archival tissue is upregulated at the protein level using immunohistochemistry. To validate TM4SF1 as a targetable TAA in BTC, we show that TM4SF1-directed CAR-T cells demonstrate robust, dose-dependent growth inhibition of human-derived BTC cell lines in vitro and significant anti-tumor activity in a heterotopic BTC cell line-derived xenograft model in vivo. Together, our data provide support for TM4SF1 as a promising TAA in BTCs that can be used for the rational development of therapeutic modalities targeting TM4SF1, including CAR-T cells, in a patient population with significant unmet need.

Background: Trophoblast cell surface antigen 2 (TROP2) is a transmembrane glycoprotein preferentially expressed in many cancers relative to normal tissues. TROP2 has recently emerged as a promising therapeutic target in breast cancer, leading to the development of TROP2-directed antibody-drug conjugates (ADCs), including datopotamab deruxtecan (Dato-DXd). However, mechanisms underlying heterogeneous responses to Dato-DXd remain poorly defined. In this study, we evaluated the effect of Dato-DXd on the breast cancer patient-derived organoids (PDOs) and analyzed their responses in correlation with the TROP2 H-score of PDOs.
Method: TROP2 expression and Dato-DXd sensitivity were evaluated by western blot analysis in breast cancer cell lines representing different subtypes. The TROP2 band intensity on western blot was quantified across the cell lines to determine TROP2 expression. We obtained surgical or biopsy specimens from patients with breast cancer at Yonsei Cancer Center. PDOs were established and subjected to TROP2 immunohistochemistry (IHC). TROP2 H-scores were quantified using ImageJ IHC Profiler. PDO cell viability following ADC exposure was assessed using the CellTiter-Glo 3D assay.
Results: We evaluated TROP2 expression in a series of breast cancer cell lines. High TROP2 expression was observed in MDA-MB-468 and HCC1937 (triple-negative breast cancer [TNBC]), T-47D (HR+/HER2-), and SK-BR-3 (HER2+). The sensitivity to Dato-DXd in IC50 value was well correlated with the TROP2 protein expression, suggesting TROP2 expression level is an important determinant of Dato-DXd response. In particular, SK-BR3 showed both response to Dato-DXd and T-DXd in line with its high TROP2 and HER2 expression, whereas BT474 showed only response to T-DXd, but not to Dato-DXd. We next evaluated TROP2 expression in PDOs of patients with breast cancer (n=34) and the median TROP2 H-score was 152. The PDOs of high TROP2 expression (H-score ≥ 100, n= 28) exhibited significantly greater sensitivity to Dato-DXd compared to TROP2-low PDOs (H-score < 100, n= 6). Importantly, Dato-DXd showed potent antitumor activity in three treatment-refractory TNBC PDOs, including models derived from tumors progressing after pembrolizumab plus chemotherapy combination (IC_{50}: OSV-001, 0.82 nM; SBO-105, 0.27 nM) and sacituzumab govitecan (IC_{50}: OSV-011, 0.55nM), whereas T-DXd showed lower activity compared to Dato-DXd in these organoids (IC_{50}: OSV-001, 200 nM; SBO-105 = 160 nM; OSV-011, not reached).
Conclusion: These findings demonstrate that TROP2 expression is a key determinant of Dato-DXd sensitivity and provide mechanistic insights into ADC resistance. Our results support the potential of TROP2-guided patient stratification to enhance therapeutic outcomes with Dato-DXd in breast cancer. Dato-DXd showed significant antitumor activity in PDOs from tumors resistant to anti-PD-1 and ADC treatment.

#2672 Characterization of small molecule inhibitors against Lipocalin-2 in inflammatory breast cancer.

Sthephanie Estrada-Mojica[1], Fatma Valiyeva[2], Pablo E. Vivas Mejia[3]

[1]University of Puerto Rico - Rio Piedras, San Juan, PR,[2]Comprehensive Cancer Center, San Juan, PR,[3]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

Inflammatory breast cancer (IBC) is a rare and very aggressive form of breast cancer (BC) where cancer cells block the lymph vessels in the skin. It only makes up about 1% to 5% of all breast cancers but grows and spreads much faster than other common BC types. No targeted therapies are currently available against IBC. Lipocalin 2 (LCN2) is a secreted glycoprotein involved in transporting small lipophilic ligands, and its abnormal expression plays an important role in the progression and metastasis of IBC. We used a library of 370,000 small molecule inhibitors (SMI) and after bioinformatic and filtering analysis we selected 24 compounds that potentially bind to LCN2. Viability and colony formation assay were performed on the IBC cell line, SUM-149. The majority of the 24 SMIs did not exhibited noticeable reduction on cell viability. However, at 1.0 μM, 12 SMIs achieved >50% reduction in cell proliferation. These results highlight the therapeutic potential and selectivity of SMIs against LCN2. Targeting this protein with our SMIs could provide a novel therapeutic strategy that improves the outcomes of IBC patients. Further studies are needed to validate and optimize the most effective compounds for future clinical development.

#1392 A mixed-methods evaluation of multilevel barriers and facilitators to inform implementation strategies for advancing equitable clinical trial accrual in a large comprehensive cancer center.

Morgan Gill[1], Syma Iqbal[2], Vibha Kodancha[1], Emmeline Friedman[1], Diana L. Hanna[2], Chanita Hughes-Halbert[3], Anthony El-Khoueiry[2], Jennifer Tsui[1]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[3]USC - University of Southern California, Los Angeles, CA

Introduction: Multilevel interventions and implementation strategies at the system, provider, and patient levels can support clinical trial enrollment. This study examines processes, facilitators, and barriers to clinical trial enrollment across a large comprehensive cancer center to inform interventions and identify opportunities for implementation strategies to sustain equitable trial participation.
Methods: Guided by the Consolidated Framework for Implementation Research (CFIR), we used a mixed-methods design to survey and interview oncology and hematology providers from September 2024 to April 2025. Providers at USC Norris Comprehensive Cancer Center's main medical campus and satellite clinics completed surveys and in-depth interviews that assessed their experiences with trial enrollment, including beliefs, attitudes, and knowledge about clinical trials; workflow and organizational culture; and patient barriers. Survey data were summarized using descriptive statistics, and interview transcripts were coded using CFIR to identify key implementation determinants.
